6.2. *Finish*—The coating shall be continuous (except as provided below), and as reasonably smooth and uniform in thickness as the mass, size, shape of the item, and necessary handling of the item during the dipping and draining operations as the galvanizing kettle will permit. Except for local excess coating thickness which would interfere with the use of the product or make it dangerous to handle (edge tears or spikes), rejection for nonuniform coating shall be made only for plainly visible excess coating not related to design factors such as holes, joints, or special drainage problems. (See Note 6.) Since surface smoothness is a relative term, minor roughness that does not interfere with the intended use of the product, or roughness that is related to the as-received (ungalvanized) surface condition, steel chemistry, or steel reactivity to zinc shall not be grounds for rejection. (See Note 7.) Surface conditions related to deficiencies related to design, detailing, or fabrication as addressed by ASTM A 385 shall not be grounds for rejection. The zinc coating on threaded components of articles galvanized under this specification shall conform to that required in M 232M/M 232. Surfaces that remain uncoated after galvanizing shall be renovated in accordance with the methods in ASTM A 780, unless directed by the purchaser to leave the uncoated areas untreated for subsequent renovation by the purchaser.

6.2.1. Each area subject to renovation shall be 25 mm [1 in.] or less in its narrowest dimension.

6.2.2. The total area subject to renovation on each article shall be no more than one-half of 1 percent of the accessible surface area to be coated on that article or 26 mm^2 per kg [36 $in.^2$ per ton] of piece mass, whichever is less.

Note 5—Inaccessible surface areas are those that cannot be reached for appropriate surface preparation and application of repair materials as described in ASTM A 780. Such inaccessible areas, for example, would be the internal surfaces of certain tanks, poles, pipes, tubes, and so forth.

6.2.3. The thickness of renovation shall be that required by the thickness grade for the appropriate material category and thickness range in Table 1 in accordance with the requirements of

Section 6.1, except that for renovation using zinc paints, the thickness of renovation shall be 50 percent higher than that required by Table 1, but not greater than 100 μm [4.0 mils].

6.2.4. When areas requiring renovation exceed the criteria previously provided or are inaccessible for repair, the coating shall be rejected.

Note 6—The requirements for the finish of a galvanized product address themselves to a visual type of inspection. They do not address the matter of measured coating thickness variations that can be encountered because of different steels or different thicknesses of a given steel being used in an assembly.

Note 7—Items that are prepared for galvanizing by abrasive cleaning will generally develop a thicker coating with a moderately rougher surface.

6.3. *Threaded Components in Assemblies*—The zinc coating on external threads shall not be subjected to a cutting, rolling, or finishing tool operation, unless specifically authorized by the purchaser. Internal threads are not prohibited from being tapped or retapped after galvanizing. Coatings shall conform to the requirements of M 232M/M 232.

6.4. *Appearance*—Upon shipment from the galvanizing facility, galvanized articles shall be free from uncoated areas, blisters, flux deposits, and gross dross inclusions. Lumps, projections, globules, or heavy deposits of zinc which will interfere with the intended use of the material will not be permitted. Plain holes of 12.5-mm [$^1/_2$-in.] diameter or more shall be clean and reasonably free from excess zinc. Marks in the zinc coating caused by tongs or other items used in handling the article during the galvanizing operation shall not be cause for rejection unless such marks have exposed the base metal and the bare metal areas have exceeded allowable maximums from Sections 6.2.1 and 6.2.2. The pieces shall be handled so that after galvanizing they will not freeze together on cooling.

Note 8—Depending upon product design or material thickness or both, filming or excess zinc buildup in plain holes of less than 12.5-mm [$^1/_2$-in.] diameter may occur that requires additional work to make the holes usable as intended.

6.5. *Adherence*—The zinc coating shall withstand handling consistent with the nature and thickness of the coating and the normal use of the article without peeling or flaking.

Note 9—Although some material may be formed after galvanizing, in general the zinc coating on the articles covered by this specification is too heavy to permit severe bending without damaging the coating.

7. SAMPLING

7.1. Sampling of each lot shall be performed for conformance with the requirements of this specification.

7.2. A lot is a unit of production or shipment from which a sample is taken for testing. Unless otherwise agreed upon between the galvanizer and the purchaser, or established within this specification, the lot shall be as follows: for testing at a galvanizer’s facility, a lot is one or more articles of the same type and size comprising a single order or a single delivery load, whichever is the smaller, or any number of articles identified as a lot by the galvanizer, when these have been galvanized within a single production shift and in the same bath. For test by purchaser after delivery, the lot consists of the single order or the single delivery load, whichever is the smaller, unless the lot identity, established in accordance with the above, is maintained and clearly indicated in the shipment by the galvanizer.

7.3. The method of selection and number of test specimens shall be agreed upon between the galvanizer and the purchaser. Otherwise, the test specimens shall be selected at random from each lot. In this case, the minimum number of specimens from each lot shall be as follows:

Number of Pieces in Lot	Number of Specimens
3 or less	all
4 to 500	3
501 to 1200	5
1201 to 3200	8
3201 to 10000	13
10001 and over	20

Note 10—Where a number of identical items are to be galvanized, a statistical sampling plan may be desired. Such a plan is contained in ASTM B 602, which addresses sampling procedures for the inspection of electrodeposited metallic coatings and related finishes. If ASTM B 602 is used, the level of sampling shall be agreed upon between the galvanizer and the purchaser at the time the coating order is placed.

7.4. A test specimen which fails to conform to a requirement of this specification shall not be used to determine the conformance to other requirements.

8. TEST METHODS

8.1. *Test Requirements*—The following tests shall be conducted to ensure that the zinc coating is being furnished in accordance with this specification. The specifying of tests for adhesion and embrittlement shall be subject to mutual agreement between the galvanizer and purchaser. Visual inspection of the coating shall be made for compliance with the requirements.

8.2. *Thickness of Coating Test*—The thickness of coating is determined by one or more of the three methods described as follows:

8.2.1. *Magnetic Thickness Measurements*—The thickness of the coating shall be determined by magnetic thickness gauge measurements in accordance with ASTM E 376 unless the methods described in Sections 8.2.2, 8.2.3, or 8.2.4 are used. For each specimen (as described in Section 3.2.9), five or more measurements shall be made at points widely dispersed throughout the volume occupied by the specimen so as to represent, as much as practical, the entire surface area of the test specimen. The average of five or more measurements thus made for each specimen is the specimen coating thickness.

8.2.1.1. For articles with surface area greater than 100,000 mm^2 [160 $in.^2$] (multi-specimen articles as described in Section 3.2.6), the average of the three specimen coating thickness grades comprising each test article is the average coating thickness for that test article. A specimen must be evaluated for each steel category and material thickness within the requirements for each specimen of the test article.

8.2.1.2. For articles with surface area equal to or less than 100,000 mm^2 [160 $in.^2$] (single-specimen articles as described in Section 3.2.8), the average of all specimen coating thickness grades is the average coating thickness for the sample.

8.2.1.3. In the case of threaded components, the thickness of coating shall be made on a portion of the article that does not include any threads.

8.2.1.4. The use of magnetic measurement methods is appropriate for larger articles and is appropriate for smaller articles when there is sufficient flat surface area for the probe tip to sit flat on the surface using ASTM E 376.

8.2.2. *Stripping Method*—The average mass of coating shall be determined by stripping a test article, a specimen removed from a test article, or a group of test articles in the case of very small items such as nails, etc., in accordance with T 65M/T 65 unless the methods described in Sections 8.2.1, 8.2.3, or 8.2.4 are used. The mass of coating per unit area thus determined is converted to equivalent coating thickness values in accordance with Table 2 (rounding up or down as appropriate). The thickness of coating thus obtained is the test article coating thickness, or in the case of a specimen removed from a test article, is the specimen average coating thickness.

8.2.2.1. The "stripping method" is a destructive test and is appropriate for single-specimen articles, but is not practical for multi-specimen articles.

8.2.3. *Determining the Mass Before and After Galvanizing*—The average mass of coating shall be determined by using the mass of the articles before and after galvanizing, subtracting the first mass from the second and dividing the result by the surface area unless the methods described in Sections 8.2.1, 8.2.2, or 8.2.4 are used. The first mass shall be determined after pickling and drying and the second after cooling to ambient temperature. The mass of coating per unit area thus determined is converted to equivalent coating thickness values according to Table 2 (rounding up or down as appropriate). The thickness of coating thus obtained is the test article coating thickness.

8.2.3.1. The "determining the mass before and after" method is appropriate for single-specimen articles, but is not practical for multi-specimen articles.

Note 11—Neither the "stripping method" nor the "determining the mass before and after" method takes into account the mass of iron reacted from the article that is incorporated into the coating. Thus, the methods may underestimate coating mass (and therefore the calculated thickness) by up to 10 percent. The accuracy of both methods will be influenced by the accuracy with which the surface area of the articles tested can be determined.

8.2.4. *Microscopy*—The thickness of coating shall be determined by cross-sectional and optical measurement in accordance with ASTM B 487 unless the methods described in Sections 8.2.1, 8.2.2, or 8.2.3 are used. The thickness thus determined is a point value. No fewer than five such measurements shall be made at locations on the test article and shall be as widely dispersed as practical, so as to be representative of the whole surface of the test article. The average of no fewer than five such measurements is the specimen coating thickness.

8.2.4.1. The microscopy method is a destructive test and is appropriate for single-specimen articles, but is not practical for multi-specimen articles.

8.2.5. *Referee Method*—In the event of a dispute over thickness of coating measurements, the dispute shall be resolved as follows:

8.2.5.1. For multi-specimen articles, a new sample shall be taken randomly from the lot of material, which has twice the number of test articles as the sample which failed to conform to this specification. If the lot size is such that the sample size cannot be doubled, then the sample size shall be as previous, but the number of widely dispersed sites at which measurements were made shall be doubled, and these sites will constitute the new sample. This new sample shall be measured using magnetic thickness gauges which have been calibrated for accuracy against reference material thickness standards. If the lot is found to be nonconforming by the new sample, the galvanizer has the right to sort the lot for conforming articles by individual test, to regalvanize nonconforming articles, or to renovate the nonconforming articles in accordance with Section 6.2.

8.2.5.2. For single-specimen articles, a new sample shall be taken randomly from the lot of material, which has twice the number of test articles as the sample which failed to conform to this specification. The test method for the new sample shall be selected by mutual agreement between the purchaser and galvanizer. If the lot is found to be nonconforming by the new sample, the galvanizer has the right to sort the lot for conforming articles by individual test, to regalvanize nonconforming articles, or to renovate the nonconforming articles in accordance with Section 6.2.

8.3. *Adhesion*—Determine adhesion of the zinc coating to the surface of the base metal by cutting or prying with the point of a stout knife applied with considerable pressure in a manner tending to remove a portion of the coating. The adhesion shall be considered inadequate if the coating flakes off in the form of a layer of the coating so as to expose the base metal in advance of the knife point. Do not use testing carried out at edges or corners (points of lowest coating adhesion) to determine adhesion of the coating. Likewise, do not use removal of small particles of the coating by paring or whittling to determine failure.

8.4. *Embrittlement*—Test for embrittlement shall be made in accordance with ASTM A 143. These tests shall not be required unless strong evidence of embrittlement is present.

9. INSPECTION, REJECTION, AND RETEST

9.1. *Inspection by the Galvanizer*—It is the responsibility of the galvanizer to ensure compliance with this specification. This shall be achieved by an in-plant inspection program designed to maintain the coating thickness, finish, and appearance within the requirements of this specification unless the inspection is performed in accordance with Section 9.2.

9.2. *Inspection by the Purchaser*—The purchaser shall accept or reject material by inspection either through the galvanizer’s inspector, the purchaser’s inspector, or an independent inspector. The inspector representing the purchaser shall have access at all times to those areas of the galvanizer’s facility which concern the application of the zinc coating to the material ordered while work on the contract of the purchaser is being performed. The galvanizer shall afford the inspector all reasonable facilities to satisfy him that the zinc coating is being furnished in accordance with this specification.

9.3. *Location*—The material shall be inspected at the galvanizer’s plant prior to shipment. However, by agreement, the purchaser is not prohibited from making tests that govern the acceptance or rejection of the materials in his own laboratory or elsewhere.

9.4. *Reinspection*—When inspection of materials to determine conformity with visual requirements of Section 6.2 warrants rejection of a lot, the galvanizer is not prohibited from sorting the lot and submitting it once again for acceptance after he has removed any nonconforming articles and replaced them with conforming articles.

9.5. The sampling plan that was used when the lot was first inspected shall be used for resampling of a sorted lot. By mutual agreement, the galvanizer is not prohibited from submitting the lot remaining after sorting and removing nonconforming articles without replacement of the nonconforming articles. In such case the now-smaller lot shall be treated as a new lot for purposes of inspection and acceptance.

9.6. Materials that have been rejected for reasons other than embrittlement are not prohibited from being stripped and regalvanized and again submitted for inspection and test at which time they shall conform to the requirements of this specification.

10. CERTIFICATION

10.1. When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each lot have been either tested or inspected as directed by this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

11. KEYWORDS

11.1. Coatings, zinc; galvanized coatings; steel products, metallic coated; zinc coatings, steel products.

Standard Specification for

Zinc

AASHTO Designation: M 120-08
ASTM Designation: B 6-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Zinc

AASHTO Designation: M 120-08
ASTM Designation: B 6-07

AASHTO M 120-08 is identical to ASTM B 6-07.

Standard Specification for

Copper Sheet, Strip, Plate, and Rolled Bar

AASHTO Designation: M 138M/M 138-08
ASTM Designation: B 152/B 152M-06a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Copper Sheet, Strip, Plate, and Rolled Bar

AASHTO Designation: M 138M/M 138-08
ASTM Designation: B 152/B 152M-06a

AASHTO M 138M/M 138-08 is identical to ASTM B 152/B 152M-06a.

Standard Specification for

General Requirements for Steel Plates, Shapes, Sheet Piling, and Bars for Structural Use

AASHTO Designation: M 160M/M 160-08
ASTM Designation: A 6/A 6M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

General Requirements for Steel Plates, Shapes, Sheet Piling, and Bars for Structural Use

AASHTO Designation: M 160M/M 160-08
ASTM Designation: A 6/A 6M-07

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 6/A 6M-07 for the information formerly contained in this standard.

Standard Specification for

Castings, Iron-Chromium, Iron-Chromium-Nickel, Corrosion Resistant, for General Application

AASHTO Designation: M 163M/M 163-07[1]
ASTM Designation: A 743/A 743M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Castings, Iron-Chromium, Iron-Chromium-Nickel, Corrosion Resistant, for General Application

AASHTO Designation: M 163M/M 163-07[1]
ASTM Designation: A 743/A 743M-06

1. SCOPE

1.1. This specification covers iron-chromium and iron-chromium-nickel alloy castings for general corrosion-resistant application. The grades covered by this specification represent types of alloy castings suitable for broad ranges of application, which are intended for a wide variety of corrosion environments.

Note 1—For alloy castings for severe corrosion-resistant service, reference should be made to M 285M/M 285. For general heat-resistant alloy castings, reference should be made to ASTM A 297/A 297M. For nickel alloy castings for corrosion-resistant service, reference should be made to ASTM A 494/A 494M.

1.2. The values stated either in SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification. SI units are applicable for material ordered to M 163M and inch-pound units are applicable for material ordered to M 163.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 285M/M 285, Castings, Iron-Chromium-Nickel, Corrosion Resistant, for Severe Service
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 262, Standard Practices for Detecting Susceptibility to Intergranular Attack in Austenitic Stainless Steels
- A 297/A 297M, Standard Specification for Steel Castings, Iron-Chromium and Iron-Chromium-Nickel, Heat Resistant, for General Application
- A 447/A 447M, Standard Specification for Steel Castings, Chromium-Nickel-Iron Alloy (25-12 Class), for High-Temperature Service
- A 494/A 494M, Standard Specification for Castings, Nickel and Nickel Alloy

- A 781/A 781M, Standard Specification for Castings, Steel and Alloy, Common Requirements, for General Industrial Use
- A 890/A 890M, Standard Specification for Castings, Iron-Chromium-Nickel-Molybdenum Corrosion-Resistant, Duplex (Austenitic/Ferritic) for General Application
- A 957, Standard Specification for Investment Castings, Steel and Alloy, Common Requirements, for General Industrial Use
- E 527, Standard Practice for Numbering Metals and Alloys in the Unified Numbering System (UNS)

3. GENERAL CONDITIONS FOR DELIVERY

3.1. Except for investment castings, castings furnished to this specification shall conform to the requirements of ASTM A 781/A 781M including any supplementary requirements that are indicated on the purchase order. Failure to comply with the general requirements of ASTM A 781/A 781M constitutes nonconformance with this specification. In case of conflict between the requirements of this specification and ASTM A 781/A 781M, this specification shall prevail.

3.2. Steel investment castings furnished to this specification shall conform to the requirements of ASTM A 957, including any supplementary requirements that are indicated in the purchase order. Failure to comply with the general requirements of ASTM A 957 constitutes nonconformance with this specification. In case of conflict between the requirements of this specification and ASTM A 957, this specification shall prevail.

4. ORDERING INFORMATION

4.1. Orders for material to this specification should include the following, as required, to describe the material adequately:

4.1.1. Description of the casting by pattern number or drawing,

4.1.2. Grade,

4.1.3. Heat-treatment,

4.1.4. Options in the specification,

4.1.5. Whether castings are to be produced using the investment casting process, and

4.1.6. Supplementary requirements desired, including the standards of acceptance.

5. PROCESS

5.1. The steel shall be made by the electric furnace process with or without separate refining such as argon-oxygen decarburization (AOD).

6. HEAT-TREATMENT

6.1. Castings shall be heat-treated in accordance with the requirements in Table 1.

Note 2—Proper heat-treatment of these alloys is usually necessary to enhance corrosion resistance and, in some cases, to meet mechanical properties. Minimum heat-treat temperatures are specified; however, it is sometimes necessary to heat-treat at higher temperatures, hold for some minimum time at temperature, and then rapidly cool the castings in order to enhance the corrosion resistance and meet mechanical properties.

Table 1—Heat-Treatment Requirements

Grade	Heat-Treatment
CF8, CG3M, CG8M, CG12, CF20, CF8M, CF8C, CF16F, CF16Fa	Heat to 1040˚C [1900˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CH10, CH20, CE30, CK20	Heat to 1093˚C [2000˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CA15, CA15M, CA40, CA40F	(1) Heat to 955˚C [1750˚F] minimum, air cool and temper at 595˚C [1100˚F] minimum, or (2) Anneal at 790˚C [1450˚F] minimum.
CB30, CC50	(1) Heat to 790˚C [1450˚F] minimum, and air cool, or (2) Heat to 790˚C [1450˚F] minimum, and furnace cool.
CF3, CF3M, CF3MN	(1) Heat to 1040˚C [1900˚F] minimum, hold for sufficient time to heat casting to temperature, and cool rapidly. (2) As cast if corrosion resistance is acceptable.
CN3M	Heat to 1175˚C [2150˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CN3MN	Heat to 1150˚C [2100˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CN7M, CG6MMN	Heat to 1120˚C [2050˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CN7MS	Heat to 1150˚C [2100˚F] minimum, 1180˚C [2150˚F] maximum, hold for sufficient time (two-hour minimum) to heat casting to temperature and quench in water.
CA6NM	Heat to 1010˚C [1850˚F] minimum, air cool to 95˚C [200˚F] or lower prior to any optional intermediate temper and prior to the final temper. The final temper shall be between 565˚C [1050˚F] and 620˚C [1150˚F].
CA6N	Heat to 1040˚C [1900˚F], air cool, reheat to 815˚C [1500˚F], air cool, and age at 425˚C [800˚F], holding at each temperature sufficient time to heat casting uniformly to temperature.
CF10SMnN	Heat to 1065˚C [1950˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CA28MWV	(1) Heat to 1025–1050˚C [1875–1925˚F], quench in air or oil and temper at 620˚C [1150˚F] minimum, or (2) Anneal at 760˚C [1400˚F] minimum.
CK3MCuN	Heat to 1150˚C [2100˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CK35MN	Heat to 1150–1200˚C [2100–2190˚F], hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CB6	Heat between 980˚C [1800˚F] and 1050˚C [1920˚F], forced air, cool to 50˚C [120˚F] maximum, and temper between 595˚C and 625˚C [1100˚F and 1160˚F].

7. CHEMICAL REQUIREMENTS

7.1. The chemical requirements are shown in Table 2.

Table 2—Chemical Requirements

		Composition, percent													
Grade (UNS)	Type	Carbon, Max	Manganese, Max	Silicon, Max	Phosphorus, Max	Sulfur, Max	Chromium	Nickel	Molybdenum	Columbium	Selenium	Copper	Tungsten, Max	Vanadium, Max	Nitrogen

[a] Grade CF8C shall have a columbium content of not less than eight times the carbon content and not more than 1.0 percent. If a columbium-plus tantalum alloy in the approximate Cb: Ta ratio of 3:1 is used for stabilizing this grade, the total columbium plus tantalum content shall not be less than nine times the carbon content and shall not exceed 1.1 percent.

[b] For grade CB30, a copper content of 0.90 to 1.20 percent is optional.

Note: CD4MCu has been deleted from M 163M/M 163 and added to ASTM A 890/A 890M. CD4MCu may now be supplied and purchased in compliance with ASTM A 890/A 890M. The chemical and mechanical property requirements of CD4MCu were identical in M 163M/M 163 and ASTM A 890/A 890M at the time of removal from M 163M/M 163.

8. REPAIR BY WELDING

8.1. Repair welding of Grade CA28MWV is not permitted unless by agreement between the manufacturer and the purchaser.

8.2. When methods involving high temperature are used in the removal of discontinuities, castings shall be preheated in accordance with Table 3. Weld repairs shall be subject to the same quality standards as are used to inspect the castings.

Table 3—Minimum Preheat Temperatures

Grade	Minimum Preheat Temperature ˚C	Minimum Preheat Temperature ˚F
CA15, CA15M	205	[400]
CA40, CA28MWV	205	[400]
Others	10	[50]

8.3. Postweld heat-treatment, if required, shall be in accordance with Table 1.

8.3.1. The martensitic grades CA6NM, CA15, CA15M, CB6, and CA40 shall be retempered after weld repairing except that local tempering will be permitted if, in the opinion of the manufacturer, furnace heat-treating will be damaging to the finished surface of a machined casting. Heat-treatment, other than tempering, of grades CA6NM, CA15, CA15M, CB6, and CA40 after weld repairing shall be performed only when agreed upon between the manufacturer and the purchaser. Weld repair on Grade CA40F is not recommended because of the risk of local hardening and possible cracking in the heat-affected zone.

8.3.2. Postweld heat-treatment is not required on the other grades of this specification. When postweld heat-treatment is believed necessary for adequate corrosion resistance in the service environment, castings should be ordered in accordance with M 285M/M 285.

9. PRODUCT MARKING

9.1. Castings shall be marked for material identification with the AASHTO specification number (M 163M/M 163) and grade symbol; that is, CF8, CA15, CB30, etc. In addition, the manufacturer's name or identification mark and the pattern number shall be cast or stamped using the low-stress stamps on all castings. Small-size castings may be such that marking must be limited consistent with the available area. The marking of heat numbers on individual castings shall be agreed upon between the manufacturer and the purchaser. Marking shall be in such position as not to injure the usefulness of the casting.

10. KEYWORDS

10.1. Corrosion resistant; iron-chromium; iron-chromium-nickel; steel castings.

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall not apply unless specified in the purchase order. A list of standardized supplementary requirements for use at the option of the purchaser is included in ASTM A 781/A 781M. Those that are ordinarily considered suitable for use with this specification are given below. Others enumerated in ASTM A 781/A 781M may be used with this specification upon agreement between the manufacturer and purchaser.

S1. MAGNETIC PARTICLE EXAMINATION

S2. RADIOGRAPHIC EXAMINATION

S3. LIQUID PENETRANT EXAMINATION

S4. ULTRASONIC EXAMINATION

S5. EXAMINATION OF WELD PREPARATION

S6. CERTIFICATION

S7. PRIOR APPROVAL OF MAJOR WELD REPAIRS

S11. INTERGRANULAR CORROSION TEST

S11.1. An intergranular corrosion test shall be performed in accordance with the appropriate practice for the particular grade involved, as listed in ASTM A 262, or as agreed upon with the purchaser. Intergranular corrosion tests on stabilized or 0.03 percent carbon maximum grades (CF3, CF3M, CF8C, and CG3M) shall be made on sensitized specimens. On all other grades of chromium-nickel steels, intergranular corrosion tests shall be made on specimens representative of the as-shipped condition.

S12. TENSION TEST

S12.1. Tensile properties shall be determined from material representing each heat. The bar from which the test specimen is taken shall be heat-treated in production furnaces to the same procedure as the castings it represents. The results shall conform to the requirements specified in Table 4.

Table 4—Tensile Requirements

Grade	Type	Tensile Strength, Min		Yield Strength, Min		Elongation in 50 mm [2 in.], Min, percent[a]	Reduction of Area, Min, percent
		MPa	[ksi]	MPa	[ksi]

CK35MN	23 Chromium, 21 Nickel with Molybdenum and Nitrogen	570	[83]	280	[41]	35	—
CB6	16 Chromium, 4 Nickel	790	[115]	580	[85]	16	35

[a] When ICI test bars are used in tensile testing as provided for in this specification, the gauge length to reduced section diameter ratio shall be 4:1.

[b] For low-ferrite or nonmagnetic castings of this grade, the following values shall apply: tensile strength, min, 450 MPa [65 ksi]; yield point, min, 195 MPa [28 ksi].

[c] These mechanical properties apply only when heat-treatment (1) has been used.

S12.2. Test bars shall be poured in separately cast keel blocks similar to Figure 1, Figure 2, or Figure 3 of ASTM A 781/A 781M.

S12.3. Tension test specimens may be cut from heat-treated castings or from as-cast castings if no heat-treatment is specified for the castings, instead of from test bars, when agreed upon between the manufacturer and the purchaser.

S12.4. Test specimens shall be machined to the form and dimensions of the standard round 50-mm [2-in.] gauge length specimen shown in Figure 4 or Figure 5 of T 244 and shall be tested in accordance with T 244.

S12.5. If the results of the mechanical tests for any heat, lot, or casting do not conform to the requirements specified, retests are permitted as outlined in T 244. At the manufacturer's option, castings may be reheat-treated and retested. When castings are reheat-treated, they may not be reaustenitized more than three times without the approval of the purchaser. Testing after reheat-treatment shall consist of the full number of specimens taken from locations complying with the specification or order.

S12.6. If any test specimen shows defective machining or develops flaws, it may be discarded and another specimen substituted from the same heat.

S13. POST WELD HEAT-TREATMENT

S13.1. Weld repairs shall be considered major in the case of a casting which has leaked on hydrostatic test or when the depth of the cavity after preparation for repair exceeds 20 percent of the actual wall thickness or 25 mm [1 in.], whichever is smaller, or when the extent of the cavity exceeds approximately 65 cm^2 [10 in.^2]. All other weld repairs shall be considered minor.

S13.2. The manufacturer shall inform the purchaser of the extent of defects present in the castings as ordered. Before any casting repairs are undertaken, the purchaser shall consider whether removal of the surface defects will compromise the integrity of the casting, and whether sufficient wall thickness is available to prevent hydrostatic leakage or degrade its life cycle. Weld repairs shall be considered major if the size or depth of defects or flaws could result in leakage or rupture when brought to anticipated ranges of pressure or stress, taking into account the fracture toughness of the material at operating temperatures. Whether the defects shall be weld-repaired or not shall be determined by agreement between the purchaser and the manufacturer.

S13.3. Grades CF8, CG3M, CG8M, CG12, CF20, CF8M, CF8C, CF16F, CF16Fa, CH10, CH20, CE30, CK20, CF3, CF3M, CF3MN, CN7M, CN7MS, CN3MN, CB30, CC50, CA6N, and CK3MCuN shall be heat-treated after major weld repairs, but it is not required after minor repairs except by agreement between the manufacturer and the purchaser.

S14. HARDNESS TESTS

S14.1. Brinell tests on non-austenitic grades shall be conducted. Grades CA15, CA15M, CB30, and CC50 shall have a Brinell hardness of 241 HB maximum. Grade CA6NM shall have a Brinell hardness of 285 HB maximum; Grade CA40 and CA40F, 269 HB maximum; and Grade CA28MWV, 302-352 HB, except for the annealed condition, when the Brinell hardness of this grade shall not exceed 269 HB.

S14.2. The location where the Brinell hardness reading is to be taken and the frequency of such Brinell hardness inspection of the castings shall be established by agreement between the manufacturer and the purchaser.

S15. LOW FERRITE IN CF8

S15.1. When low ferrite or nonmagnetic properties are required, the mechanical property requirements and volume fraction of ferrite as determined by S31, ASTM A 890/A 890M, shall be by agreement between the manufacturer and the purchaser.

---

[1] Agrees with ASTM A 743/A 743M-06 except for the addition of Section S13.2 to the Supplementary Requirements.

Standard Specification for

High-Strength Bolts for Structural Steel Joints

AASHTO Designation: M 164-05 (2008)
ASTM Designation: A 325-04b

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

High-Strength Bolts for Structural Steel Joints

AASHTO Designation: M 164-05 (2008)
ASTM Designation: A 325-04b

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 325-04b for the information formerly contained in this standard.

Standard Specification for

High-Strength Bolts for Structural Steel Joints [Metric]

AASHTO Designation: M 164M-06
ASTM Designation: A 325M-04b

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

High-Strength Bolts for Structural Steel Joints [Metric]

AASHTO Designation: M 164M-06
ASTM Designation: A 325M-04b

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 325M-04b for the information formerly contained in this standard.

Standard Specification for

Steel Bars, Carbon and Alloy, Cold-Finished

AASHTO Designation: M 169-09
ASTM Designation: A 108-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Bars, Carbon and Alloy, Cold-Finished

AASHTO Designation: M 169-09
ASTM Designation: A 108-07

1. SCOPE

1.1. This specification covers cold-finished carbon and alloy steel bars produced in straight length and coil to chemical compositions. Cold-finished bars are suitable for heat-treatment, for machining into components, or for use in the as-finished condition as shafting, or in constructional applications, or for other similar purposes (Note 1). Grades of steel are identified by grade numbers or by chemical composition.

Note 1—A guide for the selection of steel bars is contained in ASTM A 400.

1.2. Some end uses may require one or more of the available designations shown under Supplementary Requirements. Supplementary requirements shall apply only when specified individually by the purchaser.

1.3. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *product tolerance levels*—cold-finished steel bars produced with up to four increasingly tight tolerance levels for the individual product characteristics, dependent on the method of manufacture necessary to meet purchaser-ordered specifications requirements. (Select Product Tolerance Level 1 unless otherwise specified by the purchaser.)

4. ORDERING INFORMATION

4.1. Orders for cold-finished steel bars to this specification should include the following items to adequately describe the material:

4.1.1. Name of material;

4.1.2. AASHTO specification number and date of issue;

4.1.3. Chemical composition grade designation or limits;

4.1.4. Silicon level, if required;

4.1.5. Additional machinability-enhancing elements (see Footnote F to Table 1 of ASTM A 29/A 29M);

4.1.6. Condition (Surface Roughness tolerances listed in Table 7);

4.1.7. Tolerance levels (refer to tolerance levels listed in Tables 1 through 9);

4.1.8. Shape (round, hexagon, square, flat, etc.), size, and length;

4.1.9. Report of heat analysis, if required;

4.1.10. End use;

4.1.11. Additions to the specification and special or supplementary requirements, if required; and

4.1.12. For coiled product, the coil mass, inside diameter, outside diameter, and coil height limitations, when required.

Note 2—A typical ordering description is as follows: Steel Bar, M 169-___; SAE 1117; Coarse Grain; Cold Drawn; 38.10-mm (1.5-in.) diameter round by 3657.61 mm (12.0 feet) long; Heat Analysis Required; Precision Machine Parts.

5. GENERAL REQUIREMENTS

5.1. Material furnished under this specification shall conform to the applicable requirements of the current edition of ASTM A 29/A 29M.

6. MATERIALS AND MANUFACTURE

6.1. *Feedstock*—Cold-finished bars shall be produced from hot-wrought carbon or alloy steel bars (ASTM A 29/A 29M) or from hot-wrought rod designed for cold-finished bars (ASTM A 510).

6.2. *Condition*—The product bars shall be furnished in one of the following conditions as specified by the purchaser:

6.2.1. *Rounds*:

6.2.1.1. Cold drawn;

6.2.1.2. Cold drawn, turned, and polished;

6.2.1.3. Cold drawn, ground, and polished;

6.2.1.4. Cold drawn, turned, ground, and polished;

6.2.1.5. Cold drawn, turned, and ground;

6.2.1.6. Hot wrought, turned, and polished;

6.2.1.7. Hot wrought, turned, ground, and polished;

6.2.1.8. Hot wrought, turned, and ground; or

6.2.1.9. Hot wrought, rough turned.

6.2.2. *Squares, Hexagons:*

6.2.2.1. Cold drawn, or

6.2.2.2. Cold rolled.

6.2.3. *Flats*:

6.2.3.1. Cold drawn; or

6.2.3.2. Cold rolled.

6.2.4. *Special Bars Sections*:

6.2.4.1. Cold drawn, or

6.2.4.2. Cold rolled.

6.3. *Heat-Treatment*:

6.3.1. Unless otherwise specified, the bars shall be furnished as cold finished. Plain carbon steels with a maximum carbon greater than 0.55 percent and alloy steels with a maximum carbon greater than 0.38 percent shall be annealed prior to cold finishing.

6.3.2. The following heat-treatment processes may be performed singularly or in combination:

6.3.2.1. Annealed,

6.3.2.2. Normalized,

6.3.2.3. Stress relieved, or

6.3.2.4. Quenched and tempered.

7. CHEMICAL COMPOSITION

7.1. *Chemical Composition*:

7.1.1. The chemical analysis of the steel shall conform to that specified in ASTM A 29/A 29M for the steel grade ordered or to other limits as may be specified using the standard ranges in ASTM A 29/A 29M.

7.1.2. Steels may be selected from ASTM A 29/A 29M, A 304, A 322, A 576, and A 510; the *SAE Handbook*; or the ISS steel bar products guideline for bar steel.

7.1.3. When a steel cannot be identified by a standard grade number in accordance with Sections 7.1.1 and 7.1.2, the limits for each required element may be specified using the chemical ranges shown in the table “Heat Analysis Chemical Ranges and Limits of Carbon Steel Bars” of ASTM A 29/A 29M.

8. TOLERANCE LEVELS

8.1. *Cold-Finished Bars*—The permissible dimensional variations for cold-finished carbon and alloy steel bars shall not exceed the applicable tolerance levels for limits stated in Tables 1 through 9.

Table 1—Size Tolerances for Level 1 Cold-Finished Carbon Steel Bars, Cold Drawn or Turned and Polished

Size, mm (in.)[a]	Maximum of Carbon Range 0.28% or less	Maximum of Carbon Range over 0.28% to 0.55% incl	Maximum of Carbon Range to 0.55% incl, Stress Relieved or Annealed After Cold Finishing	Maximum of Carbon Range over 0.55% or All Grades Quenched and Tempered or Normalized and Tempered Before Cold Finishing
All tolerances are in millimeters (inches) and are minus.[b]				
Rounds—Cold Drawn[c] to 152.4 mm (6 in.) or Turned and Polished				
To 38.1 ($1^{1}/_{2}$) incl, in coils, or cut lengths	0.051 (0.002)	0.076 (0.003)	0.102 (0.004)	0.127 (0.005)

[a] Standard manufacturing practice is shear cut for cold-drawn bars (size limits vary by producer) which can cause end distortion resulting in those portions of the bar being outside the applicable size tolerance. When this end condition is undesirable, a saw cut end to remove end distortion should be considered.

[b] While size tolerances are usually specified as minus, tolerances may be ordered all plus, or distributed plus and minus, with the sum being equivalent to the tolerances listed.

[c] Maximum allowable deviation in roundness around the circumference of the same cross section of a round cold-drawn bar is $^{1}/_{2}$ the size tolerance range.

[d] Width governs the tolerances for both width and thickness of flats. For example, when the maximum of carbon range is 0.28 percent or less for a flat 50.80 mm (2 in.) wide and 25.40 mm (1 in.) thick, the width tolerance is 0.127 mm (0.005 in.) and the thickness tolerance is the same, namely, 0.127 mm (0.005 in.).

Table 2—Size Tolerances for Level 1 Cold-Finished Alloy Steel Bars, Cold Drawn or Turned and Polished

Size, mm (in.)[a]	Maximum of Carbon Range 0.28% of less	Maximum of Carbon Range over 0.28% to 0.55% incl	Maximum of Carbon Range to 0.55% incl, Stress Relieved or Annealed After Cold Finishing	Maximum of Carbon Range over 0.55% with or without Stress Relieving or Annealing after Cold Finishing. Also, All Carbons, Quenched and Tempered (Heat Treated), or Normalized and Tempered, before Cold Finishing

[a] Standard manufacturing practice is shear cut for cold-drawn bars (size limits vary by producer) which can cause end distortion resulting in those portions of the bar being outside the applicable size tolerance. When this end condition is undesirable, a saw cut end to remove end distortion should be considered.

[b] While size tolerances are usually specified as minus, tolerances may be ordered all plus, or distributed plus and minus, with the sum being equivalent to the tolerances listed.

[c] Maximum allowable deviation in roundness around the circumference of the same cross section of a round cold-drawn bar is $^1/_2$ the size tolerance range.

[d] Width governs the tolerances for both width and thickness of flats. For example, when the maximum of carbon range is 0.28 percent or less for a flat 50.80 mm (2 in.) wide and 25.40 mm (1 in.) thick, the width tolerance is 0.127 mm (0.005 in.) and the thickness tolerance is the same, namely, 0.127 mm (0.005 in.).

Table 3—Size Tolerances for Levels 2 and 3 Cold-Finished Round Bars, Cold-Drawn, Ground and Polished, or Turned, Ground, and Polished

Size, mm (in.) Cold Drawn, Ground and Polished[a]	Size, mm (in.) Turned, Ground, and Polished[a]	Tolerances from Specified Size, Minus Only, mm (in.)	
		Level 2	Level 3
To 38.10 ($1^1/_2$) incl	To 38.10 ($1^1/_2$) incl	0.0254 (0.001)	0.0203 (0.0008)
Over 38.10 ($1^1/_2$) to 63.50 ($2^1/_2$) excl	Over 38.10 ($1^1/_2$) to 63.50 ($2^1/_2$) excl	0.0381 (0.0015)	0.033 (0.0013)
63.50 ($2^1/_2$) to 76.20 (3) incl	63.50 ($2^1/_2$) to 76.20 (3) incl	0.0508 (0.002)	0.0381 (0.0015)
Over 76.20 (3) to 101.60 (4) incl	Over 76.20 (3) to 101.60 (4) incl	0.0762 (0.003)	0.0635 (0.0025)
—	Over 101.60 (4) to 152.40 (6) incl	0.1016 (0.004)[b]	0.0762 (0.003)[b]
—	Over 152.40 (6)	0.127 (0.005)[b]	0.1016 (0.004)[b]

[a] Maximum allowable deviation of roundness or ovality tolerances are agreed upon between purchaser and supplier.

[b] For nonresulfurized steels (steels specified to maximum sulfur limits under 0.08 percent) or for steels thermally treated, the tolerance is increased by 0.025 mm (0.001 in.).

Table 4—Straightness Tolerances for Level 1 Cold-Finished Bars[a,b]

Note 3—All grades quenched-and-tempered or normalized and tempered to Brinell 302 maximum before cold finishing; and all grades stress relieved or annealed after cold finishing. Straightness tolerances are not applicable to bars having Brinell hardness exceeding 302.

		Straightness Tolerances, mm (in.) Maximum Deviation from Straightness in Any 3048-mm (10-ft) Portion of the Bar			
		Maximum of Carbon Range, 0.28% or Less		Maximum of Carbon Range, over 0.28% and All Grades Thermally Treated	
Size, mm (in.)	Length, mm (ft)	Rounds	Squares, Hexagons, and Octagons	Rounds	Squares, Hexagons, and Octagons
Less than 15.88 ($^5/_8$)	Less than 4572 (15)	3.17 ($^1/_8$)	4.76 ($^3/_{16}$)	4.76 ($^3/_{16}$)	6.35 ($^1/_4$)
Less than 15.88 ($^5/_8$)	4572 (15) and over	3.17 ($^1/_8$)	7.94 ($^5/_{16}$)	7.94 ($^5/_{16}$)	9.53 ($^3/_8$)
15.88 ($^5/_8$) and over	Less than 4572 (15)	1.59 ($^1/_{16}$)	3.17 ($^1/_8$)	3.17 ($^1/_8$)	4.76 ($^3/_{16}$)
15.88 ($^5/_8$) and over	4572 (15) and over	3.17 ($^1/_8$)	4.76 ($^3/_{16}$)	4.76 ($^3/_{16}$)	6.35 ($^1/_4$)

[a] The foregoing tolerances are based on the following method of measuring straightness: Departure from straightness is measured by placing the bar on a level table so that the arc or departure from straightness is horizontal, and the depth of the arc is measured with a feeler gauge and a straightedge.

[b] It should be recognized that straightness is a perishable quality and may be altered by mishandling. The preservation of straightness in cold-finished bars requires the utmost care in subsequent handling. Specific straightness tolerances are sometimes required for carbon and alloy steels in which case the purchaser should inform the manufacturer of the straightness tolerances and the methods to be used in checking the straightness.

Table 5—Length Tolerances for Cold-Finished Steel Bars

Product Tolerance Level	Tolerances, mm (in.) Plus Allowances Deviation above Specified Uniform Length		
	Cutting Process	Minimum	Maximum
Level 1	Shear Cut	0.000	50.80 (2.000)
Level 2	In-Line Saw Cut	0.000	25.40 (1.000)
Level 3	Off-Line Saw Cut	0.000	12.70 (0.500)

Table 6—Across-Corner Tolerances for Hexagon and Square Cold-Finished Steel Bars[a]

Product Tolerance Level	Tolerance Range Applied to Across-Corner Calculations	
	Hexagon, mm (in.), minus	Square, mm (in.), minus
Level 1	0.64 (0.025)	0.76 (0.030)
Level 2	0.51 (0.020)	0.64 (0.025)
Level 3	0.38 (0.015)	0.51 (0.020)
	Sharp Corner Hexagon Calculation = $(1.1547 \times D)$	Sharp Corner Square Calculation = $(1.4142 \times D)$
	Round Corner Hexagon Calculation = $[1.1547 \times (D - 2r)] + 2r$	Round Corner Square Calculation = $[1.4142 \times (D - 2r)] + 2r$

[a] When required, type of corner must be specified at time of order inquiry.

Table 7—Surface Roughness Average (R_a) Tolerances for Cold-Finished Steel Bars[a]

Product Tolerance Level	Allowance Maximum Deviation of Surface Roughness Average (R_a) Measurement	
	Turned and Polished Maximum, µm (µin.) (R_a)	Ground and Polished Maximum, µm (µin.) (R_a)
Level 1	Not Required	1.0 (40)
Level 2[b]	1.5 (60)	0.8 (30)
Level 3[b]	1.0 (40)	0.5 (20)

[a] RMS (root mean square calculation) is no longer applied to measure surface roughness. Roughness average (R_a) is current technology measurement output data.

[b] Special surface R_a restrictions must be agreed upon at the time of order inquiry, between purchaser and supplier. Lower R_a values are available with additional bar passes and/or special processing conditions.

Table 8—Surface Discontinuity Tolerances for Cold-Finished Steel Bars[a]

Product Tolerance Level	Maximum Allowable Surface Discontinuity Depth					
	Carbon and Alloy Non-resulfurized		Carbon and Alloy Resulfurized (0.08–0.19% Sulfur)		Carbon and Alloy Resulfurized (0.20–0.35% Sulfur)	
	Maximum Depth 6.35 mm ($^{1}/_{4}$ in.)—15.88 mm ($^{5}/_{8}$ in.) max. mm (in.)	Maximum Depth (% of Size) over 15.88 mm ($^{5}/_{8}$ in.)–152.40 mm (6 in.) (max. percentage)	Maximum Depth 6.35 mm ($^{1}/_{4}$ in.)–15.88 mm ($^{5}/_{8}$ in.) max. mm (in.)	Maximum Depth (% of Size) over 15.88 mm ($^{5}/_{8}$ in.)–152.40 mm (6 in.) (max. percentage)	Maximum Depth 6.35 mm ($^{1}/_{4}$ in.)–15.88 ($^{5}/_{8}$ in.) max. mm (in.)	Maximum Depth (% of Size) 15.88 mm ($^{5}/_{8}$ in.)–152.40 mm (6 in.) (max. percentage)
Level 1	0.20 (0.008)	1.6	0.25 (0.010)	2.0	0.30 (0.012)	2.4
Level 2	0.15 (0.006)	1.0	0.20 (0.008)	1.3	0.25 (0.010)	1.6
Level 3	0.15 (0.006)	0.075	0.15 (0.006)	1.0	0.20 (0.008)	1.3
Level 4[b]	Nil	Nil	Nil	Nil	Nil	Nil

[a] The information in the chart is the expected maximum surface discontinuity depth within the limits of good manufacturing practice. Occasional bars in a shipment may have surface discontinuity that exceed these limits. For critical applications, the purchaser may require the cold-finish steel bar supplier to eddy current test the bars prior to shipment.

[b] Level 4 requires metal removal by turning or multiple grinding passes for small bars.

Table 9—Surface Decarburization Tolerances for Cold-Finished Steel Bars

	Tolerances, mm (in.) Plus Allowances Deviation above Specified Uniform Length	
Product Tolerance Level	Maximum Millimeters of Decarburization per Side of Bar, 6.35 mm ($^{1}/_{4}$-in.)–15.88 mm ($^{5}/_{8}$-in.) Sizes, All Shapes, max. mm (in.)	Maximum Percentage of Decarburization per Side, Based on Percentage of Size over 15.88 mm ($^{5}/_{8}$-in.)–152.40 mm (6-in.) Sizes, All Shapes, (max., %)
Level 1	0.25 mm (0.010)	1.6
Level 2	0.15 mm (0.006)	1.0
Level 3 [a]	Nil	Nil

[a] Level 3 requires metal removal by turning or multiple grinding for small bars.

9. WORKMANSHIP, FINISH, AND APPEARANCE

9.1. *Workmanship:*

9.1.1. Within the limits of good manufacturing and inspection practices, the bars shall be free of injurious imperfections which, due to their nature, degree, or extent, will interfere with the use of the material in machining or fabrication of suitable parts. (See Table 8.)

9.1.2. Table 8 contains the recommended minimum stock removal to ensure removal of surface discontinuities in cold finished bars.

9.2. *Finish:*

9.2.1. Unless otherwise specified, the bars shall have a commercial bright smooth surface finish obtained by conventional cold-finishing operations such as cold drawing or cold rolling.

9.2.2. When a superior bar surface finish is required, bars may be obtained as turned and polished; ground and polished; or turned, ground, and polished. (See Table 7.)

9.2.3. Bars that are thermally treated after cold finishing may exhibit a discolored or oxidized surface.

9.3. *Product Presentation/Appearance*:

9.3.1. The bars shall be given a surface coating of oil or other rust inhibitor to protect against corrosion during shipment.

9.3.2. The bar bundles shall be identified, packaged, and loaded to preserve the physical appearance, product tolerance, and identity of the cold-finished product, as agreed upon between the purchaser and supplier.

10. CERTIFICATION

10.1. Upon request of the purchaser in the contract or order, a manufacturer's certification that the material was manufactured and tested in accordance with this specification together with a report of the test results shall be furnished at the time of shipment.

11. KEYWORDS

11.1. Alloy steel; carbon steel bars; cold-finished; steel bars.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of these supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. HOT-ROLLING REDUCTION RATIO

S1.1. When required, purchaser may require the supplier to report the reduction ratio of the initial Bloom/Billet cross-sectional area to the finished hot-rolled cross-sectional area.

S2. STEEL MELTING PROCESS

S2.1. When required, purchaser may require the supplier to report the steel melting process (basic oxygen furnace, electric arc furnace, etc.) for each initial heat/lot number supplied to the purchaser.

S3. STEEL REFINEMENT PROCESS

S3.1. When require, purchaser may require the supplier to report the steel refinement processes performed after melting and before casting (vacuum degassed, etc.) on the heat/lot number supplied to the purchaser.

S4. CONTINUOUS CASTING PROCESS

S4.1. When required, purchaser may require the supplier to report the casting process (bloom, billet, etc.) for each heat/lot number supplied to the purchaser.

S5. COUNTRY OR COUNTRIES OF ORIGIN

S5.1. When required, purchaser may require the supplier to report the country of origin where the steel was melted for each heat/lot number supplied to the purchaser.

S5.2. When required, purchaser may require the supplier to report the country of origin where the steel was hot rolled for each heat/lot number supplied to the purchaser.

S5.3. When required, purchaser may require the supplier to report the country of origin where the steel was cold finished for each heat/lot number supplied to the purchaser.

S6. MECHANICAL PROPERTIES

S6.1. When required, purchaser may require the supplier to report the cold-finished steel bars' mechanical properties for each heat/lot number supplied to the purchaser. Mechanical properties shall be evaluated in accordance with T 244.

S7. SURFACE INSPECTION

S7.1. When required, purchaser may require the supplier to inspect the cold-finished steel bars' surface with an electromagnetic surface inspection process to detect and sort surface discontinuities that exceed the maximum allowed depth tolerances listed in Table 8 or other tolerances agreed upon between the purchaser and supplier.

S8. BAR MARKING

S8.1. When required, bar marking specification requirements shall be agreed upon between the purchaser and supplier.

Standard Specification for

Steel Sheet Piling

AASHTO Designation: M 202M/M 202-08
ASTM Designation: A 328/A 328M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Sheet Piling

AASHTO Designation: M 202M/M 202-08
ASTM Designation: A 328/A 328M-07

1. SCOPE

1.1. This specification covers carbon steel sheet piling of structural quality for use in the construction of dock walls, sea walls, cofferdams, excavations, and like applications. When the steel is to be welded, it is presupposed that a welding procedure suitable for the grade of steel and intended use or service will be utilized.

1.2. This specification is applicable to orders in either SI units (as M 202M) or inch-pound units (as M 202). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 202.

1.3. For structural products cut from coiled product and furnished without heat-treatment or with stress relieving only, the additional requirements of M 160M/M 160, including additional testing requirements and reporting of additional tests, apply.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 160M/M 160, General Requirements for Steel, Plates, Shapes, Sheet Piling, and Bars for Structural Use (Discontinued)
- M 164, High-Strength Bolts for Structural Steel Joints (Discontinued)
- M 164M, High-Strength Bolts for Structural Steel Joints [Metric] (Discontinued)
- M 291, Carbon and Alloy Steel Nuts
- M 291M, Carbon and Alloy Steel Nuts [Metric] (Discontinued)

2.2. *ASTM Standards*:

- A 6/A 6M, Standard Specification for General Requirements for Rolled Structural Steel Bars, Plates, Shapes, and Sheet Piling
- A 572/A 572M, Standard Specification for High-Strength Low-Alloy Columbium-Vanadium Structural Steel

3. GENERAL REQUIREMENT FOR DELIVERY

3.1. Sheet piling furnished under this specification shall conform to the requirements of the current edition of M 160M/M 160, for the specific sheet piling ordered, unless a conflict exists, in which case this specification shall prevail.

3.2. Coils are excluded from qualification to this specification until they are processed into finished sheet piling. Sheet piling produced from coil means sheet piling that has been cut to individual lengths from a coil. The processor directly controls, or is responsible for, the operations involved in the processing of a coil into finished sheet piling. Such operations include decoiling, leveling, hot forming or cold forming (if applicable), cutting to length, testing, inspection, conditioning, heat-treatment (if applicable), packaging, marking, loading for shipment, and certification. (See Note 1.)

Note 1—For sheet piling produced from coil and furnished without heat-treatment or with stress relieving only, two test results are to be reported for each qualifying coil. Additional requirements regarding sheet piling produced from coil are described in M 160M/M 160.

4. PROCESS

4.1. The steel may be made by any process that produces material meeting the requirements set forth in this specification.

5. CHEMICAL REQUIREMENTS

5.1. The heat analysis shall conform to the requirements prescribed in Table 2.

Table 1—Chemical Requirements

Element	Composition, Percent, Heat Analysis
Phosphorus, max	0.035
Sulfur, max	0.04
Copper (when specified), min	0.20

5.2. The steel shall conform on product analysis to the requirements prescribed in Table 2, subject to the product analysis tolerances in M 160M/M 160.

6. MECHANICAL REQUIREMENTS

6.1. The material, as represented by the test specimens, shall conform to the requirements as to tensile properties prescribed in Table 2.

Table 2—Tensile Requirements

Tensile strength, min, MPa [ksi]	450 [65][a]
Yield point, min, MPa [ksi]	270 [39]
Elongation in 200 mm [8 in.], min, percent	17[b]
Elongation in 50 mm [2 in.], min, percent	20

[a] Prior to M 202M/M 202–05, the minimum tensile strength was 485 MPa [70 ksi].

[b] See Elongation Requirement Adjustment in the Tension Tests section of M 160M/M 160. See Specimen Orientation in the Tension Tests section of M 160M/M 160.

6.2. A minimum tensile strength of 415 MPa [60 ksi] and a minimum yield point of 250 MPa [36 ksi] shall be permitted for piling sections used in the fabrication of cold-formed connections.

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified in the purchase order.

S1. INTERLOCK STRENGTH

S1.1. The minimum strength of the interlocked joint required for certain services may be specified for certain sheet-piling sections subject to specific agreement between the material purchaser and the manufacturer.

Standard Specification for

Steel Bars, Carbon, Merchant Quality, Mechanical Properties

AASHTO Designation: M 227M/M 227-97 (2005)
ASTM Designation: A 663/A 663M-89 (2000)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Bars, Carbon, Merchant Quality, Mechanical Properties

AASHTO Designation: M 227M/M 227-97 (2005)
ASTM Designation: A 663/A 663M-89 (2000)

1. SCOPE

1.1. This specification covers hot-wrought merchant quality carbon steel bars and bar size shapes produced to mechanical property requirements and intended for noncritical constructional applications. (See Section 3.2.)

1.2. Merchant quality hot-wrought steel bar is available in the following ranges of size and section:

1.2.1. Rounds, squares, and hexagons with diameters or distance across flats less than 75 mm [3 in.].

1.2.2. Bar size shapes with maximum dimensions less than 75 mm [3 in.].

1.2.3. Other bar sections with weight per foot less than 60.78 kg/m [40.84 lb/ft].

1.2.4. Flats 150 mm [6 in.] or less in width, more than 5.156 mm [0.203 in.] in thickness, and less than 60.78 kg/m or 77 cm^2 [40.84 lb/ft or 12 in.^{2}] in cross-sectional area.

1.2.5. Flats over 50 to 200 mm [6 to 8 in.] inclusive in width, 6 mm [0.230 in.] in thickness, and under 60.78 kg/m or 77 cm^2 [40.84 lb/ft or 12 in.^{2}] in cross-sectional area.

1.2.6. Hot-wrought merchant quality carbon steel bars subject to mechanical property requirements are hot-wrought in straight lengths only.

1.3. Some applications may require one or more of the available designations shown under supplementary requirements.

Note 1—Special quality hot-wrought carbon steel bars subject to mechanical property requirements are covered in M 255M/ M 255.

1.4. This specification is applicable to orders in either SI units (as M 227M) or inch-pound units (as M 227). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 227.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 255M/M 255, Steel Bars, Carbon, Hot-Wrought, Special Quality, Mechanical Properties
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- E 290, Standard Test Methods for Bend Testing of Material for Ductility

3. ORDERING INFORMATION

3.1. Orders for material under this specification should include the following information:

3.1.1. Quantity (mass or number of pieces);

3.1.2. Dimensions (cross-sectional shape, size, and length);

3.1.3. Name of material (merchant quality carbon steel bars);

3.1.4. Specification number and date of issue;

3.1.5. Grade designation;

3.1.6. Copper-bearing steel (if required);

3.1.7. Heat analysis or test report (request, if required);

3.1.8. Application and processing; and

3.1.9. Supplementary requirements (if required).

4. GENERAL REQUIREMENTS

4.1. Material furnished under this specification shall conform to the requirements of the current edition of ASTM A 29/A 29M, except as stated in Sections 1.2 and 4.2.

4.2. Merchant quality bars shall be free from visible pipe; however, they may contain pronounced chemical segregation. Internal porosity, surface seams, and other surface irregularities may be present in this quality. Deoxidation practice and grain size are at the manufacturer's option.

4.3. Unless otherwise specified, the bars shall be furnished as rolled and not pickled, blast cleaned, nor oiled.

5. MANUFACTURE

5.1. The steel shall be made by the open-hearth, basic oxygen, or electric furnace process.

6. CHEMICAL COMPOSITION

6.1. The steel shall conform on heat analysis to the following chemical requirements:

Phosphorus, max, percent	0.04
Sulfur, max, percent	0.05
Copper, when copper steel is specified, min, percent	0.20

6.2. When tension tests are waived in accordance with Section 7.1.6, chemistry consistent with the mechanical properties desired shall be applied.

7. MECHANICAL PROPERTIES

7.1. *Tensile Requirements*:

7.1.1. The material as represented by the test specimen shall conform to the applicable requirements in Table 1.

Table 1—Tensile Requirements

Grade Designation	Tensile Strength, MPa [ksi]	Yield Point,[a] Min, MPa [ksi][b]	Elongation, Min, %	
			200-mm [8-in.] Gauge Length	50-mm [2-in.] Gauge Length
310 [45]	310–380 [45–55]	175 [25.0]	27	33
345 [50]	345–415 [50–60]	195 [28.0]	25	30
380 [55]	380–450 [55–65]	210 [30.0]	23	26
415 [60]	415–495 [60–72]	230 [33.0]	21	22
450 [65]	450–530 [65–77]	250 [36.0]	17	20
485 [70]	485–585 [70–85]	270 [39.0]	14	18
515 [75]	515–620 [75–90]	285 [41.0]	14	18
550 [80]	550 min [80 min]	305 [44.0]	13	17

[a] When the tension test does not show a yield point (drop of the beam, halt of the pointer, or sharp-kneed stress-strain diagram), yield strength shall be determined by either 0.5 percent extension-under load or 0.2 percent offset. The minimum MPa [ksi] requirement does not change. The test report, if required, shall show yield strength.

[b] Rounded value.

7.1.2. Test specimens shall be prepared for testing from the material in its as-rolled condition. The tension specimen may be aged as described in T 244.

7.1.3. Test specimens shall be taken longitudinally and may be tested in full thickness or section, or they may be machined to the dimensions shown in Figures 4 or 5 of T 244. If test specimens are selected conforming to the dimensions of Figure 5, they shall be machined from a position midway between the center and the surface of the bar.

7.1.4. Test specimens for shapes and flats may be machined to the form and dimensions shown in Figure 4 of T 244 or with both edges parallel. Test specimens for material more than 40 mm [$1^1/_2$ in.] in thickness or diameter may be machined to a thickness or diameter of at least 20 mm [$^3/_4$ in.] for a length of at least 230 mm [9 in.], or they may conform to the dimensions shown in Figure 5 of T 244.

7.1.5. Tensile requirements shall be determined in accordance with T 244.

7.1.6. Shapes less than 645 mm^2 [1 in.^{2}] in cross section and bars (other than flats) less than 12.5 mm [$^1/_2$ in.] in thickness or diameter need not be subject to tension tests by the manufacturer.

7.1.7. For material more than 20 mm [$^3/_4$ in.] in thickness or diameter, a deduction from the percentage of elongation in 200 mm [8 in.] specified in Table 1 of 0.25 percent shall be made for each increase of 0.8 mm [$^1/_{32}$ in.] in the specified thickness or diameter above 20 mm [$^3/_4$ in.].

7.1.8. For material under 8 mm [$^5/_{16}$ in.] in thickness or diameter, a deduction from the percentage of elongation in 200 mm [8 in.] specified in Table 1 of 2.00 percent shall be made for each decrease of 0.8 mm [$^1/_{32}$ in.] in the specified thickness or diameter below 8 mm [$^5/_{16}$ in.].

7.1.9. For material more than 50 mm [2 in.] in thickness or diameter, a deduction from the percentage of elongation in 50 mm [2 in.] specified in Table 1 of 1.00 percent shall be made for each 25 mm [1 in.] of specified thickness or diameter or fraction thereof over 50 mm [2 in.] in thickness or diameter.

7.2. *Number of Tests*:

7.2.1. Two tension tests shall be made from each heat, unless the finished material from a heat is less than 45 Mg [50 tons], when one tension test will be sufficient. However, for material 50 mm [2 in.] and under in thickness, when the material from one heat differs 9.5 mm [$^3/_8$ in.] or more in thickness, one tension test shall be made from both the thickest and the thinnest material rolled (larger than the sizes enumerated in Section 7.1.6), regardless of mass represented. For material more than 50 mm [2 in.] thick, when the material from one heat differs 25 mm [1 in.] or more in thickness, one tension test shall be made from both the thickest and the thinnest material rolled that is more than 50 mm [2 in.] thick regardless of the mass represented.

7.3. *Test Reports*:

7.3.1. When test reports are required by the purchase order, the report shall show the results of each test required by Section 7.2, except that only one test need be reported when the amount of material from a heat in a shipment is less than 9 Mg [10 tons] and when the thickness variations described in Section 7.2 are not exceeded.

7.3.2. The thickness of the product tested may not necessarily be the same as an individual ordered thickness since it is the heat that is tested rather than each ordered item.

7.3.3. When Supplementary Requirements are specified, the report shall include a statement of compliance with the requirement or the results of tests when the requirement involves measured test values.

8. KEYWORDS

8.1. Carbon steel bars; merchant quality steel bars; steel bars.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall apply when specified by the purchaser.

S1. SPECIAL STRAIGHTNESS

S1.1. Bars may be specified to special straightness tolerance. (Refer to ASTM A 29/A 29M.)

S2. CLEANING

S2.1. The purchaser may specify that the surface of bars be descaled by pickling or blast cleaning.

S3. COATING

S3.1. The purchaser may specify oil on bars that have been descaled.

S4. BEND TESTS

S4.1. *Requirements*:

S4.1.1. The bend-test specimen shall stand being bent at room temperature through 180 degrees without cracking on the outside of the bent portion, to an inside diameter that shall have the relation to the thickness or diameter of the specimen as given in Table 2.

Table 2—Bend Requirements

	Ratio of Bend Diameter to Thickness of Specimen for Thickness or Diameter of Bar, mm [in.]				
Grade Designation	20 [$^3/_4$] and Under	Over 20 [$^3/_4$] to 25 [1] incl	Over 25 [1] to 40 [$1^1/_2$] incl	Over 40 [$1^1/_2$] to 50 [2] incl	Over 50 [2] to Under 75 [3]
310 [45]	Flat	Flat	$^1/_2$	1	1
345 [50]	Flat	$^1/_2$	1	$1^1/_2$	$2^1/_2$
380 [55]	$^1/_2$	1	$1^1/_2$	2	$2^1/_2$
415 [60]	$^1/_2$	1	$1^1/_2$	$2^1/_2$	3
450 [65]	1	$1^1/_2$	2	3	$3^1/_2$
485 [70]	$1^1/_2$	2	$2^1/_2$	3	$3^1/_2$
515 [75]	2	2	3	$3^1/_2$	4
550 [80]	2	$2^1/_2$	3	$3^1/_2$	4

S4.2. *Test Specimens*:

S4.2.1. Bend-test specimens for material 40 mm [$1^1/_2$ in.] and under in diameter or thickness may be the full thickness of the section. For flat bars more than 50 mm [2 in.] in width, the width may be reduced by milling to 40 mm [$1^1/_2$ in.].

S4.2.2. Bend-test specimens for material greater than 40 mm [$1^1/_2$ in.] in diameter or thickness may be machined to a thickness or diameter of at least 20 mm [$^3/_4$ in.] or to 25 by 12.5 mm [1 to $^1/_2$ in.] in section. Machined sides of bend-test specimens may have the corners rounded to a radius of not over 1.6 mm [$^1/_{16}$ in.] for material 50 mm [2 in.] and under in thickness, and not over 3.2 mm [$^1/_8$ in.] in radius for material over 50 mm [2 in.] in thickness.

S4.3. *Number of Tests*:

S4.3.1. Two bend tests shall be made from each heat unless the finished material from a heat is less than 45 Mg [50 tons], when one bend test will be sufficient. However, for material 50 mm [2 in.] and under in thickness, when the material from one heat differs 9.5 mm [$^3/_8$ in.] or more in thickness, one bend test shall be made from the thickest and the thinnest material rolled, regardless of mass represented. For material more than 50 mm [2 in.] thick, when the material from one heat differs 25 mm [1 in.] or more in thickness, one bend test shall be made from both the thickest and the thinnest material rolled that is more than 50 mm [2 in.] thick regardless of the mass represented.

S4.4. *Test Methods*:

S4.4.1. Bend tests shall be made in accordance with ASTM E 290.

Standard Specification for

Zinc Coating (Hot-Dip) on Iron and Steel Hardware

AASHTO Designation: M 232M/M 232-10[1]
ASTM Designation: A 153/A 153M-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Zinc Coating (Hot-Dip) on Iron and Steel Hardware

AASHTO Designation: M 232M/M 232-10[1]
ASTM Designation: A 153/A 153M-09

1. SCOPE

1.1. This specification covers zinc coatings applied by the hot-dip process on iron and steel hardware. The hot-dip galvanizing process consists of parts being immersed in molten zinc for a time sufficient to allow a metallurgical reaction between iron from the steel surface and the molten zinc, resulting in the formation of Zn/Fe alloy layers bonding the coating to the steel surface.

1.2. This specification is intended to be applicable to hardware items that are centrifuged or otherwise handled to remove excess galvanizing bath metal (free zinc). Coating thickness grade requirements reflect this.

1.3. The values stated in SI units are to be regarded as the standard. The equivalent inch-pound units may only be approximate.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 120, Zinc
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *ASTM Standards*:
- A 143/A 143M, Standard Practice for Safeguarding Against Embrittlement of Hot-Dip Galvanized Structural Steel Products and Procedure for Detecting Embrittlement
- A 780/A 780M, Standard Practice for Repair of Damaged and Uncoated Areas of Hot-Dip Galvanized Coatings
- A 902, Standard Terminology Relating to Metallic Coated Steel Products
- B 487, Standard Test Method for Measurement of Metal and Oxide Coating Thickness by Microscopical Examination of Cross Section
- B 690, Standard Specification for Prime Western Grade-Recycled (PWG-R) Zinc
- E 376, Standard Practice for Measuring Coating Thickness by Magnetic-Field or Eddy-Current (Electromagnetic) Examination Methods

- F 1470, Standard Practice for Fastener Sampling for Specified Mechanical Properties and Performance Inspection
- F 1789 Standard Terminology for F16 Mechanical Fasteners

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. The following terms and definitions are specific to this specification. ASTM A 902 contains other terms and definitions relating to metallic coated steel products. ASTM F 1789 contains other terms and definitions relating to mechanical fasteners.

3.2. *Definitions of Terms Specific to This Standard*:

3.2.1. *average coating thickness, n*—the average of the specimen coating thickness values for the samples in an inspection lot.

3.2.2. *bare spots, n*—uncoated areas on the surface of the steel part that contain no measurable zinc coating.

3.2.3. *dross inclusions, n*—the iron/zinc intermetallics, oxides, and flux remnants present in a galvanized coating in a form other than the layer growth of the coating.

3.2.4. *individual measurement, n*—the reading from a magnetic thickness gauge of a single coating spot thickness, or the microscopic reading of a coating thickness as seen in an optical microscope at one spot.

3.2.5. *inspection lot, n*—the quantity of identical parts cleaned, fluxed, and galvanized together at one time in an appropriate container that is being submitted for acceptance as a group.

3.2.6. *malleable casting, n*—a steel article that has been subjected to a prolonged anneal to decarburize or graphitize the part to remove as much of the carbon as possible or to convert the carbon to graphite, which permits plastic deformation in compression without rupture.

3.2.7. *sample, n*—a collection of individual units of product from a single inspection lot selected in accordance with Section 6 and intended to represent that inspection lot for acceptance.

3.2.8. *specimen, n*—an individual test article upon which thickness measurements or mass [weight] determinations are performed.

3.2.9. *specimen coating thickness, n*—the average thickness from no fewer than five test measurements on a specimen, when each measurement location is selected to provide the widest dispersion (in all applicable directions) of locations within the specimen volume.

3.2.10. *threaded areas, n*—the sections of a steel part that have threads formed before hot-dip galvanizing.

4. MATERIALS AND MANUFACTURE

4.1. *Steel or Iron*—Ferrous articles to be hot-dip zinc coated shall conform to specifications designated by the purchaser.

4.2. *Zinc*—The zinc used for the coating shall conform to M 120 or ASTM B 690, or both, and shall be at least equal to the grade designated as "Prime Western."

4.2.1. If a zinc alloy is used as the primary feed for the galvanizing bath, then the base material used to make that alloy shall conform to M 120 or ASTM B 690, or both.

4.2.2. The molten metal in the working volume of the galvanizing bath shall contain not less than an average value of 98.0 percent zinc by mass [weight].

Note 1—The galvanizer may choose to add trace amounts of certain elements (for example, aluminum, nickel, bismuth, or tin) to the zinc bath to help in the processing of certain reactive steels or to enhance the cosmetic appearance of the finished product. The elements can be added to the galvanizing bath as a master feed alloy, or they can be added to the bath by the galvanizer as individual feeds.

4.2.3. If high-grade or special high-grade zinc is used, the molten metal in the working volume of the galvanizing bath shall contain not less than an average value of 99.8 percent zinc by mass [weight].

4.3. *Minimum Coating Mass [Weight] or Minimum Coating Thickness*—The minimum coating mass [weight] or the minimum coating thickness shall conform to the requirements prescribed in Table 1 for the material category and thickness of material in which the article belongs.

Table 1—Thickness or Mass [Weight] of Zinc Coating for Various Classes of Material

	Mass [Weight] of Zinc Coating, g/m^2 [oz/ft^2] of Surface, Min		Coating Thickness, microns [mils], Min	
Class of Material	Average of Specimens Tested	Any Individual Specimen	Average of Specimens Tested	Any Individual Specimen
Class A—Casings—Malleable iron, steel	610 [2.00]	550 [1.80]	86 [3.4]	79 [3.1]
Class B—Rolled, pressed, and forged articles (except those which would be included under Classes C and D):				
B-1—4.75 mm [3/16 in.] and over in thickness and more than 380 mm [15 in.] in length	610 [2.00]	550 [1.80]	86 [3.4]	79 [3.1]
B-2—less than 4.75 mm [3/16 in.] in thickness and more than 380 mm [15 in.] in length	458 [1.50]	381 [1.25]	66 [2.6]	53 [2.1]
B-3—any thickness and 380 mm [15 in.] and under in length	397 [1.30]	336 [1.10]	56 [2.2]	48 [1.9]
Class C—Fasteners more than 9.5 mm [$^3/_8$ in.] in diameter and similar articles. Washers 4.75 mm and 6.35 mm [$^3/_{16}$ in. and $^1/_4$ in.] in thickness	381 [1.25]	305 [1.00]	53 [2.1]	43 [1.7]
Class D—Fasteners 9.5 mm [$^3/_8$ in.] and under in diameter, rivets, nails, and similar articles. Washers less than 4.75 mm [$^3/_{16}$ in.] in thickness	305 [1.00]	259 [0.85]	43 [1.7]	36 [1.4]

Note: Length of the piece, stated in Classes B-1, B-2, and B-3, refers to the finished dimension of the piece after fabrication.

4.4. *Threaded Articles*—The zinc coating on threads shall not be subjected to a cutting, rolling, or finishing-tool operation unless specifically authorized by the purchaser. In order to meet overtapping allowances, tapping the threads of nuts or tapped holes after galvanizing is not prohibited.

4.5. *Touch-up and Repair*—Bare spots that are found on parts after galvanizing shall be renovated by use of the methods found in ASTM A 780 if the following criteria are met. The bare spots shall have an area totaling not more than 1 percent of the surface area to be coated excluding threaded areas of the piece, and the bare spots shall not include any threaded areas of the piece. The thickness of the repair shall be equal to the surrounding galvanized coating except for repairs made by paints containing zinc dust, in which case the thickness of the repair shall be 50 percent greater than the thickness of the galvanized coating required for the class of material but shall not be greater than 100 μm (4.0 mils). Repair thickness measurements shall be made in accordance with ASTM A 780. The galvanizer shall make repairs unless directed by the purchaser to deliver items unrepaired for subsequent renovation by the purchaser.

5. WORKMANSHIP, FINISH, AND APPEARANCE

5.1. The zinc-coated articles shall be free from uncoated areas, blisters, flux deposits, dross inclusions, and other types of projections that would interfere with the intended use of the articles, or other defects not consistent with good galvanizing practice.

5.2. The zinc coating shall be smooth and reasonably uniform in thickness.

Note 2—Smoothness of surface is a relative term. Minor roughness that does not interfere with the intended use of the part or roughness that is related to the as-received (ungalvanized) surface condition of the part shall not be grounds for rejection.

Note 3—Since this specification is applicable to items that are centrifuged or otherwise handled to remove excess bath metal (Section 1.2), irregular coating distribution is not normally encountered. Drainage problems, which manifest themselves as local excess coating thickness that would interfere with function or as edge tears or spikes that present a safety hazard because of their sharpness, are grounds for rejection under the terms of Section 5.1.

5.3. Embrittlement is a potential condition of steel that is cold-worked, depending on factors such as the steel type (strength level, aging characteristics), thickness, degree of cold work, and galvanizing process. The galvanizer, the designer, and the fabricator shall take precautions against embrittlement. The precautions to fabricate properly and prepare the material for galvanizing to prevent embrittlement are described in ASTM A 143/A 143M.

Note 4—Low service temperatures increase the risk of brittle failure of all plain carbon steels including those that have been galvanized. This temperature embrittling effect varies with type of steel. The expected service temperature should thus be taken into account when selecting steels for galvanizing.

Note 5—Tin is often added to hot-dip zinc baths to control spangle in the galvanized finish. However, the presence of tin, antimony, or arsenic in the zinc bath can contribute to embrittlement in structural steels, particularly if the steels contain more than 0.10 percent copper. The concentrations of tin, antimony, or arsenic should be individually restricted for each element to 0.01 percent maximum. Use of high-grade or special high-grade zinc restricts the presence of these deleterious elements.

5.4. Malleable castings shall be of such composition as will preclude the possibility that they become embrittled by the galvanizing process or they shall be either cooled from the anneal or subsequently heat-treated so as to immunize them against embrittlement.

5.5. The zinc coating shall adhere tenaciously to the surface of the base metal.

5.6. If the galvanized material covered by this specification is bent or otherwise fabricated to the degree that causes the zinc coatings to stretch or compress beyond the limit of elasticity, any cracking or flaking of the coating resulting from bending or fabricating shall not be cause for rejection.

6. SAMPLING

6.1. Test specimens shall be selected at random from each inspection lot.

6.2. The method of selection and sample size shall be agreed upon between the galvanizer and the purchaser. Otherwise, the sample size selected from each lot shall be as follows:

Number of Pieces in Lot	Sample Size
3 or fewer	all
4 to 500	3
501 to 1200	5
1201 to 3200	8
3201 to 10000	13
10001 and over	20

6.3. A specimen that fails to conform to a requirement of this specification shall not be used to determine the conformance to other requirements.

6.4. The method of sampling for fasteners that are required to meet the standards of the Fastener Quality Act is described in ASTM F 1470. Sample quantities and definitions of terminology are included in the referenced specification.

7. TEST METHODS

7.1. Tests shall be made to ensure that the zinc coating is being furnished in accordance with this specification and as specified for the following:

7.1.1. Minimum coating mass [weight] or minimum coating thickness in Section 4.3.

7.1.2. Finish and appearance in Sections 5.1 and 5.2.

7.1.3. Embrittlement in Sections 5.3 and 5.4.

7.1.4. Adherence in Section 5.5.

7.2. *Average Mass [Weight] of Coating*:

7.2.1. The average mass [weight] of the zinc coating shall be determined by weighing specimens after pickling and drying and again after galvanizing, unless the method described in Section 7.2.2 is used. The number of specimens that are used to determine the average of an inspection lot shall be derived from Section 6.

Note 6—This method does not take into account the mass [weight] of iron reacted from the article that is incorporated into the coating. It will thus underestimate coating mass [weight] by up to approximately 10 percent. Base metal reactivity will affect the extent of underestimation.

7.2.2. In the case of materials inspected after galvanizing, the average mass [weight] of coating shall be determined by stripping the number of specimens derived in Section 6 in accordance with T 65M/T 65, and averaging the results of the individual specimens, unless the method described in Section 7.2.1 is used.

7.3. *Average Thickness of Coating:*

7.3.1. In the case of fasteners such as bolts, nuts, and screws, the determination of the thickness of coating shall be made on a portion of the article that does not include any threads.

7.3.2. The average thickness of coating shall be determined by magnetic thickness gauge in accordance with ASTM E 376 unless the method described in Section 7.3.3 is used. The thickness shall be measured on at least five widely separated spots on a specimen. No individual spot measurement shall be cause for rejection. If an individual spot does not provide a coating thickness reading, this spot must be repaired in accordance with Section 4.5. The five or more individual coating thickness measurements on a specimen must be averaged to determine the specimen average coating thickness. The average coating thickness for the inspection lot is determined by averaging the specimen average coating thickness values for the number of specimens derived from Section 6.

7.3.3. The thickness of coating shall be determined by cross section and optical measurement in accordance with ASTM B 487, unless the method described in Section 7.3.2 is used. The thickness thus determined is a point value. No less than five such measurements shall be made at locations on the specimen, which are as widely dispersed as practical, so as to be representative of the whole surface of the specimen. The average of no less than five such measurements is the specimen average coating thickness. The average coating thickness for the inspection lot is determined by averaging the specimen average coating thickness values for the number of specimens derived from Section 6.

7.4. *Finish and Appearance*—The test for finish and appearance shall be conducted through visual inspection without additional magnification.

7.5. *Embrittlement*—Hardware that is susceptible to embrittlement shall be tested in accordance with ASTM A 143/A 143M. The tests shall be performed through agreement between the galvanizer and the purchaser.

7.6. *Adherence*—Determine adherence of the zinc coating to the surface of the base metal by cutting or prying with the point of a stout knife, applied with considerable pressure in a manner tending to remove a portion of the coating. The adherence shall be considered inadequate if the coating delaminates in the form of a layer of skin so as to expose the base metal in advance of the knife point. Do not use testing carried out at edges or corners (points of lowest coating adherence) to determine adherence of coating. Likewise, do not use removal of small particles of the coating by paring or whittling to determine failure.

8. INSPECTION

8.1. The inspector representing the purchaser shall have access at all times, while work on the contract of the purchaser is being performed, to those areas of the manufacturer’s work space that concern the application of the zinc coating to the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the zinc coating is being furnished in accordance with this specification. All inspection and tests shall be made at the place of manufacture prior to shipments, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

9. REJECTION AND RETEST

9.1. For all galvanized articles except those fasteners that must meet the requirements of the Fastener Quality Act, the following sections are used to determine rejection and retesting.

9.2. When partial inspection of materials to determine conformity with visual requirements of Section 5 warrants rejection of a lot, the galvanizer is not prohibited from sorting the lot and submitting it once again for inspection.

9.3. The number of specimens in a sample of a lot permitted to fail the conformance tests shall be agreed upon between the galvanizer and the purchaser.

9.4. If a set of test specimens fails to conform to the requirements of this specification, two additional sets shall be tested, both of which shall conform to the requirements in every respect, or the lot of material represented by the specimens shall be rejected.

9.5. Materials that have been rejected for reasons other than embrittlement are not prohibited from being stripped, regalvanized, and resubmitted for test and inspection. They shall then conform to the requirements of this specification.

10. PACKAGING

10.1. The supplier shall employ such methods of packaging zinc-coated articles as shall be required to ensure their receipt by the purchaser in satisfactory condition, with the use to be made of the article being taken into consideration.

11. CERTIFICATION

11.1. When specified in the purchase order or contract, the purchaser shall be furnished certification that samples representing each inspection lot have been either tested or inspected as directed by this specification and the requirements have been met. When specified in the purchase order or contract, a report of the test results shall be furnished.

12. KEYWORDS

12.1. Coatings, zinc; galvanized coatings; steel hardware, zinc coated; steel products, metallic coated; zinc coatings, steel products.

---

[1] Agrees with ASTM A 153/A 153M-09 except for the addition of Section 4.2.3, and Note 5 in Section 5.3.

Standard Specification for

Structural Bolts, Alloy Steel, Heat-Treated, 150 ksi Minimum Tensile Strength

AASHTO Designation: M 253-05 (2008)
ASTM Designation: A 490-04a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Structural Bolts, Alloy Steel, Heat-Treated, 150 ksi Minimum Tensile Strength

AASHTO Designation: M 253-05 (2008)
ASTM Designation: A 490-04a

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 490-04a for the information formerly contained in this standard.

Standard Specification for

High-Strength Steel Bolts, Classes 10.9 and 10.9.3, for Structural Steel Joints [Metric]

AASHTO Designation: M 253M-05
ASTM Designation: A 490M-04a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

High-Strength Steel Bolts, Classes 10.9 and 10.9.3, for Structural Steel Joints [Metric]

AASHTO Designation: M 253M-05
ASTM Designation: A 490M-04a

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 490M-04a for the information formerly contained in this standard.

Standard Specification for

Steel Bars, Carbon, Hot-Wrought, Special Quality, Mechanical Properties

AASHTO Designation: M 255M/M 255-05 (2008)
ASTM Designation: A 675/A 675M-03$^{\epsilon 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Bars, Carbon, Hot-Wrought, Special Quality, Mechanical Properties

AASHTO Designation: M 255M/M 255-05 (2008)

ASTM Designation: A 675/A 675M-03$^{\epsilon 1}$

1. SCOPE

1.1. This specification covers hot-wrought, special quality, carbon steel bars and bar size shapes produced to mechanical property requirements and intended for general constructional applications.

1.2. The bars are available in nine strength grades designated 310, 345, 380, 415, 450, 485, 515, 550, and 620 [45, 50, 55, 60, 65, 70, 75, 80, and 90] corresponding to the minimum ultimate tensile strength in MPa [ksi]. The chemical composition is selected by the manufacturer to develop the required mechanical properties.

1.3. Hot-wrought, special quality, carbon steel bars subject to mechanical property requirements are hot wrought in straight lengths only. Sections and sizes available are covered in ASTM A 29/A 29M.

1.4. Some applications may require one or more of the available designations shown under Supplementary Requirements.

Note 1—Merchant-quality hot-wrought carbon steel bars subject to mechanical property requirements are covered in M 227M/M 227.

1.5. This specification is applicable to orders in either SI units (as M 255M) or inch-pound units (as M 255). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 255.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 227M/M 227, Steel Bars, Carbon, Merchant Quality, Mechanical Properties
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 29/A 29M, Standard Specification for Steel Bars, Carbon and Alloy, Hot-Wrought, General Requirements for
- E 290, Standard Test Methods for Bend Testing of Material for Ductility

3. TERMINOLOGY

3.1. *Description of Terms*:

3.1.1. *special quality*—special quality bars are used when end use, method of fabrication, or subsequent processing treatment requires quality characteristics not available in merchant quality. Typical applications involve bending or machining for general constructional uses. Some end uses or fabricating procedures can necessitate one or more requirements, which are described in the Supplementary Requirements.

4. ORDERING INFORMATION

4.1. Orders for material under this specification should include the following information:

4.1.1. Quantity (mass or number of pieces);

4.1.2. Name of material (hot-wrought special quality bars);

4.1.3. Dimensions, including length;

4.1.4. Cross section (round, square, hexagon, equal leg angle, etc.);

4.1.5. AASHTO designation and date of issue;

4.1.6. Grade designation (Table 2);

4.1.7. Leaded steel, if required (Section 7.2);

4.1.8. Copper bearing steel, if required (Section 7.3);

4.1.9. Test report, if required (Section 10);

4.1.10. Supplementary Requirements or special requirements, if required; and

4.1.11. Application and processing.

Note 2—A typical ordering description is as follows: 5000 kg [10000 lb] Hot-Wrought Special Quality Carbon Steel Bars, 25-mm diameter × 3 m [1 in. × 10 ft] Round, M 255M/M 255, Grade 345 [50], Copper Bearing, Test Report Required, S3 Special Straightness, Boiler Supports.

5. GENERAL REQUIREMENTS

5.1. Material furnished under this specification shall conform to the applicable requirements for the current edition of ASTM A 29/A 29M.

6. MATERIALS AND MANUFACTURE

6.1. *Melting Practice*—The steel shall be made by one or more of the following primary processes: open-hearth, basic oxygen, or electric furnace. The primary melting may incorporate separate degassing or refining and may be followed by secondary melting using electroslag remelting or vacuum-arc remelting. Where secondary melting is employed, the heat shall be defined as all of the ingots remelted from a single primary heat.

6.2. *Deoxidation*:

6.2.1. Unless otherwise specified, the steel shall be rimmed, capped, semi-killed, or killed at the producer's option.

6.2.2. When required, the purchaser may specify the required deoxidation practice, dependent upon strength grade specified, purchaser's methods of fabrication, and end use requirements. Killed steels can be produced to coarse or fine austenitic grain size (see Supplementary Requirement S1).

6.3. *Condition*—Unless otherwise specified, the bars shall be furnished as-rolled and not pickled, blast cleaned, or oiled. At the producer's option, bars may be cleaned for inspection.

7. CHEMICAL COMPOSITION

7.1. The steel shall conform to the chemical requirements specified in Table 1.

7.2. *Leaded Steel*—When required, lead may be specified as an added element. When lead is specified as an added element, a range from 0.15 to 0.35 percent inclusive shall be furnished. Such a steel is identified by adding the letter L after the grade designation, for example 415L [60L].

7.3. *Copper-Bearing Steel*—When required, copper may be specified as an added element. Copper-bearing steel is identified by stating "copper-bearing" on the purchase order.

7.4. When tension tests are waived in accordance with Section 8.1.1.2, chemistry consistent with the mechanical properties desired shall be applied.

8. MECHANICAL PROPERTIES

8.1. *Tension Tests*:

Table 1—Chemical Requirements (Heat Analysis)

Element	Composition, Percent
Phosphorus, max	0.040
Sulfur, max	0.050
Copper, when copper steel is specified, min	0.20
Lead	[a]

[a] When required, lead may be specified as an added element. See Section 7.2.

8.1.1. *Requirements*:

8.1.1.1. The material as represented by the test specimen shall conform to the applicable requirements in Table 2.

Table 2—Tensile Requirements

Grade Designation[c]	Tensile Strength		Yield Point, Min[a]		Elongation, Min %[b]	
	MPa	ksi	MPa	ksi	200-mm [8-in.] Gauge Length	50-mm [2-in.] Gauge Length
310 [45]	310 to 380	[45 to 55]	155	22.5	27	33
345 [50]	345 to 415	[50 to 60]	170	25	25	30
380 [55]	380 to 450	[55 to 65]	190	27.5	23	26
415 [60]	415 to 495	[60 to 72]	205	30	21	22
450 [65]	450 to 530	[65 to 77]	225	32.5	17	20
485 [70]	485 to 585	[70 to 85]	240	35	14	18
515 [75]	515 to 620	[75 to 90]	260	37.5	14	18
550 [80]	550 min	[80 min]	275	40	13	17
620 [90]	620 min	[90 min]	380	55	10	14

[a] When the tension test does not show a yield point (drop of the beam, halt of the pointer, or sharp-kneed stress-strain diagram), yield strength shall be determined by either 0.5% extension under load or 0.2% offset. The minimum MPa [ksi] requirement does not change. The test report, if required, shall show yield strength.

[b] See Sections 8.1.1.3 through 8.1.1.6 for deduction in elongation due to section size.

[c] When lead is required, add the letter "L" after the grade designation; for example, 310L [45L].

8.1.1.2. Shapes less than 645 mm^2 [1 in.^{2}] in cross section and bars (other than flats) less than 12.5 mm [$^1/_2$ in.] in thickness or diameter need not be subject to tension tests by the manufacturer.

8.1.1.3. For material greater than 20 mm [$^3/_4$ in.] in thickness or diameter, a deduction of 0.25 percent from the percentage of elongation in 200 mm [8 in.] specified in Table 2 shall be made for each increase of 0.8 mm [$^1/_{32}$ in.] in the specified thickness or diameter above 20 mm [$^3/_4$ in.].

8.1.1.4. For material under 8 mm [$^5/_{16}$ in.] in thickness or diameter, a deduction of 2.00 percent from the percentage of elongation in 200 mm [8 in.] specified in Table 2 shall be made for each decrease of 0.8 mm [$^1/_{32}$ in.] in the specified thickness or diameter below 8 mm [$^5/_{16}$ in.].

8.1.1.5. For grades 310, 345, 380, and 415 [45, 50, 55, 60, and 65] for material over 50 mm [2 in.] in thickness or diameter, a deduction of 1.00 percent from the percentage of elongation in 50 mm [2 in.] specified in Table 2 shall be made for each 25 mm [1 in.] of specified thickness or diameter or fraction thereof over 50 mm [2 in.] in thickness in diameter.

8.1.1.6. For grades 485, 515, 550, and 620 [70, 75, 80, and 90] for material over 50 mm [2 in.] in thickness or diameter, a deduction of 1.00 percent from the percentage of elongation in 50 mm [2 in.] specified in Table 2 shall be made for each 25 mm [1 in.] of specified thickness or diameter, or fraction thereof, over 50 mm [2 in.] in diameter or thickness, to a maximum deduction of 3 percent.

8.1.2. *Test Specimens*:

8.1.2.1. Test specimens shall be prepared for testing from the material in its as-rolled condition unless otherwise specified (see Supplementary Requirements). The tension specimen may be aged as described in T 244.

8.1.2.2. Test specimens shall be taken longitudinally and may be tested in full thickness or section, or they may be machined to the dimensions shown in Figures 4 or 5 of T 244. If test specimens are selected conforming to the dimensions of Figure 5, they shall be machined from a position midway between the center and the surface of the bar.

8.1.2.3. Test specimens for shapes and flats may be machined to the form and dimensions shown in Figure 4 of T 244 or with both edges parallel. Test specimens for material greater than 40 mm [$1^{1}/_{2}$ in.] in thickness or diameter may be machined to a thickness or diameter of at least 20 mm [$^{3}/_{4}$ in.] for a length of at least 230 mm [9 in.], or they may conform to the dimensions shown in Figure 5 of T 244.

8.1.3. *Number of Tests*—Two tension tests shall be made from each heat, unless the finished material from a heat is less than 45 Mg [50 tons], when one tension test will be sufficient. However, for material 50 mm [2 in.] and under in thickness, when the material from one heat differs 9.5 mm [$^{3}/_{8}$ in.] or more in thickness, one tension test shall be made from both the thickest and the thinnest material rolled (larger than the sizes in Section 8.1.1.2) regardless of the mass represented. For material more than 50 mm [2 in.] thick, when the material from heat differs 25 mm [1 in.] or more in thickness, one tension test shall be made from both the thickest and the thinnest material rolled that is more than 50 mm [2 in.] thick regardless of the mass represented.

8.1.4. *Test Method*—Tension tests shall be made in accordance with T 244 using the applicable method for determining yield point.

8.2. *Bend Tests*:

8.2.1. *Requirements*:

8.2.1.1. Bend requirements apply only to flat bars (all sizes), bars other than flats less than 12.5 mm [$^{1}/_{2}$ in.] in thickness or diameter, and shapes less than 645 mm^{2} [1 in.^{2}] in cross section. When bend tests are required for other sizes, Supplementary Requirement S6 must be specified.

8.2.1.2. The bend test specimen shall stand being bent at room temperature through 180 degrees without cracking on the outside of the bent portion, to an inside diameter which shall have the relation to the thickness or diameter of the specimen as given in Table 3.

Table 3—Bend Requirements

	Ratio of Bend Diameter to Thickness of Specimen for Thickness or Diameter of Bar, mm [in.]						
Grade Designation	20 [$^{3}/_{4}$] and Under	Over 20 [$^{3}/_{4}$] to 25 [1], incl	Over 25 [1] to 40 [$1^{1}/_{2}$], incl	Over 40 [$1^{1}/_{2}$] to 50 [2], incl	Over 50 [2] to 75 [3], incl	Over 75 [3] to 125 [5], incl	Over 5 [125]
310 [45]	Flat	Flat	$^{1}/_{2}$	1	1	2	3
345 [50]	Flat	$^{1}/_{2}$	1	$1^{1}/_{2}$	$2^{1}/_{2}$	3	$3^{1}/_{2}$
380 [55]	$^{1}/_{2}$	1	$1^{1}/_{2}$	2	$2^{1}/_{2}$	3	$3^{1}/_{2}$
415 [60]	$^{1}/_{2}$	1	$1^{1}/_{2}$	$2^{1}/_{2}$	3	$3^{1}/_{2}$	4
450 [65]	1	$1^{1}/_{2}$	2	3	$3^{1}/_{2}$	4	5
485 [70]	$1^{1}/_{2}$	2	$2^{1}/_{2}$	3	$3^{1}/_{2}$	4	5
515 [75]	2	2	3	$3^{1}/_{2}$	4	$4^{1}/_{2}$	6
550 [80]	2	$2^{1}/_{2}$	3	$3^{1}/_{2}$	4	$4^{1}/_{2}$	6
620 [90][a]							

[a] Bend requirements are not required for Grade 620 [90], but may be specified by agreement between purchaser and manufacturer. (See Supplementary Requirement S6.)

8.2.2. *Test Specimens*:

8.2.2.1. Bend-test specimens for material 40 mm [$1^{1}/_{2}$ in.] and under in diameter or thickness may be the full thickness of the section. For flat bars more than 50 mm [2 in.] in width, the width may be reduced by milling to 40 mm [$1^{1}/_{2}$ in.].

8.2.2.2. Bend-test specimens for material greater than 40 mm [$1^1/_2$ in.] in diameter or thickness may be machined to a thickness or diameter of at least 20 mm [$^3/_4$ in.] or to 25 × 12.5 mm [1 × $^1/_2$ in.] in section. Machined sides of bend-test specimens may have the corners rounded to a radius of not more than 1.6 mm [$^1/_{16}$ in.] for material 50 mm [2 in.] and under in thickness, and not more than 3.2 mm [$^1/_8$ in.] in radius for material greater than 50 mm [2 in.] in thickness.

8.2.3. *Number of Tests*—When subject to bend test, two bend tests shall be made from each heat, unless the finished material from a heat is less than 45 Mg [50 tons], when one bend test will be sufficient. However, for material 50 mm [2 in.] and under in thickness, when the material from one heat differs 9.5 mm [$^3/_8$ in.] or more in thickness, one bend test shall be made from both the thickest and the thinnest material rolled regardless of the mass represented. For material more than 50 mm [2 in.] thick, when the material from one heat differs 25 mm [1 in.] or more in thickness, one bend test shall be made from both the thickest and the thinnest material rolled that is more than 50 mm [2 in.] thick regardless of the mass represented.

8.2.4. *Test Methods*—Bend tests shall be made in accordance with ASTM E 290.

---

9. WORKMANSHIP, FINISH, AND APPEARANCE

9.1. Bars shall be free of visible pipe, undue segregation, and injurious surface imperfections.

9.2. *Surface Finish*—The bars shall have a commercial hot-wrought finish obtained by conventional hot rolling. See Section 6.3 for producer's descaling option.

---

10. CERTIFICATION

10.1. When specified by the purchaser, a manufacturer's certification that the material was manufactured and tested in accordance with this specification together with a report of the heat analysis, tensile requirements, and bend-test (if applicable) results shall be furnished. Only one test need be reported when the amount of material from a heat in a shipment is less than 9 Mg [10 tons] and when the thickness variations described in Sections 8.1.3 and 8.2.3 are not exceeded. The report shall include the name of the manufacturer, AASHTO designation number and date of issue, grade, heat number, and size.

10.2. The thickness of the product tested may not necessarily be the same as an individual ordered thickness since it is the heat that is tested rather than each ordered item.

10.3. When Supplementary Requirements are specified, the report shall include a statement of compliance with the requirement or the results of tests when the requirement involves measured test values.

---

11. KEYWORDS

11.1. Carbon steel bars; hot-wrought steel bars; steel bars.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall apply only when specified by the purchaser in the inquiry, contract, or order. Details of these supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirements of the specification itself.

S1. GRAIN SIZE

S1.1. The steel shall conform to the coarse austenitic grain size requirement or the fine grain size requirement of ASTM A 29/A 29M.

S2. THERMAL TREATMENT

S2.1. When required, the purchaser may specify that the material be stress relieved.

S3. SPECIAL STRAIGHTNESS

S3.1. Bars may be specified to special straightness tolerance (refer to ASTM A 29/A 29M).

S4. CLEANING

S4.1. The purchaser may specify that the surface of bars be descaled by pickling or blast cleaning.

S5. COATING

S5.1. The purchaser may specify oil on bars that have been descaled.

S6. BEND REQUIREMENT

S6.1. Bend requirements for Grade 620 [90] may be specified. The bend ratio shall be as agreed upon. Bend requirements for all other grades, when specified, shall be as specified in Table 3.

S7. CARBON RESTRICTION

S7.1. On grades 310 [45], 345 [50], 380 [55], and 415 [60], carbon shall be 0.35 percent max.

Standard Specification for

Structural Steel for Bridges

AASHTO Designation: M 270M/M 270-10
ASTM Designation: A 709/A 709M-09a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Structural Steel for Bridges

AASHTO Designation: M 270M/M 270-10
ASTM Designation: A 709/A 709M-09a

1. SCOPE

1.1. This specification covers carbon and high-strength low-alloy steel structural shapes, plates, and bars and quenched and tempered alloy steel for structural plates intended for use in bridges. Nine grades are available in four yield strength levels as follows:

Table 1—Yield Strength Levels

Grade SI [U.S.]	Yield Strength, MPa [ksi]
250 [36]	250 [36]
345 [50]	345 [50]
345S [50S]	345 [50]
345W [50W]	345 [50]
HPS 345W [HPS 50W]	345 [50]
HPS 485W [HPS 70W]	485 [70]
HPS 690W [HPS 100W]	690 [100]

1.1.1. Grades 250 [36], 345 [50], 345S [50S], and 345W [50W] are also included in ASTM A 36/A 36M, A 572/A 572M, A 992/A 992M, A 588/A 588M, and A 514/A 514M, respectively. When the supplementary requirements of this specification are specified, they exceed the requirements of A 36/A 36M, A 572/A 572M, A 992/A 992M, A 588/A 588M, and A 514/A 514M.

1.1.2. Grades 345W [50W], HPS 345W [HPS 50W], HPS 485W [HPS 70W] and HPS 690W [HPS 100W] have enhanced atmospheric corrosion resistance (Section 13.1.2). Product availability is shown in Table 2.

1.2. Grade HPS 485W [HPS 70W] or HPS 690W [HPS 100W] shall not be substituted for Grade 250 [36], 345 [50], 345S [50S], 345W [50W], or HPS 345W [HPS 50W]. Grade 345W [50W] or HPS 345W [HPS 50W] shall not be substituted for Grade 250 [36], 345 [50], or 345S [50S] without agreement between the purchaser and supplier.

1.3. When the steel is to be welded, it is presupposed that a welding procedure suitable for the grade of steel and intended use or service will be utilized. See Appendix X3 of ASTM A 6/A 6M for information on weldability.

Table 2—Tensile and Hardness Requirements[a]

					Minimum Elongation, Percent				
					Plates and Bars [c,e]		Shapes[e]		
Grade	Plate Thickness, mm [in.]	Structural Shape Flange or Leg Thickness, mm [in.]	Yield Point or Yield Strength,[b] MPa [ksi]	Tensile Strength, MPa [ksi]	200 mm or 8 in.	50 mm or 2 in.	200 mm or 8 in.	50 mm or 2 in.	Reduction of Area[c,d] Min, percent
250 [36]	To 100 [4], incl	to 75 [3], incl.	250 [36] min	400–550 [58–80]	20	23	20	21	—
		over 75 [3.]	250 [36] min	400 [58] min	—	—	20	19	—
345 [50]	To 100 [4], incl	all	345 [50] min	450 [65] min	18	21	18	21[f]	—
345S [50S]	[g]	all	345–450 [50–65][h,i]	450 [65]h	—	—	18	21	—
345W [50W] and HPS 345W [HPS 50W]	To 100 [4], incl	all	345 [50] min	485 [70] min	18	21	18	21[j]	—
HPS 485W [HPS 70W]	To 100 [4], incl	[g]	485 [70][b] min	585–760 [85–110]	—	19k	—	—	—
HPS 690W [HPS 100W]	To 65 [$2^{1}/_{2}$], incl	[g]	690 [100][b] min	760–895 [110–130]	—	18[k]	—	—	[l]

[a] See “Orientation” and “Preparation” under “Tension Tests” in M 160M/M 160.

[b] Measure at 0.2 percent offset or 0.5 percent extension under load as described in Section 13 of T 244.

[c] Elongation and reduction of area not required to be determined for floor plates.

[d] For plates wider than 600 mm [24 in.], the reduction of area requirement, where applicable, is reduced five percentage points.

[e] For plates wider than 600 mm [24 in.], the elongation requirement is reduced two percentage points. See elongation requirement adjustments under the Tension Tests section of M 160M/M 160.

[f] Elongation in 50 mm [2 in.], 19 percent minimum for shapes over 75 mm [3 in.].

[g] Not applicable.

[h] The yield-to-tensile ratio shall be 0.87 or less for shapes that are tested from the web location; for all other shapes, the requirement is 0.85.

[i] A maximum yield strength of 70 ksi [480 MPa] is permitted for structural shapes that are required to be tested from the web location.

[j] For wide flange shapes with flange thickness greater than 75 mm [3 in.], elongation in 50 mm [2 in.] of 18 percent minimum applies.

[k] If measured on the Figure 3 (T 244) 40-mm [$1^{1}/_{2}$-in.] wide specimen, the elongation is determined in a 50-mm [2-in.] gauge length that includes the fracture and shows the greatest elongation.

[l] 40 percent minimum applies if measured on the Figure 3 (T 244) 40-mm [$1^{1}/_{2}$-in.] wide specimen, 50 percent minimum applies if measured on the Figure 4 (T 244) 12.5-mm [$^{1}/_{2}$-in.] round specimen.

[m] Not applicable to fracture critical Tension Components. (See Table 10.)

Note: Where “—” appears in this table, there is no requirement.

1.4. For structural products to be used as tension components requiring notch toughness testing, standardized requirements are provided in this standard, and they are based upon American Association of State Highway and Transportation Officials (AASHTO) requirements for both fracture-critical and non-fracture-critical members.

1.5. Supplementary requirements are available but shall apply only if specified in the purchase order.

1.6. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system is to be used independently of the other, without combining values in any way.

1.7. For structural products cut from coiled product and furnished without heat-treatment or with stress relieving only, the additional requirements of ASTM A 6/A 6M, including additional testing requirements and the reporting of additional tests, apply.

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *main load-carrying member*—a steel member designed to carry primary design loads, including dead, live, impact, and other loads.

3.1.2. *secondary member*—a steel member used for aligning and bracing of main load-carrying members, or for attaching utilities, signs or other items to them, but not to directly support primary design loads.

3.1.3. *non-fracture-critical member*—a main load-carrying member the failure of which would not be expected to cause collapse of a structure or bridge with multiple, redundant load paths.

3.1.4. *fracture-critical member*—a main load-carrying member or tension component of a bending member the failure of which would be expected to cause collapse of a structure or bridge without multiple, redundant load paths.

3.1.5. *tension component*—a part or element of a fracture-critical or non-fracture-critical member that is in tension under various design loadings.

3.1.6. *non-tension component*—a steel member that is not in tension under any design loading.

4. ORDERING REQUIREMENTS

4.1. In addition to the items listed in the ordering information section of ASTM A 6/A 6M, the following items should be considered if applicable:

4.1.1. Type of component (tension or nontension, fracture-critical or non-fracture-critical) (see Section 10).

4.1.2. Impact testing temperature zone (see Table 3).

Table 3—Relationship between Impact Testing Temperature Zones and Minimum Service Temperatures

Zone	Minimum Service Temperature, °C [°F]
1	–18 [0]
2	Below –18 to –34 [0 to –30]
3	Below –34 to –51 [–30 to –60]

5. GENERAL REQUIREMENTS FOR DELIVERY

5.1. Material furnished under this specification shall conform to the requirements of the current edition of ASTM A 6/A 6M for the specific structural product unless a conflict exists, in which case this specification shall prevail.

5.2. Coils are excluded from qualification to this specification until they are processed into a finished structural product. “Structural products produced from coil” means structural products that have been cut to individual lengths from a coil. The processor controls, or is responsible for, the operations involved in the processing of a coil into a finished structural product. Such operations include decoiling, leveling or straightening, hot forming or cold forming (if applicable), cutting to length, testing, inspection, conditioning, heat-treatment (if applicable), packaging, marking, loading for shipment, and certification. (See Note 1.)

Note 1—For structural products produced from coil and finished without heat-treatment or with stress relieving only, two test results are to be reported for each qualifying coil. Additional requirements regarding structural products from coil are described in ASTM A 6/A 6M.

6. MATERIALS AND MANUFACTURE

6.1. For Grades 250 [36] and 345 [50], the steel shall be semi-killed or killed.

6.2. For Grades 345W [50W], HPS 345W [HPS 50W], and HPS 485W [HPS 70W], the steel shall be made to fine grain practice.

6.3. For Grade 345S [50S], the steel shall be killed. Killed steel is confirmed on the test report by a statement of killed steel, a value of 0.10 percent or more for the silicon content, or a value of 0.015 percent or more for the total aluminum content.

6.4. For Grade 345S [50S], the steelmaking practice used shall be one that produces steel having a nitrogen content not greater than 0.015 percent and includes the addition of one or more nitrogen-binding elements, or one that produces steel having a nitrogen content of not greater than 0.012 percent (with or without the addition of nitrogen-binding elements). The nitrogen content need not be reported, regardless of which steelmaking practice was used.

6.5. For Grades HPS 345W [HPS 50W], HPS 485W [HPS 70W], and HPS 690W [HPS 100W], the steel shall be made using a low-hydrogen practice, such as vacuum degassing during steel making; controlled soaking of the ingots or slabs; controlled slow cooling of the ingots, slabs, or plates; or a combination thereof.

6.6. For Grade HPS 690W [HPS 100W] the requirements fine austenitic grain size in ASTM A 6/A 6M shall be met.

6.7. Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W] shall be furnished in one of the following conditions: as-rolled, control-rolled, thermo-mechanical control processed (TMCP) with or without accelerated cooling, or quenched and tempered.

7. HEAT-TREATMENT

7.1. For quenched and tempered Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W], the heat-treatment shall be performed by the manufacturer and shall consist of heating the steel to not less than 900ºC [1650ºF], quenching it in water or oil, and tempering it at not less than 590ºC [1100ºF]. The heat-treating temperatures shall be reported on the test certificates.

7.2. For Grade HPS 690W [HPS 100W], the heat-treatment shall be performed by the manufacturer and shall consist of heating the steel to a temperature in the range from 870 to 925ºC [1600 to 1700ºF], quenching it in water, and tempering it at not less than 565ºC [1050ºF] for a time to be determined by the manufacturer. The heat-treating temperatures shall be reported on the test certificates.

8. CHEMICAL REQUIREMENTS

8.1. The heat analysis shall conform to the requirements of the specified grade, as given in Tables 4 through Table 9.

8.2. For Grade 345S [50S], in addition to the elements listed in Table 6, test reports shall include, for information, the chemical analysis for tin. Where the amount of tin is less than 0.02 percent, it shall be permissible for the analysis to be reported as <0.02 percent.

8.3. The maximum permissible carbon equivalent value shall be 0.47 percent for structural shapes with flange thickness over 50 mm [2 in.], and 0.45 percent for other structural shapes. The carbon equivalent shall be based on heat analysis. The required chemical analysis as well as the carbon equivalent shall be reported. The carbon equivalent shall be calculated using the following formula:

$$CE = C + \frac{Mn}{6} + \frac{(Cr + Mo + V)}{5} + \frac{(Ni + Cu)}{15}$$

Table 4—Grade 250 [36] Chemical Requirements (Heat Analysis)

		Plates[a]				Bars		
Product Thickness, mm [in.]	Shapes,[b] all	To 20 [$^{3}/_{4}$], incl	Over 20 to 40 [$^{3}/_{4}$ to 1$^{1}/_{2}$], incl	Over 40 to 65 [1$^{1}/_{2}$ to 2$^{1}/_{2}$], incl	Over 65 to 100 [2$^{1}/_{2}$ to 4], incl	To 20 [$^{3}/_{4}$] incl	Over 20 to 40 [$^{3}/_{4}$ to 1$^{1}/_{2}$], incl	Over 40 to 100 [1$^{1}/_{2}$ to 4], incl
Carbon max percent	0.26	0.25	0.25	0.26	0.27	0.26	0.27	0.28
Manganese percent	—	—	0.80–1.20	0.80–1.20	0.85–1.20	—	0.60–0.90	0.60–0.90
Phosphorus max percent	0.04	0.04	0.04	0.04	0.04	0.04	0.04	0.04
Sulfur max percent	0.05	0.05	0.05	0.05	0.05	0.05	0.05	0.05
Silicon max percent	0.40	0.40	0.40	0.15–0.40	0.015–0.40	0.40	0.40	0.40
Copper min percent when copper steel is specified	0.20	0.20	0.20	0.20	0.20	0.20	0.20	0.20

[a] For each reduction of 0.01 percentage point below the specified carbon maximum, an increase of 0.06 percentage point manganese above the specified maximum will be permitted up to the maximum of 1.35 percent.

[b] Manganese content of 0.85 to 1.35 percent and silicon content of 0.15 to 0.40 percent is required for shapes over 634 kg/m [426 lb/ft].

Note: Where "—" appears in this table, there is no requirement. The heat analysis for manganese shall be determined and reported as described in the Heat Analysis section of M 160M/M 160.

Table 5—Grade 345 [50] Chemical Requirements (Heat Analysis)[a]

					Silicon[b]		
Max Diameter, Thickness, or Distance Between Parallel Faces, mm [in.]	Carbon, Max percent	Manganese,[c] Max percent	Phosphorus, Max percent	Sulfur, Max percent	Plates to 40-mm [$1^{1}/_{2}$-in.] Thick, Shapes to 634 kg/m [426 lb/ft], Bars, Zees, and Rolled Tees, Max percent[d]	Plates over 40-mm [$1^{1}/_{2}$-in.] Thick and Shapes over 634 kg/m [426 lb/ft], percent	Columbium, Vanadium, and Nitrogen
100 [4]	0.23	1.35	0.04	0.05	0.40	0.15–0.40	See Footnote.[e]

[a] Copper, when specified, shall have a minimum content of 0.20 percent by heat analysis (0.18 percent product analysis).

[b] Silicon content in excess of 0.40 percent by heat analysis must be negotiated.

[c] Manganese, minimum by heat analysis of 0.80 percent (0.75 percent product analysis) shall be required for all plates more than 10 mm [$^{3}/_{8}$ in.] in thickness; a minimum of 0.50 percent (0.45 percent product analysis) shall be required for plates 10 mm [$^{3}/_{8}$ in.] and less in thickness and for all other products. The manganese-to-carbon ratio shall not be less 2-to-1. For each reduction of 0.01 percent point below the specified carbon maximum, an increase of 0.06 percent point manganese above the specified maximum is permitted, up to a maximum of 1.60 percent.

[d] Bars greater than 40 mm [$1^{1}/_{2}$ in.] in diameter, thickness, or distance between parallel faces, shall be made by a killed steel practice.

[e] Alloy content shall be in accordance with one of the following types, and the contents of the applicable elements shall be reported:

Type	Elements	Heat Analysis, Percent
1	Columbium[f]	0.005–0.05[g]
2	Vanadium	0.01–0.15
3	Columbium[f]	0.005–0.05[h]
	Vanadium	0.01–0.15
	Columbium plus vanadium	0.02–0.15[h]
5	Titanium	0.006–0.04
	Nitrogen	0.003–0.015
	Vanadium	0.06 max

[f] Columbium shall be restricted to Grade 345 [50] plate, bar, zee, and rolled tee thickness of 20 mm [$^{3}/_{4}$ in.], max, and to shapes with flange or leg thickness to 40 mm [$1^{1}/_{2}$ in.] inclusive unless killed steel is furnished. Killed steel shall be confirmed by a statement of killed steel on the test report, or by a report of the presence of a sufficient quantity of a strong deoxidizing element, such as silicon at 0.10 percent or higher, or aluminum at 0.015 percent or higher.

[g] Product analysis limits = 0.004 to 0.06 percent.

[h] Product analysis limits = 0.01 to 0.16 percent.

Table 6—Grade 345S [50S] Chemical Requirements (Heat Analysis)

Element	Composition, percent
Carbon, max	0.23
Manganese	0.50 to 1.60[a]
Silicon, max	0.40
Vanadium, max	0.15[b]
Columbium,max	0.05[b]
Phosphorus, max	0.035
Sulfur, max	0.045
Copper, max	0.60
Nickel, max	0.45
Chromium, max	0.35
Molybdenum, max	0.15

[a] Provided that the ratio of manganese to sulfur is not less than 20 to 1, the minimum limit for manganese for shapes with flange or leg thickness not exceeding 25 mm [1 in.] shall be 0.30 percent.

[b] The sum of columbium and vanadium shall not exceed 0.15 percent.

Table 7—Grade 345W [50W] Chemical Requirements (Heat Analysis)

Element	Composition, percent[a]		
	Type A	Type B	Type C
Carbon[b]	0.19 max	0.20 max	0.15 max
Manganese[b]	0.80–1.25	0.75–1.35	0.80–1.35
Phosphorus	0.04 max	0.04 max	0.04 max
Sulfur	0.05 max	0.05 max	0.05 max
Silicon	0.30–0.65	0.15–0.50	0.15–0.40
Nickel	0.40 max	0.50 max	0.25–0.50
Chromium	0.40–0.65	0.40–0.70	0.30–0.50
Copper	0.25–0.40	0.20–0.40	0.20–0.50
Vanadium	0.02–0.10	0.01–0.10	0.01–0.10

[a] Weldability data for these types have been qualified by FHWA for use in bridge construction.

[b] For each reduction of 0.01 percentage point below the specified maximum for carbon, an increase of 0.06 percentage point above the specified maximum for manganese is permitted, up to a maximum of 1.50 percent.

Note: Types A, B, and C are equivalent to ASTM A 588/A 588M Grade A, B, and C, respectively.

Table 8—Grades HPS 345W [HPS 50W], HPS 485W [HPS 70W], and HPS 690W [HPS 100W] Chemical Requirements (Heat Analysis)

Element	Composition, percent	
	Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W]	Grade HPS 690W [HPS 100W]
Carbon	0.11 max	0.08 max
Manganese		
65 mm [2.5 in.] and under	1.10–1.35	0.95–1.50
Over 65 mm [2.5 in.]	1.10–1.50	0.95–1.50
Phosphorus	0.020 max	0.015 max
Sulfur[a]	0.006 max	0.006 max
Silicon	0.30–0.50	0.15–0.35
Copper	0.25–0.40	0.90–1.20
Nickel	0.25–0.40	0.65–0.90
Chromium	0.45–0.70	0.40–0.65
Molybdenum	0.02–0.08	0.40–0.65
Vanadium	0.04–0.08	0.04–0.08
Columbium (Niobium)	—	0.01–0.03
Aluminum	0.010–0.040	0.020–0.050
Nitrogen	0.015 max	0.015 max

[a] The steel shall be calcium treated for sulfate shape control.

Note: Where "—" appears in this table, there is no requirement.

9. TENSILE REQUIREMENTS

9.1. The material as represented by test specimens, except as specified in Section 7.2, shall conform to the requirements for tensile properties prescribed in Table 2.

9.2. For Grade 250 [36], shapes less than 645 mm^2 [1 $in.^2$] in cross section and bars, other than flats, less than 12.5 mm [$^1/_2$ in.] in thickness or diameter need not be subjected to tension tests by the manufacturer.

10. IMPACT TESTING REQUIREMENTS

10.1. *Non-Fracture-Critical, T, Tension Components*—Structural products ordered for use as tension components of non-fracture-critical members shall be impact tested in accordance with T 243M/T 243 and as given in Table 10. The test results shall meet the requirements given in Table 10.

10.2. *Fracture-Critical, F, Tension Components*—Structural products ordered for use as tension components of fracture-critical members shall be impact tested in accordance with T 243M/T 243 and as given in Table 10. The test results shall meet the requirements given in Table 10.

10.3. Steel grades ordered for use without suffix T or F as listed in 10.1 and 10.2 do not require impact testing and shall be used as non-tension components or secondary members only.

Table 9—Non-Fracture-Critical Tension Component Impact Test Requirements

Grade	Thickness, mm [in.]	Min Average Energy, J [ft-lbf]		
		Zone 1	Zone 2	Zone 3
250T [36T][a]	To 100 [4] incl	20 [15] at 21°C [70°F]	20 [15] at 4°C [40°F]	20 [15] at –12°C [10°F]
345T [50T],[a,b] 345ST [50ST],[a] 345WT [50WT][a,b]	To 50 [2] incl	20 [15] at 21°C [70°F]	20 [15] at 4°C [40°F]	20 [15] at –12°C [10°F]

HPS 485WT [HPS 70WT][c,d]	To 100 [4] incl	34 [25] at –23°C [–10°F]	34 [25] at –23°C [–10°F]	34 [25] at –23°C [–10°F]
HPS 690WT [HPS 100WT][c]	To 65 [$2^{1}/_{2}$] incl	34 [25] at –34°C [–30°F]	34 [25] at –34°C [–30°F]	34 [25] at –34°C [–30°F]
	Over 65 to 100 [$2^{1}/_{2}$ to 4] incl	48 [35] at –34°C [–30°F]	48 [35] at –34°C [-30°F]	48 [35] at –34°C [-30°F]

[a] The Charpy V-notch (CVN) impact testing shall be at "H" frequency in accordance with T 243 M/T 243.

[b] If the yield point of the structural product exceeds 450 MPa [65 ksi], the testing temperature for the minimum average energy required shall be reduced by 8°C [15°F] for each increment of 70 MPa [10 ksi] above 450 MPa [65 ksi]. The yield point is the value given in the test report.

[c] The CVN-impact testing shall be at "P" frequency in accordance with T 243M/T 243.

[d] If the yield strength of the structural product exceeds 585 MPa [85 ksi], the testing temperature for the minimum average energy required shall be reduced by 8°C [15°F] for each increment of 70 MPa [10 ksi] above 585 MPa [85 ksi]. The yield strength is the value given in the test report.

[a] The Charpy V-notch (CVN) impact testing shall be at "P" frequency in accordance with T 243M/T 243 except for plates of Grades 250F [36F], 345F [50F], 345WF [50WF], HPS 345WF [HPS 50WF], and HPS 485WF [HPS 70WF], for which the sampling shall be as follows:

1. As-rolled (including control-rolled and TMCP) plates shall be sampled at each end of each plate as rolled.
2. Normalized plates shall be sampled at one end of each plate as heat-treated.
3. Quenched and tempered plates shall be sampled at each end of each plate as heat-treated.

[b] If the yield point of the structural product exceeds 450 MPa [65 ksi], the testing temperature for the minimum average energy and minimum test value energy required shall be reduced by 8°C [15°F] for each increment of 70 MPa [10 ksi] above 450 MPa [65 ksi]. The yield point is the value given in the test report.

[c] If the yield strength of the structural product exceeds 585 MPa [85 ksi], the testing temperature for the minimum average energy and minimum test value energy required shall be reduced by 8°C [15°F] for each movement of 70 MPa [10 ksi] above 585 MPa [85 ksi]. The yield point is the value given in the test report.

[d] Not applicable.

11. TEST SPECIMENS AND NUMBER OF TENSION TESTS

11.1. For Grades 250 [36], 345 [50], and 345W [50W], and non-quenched and tempered Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W], location and condition, number of tests, and preparation of test specimens shall meet the requirements of ASTM A 6/A 6M.

11.2. The following requirements, which are in addition to those of ASTM A 6/A 6M, shall apply only to HPS 690W [HSP 100W] and quenched and tempered Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W].

11.2.1. When possible, all test specimens shall be cut from the plate in its heat-treated condition. If it is necessary to prepare test specimens from separate pieces, all of these pieces shall be full thickness, and shall be similarly and simultaneously heat-treated with the material. All such separate pieces shall be of such size that the prepared test specimens are free of any variation in properties due to edge effects.

11.2.2. After final heat-treatment of the plates, one tension test specimen shall be taken from a corner of each plate as heat-treated (except as specified in Section 11.1).

Note 2—The term “plate” identifies the “plate as heat-treated.”

12. RETESTS

12.1. Grades 250 [36], 345 [50], 345S [50S], and 345W [50W], and non-quenched and tempered Grades HPS 345W [HPS 50W] and HPS 485W [HPS 70W] shall be retested in accordance with ASTM A 6/A 6M.

12.2. The manufacturer may reheat treat quenched and tempered plates that fail to meet the mechanical property requirements of this specification. All mechanical property tests shall be repeated when the material is resubmitted for inspection.

13. ATMOSPHERIC CORROSION RESISTANCE

13.1. Steels meeting this specification provide two levels of atmospheric corrosion resistance:

13.1.1. Steel grades without suffix provide a level of atmospheric corrosion resistance typical of carbon steel without copper.

13.1.2. The steel for Grades 345W [50W], HPS 345W [HPS 50W], and HPS 485W [HPS 70W] shall have an atmospheric corrosion resistance index of 6.0 or higher, calculated from the heat analysis in accordance with ASTM G 101. (See Note 3.) When properly exposed to the atmosphere, these steels can be used bare (unpainted) for many applications. The steel for HPS 690W [HPS 100W] provides an improved level of atmospheric corrosion resistance over alloy steel without copper.

Note 3—For methods of estimating the atmospheric corrosion resistance of low-alloy steels, see ASTM G 101. The user is cautioned that the ASTM G 101 predictive equation (Predictive Method Based on the Data of Larabee and Coburn) for calculation of an atmospheric corrosion resistance index has only been verified for the composition limits stated in that guide.

14. MARKING

14.1. In addition to the marking requirements of ASTM A 6/A 6M, the structural product shall be marked as follows:

14.1.1. For Grades 50W [345W] the composition type shall be included.

14.1.2. For structural products that conform to the requirements of Section 10.1, the letter *T* and the applicable zone number (1, 2, or 3) shall follow the grade designation.

14.1.3. For structural products that conform to the requirements of Section 10.2, the letter *F* and the applicable zone number (1, 2, or 3) shall follow the grade designation.

15. KEYWORDS

15.1. Alloy; atmospheric corrosion resistance; bars; bridges; carbon; fracture-critical; high-strength; low-alloy; non-fracture-critical; plates; quenched; shapes; steel; structural steel; tempered.

SUPPLEMENTARY REQUIREMENTS

Requirements other than those shown in this section may be specified subject to agreement between the supplier and the purchaser. In addition, the following supplementary requirements are also suitable for use with this specification.

S1. FREQUENCY OF TENSION TESTS

S1.1. Tension testing that is additional to the tension testing required by ASTM A 6/A 6M shall be made as follows:

S1.1.1 *Plate*—One tension test shall be made using a test specimen taken from each as rolled or as heat-treated plate.

S1.1.2 *Structural Shapes*—One tension test shall be made using a test specimen taken from each 5 Mg [5 tons] of material produced on the same mill of the same nominal size, excluding length, from each heat of steel. Each single piece exceeding 5 Mg [5 tons] in mass [weight] shall be tested. If shapes are heat-treated, one test shall be made on specimens taken from each heat of the same nominal size, excluding length, in each furnace lot.

S1.1.3 *Bars*—One tension test shall be made using a test specimen taken from each 5 Mg [5 tons] of the same heat and same diameter or thickness if the material is furnished as rolled or is heat-treated in a continuous-type furnace. For material heat-treated in a noncontinuous furnace, one test shall be taken from each heat of the same bar diameter or thickness for each furnace charge.

S2. ULTRASONIC EXAMINATION

S2.1. Refer to S8 of ASTM A 6/A 6M.

S3. MAXIMUM TENSILE STRENGTH (GRADES 345 [50], 345W [50W]), AND 345S [50S]

S3.1. Refer to S18 of ASTM A 6/A 6M.

S4. FINE AUSTENITIC GRAIN SIZE

S4.1. The steel shall be killed and have a fine austenitic grain size.

S5. ATMOSPHERIC CORROSION RESISTANCE

S5.1. When specified, the material manufacturer shall supply to the purchaser evidence of atmospheric corrosion resistance satisfactory to the purchaser.

S5.2. Refer to S23 of ASTM A 6/A 6M (applicable to Grades 250 [36] and 345 [50]).

S6. LIMITATION ON WELD REPAIR (FRACTURE-CRITICAL MATERIAL ONLY)

S6.1. Weld repair of the base metal by the material manufacturer or supplier is not permitted.

Standardized supplementary requirements for use at the option of the purchaser are listed in ASTM A 6/A 6M.

S7. SINGLE-HEAT BUNDLES

S7.1. Bundles containing shapes or bars shall be from a single heat of steel.

Standard Specification for

Wire Rope and Sockets for Movable Bridges

AASHTO Designation: M 277-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Wire Rope and Sockets for Movable Bridges

AASHTO Designation: M 277-06

1. SCOPE

1.1. This specification covers steel wire rope for use in movable bridges. Both operating and counterweight ropes are included in nominal 6 × 19 rope construction. Suitable sockets are also included.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 102M/M 102, Steel Forgings, Carbon and Alloy, for General Industrial Use
- M 120, Zinc
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings

2.2. *ASTM Standards*:

- A 29/A 29M, Standard Specification for Steel Bars, Carbon and Alloy, Hot-Wrought, General Requirements for
- A 148, Standard Specification for Steel Castings, High Strength, for Structural Purposes
- A 603, Standard Specification for Zinc-Coated Steel Structural Wire Rope
- A 709, Standard Specification for Structural Steel for Bridges

2.3. *ANSI Standard*:

- B4.1, American National Standards Institute—Sockets, Pinholes, Pins

2.4. *Military Standard*:

- MIL-P-24216, Military Specifications—Fiber Polypropylene Cores for Wire Rope

3. TERMINOLOGY

3.1. *acceptance breaking strength*—the minimum ultimate strength value on which conformance to the specification shall be based.

3.2. *bright wires*—wires in ropes that are uncoated.

3.3. *center*—the inner or foundation member (wire or twisted fibrous material) in a strand around which the wires are laid.

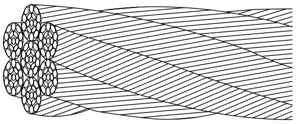
3.4. *circumference*—the measured perimeter of a circle circumscribing the wires of a strand or the strands of a wire rope.

3.5. *core*—the foundation member (a twisted fibrous material) of a wire rope around which strands are laid.

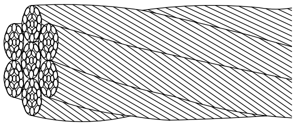
3.6. *fibers*—the material of which the centers or cores are made.

3.7. *filler wires*—small diameter auxiliary wires for supporting and positioning main wires. Filler wires are included in the actual wire count and identification of the rope construction.

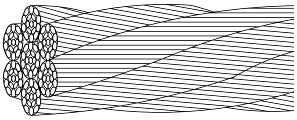
3.8. *lang lay (See Figure 1.)*—the direction of lay of the wires in the strand and of the strand in the rope is the same. As a result, the rope has an appearance that the wires are diagonal to the axis of the rope. The wires and the strands may run to the right, “right lang lay” (commonly called “lang lay”) or to the left, “left lang lay” (on specific orders only).



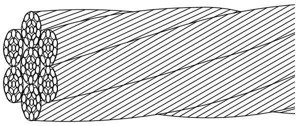
Right Regular Lay



Right Lang Lay



Left Regular Lay



Left Lang Lay

Figure 1—Lays in Wire Rope

3.9. *lay*—used by the wire rope industry in two different ways as follows:

3.9.1. The lay is the manner in which the wires in a strand or the strands in a wire rope lay (twisted). (See Figure 1.)

3.9.2. The lay is the distance parallel to the longitudinal axis in which a wire makes a complete turn (spiral or helix) about the axis of the rope. It is also called the lay length or the pitch. (See Figure 2.)

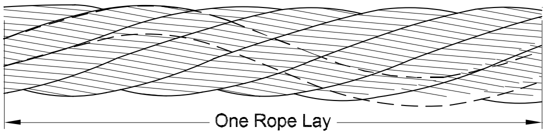


Figure 2—Lay as a Unit of Measure

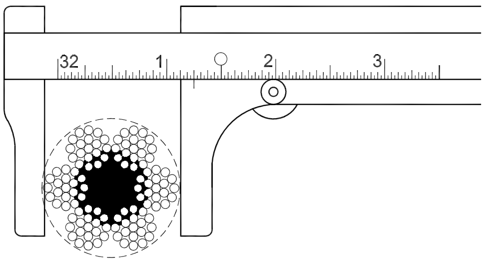
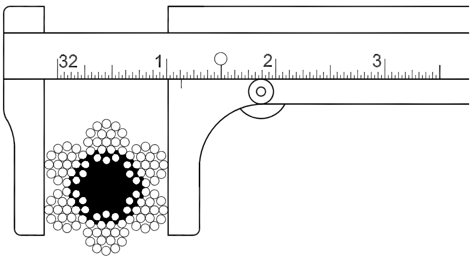
3.10. *nominal breaking strength*—the value on which designs should be based.

3.11. *ordered diameter*—the nominal diameter of the circumscribing circle of a wire rope of strand. (See Figure 3.)



Correct Way
This gives correct diameter.



Incorrect Way
This does not give correct diameter.

Figure 3—Determination of the Wire Rope Diameter

3.12. *pitch (lay length)*—the distance parallel to the longitudinal axis in which a wire makes a complete turn about the axis of the rope.

3.13. *preformed strand*—a strand in which the wires are permanently shaped to the spiral form they assume in the strand.

3.14. *preformed wire rope*—a wire rope in which the strands are permanently shaped to the spiral form they assume in the wire rope.

3.15. *prestretching*—stretching is the result of two components: the structural stretch, caused by the lengthening of the rope lay, compression of the core, and adjustment of the wires and strands to the load; and the elastic stretch caused by elongation of the wires. Prestretching is the application of a prescribed tensile force prior to delivery (see Section 5.2.4) intended to permanently adjust the rope for most of the structural stretch component, so that when it is placed in service the elastic stretch will be the only significant cause of additional elongation.

3.16. *regular lay*—designates that the wires in the rope strand lay in one direction while the strand itself rotates in the rope in an opposite direction. The rope has, therefore, an outward appearance that all wires in the rope are roughly parallel to the longitudinal axis of the rope. There are two regular lays, as follows:

3.16.1. *right regular lay (commonly called "regular lay")*—the strands run in the rope downwards to the right (clockwise) while the wires in the strands rotate to the left (counterclockwise). This is the most used lay.

3.16.2. *left regular lay*—the strands in the rope run downwards to the left (counterclockwise) while the wires in the strand run to the right (clockwise). (See Figure 1.) The left regular lay is not a commonly used lay and must be specifically ordered.

3.17. *reels, manufacturing*—reels on which the strands and the wire ropes are wound in one continuous length as they are formed on the rope closing machine.

3.18. *reels, shipping*—reels on which wire strands or wire ropes, cut to the ordered lengths, are wound from the manufacturing reel for shipment.

3.19. *rope*—a symmetrically arranged and helically twisted assembly of strands.

3.20. *sockets*— type of wire fitting, including bridge sockets, which are steel castings with baskets for securing rope ends and equipped with adjustable bolts. Closed type as "U-bolt" with or without a bearing block in the U of the bolt. Open type has two eyebolts and pin.

3.21. *strand*—a symmetrically arranged and helically twisted assembly of wires.

3.22. *6 × 19 wire rope*—a common type of construction composed of six strands, each strand containing an equal number of wires, ranging between 15 and 26. The six strands are helically twisted around a core of polypropylene, natural hard fiber, an independent wire rope, or a strand.

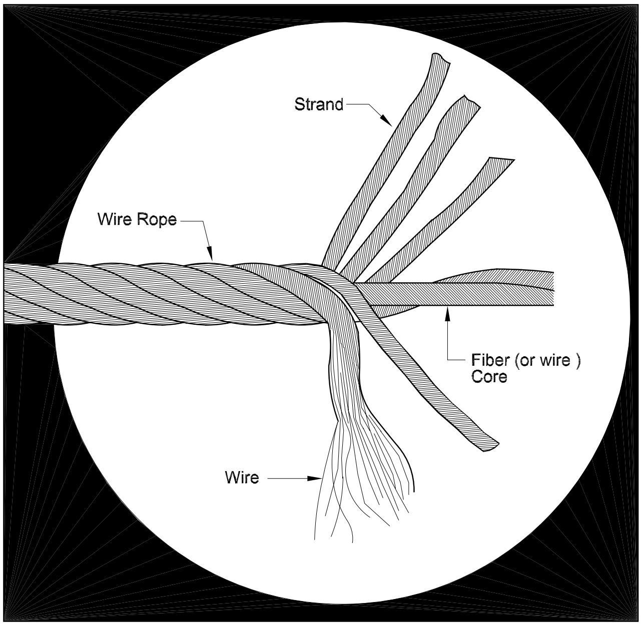


Figure 4—Components of Wire Rope

4. ORDERING INFORMATION

4.1. Orders for material under this specification shall include the following information:

4.1.1. Total length and individual lengths,

4.1.2. Nominal diameter,

4.1.3. Prestretched or non-prestretched,

4.1.4. Construction (type of core, lay, etc.),

4.1.5. Galvanizing class and type, or bright,

4.1.6. Grade of rope,

4.1.7. Details on socket requirements,

4.1.8. AASHTO designation and date of issue, and

4.1.9. Special requirements: Mechanical tests, inspection, packaging requirements.

Note 1—A typical ordering description is as follows: 2926 m (9600 ft), 38.1 mm (1.5 in.), improved plow steel, regular lay, in 732 m (2400 ft) spoolless packs to M 277, bright.

Note 2—Manufacturer should be advised to include sufficient materials to provide for the samples described in Section 7.

5. MATERIALS AND MANUFACTURE

5.1. *Base Metal*—Wire rope and strand shall be made of improved plow steel. The steel for wires shall be made by the basic oxygen or electric furnace processes.

5.2. *Construction of Wire Rope*:

5.2.1. The actual diameter of wire rope (the diameter of a circumscribed circle) shall be measured when the rope is unstressed. The measurement shall be made as required in Section 10.1.2.

The tolerance from nominal diameter of bright wire rope shall be –0 percent to +5 percent.

5.2.2. All ropes shall be preformed wire rope of 6 × 19 filler wire construction with a hard fiber or polypropylene core.

5.2.3. Ropes shall be laid in accordance with the best practice. Every effort shall be made to obtain ropes of uniform physical properties. The ropes shall be fabricated in the greatest lengths practicable, and all similar ropes for any one bridge shall be cut from ropes manufactured with one setting on one closing machine.

5.2.4. Prestretched rope shall meet the minimum modulus of elasticity shown in Table 1.

5.2.4.1. If specified, a test for modulus of elasticity shall be made on each manufactured length of wire rope. The modulus of elasticity shall be determined from a gauge length of not less than 50 diameters and shall be computed on the sum of the gross metallic cross-sectional areas of the wire making up the wire rope. Throughout the range from 10 percent of the strength listed in Table 6 to 90 percent of the prestretching tension, this modulus of elasticity shall not be less than the specified minimum shown in Table 1.

Table 1—Minimum Modulus of Elasticity of Prestretched Structural Wire Rope

Nominal Diameter Wire Rope, mm (in.)	Minimum Modulus, GPa (psi)
12.7–63.5 (0.5–2.5)	138 (20000000)

5.2.4.2. *Prestretching*—Each rope shall be prestretched using the following procedure: (1) Tension the rope to 40 percent of its ultimate tensile strength as determined in Section 7.5 and hold that load for 300 seconds. (2) Reduce the load to 5 percent of the ultimate tensile strength. (3) Repeat this load–unload cycle two more times. (4) Release the load completely.

5.2.5. All wire ropes, unless otherwise specified, shall be right regular lay, and the maximum length of rope lay shall be as follows:

- *Operating Ropes*—6.75 times nominal rope diameter
- *Counterweight Ropes*—7.5 times nominal rope diameter

The lay of the wires in the strands shall be such as to make the wires approximately parallel to the axis of the rope where they would come in contact with a circular cylinder circumscribed on the rope.

5.2.6. Fiber core for wire rope shall be one of the hard fibers or polypropylene fiber. The hard fibers are manila (abaca) and sisal (African, Java, Mauritius, Mexican, and Yucatan). A mixture of two or more species of hard fibers may be used. Polypropylene fibers shall meet the requirements of MIL-P-24216. Fiber core shall be of commercial quality and shall be thoroughly cleaned, free of waste, evenly twisted, of uniform plies and of good workmanship.

5.2.6.1. Fiber cores and centers shall be thoroughly impregnated during fabrication with a lubricant that shall contain copper compounds or other preservation material to allay deterioration of fiber parts due to rot or mildew and shall not be injurious to steel wires. This requirement is not applicable to polypropylene cores or centers.

5.2.7. The wires of uncoated (not galvanized) steel wire ropes shall be thoroughly coated with a suitable lubricant during the process of manufacture. The lubricant shall have a mineral base compounded with additives designed to provide corrosion protection and lubricating qualities during shipping, storage, handling, and the initial period of service and suitable base for subsequent field re-lubrications. The lubricant shall be free from substances injurious to steel wires and fiber cores.

5.2.8. Coated (galvanized) steel wire ropes may be lightly lubricated during fabrication at the option of the manufacturer.

5.2.9. No splicing or joining of strands shall be permitted in the manufactured length of rope. Welds made prior to wire drawing are permitted. Joining of wires by welding during stranding operation is permissible and such joints shall be dispersed sufficiently so as to maintain the minimum tensile or breaking strength as listed in Table 2.

Table 2—Tensile Properties of Wire

Diameters of Wire, mm (in.)	Minimum Tensile Strength Uncoated,[a] GPa (psi)	Minimum Elongation, percent
0.89–1.53 (0.038–0.060)	1.65 (238000)	1.50
1.54–2.54 (0.061–0.100)	1.58 (230000)	1.75
2.55–3.56 (0.101–0.140)	1.55 (225000)	2.00
3.57–4.83 (0.141–0.190)	1.50 (218000)	2.25

[a] For galvanized wire deduct 10 percent of strength.

6. ZINC COATING

6.1. When specified to be zinc coated, the wire rope is normally furnished with Class A zinc-coated wire throughout. It may be furnished with Class B or Class C mass zinc-coated outer wires and Class A inner wires or Class B mass or Class C zinc-coated wires throughout where additional corrosion protection is required by the purchaser. The purchaser must specify such increase.

6.1.1. The slab zinc, when used, shall conform to M 120 for Zinc, High Grade or better.

6.2. The weight of the zinc coating on the individual wires prior to the fabrication of the wire rope shall be not less than that specified in Table 3 for the class designated when tested in accordance with the stripping test of T 65M/T 65.

Table 3—Minimum Weight of Coating

Nominal Diameters of Coated Wire	Mass of Zinc Coating, Minimum kg/m^2 (oz/ft^2) of Uncoated Wire Surface		
mm. (in.)	Class A Coating	Class B Coating	Class C Coating
1.02–1.55, incl (0.040–0.061)	0.12 (0.40)	0.24 (0.80)	0.37 (1.20)
1.56–2.01, incl (0.062–0.079)	0.15 (0.50)	0.30 (1.00)	0.46 (1.50)
2.02–2.34, incl (0.080–0.092)	0.18 (0.60)	0.37 (1.20)	0.55 (1.80)
2.35–2.62, incl (0.093–0.103)	0.21 (0.70)	0.43 (1.40)	0.64 (2.10)
2.63–3.03, incl (0.104–0.119)	0.24 (0.80)	0.49 (1.60)	0.73 (2.40)
3.04–3.61, incl (0.120–0.142)	0.26 (0.85)	0.52 (1.70)	0.78 (2.55)
3.62–4.76, incl (0.143–0.187)	0.27 (0.90)	0.55 (1.80)	0.82 (2.70)
4.77 and larger[a] (0.188)	0.30 (1.00)	0.61 (2.00)	0.92 (3.00)

[a] This is not to imply that larger wire will be manufactured to any unlimited diameter. It only implies that the wire sizes chosen by the wire rope manufacturer must meet the requirements of this specification.

6.3. The zinc-coated wire, prior to fabrication into wire rope, shall be capable of being wrapped two turns in a close helix at a rate exceeding 15 turns per minute in around a cylindrical steel mandrel equal to five times the nominal diameter of the wire under test without cracking or flaking the zinc coating to such an extent that any zinc can be removed by rubbing with the bare fingers.

Note 3—Loosening or detachment during the adherence test of superficial small particles of zinc formed by mechanical polishing of the surface of the coated wire shall not be considered cause for rejection.

6.4. Zinc coating shall be applied by either the electrolytic-plating process or by hot dipping in molten zinc as specified by the purchaser.

6.5. Zinc coating shall be free from uncoated spots, lumps, pits, blisters, gritty areas, dross, and flux.

7. PHYSICAL REQUIREMENTS

7.1. The tensile strength of individual wires shall conform to the requirements of Table 2.

7.2. The total ultimate elongation of the wires measured on a 250-mm (10-in.) gauge length, at the breaking strength of the wire, shall be not less than shown in Table 2.

7.3. *Dimension, Permissible Variation*—The diameter variation of like-positioned wires in the strands of the wire rope shall not exceed the tolerances listed in Table 4.

Table 4—Diameter Tolerance for Like-Positioned Wires

Diameters of Wire, mm (in.)	Total Variation, mm (in.)
0.96–1.53 (0.038–0.060)	0.051 (0.002)
1.54–2.54 (0.061–0.100)	0.064 (0.0025)
2.55–3.56 (0.101–0.140)	0.076 (0.003)
3.57–4.83 (0.141–0.190)	0.089 (0.0035)

7.4. In lieu of complying with the elongation requirements in Table 2, the torsional test described in Section 7.4.1 may be performed.

7.4.1. The test specimens of the wire shall be subjected to a torsion test in which the distance between the jaws of the testing machine is 200 mm (8 in.). The number of complete successive turns of 360 degrees in one direction through which a 200-mm (8-in.) length of wire can be twisted around its longitudinal axis, without breaking or showing any signs of splitting or other defects, shall not be less than shown in Table 5.

Table 5—Torsion Test Requirements for Individual Wires

Diameter of Wire, mm (in.)	Turns
0.96 (0.038)	57
1.14 (0.045)	48
1.27 (0.050)	43
1.40 (0.055)	39
1.52 (0.060)	35

7.4.2. One end of the wire is to be rotated with respect to the other end of the wire at continuous, uniform speed until breakage occurs. During the test, the applied tension shall be sufficient to straighten the wire. The speed of rotation shall not exceed 60 turns per minute. Such tests shall be carried out by a mechanically driven device in order to secure operation at constant, uniform speed. The machine must be equipped with an automatic counter to record the number of twists causing breakage. One jaw shall be fixed axially and the other jaw moved axially and be arranged for applying tension weights to wire under test. Tests in which breakage occurs within 3 mm ($^1/_8$ in.) of the jaw shall be discarded.

7.5. *Ultimate Strength*—In order to demonstrate the strength of the rope and its fastenings, the length of the test specimen shall not be less than 0.91 m (3 ft) between sockets for wire ropes up through 25.4 mm (1 in.) diameter inclusive and not less than 1.52 m (5 ft) between sockets for wire ropes 25.4 to 63.5 mm (1 to 2.5 in.) diameter. The test shall be valid if failure occurs 50.8 mm (2 in.) or more from the sockets or holding mechanism. The test specimens shall have sockets, selected at random from those used in filling the order, attached to their ends. The number of test pieces shall be not fewer than two from each original length in which the rope is fabricated, and not more than 10 percent of the total number of finished lengths of rope to be made for the order. The test pieces shall be taken from both ends of the original lengths in which the rope is fabricated. A suitable mark shall be placed around the rope near the end of the socket, so that any movement of the latter can readily be detected. These test pieces are to be stressed to destruction in a suitable testing machine. The maximum rate of loading shall not be more than 3.5 MPa/sec (500 psi/sec). The sockets used for these tests shall not be used in the structure. Under this stress, bright (uncoated) wire rope shall develop the minimum nominal strength given in Table 6. When ropes are galvanized, deduct 10 percent from bright rope strengths shown.

Table 6—Ultimate Strength of Improved Plow Steel Rope 6 × 19 Classification Wire Rope, Bright (Uncoated), Fiber Core

Nominal Diameter, mm (in.)	Approx Mass, kg/m (lb/ft)	Nominal Strength Improved Plow Steel, kN (lb)
13 ($^1/_2$)	0.62 (0.42)	95.2 (21400)
14 ($^9/_{16}$)	0.79 (0.53)	120.0 (27000)
16 ($^5/_8$)	0.98 (0.66)	148.6 (33400)
19 ($^3/_4$)	1.41 (0.95)	211.7 (47600)
22 ($^7/_8$)	1.92 (1.29)	286.5 (64400)
25 ((1)	2.50 (1.68)	371.9 (83600)
29 ($1^1/_8$)	3.17 (2.13)	468.0 (105200)
32 ($1^1/_4$)	3.91 (2.63)	574.7 (129200)
35 ($1^3/_8$)	4.73 (3.18)	691.3 (155400)
38 ($1^1/_2$)	5.62 (3.78)	818.5 (184000)
41 ($1^5/_8$)	6.61 (4.44)	951.9 (214000)
44 ($1^3/_4$)	7.66 (5.15)	1103.2 (248000)
48 ($1^7/_8$)	8.80 (5.91)	1254.4 (282000)
51 (2)	10.00 (6.72)	1423.4 (320000)
54 ($2^1/_8$)	11.30 (7.59)	1592.5 (358000)
57 ($2^1/_4$)	12.70 (8.51)	1779.3 (400000)
60 ($2^3/_8$)	14.10 (9.50)	1939.4 (436000)
64 ($2^1/_2$)	15.62 (10.50)	2108.5 (474000)

8. SOCKETS

8.1. All sockets used with wire ropes shall be made from forged solid blanks of normalized M 102M/M 102 Class 2 steel, without the use of welding, or be machined from hot-rolled ASTM A29 alloy steels, such as Grades E4130 or 8620, and subsequently normalized or quenched and tempered to attain a 345 MPa [50 ksi] minimum yield strength and 550 MPa [80 ksi] minimum tensile strength. Sockets for ropes with 64-mm [2.5-in.] diameter may be made of ASTM A148 Grade 80-50 cast steel. All sockets shall have the minimum average energy required by ASTM A709 for Grade 50, as determined by Charpy V-notch impact test. The minimum average energy required is dependent on whether the socket is fracture-critical or nonfracturecritical, and in what temperature zone the bridge is located. The sockets shall be neatly finished to the exact dimensions shown on the plans. All socket pins shall be Class C normalized steel forgings or be machined from hot-rolled ASTM A29 alloy steels, such as Grades E4130 or 8620, and subsequently normalized or quenched and tempered to attain a 345 MPa [50 ksi] minimum yield strength and 550 MPa [80 ksi] minimum tensile strength. In every case, the dimensions of the sockets shall be such that no part under tension shall be stressed higher than 90 percent of yield strength when the rope is stressed to its specified ultimate strength. The sockets shall be attached to the ropes by using zinc of a quality not less than that defined for High Grade in the current specifications for Zinc Metal (Slab Zinc) of M 120. A reliable method of attachment shall be used that will permit the rope, when stressed to 80 percent of its ultimate strength under the test specified in Section 7.5, to slip not more than one-sixth the nominal diameter of the rope. If a greater movement shall occur, the method of attachment shall be changed until a satisfactory one is found.

The zinc used in attaching the sockets must not be too hot or it will anneal the wires. The correct temperature range for zinc for this purpose is from 455 to 565ºC (850 to 1050ºF). Filling of the socket with zinc must be performed in one continuous operation.

8.2. Sockets, pinholes, and pins shall be machined for an RC8 fit in accordance with ANSI B4.1. Sockets shall be painted in the shop as specified by the purchaser.

9. SAMPLING AND TESTING

9.1. *Wire Rope*:

9.1.1. A lot shall consist of all the wire rope of one type, class, construction, size, and material presented for delivery at one time on the same contract or order.

9.1.2. When wire rope or strand can be identified by its manufacturing reel, one sample 3.7 m (12 ft) long shall be taken from one shipping reel in the lot.

9.1.3. When wire rope or strand cannot be identified by its manufacturing reel, one sample 3.7 m (12 ft) long shall be cut from each reel or coil submitted for inspection.

9.1.4. *Resample and Retest*—If the original sample fails, two more samples will be cut and tested from the same reel or coil. Both re-samples must pass, or the cable may be rejected.

9.2. *Sockets*:

9.2.1. A lot of sockets shall consist of all the sockets of one type, class, construction, size, and material presented for delivery at one time on the same contract or order.

9.2.2. The sockets shall be stronger than the rope with which they are used. If a socket should break during the test specified in Section 7.5, two others shall be selected and attached to another piece of rope and the test repeated. This process shall be continued until the inspector is satisfied of their reliability, in which case the lot shall be accepted. If, however, 10 percent or more of all sockets tested break at a load less than the specified minimum strength, the entire lot shall be rejected, and new ones made of stronger material or to a heavier design shall be furnished.

10. INSPECTION

10.1. All tests and inspection shall be made at the place of manufacture unless otherwise specified and shall be so conducted as not to interfere unnecessarily with the operation of the works. The manufacturer shall afford the inspector representing the purchaser all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. When specified, inspection may be waived, and certified copies of test reports furnished.

10.1.1. Each reel (or coil) in the lot shall be visually examined for workmanship and measured for dimensional requirements.

10.1.2. The examination of the wire rope diameter shall be made of the free end of the rope in the shipping reel. Beginning not less than 1.5 m (5 ft) from the end of the rope, the diameter shall be measured at three places not less than 1.5 m (5 ft) apart with a slide caliper as shown in Figure 1. The average of the measured diameters shall be the diameter of the rope.

10.1.3. The examination of pitch or the lay length shall be made at the free end of the wire rope or strand on the shipping reel. Beginning not less than 3 m (10 ft) from the end of the rope, the length of five or more pitches shall be measured. The distance measured shall be divided by the number of pitches, in order to arrive at the pitch or the length of a single lay.

10.1.4. Sockets shall be visually inspected for dimensions, workmanship, and manufacturing flaws.

11. PACKAGING AND MARKING

11.1. Wire rope shall be packaged in coils or reels at the discretion of the manufacturer unless otherwise specified. Wire rope shall be packaged in such a manner so that no permanent deformation of wires in the strand or strands in the wire rope will occur. It shall be protected against damage by weather or handling. Each reel or coil shall have a strong tag securely fastened to it showing the length, size, grade, AASHTO designation, and the name or mark of the manufacturer.

11.2. Sockets shall be placed in suitable containers so as to protect them from damage until time of use. Each container shall be marked with the quantity, type of socket, size, grade, AASHTO designation, and name or mark of the manufacturer.

Standard Specification for

Castings, Iron-Chromium-Nickel, Corrosion Resistant, for Severe Service

AASHTO Designation: M 285M/M 285-07
ASTM Designation: A 744/A 744M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Castings, Iron-Chromium-Nickel, Corrosion Resistant, for Severe Service

AASHTO Designation: M 285M/M 285-07
ASTM Designation: A 744/A 744M-06

1. SCOPE

1.1. This specification covers iron-chromium-nickel alloy, stainless steel castings intended for particularly severe corrosive applications.

1.2. This specification requires postweld heat-treatment of all weld repairs affecting surfaces intended to be wetted by the corrosive medium. For applications for which postweld heat-treatment is not considered mandatory for retention of acceptable corrosion resistance, refer to M 163M/M 163.

Note 1—For general corrosion-resistant alloy castings, reference should be made to M 163M/M 163. For general heat-resistant alloy castings, reference should be made to ASTM A 297/A 297M. For nickel-base alloy castings, refer to ASTM A 494/A 494M.

1.3. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification. SI units are applicable for material ordered to M 285M and inch-pound units for material ordered to M 285.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- AWS A5.14, Specification for Nickel and Nickel Alloy Bare Welding Rods and Electrodes[1]

3. TERMINOLOGY

3.1. *Definition of Term Specific to This Standard*:

3.1.1. *wetted surface, n*—one that contacts a corrosive environment.

4. GENERAL CONDITIONS FOR DELIVERY

4.1. Except for investment castings, castings furnished to this specification shall conform to the requirements of ASTM A 781/A 781M including any supplementary requirements that are indicated on the purchase order. Failure to comply with the general requirements of ASTM A 781/A 781M constitutes nonconformance with this specification. In case of conflict between the requirements of this specification and ASTM A 781/A 781M, this specification shall prevail.

4.2. Steel investment castings furnished to this specification shall conform to the requirements of ASTM A 957, including any supplementary requirements that are indicated in the purchase order. Failure to comply with the general requirements of ASTM A 957 constitutes nonconformance with this specification. In case of conflict between the requirements of this specification and ASTM A 957, this specification shall prevail.

5. ORDERING INFORMATION

5.1. Orders for material to this specification should include the following, as required, to describe the material adequately:

5.1.1. Description of the casting by pattern number or drawing (dimensional tolerances shall be included on the casting drawing),

5.1.2. Grade,

5.1.3. Heat-treatment,

5.1.4. Identify wetted surface(s),

5.1.5. Options in the specification,

5.1.6. Whether castings are to be produced using the investment casting process, and

5.1.7. Supplementary requirements desired, including the standards of acceptance.

6. PROCESS

6.1. Alloys shall be melted by the electric furnace process with or without separate refining, such as argon-oxygen-decarburization (AOD).

7. HEAT-TREATMENT

7.1. Castings shall be heat-treated in accordance with the requirements in Table 1.

Note 2—Proper heat-treatment of these alloys is usually necessary to enhance corrosion resistance and, in some cases, to meet mechanical properties. Minimum heat-treat temperatures are specified; however, it is sometimes necessary to heat-treat at higher temperatures, hold for some minimum time at temperature, and then rapidly cool the castings in order to enhance the corrosion resistance and meet mechanical properties.

Table 1—Heat-treatment Requirements

Grade (UNS)	Heat-treatment
CF8 (J92600), CG8M (J93000), CF8M (J92900), CF8C (J92710), CF3 (J92500), CF3M (J92800), CG3M (J92999)[a]	Heat to 1040˚C [1900˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CN7M (N08007)	Heat to 1120˚C [2050˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.
CN7MS (J94650)	Heat to 1150˚C [2100˚F] minimum, 1180˚C [2150˚F] maximum, hold for sufficient time (2 h minimum) to heat casting to temperature and quench in water.
CN3MN (J94651)	Heat to 1150˚C [2100˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or cool rapidly by other means.
CK3MCuN (J93254)	Heat to 1150˚C [2100˚F] minimum, hold for sufficient time to heat casting to temperature, quench in water or rapid cool by other means.

[a] For optimum tensile strength, ductility, and corrosion resistance, the solution annealing temperatures for Grades CF8M, CG8M and CF3M should be in excess of 1040˚C [1900˚F].

8. CHEMICAL REQUIREMENTS

8.1. The materials shall conform with the chemical requirements prescribed in Table 2.

9. WORKMANSHIP, FINISH, AND APPEARANCE

9.1. Machined welding ends shall be suitably protected against damage during shipping.

10. REPAIR BY WELDING

10.1. The composition of the deposited weld metal shall be similar to that of the casting except in grade CK3MCuN. In the case of grade CK3MCuN, the composition of the deposited metal shall be similar to that of AWS A5.14ER NiCrMo-3 (UNS NO6625) or AWS A5.11 E NiCrMo-3 (UNS W86112) when postweld heat-treatment is not required, and the composition of the deposited metal shall be either similar to that of the base metal or similar to that of AWS A5.14 ER NiCrMo-3 or AWS A5.11 E NiCrMo-3 when postweld heat-treatment is required.

10.1.1. The composition of the deposited weld metal shall be similar to that of the casting except in grade CN3MN. In the case of grade CN3MN, the composition of the deposited weld metal shall be similar to that of AWS A5.14 ER NiCrMo-3 or ER NiCrMo-4 or ER NiCrMo-10 or the composition of the deposited weld metal shall be similar to that of AWS A5.11 E NiCrMo-3 or E NiCrMo-4 or E NiCrMo-10 when postweld heat-treatment is or is not required.

10.2. Weld repairs shall be considered major in the case of a casting that has leaked on hydrostatic test or when the depth of the cavity after preparation for repair exceeds 20 percent of the actual wall thickness, or 25 mm [1 in.], whichever is smaller, or when the extent of the cavity exceeds approximately 65 cm^2 [10 $\mathrm{in.}^2$]. All other weld repairs shall be considered minor. Major and minor weld repairs shall be subject to the same quality standards as are used to inspect the castings. When methods involving high temperatures are used in the removal of discontinuities, castings shall be preheated to 10°C [50°F] minimum.

Table 2—Chemical Requirements

Grade (UNS)	Type	Carbon, Max	Manganese, Max	Silicon, Max	Phosphorus, Max	Sulfur, Max	Chromium	Nickel	Molybdenum	Columbium	Copper	Selenium	Tungsten, Max	Vanadium, Max	Iron, Max	Nitrogen
		Composition, percent

---

[a] Grade CF8C shall have a columbium content of not less than eight times the carbon content and not more than 1.0 percent. If a columbian-plus-tantalum alloy in the approximate Cb:Ta ratio of 3:1 is used for stabilizing this grade, the total columbium-plus-tantalum content shall not be less than nine times the carbon content and shall not exceed 1.1 percent.

[b] For purposes of determining conformance with this specification, the observed or calculated value for carbon content shall be rounded to the nearest 0.01 percent in accordance with the rounding method of ASTM E 29.

10.3. Castings shall be postweld heat-treated in accordance with Table 1 after all major weld repairs and after those minor weld repairs involving either of the following conditions: (1) welding on a wetted surface, or (2) welding that heats a wetted surface to or above 425°C [800°F].

Note 3—The maximum wetted surface temperature of 425°C [800°F] permitted on minor weld repairs without subsequent heat-treatment for the austenitic grades is necessary to avoid sensitization to intergranular corrosion. Minor repairs of this type can be made by using a low heat input (example, 2000 J/mm [50 000 J/in.]) welding process or by cooling wetted surfaces with water during welding, or both. Wetted surface temperature measurement can be accomplished with temperature-indicating crayon or contact pyrometer.

11. REJECTION AND REHEARING

11.1. Samples that represent rejected material shall be preserved for two weeks from the date of transmission of the rejection report. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

12. PRODUCT MARKING

12.1. Castings shall be marked for material identification with the AASHTO M 285M/M 285 or ASTM A 744/A 744M specification number and grade symbol; that is, CF8, CN7M, etc. In addition, the manufacturer’s name or identification mark and the pattern number shall be cast or stamped using low-stress stamps on all castings. Small-size castings may be such that marking must be limited consistent with the available area. The marking of heat numbers on individual castings shall be agreed upon by the manufacturer and the purchaser. Marking shall be in such position as not to injure the usefulness of the casting.

13. KEYWORDS

13.1. Austenitic stainless steel; corrosion; stainless steel; steel castings.

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall not apply unless specified in the purchase order. A list of standard supplementary requirements for use at the option of the purchaser is included in ASTM A 781/A 781M. Those that are ordinarily considered for use with this specification are given below. Others enumerated in ASTM A 781/A 781M may be used with this specification upon agreement between the manufacturer and the purchaser.

S2. RADIOGRAPHIC EXAMINATION

S3. LIQUID PENETRANT EXAMINATION

S5. EXAMINATION OF WELD PREPARATION

S6. CERTIFICATION

S7. PRIOR APPROVAL OF MAJOR WELD REPAIRS

S21. INTERGRANULAR CORROSION TEST

S21.1 An intergranular corrosion test shall be performed in accordance with the appropriate practice for the grade involved, as listed in ASTM A 262, or as agreed upon with the purchaser. Intergranular corrosion tests on stabilized or 0.03 percent carbon maximum grades (CF3, CF3M, CF8C, CG3M, CK3MCuN, and CN3MN) shall be made on sensitized specimens. On all other grades of chromium-nickel steels, intergranular corrosion tests shall be made on specimens representative of the as-shipped condition.

S22. TENSION TEST

S22.1 Tensile properties shall be determined from material representing each heat. The bar from which the test specimen is taken shall be heat-treated in production furnaces to the same procedure as the casting it represents. The results shall conform to the requirements specified in Table 3.

Table 3—Tensile Requirements

Grade (UNS)	Type	Tensile Strength, Min MPa	Tensile Strength, Min [ksi]	Yield Strength, Min MPa	Yield Strength, Min [ksi]	Elongation in 50 mm [2 in.], Min, percent[a]
CF8 (J92600)	19 Chromium, 9 Nickel	485[b]	[70][b]	205[b]	[30][b]	35[b]
CF8M (J92900)	19 Chromium, 10 Nickel with Molybdenum	485	[70]	205	[30]	30
CF8C (J92710)	19 Chromium, 10 Nickel with Columbium	485	[70]	205	[30]	30
CF3 (J92500)	19 Chromium, 9 Nickel	485	[70]	205	[30]	35
CF3M (J92800)	19 Chromium, 10 Nickel with Molybdenum	485	[70]	205	[30]	30
CG3M (J92999)	19 Chromium, 11 Nickel with Molybdenum	515	[75]	240	[35]	25
CG8M (J93000)	19 Chromium, 11 Nickel with Molybdenum	520	[75]	240	[35]	25
CN7M (N08007)	20 Chromium, 29 Nickel with Copper and Molybdenum	425	[62]	170	[25]	35
CN7MS (J94650)	19 Chromium, 24 Nickel with Copper and Molybdenum	485	[70]	205	[30]	35
CN3MN (J94651)	21 Chromium, 24 Nickel with Molybdenum and Nitrogen	550	[80]	260	[38]	35
CK3MCuN (J93254)	20 Chromium, 18 Nickel with Molybdenum and Copper	550	[80]	260	[38]	35

[a] When ICI test bars are used in tensile testing as provided for in this specification, the gauge length to reduced section diameter ratio shall be 4:1.

[b] For low-ferrite or nonmagnetic castings of this grade, the following values shall apply: tensile strength, min 450 MPa [65 ksi]; yield point, min 195 MPa [28 ksi].

S22.2 Test bars shall be poured in separately cast keel blocks similar to Figures 1 or 2 of ASTM A 781/A 781M.

S22.3 Tension test specimens may be cut from heat-treated castings, or from as-cast castings if no heat-treatment is specified for the castings, instead of from test bars, when agreed upon by the manufacturer and the purchaser.

S22.4 Test specimens shall be machined to the form and dimensions of the standard round 50-mm [2-in.] gauge length specimen shown in Figure 6 of T 244, unless the purchase order is for investment castings, in which case the specimens shall be prepared in accordance with S3.2 of ASTM A 732/A 732M. Testing shall be in accordance with T 244.

S22.5 If the results of the mechanical tests for any heat, lot, or casting do not conform to the requirements specified, retests are permitted as outlined in T 244. At the manufacturer's option, castings may be reheat-treated and retested. When castings are reheat-treated, they may not be reaustenitized more than three times without the approval of the purchaser. Testing after reheat-treatment shall consist of the full number of specimens taken from locations complying with the specification or order.

S23. SURFACE CARBON ANALYSIS

S23.1 An analysis for carbon shall be made from a casting representative of each heat. The sample for the analysis shall be within 0.25 mm [0.010 in.] of the surface and taken after removal of scale and other contaminants at a location to be agreed upon between the manufacturer and purchaser. The carbon content shall meet the carbon requirement of the pertinent grade as shown in Table 2. Other sampling depths and surface carbon requirements may be agreed upon between the purchaser and manufacturer.

APPENDIX

(Nonmandatory Information)

X1. RECOMMENDED FILLER METALS FOR CAST STAINLESS STEELS

X1.1. Listed in Table X1.1, for information, are the filler metals most commonly recommended for welding cast stainless steels. Only those materials having AWS designations are included. The standard prefixes designating covered electrodes, bare rod, etc., and the usability suffixes have been intentionally omitted. Special applications, or supplier or customer preference, may dictate the use of alternate or overmatched filler materials.

Table X1.1—Recommended Filler Materials for Cast Stainless Steel

Casting ACI Designation (UNS)	Recommended Filler Material (AWS Designation)
CF8 (J92600)	308
CF8M (J92900)	316, 308Mo
CF8C (J92710)	309Cb, 347
CF3 (J92500)	308L
CF3M (J92800)	308MoL 316L
CG3M (J92999)	317L
CG8M (J93000)	317
CN3MN (J94651)	NiCrMo-3, NiCrMo-12
CN7M (N08007)	320, 320LR
CN7MS (J94650)	320, 320LR
CK3MCuN (J93254)	NiCrMo-3, NiCrMo-12

AASHTO Designation: M 291-09
ASTM Designation: A 563-07

AASHTO M 291-09 is identical to ASTM A 563-07 except for the following provisions:

1. All references to the ASTM standards contained in ASTM A 563-07, listed in the following table, shall be replaced with the corresponding AASHTO standard:

Referenced Standards

ASTM	AASHTO
A 194/A 194M	M 292M/M 292
A 325	M 164
A 490M	M 253
A 709/A 709M	M 270M/M 270
B 695	M 298
F 2329	M 232M/M 232

2. Replace Section 3.1.7 of ASTM A 563-07 with the following:

   3.1.7 AASHTO designation and year of issue, and

3. Replace Note 3 of ASTM A 563-07 with the following:

Note 3—An example of an ordering description follows: 1000 $^{7}/_{8}$–9 heavy hex nuts, Grade C, hot-dip zinc-coated, AASHTO M 291-____.

4. Sections 5.4 and 5.5 of ASTM A 563-07 are not included in AASHTO M 291-09.
5. Replace the last row in Table 3 of ASTM A 563-07 with the following:

DH[D]	$^{1}/_{4}$ to $1^{1}/_{2}$	hex thick	175	150	248	352	C24	C38

6. Add a last sentence to Footnote A in Table 3 of ASTM A 563-07 as follows:

   "When M 292 zinc-coated inch series nuts are supplied, the zinc coating, overtapping, lubrication, and rotational capacity testing shall be in accordance with M 291."

7. Add a last sentence to Footnote B in Table 3 of ASTM A 563-07 as follows:

   "When M 292 zinc-coated inch series nuts are supplied, the zinc coating, overtapping, lubrication, and rotational capacity testing shall be in accordance with M 291."

8. Add the following subsection to Section 10 of ASTM A 563-07.

   10.2 The proof load should be determined at a free running cross head speed not exceeding 1.0 in./min and shall be maintained for 10 seconds before releasing the load.

9. Replace Section 15.2.1.1 of ASTM A 563-07 with the following:

   15.2.1.1 AASHTO designation and grade,

10. Replace Section 16.1 of ASTM A 563-07 with the following:

    16.1 The party responsible for the fastener shall be the organization that supplies the fastener to the purchaser. The responsible party shall supply test reports, certified by the manufacturer, that indicate the fasteners were manufactured, sampled, tested, and inspected in accordance with this specification and meet all of its requirements.

11. Add the following Subsection S1.2 to ASTM A 563-07:

S1.2 Zinc-coated bolts and zinc-coated lubricated nuts shall be capable of conforming to the test requirement in Section S1.2.1. After this tightening test, the assembly shall show no signs of failure.

S1.2.1 A zinc-coated bolt shall be placed in a steel joint and assembled with a zinc-coated washer and a zinc-coated nut. The joint shall be one or more flat structural steel plates with a total thickness, including the washer, such that three to five full threads of the bolt are located between the bearing surfaces of the bolt head and nut. The hole in the joint shall have the same nominal diameter as the hole in the washer. The initial tightening of the nut shall produce a load in the bolt not less than 10 percent of the specified proof load. After this initial tightening, the nut position shall be marked relative to the bolt and the rotation shown in Table 1 shall be applied. During rotation, the bolt head shall be restrained from turning.

12. Add Table S1.1 to immediately follow Section S1 of ASTM A 563-07.

Table S1.1—Rational Capacity Test for Zinc-Coated Nuts

Bolt Length, in.	Nominal Nut Rotation, Deg (Turn)
Up to and including 4 × dia	300 ($^{5}/_{6}$)
Over 4 × dia but exceeding 8 × dia	360 (1)
Over 8 × dia	420 ($1^{1}/_{6}$)

13. Replace top row (A 563 Grade and ANSI Nut Style), row 3 (Grade of Bolt: A 325 Type 1) and row 4 (Grade of Bolt: A 325 Type 3) in Table X1.1 of ASTM A 563-07 with the following:

Table X1.1—Nut and Bolt Suitability Guide

			M 291 Grade and ANSI Nut Style[a]					
			Recommended[b]		Suitable[c]			
Grade of Bolt[d]	Surface Finish[e]	Nominal Size, in.	Hex	Heavy Hex	Square	Hex	Heavy Hex	Hex Thick
M 164 Types 1 and 2	Non-zinc coated	$^{1}/_{2}$ to $1^{1}/_{2}$	—	C	—	—	C3, D, DH, DH3	—
	Zinc-coated	$^{1}/_{2}$ to $1^{1}/_{2}$	—	DH	—	—	—	—
M 164 Type 3	Non-zinc coated	$^{1}/_{2}$ to $1^{1}/_{2}$	—	C3	—	—	DH3	—

14. Replace row 11 (Grade of Bolt: A 490 Types 1 and 2) and row 12 (Grade of Bolt: A 490 Type 3) in Table X1.1 of ASTM A 563-07 with the following:

Table X1.1—Nut and Bolt Suitability Guide

			M 291 Grade and ANSI Nut Style[a]					
			Recommended[b]		Suitable[c]			
Grade of Bolt[d]	Surface Finish[e]	Nominal Size, in.	Hex	Heavy Hex	Square	Hex	Heavy Hex	Hex Thick
M 253 Type 1	Non-zinc coated	$^{1}/_{2}$ to $1^{1}/_{2}$	—	DH	—	—	DH3	—
M 253 Type 3	Non-zinc coated	$^{1}/_{2}$ to $1^{1}/_{2}$	—	DH3	—	—	—	—

Standard Specification for

Carbon and Alloy Steel Nuts [Metric]

AASHTO Designation: M 291M-07
ASTM Designation: A 563M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Carbon and Alloy Steel Nuts [Metric]

AASHTO Designation: M 291M-07
ASTM Designation: A 563M-06

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM A 563M-06 for the information formerly contained in this standard.

Standard Specification for

Carbon and Alloy Steel Nuts for Bolts for High-Pressure or High-Temperature Service, or Both

AASHTO Designation: M 292M/M 292-10
ASTM Designation: A 194/A 194M-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Carbon and Alloy Steel Nuts for Bolts for High-Pressure or High-Temperature Service, or Both

AASHTO Designation: M 292M/M 292-10
ASTM Designation: A 194/A 194M-09

1. SCOPE

1.1. This specification covers a variety of carbon, alloy, and martensitic stainless steel nuts in the size range M6 through M100 [$^1/_4$ through 4 in.] nominal. It also covers austenitic stainless steel nuts in the size range M6 [$^1/_4$ in.] nominal and above. These nuts are intended for high-pressure or high-temperature service or both. Grade substitutions without the purchaser's permission are not allowed.

1.2. Bars from which the nuts are made shall be hot-wrought. The material may be further processed by centerless grinding or by cold drawing. Austenitic stainless steel may be solution annealed or annealed and strain-hardened. When annealed and strain-hardened austenitic stainless steel is ordered in accordance with Supplementary Requirement S1, the purchaser should take special care to ensure that Section 8.2.2, Supplementary Requirement S1, and Appendix X1 are thoroughly understood.

1.3. Supplementary requirements (Sections S1 through S8) of an optional nature are provided. These shall apply only when specified in the inquiry, contract, and order.

1.4. This specification is applicable to orders in either SI units (as M 292M) or inch-pound units (as M 292). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text. Material shall be furnished to SI units when the order specifies the applicable "M" designation.

- B18.2.2, Square and Hex Nuts
- B18.2.4.6M, Metric Heavy Hex Nuts

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *austenitic grades*—all grades with a prefix of “8” or “9.”

3.1.2. *ferritic grades*—Grades 1, 2, 2H, 2HM, 3, 4, 6, 6F, 7, 7M, and 16.

3.1.3. *Lot*:

3.1.3.1. Unless otherwise specified (Section 3.1.3.2), a lot is the quantity of nuts of a single nominal size and grade produced by the same manufacturing process.

3.1.3.2. When Supplementary Requirement S5 is invoked on the purchase order, the following definitions of a lot shall apply:

for Grade 8 nuts—the quantity of all the nuts of a single nominal diameter and grade made from the same heat of steel and made by the same manufacturing process.

for all other grade nuts (Sections 8.2 and 8.1.2.1)—all the nuts of a single nominal diameter and grade made from the same heat number and heat-treated in the same batch if batch-type heat-treating equipment is used or heat-treated in the same continuous run of not more than 8 hours under the same conditions if continuous-type heat treating equipment is used.

3.1.4. *Type*:

3.1.4.1. *for Grade 8 nuts*—variations within the grade designated by a letter and differentiated by chemistry and by manufacturing process.

3.1.4.2. *for Grade 6 nuts*—variations within the grade designated by the letter F and differentiated by chemical additions made for machinablility.

3.1.5. *series*—the dimensional relationship and geometry of the nuts as described in ANSI B18.2.2 or B18.2.4.6M.

4. ORDERING INFORMATION

4.1. The inquiry and order for material under this specification shall include the following as required to describe the material adequately:

4.1.1. Specification designation, year date, grade, issue date, and revision letter;

4.1.2. Quantity, number of pieces;

4.1.3. Dimensions (Section 9);

4.1.4. Options in accordance with Sections 8.2.2.1, 9.1, 9.2, 10.3, and 12; and

4.1.5. Supplementary Requirements, if any.

4.2. *Coatings*—Coatings are prohibited unless specified by the purchaser (see Supplementary Requirements S7 and S8). When coated nuts are ordered, the purchaser should take special care to ensure that Appendix X2 is thoroughly understood.

4.3. See Supplementary Requirement S3 for nuts to be used in low-temperature applications (Specification ASTM A 320/A 320M).

4.4. See Supplementary Requirement S9 for proof-load testing of nuts manufactured to dimensions and configurations other than those covered in Tables 3 or 4.

5. COMMON REQUIREMENTS

5.1. Material and fasteners supplied to this specification shall conform to the requirements of ASTM A 962/A 962M. These requirements include test methods, finish, thread dimensions, marking, certification, optional supplementary requirement, and others. Failure to comply with the requirements of specification ASTM A 962/A 962M constitutes nonconformance with this specification. In case of conflicts between the requirements of this specification and specification ASTM A 962/A 962M, this specification shall prevail.

6. MANUFACTURE (PROCESS)

6.1. Stainless steels for all types of Grade 6 and 8 nuts shall be made by one of the following processes:

6.1.1. Electric-furnace (with separate degassing and refining optional),

6.1.2. Vacuum induction furnace, or

6.1.3. Either of the above followed by electroslag remelting or consumable-arc remelting.

6.2. The steel producer shall exercise adequate control to eliminate excessive inhomogeneity, nonmetallics, pipe, porosity, and other defects.

6.3. Grades 1 and 2 nuts shall be hot or cold forged, or shall be machined from hot-forged, hot-rolled, or cold-drawn bars.

6.3.1. All Grade 1 and 2 nuts made by cold forging or by machining from cold-drawn bars shall be stress-relief annealed at a temperature of at least 538°C [1000°F].

6.3.2. Grade 1 and 2 nuts made by hot forging or by machining from hot-forged or hot-rolled bars need not be given any stress relief annealing treatment.

6.4. Grades 2H, 2HM, 3, 4, 6, 6F, 7, 7M, and 16 nuts shall be hot or cold forged or shall be machined from hot-forged, hot-rolled, or cold-drawn bars and shall be heat-treated to meet the required mechanical properties. Nuts machined from bars heat-treated in accordance with this specification need not be reheat treated. For Grade 2HM and 7M nuts, a final stress relief shall be done at or above the minimum tempering temperature after all forming, machining, and tapping operations. This final stress relief may be the tempering operation. These grades of nuts shall be reheated above the critical range of the steel, quenched in a suitable medium, and then tempered at a temperature not less than the following:

Grade and Type	Minimum Tempering Temperature, °C [°F]
2H	455 [850]
2HM	620 [1150]
3	565 [1050]
4	595 [1100]
6 and 6F	595 [1100]
7	595 [1100]
7M	620 [1150]
16	650 [1200]

6.4.1. Grade 6 and 6F nuts shall be tempered for a minimum of 1 hour at the temperature.

6.5. Grades 8, 8C, 8M, 8T, 8F, 8P, 8N, 8MN, 8R, 8S, 8LN, 8MLN, 8MLCuN, and 9C nuts shall be hot or cold forged, or shall be machined from hot-forged, hot-rolled, or cold-drawn bars.

6.6. Grades 8A, 8CA, 8MA, 8TA, 8FA, 8PA, 8NA, 8MNA, 8RA, 8SA, 8LNA, 8MLNA, 8MLCuNA, and 9CA nuts shall be hot or cold forged or shall be machined from hot-forged, hot-rolled, or cold-drawn bars and the nuts shall subsequently be carbide-solution treated by heating them for a sufficient time at a temperature to dissolve chromium carbides followed by cooling at a rate sufficient to prevent reprecipitation of the carbides.

[a] The intentional addition of Bi, Se, Te, and Pb is not permitted except for Grades 6F, 8F, and 8FA, in which Se is specified and required.

[b] Total aluminum, soluble, and insoluble.

[c] Maximum, unless minimum or range is indicated.

[d] Because of the degree to which sulfur segregates, product analysis for sulfur over 0.060 percent max is not technologically appropriate.

[e] As described in Specification ASTM A 276.

7. CHEMICAL COMPOSITION

7.1. Each alloy shall conform to the chemical composition requirements prescribed in Table 1.

8. MECHANICAL REQUIREMENTS

8.1. *Hardness Test*:

8.1.1. Requirements:

8.1.1.1. All nuts shall be capable of meeting the hardness requirements specified in Table 2.

8.1.1.2. Sample nuts of Grades 1, 2, 2H, 2HM, 3, 4, 7, 7M, and 16 that have been given the treatment described in Section 8.1.5 shall meet the minimum hardness specified in Table 2.

Table 2—Hardness Requirements

		Completed Nuts		Sample Nut After Treatment as in Section 8.1.5	
		Rockwell Hardness			
Grade and Type	Brinell Hardness	C Scale	B Scale	Brinell Hardness, Min	Rockwell Hardness B Scale, Min
1	121 min	—	70 min	121	70
2	159–352	—	84 min	159	84
2H to M36 [1½ in.], incl.	248–327	24–35	—	179	89
2H over M36 [1½ in.]	212–327	35 max	95 min	147	79
2HM and 7M	159–235		84–99	159	84
3, 4, 7, and 16	248–327	24–35	—	201	94
6 and 6F	228–271	20–28	—	—	—
8, 8C, 8M, 8T, 8F, 8P, 8N, 8MN, 8LN, 8MLN, 8MLCuN, and 9C	126–300	32 max	60 min	—	—
8A, 8CA, 8MA, 8TA, 8FA, 8PA, 8NA, 8MNA, 8LNA, 8MLNA, 8MLCuNA, and 9CA	126–192	—	60–90	—	—
8R, 8RA, 8S, and 8SA	183–271	25 max	88 min	—	—

8.1.2. Number of Tests (Grades 1, 2, 2H, 3, 4, 7, and 16 and all types of Grade 6):

8.1.2.1. Tests on the number of sample nuts in accordance with the following table shall be performed by the manufacturer following all production heat treatments:

Lot Size	Samples
Up to 800	1
801 to 8000	2
8001 to 22000	3
>22000	5

8.1.2.2. In addition, a hardness test shall be performed by the manufacturer in accordance with Section 8.1.5 on one sample nut selected from each nominal diameter and series from each grade and heat number following completion of all production heat treatments.

8.1.3. *Number of Tests, Grades 2HM and 7M*:

8.1.3.1. Each nut shall be tested by Brinell or Rockwell methods to ensure product conformance.[2]

8.1.3.2. In addition, Section 8.1.2.2 shall be met.

8.1.4. *Number of Tests, All Types of Grade 8*—Tests on the number of sample nuts in accordance with Section 8.1.2.1 shall be performed by the manufacturer.

8.1.5. *Test 2*—In addition to the testing required by Section 8.1.2.1, the manufacturer shall also perform hardness tests on sample nuts after the following test heat treatment. After completion of all production heat treatments, heat the specimen nuts to the temperatures indicated below for 24 hours, then slow cool. Test at room temperature.

Grade[a]	Temperature, °C [°F]
1	455 [850]
2, 2H, 2HM	540 [1000]
3, 4, 7, 7M	590 [1100]
16	650 [1200]

[a] Nuts intended to be coated with zinc or cadmium (marked in accordance with the requirements of Supplementary Requirements S8) are not subjected to the requirements of 8.1.5 (see Appendix X2).

8.1.5.1. *Special Requirement, Grades 2HM and 7M*—Preparation of Grades 2HM and 7M nuts for hardness test and the hardness test itself shall be performed with consideration to (1) protect legibility of markings; (2) minimize exterior dimensional changes; and (3) maintain thread fit.

8.2. *Proof Load Test*:

8.2.1. *Requirements*—All nuts listed in Tables 3 or 4 shall be capable of withstanding the proof loads specified therein. Proof-load testing of nuts manufactured to dimensions and configurations other than those covered in Table 3 or 4 is required only when S9 is specified in the order or inquiry.

Table 3—Proof Load Using Threaded Mandrel [Metric]

Nominal Size, mm	Thread pitch	Stress Area, mm^2	Proof Load, kN[a]					
			Grade 1		Grades 2, 2HM, 6, 6F, 7M		Grades 2H, 3, 4, 7, 16	
			Heavy Hex[b]	Hex[c]	Heavy Hex[d]	Hex[e]	Heavy Hex[f]	Hex[g]

See limit for proof-load test in Section 8.2.2.1. The proof load for jam nuts shall be 46 percent of the tabulated load.

[b] Based on proof stress of 130000 psi.

[c] Based on proof stress of 120000 psi.

[d] Based on proof stress of 150000 psi.

[e] Based on proof stress of 9135000 psi.

[f] Based on proof stress of 1175000 psi.

[g] Based on proof stress of 150000 psi.

[h] Based on proof stress of 80000 psi.

[i] Based on proof stress of 75000 psi.

Note: Proof loads are not design loads.

8.2.2. *Number of Tests*:

8.2.2.1. The manufacturer shall test the number of nuts specified in 8.1.2.1 following all production heat treatments. Nuts that would require a proof load in excess of 705 kN [160 000 lbf] may be furnished on the basis of minimum hardness requirements. Testing of nuts requiring a proof load in excess of 705 kN [160 000 lbf] is covered in Supplementary Requirements S1 and S4.

8.2.3. *Test Method*—The test shall be in accordance with Appendix A3, Paragraph A3.5.1 of T 244.

8.3. *Cone Proof Load*:

8.3.1. *Requirements*—This test shall be performed only when visible surface discontinuities become a matter of issue between the manufacturer and the purchaser. The requirements specified in Table 5 and Table 6 shall be met for the size range M6 to M36 [$^1/_4$ to $1^1/_2$ in.]. Nuts in the size range $^1/_4$ to $1^1/_2$ in. inclusive and M6 to M36 inclusive shall be proof-load tested. Nuts not in this size range and all types of Grade 8 nuts are not subject to this test. Also, nuts manufactured to dimensions and configurations other than those covered by ASTM A 962/A 962M, ANSI B1.1, B1.13M, B18.2.2, and B18.2.4.6M are not subject to the cone proof load test. The cone proof load applied shall be determined in accordance with the Cone Proof Load requirements in ASTM A 962/A 962M (tables, or formulae, or both) based upon the proof stresses shown in Tables 5 and 6 of M 292M/M 292.

Table 5—Proof Load Using 120° Hardened Steel Cone[a] [Metric]

Nominal Size, mm	Thread pitch	Stress Area, mm^2	Proof Load, kN [lbf][a]					
			Grade 1		Grades 2, 2HM, 6, 6F, 7M			Grades 2H, 3, 4, 7, 16
			Heavy Hex[b]	Hex[c]	Heavy Hex[d]	Hex[e]	Heavy Hex[f]	Hex[d]
M6	1.0	20.1	16.9	15.4	19.3	17.3	22.5	19.3

[a] Based upon the following equation (this equation cannot be used for extrapolating values beyond the size ranges listed in this table):

$CPL = (1 - 0.012D) \times f \times A_s \times 0.001$

where:

CPL = cone stripping proof load kN;

D = nominal diameter of nut, mm;

f = minimum proof stress of nut, MPa (See footnotes *b, c, d, e,* and *f*.);

A_s = tensile stress area of nut, in.^{2} = $0.7854\ [D - 0.9382P]^2$;

P = thread pitch, mm .

[b] Based on proof stress of 895 MPa.

[c] Based on proof stress of 825 MPa.

[d] Based on proof stress of 1035 MPa.

[e] Based on proof stress of 930 MPa.

[f] Based on proof stress of 1205 MPa.

Table 6—Proof Load Using 120° Hardened Steel Cone[a] [Inch Series]

Nominal Size, in.	Threads per inch	Stress Area, in.^{2}	Proof Load, lbf[a]					
			Grade 1		Grades 2, 2HM, 6, 6F, 7M			Grades 2H, 3, 4, 7, 16
			Heavy Hex[b]	Hex[c]	Heavy Hex[d]	Hex[e]	Heavy Hex[f]	Hex[d]
$^1/_4$	20	0.0316	3800	3550	4400	4000	5150	4400

$1^3/_8$	8	1.233	94250	86950	108750	97800	126850	108750
$1^1/_2$	8	1.492	106700	98500	123100	110800	143600	123100

[a] Based upon the following equation (this equation cannot be used for extrapolating values beyond the size ranges listed in this table):

$CPL = (1 - 0.30D) \times f \times A_s$

where:

CPL = cone stripping proof load lbf;
D = nominal diameter of nut, in.;
f = minimum proof stress of nut, psi (See footnotes *b, c, d, e,* and *f*.);
A_s = tensile stress area of nut, in.^{2} = $0.7854\,[D - 0.9743/n]^2$;
n = threads per inch.

[b] Based on proof stress of 130000 psi.

[c] Based on proof stress of 120000 psi.

[d] Based on proof stress of 150000 psi.

[e] Based on proof stress of 135000 psi.

[f] Based on proof stress of 175000 psi.

8.3.2. *Number of Tests*—Sample nuts in accordance with Section 8.1.2.1 shall be tested by the manufacturer. The manufacturer shall sample and test the number of nuts specified in Section 8.1.2.1. The lots shall be considered acceptable if the sample nut(s) withstand(s) application of the cone proof load without failure.

9. DIMENSIONS

9.1. Nuts shall be hexagonal in shape, and in accordance with the dimensions for the hex or heavy hex series, as required, by ANSI B18.2.2 and B18.2.4.6M. Unless otherwise specified, the American National Standard Heavy Hex Series shall be used and nuts shall be either double chamfered or have a machined or forged washer face, at the option of the manufacturer, and conform to the angularity requirements of ANSI B18.2.2 and B18.2.4.6M.

9.2. Unless otherwise specified, threads shall be in accordance with ANSI B1.1 or B1.13M, and shall be gauged in accordance with ANSI B1.2 and B1.13M as described in Sections 9.2.1 and 9.2.2.

9.2.1. Inch series nuts up to and including 1 in. nominal size shall be UNC Series Class 2B fit. Metric nuts up to and including M24 nominal size shall be coarse thread series tolerance 6H.

9.2.2. Inch series nuts greater than 1 in. nominal size shall be either UNC Series Class 2B fit or 8 UN Series Class 2B fit. Unless otherwise specified, the 8 UN series shall be furnished. Metric nuts over M24 nominal size shall be coarse thread series tolerance 6H.

10. WORKMANSHIP, FINISH, AND APPEARANCE

10.1. Nuts shall be free of defects and shall be of good commercial finish.

10.2. If visible surface imperfections in size M6 through M36 [$^1/_4$ through $1^1/_2$ in.] and in any grade other than Grade 8 become a matter of issue between the manufacturer and the purchaser, the cone proof load test described in Section 8.3 shall be employed.

10.3. If a scale-free bright finish is required, this shall be specified on the purchase order.

11. RETESTS

11.1. Provisions for retests by the purchaser and the purchaser's representative are specified in Supplementary Requirement S2.

12. CERTIFICATION

12.1. The producer of nuts shall furnish a certification to the purchaser or his representative showing the results of the chemical analysis, macroetch examination (carbon and alloy steels only), mechanical tests, and the minimum tempering temperature for nuts of Grade 2H, 2HM, 3, 4, 6, 6F, 7, and 7M.

12.2. Certification shall also include at least the following:

12.2.1. A statement that the fasteners were manufactured, sampled, tested, and inspected in accordance with the specification and any supplementary requirements or other requirements designated in the purchase order or contract and were found to meet those requirements;

12.2.2. The specification number, year, date, and identification symbol.

13. PRODUCT MARKING

13.1. All nuts shall bear the manufacturer's identification mark.

13.2. Nuts shall be legibly marked to indicate the grade and the process of the manufacturer, as presented in Table 7. Marking of wrench flats or bearing surfaces is not permitted unless agreed upon between manufacturer and purchaser.

Table 7—Marking of Nuts

Grade and Type	Nuts Hot Forged or Cold Punched	Nuts Machined from Bar Stock	Nuts Manufactured in Accordance with Section 6.6
1	1	1B	—
2	2	2B	—

9C	9C	9CB	9CA
16	16	16B	—

[a] The letters H and M indicate heat-treated nuts. (See Section 6.)

[b] See Supplementary Requirement S3.

13.3. For purposes of identification marking, the manufacturer is considered the organization that certifies the fastener was manufactured, sampled, tested, and inspected in accordance with the specification and the results have been determined to meet the requirements of this specification.

14. KEYWORDS

14.1. Bolting; chemical analysis; coated; marking on fasteners; plated.

SUPPLEMENTARY REQUIREMENTS

One or more of the following supplementary requirements shall be applied only when specified by the purchaser in the inquiry, contract, or order. Details of these supplementary requirements shall be agreed upon in writing by the manufacturer and purchaser. Supplementary requirements shall in no way negate any requirement of the specification itself.

S1. STRAIN-HARDENED AUSTENITIC STEEL NUTS

S1.1. Strain-hardened Grades 8, 8C, 8T, 8M, 8F, 8P, 8N, or 8MN nuts may be specified. When Supplementary Requirement S1 is invoked in the order, nuts shall be machined from cold-drawn bars or shall be cold forged to shape. No subsequent heat-treatment shall be performed on the nuts. Nuts made in accordance with this requirement shall be proof-load tested in accordance with Section 8.2.2.1 and shall withstand the proof load specified in Table S1.1 and Table S1.2. Testing nuts requiring proof loads greater than 705 kN [160000 lbf] is required only when Supplementary Requirement S4 is invoked. The hardness limits of Table 2 do not apply to strain-hardened nuts. Nuts made in accordance with this requirement shall be marked with the Grade symbol underlined.

Table S1.1—Proof-Load Testing of Strain-Hardened Nuts Using Threaded Mandrel [Metric]

Proof Load, kN[a]						
Nominal Size, mm	Thread pitch	Stress Area, mm^2	Grade 8M (Strain Hardened)	Grade 8M (Strain Hardened)	All Other Types of Grade 8 (Strain Hardened)	All Other Types of Grade 8 (Strain Hardened)
			Heavy Hex[b]	Hex[c]	Heavy Hex[d]	Hex[b]
M6	1.0	20.1	15.3	13.9	17.3	15.3
M8	1.25	38.6	27.8	25.3	31.3	27.8
M10	1.50	58.0	44.1	40.0	49.9	44.1

M27	3.0	459.0	300.6	268.5	332.7	300.6
M30	3.5	561.0	367.5	328.2	406.7	367.5
M36	4.0	817.0	506.5	449.4	563.7	506.5

[a] The proof load for jam nuts shall be 46 percent of the tabulated value.

[b] Based on proof stress of 760 MPa up to M20; 690 MPa M22 to M24; 655 MPa M27 to M30; 620 MPa for M36.

[c] Based on proof stress of 690 MPa up to M20; 620 MPa M22 to M24; 585 MPa M27 to M30; 550 MPa for M36.

[d] Based on proof stress of 860 MPa up to M20; 795 MPa M22 to M24; 725 MPa M27 to M30; 690 MPa for M36.

Note: Proof loads are not design loads.

Table S1.2—Proof-Load Testing of Strain-Hardened Nuts Using Threaded Mandrel [Inch Series]

			Proof Load, lbf[a]			
Nominal Size, in.	Threads per inch	Stress Area, in.^{2}	Grade 8M (Strain Hardened)	Grade 8M (Strain Hardened)	All Other Types of Grade 8 (Strain Hardened)	All Other Types of Grade 8 (Strain Hardened)
			Heavy Hex[b]	Hex[c]	Heavy Hex[d]	Hex[b]
$^{1}/_{4}$	20	0.0316	3480	3160	3950	3480
$^{5}/_{16}$	18	0.0524	5760	5240	6550	5760
$^{3}/_{8}$	16	0.0774	8510	7740	9675	8510
$^{7}/_{16}$	14	0.1063	11690	10630	13290	11690
$^{1}/_{2}$	13	0.1419	15610	14190	17740	15610
$^{9}/_{16}$	12	0.182	20020	18200	22750	20020
$^{5}/_{8}$	11	0.226	24860	22600	28250	24860
$^{3}/_{4}$	10	0.334	36740	33400	41750	36740
$^{7}/_{8}$	9	0.462	46200	41580	53130	46200
1	8	0.606	60600	54540	69690	60600
$1^{1}/_{8}$	8	0.790	75050	67150	82950	75050
$1^{1}/_{4}$	8	1.000	95000	85000	105000	95000
$1^{3}/_{8}$	8	1.233	110970	98640	123300	110970
$1^{1}/_{2}$	8	1.492	134280	119360	149200	134280

[a] The proof load for jam nuts shall be 46 percent of the tabulated value.

[b] Based on proof stress of 110000 psi up to $^{3}/_{4}$ in.; 100000 psi 7/8 to 1 in.; 95000 psi 11/8 to $1^{1}/_{4}$ in.; 90000 psi 13/8 to $1^{1}/_{2}$ in.

[c] Based on proof stress of 100000 psi up to $^{3}/_{4}$ in.; 90000 psi 7/8 to 1 in.; 85000 psi 11/8 to $1^{1}/_{4}$ in.; 80000 psi 13/8 to $1^{1}/_{2}$ in.

[d] Based on proof stress of 125000 psi up to $^{3}/_{4}$ in.; 115000 psi 7/8 to 1 in.; 105000 psi 11/8 to $1^{1}/_{4}$ in.; 100000 psi 13/8 to $1^{1}/_{2}$ in.

Note: Proof loads are not design loads.

S2. RETESTS BY PURCHASER’S REPRESENTATIVE

S2.1. The purchaser’s representative may select two nuts per keg (90-kg [200-lb] unit) for sizes M16 [$^{5}/_{8}$ in.] and smaller, one nut per keg for sizes over M16 [$^{5}/_{8}$ in.] up to and including M36 [$1^{1}/_{2}$ in.], and one nut per every two kegs for sizes larger than M36 [$1^{1}/_{2}$ in.] which shall be subjected to the tests specified in Section 8.

S3. LOW-TEMPERATURE REQUIREMENTS FOR GRADE 4, GRADE 7, OR GRADE 7M NUTS

S3.1. When low-temperature requirements are specified for Grade 4 or Grade 7 nuts, the Charpy test procedures and requirements as defined in ASTM A 320/A 320M for Grade L7 shall apply. When low-temperature requirements are specified for Grade 7M nuts, the Charpy test procedures and requirements as defined in ASTM A 320/A 320M for Grade L7M shall apply. Depending on the size of nuts, separate test samples of the same heat may be required and shall be processed through heat-treatment with the nuts for which the test is to apply. Impact testing is not required when the bar stock or nut is smaller than 16 mm [$^{5}/_{8}$ in.] in diameter.

S3.2. An “L” shall be added to the marking, as shown in Table 7, for nuts so tested.

S4. PROOF LOAD TESTS OF LARGE NUTS

S4.1. Proof-load testing of nuts requiring proof loads of over 705 kN [160000 lbf] is required. Testing shall be performed in accordance with Section 8.2 to the loads required in Table S4.1 and Table S4.2. The maximum load will be based entirely on the equipment available.

Table S4.1—Proof Load for Large Heavy Hex Nuts[a] [Metric]

			Proof Load, kN [b]		
Nominal Size, mm	Thread pitch	Stress Area, mm^2	Grade 1 Heavy Hex	Grade 2, 2HM, 6, 6F, 7M Heavy Hex	Grade 2H, 3, 4, 7, 16 Heavy Hex
M42	4.5	1120	1002.4	1159.2	1349.6
M48	5	1470	1315.7	1521.4	1771.4
M56	5.5	2030	1816.9	2101.0	2446.2
M64	6	2680	2398.6	2773.8	3229.4
M72	6	3460	3096.7	3581.1	4169.3

[a] ANSI B18.2.4.6.M in the size range over M36 provides dimensions only for heavy hex nuts. Refer to Section 8.3.1.

[b] Proof loads for nuts of larger dimensions or other thread series may be calculated by multiplying the thread stress area times the proof stress in the notes to Table 3 or Table 8. The proof load for jam nuts shall be 46 percent of the tabulated load.

Table S4.2—Proof Load for Large Heavy Hex Nuts[a] [Inch Series]

			Proof Load, lbf[b]		
Nominal Size, in.	Threads per inch	Stress Area, in.^{2}	Grade 1 Heavy Hex	Grade 2, 2HM, 6, 6F, 7M Heavy Hex	Grade 2H, 3, 4, 7, 16 Heavy Hex
1$^5/_8$	8	1.78	231400	267000	311500
1$^3/_4$	8	2.08	270400	312000	364000
1$^7/_8$	8	2.41	313300	361500	421800
2	8	2.77	360100	415500	484800
2$^1/_4$	8	3.56	462800	534000	623000
2$^1/_2$	8	4.44	577200	666000	777000
2$^3/_4$	8	5.43	705900	814500	950250

[a] ANSI B18.2.2 in the size range over 1$^1/_2$ in. provides dimensions only for heavy hex nuts. Refer to Section 8.3.1.

[b] Proof loads for nuts of larger dimensions or other thread series may be calculated by multiplying the thread stress area times the proof stress in the notes to Table 4 or Table 9. The proof load for jam nuts shall be 46 percent of the tabulated load.

S5. CONTROL OF PRODUCT BY HEAT NUMBER

S5.1. When control of nuts by actual heat analysis is required and this supplementary requirement is specified, the manufacturer shall identify the completed nuts in each shipment by the actual heat number. When this supplementary requirement is specified, a certificate including the results of the actual production tests of each test lot together with the heat chemical analysis shall be furnished by the manufacturer.

S6. GRAIN SIZE REQUIREMENTS FOR NON H GRADE AUSTENITIC STEELS USED ABOVE 540°C [1000°]

S6.1. For design metal temperatures above 540°C [1000°F], the material shall have a grain size of No. 7 or coarser as determined in accordance with ASTM E 112. The grain size, so determined, shall be reported on the Certificate of Test.

S7. COATING ON NUTS

S7.1. It is the purchaser's responsibility to specify in the purchase order all information required by the coating facility. Examples of such information may include but are not limited to the following:

S7.1.1. Reference to the appropriate coating specification and type, thickness, location, modification to dimensions, and hydrogen embrittlement relief.

Note S1—Modifications of thread dimensions may result in loss of load carrying capability.

S7.1.2. Reference to Specifications A 153/A 153M, B 633, B 695, B 696, B 766, F 1940, F 1941, F 2329 or other specifications.

S8. MARKING COATED NUTS

S8.1. Nuts coated with zinc shall have ZN marked after the grade symbol. Nuts coated with cadmium shall have CD marked after the grade symbol.

Note S2—As an example, the marking for zinc-coated 2H fasteners will now be 2HZN rather than 2H*.

S9. PROOF-LOAD TESTING

S9.1. Proof-load tests of nuts made to dimensions, thread pitch, and configurations other than those covered in Table 3 or Table 4 shall be made using loads agreed upon between the manufacturer and the purchaser.

APPENDIXES

(Nonmandatory Information)

X1. STRAIN HARDENING OF AUSTENITIC STEELS

X1.1. Strain hardening is the increase in strength and hardness that results from plastic deformation below the recrystallization temperature (cold work). This effect is produced in austenitic stainless steels by reducing oversized bars to the desired final size by cold drawing or other process. The degree of strain hardening achievable in any alloy is limited by its strain-hardening characteristics. In addition, the amount of strain hardening that can be produced is further limited by the variables of the process, such as the total amount of cross-section reduction, die, angle, and bar size. In large diameter bars, for example, plastic deformation will occur principally in the outer regions of the bar so that the increased strength and hardness due to strain hardening is achieved predominantly near the surface of the bar. That is, the smaller the bar, the greater the penetration of strain hardening. Thus, the mechanical properties of a given strain-hardened fastener are dependent not just on the alloy, but also on the size of bar from which it is machined.

X2. COATINGS AND APPLICATION LIMITS

X2.1. Use of coated fasteners at temperatures above approximately one-half the melting point (Celsius or Fahrenheit) of the coating is not recommended unless consideration is given to the potential for liquid or solid metal embrittlement, or both. The melting point of elemental zinc is approximately 415°C [780°F]. Therefore, application of zinc-coated fasteners should be limited to temperatures less than 210°C [390°F]. The melting point of cadmium is approximately 320°C [600°F]. Therefore, application of cadmium-coated fasteners should be limited to temperatures less than 160°C [300°F].

[2] An underline as a marking requirement for grades 2HM and 7M has been removed but is permitted.

Standard Specification for

Hardened Steel Washers

AASHTO Designation: M 293-10
ASTM Designation: F 436-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Hardened Steel Washers

AASHTO Designation: M 293-10
ASTM Designation: F 436-09

AASHTO M 293-10 is identical to ASTM F 436-09 except for the following provisions:

1. All references to the ASTM standards contained in ASTM F 436-09, listed in the following table, shall be replaced with the corresponding AASHTO standard.

Referenced Standards

ASTM	AASHTO
A 709/A 709M	M 270M/M 270
B 695	M 298
F 2329	M 232M/M 232

2. Add Sections 10.3 and 10.4 to Section 10 of ASTM F 436-09 as follows:

   10.3 If zinc-coated washers are supplied, hardness testing shall be performed after zinc coating. The zinc coating shall be removed prior to taking hardness measurements.

   10.4 If zinc-coated washers are supplied, the thickness of the zinc coating shall be measured.

3. Replace Section 14.1 of ASTM F 436-09 with the following:

   14.1 The party responsible for the washers shall be the organization that supplies the washers to the purchaser. The responsible party shall supply test reports, certified by the manufacturer, that indicate the washers were manufactured, sampled, tested, and inspected in accordance with this specification and all of its requirements.

Standard Specification for

Hardened Steel Washers [Metric]

AASHTO Designation: M 293M-06
ASTM Designation: F 436M-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Hardened Steel Washers [Metric]

AASHTO Designation: M 293M-06
ASTM Designation: F 436M-04

The AASHTO equivalent of this specification has been discontinued. Please refer to ASTM F 436M-04 for the information formerly contained in this standard.

Standard Specification for

Coatings of Zinc Mechanically Deposited on Iron and Steel

AASHTO Designation: M 298-10
ASTM Designation: B 695-04 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Coatings of Zinc Mechanically Deposited on Iron and Steel

AASHTO Designation: M 298-10
ASTM Designation: B 695-04 (2009)

AASHTO M 298-10 is identical to ASTM B 695-04 (2009) except that all references to the ASTM standards contained in ASTM B 695-04 (2009), listed in the following table, shall be replaced with the corresponding AASHTO standard:

Referenced Standards	
ASTM	AASHTO
A 153	M 232M/M 232
A 194	M 292M/M 292

Standard Specification for

Coatings of Cadmium Mechanically Deposited

AASHTO Designation: M 299-10
ASTM Designation: B 696-00 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Coatings of Cadmium Mechanically Deposited

AASHTO Designation: M 299-10
ASTM Designation: B 696-00 (2009)

AASHTO M 299-10 is identical to ASTM B 696-00 (2009).

Standard Specification for

Steel Anchor Bolts

AASHTO Designation: M 314-90 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Anchor Bolts

AASHTO Designation: M 314-90 (2008)

1. SCOPE

1.1. This specification covers externally threaded steel anchor bolts intended for anchoring structural supports to concrete foundations. Such structural supports include building columns; column supports for highway signs, street lighting, and traffic signals; steel bearing plates; and other similar applications.

1.2. The anchor bolts are subject to tensile property requirements and are available in three grades (yield strength levels). Special chemical restrictions apply when weldable steel is required.

1.3. Zinc coating (galvanizing) requirements are included for bolts requiring corrosion protection.

1.4. The recommended grade and style of nuts for each grade of anchor bolt are included.

1.5. This specification does not cover the requirements of mechanical expansion anchors or powder activated nails or studs for concrete.

1.6. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 160M/M 160, General Requirements for Steel Plates, Shapes, Sheet Piling, and Bars for Structural Use (Discontinued)
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- M 291, Carbon and Alloy Steel Nuts
- M 293, Hardened Steel Washers
- M 298, Coatings of Zinc Mechanically Deposited on Iron and Steel
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standard*:

- A 751, Standard Test Methods, Practices, and Terminology for Chemical Analysis of Steel Products

2.3. *ANSI Standards*:

- ANSI B1.1, Unified Screw Threads
- ANSI B18.2.2, Square and Hex Nuts

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *anchor bolt*—a steel bar or rod, one end of which is intended to be cast in concrete, while the opposite end is threaded and projects from the concrete, for anchoring other material to the concrete.

3.1.1.1. *discussion*—the end of the bar or rod cast in concrete may be either straight or provided with an anchor such as a hook or welded or bolted attachment to resist forces imposed on the bolt, as required.

3.1.2. *fabricator*—the manufacturer of the bolt.

3.1.3. *producer*—the manufacturer of the steel rods or bars.

3.1.4. *purchaser*—the purchaser of the finished anchor bolt or the purchaser's designated agent.

3.1.5. *supplier*—the agent who furnishes the finished bolts and nuts to the purchaser; may be the fabricator.

4. CLASSIFICATION

4.1. Anchor bolts covered by this specification are classified as follows:

4.1.1. *Grade*—The anchor bolts shall be furnished in one of three grades (Grade 36, Grade 55, or Grade 105) corresponding to the minimum yield strength of the steel (Section 8.1).

4.1.2. Weldable steel shall meet the requirements of Supplementary Requirement S1, when specifically ordered.

5. ORDERING INFORMATION

5.1. Orders for anchor bolts under this specification shall include the following information as necessary to adequately describe the desired product:

5.1.1. Quantity (number of pieces);

Note 1—If the purchaser intends to perform destructive tests on fabricated bolts, the fabricator should be advised so that an adequate number are produced, especially for sizes and grades not readily available from stock.

5.1.2. Name of material (steel anchor bolts);

5.1.3. AASHTO designation including year of issue;

5.1.4. Grade of steel (Section 4.1.1);

5.1.5. Weldable steel to meet Supplementary Requirement S1, when required;

5.1.6. *Dimensions*—diameter (based on nominal thread diameter), bolt length, thread length, length of hook (if hook is required);

5.1.7. Zinc coating or other protective coating (when required) (Section 6.4);

5.1.7.1. Specify the zinc-coating process, whether hot-dip, mechanically deposited, or no preference;

5.1.7.2. Specify length from exposed end to be coated, or entire length;

5.1.8. Number of nuts, either total number or number per bolt;

5.1.9. Number of washers, either total number or number per bolt, and dimensions if other than standard washers;

5.1.10. Specify if inspection at place of manufacture is required (Section 12.1);

5.1.11. Specify if certified test report is required (Section 14.1); and

5.1.12. Any special requirements.

6. MATERIALS AND MANUFACTURE

6.1. *Bolts*:

6.1.1. Steel for anchor bolts shall be made by the open hearth, basic oxygen, or electric furnace process.

6.1.2. Threads of anchor bolts may be rolled or cut, and shall conform to the requirements in Section 9.2.

6.1.3. Hooks on anchor bolts, when required, may be made by cold bending or hot bending, provided no cracks develop in the bend length. When hot bending is elected, at no time shall any portion of the anchor bolt reach a temperature in excess of 595ºC (1100ºF). The bending shall not significantly reduce the cross-sectional area of the bolt (Section 9.3).

6.2. *Nuts*:

6.2.1. Nuts shall conform to M 291 for inch-series threads for the grade and style indicated for each grade and size of anchor bolt, and whether plain or zinc coated, as shown in Table 1.

6.2.2. The requirements for the recommended grade and style of nut may be fulfilled by furnishing a nut of one of the grades or styles specified in M 291 that has equal or higher proof load stress.

Table 1—Nuts

Anchor Bolts			Nuts	
Grade	Size, mm (in.)	Condition	Grade	Style
36	6 to 38 ($^1/_4$ to $1^1/_2$)	Plain or Zinc Coated	A	Hex
36	Over 38 to 102 (over $1^1/_2$ to 4)	Plain or Zinc Coated	A	Heavy Hex
55	6 to 38 ($^1/_4$ to $1^1/_2$)	Plain	A	Hex
55	6 to 38 ($^1/_4$ to $1^1/_2$)	Zinc Coated	A	Heavy Hex
55	Over 38 to 102 (over $1^1/_2$ to 4)	Plain or Zinc Coated	A	Heavy Hex
105	6 to 38 ($^1/_4$ to $1^1/_2$)	Plain	D	Hex
105	6 to 38 ($^1/_4$ to $1^1/_2$)	Zinc Coated	DH	Heavy Hex
105	Over 38 to 76 (over $1^1/_2$ to 3)	Plain or Zinc Coated	DH	Heavy Hex

6.2.3. Nuts to be used on coated anchor bolts may be tapped oversize. The diametral amounts for oversize tapping indicated in M 291 as minimums are the maximum limits for oversize tapping for this anchor bolt specification.

Note 2—Steel to steel thread engagement is reduced between bolt and nut threads when the nut is tapped oversize. The purchaser should therefore be aware that nuts zinc coated and tapped oversize will have a lower tensile capacity than nuts that have not been tapped oversize. (See Table 3, M 291).

6.3. *Washers*:

6.3.1. Washers, when required, shall conform to M 293 unless otherwise specified in the order.

6.4. *Coatings for Enhanced Corrosion Resistance*:

6.4.1. *Zinc Coatings, Hot-Dip, and Mechanically Deposited*:

6.4.1.1. When zinc-coated anchor bolts, nuts, and washers are required, the purchaser shall specify the zinc coating process, for example hot-dip, mechanically deposited, or no preference.

6.4.1.2. When hot-dip is specified, the fasteners shall be zinc coated by the hot-dip process in accordance with the requirements of Class C of M 232M/M 232.

6.4.1.3. When mechanically deposited is specified, the fasteners shall be zinc coated by the mechanical deposition process in accordance with the requirements of Class 50 of M 298.

6.4.1.4. When no preference is specified, the supplier may furnish either a hot-dip zinc coating in accordance with M 232M/M 232, Class C, or a mechanically deposited zinc coating in accordance with M 298, Class 50.

6.4.2. Coatings other than hot-dip and mechanically deposited zinc coatings, when required, shall be specified in the order and the complete specification for the coating shall be included as a part of the order.

6.4.3. Threads for coated anchor bolts shall meet the requirements of Section 9.2 before the coating is applied.

7. CHEMICAL COMPOSITION

7.1. Steel shall conform to the following chemical limitations:

	Heat Analysis	Product Analysis
Phosphorus, max, percent	0.040	0.048
Sulfur, max, percent	0.050	0.058
Copper, min, percent when Cu is specified	0.20	0.18

7.2. The additional chemical limitations in Section S1.5 apply when bolts are ordered as weldable.

8. TENSILE PROPERTIES

8.1. Steel bars from which anchor bolts are made, as well as the finished anchor bolts, shall conform to the tensile requirements shown in Table 2.

Table 2—Tensile Properties

Grade	Yield Strength, Min, MPa (ksi)	Tensile Strength, Min, MPa (ksi)	Elongation,[a] Min, Percent		Reduction of Area, Min, Percent
			In 200 mm (8 in.)	In 50 mm (2 in.)	
36	248 (36)	400 to 552 (58 to 80)	20	23	40
55	379 (55)	517 to 655 (75 to 95)	18	21	30
105	724 (105)	862 to 1034 (125 to 150)	12	15	45[b]

[a] The requirement for elongation in 200 mm (8 in.) applies to bars and bolts tested full size. The requirement for elongation in 50 mm (2 in.) applies to test on machined specimens.

[b] Bolts over 50 to 63 mm (2 to 2$^1/_2$ in.), 22 percent min; over 63 to 75 mm (2$^1/_2$ to 3 in.), 20 percent min; over 76 to 102 mm (3 to 4 in.), 18 percent min.

9. DIMENSIONS

9.1. *Nominal Size*—The nominal anchor bolt diameter shall be the same as the nominal diameter of the threads.

9.2. *Thread Dimensions*—Threads on anchor bolts shall be Unified National Coarse Series, as specified in ANSI B1.1, and shall have Class 2A tolerances.

9.2.1. Bolts to be used with nuts that have been tapped oversize, in accordance with M 291, shall have Class 2A threads before coating. After coating, the maximum limit of pitch and major diameter may exceed the Class 2A limit by the following amount:

Diameter, mm (in.)	Oversize Limit, mm (in.)[a]
Up to 11.1 ($^7/_{16}$), incl	0.41 (0.016)
Over 11.1 to 25.4 ($^7/_{16}$ to 1), incl	0.53 (0.021)
Over 25.4 (1)	0.79 (0.031)

[a] These values are the same as the minimum oversize tapping required for zinc-coated nuts in M 291.

9.2.2. The gauging limits for bolts shall be verified during manufacture or use by assembly of a nut tapped as nearly as practical to the amount oversize shown above. In case of dispute, a calibrated thread ring gauge of that same size (Class × tolerance, gauge tolerance plus) shall be used.

Assembly of the gauge or the nut described above must be possible with hand effort following application of light machine oil to prevent galling and damage to the gauge. Length of threads shall be the specified length, plus 25 mm (1 in.), minus zero.

9.3. *Bar Diameter*:

9.3.1. When threads are rolled, the diameter of the bar before threading shall not be less than the minimum pitch diameter specified for Class 2A threads in ANSI B1.1.

9.3.2. When the threads are cut, the diameter of the bar before threading shall not be less than the specified diameter less the tolerance in M 160M/M 160 for round bars.

9.3.3. The bend section of bent bars shall have a cross-sectional area not less than 90 percent of the area of straight portions of the bar. The area in the bend shall be calculated by the formula:

$$A_b = 0.25\,\pi D \cdot d \qquad (1)$$

where:

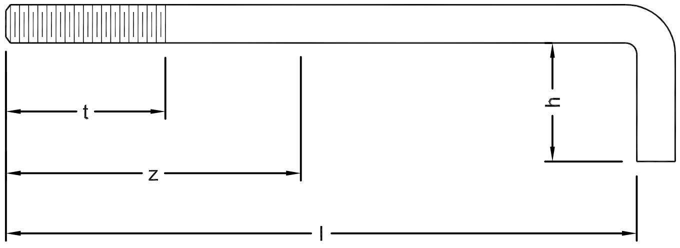
A_b = cross-sectional area in the bend;

d = minor (or minimum) diameter at any point, generally in the plane of the bend; and

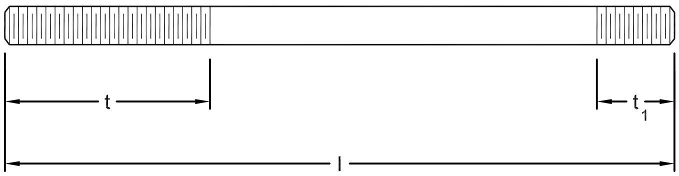
D = major diameter, at the same cross section as and at 90 degrees to the minor diameter.

9.4. *Bolt Dimensions*:

9.4.1. The overall length of straight anchor bolts, or length to the inside of the hook, shall be the specified length plus or minus 13 mm ($^1/_2$ in.) for bolt lengths of 600 mm (24 in.) or less, and plus or minus 25 mm (1 in.) for longer bolts (Figure 1).



Anchor Bolt with Hook



Straight Anchor Bolt

Note: h = length of hook;
l = length of bolt;
t = length of threads (exposed end);
t_1 = length of threads (encased end), when required;
z = length of zinc coating, min, when partial zinc coating is required.

Figure 1—Anchor Bolt Dimensions

9.4.2. The length of hooks shall be the specified length, plus or minus 10 percent of the specified hook length, or ±13 mm ($^1/_2$ in.), whichever is greater (Figure 1).

9.4.3. The bend angle of hooks shall be the specified angle plus or minus five degrees.

9.5. *Coated Length*:

9.5.1. When only the exposed end of the anchor bolt is required to be zinc coated, the length of zinc coating shall be at least equal to the length specified in the order. There is no limit on extra length of zinc coating.

10. NUMBER OF TESTS AND RETESTS

10.1. The steel producer shall conduct tests for tensile properties and chemical analysis and shall certify the results to the fabricator of the anchor bolts. The fabricator shall be responsible for tests for zinc coating and dimensional requirements.

10.2. The purchaser shall have the right to perform any of the inspections and tests set forth in this specification. Tests may be made on either the bar stock or on the completed anchor bolts.

10.3. One test for chemical composition shall be made from each heat. One test for tensile properties shall be made for each diameter of each heat, and if the bars are heat-treated, for each furnace lot. The number of tests for zinc coating shall be as specified in M 232M/M 232.

10.3.1. Where identity to a specific heat number (and furnace lot number for heat-treated bars) has not been maintained, the number of tests shall be based on the quantity of bolts of a given description, as shown in Table 3.

Table 3—Number of Tests

	Number of Specimens	
Number of Bolts in Order of Each Description	25.4-mm (1-in.) Diameter and Smaller	Over 25.4-mm (1-in.) Diameter
100 and fewer	1	1
101 to 250	1	2
251 to 500	2	3
501 to 1000	3	5
1001 and more (additional per 1000 bolts)	1	2

10.4. If a sample fails to meet any tensile property requirement and the results are within 14 MPa (2 ksi) of the required tensile strength, within 7 MPa (1 ksi) of the required yield strength, or within two percentage points of the required elongation, a retest shall be permitted on two randomly selected specimens for each original tensile specimen failure from the lot. If all results of these retest specimens meet the specified requirements, the lot shall be accepted.

10.4.1. If any test specimen shows defective machining, it may be discarded and another specimen substituted.

10.5. If a sample fails to meet any requirement, other than a tensile property requirement, and the results are within 10 percent of the limit, a retest will be permitted on two randomly selected specimens for each original nonconforming specimen from the lot. If the results of tests on these retest specimens, for the requirement that was originally nonconforming, meet the specified requirement, the lot shall be accepted.

10.6. If a sample is determined to have threads not conforming to the requirements, where the determination was made using other than standard thread gauges, and the fabricator contests the rejection of the anchor bolts or nuts, the final determination of acceptability shall be as follows. The fabricator shall have full size tension tests made on the anchor bolt and nut assembly in the presence of the purchaser's representative. The assembly must develop a tensile load at least equal to the stress area of the bolt multiplied by the minimum tensile strength for the grade of anchor bolt specified. The stress area is calculated from the equation:

$$A_s = 0.7854\,[D-(0.9743/n)]^2 \qquad (2)$$

where:

A_s = stress area, mm^2 (in.^{2});

D = nominal diameter of bolt, mm (in.); and

n = threads per mm (in.).

11. TEST METHODS

11.1. Chemical analyses shall be performed in accordance with ASTM A 751.

11.2. Tensile property tests shall be conducted according to T 244, with the following exceptions:

11.2.1. Tension test specimens shall be the full section of the bar as rolled, except that bars greater than 38-mm ($1^1/_2$-in.) diameter in Grade 36 or Grade 55, or greater than 32-mm ($1^1/_4$-in.) diameter in Grade 105, may be machined to provide standard 12.5-mm (0.500-in.) specimens as described in Table 5 of T 244 when equipment of sufficient capacity for full-size testing is not available. In the event that bolts are tested by both full size and by machined specimen methods, the full size test shall govern if a controversy between the two methods exists.

11.3. Determine the quantity of zinc coating by the methods of M 232M/M 232.

12. INSPECTION

12.1. If the inspection described in Section 12.2 is required by the purchaser, it shall be specified in the inquiry and contract or order.

12.2. The inspector representing the purchaser shall have free entry to all parts of the fabricator's works that concern the manufacture of the material ordered. The fabricator shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests and inspections required by the specification that are requested by the purchaser's representative shall be made, if possible, before shipment, and shall be conducted so as not to interfere unnecessarily with the operation of the works.

13. REJECTION AND REHEARING

13.1. Material that fails to conform to the requirements of this specification may be rejected. Rejection should be reported to the fabricator promptly and in writing. In case of dissatisfaction with the results of the test, the fabricator may make claim for a rehearing.

14. CERTIFICATION AND REPORTS OF TESTING

14.1. When specified by the purchaser, a certification that the material was manufactured and tested in accordance with this specification shall be furnished and shall include a report of the tensile test results and chemical analysis (including carbon equivalent for weldable bolts). The report shall include the name of the steel producer, AASHTO designation number, grade, heat number, size, and authorized signature.

15. PRODUCT MARKING

15.1. Bars from which the anchor bolts are made shall be identified as specified in M 160M/M 160.

15.1.1. The end of each fabricated anchor bolt intended to project from the concrete shall be painted to identify the grade as follows:

Grade	Paint Color
36	Blue
55	Yellow
105	Red

SUPPLEMENTARY REQUIREMENT

The following supplementary requirement shall apply only when specified in the purchase order or contract:

S1. BOLTS SUITABLE FOR WELDING

S1.1. The material described in this section is intended for welding. This supplemental section, by chemical composition restrictions and by a carbon equivalent formula, provides assurance of weldability.

S1.2. Welding technique is of fundamental importance when bolts produced to this supplementary section are welded. It is assumed that suitable welding procedures for the steel being welded and the intended service will be selected.

S1.3. The requirements of this supplementary requirement supersede conflicting provisions of the general specification.

S1.4. Because of the embrittling effects of welding temperatures on cold-forged steel, this supplemental section is limited to hot-forged bolts, or, if not forged, to the thread bars, studs, or bolts produced from hot-rolled bars without forging. Cold-forged bolts or cold-drawn threaded bars are suitable if they are given a thermal treatment by heating to a temperature of not less than 815ºC [1500ºF] and air-cooled.

S1.5. *Chemical Composition*:

S1.5.1 Steel shall conform to the following limitations:

	Heat Analysis	Product Analysis
Carbon, max, percent	0.30	0.33
Manganese, max, percent	1.35	1.41
Phosphorus, max, percent	0.040	0.048
Sulfur, max, percent	0.050	0.058
Silicon, max, percent	0.50	0.55

S1.5.2 *Carbon Equivalent*—In addition to the requirements in Section S1.5.1, the analysis shall be such as to provide a carbon equivalent (CE) meeting the following requirements:

S1.5.2.1. For alloy or low-alloy steel, the carbon equivalent shall not exceed 0.45 percent when calculated as follows:

$$\mathrm{CE} = \%\mathrm{C} + \frac{\%\mathrm{Mn}}{6} + \frac{\%\mathrm{Cu}}{40} + \frac{\%\mathrm{Ni}}{20} + \frac{\%\mathrm{Cr}}{10} - \frac{\%\mathrm{Mo}}{50} - \frac{\%\mathrm{V}}{10} \qquad \textit{(S1.1)}$$

S1.5.2.2. For carbon steel, the carbon equivalent shall not exceed 0.40 percent when calculated as follows:

$$\mathrm{CE} = \%\mathrm{C} + \frac{\%\mathrm{Mn}}{4} \qquad \textit{(S1.2)}$$

S1.6. *Marking*—Each fabricated anchor bolt conforming to this Supplementary Requirement S1 shall be designated by a white paint mark on the side of the bar near the end to be encased in concrete.

Standard Practice for

Qualification of Deformed and Plain Reinforcing Steel Bar, Welded Wire, and Wire Producing Mills

AASHTO Designation: R 53-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Qualification of Deformed and Plain Reinforcing Steel Bar, Welded Wire, and Wire Producing Mills

AASHTO Designation: R 53-10[1]

1. SCOPE

1.1. This recommended practice shall apply to all producing mills that supply deformed and plain steel reinforcement bars, welded wire, or wire for use on State Transportation Agency projects.

1.2. The initial qualification and all subsequent qualifications of the producing mill's quality system and compliance testing will be in accordance with the procedure outlined herein.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 31M/M 31, Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement
- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement
- M 55M/M 55, Steel Welded Wire Reinforcement, Plain, for Concrete
- M 221M/M 221, Steel Welded Wire Reinforcement, Deformed, for Concrete
- M 225M/M 225, Steel Wire, Deformed, for Concrete Reinforcement
- M 227M/M 227, Steel Bars, Carbon, Merchant Quality, Mechanical Properties
- M 322M/M 322, Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement
- R 18, Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 82/A 82M, Standard Specification for Steel Wire, Plain, for Concrete Reinforcement
- A 185/A 185M, Standard Specification for Steel Welded Wire Reinforcement, Plain, for Concrete
- A 496/A 496M, Standard Specification for Steel Wire, Deformed, for Concrete Reinforcement
- A 497/A 497M, Standard Specification for Steel Welded Wire Reinforcement, Deformed, for Concrete
- A 615, Standard Specification for Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement
- A 706/A 706M, Standard Specification for Low-Alloy Steel Deformed and Plain Bars for Concrete Reinforcement

- A 880-95, Standard Practice for Criteria for Use in Evaluation of Testing Laboratories and Organizations for Examination and Inspection of Steel, Stainless Steel, and Related Alloys
- A 996/A 996M, Standard Specification for Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement

3. TERMINOLOGY

3.1. *compliance testing*—testing performed in accordance with referenced AASHTO and ASTM standards and/or test methods.

3.2. *documented quality system*—the producing mill shall maintain documentation of their quality system by use of a Quality Manual (QM).

3.3. *nonconformance*—not meeting the requirements of this specification.

3.4. *producing mills (deformed and plain reinforcing steel bar, welded wire, or wire)*—locations where steel billets, rail steel, and axle steel are heated and rolled into finished steel bars or rods, or where welded wire, or wire products are produced.

3.5. *test report*—information (test values, chemical analysis, etc.) as required by the referenced specification and contained in a report form generated by the producing mill. Origin of materials (steel billets, rail-steel, axle-steel, and rod) used to roll the bars or wire is also shown on this report.

3.6. *qualification agency*—The entity that performs this qualification procedure at the producing mill. AASHTO's National Transportation Product Evaluation Program's (NTPEP) Project Panel on Reinforcing Steel is responsible for oversight of the program and securing the services of the qualification agency.

4. PURPOSE

4.1. This document establishes a uniform procedure for the qualification of producing mills that supply deformed and plain steel reinforcement bars, welded wire, or wire for use on State Transportation Agency projects.

4.2. This document describes the procedures and conditions for producing mill qualification.

5. QUALIFICATION PROCEDURE

5.1. *General*—Qualification shall be based on satisfactory compliance to an audit of:

5.1.1. The producing mill's Documented Quality System, and

5.1.2. Compliance testing.

Note 1—Subsequent qualifications of producing mills that have demonstrated compliance to a recognized international/national quality program may have the Documented Quality System audit waived. In such cases, compliance testing will be the focus of qualification.

5.2. *Application*:

5.2.1. The producing mill shall submit a request for attaining mill qualification to the Qualification Agency.

5.2.2. Upon receipt of the request, the qualifying agency shall furnish the producing mill a copy of the application form. The completed application form shall be submitted to the Qualification Agency along with a copy of the mill's QM, meeting the requirements of R 18, Section 6. Frequency of calibration shall be on an annual basis. Other formats for the QM may be acceptable after review and acceptance by the Qualification Agency.

5.2.3. After receipt of the application form, the Qualification Agency shall arrange to perform an on-site audit of the applying producing mill's facility.

5.3. *Quality System Audit*:

5.3.1. The Qualification Agency shall use an approved standardized audit checklist and verify compliance with the procedures outlined in the producing mill's Documented Quality System.

5.4. *Compliance Testing*:

5.4.1. Compliance testing will be performed on product manufactured by the producing mill using the producing mill's testing equipment. Calibration of testing equipment shall be current at the time of the audit. The Qualification Agency will designate samples. All testing will be witnessed by the representative(s) of the Qualification Agency. As an option, compliance testing may also be performed on State Agency or Qualification Agency contracted equipment.

5.5. *Sampling and Testing*:

5.5.1. A minimum of ten heats/lot over the range of production sizes and grades will be sampled from material available from stock.

5.5.2. Three samples from different pieces within the same heat/lot will be obtained. Each sample will require enough length to provide for one tensile test, one bend test, one weld shear (for welded wire), and for two retests. Supply enough material to evaluate members in both the primary and secondary directions.

5.5.3. The producing mill shall provide the necessary resources to obtain and test the samples in accordance with the referenced specification.

5.5.4. Test results will be recorded on the worksheet supplied by the Quality Reviewer.

5.6. *Evaluation of Test Results*:

5.6.1. Compliance test results will be compared to the requirements of referenced specification(s). All test results of all samples shall meet the requirements of the applicable specification(s).

5.6.2. In the event that the test results from an individual sample do not meet the requirements of the referenced specification, retesting of material from the nonconforming heat in addition to two additional heats of the same size and grade will be performed during the compliance testing period. All of the retested samples shall meet the requirements of the applicable specification(s).

5.6.3. In the event that the test results from an individual sample do not meet the requirements of the referenced specification, it is the responsibility of the producing mill to submit to the NTPEP Project Panel on Reinforcing Steel objective corrective actions that satisfy the basic cause analysis of the nonconformance and implemented corrective action upon requesting requalification.

5.7. *Audit Results*—Producing mills, having been qualified in accordance with this procedure, will have their audit results posted for review and approval by each State Transportation Agency. The review and approval will be in accordance with the NTPEP Project Panel on Reinforcing Steel's workplan.

---

[1] This practice is intended to be used for the national qualification program for reinforcing steel.

Standard Specification for

Sodium Chloride

AASHTO Designation: M 143-03 (2007)
ASTM Designation: D 632-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Sodium Chloride

AASHTO Designation: M 143-03 (2007)
ASTM Designation: D 632-01

AASHTO M 143-03 (2007) is identical to ASTM D 632-01 except that all references to ASTM C 136 contained in AASHTO M 143-03 (2007) shall be replaced with AASHTO T 27.

Standard Specification for

Calcium Chloride

AASHTO Designation: M 144-07
ASTM Designation: D 98-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Calcium Chloride

AASHTO Designation: M 144-07
ASTM Designation: D 98-05

AASHTO M 144-07 is identical to ASTM D 98-05 except for the following provisions:

1. All references to ASTM D 345 contained in ASTM D 98-05 shall be replaced with AASHTO T 143.
2. AASHTO M 144-07 does not reference MIL-STD-105 (Section 7.1, ASTM D 98-05), and does not include Federal Government packaging requirements (Sections 10.3 through 10.6, ASTM D 98-05).

Standard Specification for

Epoxy Protective Coatings

AASHTO Designation: M 200-73 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Epoxy Protective Coatings

AASHTO Designation: M 200-73 (2007)

1. SCOPE

1.1. This specification covers two-component epoxy resin adhesive for use as protective and or skid resistant overlays on portland cement concrete surfaces and bridge decks. Two classes of epoxy resin adhesive are provided.

1.2. *Classes*:

1.2.1. Class I, bitumen modified coating is for use in protective coatings for skid resistant and/or protective overlays for cement concrete bridge decks and surfaces. It includes a recommended practice for the preparation of the concrete surface and for the application of the epoxy prime coat when required, epoxy top coat, glass fabric when required, and cover material. Each system may be used as a wearing course or as a protective coating beneath an asphalt concrete pavement.

1.2.2. Class II, oil modified coating is for use, with suitable aggregate, in mortar overlays 9.5 to 12.7 mm ($^3/_8$ to $^1/_2$ in.) thick as skid resistant and/or protective overlays for cement concrete bridge decks and surfaces. It is also suitable for application in a thin layer under asphaltic concrete as described for Class I material. It is not generally recommended as a wearing course in thin layers.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 55, Water in Petroleum Products and Bituminous Materials by Distillation

2.2. *ASTM Standards*:

- D 154, Standard Guide for Testing Varnishes
- D 412, Standard Test Methods for Vulcanized Rubber and Thermoplastic Elastomers—Tension
- D 482, Standard Test Method for Ash from Petroleum Products
- D 570, Standard Test Method for Water Absorption of Plastics
- D 638, Standard Test Method for Tensile Properties of Plastics
- D 664, Standard Test Method for Acid Number of Petroleum Products by Potentiometric Titration
- D 1078, Standard Test Method for Distillation Range of Volatile Organic Liquids

- D 1084, Standard Test Methods for Viscosity of Adhesives
- D 1652, Standard Test Method for Epoxy Content of Epoxy Resins
- D 1668, Standard Specification for Glass Fabrics (Woven and Treated) for Roofing and Waterproofing
- D 2240, Standard Test Method for Rubber Property—Durometer Hardness

2.3. *Other Standard*:

- FSS HH-C-466, Cloth, Glass, Coated (For Membrane Waterproofing and Built-Up Roofing) Also refer to ASTM D 1668 as noted above.

CLASS I—BITUMEN-MODIFIED EPOXY RESIN MIXTURE

3. MATERIALS

3.1. Epoxy Resin Mixture shall be furnished in two components for combining in equal volumes immediately before use in accordance with the written instructions of the manufacturer.

3.2. *Top Coat*:

3.2.1. *Component A (Modified-Epoxy Resin)*—Top coat shall consist of a condensation product of epichlorohydrin with bisphenol A, shall contain no reactive diluents, no insolubles, and shall conform to the requirements of Table 1.

Table 1—Requirements for Component A

Property	Top Coat
Epoxide equivalent[a]	225 to 275
Viscosity, Pa·s (poises), 25˚C (77˚F) (Spindle No. 3, 20 r/min)	0.8 to 1.6 (8 to 16)
Ash, mass, percent, max	0.2
Volatile loss (to 177˚C (350˚F)) cm^3, max	3.00
Specific gravity, 25/25˚C (77/77˚F)	1.10 to 1.25

[a] Grams of material containing one gram equivalent of epoxide.

Note 1—When the slope of the concrete surface exceeds about 3 percent, a thixotropic agent approved by the engineer may be added to Component A by the formulator to either or both coats. If a thixotropic agent is used, the requirement for ash, viscosity, and epoxide equivalent will not apply.

3.2.2. *Component B (Modified-Amine Hardening Agent)*—Top coat shall be the hardening agent for Component A Top Coat and shall be composed of a bitumen which has been especially treated with a modified aliphatic polyamine. It shall contain no contaminants, reactive diluents, or insolubles and shall conform to the requirements of Table 2.

Table 2—Requirements for Component B

Property	Top Coat
Viscosity, Pa·s (poises), 25˚C (77˚F) (Spindle No. 2, 20 r/min)	0.2 to 0.8 (2 to 8)
Ash, mass, percent, max	0.5
Volatile loss (to 177˚C (350˚F)) cm^3, max	3.00
Specific gravity, 25/25˚C (77/77˚F)	1.10 to 1.25
Water, mass, percent, max	2.0
Alkalinity, equivalent/100 g	0.19 to 0.27

3.3. *Prime Coat:*

3.3.1. When a prime coat is ordered, the prime coat shall consist of a mixture of Component A and Component B to which has been added toluene or 2-nitro propane not in excess of 10 percent of the total volume.

3.3.2. Component A Primer shall be composed of Component A Top Coat to which has been added toluene to produce a mixture of flowing consistency. In areas subject to air pollution control regulations forbidding the use of toluene, 2-nitro propane shall be used.

3.3.3. Component B Primer shall be composed of Component B Top Coat to which has been added toluene to produce a mixture of flowing consistency while maintaining a 1:1 ratio with Component A Primer. In areas subject to air pollution control regulations forbidding the use of toluene, 2-nitro propane shall be used.

3.4. *Physical Requirements of Cured Epoxy Resin System*—When Component A Top Coat and Component B Top Coat are combined on an equal basis the mixture shall conform to the requirements of Table 3.

Table 3—Physical Properties of the Cured System

Property	Top Coat
Water absorption, mass, percent, max	0.3
Tensile strength, min Pa (psi)	2758 (400)
Elongation, percent, min	35
Gel time, minutes	25–50
Shore D hardness, 25˚C (77˚F)	35–65
Bond strength, direct tension, min, Pa (psi)	621 (90)
Flexural creep, min:	
24 hours, in. (mm)	0.010 (0.2540)
7 days, in. (mm)	0.015 (0.3810)

3.5. *Thixotropic Agent (Mineral Filler)*:

3.5.1. When mineral fillers are specified or permitted, they shall be inert and nonsettling or readily dispersible. The filler shall have a fineness such that at least 99 percent shall pass the 0.045-mm (No. 325) sieve and 100 percent shall pass the 0.150-mm (No. 100) sieve.

3.6. *Aggregates*:

3.6.1. *Surface Application*—The aggregate for surface application shall be nonfriable, nonpolishing, clean, and free from surface moisture. It shall be durable and sound and shall have a proven record of performance in applications of this type. Known suitable aggregates include aluminum oxide, emery, silica sand, garnet, and blast-furnace slag. The grading of the aggregate shall conform to the requirements given in Table 4.

Table 4—Aggregate Gradation

Sieve Designation		Mass, Percent, Passing	
mm	No.	Grade A	Grade B
4.75	4	—	100
2.36	8	100	0–5
0.600	30	0–3	—
0.075	200	0–1	0–1

3.6.2. Aggregate, which will be exposed to traffic, shall have a minimum Mohs' scale of hardness of 7.

3.7. *Waterproofing Fabric*:

3.7.1. Waterproofing fabric shall be woven glass fabric conforming to FSS HH-C-466 or to ASTM D 1668, except that the requirement for minimum mass of coating shall be waived.

Note 2—Grade A Aggregate is recommended when the Coal-Tar Coating is to be used as a Wearing Course. Grade B aggregate is recommended when the Coal-Tar Epoxy Coating is to be followed by an asphaltic concrete Wearing Course.

4. PACKAGING

4.1. *Packaging*—The two components of the epoxy resin system furnished under this specification shall be supplied in separate containers that are nonreactive with the materials contained therein.

4.2. *Marking*—Each container of the two components shall be labeled with the name of the mixture, the component type, the name of the manufacturer, the lot or batch number, the date of packaging, and the quantity contained therein. The proper component type shall also be placed on each lid and shall show whether it is formulated for use as a primer or as a top coat. Each label shall include essentially the following text for *Directions for Use*:

DIRECTIONS FOR USE

The contents of the separate packages containing Components A and B must be thoroughly stirred before use to redisperse any mineral filler used. ***Do not use the same paddle to stir Component A as is used to stir Component B***. To mix the adhesive, blend one part by volume of Component A with one part by volume of Component B and stir thoroughly. Do not mix more material than can be used before it hardens.

Equipment and tools must be cleaned with toluene before the adhesive has set. Components A and B should be stored at a temperature between 24 and 27ºC (75 and 80ºF) for several hours before use.

Warning—This material will cause severe dermatitis if proper precautions are not followed. ***Do not let it come in contact with the skin or eyes***. Use gloves and protective creams on the hands. If contact with the skin occurs, wash thoroughly with soap and water. If any gets in the eyes, flush for 10 minutes with water and secure immediate medical attention. ***Do not attempt to remove this material from the skin with solvents***.

5. CERTIFICATION

5.1. At the request of the purchaser, the manufacturer of the epoxy resin system shall certify that Components A and B meet the requirements of this specification. Such certification shall consist of either a copy of the manufacturer's test report or a statement by the manufacturer, accompanied by a copy of the test results, that the Components A and B have been sampled and tested. Such certification shall indicate the date of testing and shall be signed by an authorized agent of the formulator or manufacturer.

5.2. At the request of the purchaser, the formulator shall certify that the mineral filler used in either component meets the following:

5.2.1. The filler shall be inert and nonsettling or readily dispersible. It shall have a fineness such that at least 99 percent shall pass the 0.045-mm (No. 325) sieve and 100 percent shall pass the 0.150-mm (No. 100) sieve.

6. METHOD OF TESTING

6.1. Tests shall be conducted in accordance with the following methods:

6.1.1. *Epoxide Equivalent*—ASTM D 1652.

6.1.2. *Viscosity*—ASTM D 1084, Viscosity of Adhesives, Method B. Using Spindle No. 3 at 20 r/min for Component A and Spindle No. 2 at 20 r/min for Component B, except that the temperature shall be 25.0 ± 0.5ºC (77 ± 1ºF).

6.1.3. *Ash*—ASTM D 482.

6.1.4. *Volatile Loss*—ASTM D 1078, except that a 10 mL graduated cylinder with 0.1 mL subdivisions shall be used as a receiver and the distillation shall be discontinued when the temperature reaches 177ºC (350ºF). Record the volume of the distillate in the receiver as volatile loss.

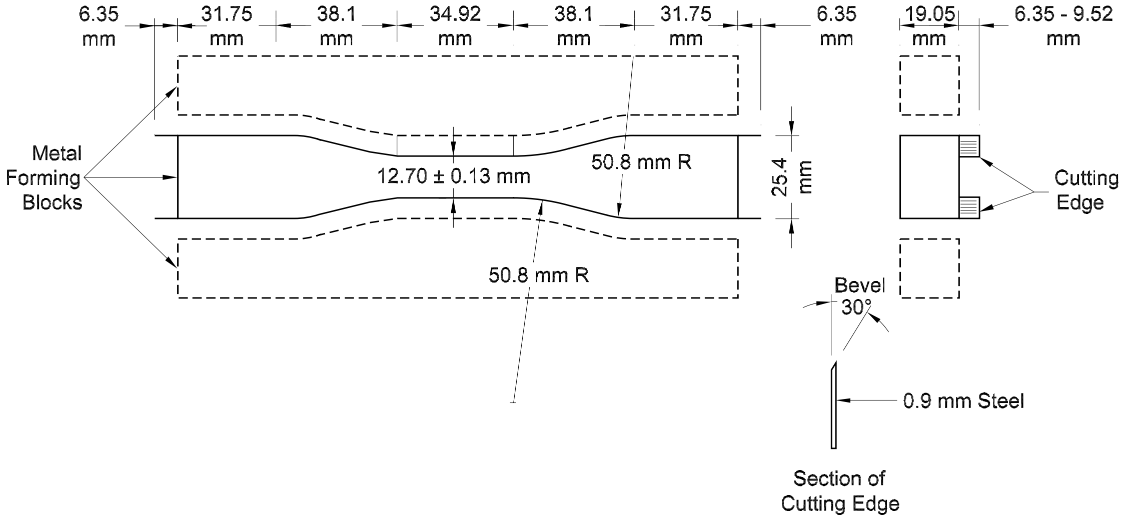
6.1.5. *Specific Gravity*—ASTM D 154.

6.1.6. *Water Content*—AASHTO T 55.

6.1.7. *Alkalinity*—ASTM D 664, titrated to the first end-point, which will occur at a pH of about 6.3.

6.1.8. *Water Absorption*—ASTM D 570, 0.5-hour boiling water immersion after seven-day cure at 25ºC (77ºF).

6.1.9. *Tensile Strength and Elongation*—ASTM D 638. The speed of testing shall be 5.1 mm (0.20 in.) per minute ±25 percent (Speed B) using specimens cut from a laboratory cast sheet 3.2 mm ($^1/_8$ in.) thick. The cast shall be allowed to harden for 18 hours at 25ºC (77ºF) plus 5 hours at 70ºC (158ºF) and allowed to return to room temperature before cutting and testing. The test specimens shall be cut using Die C of ASTM D 412, having a gauge length of 25.4 mm (1 in.) and a width of 12.7 mm (0.500 in.), or by use of a die similar to that shown in Figure 1.



Metric Equivalents

mm	in.
50.8	2
38.1	1 1/2
34.92	1 3/8
31.75	1 1/4
25.40	1
19.05	3/4
12.7	1/2
9.52	3/8
6.35	1/4
0.13	5/1000
0.9	20 gauge

Note: Cutting edge is of 0.9 mm spring steel and is held between three metal blocks machined to conform to the above dimensions.

Figure 1—Cutting Die for Tensile Test

6.1.10. *Gel Time*—The following procedure shall be used to determine gel time. Measure 30 mL (1 oz) of Component A and 30 mL (1 oz) of Component B each at 25ºC (77ºF) into an unwaxed paper cup and record the time. Immediately, the two components shall be mixed by stirring for three minutes with a wooden tongue depressor, periodically scraping the walls and the bottom of the cup. The mixture shall be poured into a 240 mL (8 oz) unwaxed paper cup placed on a wooden bench top. Starting 20 minutes from the time recorded above the mixture shall be probed every two minutes with a small stick, until a small ball forms in the center of the container. The total time, including mixing, required for the ball to form shall be recorded as gel time. The test shall be performed in a room or enclosed area maintained at 25 ± 2ºC (77 ± 3.6ºF) and 50 ± 5 percent relative humidity.

6.1.11. *Shore Hardness*—ASTM D 2240, except that the specimen for testing shall be prepared and cured using the following procedure. Measure 30 mL (1 oz) of Component A and 30 mL (1 oz) of Component B at 25 ± 2ºC (77 ± 3.6ºF) into an unwaxed paper cup. The two components shall be mixed by stirring for 3 minutes with a wooden tongue depressor, periodically scraping the walls and bottom of the cup. The mixture shall be poured into an unwaxed paper container with a diameter not less than 60 mm (2.36 in.) placed on a wooden bench top. The mixture shall be allowed to harden without being disturbed, 24 hours in a room or enclosed area maintained at 25 ± 2ºC (77 ± 3.6ºF) and 50 ± 5 percent relative humidity before testing.

6.1.12. *Bond Strength*—The cured epoxy mixture shall develop a bond strength that is equal to or greater than the cohesive strength of the concrete when tested for adhesion as specified in the report of A.C.I. Committee 403 title No. 59-43. This test comprises bonding a standard 51-mm (2-in.) pipe cap to the concrete surface and measuring the tensile force required to bring about separation.

6.1.13. *Low Temperature Creep*—California Test Method 419A.

7. RECOMMENDED CONSTRUCTION PRACTICE

7.1. *Preparation of Surfaces*—Surfaces of concrete to be treated shall be sandblasted before applying tar-epoxy mixture.

7.1.1. When the mixture is to be applied to old surfaces having heavy local deposits of oil, grease, and other adherent foreign materials, which will interfere with proper cleaning, these deposits shall be completely removed using any suitable means. Possible methods include solvents, such as trichloroethylene or xylene, heavy-duty detergents and/or mechanical means such as scraping. Where the concrete surface has deteriorated, it shall be cleaned down to sound material and patched, if necessary.

7.1.2. New concrete shall be aged at least 14 days before any coating is applied.

7.1.3. Both old and new concrete shall then be cleaned by sandblasting. Sandblasting shall be accomplished in such a manner as to insure the removal of all laitance or any other substance that would prevent good adhesion of the epoxy. Suitable traps shall be installed in sandblasting equipment to prevent water or oil from being deposited on the bridge surface. After sandblasting, the surface shall be swept, vacuumed, hosed, or blown free of all dust and grit. The surface of the concrete shall be dry when the epoxy coating is applied.

7.1.4. Unless specifically permitted, bitumen modified epoxy mixture shall be applied only when the air temperature is above 10ºC (50ºF).

7.2. *Preparation of Mixtures*—Equal parts, by volume, of the two components shall be mixed mechanically batchwise, or continuously in automatic paving equipment which provides continuous metering, mixing, and application at a controlled rate. Caution shall be exercised to make certain that Component A Primer, is mixed with Component B Primer, and that Component A Top Coat, is mixed with Component B Top Coat.

7.2.1. If the components are to be mixed batchwise, mixing shall be performed with a propeller-type stirrer, or other power agitator attached to a 12.7 mm ($^1/_2$ in.) heavy-duty drill. Care must be exercised to incorporate thoroughly mixed material at the sides and bottom of the mixing container. Mixing time shall be not less than 5 minutes at 15 to 27ºC (60 to 80ºF) or 3 minutes at 27 to 38ºC (80 to 100ºF).

7.2.2. The mixed material will set quickly if allowed to remain in a large mass such as in the mixing container. The pot life is approximately as follows:

Air Temperature	Pot Life (Measured from Beginning of Mixing)
15°C–21°C (60°F–70°F)	18 min
21°C–27°C (70°F–80°F)	12 min
27°C–32°C (80°F–90°F)	10 min
32°C–38°C (90°F–100°F)	8 min

7.3. *Application of Primer*—The resinous material for the prime coat shall be distributed evenly over the entire area to be surfaced at a minimum thickness of 0.38 mm (15 mils) 0.4 kg/m^2 (0.75 lb/yd^2 approximately). The prime coat shall be applied uniformly to all areas to be subsequently given a second coat and so that no gray areas remain. Care shall be taken to treat the curbs on each side to a height of at least 50 mm (2 in.). The prime coat shall be spread with rollers or approved mechanical equipment touched up by hand.

7.4. *Application of Top Coat*—After the prime coat has set sufficiently to walk on or to operate equipment over (and in any case within 24 hours), the top coat mixture shall be distributed evenly over the entire area to be surfaced at the rate specified in Section 7.4.1. If binder is mixed batchwise, it shall be leveled with lutes, brooms, paint rollers, or screeds.

7.4.1. The exact rate of application of the top coat mixture shall be determined by the engineer. As a check on the rate of application, measured volumes of the mixture shall be applied to measured areas of the surface. The top coat shall be applied at a rate such that the total application for the two coats will give a thickness of 1.5 mm (60 mil) (0.66 m^2/L (27 sq ft/gal)) or 1.6 kg/m^2 (3 lb/yd^2) approximately. One liter has a mass of approximately 1.15 kg (1 gallon has a mass of approximately 9.6 pounds).

7.5. *Application of Fabric*—When fabric is to be incorporated to form an impervious membrane beneath an asphaltic wearing course, the fabric shall be immediately embedded in the epoxy top coat. To provide a watertight seal at the curb and deck joint, it is recommended that a glass fabric tape approximately 200 mm (8 in.) wide be applied to the deck and 50 mm (2 in.) of the curb before applying the full width of fabric to the flat surface of the deck. All fabric shall be lapped at least 50 mm (2 in.) transversely and longitudinally.

7.6. *Application of Aggregate*—While the epoxy mixture is still liquid, the surfacing aggregate shall be dropped into the epoxy in excess of the rate necessary to cover the surface. The aggregate must be sprinkled or dropped vertically in such a manner that the level of the epoxy mixture is not disturbed. The aggregate shall be applied within 5 minutes after the application of the epoxy, except at temperatures below 21ºC (70ºF) when a maximum of 10 minutes is allowable.

7.7. After the aggregate is spread, all vehicular and foot traffic shall be prohibited in the area until the epoxy cement is hardened and the embedded aggregate cannot be removed. When the epoxy has completely hardened, excess aggregate shall be swept up for recovery or disposal.

CLASS II—OIL-MODIFIED EPOXY RESIN MIXTURE

8. MATERIALS

8.1. The oil modified epoxy resin mixture shall be furnished in two components to be combined in equal volumes immediately prior to use in accordance with the written instructions of the manufacturer.

8.1.1. Component A (Transparent Modified Epoxy Resin) shall be based on a liquid epoxy resin, a condensation product of hisphenol A and epichlorohydrin. The component shall be homogeneous and shall conform to the requirements of Table 5.

Table 5—Requirements for Component A

Property	Specific Value
Epoxide equivalent	275 to 300
Viscosity, Pa·s (Poises) 25˚C (77˚F), spindle No. 3, r/min	2.5 (25) max
Water content, mass, percent	0.2 max
Volatile loss, mL to 121˚C (250˚F), at 1.3 kPa (10 mm) absolute pressure	2.0 max

8.1.2. Component B (Transparent Modified Amine Curing Agent) shall be the curing agent for use with Component A and shall be composed of a polyamine modified with petroleum oils, flexibilizers, and accelerators. It shall contain no contaminants or insolubles and shall conform to the requirements of Table 6.

Table 6—Requirements for Component B

Property	Specific Value
Alkalinity, ep./100 g	0.21 to 0.25
Viscosity, Pa·s (Poises) 25˚C (77˚F), spindle No. 1, 20 r/min	1.5 max
Water content, mass, percent	0.2 max
Volatile loss, mL to 177˚C (350˚F)	1.0 max

8.1.3. When Components A and B are combined on an equal basis by volume, the mixture shall conform to the requirements of Table 7.

Table 7—Physical Properties of the Cured System

Property	Specific Value
Water absorption, mass, percent	0.5 max
Tensile strength, kPa (psi), 25 ± 1˚C (77 ± 2˚F)	6205 (900) min
Elongation at max load, percent 25 ± 1˚C (77 ± 2˚F)	40 min
Gel time, minutes, 25 ± 1˚C (77 ± 2˚F)	30 to 60
Shore hardness, 25 ± 1˚C (77 ± 2˚F)	35 to 65

9. METHODS OF TESTING

9.1. For tests to be performed on cured material, the curing schedule shall be a minimum of 24 hours at 24 to 27ºC (75 to 80ºF) followed by 20 ± 2 hours at 57 ± 3ºC (135 ± 5ºF).

9.1.1. *Epoxide Equivalent*—ASTM D 1652.

9.1.2. *Viscosity*—Brookfield.

9.1.3. *Water Content*—AASHTO T 55.

9.1.4. *Volatile Loss, Component A*—ASTM D 1189, and Component B—ASTM D 1079.

9.1.5. *Alkalinity*—ASTM D 664. Titrated to the first end point which will occur at a pH of about 6.3.

9.1.6. *Water Absorption*—ASTM D 570, 0.5 hour in boiling water.

9.1.7. *Tensile Strength and Elongation, ASTM D 638*—Individual specimens shall be cast to conform to dimensions for Type I. Thickness shall be 33 ± 5 mm (0.13 ± 0.02 in.). Speed of testing shall be 5.1 mm per min (0.20 in. per minute) ± 25 percent (Speed B).

9.1.8. *Gel Time*—The gel time shall be determined by weighing into a 240 mL (8 ounce) unwaxed paper cup sufficient amounts of each component, in the proper ratio for the particular material being tested, to make a total mass of 60.0 ± 0.2 g. The time shall be recorded and the two components mixed together by stirring for three minutes with a wooden tongue depressor or small spatula, periodically scraping the walls and bottom of the cup. The cup shall then be set on a wooden block and probed every two minutes with a small glass rod starting 20 minutes from the initiation of mixing. The time at which a semi-solid gel is formed shall be recorded as the gel time.

9.1.9. *Shore D Hardness*—ASTM D 2240 as modified in Section 7.1.11.

10. PACKAGING

10.1. Components shall be packaged and marked as set forth under "Packaging" in Sections 4.1 and 4.2.

Standard Specification for

Expanded and Extruded Foam Board (Polystyrene)

AASHTO Designation: M 230-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Expanded and Extruded Foam Board (Polystyrene)

AASHTO Designation: M 230-07

1. SCOPE

1.1. This specification covers expanded and extruded polystyrene board used for lightweight fill or highway pavement insulation applications.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 177, Standard Test Method for Steady-State Heat Flux Measurements and Thermal Transmission Properties by Means of the Guarded-Hot-Plate Apparatus
- C 272, Standard Test Method for Water Absorption of Core Materials for Structural Sandwich Constructions
- C 303, Standard Test Method for Dimensions and Density of Preformed Block and Board-Type Thermal Insulation
- C 518, Standard Test Method for Steady-State Thermal Transmission Properties by Means of the Heat Flow Meter Apparatus
- C 578, Standard Specification for Rigid, Cellular Polystyrene Thermal Insulation
- D 1621, Standard Test Method for Compressive Properties of Rigid Cellular Plastics
- D 1622, Standard Test Method for Apparent Density of Rigid Cellular Plastics
- D 2863, Standard Test Method for Measuring the Minimum Oxygen Concentration to Support Candle-Like Combustion of Plastics (Oxygen Index)

3. GENERAL REQUIREMENTS

3.1. The expanded polystyrene board shall be formed by the expansion of polystyrene base resin in an extrusion process. The board shall be homogeneous and shall consist of a continuum of closed cells.

4. PHYSICAL PROPERTIES

4.1. The board shall conform to the requirements prescribed in Table 1 when tested by the procedures specified in Section 6.

4.2. Design data should specify both the required compressive strength and thickness. (Normal manufacturing processes and distribution systems allow for 105-kPa, 170-kPa, 275-kPa, 415-kPa, and 690-kPa boards. Boards are manufactured based upon need, with 275-kPa board normally used as insulation for AASHTO's axle loadings of 98 kN.)

Table 1—Physical Property Requirements

Foam Classification Type ASTM C 578	Compressive Strength[a] kPa ASTM D 1621	Thermal Resistance[b] [R-value at 23.9ºC] ASTM C 518 or C 177	Max Water Absorption (% by Vol) ASTM C 272	Oxygen Index (%) ASTM D 2863	Minimum Density[c] (kg/m^3) ASTM C 303 or ASTM D 1622
X	105 min	0.88 min	0.3	24 min	21
IV	170 min	0.88 min	0.3	24 min	26
VI	275 min	0.88 min	0.3	24 min	29
VII	415 min	0.88 min	0.3	24 min	35
V	690 min	0.88 min	0.3	24 min	48
II	105 min	0.70 min	3.0	24 min	22

[a] Compressive strength to be determined at five percent deflection of specimen thickness or yield, whichever occurs first. A minimum of 275 kPa required for AASHTO's normal axle loading of 98 kN.

[b] Units: °C × m^2/W. Tabulated values show required thermal resistance of a 25-mm thickness at a mean temperature of 23.9ºC.

[c] When used for lightweight fill, the maximum density shall not exceed 1.25 × minimum density.

5. DIMENSIONAL TOLERANCES

5.1. Normally, extruded polystyrene foam boards shall be either 610 by 2440 mm or 1220 by 2440 mm with the thickness being specified by the user.

5.2. The permissible variations from the ordered dimensions shall be as follows (ASTM C 578):

5.2.1. Length ±0.8 mm per 305 mm of length,

5.2.2. Width ±1.6 mm per 305 mm of width,

5.2.3. Thickness ±1.6 mm per 25 mm of thickness (Note 1).

Note 1—When used for insulation, the thickness of board used shall be based upon heat flow theory and local conditions.

6. METHODS OF TESTING

6.1. The physical properties enumerated in this specification shall be determined in accordance with the following methods of the American Society for Testing and Materials (ASTM):

6.1.1. *Compressive Strength*—ASTM D 1621, Procedure A, except that the compressive strength shall be determined when the specimen is compressed 5 percent of measured thickness or at the first major load deviation, whichever comes first. A major load deviation shall be that point on the stress-strain curve where the stress load drops significantly below the normal stress fluctuation characteristic of the material under test (Note 2).

Note 2—Construction requirements should specify a smooth surface upon which the board is to be placed to prevent point loadings, wooden skewers or piles of non-frost susceptible sand or gravel used to hold the boards from "separating" or "shoving" during covering, and a minimum of 250 mm of granular material above the insulation for "stress absorption" or prevention of crushing of the insulation by construction traffic. An on-site test with the proposed methods of construction, including layer thickness and construction equipment, is recommended to ensure that there is no separation of the boards nor crushing of the insulation. The potential for differential icing should be taken into consideration when selecting the depth of cover over the extruded foam board.

6.1.2. *Oxygen Index*—ASTM D 2863. This test shall be used to establish the minimum oxygen index.

6.1.3. *Water Absorption*—ASTM C 272.

6.1.4. *Thermal Resistance*—Test in accordance with ASTM C 177 or ASTM C 518. Tests shall be conducted with a temperature differential of 28 ± 1ºC.

6.1.5. *Density*—Test in accordance with ASTM C 303 or ASTM D 1622.

7. HAZARDS

7.1. *Health and Safety*—Each manufacturer has a duty to warn when shipment, storage, installation, use, or ultimate disposal of a product may expose individuals to health or safety hazards. The manufacturer shall provide the user with appropriate information regarding any known hazards associated with the recommended handling and use of the product, and shall recommend the protective measures to be employed in its safe utilization.

Standard Specification for

Epoxy Resin Adhesives

AASHTO Designation: M 235M/M 235-03 (2007)[1]
ASTM Designation: C 881-99

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Epoxy Resin Adhesives

AASHTO Designation: M 235M/M 235-03 (2007)[1]
ASTM Designation: C 881-99

1. SCOPE

1.1. This specification covers two-component, epoxy-resin bonding systems for application to portland cement concrete, which are able to cure under humid conditions and bond to damp surfaces.

1.2. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with this specification.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazards statements, see Section 9.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 882, Standard Test Method for Bond Strength of Epoxy-Resin Systems Used With Concrete By Slant Shear[2]
- C 884, Standard Test Method for Thermal Compatibility Between Concrete and an Epoxy-Resin Overlay[2]
- D 570, Standard Test Method for Water Absorption of Plastics[3]
- D 638, Standard Test Method for Tensile Properties of Plastics[3]
- D 648, Standard Test Method for Deflection Temperature of Plastics Under Flexural Load in the Edgewise Position[3]
- D 695, Standard Test Method for Compressive Properties of Rigid Plastics[3]
- D 1259, Standard Test Methods for Nonvolatile Content of Resin Solutions[4]
- D 1652, Standard Test Method for Epoxy Content of Epoxy Resins[5]
- D 2393-95, Test Method for Viscosity of Epoxy Resins and Related Components [6]
- D 2566, Test Method for Linear Shrinkage of Cured Thermosetting Casting Resins During Cure (Withdrawn 1993)[6]

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *binder, n*—the cementitious part of a grout, mortar, or concrete that binds the aggregate or filler into a cohesive mass.

3.1.2. *bonding system, n*—the product resulting from the combination of all the components supplied for use as a bonding material.

3.1.3. *component, n*—a constituent that is intended to be combined with one or more other constituents to form a bonding system.

3.1.4. *contact strength, n*—bond strength measured by slant shear after a specified contact and cure time.

3.1.5. *contact time, n*—specified time between when the epoxy system is applied and when the two segments are bonded together and still achieve a specified bond strength after a specified curing time and temperature.

3.1.6. *curing agent, n*—a substance that causes the conversion of a fluid resin system to a solid cured resin by means of a chemical reaction.

3.1.7. *epoxy equivalent, n*—the weight of resin containing one molecular weight of epoxy groups.

3.1.8. *epoxy resin, n*—a resin that contains or did contain epoxy groups principally responsible for its polymerization.

3.1.9. *filler, n*—a finely divided solid, predominantly passing the 75-µm [No. 200] sieve, that is used to improve certain properties of the bonding system or to reduce cost.

3.1.10. *formulator, n*—the agency responsible for preparing the separate components and for recommending the proportions to be used in preparing the final bonding system.

3.1.11. *lot or batch, n*—that quantity of manufactured material which has been subjected to the same unit chemical or physical processes intended to make the final product substantially uniform.

3.1.12. *manufacturer, n*—a producer of a basic constituent part of a component.

3.1.13. *reactive diluent, n*—a relatively free flowing liquid used to reduce the viscosity of the liquid resin or resin mixture, and which contains reactive groups that cause it to become an integral part of the cured resin.

3.1.14. *working (pot) life, n*—the time after mixing during which a bonding system or mixture containing it retains sufficient workability for proper use.

4. CLASSIFICATION

4.1. This specification provides for the classification of epoxy-resin bonding systems by type, grade, class, and color.

4.2. *Types*—Seven types of systems that are distinguished by the requirements of Table 1 are recognized.

Table 1—Physical Requirements of Bonding Systems

	Type						
Property	I	II	III	IV	V	VI	VII
Viscosity Pa·s [P]:							
Grade 1, max	2.0 [20]	2.0 [20]	2.0 [20]	2.0 [20]	2.0 [20]	—	—
Grade 2, min	2.0 [20]	2.0 [20]	2.0 [20]	2.0 [20]	2.0 [20]	—	—
Max	10 [100]	10 [100]	10 [100]	10 [100]	10 [100]		
Consistency, mm [in.]:							
Grade 3, Types I, II, III, IV, V, VI, VII, max	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]	6.0 [$^{1}/_{4}$]
Gel time, minutes, min	30	30	30	30	30	30	30
Bond strength, min MPa [psi]:

14 days	—	—	—	—	—	—	7.0 [1000]

[a] Not required for Viscosity Grade 3 Systems

4.2.1. *Type I*—For use in non-load-bearing application for bonding hardened concrete to hardened concrete and other materials, and as a binder in epoxy mortars or epoxy concretes.

4.2.2. *Type II*—For use in non-load-bearing applications for bonding freshly mixed concrete to hardened concrete.

4.2.3. *Type III*—For use in bonding skid-resistant materials to hardened concrete, and as a binder in epoxy mortars or epoxy concretes used on traffic-bearing surfaces (or surfaces subject to thermal or mechanical movements).

4.2.4. *Type IV*—For use in load-bearing applications for bonding hardened concrete to hardened concrete and other materials and as a binder for epoxy mortars and concretes.

4.2.5. *Type V*—For use in load-bearing applications for bonding freshly mixed concrete to hardened concrete.

4.2.6. *Type VI*—For bonding and sealing segmental precast elements with internal tendons and for span-by-span erection when temporary post tensioning is applied.

4.2.7. *Type VII*—For use as a non-stress-carrying sealer for segmental precast elements when temporary post tensioning is not applied as in span-by-span erection.

Note 1—Epoxy resin systems will adhere to a wide variety of materials, including wood, metals, masonry, and most plastics. Polyethylene, TFE-fluorocarbon, cellophane, and greased or waxed surfaces are among the few materials to which these systems will not adhere.

4.3. *Grades*—Three grades of systems are defined according to their flow characteristics and are distinguished by the viscosity and consistency requirements of Table 1.

4.3.1. *Grade 1*—Low viscosity.

4.3.2. *Grade 2*—Medium viscosity.

4.3.3. *Grade 3*—Non-sagging consistency.

4.4. *Classes*—Classes A, B, and C are defined for Types I through V, and Classes D, E, and F are defined for Types VI and VII, in accordance with the range of temperatures for which they are suitable (Note 2).

4.4.1. *Class A*—For use below 4.0ºC [40ºF] the lowest allowable temperature to be defined by the manufacturer of the product.

4.4.2. *Class B*—For use between 4.0 and 15.0ºC [40 and 60ºF].

4.4.3. *Class C*—For use above 15.0ºC [60ºF] the highest allowable temperature to be defined by the manufacturer of the product.

4.4.4. *Class D*—For use 4.0 and 18.0ºC [40 and 65ºF].

4.4.5. *Class E*—For use between 15.0 and 30.0ºC [60 and 80ºF].

4.4.6. *Class F*—For use between 25.0 and 30.0ºC [75 and 90ºF].

Note 2—The temperature in question is usually that of the surface of the hardened concrete to which the bonding system is to be applied. This temperature may be considerably different from that of the air. Where unusual curing rates are desired, it is possible to use a class of bonding agent at a temperature other than that for which it is normally intended. For example, a Class A system will cure rapidly at room temperature.

4.5. *Color*—Epoxy resin systems are normally unpigmented, but they can be colored or darkened. If a specific color is desired, it should be so stated by the purchaser.

5. ORDERING INFORMATION

5.1. The purchaser shall specify the type, grade, class, and color of bonding system desired and the size of units in which the components shall be furnished. Special requirements regarding filling of either the components or the final bonding system should be stated. The product furnished under this specification is intended to be resistant to moisture and therefore should be suitable for either indoor or outdoor exposure.

5.2. The purchaser may specify a minimum gel time of 5 minutes for Types I and IV when automatic proportioning, mixing, and dispensing equipment are used.

6. MATERIALS AND MANUFACTURE

6.1. The systems covered by this specification shall be furnished in two components for combining immediately prior to use in accordance with written instructions of the formulator. Component A shall contain an epoxy resin with or without a reactive diluent. Component B shall contain one or more curing agents, which on mixing with Component A shall cause the mixture to harden. A suitable inert filler may be uniformly incorporated in one or both components. The filler shall be either nonsettling or readily dispersible in any component in which it is incorporated. All systems shall cure under humid conditions, and bond to damp surfaces.

7. CHEMICAL COMPOSITION

7.1. The epoxy-resin constituent of Component A shall have an epoxy equivalent of 155 to 275.

8. PHYSICAL PROPERTIES

8.1. A mixture of Components A and B in the proportions recommended by the formulator shall conform to the properties prescribed in Table 1.

9. SAFETY HAZARDS

9.1. **Caution**—Epoxy resins contain irritants, especially to the skin, eyes, and respiratory system. Persons handling these materials shall use appropriate protective clothing, including rubber or plastic gloves. If an epoxy resin should contact the skin, it shall be removed immediately with a dry cloth or paper towel, and the area of contact washed thoroughly with soap and water. Solvents shall ***not*** be used, because they carry the irritant into the skin. Cured epoxy resins are innocuous.

10. SAMPLING

10.1. Take a representative sample of each of the two components from a well-blended lot prior to packaging or by withdrawing samples from no fewer than 5 percent of the containers comprising the lot or shipment. Unless the samples of the same component taken from containers show visual evidence of variability, they may be combined into a single composite sample. In place of the foregoing, packaged materials may be sampled by a random selection of containers of each component from each lot, provided such a procedure is acceptable to the purchaser.

11. TEST METHODS

11.1. *Consistency*—Test Method to Determine the Consistency of an Epoxy Resin System.

11.1.1. *Scope*—This test provides a method for determining the consistency of Grade 3 epoxy resin systems.

11.1.2. *Significance and Use*—This test method is used to determine compliance with the requirements of the specification.

11.1.3. *Apparatus*:

11.1.3.1. *Paper cup*—approximately 0.100-L [3-oz] unwaxed paper cup.

11.1.3.2. *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.1.3.3. *Glass panel*.

11.1.3.4. *Conditioning*—Condition the individual components and any equipment with which they will come in contact to the following temperatures: Class A, 32 ± 2ºF [0 ± 1ºC]; Class B, 10 ± 1ºC [50 ± 2ºF]; Class C, 23 ± 1º C [73 ± 2ºF]; Class D, 18 ± 1ºC [65 ± 2ºF]; Class E, 27 ± 1ºC [80 ± 2ºF]; Class F, 32 ± 1ºC [90 ± 2ºF] or the temperature at which the material will be used (Note 2).

11.1.4. *Procedure*—Prepare approximately 30 cm^3 of the bonding system. Weigh the necessary amounts of the components to an accuracy of 1 percent into a single approximately 100-cm^3 [3-oz] unwaxed paper cup. Mix immediately with a wooden tongue depressor or stick of similar size. Note the time at which mixing begins. Mix for 3 minutes, taking care to scrape the side and bottom of the cup periodically. Immediately apply about 2 cm^3 of the mixture to a glass panel. Form a semicylindrical bead of the bonding system by drawing the applicator blade through the sample in a straight line with the panel horizontal. Immediately raise the panel to a position inclined no greater than 10º from vertical and with the bead horizontal. Maintain the panel and sample at their original temperature until the bonding system has cured, as determined by an inability to indent it appreciably with a pencil point or fingernail. Determine the consistency by measuring the flow of the lower edge of the bead from its original position at three points along its length.

11.1.5. *Report*—Report the average value to the nearest 1 mm [$^1/_8$ in.].

11.1.6. *Precision and Bias*:

11.1.6.1. *Precision*—The precision of the procedure in this test method for consistency is being determined.

11.1.6.2. *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.2. *Gel Time*—Test method to determine the gel time of an epoxy resin system.

11.2.1. *Scope*—This test method determines the time after mixing when an epoxy resin system gels.

11.2.2. *Significance and Use*—This test method is used to determine compliance with the requirements of the specification.

11.2.3. *Apparatus*:

11.2.3.1. *Paper cup*—250-cm^3 [approximately 8-oz] unwaxed paper cup.

11.2.3.2. *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.2.4. *Conditioning*—Condition the individual components and any equipment with which they will come in contact to the temperatures set forth in Section 11.1, depending on the class of system in question, or to the temperature at which the material will be used, providing that temperature is within the ranges established in Section 4.4 for Types I, II, III, and V. For Types VI and VII use the highest temperature of the specified class (Note 2). Prepare 60 g of the bonding system for Types I through V and 4.0 L [1 gal] for Types VI and VII using the procedures set forth in Section 11.1.

11.2.5. *Procedure*—Transfer as much as possible of the sample into an approximately 250-cm^3 [8-oz] unwaxed paper cup and set it on a wooden surface in a location maintained at the original conditioning temperature and not subject to abnormal room air movement. Determine the time at which a soft, gelatinous mass forms in the center of the sample by probing every 2 minutes with a wooden tongue depressor or similar device, starting 8 minutes after the beginning of mixing.

11.2.6. *Report*—The gel time is the interval between the beginning of mixing and the formation of the gelatinous mass.

11.2.7. *Precision and Bias*:

11.2.7.1. *Precision*—The precision of the procedure in this test method for gel time is being determined.

11.2.7.2. *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.3. *Filler Content*—Test Method to Determine the Filler Content of Epoxy Resin Systems.

11.3.1. *Scope*—This test method is a quantitative test to determine the filler content of epoxy resin systems.

11.3.2. *Significance and Use*—The filler content of an epoxy resin system must be known in order to determine the epoxy equivalent.

11.3.3. *Apparatus*:

11.3.3.1. 150-mL beaker.

11.3.3.2. Medium-porosity, fritted-disk filtering crucible.

11.3.3.3. *Mixing blade*—Ordinary wooden tongue depressor or stick of similar size.

11.3.4. *Reagents*:

11.3.4.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available.[7] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

11.3.4.2. Methyl ethyl ketone (MEK).

11.3.4.3. Benzene.

11.3.5. *Procedure*—Weigh, to the nearest 0.1 mg, approximately 10 g of the epoxy resin component into a 150-mL beaker. Add 50 mL of methyl ethyl ketone (MEK) to the beaker, and stir the contents until all the soluble matter is dissolved. If the sample is black, owing to the presence of bituminous material, the solvent used shall be a mixture of 1 + 1 MEK and benzene, by volume. Dry a medium-porosity, fritted-disk filtering crucible to constant weight at 110 ± 5ºC [230 ± 9ºF]. Wet the filter with MEK, then filter the contents of the beaker through the filtering crucible with the aid of a vacuum. Transfer the contents of the beaker entirely to the crucible, and wash the beaker and the residue on the filter with MEK. The total volume of solvent used to transfer and wash the residue should be about 200 mL. Dry the filter and residue to constant weight at 110 ± 5ºC [230 ± 9ºF].

11.3.6. *Report*—Calculate the percentage of filler in the component, and report the value to the nearest 0.1 percent.

11.3.7. *Precision and Bias:*

11.3.7.1. *Precision*—The precision of the procedure in this test method for filler content is being determined.

11.3.7.2. *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11.4. *Epoxy Equivalent*—Determine the epoxy equivalent of Component A in accordance with ASTM D 1652. Calculate the epoxy equivalent after correcting for any filler and volatile contents of the component as follows:

$$x = y\,(1 - f - v) \qquad (1)$$

where:

x = corrected weight per epoxy equivalent of the component,

y = weight per epoxy equivalent of the total component as determined by ASTM D 1652,

f = weight fraction of filler in the component, and

v = weight fraction of volatile matter in the component.

11.5. *Viscosity*—Determine the viscosity of the freshly mixed resin system by means of ASTM D 2393-95, except that the determination shall be made at the temperature given in Section 11.1 for the class of material in question.

11.6. *Absorption*—Determine the absorption by means of ASTM D 570. The test specimens shall have the shape and dimensions specified for molded plastics, shall be cured for 14 days at a temperature of 23 ± 1ºC [73 ± 2ºF], shall be tested in accordance with the procedure for 24-hour immersion, and shall be reconditioned, if necessary, as directed in ASTM D 570.

11.7. *Bond Strength*—Determine the bond strength in accordance with ASTM C 882.

11.8. *Thermal Compatibility*—Determine the thermal compatibility in accordance with ASTM C 884.

11.9. *Heat Deflection Temperature*—Determine the heat deflection temperature in accordance with ASTM D 648, except condition, mix, cure, and start testing the resin components at 23 ± 1ºC [73 ± 2ºF].

11.10. *Linear Coefficient of Shrinkage*—Determine the linear coefficient of shrinkage in accordance with ASTM D 2566, except condition, mix, cure, and test the resin components at 23 ± 1ºC [73 ± 2ºF].

11.11. *Compressive Yield Strength and Modulus*—Determine the compressive yield strength and modulus in accordance with ASTM D 695, except condition, mix, and cure the resin components at the lowest application temperature of the specified class. Test at 23 ± 1ºC [73 ± 2ºF] without delay. Use of a 25.4 × 25.4 × 50.8-mm [1 × 1 × 2-in.] specimen is also acceptable.

11.12. *Tensile Strength and Elongation at Break*—Determine the tensile strength and elongation at break in accordance with ASTM D 638, except condition, mix, and cure at the lowest application temperature of the specified class. Test at 23 ± 1ºC [73 ± 2ºF], without delay.

11.13. *Contact Strength*—Determine the contact strength in accordance with ASTM C 882 except condition the material and the specimens at the highest application temperature of the specified class and apply the bonding system at a thickness of 2 mm [$^1/_{16}$ in.] on the slanted surface of each half cylinder. Maintain at the highest application temperature and assemble the two half cylinders after 1 hour for Type VI and 8 hours for Type VII. Cure at the assembly temperature and test at 23 ± 1ºC [73 ± 2ºF]. Contact strength is expressed in terms of pascals [pounds per square inch] obtained after a specified time of cure.

12. REJECTION AND REHEARING

12.1. The purchaser has the right to reject material that fails to conform to the requirements of this specification. Rejection shall be reported to the producer or supplier promptly and in writing. In case of dissatisfaction with the results of the test, the producer or supplier has the right to a rehearing.

12.2. If all requirements of this specification are met, except those pertaining to bond strength, the bond tests shall be repeated. If the sample again fails to meet the bond strength requirements, the entire lot shall be rejected.

12.3. *Retest*—Lots of material that have been rejected may be reworked by the producer to correct the defects and resubmitted for test provided specific approval of the purchaser has been obtained for such resubmission. Before resubmission of the material, full particulars concerning the action taken to correct the defects in the original material shall be made available to the purchaser.

13. PACKAGING AND PACKAGE MARKING

13.1. *Packaging*—The two components furnished under this specification shall be supplied in separate containers that are nonreactive with the contents. They are usually supplied in amounts such that the recommended proportions of the final mixture can be obtained by combining one container of Component A with one container of Component B.

13.2. *Marking*—Containers shall be identified as "Component A—Contains Epoxy Resin" and "Component B—Contains Curing Agent" and shall show the type, grade, class, and color. Each container shall be marked with the name of the formulator, the lot number, the date of packaging, the quantity contained therein, and the recommended mixing ratio, by both weight and volume.

14. KEYWORDS

14.1. Bonding; bonding systems; contact strength; contact time; epoxy resin.

Standard Practice

Evaluation of Transportation-Related Earthborne Vibrations

AASHTO Designation: R 8-96 (2009)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Evaluation of Transportation-Related Earthborne Vibrations

AASHTO Designation: R 8-96 (2009)[1]

1. SCOPE

1.1 This standard practice is to provide guidance for the assessment of potential or alleged structural damage due to earthborne vibrations related to transportation facility construction, maintenance, or operation.

2. INTRODUCTION

2.1 The construction, maintenance, and operation of transportation facilities generate vibrations, which are transmitted through the air and earth and are subsequently received or "sensed" by structures or inhabitants. Only earthborne vibrations are addressed in this standard practice. (See Section X2.8, Appendix X2.)

2.2 Currently accepted practice in monitoring earthborne vibrations considers two parameters—earth particle velocity and wave frequency—determined at the site of concern (Siskind et al. 1980; see Figure 1). Sensing instruments are usually set out on the ground adjacent to the subject structure. For determination of safe vibration control limits, special concerns may dictate placement of sensors directly on specific parts of a structure such as the foundation, a supporting column, or a wall.

2.3 Much of the data concerning structural damage has been determined from blasting activities. Blasting is a commonly used construction-related procedure that produces vibrations characterized by a wide frequency range and potentially high intensities but of very short duration.

Transportation-related activities, such as vehicular or rail traffic, may be the source of repetitive, cyclical vibrations of much lower intensity than those caused by blasting. There may be concern in this regard because of potential for fatigue of structural components. Documentation of specific damage due to such transportation-related vibrations is scarce (Whiffin and Leonard 1971; Ames et al. 1976).

2.4 People "sense" or respond to a much broader range of vibration frequencies and intensities than do structures. Intrusive vibration levels can annoy humans at much lower intensities than levels considered critical for structures (see Figure 2). Such sensitivity causes concern for structural damage potential even at the extremely low levels of vibration that are a recognized nuisance to people. Various threshold limits have been recommended in standards aimed at minimizing damage to various structures. Recommended safe vibration limits are based upon the appearance of "threshold cracks" or cosmetic cracking. Such cracks appear at lower vibration levels than do architectural or minor damage. The applicability of specific limitations is often the subject of litigation requiring expert witness opinion.

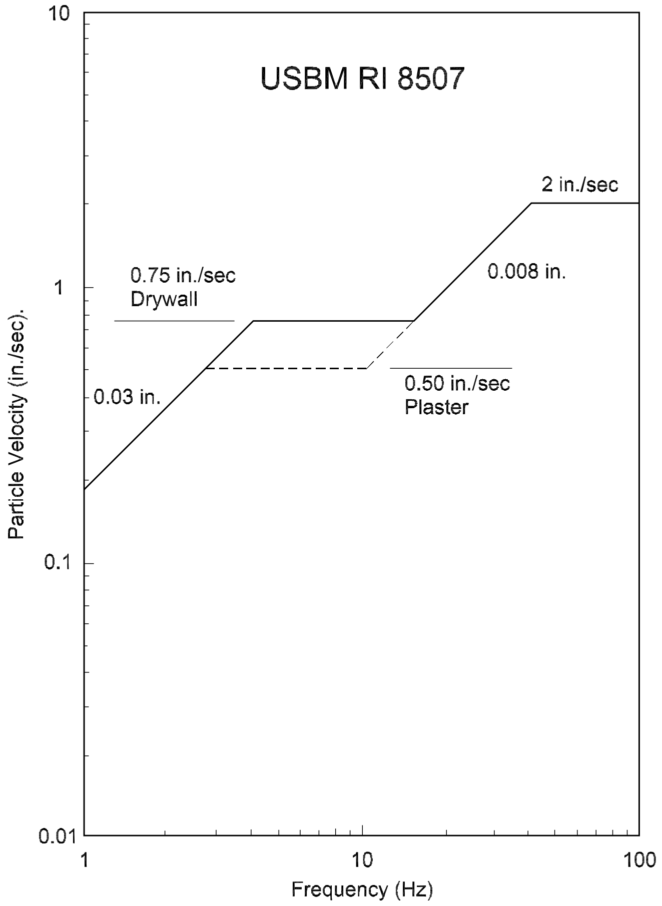

Figure 1—Safe Vibration Limit Recommendations for Residential Structures

2.5 Concerns of anticipated or perceived damage can be related to structures or their contents. Practically all buildings contain fine cracks or imperfections that are not noticed until concern is stimulated by perception of abnormal vibrations. Evaluation of the potential effects of transportation-related earthborne vibrations requires documentation of the background or pre-existing condition of the structure or component of concern. Such an evaluation should also include a determination of the intrusive vibration characteristics (amplitudes and frequencies) at the point of interest. Dowding (1992) reviews the various methods for determining ground vibration frequencies. Analysis of the results may necessitate modification at the vibration source or mitigation of effects at the location of concern.

3. PROCEDURE

3.1 A survey of the site should be made by personnel capable of locating, evaluating, and documenting significant or apparent evidence of distress. Such surveys preferably should be made before the onset of any objectionable vibration-producing activity. The scope of the inspection should be appropriate for both the subject of concern and the intensity of the vibrations. Photographic or video documentation of the inspection is recommended. Any procedures requiring intrusion on property should be specifically permitted by the property owner, preferably in writing. Specialists in vibration monitoring are often contracted for survey services.

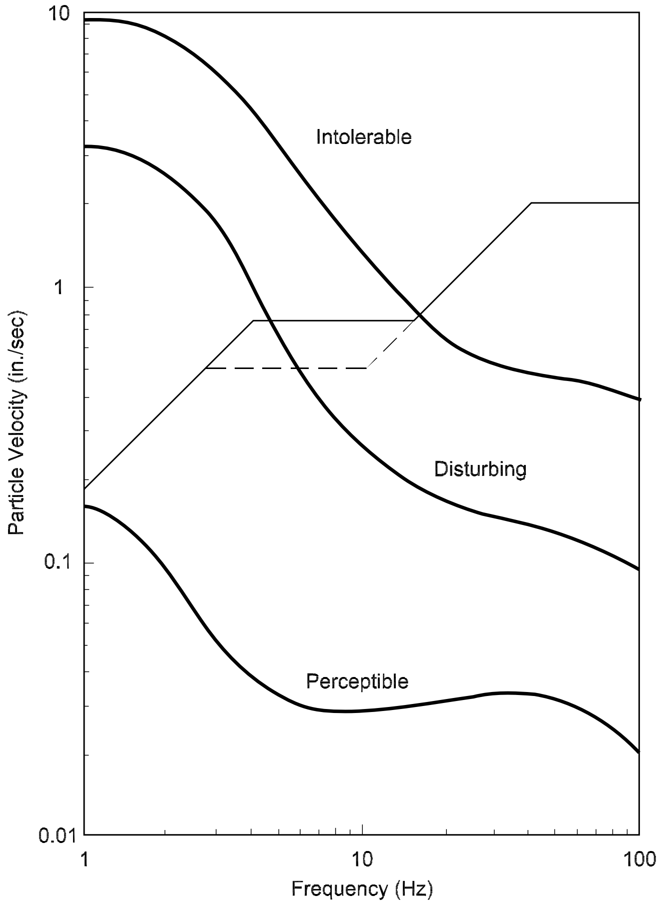

Figure 2—Safe Vibration Limit (USBM RI 8507) and Human Perception (Rathbone)

3.2 All vibrations arriving at the monitoring location within the selected sensitivity range of the seismograph are recorded. For comparison purposes, it is often useful to obtain recordings of the normal or background vibrations at the site when the specific objectionable source is not present. The sensitivity range of the instrument should be selected so that recording is initiated below the intensity of the objectionable vibrations and extends above the highest expected intensity. It may be necessary to estimate or predetermine the expected intensity level to be sensed in order to select the appropriate instrument range setting to be used during monitoring. It is necessary to determine the time when the vibration source is active. Specific activities of the vibration source, such as driving of piles, as opposed to extraction, vibratory compaction, or pavement-breaking activities, should be indexed in time for proper correlation with the arrivals on the vibration records. Since the determination of frequency is important, instruments that provide a time-history or waveform of each velocity component for a vibration event are preferred.

3.3 A field calibration procedure should be conducted before the start of monitoring and recording. The incoming ground vibrations should be measured on the ground at foundation level, as close to the structure as possible to be consistent with studies providing safe vibration limits (Siskind and Stagg 1985). The transducer is positioned with the longitudinal axis (indicated by an arrow) toward the vibration source or parallel to the structure. Transducers must be adequately coupled with the ground or the structural component being monitored. (See Section X1.5, Appendix X1.) Instrument manufacturers provide appropriate instructions and recommendations for special installations. Some published threshold criteria are based on specific monitoring procedures.

Consistent procedures in the placement and location of transducers during monitoring are recommended for comparison of results.

3.4 Records of the incoming vibrations are typically displayed in a waveform plot or strip chart plot. The peak particle velocities in longitudinal, transverse, and vertical planes are shown along with the respective dominant or principal frequencies. The highest recorded particle velocity among the three planes is indexed to its time of occurrence within the recorded interval. This velocity is reported as the peak particle velocity for a particular event.

3.5 The recorded peak particle velocity is compared with criteria appropriate for the subject of concern. Many currently used digital instruments produce a record that displays the particle velocities and associated zero crossing frequencies, or arrivals plotted against a base of the U.S. Bureau of Mines (USBM) RI 8507 curve, which is a commonly accepted criterion for threshold cracking concerns in the United States (see Figure X2.1). Other criteria may be applicable in special circumstances (see Appendix X2).

3.6 In the event of a complaint, a site visit should be made as soon as possible to assess the situation and to compile necessary documentation. A report document should include all relevant data such as the basis for the investigation, time and date of the survey, persons involved, and a description of the property. It should also include a description of the instrumentation, description and log of the monitoring procedure, the monitoring results, and the conclusions reached based on comparison with applicable criteria, standards, or expert recommendation.

3.7 The following information should be obtained when complaints of intrusive vibrations are received:

3.7.1 Time and date of the complaint;

3.7.2 Name, address, and phone number of the complainant;

3.7.3 The alleged damage and/or complaint;

3.7.4 The time and date on which the damage occurred;

3.7.5 The type and location of the alleged damaging or intrusive vibration source;

3.7.6 A photograph or sketch of the physical problem;

3.7.7 Any actions that are demanded; and

3.7.8 Reference to any previous complaints by the complainant or in the vicinity.

APPENDIXES

X1. GENERAL INFORMATION

X1.1. *Threshold*:

X1.1.1. The point at which a physiological or psychological effect is initiated.

X1.2. *Threshold Cracking*:

X1.2.1. The manifestation of cosmetic damage; the formation of the most superficial interior cracking, which occurs in all homes due to various environmental factors and household activities. Safe vibration limits are set to avoid these types of cracks.

X1.3. *Architectural or Minor Damage*:

X1.3.1. Non-structural damage that does not affect the strength or function of a structure, such as cracked plaster or wallboard, cracked or broken windows, or hairline cracks in masonry walls.

X1.4. *Major Damage*:

X1.4.1. Damage resulting in serious weakening of a structure; for example, substantial settlements or shifting of foundations, distortion or weakening of the superstructure, large cracks in foundation or bearing walls, or walls out of plumb.

X1.5. *Transducers*:

X1.5.1. Velocity-sensing transducers (geophones) with response capability in three mutually perpendicular axes or components: one vertical and two horizontal (radial and transverse). The frequency response of the transducer should be linear from at least 4 Hz to more than 200 Hz. Sensitivity should range from less than 0.02 in./s to more than 5.0 in./s.

X1.5.2. Accelerometers are sometimes used as transducers in specialized applications. Such applications include low-frequency studies, structure response analyses, and high-frequency or close-in work (Oriard 1980; Stagg and Engler 1980). Accelerometers measure acceleration, the rate at which particle velocity changes, in terms of *g*, the acceleration of gravity. The recorded signal can be electronically integrated to produce a record of particle velocity.

X1.5.3. It is extremely important that transducers are adequately coupled to monitoring surfaces (Stagg and Engler 1980; Siskind and Stagg 1985). Sandbags are not always sufficient (Duvall 1961; Robertson 1993). In general, surface placement techniques are adequate only for low-frequency, low-amplitude levels (less than 1.0 in./s at less than 20 Hz) and acceleration levels of less than 0.2 *g* (Stagg and Engler 1980). A study by Blair (1987) suggests a lower acceleration value of 0.1 *g*. The preferred emplacement method of the USBM is to bury transducers in soils and to firmly anchor (such as gluing or bolting) transducers to hard surfaces.

X1.6. *Limiting Velocity*:

X1.6.1. Maximum vibration levels not to be exceeded to prevent threshold cracking or damage.

X1.7. *Peak Particle Velocity (PPV)*:

X1.7.1. The maximum recorded particle velocity from any one of the three axes of movement (vertical [V_v], horizontal [V_h], and transverse [V_t]) for a recorded vibration event.

X1.8. *Resultant or Vector Sum*:

X1.8.1. See Peak True Vector Sum.

X1.9. *True Vector Sum (V)*:

X1.9.1. The resultant of vectorially adding the three components of velocity at the same instant of time.

$$\bar{V} = \sqrt{V_v^2 + V_h^2 + V_t^2} \qquad (X1.1)$$

X1.9.2. *Peak True Vector Sum*:

X1.9.3. The highest true vector sum value of the three components of velocity during the record interval.

X1.10. *Peak Pseudo Vector Sum*:

X1.10.1. The resultant of vectorially adding the maximum velocity from each of the three traces regardless of the time at which they occurred on the record. This practice, although sometimes used, is not appropriate.

X1.11. *Dominant or Principal Frequency*:

X1.11.1. The frequency associated with the peak particle velocity. It may be found by zero crossing, Fourier frequency, or response spectrum techniques as described by Dowding (1992).

X1.12. *Natural or Resonant Frequency*:

X1.12.1. A structure will continue to oscillate when the source of excitation is discontinued. This motion by the structure is called free vibration. The number of times per second a structure vibrates during free vibration is the natural frequency of the structure. The amplitude of vibration will be the greatest when the frequency of the incoming ground vibration is the same as the natural frequency of the structure. Natural frequencies of residential structures were calculated by Dowding et al., 1981. For whole structures, they ranged from 3 to 11 Hz and for individual walls, they ranged from 12 to 20 Hz.

X1.13. *Time-History*:

X1.13.1. The waveform plot, as in velocity versus time (velocity time-history) or acceleration versus time (acceleration time-history), of a vibration event.

X1.14. *Background Vibrations*:

X1.14.1. Vibrations normally present prior to the onset of any activity generating vibrations of special interest.

X1.15. *Site Inspection or Survey*:

X1.15.1. The systematic documentation of the existing condition of a structure or site. The extent or content of the inspection depends on the site. Dowding (1985) gives an example of such an investigation form.

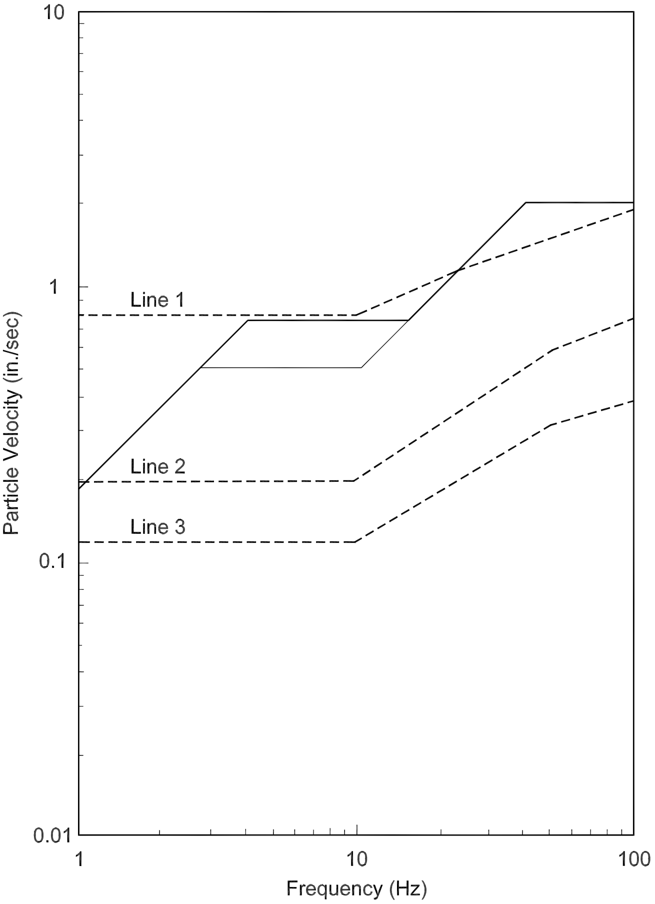
X1.16. *Liquefaction*:

X1.16.1. A condition in which a cohesionless soil will lose its strength and undergo large deformations due to the buildup and maintenance of high pore pressures that are equal or close to the confining pressure in the soil (after Seed 1979). The pore pressure buildup may be due to static stresses, but more commonly it is due to cyclic stress applications. For more information, the reader is referred to, among others, Seed 1979; Seed et al. 1983; Tokimatsu and Seed 1987; Kramer and Seed 1988; Rollins and Seed 1990; Fiegel and Kutter 1994.

X2. CRITERIA FOR LIMITING VIBRATIONS

X2.1. *Threshold for Earthborne Vibrations*:

X2.1.1. At the present, there is no universally accepted standard for limiting earthborne vibrations. Various approaches are being implemented to address specific concerns. In the United States, the USBM RI 8507 threshold recommendations are most commonly referenced. The German guidelines DIN 4150 (see Figure X2.1) and the British Standard BS 7385 (see Figure X2.2) are examples of criteria used in other countries as a basis for evaluation of potential damage. Note the basis for the guideline levels of DIN 4150 are unknown; however, they are considered safe and very conservative (Dowding 1992; Siskind 1994). Special interest groups, such as historical preservation societies as one example, issue threshold guidelines for concerns within their jurisdiction. The basis for the guidelines should be established in any particular application.



(Adapted from DIN 4150)

Line	Type of Structure
1	Buildings used for commercial purposes, industrial buildings, and buildings of similar design
2	Dwelling and buildings of similar design and/or use
3	Structures that, because of their particular sensitivity to vibration, do not correspond to those listed in lines 1 and 2, and are of great intrinsic value (e.g., buildings that are under a preservation order)

Figure X2.1—Vibration Guidelines—USBM RI 8507 (Solid Line) Compared to DIN 4150 (Dashed Line)

X2.2. *Peak Particle Velocity and Frequency*:

X2.2.1. The current USBM threshold recommendations and the other aforementioned criteria recognize the relationship of peak particle velocity and frequency. The USBM recommendations are the result of tests on essentially residential structures. Recommendations include a caution that threshold damage may occur at displacements greater than 0.030 in. at frequencies below 4 Hz and 0.008 in. at frequencies between 12 and 40 Hz. (See Figure 1.)

X2.3. *Peak True Vector Sum Particle Velocity*:

X2.3.1. The threshold recommendations of the USBM for assessing damage potential are based on the maximum particle velocity without preference to any of the three components. Some instruments provide a value known as the true vector sum or resultant. This value is sometimes used to express the maximum intensity of a vibration event. The peak true vector sum is a conservative estimate of the peak particle velocity as it is always greater than the maximum particle velocity from any one of the three components.

X2.3.2. There is no frequency associated with the true vector sum. Therefore, the true vector sum or the resultant cannot be used in conjunction with the USBM RI 8507 curve. The use of the true vector sum is limited to a few regulations requiring compliance with a specified peak particle velocity limit without regard to frequency. Most of these regulations are historically linked to two USBM publications: RI 5968, published in 1962 and Bulletin 656, published in 1971 (Siskind 1991). Both publications advocated the use of particle velocity as the best descriptor of ground vibration damage. RI 5968 was the first to recommend a maximum single component amplitude of 2.0 in./s, without regard to frequency, as a safe particle velocity criterion.

X2.4. *Peak Particle Velocity for Underground Structures*:

X2.4.1. Threshold cracking recommendations are developed for specific categories of structures. USBM 8507 is based on residential structures. The application of such criteria to markedly different types of structures such as foundation walls, buried pipelines, and other underground structures is common and inaccurate. Whereas aboveground structures have freedom to respond to ground motion, buried structures are restrained in their response.

X2.4.2. Recent studies have demonstrated that the vibration amplitude at ground level is much greater than that actually measured on a buried pipeline (Linehan et al. 1992; Siskind and Stagg 1993). It can be shown that a ground strain criterion is analytically more appropriate for buried structures than a criterion based on velocity. Hence, the use of strain and resulting stresses to develop criteria for buried structures is advocated (Esparza, Westine, and Wenzel 1981; Dowding and Corser 1981). A buried steel pipeline can sustain allowable strains at vibration levels of 5.0 in./s to 45.0 in./s. (Westine et al. 1978; Linehan et al. 1992; Siskind and Stagg 1993). At least one major utility has established a criterion of a peak particle velocity of 4.0 in./s over their buried optical fiber cables.

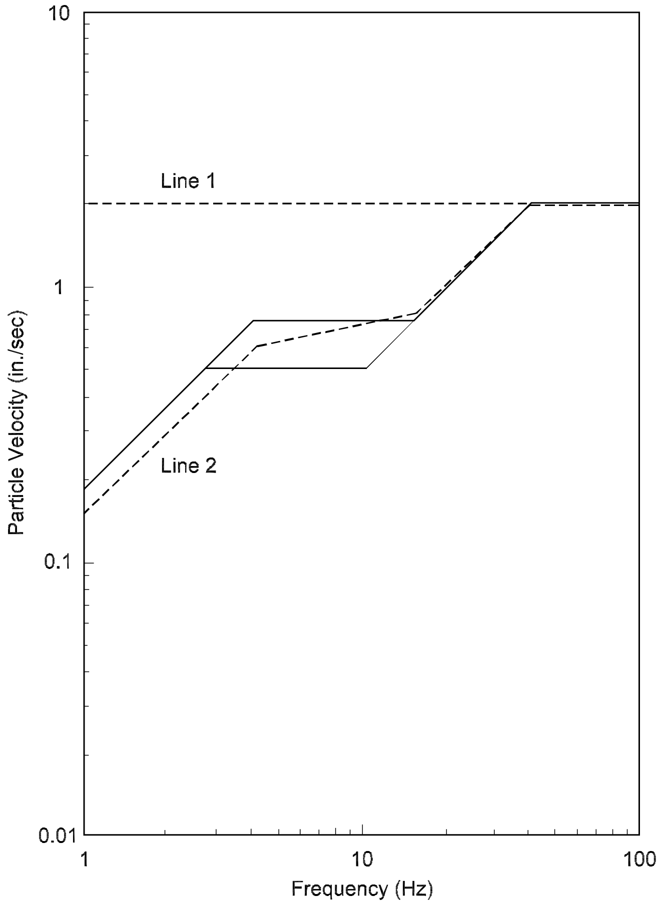
X2.4.3. A tunnel with a shotcrete liner can experience a particle velocity of 36.0 in./s before the appearance of threshold cracking (Hendron 1977). A restrained monolithic concrete block can experience 10.0 in./s before cracking (Crawford and Ward 1965; Oriard 1987). Prediction equations for stresses and strains in buried pipelines are presented in Esparza (1981, 1991) and Dowding (1985).

X2.5. *Cumulative Effect of Repeated Ground Vibration*:

X2.5.1. There is considerable concern about the cumulative effect of repeated ground vibration or fatigue on a structure. Documentation in the literature is limited. For example, most large metropolitan areas have many residential structures in close proximity to subway systems. Over the years such structures have been exposed to numerous cycles of low level vibrations without any apparent attributable damage. Comprehensive studies were conducted by the USBM (Stagg et al. 1984). Tests in a residential structure subjected to repeated, mechanically induced vibration levels equal to 0.5 in./s on the ground outside produced threshold cracking after 56,000 cycles.

X2.6. *Continuous Ground Vibrations*:

X2.6.1. The vibration levels that can be tolerated from a transient or short duration event, such as a blast, are higher than the levels from a steady-state or continuous vibration source, such as a vibratory compactor (Wiss 1981). Guidance on human response to vibrations of various durations is provided by ANSI S3.29-1983 and the British Standard BS 6472:1992. Because of their longer duration, incoming continuous ground vibrations with dominant frequencies close to the natural frequency of a structure are more likely to be amplified due to structural resonance (Crum and Siskind 1993). With regard to threshold cracking, Wiss (1967) stated, common practice for continuous vibrations is to reduce the allowable transient level of 2.0 in./s by as much as 80 percent.



(Adapted from BS 7385)

Line	Type of Building
1	Reinforced or framed structures Industrial and heavy commercial buildings
2	Unreinforced or light framed structures Residential or light commercial type buildings

Figure X2.2—Vibration Guidelines—USBM RI 8507 (Solid Line) Compared to BS 7385 (Dashed Line)

X2.7. *Soil Liquefaction*:

X2.7.1. Building damage due to the potential liquefaction of certain soils or the permanent displacement of the ground as a result of vibrations is another area of concern. Saturated, loose, uniformly, or poorly graded sands and silts are sensitive to cyclic vibrations such as might be produced by vibratory pile driving (Wiss 1981; Clough and Chameau 1980), vibratory compaction (Tynan 1973), or vibrating tampers conducting a seismic reflection survey (Hryciw et al. 1990). In some cases, these materials may liquify as a result of a single impact (Tynan 1973; Tschebotarioff 1973) or densify as due to an explosion (Dowding 1994). These activities can produce noticeable settlement even at low vibration levels (0.1 to 0.7 in./s) which are known not to produce threshold cracking (Dowding 1994; Leathers 1994; Leznicki et al. 1994; Kim et al. 1994). In such cases, the limiting criteria may be dictated by the soil conditions.

X2.8. *Airborne Vibrations*:

X2.8.1. Only earthborne vibrations are addressed in this standard practice. However, airborne vibrations can also produce noticeable structural responses. For information on airborne vibrations, the reader is referred to, among others, Siskind et al. 1980(1); Stachura et al. 1981 and 1984.

---

[1] An earlier version of this standard, R 8-81 (1990), was deleted by the Subcommittee on Materials in 1993 and did not appear in the 17th Edition. R 8-96 (2009) is a major revision of this standard practice.

Standard Practice for

Definition of Terms Related to Quality and Statistics As Used in Highway Construction

AASHTO Designation: R 10-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Definition of Terms Related to Quality and Statistics As Used in Highway Construction

AASHTO Designation: R 10-06

1. SCOPE

1.1 This standard practice is to provide standard definitions for terms used in specifications, test methods, and the various quality assurance procedures.

2. GENERAL PROVISIONS

2.1 It is recommended that AASHTO specifications and procedures, including standard practices, incorporate the following accepted terms as defined. These terms and their definitions are directed primarily to the various quality assurance sampling and acceptance plans. Where a definition conflicts with a standard, the standard will govern.

3. DEFINITIONS

3.1 *acceptable quality level (AQL)*—the level of established actual quality for a quality characteristic that is fully acceptable. [For example, when the quality measure used is percent within limits (PWL), the AQL is the established (not estimated) PWL at which the quality characteristic is fully acceptable. Acceptance plans should be designed so that AQL material will receive an expected pay (EP) of 100 percent.]

3.2 *acceptance*—the process whereby all factors used by the agency (i.e., sampling, testing, and inspection) are evaluated to determine the degree of compliance with contract requirements and to determine the corresponding value for a given product.

3.3 *acceptance constant (k)*—the minimum allowable quality index (*Q*). [The acceptance constant *k* is the acceptance limit associated with the quality index quality measure. In other words, for acceptance, *Q* must be greater than or equal to *k*.]

3.4 *acceptance limit*—in variables acceptance plans, the limiting upper or lower value, placed on a quality measure, that will permit acceptance of a lot. [While the test values for material samples are evaluated against specification limits and engineering limits, the computed quality level for a specific quality measure is evaluated against the acceptance limit. For example, the minimum allowable PWL called for in a QA specification might be 65 PWL. This is the acceptance limit.]

3.5 *acceptance number (c)*—in attributes acceptance plans, the maximum number of defective or nonconforming units in the sample that will permit acceptance of the inspected lot or batch.

3.6 *acceptance plan*—also called “acceptance sampling plan” or “statistical acceptance plan. ” An agreed upon process for evaluating the acceptability of a lot of material. It includes: lot size and sample size (i.e., number of samples), quality measure, acceptance limit(s), evaluation of risks, and pay adjustment provisions.

3.7 *acceptance sampling and testing*—sampling and testing performed by the agency, or its designated agent, to evaluate acceptability of the final product. Also called “verification sampling and testing” when specifically used to validate the contractor’s data.

3.8 *acceptance quality characteristic (AQC)*—a quality characteristic that is measured and used to determine acceptability.

3.9 *accepted reference value*—a value that serves as an agreed-upon reference for comparison, and which is derived as: (1) a theoretical or established value, based on scientific principles, (2) an assigned or certified value, based on experimental work of some national or international organization, or (3) a consensus or certified value, based on collaborative experimental work under the auspices of a scientific or engineering group.

3.10 *accredited laboratories*—laboratories which are recognized by a formal accrediting body as meeting quality system requirements including demonstrated competence to perform standard test procedures.

3.11 *action limits*—see *control chart limits*.

3.12 *accuracy*—the degree to which a measurement, or the mean of a distribution of measurements, tends to coincide with the true population mean. [When the true population mean is not known, the degree of agreement between the observed measurements and an accepted reference value may be used to quantify the accuracy of the measurements.]

3.13 *adjusted pay schedule*—see *pay adjustment schedule*.

3.14 *adjusted pay system*—see *pay adjustment system*.

3.15 *aesthetic value*—the worth of an item of construction in terms of pleasing appearance or gratifying performance.

3.16 *alpha* (α) *error*—see *seller’s risk*.

3.17 *alpha sub PF* (α_{PF})—see *seller’s risk*. For acceptance plans with pay adjustments, the probability that acceptable quality level (AQL) material or construction will be assessed a pay factor less than PF with respect to a single acceptance quality characteristic. For example, α_{100} for a compressive strength pay adjustment acceptance plan is the probability that AQL compressive strength material will be assessed less than 100 percent pay for compressive strength; this probability includes the probability of rejection, α_0, with respect to compressive strength. [The use of α_{PF} addresses the need to quantify, for pay adjustment acceptance plans, the probabilities associated with each possible pay decision regarding AQL material (e.g., payment of 0, 70, 80, 90, 100, or 105 percent for AQL material). A seller (contractor) is usually most interested in α_{100}.]

3.18 *alternative hypothesis* (H_a)—the hypothesis to be accepted if the null hypothesis (H_o) is disproved (i.e., rejected).

3.19 *analysis of variance (ANOVA)*—a mathematical method of isolating causes of variation.

3.20 *assignable cause*—a source of variation, usually due to error or process change, which can be detected by statistical methods and corrected within economic limits. [When assignable causes are identified and removed, the production process is “under control”.]

3.21 *attribute*—a characteristic that, by its presence or absence, classifies a unit or segment as conforming or nonconforming.

3.22 *attributes acceptance plan*—a statistical acceptance procedure where the acceptability of a lot of material or construction is evaluated by (1) noting the presence or absence of some characteristic or attribute in each of the units or samples in the group under consideration, and (2) counting how many units do or do not possess this characteristic.

3.23 *average*—a measure of central value that usually refers to the arithmetic mean $(\bar{X})$. May also refer to the median or mode. [The mean, median, and mode are equal for a normal distribution. As a distribution becomes more skewed, the mean, median, and mode will differ more and more.]

3.24 *average absolute deviation (AAD)*—for a series of test results, the mean of absolute deviations from a target or specified value. [Its use as an acceptance measure is not recommended.]

3.25 *average run length (ARL)*—in a sample sense, the average number of times that a process will have been sampled and evaluated before a shift in process level is signaled. In a unit sense, the average number of units that will have been produced before a shift in level is signaled. [A long ARL is desirable for a process located at its specified level (to minimize calling for unneeded investigation or corrective action) and a short ARL is desirable for a process shifted to some undesirable level (so that corrective action will be called for promptly). ARL curves are used to describe the relative quickness in detecting level shifts of various control chart systems.]

3.26 *batch*—a specified quantity of material produced through a uniform operation or process. [A batch is usually smaller than a lot.]

3.27 *beta (*β*) error*—see *buyer's risk*.

3.28 *beta sub PF (*β_{PF}*)*—see *buyer's risk*. For acceptance plans with pay adjustments, the probability that rejectable quality level (RQL) material will be assessed a pay factor greater than or equal to *PF*. For example, β_{100} for a compressive strength pay adjustment acceptance plan is the probability RQL compressive strength material will be assessed 100 percent pay or more for compressive strength. [The use of β_{PF} addresses the need to quantify, for pay adjustment acceptance plans, the probabilities associated with each possible pay decision regarding RQL material (e.g., payment of 0, 70, 80, 90, 100, or 105 percent for RQL material). A buyer (agency) is usually most interested in β_{100}.]

3.29 *bias*—an error, constant in direction, that causes a measurement, or the mean of a distribution of measurements, to be offset from the true population mean.

3.30 *biased sampling*—a sampling procedure whereby samples obtained from a lot do not have an equal probability of being chosen. [Some examples of conventional biased approaches to sampling which have been utilized by agencies and contractors include representative sampling, uniform interval sampling, quota sampling, and selective sampling.]

3.31 *buyer's risk (*β*)*—also called "agency's risk or risk of a Type II" or "beta (β) error. " It is the risk to the agency of accepting rejectable quality level (RQL) material or workmanship. [For an accept/reject acceptance plan, it is the probability that an acceptance plan will erroneously accept RQL material or workmanship with respect to a single acceptance quality characteristic. For variables acceptance plans using adjusted pay schedules, it is equivalent to β_{PF}, where $PF = 100$. It is the probability that a variable payment acceptance plan will erroneously fully accept RQL material or workmanship at 100 percent pay or greater with respect to a single acceptance quality characteristic.]

3.32 *calibration*—a set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or between values represented by a material measure or a reference material, and the corresponding values realized by standards. [The purpose of calibration is to ensure that measurements made by the laboratory are traceable to the International System of Units (SI). Where traceability of measurements to SI units is not possible or relevant, measurements must be traceable to certified reference materials, agreed methods, or consensus standards. Uncertainty estimates obtained during calibration are used to judge if an instrument is suitable for its intended purpose. There is a need to re-establish traceability or recalibrate only when instrument measurements drift out of control (as determined through verification of calibration). See *standardization.*]

3.33 *certified technician*—a technician certified by some agency as proficient in performing certain duties. [A certified technician is considered to be qualified. A qualified technician may or may not be certified. See *qualified technician*.]

3.34 *chance cause*—a source of variation that is inherent in any production process and cannot be eliminated because it is due to random, expected causes.

3.35 *characteristic*—a measurable property of a material, product, or item of construction.

3.36 *class*—a group of data values (measurements, observations, or test values) that all satisfy a given set of conditions associated with a frequency distribution.

3.37 *class frequency*—the number of data values falling into a particular class.

3.38 *classification*—the acts of evaluating if an attribute or variable does or does not conform to requirements, and the documentation of results.

3.39 *class interval*—the difference in value between the lower and the upper limits of a given class.

3.40 *class limits*—the upper and lower values that define a given class.

3.41 *class midpoint*—the central value of a particular class.

3.42 *cluster sampling*—the random selection of clusters (i.e., groups or bundles) from a population. For each cluster selected, random sampling of the contained elements may then be performed. [Examples of cluster sampling are selection of city blocks as primary sampling units; selection of a household as a cluster of people (of which only one may be interviewed); selection of bundles of rods or pipe from a shipment; and selection, from a shipment, of cartons that contain boxes or packages within them.]

3.43 *coefficient of determination* (r^2)—a measure of the relationship between a single dependent random variable or response Y and a known independent variable X. It represents the proportion of the total variation of Y due to X. For instance, if $r^2 = 0.81$ ($r = \pm 0.9$. See *correlation coefficient*.), then 81 percent of the variation in the values of Y may be accounted for by the relationship with the variable X. [The value of r^2 from a regression model cannot be evaluated as “good” or “bad” in singularity; it can only be judged relative to other models that have been estimated on similar phenomena. Thus, an r^2 of 0.30 for one phenomenon might be extremely informative, while for another phenomenon it might be uninformative.]

3.44 *coefficient of variation* (v)—the ratio of the standard deviation to the mean expressed as a percent. It provides a measure of dispersion or spread relative to the mean.

3.45 *combined pay factor*—see *composite pay factor*.

3.46 *component of variance*—a part of the total variance identified with a specified source of variability.

3.47 *composite pay factor*—also called “combined pay factor or overall pay factor.” A multiplication factor, often expressed as a percentage, which considers two or more quality characteristics and is used to determine the contractor’s final payment for a unit of work. [It is usually established using a performance model and life-cycle cost analysis.]

3.48 *computer simulation*—use of a computer to generate conditions approximating actual or operational conditions. [Computer simulation is a powerful and convenient tool to solve certain problems that are intractable by other methods.]

3.49 *confidence interval*—an estimate of an interval in which the estimated parameter will lie with predetermined probability (called the confidence level).

3.50 *confidence level*—if a large number of confidence intervals are constructed, the proportion of time that the estimated parameter will lie within the interval. [A confidence level is usually expressed as a percentage, typically ranging from 90 to 99 percent. *Confidence level* = 1 – α.]

3.51 *confidence limits*—the end points of a confidence interval.

3.52 *conflict resolution*—see *dispute resolution*.

3.53 *conformal index (CI)*—a measure of the dispersion of a series of results around a target or specified value, expressed as the square root of the quantity obtained by summing the squares of the deviations from the target value and dividing by the number of observations. The standard deviation is a measure of precision, but the CI is a measure of exactness (accuracy) or degree of conformance with the target. [Its use as an acceptance measure is not recommended.]

$$CI = \sqrt{\sum\left(X_i - T\right)^2 / n} \qquad (1)$$

3.54 *conformance*—an affirmative indication or judgment that a product or process has met project requirements; also, the state of having met the requirements.

3.55 *control chart*—also called “statistical control chart.” A graphical plot of quality control measurements or test results used to identify variation in a production or placement process due to either chance causes or assignable causes. [Control charts have statistically derived control limits. Plotted values may be for individual measurements or the averages of groups of measurements. The control limits can be established statistically based on sample sizes of $n = 1$ or $n > 1$. Sample sizes of $n > 1$ are preferred, with sample sizes of $n = 3$, 4, or 5 being the most common.]

3.56 *control chart factor*—a factor, varying with sample size, to convert specified statistics or parameters into a central line value or control limit appropriate to the control chart.

3.57 *control chart method*—the method of using control charts to determine whether or not processes are in a stable state.

3.58 *control chart limits*—also called “action limits.” Statistically derived boundaries applied to a control chart in controlling material production or placement. [Control chart limits are expressed as the upper control limit (UCL) and the lower control limit (LCL). When values of the material characteristics fall within these limits, the process is “under control.” When values fall outside the limits, there is an indication that some assignable cause is present causing the process to be “out of control.”]

3.59 *controlled process*—a production process in which the mean and variability of a series of tests on the product remain stable, with the variability due to chance cause only. [A process might be “under control” but produce out-of-specification material if the specification limits are tight. Similarly, a process might be “out of control” in that the mean or variability is outside of control limits, yet the specification limits might be wide enough that the material produced is within specifications.]

3.60 *correlation coefficient (r)*—a measure of the relationship between a single dependent (response) random variable *Y* and a known independent variable *X*. [The correlation coefficient ranges in value from –1 to +1, indicating a perfect negative relationship at –1, absence of relationship at 0, and perfect positive relationship at +1. Thus, when *Y* varies directly with *X*, the correlation coefficient is positive; when *Y* bears an inverse relationship to *X*, the correlation coefficient is negative. See *coefficient of determination.*]

3.61 *criticality*—the classification of contract requirements by the degree to which they affect safety, performance, or life-cycle cost.

3.62 *data*—measurements or test values organized for computation or analysis.

3.63 *defect*—a failure to meet a requirement with respect to a single quality characteristic.

3.64 *defective*—having one or more defects.

3.65 *dependent variable*—see *response variable*.

3.66 *design of experiments*—also called “experimental design.” The arrangement in which an experimental program is to be conducted, and the selection of the levels (versions) of one or more factors or factor combinations to be included in the experiment.

3.67 *deviation*—the difference between an individual value and its stated value or intended level. [In practice, deviation is usually taken to infer the deviation from the mean or deviation from the target value.]

3.68 *disincentive*—a pre-established decrease in payment to the contractor applied to a contract bid item for which the level of materials quality and workmanship, determined by statistical means, does not meet the specified acceptable quality level (AQL). The disincentive is usually expressed as a percentage of the original contract bid price.

3.69 *dispersion*—the extent to which data values are scattered about a target or central value.

3.70 *dispute resolution*—also called “conflict resolution.” The procedure used to resolve conflicts resulting from discrepancies between the agency’s and contractor’s results of sufficient magnitude to impact payment. [The procedure may, as an initial step, include the testing of independent samples and, as a final step, third-party arbitration.]

3.71 *distribution*—an arrangement of data which shows the frequency of occurrence of each successive individual measurement or range of measurements.

3.72 *distribution curve*—the smooth curve describing an arrangement of data that shows the frequency of occurrence.

3.73 *documentation*—proof in the form of detailed records or charts supporting the effectiveness of a quality assurance system.

3.74 *end-result specifications*—specifications that require the contractor to take the entire responsibility for producing and placing a product. The highway agency’s responsibility is to either accept or reject the final product or to apply a pay adjustment that is commensurate with the degree of compliance with the specifications. [End-result specifications have the advantage of allowing the contractor flexibility in exercising options for new materials, techniques, and procedures to improve the quality and/or economy of the end product.]

3.75 *engineering limits*—the absolute limiting value(s) placed on a quality characteristic beyond which the result for an individual sample is considered to be unacceptable. [Engineering limits are established to identify material that does not provide the minimum required engineering properties. They usually have an upper engineering limit (UEL), a lower engineering limit (LEL), or both. The engineering limits may be the same as the specification limits.]

3.76 *estimator*—a statistic used to estimate a parameter to help describe the population. [The estimate may be given as a point estimate or as an interval estimate.]

3.77 *event*—the occurrence, or absence, of an attribute.

3.78 *expected pay (EP) curve*—a graphical representation of an acceptance plan that shows the relationship between the established actual quality of a lot and its expected pay. [The EP is the mathematical pay expectation, or average pay the contractor can expect to receive over the long run for submitted lots of a given quality. The EP should be 100 percent pay for AQL material. Both OC and EP curves should be used to evaluate how well an acceptance plan is theoretically expected to work.]

3.79 *experimental design*—see *design of experiments*.

3.80 *F-test (F-statistic)*—a hypothesis test involving the comparison of the variances of two sets of data. The null hypothesis is the variance of one population equals the variance of another population.

3.81 *frequency*—the number of items or values that occur within a given interval (or class).

3.82 *frequency distribution*—a grouping of data values into intervals (or class intervals) showing the number of values in each interval.

3.83 *frequency histogram*—also called “histogram.” A type of bar chart that depicts the frequency of occurrence of each data value as a rectangle (or bar). The width of each rectangle represents the data interval, while the height represents the number of data values in the interval (or class interval).

3.84 *frequency polygon*—a broken line graph constructed by drawing line segments that join the mid-points of the top of each rectangle (or bar) in a frequency histogram.

3.85 *frequency table*—a tabular presentation of data consisting of a minimum of two columns. One column presents the data intervals (or classes) in some useful order and the other column presents the corresponding frequencies.

3.86 *graduated reduction in contract price*—reductions that are initially small for slight deviations from specified requirements but increase rapidly as the size of deviations increases.

3.87 *grand mean*—the sum of the means of sets or subgroups of data divided by the total number of sets or subgroups.

3.88 *histogram*—see *frequency histogram*.

3.89 *hypothesis*—a tentative theory or supposition provisionally adopted to explain certain facts and to guide in the investigation of others. It is a statement concerning the value of a population parameter which can be tested statistically to determine the validity of the statement.

3.90 *hypothesis test*—a statistical procedure based on probability theory used to determine whether a hypothesis is a reasonable statement and should not be rejected, or is unreasonable and should be rejected. [Reasonableness is determined by testing the hypothesis at a specific level of statistical significance.]

3.91 *incentive/disincentive provision (for quality)*—a pay adjustment schedule which functions to motivate the contractor to provide a high level of quality. [A pay adjustment schedule, even one which provides for pay increases, is not necessarily an incentive/disincentive provision, as individual pay increases/decreases may not be of sufficient magnitude to motivate the contractor toward high quality.]

3.92 *increments*—small quantities of material of equal size that are obtained from a sampling location and combined to form a sample.

3.93 *independent assurance (IA)*—activities that are an unbiased and independent evaluation of all the sampling and testing (or inspection) procedures used in the quality assurance program. [IA provides an independent verification of the reliability of the acceptance (or verification) data obtained by the agency and the data obtained by the contractor. The results of IA testing or inspection are not to be used as a basis of acceptance. IA provides information for quality system management.]

3.94 *independent sample*—a sample taken without regard to any other sample that may also have been taken to represent the material in question. [An independent sample is sometimes taken to verify an acceptance decision. This is possible because the data sets from independent samples, unlike those from split samples, each contain independent information reflecting all sources of variability, i.e., sampling, testing, materials, and construction.]

3.95 *independent t-test*—a hypothesis test involving the comparison of the means of two independently obtained sets of data. The null hypothesis is the mean of one normal population equals the mean of another normal population.

3.96 *inference*—a logical conclusion about a population based on a sample.

3.97 *inherent variability*—also called “inherent variance.” The effect of random or inconsequential causes in a given process. [The four components of inherent variability include sampling variability, testing variability, materials variability, and construction variability.]

3.98 *iteration*—(1) the act or process of repeating something; a replication. [Iteration, as opposed to replication, is the preferred term for use with respect to Monte Carlo simulations.] (2) The method of successive trials, each trial producing a result that successively better approximates the desired result.

3.99 *item*—an object or quantity of material on which a set of observations can be made.

3.100 *kurtosis*—the degree of peakedness in a probability distribution. For the normal distribution, the kurtosis coefficient equals 0. A positive kurtosis coefficient indicates a relatively peaked distribution in comparison with the normal distribution, while a negative coefficient indicates a relatively flat distribution.

Population kurtosis coefficient:

$$\gamma_2 = \left[\sum \left(X_i - \mu \right)^4 / n\sigma^4 \right] - 3 \tag{2}$$

Sample kurtosis coefficient:

$$g_2 = \left[n\left(n+1\right) \sum \left(X_i - \bar{X} \right)^4 \Big/ s^4 \left(n-1\right)\left(n-2\right)\left(n-3\right) \right] - \left[3\left(n-1\right)^2 \Big/ \left(n-2\right)\left(n-3\right) \right] \tag{3}$$

3.101 *linear regression*—see *simple linear regression*.

3.102 *lot*—a specific quantity of material from a single source which is assumed to be produced or placed by the same controlled process.

3.103 *lot acceptance plan*—see *acceptance plan*.

3.104 *lower control limit (LCL)*—see *control chart limits*.

3.105 *lower specification limit (LSL)*—the lower statistically based limiting value associated with a quality characteristic and used to evaluate the acceptability of a lot.

3.106 *materials and construction (M&C) variable*—a characteristic of materials and/or construction that can be directly or indirectly controlled. Thickness is an example of an *M&C* variable that is controlled directly; compressive strength is an example of one controlled indirectly.

3.107 *materials and methods specifications*—see *method specifications.*

3.108 *materials sample*—see *sample.*

3.109 *mean* $(\bar{X})$—the arithmetic average of a set of measurements or test values.

3.110 *median*—a type of average. The midpoint of an array of values after they have been ordered from the smallest to the largest, or the largest to the smallest. There are as many values above the median as below it in the data array.

3.111 *method of least squares*—a technique of estimation of a parameter which minimizes Σe^2, where e is the difference between the observed value and the predicted value derived from the assumed model.

3.112 *method specifications*—also called “materials and methods specifications.” Specifications that require the contractor to produce and place a product using specified materials in definite proportions and specific types of equipment and methods under the direction of the agency. [Experience has shown this tends to obligate the agency to accept the completed work regardless of quality.]

3.113 *mixture design*—also called “mix design.” (1) The process of determining and quantifying the required characteristics of a mixture, including developing, evaluating, and testing trial mixtures to verify that the required characteristics can be met. For portland cement concrete (PCC) mixtures, some examples of required characteristics are workability, durability, and strength; and for hot mix asphalt (HMA), examples are rutting resistance and fatigue cracking resistance. [The mixture design process leads to the development of a mixture specification.] (2) A quantified description (resulting from the mixture design process) of a mixture developed, evaluated, and tested to meet the specifications.

3.114 *mixture proportioning*—the identification of mixture ingredients and the selection of appropriate quantities of these ingredients to fulfill the mixture design. [The mixture proportioning process results in a quantification of the mixture ingredients by weight or by volume.]

3.115 *mode*—a type of average. The value in a distribution that occurs most frequently. For grouped data, it is the midpoint of the class containing the most values.

3.116 *Monte Carlo simulation*—a simulation technique (usually performed by a computer and particularly useful for QA applications) that uses random numbers to sample from probability distributions to produce hundreds or thousands of scenarios (called iterations, trials, or runs). [A complete Monte Carlo simulation thus uses each result from each individual iteration.]

3.117 *multiple deficiencies*—more than one defect in a unit of product with respect to the characteristic(s) under consideration.

3.118 *multiple linear regression*—a means of predicting a dependent (response) random variable *Y*, using more than one known independent variable X_i. [The so-called independent variables are independent of *Y* but not necessarily independent among themselves. $Y = a + bX_1 + cX_2$, where $X_2 = \sin X_1^2$ is an example of a multiple linear regression equation. Note that in all cases X_i may be any function, not necessarily of the first degree. The concept of linear is that used in linear algebra—namely the parameters occur linearly.]

3.119 *music bar chart*—see *run chart*.

3.120 *n*—see *sample size*. The symbol for the number of samples or sample measurements obtained and used in a statistical analysis.

3.121 *non-central t distribution*—also called "noncentral Student t distribution." The noncentral *t* distribution is a generalization of the Student *t* distribution and is used when the population mean and standard deviation are both unknown. If $\overline{x}$ and *s* are the mean and standard deviation of an independent random sample of size *n* from a normal distribution with mean μ and $\sigma^2 = n$, then

$$t(v) = \frac{\overline{x} - \mu}{s} \tag{4}$$

$$v = n - 1 \tag{5}$$

When the mean of the normal distribution is not μ, then the ratio has the noncentral *t* distribution. The noncentrality parameter is the difference between the sample mean and μ. The noncentral *t* distribution allows us to determine the probability that we would detect a difference between $\overline{X}$ and μ in a *t*-test. The formula for the probability that a noncentral *t* variate falls in the range [–*t*, *t*] is:

$$\Pr((-t) < \overline{x} < t \,|\, (v, \delta)) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta^2\right)^j}{j!} e^{\frac{\delta^2}{2}} \right) I\left(\frac{\overline{x}^2}{v + \overline{x}^2} \,\middle|\, \frac{1}{2} + j, \frac{v}{2} \right) \tag{6}$$

where *I*(*x*|*a*,*b*) is the incomplete beta function with parameters *a* and *b*, δ is the noncentrality parameter, and ν is the degrees of freedom.

3.122 *nonlinear regression*—a means of predicting a dependent (response) random variable *Y*, using an equation in which the parameters do not occur linearly. The exponential equation, $Y = ae^{bx+c}$, is an example of a nonlinear regression equation. [However, by taking the logarithm to the base *e*, the equation can be transformed into the form $\log_e Y = \log_e a + bX + c$. Such a model is called intrinsically linear. On the other hand, $Y = e^{-ax} - e^{-bx}$ cannot be transformed; such a model is called intrinsically nonlinear.]

3.123 *normal curve*—see *standard normal distribution*.

3.124 *normal distribution*—see *standard normal distribution*.

3.125 *normality*—the state of being normally distributed or having a normal distribution.

3.126 *null hypothesis* (H_o)—the hypothesis being tested. [Contrary to intuition, the null hypothesis is often a research hypothesis that the analyst would prefer to reject in favor of the alternative hypothesis. The null hypothesis can never be proved true. It can, however, be shown, with specified risks of error, to be untrue. If it is not disproved (i.e., not rejected), one usually acts on the assumption that there is no reason to doubt that it is true.]

3.127 *observation*—(1) the process of obtaining information regarding the presence or absence of an attribute of a test specimen, or of making a reading on a characteristic or dimension of a test specimen, or (2) the attribute or measurement information obtained from the process. [The term "observed value" is preferred for this second usage.]

3.128 *observed value*—the value obtained by carrying out the complete protocol of the test method once, being either a single test determination or an average or other specified combination of a specified number of test determinations.

3.129 *operating characteristic (OC) curve*—a graphic representation of an acceptance plan that shows the relationship between the actual quality of a lot and either (1) the probability of its acceptance or (2) the probability of its acceptance at various payment levels.

3.130 *overall pay factor*—see *composite pay factor*.

3.131 *paired t-test*—also called "*t*-test for paired measurements (samples)." A statistical test used to compare the test values for multiple pairs of split samples. The test uses the differences between the pairs of test values and determines whether the average difference from 0 is statistically significant.

3.132 *parameter*—a constant or coefficient that describes some characteristic of a population. Some examples of parameters are the population standard deviation, the population mean, and the population regression coefficients. [In most highway QA applications, the true population parameter value is unknown. The parameter value can be estimated by calculating a statistic from the sample data.]

3.133 *pavement condition indicator*—also called "pavement distress indicator." A measure of the condition of an existing pavement section at a particular point in time, such as cracking measured in ft/mi or in mm/km, or wheel path faulting measured in in./mi or mm/km. [When considered collectively, pavement condition indicators provide an estimate of the overall adequacy of a particular roadway.]

3.134 *pavement distress indicator*—see *pavement condition indicator*.

3.135 *pavement performance*—the history of pavement condition indicators over time or with increasing axle load applications.

3.136 *pay adjustment*—the actual amount, either in dollars or in dollars per area/weight/volume, that is to be added or subtracted to the contractor's bid price or unit bid price.

3.137 *pay adjustment schedule (for quality)*—also called "price adjustment schedule" or "adjusted pay schedule." A pre-established schedule, in either tabular or equation form, for assigning pay factors associated with estimated quality levels of a given characteristic. The pay factors are usually expressed as percentages of the contractor's bid price per unit of work but may also be given as direct dollar amounts.

3.138 *pay adjustment system (for quality)*—also called "price adjustment system" or "adjusted pay system." All pay adjustment schedules along with the equation or algorithm that is used to determine the overall pay factor for a submitted lot of material or construction. [A pay adjustment system, and each pay adjustment schedule, should yield sufficiently large pay increases/decreases to provide the contractor sufficient incentive/disincentive for high/low quality.]

3.139 *pay factor (PF)*—a multiplication factor, often expressed as a percentage, that considers a single quality characteristic and is used to determine the contractor's payment for a unit of work.

3.140 *percent conforming*—for attribute acceptance plans, the percentage of units having no departure of an attribute from its intended level. [Percent conforming + percent nonconforming = 100.]

3.141 *percent defective (PD)*—the percentage of the lot falling outside specification limits. $PD = 100 - PWL$. [PD may refer to either the population value or the sample estimate of the population value. The term "percent nonconforming" should not be used as a synonym for PD.]

3.142 *percent nonconforming*—the percentage of units having at least one departure of an attribute from its intended level.

3.143 *percent within limits (PWL)*—the percentage of the lot falling above a lower specification limit, beneath an upper specification limit, or between upper and lower specification limits. $PWL = 100 - PD$. [PWL may refer to either the population value or the sample estimate of the population value. The term "percent conforming" should not be used as a synonym for PWL.]

3.144 *performance specifications*—specifications that describe how the finished product should perform over time. [For highways, performance is typically described in terms of changes in physical condition of the surface and its response to load, or in terms of the cumulative traffic required to bring the pavement to a condition defined as "failure." Specifications containing warranty/guarantee clauses are a form of performance specifications. Other than the warranty/guarantee type, performance specifications have not been used for major highway pavement components (subgrades, bases, riding surfaces) because there have not been suitable nondestructive tests to measure long-term performance immediately after construction. They have been used for some products (e.g., highway lighting, electrical components, and joint sealant materials) for which there are suitable tests of performance.]

3.145 *performance-based specifications*—quality assurance specifications that describe the desired levels of fundamental engineering properties (e.g., resilient modulus, creep properties, and fatigue) that are predictors of performance and appear in primary prediction relationships (i.e., models that can be used to predict stress, distress, or performance from combinations of predictors that represent traffic, environment, supporting materials, and structural conditions).

3.146 *performance-related specifications*—quality assurance specifications describing the desired levels of key materials and construction quality characteristics that have been found to correlate with fundamental engineering properties that predict performance. These characteristics (e.g., air voids in hot mix asphalt (HMA) pavements and compressive strength of portland cement concrete) are amenable to acceptance testing at the time of construction. [True performance-related specifications not only describe the desired levels of these quality characteristics, but also employ the quantified relationships containing the characteristics to predict as-constructed pavement performance. They thus provide the basis for rational acceptance/pay adjustment decisions.]

3.147 *performance-related variable*—a characteristic of materials and/or construction that has an influence on performance, either by itself or interactively when in combination with other *M&C* variables. [Any variable that is a primary or secondary predictor is a performance-related variable.]

3.148 *polynomial regression*—a means of predicting a dependent (response) random variable Y, using a known independent variable X, through a polynomial equation. $Y = a X^2 + bX + c$ is an example of a curvilinear, polynomial regression equation.

3.149 *pooled sample standard deviation* (S_p)—the square root of the pooled variance. See *pooled sample variance*.

$$S_p = \sqrt{\frac{s_p^2\left(n_1 - 1\right) + s_2^2\left(n_2 - 1\right) + \ldots s_x^2\left(n_x - 1\right)}{n_1 + n_2 + \ldots n_x - N}} \qquad (7)$$

where:

s_x = the sample standard deviation of each data set,

n_x = the number of results in each data set, and

N = the total number of data sets.

3.150 *pooled sample variance* (s_p^2)—a weighted average of sample variances each weighted by the degrees of freedom ($n_x - 1$). [The pooled sample variance is used when an average of several sample variances represented by different sample sizes is desired.]

$$S_p^2 = \frac{s_1^2\left(n_1 - 1\right) + s_2^2\left(n_2 - 1\right) + \ldots s_x^2\left(n_x - 1\right)}{n_1 + n_2 + \ldots n_x - N} \qquad (8)$$

where:

s_x = the sample standard deviation of each data set,

n_x = the number of results in each data set, and

N = the total number of data sets.

3.151 *population*—a collection of all possible individuals, objects, or items that possess some common specified characteristic(s) which can be measured.

3.152 *population standard deviation* (σ)—a measure of the dispersion of a complete series of results around their mean. The population standard deviation is the square root of the population variance.

$$\sigma = \sqrt{\frac{\sum\left(x - \mu\right)^2}{n}} \qquad (9)$$

3.153 *population variance* (σ^2)—a measure of the dispersion of a complete series of results around their mean, expressed as the sum of the squares of the deviations from the mean of the results divided by the number of observations.

$$\sigma^2 = \sqrt{\frac{\sum\left(x - \mu\right)^2}{n}} \qquad (10)$$

3.154 *power curve*—a curve, used in hypothesis testing, to indicate the probability of rejecting a hypothesis. The curve shows the relation between the probability (1–β) of rejecting the hypothesis that a sample belongs to a given population with a given characteristic and the actual population value of that characteristic. [If β is plotted instead of (1–β), the curve is analogous to the OC curve used in accept/reject acceptance plans.]

3.155 *precise*—see *precision*.

3.156 *precision*—(1) the degree of agreement among a randomly selected series of measurements; or (2) the degree to which tests or measurements on identical samples tend to produce the same results.

3.157 *prescriptive specifications*—see *method specifications*.

3.158 *present serviceability index (PSI)*—a mathematical combination of values obtained from certain physical measurements of a large number of pavements, so formulated as to predict a serviceability rating for those pavements within prescribed limits.

3.159 *price adjustment schedule*—see *pay adjustment schedule*.

3.160 *price adjustment system*—see *pay adjustment system*.

3.161 *primary prediction relationship*—an equation that can be used to predict stress, distress, or performance from particular combinations of predictor variables that represent traffic, environmental, roadbed, and structural conditions. Some examples of predictor variables are annual rate of equivalent single axle load accumulation, annual precipitation, roadbed soil modulus, and concrete flexural strength.

3.162 *probability factor*—a tabular value which, when multiplied by the standard deviation of a group of measurements, indicates the frequency or probability of occurrence of measurements within a specified range.

3.163 *probability sample*—one in which every increment in the lot has a known chance of inclusion. [A probability sample in which each increment in the lot has an equal probability of being chosen is known as a random sample.]

3.164 *probability sampling*—a method of making use of the laws of chance for the purpose of selecting increments on which measurements are to be made.

3.165 *process control*—see *quality control*.

3.166 *process control materials and construction (M&C) variable*—a characteristic of materials and/or construction whose specification enhances the control of another M&C variable. An example of a process control M&C variable is soil moisture content to control density and compaction.

3.167 *process under statistical control*—see *controlled process*.

3.168 *product reliability*—see *reliability*.

3.169 *Q table*—a table of values that relates the quality indices (Q_U or Q_L) to the estimated percent within limits (PWL) or percent defective (PD) for a sample of a particular size (n).

3.170 *qualified technician*—a technician that has been determined to be qualified (i.e., meeting some minimum standard) to perform specific duties. [A qualified technician may or may not be certified. See *certified technician*.]

3.171 *quality*—(1) the degree of excellence of a product or service; (2) the degree to which a product or service satisfies the needs of a specific customer; or (3) the degree to which a product or service conforms with a given requirement.

3.172 *quality assurance (QA)*—(1) all those planned and systematic actions necessary to provide confidence that a product or facility will perform satisfactorily in service; or (2) making sure the quality of a product is what it should be. [QA addresses the overall process of obtaining the quality of a service, product, or facility in the most efficient, economical, and satisfactory manner possible. Within this broad context, QA includes the elements of quality control, independent assurance, acceptance, dispute resolution etc. The use of the term QA/QC or QC/QA is discouraged and the term QA should be used. QA involves continued evaluation of the activities of planning, design, development of plans and specifications, advertising and awarding of contracts, construction, and maintenance, and the interactions of these activities.]

3.173 *quality assurance specifications*—specifications that require contractor quality control and agency acceptance activities throughout production and placement of a product. Final acceptance of the product is usually based on a statistical sampling of the measured quality level for key quality characteristics. [QA specifications typically are statistically based specifications that use methods such as random sampling and lot-by-lot testing, which let the contractor know if the operations are producing an acceptable product.]

3.174 *quality characteristic*—a product attribute that is measured either for quality control (QC) purposes or for conformance with acceptance requirements. [Quality characteristics are specific material properties which are evaluated by QC and acceptance sampling and testing. Quality characteristics which are specified are typically selected because they: (a) relate to initial and long-term performance; (b) are quantifiable or measurable; and (c) can be measured with good repeatability.]

3.175 *quality control(QC)*—also called “process control.” The system used by a contractor to monitor, assess and adjust their production or placement processes to ensure that the final product will meet the specified level of quality. Quality control includes sampling, testing, inspection and corrective action (where required) to maintain continuous control of a production or placement process.

3.176 *quality control plan*—a project-specific document prepared by the contractor that identifies all QC personnel and procedures that will be used to maintain all production and placement processes “in control” and meet the agency specification requirements. The document also addresses actions to be taken in the event that a process goes “out of control”.

3.177 *quality index (Q)*—a statistic which, when used with appropriate tables, provides an estimate of either the percent within limits (PWL) or the percent defective (PD) for a Lot. [It is typically computed from the mean and standard deviation of a set of sample values. The lower quality index (Q_L) is computed relative to the lower specification limit (LSL). The upper quality index (Q_U) is computed relative to the upper specification limit (USL).]

$$Q_L = \frac{\bar{X} - L}{s} \tag{11}$$

where:

$\bar{X}$ = sample mean, and

s = sample standard deviation,

or

$$Q_U = \frac{U - \bar{X}}{s} \tag{12}$$

L = lower specification limit, and

U = upper specification limit.

3.178 *quality-level analysis (QLA)*—a statistical procedure that provides an estimate of the percentage of a given lot that is within specification limits (PWL) or outside specifications limits (PD).

3.179 *quality limits*—the upper or lower limiting values provided in the specifications that are used to evaluate the acceptability of materials produced or placed. [There are three general types of quality limits that are typically included in quality assurance specifications. They include: specification limits, engineering limits, and acceptance limits. Although each type of quality limit serves a different specific function, they are used together to evaluate the acceptability of a lot.]

3.180 *quality measure*—any one of several mathematical tools that are used to quantify the level of quality of an individual quality characteristic. [Typical quality measures used in quality assurance are selected because they quantify the average quality, the variability, or both. Examples of quality measures that may be used include; mean, standard deviation, percent defective (PD), percent within limits (PWL), average absolute deviation (AAD), moving average, and conformal index (CI). PWL or PD are the quality measures that are recommended for use in quality assurance specifications.]

3.181 *quantified checklist*—a list of characteristics that are classified by attribute state, and the results converted to numbers by calculating the percent conforming.

3.182 *quota sampling*—a procedure in which samples are obtained at the discretion and convenience of the sampler to satisfy the required number of samples for a lot. [This procedure may result in random or non-random samples being obtained.]

3.183 *R chart*—a control chart that plots the range (*R*) values for subgroups of measurements or test values against statistically derived control limits.

3.184 *random*—depending entirely on chance.

3.185 *random distribution*—a distribution of values resulting from chance alone.

3.186 *random error of result*—a component of the error, which in the course of a number of test results for the same characteristic, varies in an unpredictable way.

3.187 *random locations*—sampling locations determined by the use of random numbers.

3.188 *random number*—a number selected entirely by chance as from a random number table or a random number generator.

3.189 *random number table*—a collection of digits, randomly displayed in columns and rows, that are used to determine random numbers.

3.190 *random sample*—a sample in which each increment in the lot has an equal probability of being chosen. [Samples are taken at times or locations chosen by a method not influenced by opinion or judgment thus eliminating any bias.]

3.191 *random sampling*—a sampling procedure whereby each sample obtained from the lot has an equal probability of being selected.

3.192 *range*—the difference between the highest individual value and the lowest individual value in a set of sample values.

3.193 *realistic values*—Values that can be expected to be obtained under normal conditions.

3.194 *recipe specifications*—see *methods specifications*.

3.195 *rejectable quality level (RQL)*—the level of established actual quality for a quality characteristic that is rejectable when using a particular quality measure. [For example, when the quality measure used is percent within limits (PWL), the RQL is the established (not estimated) PWL at which the quality characteristic is rejected. It is desired to require removal and replacement, corrective action, or the assignment of a relatively low pay factor when RQL work is detected.]

3.196 *reliability*—the degree to which a test produces consistent or dependable results. [Test reliability is increased as both precision and accuracy are improved.] Reliability can also refer to product reliability, defined as (1) the degree of conformance or failure of the specific product to meet the consumer's quality needs; and (2) the probability of a product performing without failure a specified function under given conditions for a specified period of time. In (1) and (2), reliability is that aspect of quality assurance that is concerned with the quality of product function over time. Another quality assurance usage of the term reliability is within the context of pavement design, where a reliability factor is employed to address the uncertainty associated with predicting pavement performance at the time of design.

3.197 *repeatability*—degree of variation among the results obtained by the same operator repeating a test on the same material. The term repeatability is therefore used to designate test precision under a single operator.

3.198 *repeatability conditions*—conditions where independent test results are obtained with the same method on identical test items in the same laboratory by the same operator using the same equipment within short intervals of time. [See *precision.* The "same operator, same equipment" requirement means that for a particular step in the measurement process, the same combination of operator and equipment is used for every test result. Thus, one operator may prepare the test specimens, a second measure the dimensions and a third measure the mass in a test method for determining density. By "within short intervals of time" is meant that the test results, at least for one material, are obtained in a time period not less than in normal testing and not so long as to permit significant change in test material, equipment or environment.]

3.199 *repeatability limit (r)*—the value below which the absolute difference between two individual test results obtained under repeatability conditions may be expected to occur with a probability of approximately 0.95 (95 percent). [The repeatability limit is 2.8 ($\approx 1.96\sqrt{2}$) times the repeatability standard deviation. This multiplier is independent of the size of the interlaboratory study, as explained in ASTM E 177.2. The approximation to 0.95 is reasonably good (say 0.90 to 0.98) when many laboratories (30 or more) are involved, but is likely to be poor when fewer than eight laboratories are studied.]

3.200 *repeatability standard deviation* (S_r)—the standard deviation of test results obtained under repeatability conditions. [It is a measure of the dispersion of the distribution of test results under repeatability conditions. In an interlaboratory study, this is the pooled sample standard deviation of test results obtained under repeatability conditions. See ASTM E 691. The repeatability standard deviation, usually considered a property of the test method, will generally be smaller than the within-laboratory standard deviation.]

3.201 *replicate sample*—two or more samples taken under identical conditions. [Replicate samples may be taken to estimate sampling and testing variability, for possible use if a dispute arises, or simply because they are required to calculate a test result (e.g., the average of two cylinders to calculate the compressive strength of concrete). See *split sample.*]

3.202 *replication*—(1) the act or process of duplicating or repeating something; an iteration; or (2) the execution of an experiment more than once to increase precision and to obtain a better estimate of the residual variation (i.e., the remaining variation in a set of data after the variation due to certain effects, factors, and interactions has been removed). [Replication, as opposed to iteration, is the preferred term for use with respect to experimental design.]

3.203 *representative sample*—a single, non-random sample which, in the opinion of the sampler, represents an average condition of a material or an item of construction.

3.204 *reproducibility*—degree of variation among the test results obtained by different operators performing the same test on the same material. [It measures the human influence or human error in the execution of a test. The term reproducibility is used to designate inter-laboratory test precision.]

3.205 *reproducibility conditions*—conditions where test results are obtained with the same method on identical test items in different laboratories with different operators using different equipment.

[Identical test items means either the same test units or test specimens are tested by all the laboratories as for a nondestructive test or test units or test specimens are taken at random from a single quantity of material that is as nearly homogeneous as possible. A different laboratory of necessity means a different operator, different equipment, different location, and under different supervisory control.]

3.206 *reproducibility limit (R)*—the value below which the absolute difference between two test results obtained under reproducibility conditions may be expected to occur with a probability of approximately 0.95 (95 percent). [The reproducibility limit is 2.8 ($\approx 1.96\sqrt{2}$) times the reproducibility standard deviation. The multiplier is independent of the size of the interlaboratory study (that is, of the number of laboratories participating), as explained in ASTM E 177.2. The approximation to 0.95 is reasonably good (e.g., 0.90 to 0.98) when many laboratories (30 or more) are involved but is likely to be poor when fewer than eight laboratories are studied.]

3.207 *reproducibility standard deviation (S_R)*—the standard deviation of test results obtained under reproducibility conditions. [The reproducibility standard deviation includes, in addition to between-laboratory variability, the repeatability standard deviation and a contribution from the interaction of laboratory factors (i.e., differences between operators, equipment and environments) with material factors (i.e., the differences between properties of the materials other than that property of interest).]

3.208 *re-sampling*—the process of obtaining a new sample, if warranted, to replace the original sample for an individual sublot. [See *re-testing*.]

3.209 *residual error*—the difference between the observed result and the predicted value (estimated treatment response), i.e., the observed result minus predicted value.

3.210 *response variable*—also called *dependent variable*. The variable that shows the observed results of an experimental treatment.

3.211 *re-testing*—the process of performing another test to confirm the initial test. Re-testing should be performed using a second test portion or specimen prepared from the same original sample. [See *re-sampling.*]

3.212 *risk of a Type I error*—see *seller's risk*.

3.213 *risk of a Type II error*—see *buyer's risk*.

3.214 *robustness*—insensitivity of a statistical test to departures from underlying assumptions. [Many statistical test procedures depend on the form of the assumed distribution of the population sampled to obtain exact values for the probability statements. If departures from the assumed distribution do not materially affect the decisions that would be based on the statistical tests involved, the test is considered robust. For example, tests based on an assumption of normality that compare averages generally are robust even though the underlying distribution of individual items in the population is not normal. On the other hand, the F-statistic for comparing variances may be an indicator of lack of normality rather than a simple variance comparison. The term robustness can also refer to the condition of a product or process design that remains relatively stable, with a minimum of variation, even though factors that influence operations or usage, such as environment and wear, are constantly changing.]

3.215 *root-mean-square deviation (RMS)*—a measure of the dispersion of a series of results around their average, expressed as the square root of the quantity obtained by summing the squares of the deviations from the average of the results and dividing by the number of observations.

$$RMS = \sqrt{\sum\left(X_i - \bar{X}\right)^2 / n} \qquad (13)$$

[Both sample standard deviation (*s*) and RMS give biased estimates of the population standard deviation (σ). However, the sample variance (s^2) provides an unbiased estimate of the population variance (σ^2).]

3.216 *rounding*—the process of dropping one or more digits so that the reported value contains only those digits which are significant or necessary in subsequent computations.

3.217 *ruggedness*—insensitivity of a test method to departures from specified test or environmental conditions. [An evaluation of the ruggedness of a test method or an empirical model derived from an experiment is useful in determining whether the results or decisions will be relatively invariant over some range of environmental variability under which the test method or the model is likely to be applied.]

3.218 *ruggedness test*—a planned experiment in which environmental factors or test conditions are deliberately varied in order to evaluate the effects of such variation. [Since there usually are many environmental factors that might be considered in a ruggedness test, it is customary to use a "screening" type of experiment design which concentrates on examining many first order effects and generally assume that second order effects such as interactions and curvature are relatively negligible. Often in evaluating the ruggedness of a test method, if there is an indication that the results of a test method are highly dependent on the levels of the environmental factors, there is a sufficient indication that certain levels of environmental factors must be included in the specifications for the test method, or even that the test method itself will need further revision. See ASTM E 1325.]

3.219 *run*—(1) an uninterrupted sequence of occurrences of the same attribute or event in a series of observations, or (2) a consecutive set of successively increasing run-up or successively decreasing run-down values in a series of variable measurements. [In control chart applications, some variable measurements are treated as attributes in determining runs. For example, a run might be considered a series of a specified number of consecutive points above or below the central line.]

3.220 *run chart*—also called *music bar chart*. A control chart that presents individual measurements or test values for a specific quality characteristic on a vertical axis and the individual sample numbers (in consecutive order) on a horizontal axis.

3.221 *sample*—also called *materials sample* when intended to mean: (1) a small physical quantity of material or a measurement obtained, in some manner so that the portion (i.e., sample) is representative of the whole, or (2) a quantity of material fabricated in a lab on which future tests can be run. [A sample may be made up of one or more increments of equal size that are combined.] Also called *statistical sample* when intended to mean: (1) all of the individual samples obtained from a lot which provide information that may be used to quantify the quality of the entire lot, or (2) the integer number of random material samples obtained from a sublot or lot. [The context in which the word sample is used determines its meaning. For example, "obtain a sample here" could mean either obtain a physical quantity of material at this location or take a test (obtain a measurement) at this location; while "the sample size equaled 9" would mean that a total of 9 individual material samples were obtained in a random manner and thus comprised the statistical sample of size $n = 9$.]

3.222 *sample size (referring to a materials sample)*—the size of a physical sample (e.g., 5 kg or 100 ml). [The preferred terminology when referring to a materials sample is "size sample" or "size of sample".] See *sample size (n) (referring to a statistical sample).*

3.223 *sample size (n) (referring to a statistical sample)*—the number of random individual observations, (i.e., data points, test results, measurements, etc.) under consideration or comprising a sublot or lot. [The sample size (i.e., number of random observations) has important implications on how representative the information is of the population. The greater the sample size (n), the greater the degree of confidence in inferences made about the population.] See *sample size (referring to a materials sample).*

3.224 *sample standard deviation (s)*—a biased measure of the dispersion of a series of results around their mean, expressed as the square root of the quantity obtained by summing the squares of the deviations from the mean of the results and dividing by the number of observations minus one.

$$S = \sqrt{\frac{\sum (x - \bar{x})^2}{n-1}} \qquad (14)$$

3.225 *sample variance (s^2)*—an unbiased measure of the dispersion of a series of results around their mean, expressed as the sum of the squares of the deviations from the mean of the results divided by the number of observations minus one.

$$S^2 = \frac{\sum (x - \bar{x})^2}{n-1} \qquad (15)$$

3.226 *sampling with replacement*—a procedure used with some probability sampling plans in which a selected unit is replaced after any step in the selection process so that the same sampling unit is available for selection again at the next step of selection or at any other succeeding step of the sample selection procedure.

3.227 *secondary relationship*—an equation that shows how one or more materials and construction variables are related to at least one predictor variable. The equation $S_f = 9.5\sqrt{S_c}$ (where S_f is concrete flexural strength and S_c is concrete compressive strength) is an example of a secondary relationship.

3.228 *segments*—arbitrary divisions of a lot which may be either real or imaginary.

3.229 *selective sampling*—a non-random procedure in which a sample is obtained only for informational purposes to guide quality control or acceptance actions.

3.230 *seller's risk* (α)—also called "contractor's risk," or "risk of a Type 1 or alpha (α) error." The risk to the contractor of having acceptable quality level (AQL) material or workmanship rejected. [For an accept/reject acceptance plan, it is the probability that an acceptance plan will erroneously reject AQL material or workmanship with respect to a single acceptance quality characteristic. For variables acceptance plans using adjusted pay schedules, it is equivalent to α_{PF}, where $PF = 100$. It is the probability that a variable payment acceptance plan will erroneously accept AQL material or workmanship at less than 100 percent pay with respect to a single acceptance quality characteristic.]

3.231 *significant digits*—also called "significant figure." (1) Any of the digits 0 through 9, except leading zeros and some trailing zeros, which are used with their place value to denote a numerical quantity to some desired approximation. (2) The digits of the decimal form of a number beginning with the leftmost nonzero digit and extending to the right to include all digits warranted by the accuracy of measuring devices used to obtain the numbers.

3.232 *significant figures*—see *significant digits*.

3.233 *significance level (α)*—the probability of rejecting a null hypothesis when it is in fact true. [This probability, often denoted by α, is generally specified before any samples are drawn, so that results will not influence the level selected.]

3.234 *simple linear regression*—a means of fitting a straight line to data so that one can predict a dependent (response) random variable *Y*, using a known independent variable *X*. $Y = aX + b$ is an example of a simple linear regression equation.

3.235 *skewness*—a lack of symmetry in a probability distribution. When the distribution has a greater tendency to tail to the right, it is said to have positive skewness. When the distribution has a greater tendency to tail to the left, it is said to have negative skewness. For the normal distribution (as well as for any other symmetrical distribution), the skewness coefficient equals 0.

Population skewness coefficient: $\gamma_2 = \sum \left(X_i - \mu \right)^3 \Big/ 2n\sigma^3$

Sample skewness coefficient: $g_2 = n \sum \left(X_i - \bar{X} \right)^3 \Big/ \left[s^3 \left(n-1 \right) \left(n-2 \right) \right]$

3.236 *specification limit(s)*—the statistically based limiting values(s) placed on a quality characteristic which are applied with a particular quality measure (such as PWL) to evaluate the quality of a lot. [Specification limits are usually comprised of an upper specification limit (USL), a lower specification limit (LSL), or both. It is important to recognize that since specification limits are statistical limits, individual sample test results may fall beyond the USL or LSL and still be included in the acceptance determination. The specification limits are used for computation of quality levels (e.g., PWL), which are used in calculating pay factors for a lot.]

3.237 *specimen*—also called *test portion*. A portion of a material sample that is prepared and tested. Some test methods require material samples to be split into multiple specimens for testing. [The part of a sample actually tested. Usually obtained by reducing the sample by quartering, riffling, or taking an aliquot quantity. The portion of a test unit needed to obtain a single test determination. In inter-laboratory evaluation of test methods and other statistical procedures, it is best to reserve the word sample for the total amount of material involved and not the individual test specimens, pieces, or portions being tested.]

3.238 *split sample*—a sample that has been divided into two or more portions representing the same material. [Split samples are sometimes taken to verify the acceptability of an operator's test equipment and procedure. This is possible because the variability calculated from differences in split test results is comprised solely of testing variability. See *replicate sample.*]

3.239 *standard deviation (s, s_p or σ)*—a measure of the variability of a set of values which is represented by the principal square root of the variance. See *sample standard deviation, pooled sample standard deviation,* and *population standard deviation.*

3.240 *standard deviation known acceptance plan*—also called a *variability known acceptance plan.* A variables acceptance plan developed with the assumption that the standard deviation of the process is known. [Typically, for highway construction processes, the standard deviation cannot be presumed to be known. See *standard deviation unknown acceptance plan.*]

3.241 *standard deviation unknown acceptance plan*—also called a *variability unknown acceptance plan.* A variables acceptance plan developed with the assumption that the standard deviation of the process is unknown. [Typically, for highway construction processes, the standard deviation cannot be presumed to be known. With the standard deviation unknown (and the mean unknown), the beta distribution is used to estimate percent within limits or percent defective.]

3.242 *standard error (of statistic)*—the standard deviation(s) of the sampling distribution of a statistic. For example, the standard error of the mean ($\bar{X}$) is the standard deviation of the sampling distribution of $\bar{X}$ (i.e., $s_{\bar{X}} = s/\sqrt{n}$).

3.243 *standard error of estimate (SEE)*—in regression analysis, the standard deviation of the errors of estimate in dependent (response) variable *Y*.

$$SEE = \sqrt{\sum\left(Y_i - \hat{Y}_x\right)^2 \Big/ (n-2)} \qquad (16)$$

3.244 *standardization*—a process that determines (1) the correction or correction factor to be applied to the result of a measuring instrument, measuring system, material measure, or reference material when its values are compared to the values realized by standards, (2) the adjustment to be applied to a piece of equipment when its performance is compared with that of an accepted standard or process. [Standardization in case (1) is a simplified form of calibration that estimates systematic error but does not identify random error. Standardization, therefore, does not address all of the elements of uncertainty of measurement and does not lead to traceable measurements. An example of case (2) standardization is adjusting the number of blows of a mechanically operated hammer so it applies the energy equivalent to that of a manually operated hammer. See *calibration.*]

3.245 *standard normal distribution*—a mathematical construct of a continuous probability distribution having a symmetrical, asymptotic bell-shaped curve that is fully defined by μ and σ, where μ = 0 and σ = 1, and for which the mean, median, and mode are all equal. All distribution curves having a similar shape can be modeled by the standard normal distribution via the *z*-score transformation. [The standard normal distribution is defined by the following equation:

$$f_{(x)} = \frac{1}{\sqrt{2\pi}} e^{\frac{-\left(\frac{x-\mu}{\sigma}\right)^2}{2}}$$

The *z*-score transformation is defined as follows: $Z = \dfrac{x - \bar{x}}{s}$

Most construction data exhibit an approximately normal distribution and can be transformed to the standard normal distribution using the transformation.]

3.246 *statistic*—a quantity calculated from a sample of observations, most often to form an estimate of some population parameter.

3.247 *statistical control chart*—see *control chart.*

3.248 *statistical measure*—statistic or mathematical function of a statistic. [The word "statistical" emphasizes that measures are subject to inherent errors and that, in estimating a population parameter, they represent a sample, with inherent sampling variability, e.g., sample standard deviation (*s*) or sample mean ($\bar{X}$).]

3.249 *statistical sample*—see *sample*.

3.250 s*tatistical specifications*—see statistically based specifications.

3.251 *statistically based specifications*—also called "statistical specifications" or "statistically oriented specifications." Specifications based on random sampling, and in which properties of the desired product or construction are described by appropriate statistical parameters.

3.252 *statistically defensible acceptance decisions*—decisions based on data obtained by random sampling. Such decisions have been evaluated by the use of statistical procedures.

3.253 *statistically oriented specifications*—see *statistically based specifications*.

3.254 *statistics*—a branch of mathematics that deals with the collection, analysis, interpretation, and presentation of masses of numerical data. Statistics uses mathematical theories of probability to impose order and regularity on sets of data.

3.255 *stratified random sampling*—a sampling procedure whereby samples are randomly obtained from each sublot.

3.256 *student t distribution*—also called "Student's *t* distribution." A family of continuous sampling distributions employed in small sampling theory where the standard deviation is unknown. The probability density function of the *t* distribution of *Z* is defined as:

$$fz(x) = \frac{1}{\sqrt{n}B\left(\frac{n}{2},\frac{1}{2}\right)}\left(1+\frac{x^2}{n}\right)^{-\frac{n+1}{2}} \qquad (17)$$

where:

$$B(\alpha,\beta) = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}$$

and Γ is the gamma function.

3.257 *subgroup*—a set ($n > 1$) of quality control sample values from within a lot whose mean or range are plotted on a control chart. [Also (1) object sense, a set of units or quantity of material obtained by subdividing a larger group of units or quantity of material, and (2) measurement sense, a set of groups of observations obtained by subdividing a larger group of observations.]

3.258 *sublot*—a subdivision of a lot.

3.259 *surrogate materials and construction (M&C) variable*—a characteristic of materials and/or construction that can be used to substitute for a performance-related M&C variable. For example, concrete compressive strength can be a surrogate for concrete flexural strength.

3.260 *systematic sampling*—see *uniform interval sampling*.

3.261 *table of random numbers*—see *random number table*.

3.262 *target miss*—the difference between the desired (i.e., intended) process average and the actual process average.

3.263 *target value*—the value that is placed on a quality characteristic that represents the mean of the expected distribution of the specified population.

3.264 *t (tee) test*—see *independent t-test* and *paired t-test.*

3.265 *test determination*—(1) the process of deriving from one or more test observations (observed values) the presence or absence of an attribute or the value of a characteristic or dimension of a single test specimen, or (2) the attribute (presence or absence) or value derived from the process [See *specimen*.]

3.266 *test observation*—see *observation.*

3.267 *test portion*—see *specimen*.

3.268 *test result*—the value of a characteristic obtained by carrying out a specified test method. [The test method should specify that one or a number of individual observations be made and their average or another appropriate function, such as the median or the standard deviation, be reported as the test result. It also may require standard corrections to be applied, such as correction of gas volumes to standard temperature and pressure. A test result, therefore, can be a result calculated from several observed values. In the simple case, the test result is the observed value itself.]

3.269 *test specimen*—see *specimen*.

3.270 *test unit*—the total quantity of material (containing one or more test specimens) needed to obtain a test result as specified in the test method.

3.271 *tolerance limit(s)*—the limiting value(s) placed on a quality characteristic to define its absolute conformance boundaries such that nothing is permitted outside the boundaries. [A distinction between tolerance limit(s) and specification limit(s) is that tolerance limit(s) apply to process control and specification limit(s) to statistical acceptance.]

3.272 *tolerances*—see *tolerance limit(s).*

3.273 *total quality management (TQM)*—a comprehensive and structured approach to organizational management that seeks to improve the quality of products and services through ongoing refinements in response to continuous feedback. The goal is to imbed awareness of quality in all organizational processes. It is a philosophy of doing the right thing the first time.

3.274 *treatment*—also called "treatment combination." A combination of the levels of each of the factors assigned to an experimental unit.

3.275 *treatment combination*—see *treatment*.

3.276 *trueness*—the closeness of agreement between the population mean of the measurements or test results and the accepted reference value. [The measure of trueness usually is expressed in terms of bias. Greater bias means less favorable trueness. Population mean is, conceptually, the average value of an indefinitely large number of test results. Trueness is the systematic component of accuracy.]

3.277 *unbiased*—not influenced by opinion or judgment.

3.278 *unbiased estimator*—a statistic whose mathematical expected value (i.e., average value over the long run) is equal to the value of the population parameter being estimated. For example, the sample mean is an unbiased estimator of the population mean. On the other hand, the sample range is a biased estimator of the population range.

3.279 *uncertainty*—an indication of the variability associated with a measured value that takes into account two major components of error: (1) bias, and (2) the random error attributed to the imprecision of the measurement process. [Quantitative measures of uncertainty generally require descriptive statements of explanation because of differing traditions of usage and because of differing circumstances. For example: (1) the bias and imprecision may both be negligible; (2) the bias may not be negligible while the imprecision is negligible; (3) neither the bias nor the imprecision may be negligible; (4) the bias may be negligible while the imprecision is not negligible.]

3.280 *uniform interval sampling*—a procedure in which samples are obtained at fixed intervals of material production or material quantity. [Sample selection procedure in which every k^{th} element is selected from the universe or population; for example, u, $u + k$, $u + 2k$, $u + 3k$, etc., where u is in the interval 1 to k. If $k = 20$ and $u = 7$ is the initial unit selected, then sampling units 7, 27, 47, 67, …, would comprise the sample. When *N/k* is not an integer, there is a small bias due to the end effect. When *u* is selected by a chance process and *N*/*k* is an integer, the systematic sample will provide unbiased estimates of the population average or total. Situations for which *N*/*k* is not an integer usually ignore the small or negligible bias in estimating the mean or total. Schemes have been developed for non-integer *N*/*k* to overcome sampling bias. Estimation of the precision of an average computed from a systematic sample is a difficult problem that has no generally satisfactory solution. Independent replicate systematic samples provide an approach to variance estimation, but have been rejected by some writers. In some ASTM situations where replicate samples may be obtained on a routine basis, the technique may be useful.]

3.281 *unit*—an object on which a measurement or observation may be made. [The word unit is commonly used in the sense of a unit of product (service, etc.), the entity of product inspected in order to determine its classification, or its measurements. This entity may be a single article, a set of like articles treated collectively, a subassembly, a stated quantity of material, etc. The unit of product or service need not be the same as the unit of purchase, supply, production, or shipment.]

3.282 *upper control limit (UCL)*—the statistically established control chart limit for values above the central line (target) of a control chart. [The UCL for a control chart plotting individual values ($n = 1$) is established at +2 standard deviations from the control chart target. The UCL for a control chart plotting subgroups of data ($n > 1$) is established at +3 standard deviations from the control chart target. (See *control chart limits*.)]

3.283 *upper specification limit (USL)*—the upper statistically based limiting value associated with a quality characteristic and used with a quality measure to evaluate the quality of a lot.

3.284 *upper tolerance limit (UTL)*—a tolerance limit applicable to the upper conformance boundary.

3.285 *use value*—the obtained characteristics and qualities of a material, product, or item of construction, associated with accomplishment of functional performance.

3.286 *validation*—the mathematical comparison of two independently obtained sets of data (e.g., agency acceptance data vs. contractor data) to determine whether it can be assumed they came from the same population.

3.287 *value engineering*—an organized effort directed at analyzing the function of highway components with the purpose of achieving the required function at the lowest possible cost.

3.288 *variability*—differences in measured test values for a given quality characteristic within a stable pattern due to chance, or outside this normal pattern due to an assignable cause(s).

3.289 *variability known acceptance plan*—see *standard deviation known acceptance plan*.

3.290 *variability unknown acceptance plan*—see *standard deviation unknown acceptance plan*.

3.291 *variable*—a measurement that can have a series of different values.

3.292 *variables, method of*—measurement of quality by the method of variables consists of measuring and recording the numerical magnitude of a quality characteristic for each of the units in the group under consideration. [This involves reference to a continuous scale of some kind.]

3.293 *variables acceptance plan*—a statistical acceptance procedure where quality is evaluated by (1) measuring the numerical magnitude of a quality characteristic for each of the units or samples in the group under consideration, and (2) computing statistics such as the average and the standard deviation of the group.

3.294 *variables data*—measurements which vary and may take any of a specified set of numerical values. [The term “random variable” or “variant” is often used to indicate that each of the specified set of values is associated with a specified relative frequency or probability, and that each is a random sample from a continuous or a discrete, or discontinuous, population encompassing the specified values.]

3.295 *variance*—a measure of dispersion of a set of values from their mean, expressed as a function of the sum of all squared deviations from the mean. See *sample variance, pooled sample variance,* and *population variance.*

3.296 *variation*—see *variability*.

3.297 *verification sampling and testing*—see *acceptance sampling and testing*.

3.298 *warning limits (upper, lower)*—boundaries established within the upper and lower control chart limits on control charts that plot subgroups of data. They are used to warn of possible problems in the production or placement process that may lead to the process going “out of control.” [Warning limits are established at ±2 standard deviations from the control chart target. Warning limits are not used with control charts that plot individual sample values (i.e., run charts).]

3.299 *within-laboratory standard deviation*—the standard deviation of test results obtained within a laboratory for a single material under conditions that may include such elements as different operators, equipment, and longer time intervals. [Because the training of operators, the agreement of different pieces of equipment in the same laboratory and the variation of environmental conditions with longer time intervals depend on the degree of within-laboratory control, the within-laboratory standard deviation is likely to vary appreciably from laboratory to laboratory.]

3.300 *workmanship inspection*—examination or measurement for determination of conformance to requirements of construction processes, components, or products.

3.301 $\bar{X}$ *Chart*—a control chart that plots the mean ($\bar{X}$) values for subgroups of measurements or test values against statistically derived control limits.

3.302 *zero defects*—a total quality management philosophy, aimed at preventing problems or defects from occurring, which is stated as: “Do the job right the first time.”

Standard Practice for

Regulatory Information for Chemicals Used in AASHTO Tests

AASHTO Designation: R 16-04 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Regulatory Information for Chemicals Used in AASHTO Tests

AASHTO Designation: R 16-04 (2009)

1. SCOPE

1.1. This standard practice provides a reference listing of chemicals used in the various AASHTO Test Methods (see Table 1). It includes current regulatory codes and hazard classifications. The list does not include radiation hazards. This practice is not intended as a substitute for law or regulation.

1.2. The chemical list must be provided to all laboratory employees engaged in performing AASHTO tests. In addition, all laboratory employees must be trained in proper handling procedures as stated in the OSHA 1910.1200 Hazard Communication Standard or governing state regulation. Laboratories performing AASHTO tests shall establish a Chemical Hygiene Plan as set out in 29 CFR 1910.1450, including the training requirements therein.

1.3. This practice supplements data found in MSDSs supplied by manufacturers. This practice is for quick reference ability and is not intended to replace MSDSs.

2. INTRODUCTION

2.1. In an effort to assure uniform compliance with regulations, the following definitions are cited:

2.1.1. A hazardous chemical includes any substance that is in the definition of health hazard adopted by the United States Occupational Safety and Health Administration.

2.1.2. A hazardous waste includes, but is not limited to, any substance that has been assigned a code number from the EPA “Unlisted (Characteristic) Hazardous Wastes” code. All hazardous waste must be disposed of in accordance with EPA, state, and local regulations.

2.2. Should there be any questions regarding whether a substance is hazardous, contact the local governing authority.

3. CHEMICAL LIST

3.1. This section contains definitions of the terms and abbreviations contained in the list. All information is valid as of the date of this practice.

3.2. CAS NO. is the number assigned to a substance by the Chemical Abstracts Service.

3.3. TEST METHOD refers to the AASHTO test method in which the chemical is used.

3.4. NIOSH REL is the Recommended Exposure Limit established by the National Institute for Occupational Safety and Health. The value corresponds to the concentration in air to which the employee may be exposed. These limits are a time-weighted average for an eight-hour workday.

3.4.1. Abbreviations under NIOSH REL and OSHA PEL:

- ppm is parts per million
- mg/m^3 is milligrams per cubic meter
- $\mu g/m^3$ is micrograms per cubic meter
- CL is Ceiling Limit
- STEL is Short-Term Exposure Limit, which is for a 15-minute duration
- f is fume
- d is dust
- rf is respirable fraction

3.5. OSHA PEL is the Permissible Exposure Limit established by the Occupational Safety and Health Administration. These PELs went into effect September 1, 1989. The PELs are time-weighted average concentrations just as the NIOSH RELs are.

3.5.1. See Section 3.4.1 for abbreviations used.

3.6. CARCIN denotes substances which are listed as carcinogens in one of the following three sources:

3.6.1. NTP denotes a substance listed on National Toxicology Program's Annual Report on Carcinogens.

3.6.2. IARC denotes a substance listed in the International Agency for Research on Cancer's Monographs, Groups I and II.

3.6.3. OSHA's 29 CFR 1910 subpart Z.

3.7. SKIN—An "X" in this column denotes a substance for which skin contact is to be avoided as it may be a route of entry. This includes mucous membranes and eyes.

3.8. DOT LABEL denotes Department of Transportation Hazard Class for transportation of these substances.

3.8.1. Abbreviations under DOT LABEL

- FLAM. is flammable
- LIQ. is liquid
- ST. ANDR. † is St. Andrew's Cross (poison label)

3.9. RCRA NO. is the number assigned to a substance under the Resource Conservation and Recovery Act.

3.10. SHIP CODE is the identification number assigned by the U.S. Department of Transportation in the Emergency Response Guidebook to hazardous materials for international and domestic shipment.

3.11. DOT GUIDE is a number assigned by the U.S. Department of Transportation for providing guidance primarily during the initial phases of an incident.

Standard Practice for

Technician Training and Qualification Programs

AASHTO Designation: R 25-00 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Technician Training and Qualification Programs

AASHTO Designation: R 25-00 (2009)

1. SCOPE AND LIMITATION

1.1. This document provides a guideline for establishing evaluation and qualification procedures for personnel engaged in sampling and testing of soils, aggregates, hot mix asphalt, and portland cement concrete in accordance with AASHTO test methods. The guideline is intended for use by organizations providing qualification of sampling and testing technicians at the basic testing level for acceptance of materials and independent assurance testing.

1.2. The terms used in this standard regarding “technician” or “qualification” are meant to be generic descriptions. Each state will need to use appropriate terminology consistent with state law and practices.

1.3. This guideline does not purport to address all possible events and procedures inherent in the administration and use of a technician qualification program (TQP).

3. INTRODUCTION

3.1. This guideline is provided to:

(a) Help individual states, and where desired, combinations of states and other public agencies develop a TQP for use in conjunction with quality assurance (QA) specifications as described in the *Implementation Manual for Quality Assurance* and the *Quality Assurance Guide Specification*.

(b) Describe the activities and organizational needs for the development and operation of a technician qualification program that provides a flexible and effective means for ensuring qualified personnel perform sampling and testing.

(c) Describe coverage for Level I tests, the basic tests performed to identify material or product characteristics, for acceptance and/or payment under project contracts incorporating soils, aggregates, portland cement concrete, and hot mix asphalt. Examples of the basic tests that could be included under Level I are shown in Appendix A.

(d) More advanced levels of training and qualification within a TQP are not covered by this guideline but may be considered to address mix designs, plant control, and quality control/quality assurance (QC/QA) operations.

3.1.1. A successful TQP requires the full support and commitment from agencies and industry that have a vested interest in technician training and qualification. Involvement of all those with a common interest in technician training and qualification helps in understanding the multiple perspectives of the team members, and this, in turn, helps develop policies and procedures that will be supported by their respective organizations.

3.1.2. Development of an agreement at the program inception and prior to major changes is recommended as the best means for gaining the needed understanding and support for the program.

3.1.3. Consideration of reciprocal agreements between states, and where feasible, regions, regarding materials technician qualification acceptance is a means of addressing economy and business process efficiencies and should be an integral part of all TQPs.

3.2. *Background:*

3.2.1. Historic roles and responsibilities of industry and agencies have changed for sampling and testing activities under QA specifications. QA specifications allow the use of contractor test results in making acceptance decisions, and the use of consultants in independent assurance and verification sampling and testing programs, for materials and construction quality control.

3.2.2. Qualification programs and associated training have been shown to be an effective tool for improving the quality of highways and bridges by verifying that essential knowledge and skills are possessed by agency or industry personnel who monitor, inspect, and control construction operations. Qualification programs for personnel have proven to be useful, common “yardsticks” for measuring expertise and performance among public transportation agencies, private construction contractors, and independent materials laboratories.

3.2.3. As the use of QC/QA specifications increases, the need for TQPs as an equitable means for test result comparison and credibility between contract parties has become apparent. Each state using QC/QA specifications should have provisions requiring the use of qualified technicians involved in construction project testing and inspection activities.

(b) Industry contributions;
(c) State Planning and Research (SP&R) Funds;
(d) Federal Highway Administration;
(e) Contributed time, facilities or equipment from industry, consultants, and academia; or
(f) Other innovative funding mechanisms, such as loans paid back from generated income for courses.

4.5.1. Multi-state or regional involvement may result in additional funding sources and a decrease in costs to the individual participants.

4.5.2. Course fees should be reasonable but adequate to enable the program to become self-sufficient. It is necessary to make a long-term commitment and conduct the program as if it were a business, knowing that the program may lose money initially but should become self-sufficient after several years of operation. Areas where operational support may be available include the following:
(a) Manuals that are developed for qualification and training may be sold publicly, provided that copyright laws are followed;
(b) Continued financial support from the agency and industry;
(c) Continued use of contributed facilities, equipment, etc., from the agency and industry.

4.6. *Organizational Task Groups*—Task groups should be formed as soon as possible to simultaneously address the many TQP start-up issues. Each task group should be made up of four to six members with its chairman coming from the oversight committee. Other participating members may or may not be on the oversight committee. All members of the task group should have a working relationship and experience with the function of the particular task group. The task groups should be established and used to develop programs, plans, and policies for presentation and approval from the oversight committee. Recommended areas where task groups should be formed initially include the following:

4.6.1. A funding task group:
(a) To identify areas of financial support; and
(b) To develop operational budgets and cost review of courses, manuals, etc.

4.6.2. An administrative task group:
(a) To set guidelines and write contracts for third-party administrators (e.g., director, university or consultant);
(b) To work with oversight committee to ensure proper representation and replacement as necessary;
(c) Conduct program reviews;
(d) Address and resolve candidates issues; and
(e) Identify roles and responsibilities of operational components of the program.

4.6.3. A record-keeping and documentation task group:
(a) To establish security guidelines for records and designate support staff; and
(b) To provide storage and security of applications, test results, test papers, etc.

4.6.4. A task group for each qualification area (hot mix asphalt, portland cement concrete, soils, and aggregates:
(a) To develop requirements for training and qualification programs;
(b) To establish experience and hands-on performance requirements;

(c) To establish course outlines; and

(d) To establish examinations criteria.

4.7. Options for leading the development, administration, and implementation of TQP qualification programs have been developed and implemented through cooperative partnerships among public agencies, private sector organizations, and educational institutions. Options should be considered when determining who will be asked to lead the development, administration, and implementation of a state or regional TQP.

4.7.1. *Agency In-House*—Agency in-house TQPs usually assign responsibilities for developing, administering, and implementing a TQP into technical services, personnel/human resources, or product quality management areas.

4.7.1.1. The main advantages of an in-house TQP are:

(a) Lower costs to contractors;

(b) No cost to DOT employees;

(c) Trainers knowledgeable of subject matter and familiar with specifications;

(d) Control of material being instructed; and

(e) In-house knowledge of TQP requirements for technician's skills, experience, qualifications, requalification, and disqualification.

4.7.1.2. The main disadvantages of the program are:

(a) Turnover of instructors;

(b) Fewer employees available to be instructors; and

(c) Fiscal and manpower costs to the SHA.

4.7.2. *Consultants*—Using a third-party consultant to develop, administer, and implement a state or regional TQP is similar to outsourcing other non-core tasks within a government agency. The third-party consultant may be designated as a program director responsible for the day-to-day operations reporting directly to the oversight committee. The program director, ideally, would have no relationship with either the state(s) or industry in order to eliminate potential appearance of a conflict of interest. Advantages of a third-party consultant include the availability of time and commitment to organizational needs, independence from all interested parties, and facilitating and overseeing the development of various programs to provide consistency between programs. A third-party consultant may also bring expertise and focus to the organization and provide the necessary staffing to expedite the product delivery schedule.

4.7.3. *University/College*—The advantages of using a university or college to develop, administer, and implement a state or regional TQP are:

(a) Access to the diverse expertise found at a university or college; and

(b) Support facilities and services, e.g., mail, guest housing, meals, printing, janitorial, accounting, classrooms, laboratories, computers, fleet vehicles, student workers, and administration support staff.

4.7.4. *Public/Private*—State and regional qualification programs have been developed and implemented through cooperative partnerships among public agencies, private sector organizations, and educational institutions. These types of programs foster a cooperative agreement between industry groups and state agencies that will be very beneficial to everyone involved in this field. All the partners can contribute their expertise to people from both industry and agencies. This training to mixed groups will assure greater understanding and cooperation when constructing the project.

4.7.5. *Private National Engineering and Technical Organizations*—Several national engineering and technical organizations have created more generic qualification programs that are available to personnel from both agencies and industry.

5. TRAINING AND QUALIFICATION POLICIES

5.1. In developing state and regional TQPs, the following guiding principles should be followed:

(a) Develop the TQP using AASHTO sampling and testing procedures whenever possible. A state may require an additional endorsement to the TQP to cover unique or additional procedures in their state;

(b) Address soils, aggregates, hot mix asphalt (HMA), and portland cement concrete (PCC) as the primary qualification topics; and

(c) Address a technician qualification Level I that involves basic sampling procedures and test methods initially, with additional qualification levels developed as the scope of the TQP progresses.

5.2. *Focus*—In order to support the overall objective of improving the quality of the construction of highways through the improved work performance of those involved with the construction project, the TQP *must be directly work-related*. The scope and content of all qualification testing must be based on realistic and practical work needs. Because the TQP focuses on work performance, everyone involved—managers, supervisors, program administrators, and participants—should treat qualification activities as natural extensions of their work duties and responsibilities.

5.3. *Leveraging and Aligning Activities and Programs between States and Regions*—There is a wide variation in the development and implementation of TQPs between states and regions. This is an opportunity and a challenge for states and regions considering, or just beginning, TQP initiatives. No single “best way” to implement a TQP has emerged, but there is much to be learned from states and regions with established TQPs.

5.3.1. Whenever possible, consideration should be given to developing state technician qualification requirements by participating in a regional TQP. Participating in a regional program has the positive benefit of pooling and leveraging state resources and also of allowing qualified technicians to work across state boundaries without having to retrain and requalify. Gaining these benefits will lower the states’ and contractors’ cost of doing business while still ensuring that high-quality testing is performed.

5.3.2. To facilitate reciprocity and efficiency, consideration should be given to developing qualification policies based on AASHTO standard test procedures. If an AASHTO test procedure is not available, then a state or region should adopt ASTM procedures or another agreed-upon method.

5.3.3. The SHA should have a written policy regarding reciprocity. The policy should be clear to applicants seeking reciprocity. Any requirements for classroom training, performance, or written examinations should be identified. If participating in a regional approach to training and qualification is not selected, SHAs should specify if, when, and how qualification from other states or regions can be used. Conducting regional qualification conferences to share questions between states and discuss the best practices for policies, procedures, and specifications is an effective means for streamlining and improving TQP implementation.

5.3.4. Once policies and procedures for developing a TQP are established, the next challenge is implementation. Given the experiences of states and regions that have already implemented TQPs, it is recommended that program elements be tested as pilots before fully implementing them as an integrated program. Well-designed pilots will maximize feedback and learning and help gain the support of those in government and industry that will be affected by the changes.

5.4. *Consideration of Prerequisites*—In addition to the required training, work experience may be used as an integral part of the qualification process to ensure technicians have the required knowledge, skills, and abilities. This assurance may be accomplished by establishing prequalification relevant work experience or education requirements, establishing work experience criteria prerequisites for participation in advanced qualification levels, or requiring relevant work experience to maintain and validate the requalification process.

5.4.1. The TQP should consider any prerequisites necessary for entry-level training. Demographics and the characteristics of the labor pool available to the state may need to be considered as a starting point. Minimum requirements in reading level and math skill capabilities may need to be identified as an entry-submittal gateway. If there is a problem noted with the applicants' reading and math skills that would hinder their performance, establishment of training to correct these deficiencies for the applicants may be advisable.

---

6. TRAINING

6.1. A well-planned and supportive training program is the basis for a successful qualification program. A good training program will ensure qualified technicians and testers will be performing inspection on construction projects.

The training program should be offered to all individuals including those from SHAs, local agencies, contractors, producers, or consultants. The program should be administered the same for all individuals.

6.1.1. Training should be structured to fit the qualification test criteria. Since the program is directed toward highway construction, AASHTO test procedures should be used to the maximum extent.

6.1.2. When training is part of a qualification program, the training portion of the program should be developed prior to the qualification program. Development and maintenance of a training program may be handled by:

(a) State highway agency;
(b) University or vocational-technical school;
(c) Consultants; or
(d) Public/private consortium.

6.1.3. The program administration requires the following resources:

(a) Funding and fees;
(b) Staffing (instructors, coordinators, proctors, etc.);
(c) Training facilities;
(d) Materials (manuals and equipment);
(e) Record keeping;
(f) Governing board/advisory committee; and
(g) Organizational task groups.

6.1.4. The above resources need to be considered when choosing who will handle the development and maintenance of the program.

6.1.4.1. Training materials may be developed solely for the TQP or developed with another state/region. There are also existing training manuals and aides that are available for use.

6.1.4.2. Training may include lecture, hands-on training, or self-study methods. Inclusion of hands-on training will help to ensure that the technician is competent and should raise their comfort level in performing materials sampling and testing.

6.1.4.3. Qualified technicians will need to be kept aware of specification, equipment, or administration changes in the training program. This need may be satisfied by requalification training, update courses, or special training efforts.

6.1.4.4. Trainers need to have the technical knowledge and presentation skills necessary to instruct the courses. Competence and conduct criteria for the instructors, examiners, and proctors need to be defined and enforced.

7. EXAMINATION AND METHODS

7.1. A successful qualification program must have documented policies and procedures for examination methods to ensure consistent and fair administration by all examiners and proctors.

7.1.1. The program oversight committee should empower and formally task an individual, such as a TQP manager, to direct and coordinate all qualification examination activities. Typical duties of this individual are scheduling of examinations; registration of applicants; maintaining and ensuring the security of examination materials; notifying participants of their success or failure in their examination; and maintaining all completed examination materials.

7.1.2. Written and performance examinations should be given to determine if the applicants possess the knowledge and skills necessary to satisfy the established qualification requirements. “Grandfathering” technicians and testers, or a waiver of training and testing in lieu of qualification examination should not be permitted. If actually performing the tests, a licensed professional engineer should demonstrate competency according to the TQP.

7.2. *Examination Controls and Integrity*—To avoid conflicts of interest, the examiner should not be the immediate supervisor of those being qualified. Examination procedures should be documented and included in the policy and procedures manual. The documentation should include procedures to:

(a) Develop and revise qualification exams;
(b) Establish examination pass-fail criteria;
(c) Determine examination duration;
(d) Determine disciplinary action for cheating;
(e) Document examination security procedures;
(f) Develop the detailed plan for conducting examinations;
(g) Develop retesting policy and procedures;
(h) Design a process to notify individuals of examination times and results;
(i) Develop procedures to ensure the confidentiality of score reporting;
(j) Establish requirements for examiners and proctors; and
(k) Establish a procedure to update or change tests when there is a change in a test method or specification.

7.3. *Examination Methods*—Written and performance examinations should be given to ensure that applicants have a complete understanding of the materials and calculations as well as the ability to perform test procedures. Care and good judgment are needed in developing fair and impartial written and performance examinations.

Prior to the examinations, the proctors should thoroughly explain to the applicants:

(a) The examination process and rules;

(b) What the exams will be comprised of;

(c) Minimum scores necessary to pass; and

(d) The retesting policy.

7.3.1. *Written Examination*—The written examination may be closed- or open-book and should have a designated time limit. Examinations may consist of various types of questions, including true/false, multiple choice, essay, fill-in-the-blank, word problems, and calculations.

A large database of questions for use in the written examination of each qualification area should be developed and a set of questions randomly selected for each examination given. The use of randomly selected questions will assist in ensuring the credibility of the process by providing a different set of questions for each examination. To protect examination integrity, course participants should not retain a copy of their completed written examinations.

7.3.2. *Performance Examination*—Performance examinations measure the applicants' ability to properly perform the prescribed test methodology. All proctors and examiners should evaluate each applicant's proficiency by using standardized checklists that identify specific test method steps or tasks. The degree of detail of the performance checklists will be influenced by whether the performance examination is open- or closed-book. Inspection checklists developed by AMRL and CCRL are excellent references for the evaluation of AASHTO and ASTM test methods. Time limits can be set for the complete performance of each test method. The examinee may be asked to explain various steps of the procedure to reduce the full test time.

7.4. *Re-Examination Policy–Written/Performance*—Whenever a participant fails a written/performance qualification examination, some allowance should be provided for retesting. A policy should be established to address the following areas:

(a) Maximum number of retests allowed;

(b) When retesting will be permitted;

(c) Maximum time limit for retaking the written/performance examination; and

(d) Guidelines if the applicant fails the retest.

7.4.1. The number of retests allowed and the time limits are needed to avoid frivolous, trial-and-error attempts and encourage the participants to properly prepare for testing. The re-examination policy will also influence the size of the test question database needed for written examinations.

7.5. *Notification of Results*—Notification of an applicant's successful or unsuccessful completion of the qualification requirements should be mailed to the applicant promptly after completion of the examination. If the applicant is unsuccessful, the procedure for re-examination should be explained.

7.6. *Confidentiality of Records*—Personal information and records of the examination are generally considered to be confidential and not to be released publicly. Confidential information includes:

(a) Personal and professional information provided by the participants applying for testing and qualification; and

(b) Specific test results and scores for participants.

7.7. *Examination Materials Security*—The qualification training program should provide specific procedures and precautions for establishing and maintaining the security of examination materials at all times. Violation of security compromises the integrity and validity of the qualification process. Applicants should not retain a copy of the written examination. After the performance test, examiners and proctors may inform the applicants of their weaknesses and the details of correct procedures.

7.8. *Examiner and Proctor Qualifications*—Examiners and proctors should complete an orientation or training session. Examiners for the performance examination must be qualified in that examination area. Examiners may be employees of agencies, contractors, or industry associations.

7.9. *Examination Appeals*—An applicant wishing to register a complaint or protest regarding an examination or examiner must do so in writing to the TQP Manager within a specified period of time. The written complaint must specify the examination date, the examiner, and the nature of the complaint or protest.

7.9.1. Complaints and protests should be reviewed and a recommendation made to the oversight committee. All complaints and protests should be promptly answered in writing.

---

8. QUALIFICATION

8.1. Each qualifying agency that issues through their TQP the status of qualification or certification must maintain a written policy for administration of their TQP.

8.2. Each agency must maintain a registry of trained technicians who have successfully completed a training program. The registry should include:

(a) Name, Social Security number or qualification identification number, and address;
(b) Courses, and dates completed; and
(c) Course content:
    Test methods included;
    Lecture or laboratory;
    Written examination; and
    Performance examination.

8.3. The qualifying agency shall provide the qualified technician with documentation of the qualification. This documentation may be in the form of a registration card or letter. The document should include any expiration date.

8.3.1. The qualifying agency may require the registered technician to maintain a current address on file as a condition of registration.

8.4. Establishing a registration policy is the responsibility of the TQP Manager. A registration application should include:

(a) Program administration and information contact(s);
(b) Listing of qualification training courses and examinations and fee schedule;
(c) Refund policy;
(d) Payment policy;
(e) Enrollment and lodging information;

(f) Participant and employer information; and

(g) Resume application.

8.5. Enrolling and scheduling course participants and collecting fees can become a tedious and cumbersome task. It is highly recommended that a database software package be used to expedite the registration and record-keeping process.

8.6. The qualifying agency must adopt a policy to protect the privacy of all qualified technician's records.

8.6.1. The TQP should establish a period for which the qualification remains valid.

8.7. The TQP should include a requalification policy. The requalification process may include refresher courses, observations, and/or retesting.

8.8. The TQP should include a written policy regarding the removal of qualification status or disciplinary measures regarding technician performance. Progressive levels of discipline that lead up to disqualification may be provided.

9. TECHNICIAN LEVEL I TEST METHODS

9.1. Each state or region should develop a set of test methods to support a Level I TQP. This level depends, to some extent, upon the specifications and materials requirements. It is hoped that a Level I TQP will be the starting point for reciprocity between the SHAs. The list of tests shown in Appendix A was developed as an example during the November 1996 Technician Certification Program Workshop and represents some of the tests available to each state when selecting those tests to include in their TQP.

10. SUMMARY

10.1. Training and qualification programs can result in significant improvements in the quality of the American transportation system. TQPs can improve the abilities of technicians and help ensure validity of their testing, thereby resulting in fewer claims, legal disputes, and less adversarial relationships between all parties. Improved worker skills reduce the risks to both the owner/agency and contractor/producer and better identify the quality of each component and the final product. Training will improve the quality standards of highway workers, giving them more confidence and pride in the performance of their jobs. TQPs can be used to establish a career path for SHA and industry employees, providing promotional opportunities based on merit. Improved worker performance should lead to longer-lasting roads and a more effective use of taxpayer dollars, while providing an improved infrastructure for the traveling public.

APPENDIXES

(Nonmandatory Information)

X1. QUALIFYING TESTS—SOILS AND AGGREGATES

Recommended Test and Corresponding AASHTO Test or Other Test

X1.1. *Gradation*

- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 100, Specific Gravity of Soils

X1.2. *Liquid Limit, Plastic Limit, and Plasticity Index*

- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils

X1.3. *Compaction/Density*

- T 99/T 180, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop

X1.4. *Moisture Content*

- T 255, Total Evaporable Moisture Content of Aggregate by Drying

X1.5. *Sampling and Splitting*

- T 2, Sampling of Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

X1.6. *Deleterious Materials*

- T 21, Organic Impurities in Fine Aggregates for Concrete
- T 71, Effect of Organic Impurities in Fine Aggregate on Strength of Mortar
- T 112, Clay Lumps and Friable Particles in Aggregate
- T 194, Determination of Organic Matter in Soils by Wet Combustion
- T 267, Determination of Organic Content in Soils by Loss of Ignition

X1.7. *Lightweight Pieces*

- T 113, Lightweight Pieces in Aggregate

X1.8. *Dry Rodded Unit Weight*

- T l9M/T 19, Bulk Density (“Unit Weight”) and Voids in Aggregate

X1.9. *Soil Preparation*

- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test

---

X2. QUALIFYING TESTS—PORTLAND CEMENT CONCRETE

Recommended AASHTO or Other Test Designations

X2.1. Sampling

- T 141, Sampling Freshly Mixed Concrete

X2.2. Aggregate Gradations

- T 27, Sieve Analysis of Fine and Coarse Aggregates

X2.3. Moisture Content of Coarse and Fine Aggregate

- T 255, Total Evaporable Moisture Content of Aggregate by Drying

X3.10. *Sand Equivalent*

- T 176, Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test
- T 245, Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor
- ASTM D 1560, Standard Test Methods for Resistance to Deformation and Cohesion of Bituminous Mixtures by Means of Hveem Apparatus

X3.11. *Fine Aggregate Angularity*

- T 304, Uncompacted Void Content of Fine Aggregate

X3.12. *Coarse Aggregate Angularity*

- ASTM D 5821, Standard Test Method for Determining the Percentage of Fractured Particles in Coarse Aggregate
- ASTM D 4791, Standard Test Method for Flat Particles, Elongated Particles, or Flat and Elongated Particles in Coarse Aggregate

X3.13. *Moisture Susceptibility*

- T 283, Resistance of Compacted Hot Mix Asphalt (HMA) to Moisture-Induced Damage

Standard Practice for

Evaluating Deicing Chemicals

AASHTO Designation: R 34-03 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Evaluating Deicing Chemicals

AASHTO Designation: R 34-03 (2008)

1. SCOPE

1.1. This practice includes a set of test procedures for the evaluation of deicing chemicals.

1.2. *This procedure may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *SHRP Documents*:

- SHRP H-332, Handbook of Test Methods for Evaluating Chemical Deicers
- SHRP H-332—Appendix B, Containing the following 11 tests:
  - SHRP H-205.1, Ice Melting Capacity of Solid Deicing Chemicals
  - SHRP H-205.2, Ice Melting Capacity of Liquid Deicing Chemicals
  - SHRP H205.3, Ice Penetration of Solid Deicing Chemicals
  - SHRP H205.4, Ice Penetration of Liquid Deicing Chemicals
  - SHRP H-205.5, Ice Undercutting by Solid Deicing Chemicals
  - SHRP H-205.6, Ice Undercutting by Liquid Deicing Chemicals
  - SHRP H205.7, Evaluation of Corrosive Effects of Deicing Chemicals on Metals
  - SHRP H-205.8, Rapid Evaluation of Effects of Deicing Chemicals on Concrete
  - SHRP H-205.9, Evaluation of Scaling Effects of Deicing Chemicals on Concrete Surfaces
  - SHRP H-205.10, Evaluation of Frictional Characteristics of Deicing Chemicals
  - SHRP H-205.12, Evaluation of Corrosive Effects of Deicing Chemicals on Steel Reinforcement in Concrete

3. GENERAL PROVISIONS

3.1. It is recommended that the procedures included in Section 2 be used for the complete characteristics of deicing chemicals.

Standard Practice for

Independent Assurance (IA) Programs

AASHTO Designation: R 44-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Independent Assurance (IA) Programs

AASHTO Designation: R 44-07

1. SCOPE AND LIMITATIONS

1.1. *Independent Assurance (IA)*—Independent assurance is used in industry as an internal audit and review to support the accuracy of data and processes. In the highway industry it is the outgrowth of a report from the Congressional House Committee on Oversights and Investigations ("Blatnik Committee") that requires state departments of transportation (DOTs) to perform IA sampling and testing whenever federal funds are involved.

1.2. *Purpose of IA*—Independent assurance is an unbiased and independent assessment of all sampling, testing, and workmanship. This assessment includes evaluation of procedures and equipment used for the acceptance of highway materials and construction. 23 CFR Part 637 requires each state to have an IA Program. Independent assurance is used for verification of sampling procedures, testing procedures, and testing equipment.

1.3. Independent assurance is distinct from, and not intended as an acceptance process or for use in, verification of contractor sampling and testing results. Independent assurance is distinct from, and not intended for, quality control (QC) purposes. If IA results indicate a potential problem with quality, the results may be used to initiate additional testing.

1.4. Independent assurance sampling shall be done in such a manner as to minimize variability. In order to eliminate material and process variability, split samples should be used. Independent assurance samples may be taken independently of verification or acceptance samples, or may be a split of a verification or an acceptance sample.

1.5. Deficiencies in acceptance or QC processes that are identified through the IA program must be investigated and resolved. Otherwise, there is no purpose in identifying deficiencies.

1.6. This standard practice is applicable to design/build and warranty specifications as well as more conventional contracting methods. As a management principle, IA is a responsibility of the DOT that cannot be delegated to the contractor. (For example, contractors shall not hire their own IA inspectors or testers.)

1.7. Independent assurance is an essential tool that helps to ensure integrity within the quality assurance (QA) program. Independent assurance helps to prevent fraud and other criminal activities by evaluating sampling and testing procedures and competency. Independent assurance must be consistent throughout the agency. (It keeps the honest people honest by providing a "level playing field" for all contractors.)

Note 1—Many of the principles included herein have universal application. Although this standard practice for IA programs is developed specifically for construction materials, it can be applied to other processes. The principles inherent in the use of unbiased, consistent, and reliable information are applicable for any management effort. For example, construction workmanship is frequently inspected by either measurement or examination.

3. DEFINITIONS (REFERENCE R 10)

3.1. *acceptance sampling and testing*—sampling and testing performed by the agency, or its designated agent, to evaluate acceptability of the final product. Also called verification sampling and testing when specifically used to validate the contractor’s data.

3.2. *accredited laboratories*—laboratories which are recognized by a formal accrediting body as meeting quality system requirements including demonstrated competence to perform standard test procedures.

3.3. *certified technician*—a technician certified by some agency as proficient in performing certain duties. [A certified technician is considered to be qualified. A qualified technician may or may not be certified.]

3.4. *independent assurance (IA)*—activities that are an unbiased and independent evaluation of all the sampling and testing (or inspection) procedures used in the QA program. [Independent assurance provides an independent verification of the reliability of the acceptance (or verification) data obtained by the agency and the data obtained by the contractor. The results of IA testing or inspection are not to be used as a basis of acceptance. Independent assurance provides information for quality system management.]

3.5. *independent sample*—a sample taken without regard to any other sample that may also have been taken to represent the material in question. [An independent sample is sometimes taken to verify an acceptance decision. This is possible because the data sets from independent samples, unlike those from split samples, each contain independent information reflecting all sources of variability, i.e., sampling, testing, materials, and construction.]

3.6. *quality assurance (QA)*—(1) all those planned and systematic actions necessary to provide confidence that a product or facility will perform satisfactorily in service; or (2) making sure the quality of a product is what it should be. [QA addresses the overall process of obtaining the quality of a service, product, or facility in the most efficient, economical, and satisfactory manner possible. Within this broad context, QA includes the elements of QC, IA, acceptance, dispute resolution, etc. The use of the term QA/QC or QC/QA is discouraged, and the term QA should be used. QA involves continued evaluation of the activities of planning, design, development of plans and specifications, advertising and awarding of contracts, construction and maintenance, and the interactions of these activities.]

3.7. *split sample*—a sample that has been divided into two or more portions representing the same material. [Split samples are sometimes taken to verify the acceptability of an operator's test equipment and procedure. This is possible because the variability calculated from differences in split test results is comprised solely of testing variability. See *replicate sample* in Section 3.201 of R 10.]

3.8. *validation*—the mathematical comparison of two independently obtained sets of data (e.g., agency acceptance data vs. contractor data) to determine whether it can be assumed they came from the same population.

3.9. *workmanship inspection*—examination or measurement for determination of conformance to requirements of construction processes, components, or products.

4. DEVELOPMENT OF IA PROGRAMS

4.1. Independent assurance programs can be administered by project, system, or a combination of the two. There are advantages to all three bases:

4.1.1. *Independent Assurance by Project*—The project basis, based on a quantity, may provide an easier way to monitor compliance and ensure that all materials are covered on an individual project. This basis may fit better when the DOT can accurately estimate initial quantities and the rest of the QA program is quantity-based.

4.1.2. *Independent Assurance by System*—The system basis is typically administered statewide. It is personnel-related rather than project-related and allows easier tracking of individuals. This basis is usually applied on a time-based, rather than a quantity-based frequency.

4.1.3. *Independent Assurance by Combination of Project and System*—The combination basis is both time-based and quantity-based. Thus, it is possible to use the advantages of both the project and system bases.

4.2. *Independent Assurance Applied to Testing*—IA provides an independent validation of the reliability of the acceptance or verification data obtained by the DOT and the data obtained by either the DOT or the contractor. The results of IA testing or inspection are not to be used as a basis of acceptance, but all IA-identified discrepancies should be resolved before acceptance is completed.

4.3. *Independent Assurance Applied to Documentation*—IA provides a management tool that can be used to audit test results for completeness and suspicious, erroneous, or missing data. [This is most efficiently done by establishing a database of all test results, including IA, with the data entered into a laboratory information management system (LIMS).]

4.4. *Independent Assurance Applied to Training*—IA should be used to evaluate the effectiveness of the training and qualification process as defined in Section 5. The IA evaluation can be linked directly to the qualification process to provide an effective feedback loop.

4.5. *Independent Assurance Applied to Certified Products*—IA should be used to assure a certified product meets the specifications required by the state DOTs. An example of this is the DOTs observation of a certified product technician performing tests. It is important to verify through a QA program that certified products meet specifications.

4.6. *Resolution of IA Issues*—Final project material certification requires the resolution of exceptions, deficiencies, etc. This is a primary ingredient in an IA program.

4.7. *Independent Supervision*—Independence in supervision and reporting should be maintained. However, this is not always practical. There should be no overlap in the direct supervision of the IA and other QA functions.

4.8. *Communication*—IA should allow facilitation of communication between the IA personnel and those that oversee the QA program independent of project, district, or region personnel.

4.9. *Observations, Standardization Checks, Split Samples, and Proficiency Samples*—The use of observations, standardization checks, split samples, and proficiency samples are tools to help assure that testing personnel and equipment are obtaining proper results.

4.10. *Initial and Periodic IA Testing*—IA testing is most effective near start-up for each project as well as when acceptance personnel change or are newly employed. Periodic IA testing is necessary throughout the project to identify equipment malfunction and maintain integrity of personnel.

5. QUALIFIED PERSONNEL (REFERENCE R 25)

5.1. *General Requirements*—The primary objective in establishing technician qualification programs is to assure that technicians are capable of performing the appropriate sampling and testing procedures correctly. In addition, it is likely that technicians will continue to perform the test correctly if they understand the importance of the test and the consequences of conducting improper sampling and testing procedures. The ultimate objective is to assure that cost-effective QC and highway materials are incorporated into the finished highway infrastructure element.

5.2. Technician qualification programs can vary in format while achieving the primary objective of producing qualified technicians. Currently, several DOTs have combined to develop regional programs that promote reciprocity in establishing qualification requirements. Similarly, many individual DOTs are pursuing their own programs. While DOT or regional flexibility for a technician qualification program format is readily supported, the following items are recommended fundamental elements of a complete qualification program:

- Formal training of personnel including all sampling and testing procedures with instructions on the importance of proper procedures and the significance of test results.
- Hands-on training to demonstrate proficiency of all sampling and testing to be performed.
- A period of on-the-job training with a qualified individual to assure familiarity with applicable procedures.
- A written examination and the hands-on demonstration of the various sampling and testing methods.
- Requalification at prescribed intervals (data from the IA program can be used as one element of requalification).
- The qualification program should have a documented process for removing or re-educating personnel that perform the sampling and testing procedures incorrectly.
- “Grandfathering”, the acceptances of a Professional Engineer or Engineer-in-Training certificate, or lifetime qualification are not considered to be appropriate criteria for achieving or maintaining qualification status.
- The qualification of IA personnel should exceed that of personnel doing QC or acceptance testing because when differences are found within the testing results or procedures, IA personnel should have the knowledge to identify the cause of the difference and correct the problem.
- A feedback loop that uses the IA database to improve training and qualification programs should be established.

6. QUALIFIED LABORATORIES (REFERENCE R 18)

6.1. *General Requirements*—Capable laboratories are as defined by appropriate programs established by each DOT. As a minimum, the qualification program shall include provisions for checking test equipment, and the laboratory shall keep records of standardization checks. Standardization is used as a generic term to represent calibration, checks, standardization, validation, or verification. The correct basis is dependent on the actual equipment and desired outcome.

6.2. The primary objective in establishing laboratory accreditation and qualification requirements is to ensure the capabilities of the laboratories. The ultimate objective is to assure that maximum QC and superior highway materials are incorporated into the finished highway infrastructure element.

6.3. *Equipment Documentation*—A list or record of all laboratory equipment requiring standardization is necessary for a qualified laboratory under 23 CFR Part 637.

6.4. DOTs should develop test procedures or test manuals referencing standard testing procedures, handling, identification, conditioning, storage, retention, and disposal of test samples.

6.5. *Testing Proficiency*—Testing personnel and equipment should be routinely evaluated by observations, standardization checks, split samples, or proficiency samples in order to provide appropriate reviews for laboratories.

6.6. *Evaluation Frequency*—Laboratory evaluations should be made on a prescribed cycle; ideally 12 to 18 months. Data from the IA program along with observations during IA tests should be used as part of the ongoing evaluation of the laboratory.

7. INDEPENDENT ASSURANCE PROJECT BASIS

7.1. *Advantages of IA Project Basis*—Since the IA project basis is quantity-based, it may fit better when the DOT can accurately estimate initial quantities and when the rest of the QA program is quantity-based. It facilitates establishing IA sample requirements at contract award and ensures key materials are tested on each project.

7.2. *Goal*—The goal is to evaluate the sampling and testing skill level of DOT project inspectors and technicians and contractor technicians performing tests used in the acceptance decision on DOT projects.

7.3. *Frequency*—This should be related to the risk for the test as related to quality. Most DOTs test at the rate of 10 percent of the rate used for acceptance tests. For an effective IA program, this rate should be considered a minimum if risk data are not available.

7.4. *Reporting*—A project materials certification by the DOT is required by 23 CFR Part 637 for each project. The CFR requires the certification to include a statement that all IA samples and tests fall within the tolerance limits of the program. A compilation of these reports provides an opportunity for DOTs to analyze trends, identify training needs, and make DOT-wide improvements.

8. INDEPENDENT ASSURANCE SYSTEM BASIS

8.1. *Advantages of IA System Basis*—Since the IA System Basis is technician-based, it allows an agency to ideally target all test equipment and personnel. Agencies with projects that are remote or located far apart may prefer this basis as well as those that have a large number of “small” quantity projects. It facilitates personnel testing when testers move between projects frequently and agrees with the overall QA system philosophy.

8.2. *Goal*—See Section 7.2.

8.3. *Frequency*—Each person conducting tests should be evaluated a minimum of once each calendar year. However, on critical projects, the personnel evaluations should exceed this minimum.

8.4. *Annual Report*—23 CFR Part 637 requires that if the DOT uses the system basis to the IA program, the DOT shall provide an annual report to the FHWA summarizing the results of the IA program. These reports provide an opportunity for DOTs to analyze trends, identify training needs, and make DOT-wide improvements.

8.4.1. Examples of desirable information to include in the annual report are:

- The number or percent of technicians evaluated;
- How often the technicians were evaluated;
- A general statement as to why all technicians were not evaluated, when appropriate;
- What, if any, problems occurred and why; and
- A general statement as to how any problems that were reported were resolved.

9. INDEPENDENT ASSURANCE COMBINATION BASIS

9.1. *Advantages of IA Combination Basis*—While not specifically addressed by 23 CFR Part 637, various combinations of the project and system bases are possible. This combination provides an opportunity for DOTs to maximize the effectiveness of their IA system. Examples include:

- Some DOT districts/regions use the system basis, and other districts/regions use the project basis.
- Some materials are IA-tested by the system basis, and other materials are IA-tested by the project basis.

10. COMPARISON OF TEST RESULTS

10.1. Independent assurance typically uses split samples to determine if the results of the testing devices used and personnel performing the tests compare within statistically determined limits. Both the means and the variabilities of the results can be compared.

10.2. There are at least two procedures for comparing the means; the difference two-sigma (d2s) limits and the paired *t*-test. The comparison of a single split sample by using the d2s limits is simple and can be done for each split sample that is obtained. However, since it is based on comparing only single data values, it is not very powerful for identifying differences when they exist. It is recommended that each individual split sample be compared using the d2s limits, and then, when possible, the paired *t*-test also be used on the accumulated split-sample results to allow for a comparison with more discerning power. If either of these comparisons indicates a difference, then an investigation to identify the cause of the difference should be initiated.

10.2.1. *d2s Difference Two-sigma Limits*—This procedure uses the difference between two tests and compares this difference to an allowable difference established for the specific test method. The allowable difference might be taken from an AASHTO or ASTM precision statement for the test procedure, or it may be developed based on split-sample data collected by the agency. The d2s is an index that indicates a maximum acceptable difference between two results obtained on test portions of the same material. It is the difference between two individual test results that would be equaled or exceeded in the long run in only one case in 20. $\text{d2s} = 2 \times \sqrt{2} \times (1\text{s})$, where 1s is the standard deviation. This is the simplest, but least powerful comparison that can be made because it includes a comparison between only two test values.

10.2.1.1. *Setting d2s Limits*—If d2s limits are used, it is essential that the multilaboratory d2s values be used, and not the single-operator limits. It is not appropriate to use either specification or acceptance limits for establishing d2s limits.

10.2.1.2. Using d2s limits is easy and requires little to no effort by the DOT. The advantage is that it is easily implemented and requires no expenditure of either personnel or funding by the DOT. It also lets the DOT implement the IA basis immediately.

10.2.1.3. The disadvantage of using AASHTO or ASTM d2s limits is that the limits are determined from a national pool of data and are not state-specific. They may or may not apply well to a given DOT with state-specific procedures and contractors. AASHTO and ASTM have test procedures with multiple test options that tend to increase the d2s values. For these reasons, many DOTs establish their own limits based on statewide “round-robin” test results.

10.2.1.4. The limits should be evaluated periodically (e.g., every five years) by round-robin testing programs to continually update the 1s value. If the 1s values change, then the d2s limits would also change. The 1s values from the previous study and the 1s values from the new study should be compared to see if they are significantly different. If not, the limits should be left as they are, or possibly combined with the results from both “round-robin” programs to determine the new 1s value to use to set the d2s value.

10.2.2. *Paired t-Test*—It is desirable, when possible, to compare the means of more than one set of tests. For this purpose, a second statistical process, the *t*-test for paired measurements (referred to as a paired *t*-test), can be used. Both the d2s and paired *t*-test procedures are based on the same underlying principle. However, since more data are employed, the paired *t*-test is more powerful at detecting differences when they exist. After the split samples are collected and tested, the *t*-test for paired measurements can be performed. This test uses the difference between each pair of tests and determines whether the difference is statistically different from 0. Thus, it is the difference *within* pairs, not *between* pairs, that is being tested. The equation for the *t*-test for paired measurements is provided in Equation (1):

$$t = \frac{\left|\overline{X}_d\right|}{\frac{s_d}{\sqrt{n}}} \qquad (1)$$

where:

$\overline{X}_d$ = average of the differences between the split-sample test results,

s_d = standard deviation of the differences between the split-sample test results, and

n = number of split-samples.

The calculated t value is then compared to the critical value, t_{crit}, obtained from a *t*-table with $n - 1$ degrees of freedom and for a pre-selected level of significance, α (usually 0.05 or less). Since it is of interest to determine whether the means are *different*, a *two-sided* test must be conducted. Therefore, if the *t*-table used is based on a two-sided test, then use $t_{\text{crit}} = t_\alpha$. If the *t*-table used is based on a one-sided test, then use $t_{\text{crit}} = t_{\alpha/2}$.

10.2.2.1. One of two decisions will be made:

10.2.2.1.1. The difference between the paired *t*-test results is greater than the critical t value, and is likely to occur from chance if they are actually equal (when $t \geq t_{\text{crit}}$).

10.2.2.1.2. There is no reason to believe that the paired *t*-test results are different because the average difference is not so different from 0 as to be unlikely to have occurred from chance if they are actually equal (when $t < t_{\text{crit}}$).

Note 2—A table of critical *t* values can be found in *Materials Control and Acceptance-Quality Assurance*, 2000; *Optimal Procedures for Quality Assurance Specifications*, 2003; and most basic statistics textbooks. Most computer spreadsheet programs contain statistical test procedures for the paired *t*-test.

10.2.2.2. The power of the test (i.e., the ability to determine differences when they exist) improves as the number of paired samples increases. As an example, when comparing three split-sample pairs, the probability of detecting a difference of 1s between the means of two populations is less than 20 percent for a two-sided test and a little over 30 percent for a one-sided test, whereas the same probabilities are nearly 100 percent for 20 split-sample pairs.

10.3. An *F*-test is used to test the variabilities of the two sets of test results. The following procedure is used to test whether or not the variances, i.e., standard deviations squared, of the two samples are different at a pre-selected level of significance (α).

10.3.1. Let the two sample sizes be n_1 and n_2 and denote the two sample variances by s_1^2 and s_2^2.

10.3.2. Let $s_{\max}^2$ be the larger of s_1^2 and s_2^2, and let $s_{\min}^2$ be the smaller of s_1^2 and s_2^2.

10.3.3. Then calculate *F* from Equation (2):

$$F = \frac{s_{\max}^2}{s_{\min}^2} \qquad (2)$$

The calculated *F* value is compared to the critical *F*-value, F_{crit}, which is the value for $F_{\alpha/2}$ determined from tables of the *F*-distribution for the appropriate degrees of freedom in the numerator and in the denominator. The degrees of freedom for the two samples are $df_1 = n_1 - 1$ and $df_2 = n_2 - 1$. The *F*-distribution is defined by these two degrees of freedom, and it is important to make sure that the appropriate degrees of freedom are used for the numerator and the denominator. For example, if s_2^2 is the larger variance, then its degrees of freedom are in the numerator. Also note that since the test indicates whether or not the two variances are *equal*, i.e., a *two-sided* test, the critical *F*-value is determined at $\alpha/2$ rather than at α.

10.3.4. Once the value for F_{crit} is determined from the table (making sure the appropriate degrees of freedom for the numerator and denominator are used), one of two decisions will be made:

10.3.4.1. If the difference between the *F*-test results is greater than the critical *F value*, and is likely to occur from chance if they are actually equal (when $F \geq F_{\text{crit}}$), then conclude that the two sets of tests have significantly different variabilities.

10.3.4.2. There is no reason to believe that the variabilities are significantly different when $F < F_{\text{crit}}$.

Note 3—A table of critical *F* values can be found in *Materials Control and Acceptance-Quality Assurance*, 2000; *Optimal Procedures for Quality Assurance Specifications*, 2003; and most basic statistics textbooks. Most computer spreadsheet programs contain statistical test procedures for the *F*-test.

11. KEYWORDS

11.1. Independent assurance; quality assurance; quality assurance, program; quality control.

Standard Specification for

Epoxy Resin Adhesives for Bonding Traffic Markers to Hardened Portland Cement and Asphalt Concrete

AASHTO Designation: M 237-96 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Epoxy Resin Adhesives for Bonding Traffic Markers to Hardened Portland Cement and Asphalt Concrete

AASHTO Designation: M 237-96 (2009)

1. SCOPE

1.1. This specification covers epoxy resin adhesives for bonding traffic markers to pavement surfaces.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 200, Epoxy Protective Coatings
- T 48, Flash and Fire Points by Cleveland Open Cup
- T 79, Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3ºC (200ºF)
- T 192, Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve
- T 237, Testing Epoxy Resin Adhesive

2.2. *ASTM Standards*:

- D 97, Standard Test Method for Pour Point of Petroleum Products
- D 185, Standard Test Methods for Coarse Particles in Pigments
- D 281, Standard Test Method for Oil Absorption of Pigments by Spatula Rub-out
- D 476, Standard Classification for Dry Pigmentary Titanium Dioxide Products
- D 1208, Standard Test Methods for Common Properties of Certain Pigments
- D 1209, Standard Test Method for Color of Clear Liquids (Platinum-Cobalt Scale)
- D 1210, Standard Test Method for Fineness of Dispersion of Pigment-Vehicle Systems by Hegman-Type Gage
- D 1257, Standard Specification for High-Gravity Glycerin
- D 1483, Standard Test Method for Oil Absorption of Pigments by Gardner-Coleman Method
- D 1514, Standard Test Method for Carbon Black—Sieve Residue
- D 1544, Standard Test Method for Color of Transparent Liquids (Gardner Color Scale)
- D 1747, Standard Test Method for Refractive Index of Viscous Materials

- D 2752, Standard Test Methods for Air Permeability of Asbestos Fibers
- D 3272, Standard Practice for Vacuum Distillation of Solvents From Solvent-Reducible Paints For Analysis

2.3. *Federal Standards*:

- Fed. Std. No. 141, Paint, Varnish, Lacquer and Related Materials; Methods of Inspection, Sampling and Testing, Method 4184 Percent Air, Method 4242 Color, Heilige-small
- Fed. Std. No. 595, Colors used in Government Procurement

3. CLASSIFICATION

3.1. *Type I*—Rapid Setting, High Viscosity, Epoxy Adhesive. This type of adhesive provides rapid adherence of traffic markers to the surface of the pavement.

3.2. *Type II*—Standard Setting, High Viscosity, Epoxy Adhesive. This type of adhesive is recommended for adherence of traffic markers to pavement surfaces when rapid set is not required.

3.3. *Type III*—Rapid Setting, Low Viscosity, Water Resistant, Epoxy Adhesive. This type of rapid setting adhesive, due to its low viscosity, is appropriate only for use with embedded traffic markers. It is more water-resistant than Type I or Type II.

3.4. *Type IV*—Standard Set Epoxy for Blade Deflecting-Type Plowable Markers.

4. MATERIALS

4.1. The material shall be furnished in two separate components for combining in equal volumes immediately prior to use.

4.2. *Composition*:

4.2.1. The composition of the components for Type I and Type II shall conform to the requirements prescribed in Table 1.

4.2.2. The composition of the components for Type III shall conform to the requirements prescribed in Table 2.

4.2.3. The components for Type IV shall conform to the requirements prescribed in Table 3.

4.2.4. Other epoxies meeting the physical requirements of Sections 4.3 and 4.4 for the type specified may be used with the approval of the purchaser.

Table 1—Chemical Composition of Ingredients of Composition for Type I and Type II Epoxy

	Parts by Mass	
	Type I	Type II
Component A		
Epoxy Resin[a]	90.00	87.00
Orthocresyl Glycidyl Ether[b]	10.00	
Aliphatic Glycidyl Ether[c]		13.00
Titanium Dioxide ASTM D 476, Type I or Type II	3.00	3.00
Talc[d]	50.00	30.00
Fibrillated Polyethylene Fiber[e]	2.00*	4.00**
Glycerin, ASTM D 1257	0.50	
Silicone Anti-Foam, Type DB100, 100% Solids		0.005
Component B		
High Functionality Polymercaptan Hardener[f]	60.00	
2, 4, 6-Tri (Dimethylaminomethyl) Phenol[g]	7.00	
Polysulfide Polymer[h]	35.00	
N-Aminoethyl Piperazine[i]		23.16
Nonylphenol[j]		52.00
Furnace Black[k]	0.10	0.10
Talc[d]	50.00	70.00
Fibrillated Polyethylene Fiber[e]	2.00*	0.70**
Silicone Anti-Foam, Type DB100, 100% Solids	0.01	0.005

* A range of 11.5 to 2.5 parts is permitted in the A component and in the B component to achieve the required viscosity and thixotropy. Small preproduction batches should be made to determine the fiber level best suited for manufacturing equipment level.

** A range of 3.0 to 5.0 parts is permitted in the A component and 0.3 to 1.0 parts in the B component, to achieve the required viscosity and shear ratio.

[a] Di-glycidyl ether of bisphenol A: Brookfield viscosity, 10–16 Pa·s (100–160 poise) at 25˚C; epoxide equivalent 180–200; color. Gardner 1933, 3 maximum.

[b] Brookfield viscosity at 25˚C, MPa·s (5–10 centipoise); density kg/m_3, 1078–1090 kg/m_3 (weight per gallon 9.00–9.10 pounds; epoxide equivalent 180–200).

[c] Aliphatic mono functional reactive glycidyl ether, derived from an aliphatic alcohol: Brookfield viscosity at 25˚C, 1 to 15 MPa·s (1 to 15 centipoise); epoxide equivalent 220–250; specific gravity 0.88–0.95.

[d]

Specific Gravity	2.68 to 2.86
Hegman Rating	3.25 to 6.0
Particle Shape	Platey
Maximum Particle Size, Microns	55
Percent passing 45-µm (U.S. No. 325) Screen, minimum	99
Dry Brightness, minimum	86

[e] High density, fluff dried, pure fibrillated polyethylene; melting point 120˚C–130˚C; specific gravity, 0.915–0.965; molecular mass, 30000–150000; fiber size, average length, 0.90-mm diameter, 10 microns; fiber strength, 31.4–39.2 MPa; elongation at rupture, 45–57 percent; moisture content, less than 2 percent.

[f] Liquid polymercaptan resin: Brookfield viscosity, 10–13 Pa·s (100–130 poise) at 25˚C; specific gravity 1.14–1.16; mercaptan value, 3.6 meg/gram: color, Gardner 1933, 1. Infrared curve shall match the printed curve in this specification.

[g] Formula weight 265; specific gravity at 25˚C; 0.937 refractive index 1.514 at 25˚C; vacuum distillation. 96 percent shall have been distilled over a temperature between 130 and 160˚C, 66.7 to 200.0 Pa absolute pressure (0.5 to 1.5-mm Hg vacuum pressure); flash point, Tag Open Cup, 149˚C minimum; water content 0.06 percent maximum.

[h] Specific gravity, 1.24–1.30 at 20˚C/20˚C: Brookfield viscosity, 0.7–1.2 Pa·s (700–1200 centipoise) at 25˚C; pH water extract 6.0–8.0; moisture content, 0.1 percent maximum; pour point, –26˚C; average molecular mass, 1000; flash point, Cleveland Open Cup, 93˚C (200˚F) minimum; sulfur content, 36–40; color, Heilige, 9–12. The product shall be a dysfunctional mercaptan made from 98 mole percent of bis (2-chloroethyl) formal and 2 mole percent of trichloropropane.

[i] Color (APHA), 100 maximum; amine value based on titration which reacts with the three nitrogens in the molecule (1250–1350); appearance, clear and substantially free of suspended matter.

[j] Color (APHA), 100 maximum; parn. nonylphenol, 85 percent minimum; water (Karl Fischer) 0.05 percent maximum.

[k] Surface area, 5–185, m_2/g; particle diameter, 18–30 millimicrons; fixed carbon (moisture free), 96–98 percent; volatile matter, 1–4 percent.

Table 2—Chemical Composition of Type III Epoxy

	Parts by Mass
Component A	
[Density = 1878 kg/m^3 (15.67 lb/gal)]	
Epoxy Resin[a]	20.03
Epoxy Resin[b]	14.69
Aliphatic Epoxy Resin[c]	9.78
Titanium Dioxide ASTM D476 Type I or II	2.18
Calcium Silicate[d]	21.14
Barium Sulfate[e]	32.05
Fluorinated Alkyl Ester Surfactant[f]	0.13
Component B (Hardner)	
[Density = 1950 kg/m^3 (16.27 lb/gal)]	
*Precatalyzed Polymercaptan Hardner[g]	30.17
*Precatalyzed Polymercaptan Hardner[h]	5.45
Mercapto Silane[i]	0.72
Calcium Silicate[d]	26.78
Barium Sulfate[e]	40.10
Carbon Black[j]	0.10
*2, 4, 6, Tri (Dimethyl Amino Methyl) Phenol	0.57

* Available from Diamond Shamrock Corporation.

[a] Epoxide equivalent 176–181; Brookfield viscosity at 25°C, 35–70 Pa·s (350–700 poise); color, Gardner, max 2: the reactive diluent shall be neopentylglycoldiglycidal ether.

[b] Epoxide equivalent 180–190; Brookfield viscosity at 25°C, 7–10 Pa·s (70–100 poise); color, Gardner, max 2: the reactive diluent shall be neopentylglycoldiglycidal ether.

[c] 1–4 butane dioldiglycyl ether, viscosity 25°C, 19 MPa·s (19 cps); epoxide equivalent mass 136.

[d] Specific gravity 2.9, pH (Aqueous solution), 9.9; refractive index 1.63.

[e] Specific gravity, 25°C, 2.9, pH, Aqueous solution, 3.8–4.5; refractive index 1.64; oil absorption, 11 percent by mass.

[f] Brookfield viscosity, 25°C, 15 Pa·s (15000 cps); specific gravity, 25°C, 1.15; refractive index, 25°C, 1.445; active ingredients, 100 percent.

[g] Brookfield viscosity, 25°C, 0.25 Pa·s (250 cps); specific gravity, 25°C, 1.06; mercaptan value meg/g 5.75; color, Gardner, max, 2.

[h] Brookfield viscosity, specific gravity, 25°C, 106; mercaptan value meg/g 552; color, Gardner, max, 2.

[i] Brookfield viscosity, 25°C, 3.0 MPa·s (3.0 centipoise); density or unit mass, 25°C, 984 kg/m_3 (8.208 lb/gal); color, water white; refractive index, 25°C, 1.43; boiling point, 1.3 kPa absolute pressure (10 mm-Hg), 106°C.

[j] Surface area 115–130 m_2/g; particle diameter 18–30 millimicrons; pH, 7.0–8.5; fixed carbon (moisture free), 96–98 percent; volatile matter, 1–4 percent; oil absorption, stiff past endpoint 0.80–0.90 mL/g.

Table 3—Chemical Composition of Type IV Epoxy

	Parts by Mass
Component A	
Epoxy Resin Epon 828, Shell (or equal)	100.00
Titanium Dioxide (TT-P-442, Type III, Class A)	7.68
Talc #13 (or equal)	36.64
Component B	
N-Aminoethyl Piperazine Jefferson (or equal)	25.10
Nonylphenol	50.03
Talc Fiberene C-400, Sierra (or equal)	69.28
Molacco Black (or equal)	0.23

4.3. *Physical Requirements—Individual Components*:

4.3.1. Requirements for components A and B are the same for all types except as noted.

4.3.2. Viscosity, Pa·s (Poise), TE Helipath Spindle at 25 ± 1ºC (77 ± 2ºF). Type I, 350 to 500 (3500 to 5000), Type III, 4 to 6 (40 to 60). Viscosity, Pa·s (Poise), TD Helipath at 25 ± 1ºC (77 ± 2ºF). Type II, 100 to 300 (1000 to 3000).

4.3.3. Shear ratio, 25ºC (77ºF), 2 minimum, for Types I and II.

4.3.4. Density, kilograms per cubic meter (pounds per gallon) at 25ºC (77ºF):

	Component A	Component B
Type I	1402 to 1462 (11.7 to 12.2)	1402 to 1462 (11.7 to 12.2)
Type II	1270 to 1306 (10.6 to 10.9)	1354 to 1390 (11.3 to 11.6)
Type III	1797 to 1893 (15.0 to 15.8)	1929 to 1965 (16.1 to 16.4)
Type IV	1414 to 1438 (11.8 to 12.0)	1390 to 1414 (11.6 to 11.8)

4.3.5. Skinning (original container), none.

4.3.6. Percent air, two maximum.

4.3.7. *Infrared Curves*—Components A and B shall match curves originally approved by the purchaser.

4.3.8. *Storage Stability*:

4.3.8.1. The Components A and B shall not change in viscosity and shear ratio by more than ±15 percent when stored for 14 days in closed containers at 47.0 ± 1.8ºC (115 ± 3ºF). All measurements shall be made at 25 ± 1ºC (77 ± 2ºF) using the same spindle and apparatus as in Section 4.3.2 above.

4.3.8.2. The adhesive shall meet all other requirements for 12 months from date of manufacture. Any settling of the fillers must be easily redispersible with a paddle.

4.4. Physical Requirements for the Mixed Epoxy (Component A mixed with Component B) Types I, II, III, and IV.

4.4.1. *Gel time, minutes*:

- Type I, 6–10
- Type II, 6–10
- Type III, 6–10
- Type IV, 6–10

4.4.2. *Bond strength to concrete*, maximum time, minutes to reach 1380 kPa (200 psi). (See Table 4.)

Table 4—Bond Strength to Concrete

	Type I	Type II, Type IV	Type III
at 25 ± 1°C (77 ± 2°F), max	35	210	35
at 10 ± 1°C (50 ± 2°F), max	45	—	45
at –1 ± 1°C (31 ± 2°F), max	85	—	85

4.4.3. *Slant shear strength* (See Table 5.)

Table 5—Slant Shear Strength

	Type I	Type II, Type IV	Type III
24 h at 25 ± 1°C, kPa (psi), min	6895 (1000)	13 790 (2000)	6895 (1000)
24 h at 25 ± 1°C, plus water soak, kPa (psi), min	5516 (800)	10 342 (1500)	6895 (1000)

4.4.4. *Tensile adhesion and cohesion,*

4.4.4.1. *Ceramic marker bottom, kPa (psi), minimum*:
- Type I, 4830 (700)
- Type II, 4830 (700)
- Type III, 4830 (700)
- Type IV, 4830 (700)

4.4.4.2. *Ceramic marker bottom, including post cure, kPa (psi), minimum*:
- Type I, 4830 (700)
- Type II, 4830 (700)
- Type III, 4830 (700)
- Type IV, 4830 (700)

4.4.4.3. *Reflective pavement marker, bottom kPa (psi), minimum*:
- Type I, 3450 (500)
- Type II, 3450 (500)
- Type III, 3450 (500)
- Type IV, 3450 (500)

4.4.5. *Color*—Color for all types shall be approximately that of Color 26132 to 26152 of Federal Standard No. 595.

4.5. *Certificate of Compliance*—The manufacturer shall furnish to the purchaser a Certificate of Compliance for Component A, Component B, and for the mixed epoxy. The certificate shall certify conformance to this specification. Test results shall be maintained and available upon request.

4.6. *Test Methods*:

4.6.1. *Brookfield Viscosity*—AASHTO T 237.

4.6.2. *Epoxide Equivalent*—AASHTO T 237.

4.6.3. *Color, Gardner*—ASTM D 1544.

4.6.4. *Color, Heilige*—Fed. Std. No. 141, Method 4242.

4.6.5. *Color, APAH*—ASTM D 1209.

4.6.6. *Gel Time*—AASHTO T 237.

4.6.7. *Oil Absorption*—ASTM D 1483.

4.6.8. *pH*—ASTM D 1208.

4.6.9. *Hegman Rating*—ASTM D 1210.

4.6.10. *Maximum Particle Size*—ASTM D 185.

4.6.11. *Percent Passing 45-μm (No. 325) Screen*—AASHTO T 192.

4.6.12. *Infrared Curve*—AASHTO T 237.

4.6.13. *Refractive Index*—ASTM D 1747.

4.6.14. *Vacuum Distillation*—ASTM D 3272.

4.6.15. *Flash Point, Tag Open Cup*—AASHTO T 79.

4.6.16. *Flash Point, Cleveland Open Cup*—AASHTO T 48.

4.6.17. *Water Content*—ASTM D 1208.

4.6.18. *Pour Point*—ASTM D 97.

4.6.19. *Specific Gravity*—AASHTO T 237.

4.6.20. *Surface Area*—ASTM D 2752.

4.6.21. *Bond Strength to Concrete*—AASHTO T 237.

4.6.22. *Tensile Adhesion and Cohesion*—AASHTO T 237.

4.6.23. *Slant Shear Strength*—AASHTO T 237.

4.6.24. *Shear Strength*—AASHTO T 237.

4.6.25. *Shear Ratio*—AASHTO T 237.

4.6.26. *Percent of Air*—Fed. Std. No. 141, Method 4184.

5. PACKAGING AND MARKING

5.1. Components shall be packaged and marked as set forth under "Packaging" in M 200 except that the proper mixing ratio shall always be specified.

6. RECOMMENDED PRACTICE

6.1. *Surface Preparation*:

6.1.1. Road surface must be cleaned by sandblasting the area to which marker is to be bonded except for recessed or sawn installations. Sand must be clean and dry.

6.1.2. When markers are to be placed over existing traffic paint stripes, all old paint and primer, if present, must be removed.

6.2. *Adhesive Mixing and Metering*:

6.2.1. Machine mixer and applicator must be capable of accurately and uniformly proportioning Component A to Component B in a volume ratio of 1 to 1 within ±5 percent by volume of each component (i.e., within range of 47.5 percent to 52.5 percent for each compound).

6.2.2. Mixing chamber must produce the mixed adhesive with a uniform gray color with no visible evidence of streaks of either black or white on the surface or within the mixed adhesive.

6.2.3. Voids in a cured undisturbed sample 1.6 mm ($^1/_{16}$ in.) thick from the extrusion nozzle shall not exceed 4 percent.

6.2.4. Periodic checks of the proportioning equipment shall be made to determine the actual volume ratio of A to B. This shall be done by placing containers before the mixing chamber and the actual volume of A and B measured.

6.2.5. The ambient temperature during application of Types II and IV epoxy shall be at least 10ºC (50ºF) and preferably higher than 15.6ºC (60ºF). These adhesives harden relatively slow at 10ºC (50ºF) but the hardening rate rapidly accelerates as temperature increases.

Standard Specification for

Glass Beads Used in Pavement Markings

AASHTO Designation: M 247-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Glass Beads Used in Pavement Markings

AASHTO Designation: M 247-09

1. SCOPE

1.1. This specification covers glass beads to be dropped or sprayed upon pavement markings so as to produce a reflectorized pavement marking.

1.2. *Types*:

1.2.1. *Type 0*—shall be known as a uniform gradation.

1.2.2. *Type 1*—shall be known as a standard gradation.

1.2.3. *Types 2, 3, 4, and 5*—shall be known as modified gradations.

1.3. *Coatings*:

1.3.1. *Flotation*—Any of the above gradation types may be obtained with oleophobic properties at the request of the purchaser (Note 1).

1.3.2. *Moisture Resistance*—Any of the above types may be obtained with hydrophobic properties if so specified by the purchaser.

1.3.3. *Adherence*—Any of the above types may be obtained with an adhesion coating if so specified by the purchaser.

Note 1—Any of the above types of beads may be specified with a combination of two of the above coatings. Dual coated beads must test positive for the presence of both specified properties.

1.4. The values stated in SI units are to be regarded as the standard.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards:*

- D 75, Standard Practice for Sampling Aggregates
- D 1214, Standard Test Method for Sieve Analysis of Glass Spheres

- D 1155, Standard Test Method for Roundness of Glass Spheres
- D1213-54 (1975), Test Method for Crushing Resistance of Glass Spheres (Withdrawn 1983)
- E 105, Standard Practice for Probability Sampling of Materials
- E 1617, Standard Practice for Reporting Particle Size Characterization Data
- E 1994, Standard Practice for Use of Process Oriented AOQL and LTPD Sampling Plans

2.2. Federal Standards:

- Federal Standard No. 40, CFR 261.24, Table 1 Maximum Concentration of Contaminants for the Toxicity Characteristic

2.3. Other Standards:

- ANSI/ASQ Z.4 and Z1.9, Sampling Procedure and Tables for Inspection by Attributes

3. GENERAL REQUIREMENTS

3.1. The beads shall be transparent, clean, colorless glass, smooth and spherically shaped, free from milkiness, pits, or excessive air bubbles and conform to the following specific requirements:

3.2. The glass beads must not exhibit a characteristic of toxicity, relative to heavy metals, when tested in accordance with EPA 40 CFR 261.24.

4. SPECIFIC PROPERTIES

4.1. *Gradation*—The beads shall meet the gradation requirements for type as given in Table 1.

Table 1—Gradation of Glass Beads

Sieve Designation		Mass Percent Passing					
Standard, mm	Alternate No.	Type 0	Type 1	Type 2	Type 3	Type 4	Type 5
2.35	8						100
2.00	10					100	95–100
1.70	12				100	95–100	80–95
1.40	14				95–100	80–95	10–40
1.18	16		100	100	80–95	10–40	0–5
1.00	18				10–40	0–5	0–2
0.850	20		95–100	90–100	0–5	0–2	
0.710	25				0–2		
0.600	30	100	75–95	50–75			
0.425	40	90–100		15–45			
0.300	50	50–75	15–35	0–15			
0.180	80	0–5	0–5				
0.150	100		0–5				

4.2. *Roundness*—The glass beads shall have a minimum of 70 percent true spheres.

4.3. *Refractive Index*—The glass beads shall have a refractive index of 1.50–1.55.

4.4. *Coatings: Flotation, Flow, Moisture Resistance, and Adherence*—When tested in accordance with Section 5.3, the presence of the purchaser specified coatings will be unambiguous. Beads will flow properly when tested in accordance with the procedure in Section 5.3.1 unless they are specified to be moisture resistant, in which case the procedure in Section 5.3.2 will be followed.

4.5. The beads shall be dry and free of lumps and clusters.

5. METHODS OF SAMPLING AND TESTING

5.1. *The sampling shall be random in the following ratios*—45 kg (100 lb) of sample (in full bags) per 4535 kg (10000 lb) shipped. Upon arrival material shall be reduced in a sample splitter to a size of approximately 1 kg (2 lb). Alternatively, Statistical Process Control Methods following ASTM E 105 and E 1994, and D 75 or ANSI/ASQ Z1.4 and Z1.9 may be used to monitor the quality of the product so that it meets the requirement of the applicable detail specification. The supplier shall state in a Declaration of Conformity the sampling plans and test methods used.

5.2. The following requirements shall be tested with the following test methods:

5.2.1. *Gradation*—ASTM D 1214. Alternatively a mechanical, optical or instrumental method with traceable standards is acceptable provided that it correlates to acceptable results obtained using ASTM D 1214, or documentation showing correlation to the referee method referenced in ASTM D 1214, and follows ASTM E 1617. In the event of nonconformity, ASTM D 1214 “Hand Sieve” will be the referee method.

5.2.2. *Roundness*—ASTM D 1155. Alternatively a mechanical, optical, or instrumental method with traceable standards is acceptable provided that it correlates to acceptable results obtained using ASTM D 1155, or documentation showing correlation to the referee method referenced in ASTM D 1155, and follows ASTM E 1617. In the event of nonconformity, ASTM D 1155, Procedure B, will be the referee method.

5.2.3. *Refractive Index* shall be tested by a liquid immersion method (Becke Line Method or equal) at a temperature of 25 ± 5°C (77 ± 9°F).

5.3. *Coatings Tests*:

5.3.1. *Flow Characteristics Test*—Referee Method.

5.3.1.1. A 100 g sample of beads is placed in a Corning 3140 crystallizing dish (or equivalent), 100-mm diameter by 50-mm depth. Place the dish in a Corning 3080 Desiccator (or equivalent) 250-mm inside diameter by 330-mm overall height and 130-mm chamber depth, which shall be filled with a sulfuric acid-water solution having a specific gravity of 1.10 (approximately 94 percent humidity) to a point 25.4 mm below the top of a size 5 Coors 60003 Desiccator Plate (or equivalent). The sample shall remain in the covered Desiccator at 25 ± 5°C for 4 hours. Remove the sample from the Desiccator and transfer the beads to a metal pan. The beads shall flow without stoppage when poured slowly through a standard glass funnel (Corning 6120 or equivalent), 127-mm diameter, 102-mm stem length, and 11-mm stem inside diameter (Note 2).

Note 2—The test operations should be performed immediately on removal of the beads from the Desiccator.

5.3.2. *Moisture Resistant Coating Test*—Referee Method.

5.3.2.1. A 100-g sample of beads is placed in a 600-mL beaker. With the beaker held at approximately a 45-degree angle, 100 mL of distilled water is slowly added to the beaker. The water is carefully poured down the side of the tilted beaker. The beads are to remain undisturbed. The beaker is allowed to stand, undisturbed, for 5 minutes. At the end of the standing time, the water is carefully poured from the beaker. It may be necessary to slightly rotate the beaker to avoid trapping pockets of water. Holding the beaker at the "pour angle," the beads are transferred to a clean, dry 600-mL beaker. A thin, even layer of beads may coat the inside of the original beaker. The second beaker is allowed to stand, undisturbed, for five minutes. At the end of the standing time, the beads are slowly poured into a standard glass funnel (Corning 6120 or equivalent), 127 mm in diameter, 102-mm stem length and 11-mm stem inside diameter. The beads should flow through the funnel stem without stopping. Slight initial agitation to start the flow of beads through the funnel is permissible.

5.3.3. *Flotation Test*—Referee Method.

5.3.3.1. Determine the mass of approximately 1 g to the nearest 0.0005 g, evenly distribute beads into a clean standard 100-mm glass Petri dish previously weighed to the nearest 0.0005 g. The dish is vibrated slightly to attain as near as possible a monolayer of beads. Xylene, C.P. Grade, is introduced at one side of the dish at a rate of 10 to 15 mL per minute from a burette until 30 mL has been added. The floating beads are then carefully drawn off by suction through a suitably constricted delivery tube connected to a receiving flask. Excess xylene is drawn off so that no remaining beads are lost and the dish dried in an oven at 110 ± 5ºC. The dish is weighed and the percentage of floating beads calculated.

5.3.4. *Adherence Coating Oven Test*—Referee Method.

5.3.4.1. Prepare a solution by weighing 0.2 grams of dansyl chloride and dissolving in 25 ml of acetone. (See Note 3.) This solution can be used for several tests during the day, but must be kept refrigerated in a closed dark container between uses. Make a fresh solution daily.

Warning—Dansyl chloride is hazardous. Do not allow skin contact or touch the beads after testing.

Note 3—Dansyl chloride tests for the presence of amino functional groups which are present in most common adhesion coatings. If the supplier is using alternate adhesion chemistry, a comparable simple test must be supplied. Dansyl chloride will oxidize on prolonged contact with air and light. Solutions should be stored in a dark, brown glass jar. Fresh solutions are a pale, yellow green. Unusable stale solutions are yellow brown.

5.3.4.2. Weigh 10 grams of beads and place in aluminum trays. Saturate the glass bead sample with the dansyl chloride solution using an eyedropper. Dry the beads in an oven at 60°C (140°F) for 15 minutes. Beads will be yellow and agglomerated. Rinse the beads by placing them in the funnel containing new filter paper and pouring 100 ml of acetone over them. Use suction during the step. Remove the beads from the funnel, and again place in aluminum trays. Dry the beads in the oven until free flowing. Place the beads on glass filter paper and inspect them under ultra-violet light. Inspection must be in a dark room. A yellow-green fluorescence will be observed if adherence coating present. (See Notes 3 and 4.) If all beads have a yellow-green fluorescence with the oven test, the beads are properly coated with adherence coating. If some or no beads have a yellow-green fluorescence then this is cause for rejection.

Note 4—Fluorescence is proportional to the intensity of the incident UV light. Longwave UV lamps designed for quality control, industrial inspection, and nondestructive testing are typically 100W. Portable lamps with 6 or 8W bulbs will show much less fluorescence on the same samples. Longwave UV bulbs emit at 365 nm wavelength. Shortwave UV lamps, 254 or 302 nm, and low-watt penlight lamps are not sufficient for this test.

5.3.5. *Alternative Flotation Test*—As Permitted by Purchasing Agency

5.3.5.1. A 15 to 20 g sample of beads is placed in a 60 mL (2 oz.) aluminum weighing dish, 57-mm inside diameter by 16-mm depth. The filled dish should be placed on a flat surface and shaken lightly so that the beads present a flat surface. Carefully place small drops of hexadecane [approximately

5 mm (0.187 in.) in diameter or 0.05 mL volume] on the test beads in three locations so that the drops are not touching. The dish should be left flat and the drops should be put in the center of the dish. Do not touch the beads with the dropper tip. A positive test for the presence of coating occurs if all three drops applied show clear, well-rounded appearance with high contact angle, i.e., the test liquid beads up. A negative test for coating shows the loss of contact angle of the drop, i.e., if wetting of the beads as evidenced by a darkening of the surface or sinking of the drop into the surface or bead interface occurs within 2 min ± 10 s.

5.3.6. *Alternative Moisture Resistance Test*—As Permitted by Purchasing Agency.

5.3.6.1. The above Alternative Flotation test in Section 5.3.6 is performed with three distilled water drops instead of hexadecane.

5.3.7. *Alternative Adherence Test*—As Permitted by Purchasing Agency.

5.3.7.1. The test in Section 5.3.4 is performed with the following exceptions:

5.3.7.2. One eyedropper full (1.0 ml) of 0.02 wt% dansyl chloride (5-dimethylaminonaphthalene-1-sulfonyl chloride) solution in acetone is dropped around the center of the 10 grams of beads. Do not disturb or mix the beads after wetting. After 30 minutes a positive test for the presence of coating occurs if the wetting area shows clear fluorescence, a bright green to blue glow, under strong long UV light (365 nm) against a dark background in a darkened room or stray light-free enclosure. A negative test for coating occurs if the wetted surface of the beads shows no fluorescence. The reaction may be speeded by heating the tested sample to 60 ± 5°C (140 ± 9°F) for 5 min. It is best practice to use heat and simultaneously test the sample alongside beads known to have no adhesion coating. A positive presence of coating should be unambiguous.

6. PACKAGING AND MARKING

6.1. Glass beads shall be furnished in kilogram (pound) lots as specified by the purchaser and packaged in moisture-proofed bags. Containers are to be guaranteed to furnish dry and undamaged beads. Each package shall contain the following information: name and address of manufacturer, shipping point, trademark or name, the wording “glass beads,” the specification number, number of kilograms (pounds), the lot or batch number and the month and year of manufacture.

Standard Specification for

Ready-Mixed White and Yellow Traffic Paints

AASHTO Designation: M 248-91 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Ready-Mixed White and Yellow Traffic Paints

AASHTO Designation: M 248-91 (2007)

1. SCOPE

1.1. This specification covers alkyd resin type, ready-mixed white and yellow traffic paints for use on bituminous and portland cement concrete pavements.

1.2. Intended use of the traffic paint.

1.2.1. These paints may be reflectorized for night visibility by adding reflective spheres before the paint film dries or sets, using the drop-on or pressurized methods. Generally, the reflective spheres are evenly dispersed to a wet film of 0.38 mm (15 mils) at a rate of 600 to 720 kg/m (5 to 6 lb/gal) of paint. The amount may be altered by the purchaser.

1.3. *Types*:

1.3.1. *Type S Traffic Paint*—This type is a slow drying paint which shall be used in areas where coning is acceptable for 1 hour or more.

1.3.2. *Type N Traffic Paint*—This type has immediate drying properties and shall be used in areas where coning of roadway is acceptable for 15 to 30 minutes.

1.3.3. *Type F Traffic Paint*—This type shall be used where faster drying time is required with a minimum of coning. With good drying conditions, this paint should dry in 3 to 6 minutes if heated to 51.5 ± 2.5ºC (125 ± 5ºF) in the applicator.

1.4. The values stated in SI units are to be regarded as the standard.

Note 1—It is advisable to consult local air pollution regulations regarding solvents prior to selecting type of paint to be used.

2.3. *Military Standards*:

- MIL-C-429, Chlorinated Paraffin, Technical

3. CLASSIFICATION

3.1. *Types*—Ready-mixed alkyd resin type paint covered by this specification shall be furnished in the following types, as specified in the invitation for bids, contracts, or order:

3.1.1. *Type S*—Medium oil soya modified alkyd resin. Primary solvent is VM and P Naphtha.

3.1.2. *Type N*—Medium oil soya-modified pentaerythritol alkyd resin; chlorinated rubber, 4 to 1. Primary solvent is toluene.

3.1.3. *Type F*—Medium oil soya/linseed alkyd resin; chlorinated rubber; chlorinated paraffin; 1.03 to 1.30 to 1.00. Primary solvent is MEK.

4. MATERIALS

4.1. The materials used in manufacture shall conform to the requirements of the following specifications:

4.1.1. *Lead Chromate*—ASTM D 211, Type III.

4.1.2. *Titanium Dioxide*—ASTM D 476, Type III Rutile (T_1O_2 80 percent purity, minimum).

4.1.3. *Calcium Carbonate*—ASTM D 1199, Type GC-II.

4.1.4. *Magnesium Silicate*—ASTM D 605.

4.1.5. *Zinc Oxide*—ASTM D 79.

4.1.6. *Alkyd Resin Solution Type S*—The resin shall be supplied as a 60 mass percent solution in VM and P naphtha. The resin solids shall be a medium oil soya modified resin. No rosin shall be permitted. The oil fatty acids shall be either alkali refined soya oil or fatty acids of soya oil having an iodine number of 115 to 130. No recovered oil, marine or soya food fatty acid derivatives shall be used. The resin shall comply with the requirements in Table 1.

Table 1—Characteristics of Alkyd Resin Solutions

Characteristics	Alkyd Resin Type S	Alkyd Resin Type N	Alkyd Resin Type F
Solids, mass percent	60 ± 1	60 ± 1	60 ± 1
Phthalic acid, mass percent	30 min	30 min	33–37
Oil acid, mass percent	50 min	54 min	48–55
Iodine No.	115–130	115–130	115 min
Color, gardner, (max)	9	9	9
Acid number, (max)	8	8	8
Viscosity:			
Reduced to 45 mass-percent solids	D to H	D to H	D to G

4.1.7. *Alkyd Resin Type N*—The resin shall be supplied as a 60 mass percent solution in toluene. The resin solids shall be a medium oil soya-modified pentaetythritol resin. No rosin shall be permitted. The oil fatty acids shall be either alkali refined soya oil or the fatty acids of soya oil having an iodine number of 115 to 130. No recovered oil, marine, or soya food fatty acid derivatives shall be used. The resin shall comply with the requirements in Table 1.

4.1.8. *Alkyd Resin Type F*—The resin shall be supplied at 60 mass percent solids in VM and P naphtha. The resin solids shall be either alkali refined soya oil or linseed oil or mixture of the two, having an iodine number of 115 minimum.

4.1.8.1. The solution must tolerate a 500 mass percent dilution with VM and P naphtha. A solution containing 100 g of 20 MPa·s (20 centipoise) chlorinated rubber, 130 g of resin solution, and 290 g of methyl ethyl ketone shall be clear, transparent, and show no separation after 24 hours of storage at 27 ± 3ºC (80 ± 5ºF) in a $^{3}/_{4}$ full test tube.

4.1.8.2. The alkyd resin, reduced to 45 percent solids with VM and P and Naphtha, shall have a viscosity of D to G. The resin shall comply with the requirements in Table 1.

4.1.9. *Chlorinated Rubber*—The rubber shall have a fixed chlorine content of 65.0 percent minimum when previously dried at 100 ± 5ºC (212 ± 9ºF) for 24 hours.

4.1.9.1. A 20 mass percent solution in toluene shall have a maximum color of 4 (Gardner) and a Brookfield viscosity of 9 to 25 MPa·s (9 to 25 centipoises).

4.1.10. *Chlorinated Paraffin*—MIL-C-429A.

4.1.11. *VM and P Naphtha*—TT-N-95.

4.1.12. *Toluene*—ASTM D 362.

4.1.13. *Methyl Ethyl Ketone*—ASTM D 740.

4.1.14. *Driers*—ASTM D 600 Class B.

4.1.15. *Suspending Agent*—Organo Montmorillonite.

4.1.16. *Chlorinated Rubber Stabilizer for Types N and F paint*—Epichlorohydrin or propylene oxide.

5. REQUIREMENTS

5.1. *Color*—The yellow paint shall match color chip No. 33538 of Fed. Std. No. 595a.

5.2. *Pigment*—The pigment used in the formulation of the paint shall conform to Tables 2 and 3 for the respective types and color.

5.2.1. The extracted pigment upon analysis shall conform to the quantitative requirements of Tables 2 and 3 for the respective types.

5.3. *Vehicles*—All vehicles shall be free from rosin and rosin derivatives. The component parts of the vehicle used shall be as indicated in Table 4 for the respective types.

Table 2—Composition of Pigment White Traffic Paint

	Mass, Percent					
	Type S		Type N		Type F	
Pigment Ingredients	Min	Max	Min	Max	Min	Max
Titanium dioxide	29	31	29	31	34.0	36.0

Drying time, minutes[a]	—	69	—	15	—	5

[a] ASTM D 711.

5.5. *Qualitative Requirements*:

5.5.1. *Condition in Container*—The respective types of paint shall not show excessive settling, gelling, or curdling and shall be easily redispersed with a hand paddle to a smooth, homogeneous state. After storage for periods up to six months from date of packaging, the pigment shall be readily dispersed and viscosity of the paint shall not have changed more than 5 KU from that of the freshly delivered paint.

5.5.2. *Spraying Properties*—The paint as received shall have satisfactory spraying and hiding properties when applied through a nozzle on a conventional traffic striper to a metal plate at a wet film thickness of 0.38 mm (15 mils).

5.5.3. *Appearance*—The sprayed film shall dry to a smooth uniform finish free from roughness, unevenness, and other surface imperfections.

5.5.4. *Skinning*—The paint shall not skin within 48 hours in a three-quarters-filled, tightly closed container.

6. PACKING AND MARKING

6.1. The paint shall be delivered in such containers as may be specified in the contract. Each container shall bear a label with the following information shown thereon: name and address of manufacturer and contractor, shipping point, trade mark or trade name, kind of paint, formula, number of liters (gallons), date of manufacture and lot number, title and number of this specification, and type of paint.

7. METHODS OF SAMPLING AND TESTING

7.1. Except as shown in Section 6.2 the paint shall be sampled and tested in accordance with the appropriate method in Fed. Std. No. 141. If no method exists in the Federal Test Method, the appropriate ASTM Method shall be used.

Note 2—Because of the volatility of the solvents used, extreme care must be taken when testing Type F paint for pigment and solids. It is recommended that closed containers, weighing bottles and transfer devices such as syringes or pipettes be used. High results for pigments and solids can be expected if weighing precautions are not taken.

7.2. The purchaser may utilize X-ray analysis, gas chromatography, infra-red, or ultra-violet spectral analysis of the paint or its components to determine whether specified ingredients were used. Evidence of adulteration or improper formulation shall be cause for rejection.

Standard Specification for

White and Yellow Reflective Thermoplastic Striping Material (Solid Form)

AASHTO Designation: M 249-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

White and Yellow Reflective Thermoplastic Striping Material (Solid Form)

AASHTO Designation: M 249-09

1. SCOPE

1.1. This specification covers a reflectorized thermoplastic pavement striping material that is applied to the road surface in a molten state by mechanical means with surface application of glass beads at a rate specified by the purchaser. Upon cooling to normal pavement temperature, it produces an adherent reflectorized stripe of specified thickness and width capable of resisting deformation by traffic.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 247, Glass Beads Used in Pavement Markings
- T 250, Thermoplastic Traffic Line Material

2.2. *ASTM Standard*:

- D 36, Standard Test Method for Softening Point of Bitumen (Ring-and-Ball Apparatus)
- E 313, Standard Practice for Calculating Yellowness and Whiteness Indices from Instrumentally Measured Color Coordinates

2.3. *Federal Standards*:

- Fed. Std. No. 141, Paint, Varnish, Lacquer, and Related Materials: Methods of Inspection, Sampling and Testing
- Fed. Std. No. 595b, Colors

3. MATERIALS

3.1. The thermoplastic material shall be homogeneously composed of pigment, filler, resins, and glass reflectorizing spheres.

3.1.1. The thermoplastic material shall be available in both white and yellow.

3.1.2. The resin shall be alkyd or hydrocarbon as specified by the purchaser.

3.1.3. The vendor shall have the option of formulating the material according to his own specifications. However, the physical and chemical properties contained in this specification shall apply regardless of the type of formulation used. The material, upon heating to application temperature, shall not exude fumes that are toxic, or injurious to persons or property. The pigment beads and filler shall be well dispersed in the resin. The material shall be free from all skins, dirt, and foreign objects.

3.1.4. *Glass Beads (Pre-Mix)*—The beads shall be uncoated and conform to AASHTO M 247, Type I.

3.1.5. Yellow pigment shall be lead and lead-chromate free.

4. REQUIREMENTS

4.1. *Specific Gravity*—The specific gravity of the white and yellow thermoplastic traffic line material shall not exceed 2.15.

4.2. *Composition*—The pigment, beads, and filler shall be uniformly dispersed in the resin. The material shall be free from all skins, dirt, and foreign objects and shall comply with requirements according to Table 1.

Table 1—Composition (percent by weight)

Component	White	Yellow
Binder	18.0 min	18.0 min
Glass beads	30–40	30–40
Titanium dioxide	10.0 min	—
Calcium carbonate and inert fillers	42.0 max	See Note 1.
Yellow pigments	—	—

Note 1—Amount of yellow pigment, calcium carbonate, and inert fillers shall be at the option of the manufacturer, providing all other requirements of this specification are met.

4.2.1. The material shall be provided in either granular or block form as specified by the purchaser.

4.3. *Physical Characteristics*:

4.3.1. *Color*—The thermoplastic material after heating for 240 ± 5 minutes at 218 ± 2ºC (425 ± 3ºF) and cooled to 25 ± 2ºC (77 ± 3ºF) shall meet the following:

White: Daylight reflectance at 45 degrees–0 degrees—75 percent minimum. For highway use the color shall match Federal Test Standard Number 595b, Color 17886.

Yellow: Daylight reflectance at 45 degrees–0 degrees—45 percent minimum.

(a) For highway use, the color shall match Federal Test Standard Number 595b—Color 13538.
(b) For airport use, the color shall comply with the requirements established by the FAA. The chromaticity and luminance factors shall be within the limits in Table 2 when determined under standard conditions:
    (a) angle of illumination, 45 degrees;
    (b) direction of view, perpendicular to surface; and
    (c) illuminant, CIE standard illuminant D65.

Note 2—The chromaticity and luminance factors of ordinary colors and colors of retro-reflecting materials shall be determined under the following standard conditions:

(a) angle of illumination: 45 degrees;
(b) direction of view: perpendicular to surface; and
(c) illuminant: CIE standard illuminant D65.

Table 2—CIE Equations

Yellow	
Orange boundary	$y = 0.130 + 0.636x$
White boundary	$y = 0.910 - x$
Green boundary	$y = 1.35x - 0.093$
Luminance factor	ß = 0.27 (mnm)
White	
Purple boundary	$y = x$
Blue boundary	$y = 0.610 - x$
Green boundary	$y = 0.040 + x$
Yellow boundary	$y = 0.710 - x$
Luminance factor	ß = 0.35 (mnm)

4.3.2. *Drying Time*—When applied at a temperature range of 211 ± 7ºC (412.5 ± 12.5ºF) and thickness of 3.2 to 4.8 mm ($^1/_8$ to $^3/_{16}$ in.), the material shall set to bear traffic in not more than 2 minutes when the air temperature is 10 ± 2ºC (50 ± 3ºF) and not more than 10 minutes when the air temperature is 32 ± 2ºC (90 ± 3ºF).

4.3.3. *Cracking Resistance at Low Temperature*—After heating the thermoplastic material for 240 ± 5 minutes at 218 ± 2ºC (425 ± 3ºF), applying to concrete blocks, and cooling –9.4 ± 1.7ºC (15 ± 3ºF), the material shall show no cracks.

4.3.4. *Impact Resistance*—After heating the thermoplastic material for 240 ± 5 minutes at 218 ± 2ºC (425 ± 3ºF) and forming test specimens, the impact resistance shall be a minimum of 1.13J (10 in.-lb).

4.3.5. *Softening Point*—After heating the thermoplastic material for 240 ± 5 minutes at 218 ± 2ºC (425 ± 3ºF) and testing in accordance with ASTM D 36 the materials shall have a softening point of 102.5 ± 9.5ºC (215 ± 15ºF).

4.3.6. *Flowability*—After heating the thermoplastic material for 240 ± 5 minutes at 218 ± 2ºC (425 ± 3ºF) and testing for flowability, the white thermoplastic shall have a maximum percent residue of 18 and the yellow thermoplastic shall have a maximum percent residue of 21.

4.3.7. *Yellowness Index*—The white thermoplastic material shall not exceed a yellowness index of 0.12.

4.3.8. *Flowability—Extended Heating*—After heating the thermoplastic material 8.0 ± 0.5 hours at 218 ± 2ºC (425 ± 3ºF), with stirring the last six hours, and tested for flowability, the thermoplastic shall have a maximum percent residue of 28.

4.4. *Storage Life*—Thermoplastic material shall meet the above requirements and melt uniformly with no evidence of skins or unmelted particles for a period of 1 year. Any material not meeting the above requirements shall be replaced by the manufacturer.

5. APPLICATION PROPERTIES

5.1. The thermoplastic material shall be capable of being applied by spraying, screed extrusion, or ribbon extrusion, as specified by the purchaser, at temperatures of 211 ± 7ºC (412 ± 12.5ºF) from approved equipment to produce a line 3.2 to 4.8 mm ($^1/_8$ to $^3/_{16}$ in.) thick which shall be continuous and uniform in shape having clear and sharp dimensions, particularly when extruded.

5.2. The material shall not exude fumes that are toxic, obnoxious, or injurious to persons or property when it is heated during applications.

5.3. The application of additional surface dressing glass beads shall be by means of a pressurized bead dispenser or by drop-on methods at a rate specified by the purchaser and agreed upon by the applicator.

6. PACKAGING AND MARKING

6.1. The thermoplastic material shall be packaged in suitable containers to which it will not adhere during shipment and storage.

6.1.1. In granular form, it shall be in white or yellow plastic bags of a suitable size to contain approximately 23 kg (50 lb) and shall be made of a material that when introduced into the mix hopper of the application equipment, it will become a part of the mix without any adverse effect to the performance of the thermoplastic material.

6.1.2. In block form, blocks of cast thermoplastic material shall be approximately 300 by 915 by 51 mm (12 by 36 by 2 in.) and shall have a mass of approximately 23 kg (50 lb).

6.1.3. Each container label shall designate the color, manufacturer’s name, batch number, and date of manufacture. Each batch manufactured shall have its own separate number. The label shall specify that the material shall be heated to 211 ± 7ºC (412 ± 12.5ºF) during application.

6.2. The contractor shall assume all cost resulting from the use of patented materials, equipment, devices, or processes used on or incorporated in the work, agrees to indemnify and save harmless the purchaser and his duly authorized representatives from all suits at law, or action of every nature for or on account of the use of any patented materials, equipment, devices, or processes.

7. SAMPLING

7.1. The minimum size batch of thermoplastic traffic striping material sampled and tested shall not be less than 1360 kg (3000 lb) unless the total order is less than this amount. Any manufacturer not familiar with the technique of making this material should consult the purchaser. A small trial batch should be made prior to making the thermoplastic traffic striping material in large quantities to make certain the finished product will comply with all the requirements of this specification.

8. TESTING

8.1. The material shall be tested in accordance with T 250 or with the appropriate method in Federal Standard No. 141 or ASTM designation.

Standard Specification for

Retroreflective Sheeting for Flat and Vertical Traffic Control Applications

---

AASHTO Designation: M 268-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Retroreflective Sheeting for Flat and Vertical Traffic Control Applications

AASHTO Designation: M 268-10

1. SCOPE

1.1 This specification covers retroreflective sheeting, translucent ink, and overlay film intended for traffic control applications. The sheeting serves as the reflectorized background for sign messages and legends and symbols applied to the reflectorized background. Messages may be applied in opaque black or transparent colors.

1.2 All material furnished under this specification shall have been manufactured within 18 months of the delivery date. All material shall be supplied by the same manufacturer.

1.3 The values stated in inch-pound units are to be regarded as the standard.

1.4 *This specification does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. DISCUSSION

3.1 The retroreflective sheeting classifications established in this specification are not intended to describe any specific materials, but are instead intended to establish meaningful minimum retroreflectivity intervals. These intervals are correlated with human performance factors by which sheeting may be classified.

3.2 Classifications are provided as a means for differentiating functional performance based on minimum retroreflectivity levels at standard combinations of entrance and observation angles. The combinations of entrance and observation angles shown in this specification provide a mechanism to categorize retroreflective sheeting materials into Type classifications. It should be recognized that performance characteristics outside these standard geometries cannot always be reasonably predicted, especially for retroreflective sheeting of microprismatic construction, and may vary between particular products meeting the same Type. It is the responsibility of the user of this specification to determine the suitability of any reflective sheeting material for its intended application.

3.3 When tested in accordance with ASTM E 810, the average coefficient of retroreflection (R_A) for a set of three samples taken from the same roll must not vary more than 20 percent between R_A measured at 0, 45, 90 and 120 degrees of rotation in order to be considered rotationally insensitive. Other rotational angles can be specified for testing by the user. The test shall be conducted at an observation angle of 0.5 degrees and an entrance angle of –4.0 degrees. Other combinations of observation and entrance angle can be specified for testing by the user. Calculate the percent difference by dividing the absolute difference between R_A (0) and R_A (45) by R_A (0). Repeat the calculation replacing R_A (45) with R_A (90) and R_A (120). R_A (0) is established with the sheeting aligned in its optimum rotation.

3.3.1 For sheeting not meeting the 20 percent maximum rotational sensitivity requirement, the manufacturer must provide identification marks or other features (such as a datum mark, tiles, or distinct seal pattern) in or on the sheeting face denoting the optimum orientation of the sheeting. The markings or features must be visible from a minimum distance of 2 ft and must be arrayed in such a manner that they will be readily distinguishable on cut-out legends, symbols, or borders. The manufacturer must provide fabrication guidelines outlining optimum sheeting orientation upon user request.

3.3.2 When utilizing sheeting (for permanent signs) that does not meet the 20 percent maximum rotational requirement, fabricate signs by applying white sheeting for cut-out legends, symbols, borders, and route marker attachments within the parent sign face in the optimum rotation according to the identification markings; and apply all background sheeting uniformly oriented.

3.4 *Delineators*—Retroreflective sheeting materials suitable for use on delineators are typically of microprismatic construction. The Type of retroreflective sheeting shall be specified by the user.

4. CLASSIFICATIONS

4.1 This specification establishes four Types of retroreflective sheeting, with successively increasing minimum coefficients of retroreflection. Retroreflective sheeting materials shall meet all of the performance requirements in Section 5 to qualify as a particular Type under this specification. Minimum coefficients of retroreflection are shown in Tables 4, 5, 6, and 7 for retroreflective sheeting Type A, Type B, Type C, and Type D respectively. The designated Type is exclusive to the highest specified minimum R_A satisfied at observation angle of 0.5 degrees and an entrance angle of –4.0 degrees. Using higher retroreflectivity sheeting to manufacture signs where lower retroreflectivity sheeting Types are specified must be approved by the end user.

4.2 The following are general descriptions of the Types of retroreflective sheeting established by this specification. These are provided for descriptive information only and are not intended to be limitations or recommendations.

Note 1—The *Manual on Uniform Traffic Control Devices* (MUTCD) requires that traffic control signs, unless illuminated, be retroreflective to show the same shape and similar color both day and night. Therefore, any retroreflective sheeting materials meeting this specification would satisfy that requirement. However, when determining the appropriateness of a particular Type of sheeting for a particular application, consideration should be given to the pertinent highway characteristics where the materials will be installed, such as traffic volumes, traffic speeds, and roadway geometrics, as well as available resources. Brighter materials (meeting Type B, C, or D) should be considered for use on complex roadway environments where the driving task may be more involved.

4.2.1 *Type A*—Retroreflective sheeting materials meeting Type A are typically constructed of encapsulated microscopic glass bead lens construction.

4.2.2 *Type B*—Retroreflective sheeting materials meeting Type B are typically constructed of unmetallized microprismatic optics. These triangular microprismatic materials do not have a significant 1-degree observation angle performance.

4.2.3 *Type C*—Retroreflective sheeting materials meeting Type C are typically constructed of unmetallized microprismatic optics. These triangular microprismatic materials have a significant 1-degree observation angle performance.

4.2.4 *Type D*—Retroreflective sheeting materials meeting Type D are typically constructed of unmetallized microprismatic optics. These materials have 0.5- and 1-degree observation angle performance approximately two times greater than Type C materials.

4.3 *Adhesive Backing Classes*—The adhesive backing classes shall be specified by the end user and shall be classified as follows:

4.3.1 *Class 1*—The adhesive backing shall be pressure-sensitive and require no heat, solvent, or other preparation for adhesion to smooth, clean surfaces.

4.3.2 *Class 2*—The adhesive backing shall be activated by applying heat and pressure to the material. The temperature necessary to form a durable permanent bond shall be a minimum of 66°C (150°F). Reflective sheeting materials with Class 2 adhesive shall be repositionable under normal shop conditions and at substrate temperatures up to 38°C (100°F) without damage to the sheeting.

Reflective sheeting materials with Class 2 adhesive may be perforated to facilitate removal of air in heat-vacuum laminators, but the perforations must be of a size and frequency such that they do not cause objectionable blemishes in the finished sign.

4.3.3 *Class 3*—The adhesive backing shall be a positionable low-tack pressure-sensitive adhesive that requires no heat, solvent, or other preparation for adhesion to smooth, clean surfaces. Reflective sheeting materials with Class 3 adhesive shall be repositionable up to a temperature of 38°C (100°F) without damage to the sheeting.

4.3.4 *Class 4*—The adhesive backing shall be a low-temperature pressure-sensitive adhesive that permits sheeting applications down to –7°C (+20°F) without the aid of heat, solvent, or other preparation for adhesion to smooth, dry, and clean surfaces.

5. SHEETING PROPERTIES

5.1 *Test Conditions*—Unless otherwise specified in this specification, condition all adhesively bonded and unbonded test samples and specimens at a temperature of 73 ± 3°F (23 ± 2°C) and 50 ± 5 percent relative humidity for 24 hours prior to testing.

5.2 *Panel Preparation*—Unless otherwise specified in this specification, when tests are to be performed using test panels, apply the specimens of retroreflective material to smooth aluminum cut from Alloy 6061-T6 or 5052-H38, in accordance with Specification ASTM B 209 or B 209M. The sheets shall be 0.020 in. (0.508 mm), 0.040 in. (1.016 mm), or 0.063 in. (1.600 mm) in thickness, and a minimum of 8 by 8 in. (200 by 200 mm). Prepare the aluminum in accordance with Specification ASTM B 449, Class 2, or degrease and lightly acid etch before the specimens are applied. Apply the specimens to the panels in accordance with the recommendations of the retroreflective sheeting manufacturer.

5.3 *Adhesive*—For testing purposes, subject two pieces of reflective sheeting, each 2 in. by 6 in. (51 mm by 152 mm) in size, to a temperature of 160°F (71°C) and a pressure of 2.5 lb/in.^{2} (0.176 kg/cm^2) for 4 hours. Bring the pieces to equilibrium at standard conditions and cut one, 1 in. by 6 in. (25 mm by 152 mm) specimen from each piece, and remove the liner by hand. Apply 4 in. (102 mm) of one end of each specimen to a test panel. Condition as specified in Section 5.1. Suspend the panels in a horizontal position with the specimen facing downward. The adhesive backing of the retroreflective sheeting shall produce a bond that will support a $1^3/_4$-lb (0.79-kg) weight for adhesive classes 1, 2, and 3 or a 1-lb (0.45-kg) weight for adhesive Class 4 for 5 minutes, without the bond peeling for a distance of more than 2 in. (51 mm). The test panel must have a minimum thickness of 0.040 in. (1.016 mm).

5.4 *Liner Removal*—The liner, when provided, shall be easily removed without soaking in water or other solutions, and shall not break, tear, or remove adhesive from the sheeting. The protective liner, if any, shall be easily removed following accelerated storage for 4 hours at 160°F (71°C) under a weight of 2.5 psi (17.2 kPa).

5.5 *Daytime Color*—Determine the chromaticity and luminance factor percent *Y* for CIE standard illuminant D65 and the 1931 CIE (2-degree) standard observer in accordance with ASTM E 308, E 991, E 1164, E 1347, E 1349, E 2152, E 2153, and E 2301, as applicable. The luminance factor is the sum of the reflectance luminance factor and the fluorescence luminance factor. Bispectral measurement provides the individual factors, while measurement with simulated ASTM D 65 provides their sum.

For fluorescent specimens, it is necessary either that the physical illumination of the specimen be a good approximation to illuminant ASTM D 65, requiring an instrument with an appropriately filtered light source, or else that a bispectral photometer conforming to ASTM E 2301 be used.

There are three types of 45/0 (0/45) instruments: annular, circumferential, and uniplanar. Measurement of prismatic sheeting with circumferential instruments may require multiple measurements. Measurement of prismatic sheeting with uniplanar instruments will require multiple measurements.

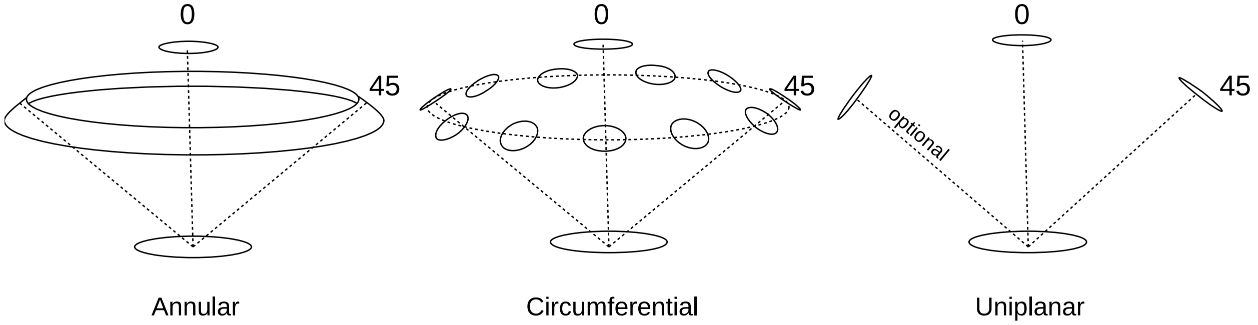

Figure 1—Types of 45/0 (0/45) Instruments

If the measurement geometry is circumferential, then the testing laboratory must verify that the apertures in the ring are sufficiently close for acceptable approximation to an annular measurement. This may depend on the optical construction of the specimen, and must be determined by the testing laboratory. Multiple measurements of the same specimen area at different rotations may be averaged to improve the approximation to an annular measurement.

If the measurement geometry is uniplanar, then a sequence of measurements shall be made on the same specimen area at incremental rotations, and the measurement values shall be taken as averages over all the rotations. The number of rotations shall be large enough for acceptable approximation to an annular measurement. The number depends on the optical construction of the specimen and must be determined by the testing laboratory.

Instruments (spectrophotometers, colorimeters) used to measure daytime color shall have 45/0 or 0/45 illumination and viewing geometry. The referee instrument shall have 10-degree apertures for both illumination and viewing. Use of aperture sizes deviating from these may affect the measurement results.

Table 1—Daytime Luminance Factor (%*Y*) for Types A, B, C, and D

Color	Minimum	Minimum for Higher Daytime Conspicuity[a]	Maximum
White	27	40	—
Yellow	15	24	45
Orange	12	14	30
Green	3.0	—	12
Red	2.5	—	15
Blue	1.0	—	10
Brown	1.0	—	9.0
Fluorescent Yellow-Green[b]	60	—	None
Fluorescent Yellow[b]	45	—	None
Fluorescent Orange[b]	25	—	None

[a] Minimum values for higher daytime conspicuity are supplementary requirements that apply when specified by the end user.

[b] The luminance factors for fluorescent colors shown in Table 1 consist of the sum of a reflectance luminance factor and fluorescence luminance factor. The luminance factor may be determined using a good approximation to illuminant D65, requiring an instrument with an appropriately filtered light source, or a bispectral photometer conforming to ASTM E 2301 be used.

Table 2—Color Specification Limits (Daytime) for Types A, B, C, and D[a]

Color	1		2		3		4	
	x	*y*	*x*	*y*	*x*	*y*	*x*	*y*
White	0.303	0.300	0.368	0.366	0.340	0.393	0.274	0.329
Yellow	0.498	0.412	0.557	0.442	0.479	0.520	0.438	0.472
Orange	0.558	0.352	0.636	0.364	0.570	0.429	0.506	0.404
Green[b]	0.026	0.399	0.166	0.364	0.286	0.446	0.207	0.771
Red	0.648	0.351	0.735	0.265	0.629	0.281	0.565	0.346
Blue[b]	0.140	0.035	0.244	0.210	0.190	0.255	0.065	0.216
Brown	0.430	0.340	0.610	0.390	0.550	0.450	0.430	0.390
Fluorescent Yellow-Green	0.387	0.610	0.369	0.546	0.428	0.496	0.460	0.540
Fluorescent Yellow	0.479	0.520	0.446	0.483	0.512	0.421	0.557	0.442
Fluorescent Orange	0.583	0.416	0.535	0.400	0.595	0.351	0.645	0.355

[a] The four pairs of chromaticity coordinates determine the acceptable color in terms of the *Commission Internationale de l'Eclairage* (CIE) Standard Colorimetric System measured with CIE Standard Illuminant D 65.

[b] The saturation limit of green and blue may extend to the border of the CIE chromaticity locus for spectral colors.

5.6 *Nighttime color*—Nighttime color shall be determined in accordance with ASTM E 811 and evaluated using the CIE system in ASTM E 308. (The saturation limit shall be considered to extend to the boundary of the chromaticity locus of spectral colors.) Measure using CIE Illuminant A, observation angle of 0.33 degrees, entrance angle of +5 degrees, source, and receiver apertures not exceeding 10 minutes of arc, CIE 1931 (2-degree) standard observer.

Table 3—Color Specification Limits (Nighttime) for Types A, B, C, and D

Color	1		2		3		4	
	x	*y*	*x*	*y*	*x*	*y*	*x*	*y*
White (NA)								
Yellow	0.513	0.487	0.500	0.470	0.545	0.425	0.572	0.425
Orange	0.595	0.405	0.565	0.405	0.613	0.355	0.643	0.355
Green	0.007	0.570	0.200	0.500	0.322	0.590	0.193	0.782
Red	0.650	0.348	0.620	0.348	0.712	0.255	0.735	0.265
Blue	0.033	0.370	0.180	0.370	0.230	0.240	0.091	0.133
Brown	0.595	0.405	0.540	0.405	0.570	0.365	0.643	0.355
Fluorescent Yellow-Green	0.480	0.520	0.473	0.490	0.523	0.440	0.550	0.449
Fluorescent Yellow	0.554	0.445	0.526	0.437	0.569	0.394	0.610	0.390
Fluorescent Orange	0.625	0.375	0.589	0.376	0.636	0.330	0.669	0.331

5.7 *Color*—When evaluated according to Sections 5.5 and 5.6, the sheeting shall be uniform in color and devoid of streaks throughout the length of each lot or roll. Sheeting used for side by side overlay applications shall have a Hunter Lab Delta E of less than 3 units. The sheeting shall conform to the daytime and nighttime color requirements of the following tables.

5.8 *Coefficient of Retroreflection*—The coefficient of retroreflection (R_A) is expressed using the units of cd/lux/m^2 (cd/fc/ft^2) and determined in accordance with ASTM E 810. When no rotation angle is specified, measurements are taken at 0 and 90 degrees and then averaged. Compliance with the minimum coefficient of retroreflection for the 1.0-degree observation angle is required for Types C and D. Compliance with the minimum coefficient of retroreflection for the 1.0-degree observation angle is required for Types A and B when specified by the end user.

Table 4—Minimum Coefficient of Retroreflection (R_A) for Type A Sheeting

Observation Angle, degree	Entrance Angle (deg.)	White	Yellow	Orange	Red	Green	Blue	Brown
0.2	–4	240	180	90	35	25	12	7.5
0.2	+30	120	90	45	20	12	6.0	3.5
0.5	–4	95	70	35	15	9.5	4.5	3.0

1.0	+30	40	30	15	6.0	4.0	2.0	1.0	35	25	12

5.9 *Accelerated Laboratory Weathering*—Accelerated laboratory weathering may be used for provisional qualification of sheeting before the results from accelerated outdoor weathering are available. When they become available, the results from outdoor weathering take precedence over the results from laboratory-accelerated weathering tests.

5.10 Accelerated laboratory weathering testing will be performed for 2200 hours according to ASTM G 151 and G 155, Cycle 1. Following weathering, gently wash the panels using a soft cloth or sponge and clean water or a dilute solution of a mild detergent (1 percent by weight in water, maximum concentration). After washing, rinse thoroughly with clean water, and blot dry with a soft clean cloth. Following cleaning, the applied sheeting shall show no appreciable discoloration, cracking, streaking, crazing, blistering, or dimensional change. The sheeting shall exhibit a Hunter Lab Delta E of 5 or less when compared to the sample prior to exposure. In addition, the chromaticity coordinates, after exposure, must remain within the appropriate four pairs of chromaticity values listed in Tables 2 and 3. Following accelerated laboratory weathering, the sheeting shall exhibit a minimum of 80 percent of the coefficient of retroreflection for the particular Type as listed in Tables 4, 5, 6, and 7.

5.11 Accelerated laboratory weathering testing may be performed by an alternate method, as identified in ASTM G 151, as approved by the user.

5.12 *Accelerated Outdoor Weathering*—Accelerated outdoor weathering will be performed at an acceptable location as approved by the user, or by default, in climates equivalent to Phoenix, AZ and Miami, FL. Sheeting material shall be open backed and placed on an outdoor rack with a 45-degree angle facing the equator. Labeling, conditioning and handling of panels prior to exposure and during evaluation periods shall be in accordance with ASTM G 147. The sheeting will be evaluated annually for 3 years. Following weathering, gently wash the panels using a soft cloth or sponge and clean water or a dilute solution of a mild detergent (1 percent by weight in water, maximum concentration). After washing, rinse thoroughly with clean water, and blot dry with a soft clean cloth. After washing and drying, condition the panels at room temperature for at least 2 hours prior to conducting any measurements. After panels have been washed, dried, and conditioned, the applied sheeting shall show no appreciable discoloration, cracking, streaking, crazing, blistering, or dimensional change. The sheeting shall exhibit a Hunter Lab Delta E of 5 or less when compared to the sample prior to exposure. In addition, the chromaticity coordinates, after exposure, must remain within the appropriate four pairs of chromaticity values listed in Tables 2 and 3. Following accelerated outdoor weathering, the sheeting shall exhibit a minimum of 80 percent of the coefficient of retroreflection for the particular Type as listed in Tables 4, 5, 6, and 7.

5.13 *Shrinkage*—Condition a 9 in. (230 mm) by 9 in. (230 mm) retroreflective sheeting specimen with liner, a minimum of 1 hour at standard conditions (see Section 5.1). Remove the liner and place the specimen on a flat surface with the adhesive side up. Ten minutes after the liner is removed and again after 24 hours, measure the specimen to determine the amount of dimensional change. The sheeting shall not shrink in any dimension more than $^1/_{32}$ in. (0.8 mm) in 10 minutes and not more than $^1/_8$ in. (3 mm) in 24 hours.

5.14 *Workability*—The sheeting shall show no cracking, scaling, pitting, blistering, edge lifting, inter-film splitting, curling, or discoloration when processed and applied using mutually acceptable processing and application procedures.

5.15 *Positionability*—Sheeting, with Class 3 adhesive, used for manufacturing legends and borders shall provide sufficient positionability during the fabrication process to permit removal and reapplication without damage to either the legend or sign background and shall have a plastic liner suitable for use on bed cutting machines. Thereafter, all other adhesive and bond requirements contained in the specification shall apply.

Positionability shall be verified by cutting 4-in. (100-mm) letters E, I, K, M, S, W, and Y out of the positionable material. The letters shall then be applied to a sheeted aluminum blank using a single pass of a 2-lb (0.9 kg) roller. The letters shall sit for 5 minutes and then a putty knife shall be used to lift a corner. The thumb and fore finger shall be used to slowly pull the lifted corner to lift letters away from the sheeted aluminum. The letters shall not tear or distort when removed.

5.16 *Thickness*—The thickness of the sheeting without the protective liner shall be less than or equal to 0.015 in. (0.4 mm), or 0.025 in. (0.6 mm) for prismatic material.

5.17 *Processing*—The sheeting shall permit cutting and color processing according to the sheeting manufacturer's specifications at temperatures of 60 to 100°F (15 to 38°C) and within a relative humidity range of 20 to 80 percent. The sheeting shall be heat resistant and permit forced curing without staining the applied or unapplied sheeting at temperatures recommended by the manufacturer. The sheeting shall be solvent resistant and capable of being cleaned with VM&P naphtha, mineral spirits, and turpentine.

5.17.1 Transparent color and opaque black inks shall be single component and low odor. The inks shall dry within 8 hours and not require clear coating. After color processing on white sheeting, the sheeting shall show no appreciable discoloration, cracking, streaking, crazing, blistering, or dimensional change when tested for durability (Sections 5.9 and 5.10). The ink on the weathered, prepared panel shall exhibit a Hunter Lab Delta E of 5 or less when compared to the original.

5.17.2 Transparent color electronic cutting films shall be acrylic. After application to white sheeting, the films shall show no appreciable discoloration, cracking, streaking, crazing, blistering, or dimensional change when tested for durability (Sections 5.9 and 5.10). The films on the weathered, prepared panel shall exhibit a Hunter Lab Delta E of 5 or less when compared to the original.

5.17.3 Black screen ink, when applied to white sheeting, must be completely opaque.

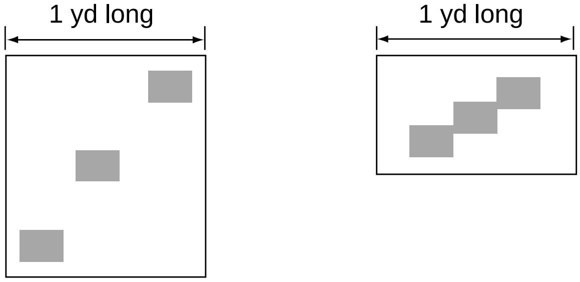
5.18 Transparent colors screened, or transparent acrylic electronic cutting films, on white sheeting, shall meet the minimum coefficient of retroreflection values as listed in Tables 4, 5, 6, and 7 for the color applied. After accelerated laboratory and accelerated outdoor testing, the colors shall retain a minimum 80 percent of the coefficient of retroreflection as listed in Tables 4, 5, 6, and 7.

5.19 *Identification*—The sheeting shall have a distinctive overall pattern in the sheeting unique to the manufacturer. If material orientation is required for optimum retroreflectivity, permanent orientation marks shall be incorporated into the face of the sheeting. Neither the overall pattern nor the orientation marks shall interfere with the reflectivity of the sheeting.

5.20 *Packaging*—Both ends of each box shall be clearly labeled with the sheeting type, color, adhesive type, manufacturer's lot number, date of manufacture, and supplier's name. Material Safety Data Sheets and technical bulletins for all materials shall be furnished to the Agency with each shipment.

6. SAMPLING

6.1 *Sampling*—A full width by 1-yard (0.9-m) long sample is selected at random to represent the entire sheet, roll, or lot. For the purpose of testing the coefficient of retroreflectivity, three samples shall be spaced evenly across (left, center, and right) and spaced evenly down the specimen as shown in Figure 2.



(a) (b)

Figure 2—Selecting Samples

6.1.1 For determining conformance to all other requirements, single samples taken at random shall be tested.

6.1.2 For the purpose of testing and qualification, producers shall include a physical sample with the following information:

6.1.2.1 Company name;

6.1.2.2 Physical and mailing address;

6.1.2.3 Company's material designation (product name, style number, etc.);

6.1.2.4 Contact person and phone number;

6.1.2.5 AASHTO sheeting type; and

6.1.2.6 AASHTO backing class.

APPENDIX

(Nonmandatory Information)

X1. PROCEDURE FOR ESTABLISHMENT OF MINIMUM COEFFICEINTS OF RETROREFLECTION

X1.1. The retroreflective sheeting grades established in this specification are not intended to describe any specific materials. The following information serves to explain the theory and research applied to the creation of the values.

X1.1.1. *White Sheeting*—for white sheeting within a particular grade, the relationships for minimum coefficients of retroreflection for the various standard combinations of observation and entrance angles are shown in Table X1.1.

Note X1—The basic facts for each value listed in the tables for the coefficient of retroreflection are found in Table X1.2.

X1.1.2. *Color Sheeting*—For color sheeting within a particular grade, the factors shown in Table X1.3 are applied to the minimum coefficients of retroreflection obtained for white sheeting for that grade in Table X1.1.

Table X1.1—Minimum Coefficients of Retroreflection (R_A) for White Sheeting within a Grade[*]

Observation Angle	Entrance Angle	AASHTO Sheeting Type			
		A	B	C	D
0.2	–4	240	335	580	580
0.2	30	120	120	200	200
0.5	–4	95	135	235	465
0.5	30	50	45	80	160
1.0	–4	4.5	15	60	120
1.0	30	2.5	5.5	20	40

[*] Notes:
1. Build a simple specification table that is supported through research findings; for instance, psychophysical principles of vision vetted through over a century of research have shown through such mechanisms as threshold versus intensity relationships that human visual performance is roughly approximated using Weber's Law. In other words, as the baseline condition increases (in this case, sign luminance through retroreflective materials), we need larger differences to observe measureable changes.
2. Maintain known alpha and beta geometries from ASTM D 4956.
3. The lowest class is to be based on encapsulated beaded materials.
4. Previous work has shown that of all the current ASTM D 4956 alpha/beta geometries, the 0.5/–4.0 combination is best correlated with performance.

   Using geometry of 0.5/–4.0, this specification uses increasing multipliers to set thresholds for class distinctions. Research has shown that the Class B and C materials have statistically longer legibility distances than Class A materials. While Classes B and C have about the same total light return, the returned light is spread more for Class C materials than it is for Class B materials. The wider spread of returned light may be useful for signs with small letters such as street name signs. Class D materials are similar to C materials in terms of the light distribution but Class D materials are more efficient with the light returned to the driver.

Table X1.2—Specific Notes for the Development of the Recommendations

Observation Angle	Entrance Angle	AASHTO Sheeting Type			
		A	B	C	D
0.2	−4	$a \times 2.5$	$b \times 2.5$	$c \times 2.5$	$c \times 2.5$
0.2	30	$a \times 1.25$	$b \times 0.875$	$c \times 0.875$	$c \times 0.875$
0.5	−4	a	$b = \sqrt{2} \times a$	$c = \sqrt{3} \times b$	$d = \sqrt{4} \times c$
0.5	30	$a \times 0.5$	$b \times 0.35$	$c \times 0.35$	$d \times 0.35$
1.0	−4	$a \times 0.05$	$b \times 0.125$	$c \times 0.25$	$d \times 0.25$
1.0	30	$a \times 0.05$	$b \times 0.04375$	$c \times 0.0875$	$d \times 0.0875$

Table X1.3—Minimum Coefficient of Retroreflection (R_A) Factors for Color Sheeting[a]

Yellow	Orange	Red	Green	Blue	Brown	Fluorescent Yellow-Green	Fluorescent Yellow	Fluorescent Orange
0.75	0.38	0.15	0.10	0.05	0.03	0.80	0.60	0.30

[a] The above factors, when applied to the coefficients for white sheeting established in Table X1.1, establish minimum coefficients of retroreflection for color sheeting materials.

Standard Specification for

Acrylic Prismatic Reflectors and Embossed Aluminum Frames for Signs

AASHTO Designation: M 290-96 (2008)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Specification for

Acrylic Prismatic Reflectors and Embossed Aluminum Frames for Signs

AASHTO Designation: M 290-96 (2008)

1. SCOPE

1.1 This specification covers acrylic prismatic reflectors and embossed aluminum frames used in cut-out letters, symbols, and accessories on signing projects.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- T 257, Instrumental Photometric Measurements of Retroreflective Materials and Retroreflective Devices

2.2 *ASTM Standards*:

- B 117, Standard Practice for Operating Salt Spray (Fog) Apparatus
- B 209, Standard Specification for Aluminum and Aluminum-Alloy Sheet and Plate
- D 788, Standard Classification System for Poly(Methyl Methacrylate) (PMMA) Molding and Extrusion Compounds
- D 1730, Standard Practices for Preparation of Aluminum and Aluminum-Alloy Surfaces for Painting

2.3 *ANSI Standard*:

- ANSI D6.1, *Manual on Uniform Traffic Control Devices*

2.4 *Federal Standard*:

- L-P 380, Plastic Molding Material, Methacrylate

3. DESCRIPTION OF TERMS

3.1 *legend*—the entire message and border for a sign.

3.2 *message*—a group of words, numbers, and/or symbol for a sign.

4. ORDERING INFORMATION

4.1 Orders for material under this specification shall include the following information:

4.1.1 Quantity;

4.1.2 Name of material;

4.1.3 Style of letter and size, or size of reflector;

4.1.4 Color (colorless, yellow, red, green);

4.1.5 Legend description; and

4.1.6 AASHTO designation and date of issue.

5. MATERIALS

5.1 The reflector lens shall be methylmethacrylate meeting requirements of the latest version of one of the following specifications:

5.1.1 Federal Specification L-P-380, Type 1, Class 3; and

5.1.2 ASTM D 788, Grade 8.

5.2 The purchaser shall specify the type, class, or grade of methylmethacrylate to be used in the manufacture of the reflectors.

5.3 Legend frames shall be fabricated from aluminum sheet, ASTM B 209, Alloy 3003-H14.

6. MANUFACTURE

6.1 Reflectors shall consist of a transparent acrylic plastic face, herein referred to as the lens, and a light-colored, opaque back of similar material fused to the lens under heat and pressure around the entire perimeter. The reflector shall form a unit permanently sealed against dust, water, and water vapor. The reflector lens shall be colorless, yellow, red, or green as required by the plans.

6.2 The lens shall consist of a smooth front surface free from projections or indentations, which are detrimental to the reflectance of the unit. The manufacturer’s trademark shall be molded legibly into the face of the lens. The rear surface of the lens shall have a prismatic configuration such that it will cause adequate internal reflection of light.

6.3 Reflectors shall be designed so as to facilitate insertion into accurately sized holes in embossed legend frames. When installed in the legend frame, reflectors shall be restrained so as to prevent their displacement. The retention of reflectors in frames by use of adhesive tape is not acceptable. The reflector size shall be such as to permit free movement in the mounting hole to allow for differences of expansion and contraction between plastic reflector and aluminum sign frame.

6.4 Frames shall be embossed and shall be fabricated from aluminum sheet having a thickness of 1 mm (0.040 in.). The form of the legend shall conform to the requirements of ANSI D6.1 and the plans and specifications for the project. Mounting holes shall be provided within the frames to permit the use of an approved fastener. The size and spacing of reflector holes for reflectorized frames shall be such as to afford maximum night legibility and visibility to the finished cut-out figure. Legend frames, which are not intended to be reflectorized, shall not contain holes for reflectors. After metal fabrication has been completed, the frames shall be degreased, etched, neutralized, and treated with an amorphous chromate coating in accordance with ASTM D 1730. Frames shall be finished with the material and color specified by the purchaser.

7. PHYSICAL REQUIREMENTS

7.1 *Specific Intensity per Unit Area (SIA)*:

7.1.1 The SIA of each colorless reflector intended for use in cut-out letters, symbols, and accessories shall be equal to or exceed the minimum values in Table 1 when tested in accordance with T 257. SIA is expressed in candelas per lux per square meter (candelas per foot-candle per square foot).

Table 1—Required Specific Intensity per Unit Area Values for Colorless Reflectors

Observation Angle, Degrees	Entrance Angle, Degrees	Specific Intensity per Unit Area	
		$cd/lx/m^2$	$cd/fc/ft^2$
$^1/_{10}$	0	2020	2020
$^1/_{10}$	20	806	806
$^1/_6$	0	1440	1440
$^1/_6$	20	576	576
$^1/_3$	0	1010	1010
$^1/_3$	20	403	403

Note: For yellow reflectors the SIA shall be 60 percent of the listed value. For green or red reflectors the SIA shall be 25 percent of the listed value for colorless reflectors.

7.2 *Seal*:

7.2.1 The seal test shall be used to determine if a reflector is adequately sealed against dust and water. Not more than four percent of the reflectors tested shall show evidence of water intake when tested as specified in Section 10.2.

7.3 *Heat Resistance*:

7.3.1 The heat resistance test shall be used to determine the durability of the reflectors. No specimen shall show significant change in shape and general appearance when tested as specified in Section 10.3 and compared with unexposed control standards.

7.4 *Corrosion*:

7.4.1 The salt fog cabinet test of the legend specimen shall be used to evaluate the durability of the legend and its coating. No significant peeling, cracking, or disbonding of the coating shall be observed after 1000 hours under test as specified in Section 10.4.

8. SAMPLING

8.1 For qualification of product, 53 sample reflectors of each size, type, and color to be used shall be submitted by the manufacturer for testing from each manufacturer's lot of 25,000 or fewer reflectors.

8.2 For project acceptance purposes, 53 reflectors of each size, type, and color to be used shall be sampled at random by the purchaser from each shipment of reflectors, when they are received separately from the legend frames, or from the finished legend when these are received already made up. Specimens used in the seal and heat resistance tests shall not be used to perform reflectance tests. If the same specimens are used to perform seal and heat resistance tests, the heat resistance tests shall be performed last.

8.3 The sampling procedure for reflectors incorporated into legend shall be such as will provide the desired degree of randomness, but not unduly delay the production or delivery of signs.

Note 1—One method could be to list in the plans or specifications the extra legend that the manufacturer is to furnish, which will provide the required number and size of reflectors for test. The engineer will substitute this extra legend at random for legend intended for sign usage. The legend for which substitutions are thus made shall be the legend used for laboratory testing as set forth in this specification. A degree of randomness of sampling is obtained in that the supplier does not know which of several letters or symbols intended for sign usage will ultimately be used to supply reflectors for testing.

9. RETESTING

9.1 *Specific Intensity per Unit Area (SIA)*:

9.1.1 Failure of a reflector to meet the SIA minimum shall constitute failure of the reflector being tested. Upon failure of more than two but less than four of the 50 specimens tested, a resample of 100 reflectors shall be tested. Failure of more than three of these specimens shall be cause for rejection of the lot. Failure of four or more of the reflectors in the original sample of 50 shall be cause for rejection of the lot without retest.

9.2 *Seal*:

9.2.1 Upon failure of more than two but fewer than four of the specimens, a resample of 100 reflectors shall be tested. Failure of more than three of these specimens shall be cause for rejection of the lot. Failure of four or more of the reflectors in the original sample of 50 shall be cause for rejection of the lot without retest.

9.3 *Heat Resistance*:

9.3.1 No failure of the initial three specimens will be permitted, and no retest will be allowed.

9.4 *Corrosion*:

9.4.1 No failure of the initial three specimens will be permitted, and no retest will be allowed.

10. TEST PROCEDURES

10.1 *Optical (Photometric) Tests*:

10.1.1 Photometric tests shall be conducted in accordance with T 257, with the reflector spinning at a rate such that the meter reading is steady.

10.2 The seal test is performed by submerging 50 specimens in a water bath at room temperature. The submerged specimens are subjected to a vacuum of 16.9 kPa (5 in. of mercury) for 5 minutes.

Restore atmospheric pressure and leave the specimens submerged for an additional 5 minutes. Examine the specimens for water intake.

10.3 The heat resistance test is performed by placing three reflectors in a horizontal position on a grid or perforated shelf in a circulating air oven. The oven shall be operated at 52º ± 3ºC (125º ± 5ºF). The specimens shall remain in the oven for 4 hours and shall not interfere with the free flow of air. At the conclusion of the test the samples shall be removed from the oven and permitted to cool to room temperature in air and visually examined.

10.4 *Corrosion Test*—Three assembled cut-out letters, symbols or accessories shall withstand the combined corrosion test set forth in ASTM B 117.

11. PACKAGING

11.1 Each cut-out letter, symbol, or accessory, completely assembled with reflectors, shall be supplied in an individual package with contents marked thereon.

11.2 Individual reflectors and separate legends, if so furnished, shall be packed so as to avoid damage by abrasion or other means.

Standard Specification for

Inorganic Zinc-Rich Primer

AASHTO Designation: M 300-03 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Inorganic Zinc-Rich Primer

AASHTO Designation: M 300-03 (2007)

1. SCOPE

1.1. This specification covers self-curing inorganic zinc-rich primers for use on iron and steel surfaces.

1.2. *Intended use of the primers*.

1.2.1. Types I and II are intended for use on bridges, similar structural steel, and other ferrous metal surfaces subject to corrosive atmospheric environments such as marine, industrial, and high humidity.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. Reference to standard specifications, testing procedures and other standard procedures contained in this document shall be the latest edition of the published document at the date of this "Evaluation Criteria."

2.1.1. *AASHTO Standard*:

- *Standard Specifications for Highway Bridges*

2.1.2. *ASTM Standards*:

- B 117, Standard Practice for Operating Salt Spray (Fog) Apparatus
- D 185, Standard Test Methods for Coarse Particles in Pigments
- D 512, Standard Test Methods for Chloride Ion In Water
- D 520, Standard Specification for Zinc Dust Pigment
- D 521, Standard Test Methods for Chemical Analysis of Zinc Dust (Metallic Zinc Powder)
- D 562, Standard Test Method for Consistency of Paints Measuring Krebs Unit (KU) Viscosity Using a Stormer-Type Viscometer
- D 610, Standard Practice for Evaluating Degree of Rusting on Painted Steel Surfaces
- D 1475, Standard Test Method For Density of Liquid Coatings, Inks, and Related Products
- D 1640, Standard Test Methods for Drying, Curing, or Film Formation of Organic Coatings at Room Temperature
- D 1654, Standard Test Method for Evaluation of Painted or Coated Specimens Subjected to Corrosive Environments
- D 1735, Standard Practice for Testing Water Resistance of Coatings Using Water Fog Apparatus
- D 2247, Standard Practice for Testing Water Resistance of Coatings in 100 % Relative Humidity

- D 2369, Standard Test Method for Volatile Content of Coatings
- D 2371, Standard Test Method for Pigment Content of Solvent-Reducible Paints
- D 3363, Standard Test Method for Film Hardness by Pencil Test
- D 4417, Standard Test Methods for Field Measurement of Surface Profile of Blast Cleaned Steel
- D 4541, Standard Test Method for Pull-Off Strength of Coatings Using Portable Adhesion Testers
- D 4752, Standard Practice for Measuring MEK Resistance of Ethyl Silicate (Inorganic) Zinc-Rich Primers by Solvent Rub
- D 4940, Standard Test Method for Conductimetric Analysis of Water Soluble Ionic Contamination of Blasting Abrasives
- D 5894, Standard Practice for Cyclic Salt Fog/UV Exposure of Painted Metal, (Alternating Exposures in a Fog/Dry Cabinet and a UV/Condensation Cabinet)
- D 6580, Standard Test Method for The Determination of Metallic Zinc Content in Both Zinc Dust Pigment and in Cured Films of Zinc-Rich Coatings

2.1.3. *Federal Standards*:

- Fed. Std. No. 141, Paint, Varnish, Lacquer, and Related Materials: Methods of Inspection, Sampling and Testing
- Fed. Std. No. 29, CFR 1910.1200 OSHA Hazard Communication Standard
- Fed. Std. No. 40, CFR, Part 59, Subpart D, Section 59.400 Through 59.413 National Volatile Organic Compound Emission Standards for Architectural Coatings

2.1.4. *ANSI Standards*:

- American National Standards Institute (ANSI) B94.50, Style E

2.1.5. *The Society for Protective Coatings (SSPC) Standards*:[1]

- AB-3, Abrasive Specification Number 3, Newly Manufactured or Re-Manufactured Steel Abrasive
- SP-5, White Metal Blast Cleaning

2.1.6. *Other Documents*:

- Commercial Item Description (CID) A-A-1689B; Tape, Pressure-Sensitive Adhesive, Plastic Film[2]

3. CLASSIFICATION

3.1. *Types*—Inorganic zinc-rich primers covered by this specification shall be furnished in the following types, as specified in the invitation for bids, contract, or order.

3.1.1. *Type I*—Inorganic zinc-rich primer solvent-base multiple components.

3.1.2. *Type II*—Inorganic zinc-rich primer water-base multiple component system.[3]

4. MATERIALS

4.1. The materials used in the manufacture of the primer shall conform to the requirements of the following specifications.

4.1.1. *Zinc Dust*—ASTM D 520, Type II

4.1.2. Vehicle shall be either a solvent solution or water solution of silicates, curing aids, tinting colors, suspension, and pot life control agents of the manufacturer's choosing if no changes are made after initial approval of the primer.

4.1.3. The Volatile Organic Compound (VOC) content shall be stated by the manufacturer in accordance with Section 6.2.

4.1.4. *Pigment*—The pigment used in the formulation shall be basically zinc dust. Small amounts of color and extender pigments may be used if the quantitative requirements of the complete paint are met.

5. REQUIREMENTS

5.1. *Color*—The color of the inorganic zinc primer shall be as mutually agreed upon and such that a definite contrast between it and the color of blasted steel is readily apparent.

5.2. *Pigment*—The extracted pigment upon analysis shall conform to the minimum quantitative requirements specified in Table 1, and shall not vary more than a –2 percent or +3 percent metallic zinc content from the initially approved primer.

5.2.1. The x-ray diffraction pattern of the extracted pigment shall be obtained for the initially approved primer.

5.3. *Primer Quantitative Requirements*—The mixed primer shall meet the quantitative requirements specified in Table 1. Primer must meet applicable VOC content limitations for its intended use categories (shop or field application) as defined by Federal and local regulations. Primers for field coating shall comply with the requirements of 40 CFR, Part 59, Subpart D, Section 59.400 through 59.413. If thinning is necessary for application, the maximum amount of solvent added shall be such that the final product still complies with all the requirements of this section, including the VOC requirements.

Table 1—Requirements

Characteristics	Minimum Requirement	Test Method
Total solids, percent by mass of paint	78	ASTM D 2369
Pigment, percent by mass of total solids	85	ASTM D 2371
Metallic zinc, percent by mass of pigment	85	ASTM D 521
Metallic zinc, percent by mass of total solids	72	ASTM D 6580 or ASTM D 521

5.4. *Physical Properties*—The mixed primer shall meet the physical requirements of Table 2.

Table 2—Properties of Mixed Paint

Characteristics	Minimum Requirement	Maximum Requirement	Test Method
Density, kg/m^3 (lb/gal)	2217 (18.5)		ASTM D 1475
Viscosity, KU @ 25°C (77°F)	Manufacturer's recommendation		ASTM D 562
Set to touch, minutes @25°C (77°F) wet film thickness of 75 to 100 μm (3 to 4 mils)	—	30	ASTM D 1640
Dry hard, hours @ 25°C (77°F) wet film thickness of 75 to 100 μm (3 to 4 mils)	—	24	ASTM D 1640
Pot life @ 25°C (77°F), hours	8		Section 5.5.3.1

5.5. *Primer Qualitative Requirements*—The primer shall meet the following qualitative requirements.

5.5.1. *Mixing*—The raw materials of the liquid portion of the inorganic primer shall be mixed and dispersed as required to produce a product that is uniform, stable, free from grit, and conforms to the requirements of this specification.

5.5.2. The pigment portion of multi-component paints, prior to mixing, shall be dry and loosely packed. After mixing, all types of coarse particles and skins as residue retained on a standard 250-µm (60-mesh) screen shall be no more than 0.5 percent by mass of total paint, regardless of type, in accordance with ASTM D 185.

5.5.3. *Storage Life*—The vehicle component shall not show thickening, curdling, gelling, gassing, or hard caking after being stored unmixed for nine months from date of manufacture in a tightly covered, unopened container at a temperature of 10 to 32ºC (50 to 90ºF).

5.5.4. *Working Properties*—The mixed paint shall spray easily, and shall show no streaking, running, sagging, or other objectionable features when tested in accordance with Federal Standard No. 141, Methods 4331, and 4541.

5.5.4.1. *Pot Life*—After mixing, the pot life shall be determined by placing 350 to 400 mL of the mixed paint into a 500 mL (1 pint) double-friction, top-round paint can and sealing the lid. Place the sealed can into a water bath maintained at a temperature of 25°C (77°F). After 8 hours the mixed paint shall not show curdling, gelling, gassing, hard caking, or a change in viscosity greater than ±5 KU from the initial viscosity of the sample when determined in accordance with ASTM D 562.

5.5.5. *Test Panel Preparation*—Steel test panels (ASTM A 36 hot-rolled steel, or equivalent), measuring 100 by 150 by 1.5 mm (4 by 6 by $^{1}/_{16}$ in.) unless otherwise designated shall be blast cleaned and coated with the zinc-rich primer. The panels shall be cleaned and coated on both sides and all edges.

5.5.5.1. The panels shall be cleaned in accordance with SSPC-SP5 using recyclable metallic abrasives in accordance with SSPC-AB3. The abrasives shall have a maximum chloride content of 15 ppm determined in accordance with ASTM D 512 and a maximum conductivity of 150 micromhos/cm determined in accordance with ASTM D 4940. The abrasive mixture shall be approximately 60 percent SAE shot number S230 and 40 percent SAE grit number G40. Both the shot and grit shall have a Rockwell hardness of C45 ± 3. The surface profile of the cleaned panels shall be 40 to 65 μm (1.5 to 2.5 mils) when determined in accordance with ASTM D 4417, Method C. The profile shall be clean, sharp, and free of embedded friable material, with adequate roughness to insure effective adhesion of the primer.

5.5.5.2. The primer shall be applied to the cleaned test panels using airless spray equipment except when the paint manufacturer's application information specifically states only other methods of application are to be used. All primers shall be applied to panels mounted vertically at a distance of 530 mm (21 in.) from the tip of the spray gun. The equipment shall be capable of developing sufficient pressure to properly atomize the primer. The orifice size, application pressure, pump type and ratio, hose size and length, and any atypical application requirements shall be reported. If the pressure used varies by more than 10 percent from the suggested pressure listed in the manufacturer's application data information, the actual pressure used and a statement explaining the deviation shall be reported.

5.5.5.3. The dry film thickness shall be 65 to 90 μm (2.5 to 3.5 mils) unless otherwise designated. Before any exposure tests, all panels shall be aged 14 days at 24 to 26°C (75 to 79°F) and 45 to 55 percent relative humidity. After aging of the test panels to be evaluated for salt fog resistance, cyclic weathering resistance, bullet hole immersion, and humidity tests, the panels shall have the edges sealed and protected by applying vinyl tape around the outside edges. The vinyl tape shall extend 5 mm ($^3/_{16}$ in.) onto the coated surface from the edge of the panel. The vinyl tape shall be in accordance with CID A-A-1689B and have an approximate vinyl thickness of 110 μm (4.3 mils) with an approximate neoprene adhesive thickness of 25 μm (1 mil).

5.5.5.4. The test panels for salt fog resistance and cyclic weathering resistance shall be scribed in accordance with ASTM D 1654. The scribe shall be a single "X" centered on the test panel with rectangular dimensions of 50-mm (2-in.) top width and 100-mm (4-in.) height. To insure proper positioning, cleanliness, and depth of the scribe, a template and a scribe cutting tool shall be used. The scribe cutting tool shall be a straight shank tungsten carbide tip, lathe cutting tool in accordance with ANSI B 94.50, Style E. The operator shall bear down hard and go over each arm of the scribe twice to insure a clean scribe of sufficient depth to remove any zinc particles from the scribe and to expose clean steel. The exposed steel in the cut of the scribe shall be verified with a microscope.

5.5.6. *Mudcracking*—The coating, when applied in accordance with Sections 5.5.5 through 5.5.5.3 to a 125- to 150-μm (5- to 6-mil) dry film thickness, shall show no mudcracking that is visible to the unaided eye.

5.5.7. *Adhesion*—The coating, when applied and hardened in accordance with Sections 5.5.5 through 5.5.5.3, shall be tested for adhesion in accordance with ASTM D 4541, using apparatus under Appendix A4. The adhesive used to perform this test shall be a two-compound epoxy, containing no solvents (e.g., 100 percent solids). A minimum of four tests shall be performed on each panel. The average of the tests shall be a minimum pull-off adhesion value of 2.4 MPa (350 psi).

5.5.8. *Salt Fog Resistance*—This is an optional test, as determined by the purchaser. The coating, when applied, hardened, and scribed in accordance with Sections 5.5.5 through 5.5.5.4, shall pass 5000-hour minimum exposure to salt fog (ASTM B 117) without any blistering or rusting of the coated portion, with no undercutting from the scribe. (Slight rusting in the scribe mark will be permissible and resulting staining should be ignored.) Strips 6 mm ($^1/_4$ in.) wide along the edges of the panel may be ignored. Testing shall be done in triplicate.

5.5.9. *Cyclic Weathering Resistance Test*—Suitable size panels shall be prepared in accordance with Sections 5.5.5 through 5.5.5.4 and tested in accordance with ASTM D 5894, Cyclic Salt Fog/UV Exposure of Painted Metal (Alternating Exposures in a Fog/Dry Cabinet). The coating shall pass fifteen 336-hour cycles without any blistering or rusting of the coated portion, with no undercutting from the scribe. (Slight rusting in the scribe mark will be permissible and resulting staining should be ignored.) Strips 6-mm ($^1/_4$-in.) wide along the edges of the panel may be ignored. Testing shall be done in triplicate.

5.5.10. *Bullet Hole Immersion Test*—The coating shall be applied in accordance with Sections 5.5.5 through 5.5.5.3 at a dry film thickness of 75 to 90 μm (3.0 to 3.5 mils) except for the panel size, which shall be 75 by 150 by 1.5 mm (3 by 6 by $^1/_{16}$ in.). A circular area of 38.1 mm (1.5 in.) in diameter, in the middle of each panel, shall be left uncoated. A small magnet may be used to hold a circular template in place for this purpose. Coat only the face of the panel with the primer being tested. The backside shall be coated with an electrochemically inert barrier-type coating such as a vinyl or epoxy barrier coating. After curing in accordance with Section 5.5.5.3 each panel shall be immersed in a 1-liter (1-quart) jar containing a 5.0 percent solution of sodium chloride. The jars must be tightly covered to prevent evaporation of water. The 5.0 percent salt water must be changed weekly. After immersion at 23 ± 3ºC (75 ± 5ºF), for 650 hours, no rusting or corrosion as determined by ASTM D 610 shall have occurred either within the circular bare area or over the zinc-rich painted surface.

5.5.11. *Humidity Test*—The coating when applied and hardened in accordance with Sections 5.5.5 through 5.5.5.4 shall show no rust, blistering, or loss of adhesion after 4000 hours of exposure using ASTM D 1735.

5.6. *Primer Field Performance Requirements*—Documented information detailing the past history and experience with the coating in terms of service life under specific conditions shall be required. It must be shown that less than one percent rust has occurred after three years of service in a coastal or marine environment. All details relative to surface preparation and application of the coatings shall be supplied. Sufficient identifiable characteristics shall be provided to permit laboratory test verification of coating identity. These characteristics shall include formulation information readily verifiable in a laboratory, including the general nature of the vehicle, pigment and volatile portions, the density, the percent solids by mass and volume, an infrared spectrum (2.5 to 15 microns) of the vehicle component of each coat, and other procedures used for the quality control during manufacture of the coating.

5.6.1. New products that do not have three-year field performance information can be accepted under an experimental basis.

Note 1—Manufacturers must specify a minimum cure before top coating. Either ASTM D 4752 or D 3363 shall be used to determine cure.

5.7. Primers having a slip coefficient requirement shall meet the AASHTO Class B slip coefficient of not less than 0.5 as defined by the AASHTO *Standard Specifications for Highway Bridges*.

5.8. *Material Quality Assurance*:

5.8.1. In order to determine the acceptability of a lot or batch of a qualified product, the paint shall meet the requirements of Sections 5.2 through 5.4.

5.8.2. Viscosity of the mixed paint shall be determined in accordance with ASTM D 562. Variance shall be within ±10 Krebs Units or equivalent units of another viscometer of the viscosity of the initially approved primer.

5.8.3. Density of the mixed paint shall be determined in accordance with ASTM D 1475. Variance shall be within 48 kg/m^3 (0.4 lb/gal) of the density of the initially approved primer.

5.8.4. Solids percent by mass of the mixed paint shall be determined in accordance with ASTM D 2369. The percent solids by mass shall be no less than that specified in Table 1. Variance shall be within ±2 percent of the percent solids by mass of the initially approved primer.

5.8.5. The infrared spectrum (2.5 to 15 microns) of the vehicle component shall agree with the infrared spectrum of the vehicle component from the paints used in Sections 5.5 through 5.5.5.11. Agreement shall be both in peak position and relative intensity of the peaks, or by other analytical procedure.

5.8.6. The x-ray diffraction pattern of the extracted pigment shall match that of the initially approved primer. This test shall be performed at the discretion of the purchaser.

5.8.7. The solids percent by mass of the vehicle component shall not vary more than ±2 percent of the solids content of the vehicle component from the initially approved primer. The solids content shall be determined in accordance with ASTM D 2369.

6. PACKAGING AND MARKING

6.1. The primer shall be delivered in such containers as may be specified in the contract. Each container shall bear a label with the following information shown thereon: name and address of manufacturer, trademark or trade name, kind of paint, date of manufacture and lot number, mixing instructions, and equipment cleanup instructions. The label on the containers must also contain all appropriate health and physical hazard warnings as described in 29 CFR 1910.1200 OSHA Hazard Communication Standard.

6.2. The VOC content shall be stated on label, and/or product data sheet, and/or Material Safety Data Sheet, or all three.

7. RECOATABILITY

7.1. The primer shall show adequate recoatability when tested in accordance with the following method:

7.1.1. Panels primed in accordance with Sections 5.5.5 through 5.5.5.3 shall be placed into humidity cabinet per Section 5.5.11. Panels are then cleaned in accordance with the manufacturer’s recommendation and recoated and cured in accordance with Sections 5.5.5 through 5.5.5.3. Adhesion testing shall be performed in accordance with ASTM D 4541, using apparatus under Appendix A4. The adhesive shall be in accordance with Section 5.5.7. A minimum of four tests shall be performed on each panel. The average of the tests shall be a minimum pull off adhesion value of 2.4 MPa (350 psi).

8. TOPCOATABILITY

8.1. Topcoats shall show adequate adhesion when tested in accordance with the following method:

8.1.1. Panels primed in accordance with Sections 5.5.5 through 5.5.5.3 shall be placed into humidity cabinet per Section 5.5.11. The panels shall then be cleaned and the topcoat for the system shall be applied in accordance with the manufacturer’s requirements. The topcoated panels shall then be aged in accordance with Section 5.5.5.3. Aged panels shall be exposed for 30 days in accordance with ASTM D 2247. After exposure, adhesion testing shall be performed in accordance with ASTM D 4541, using apparatus under Appendix A4. The adhesive shall be in accordance with Section 5.5.7. A minimum of four tests shall be performed on each panel. The average of the tests shall be a minimum pull-off adhesion value of 2.4 MPa (350 psi).

9. METHODS OF SAMPLING AND TESTING

9.1. The primer shall be sampled by lot for testing. The material can be sampled either at the manufacturer or after reaching its destination.

Standard Practice for

Evaluation of Protective Coating Systems for Structural Steel

AASHTO Designation: R 31-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Evaluation of Protective Coating Systems for Structural Steel

AASHTO Designation: R 31-09

1. SCOPE

1.1. This standard practice covers testing criteria for evaluation of protective coating systems for use on iron and steel surfaces. It is not recommended for the evaluation of hot-dip galvanizing or metalizing.

1.2. The protective coating systems are intended for use on bridges, similar structural steel, and other ferrous metal surfaces, both new and existing, prepared by abrasive blast cleaning, which are subject to corrosive atmospheric environments, such as marine, industrial, deicing chemicals, and high humidity.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard practice may involve hazardous materials, operations, and equipment. It does not purport to address all safety problems associated with its use. It is the responsibility of the user of this standard practice to establish the appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Note 1—The testing format for this standard practice has been developed around a three-coat system consisting of a zinc primer, epoxy or urethane intermediate, and an aliphatic urethane finish coat.

2. REFERENCED DOCUMENTS

2.1. Reference to standard specifications, testing procedures, and other standard procedures contained in this document shall be the latest edition of the published document at the date of this "Evaluation Criteria."

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *volatile organic compound (VOC)*—any organic compound that participates in atmospheric photochemical reactions, that is, any organic compound other than those which the U.S. EPA Administrator designates as having negligible photochemical reactivity. For a list of compounds that the U.S. EPA Administrator has designated as having negligible photochemical reactivity, also referred to as exempt compounds, refer to 40 CFR 51.100(s).

3.1.2. *VOC content*—the weight of VOC per volume of coating, calculated according to the procedures in 40 CFR 59.406(a).

3.1.3. *dry film paint thickness*—the depth of coating to the top of the surface profile peaks, measured in accordance with SSPC PA 2.

3.1.4. *minimum (laboratory) recoat time*—the period of time required to sufficiently cure the applied coating when applied within the manufacturers' recommended wet film thickness range and obtain dry film thickness readings of the coating (without causing physical damage to the applied film).

4. CLASSIFICATION

4.1. *Primer*—Primers act as the initial barrier over the prepared steel substrate. Single-coat systems shall consist only of the primer. Primers recommended for use on structures with painted connections designed for Class B allowable stress will be evaluated for Class B slip coefficient as detailed in Section 9.1 of this standard practice. Primers intended only for use on structures as maintenance applications (i.e., blast and recoat) may not be evaluated for Class B slip coefficient as detailed in Section 9.1 of this standard practice.

4.2. *Touch-Up Primer*—The touch-up primer shall be as recommended by the manufacturer at the time of application. Touch-up procedures for the intermediate and finish coats shall be detailed in the product data sheets or by written submission.

4.3. *Intermediate Coat*—The intermediate coat for a three-coat system serves as a tie coat between primer and finish coat as well as a protective barrier for the structural steel. The manufacturers for each (three-coat) coating system submitted for evaluation shall recommend the appropriate intermediate coat.

4.4. *Finish Coat*—The finish coat for each system evaluated serves as the final barrier coating and provides the desired aesthetic finish for the surface of the structure. The manufacturers for each coating system submitted for evaluation shall recommend the appropriate finish coat.

5. MATERIALS

5.1. The materials used in the manufacture of the system shall conform to the requirements of the following specifications:

5.1.1. *Zinc Dust*—ASTM D 520, Type II.

5.1.1.1. Manufacturers shall submit a certificate of analysis from the zinc suppliers showing conformance with the requirements.

5.1.1.2. Each coating (primer, intermediate, and finish coat) shall be tested by an NLLAP (National Lead Laboratory Accreditation Program) accredited laboratory to determine its total lead content. The total lead content shall be determined using a dry film sample in accordance with ASTM D 3335. The percentage of total lead in each coating shall not exceed 0.01 percent (100 ppm).

6. GENERAL REQUIREMENTS

6.1. *Color*—For production, the color of the coatings shall be as mutually agreed, except that the intermediate coat shall contrast in color a minimum of 10.0 ΔE* from the primer to the finish coat. For testing purposes, the finish coat color shall comply to Section 8.2.7.

6.2. *Pigment*—Prime pigments shall be used except for shaders. Leachable, heavy-metal compounds shall not exceed the regulatory limits of 40 CFR, 261.24, Table 1, when tested in accordance with Section 9.7.4. Total levels of lead, cadmium, and chromium shall not exceed 20 times the specified limits for these elements. If titanium dioxide is used in the finish coat, it shall meet the requirements of ASTM D 476, Type IV.

6.3. *Slip Coefficient for Primer*—Primer coatings for use on new and rehabilitated structures with painted connections designed for Class B allowable stress shall meet the Class B slip coefficient requirements specified in the AASHTO *Standard Specifications for Highway Bridges*. The test data indicating compliance shall also state the type and quantity of reducer, cure time, and maximum coating thickness for that coating as tested.

7. MANUFACTURER'S REQUIREMENTS

7.1. The manufacturer shall supply chemical test results that will define the character and nature of the coating system being submitted. Actual results shall be verified by the select laboratory, and shall be part of the select laboratory's report. Properties (determined in a mixed condition) shall be stated on the informational spreadsheet, certified Product Data Sheet and/or the MSDS as follows:

7.1.1. Total solids, percent by mass in accordance with ASTM D 2369.

7.1.2. Volatile organic compound content in accordance with ASTM D 3960.

7.1.3. EPA exempt solvents, identify compound and percent by volume.

7.1.4. Water, percent by mass, in accordance with ASTM D 4017.

7.1.5. Pigment, percent by mass, in accordance with ASTM D 2371 or D 3723.

7.1.6. Metallic zinc content, percent by mass, in the primer shall be determined in accordance with ASTM D 6580. An optional test method is T 337.

7.1.7. Total solids, percent by volume, in accordance with ASTM D 2697.

7.1.8. Mass per volume (grams per liter) in accordance with ASTM D 1475.

7.1.9. Viscosity (Stormer at 25°C) KU in accordance with ASTM D 562 (not suitable for viscosities above 143 KU).

7.1.10. Viscosity (Brookfield at 25°C) cP in accordance with ASTM D 2196. The instrument model (i.e., LV, DV, DVII+), spindle size, and revolutions per minute shall be reported.

7.1.11. Pot life in hours, at specified temperature and specified humidity, shall be evaluated in the laboratory through viscosity measurements taken at regular intervals and reported in Krebs Units. Materials with manufacturer's stated pot life shall be evaluated at 25, 50, 75, and 100 percent of the stated pot life. Materials without manufacturer's stated pot life shall be evaluated at 2-hour increments for 8 hours.

7.1.12. Sag resistance (Leneta) in micrometers wet film thickness in accordance with ASTM D 4400.

7.1.13. Recommended film thickness in micrometers.

- Minimum and maximum wet film thickness.
- Minimum and maximum dry film thickness.
- Maximum allowable dry film thickness for the primer on faying surfaces.

7.1.14. Minimum (and maximum when applicable) drying time in accordance with ASTM D 1640 at 25°C and 50 percent relative humidity.

- Dry to touch.
- Dry to handle.
- Dry to recoat.

7.1.15. Mixing ratio for multi-component coatings, by volume.

7.1.16. Mixing ratio for multi-component coatings, by mass.

7.1.17. Shelf life of each component stored at 25°C.

7.1.18. Total heavy metals content for mixed coatings in accordance with ASTM D 3335 and D 3718. Heavy metals to be tested will include lead, chromium, and cadmium for each coating.

7.1.19. Leachable heavy metals content for mixed coatings in accordance with ASTM D 3335 and D 3718. Analysis shall include Arsenic, Barium, Cadmium, Chromium, Lead, Mercury, Selenium, and Silver for each coating.

7.1.20. Epoxide values determined in accordance with ASTM D 1652, Method A.

7.1.21. Amine values determined on the amine or amidomine contained in the appropriate component of two component epoxy coatings, in accordance with ASTM D 2073.

7.1.22. Isocyanate group content determined in accordance with T 339.

7.1.23. Hindered amine light stabilizers (HALS) determined in accordance with T 338.

7.1.24. Ultraviolet (UV) absorbers.

7.1.25. The minimum and maximum surface profile requirements (height in micrometers).

7.1.26. Application requirements for
- Ambient temperature
- Surface temperature
- Material temperature
- Humidity
- Tip size
- Application pressure

8. TESTING REQUIREMENTS

8.1. *General*:

8.1.1. Tests must be administered or performed by an authorized testing facility as approved by AASHTO's National Transportation Product Evaluation Program (NTPEP). The principal facility evaluating a specific coating system or any laboratory performing testing for the principal facility must obtain prior approval from the NTPEP before initiating any testing.

8.1.2. All testing equipment shall be cleaned prior to performance of each testing cycle, unless specifications require more frequent cleaning.

8.1.3. *Coating Evaluation Requirements*:

8.1.3.1. *Manufacturer*—Before any testing, the manufacturer shall contact the NTPEP Lead State or the NTPEP Coordinator and obtain a current copy of the Structural Steel Coatings Work Plan and all necessary application forms for submission of a coating system.

8.1.3.2. *NTPEP Lead State*—The NTPEP Lead State will provide reporting criteria and system numbers to the selected testing laboratory. The NTPEP Lead State will also determine the coating systems that shall be used as system monitors for the testing.

8.1.3.3. *Testing Laboratory*—The following information will be provided to the NTPEP Lead State by the testing laboratory:

8.1.3.3.1. Identify what test the Principal Testing firm will perform. Provide Standard Operating Procedures for each test performed.

8.1.3.3.2. Identify what tests will be performed by an authorized outside firm, the name, address and telephone number of the firm and the contact person for the firm. Provide Standard Operating Procedures for each test performed by the authorized outside firm.

8.1.4. The Principal Testing firm performing the testing shall be responsible for application of protective coatings to test panels.

8.1.5. Upload testing results for all samples, panels, or tests performed to the appropriate SSC Module of DataMine. Manufacturers will be allowed the option of not having the final test results for their system made public information.

8.2. *Test Panel Requirements for Test (Applicable to Test Nos. 2 through 8)*

8.2.1. All steel test panels, except Test No. 4 panels, shall be ASTM A 36 or A 572 hot-rolled steel or equivalent with dimensions shown below. Certified mill test reports shall be provided as prepared by the steel manufacturer or testing laboratory for all ASTM A 36 or A 572 steel identifying actual physical and chemical analysis of the material. Test panels for Test No. 4 shall be standard Taber panels, meeting the requirements of ASTM D 4060.

Test Panel Dimensions

Test	Width (mm)	Length (mm)	Thickness (mm)
2,3,5,6	100	150	6
8	102	305	6

8.2.2. Three test panels shall be prepared for each complete system for each test, except Test 8, which shall require five. Test 5 requires three additional test panels to be prepared with the primer only. Test 3 requires three additional test panels to be prepared. The additional panels for Test 3 shall not be scribed.

8.2.3. Control panels shall be coated in bulk lots by a single applicator for use by all selected laboratories. The location and date of application shall be reported. All control panels utilized during the testing evaluation of a system shall be from the same lot. The quantity of control panels to be coated, the control system to be used, and the application parameters shall be approved by NTPEP. During transportation and storage, control panels shall be protected such that coating damage will not occur. Beyond 30 days, the storage temperature and relative humidity for these panels shall be 25 ± 5°C and 50 ± 20 percent.

8.2.4. The panels shall be cleaned in accordance with SSPC-SP 5 using recyclable metallic abrasives in accordance with SSPC AB3. The abrasives shall have a maximum chloride content of 15 ppm determined in accordance with ASTM D 512 and a maximum conductivity of 150 micromhos per cm determined in accordance with ASTM D 4940. The abrasive mixture shall be approximately 60 percent SAE shot number S230 and 40 percent SAE grit number G40. Both the shot and grit shall have a Rockwell hardness of C 45 ± 3. The surface profile of the cleaned panels shall be 65 to 90 µm when determined in accordance with ASTM D 4417, Method C. The profile shall be clean, sharp, and free of embedded friable material, with adequate roughness to insure effective adhesion of the applied primer.

Note 2—The SP 5 is required rather than SP 10 only for the convenience of the laboratory in order to guarantee that all panels are prepared identically and to assure comparative testing results. Steel surfaces prepared to a lesser degree may not yield same performance.

8.2.5. Each coating shall be applied within the dry film thickness (DFT) range recommended by the manufacturer. If no DFT range is recommended, apply the coating at the recommended DFT ± 13 µm.

8.2.6. *Dry Film Paint Thickness*—The dry film paint thickness shall be taken in accordance with ASTM D 7091, with the following exception:

8.2.6.1. Measure the dry film coating thickness on each test panel utilizing a Type II dry film thickness gauge calibrated according to SSPC PA2 as follows: Take two gauge readings from the top third, the middle third, and the bottom third of the test panel. Readings should be taken at least 25 mm from any edge. To facilitate consistent measurements at fixed positions on the panel, the laboratory shall use a template providing six fixed locations on the panels. Discard any gauge reading that cannot be repeated consistently. The average of the acceptable gauge readings shall be no less than the manufacturer's recommended thickness. No single gauge reading shall be less than 80 percent of the manufacturer's recommended minimum. The average of the acceptable gauge readings shall be no more than 120 percent of the manufacturer's recommended maximum. Recommended maximum dry film thickness must be detailed on the product submission.

8.2.6.2. All products shall be applied using proper airless equipment except when this method is specifically not allowed by the coating manufacturer. All coatings shall be applied to panels mounted vertically at a distance of 530 mm from the tip of the spray gun. The equipment shall be capable of developing sufficient pressure to properly atomize the coating. Orifice size, application pressure, pump type and ratio, hose size and length, and any atypical application requirements shall be recorded. If the pressure used varies by more than 10 percent from the suggested pressure listed in the manufacturer's application data information, the actual pressure used and a statement explaining the deviation shall be provided in the final report.

8.2.7. For testing purposes the color of the final topfinish coat shall conform to Federal Standard No. 595 Color Chip No. X6134 (grey) ("X" signifies that the gloss is undesignated). Acceptable finish coat color shall be within 3.0Δ* of the required standard.

8.2.8. Each sample shall be marked and identified by a NTPEP-assigned system code number. The identification code number shall be placed on the back of each panel with permanent yellow paint stick. It will also be typed and placed in front of the corresponding panel when photographs are taken. The number will have a minimum height of 10 mm and will identify the following information, which will be part of the final report:

8.2.8.1. Test number being performed.

8.2.8.2. Replica test being performed (i.e., salt No. 3).

8.2.8.3. Date of panel preparation.

8.2.8.4. Date that the test evaluation was performed.

8.2.9. Coatings shall be applied to test panels at the minimum (laboratory) recoat time as defined in Section 3 of this specification. Curing of the coated test panels, for the complete system, shall be a minimum of 30 days and no more than 45 days. The curing climate shall be at 25 ± 2°C and 55 ± 5 percent relative humidity. The back of all test panels shall be coated with the primer for one and two coat systems and primer and intermediate for three coat systems.

8.2.10. After preparation of the test panels with the coating system to be evaluated, the edges shall be sealed and protected by applying vinyl tape around the entire outside edge. The vinyl tape shall extend 5 mm onto the coated surface from the edge of the panel and shall be applied after the coating has cured. The vinyl tape shall meet the requirements of CID A-A-1689B and have an approximate vinyl thickness of 110 µm with an approximate neoprene adhesive thickness of 25 µm.

8.2.11. Test panels shall be scribed in accordance with ASTM D 1654 with parallel 100 mm lines centered on the panel 25 mm from the edges of the panel and separated by 50 mm. The scribing tool shall be a straight-shank tungsten carbide tip, lathe cutting tool (ANSI B94.50, Style E). The entire length of the scribe shall expose the steel substrate as verified with a microscope.

8.3. Photographic Requirements (applicable to Test Nos. 1 through 7).

8.3.1. Color photographs of each sample or panels shall be taken as follows:

8.3.1.1. All photographs shall include the code identification number for each sample or panel and the number of hours.

8.3.1.2. A photograph of the coated surface of each sample or panel shall be taken after the application of the entire system to be evaluated.

8.3.1.3. *Test No. 1*—Surface of each sample prior to and after each test.

8.3.1.4. *Test No. 2 and No. 3*:

8.3.1.4.1. Each time frame designated.

8.3.1.4.2. The panel shall be photographed and its condition documented at the end of every third 336-hour cycle for the ASTM D 5894 Cyclic Weathering Resistance Test and 1,000 hours for ASTM B 117 Salt Fog Resistance Test.

8.3.1.4.3. Rust creepage evaluation: (1) after washing and prior to scraping of the scribe, and (2) after scraping of the scribe.

8.3.1.5. *Test Nos. 4, 5, and 6*—At the completion of each test.

8.4. *Dry Film Paint Thickness*—The dry film paint thickness shall be taken in accordance with ASTM D 7091, with the following exception.

8.4.1. Measure the dry film coating thickness on each test panel utilizing a Type II dry film thickness gauge calibrated according to SSPC PA 2 and as follows: Take two gauge readings from the top third, the middle third, and the bottom third of the test panel. Readings should be taken at least 25 mm from the edge. To facilitate consistent measurement at fixed positions on the panel, the laboratory shall use a template, providing six fixed locations on the panels. Discard any gauge reading that cannot be repeated consistently. The average of the acceptable gauge readings shall be no less than the manufacturer's recommended minimum thickness. No single gauge reading shall be less than 80 percent of the manufacturer's recommended minimum. The average of the acceptable gauge readings shall be no more than 120 percent of the manufacturer's recommended maximum. Recommended maximum dry film thickness must be detailed on the product submission.

9. TESTS TO BE PERFORMED BY SELECTED LABORATORY

9.1. *Test No. 1*—Slip Coefficient Test.

9.1.1. All primers shall be tested and the results reported for slip coefficient according to the *Standard Specifications for Highway Bridges*, Division I, Section 10.32.3.3.3. Tests are to be performed in accordance with "Appendix A, Testing Method to Determine the Slip Coefficient for Coatings Used in Bolted Joints," *Specifications for Structural Joints Using ASTM A 325 or A 490 Bolts*, as adopted by the Research Council on Structural Connections (RCSC). Primers with a slip coefficient of not less than 0.5 shall meet Class B.

9.1.2. *Sample Preparation Requirements for Slip Coefficient*:

9.1.2.1. The surface shall be prepared in accordance with SSPC-SP 5. The surface shall be abrasive blasted using 100 percent steel shot (selected to create a worst-case scenario). The steel shot shall conform to the requirements of SAE shot number S 280 and SSPC AB-3. The steel shot shall have a hardness of Rockwell C 45 ± 3. The surface profile shall be between 50 and 90 μm as determined using ASTM D 4417 Method C.

9.1.2.2. The thickness of coating to be tested on each surface shall be 50 μm greater than the film thickness recommended in Section 6.4.3.10.1. The maximum thickness tested shall be reported by the testing laboratory.

9.1.2.3. A minimum cure time as recommended by the manufacturer is required for primer testing. Curing of the coated test panels shall be 25 ± 2°C and 65 ± 5 percent relative humidity.

9.2. *Test No 2*—Salt Fog Resistance Test.

9.2.1. A salt fog resistance test shall be performed in accordance with ASTM B 117. The complete system shall be exposed for durations of 4,000 and 5,000 hours.

9.2.2. *Evaluation*—Evaluate each panel for Blistering and Rust Creepage at each 1,000-hour increment of exposure and after scraping in accordance with ASTM D 1654, Method 2, Scraping, (where applicable after cleaning).

9.2.2.1. Blistering shall be evaluated in accordance with ASTM D 714. Blister size and frequency shall be converted to a numerical value using Table 1.

Table 1—Blister Value Conversion Table (No blisters equals a conversion number of 10.)

Blister	Blister Frequency			
Size	Few[a]	Medium	Medium Dense	Dense
#8	9	8	7	6
#6	8	7	6	5
#4	7	6	5	4
#2	6	5	4	3
#1	5	4	3	2

[a] Adjustment Values for "Few" Blister Frequency.

Number of Blisters	Value
1	x.8
2	x.6
3	x.4
4	x.2
5 or more	x.0

Note: If a specific number of blisters is reported under the frequency "Few" then use the appropriate decimal "Value" provided above. Example: A report of two #6 blisters converts to a value of 8.6.

9.2.2.2. *Rust Creepage at the Scribe*—Rust creepage (a.k.a. cutback, undercut, loss of adhesion, deterioration, disbondment) shall be measured perpendicular from the center of the scribe to the furthest point of cutback. Cutback shall be measured in millimeters to the nearest 0.5 mm. For both intermediate and final evaluations, the maximum cutback shall be measured at 5-mm intervals along the scribe on each side of the scribe. (For each 100-mm scribe line, 40 measurements are required.) Report the average and maximum cutback measurements. Defects at the scribe having the appearance of a "blister" will be defined to be rust creepage (cutback).

9.3. *No. 3*—Cyclic Weathering Resistance Test.

9.3.1. A cycling weathering resistance test shall be performed in accordance with ASTM D 5894 for the following durations:

Test Panel Cycle Requirements

	(Number of 336-h Cycles)				
Test Panels: Complete System	3	6	9	12	15

9.3.2. Color change testing shall be performed in accordance with ASTM D 2244 to obtain calculations of color differences from instrumentally measured color coordinates CIE 1976 L*a*b*. Testing shall be performed in accordance with ASTM E 1349 using Illuminant D 65 and 2-degree observer. Report color changes as ΔE*. Specular gloss retention shall be performed in accordance with ASTM D 523 using an incidence angle of 60 degrees. The difference in color, gloss values, and percent of gloss retention shall be reported.

9.3.3. *Evaluation*—Follow evaluation procedures of Section 9.2.2. All testing intervals shall be evaluated.

9.4. *Test No. 4*—Abrasion Resistance Test.

9.4.1. A test for abrasion shall be performed in accordance with ASTM D 4060 using CS-17 wheel and 1 kg weight for 1,000 cycles. The test shall be performed on panels coated with the full system to be tested (i.e., primer/intermediate/finish). The hardness of the abrasive wheel shall be checked in accordance with ASTM D 2240 for each test performed.

9.4.2. *Reporting Data*—The system shall be tested to identify its “wear index” in milligrams per cycle and “weight loss” in milligrams.

9.5. *Test No. 5*—Adhesion Test.

9.5.1. A test for adhesion shall be performed in accordance with ASTM D 4541, using a Type IV tester as described in Annex A, Section A4. The adhesive used to perform this test shall be a two-component epoxy, containing no solvents (e.g., 100 percent solids). The test shall be performed on panels having the primer coat only and on panels having the complete system. A minimum of four tests shall be performed on each panel.

9.6. *Test No. 6*—Freeze Thaw Stability.

9.6.1. Prepared panels shall be exposed to a 30-day freeze/thaw/immersion cycle. One 24-h cycle shall consist of 16 h at –30 ± 5°C followed by 4 h of thawing at 50 ± 5°C and four hours tap water immersion at 25 ± 2°C. This work is done with the panels remaining in the freezer mode on weekends and holidays. Upon completion of the test, adhesion tests shall be performed as required in Section 9.5.

9.7. *Test No. 7*—Coating Identification Tests.

9.7.1. An analysis of vehicle solids by Fourier transform infrared (FT/IR) spectroscopy consisting of 32 scans minimum per sample shall be performed as follows:

9.7.1.1. For zinc primer solvent-based coats infrared spectrum (2.5 to 15 µm) of each liquid vehicle component via the potassium bromide sandwich technique.

9.7.1.2. For two-component, solvent-based finish coats infrared spectrum (2.5 to 15 µm) of each single component via the potassium bromide sandwich technique, and of the mixed and dried components in appropriate mixing ratios (dried film) via the potassium bromide single-pellet technique.

9.7.1.3. For zinc primer water-based coats infrared spectrum (2.5 to 15 µm) of the liquid vehicle component after drying and applying the potassium bromide single-pellet technique.

9.7.1.4. For two-component water-based finish coats infrared spectrum (2.5 to 15 µm) of each single component after drying and applying the potassium bromide single-pellet technique and also, of the mixed and dried components in appropriate mixing ratios (dried film) via the single-pellet technique.

9.7.2. The volatile organic compound (VOC) content shall be determined on unthinned, mixed coatings in accordance with the ASTM D 3960 for primers, intermediates, and finish coats. Multi-component coatings will be blended together in the specified mixing ratios prior to testing.

9.7.3. Analyze mixed coatings for total heavy metals content (lead, chromium, and cadmium) in accordance with ASTM D 3335 and D 3718.

9.7.4. Dry film analysis for leachable heavy metals shall include Arsenic, Barium, Cadmium, Chromium, Lead, Mercury, Selenium, and Silver for each coating. The dried film shall be removed from a non-metallic glass test panel and pulverized to pass through a 250-µm sieve. The pulverized film passing the 250 µm sieve shall be extracted in accordance with the TCLP, Method 1311 of EPA SW 846. The extract shall then be analyzed for heavy metals using the appropriate EPA SW 846 test method for each metal.

9.7.5. Epoxide values can be determined in accordance with ASTM D 1652, Method A. This method measures a quantity called the weight per epoxy equivalent (WPE), which is defined as the grams of resin containing one gram equivalent of epoxy groups. However, since this method was intended for raw materials, the WPE of the epoxy component of a two-component coating will actually be the grams of that component (not the grams of actual resin) which contains one gram equivalent of epoxy groups.

9.7.5.1. For clear components, the method can be used as written. For pigmented compounds, the sample must first be weighed into a centrifuge tube, then thinned 50 to 100 percent with xylene or toluene. If a glass stirring rod is used to aid in dispersing the sample in a thinner, it may be necessary to use an additional small amount of thinner to rinse residues off of the rod and back into the centrifuge tube.

9.7.5.2. The sample is then centrifuged to remove the pigment, and the supernatant should then be transferred to the container in which the ASTM D 1652 procedure will be done. The pigment in the bottom of the centrifuge tube should then be redispersed in 2 or 3 mL of solvent, recentrifuged, and the supernatant combined with the original supernatant for analysis.

9.7.6. Amine values can be determined on the amine or amidoamine contained in the appropriate component of two component epoxy coatings, in accordance with ASTM D 2073. This method is only applicable to clear, unpigmented component. If the component is pigmented, the following modification to ASTM D 2073 will be necessary:

9.7.6.1. Weigh 1.0 g of the pigmented component to the nearest 0.1 mg into a glass centrifuge tube and thin with approximately one milliliter of methylene chloride. If a glass stirring rod is required to disperse the pigmented component with the methylene chloride, it may be necessary to use a small additional amount of methylene chloride to rinse any material off of the glass stirring rod before removing it from the centrifuge tube.

9.7.6.2. Separate the pigment by high-speed centrifugation, and transfer the supernatant into a 25-mL low-form beaker. The pigment in the bottom of the centrifuge tube should be redispersed in an additional 2 to 3 mL of methylene chloride, recentrifuged, and the supernatant combined with the original supernatant for analysis. At this point, follow the titration procedure described in ASTM D 2073.

Note 3—Even though the titration is followed potentiometrically and the end points will not be obscured by the color of the pigment, the pigment must still be removed to prevent the possibility of any basic pigments reacting with the hydrochloride acid used in the titration procedure.

9.7.7. Isocyanate group content will be determined in accordance with T 339.

9.7.8. The presence of hindered amine light stabilizers (HALS) in the polyol portion of a two-component urethane coating will be verified in accordance with T 338.

9.7.9. Verify the following coating characterization tests reported by the manufacturer for mixed single and multiple component coatings. Also, perform single component characterization on multiple component coatings for the properties noted below with an asterisk:

9.7.9.1. *Total solids, percent by mass in accordance with ASTM D 2369.

9.7.9.2. Volatile organic compound content in accordance with ASTM 3960.

9.7.9.3. EPA exempt solvents, identify compound and percent by volume.

9.7.9.4. Water, percent by mass, in accordance with ASTM D 4017.

9.7.9.5. *Pigment, percent by mass, in accordance with ASTM D 2371 or D 3723.

9.7.9.6. Metallic zinc content, percent by mass, in the primer shall be determined in accordance with ASTM D 6580. An optional test method is T 337.

9.7.9.7. *Total solids, percent by volume, in accordance with ASTM D 2697.

9.7.9.8. *Mass per volume (grams per liter) in accordance with ASTM D 1475.

9.7.9.9. *Viscosity (Stormer at 25°C) KU in accordance with ASTM D 562 (not suitable for viscosities above 143 KU).

9.7.9.10. *Viscosity (Brookfield at 25°C) cP in accordance with ASTM D 2196. The instrument model (i.e., LV, DV, DVII+), spindle size, and revolutions per minute shall be reported.

9.7.9.11. Pot life in hours, at specified temperature and specified humidity, shall be evaluated in the laboratory through viscosity measurements taken at regular intervals and reported in Krebs Units. Materials with manufacturer's stated pot life shall be evaluated at 25, 50, 75, and 100 percent of the stated pot life. Materials without manufacturer's stated pot life shall be evaluated at 2-h increments for 8 h.

9.7.9.12. Sag resistance (Leneta) in micrometers wet film thickness in accordance with ASTM D 4400.

9.7.9.13. Rating of application properties, including mixing, setting, and ability to spray, shall be evaluated and reported in accordance with Annex A1.

9.8. *Test No. 8*—2-Year Atmospheric Testing.

9.8.1. Each complete system shall be subjected to a 2-year atmospheric test at a location designated by the NTPEP Structural Steel Coatings project panel. The distance from high tide to the ocean side test fence shall be monitored every 30 days. This data shall be included in the final report from the test facility. The test panels shall be exposed within 10.7 m of the ocean from the fence. Corrosion rate of bare steel shall be measured in accordance with ASTM G 92. The bare steel panels used to monitor rate of corrosion shall be from the same heat of steel as the test panels.

9.8.2. Five test panels meeting the materials, surface preparation, application, and curing requirements of Section 8.2 shall be prepared with the complete system. Panels shall be a 6 by 102 by 305 mm with a single 100-mm scribe in the center of the panel. The panel edges shall be coated up to 6 mm in from the edge with an embedding compound, such as Morton International 1-12 epoxy resin, after the complete system has cured. Panels will be oriented to face the ocean and be inclined from the oceanside at an angle of 30 degrees from level along the long leg. The panels shall be exposed for 2 years and then inspected and photographed in accordance with ASTM D 1654, D 610, and D 714. Total UV, total solar energy, temperature (minimum, maximum, average), relative humidity (minimum, maximum, average), average dew point, time of wetness, and rain fall will be monitored and documented in a monthly summary. These values will be made part of the final report.

10. INSPECTION OF TESTING

10.1. Authorized specifying agency representatives will be permitted (at any time) access to inspect testing procedures being performed and/or review test records of any coating systems being evaluated under this specification.

11. TEST REPORT AND PROTECTIVE COATING INFORMATION

11.1. The principal testing firm will be responsible for compiling and entering all required data into the Structural Steel Coatings Module for Data Mine.

11.2. The required data shall, at a minimum, consist of the following:

11.2.1. Digital color photographs.

11.2.2. Individual test results for each test performed.

11.2.3. Specification information for the specific coating system contained in the report as follows:

11.2.3.1. Name, address, telephone number, and fax number of the manufacturer, and the manufacturer's technical representative.

11.2.3.2. Product name and/or identification number for each coating tested (primer, intermediate, and finish coat).

11.2.3.3. The manufacturer's recommended minimum and maximum dry film thickness (in micrometers) for each coating (primer, intermediate, and finish coat).

11.2.3.4. The manufacturer's recommended minimum (recoat) time, (hours), with specified temperature (°C), and relative humidity (%) for each coating.

11.2.3.5. Requirements of Section 7.

11.3. Certificate of Testing (see Figure 1) uploaded to DataMine as a portable document file (PDF).

ORGANIZATION LETTERHEAD
(Testing Firm)

“AASHTO” CERTIFICATE OF TESTING

We hereby certify that this coating system manufactured by

____(coating manufacturer)

______________________ ______________________ ______________________,
(prime coat) (intermediate coat) (finish coat)

was tested in accordance with the requirements for each applicable test as defined by AASHTO R 31, its support specifications, and that all information presented is truthful and without bias.

All record and documents pertaining to this certificate and not submitted herewith will be maintained available by the undersigned for a period of not less than seven years.

12. REQUALIFICATION

12.1. Requalification shall occur every 5 years from the date of system acceptance. If changes in formulation occur at any time, complete retesting will be required. Any change in an ingredient amount, quality, or type will constitute a formulation change. If the formulation has remained unchanged, the 5-year requalification will include only the physical property tests, and chemical property tests (includes instrumental identification test). Requalification at 10 years will require complete retesting. Continued requalification will require this testing cycle be continued at 5-year intervals. Significant changes in the testing standard could result in partial or complete retesting at the end of any 5-year cycle.

ANNEX

(Mandatory Information)

A1. RATING OF APPLICATION PROPERTIES

A1.1. *Scope*—The Testing Laboratory shall include ratings for each of the following parameters. Products requiring special application procedures or equipment by manufacturers' recommendation shall also be detailed in the report.

A1.1.1. *C1 Mixing*—During mixing of the products, evaluate each product on a 10-to-1 scale. Place a checkmark across from the mixing characteristic exhibited by the product.

Characteristic	Rating	√
One component—Little or no settling; easily mixed by hand	10	☐
One component—Some settling, but easily mixed by hand.	9	☐
One component—Blends easily when mixed with mechanical agitation, typically in less than thirty seconds with 3/8" drill motor and a jiffy mixer for a gallon sample.	8	☐
One component—Mixes with some difficulty, typically requiring more than three minutes with 3/8" drill motor and a jiffy mixer for a gallon sample. **Two components**—Both components and their blend mix easily as defined in Rating 8.	7	☐
One component—Mixes with difficulty, typically requiring more than three minutes with 3/8" drill motor and a jiffy mixer for a gallon sample. Settled layer about one inch thick or very hard to agitate. Thin material on top requires effort to prevent splash out of can. **Two components**—Both components settled and mixed as defined in Rating 7; blend mixes easily or one of the components is a powder.	6	☐
One component—Same as Rating 6, but had to scrape bottom of can. **Two components**—One of the components mixes with difficulty as in Rating 6. Blend settles ten to thirty minutes after mixing; continuous agitation required. **Multi-component systems**—One of the components is a powder. All components and their blend mix easily.	5	☐
One component—Extremely thick; must first break up settled material by hand, then mix with power equipment. **Two components**—Both components mix with difficulty as in Rating 6. **Multi-component systems**—One of the components is a powder and one of the liquid components is difficult to mix as in Rating 6.	4	☐
Two components—One of the components is extremely thick. Must first break up settled materials by hand, then mix with power equipment. **Multi-component systems**—One of the components is a powder and both the liquid components are difficult to mix as in Rating 6.	3	☐
Considerable effort is needed to mix products with normal job site mixing equipment.	2	☐
Heavily settled; cannot re-disperse products with normal job site mixing equipment.	1	☐

A1.1.2. *C2 Spray-Ability*—During the spraying of the products, evaluate their respective atomization characteristics on a 10 to 1 scale. Place a checkmark across from the atomization characteristic(s) exhibited by the product.

Characteristic	Rating	√
Excellent Atomization—Excellent definition to spray pattern. No runs or sags if sprayed in one pass. Easy to control film build. No tip plugging. Positive shut off of coating material at tip. No dripping from spray tip. No mist coat required.	10	☐
Good Atomization—Good definition to spray pattern. No runs or sags if sprayed in one pass. Easy to control film build. No tip plugging, but some build-up on spray tip. Mist coat required to prevent out-gassing. Less than 2-minute wait necessary between mist and full coats.	9	☐
Atomizes satisfactorily, but lacks some definition of spray pattern—Less than two tip plugs per gallon. Some build-up on spray tip. Mist coat required to prevent out-gassing. Two 5-minute waits necessary between mist and full coats.	8	☐
Atomizes satisfactorily, but lacks definition of spray pattern—Two to four tip plugs per gallon. Spray tip requires occasional wiping. Mist coat somewhat difficult to apply consistently over the surfaces.	7	☐
Atomizes, but poor definition of spray pattern—Four to six tip plugs per gallon. Frequent drips from spray tip. Mist coat difficult to apply consistently over the surfaces.	6	☐
Poor atomization with airless, but coating levels satisfactory—Seven or more tip plugs per gallon. Consistent mist coat cannot be applied without multiple passes. Some out-gassing evident.	5	☐
Poor Atomization with airless, and coating levels poorly—Consistent mist coat impossible to apply. Out-gassing impossible to eliminate.	4	☐
Cannot be applied using airless equipment, but can be applied satisfactory with conventional equipment.	3	☐
Can be sprayed with conventional equipment with special effort.	2	☐
Cannot be sprayed with conventional or airless equipment.	1	☐

A1.1.3. *C3 Settling*—During the application of the products, evaluate the settling characteristics of the mixed coating on a 10-to-1 scale. Place a checkmark across from the settling characteristic(s) exhibited by the product.

Characteristic	Rating	√
No agitation required after mixing.	10	☐
No agitation required after mixing, but settles over night (16 h).	9	☐
No agitation required after mixing, but settles in 8 h.	8	☐
Agitation required, some settling after 4 h.	7	☐
Agitation required, some settling after 2 h but not noticeable settling in 30 min.	6	☐
Agitation required, some settling after 1 h but not noticeable settling in 30 min.	5	☐
Settles in 10 to 30 min, material easily re-dispersed with stirring stick	4	☐
Settles in 10 to 30 min, mechanical agitation required to re-disperse material.	3	☐
Settles in less than 10 min.	2	☐
Falls out of suspension immediately. Cannot maintain suspension.	1	☐

APPENDIXES

(Nonmandatory Information)

X1. CHARACTERIZATION TESTS FOR PRODUCT VERIFICATION

X1.1. The following tests are recommended for determining if the coatings supplied are the same quality as the manufacturer's materials originally tested and certified for acceptance. The most pertinent and feasible ones may be selected to verify compliance.

X1.1.1. *Group I Tests*—Most commonly used tests.

X1.1.1.1. Infrared analysis: see requirements of Section 9.7.1.

X1.1.1.2. For zinc prime coats infrared spectrum (2.5 to 15 µm) of non-zinc containing vehicle component(s).

X1.1.1.3. For two-component finish coats infrared spectrum (2.5 to 15 µm) of each single component and also of the mixed components (when applicable) in appropriate mixing ratios.

X1.1.1.4. Viscosity of mixed coating and individual components determined in accordance with ASTM D 562.

X1.1.1.5. Mass per volume (grams per liter) of mixed coating and individual components in accordance with ASTM D 1475.

X1.1.1.6. Total solids, percent by mass of mixed coating and individual components in accordance with ASTM D 2369.

X1.1.1.7. Dry time of mixed coating in accordance with ASTM D 1640.

X1.1.1.8. Pigment, percent by mass of total solids of mixed coating and individual components in accordance with ASTM D 2371.

X1.1.2. *Group II Tests*—Less frequently used tests because they pertain to zinc content and are useable only with zinc primers.

X1.1.2.1. Metallic zinc, percent by mass in the primer; see requirements of Section 6.4.3.3.

X1.1.2.2. Total zinc, percent by mass of pigment (zinc dust) in accordance with ASTM D 521.

X1.1.2.3. Metallic zinc, percent mass of pigment (zinc dust) in accordance with T 337.

X1.1.2.4. Zinc oxide, percent mass of pigment (zinc dust) in accordance with ASTM D 521.

X1.1.2.5. Lead and cadmium content of the mixed coating in accordance with ASTM D 3335.

Note X1—The coating evaluation tests use standard colors for uniform analysis of results. Use of different colors than those tested may change some of the baseline parameters.

X2. GUIDE FOR PROJECT VERIFICATION TESTING

X2.1. The extracted pigment upon analysis shall conform to the originally approved batch and the pigment content, percent by mass, shall not vary more than –2 percent or +3 percent. Allowances for the finish coats will be permitted in order to produce the desired color.

X2.2. *Vehicle*:

X2.2.1. The vehicle solids shall not be more than ±2 percent from the initially approved batch.

X2.2.2. The infrared spectra of the vehicle/resin shall match that of the initially approved batch.

Standard Specification for

Inertial Profiler

AASHTO Designation: M 328-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Inertial Profiler

AASHTO Designation: M 328-10

1. SCOPE

1.1 The objective of this specification is to define the required attributes of an inertial profiler which, when combined with an operator, becomes a complete inertial profiling system (IPS). The system may be used to measure a longitudinal pavement profile for construction quality control and acceptance or for network data collection. The equipment may be added to a host vehicle as a single-function device or a component of a multifunctional data collection device. The equipment shall be able to calculate summary roughness indices, particularly the International Roughness Index (IRI). This specification is designed to apply to both low-speed and high-speed profilers.

1.2 The equipment shall be capable of outputting the pavement elevation profile as a temporary display, a printed record, and a data file.

1.3 It is not the intent of this specification to relieve the supplier from the final responsibility to provide an appropriate product for the intended function, nor is it intended to specify all the design details. The objective is to provide a sufficiently detailed specification that the function is clearly defined. It is intended to be sufficiently detailed that the data collected from multiple profilers will be identical.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- R 56, Certification of Inertial Profiling Systems

2.2 *ASTM Standards*:

- E 867, Standard Terminology Relating to Vehicle-Pavement Systems
- E 1926, Standard Practice for Computing International Roughness Index of Roads from Longitudinal Profile Measurements
- E 2560, Standard Specification for Data Format for Pavement Profile

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *accelerometer*—transducer that provides an output proportional to acceleration.

3.1.2 *aliasing*—the term used to describe the error that can result when a signal is sampled at a rate less than twice the frequency of the various sinusoidal components that compose the signal. To avoid aliasing, the signal is band limited so that the sampling frequency used will be greater than twice as high as the highest frequency component in the signal. It is also described as the error that results from sampling a long wavelength signal that is mixed with a short wavelength noise signal.

3.1.3 *anti-aliasing filter*—a low-pass analog filter that suppresses short wavelength contamination of longer wavelength measurements to improve the accuracy of the sampling process.

3.1.4 *continuous IRI*—a series of IRI values calculated over a running interval, one for each profile data point throughout the test section. Each IRI value is provided at the midpoint of the running interval.

3.1.5 *filtering*—procedure to extract desired information from a signal that also contains unwanted information (commonly called noise). Digital filtering is a calculation procedure that takes one set of numbers and transforms them into another set in which the noise is reduced. Moving average is one type of such transformation or filter.

3.1.6 *index*—measure or standard. Within the context of this test method, a suitably chosen index quantifies the ride quality of a pavement.

3.1.7 *inertial profiler*-the combination of the profiling equipment and the host vehicle.

3.1.8 *low-pass filter*—smoothing type filter that reduces the effect of short wavelengths that are associated with rapid elevation changes such as expansion joint ribs.

3.1.9 *measurement range*—the detectable range of heights, accurately measurable by the sensor.

3.1.10 *moving average*—filtering process whereby each data point is replaced with the average value of several adjacent points or elevations. It is a smoothing process because the changes from one elevation point to the next will not be as significant due to the fact that that difference has been divided by the total number of data points in the averaging scheme. It is a type of low-pass filter.

3.1.11 *profile*—two-dimensional slice of the roadway surface, taken along an imaginary line, such as the wheel path, in the longitudinal or travel direction. It represents the perpendicular deviations of the pavement surface from an established reference parallel to the horizontal.

3.1.12 *repeatability*—consistency in successive measurements of the same quantity. It is a quantifier of the variability in measurement error.

3.1.13 *report interval*—the travel distance between the outputs of a profile *index* value.

3.1.14 *roughness*—according to ASTM E 867, the deviation of a surface from a true planar surface with characteristic dimensions that affect vehicle dynamics, ride quality, dynamic loads, and drainage.

3.1.15 *running interval*—set longitudinal distance that is stepped through a test segment by an increment shorter than its length.

3.1.16 *sample interval*—the longitudinal distance between data capture points. The data include location, height, and accelerometer values. These data points are combined to create one profile data point. These points, in turn, may be combined to create a final value in the reported profile.

3.1.17 *sampling rate*—the rate at which the height sensor measures vertical displacement. A typical sampling rate provides many height measurements from which a single value is derived for reporting at the sample interval.

3.1.18 *sensors*—devices that measure physical quantities. They are responsive to a change in a physical measurement such as distance, temperature, and acceleration.

3.1.19 *transducer*—device that converts variables of one type (i.e., distance,) into those of another type (i.e., voltage). These conversions must conform to a known transformation (i.e., proportional) to be useful.

4. GENERAL EQUIPMENT REQUIREMENTS

4.1 *General*—The equipment shall function independently from the vehicle suspension dynamics and vehicle speed throughout the operating range of 20 to 70 mph for high-speed profilers and less than 25 mph for low-speed profilers.

Note 1—Due to system dynamics, profiles collected at low speeds may require a governor to keep the speed constant.

4.1.1 The equipment shall be equipped with various sensors, interface hardware, computer hardware, and software that, working together, perform the measurement and recording of the longitudinal profile. The profile of the traveled trace(s) is the combination of a processed elevation and the distance traveled. The data shall be stored internally during the test and transferable onto suitable high-density removable storage media after the test. The computer shall have the capability to process the collected data, to display and print the derived profile(s), and to report industry standard indices, including IRI. The computer shall be capable of producing profile files in formats described by University of Michigan Transportation Research Institute as an .ERD and by ASTM E 2560.

4.1.2 The equipment shall mount on or in the host vehicle with minimum disturbance to the vehicle and in a fashion that the driver or a passenger can conveniently and safely operate it.

4.2 *Measuring Profile*—The longitudinal pavement profile shall be measured using equipment in which three primary transducers are used. These transducers include (1) a height sensor that measures the distance between a vehicle reference point and the pavement while the vehicle is traveling; (2) an accelerometer that measures the vertical acceleration of the vehicle as it moves vertically in response to the pavement profile; and (3) a distance sensor that provides a location reference for the vehicle as it travels. The run-time software and post-processing software shall be used to combine these three measurements so that the effects of the vertical vehicle movement are eliminated, leaving the pavement profile of the traveled pavement. Each height sensor shall have an individual accelerometer to determine its reference plane.

4.2.1 In addition to a manual triggering system, an automated triggering system shall be provided that detects a reference mark to start, stop, and event mark the data collection process. The triggering system shall be capable of repeatability within 6 in. over the range of operating speeds.

4.2.2 The equipment shall have an undistorted response (profile amplitude error of less than 5 percent and location error of less than 17 percent) for all wavelengths between 1.0 and 150 ft when operated between 20 and 70 mph for high-speed profilers and 15 and 25 mph for low-speed profilers. It shall also have a minimum of a 30 percent reduction in profile amplitude for wavelengths shorter than 0.5 ft and longer than 300 ft. [These are the typical set-points for filters currently provided on the equipment.] The filters will have a minimum of a 70 percent reduction for wavelengths shorter than 0.3 ft and longer than450 ft.

4.2.3 The equipment shall be capable of obtaining and storing profile measurement data at selected longitudinal distance intervals of the distance transducer. It shall be capable of determining a profile value (sampling interval) every 2.0 in. or less at the maximum collection speed of the vehicle.

4.3 *Calculating Roughness Indices*—The roughness of each profile trace shall be computed in post processing using the data collected and stored on either internal or external storage media. The IRI shall be calculated and reported as described in ASTM E 1926, in inches per mile or selected SI units as required. When multiple traces are measured simultaneously, each trace shall have independent results available as well as averages.

4.3.1 The roughness of each profile trace shall be produced using any user-selected report interval chosen for the calculation. A plot of roughness using any report interval shall also be printable.

4.3.2 The computer shall also be capable of calculating a continuous IRI with a relatively short running interval 25 to 528 ft and reporting the value and location of continuous IRI values above a user settable threshold.

4.4 *Calibration*—The equipment shall have built-in provisions to facilitate the calibration and verification of each transducer signal. Any external devices required for calibration shall be included with the equipment. In addition, it shall have an alarm system that alerts the operator if speed, height, or acceleration signals are out of range. These systems, in conjunction with a calibration protocol specified by the supplier, shall ensure the accuracy of the data.

5. EQUIPMENT

5.1 *General Requirements*—The profiler shall meet the following requirements:

1. The profiler shall be capable of measuring profile on pavement with an IRI range of 5 in. per mile to 300 in. per mile for a (0.1mile) interval.
2. The profiler shall measure longitudinal distance data in feet, meters, kilometers, and miles in an incrementing or decrementing mode from a selected starting point and relate the longitudinal distance to any test point. Optionally, the equipment may also report in station format (especially bump locations) for ease of contractor interface.

Note 2—The measurements taken on a specific lane can differ significantly from the project stations due to the horizontal and vertical curvature of the pavement.

5.2 *Functional Hardware Modules*—The following minimum specifications shall apply to the profiler:

(a) Roadway roughness testing shall be supported at vehicle speeds up to 70 mph for high-speed profilers and 25 mph for lightweight units.
(b) Operating ambient temperature range shall be 35 to 110°F; non-operating temperature range shall be 0 to 140°F.
(c) Operating humidity should not exceed 90 percent (noncondensing), nonoperating humidity range shall not exceed 100 percent (noncondensing).
(d) Power consumption of all installed equipment shall not exceed the capacity of the equipment providing operating power. Complete discharge of this system shall not impact the vehicle's regular electrical system.

Note 3—Local environmental conditions may require extending the suggested temperature limits.

5.2.1 *Processing Subsystem*—The Owner-Agency should specify the processing subsystem to be compatible with their existing computer systems as they may require. They should specify computer system parameters, including memory, operating system, interfaces, removable storage, etc. Equipment must be ruggedized for the mobile environment.

5.2.2 *Data Display*—Data display parameters shall be specified by the Owner-Agency. The size and type of display(s) as well as the format of the displayed data should be specified.

5.2.3 *Keyboard*—The keyboard shall be specified by Owner-Agency. Specify the type of keyboard required and any auxiliary devices such as event pads.

5.2.4 *Printer*—The printer shall be specified by Owner-Agency. Specify type of printer required. The profiler shall not require the printer in order to function and shall be able to collect data without the printer being present.

5.2.5 *Event Marker*—The profiler should have a method for marking or recording various points of interest or events in the measurement process, such as bridges, intersections, etc. The method should be user configurable to minimize its size and maximize its effectiveness.

5.2.6 *Data Acquisition System (DAS)*—All real-time data collection shall be provided by the hardware and software components of the DAS interfaced to the processing subsystem. The DAS may be contained within the physical space of the processing subsystem in whole or in part as required by the design. The DAS shall provide all interfaces to collect data; to derive distance, speed, and location; and to develop profile data from the transducers mounted on the vehicle. It shall activate the tests, process the trigger signals, and process operator inputs from the keyboard and shall pass information on the feature and its location to the processing unit for display and logging.

5.2.6.1 *Distance Transducer*—A vehicle-mounted distance transducer shall be provided to produce a pulse for units of distance traveled by the vehicle on the roadway. (Optionally, an electronic interface shall be provided for vehicles with electronic odometer or antilock brake system pulse signals.) The DAS shall accept these pulses and, in combination with the DAS software, shall determine distance traveled and vehicle speed. The computer shall process the signals and record the data from the unit. The calibration procedure shall establish and record the data to allow the recorded distance pulses to be interpreted into the desired measurement units selected by the operator. The measured distance shall be accurate to 0.15 percent per mile for test vehicle speeds up to the maximum specified for the equipment utilized.

5.2.6.2 *Height Sensor*—The reference height of the vehicle above the pavement shall be obtained through a noncontact height sensor module.

Provisions shall be made to allow an accelerometer to be mounted to the height sensor case. The sensor module shall communicate with and receive power from the DAS.

The height sensor shall have a resolution of at least 0.001 in. and a sufficient linear measurement range to cover the vehicle suspension motion and variation in pavement elevation. The height sensor shall operate at a sufficient sampling rate (typically 15 samples per inch or finer) to provide accurate coverage at the maximum operating speed for equipment utilized. This sample frequency allows for the implementation of an anti-aliasing filter and has sufficient short wavelength data for dropping outliers and the implementation of a tire bridging algorithm. Moisture (except freestanding), temperature, coarse pavements, or color changes in the pavement shall not affect the functionality of the sensor. The samples shall be stored referenced to time or distance, or both, so that the height data may be aligned with the accelerometer and position data to provide a longitudinal profile.

Note 4—Coarse surface textures, such as those found on open-graded surface mixes, chip-sealed, tined (transverse or longitudinal), or grooved pavement, for example, are very challenging to inertial profilers with dot, single point height sensors. Coarse texture is likely to adversely affect the repeatability and accuracy of the profile and the calculated index. Adherence to the requirements of this standard on smooth-textured surfaces does not guarantee acceptable performance of inertial profilers on coarse-textured surfaces. Certification testing on surfaces with the same texture type expected in the final application is required.

5.2.6.3 *Vertical Acceleration Sensor*—The vertical displacement of the height sensor that is used to calculate elevation shall be sensed using an accelerometer. The DAS shall provide hardware and software to amplify and filter/integrate the accelerometer signal as required to obtain the vertical displacement values for storage and for further post-processing into the required profile values. A minimum of one accelerometer shall be mounted in vertical alignment with each height sensor. It shall be rigidly mounted to the height sensor with its sensitive axis perpendicular to the pavement surface. The frequency response, signal-to-noise ratio, and precision of the accelerometer must be commensurate with those required of the final profile given the operating speed range of the test vehicle.

5.3 *Functional Software Modules*—The equipment computer shall contain the necessary software modules to perform all tasks required. These functions include:

- Auto execution,
- Program initialization,
- Operation selection,
- Data collection and management,
- Data save,
- Direct data entry,
- Data retrieve,
- Data manipulation,
- Data output,
- Data transfer,
- Data display, and
- Equipment calibration.

5.3.1 *Auto Execution*—The equipment computer shall provide an automatic execution function that shall configure equipment components, load the main control program of the computer, and start up all required operations.

5.3.2 *Program Initialization*—The software shall provide a central program initialization function that shall be loaded by the operating software following all other drivers and reserved memory. The initialization program shall perform start-up initialization, activate the DAS, initialize program control parameters and system self-check, and activate a start up that requires no operator input.

5.3.3 *Operation Selection*—The operation selection function shall display a main menu of computer operation functions that can be performed when selected by the operator. The main menu selection instructions shall be displayed to the operator along with the main menu choices. The selection shall be provided via the computer keyboard or other input device.

5.3.4 *Equipment Operation Functions*—The equipment computer shall provide a set of operation functions selected by the operator main menu. The equipment operation functions shall provide everything necessary for the operator to perform data collection in a user-friendly manner. It shall not be necessary for the operator to use operating commands directly to perform any of the required functions with the exception of formatting and copying diskettes. The equipment operations shall:

1. Perform data collection;
2. Create data files and save data to them;
3. Provide for input and storage of IDs (driver, operator, and vehicle; see Section 5.3.4.1) that are changed infrequently, and other parameters that are changed for each test;
4. Perform data collection control setup;
5. Support operator-activated calibration and equipment checkout; and
6. Provide a data manipulation mode to transform the data using operator-selected filters and mathematical transformations to create the required output profiles and indices.

5.3.4.1 *IDs and Parameters*—The user shall be able to change and save calibration data; IDs for the vehicle, driver, and operator; date and time used; test location data, etc., and information about the computer files on storage media.

The equipment shall contain provisions to accept up to 16 variables, similar to those listed below, from the operator prior to testing a roadway section. The software shall ensure that the operator enters all required variables. Required numeric variables shall default to ASCII zeros. Alpha variables shall default to blanks. The variable data shall be saved in the files along with the test data for further post-processing.

Variable	Length	Type	Example
Project	25	A/N	Name 1
Route	15	A/N	IH 20
County	10	A/N	67
Direction	2	A	NB
Begin Ref.	7	N	45.678
Lane	5	A/N	R1
User Ref.	15	A/N	New Pmt.
Operator ID	10	A/N	RO5467
Driver ID	10	A/N	A124
Vehicle ID	10	A/N	9812
Equip. ID	10	A/N	MS6716
Software 1	10	A/N	P2356.9.1
Software 2	10	A/N	C4579.2.3
Average Speed	3	N	45.7
Maximum Speed	3	N	49.1
Minimum Speed	3	N	42.8

Abbreviations: A = alphabetic, N = numeric

Note 5—The variables defined in the table above are given only as examples. Specific variables and their definitions may differ among Owner-Agencies. For example, the lengths of the variables and their types may differ.

5.3.4.2 *Calibration*—The operational computer software shall allow the operator to perform a distance sensor calibration and use the calculated factor to perform the operational distance measurements. The calibration software shall also allow the operator to save the factor calculated or change the calibration factor to other than the calculated value. The operator shall only need to enter the distance traveled in feet, meters, kilometers, or miles and not make any calculations to determine the calibration factor.

The calibration software shall also allow the operator to perform a profile equipment calibration. This includes the verification of the height sensor using at least four gauge blocks provided by the supplier. The auto-calibrating function of the accelerometer shall be supported as required. The values determined in calibration shall be stored and recorded as above for use in data processing.

5.3.4.3 *Roadway Testing*—The operational computer software shall provide all necessary functions for the operator to select and perform roadway testing for a specific location. The beginning and ending points as well as any sectioning shall be automatically detected and stored along with the primary data. The testing software shall perform testing as required by the operator. The software shall also detect abnormal conditions in the test cycle and report the condition to the operator. The testing software shall save the displacement values from the height and DMI sensors, and the acceleration values as well as the derived elevation profile values generated by the DAS in internal memory during testing and output them to the monitor and printer for review. These results may also be transferred to removable media if selected by the operator.

The test software shall activate the testing using the timing and control parameters stored by the test control setup software. The software shall monitor the signals to verify that the testing is being performed properly and indicate detectable errors.

The test software shall receive, display, and store raw data received from the vehicle-mounted transducers. The test software shall receive, display, and store with each test the corresponding distance and test speed. The current distance measurement shall be displayed constantly on the monitor when in test mode.

The test software shall output collected data as well as an operator-selected profile index to the monitor in real-time.

The test software shall receive, display, and store pertinent feature data (entered by keyboard, etc.) relating to the test site observed during testing of a roadway; e.g., posted speed limit changes, surface changes, bridges, etc. It shall accept this operator input data in real-time as the vehicle moves down the highway. The corresponding reference point shall be stored at the time of the feature data entry.

The equipment shall be capable of calculating, displaying, and storing the average roughness value obtained from the stored data at user-specified intervals. The computer shall be capable of collecting and storing internally at least 25 miles of profile data. Additionally, the computer shall be capable of putting the accumulated roughness test results through mathematical functions and printing results when enabled by the operator. For example, the ability to compare multiple runs for the coefficient of variation and to tag outliers, or the ability to compare a verification run to runs made previously should be included to enhance the user friendliness of the equipment. These processes shall not necessarily be done in real time but in post-processing. The equipment shall be capable of performing all required post-processing operations.

5.3.5 *Equipment Shutdown*—The operational software shall provide equipment shutdown that shall be operator activated via the keyboard. Prior to shutting down, the computer shall save all active parameters to the internal storage media for retrieval the next time the equipment is started up. Preferably, the computer shall also store a backup file of the previous shutdown that can be retrieved in an emergency. These files shall be updated at each shutdown.

6. MOUNTING AND INSTALLATION OF EQUIPMENT

6.1 The supplier shall provide all parts and labor necessary for the installation of the equipment. Installation of the new equipment shall include a mounting arrangement that can be easily used by the driver or passenger operator as designated.

6.2 Careful consideration shall be given to the mounting and location of equipment. Mounting of equipment shall be made in a manner to withstand normal vibrations that occur while traveling at the normal operating speeds for the equipment utilized. The location of equipment shall be accessible to the operator and not impede safety.

6.3 Electronic components shall be restrained where possible with tie downs or other applicable methods.

7. PROFILER ACCURACY

7.1 *Profile Precision*—The precision shall be measured in accordance with the repeatability determined in R 56.

7.2 *Profile Bias*—The bias shall be measured in accordance with the accuracy determined in R 56.

8. MANUALS

8.1 Upon delivery of the profiler, the following shall be required:

1. Two copies of the operating procedures for all operational software.
2. Two copies of the schematics block diagrams, and wiring diagrams covering the electronic circuitry of the installed equipment.
3. Two complete parts lists detailing the components of all equipment used.

9. WARRANTIES

9.1 The equipment supplier shall warrant all components of the equipment for a period of not less than 1 year from date of acceptance to be free from defects in material and workmanship.

Standard Practice for

Evaluating Faulting of Concrete Pavements

AASHTO Designation: R 36-04 (2009)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Evaluating Faulting of Concrete Pavements

AASHTO Designation: R 36-04 (2009)[1]

1. SCOPE

1.1 This protocol describes a method for evaluating faulting in jointed concrete pavement surfaces.

Note 1—Faulting is defined as the difference in elevation across a transverse joint or transverse crack as shown in Figure 1.

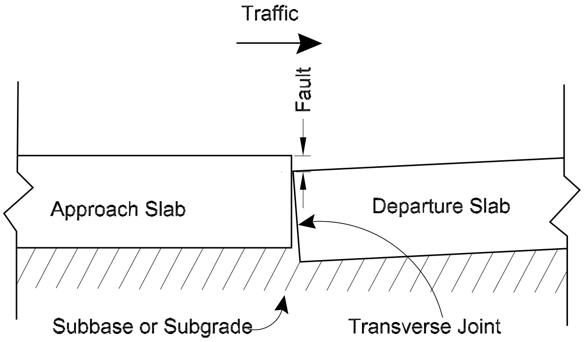

Figure 1—View of Longitudinal Section of Faulting at a Transverse Joint or Crack

1.2 Although the faulting is measured, detailed specifications are not included for equipment or instruments used to make the measurements. Any equipment that can measure with the accuracy stipulated herein and that can be adequately calibrated is considered acceptable.

1.3 *This standard practice may involve hazardous materials, operation, and equipment. The procedure does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this protocol to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. SIGNIFICANCE AND USE

2.1 This standard practice standardizes the procedures for estimating and summarizing faulting on concrete pavement surfaces. It provides consistent estimates of faulting for network-level pavement management. The procedure is intended to measure faulting with a vehicle traveling in the designated lane at highway speeds; however, the provisions for manual measurements are included.

3. FAULT MEASUREMENT

3.1 It is each agency's responsibility to designate the lane(s) and direction(s) of travel to be surveyed on the basis of sound engineering principles and pavement management needs within the agency.

3.2 Calculate faulting to the nearest 1 mm (0.04 in.) by the following formula:

$$F = \left|P_1 - P_2\right| \tag{1}$$

where:

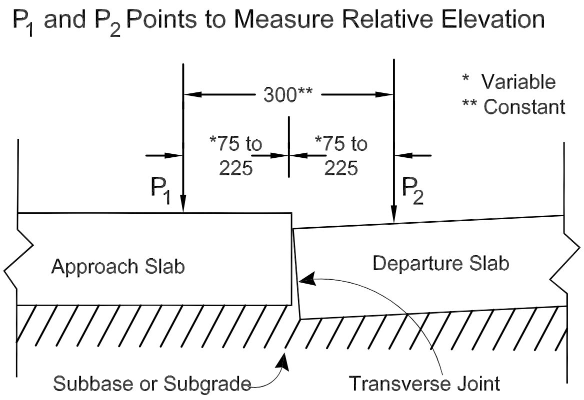
F = faulting that is the absolute value for the measured difference, mm; and

P_1, P_2 = heights measured on either side of a transverse joint or transverse crack in the outside wheelpath, mm.

4. RECORDING OF DATA

4.1 Maintain the length of the data summary interval of 0.1 km (0.1 mile). As a minimum, measure faulting across all transverse joints or transverse cracks in the outside wheelpath of the survey lane.

4.2 For automated surveys, take measurements at points 75 to 225 mm (3 to 8.8 in.) from the joint or crack and separated by 300 mm (11.8 in.) as shown in Figure 2.



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Points to Measure for Faulting by Automated Measurements

4.3 For manual measurements, include the sampling rate level of at least 10 percent of all transverse joints or transverse cracks. The 10 percent sampling rate should be uniformly spaced (preferably every tenth joint or crack or more frequently) throughout the project to assess the condition. The location should be documented along with the measurement.

4.4 For automated methods, record faulting at all joints in a format amenable to automated plotting to assist in further evaluation of the data.

4.5 When using manual methods, record all faulting measured.

Note 2—Care must be taken to not measure spalling and classify it as faulting.

5. REPORT

5.1 At a minimum, record the following data:

5.1.1 *Section Identification*—List the following information, if available:

5.1.2 Length of the data collection section (m);

5.1.3 Maximum value of faulting for all joints per 0.1 km (0.1 mile);

5.1.4 Average and standard deviation for all joints per 0.1 km (0.1 mile);

5.1.5 *Optional*—Pavement surface temperature;

5.1.6 Date of collection (month/day/year);

5.1.7 Total number of transverse joints and transverse cracks with measurable faulting; and

5.1.8 Equipment axle loads and orientation of sensors to axles of influence.

Note 3—There may be variations in faulting as a result of the axle loads and orientation of sensors to axles of influence.

6. KEYWORDS

6.1 Concrete pavement; fault measurement; faulting; jointed concrete pavement; joints.

APPENDIX

(Nonmandatory Information)

X1. GUIDELINES—QUALITY ASSURANCE PLAN

X1.1. *Quality Assurance Plan*—Each agency shall develop a quality assurance plan. The plan shall include survey personnel certification training records, accuracy of equipment, daily quality control procedures, and periodic and ongoing quality control. The following guidelines can be used for developing such a plan.

X1.2. *Certification and Training*—Agencies are individually responsible for training and/or certifying their data collection personnel and contractors for proficiency in using the profile measuring equipment according to this standard practice and other applicable agency procedures.

X1.3. *Equipment Calibration*—Equipment calibration (accelerometers and noncontact sensors) is done in accordance with specific manufacturer recommendations. The equipment must operate within the manufacturer's specifications. A regular maintenance and testing program is established for the equipment in accordance with the manufacturer's recommendations.

X1.4. *Verification Sections*—Verification sections are selected with known faulting. Faulting on these sections is measured by equipment operators on a regular basis. Evaluations of these measurements provide information about the accuracy of field measurements and give insight into needed equipment calibration. Verification sections are rotated on a regular basis in order to assure that the operators are not repeating previously known faulting values during the verification. As an alternate to verification sections, remeasure and compare up to five percent of the data as a daily or weekly quality check.

X1.5. *Quality Checks*—Additional quality checks can be made by comparing previous year's faulting statistics with current measurements. At locations where large changes occur, the pavement manager can require additional checks of the data.

Standard Practice for

Application of Ground Penetrating Radar (GPR) to Highways

AASHTO Designation: R 37-04 (2009)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Application of Ground Penetrating Radar (GPR) to Highways

AASHTO Designation: R 37-04 (2009)[1]

1. SCOPE

1.1 This standard practice provides guidance to the highway engineer in the application of noncontact ground penetrating radar (GPR) to transportation facilities. It is intended to instruct the engineer regarding the specific uses of noncontact radar for pavement layer thickness surveys, quality control of new pavement construction, evaluation of granular base material, identification of zones of asphalt stripping, and assessment of bridge decks. GPR has numerous applications for the transportation industry, but at this time requires extensive training in its use and interpretation of the data output, as well as experience in local pavement conditions.

3. SUMMARY OF METHOD

3.1 *Principles of GPR*—GPR utilizes radio waves as an energy source. They are transmitted into the pavement and reflected at layer interfaces. Radio waves have free space wavelengths on the electromagnetic spectrum ranging from 0.001 m to 10 m. GPR operates in the range of 0.1 m to 10 m, which is the low end of the radio wavelength spectrum. As with all electromagnetic waves, radio waves travel through a vacuum at the speed of light. When the radar waves pass through a medium other than a vacuum, the velocity of propagation becomes a function of the dielectric constant of the medium. A dielectric is defined as an insulator between two electrical conductors; the dielectric constant for any material measures its effectiveness when used as the dielectric of a capacitor. For example, air has a dielectric constant of one. If air in a capacitor is replaced by mica, the resulting capacitance is six times greater, so mica has a dielectric constant of six. Some representative dielectric constant values for earth materials are given in Table 1.

Table 1—Dielectric Constants for Construction Materials (Reference 8.5)

Material	Relative Dielectric Constant ($\in_r$)
Air	1
Water (fresh)	81
Water (salt)	80
Sand (dry)	3–5
Sand (wet)	20–30
Silts	5–30
Clays	5–40
Granite	4–6
Limestone	4–8
Portland Cement Concrete (cured)	6–11
Bituminous concrete	3–6

3.2 The velocity of a radar wave through a given medium varies in inverse proportion to the square root of the material's relative dielectric constant $\in_r$. For example, if a material with a dielectric constant value of 4 has a radar wave passing through it, the wave does travel half as fast as it does through air ($\in_r = 1$) and twice as fast as it would through a material having an $\in_r$ value of 16. In general, radio waves propagate through dielectric materials, but are reflected from conductive materials. When there is a boundary between two materials having different dielectric properties, some of the radar energy will be reflected, and a portion will pass through the boundary. The time required for a radar pulse to travel from the source to an interface and back is the two-way travel time, and is dependent on the depth of the interface and the dielectric constant of the material overlying the interface. Converting two-way travel time to information about the depth to the interface can be done by means of the following formula:

$$d = v \times t/2 \qquad (1)$$

where:

d = depth,

v = velocity, and

t = two-way time.

3.3 The velocity of the radar wave is primarily dependent on the dielectric constant of the medium, and can be calculated with the following equation:

$$v = c/\sqrt{\in_r} \qquad (2)$$

where:

c = speed of light.

As can be seen from the data in Table 1, the moisture content has a large influence on the dielectric constant, and therefore affects the two-way travel time, so that the greater the amount of water saturation, the lower the radar wave velocity.

3.4 There is another electrical property upon which GPR depends, and that is conductivity. Attenuation of the radar waves (which causes the waves to decrease in amplitude and energy) is caused by higher conductivity of a medium and results in less depth of penetration. Attenuation is related to the frequency spectrum emitted by the radar—the higher the frequency, the greater the attenuation of the signal. For most pavement materials in dry condition, attenuation of the wave is not a serious problem. However, with some materials, particularly new concrete (within at least 180 days of placement), signal attenuation can have a significant impact on the amount of energy reflected from the pavement structure.

3.5 In discussing frequency of GPR antennae, it is to be noted that the signal output is not a single frequency, but rather is a frequency spectrum (bandwidth). An antenna that has a 1-GHz output actually produces a bandwidth frequency distribution having a mean value of 1GHz. This signal is produced in short pulses, with a comparatively long period of time between pulses, so that the reflected signals may be recorded. The electromagnetic signal pulse is on the order of 1 nanosecond in duration, while the time between pulses may be tens of thousands of nanoseconds. Higher-frequency signal pulses have shorter pulse periods; a 1-GHz signal will have a 1 nanosecond pulse, while a 2-GHz signal will have a pulse of 0.5 nanoseconds in duration.

4. SIGNIFICANCE AND USE

4.1 GPR is a geophysical technique that uses radio waves to acquire subsurface information. The system operates by transmitting energy waves into the earth and recording the waves that are reflected off interfaces between layers of material with different electrical properties. GPR has been used for several decades as a tool for geologic investigations, particularly for environmental and groundwater applications. In more recent times, a type of radar system developed specifically for transportation applications has evolved using high-frequency, noncontact antennas that can travel over highways and bridges at the speed of traffic while acquiring data. The information from these GPR systems can be used to find voids under pavement, study pavement layer thicknesses, evaluate moisture or density variations, and assess the condition of bridge decks.

4.2 GPR can be used as a nondestructive testing tool in assessing transportation facilities, particularly in the areas of pavement management and bridge deck evaluation. It is an evolving science that has not yet reached the stage of being common practice in state transportation departments, but it shows promise as an emerging technology to replace or augment more traditional and labor-intensive testing methods such as core drilling. The development of GPR is evolving rapidly, which is common to computer-dependent systems, so that it may become a more commonly used application in transportation engineering projects in the future, depending on the level of commitment to more sophisticated technology on the federal and state levels.

4.3 Agencies planning to use a great deal of GPR data; e.g., using GPR as part of a network-level pavement management system, are likely to find it most cost-effective to purchase one or more GPR systems and invest in the personnel training necessary for its usage. The cost of training is largely a function of the data processing software used to evaluate data. As the software packages become more user-friendly, there will be progressively less training required for the user.

4.4 Transportation agencies that plan to use a limited amount of GPR data, such as occasional distressed pavement examinations on discrete stretches of highway, may find it advantageous to hire consultant contractors to conduct the surveys and perform the analysis, rather than investing in the equipment and training necessary to do it themselves.

5. EQUIPMENT

5.1 *Types of GPR Systems*—There are two basic types of GPR systems, the difference being in the type of antenna used to produce the radar waves. Ground-coupled antennas are used primarily in geologic and environmental applications. They generate radar waves with frequencies of 50 to 500 MHz, although some systems can produce radar wave frequencies of greater than 1 GHz. As the name implies, ground-coupled radar antennas must keep in contact with the ground during a GPR survey so that they are dragged by hand or towed slowly (at speeds less than 10 kph). The antenna in a ground-coupled system is generally a bowtie (dipole) antenna that generates a signal that covers a wide area and has scattered reflections. The system is capable of providing subsurface information to a depth of up to 15 m or 16 m, depending on the geologic conditions encountered and selection of antenna frequency, but often will yield little information in the uppermost meter of the surface layer because of a phenomenon known as “ringing” caused by a bistatic coupling mismatch. This problem can be minimized by selecting a high-frequency GPR system if the desired target is known to be near the surface. Ground-coupled GPR systems are used for mapping bedrock and soil strata, detecting buried drums and pipelines, and tracing contaminant plumes.

5.1.1 The type of GPR system most used for transportation facilities, and which is the main focus of this standard practice, utilizes the noncontact horn antenna, which is suspended over the surface of the ground and which can perform surveys at speeds of up to 80 km/h. Usually, the antenna in this system is designed with a narrowly focused beam of electromagnetic energy, rather than the larger beam width used in ground-coupled GPR, resulting in less back scatter from the surrounding area. The operating center frequency range is typically around 1 GHz, but some systems are now available that have frequencies as low as 0.5 GHz and as high as 2.5 GHz. These high-frequency broadband radar signals yield excellent resolution, permitting identification of very thin layers. The noncontact systems have the advantage of providing near-surface information, unlike most ground-coupled GPR systems. The drawback of high-frequency signal generation is that, under typical conditions, the depth of penetration is limited to about 0.6 m. Therefore, noncontact GPR can yield information about pavement and subbase strata but will yield very little information below that.

5.2 *GPR Equipment*—A GPR system consists of the following components: a signal generator; an antenna that transmits and receives the radar pulse signal; a sampler/recorder that collects the returned signal and stores it; a signal processing system to convert the pulse data into a waveform; a monitor for viewing the data; and a recording system for storing data. The antenna is on a boom directly attached to the front or the back of the vehicle. All the other equipment is contained within the survey vehicle. A distance calibration system is tied into the GPR survey so that anomalies can be located precisely. It is useful to operate a synchronized video imaging system during the GPR survey so that a visual record of the pavement surface is available during the data processing. Two operators are recommended during the survey, one to devote full attention to the safe operation of the vehicle, and one to operate the equipment.

5.2.1 The minimum GPR configuration is a single antenna radar system. For pavement surveys, a single antenna pass per lane is adequate for thickness evaluation. For condition surveys (void mapping and bridge deck evaluation), multiple antenna passes per lane are preferable to achieve the required level of detail. This can be achieved by making multiple passes with a single antenna vehicle or by using a radar vehicle equipped with multiple antenna systems (Figure 1). Obviously, in a high-traffic area with limited highway access, the multiple antenna vehicle is more efficient to use for this type of survey as it requires less traffic protection and fewer cycles of entering and exiting the highway.

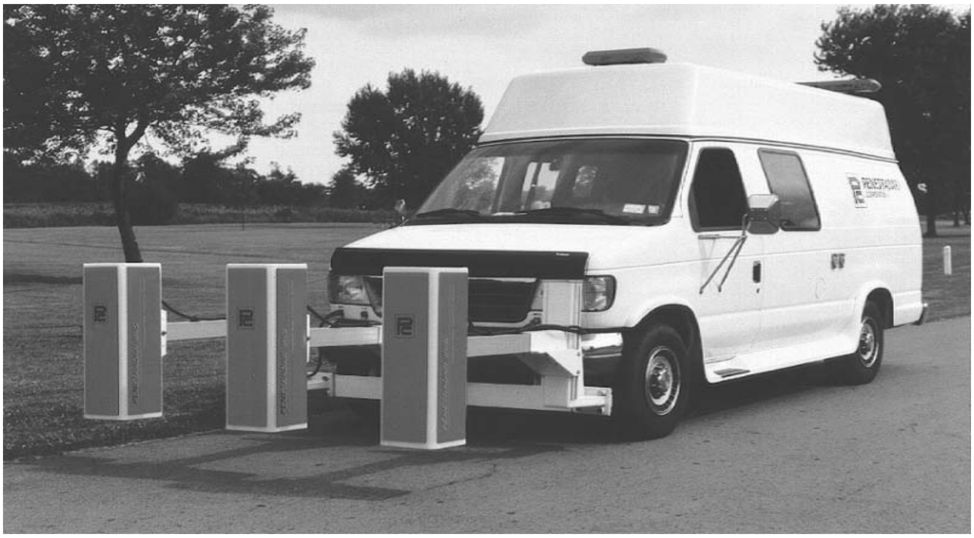

Figure 1—Multiple Antennae on a GPR Survey Vehicle

5.3 *Data Output*—When the GPR electromagnetic energy is directed into the ground, some of it is reflected from interfaces between materials of differing dielectric values and returns to the GPR receiver; the reflected pulses are the only part of the transmitted signal that is seen on the GPR monitor. The energy of the reflected radar pulse is converted to a waveform that is displayed on a monitor as a graph of amplitude (in volts) against time. Reflections are “in phase” with the emitted signal if the pulse travels from a layer with a low to a higher dielectric and “out of phase” if the signal goes from high to low dielectric (Figure 2). The waveforms can then be displayed in a variety of formats; one method is to use the stacked waveform approach (Figure 3). The most common way of viewing GPR data is by the use of a color transform system. The line scans shown in Figure 2 are color-coded based on signal amplitude, the individual waveforms are then stacked side by side to form a color-coded image of subsurface condition as shown in Figure 4.

b) Out of phase reflections (layer 2 has a lower dielectric than layer 1)

Figure 2—Typical GPR Reflections

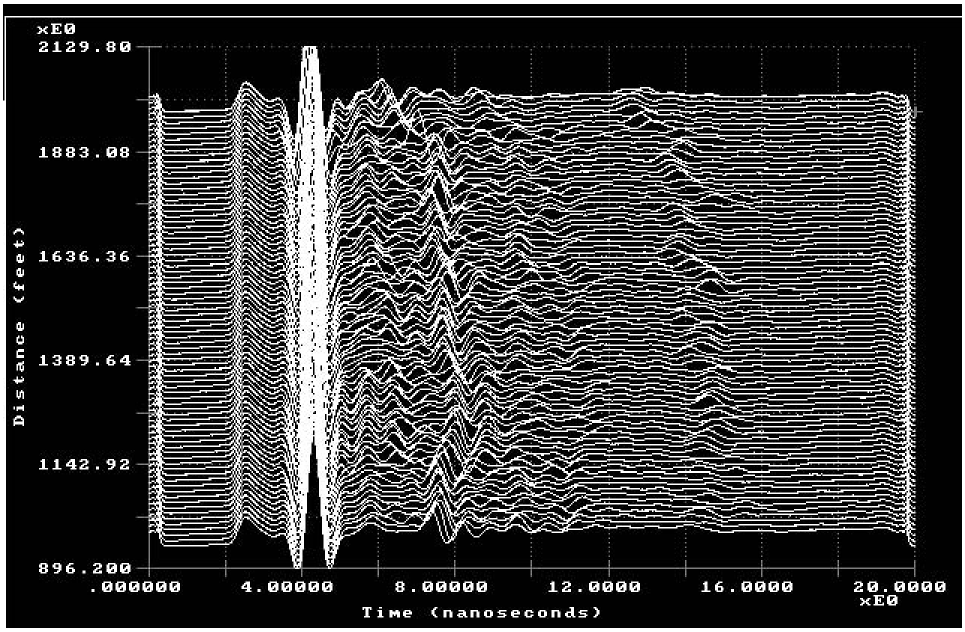

Figure 3—Stacked GPR Waveforms from a Section of Highway

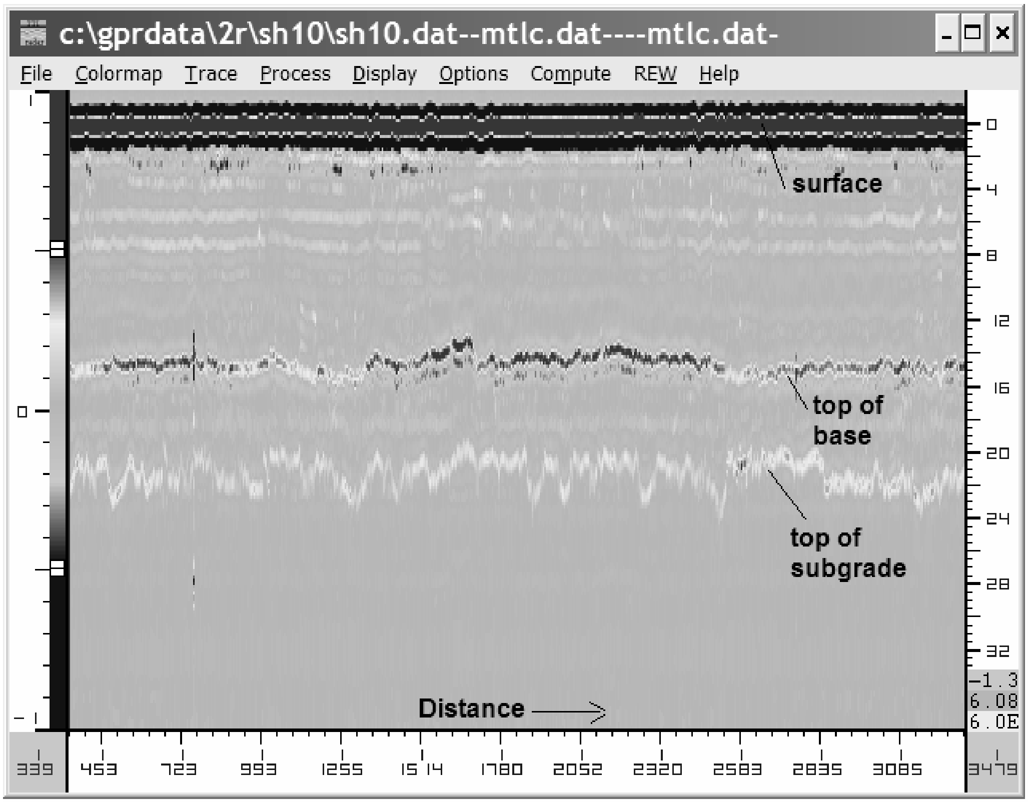

Figure 4—Color Transform Output. The depth scale is on the right of the figure and the distance along the highway is shown in the lower scale.

5.3.1 The amplitude of the displayed waveform is a function of the difference in dielectric constant between two material layers; the greater the contrast, the larger the waveform amplitude of the returned signal. Two layers may have different material characteristics, but unless they have differing dielectric constants as well, they will not yield a noticeable GPR reflection. The reflected amplitude is also a function of the conductivity of the material through which the radar pulse travels. Lossy dielectrics (i.e., material having higher conductivity) tend to attenuate the signal, reducing its amplitude and yielding a less distinct contrast between layers.

5.4 *Data Processing*—Current GPR units may produce waveforms at the rate of 50 per second, or 180 000 scans per hour (Section 8.1). It is recommended that computers are used to store the data output onto hard drives or CD-ROMs.

5.4.1 While great strides have been made in developing computer software for signal processing and storage, it should be noted that, for the most part, interpretation of the GPR profile is still done manually by experienced operators. Some forms of data interpretation software have been developed and are on the market, but at this stage they are proprietary and are used exclusively by GPR consultants, contractors, and a limited number of state agencies. Government agencies interested in the purchase of a GPR system must recognize that the operation of this equipment requires a substantial investment in training the operators. As an alternative, the agency can hire an expert vendor to perform the GPR surveys.

5.4.2 Pavement materials are complex, and the interpretation of overlapping signals from multiple thin layers can complicate the analysis. With anomaly detection projects (such as voids or stripping detection), ground truth in the form of cores is required to verify the interpretation. Limited coring and augering is recommended on all GPR projects to aid in calibrating and validating results.

6. GENERAL REQUIREMENTS

6.1 *Performance Specifications*—When purchasing GPR equipment for highway applications, the buyer is advised to consider the initial performance, long-term durability in daily highway use, and future product support from the manufacturer. The initial performance assessment of a system must include evaluation of the signal-to-noise ratio ("clutter") and signal stability ("jitter"), so that the user has a clean radar signal with which to work.

6.1.1 Specifications for equipment performance are available in Section 2 of the Texas Transportation Institute Research Report 1233-1, "Implementation of the Texas Ground Penetrating Radar System" (1992). These performance standards were developed for the Texas Department of Transportation and have since been used by transportation departments in Florida and North Carolina.

6.2 *Hiring Consultant Contractors*—State agencies that are interested in using GPR for a limited amount of work, and that do not wish to purchase their own GPR systems, are advised to hire consultant contractors to perform this work. The hiring agency needs to ensure that the consultant has the appropriate hardware and software for the job and has had experience working with a variety of transportation applications. The consultant must be able to provide references and a list of experience in the GPR application for which he or she is hired. The consultant's final output must be validated with cores as a quality control check.

6.3 *Environmental Effects*—GPR surveys are not recommended when there is standing water, snow, or ice on the surface of the pavement because the high dielectric value of water will cause attenuation of the electromagnetic signal and erroneous peak voltage amplitudes in the returned signal. The presence of deicing salts on the road surface has a similar detrimental effect.

7. APPLICATIONS TO TRANSPORTATION FACILITIES

7.1 GPR is a tool that can be used for a variety of highway applications, including pavement thickness surveys, quality control of new pavement construction, detection of voids under pavement, evaluation of granular base material, mapping zones of asphalt stripping, and bridge deck assessment.

7.2 *Pavement Thickness Surveys*—This is one of the most useful applications of GPR to transportation systems; for pavement management systems at the network or project level; the method has been described in ASTM D 4748. The GPR data can be used as a first step in pavement layer thickness surveys, to be followed by falling weight deflectometer surveys, with pavement coring as the final step. GPR can be used to obtain the thickness of the top pavement layer and identify significant changes in the structure (such as changes in base type). On a cautionary note, it is useful to recognize that it is difficult to identify base thickness of older pavements using GPR because the base and subgrade materials tend to intermingle over time so that there is no dielectric contrast between the layers, and there will be no clear radar reflection from their interface. In general, GPR works much better on flexible pavements than rigid ones because there is a more distinctive reflection between the asphalt and underlying strata than there is with concrete pavement, and concrete tends to attenuate the radar signal more than asphalt. If concrete pavement overlies cement stabilized base layers, there will be virtually no reflections produced because the two materials share a similar dielectric value. *Additionally, GPR should not be attempted on concrete pavements* fewer *than 180 days old due to their potentially high moisture content.*

7.2.1 The great advantages of using GPR for pavement thickness surveys are that it provides continuous coverage, is nondestructive, and can be performed without closing lanes to traffic.

7.3 *Quality Control of New Pavement Construction*—GPR works well on asphalt paving projects as a postconstruction tool for quality control. The interfaces between the pavement base and the top of subgrade normally yield clear radar reflections. GPR can be used to check for proper pavement thickness and can also locate construction defects and asphalt segregation. A homogeneous and defect free layer will generate a reflection from the top and bottom of the layer. If a defect is present within the layer, it will appear as an extra reflection between the reflections from the top and bottom of the layer.

7.3.1 *Segregation Detection with GPR*—The amplitude of the surface reflection from a new asphalt surface is related to the density of that layer. Significant decreases in amplitude would identify areas that are lower in density. Asphalt “end load” segregation and poorly compacted longitudinal construction joints will cause localized decreases in the amplitude of surface reflection and the computed surface dielectric. Examples of GPR from a normal and segregated asphalt surface are shown in Figure 5.

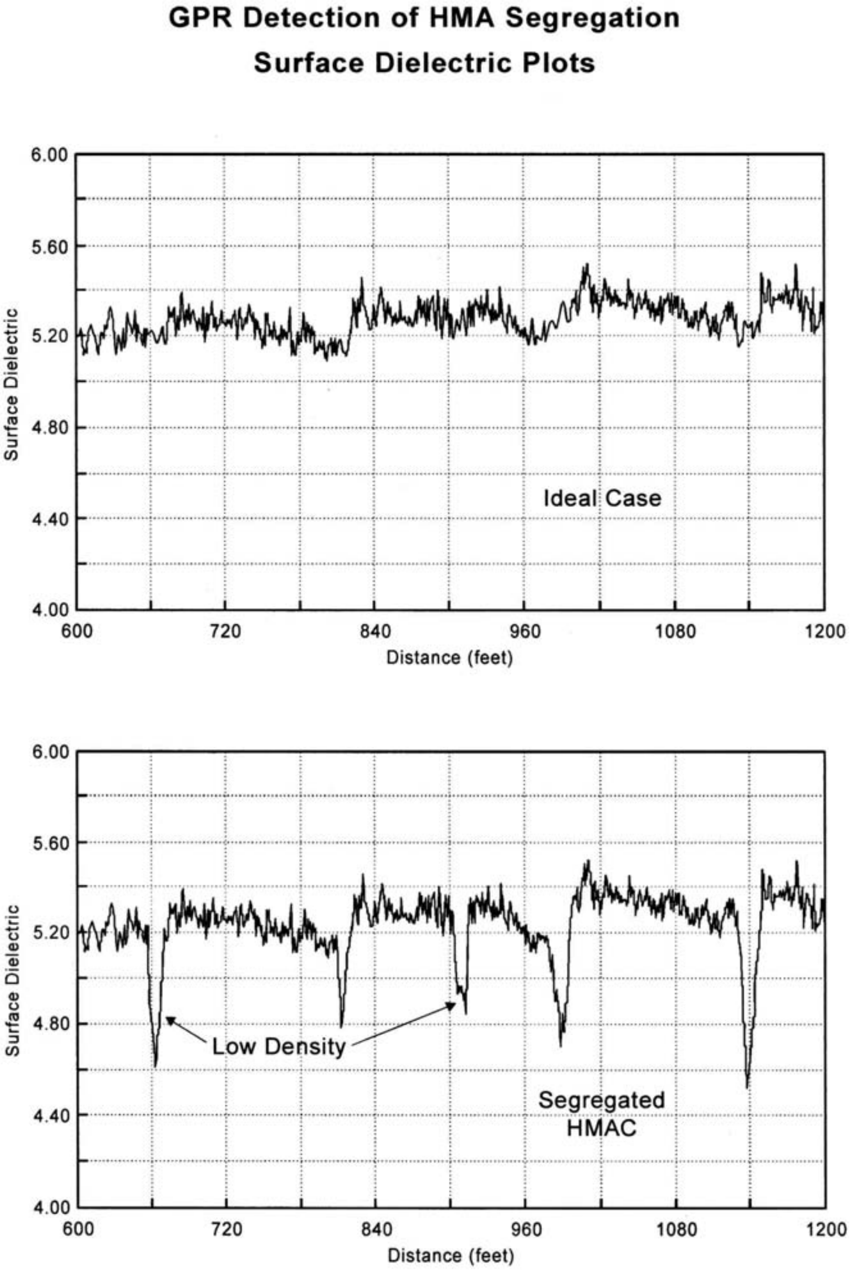

Figure 5—Surface Dielectric Profiles from a Well-Compacted Asphalt Surface and a New Asphalt Surface with "End-Load" Segregation

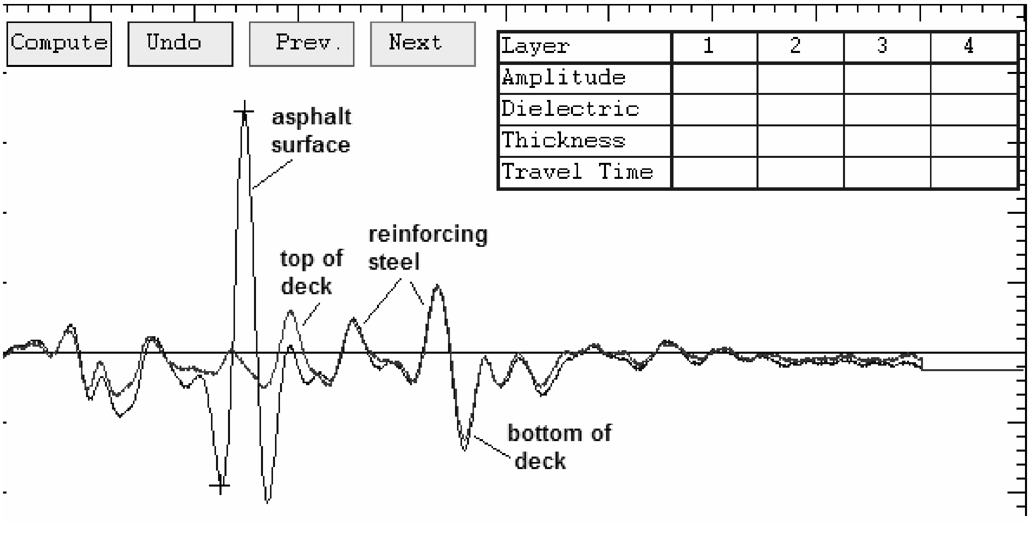
7.4 GPR does not work well on newly constructed concrete pavements because radar waves are strongly attenuated by fresh concrete due to its potentially high moisture content. Thus, it is recommended that GPR not be used within 180 days of placement.

7.5 *Detection of Voids Under Pavement*—Voids can develop beneath concrete pavements, particularly under joints. GPR is effective in determining the location of moisture filled voids. However, it is not effective at finding the volume of moisture filled voids, and it is difficult to distinguish between water filled voids and areas of saturated base. GPR can also be used to locate air filled voids under concrete, but the air filled voids need to be at least 15 mm thick. If voids are caused by loss of material at a significant depth below the pavement;—e.g., migration of soil through a defective culvert or buried pipeline which causes a void to travel up toward the surface—a ground-coupled radar system may be used to determine the size and location of the deep voids. This could be done as a two-step GPR survey, with an air horn antenna system used to detect voids immediately under the pavement and the ground-coupled system used to see whether there are void problems at depth.

7.6 *Evaluation of Granular Base Material*—Radar reflections from the top of the base layer will have an amplitude that is a function of the dielectric constant of the granular base material; the wetter the base, the higher the amplitude of reflection and calculated dielectric value. The higher the reflection, the higher the moisture content of the base. Dielectric values of 10 to 16 signify a moist base, while values above 16 indicate a wet area with potentially low shear strength and susceptibility to freeze–thaw damage (Section 8.2).

7.7 *Detection of Asphalt Stripping*—Stripping in asphalt is a phenomenon by which the bond between asphalt and aggregate deteriorates, with a resulting low-density zone. The stripped layers should be removed before repaving, either by patching or by milling if large areas of stripping are present. A stripped layer will show up on a radar survey as an out of phase reflection peak (similar to that shown in Figure 2b) because the radar wave is traveling from a higher dielectric material to a lower one; the low dielectric is a function of the low density of the dry, stripped material.

7.8 *Bridge Deck Assessment*—Delaminations in bridge decks are the result of separation of the concrete from reinforcing steel bars and are caused by corrosion of the steel; the steel corrosion is exacerbated by chlorides from deicing salts diffusing through the concrete. Traditional methods of delamination detection, such as hammer and chain drag, do not work well on asphalt-covered decks and sampling cores is time-consuming and disruptive to traffic. GPR has become a means of locating areas of delamination on bridge decks with asphalt overlays. One GPR analysis method is to measure the dielectric values of the concrete under the asphalt. If the concrete has high moisture and chloride contents as a result of corrosion and concrete breakdown, it will produce an anomalously large reflection at the asphalt/concrete interface (Section 8.3). Another method is to measure the amplitude of the reflection at the bottom of the deck, where the radar wave reenters the air and shows as a negative reflection (Figure 6). If the radar signal has been strongly attenuated as a result of moisture and chloride within the concrete deck, the amplitude of the reflected signal will be greatly reduced (Section 8.1).



Layer	1	2	3	4
Amplitude				
Dielectric				
Thickness				
Travel Time				

Figure 6—Typical Radar Return Waveform from Asphalt-Covered Bridge Deck (with some processing to show the "true" reflection from concrete deck). Delamination problems are anticipated if either the reflection from the top of the deck increases significantly or the reflection from the bottom of the deck decreases.

7.8.1 GPR will not be effective in assessing bridge decks if the structures have standing water on them, deicing salts on the surface, or are at subfreezing temperatures; all of these factors affect the dielectric properties of the concrete in such a way as to render the radar data ineffective.

Standard Practice for

Measuring Pavement Profile Using a Rod and Level

AASHTO Designation: R 40-10[1,2]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Measuring Pavement Profile Using a Rod and Level

AASHTO Designation: R 40-10[1,2]

1. SCOPE

1.1 The rod and level can be used to accurately measure the profile of a pavement. The profile data can be used to evaluate the roughness of the pavement by computing a roughness index such as international roughness index (IRI) or to evaluate effects such as frost heave or swelling of soils. In computing roughness indices, only the relative elevations and not the absolute elevations are needed. The guidelines in this standard practice can be applied to conventional survey equipment such as an optical level and graduated staff, which require the readings to be manually recorded, as well as automated equipment that is capable of automatically storing the measured data.

1.2 *This standard practice may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENT

2.1 *ASTM Standard*:

- E 1364, Standard Test Method for Measuring Road Roughness by Static Level Method

3. SUMMARY OF METHOD

3.1 To measure the pavement profile using the rod and level, two persons are generally needed. One person is needed to hold the rod (rod-person) and another to operate the level and take readings (instrument operator). If the level is not capable of automatically recording the readings, an additional person (record keeper) to record the readings will make the process quicker. An experienced crew of three would require fewer than 10 seconds to obtain one reading. This involves the positioning of the rod by the rod-person, reading the level by the instrument operator, and recording the measurements by the record keeper.

3.2 Relative elevations are measured along the roadway at prescribed intervals. A rod is set on the roadway, and the rod reading is recorded.

3.3 Rod readings are then converted to either a true elevation or a reference elevation from which profile statistics are then computed.

4. SIGNIFICANCE AND USE

4.1 Longitudinal profile measurements are used during construction to assess the smoothness of new pavement. Elevation profiles, when converted to roughness measurements, are also gathered for estimating the performance of in-service pavements which can then be utilized in a pavement management system.

5. APPARATUS

5.1 The rod and level used in routine surveying and road construction generally will not have the resolution needed for pavement profile measurements. For pavement profile measurements, precision leveling instruments are required. The instrument used for profile measurement shall satisfy the resolution criteria noted in ASTM E 1364, Table 1.

5.2 The rod used shall be equipped with a bubble level so that it can be held vertical accurately. A suitable base shall be selected for the rod in order to reduce the sensitivity to small variations in rod placement. For smooth-textured pavements, any type of base is suitable. For textured surfaces, a circular pad with a diameter of at least 2.0 cm (0.8 in.) is recommended. As only relative elevations are required for computing roughness indices, no correction is required for attaching a pad to the bottom of the rod.

Note 1—It is recommended that an invar rod be used to minimize the effects of temperature changes. This is particularly important for Class 1 surveys on smooth roads, for which the resolution requirements given in ASTM E 1364, Table 1 are more stringent.

6. EQUIPMENT MAINTENANCE, ADJUSTMENT, AND VERIFICATION

6.1 *Maintenance*—Use shockproof packaging when transporting the instrument. Clean the instrument after completing a profile measurement. Before cleaning the lenses, blow the dust off the lenses. Clean the lenses using a soft cloth. Do not touch the lenses with the fingers. If the instrument becomes wet in the field, dry it completely before packing. Inspect the tripod regularly to ensure that the connections are not loose.

6.2 *Adjustment*—The user manual for the level shall be consulted on how to perform adjustments of the instrument. Different makes and models of levels will require different adjustments to be performed. The following are some common adjustments that are required in levels in order to obtain accurate measurements. The user manual for the level shall be consulted to determine whether the following adjustments are needed for the level being used and, if so, how to perform the specific adjustment.

6.2.1 *Make Axis of Level Bubble Perpendicular to Vertical Axis*—After setting up the level, center the bubble. Move the telescope 180 degrees about the vertical axis. If the bubble moves, the instrument needs adjustment.

6.2.2 *Adjust Horizontal Crosshairs*—This adjustment will ensure that the horizontal crosshairs are truly horizontal when the instrument is leveled.

6.2.3 *Adjust Line of Sight*—This adjustment will make the axis of sight perpendicular to the vertical axis and parallel to the axis of the level. The method of adjustment for this error is commonly referred to as the two-peg method.

6.3 *Verification*—Verify the accuracy of the markings on the rod using a standardized tape.

7. SITE INSPECTION AND PREPARATION

7.1 Identify the two wheelpaths in the lane to be profiled.

7.2 Clean loose stones and debris from both wheelpaths to prevent slippage of the rod during measurements.

7.3 *Locate the center of the travel lane using the following guidelines*:

7.3.1 Case I—Where the wheelpaths can be easily identified, consider the center of the travel lane to be midway between the two wheelpaths.

7.3.2 Case II—Where the wheelpaths are not clearly identifiable, but the two lane edges are well defined, consider the center of the travel lane to be midway between the two lane edges.

7.3.3 Case III—Where only one lane edge is well defined, consider the center of the travel lane to be 1.8 m (6 ft) from the edge.

7.4 Use a chalk line to mark a straight line in each wheelpath. Position the line 0.8 m (32.5 in.) from the center of the travel lane.

7.5 Record the method used to locate the wheelpaths in the comment field of the data collection form or logbook. This will help in locating the wheelpaths used for profile measurements at a future date.

7.6 The measurement of pavement profiles using the rod and level is labor intensive and time consuming. Measurements will be taken along the wheelpaths at typical intervals of 70 mm (2.75 in.). Measurement accuracy must be verified at regular intervals by establishing a set of control points along the wheelpath; for example, at 30.5-m (100-ft) intervals starting from the beginning of the section. Determine the locations at which readings are to be taken, including control points, using one of the following methods:

7.6.1 Lay a surveyor's tape along the chalk line and mark distances on the pavement at 70-mm (2.75-in.) intervals using a suitable marker. Make markings along the entire length of the section on both wheelpaths.

7.6.2 Place a surveyor's tape on the wheelpath with the zero of the tape corresponding to the start of the section. Secure both ends of the tape with a weight or adhesive tape. Reference distances along the section from the tape.

8. LONGITUDINAL PROFILE MEASUREMENT

8.1 Record the required information in the data collection form or logbook.

8.2 Set up the level at a suitable location, taking into account the range of the level. With some instruments, it might be possible to cover the entire test length from one instrument setup located near the center of the test section. Place the level where it will not be disturbed by passing traffic and where it will not settle. When setting the tripod, set it as low as practical to reduce the error caused by the rod not being exactly vertical. Thereafter, level the instrument using the leveling screws.

8.3 The rod-person shall place the rod at the zero position of the section and use the bubble level attached to the rod to hold the rod vertical. When the rod is vertical, the rod-person shall signal to the instrument operator to take a reading. If the readings are recorded manually by a third crew member, the instrument operator shall call out the reading to the record keeper, who shall record it on a form or in the logbook. If an automated system is used, the instrument operator shall make sure that the reading is saved.

8.3.1 The rod-person shall place the rod 70 mm (2.75 in.) away from the initial reading, and a new reading shall be recorded. This process shall be continued until either the entire test section is surveyed, the next control point is reached, or the horizontal range or the vertical range of the level is exceeded. Relocate the level whenever the vertical or horizontal range is exceeded.

Note 2—The horizontal range of the level is exceeded if the distance between the level and the rod is too short or too long to focus properly. The vertical range of the level is exceeded if the rod cannot be read due to the slope of the road.

8.3.2 After taking measurements for a distance of 30.5 m (100 ft), place the rod at the previous control point and repeat the measurement at that point. The readings must agree within the resolution of the instrument. If the readings do not agree, take new readings for the length of pavement between the control points.

8.3.3 Use this procedure even if the level is not relocated between the two control points being considered. If the level is relocated between two control points, apply the same procedure, treating the pivot point (Section 8.5) as a control point.

8.4 When the level requires relocation, mark the location at which the rod was held for the last reading. This position is called a pivot point. Place the rod at the location where the first reading was taken with the current setup of the level and take a reading. Compare this reading with the first reading that was taken at this location.

8.4.1 If the readings do not agree within the required resolution of the instrument as determined in Section 5.1, repeat all readings taken from the current position of the level.

8.4.2 If the readings agree, place the rod on the pivot point and record the last reading from the current setup of the instrument (foresight) and relocate the level. Place the rod at the pivot point and take a reading (backsight). Continue the measuring process as described in Section 8.3 at intervals of 70 mm (2.75 in.). If the level must be repositioned, follow the procedure described in Section 8.5.

Note 3—The first reading taken after the level is set up is referred to as a backsight, while the last reading taken at that setup before the level is moved is referred to as a foresight. Other readings taken between a backsight and a foresight are referred to as intermediate sights.

8.5 At the end of the test section, if the entire survey is performed from one level position, place the rod at the zero position (the point from which the survey began) and take a reading. This reading must agree with the first reading taken at this location at the start of the survey within the resolution of the instrument. If the readings do not agree, repeat all profile measurements.

8.6 At the end of the test section, if the level was repositioned during the survey, place the rod at the last pivot point and take a reading. This reading must agree with the previous reading taken at the same position within the resolution of the instrument. If it does not agree, repeat the profile measurements from the last pivot point to the end of the section.

9. INTERFERENCES

9.1 If the level is sensitive to temperature variations, cover it with an umbrella to protect it from direct sunlight.

9.2 Avoid making measurements during windy conditions. Movement of the level could occur.

9.3 If the level has to be set up at more than one position during profile measurements, make the length to backsights and foresights equal. This will eliminate errors due to curvature and refraction at turning points.

9.4 If the line of sight is set too close to the layer of air above the ground, significant refraction can occur under certain atmospheric conditions.

10. CALCULATIONS

10.1 During field profile measurements, the crew is expected only to record the readings of the level using the procedures described in Section 8. The computation of the elevation profile from this data will be done in the office in the following manner:

10.1.1 For profile computations, the elevation of the location where the first reading (first backsight) was measured is needed. However, as only relative elevations are needed to compute roughness indices (such as IRI), an arbitrary value can be selected for the elevation of this point. Obtain the relative elevation of any point measured from the initial instrument setup using the following equations:

$$\text{Instrument Height } (IS) = BM + RR_1 \qquad (1)$$

$$\text{Relative Elevation of a Point} = IS - RR \qquad (2)$$

where:

IS = initial instrument height;

BM = elevation of point where the first backsight was taken (assume any value; e.g., 10 m (32.8 ft));

RR_1 = rod reading at first backsight; and

RR = rod reading at any point from the initial instrument setup.

10.1.2 Once the position of the level is changed, the instrument height will also change. Obtain the new instrument height using the following equation:

$$Nht = Oht + BS - FS \qquad (3)$$

where:

Nht = new instrument height;

Oht = old instrument height;

BS = backsight at pivot point with the instrument at new setup location; and

FS = foresight at pivot point with the instrument at the previous setup.

10.1.3 Relative elevation of points measured from a new instrument location can be determined by using Equation 2 and substituting the new instrument height for the initial instrument height.

11. QUALITY CONTROL

11.1 *Field Quality Control*—Field quality control measurements shall be made to ensure that the level has not moved in the current position. Field quality control measurements are made before the level is moved and at the end of the survey. These measurements are described in Sections 8.6, 8.7, and 8.8.

11.2 *Office Quality Control*—The computation of the elevation profile from the raw field data shall be performed in the office using a computer. Using the computer will prevent mathematical errors during computation. The quality control used in the field will not detect an incorrect reading being recorded at an intermediate location. The plot will only allow for the detection of significant erroneous readings.

12. REPORT

12.1 *Use the data collection form or a logbook to record readings and report the following information*:

12.1.1 Serial number and identification of rod and level used;

12.1.2 Date information was collected;

12.1.3 Names of instrument operator, rod-person, and data recorder;

12.1.4 Roadway identification;

12.1.5 Location of the wheelpaths (for longitudinal profiles); and

12.1.6 Rod readings as measured at each point.

13. KEYWORDS

13.1 Longitudinal profile; pavement profile; rod and level.

Standard Practice for

Measuring Pavement Profile Using a Dipstick$^{\text{fi}}$

AASHTO Designation: R 41-05[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Measuring Pavement Profile Using a Dipstick$^{\text{fi}}$

AASHTO Designation: R 41-05[1]

1. SCOPE

1.1. This standard practice is used to manually collect precision profile data utilizing the Face Technologies Dipstick®. The dipstick measures profiles (relative elevation differences) at a rate and accuracy greater than traditional rod and level surveys. Procedures for measuring both longitudinal and transverse profiles are described.

1.2. Experienced operators have been able to obtain 500 readings per hour using this procedure.

1.3. *This standard practice may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENT

- *Dipstick Manual*. Face Technologies, Norfolk, Virginia.

3. DEFINITIONS

3.1. *dipstick*—the dipstick is a manually operated device that houses an inclinometer and measures relative elevation differences from one foot to the other. The dipstick measurements can either be recorded manually or stored in a handheld computer using either a trigger or an automatic storage method.

4. SUMMARY OF PRACTICE

4.1. For longitudinal profile measurements, the wheelpaths are first located then cleared of any excess debris. Chalk lines are established to ensure the same path is surveyed in both directions. The dipstick is then moved along the chalk line and measurements are recorded at 0.3-m (1-ft) intervals. The dipstick is "walked" up and back along the same line, thereby allowing a closure error to be calculated. If the closure error exceeds a given amount, the recorded measurements are questionable and the survey may need to be repeated. Collected information can then be used to calculate various roughness indices such as the international roughness index.

4.2. Transverse dipstick measurements are conducted in a fashion similar to the longitudinal. That is, the location for the transverse measurement is established, a chalk line is snapped perpendicular to the travel lane, the dipstick is walked over and back across the lane, and the closure error is calculated. Measurements are recorded at 0.3-m (1-ft) intervals and can be used to calculate rutting using various computational methods.

5. SIGNIFICANCE AND USE

5.1. Longitudinal profile measurements are used during construction to assess the pavement smoothness and are often used to determine contractor pay factors. Elevation profiles, when converted to roughness measurements, are also gathered for estimating the performance of in-service pavements, which can then be utilized in a pavement management system. Increasingly, dipstick measurements are being utilized to check high-speed profiling devices.

5.2. Transverse dipstick measurements are used to develop a cross-profile of the roadway. Cross-profiles are then used to calculate rut depths along a given roadway. This method of rut depth determination can be more accurate than using a straightedge and allows rut depths to be calculated based on differing standards such as a 3.6-m (12-ft) wire line, 1.8-m (6-ft) straightedge, or 1.2-m (4-ft) straightedge.

6. EQUIPMENT

6.1. *The Face Technologies Dipstick*—A manually operated device for the collection of precision profile measurements at a rate and accuracy greater than traditional rod and level survey procedures for individual readings.

6.1.1. The body of the dipstick houses an inclinometer (pendulum), LCD panels, and batteries for power supply. The sensor of the dipstick is mounted in such a manner that its axis and the line passing through the contact points of the footpads are coplanar. The sensor becomes unbalanced as the dipstick is pivoted from one leg to the other as it is moved down the pavement, causing the display to become blank. After the sensor achieves equilibrium, the difference in elevation between the two points is displayed.

6.1.2. The dipstick is equipped with a choice of hardened-steel spike feet or ball-and-swivel footpads. The swivel pads shall be used on pavements.

6.2. The profile that is computed from dipstick measurements may have a shift from the true profile. This shift can be eliminated by applying a bias correction to distribute the closure error.

7. DIPSTICK MAINTENANCE

7.1. *Maintenance*—Specific, detailed maintenance procedures are contained in the manuals provided with each individual piece of equipment, and the operator shall become intimately familiar with the maintenance recommendations contained in all equipment manuals.

7.1.1. It is not the intention of this standard practice to supersede manufacturers’ minimum services and service intervals, but to provide supplementary service requirements. Where there is a conflict between this guide and the manufacturers’ instructions, the more stringent requirements shall be followed.

7.1.2. *Routine Maintenance*—Routine maintenance includes those functions that can be easily performed by the operator with minimal disassembly of a particular device. Routine maintenance for the dipstick includes the cleaning and lubrication of the ball and socket joints on the footpads, replacement of the batteries, and cleaning of the battery contacts. These items are basic and easily performed preventive measures and shall always be completed prior to operation of the equipment.

7.1.3. *Major Maintenance*—Major preventive services shall include much more than the routine checks and will require some disassembly of the equipment by personnel with technical capabilities beyond the skill of the operators such as the manufacturer. Items such as battery connector replacement would fall into the major maintenance category. The appropriate service intervals are outlined in the equipment manufacturer's manual.

8. DIPSTICK PREOPERATIONAL CHECKS

8.1. Check the condition of footpads and replace if necessary. Clean and lubricate the ball-and-socket joints on the footpads to ensure smooth pivoting of the instrument. When the joint is dirty, pivoting becomes difficult and slippage of the footpad can occur. A cleaning agent such as WD-40 and a light oil for lubrication will work for the ball-and-socket joint.

8.2. Install a fresh set of batteries in the instrument and securely close the battery compartment. Batteries shall be changed after 4 hours of usage to ensure continuity of measurements.

8.3. Check and, if necessary, retighten the handle on the instrument.

8.4. *Zero Check, Manual Dipstick*—Perform the zero check prior to and after any dipstick measurements. This test shall be performed on a smooth, clean surface where the instrument can be properly positioned (the carrying case for the dipstick or a flat board will suffice). After positioning the dipstick, draw two circles around the two footpads, and note the reading on the display (reading = $R1$). The instrument shall then be rotated 180 degrees, and the two footpads placed on the two circles that were drawn earlier. Note the reading obtained (reading = $R2$). If the readings from the two placements ($R1$ and $R2$) add up to within ±0.1mm (0.003 in.), the dipstick has passed the zero check. If the addition of two readings does not fall within these limits, zero adjustment is necessary. The zero adjustment shall be performed using the following procedure.

8.4.1. Obtain the average of the two dipstick readings in Equation 1:

$$e = 0.5\,(R1 + R2) \qquad (1)$$

Then subtract this value from $R2$ to obtain $R2o$ in Equation 2:

$$R2o = R2 - e \qquad (2)$$

8.4.2. With the dipstick still in the $R2$ reading position, loosen the setscrew. Adjust the start end, moving the pin up or down so that the display reads $R2o$. Thereafter, tighten the setscrew and rotate the dipstick back to the $R1$ reading position and read the display (reading = $R1o$). Now the addition of $R1o$ and $R2o$ should be within tolerance. If this sum is not within tolerance, repeat the adjustment procedure until the two readings are within tolerance.

8.4.3. This zero adjustment is the only adjustment the operator is allowed to make on the dipstick.

8.5. *Zero Check, Automated Dipstick*—This check should be performed on a smooth, clean, and stable surface (carrying case for the dipstick or a flat board will suffice) where the instrument can be properly positioned. Circles shall be drawn around the two footpads and the CAL button depressed once. The instrument should then be rotated 180 degrees, and the two footpads placed in the circles drawn earlier. The CAL button should again be depressed once. The display will flash 'CAL' three times, after which the error is automatically stripped out of the readings. Note the reading at switch end of dipstick. Rotate dipstick and place two footpads in the circles, and note reading at switch end. If the two readings that were noted add up to within ±0.1 mm (±0.003 in.), the dipstick has passed the zero check. The zero check can only be performed once. If check is not successful, the dipstick must be turned off, turned back on, and the zero check repeated.

8.6. *Calibration Check, Manual and Automated Dipstick*—Check the calibration of the device before and after any dipstick measurements, after the zero check and zero adjustments are performed. To check the calibration, place the 3.2 mm (0.125 in.) calibration block under one of the dipstick footpads. The reading displayed, minus 3.2 mm (0.125 in.), should equal the previous reading plus 0.1 mm (0.003 in.). If the answer is not within this tolerance, Face Technologies shall be contacted to repair the dipstick.

8.6.1. Both the zero check and calibration check shall be performed at the beginning and end of data collection.

9. CALIBRATION

9.1. *Dipstick Calibration*—Calibration of the dipstick is fixed during manufacture and cannot be altered by the user. Factory calibration accuracy is stated to be 0.038 mm (0.0015 in.) per reading. The user can verify the calibration against a standard calibration block that is provided with the dipstick. If the dipstick fails the calibration test, it shall be returned to the manufacturer for repair.

9.2. *Gauge Block Calibration*—The gauge block used during the calibration check shall be calibrated to an accuracy of 3.175 ± 0.025 mm (0.125 ± 0.001 in.) using a local calibration laboratory or a calibration micrometer to ensure the minimum 4:1 ratio of accuracy of gauge blocks to the dipstick. The gauge block shall be recalibrated once every year, or more frequently, depending on (1) presence of oxidation, (2) evidence of erosion, and (3) possible damage caused by accidental mishandling in the field.

9.2.1. If the calibration block (gauge block) thickness is not within 3.175 ± 0.025 mm (0.125 ± 0.001 in.), all data collected since the last check of the block are suspect and may have to be disregarded.

10. SITE INSPECTION AND PREPARATION

10.1. *General Pavement Condition*—The pavement shall be clear of ice, snow, and puddles of water before profile measurements can be taken with the dipstick, as such conditions can affect the profile measurements. Clean loose stones and debris from the area to be profiled to prevent slippage of the dipstick footpads during measurements.

10.2. *Identify Wheelpaths*—For longitudinal profiles, use a chalk line to mark a straight line in each wheelpath 0.8 m (32.5 in.) from the center of the travel lane. The center of the travel lane shall be located using the following guidelines:

10.2.1. *Case I*—Where the wheelpaths can be easily identified, consider the center of the travel lane to be midway between the two wheelpaths.

10.2.2. *Case II*—Where the wheelpaths are not clearly identifiable, but the two lane edges are well defined, consider the center of the travel lane to be midway between the two lane edges.

10.2.3. *Case III*—Where only one lane edge is well defined, consider the center of the travel lane to be 1.8 m (6 ft) from the edge.

10.2.4. A comment in the data collection sheet or field book shall be made on how the centerline of the lane was defined. This information will help to collect consistent data in future profile measurements at that location.

10.3. *Identify Transverse Profile Locations*—Lay out and mark straight lines for transverse profile measurements. The lines shall be perpendicular to the edge of the pavement at specified testing intervals. The location of lines shall be adjusted to avoid raised pavement markings and similar anomalies. The need for and magnitude of such adjustments are to be recorded on the data sheets.

11. LONGITUDINAL PROFILE TEST PROCEDURE

11.1. To start profile measurements, the dipstick shall be placed on a marked wheelpath line at the start point with the "start arrow" pointing forward. A clockwise rotation is recommended because the handle can start to unscrew if you use a counterclockwise rotation. However, it is prudent to keep the same motion for all measurements so that any potential errors introduced by the rotational direction are consistent in all dipstick data.

11.1.1. As the dipstick is walked along the marked wheelpath, the readings shall be recorded each time the dipstick is rotated. If a manual dipstick is used, the data shall be recorded on a data sheet or in a field book; in the auto-read dipstick, the readings are stored in the computer attached to the dipstick. In this case, the operator shall use either the trigger to instruct the computer to store the reading or the automatic storage scheme in the lowest production rate possible. The trigger is preferred because this ensures adequate time for the pendulum to stabilize. Use of the automatic storage mode, even at the lowest production rate, may not allow adequate time for stabilization, thus introducing possible errors in the data.

11.2. Frequently, an operator will introduce bias in the readings by leaning the dipstick handle laterally from a true vertical position during operation. The operator must not apply any lateral pressure on the handle while the reading is taken. Two runs on each wheelpath of the section shall be undertaken by the dipstick operator, consisting of one run up the wheelpath and one run back down the same wheelpath. This will accomplish a closed-loop survey for each wheelpath.

11.3. Minor localized cracks and holes in the pavements as well as open joints shall be avoided during the dipstick profile measurement process (e.g., instances where one footpad sinks into a crack or hole or into an open or faulted joint). Also, care shall be exercised not to place the footpad partially on top of an opening or very wide crack as this may cause slippage during the next advance motion of the dipstick. If the use of swivel pads is not feasible for some reason, then the operator shall avoid isolated depressions by locating the test point on either side of small cracks or holes. If the crack or hole is too big to avoid in this manner, then most likely it should be measured as part of the surface profile and its presence noted in the comment section of the data sheet or in the field log book.

11.4. The dipstick measurements for each wheelpath shall be taken continuously. However, if, for any reason, the operator has to stop measurements (e.g., a sudden heavy storm), the point where the last reading was taken shall be clearly marked (draw a circle around the footpad). The operator may continue the dipstick measurements later from this position after placing a comment on the data collection sheet assuming that this point is clearly identifiable on the pavement.

11.5. After the forward and the return run have been completed on one wheelpath, the post data-collection check and quality control check shall be completed before taking measurements on the other wheelpath.

11.5.1. *Post Data-Collection Check*—To ensure the accuracy of the collected data, the operator must conduct the zero and calibration checks outlined in Sections 8.4, 8.5, and 8.6 after completing measurements on a wheelpath. If the dipstick fails either of these checks, the data shall be considered as suspect. If the dipstick fails the zero check, repeat the profile measurements after adjusting the dipstick as noted in Section 8.4 or 8.5. If the dipstick fails the calibration test, follow the procedure under Section 8.6. If the dipstick satisfies these checks, proceed with the quality control checks.

11.6. *Quality Control Check*—Various forms of error may be introduced into the dipstick measurements, including operator bias, footpad slippage, low battery power, and recording errors. A closed-loop survey is used to establish the total accumulated error in the profile measurements acquired with the dipstick. A closed-loop survey is accomplished by completing an initial run along one wheelpath and a return run along the exact same wheelpath (1 closed loop = 2 runs). The final value of the running sum of the two runs should theoretically result in a zero elevation difference. Any difference in elevation that is obtained is assumed to be due to operator error. By dividing the accumulated error by the length of the loop survey, the error per reading can be obtained. The maximum error allowed is 0.076 mm (0.003 in.) per reading. If the allowable elevation difference is exceeded during a dipstick measurement of a section, the section shall be retested until acceptable results are obtained.

12. TRANSVERSE PROFILE TEST PROCEDURE

12.1. Dipstick transverse profile measurements shall be collected at preestablished intervals. Elevations for each transverse profile location will be measured from the outside edge of the pavement and shall extend over the full lane width with the actual distance depending on lane width and pavement striping. The starting point shall be the junction of the transverse measurement line and the inside edge of the white paint stripe along the outside edge of the lane. If no outside edge stripe is present, then the beginning point shall be either the shoulder-lane joint or a point approximately 0.9 m (3 ft) from the center of the outside wheelpath. A comment shall be recorded noting how the starting point was determined. The initial elevation is arbitrarily established as zero and the subsequent readings are recorded relative to this benchmark. The combination of these measurements provides a measure of the pavement cross slope.

12.2. To begin the transverse profile measurements, the dipstick is placed at the outside edge of the pavement starting with the start arrow pointing toward the pavement centerline.

12.2.1. If the manual dipstick is being used, the measurements shall be recorded on a data form or in a field book. If the auto-read dipstick is used, it shall be triggered to record the readings.

12.3. The dipstick operator shall complete two runs per transverse profile of each section; one run up the transverse line and a return run back along the transverse profile to complete the closed-loop survey.

12.4. After the forward and the return run have been completed, the post data-collection check and quality control check need to be completed before finishing.

12.4.1. *Post Data-Collection Check*—To ensure the accuracy of the collected data, the operator must conduct the zero and calibration checks outlined in Sections 8.4, 8.5, and 8.6 after completing the transverse measurements. If the dipstick fails either of these checks, the data shall be considered as suspect. If the dipstick fails the zero check, repeat the transverse profile measurements after adjusting the dipstick as noted in Section 8.4 or 8.5. If the dipstick fails the calibration check, follow the procedure in Section 8.6. If the dipstick satisfies these checks, proceed with the quality control checks.

12.5. *Quality Control*—The total accumulated error in the transverse profile measurement shall be established by a closed-loop survey. The forward and return runs along a transverse section are utilized to compute this error. The maximum allowable error for the transverse profile measurements is 0.076 mm (0.003 in.) per reading, or 1.8 mm (0.072 in.) total for a 3.6-m (12-ft) lane width.

13. REPORT

13.1. *The report shall contain the following information*:

13.1.1. Serial number of the dipstick used;

13.1.2. Date information was collected;

13.1.3. Dipstick operator and data recorder;

13.1.4. Roadway identification;

13.1.5. Results of preoperational checks (zero and calibration checks);

13.1.6. Location of the wheelpaths (for longitudinal profiles);

13.1.7. Dipstick readings as collected at each point;

13.1.8. Post data-collection checks (zero and calibration checks); and

13.1.9. Quality control summary information.

14. PRECISION AND BIAS

14.1. No precision or bias statements are available at this time.

15. KEYWORDS

15.1. Dipstick; pavement profile.

Standard Practice for

Quantifying Roughness of Pavements

AASHTO Designation: R 43M/R 43-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Quantifying Roughness of Pavements

AASHTO Designation: R 43M/R 43-07

1. SCOPE

1.1. This standard practice describes a method for estimating roughness for a pavement section. An international roughness index (IRI) statistic is calculated from a single longitudinal profile measured with a road profiler in both the inside and outside wheel paths of the pavement. The average of these two IRI statistics is reported as the roughness of the pavement section.

1.2. This standard practice recognizes the need for a quality assurance (QA) plan and proposes guidelines for the development of a QA plan.

1.3. Measurements of profile are made in accordance with ASTM E 950. If any part of this standard practice is in conflict with its referenced documents, such as ASTM standards, this standard practice takes precedence for its purpose.

1.4. The values in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in parentheses. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.5. *This standard practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard practice to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- E 867, Standard Terminology Relating to Vehicle-Pavement Systems
- E 950, Standard Test Method for Measuring the Longitudinal Profile of Traveled Surfaces with an Accelerometer Established Inertial Profiling Reference
- E 1166, Standard Guide for Network Level Pavement Management

2.2. *Other Documents*:

- Sayers, Michael W. On the Calculation of IRI from Longitudinal Road Profile. University of Michigan, Transportation Research Institute, Preprint TRB, 74th Annual Meeting, Washington, DC, January 1995.
- Sayers, Michael W., T. D. Gillespie, and W. D. O. Paterson. Guidelines for Conducting and Calibrating Road Roughness Measurements. *The World Bank Technical Paper*, Number 46. The World Bank, 1986.

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *roughness*—according to ASTM E 867, the deviation of a surface from a true planar surface with characteristic dimensions that affect vehicle dynamics and ride quality. In this standard practice, the term "roughness" is the average of two IRI statistics calculated from longitudinal profile measurements, one in each pavement wheel path.

3.1.2. *longitudinal profile*—the set of perpendicular deviations of the pavement surface from an established horizontal reference plane to the lane direction.

3.1.3. *international roughness index* (IRI)—a statistic used to estimate the amount of roughness in a measured longitudinal profile. The IRI is computed from a single longitudinal profile using a quarter-car simulation as described in the report "On the Calculation of IRI from Longitudinal Road Profile" (Sayers 1995). Computer programs to calculate the IRI statistic from a longitudinal profile are referenced in Appendix X1 of this procedure.

4. SIGNIFICANCE AND USE

4.1. This standard practice outlines standard procedures for measuring longitudinal profile and calculating the IRI for highway pavement surfaces to help produce consistent estimations of IRI for network-level pavement management.

5. QUALITY ASSURANCE

5.1. Agencies using this standard practice are required to develop a satisfactory quality assurance (QA) plan. At a minimum, the plan shall include the requirements listed in the following sections:

5.1.1. Qualification and training records of individuals conducting the survey;

5.1.2. Accuracy and calibration records of equipment used in the survey; and

5.1.3. Periodic and ongoing quality control program and the content of the program.

Note 1—The estimate of roughness of pavements can be used both at network- and project-level pavement management. Guidelines for network level are included in ASTM E 1166, which can be used as a source for the development of a QA plan.

Note 2—The guidelines that can be used for the development of a quality assurance plan are given in Appendix X2.

6. DATA COLLECTION

6.1. Agencies using this standard practice are expected to designate the lane(s) and direction(s) of travel to be surveyed based on sound engineering principles and management needs within the agency.

6.2. Locate (place) the two sensors, separated approximately 1.6 to 1.8 m (58 to 71 in.) in the wheel paths. The longitudinal profile points used for calculating the IRI shall have a longitudinal spacing not greater than 150 mm (6 in.). Long wavelength filters are used to remove all wavelengths exceeding 90 m (300 ft).

Note 3—The use of anti-aliasing filters and averaging to remove small wavelength content from the profile is left to the discretion of the agency and equipment manufacturers.

7. CALCULATIONS

7.1. Calculate IRI values for each 0.1 km (0.1 mi) for both wheel paths. Compute an average of the two IRI values to determine roughness.

Note 4—The tenth of a kilometer (tenth of a mile) values are needed to calculate average values for each data collection section.

8. REPORT

8.1. *Report the following information*:

8.1.1. Roughness calculated in Section 7.1 to the nearest 0.01 m/km (one inch per mile);

8.1.2. Length of the data summary interval of 0.1 km;

8.2. *Report the following minimum data recorded and stored for each section*:

8.2.1. *Section Identification*—List all available information necessary to locate the section using agency's current referencing system;

8.3. IRI for each of the two wheel paths (m/km) [in./mi];

8.3.1. Average of both IRIs calculated for the section (m/km) [in./mi];

8.3.2. Date of data collection (month/day/year);

8.3.3. Length of section in meters for which the data are collected;

8.3.4. Profile sampling interval;

8.3.5. Long wavelength filter setting; and

8.3.6. *Optional*—Pavement surface temperature.

9. KEYWORDS

9.1. Inertial profiler; International Roughness Index; longitudinal pavement profile; pavement; pavement ride quality; pavement smoothness; roughness.

APPENDIXES

(Nonmandatory Information)

X1. FORTRAN PROGRAM TO CALCULATE IRI FROM PROFILE

X1.1. A program that complies with the requirements of R 43M/R 43 was developed by Sayers in 1995 at the University of Michigan.

Note X1—This standard practice requires IRI to be reported in units of meters per kilometer (m/km), the profile elevations (Variable PROF in subroutine IRI) are measured in millimeters, and the input distance between elevation points (variable *dx* in subroutine IRI) is measured in meters. Consequently, the UNITSC value in the program should be set to one (1.0).

Note X2—Another software program is available from the University of Michigan Transportation Research Institute (UMTRI), named RoadRuf. This Microsoft Windows based software contains procedures for calculating IRI and many other profile analysis capabilities. The software can be made to comply with the requirements of this protocol. It is public domain and can be downloaded from the Internet at http://www.umtri.umich.edu/erd/roughness/rr.html. Setup options are discussed in the accompanying documentation.

X2. GUIDELINES—QUALITY ASSURANCE PLAN

X2.1. *Quality Assurance (QA) Plan*—Each agency shall develop a QA plan. The plan shall include survey personnel certification training records, accuracy of equipment, daily quality control (QC) procedures, and periodic and ongoing QC activities. The following guidelines can be used for developing such a plan.

X2.2. *Certification and Training*—Agencies are individually responsible for training and/or certifying their data collection personnel and contractors for proficiency in using the profile measuring equipment according to this standard practice and other applicable agency procedures.

X2.3. *Equipment Calibration*—Equipment calibration (accelerometers and noncontact sensors) is done in accordance with specific manufacturer recommendations. The equipment must operate within the manufacturer's specifications. A regular maintenance and testing program is established for the equipment in accordance with the manufacturer's recommendations.

X2.4. *Verifications Sections*—Verifications sections are selected with known IRI statistics for both wheel paths. These sections are measured by equipment operators on a regular basis. Evaluations of these measurements can provide information about the accuracy of field measurements and give insight into needed equipment calibration. Verification sections are rotated on a regular basis in order to assure that the operators are not repeating previously known IRI statistics during the verification. An alternate to verification sections is to remeasure and compare up to 5 percent of the data as a daily or weekly quality check to ensure system stability and repeatability.

X2.5. *Quality Checks*—Additional quality checks can be made by comparing the most recent IRI statistics with current measurements. At locations where large changes occur, the pavement manager may require additional checks of the data.

Standard Practice for

Determining Rut Depth in Pavements

AASHTO Designation: R 48-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determining Rut Depth in Pavements

AASHTO Designation: R 48-10

1. SCOPE

1.1. This practice describes a method for determining rut depth in pavement surfaces from transverse profile measurements. Five transverse profile points are the minimum number of points required to determine rut depth. While this practice is based on a five-measurement transverse profile, more than five measurements greatly improve the accuracy and enhance the likelihood of identifying the maximum and average rut depth given survey vehicle wander and various rut configurations.

1.2. Procedures are defined for measuring a transverse profile and deriving a rut depth, but detailed specifications are not included for equipment, instruments, or software used to make the measurements. Any equipment and/or procedure that can measure as specified, with the accuracy stipulated herein, and that can be adequately calibrated is acceptable for this method.

1.3. *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this protocol to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENT

2.1. *FHWA Document*:

- FHWA-RD-01-024, *Characterization of Transverse Profiles*, Federal Highway Administration, 2001

3. TERMINOLOGY

3.1. *rut*—a longitudinal depression in a wheelpath consisting of consecutive rut depth determinations that measure a depression and extend for more than 50 m (150 ft).

3.2. *summary interval*—a longitudinal portion of a pavement lane over which the data are summarized as defined by the agency. This distance is generally 0.1 km (0.1 mi).

4. SIGNIFICANCE AND USE

4.1. This practice outlines standard procedures for measuring a transverse profile of the pavement from which a rut depth may be derived and summarizing the rut depth over a designated interval. Its purpose is to produce consistent estimations of rut depth for network-level pavement management. The intention is to measure rut depth in a vehicle traveling in the designated lane at highway speeds.

5. RUT MEASUREMENT

5.1. Each agency designates the lane(s) and direction(s) of travel to be surveyed based on sound engineering principles and management needs within the agency.

5.2. Transverse profiles should be measured at a maximum spacing of 10 m (33 ft) in the longitudinal direction for the purpose of determining rut depth.

5.3. Transverse profiles are measured across both wheelpaths of the survey lane. The goal of this practice is to obtain a transverse profile from which the depth of both ruts in a traffic lane can be derived. The reported summary statistics are the deepest rut found in each wheelpath and the average rut depth within the longitudinal summary interval.

5.3.1. The transverse locations for the five-measurement procedure are shown in Figure 1.

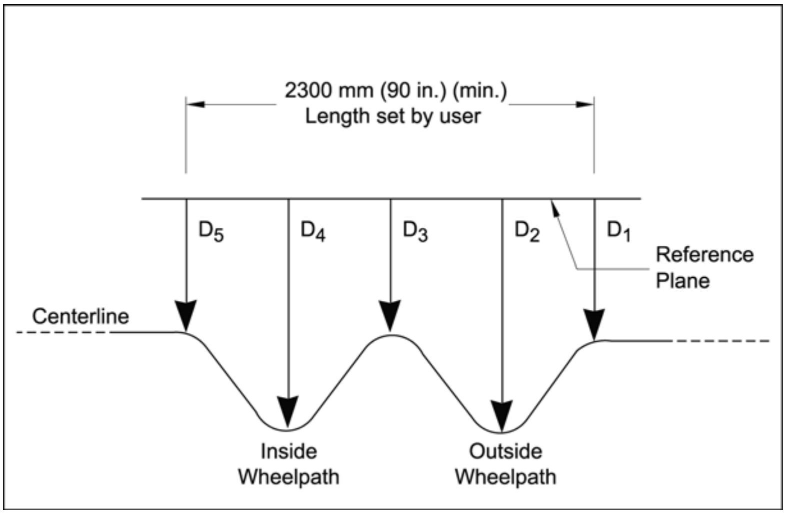

Figure 1—Rut Depth Measurements

5.3.1.1. Spacing between measurement points depend on pavement geometry and typically are not even.

5.3.1.2. For best rut values, the span between D_1 and D_5 measurements should be no less than 500 mm (20 in.) smaller than the lane width. Depending on equipment, safe operation often dictates a shorter span, which compromises the rut value.

5.3.2. Each height measurement, *Di*, shall be made in a manner to minimize variability of measurement due to the pavement surface not being a true planar surface.

5.3.3. The depth measurements shall be made to a resolution of 3 mm (0.12 in.) and an accuracy of ±3 mm (±0.12 in.) with a 95 percent confidence.

5.3.4. *The Basic Five-Point Rut Depth Calculations*:

$$R_o = D_2 - \frac{D_1 + M}{2} \qquad (1)$$

$$R_i = D_4 - \frac{M + D_5}{2} \qquad (2)$$

where:

$$M = \frac{D_1 + D_5}{2} \text{ or } D_3, \text{ whichever, is less} \qquad (3)$$

R_o = rut depth outside wheelpath estimate, mm;

R_i = rut depth inside wheelpath estimate, mm; and

D_1, D_2 ... D_5 = height measured as shown in Figure 1 (mm).

Note 1—This calculation allows for a negative rut depth. The negative rut can come from unusual cross sections, lateral offset of the measurement location, or atypical rut configurations.

5.3.5. The transverse profile is determined on the basis of the vertical distance between an imaginary string line run across the traffic lane from the shoulder to the lane line. The string line may bend at the hump between the wheelpaths where the hump is higher than the outside and inside edges of the lane. For manual measurements, the use of a string line will require D_1 and D_5 to be zero.

Note 2—This procedure is defined with knowledge of FHWA-RD-01-024 *Characterization of Transverse Profiles,* which compared ruts calculated from three- and five-point measurements to significantly denser systems. Users of this standard are advised to review this reference when making transverse measurement collection system decisions.

5.3.6. The five-point system has limited accuracy due to variances in rut configuration and vehicle wander during the collection process. These limitations are further complicated by keeping the sensor systems within a safe envelope while traveling the road.

Note 3—The addition of two sensors at each primary measurement location (D_1, D_2, D_3, D_4, D_5) spaced 150 mm (6 in.) apart and the application of appropriate algorithms dramatically improve the reliability of the derived rut values. For maximum effectiveness, both of the outside sensors need to target beyond the 2300-mm (90-in.) dimension at each end to extend the simulated string to within 250 mm (10 in.) of the lane width.

5.3.7. Technology is available to provide more than 1000 data points across the entire lane width. With such a transverse profile measurement, algorithms can be applied that remove texture effects, compensate for vehicle wander, and resolve a string-line rut value for each wheelpath. *This is the preferred methodology for rut data collection.*

6. OBTAINING THE DATA

6.1. Obtain and store the maximum and average rut depth determined from each wheelpath within the selected data summary interval.

7. REPORT

7.1. *At a minimum, record the following data*:

7.1.1. *Section Identification*—Record agency's information available to locate the section using its current referencing system;

7.1.2. Date of collection;

7.1.3. Length of data collection section (km (mi));

7.1.4. Maximum rut depth in each wheelpath for each summary interval;

7.1.5. Average rut depth in each wheelpath for each summary interval;

7.1.6. Sampling interval (m (ft));

7.1.7. Summary interval (km (mi));

7.1.8. Method agency utilizes to calculate maximum rut depth and average rut depth when negative rut depths are measured.

8. KEYWORDS

8.1. Pavement; pavement distortion; pavement distress; pavement evaluation; pavement management; pavement monitoring; rut; transverse profile; wheelpath; five-point rut estimate.

APPENDIX

(Nonmandatory Information)

X1. GUIDELINES—QUALITY ASSURANCE PLAN

X1.1. *Quality Assurance Plan*—Each agency shall develop a quality assurance plan. The plan shall include survey personnel certification training records, accuracy of the equipment, daily quality control procedures, and periodic and ongoing quality control. The following guidelines can be used for developing such a plan.

X1.2. *Certification and Training*—Agencies are individually responsible for training and/or certifying their data collection personnel and contractors for proficiency in using the profile measuring equipment according to this practice and other applicable agency procedures.

X1.3. *Equipment Calibration*—Equipment calibration (accelerometers and noncontact sensors) is done in accordance with specific manufacturer recommendations. The equipment must operate within the manufacturer's specifications. A regular maintenance and testing program is established for the equipment in accordance with the manufacturer's recommendations.

X1.4. *Verification Sections*—Verification sections are selected with known rut depths. These sections are measured by equipment operators on a regular basis. Evaluations of these measurements can provide information about the accuracy of field measurements and give insight into needed equipment calibration. Verification sections are rotated on a regular basis in order to assure that the operators are not repeating previously known rut depth values during the verification. An alternate to verification sections is to remeasure and compare up to 5 percent of the data as a daily or weekly quality check.

X1.5. *Quality Checks*—Additional quality checks can be made by comparing the most recent rut depth statistics with current measurements. At locations where large changes occur, the pavement manager may require additional checks of the data.

Standard Practice for

Accepting Pavement Ride Quality When Measured Using Inertial Profiling Systems

AASHTO Designation: R 54-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Accepting Pavement Ride Quality When Measured Using Inertial Profiling Systems

AASHTO Designation: R 54-10[1]

1. SCOPE

1.1 This practice provides guidance and example specification language intended for use by Owner-Agencies in development of specific contract language when requiring the measurement and evaluation of ride quality and compliance using inertial profiling systems (IPS) and IRI as the quality measure.

1.2 If any part of this practice is in conflict with references made, such as ASTM or AASHTO Standards, this practice takes precedence for its purposes.

1.3 The values stated are in U.S. Customary units and are to be regarded as the standard.

1.4 *This specification does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this specification to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 328, Inertial Profiler
- R 56, Certification of Inertial Profiling Systems
- R 57, Operating Inertial Profiling Systems

2.2 ASTM Standard:

- E 1926, Standard Practice for Computing International Roughness Index of Roads from Longitudinal Profile Measurements

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *International Roughness Index (IRI)*—a statistic used to determine the amount of roughness in a measured longitudinal profile. The IRI is computed from a single longitudinal profile using a quarter-car simulation as described in the paper "On the Calculation of International Roughness

Index from Longitudinal Road Profile" (Sayers 1995). The IRI is reported as described in ASTM E 1926.

3.1.2 *localized roughness*—any 25-foot segment of roadway that contributes disproportionately to the overall roughness index value. Areas of localized roughness are identified using a report of continuous IRI with a base length of 25 feet. This yields the IRI of every possible 25-foot segment. Any segment for which the continuous report exceeds a threshold IRI value is considered a defective segment requiring correction.

Note 1—The threshold IRI value in inches per mile should be determined by each Owner-Agency. A typical range of values for various highway types is shown below:

Table 1—Typical Threshold Values for Localized Roughness

Roadway Type	IRI (in. per mile)
Interstate	140 to 160
State primary	150 to 170
State secondary	160 to 190

3.1.3 *longitudinal elevation profile*—a longitudinal profile containing a series of relative pavement surface elevation measurements referenced to a common horizontal datum.

3.1.4 *report interval*—the longitudinal distance between the outputs of a profile index value.

3.1.5 *roughness*—the deviation of a surface from a true planar surface with characteristic dimensions that affects vehicle dynamics and ride quality.

3.1.6 *Type A Roughness Measurement*—a test procedure to measure the surface profile index known as the International Roughness Index (IRI) using an inertial profiler.

3.1.7 *Type B Roughness Measurement*—a test procedure to measure surface profile deviations using a straightedge.

4. SIGNIFICANCE AND USE

4.1 This example provides specification language for measuring and accepting ride quality on newly constructed paving projects using an IPS and the IRI quality measure. If an Owner-Agency elects to use some other ride quality index, the fundamental methodology described herein remains valid, but not the individual settings.

Note 2—The IPS should be verified on the same pavement surface type and texture as that being measured. When profiling pavements with rough macro texture, a height sensor with a large footprint is needed. The consequence of not using a large footprint sensor may be an upward bias in the IRI as measured by an IPS with a conventional point laser.

5. EQUIPMENT AND OPERATOR

5.1 Provide an approved 10-ft straightedge.

5.2 Provide an inertial profiler meeting all requirements and specifications found in M 328 and currently certified in accordance with R 56. Operate the equipment in accordance with R 57.

5.3 Provide the Owner-Agency a copy of the equipment certification. Display a current decal on the equipment indicating the expiration date of certification.

Note 3—An equipment certification or decal would be required only if the Owner-Agency had a certification program that issued them, or where it recognizes another agency's certification program in which certifications, decals, or both are issued.

5.4 Provide a qualified profiler operator. Provide the Owner-Agency a copy of the operator's qualifications or current certification.

6. WORK METHODS

6.1 *Quality Control (QC) Testing (nondirected)*—Perform QC tests on a daily basis throughout the duration of the project. Use an approved straightedge, inertial profiler, profilograph, or any other appropriate means.

6.2 *Quality Control Testing (directed)*—Use Type A Roughness Measurement. Use Type B Roughness Measurement only when Type A Roughness Measurement cannot be used or when specified by the Owner-Agency. Measure the finished surface of the completed project or at the completion of a major stage of construction as approved by the Owner-Agency. Coordinate with and receive authorization from the Owner-Agency before starting testing. Obtain roughness measurements within 7 days after receiving authorization and submit results to the Owner-Agency within 24 hours of data collection.

6.2.1 Operate the profiler in accordance with R 57 and provide the Owner-Agency the results of the Daily Measurement Control on a daily basis. The Owner-Agency may require QC testing be performed at off-peak times for traffic flow. Operate the inertial profiler in a manner that does not unduly disrupt traffic flow as determined by the Owner-Agency. Use an approved traffic control plan. Traffic control for QC and verification testing by the Owner-Agency is at the expense of the contractor. Provide all profile measurements to the Owner-Agency in electronic data files of the format specified in R 57.

6.3 *Verification Testing*—Within 10 working days after the contractor's QC testing under Section 6.2 is completed, the Owner-Agency may perform verification testing using an inertial profiler meeting the requirements of R 56. If the verification testing produces an IRI obtained over the same section of roadway that differs from that obtained using the contractor's profiler by more than the percentages shown in Table 2, then the Owner-Agency and contractor shall attempt to resolve the differences to their mutual satisfaction.

Table 2—Typical Allowable IRI Differences

Mean of Agency and Contractor's IRI (in./mi)	Max. Allowable Difference[a]
Fewer than 50	8.5% of mean IRI
50 to 150	6.0% of mean IRI
Greater than 150	7.0% of mean IRI

[a] Actual values should be set by the Owner-Agency.

6.3.1 If the differences cannot be resolved, then referee testing will be conducted. The Owner-Agency will conduct the referee testing and the results will be final and will be used to establish pay adjustments. Referee testing will be conducted using an inertial profiler that recently has been certified in accordance with R 56. The certification should not be more than 90 days old unless both parties agree otherwise.

6.3.2 If the testing confirms the Owner-Agency profiler and fails to confirm the contractor's profiler, then the contractor's profiler shall be taken out of service until it has been recertified in accordance with R 56. A similar requirement will apply if the testing confirms the contractor equipment but fails to confirm the Owner-Agency. If the referee testing fails to confirm either the Owner-Agency or contractor equipment, then both profilers shall be removed from service until recertified.

6.4 *Evaluation of Profiles*—The contractor shall evaluate profiles for acceptance, incentive payments, disincentive payments, or corrective action using the current version of ProVAL and provide the results to the Owner-Agency within 24 hours of completing testing under Section 6.2. Analyze the entire profile. Exclude any areas specifically identified in the contract. Exclude from the analysis for localized roughness the first 12.5 ft after the start of the paving operations and last 12.5 ft prior to the end of the paving operation. Also exclude the first 12.5 ft on either side of bridge structures, manhole covers, utility covers, and approach slabs. Determine pay adjustments in accordance with Sections 6.4.3 and 6.4.4. The Owner-Agency will verify the analysis.

Note 4—The Profile Viewer and Analysis (ProVAL) software program developed for the Federal Highway Administration, which can be used to import, display, and analyze the characteristics of pavement profiles from many different sources, is available at http://www.roadprofile.com.

6.4.1 *Type A Roughness Measurement*—The Owner-Agency may use the QC test results obtained under Section 6.2 to determine pay adjustments for ride quality provided it is able to verify the contractor's profile data. Areas excluded from measurement under Type A Roughness Measurement shall be measured in accordance with Section 6.4.2.

6.4.2 *Type B Roughness Measurement*—Typically used where an IPS cannot be effectively operated. There are no pay adjustments when Type B Roughness Measurement is used. In a manner approved by the Owner-Agency, correct surface areas that have more than $^1/_4$-in. variation between any two contacts on the straightedge. There is no payment for correcting deficient areas. Following correction, retest the area to verify compliance.

6.4.3 *Pay Adjustment Schedule*—The pay adjustment factors from Table 3 will be used in conjunction with the histogram printout from ProVAL's Smoothness Assurance Module based on a report of continuous IRI with a base length of 528 ft, to compute a final pay factor (incentive or disincentive). The final pay factor (PF) computed to three decimals is equal to the sum of the products of the individual pay adjustment factors shown in Table 3 times ProVAL's corresponding histogram percentages all divided by 100. In addition to the final pay factor determined from Table 3, disincentives for localized roughness may apply as described in Section 6.4.4.

Table 3—Pay Adjustment Factors and Computation of Final Pay Factor

IRI range, in./mi[a] (1)	Pay Adjustment Factors (2)	Percent of Pavement within IRI Range taken from ProVAL's Smoothness Assurance Module (SAM) (3)	Pay Adjustment (4)
> ##.0	0.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	0.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	0.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	0.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	1.00	#.# or ##.#	#.# or ##.#
##.1 – ##.0	1.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	1.##	#.# or ##.#	#.# or ##.#
##.1 – ##.0	1.##	#.# or ##.#	#.# or ##.#
< ##.0	1.##	#.# or ##.#	#.# or ##.#
	Final Pay Factor (PF) = (Sum/100) =		#.### or 0.###

[a] The number of steps in the table as well as the IRI Ranges and pay adjustment factors should be set by the Owner-Agency.

Note 5—A different set of pay adjustment factors may be used for different project requirements. This pay adjustment table is just one style of many possible pay tables and was designed to utilize quality assurance features within ProVAL. For this table, the final pay factor is determined by taking the values in column (2) and multiplying them by column (3). The results are shown in column (4). The results in column (4) are then summed and divided by 100 to obtain the Final Pay Factor (incentive or disincentive).

6.4.4 *Localized Roughness*—The adjustment factors from Table 4 will be used in conjunction with the histogram printout from ProVAL's Smoothness Assurance Module based on a report of continuous IRI with a base length of 25 feet, to compute the percent disincentive for localized roughness. The amount of the disincentive computed to three decimals is equal to 100 minus the sum of the products of the individual adjustment factors shown in Table 4 times ProVAL's corresponding histogram percentages. The Owner-Agency will either assess the disincentive per Table 4, or require that corrective action be taken. If corrective action is required, re-profile the corrected area and provide the Owner-Agency the results. If the corrective action is not successful, the Owner-Agency will assess the disincentive or require continued corrective action.

Table 4—Disincentives for Localized Roughness

IRI range, in./mi[a] (1)	Pay Adjustment Factors (2)	Percent of Pavement within IRI Range taken from ProVAL's Smoothness Assurance Module (SAM) (3)	Pay Adjustment (4)
> ###.0	0.##	#.# or ##.#	#.### or ##.###
###.1 – ###.0	0.##	#.# or ##.#	#.### or ##.###
###.1 – ###.0	0.##	#.# or ##.#	#.### or ##.###
###.1 – ###.0	0.##	#.# or ##.#	#.### or ##.###
< ###.0	1.00	#.# or ##.#	#.### or ##.###
		Final Percent Disincentive = (100 – Sum) =	#.### or ##.###

[a] The number of steps in the table as well as the IRI Ranges and pay adjustment factors should be set by the Owner-Agency.

Note 6—A different set of pay adjustment factors may be used for different project requirements. This pay adjustment table is just one style of many possible pay tables and was designed to utilize quality assurance features within ProVAL. For this table the final percent disincentive is determined by taking the values in column (2) and multiplying them by column (3). The results are shown in column (4). The results in column (4) are then summed and subtracted from 100 to obtain the final percent disincentive.

6.4.5 *Deficiencies and Corrective Work*—All corrective work will be at the Contractor's expense.

- A defective segment is any area of localized roughness as determined in Section 6.4.4.
- Propose a plan and methodology to correct deficiencies and receive approval from the Owner-Agency before beginning any corrective work. This must be done with the purpose of correcting the minimum area needed to decrease the roughness to acceptable limits. ProVAL's Smoothness Assurance Module is an example of a computer program than can be used to assist in developing a plan.
- The Owner-Agency will determine the final disposition of defective segments, which may include corrective actions, assessment of a penalty, or some combination thereof.
- After making corrections, reprofile the corrected pavement section to verify that the corrections have produced the required improvements. If the corrective action does not produce the required improvement, the Owner-Agency may assess the penalty, or require or allow continued corrective action.
- Corrective actions will not be allowed on nondeficient sections to obtain incentive payments.

7. MEASUREMENT AND PAYMENT

7.1 *Measurement and Payment*—The work performed, materials furnished, equipment, labor, tools, and incidentals will not be measured or paid for directly, but will be subsidiary to bid items of the contract. The final pay factor as determined in Section 6.4.3 and the percent disincentive for localized roughness as determined in 6.4.4 will be applied to the unit bid price for the quantity of pavement placed and accepted. The appropriate incentive or disincentives will be applied separately.

Standard Practice for

Quantifying Cracks in Asphalt Pavement Surfaces

AASHTO Designation: R 55-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street NW, Suite 249
Washington, DC 20001

Standard Practice for

Quantifying Cracks in Asphalt Pavement Surfaces

AASHTO Designation: R 55-10[1]

1. SCOPE

1.1. This practice covers the procedures for quantifying cracking in asphalt pavement surfaces, both in wheelpath and non-wheelpath areas. Detailed specifications are not included for equipment or instruments used to make the measurements. According to this standard, any process that can quantify, with the accuracy stipulated herein, and that can be adequately validated, is considered acceptable.

Note 1—Standardization will produce consistent pavement condition estimates for network-level pavement management. As an option, the user may define and collect other data, such as edge cracking, centerline cracks, and transverse cracks. This standard is designed for use primarily with automated data collection equipment. However, accommodations have been made for manual methods.

1.2. Either automated or manual data collection surveys as defined below are acceptable.

1.2.1. *Automated Data Collection*—Use a vehicle traveling at near highway speeds and collect data on the entire length of roadway (100 percent sample).

1.2.2. *Manual Data Collection*—Observe distresses and record data on a statistically reliable sample of the lane surveyed. The confidence level in the results for each section should exceed 85 percent. Rating continuous film or tape in an office setting is considered a manual survey.

1.3. *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. TERMINOLOGY

2.1. *crack*—a discontinuity in the pavement surface with minimum dimensions of 1-mm ($^1/_{25}$-in.) width and 25-mm (1-in.) length.

3. SIGNIFICANCE AND USE

3.1. This practice covers the procedures for quantifying cracking in asphalt pavement surfaces both in wheelpath and non-wheelpath areas for network-level pavement management applications. The intent of this practice is to quantify and differentiate between load-associated (fatigue) and nonload-associated (environmental, reflective, etc.) pavement cracking and joints.

Note 2—At the time this standard was drafted, it was already identified in the *Highway Performance Monitoring System Reassessment 2010+* as the collection and reporting standard for pavement cracking. However, this standard was not written specifically for that use and makes no assertion about the fitness of that or any other application beyond use in network-level pavement management.

4. PROCEDURE

4.1. *General Guidelines*—Each agency shall designate the lane(s) and direction(s) of travel to be surveyed or rated based on sound engineering principles and management needs within the agency. The following guidelines are recommended as minimums to provide long-term uniformity:

4.1.1. Survey a 2.5-m (8-ft) strip in the outside lane as shown in Figure 1. As another option, survey the 3.6-m (12-ft) full lane width.

4.1.2. For undivided highways, survey one direction.

4.1.3. For divided highways, survey the outside lane in both directions.

4.1.4. For each survey cycle, it is desirable to use the same direction(s) of travel and survey lane(s).

4.2. *Cracking Types*—Cracks may include longitudinal cracks, transverse cracks, and interconnected cracks. The intent of this practice is to quantify and differentiate between load-associated (fatigue) and nonload-associated (environmental, reflective, etc.) pavement cracking and joints.

4.2.1. For this practice, increased cracking intensity in the wheelpath as compared with the non-wheelpath areas is assumed to quantify load-associated cracking.

4.2.2. Nonload-associated cracking is quantified by the cracking measured in the non-wheelpath areas.

4.2.3. Sealed cracks will not be quantified by manual surveys. Automated data collection equipment will not quantify any discontinuity greater than 25-mm (1-in.) width.

4.3. *Cracking Estimates by Type*:

4.3.1. *Rating Wheelpath Cracks*—Wheelpath cracking is determined in both the inside and outside wheelpath as shown in Figure 1.

4.3.2. *Rating between Wheelpath Cracks*—Non-wheelpath cracking is determined in the area between the wheelpaths as shown in Figure 1.

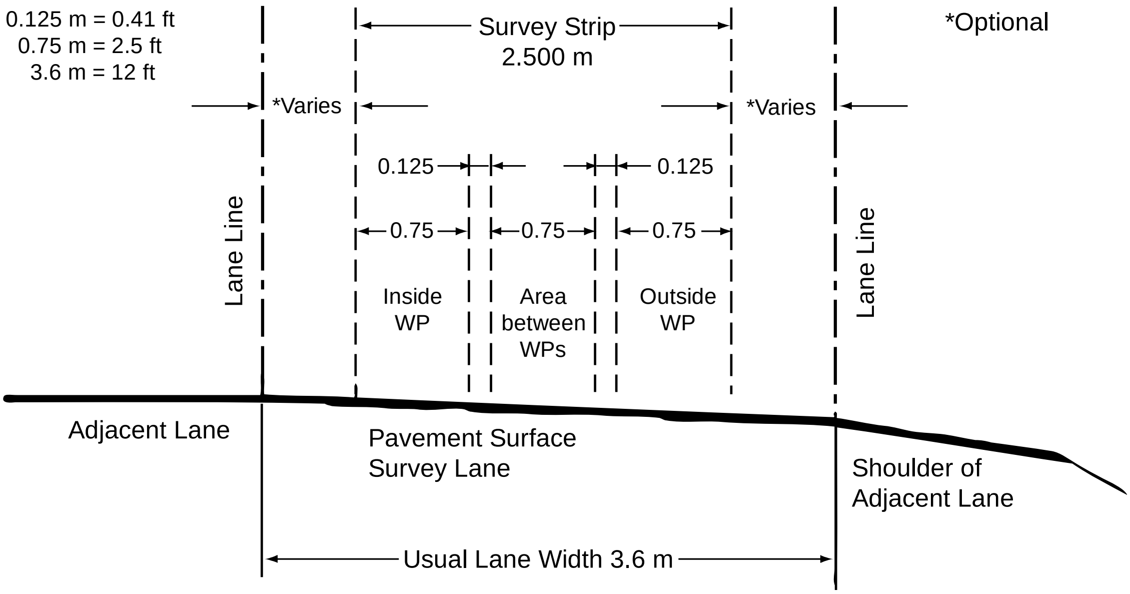

Figure 1—Cross Section of Survey Lane Showing Wheelpaths and Defined Survey Area between Wheelpaths

4.3.3. Determining any additional non-wheelpath cracking for the remainder of the lane width is optional and will be defined by the agency.

4.3.4. Classify cracking by severity and intensity as indicated below.

4.3.4.1. *Severity Level 1*—Cracks ≤3 mm (≤$^1/_8$ in.).

4.3.4.2. *Severity Level 2*—Cracks with dimensions >3 mm (>$^1/_8$ in.) and ≤6 mm (≤$^1/_4$ in.) width.

4.3.4.3. *Severity Level 3*—Cracks with dimensions >6 mm (>$^1/_4$ in.) width.

4.3.5. Quantify intensity of cracking at each level as the total length of cracking per unit area (m/m^2 or ft/ft^2) for each defined survey strip as shown in Figure 1.

Note 3—The sample area is a function of the sample length the agency has chosen in Section 5.

5. RECORDING OF DATA

5.1. *Automated Data Collection*—The entire length of the pavement shall be surveyed (100 percent sample). The data summary interval shall be 0.1 km (0.062 mi).

5.2. *Manual Data Collection*—The number of samples for a given homogeneous section of pavement is determined by the desired confidence level and the variance in the samples. The minimum 85 percent confidence interval of the mean should be no greater than 10 percent of its value. Each section shall have at least four samples. For the purpose of establishing the confidence level, the total crack length for all severity levels within a survey strip may be added together. Table 1 shows the confidence interval for example sample counts and confidence levels as a function of the standard deviation of the samples. It is understood that the samples should be distributed throughout the section.

Table 1—Confidence Interval for Sample Counts

CONFIDENCE INTERVAL		
Number of Samples	85 Percent Confidence	95 Percent Confidence
5	1.034*s*	1.802*s*
10	0.691*s*	1.204*s*
20	0.476*s*	0.829*s*

Note: Where *s* is the standard deviation of the samples

5.2.1. *Data Collection Section*—This section should be a relatively homogenous section of pavement based on visible construction and general condition. Section length may be determined from historical data sources or by delineators inserted during data collection. The more homogeneous the section, the fewer samples required to achieve the required confidence.

5.2.2. *Data Collection Sample*—The exact length of each data collection sample is determined by the agency and shall be between 0.03 km (0.02 mi) and 1.0 km (0.62 mi). Larger samples tend to have less variation.

Note 4—Agencies should experiment with sample size, number, and section definition to minimize the data collection effort necessary to achieve the required confidence.

6. REPORT

6.1. An example of a report is given in Table 2.

Table 2—Example of Data Reporting

Severity Level	Outside Wheelpath, m/m^2	Inside Wheelpath, m/m^2	Between Wheelpath, m/m^2	Optional Areas and Distress		
				Edge Cracking	Joints	Transverse Cracking
1	12	19	5	User defined	User defined	User defined
2	25	10	2	User defined	User defined	User defined
3	10	12	4	User defined	User defined	User defined

6.2. *At a minimum, report the following data*:

Note 5—For reporting requirements, “sample” in the manual data collection mode is equivalent to “interval” for the automated data collection mode.

6.2.1. *Section Identification*—For each data collection section, the agency shall list all information necessary to locate the section using their current referencing system;

6.2.2. Length of the data collection section (km (mi));

6.2.3. Sample length (m (ft)) if not 100 percent;

6.2.4. *Sample Location*—The beginning location of the sample;

6.2.5. Length within the sample for each severity level of wheelpath cracking (m (ft));

6.2.6. Length within the sample for each severity level of non-wheelpath cracking (m (ft)); and

6.2.7. The date of collection (month/day/year).

7. KEYWORDS

7.1. Asphalt pavement; between wheelpath; crack; edge cracking; inside wheelpath; outside wheelpath; pavement management; survey strip; transverse crack.

8. REFERENCES

8.1. FHWA, Highway Performance Monitoring System Reassessment 2010+, available at http://www.fhwa.dot.gov/policy/ohpi/hpms/2010/ch2.cfm.

APPENDIX

(Nonmandatory Information)

X1. QUALITY ASSURANCE

X1.1. *Quality Assurance Plan*—Each agency shall develop an adequate quality assurance plan. Quality assurance includes survey personnel certification training, accuracy of equipment, daily quality control procedures, and periodic and ongoing control activities. The following guidelines are suggested for developing such a plan.

X1.2. *Qualification and Training*—Agencies are individually responsible for training and qualifying their survey personnel and/or qualifying contractors for proficiency in pavement rating or in operating equipment that must be used as a part of quality assurance.

X1.3. *Equipment*—The basic output of any equipment used shall be checked or calibrated according to the equipment manufacturer's recommendations. The equipment must operate within the manufacturer's specifications. A regular maintenance and testing program must be established for the equipment in accordance with the manufacturer's recommendations.

X1.4. *Validation Sections*—Sections shall be located with established cracking types and levels. These sections shall be surveyed on a monthly basis during data collection season. Comparison of these surveys can provide information about the accuracy of results and give insight into which raters or operators need additional training. Validation sections shall be rotated or replaced on a regular basis in order to ensure that raters or operators are not repeating known numbers from prior surveys. As an alternate to this procedure, up to 5 percent of the data may be audited and compared as a basis for a quality check.

X1.5. *Additional Checks*—Additional checks can be made by comparing the previous year's survey summaries with current surveys. At locations where large changes occur, the data shall be further evaluated for reasonableness and consistency of trends.

Standard Practice for

Certification of Inertial Profiling Systems

AASHTO Designation: R 56-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Certification of Inertial Profiling Systems

AASHTO Designation: R 56-10[1]

1. SCOPE

1.1 This practice describes a certification procedure for test equipment used to measure a longitudinal surface elevation profile of highways based on an inertial reference system that is mounted on a host vehicle. The minimum requirements stipulated herein are intended to focus on the need for accurate and repeatable profile measurements during construction. It is also applicable to certifying the performance of profiler systems utilized in network data collection.

1.2 This practice describes minimum performance requirements for inertial profiling systems to be used for quality control/quality assurance (QC/QA) of surface roughness on Owner-Agency paving projects where a profile-based roughness construction specification is applicable. The same approach should be utilized for network data collection systems; however, different performance criteria may be employed.

1.3 The filtering methods and threshold values recommended in this document were established to ensure adequate determination of the International Roughness Index (IRI) and the profile features that affect it. An Owner-Agency planning to use an index other than the IRI should filter the profile and set thresholds accordingly. In particular, replace the preprocessor filter in Step 3, Appendix X.1 with a filter that corresponds to the relevant waveband for the alternative index.

1.4 If any part of this practice is in conflict with referenced documents, such as ASTM Standards, this practice takes precedence for its purposes.

1.5 *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this practice to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 328, Inertial Profiler
- R 57, Operating Inertial Profiling Systems
- R 40, Measuring Pavement Profile Using a Rod and Level

2.2 *ASTM Standards*:

- E 867, Standard Terminology Relating to Vehicle-Pavement Systems
- E 1926, Standard Practice for Computing International Roughness Index of Roads from Longitudinal Profile Measurements

2.3 *Other*:

- Karamihas, S. M. Development of Cross Correlation for Objective Comparison of Profiles. *International Journal of Vehicle Design*, Vol. 36, Nos. 2/3 (2004), pp. 173–193.

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *high-pass filtering*—reduces the effect of long wavelengths that are associated with gradual elevation changes such as hills.

3.1.2 *International Roughness Index (IRI)*—a statistic used to determine the amount of roughness in a measured longitudinal profile. The IRI is computed from a single longitudinal profile using a quarter-car simulation as described in the paper "On the Calculation of International Roughness Index from Longitudinal Road Profile" (Sayers 1995). Computer programs to calculate the IRI statistic from a longitudinal profile are referenced in ASTM E 1926.

3.1.3 *longitudinal profile*—a two-dimensional slice of the roadway surface taken along the travel direction, such as along the wheel path. It represents the perpendicular deviations of the pavement surface from an established reference parallel to the horizontal.

3.1.4 *report interval*—the longitudinal distance between the outputs of a profile index value.

3.1.5 *sample interval*—the longitudinal distance between data capture points. The data include location, height, and accelerometer values. These data points are combined to create one profile data point. These points, in turn, may be combined to create a final value in the reported profile.

4. SIGNIFICANCE AND USE

4.1 This practice outlines standard procedures for certifying and verifying the operational accuracy and repeatability of inertial profiling equipment. It also provides guidance for qualifying the equipment operators.

5. EQUIPMENT

5.1 *Minimum Requirements*—The inertial profiling system must meet all requirements and specifications found in M 328.

5.2 *Operating Parameters*—The inertial profiler must be capable of providing relative elevation measurements that meet the following requirements:

5.2.1 *Report Interval*—The interval at which relative profile elevations are reported must be less than or equal to 2 in.

5.2.2 *High-Pass Filter*—The algorithm for high-pass filtering the profile data shall have an undistorted response (profile amplitude and location error of less than 5 percent) for all wavelengths shorter than 150 ft when operated between 20 and 70 mph for high-speed profilers and 15 and 25 mph for low-speed profilers. It shall also have a minimum of a 30 percent reduction in profile amplitude for wavelengths longer than 300 ft. The filter will have a minimum of a 70 percent reduction for wavelengths longer than 450 ft.

5.3 The profiler software must also be able to calculate and report the IRI (in inches per mile and appropriate SI units) from the corresponding measured true profile and permit the operator to:

- Automatically trigger the start of data collection at the designated location;
- Provide the measured true profiles in electronic text files following the formats prescribed by R 57, in addition to any binary data file storage provided. These profile data are necessary to evaluate profiler accuracy and repeatability and to verify the height and distance measurements as described herein.

6. EQUIPMENT CALIBRATION VERIFICATION

6.1 *General*—This section refers to two important calibration and verification procedures: the block test and the bounce test. It is highly recommended that operators perform these procedures and calibrate their distance measurement instrument (DMI) immediately prior to certification and on a regular basis during normal operation as recommended by the manufacturer. Operators should adhere to the procedures specified in R 57 for calibrating and checking their equipment. The certifying agency shall provide adequate opportunity and facilities to perform these procedures, but it is the responsibility of the profiler operator to provide the needed equipment (e.g., calibration blocks, etc.).

6.1.1 *Calibration Verification Log*—Maintain a log that is to be kept with the inertial profiler to provide a verification of calibration history. The results of the routine bounce tests and verification runs should also be included in this log. The log should contain a record any repairs, replacement of components, and changes in native software versions. If the log is electronic, a backup copy should be kept in a secure location.

7. OPERATOR CERTIFICATION

7.1 Operators of inertial profilers used for QA testing of pavement ride quality must pass a proficiency test and be certified to operate an inertial profiler. Applicants for certification will be tested on the following:

- Owner-Agency ride smoothness specification,
- Operating inertial profilers,
- Collection of profile data, and
- Evaluating the quality of the data collected and the IRI value calculated.

Applicants for certification shall undergo both written and practical examinations. They must pass both portions of the test to be certified. Prior to taking the proficiency test, applicants should have completed a profile training course such as NHI Course 131100 and must have undergone training on the use of the specific inertial profiler they will be operating in the field. Applicants must know how to perform vertical and horizontal calibrations and collect profile data with the inertial profiler. Applicants must bring the inertial profiler with them at the time of testing.

Upon passing the proficiency test, successful applicants will be given documentation that will verify that they are certified to operate the inertial profiler for QA testing on paving projects. The documentation shall identify the specific type or brand of inertial profiler the operator is certified to operate. The initial duration and requirements for renewal of this certification shall be set by the Owner-Agency. Renewal should be required at least every 3 years.

8. EQUIPMENT CERTIFICATION

8.1 Certification frequency shall be as specified by the Owner-Agency. The inertial profiler must successfully perform and pass certification tests to establish compliance with the minimum requirements for accuracy and repeatability set forth in this procedure. An inertial profiler shall be recertified after any major component repairs or replacements as identified in R 57.

8.2 *Dynamic Certification Testing*—Certification tests shall be conducted at a site approved by the Owner-Agency, and involve test sections, reference profiles, and devices used to establish reference profiles as described in the following:

8.2.1 *Test Sections*—Perform dynamic certification testing on sections over a range of roughness. The reference profiles on the smooth section shall have an average IRI within the range of 30 to 75 inch per mile while the corresponding reference profiles on the medium-smooth section shall have an IRI within the range of 95 to 135 inch per mile. If pavements with considerable distress are to be measured, as in network data collection, a third, medium-rough, site should be selected with roughness up to 200 inch per mile.

The surface macro-texture of the test sections should reflect common Owner-Agency specifications for the pavement surfaces to be evaluated. It is imperative that all the surface types on which the profiler will be expected to collect data be included in this process since current height sensors remain sensitive to some surface features.

Each test section will be at least 528 ft in length, with proper lead-in distance and a safe stopping distance available. For complete evaluation, the test section length should approach four times the length of the longest wavelengths being considered.

Test sections should not include significant grade or grade change. Also, significant horizontal curvature or super-elevation should be avoided. If any lateral "g" forces or vehicle roll are sensed during testing at the highest speed employed, the course has too much curvature or single wheel-path elevation changes.

Note 1—Coarse surface textures, such as those found on open-graded surface mixes, chip-sealed, tined (transverse or longitudinal), or grooved pavement, for example, are very challenging to inertial profilers with dot, single point height sensors. Coarse texture is likely to adversely affect the repeatability and accuracy of the profile and the calculated index. Adherence to the requirements of this standard on smooth-textured surfaces does not guarantee acceptable performance of inertial profilers on coarse-textured surfaces. Certification testing on surfaces with the same texture type expected in the final application is required.

8.2.2 *Reference Profiles*—The reference profile for each test section shall be measured in accordance with R 40 except that the maximum horizontal measurement interval and reporting interval shall not be greater than 2.75 in. and the minimum vertical resolution shall not exceed 0.01 in. Other Owner-Agency approved survey techniques that produce third order or better survey accuracy may be used.

Devices that measure and integrate differential elevations, such as the Dipstick® and Walking Profiler, may be used to establish the reference profiles using multiple staggered runs as required to meet the interval requirement. However, the measurements from these devices must be checked with the rod and level at distances along the test profile trace that are multiples of the reporting interval for these devices. The rod and level measurement locations shall be no more than 100 ft apart. Reference profile measurements shall be made on the designated profile trace of each test section as well as on the lead-in to the section. The measured lead-in distance shall be at least equal to the longest wavelength of interest (150 ft for the profiles used to collect IRI). The total lead-in should be at least two times the longest wavelength of interest, with four times being very desirable.

8.2.3 Ten repeat runs of the candidate inertial profiler shall be made on the designated profile trace of each test section in the prescribed direction of measurement. For high-speed profilers, make five runs at the maximum desired certification speed and five runs at the minimum certification speed. Data collection shall be automatically triggered at the starting location of each run of the section, and reported so that a longitudinal position of "zero" occurs at the starting location. An automatically detected mark at the end of the section may be used to verify the DMI repeatability and accuracy.

8.3 *Test Data*—Profile data shall be reported in a format specified by the Owner-Agency.

8.3.1 During the certification tests, the same trace(s) is measured for all runs on a given test section. There will be twice as much data collected and analyzed when dual-path inertial profilers are tested. To facilitate the analysis of the data, the files from the tests described herein shall be named according to the following convention:

- The first three characters of the file name are reserved for identifying the profiler tested. This identification will be established by the testing agency and given to the operator of the profiler on or before the day of testing.
- The fourth character shall be "S" for runs made on the smooth section or "M" for runs on the medium-smooth section and "R" for runs made on the medium-rough section.
- The fifth character shall be "L" or "H" for low- or high-speed runs. "G" is used for governed runs on lightweight profilers.
- The sixth character shall designate the trace or wheel path tested. For dual-sensor profilers, the letter "B" shall be used to indicate that both wheel paths were profiled in the same run. For single-sensor profilers, the designation for the test trace will be given by the testing agency to the operator of the profiler on or before the day of testing.
- The seventh and eighth characters shall designate the run number (01 to 10).
- The file extension shall be the one appropriate for the data type being transmitted and will be specified by the agency.

8.3.1.1 The performance of the profiler is evaluated by analyzing the test data using cross correlation as described in the following sections to establish the repeatability and accuracy for the application of the device. The profiles are filtered to focus the evaluation on the profile features critical to the index being subsequently applied to the collected data. The available free software ProVAL can perform the calculations specified below. The method employed is described in the "Development of Cross Correlation for Objective Comparison of Profiles" by S. M. Karamihas, published in the *International Journal of Vehicle Design*, Vol. 36, Nos. 2/3 (2004), pp. 173–193.

8.3.1.2 *Equipment Repeatability*—Evaluate repeatability using cross correlation of the filtered output as described in Section 8.3.1.4. Calculate the repeatability agreement score of each trace. For single-sensor set profilers, one score for each path will be determined: one for the path in the smooth section, one for the medium-smooth section, and one for the medium-rough section as defined in Section 8.2.1. For dual-path profilers, twice as many scores will be determined, two for each test section.

When the IRI is applied to the profile, the IRI filter should be used. On each trace, cross correlate each of the ten profiles to each of the remaining nine. (Since all of the profiles have the same reporting interval, 45 comparisons will be needed rather than 90 because the process has reciprocity.) The repeatability agreement score for each trace is the average of all 45 values. For IRI, experience has shown that on pavements with IRI values less than 150 inch per mile, an agreement score of 0.92 or greater is required on all traces to provide IRI values within 5 percent with a 95 percent confidence level. A lower agreement score may be acceptable for other applications such as network-level collection given the higher distress levels encountered.

If an alternate index is applied, a filter appropriate to that index should be applied and suitable thresholds established based on independent analysis.

8.3.1.3 *Equipment Accuracy*—Evaluate accuracy using cross correlation of the appropriate filtered output as described in Section 8.3.1.4. On each trace, cross correlate each of the ten profiles to the reference profile. The accuracy agreement score for each trace is the average of the ten individual cross correlation values. Based on the same rationale as in Section 8.3.1.2, a score of 0.90 or greater for applications using IRI should be required for passing for new construction quality control.

A different value may be acceptable in applications utilizing other indexes.

8.3.1.4 *Cross Correlation*—Cross correlate profiles as described in Appendix X1. When cross correlating two profiles, the following processing steps are required:

- If the reference profile contains grade information, it should first be removed by application of a high-pass filter set at least three times the longest wavelength of interest.
- Apply the filter associated with the application to both traces before cross correlating them. For profiles used to determine the IRI, the IRI filter should be applied.
- When comparing a profile from a candidate device to a reference profile, interpolate the candidate profile to the recording interval of the reference profile. (It is important that this step is performed *after* the filter is applied.)
- Cross correlate the two profiles several times by shifting one profile over every possible offset up to 3 ft in either direction. When comparing a profile from a candidate device to the reference device, shift the candidate profile.
- The cross correlation of the two profiles is the maximum (best) value found over the 6-ft range.

8.3.2 *Verification of Computed Ride Statistics (IRI)*—The test equipment software must be capable of computing and reporting the IRI of each profile trace tested. The performance of the calculation software is verified by comparing the calculated values with the values determined by a program of known accuracy. An example of such a program is ProVal. Each IRI value should be comparable to the value from the reference program with an error not greater than 2 percent. Other ride indexes may be verified in a similar fashion.

8.4 *Distance Measurement Index Test*—Test the accuracy of the DMI on one test section.

8.4.1 *Distance Measurement Index Test Section*—Provide a section for DMI testing. The test section will be at least 1000 ft in length, with proper lead-in distance and a safe stopping distance available. This test section may incorporate the test sections that are used for accuracy and repeatability testing. Clearly mark the starting and ending points of the test section. Measure the distance between the starting and ending points with a temperature-compensated steel tape, pulled taut but still following the pavement contour.

Note 2—The same runs may be used for verification of DMI accuracy as are used for testing accuracy and repeatability of the collected profile. The ideal test of DMI accuracy would be performed over a known but undisclosed length of pavement.

8.4.2 At least three auto-triggered runs at the lowest and highest test speeds of the candidate inertial profiler shall be made on the designated length of pavement in the prescribed direction of measurement. At the end of each run, record the reading from the profiler's DMI. For high-speed profilers, this results in at least six values. Collection speed governed devices should make at least five runs.

8.4.3 *Distance Measurement Index Accuracy*—Compute the absolute difference between the DMI readings and the known distance of the path tested for each run. The average of the absolute differences for both the high-speed and low-speed runs, if applicable, must be less than 0.15 percent to pass the test.

8.5 *Test Results*—The results of the certification tests shall be documented by the testing agency. The distribution of the results of the certification shall be determined by the testing agency. Results of certification shall include the following information:

- Identification of the profiler tested (i.e., make, model serial number, software version, Owner, etc.);
- Date of last certification;
- Operator of the profiler;
- Name of the individual from the testing agency who conducted the test;
- Date of test;
- Number of paths the profiler can measure in the same run;
- Filter type, name of the filter program, and the applicable program version number used to evaluate the profiler accuracy;
- Overall determination from the test: Pass or Fail;
- Known longitudinal distance of the DMI test section; and
- Average absolute difference between the DMI readings and the known distance, expressed in distance unit and as a percentage of the known longitudinal distance.

The following information is to be provided for each trace:

- Overall repeatability score;
- Overall accuracy score;
- The average percent difference of the IRIs computed from the profiles and those from the reference software.

8.6 The report will also label each test result with a Pass or Fail depending on whether the given test value meets or fails to meet the prescribed criterion. The profiler must pass all tests to be certified. A decal or other approved marking shall be placed on the profiler as evidence of certification. This decal shall show the expiration date (month and year) of the certification.

9. KEYWORDS

9.1 Inertial profiler; IRI; International Roughness Index; pavement ride quality; profiler certification.

APPENDIX

(Nonmandatory Information)

X1. CROSS CORRELATION

X1.1. Cross correlate any pair of profiles using the following steps. When cross correlation is performed for repeatability analysis, either profile may be selected as the "reference."

Step 1: Identify a reference profile (*Q*). It will also be considered the location reference. As such, the start of the section of interest shall occur at a longitudinal location of "zero," with at least 150 ft of profile upstream of the section start and 5 ft of profile after the section end. The profile will have a recording interval Δx.

Step 2: Identify a segment of the correlated (or candidate) profile (*p*). Using auto-triggering, the profiler should place the section starting point at a longitudinal location of "zero," with at least 150 ft of profile upstream of the section start.

Step 3: Preprocess the reference profile and the candidate profile by applying the IRI filter to them. This includes the 9.84-in. moving average, the conversion to slope, and the quarter-car simulation.[2]

Step 4: Crop the preprocessed reference profile to include only the section of interest. For a section length of L_q, a number of samples within the section of interest is $N_q + (L_q/\Delta x + 1)$. Offset the cropped profile to have a mean of zero. Calculate the standard deviation of the preprocessed, cropped, and shifted reference profile (*q*), and the result is σ_q.

Step 5: Rewrite the preprocessed candidate profile (*p*) to the recording interval of the reference profile (*q*). Calculate the value at each location using linear interpolation of the surrounding points. Offset the resulting profile to have a mean of zero. The preprocessed, interpolated profile (*p*) will be cross correlated to the reference profile.

Step 6: Cross correlate the reference profile (*q*) to the candidate profile (*p*) several times, over a range of longitudinal offsets from a lead of 3 ft to a lag of 3 ft. For a sample interval of Δx, cross correlation will be performed $2M + 1$ times, where $M = \text{int}(3/\Delta x)$, where Δx is in feet.[3] This produces a correlation function, ρ_m, where *m* is an integer subscript that ranges from $-M$ to M:

$$\rho_m = \frac{1}{\max\left(\sigma_{\hat{p}}, \sigma_q\right)^2} \sum_{i=1}^{N_q} \left(\hat{p}_{i+m} q_m\right)$$

Each increment of the subscript m represents a unique longitudinal offset of the candidate profile of $m\Delta x$. At each step (i.e., each increment of the subscript *m*), the candidate profile (*p*) must be conditioned by removing the mean to produce a vertically shifted profile $\left(\hat{p}\right)$. Note also that the standard deviation of the candidate profile $\left(\sigma_{\hat{p}}\right)$ must be recalculated at each step.

Step 7: Search the function ρ_m for its maximum cross correlation value $\rho_{\max}$.

Step 8: Calculate the adjustment factor for overall roughness as follows:

$f = \min(\sigma_p, \sigma_q)/\max(\sigma_p, \sigma_q)$

Step 9: Calculate the "agreement score" for the two profiles: $f \bullet \rho_{\max}$.

---

[1] Formerly PP 49. First published as a full standard in 2010.

[2] Application of the IRI filter is described in "On the Calculation of International Roughness Index from Longitudinal Road Profile" (Sayers 1995). Do NOT rectify the signal (i.e., do not take the absolute value of every point in the signal).

[3] The "int()" function truncates the argument at the decimal point.

Standard Practice for

Operating Inertial Profiling Systems

AASHTO Designation: R 57-10[1]

American Association of State Highway and Transportation Officials

Washington, D.C. 20001

Standard Practice for

Operating Inertial Profiling Systems

AASHTO Designation: R 57-10[1]

1. SCOPE

1.1. This practice describes the procedure for operating and verifying the calibration of an inertial profiling system. This practice is meant to be performed as a Quality Control/Quality Assurance (QC/QA) test for use with the appropriate smoothness specification for paving operations. It is not meant to be required as a QA procedure to monitor daily paving operations; however, this method is recommended when inertial profiling systems are used for QC testing and for network-level data collection.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 328, Inertial Profiler
- R 56, Certification of Inertial Profiling Systems

2.2. *ASTM Standards*:

- E 1926, Standard Practice for Computing International Roughness Index of Roads from Longitudinal Profile Measurements
- E 2560, Standard Specification for Data Format for Pavement Profile

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *International Roughness Index (IRI)*—a statistic used to determine the amount of roughness in a measured longitudinal elevation profile. The IRI is computed from a single longitudinal elevation profile using a quarter-car simulation as described in the paper “On the Calculation of International Roughness Index from Longitudinal Road Profile” (Sayers 1995). Computer programs to calculate the IRI statistic from a longitudinal elevation profile are referenced in ASTM E 1926.

3.1.2. *longitudinal elevation profile*—a series of relative pavement surface elevation measurements taken along a longitudinal path and referenced to a common horizontal datum.

3.1.3. *roughness*—the deviation of a surface from a true planar surface with characteristic dimensions that affects vehicle dynamics and ride quality.

4. SIGNIFICANCE AND USE

4.1. This practice outlines standard procedures for operating inertial profiling systems for project level QC/QA determinations. These procedures can also be used for network-level data collection and analyses and are recommended for project-level QC determinations.

5. EQUIPMENT

5.1. *Minimum Requirements*—The inertial profiling system must meet all requirements and specifications found in M 328 and must be currently certified in accordance with R 56.

Note 1—For consistent pavement profile determination, maintain air pressure on the wheels of the host vehicle according to the manufacturer's specification. The host vehicle and all system components will be in good repair and proven to be within the manufacturer's specifications. The operator of the inertial profiler shall have all tools and components necessary to adjust and operate the inertial profiler according to the manufacturer's instructions.

5.2. *Repair, Adjustment, and Upgrade of Inertial Profilers*:

5.2.1. Major component repairs or replacement to an inertial profiler that would require the recertification of the equipment include, but are not limited to, the following:

- the accelerometer and its associated hardware;
- the noncontact height sensor and its associated hardware;
- any printed circuit board necessary for the collection of raw sensor data or the processing of the inertial profiles;
- change of host vehicle in the case of permanently mounted equipment; or
- major repairs to host vehicle.

5.2.2. The operator of the inertial profiler will be allowed to make minor adjustments to the equipment without having to complete the recertification process as long as the adjustments allow the equipment to fulfill the verification of calibration process in Section 5.3. Minor adjustments to the system include, but are not limited to, the following:

- inspecting, resoldering, or replacing connectors;
- cleaning components, normal adjustments to power supply voltage levels as required by the manufacturer;
- setting software parameters and/or scale factors as required by the manufacturer in a routine calibration procedure; or
- mounting on different suitable host vehicle(s) in the case of portable equipment.

5.3. *Verifying Calibration*—The following verification procedure is required for QA testing and is recommended when an inertial profiler is to be used as a QC instrument on a daily basis.

5.3.1. *Standards*:

5.3.1.1. *Longitudinal*:

5.3.1.1.1. The longitudinal verification standard shall be a straight and level roadway test section of at least 528 ft in length in addition to lead-in equal to 1.5 times the longest wavelength of interest.

5.3.1.1.2. Measure this length accurately to within 0.05 percent using a temperature-compensated steel survey measurement tape since the distance to be measured is the travel length the wheels encounter.

5.3.1.2. *Vertical*:

5.3.1.2.1. The vertical measurement standard shall be flat plates or blocks of known thickness and low thermal expansion.

5.3.1.2.2. Mark the blocks with the known thickness. Certify the block thickness accurate to within 0.001 in. As a minimum, test a smooth base plate and both a 1-in. and a 2-in. gauge block.

5.3.2. *Procedure*:

5.3.2.1. *Frequency of Verifying Calibration*:

5.3.2.1.1. Perform the longitudinal and vertical verification of calibration of the inertial profiler prior to use on each paving project in accordance with the manufacturer's recommendation and at such times as the Owner-Agency determines that verification is necessary.

5.3.2.1.2. Check the cold tire air pressure on the wheels of the host vehicle at least daily and maintain according to the manufacturer's recommendations.

5.3.2.1.3. Maintain a log with the inertial profiler in accordance with R 56.

5.3.2.2. *Longitudinal Verification of Calibration*:

5.3.2.2.1. Perform the longitudinal verification of calibration by navigating the inertial profiler over a measured test section of at least 528 ft in length in addition to lead-in equal to 1.5 times the longest wavelength of interest.

5.3.2.2.2. The inertial profiler's distance measuring subsystem, after tire and electronic warm-up in accordance with the manufacturer's recommendations, must measure the length of the test section to within 0.15 percent of its actual length.

5.3.2.2.3. Adjust the inertial profiler's distance measurement subsystem according to the manufacturer's guidelines as needed.

5.3.2.2.4. Failure to meet the specified tolerance, after attempts to adjust have been performed, will require recalibration and reverification as described under Verifying Calibration.

5.3.2.3. *Vertical Verification of Calibration*:

Block Test—Vertical height sensor check tests shall be performed in accordance with the manufacturer's recommended procedures. In the absence of manufacturer's procedures, perform the block test as described in Section 5.3.2.3.1.

5.3.2.3.1. *Block Test*—Vertical height sensor check tests are run after the profiler has reached operational stability as specified by the manufacturer. This test will be conducted with the inertial profiler on a relatively flat and level area. Its purpose is to check the height measurements (in inches or millimeters) from the height sensor(s) of the test vehicle using blocks of known heights. During the test, do not lean on the profiler or cause it to move in any way. Under windy conditions, it may be necessary to perform this test indoors. The test procedure consists of the following steps:

- Position a smooth base plate under the height sensor of the profiler and allow the system to take height measurements.
- Position a 0.25-in. block underneath the height sensor on top of the base plate and allow the system to take height measurements.
- Carefully remove the 0.25-in. block from the base plate and replace it with a 0.50-in. block. Make another set of height measurements.
- Carefully replace the 0.50-in. block with a 1.00-in. block and take another set of height measurements.
- Finally, carefully replace the 1.00-in. block with a 2.00-in. block and take the last set of height measurements.

As a minimum, test a base plate and both the 1-in. and 2-in. measurement blocks. If the equipment fails the minimum test, then perform the full range of check tests to determine system linearity problems, stand-off problems, or complete system failure.

The owners of the profiler must furnish their own base plate and gauge blocks. Measure the thickness of the gauge blocks at three different positions on each side of the plate or block with a device capable of measuring to the nearest 0.001 inch. For each block, an average thickness shall be determined from the measurements made which shall be used in checking the height sensors as described in this test. The average thickness shall be marked on each gauge block.

The operator of the profiler should tabulate the measurements and record them in a calibration log.

Determine the difference between each measurement on a gauge block and the average of the ten measurements on the base plate to get the thickness of the gauge block as measured by the height sensor. Repeat this calculation for each gauge block. Determine the absolute values of the differences between the computed thickness and the known average block thickness. The average of the absolute differences should be less than or equal to 0.01 in. for each gauge block.

5.3.2.3.2. *Bounce Test*—To perform the bounce test, position the host vehicle on a surface as flat and level as possible. Power the system and ensure the profiler has reached operational stability as specified by the manufacturer. Center a thin, smooth, flat, non-glossy material plate under each sensor. Using the equipment's normal data collection software, initiate a data collection run using a simulated travel speed at the midpoint of the manufacture's recommended data collection speed range. (The only difference between a bounce test and a normal data collection run is that there is an artificial longitudinal travel signal supplied and the vehicle is not actually traveling along the road. The bounce test utilizes the same data collection software and routines used during normal data collection.)

The bounce test will require a profile collection run with a minimum simulated travel distance of 2,184 ft. Allow the profiler to collect a minimum of 828 ft of static profile with the host vehicle as motionless as possible. Next, the sensor(s) should be moved vertically for a total displacement of approximately 1 to 2 in. (a yardstick may be helpful until the operator gets used to the procedure) keeping the sensors as close to perpendicular to the surface as possible during this movement. This movement must continue until a minimum of 528 ft of simulated longitudinal distance has been covered.

The typical method for full-size high-speed host vehicles is to push the mounting system (bumper) down an inch or so and let the vehicle suspension rebound to create the total vertical travel of 1 to 2 in. The typical method for lightweight slow-speed host vehicles is to stand toward the center of the vehicle platform and hop up and down such that all four corners of the vehicle suspension travel approximately 1 to 2 in. vertically. After a minimum of 528 ft of bounce profile is collected, allow the profiler to collect an additional minimum of 828 ft of static profile. The profiles shall then be saved and analyzed in ProVAL using the Ride Statistics Continuous analysis with a 528 ft base length for each profile collected.

When reviewing the analysis results, ignore the first and last 300 ft of the profile as it is lead-in and lead-out distance. Ensure the remaining static portions result in an IRI of less than 3 in. per mile and the bounce portion is less than 8 in. per mile. The two static IRI portions should be about the same. See Appendix X1 for further details concerning the bounce test.

5.3.2.4. *Daily Measurement Control*—The operator should select a reasonable method to verify daily that the inertial profiling system utilized can produce consistent results under normal operating conditions on pavements typically encountered during data collection. Options include using a Test Section as described in R 56; Control Sections, or Checks using previous day's data. The surface texture of the section used for daily verification should be similar to that on which measurements are to be obtained for QC/QA purposes.

5.3.2.4.1. Control sections can be established by selecting one or more 0.1-mile sections with a maximum IRI of 120 in. per mile that will maintain a consistent ride profile over the time period when daily checks are needed. A profiler certified within the past 90 days should determine the IRI of the section by making a series of at least five profile measurements. The average IRI of the measurements shall be used to establish the IRI of the control section; provided that the cross correlation of the measurements as determined using the latest version of ProVAL is at least 88 percent (value is dependent on the filters used, spectral content of the measured surface, operator, etc.). Once established, this control section can be used to validate on a daily basis that an inertial profiler is operating properly. A control chart should be established and maintained by plotting daily runs to determine profile drift as the section ages. Typically, no single IRI determination should vary more than 5 percent from the original control section IRI.

5.3.2.4.2. Checks using the previous day's data can be used when data is being collected on a fairly continuous basis such as on a construction project or during annual network-level analyses. Under these circumstances, it is possible to rerun short sections of pavement that were measured on the previous day for comparison purposes. The current day's IRI value should not differ by more than 6 percent from the previous day's IRI value.

5.3.2.4.3. *Calibration Verification Log*—Maintain a log to be kept with the inertial profiler in accordance with R 56.

6. TEST PROCEDURE

6.1. Table 1 outlines the steps for measuring the pavement profile using an inertial profiler.

Table 1—Measuring Pavement Profile for QA Purposes

Step	Action
1	Clean the roadway path to be measured of all debris and other loose material.
2	When measuring the pavement profile, operate the inertial profiler at a constant speed within the certified range.
	All data collected above or below the certified speed range are not acceptable.[a]
	Remeasure any pavement segment where the travel speed of the profiler is less than or exceeds the manufacture's recommended operational speed at any point during data collection.
3	A pre-section length of roadway of up to 450 ft may be required to stabilize the inertial profiler's filters and achieve the same accuracy in the first 0.1 mile that is achieved through the rest of the job. The pre-section length is dependent on the filter type, the grade change on entering the test segment, and the accuracy required of the first 0.1 mile of measured pavement. Typically, this pre-section shall be at least 300 ft in length and located immediately before the section of pavement to be tested. Shorter sections have been used when the physical constraints of the project required it and the other project conditions made it acceptable.
	Take the inertial profiler measurements on one or more longitudinal lines as specified by the Owner-Agency.
	If two longitudinal traces are specified, set the sensor path spacing to the values specified by the Owner-Agency. If such is not specified, sensor path spacing shall be between 65 and 71 in.
	If two longitudinal traces are specified, but the profiling system collects profile data only in one longitudinal path at a time, the longitudinal traces shall be taken in each wheel path of the lane independently.
4	Collect measurements in the direction of traffic. Multiple runs provide the opportunity to reject runs with known operator and/or equipment errors. When using an inertial profiler that collects a single trace per pass, take care to ensure that the measurements from each trace in a travel lane start and stop at the same longitudinal locations.
5	Data Collection (QA data collection is meant to be performed at the end of the paving operation or staged as prescribed by the Owner-Agency).
	Submit a table to the Owner-Agency that identifies the lane(s), trace(s), and distance location(s) tested for each file created during the QA testing.
6	Present the profile elevation data to the Owner-Agency in an approved electronic file format. The format must be readable by ProVAL.[b]
7	Compute a summary roughness statistic. The recommended index to compute is the continuous IRI reported as a histogram that presents the percentage of the job that falls within IRI categories selected by the agency.

[a] Failure to maintain the minimum certified speed will cause the inertial referencing subsystem to "droop" and the pavement profile elevations will not be usable.

[b] The Owner-Agency will calculate the IRI values and any associated pay factors.

Note 2—ProVAL is a computer software program developed under the auspices of FHWA and is available for use to calculate and compare profiles and their indices. The software also has the ability to calculate the continuous IRI histogram.

6.2. In order to ensure collection of quality profiles, the host vehicle may need to be operated at the lower end of the certified speed range when profiling on vertical and horizontal curves and super-elevations. Higher speeds may cause excessive pitch and roll in the host vehicle, which will adversely affect the integrity of the measurements. In addition, rapid longitudinal accelerations and decelerations (for example, speed changes such as heavy braking) may adversely affect the profile measurements.

6.3. *Test Data Description and Format*—In addition to proprietary file formats, provision shall be made for export of profile data in the format as per ASTM E 2560 or other ProVAL compatible formats.

7. KEYWORDS

7.1. Inertial profiler; International Roughness Index; ride quality; road profile; roughness; smoothness.

APPENDIX

(Nonmandatory Information)

X1. BOUNCE TEST PURPOSE, REASONING, AND ERROR

X1.1. A bounce test is a sanity check on the profiler to ensure that the data from the height sensor and accelerometer are legitimate and being properly combined to compute the longitudinal elevation profile. While the host vehicle is stationary, an artificial signal is supplied to the profiler to simulate a travel speed within the manufacturer's recommended range for collecting road profile data. A routine data collection run is initiated, after which the suspension on the host vehicle is excited to cause the sensor(s) to move vertically. Since the sensor footprint is hovering over the same location, the end result, in theory, should be a perfectly flat and level road profile the IRI of which would equal zero if all is working correctly. In practice, a perfectly flat profile with a zero IRI is not possible. Sources of error in a bounce test include:

- Signal noise of the height sensor, accelerometer, and respective circuitry;
- Inability to position the host vehicle in such a manner that the sensors are perfectly perpendicular to a known flat and level surface;
- Inability to bounce the host vehicle such that sensors maintain a perpendicular orientation to the flat and level surface (sensor footprint moves laterally or fore and aft due to pitch and roll of the host vehicle while bouncing);
- Equipment malfunction; and
- Error in signal and data processing.

X1.2. There are two levels of acceptable error in both static (non-bounce) and bounce profiles in which a minimum of 528 ft of simulated longitudinal distance is traveled. The limits of IRI of those profiles are in 3 in. per mile and 8 in. per mile, respectively.

Standard Practice for

Statistical Procedures

AASHTO Designation: R 4-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Statistical Procedures

AASHTO Designation: R 4-97 (2009)

1. SCOPE

1.1. This standard practice is to provide guidance in the use and application of statistical procedures in the precision analysis of sampling, testing, and acceptance of construction materials.

2. GENERAL PROVISIONS

2.1. It is recommended that AASHTO specifications for materials and for sampling and testing incorporate accepted statistical standard procedures. The following ASTM designations provide guidance in this area and their latest published revisions are adopted as a standard practice for the development of AASHTO standards.

- ASTM C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- ASTM C 802, Standard Practice for Conducting an Interlaboratory Test Program to Determine the Precision of Test Methods for Construction Materials
- ASTM D 2915, Standard Practice for Evaluating Allowable Properties for Grades of Structural Lumber
- ASTM D 3665, Standard Practice for Random Sampling of Construction Materials
- ASTM D 4460, Standard Practice for Calculating Precision Limits Where Values are Calculated from Other Test Methods
- ASTM E 105, Standard Practice for Probability Sampling of Materials
- ASTM E 122, Standard Practice for Calculating Sample Size to Estimate, with Specified Precision, the Average for a Characteristic of a Lot or Process
- ASTM E 141, Standard Practice for Acceptance of Evidence Based on the Results of Probability Sampling
- ASTM E 177, Standard Practice for Use of the Terms Precision and Bias in ASTM Test Methods
- ASTM E 178, Standard Practice for Dealing With Outlying Observations
- ASTM E 456, Standard Terminology Relating to Quality and Statistics
- ASTM E 1488, Standard Guide for Statistical Procedures to Use in Developing and Applying Test Methods
- ASTM G 16, Standard Guide for Applying Statistics to Analysis of Corrosion Data

Standard Practice for

Acceptance Sampling Plans for Highway Construction

AASHTO Designation: R 9-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Acceptance Sampling Plans for Highway Construction

AASHTO Designation: R 9-05 (2009)

1. SCOPE

1.1 *Definition of Acceptance Plan*—An agreed upon method of taking samples and making measurements or observations on these samples for the purpose of evaluating the acceptability of a lot of material or construction (*Transportation Research Circular Number E-C037*, 2002).

1.2 *Purpose of Acceptance Plan*—This standard practice provides guidelines in the preparation of statistically based acceptance plans using statistical and quality assurance (QA) principles. The acceptance plans must be realistic, fair to both the contractor and agency, and must be statistically accurate. This standard practice includes the basic criteria for the most common AASHTO applications. It uses the broad definition of acceptance plan to include the separate functions of both quality control (QC) and acceptance. Other aspects are provided where deemed important, but should not be interpreted to define a complete QA program. References are given for more advanced criteria and special applications.

1.3 *Target Audience*—It is assumed that the user is a mid-level materials engineer and has an understanding of statistics, including the calculation of the mean and standard deviation, the development of histograms, and the use of continuous probability density functions or distributions.

1.4 *Background Sources*—Preparatory knowledge of acceptance plans is included in the course entitled *Materials Control and Acceptance—Quality Assurance* (2000); in the manual *Optimal Procedures for Quality Assurance Specifications* (2003); and in most basic statistics textbooks.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 4, Statistical Procedures
- R 10, Definition of Terms Related to Quality and Statistics As Used in Highway Construction
- R 25, Technician Training and Qualification Programs
- R 38, Quality Assurance of Standard Manufactured Materials

2.2 *ASTM Standards*:

- D 3665, Standard Practice for Random Sampling of Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 178, Standard Practice for Dealing With Outlying Observations
- MNL 7A, *Manual on Presentation of Data and Control Chart Analysis*, Committee E-11 on Quality and Statistics

2.3 *FHWA Standard*:

- FHWA/RD-02/095, *Optimal Procedures for Quality Assurance Specifications*, 2003.

---

3. DEFINITIONS

3.1 *The following definitions are provided in this standard practice to help the reader become acclimated to general QA terms*:

3.1.1 *population (lot)*—a specific quantity of similar material, construction, or units of product subject to either an acceptance or process control decision. This can range from all of the history of a material to a single lot (*Transportation Research Circular Number E-C037*, 2002).

3.1.2 *sample*—a small part of a population (lot) that represents the whole (R 10). This implies a statistical sample. Thus, the use of the term sample size, n, denotes the number of test values used to make a decision. (This should not be confused with size of sample that indicates a quantity of material).

3.1.3 *sampling and testing*—sampling, testing, and the assessment of test results done to determine whether or not the quality of produced material or construction is acceptable in terms of the specifications (R 10). The results are best used to estimate a population. This is true for both QC and acceptance functions. To estimate a population, two measures are needed, one is the center of the estimated population and the other is a measure of its variability.

3.1.4 *types of acceptance plans*—a statistical acceptance plan is one based on either an analysis of variables or attributes. This standard practice focuses on analysis of variables for acceptance. Analysis by attributes is based on noting the presence or absence of some characteristic or attribute. Attribute analysis is most often used in visual inspections or when an item can only be classified as either acceptable or not acceptable or pass/fail. Attribute plans are sometimes used with "screening tests" in which the material is tested before it is incorporated in the construction. Variables analysis is applicable to materials and construction in which quality is evaluated by measuring the numerical magnitude of a quality characteristic. A quality characteristic is a characteristic of a unit or product that is actually measured for acceptance purposes (*Transportation Research Circular Number E-C037*, 2002).

3.1.5 *variability known acceptance plans*—acceptance plans that assume a known and constant variability. These types of acceptance plans measure only the average and are not appropriate for highway materials and construction.

3.1.6 *variability unknown acceptance plans*—acceptance plans that measure both the product average and variability as estimates of a population. This is the type of acceptance plan discussed in this standard practice.

3.2 *For those definitions that are not described within, two useful reference sources are*:

3.2.1 Definition of Terms for Specifications and Procedures (R 10).

3.2.2 Glossary of Highway Quality Assurance Terms (*Transportation Research Circular Number E-C037*, 2002).

4. DEVELOPMENT AND REVISION OF ACCEPTANCE PLANS

4.1 The development and the revision of acceptance plans is a design process that should continuously evolve and improve as new processes, test methods, etc., are found. The development steps outlined below provide a rational development procedure and will be useful to those embarking on an initial statistical acceptance plan. The procedure assumes that some users may want to know how to initiate, proceed through the development, and eventually implement the plan. For those revising an existing plan, some steps may not be needed. However, in both cases it is important that the plan be analyzed to ensure it produces the desired results. The user may enter the steps at any point of interest.

- Initiation and Planning
- Acceptance Plan Development Steps
- Develop QC Procedures
- Develop Acceptance Procedures
- Risks and Risk Analysis
- Pay Factors
- Implementation Steps

5. INITIATION AND PLANNING

5.1 It is important to identify and establish the needs for a new or modified acceptance plan. Some possible reasons for doing this are:

- The present quality levels are substandard.
- Premature failures have occurred that are related to the current acceptance plan.
- A new or different quality measure, e.g., standard deviation, percent within limits, etc., is needed.
- A new quality characteristic, e.g., permeability, resilient modulus, thickness, smoothness, etc., upon which to base acceptance has been identified.
- The risks between contractor and agency are not properly balanced or are too high for one or both.
- A more rigorous acceptance procedure is needed.

5.2 Define the goals and expectations of the acceptance plan. The primary goal is to identify potential benefits to the agency and to the industry. To achieve this goal, determine the criteria to be used to judge success. Examples of these criteria may be improved quality, a more knowledgeable industry, shared responsibility with industry, and/or faster completion times.

5.3 At this point, seek industry acceptance of and participation in the development of the acceptance plan. This is necessary to aid in industry cooperation and eventual positive reception.

6. ACCEPTANCE PLAN DEVELOPMENT STEPS

6.1 Develop the initial acceptance plan for one material and/or construction area, as opposed to several simultaneously. This is recommended to simplify the development process.

6.2 Determine if outside expertise is required. The agency may not have sufficient knowledge in such areas as statistical analysis or new areas such as nondestructive testing.

6.3 Look for other agencies or sources that have developed practices to provide guidance on how to proceed with selection of quality characteristics, the use of pay equations, composite pay factors, etc. Contact and interview those agencies and keep in mind industry associations that may have practices that can be used. Learning from the mistakes that others have made can save time and effort. Conduct a thorough literature search to identify current practices. Recent Transportation Research Board and National Cooperative Highway Research Program publications can provide guidance.

6.4 Develop an outline for the acceptance plan. This includes such items as:

6.4.1 QC requirements,

6.4.2 Acceptance requirements,

6.4.3 Independent assurance (IA) requirements,

6.4.4 Agency validation (if contractor's tests are used in the acceptance decision),

6.4.5 Conflict resolution, and

6.4.6 Determination of pay factors, both individual and combined.

6.5 Develop the acceptance plan introductory information. A fundamental concept in statistical acceptance plans is the separation of the QC and acceptance functions. The contractor is *always* responsible for QC and the agency is responsible for acceptance. Maintaining the separation of the functions for QC and acceptance is very important. Additionally, address the needs and requirements for both technician and laboratory qualification in the introductory information (R 25).

6.6 A very important point that must be understood is the relationship between sample statistics and population parameters for both QC and acceptance procedures. The sample result is always an estimate of the population. The larger the sample size, the better the estimate of the population.

6.7 *Random Sampling*—Random sampling is a sampling procedure whereby any individual measurement in the population is as likely to be included as any other (*Materials Control and Acceptance-Quality Assurance*, 2000).

6.8 A basic assumption in a sampling plan is the necessity of taking samples in a random manner (*Materials Control and Acceptance-Quality Assurance*, 2000). Random sampling is achieved most commonly through the use of random number tables or random number generators on calculators or computers (ASTM D 3665). Random sampling always removes the selection of the sample tonnage, location, time, etc. from the decision of the sampler. Intuitively selecting a "random" sample is not random. Random sampling is a necessary requirement for all acceptance and IA sampling. Under some circumstances it is required for QC sampling.

6.9 Describe and discuss the need for the IA function and how it will be implemented in the acceptance plan. Independent assurance is a management tool that requires a third party, not directly responsible for QC or acceptance, to provide an independent evaluation of the testing process.

6.9.1 The IA program is an independent evaluation of testing procedures and equipment and inspection procedures and is designed to provide continuity to the acceptance plan. It may involve a separate and distinct schedule of sampling, testing, and observation.

6.9.2 It is very important that an IA program compare results and detect deficiencies, when they exist, in a timely manner. This improves the reliability of testing results. The timely comparison of data may be restricted by agency resources, including personnel, facilities, and geographical constraints. These resource needs must be considered in the IA program.

6.9.3 It is very important that qualified personnel conduct IA tests and use different sampling and testing equipment than the equipment used for QC or acceptance.

7. DEVELOP QUALITY CONTROL (QC) PROCEDURES

7.1 *Quality Control (QC)*—Also called process control. Those QA actions and considerations necessary to assess and adjust production and construction processes so as to control the level of quality of the end product (*Transportation Research Circular Number E-C037*, 2002).

7.2 *Purpose of QC*—The purpose of a QC plan is to measure quality characteristics and inspect activities that impact production at a time when corrective action can be taken to prevent nonconforming material from being incorporated in the project. (See *AASHTO Implementation Manual for Quality Assurance* (*1995)* for examples of QC plans for hot mix asphalt (HMA) concrete and both structural and paving portland cement concrete (PCC)).

7.3 A QC plan can be either contractor-specific or generic. Ideally, the plan should be contractor- and operation-specific. However, some agencies choose to develop a generic plan to be used by all contractors or suppliers. In either case, the contractor should develop control limits based on the production capabilities of the specific operation.

7.4 A very important part of a QC plan is the requirement that those persons performing the tests be qualified. This can be accomplished several ways, but some agencies require certification to determine qualification. (See R 25 and R 38 for more detailed information.)

7.5 The QC function is the responsibility of the contractor and is a separate function from acceptance. This means that control limits used for QC control charts must be developed separately from the specification limits.

7.6 Measure the quality characteristics chosen for QC early in the production activity to assess the quality as quickly as practical. Therefore, the QC tests should be relatively rapid tests.

7.7 Examples of QC tests for hot mix asphalt (HMA) are aggregate quality tests, binder physical properties, gradation of critical sieves, degree of aggregate coating, plant and discharge temperatures, moisture content of the fine aggregate and of the finished mix, and the use of a density gauge for field compaction control.

7.8 Examples of QC tests for portland cement concrete (PCC) are aggregate quality tests, gradation of critical sieves, air content, water–cement content, mix temperature, and slump.

7.9 The use of control charts is an important part of the QC function. Statistical control charts are the most effective control charts to use. This tool provides, in real time, the contractor and agency a visual estimate of the population of the quality characteristic being produced.

7.10 Since estimating the population being produced is the purpose of QC, the use of the most appropriate procedures is recommended. The most effective and simplest pair of statistical control charts is the joint use of:

7.10.1 An average chart ($\overline{X}$ chart) to measure the center.

7.10.2 A range chart (R chart) to measure the variability. The range is recommended because of the simplicity to measure it.

7.11 An example of an average and range control chart is shown in Figure 1.

7.11.1 The mean of the $\overline{X}$ chart is the center of production. This may or may not be the center of the specification limits. In fact, there may not be a specification requirement for this QC measure.

7.11.2 Control limits, also called action limits, are boundaries established by statistical analysis for material production control using the control chart technique. When values of the process fall within these limits, the process is "under control" (R 10). The limits are set at the equivalent of $\pm 3\sigma_{\overline{X}}$ from the mean of the $\overline{X}$ chart. Both an upper control limit (UCL) and a lower control limit (LCL) are used.

7.11.3 Since an estimate of variability is desired, the sample size used to plot statistical control charts must be at least two, i.e., $n \geq 2$.

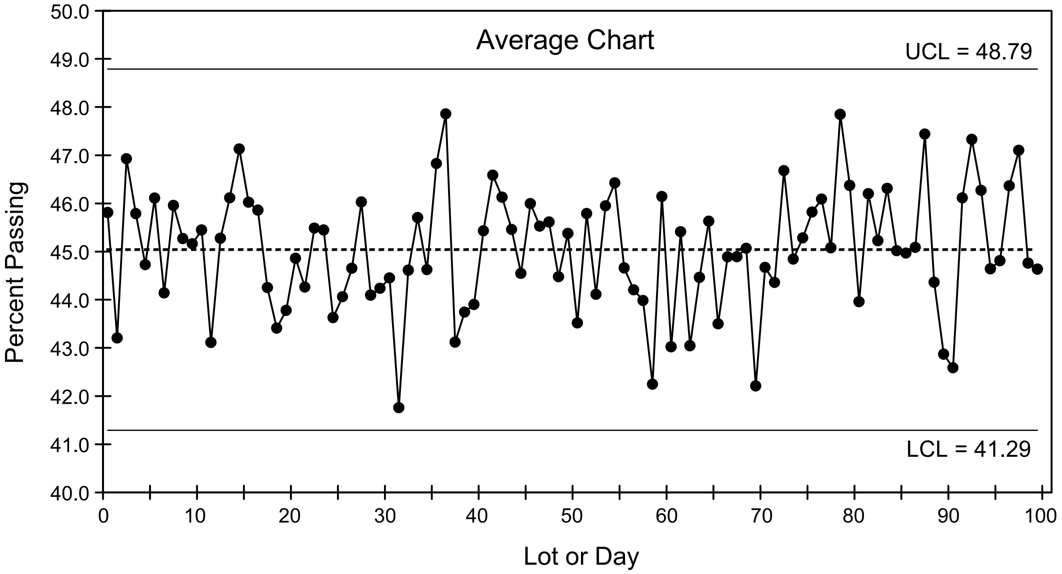
7.11.4 Warning limits are boundaries established on control charts within the UCL and LCL to warn the producer of possible problems in the production process that may lead to the process going out-of-control (R 10). These limits are often set at $\pm 2\sigma_{\overline{X}}$. When values fall outside these limits, there is approximately a 5 percent chance the process is out-of-control. (For the purpose of clarity, these are not shown on Figure 1.)

7.11.5 The center of the R chart is the mean range and the control limits are typically set at $\pm 3\sigma R$. In this case, σR is the standard deviation of the ranges. However, the LCL for the R chart is zero for most practical sample sizes.

7.12 Control limits are intended to show when a process is out-of-control. The chance of a point being more than $\pm 3\sigma_{\overline{X}}$ away from the average is only 0.3 percent. So, a value outside the action limit is an indication that the process has changed.

7.12.1 In the case that a point is more than $\pm 3\sigma_{\overline{X}}$ from the average, the contractor may decide to quickly take another test in an attempt to confirm that the process has, in fact, changed before altering production. If the second test result is close to the first, this provides an indication that the process may have changed. (If a check test is made, include both test results in the QC documentation.) Although the check sample would not have been obtained in a random manner, it is a permissible course of action. This is one good example of why QC and acceptance must be maintained as separate functions.

7.13 The calculation and use of control chart limits are beyond the scope of this standard practice. (See ASTM MNL 7A for more information on control charts.)



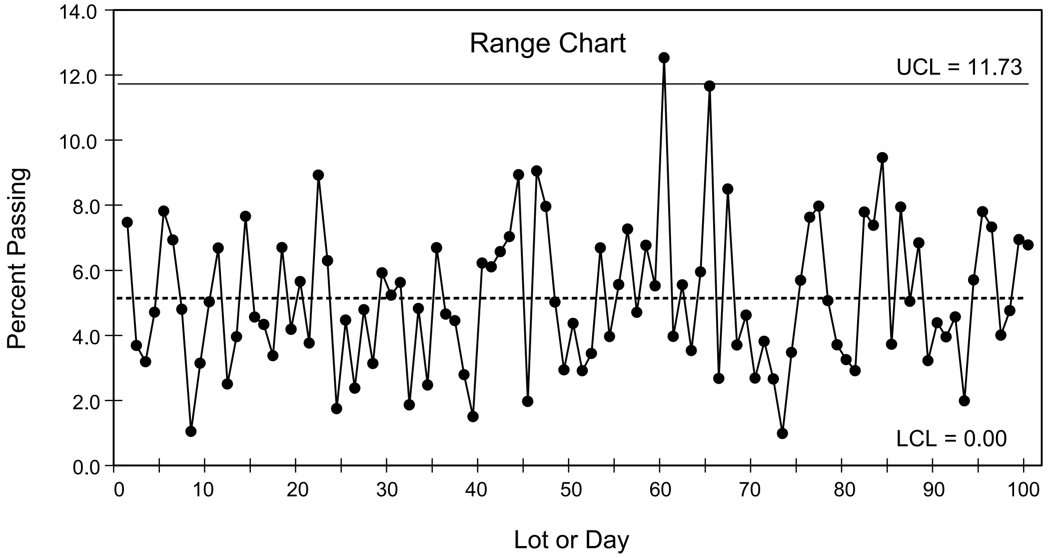


Figure 1—Examples of Average and Range Charts for the 2.36-mm Sieve

8. DEVELOP ACCEPTANCE PROCEDURES

8.1 *Acceptance*—Sampling and testing, or inspection, to determine the degree of compliance with contract requirements *(Transportation Research Circular Number E-C037,* 2002*)*.

8.2 *Purpose of Acceptance Procedures*—These procedures are intended to accept adequate quality level product and reject inadequate quality level product as often as feasible.

8.3 Most previous work in acceptance plans has been in terms of percent within limits (PWL) and some work has been done using percent defective (PD). Percent within limits and PD are complementary and add up to 100 percent. One can be converted to the other by Equation 1:

$$PD + PWL = 100\% \qquad (1)$$

This relationship is shown graphically in Figure 2. The PWL is sometimes called the percent conforming; also, the percent nonconforming may be a more appropriate term than percent defective. The PWL approach is preferred by some agencies over PD because it is a positive expression. Also, in terms of the theory of acceptance sampling plans, the material outside of the limits may not be strictly defective but of lesser quality than material within the limits.

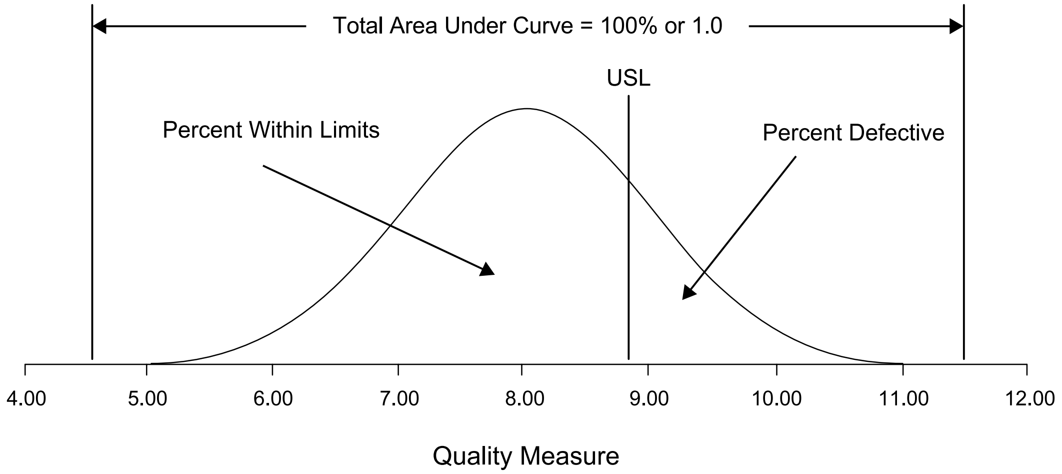

Figure 2—Complementary Relationship between Percent within Limits and Percent Defective

8.4 The PWL procedure produces an estimate of the population. Conceptually, as the sample size, *n*, increases, the estimate of the population improves. The PWL concept is one of small sample sizes and the distribution used is the noncentral *t* distribution. This distribution converges with the normal distribution when *n* approaches infinity. Since PWL is an estimate of a population, it must use an estimate of both the central tendency and the variability.

8.5 *Specification and Acceptance Limits*—In the development of an acceptance plan, specification and acceptance limits must be determined, and the acceptable quality level (AQL) and rejectable quality level (RQL) must be selected. The AQL, RQL, specification limits, and acceptance limits are intimately related, and the decisions regarding these are typically made concurrently.

8.6 *Specification Limits*—The limiting value(s) placed on a quality characteristic, established preferably by statistical analysis, for evaluating material or construction within the specification requirements. The term can refer to either an individual upper specification limit (USL) or lower specification limit (LSL), called a single specification limit; or to USL and LSL together, called double specification limits (*Transportation Research Circular Number E-C037,* 2002). As discussed below, specification and acceptance limits are different and serve different purposes.

8.7 Specification limits are based on engineering requirements and are expressed in the same units as those used for the quality characteristic of concern (e.g., percent, millimeters, kilograms per square millimeter, etc.). The acceptance limits are the limiting values placed on a quality measure that will permit acceptance of the lot. In PWL acceptance plans they are expressed in statistical units (PWL).

8.8 *Establishing the Specification Limits*—Establishing specification limits requires determining what constitutes acceptable (AQL) and unacceptable (RQL) material. The determination of both AQL and RQL are engineering decisions. The AQL decision defines acceptable material or construction, and addresses the product that will provide satisfactory service at an affordable cost when used for the intended purpose. Acceptable material is often determined based on what has performed well in the past. However, if performance data are available, it is preferable to quantify performance. Statistics has been a valuable tool in defining the parameters (mean and standard deviation) for acceptable material. Caution should be exercised if a lower variability is chosen for the specification than has been shown to be readily achievable. Arbitrarily "tightening the specs" can increase the cost of the product above what is considered cost-effective.

8.8.1 *Acceptable Quality Level (AQL)*—That minimum level of actual quality at which the material or construction can be considered fully acceptable (for that quality characteristic). For example, when quality is based on PWL, the AQL is that actual (not estimated) PWL at which the quality characteristic can just be considered fully acceptable (*Transportation Research Circular Number E-C037*, 2002). Acceptance plans should be designed so that AQL material will receive an average pay over the long run of 100 percent.

8.8.2 *Rejectable Quality Level (RQL)*—That maximum level of actual quality at which the material or construction can be considered unacceptable (rejectable) (*Transportation Research Circular Number E-C037*, 2002). For example, when quality is based on PWL, the RQL is that actual (not estimated) PWL at which the quality characteristic can just be considered fully rejectable. [It is desired to require removal and replacement, corrective action, or the assignment of a relatively low pay factor when RQL work is detected.]

8.8.3 Setting specification limits is slightly more complicated for double specification limits as compared to a single specification limit. For a quality characteristic with a single specification limit, the limit can be set at the appropriate number of standard deviations (process variability) above the minimum desired value to obtain the necessary PWL. But for a specification with double limits, there may be concern that in addition to the number of standard deviations (process variability) used to set the limits, a "target miss" may be warranted.

8.8.4 *Target Miss*—The failure of a contractor to center the process exactly on the target value. (For more detailed information on target miss, see *Optimal Procedures for Quality Assurance Specifications*, 2003.)

8.8.5 The proper way to address the issue of "target miss," is to determine how variable the actual process means are about the target value. This variability regarding where the process will be centered, called "target miss variability," can then be combined with the typical process variability to obtain the correct standard deviation value for use in establishing specification limits. The "target miss variability" and the "process variability" can be combined simply by adding their associated variances, *not* their standard deviations (see Equations 2 and 3). This assumes that the amount of process variability is independent of where the process is centered. (The example in Appendix X1 includes a calculation of "target miss" variability).

$$\hat{\sigma}^2_{\text{combined}} = \hat{\sigma}^2_{\text{target - miss}} + \hat{\sigma}^2_{\text{process}} \tag{2}$$

$$\hat{\sigma}_{\text{combined}} = \sqrt{\hat{\sigma}^2_{\text{combined}}} \tag{3}$$

where:

$\hat{\sigma}^2_{\text{combined}}$ = estimated combined target miss and process variance,

$\hat{\sigma}^2_{\text{target - miss}}$ = estimated target miss variance,

$\hat{\sigma}^2_{\text{process}}$ = estimated process variance, and

$\hat{\sigma}_{\text{combined}}$ = estimated combined standard deviation.

8.9 Select the specification limit(s) in concert with the quality measure, i.e., the measure that is used to quantify quality and the AQL and RQL. For instance, the AQL might be set at 90 PWL. This means that when the population has 90 percent of the product within specification limits, the product is completely acceptable. However, the same product could be defined by an AQL of 85 PWL with more restrictive specification limits or by many other possible combinations of AQL and specification limits. Selecting lower values of AQL may give the perception that lower quality levels are acceptable. It is recommended that AQL values be set at 90 or 95 PWL unless there is an overriding reason to select another value.

8.9.1 It is important to distinguish between a population (e.g., $N = 4$) and a sample (e.g., $n = 4$), because different equations are used to determine a population's variability than are used to estimate a sample's variability. When working with a population, it is desirable to have a large number of data points. However, sample sizes upon which to base acceptance or process control decisions are typically small, e.g., from four to ten, depending on the lot size. Larger lot and sample sizes are suggested to offer the advantage of lowering the risks of making a wrong acceptance or rejection decision.

8.10 *Acceptance Limit*—In variables acceptance plans, the limiting upper or lower value, placed on a quality measure, which will permit acceptance of a lot. (Unlike specification limits placed on a quality characteristic, an acceptance limit is placed on a quality measure. For example, in PWL acceptance plans, PWL refers to specification limits placed on the quality characteristic, and the minimum allowable PWL identifies the acceptance limit for the PWL quality measure.) (*Transportation Research Circular Number E-C037,* 2002)

8.11 *Acceptance Limits with Pay Adjustments*—For acceptance plans with pay adjustment provisions, additional acceptance limits, often expressed in the form of an equation or equations, are used to distinguish among the various possible pay levels.

8.12 *An Example of Specification and Acceptance Limits, AQL and RQL.*

8.12.1 An agency has decided, based on a large number of project data that it collected and analyzed, that a "typical" standard deviation for a lot defined in the acceptance plan for asphalt content for HMA is 0.18 percent. It has further been decided that PWL will be used as the quality measure. (See the example in Appendix X1 on how to properly select the "typical" standard deviation.)

8.12.2 *Determine AQL Material*—Since asphalt content has a stipulated target value, i.e., the job mix formula (JMF) asphalt content, the agency may choose to determine AQL material as a lot for which the average asphalt content is equal to the JMF target value and for which the standard deviation is equal to or less than the "typical" value of 0.18 percent. This defines AQL material in terms of the desired population mean and standard deviation, but the AQL definition must also be related to the required quality measure, which in this case is PWL.

8.12.3 *Set Specification Limits*—Since the specification limits and the AQL are related, the agency might decide to set the AQL as a value of 90 PWL. This selection of 90 PWL for the AQL is arbitrary, but is a commonly used value and one suggested in the AASHTO *Quality Assurance Guide Specification* (1995). The AQL population defined from past projects in terms of mean and standard deviation should just meet this PWL definition for AQL. So, in this case, the specification limits would be set such that a population with a mean at the JMF and a standard deviation of 0.18 percent would have 90 percent of its area within the specification limits. These limits can be determined by finding the *Z*-value from a standard normal table that corresponds to an area of 0.90 within the mean ± *Z* standard deviations (i.e., $\mu \pm Z\sigma$). (This example assumes the contractor can hit the JMF consistently, and no target miss is necessary. See the example in Appendix X1 on the addition of a target miss value).

8.12.4 Table 1 presents some typical ± *Z* regions within which selected areas of the normal distribution fall. From this table, it is seen that 0.90 (or 90 percent) of the normal distribution falls within ±1.645 standard deviations from the population mean.

Table 1—$\mu \pm Z\sigma$ Regions for Selected Areas under the Normal Distribution

Area	0.99	0.95	0.90	0.85	0.80
± *Z*	2.576	1.960	1.645	1.439	1.282

8.12.5 Figure 3 shows the specifications set at the JMF asphalt content ±1.645 times the typical standard deviation value, or JMF ± 1.645 (0.18 percent) = JMF ± 0.30 percent. In this case, the AQL is 90 PWL and the specification limits are JMF ± 0.30 percent.

8.12.6 Alternatively, using the same AQL population, the agency could decide to establish the AQL as 85 PWL. In this case, the specification limits would be set at the JMF ± 1.439 times the typical standard deviation value (see Table 1), or JMF ± 1.439 (0.18 percent) = JMF ± 0.26 percent. The specification limits are different in this case because the definition for AQL in terms of PWL is different. However, although the same population is desired in both cases, the perception is that quality is not as important with an AQL of 85 compared to an AQL of 90.

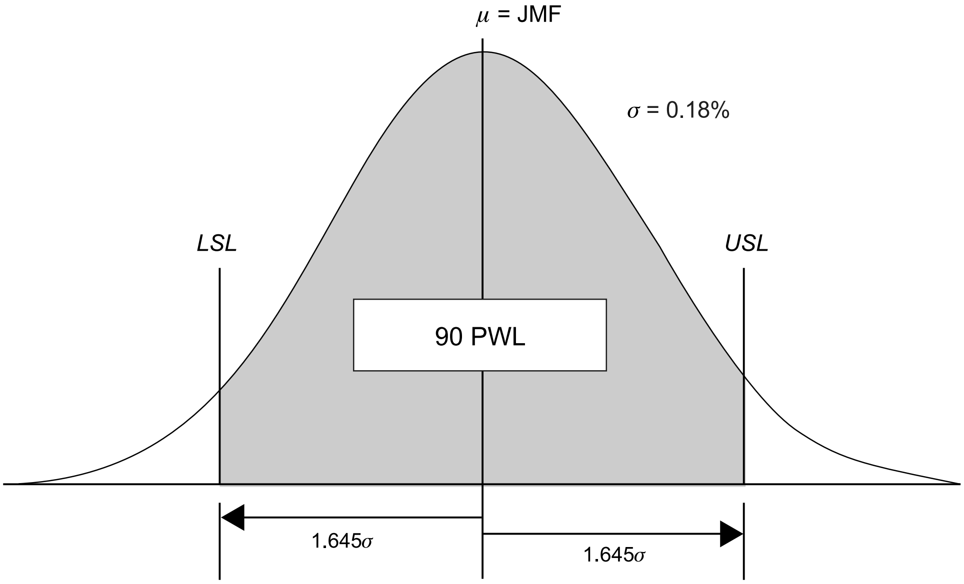

Figure 3—AQL Material for Example 8.12

8.12.7 *Determine RQL Material*—There is no single correct way to establish either the AQL or the RQL. Once the AQL and specification limits are established, the RQL can be determined in a number of ways. One way is to decide that the material should be rejected once a "large" percentage of material is outside the specification limits. Determining what constitutes a "large" percentage then needs to be decided. The agency may decide that the material is unacceptable once half of it is outside of the specification limits. In this case, the RQL would be established as a PWL value of 50. Any lot with an estimated PWL value of 50 or less would then be required to be removed and replaced or other penalty applied. Typical values for RQL are between 70 and 30 PWL.

8.12.8 Alternately, the agency might base the definition of RQL on the analysis of past project data. The agency might decide that past projects had performed inadequately when the average asphalt content was 0.25 percent above or below the JMF target value. In this case, the agency might decide to set the RQL based upon the PWL value for a population with a mean 0.25 percent above or below the JMF target and with a standard deviation equal to the "typical" value of 0.18 percent. Figure 4 illustrates the case of the RQL population when the specification limits are JMF ± 0.30 percent. In this case, it can be seen that the PWL for the RQL population corresponds to the area of the population that lies within the specification limits. In this case, the RQL might be defined as a lot with a PWL value of 60 (rounded from 61) as shown in Figure 4.

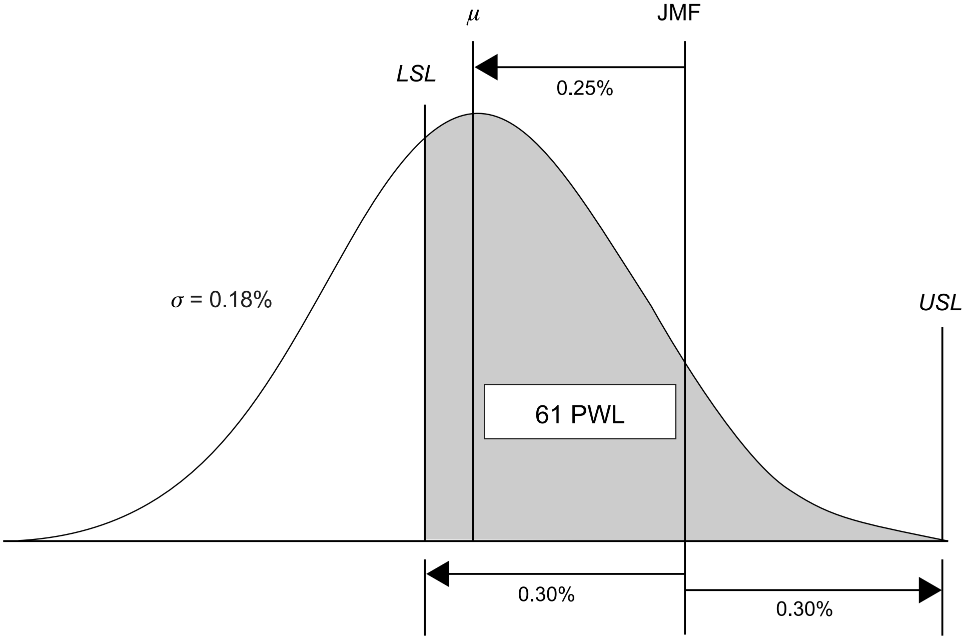

Figure 4—RQL Material for Example 8.12

8.12.9 The above approach to defining RQL material contains a number of simplifying assumptions. It looks only at how far the population mean departs from the target value and does not consider the population standard deviation. This assumes that the typical standard deviation value of 0.18 percent will be achieved on all projects. This approach also does not consider the interaction and effect of other quality characteristics, such as density, thickness, etc., on the performance of past projects.

8.13 *Application of PWL*—Determining the PWL is similar in concept to determining the area under the normal curve. The theory in the use of the PWL (or PD) method assumes that the population being sampled is normally distributed. In practice, it has been found that statistical estimates of quality are reasonably accurate provided the sampled population is at least approximately normal; i.e., reasonably bell shaped and not bimodal or highly skewed. This has been found to be true for most material and construction measures not associated with a physical constraint; e.g., since gradation cannot exceed 100 percent passing a top size sieve, a measure of this characteristic is often skewed and therefore not normally distributed.

8.13.1 When the average and standard deviation are known (or assumed known), the area under the normal curve can be calculated to determine the percentage of the population that is within certain limits. However, when the average and standard deviation are unknown—as in the case of determining the acceptance for a lot—the percentage of the lot that is within the specification limits can be estimated. In this latter case, instead of using the *Z*-value and the standard normal curve, the quality index, *Q*, is used to estimate PWL. The *Q*-value is used with a PWL table to determine the estimated PWL for the lot.

8.13.2 A sample table relating *Q* values with the appropriate PWL estimate is shown in Table 2 for a sample size of $n = 5$. A more complete set of PWL tables in this format, for sample sizes from $n = 3$ to $n = 30$, is available (*Quality Assurance Software for the Personal Computer*, 1996).

Table 2—A PWL Estimation Table for Sample Size *n* = 5

Q	0.00	0.01	0.02	0.03	0.04	0.05	0.06	0.07	0.08	0.09
0.0	50.00	50.36	50.71	51.07	51.42	51.78	52.13	52.49	52.85	53.20
0.1	53.56	53.91	54.27	54.62	54.98	55.33	55.69	56.04	56.39	56.75
0.2	57.10	57.46	57.81	58.16	58.52	58.87	59.22	59.57	59.92	60.28
0.3	60.63	60.98	61.33	61.68	62.03	62.38	62.72	63.07	63.42	63.77
0.4	64.12	64.46	64.81	65.15	65.50	65.84	66.19	66.53	66.87	67.22
0.5	67.56	67.90	68.24	68.58	68.92	69.26	69.60	69.94	70.27	70.61
0.6	70.95	71.28	71.61	71.95	72.28	72.61	72.94	73.27	73.60	73.93
0.7	74.26	74.59	74.91	75.24	75.56	75.89	76.21	76.53	76.85	77.17
0.8	77.49	77.81	78.13	78.44	78.76	79.07	79.38	79.69	80.00	80.31
0.9	80.62	80.93	81.23	81.54	81.84	82.14	82.45	82.74	83.04	83.34
1.0	83.64	83.93	84.22	84.52	84.81	85.09	85.38	85.67	85.95	86.24
1.1	86.52	86.80	87.07	87.35	87.63	87.90	88.17	88.44	88.71	88.98
1.2	89.24	89.50	89.77	90.03	90.28	90.54	90.79	91.04	91.29	91.54
1.3	91.79	92.03	92.27	92.51	92.75	92.98	93.21	93.44	93.67	93.90
1.4	94.12	94.34	94.56	94.77	94.98	95.19	95.40	95.61	95.81	96.01
1.5	96.20	96.39	96.58	96.77	96.95	97.13	97.31	97.48	97.65	97.81
1.6	97.97	98.13	98.28	98.43	98.58	98.72	98.85	98.98	99.11	99.23
1.7	99.34	99.45	99.55	99.64	99.73	99.81	99.88	99.94	99.98	100.00

Note: Values in the body of the table are estimates of PWL corresponding to specific values of $Q_L = (\overline{X} - LSL) / s$ or $Q_U = (USL - \overline{X}) / s$
For negative *Q* values, the table values must be subtracted from 100.

8.13.3 *Calculation and Rounding Procedures*—The calculation procedures and rounding rules can influence the estimated PWL value that is obtained. This can become a point of contention, particularly if the pay determination is based on the estimated PWL value. It is, therefore, important that the agency specify the exact calculation process, including number of decimal places to be carried in the calculations, as well as the exact manner in which the PWL table is to be used.

8.13.4 Conceptually, the *Q*-value performs identically the same function as the *Z*-value does for a normal distribution. Except now the reference points are the individual sample mean ($\overline{X}$) and standard deviation (*s*) instead of the population mean (μ) and standard deviation (σ) and the points of interest with regard to areas under the curve are the specification limits.

$$Q_L = \frac{\overline{X} - LSL}{s} \tag{4}$$

and

$$Q_U = \frac{USL - \overline{X}}{s} \tag{5}$$

where:

Q_L = quality index relative to the lower specification limit,

Q_U = quality index relative to the upper specification limit,

LSL = lower specification limit,

USL = upper specification limit,

$\overline{X}$ = sample mean for the lot, and

s = sample standard deviation for the lot.

8.13.5 The *Q*-value, therefore, represents the distance in sample standard deviation units that the sample mean is offset from the specification limit. A positive *Q*-value represents the number of sample standard deviation units that the sample mean falls inside the specification limit. Conversely, a negative *Q*-value represents the number of sample standard deviation units that the sample mean falls outside the specification limit. These cases are illustrated in Figure 5. *QL* is used when there is a one-sided lower specification limit, while *QU* is used when there is a one-sided USL. For two-sided specification limits, the PWL value is estimated as:

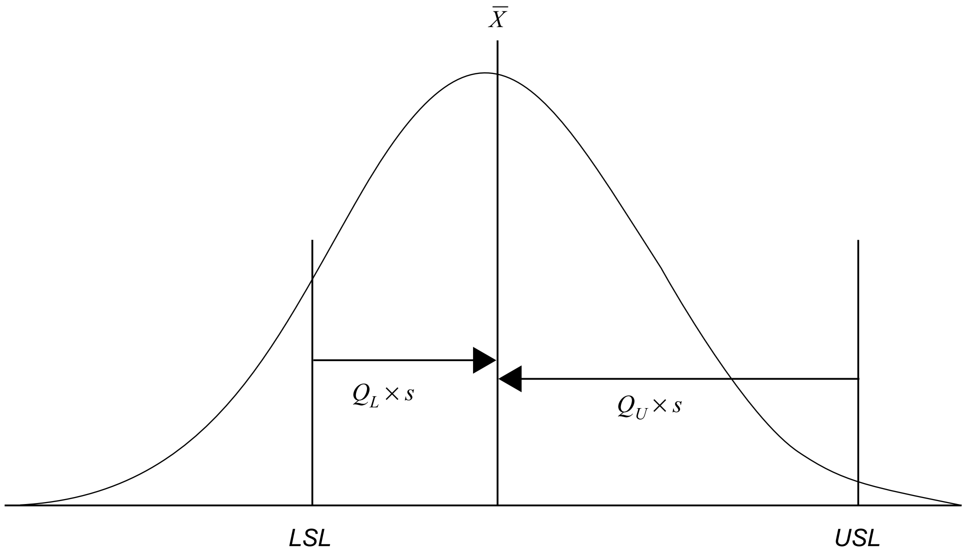
$$PWL_T = PWL_U + PWL_L - 100 \tag{6}$$

where:

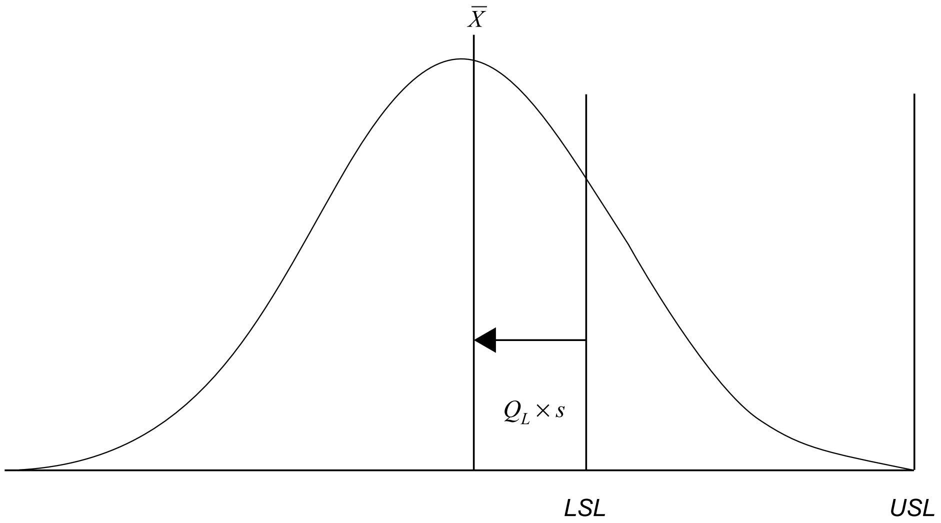
PWL_T = percent within the upper and lower specification limits.

PWL_U = percent below the upper specification limit (based on Q_U).

PWL_L = percent above the lower specification limit (based on Q_L).



(a) Illustration of Positive Quality Index Values



(b) Illustration of a Negative Quality Index Value

Figure 5—Illustration of the Quality Index, *Q*

8.13.6 Intuitively, PWL is a good measure of quality since it is reasonable to assume that the more of the product that is within the specification limits, the better the quality of the product should be. (A detailed discussion and analysis of the PWL measure of quality is presented in *Optimal Procedures for Quality Assurance Specifications*, 2003.)

8.14 If the agency conducts the acceptance tests, sampling and testing must be performed in qualified laboratories and by qualified sampling and testing personnel. There are no additional requirements for verification other than the typical IA requirement.

8.15 However, if the contractor/third party conducts tests used in the acceptance decision, a validation procedure is necessary as required in FHWA 23 CFR 637 (1995). The requirements are:

8.15.1 The sampling and testing must be performed in qualified laboratories and by qualified sampling and testing personnel.

8.15.2 The quality of the material must be validated by verification sampling and testing. The verification sampling and testing is to be performed on samples that are taken independently from those used in the acceptance decision.

8.16 Statistically sound verification procedures must be developed and used. There are several forms of verification procedures, and some forms are more efficient than others. It is in the best interest of both parties to make the verification process as effective and efficient as practicable.

8.17 FHWA 23 CFR 637 states that the verification samples shall be taken independently. This requirement does not allow the direct comparison of split samples for validation. However, this does not prohibit the use of split sample test results. For instance, the contractor may test 100 samples and the agency select the split portion of all one hundred samples but test only 20 of the samples. Then the agency can compare their 20 tests results to the 80 contractor test results that are not paired with those of the agency, using the *F*-test and independent *t*-test.

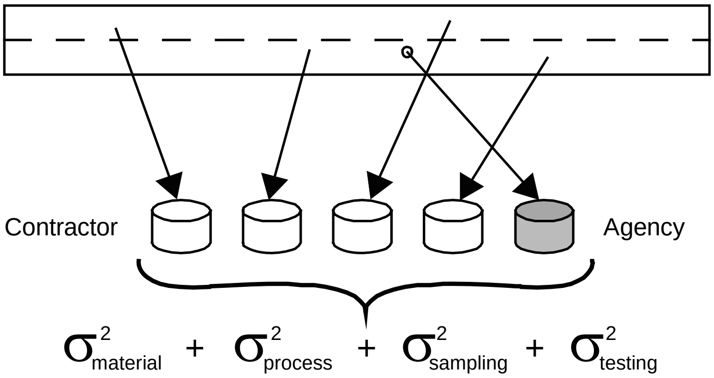
8.17.1 There is a difference in the information provided by split and independent sampling procedures, and the difference is related to the concept of components of variability.

8.17.2 *Split Sample*—A sample that has been divided into two or more portions representing the same material. (Split samples are sometimes taken to verify the acceptability of an operator's test equipment and procedure. This is possible because the variability calculated from differences in split test results is comprised solely of testing variability.) (*Transportation Research Circular Number E-C037*, 2002)

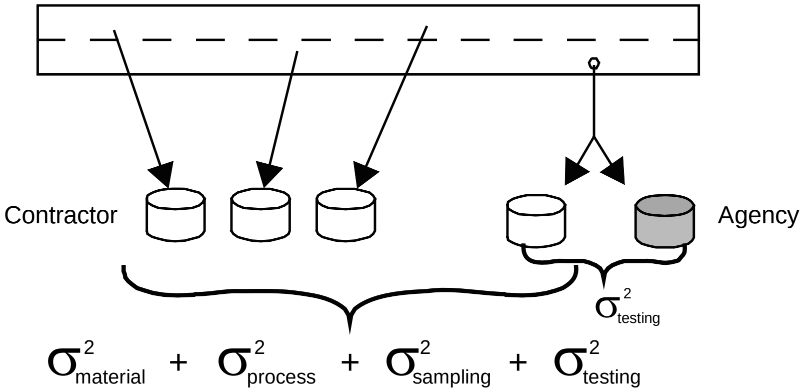
8.17.3 *Independent Sample*—A sample taken without regard to any other sample that may also have been taken to represent the material in question. [An independent sample is sometimes taken to verify an acceptance decision. This is possible because the data sets from independent samples, unlike those from split samples, each contain independent information reflecting all sources of variability, i.e., materials (which often includes both the material and the process variabilities), sampling, and testing.] (*Transportation Research Circular Number E-C037*, 2002)

8.17.4 The five specimens shown in Figure 6(a) have been taken independently. The variability represented by them includes all sources of variability; i.e., material, process, sampling, and testing. Thus, if the total variability is to be evaluated, independent samples must be taken.

8.17.5 In Figure 6(b), four of the five specimens have been taken independently; however, the two on the far right are split samples from the same batch, i.e., they are two results that represent the same material. The variability represented by these two specimens includes only the component of testing variability. However, either of the two specimens on the far right can be combined with the other three to measure all sources of variability; but both cannot be used with the other three in an analysis. Specimens tested by different laboratories may be combined, from a statistical standpoint, if found not to be statistically different. However, a higher variability is likely to result and, thus, this is not recommended.



(a) Independent Samples



(b) Split Samples

Figure 6—Components of Variance for: (a) Independent Samples and (b) Split Samples

8.17.6 The analysis of the variability for split samples will be a smaller value, $\sigma^2_{\text{testing}}$, than the variability for independent samples, $\sigma^2_{\text{overall}}$, because the latter includes all components of variability. But the decision of whether to use split or independent samples should not be made based on the magnitude of the variability but, instead, on the component(s) of variability that is (are) desired to be measured. So, the choice of whether to use split or independent samples is not an arbitrary decision.

8.18 *Definition of Verification*—The process of determining or testing the truth or accuracy of test results by examining the data and/or providing objective evidence. (Verification sampling and testing may be part of an IA program (to verify contractor QC testing or agency acceptance) or part of an acceptance program (to verify contractor testing used in the agency's acceptance decision)) (*Transportation Research Circular Number E-C037*, 2002).

8.19 *Verification Procedures*—The ability of the comparison procedure to identify differences between two sets of test results depends on the number of tests from each set that are being compared. The greater the number of test results from each set, the greater the ability of the procedure to identify statistically valid differences. A rule of thumb is a minimum agency rate of 10 percent of the contractor's testing rate. It is preferred to conduct a risk analysis to determine whether a higher rate is warranted. It also must be decided whether the test method or the process is to be verified. This relates to the use of split or independent samples.

8.20 *Hypothesis and Level of Significance*—An hypothesis is a statement of an assumption about a set of data. The null hypothesis, H_o, defines an assumed set of conditions. (The null hypothesis cannot be proved true. It can be shown, with specified risks, to be untrue). The alternative hypothesis, H_a, is the hypothesis that is accepted when the null hypothesis is disproved (i.e., rejected). The level of significance, α, is the probability of rejecting a null hypothesis when it is, in fact, true (*Transportation Research Circular Number E-C037*, 2002). Typical levels of significance are 0.10, 0.05, and 0.01. If, for example, $\alpha = 0.01$ is used and the null hypothesis is rejected, then there is only one chance in 100 that H_o is true and was rejected in error.

8.21 *Test Method Verification Procedures*—These procedures compare results of split samples. The two procedures used most often for test method verification are the d2s limits and the paired *t*-test.

8.21.1 *d2s Limits*—This is the simplest procedure that can be used for verification. It is also the least powerful. Because the procedure uses only two test results, it cannot detect real differences unless the results are far apart. The value provided by this procedure is contained in many AASHTO test methods. The d2s limit indicates the maximum acceptable difference between two results obtained on test portions of the same material (and thus, applies only to split samples), and is provided for single and multi-laboratory situations. It represents the difference between two individual test results that has approximately a 5 percent chance of being exceeded if the tests are actually from the same population.

8.21.2 When this procedure is used for test method verification, a sample is split into two portions and the contractor tests one split sample portion while the agency tests the other split sample portion. The difference between the contractor and agency test results is then compared to the d2s limits. If the test difference is less than the d2s limit, the two tests are considered verified, i.e., they are assumed to have come from the same population. If the test difference exceeds the d2s limit, then the contractor's test result is not verified, and the source of the difference is investigated.

8.21.3 *Paired t-test*—For the case in which it is desirable to compare more than one pair of split sample test results, the *t*-test for paired measurements can be used. This test uses the differences between pairs of tests and determines whether the average difference is statistically different from 0. Thus, it is the difference within pairs, not between pairs, that is being tested. The *t*-statistic for the *t*-test for paired measurements is:

$$t = \frac{\left|\overline{X}_d\right|}{\dfrac{s_d}{\sqrt{n}}} \qquad (7)$$

where:

$\overline{X}_d$ = average of the differences between the split sample test results,

s_d = standard deviation of the differences between split sample test results, and

n = number of split sample pairs.

8.21.4 The calculated *t*-value is then compared to the critical value, t_{crit}, obtained from a table of *t*-values at a level of $\alpha/2$ and with $n - 1$ degrees of freedom. (A table of critical *t* values can be found in *Materials Control and Acceptance-Quality Assurance*, 2000; *Optimal Procedures for Quality Assurance Specifications*, 2003; and most basic statistics textbooks. Computer spreadsheet programs contain statistical test procedures for the paired *t*-test.)

8.21.5 Since the use of d2s limits is not very powerful, it is recommended that each individual split sample be compared using the d2s limits, but that the paired *t*-test also be used on the accumulated split samples to provide for a comparison with more discerning power.

8.21.6 The above recommendation also applies to the IA component of the acceptance plan because it also uses split samples.

8.22 *Process Verification Procedures*—Just as there are statistical tests for verification of split sample test results, there are also tests for verification of independently obtained test results. The tests most often used are the *F*-test and *t*-test, which are usually used together.

8.22.1 *F-test and t-test*—This procedure involves two statistical tests, where the null hypothesis for each test is that the contractor's test results and the agency's test results are from the same population. Specifically, the null hypotheses are that (1) the variability of the two data sets are equal for the *F*-test, and (2) the means of the two data sets are equal for the *t*-test. It is important to compare both the means and the variances when comparing two sets of data. A different test is used for each comparison. The *F*-test provides a method for comparing the variances of the two sets of data. Differences in means are assessed by the *t*-test.

8.22.2 The procedures involved with the *F*-test and *t*-test may, at first, seem complicated and involved. Some of the complexity of the *F*-test and *t*-test comparisons can be eliminated by the use of computer programs. Many spreadsheet programs have the ability to conduct these tests. (An example of the *F*-test and *t*-test is shown in Appendix X2).

8.23 *Dispute Resolution*—Also called conflict resolution. For QA programs permitting contractor acceptance testing, procedures to resolve conflicts resulting from discrepancies between the agency's and contractor's results of sufficient magnitude to impact pay. (The procedure may, as an initial step, include the testing of independent samples and, as a final step, third-party arbitration.) (*Transportation Research Circular Number E-C037*, 2002). Dispute resolution procedures to identify testing errors are considered an important part of any QA program.

8.24 *Dispute Resolution Procedure*—It is intended to provide a means to minimize adversarial relationships and claims. The use of appropriate procedures should help avoid disputes and claims. Establish a formal monitoring program that will provide both the contractor and the agency assurances that all data are reliable, unbiased, and truly indicate quality. There are many aspects of dispute resolution addressed in detail in *AASHTO Implementation Manual for Quality Assurance* (1995). Two are briefly discussed here.

8.24.1 *Identifying Outlying Observations*—An outlying observation, or "outlier," is one that appears to deviate markedly from other sample test values from which it was taken (ASTM E 178). When considering outliers, two conditions exist:

1. The value may be an extreme value of the population or excessive variability of the population. In either case the value should be retained and used in further evaluations or computations.
2. It may be the result of gross deviation from prescribed sampling and or test procedures, or in calculating or recording the numerical value, in which case it should be discarded.

Use a procedure to determine which decision to make; i.e., the value is not an outlier and should be retained or the value is an outlier and should be discarded. (See ASTM E 178 for further discussion of outliers). It should be remembered that because of the way specification limits are set, some results of AQL material may be outside of the specification limits. Thus, to arbitrarily discard values is not a valid procedure.

8.24.2 *The Proper Policy for Resampling and Retesting*—If resampling and/or retesting is allowed, establish specific procedures stating when and how it should be done. An example of when retesting may be warranted is the requirement of a "remove and replace" provision when the quality is estimated to be at or below the RQL. It may be decided that the quality estimate should be improved by testing another set of samples because the economic consequences of "remove and replace" are severe. This is an acceptable practice if all the test results—the original and retests—are used and none of the results are discarded.

9. RISKS AND RISK ANALYSIS

9.1 Establishing the acceptance limits is an important step. Making the limits too restrictive deprives the contractor of a reasonable opportunity to meet the specification. If the limits are not sufficiently restrictive they will be ineffective in controlling quality. Both engineering requirements and economical process capabilities should be considered when establishing acceptance limits. Selection of the limits relates to the determination of risks. The concept of risks for acceptance is similar to that discussed in Section 8 for verification testing to evaluate whether test results came from the same population. A well-written QA plan takes these risks into consideration in a manner that is fair to both the contractor and the agency. Too large a risk for either party undermines credibility. Thus, the risks should be balanced and should be reasonably small. For most highway products, if this is not possible because of the sample size selected, the risks to the contractor should be less than that to the agency except for potential catastrophic failures.

9.1.1 *Risks: Definitions and Levels*

9.1.1.1 *Seller's Risk* (*α*)—Also called contractor's risk or risk of a Type I error. The probability that an acceptance plan will erroneously reject AQL material or construction with respect to a single acceptance quality characteristic. It is the risk the contractor or producer takes in having AQL material or construction rejected (*Transportation Research Circular Number E-C037,* 2002).

9.1.1.2 *Buyer's Risk* (*β*)—Also called agency's risk or risk of a Type II error. The probability that an acceptance plan will erroneously fully accept (100 percent or greater) RQL material or construction with respect to a single acceptance quality characteristic. It is the risk the highway agency takes in having RQL material or construction fully accepted. [The probability of having RQL material or construction accepted (at any pay) may be considerably greater than the buyer's risk.] (*Transportation Research Circular Number E-C037*, 2002).

9.1.1.3 The α and β risk levels that might be appropriate vary depending upon the material or construction process that is involved. The appropriate risk level is a subjective decision that can vary from agency-to-agency. However, as an economic decision, typical practice limits risks to no more than five percent.

9.1.1.4 The more critical the application, the lower should be the buyer's risk. But only under rare circumstances should the buyer's risk be lower than the seller's risk.

9.2 *Risks Concepts*—As noted in the section on verification testing in Section 8, the concept of α and β risks derives from statistical hypothesis testing in which there is either a right or wrong decision. As such, when α and β risks are applied to materials or construction, they are only truly appropriate for the case of a pass/fail or accept/reject decision and, in fact, may lead to considerable confusion if an attempt is made to apply them to the pay adjustment case. When materials not only can be accepted or rejected, but can also be accepted at an adjusted pay, then additional interpretations or clarifications must be applied to the definitions of risks.

9.2.1 For example, in the definition for buyer's risk above, it states that β is the probability that RQL material will be accepted at 100 percent pay or greater. The definition must then go on to point out that there may be a much greater probability that the RQL material will receive some reduced pay. While it is not stated as directly, the same reasoning is true for the seller's risk. The definition indicates that α is the probability that AQL material will be rejected. Although not stated in the definition, it is also true that there may be a much greater probability that the AQL material will be accepted at a reduced pay.

9.3 *Operating Characteristic (OC) Curves*—α and β are very narrowly defined to occur at only two specific quality levels. β is the probability of accepting, at full pay or more, material that is exactly at the RQL, while α is the probability of rejecting material that is exactly at the AQL. These definitions do not therefore provide an indication of the risks over a wide range of possible quality levels. To evaluate how the acceptance plan will actually perform in practice, it is necessary to construct an operating characteristic (OC) curve.

9.3.1 *OC Curve*—A graphic representation of an acceptance plan that shows the relationship between the actual quality of a lot and either (1) the probability of its acceptance (for accept/reject acceptance plans) or (2) the probability of its acceptance at various pay levels (for acceptance plans that include pay adjustment provisions) (*Transportation Research Circular Number E-C037*, 2002).

9.3.2 An example of an OC curve for a pass/fail or accept/reject acceptance plan, case (1) in the above definition, is shown in Figure 7. Probability of acceptance is shown on the vertical axis for the range of quality levels indicated on the horizontal axis. An example of an OC curve for an acceptance plan with pay adjustment provisions, case (2) in the above definition, is shown in Figure 8. The axes are the same as for Figure 7, but there are multiple curves, one for each of several selected pay levels.

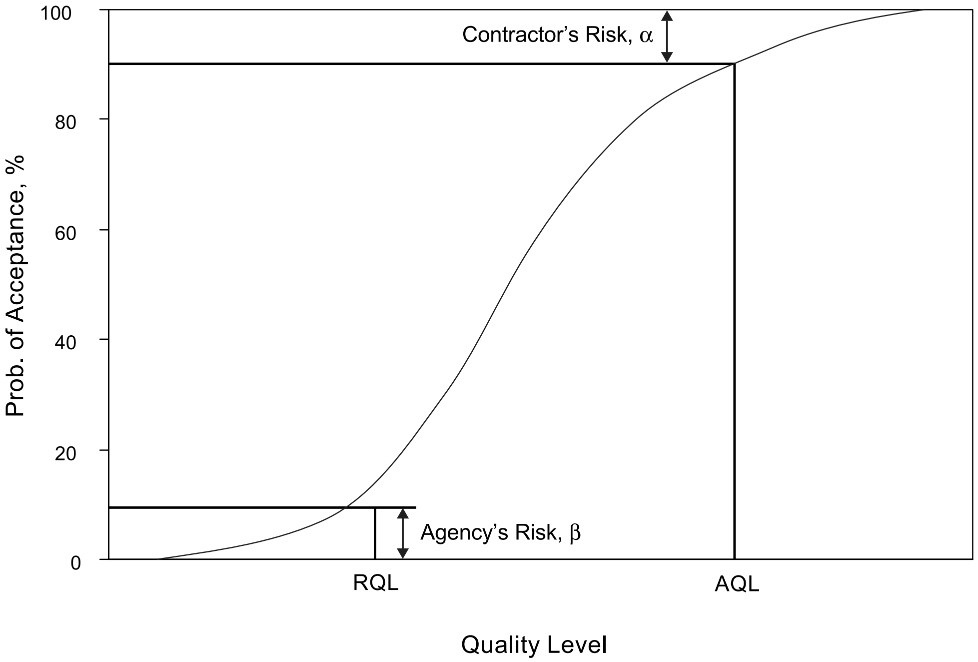


Figure 7—Typical OC Curve for an Accept/Reject Acceptance Plan

9.3.3 Each curve plotted in Figure 8 represents the probability of receiving a pay factor equal to or greater than the one indicated for the line. For example, for the OC curves in Figure 8, material that is of exactly AQL quality has approximately a 45 percent chance of receiving a pay factor of 1.04 (104 percent) or greater. This same AQL material has approximately a 60 percent chance of receiving full pay (100 percent) or greater, which also means that it has approximately a 40 percent chance of receiving less than 100 percent pay. This AQL material has essentially a 100 percent chance of receiving a pay factor of 0.80 (80 percent) or greater.

9.3.4 On the other hand, for the OC curves in Figure 8, material that is of exactly RQL quality has approximately a 50 percent chance of receiving a pay factor of 0.80 (80 percent) or greater, and approximately an 80 percent chance of receiving a pay factor of 0.70 (70 percent) or greater. Similar pay probabilities can be determined for any level of actual quality, and additional curves could be developed for any specific pay factor.

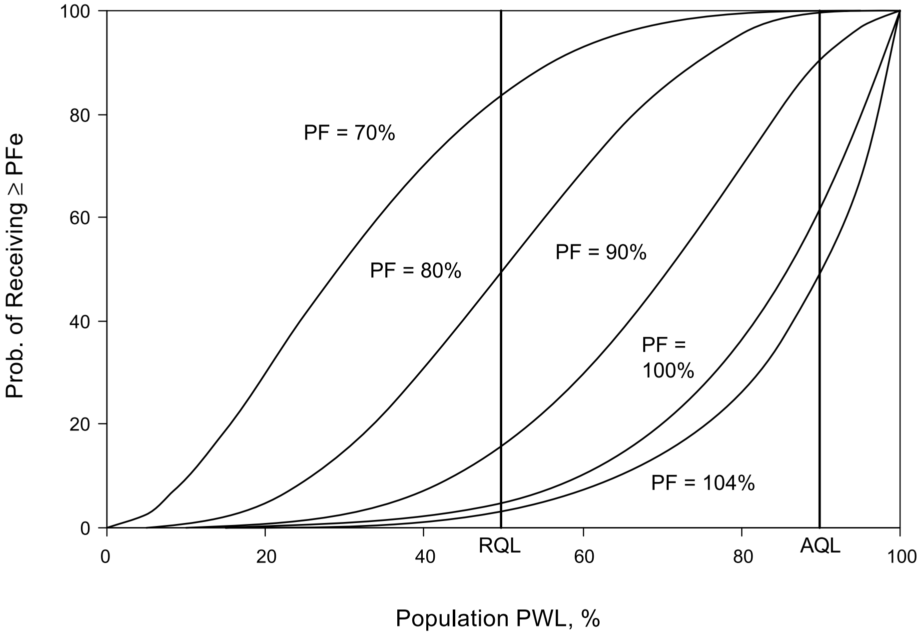

Figure 8—Typical OC Curves for an Acceptance Plan with Pay Adjustments

9.4 *Pay Adjustment System Plans*—As discussed above and shown in Figure 8, the consideration of only α and β risks is not sufficient when pay adjustments are used. From Figure 8 it can also be seen that using multiple OC curves is not an easy way to evaluate an acceptance plan.

9.5 *Expected Pay (EP) Curves*—Thus, another way to present the pay performance for an acceptance plan is with what is called an expected pay (EP) curve.

9.5.1 *Definition of EP Curve*—A graphic representation of an acceptance plan that shows the relation between the actual quality of a lot and its EP, i.e., mathematical pay expectation, or the average pay the contractor can expect to receive over the long run for submitted lots of a given quality (*Transportation Research Circular Number E-C037*, 2002). Both OC and EP curves should be used to evaluate how well a pay adjustment acceptance plan is theoretically expected to work.

9.5.2 An example of an EP curve is shown in Figure 9. Quality levels are indicated on the horizontal axis in the usual manner, but instead of probability of acceptance, the vertical axis gives the expected (long-term average) pay factor as a percent of the contract price.

9.5.3 Although the risks have a different interpretation when associated with EP curves than with OC curves, the same type of information is provided. It is a generally accepted tenet that the average pay for material that is just fully acceptable should be approximately 100 percent of the contract price. For the example in Figure 9, AQL work receives an expected pay of 100 percent, as desired, while truly superior work that is better than the AQL receives an expected pay of 102 percent. At the other extreme, RQL work corresponds to an expected pay of 70 percent. For still lower levels of quality, the curve levels off at a minimum expected pay of 50 percent.

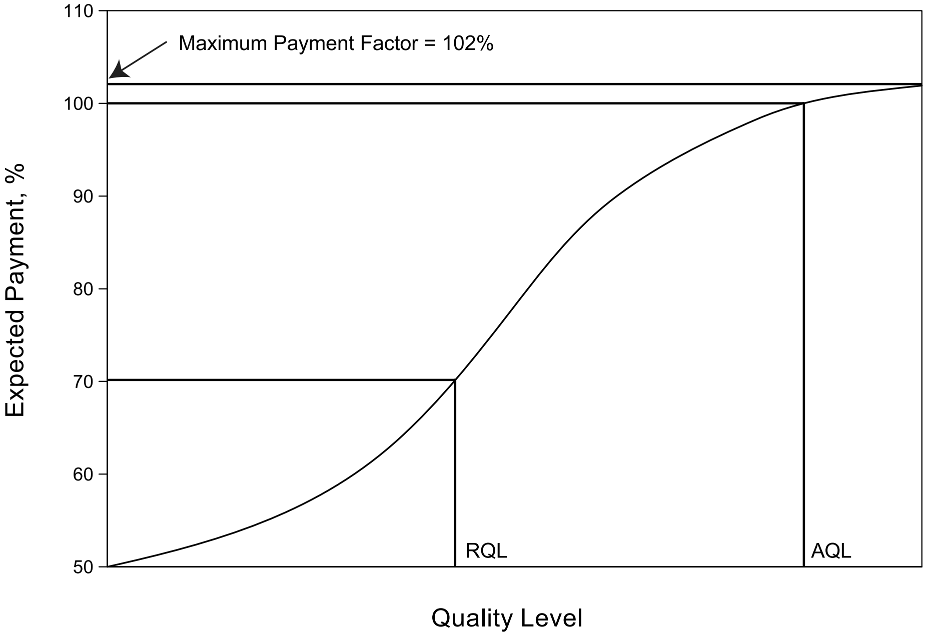

Figure 9—Typical EP Curve

9.6 *Evaluating Risks*—The way potential risks are evaluated depends upon the type of acceptance plan that is used. The factors to be considered are: α, β, n, AQL, and RQL.

9.7 *Accept/Reject Plans*—The evaluation of risks is straightforward for accept/reject (pass/fail) acceptance plans. As noted above, α and β risks and OC curves were developed specifically for this type of situation. Therefore, they can be directly used to assess the risks to both parties.

9.7.1 To reiterate, the α risk is the probability that AQL material will be rejected; while the β risk is the probability that RQL material will be accepted. However, since contractors will not operate at only these two quality levels, to fully consider risks the OC curve, which illustrates probability of acceptance for any quality level, must be developed for the acceptance plan under consideration. An example is used to illustrate how this can be done.

9.7.2 *Example of Accept/Reject Acceptance Plans-OC Curves*—Two computer programs are available to assist in developing OC curves. Program NONCENTT uses an analytical approach based on the noncentral *t* distribution and the symmetrical Beta distribution to estimate PWL and can also determine the α and β risks and develop the OC curve for one-sided acceptance plans (Barros, 1982). Program OCPLOT, found and discussed in Weed (1996), uses simulation methods to determine the α and β risks and to plot the OC curve for both one-sided or two-sided acceptance plans. In this example, the agency has:

- Decided to use asphalt content as an accept/reject property for an HMA pavement (note, this is *not* recommended, but is used here solely for the purpose of illustrating the use of an OC curve for an accept/reject situation).
- Established a lower specification limit of 5.60 percent and an upper specification limit of 6.40 percent for asphalt content.
- Decided to use the PWL, based on a sample size of four, as the quality measure.
- Selected 90 PWL for the AQL and 50 PWL for the RQL.
- Decided that the lot will be accepted if the estimated PWL is greater than or equal to 70, i.e., the acceptance limit is 70 PWL.
- Decided to use program OCPLOT to evaluate the risks associated with the acceptance plan.

Table 3 and Figure 10 show the results of the OCPLOT analysis of this proposed acceptance plan. For comparison purposes, Table 3 also includes the probability of acceptance values calculated using program NONCENTT. The OCPLOT values are approximations due to the fact that they were derived by simulation. The NONCENTT values are also approximations because the procedure was developed for one-sided acceptance limits. Table 3 shows that there is little difference between the results of the two programs. Since OCPLOT is generally more available, better documented, and easier to use, it is used for all example problems in this standard practice.

9.7.3 From the OCPLOT values in Table 3, it can be seen that the seller's risk is $\alpha = 1.000 - 0.905 = 0.095$ (or 9.5 percent) and the buyer's risk is $\beta = 0.144$ (or 14.4 percent). Further, both Table 3 and Figure 10 show the probability of acceptance over the total range of possible lot quality levels, as defined by the actual PWL for the lot. The agency must now decide whether or not it considers these levels of risk to be appropriate. If the risks are determined to be too high, consider changing the acceptance limit and/or the sample size.

Table 3—OC Table from OCPLOT for the Example Problem

Population PWL	Probability of Acceptance (OCPLOT)	Probability of Acceptance (NONCENTT)
100	1.000	1.000
95	0.976	0.975
90 (AQL)	0.905 ($\alpha = 0.095$)	0.906
85	0.810	0.810
80	0.696	0.701
75	0.579	0.589
70	0.466	0.482
65	0.363	0.382
60	0.288	0.295
55	0.200	0.220
50 (RQL)	0.144 ($\beta = 0.144$)	0.158
45	0.093	0.109
40	0.066	0.071
35	0.038	0.043
30	0.021	0.024
25	0.013	0.012
20	0.000	0.000

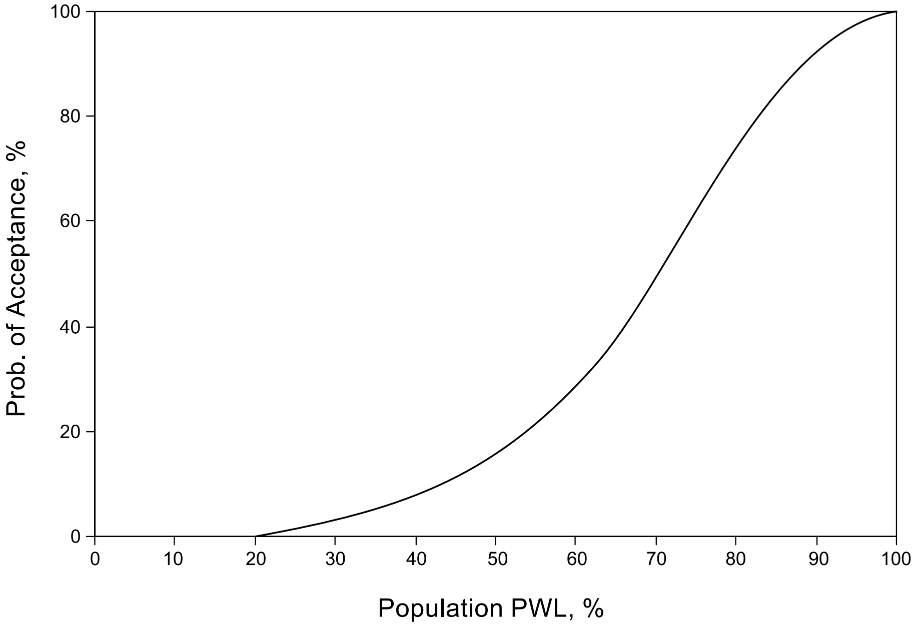

Figure 10—OC Curve for the Accept/Reject Acceptance Plan Example

9.8 *Pay Adjustment System Plans*—The evaluation of risks becomes more complicated when the acceptance plan includes pay adjustment provisions. As discussed above, α and β risks, which were developed from hypothesis testing, where there is a decision to accept or reject the null hypothesis, are not sufficient when the decision involves not only accept or reject, but also accept at an adjusted pay level.

9.8.1 The *Transportation Research Circular Number E-C037* (2002) definitions for seller's and buyer's risks do not attempt to incorporate the concept of pay adjustments. Whether or not a lot received 105 percent, 100 percent, 75 percent, or 50 percent pay would have no impact with regard to the seller's risk based on this definition. Obviously, however, these different pay levels would have quite an impact on how the contractor perceived its risks.

9.8.2 Similarly, the buyer's risk definition disregards the impact of partial pays when determining the buyer's risk. However, when considering its risks, the agency will certainly be interested in the probability of accepting RQL material at reduced pay levels as well as at 100 percent pay or greater.

9.8.3 Since the use of α and β risks to evaluate pay adjustment system plans is not sufficient, an additional method is necessary to properly evaluate the risks when pay adjustments are added to the acceptance decision. The EP curve (see Figure 9) is another method for considering the pay adjustment aspects of the acceptance plan. However, EP alone is also not sufficient to fully evaluate the risks that are involved. Multiple OC curves for various pay levels (see Figure 8) should also be developed when evaluating acceptance plans with pay adjustment provisions. An example will help to illustrate the evaluation of risks for pay adjustment acceptance plans.

9.8.4 *Example of Pay Adjustment System Plans-EP Curves*—Consider the previous asphalt content example where the sample size was four, the allowable specification range was 5.60 percent to 6.40 percent, and the AQL and RQL were defined as 90 PWL and 50 PWL, respectively. Instead of a simple accept/reject acceptance plan, the agency chooses to use the AASHTO equation (Equation 8) to establish the pay factor for a lot:

$$PF = 55 + (0.50 \times PWL) \tag{8}$$

where:

PF = pay factor for the lot, as a percent of contract price; and

PWL = estimated PWL value for the lot.

9.8.4.1 Throughout this standard, the AASHTO equation has been used as an example to develop concepts that are applicable to all acceptance plans. However, for the reasons stated in Sections 9.1.3, 9.1.4, 9.8.8, and 10.3, its use is not generally recommended.

9.8.5 From the above equation, it can be seen that the maximum pay factor is 105 percent at 100 PWL, while the pay factor at the AQL (i.e., 90 PWL) is 100 percent and the pay factor at the RQL (i.e., 50 PWL) is 80 percent. The intent of the acceptance plan is that the average pay for AQL material be 100 percent, as in this example.

9.8.6 With the above information, the OCPLOT program can be used to develop the EP curve shown in Figure 11. It can be seen in this figure that, as desired, the EP for AQL material is 100 percent. This means that a contractor that consistently produces AQL material will receive an average pay factor of 100 percent in the long-run. Similarly, the EP for RQL material is 80 percent as desired from the pay equation.

9.8.7 The EP curve has the advantage of combining all of the possible pay levels into a single expected, or long-term average, pay for each given quality level. While it is an improvement over only considering α and β risks, the use of the EP alone still has some deficiencies. The primary deficiency is that, while it considers the average long-term pay factor, it fails to consider for a given quality level the variability of the individual lot pay factors that comprise this long-term average. This variability is directly related to the sample size; i.e., the variability about the average pay factor decreases as the size of the individual samples increases. To fully evaluate the risks, it is necessary to also consider this variability about the expected pay values.

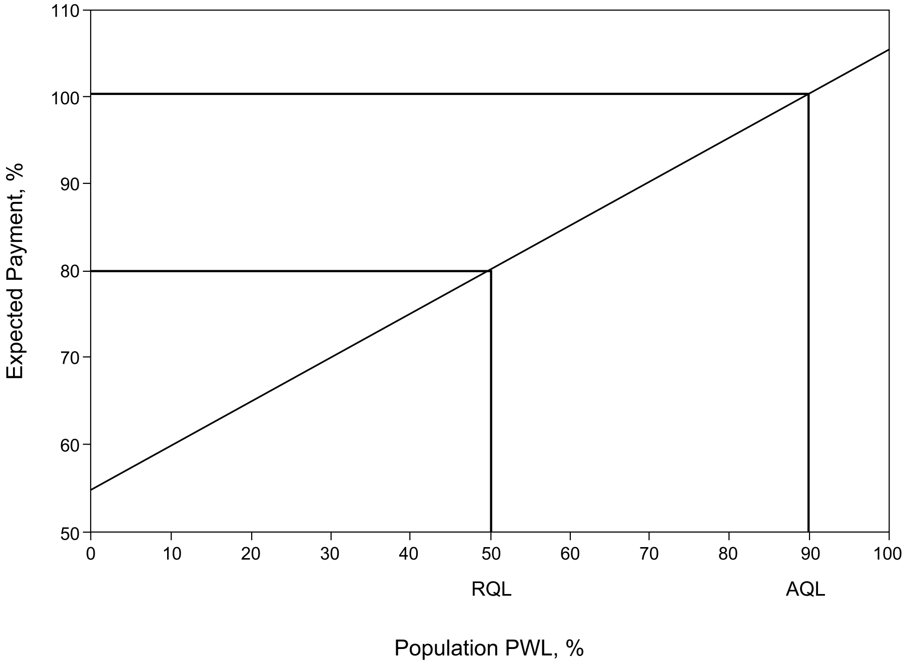

Figure 11—EP Curve from OCPLOT for the Pay Adjustment System Plan Example

9.8.8 The OCPLOT program output can be used to demonstrate this variability of the individual lot pay factors. Figure 12 shows for an AQL population a histogram that displays the individual lot PWL estimates along with their corresponding pay values for 1,000 simulated lots using a sample size of four for each individual lot. Figure 13 shows similar information for an RQL population. The high degree of variability of the individual lot pay factors is obvious from these histograms. For example, for AQL material, in Figure 12 at least one lot has an estimated PWL = 44 with a pay factor of 77 percent. Over a large number of lots, the high and low estimates for lot PWL will tend to balance out to give the correct average pay factor. If, however, there are only a small number of lots on a project, then it is possible that a significantly low estimated PWL value could negatively impact the pay that the contractor would receive. Similarly, higher PWL estimates could be obtained that would provide a larger pay than is deserved. But from a contractor's perspective, the potential negative pay likely outweighs the positive pay.

9.8.9 The variability associated with the estimate of the lot PWL can be reduced by increasing the size of the sample obtained from each lot. Figure 14 shows a histogram that displays for an AQL population the individual lot PWL estimates along with their corresponding pay values for 1,000 simulated lots using a sample size of 20 for each individual lot. Figure 15 shows similar information for an RQL population. When these figures are compared with Figures 12 and 13, for sample sizes of four, the smaller spread of the individual PWL and pay factor estimates is apparent.

9.8.10 While Figures 12 through 15 illustrate the relative variabilities of the individual PWL and pay factor estimates associated with different sample sizes, they do not provide any quantitative measure for the variabilities. One way to quantify these variabilities is to calculate the standard deviation of the individual PWL or pay estimates. (More information on how to do this can be found in *Optimal Procedures for Quality Assurance Specifications*, 2003.)

9.8.11 *Example: Pay Adjustment System Plans—Multiple OC Curves.* Another step that is necessary to evaluate fully the risks for a pay adjustment system plan is to plot OC curves, such as those shown in Figures 8 and 16, associated with receiving various pay factors.

9.8.12 Using the OCPLOT program to develop multiple OC curves for the asphalt content acceptance plan from the previous example, Figure 16 shows OC curves for the probability of receiving greater than or equal to various levels of pay factor for a sample size of four using the pay relationship shown in Equation 9. These OC curves would be considered along with the EP curve from the previous example to evaluate the risks associated with the acceptance plan.

9.8.13 While the EP curve in Figure 11 shows that the average long-term pay is 100 percent for AQL material, the OC curves in Figure 16 show that the probability is about 60 percent that any individual lot of AQL material will receive 100 percent pay or greater. This means that there is about a 40 percent chance that a contractor would receive less than full pay for a lot that was of AQL quality. This risk seems high, however, it is somewhat offset by the fact that the OC curves also indicate that there is nearly a 50 percent chance of receiving a pay of 104 percent or greater. The risk is further mitigated by the fact that contractors intent on obtaining the maximum allowable incentive payment will often try to operate at quality levels higher than the AQL.

9.8.14 OCPLOT works by simulating a large number of estimated individual lot PWL values, determining the corresponding payment factors from the payment equation, and then averaging all of the individual estimated pay factors to determine the expected pay. Figure 16 indicates that the probability is approximately 40 percent that any individual lot of AQL material will receive less than 100 percent payment. Projects, however, consist of multiple lots. Although the analysis goes beyond the scope of this standard practice, the probability that a project operating at the AQL will receive less than 100 percent payment remains constant regardless of the number of lots on the project. However, also regardless of the number of lots per project, the expected, or average, payment over a number of projects will be 100 percent. Once again, however, this seemingly high percentage of AQL projects that would receive a relatively small reduction from full payment is mitigated by the fact that about 60 percent of AQL projects would receive greater than 100 percent payment, and by the fact that many contractors will try to operate at quality levels that are higher than the AQL.

9.9 *Reducing Risks*—As discussed above, for small sample sizes, the risks of not receiving appropriate average pay factor can be calculated and balanced for any combination of quality levels, such as the AQL and RQL. But the risk of a small number of lots, even at the AQL, having a negative price adjustment can be large. There are at least two potential solutions.

9.9.1 *Lot Size vs. Sample Size*—Use larger sample sizes. By increasing the sample size, both the contractor's risk (α) and the agency's risk (β) can be reduced. For this to be practical, larger lot sizes are usually necessary. Some agencies designate the total project as a lot. This naturally allows larger sample sizes. If the total project is selected as the lot this will impact how the typical process variability is determined. (See Appendix X1 and *Optimal Procedures for Quality Assurance Specifications*, 2003.) This means that larger quantities of material will be subjected to negative and positive pay. However, if the normal distribution assumption has not been violated, the PWL estimates will improve, so the pay will more nearly reflect the quality produced. Using sample sizes in the neighborhood of $n = 8$ to $n = 10$ can have a significant impact on reducing the risks to acceptable levels.

9.9.2 *Multiple Pay Equations*—If the use of larger sample sizes is not an option and if the agency considers the risks to be too large for the small sample sizes used, changing the pay determination procedure is an option. Depending upon the initial expected payment values, the payment equation could be modified to allow for higher or lower pay factors for various PWL values. The AASHTO pay relationship in Equation 8 is simple because it is a straight line. However, it may not be true that all materials have a straight-line relationship between quality, as measured by PWL, and value, as represented by the pay factor. It may be decided that the disincentives should not be as great for PWL values near the AQL as they are for PWL values further from the AQL. This could be represented by two or more straight line pay equations, or by a single curvilinear pay equation. Another option might be to use multiple pay factor equations for different sample sizes. To accomplish this, the procedure discussed in Sections 9.8.8 through 9.8.12 can be used iteratively.

---

10. PAY FACTORS

10.1 Several decisions must be made concerning pay relationships. These are extremely important. From a contractor's perspective, the pay factor schedule is one of the most important parts of the acceptance plan. Relating quality and performance to pay is the most desirable form of pay relationship because the relationship supports and defends the decision. This is true because negative pay adjustments are typically viewed with skepticism by the contracting industry. However, when the pay schedule can be shown to be related to quality and, preferably, to performance, it is viewed to be more credible than when it is established arbitrarily.

10.1.1 *Pay Factor Rationale*—The primary purpose of a pay schedule is to provide sufficient incentive to produce the desired quality level at the time of initial construction. A secondary purpose of the pay schedule is to recoup part of the anticipated future costs that are likely to occur when poor quality is received.

10.1.2 *Pay Factor Equations (for Individual Quality Characteristics)*—There are two types of pay factor schedules, "stepped" and "continuous." An example of a stepped pay factor schedule is shown in Table 4 and Figure 17.

Table 4—Typical Stepped Pay Schedule Based on PWL

Estimated PWL	Pay Factor, %
95.0–100.0	102
85.0–94.9	100
50.0–84.9	90
0.0–49.9	70

10.1.3 The use of a continuous (equation-type) pay schedule is becoming more commonplace. The AASHTO equation shown in Equation 9 is one such equation. It is also plotted in Figure 17 (AASHTO *Quality Assurance Guide Specification*, 1995).

$$PF = 55 + (0.50 \times PWL) \qquad (9)$$

where:

PF = pay factor as a percent of contract price, and

PWL = estimated percent within limits.

As noted above, although Equation 9 is simple to use, it may not be likely that there is a straight-line relationship between quality, as measured by *PWL*, and value, as indicated by pay factor. It is best if the pay equation can be related to performance.

10.1.4 Although risk analysis would show these two types of pay schedules to have very nearly the same long-term pay performance, there is a distinct advantage associated with the continuous form. Small changes in the quality estimate can cause large differences in the pay when the quality measure is near a boundary in a stepped pay schedule. A continuous pay schedule avoids this problem.

10.1.5 The AASHTO equation is only one of many possible equations. (When used, consideration should be given to the effects of few lots when small sample sizes are used, as discussed in Section 9.9.) However, the concepts incorporated in the AASHTO equation are important (see Section 9.8.4.1). These concepts, which apply to any pay equation, are:

- The pay is 1.00 (100 percent) when the PWL is at the AQL. Assuming an AQL of 90 PWL, the equation meets this requirement.
- The average pay is 1.00 (100 percent) when at the AQL. For the average pay to be 1.00, clearly, there must be an incentive that allows pay above 1.00 to compensate for lower pay factors from estimated quality levels below the AQL.

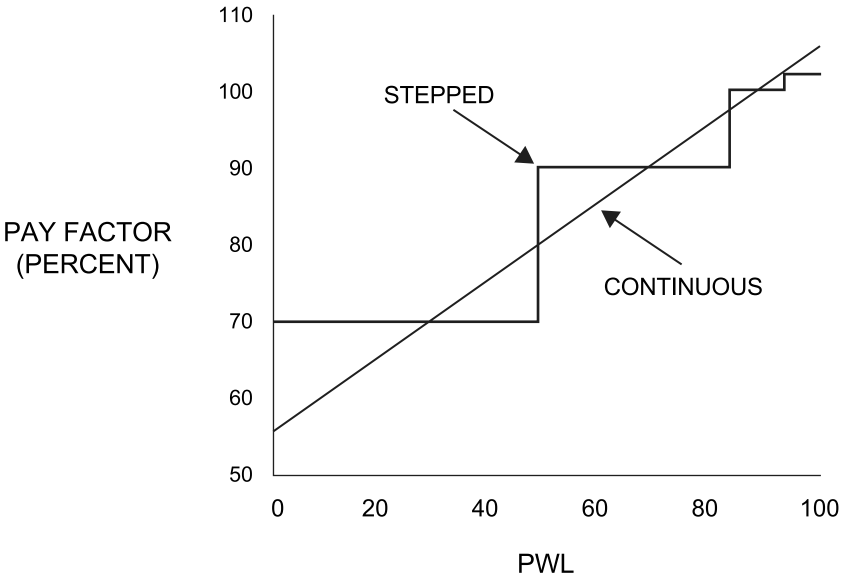

Figure 17—Example of Stepped and Continuous Pay Schedules

10.1.6 *Pay Factors for Composite Quality Characteristics*—Most acceptance plans will contain multiple quality characteristics. In absence of a model to relate these, several methods are currently in use to combine them:

10.1.6.1 The approach that uses the minimum individual pay factor for the composite is based on the "weak link" approach. The least pay factor indicates the value of the combined quality characteristics.

10.1.6.2 The approaches that average or multiply the individual pay factors are based on the concept that all factors contribute equally to the total. However, the outcome of the two can be quite different depending on the individual pay factors.

10.1.6.3 *Pay Factor Examples*—The results based on either the minimum, the average, or multiplying for three quality characteristics in Table 5 demonstrate the differences in the resulting combined pay for various individual pay factor values. In this example, the average approach is the most stable and the approach using multiplication has the greatest differences in values.

Table 5—Results of Different Methods for Combining Individual Pay Factors

Strength	Permeability	Thickness	Minimum	Average	Multiply
1.00	1.00	1.00	1.00	1.00	1.00
1.05	1.05	1.05	1.05	1.05	1.16
0.80	0.80	0.80	0.80	0.80	0.51
1.00	0.80	1.05	0.80	0.95	0.84

10.1.7 *Weighted Pay Factors*—Several agencies use a weighting system to combine individual pay factors based on the concept that some characteristics are more important than others. An example of a weighted pay factor equation is shown in Equation 10.

$$CPF = W_1(PF_1) + W_2(PF_2) + W_3(PF_3) + \ldots \qquad (10)$$

where:

CPF = Composite pay factor,

W_1 = Weighting factor one,

PF_1 = Pay Factor for quality characteristic one,

W_2 = Weighting factor two,

PF_2 = Pay Factor for quality characteristic two,

W_3 = Weighting factor three, and

PF_3 = Pay Factor for quality characteristic three.

10.1.8 *Risks Associated with Composite Pay Factors*—Using more quality characteristics than needed to define product quality is unnecessary and is an encumbrance upon both the agency and the contractor. The risks discussed in Section 9 apply to each pay factor. When using composite quality characteristics, the calculation of risks is more complicated. It is important that the quality characteristics not be highly interrelated. If the quality characteristics are interrelated, care must be taken to either not use both or to minimize the joint effect of them. While there is no minimum number of quality characteristics that should be used, the intent is to use those that are most indicative of quality. (For more discussion on composite pay factors see *Optimal Procedures for Quality Assurance Specifications*, 2003.)

10.1.9 *Composite Quality Measures*—Another approach is to base the pay equation on a single quality measure that is a composite of the individual quality measures. This approach combines the various decision-making steps into a single performance indicator and perhaps simplifies the procedure. (This topic is discussed in detail in *Optimal Procedures for Quality Assurance Specifications*, 2003 and Weed, 2003.)

10.1.9.1 An example of this approach is shown in Equation 11 for HMA air voids and thickness:

$$CPWL = 100 - 0.331PWL_{AV} - 0.193PWL_{\mathrm{THICK}} - 0.00476PWL_{AV}PWL_{\mathrm{THICK}} \qquad (11)$$

where:

$CPWL$ = composite PWL quality measure,

PWL_{AV} = PWL air voids, and

PWL_{THICK} = PWL thickness.

11. IMPLEMENTATION STEPS

11.1 *Simulate Acceptance Plan*—Data can be used from existing projects to analyze how the acceptance plan will work and what the pay would have been if the acceptance plan had been used. But it must be remembered that the contractor will not have bid under, nor will react to, the proposed acceptance plan.

11.2 *Technician Qualification Training*—There are two important parts of training to emphasize during and beyond implementation of the acceptance plan.

11.2.1 Emphasize the importance of having qualified, trained technicians. This effort must be an ongoing program to not only initially train and qualify technicians but to stress the need for continuous training.

11.2.2 Provide combined agency/industry training where both parties to the contract hear the same information and get to express their viewpoints in a constructive training atmosphere.

11.3 *Pilot Projects*—Pilot projects are intended as one way to ease into the acceptance plan on a limited basis. This allows the contractors to develop bidding strategies, to see how the acceptance plan works in a limited manner, and allows the agency to examine the outcome and, if desired, to fine-tune the acceptance plan. Clearly specify the contractor's risk in the specification so that contractors will know their risk and how to bid.

11.4 *Reevaluate the Acceptance Plan*—Based on the outcome of the pilot projects, it may be desirable to change certain aspects of the acceptance plan. If so, this is a good opportunity to do it. If problems are found, look at potential reasons for the problems. For example, if one quality characteristic is a consistent source of a large pay adjustment, examine the test procedures used to evaluate that quality characteristic. Are the procedures being used correctly? Is the variability of the results within expected limits?

11.5 *Phase-In Acceptance Plan*—Consider applying percentages of incentive/disincentive over a short time period to encourage contractor participation. A schedule of 25 percent, 50 percent, and 100 percent over 3 years is one strategy that has been successful. Do not rush into full implementation. A 5-year timetable for full implementation is realistic.

11.6 *Monitor Performance of Acceptance Plan*—An annual review of the acceptance plan is desirable.

11.6.1 Analyze project data for each quality characteristic to determine how well the process standard deviations that are being attained compare with the "typical" values used when developing the acceptance plan. The desired AQL not being consistently achieved may indicate that the technology is not sufficient to allow the contractors to achieve the AQL.

11.6.2 *Look for Administrative Problems*—Is the definition for a lot creating any problems? Are lots open for long periods before the pay factor can be determined?

11.6.3 *Consider Contractor Concerns*—Does the industry think the plan is working as intended? Do they have constructive suggestions as to how it can be improved? Listen to industry's concerns.

11.6.4 *Identify Technology Changes*—Consider including significant technology changes as they occur. As stated previously, the acceptance plan should be dynamic.

11.6.5 *Tie Results of the Acceptance Plan into the Pavement Management System (PMS)*—For the acceptance plan to be a true measure of quality, closing the loop relating quality to performance requires the integration of the quality levels and/or pay factors with the agency's pavement management system. This may be a source of performance information for future modifications of the specifications.

11.6.6 *Compare the Quality Levels Achieved with the Criteria Established for Success*—Close the loop with the goals and expectations that were set in the initiation and planning stage. Is the plan performing the way it was anticipated? If not, why not? Are further revisions needed?

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLE ACCEPTANCE PLAN DEVELOPMENT

X1.1. ***Step 1:*** *Decide on the Quality Characteristic to be Measured, the Lot Size, Sublot Size, and Sample Size*—The agency wants to establish a variables type acceptance plan for asphalt content. The agency will perform the acceptance tests and *Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Oven Test* (T 308) has been chosen as the method of test. The sample will be taken from the paving site and brought to the field lab for testing. The preliminary decision for lot size has been established as 4,000 tons and sublots will be 500 tons. This sets the sample size, $n = 8$. After the risks have been analyzed, these decisions of lot, sublot, and sample size may have to be adjusted.

X1.2. ***Step 2:*** *Collect Project Data*—A random sampling plan is used to collect data from projects, under the conditions and with the lot and sublot definitions decided upon in Step 1. Ten typical projects throughout the agency jurisdiction are sampled over the period of 30 paving days to provide the data. This allows the agency and contractor an opportunity to assess the viability of the proposed sampling and testing program.

X1.3. ***Step 3:*** *Analyze the Data*—The analysis determines several properties. One is the appropriate probability distribution to use to represent the product. This includes estimates for population parameters—mean, standard deviation, variance, bias, and skewness—on a lot-by-lot basis. "Typical" values, particularly for process standard deviation, are also developed. Using computerized statistical programs, which include histograms and calculation of statistical measures, asphalt content was found to be approximately normally distributed (see FHWA-RD-98-077, 1998).

X1.3.1. ***Step 3a:*** Next, develop a value for the "process" variability that is consistent with Step 1. Conceptually, the *individual* standard deviation, s, values for each lot are pooled to get a typical "within-lot" standard deviation for each project. It is *not* appropriate to combine all test results from a project and then to calculate a standard deviation for these combined data. To estimate the "within-lot" standard deviation, the lot variances, rather than standard deviations, are used. The sample variance is an *unbiased* estimator of the population variance, whereas the sample standard deviation is a *biased* estimate of the population standard deviation. The square root of the pooled lot variance is an unbiased estimate of the within-lot standard deviation. The pooled variance is a weighted average based on the sample sizes associated with the individual lot variances. The formula for this estimate is shown in Equation X1.1, if there are k individual lots,

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2 + \cdots + (n_i - 1)s_i^2}{n_1 + n_2 + \cdots n_i - k} \qquad (X1.1)$$

where:

s_p^2 = pooled estimate for the within-lot variance;

s_i^2 = variance for lot i, where $i = 1, 2, \ldots k$;

n_i = number of values for lot i; and

k = number of lots in the project.

The pooled standard deviation is then the square root of the pooled variance.

Example of Within-Lot Pooled Standard Deviation—The test results for 12 lots from one project are shown in Table X1.1. The "within-lot" standard deviation, as determined from the pooled lot variance, is $\sqrt{0.0229}$ = 0.151. This is not the same as the average standard deviation of 0.148.

Table X1.1—Example Summary of Test Results for a Project

Lot	Test Results	n	JMF	Lot Mean	Lot Std Dev	Lot Variance
1	4.8, 5.0, 5.1, 4.8, 4.9, 5.1, 5.2, 4.8	8	5.0	4.96	0.160	0.0255
2	4.7, 5.1, 5.1, 5.0, 4.9, 4.8, 5.0, 4.8	8		4.92	0.149	0.0221
3	5.2, 5.3, 4.7, 4.9, 5.0, 4.9, 4.8, 5.0	8		4.98	0.198	0.0393
4	5.3, 5.1, 4.9, 5.0, 5.1, 4.8, 4.9, 5.0	8		5.01	0.155	0.0241
5	5.2, 5.0, 4.6, 4.8, 4.7, 4.9, 5.0, 4.8	8		4.88	0.191	0.0364
6	4.8, 4.9, 4.9, 4.8, 5.0, 4.9, 4.8, 4.8	8		4.86	0.074	0.0055
7	4.9, 4.7, 4.9, 4.6, 4.7, 5.0, 4.9, 4.8	8		4.81	0.136	0.0184
8	4.9, 5.1, 5.2, 4.7, 4.7, 4.8, 4.9, 4.8	8		4.89	0.181	0.0327
9	4.9, 4.7, 5.1, 5.0, 4.8, 4.9, 4.9, 4.8	8		4.89	0.125	0.0155
10	4.9, 4.6, 5.0, 4.8, 4.9, 4.7, 5.0, 4.9	8		4.85	0.141	0.0200
11	5.0, 4.9, 4.8, 5.1, 4.8, 5.1, 4.9, 5.0	8		4.95	0.120	0.0143
12	5.0, 5.2, 4.9, 4.8, 5.0, 5.1, 5.2, 4.9	8		5.01	0.146	0.0210
	Average	96		4.92	0.148	0.0229
	Pooled for 12 Lots	12			0.151	0.0229

Note: In the above example, the pooled variance is equal to the average of the individual lot variances. This is true only because the sample size, n, was the same for each lot. If the sample size were not constant for each lot, as may happen with historical data, then the pooled variance and the average of the individual variances would typically not be the same.

X1.3.2. ***Step 3b:*** *Select a "Typical" Process Variability*—After determining typical within-lot variabilities for the ten projects, it can then be determined whether the data from different contractors are reasonably consistent, or whether some have appreciably lower or higher variabilities than others.

The typical process variability should not be set for the most or least consistent contractor. Once the project variability data are available, a decision must be made regarding what variability to use as the “typical” process variability. This typical variability will then be used to establish specification limits. There is no single “correct” way to decide upon the typical variability to use.

Example of Process Variability—Data from the ten projects are shown in Table X1.2.

Table X1.2—Example Process Variability Results

Project	Project “Within-Lot” Standard Deviation	Project	Project “Within-Lot” Standard Deviation
1	0.151	6	0.169
2	0.205	7	0.178
3	0.166	8	0.225
4	0.154	9	0.199
5	0.113	10	0.181

The typical within-lot process variability value is based on consideration of all of the ten project data rather than just a single best or worst project. When the standard deviation values are ordered from smallest to largest, this yields: 0.113, 0.151, 0.154, 0.166, 0.169, 0.178, 0.181, 0.199, 0.205, and 0.225. A subjective decision is then made to choose a mid-value (0.18) as the “typical” value. The three projects with higher standard deviations would have to reduce their variability to meet the specifications, but the other seven should have little trouble.

X1.3.3. ***Step 3c:** Determine if a “Target Miss” Is Appropriate*—In addition to the typical “process” variability, another factor that needs to be considered is the capability of contractors to center their processes on the target value. The “target miss” data from the ten projects are shown in Table X1.3.

Example of Determining the “Target Miss” and Combined Standard Deviation

Table X1.3—Example Project “Target Miss” Results

Project	Project “Target Miss” Averages	Project	Project “Target Miss” Averages
1	–0.08	6	–0.11
2	–0.20	7	+0.04
3	–0.10	8	+0.05
4	–0.04	9	+0.11
5	+0.06	10	–0.07

The mean for these ten project “target misses” is –0.034. This indicates that, on the average, the test results are only slightly lower than the JMF. It is decided that the contractors are able to hit the JMF reasonably well. However, the standard deviation for these ten “target misses” is 0.096, with a corresponding variance of 0.00922. Using these data with the previously selected typical process variability of a standard deviation of 0.18, producing a corresponding variance of 0.0324, the combined standard deviation for establishing specification limits is then calculated using Equations X1.2 and X1.3.

$$\hat{\sigma}^2_{\text{combined}} = \hat{\sigma}^2_{\text{center}} + \hat{\sigma}^2_{\text{process}} \qquad (X1.2)$$

$$\hat{\sigma}_{\text{combined}} = \sqrt{\hat{\sigma}^2_{\text{combined}}} \qquad (X1.3)$$

where:

$\hat{\sigma}^2_{\text{combined}}$ = estimated combined “target miss” and “process” variance,

$\hat{\sigma}^2_{\text{center}}$ = estimated “target miss” variance,

$\hat{\sigma}^2_{\text{process}}$ = estimated “process” variance, and

$\hat{\sigma}_{\text{combined}}$ = estimated combined standard deviation.

Using the project data, the above equations result in:

$$\hat{\sigma}^2_{\text{combined}} = 0.00922 + 0.0324 = 0.04162 \qquad \textit{(X1.4)}$$

$$\hat{\sigma} = \sqrt{0.04162} = 0.204 \qquad \textit{(X1.5)}$$

The combined standard deviation is determined to be approximately 0.20 percent asphalt content.

X1.4. ***Step 4:** Determine the Specification Limits, Acceptance Limits, AQL, and RQL—t* has been decided that the AQL will be 90 PWL.

X1.4.1. ***Step 4a:*** Using the AQL with the combined estimated standard deviation of 0.20 percent that was found in Step 3, defines AQL material as shown in Figure X1.1. The specification limits are: JMF ± (1.645 × 0.20) = JMF ± 0.33, rounded to ±0.35 (See Table 1). If a “target miss” value had been found to be significant, this value would have been added to the tolerance.

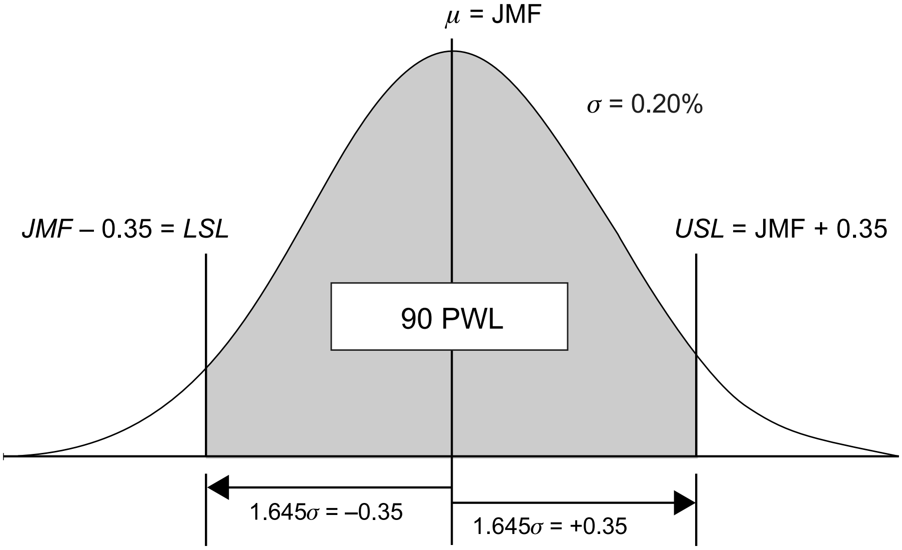

Figure X1.1—AQL Material for the Asphalt Content Example

X1.4.2. ***Step 4b:*** For this example, the analysis of performance data indicates that the RQL should be set at PWL = 50. Figure X1.2 shows two possible populations that represent RQL material. When the average value is ±0.35 from the JMF, the population is centered at either the LSL or USL and 50 percent of the population is estimated to be outside the specifications.

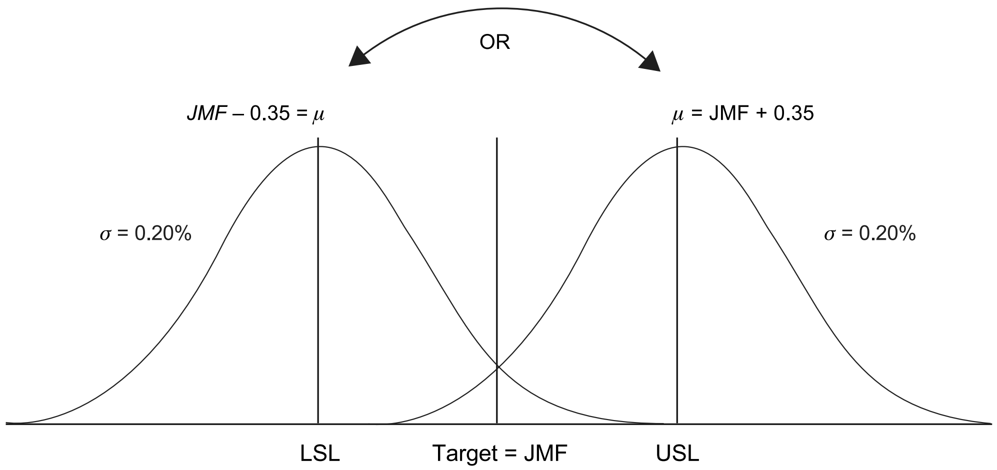

Figure X1.2—RQL Material for the Asphalt Content Example

X1.5. ***Step 5:** Determine Risks*—If the quality characteristic will be evaluated on an accept or reject basis, calculate the buyer's and seller's risks and skip Step 6. If the quality characteristic will be evaluated on a pay factor basis, skip Step 5 and proceed to Step 6.

As a first try, the acceptance limit is set at 70 PWL, i.e., any lot with a PWL of 70 or greater is accepted, while any lot with a PWL less than 70 is rejected. Using OCPLOT and the pass/fail option, calculate the OC table, OC Curve, and determine α and β. At its highest precision level, OCPLOT simulates 5000 lots. An example of the completed input screen from OCPLOT for this example problem is shown in Figure X1.3.

Since OCPLOT uses simulation, the probability of acceptance values will change slightly each time the program is run. For this example, OCPLOT was run five times, with each trial simulating 5000 lots. The five values were then averaged to obtain the probability of acceptance for various population PWL values. These average values are shown in Table X1.4 and Figure X1.4. The $\alpha = 0.021$ (2.1 percent) and $\beta = 0.067$ (6.7 percent) values are determined to be reasonable.

Note X1—If these values were not considered reasonable, then either the sample size or the acceptance limit could be changed and OCPLOT could be run again. This iterative process would continue until the risks were considered reasonable.

X1.6. ***Step 6:*** If the quality characteristic will be evaluated on a pay factor basis, an appropriate pay equation with reasonable risks must be identified.

X1.6.1. ***Step 6a:*** Use OCPLOT with the Pay Adjustment option to decide on the pay equation and to calculate the EP Curve. An example of the completed input screen from OCPLOT for this example problem is shown in Figure X1.5.

Once again, five runs of OCPLOT, each with 5000 lots, were performed and the average EP values were calculated. These are shown in Table X1.5 and Figure X1.6. The AASHTO pay equation, $PF = 55 + (0.50 \times PWL)$, is used as a first try. The EP curve duplicates the pay equation. The average pay at the AQL is 100 percent, as desired, while the average pay at the RQL is 80.0 percent, as indicated by the pay equation chosen.

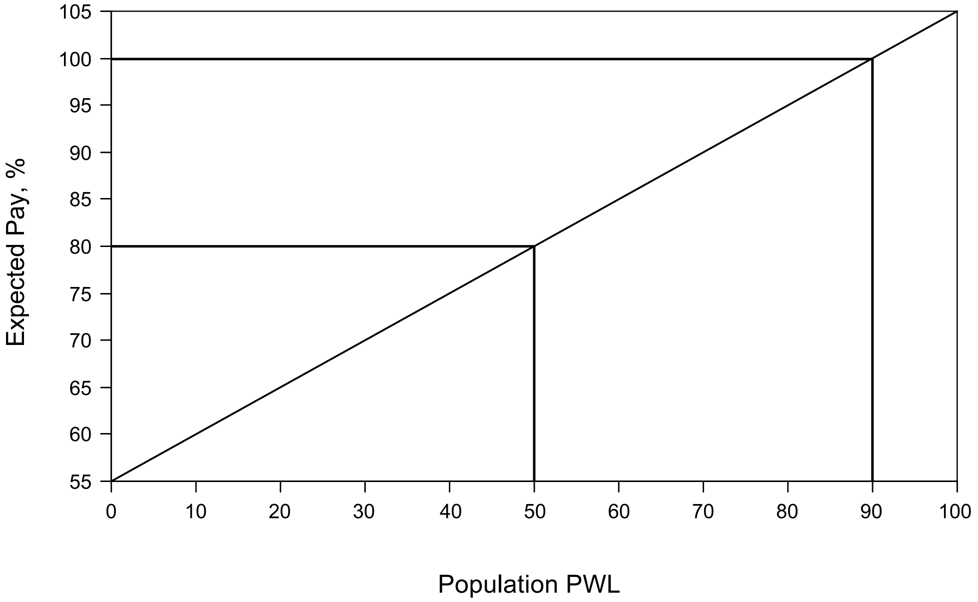

Figure X1.6—EP Curve for the Asphalt Content Example

X1.6.2. ***Step 6b:*** Next, the performance at the AQL is examined. As shown in Figure X1.7, when at the AQL, some lots would be estimated to have a PWL between 60 and 70, resulting in pay factors of 90 percent and less. However, several would be estimated to be at a PWL of more than 95, resulting in pay factors of more than 102 percent. So while there is about a 40 percent chance that a contractor would receive less than full pay for a lot that was of AQL quality, this risk is somewhat offset by the fact that the histograms also indicate that there is about a 60 percent chance of receiving a pay of 100 percent or greater.

Figure X1.7 shows that AQL material may be paid up to 5 percent too much and up to about 15 percent too little. If the agency decides that this pay factor equation results in reasonable risks, then this evaluation of risks must be explained to the contracting community. If it is decided that too much variability exists, one solution is to increase the sample size with a commensurate lot size increase; another solution is to choose a different pay factor equation. Choosing a larger sample size will not affect the expected pay values, but it will decrease the spread of the estimated PWL values, thereby decreasing the maximum underpayment, and possibly overpayment, at the AQL. Similarly, a payment equation with a shallower slope, or a series of straight line equations that have shallower slopes near the AQL and steeper slopes further away from the AQL, will tend to reduce the amounts of the over or underpayments at the AQL. If the pay factor equation is changed, this will also change the EP values.

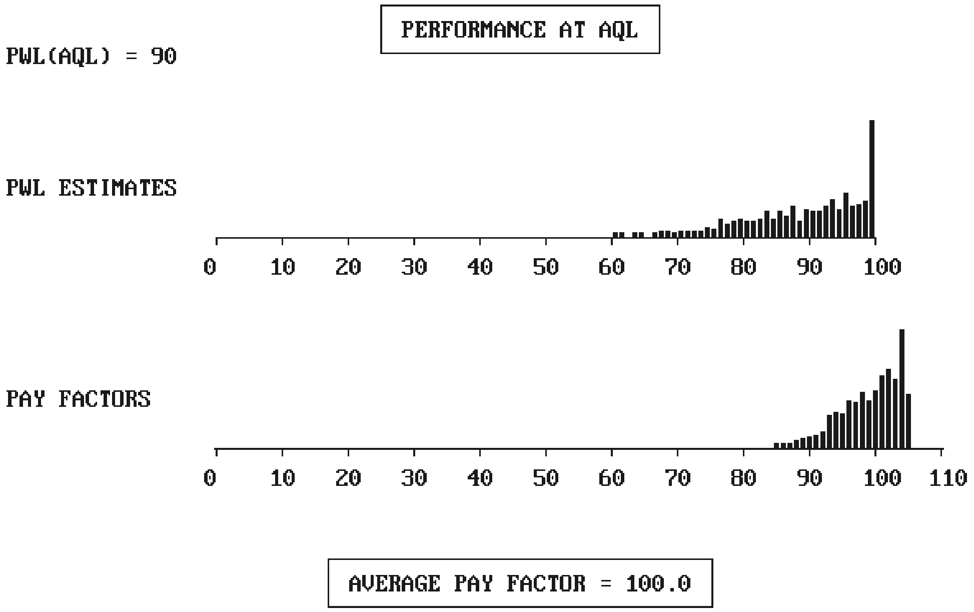

Figure X1.7—Histogram for an AQL Population Showing Variability of Individual PWL and Pay Factor Estimates for a Sample Size of 8

X1.6.3. ***Step 6c:*** Next, the performance at the RQL is examined. This is shown in Figure X1.8. Although not as critical as the performance at the AQL, the agency is interested in the PWL estimates when the material is at the RQL. Figure X1.8 shows that when at the RQL some lots would be estimated to be at a PWL of above 80, resulting in pay factors as high as about 95 percent. As in Step 6b, if the agency decides that this pay factor equation results in reasonable risks at the RQL it can select this pay factor equation. If it is decided that too much variability exists, one solution is to increase the sample size with a commensurate lot size increase; another solution is to choose a different pay factor equation.

Note X2—Step 6 may require a number of iterations to arrive at an acceptable pay factor relationship. The pay equation should not be selected arbitrarily or just for the sake of simplicity. Ideally, the pay factor equation should relate the quality of the material or construction, as represented by the quality measure, PWL in this example, to the value of the material or construction, as represented by the pay factor. This relationship may be more complex than a simple linear relationship. A number of different performance models are available to assist in establishing this performance to pay factor relationship. Some of these approaches are discussed in *Optimal Procedures for Quality Assurance Specifications* (2003).

X2. EXAMPLE OF *F*-TEST AND *T*-TEST METHOD FOR COMPARING TWO SETS OF DATA

X2.1. *Purpose*:

X2.1.1. The purpose of this procedure is to provide a method for comparing two sets of data, such as contractor and agency test results. The statistical tests used to make the comparisons are called hypothesis tests, where the assumption (null hypothesis, H_o) for each test is that the data sets are from the same population. In other words, the null hypotheses are that the variabilities of the two data sets are equal for the *F*-test, and that the means of the two data sets are equal for the *t*-test.

X2.2. *Analysis*:

X2.2.1. When comparing two data sets, it is important to compare both the means and the variances. A different test is used for each of these comparisons. The *F*-test provides a method for comparing the variances (standard deviation squared) of the two sets of data. Differences in means are assessed by the *t*-test. Test results generated from construction processes and material properties usually follow a normal distribution. For normal distributions, the ratios of variances follow an *F*-distribution, while the means of relatively small samples follow a *t*-distribution. Hypothesis tests for equal variances and means can therefore be conducted using these distributions.

For samples from the same normal population, the statistic *F*, which is the ratio of the two sample variances, has a sampling distribution called the *F*-distribution. Tables are available for the *F*-distribution just like they are for the normal distribution. For process verification testing, the *F*-test is based on the ratio of the sample variance of the contractor's test results, s_c^2, and the sample variance of the agency's test results, s_a^2.

Similarly, the *t*-statistic and the *t*-test can be used to test whether the sample mean of the contractor's test results, $\overline{X}_c$, and that of the agency's test results $\overline{X}_a$, came from populations with the same mean.

The equations and solutions for the *F*-test and *t*-test are presented in the following sections, but it is recommended that a computer program be used in practice to perform the calculations. Spreadsheet programs, such as Microsoft® Excel, have both *F*-tests and *t*-tests. Some agencies have chosen to develop their own computer packages.

When comparing contractor and agency samples, it is important that random sampling was used when obtaining the samples. Also, because sources of variability influence the population parameters, the two sets of test results must have been sampled over the same time period, and the same sampling and testing procedures must have been used. If it is determined that a significant difference is likely between either the variances or the means, the source of the difference should be identified. The identification of a difference is just that; i.e., it detects that a difference exists. The reason for the difference must still be determined.

Before comparing contractor and agency samples, a level of significance, α, must be selected. While α values of 0.10, 0.05, and 0.01 are common, many agencies select a value of 0.01 to minimize the likelihood of incorrectly concluding that the results are different when they actually came from the same population. However, it should be recognized that selecting a low α value reduces the chance of detecting a real difference when one actually exists.

X2.3. *Procedure*:

X2.3.1. *F-test for Sample Variances*

Since the values used for the *t*-test are dependent upon whether or not the variances are assumed equal for the two data sets, it is necessary to test the variances before the means. The intent is to determine whether the difference in the variability of the contractor's tests and the agency's tests is larger than might be expected by chance if they came from the same population. It does not matter which variance is larger. After comparing the *F*-test results, one of the following will be concluded:

- The two sets of data have different variances because the difference between the two sets of test results is greater than is likely to occur from chance if their variances are actually equal.
- There is no reason to believe the variances are different because the difference is not so great as to be unlikely to have occurred from chance if the variances are actually equal.

X2.3.2. *Steps Involved in the F-test*

The first step is to choose α, the level of significance for the test. For this discussion, $\alpha = 0.01$ is used. Next, compute the variance for the contractor's tests, s_c^2, and the agency's tests, s_a^2. Then use the simple ratio equation to compute *F*, where $F = s_c^2 / s_a^2$ or $F = s_a^2 / s_c^2$. *Always use the larger of the variances in the numerator so the ratio will be greater than 1.*

The next step is to determine the critical *F* value, F_{crit}, from the *F*-table (see Table X2.1 at the end of this appendix) for the α level of significance chosen, and using the degrees of freedom ($n - 1$) associated with each set of test results. Thus, the degrees of freedom associated with the contractor's variance, s_c^2, is ($n_c - 1$) and the degrees of freedom associated with the agency's variance, s_a^2, is ($n_a - 1$). The values in this *F*-table are tabulated to test if there is a difference (either larger or smaller) between the two variance estimates. This is known as a two-tailed test. Care must be taken when using other tables of the *F*-distribution, since they are usually based on a one-tailed test, i.e., testing whether one variance is larger than another. This means that the F_{crit} values in Table11 are the same values that would be listed at the 99.5 percentile (even though the 99.0 percentile would normally be associated with $\alpha = 0.01$) for a one-tailed test.

Once the value for F_{crit} is determined from the table (making sure the appropriate degrees of freedom for the numerator and denominator are used), if $F \geq F_{crit}$, then decide that the two sets of tests have significantly different variabilities. If $F < F_{crit}$, then decide that there is no reason to believe that the variabilities are significantly different.

X2.3.3. *F-test Example Problem 1*

A contractor has run 12 asphalt content tests and the agency has run 6 tests over the same period of time using the same sampling and testing procedure. The results are shown below. Based on their variability, is it likely that the tests came from the same population?

Contractor Tests	Agency Tests
6.41	5.42
6.23	5.78
6.08	6.23
6.55	5.38
6.11	5.62
5.97	5.79
6.28	
6.07	
5.92	
5.76	
6.06	
5.71	
$\bar{X}_c = 6.10$	$\bar{X}_a = 5.70$
$s_c^2 = 0.061$	$s_a^2 = 0.097$

Use the *F*-test to determine whether or not to assume the variance of the contractor's tests differs from the variance of the agency's tests.

Step 1: Compute the variance, s^2, for each set of tests.

$s_c^2 = 0.061 \qquad s_a^2 = 0.097$

Step 2: Compute *F*:

$$F = \frac{s_a^2}{s_c^2} = \frac{0.097}{0.061} = 1.59$$

Step 3: Determine F_{crit} from the *F*-distribution table making sure to use the correct degrees of freedom for the numerator ($n_a - 1 = 6 - 1 = 5$) and the denominator ($n_c - 1 = 12 - 1 = 11$). From Table X2.1, $F_{crit} = 6.42$.

Conclusion: Since $F < F_{crit}$ (i.e., $1.59 < 6.42$), there is no reason to believe that the two sets of data have different variabilities. That is, they could have come from the same population.

Note X3—To simplify the example, the means were rounded to two decimal points and the variances to three. This can result in a significant difference in the computed result. In practice, several more decimal points should be used (see Section X2.15.3).

X2.3.4. *F-test Example Problem 2*

A contractor has run ten air void tests from cores and the agency has run five air void tests over the same period of time using the same sampling and testing procedure. The results are shown below. Based on their variability, is it likely that the tests came from the same population?

Contractor Tests	Agency Tests
6.42	7.52
7.18	11.38
5.04	9.20
4.56	5.32
7.12	3.18
7.98	
6.32	
6.08	
5.92	
5.78	
$\overline{X}_c = 6.24$	$\overline{X}_a = 7.32$
$s_c^2 = 1.036$	$s_a^2 = 10.299$

Step 1: Compute the variance, s^2, for each set of tests.

$s_c^2 = 1.036$ $\quad$ $s_a^2 = 10.299$

Step 2: Compute F: $\quad F = \frac{s_a^2}{s_c^2} = \frac{10.299}{1.036} = 9.94$

Step 3: Determine F_{crit} from the F-distribution table making sure to use the correct degrees of freedom for the numerator ($n_a - 1 = 5 - 1 = 4$) and the denominator ($n_c - 1 = 10 - 1 = 9$). From Table X2.1, $F_{crit} = 7.96$.

Conclusion: Since $F > F_{crit}$ (i.e., $9.94 > 7.96$), it is unlikely that the two data sets came from the same population. Therefore, conclude that the contractor and agency results came from different populations. Since the results are different the agency should investigate the cause of the difference.

Note X4—To simplify the example the means were rounded to two decimal points and the variances to three. This can result in a significant difference in the computed result. In practice, several more decimal points should be used.

X2.3.5. *t-Test for Sample Means*

Once the variances have been tested and assumed to be either equal or not equal, the means of the test results can be tested to determine whether they differ from one another or can be assumed to be equal. The desire is to determine whether it is reasonable to assume that the contractor's tests came from the same population as the agency's tests. A *t*-test is used to compare the sample means. Two approaches for the *t*-test are necessary. If the sample variances are assumed equal (*F*-test Example Problem 1 above), then the *t*-test is conducted based on the two samples using a pooled estimate for the variance and the pooled degrees of freedom. This approach is *t*-test example 1 described below. If the sample variances are assumed to be different (*F*-test Example Problem 2 above), then the *t*-test is conducted using the individual sample variances, the individual sample sizes, and the effective degrees of freedom (estimated from the sample variances and sample sizes). This approach is *t*-test Example 2 below.

In either of the two cases discussed in the previous paragraph, one of the following decisions is made:

- The two sets of data have different means because the difference in the sample means is greater than is likely to occur from chance if their means are actually equal.

- There is no reason to believe that the means are different because the difference in the sample means is not so great as to be unlikely to have occurred from chance if the means are actually equal.

Conceptually, for the *t*-test in which the sample variances are equal, the equation used to calculate the *t*-value divides the difference between two means by the pooled standard deviation. The pooled standard deviation is the square root of the pooled variance, which is the weighted average of the two variances using the degrees of freedom for each sample as the weighting factor. (Again, conceptually, this is similar to the *Z*-equation in which the difference between the mean and a point of interest is expressed in standard deviation units. But because small sample sizes are used, the *t*-distribution is used.)

To determine the critical t value, t_{crit}, against which the computed *t*-value is compared, it is necessary to select the level of significance, α. Again, a value of $\alpha = 0.01$ is common. Next, the critical *t*-value, t_{crit}, is obtained from the *t*-table (see Table X2.2 at the end of this appendix) for the pooled degrees of freedom. The pooled degrees of freedom for the case where the sample variances are assumed equal are $(n_c + n_a - 2)$. If $t \geq t_{crit}$, then decide that the two sets of tests have significantly different means. If $t < t_{crit}$, then decide that there is no reason to believe the means are significantly different.

X2.3.6. *t-test Example Problem 1: Sample Variances Assumed to Be Equal*

Use *F*-test Example Problem 1 above (see Section X2.3.3) in which a contractor has run 12 asphalt content tests and the agency has run six tests over the same period of time using the same sampling and testing procedures. Based on their means, is it likely that the tests came from the same population?

Use the *t*-test for the case of equal variances (determined above in *F*-test Example Problem 1) to determine whether or not to assume the mean of the contractor's tests differs from the mean of the agency's tests.

In *F*-test Example Problem 1, it was determined that $s_c^2 = 0.061$ and $s_a^2 = 0.097$.

Step 1: Compute the sample mean, $\bar{X}$, for each set of tests (see Section X2.3.3).

$\bar{X}_c = 6.10$ $\bar{X}_a = 5.70$

Step 2: Compute the pooled variance, s_p^2, using the sample variances from above.

$$s_p^2 = \frac{s_c^2(n_c - 1) + s_a^2(n_a - 1)}{n_c + n_a - 2}$$

$$s_p^2 = \frac{0.061(12-1) + 0.097(6-1)}{12+6-2} = 0.072$$

Step 3: Compute the *t*-statistic, t, using the equation for equal variances.

$$t = \frac{\left|\bar{X}_c - \bar{X}_a\right|}{\sqrt{\frac{s_p^2}{n_c} + \frac{s_p^2}{n_a}}}$$

$$t = \frac{\left|6.10 - 5.70\right|}{\sqrt{\frac{0.072}{12} + \frac{0.072}{6}}} = 2.981$$

Step 4: Determine the critical t value, t_{crit}, for the pooled degrees of freedom.

Degrees of freedom = $(n_c + n_a - 2) = (12 + 6 - 2) = 16$.

From Table X2.2, for $\alpha = 0.01$ and 16 degrees of freedom, $t_{crit} = 2.921$.

Conclusion: Since 2.981 > 2.921, we reject the null hypothesis, and assume that the sample means are not equal. We therefore assume that they came from different populations. We therefore conclude that it is unlikely (but not impossible) that the contractor and agency test results represent the same process. In other words, the agency tests do not verify the contractor tests. Therefore, the agency should investigate the cause for the difference in means.

Note X5—To simplify the example, the means were rounded to two decimal points and the variances to three. This can result in a significant difference in the computed result. In practice several more decimal points should be used.

X2.3.7. *t-Test Example Problem 2: Sample Variances Assumed to Be Different*

The *F*-test Example Problem 2 above, in which a contractor ran ten air void tests from cores and the agency ran five tests over the same period of time, concluded that based on the variances the contractor and agency results came from different populations. Based on their means, is it likely that the tests came from the same population?

In *F*-test Example Problem 2, it was determined that $s_c^2 = 1.036$ and $s_a^2 = 10.299$.

Step 1: Compute the mean, $\bar{X}$, for each set of tests (see Section X2.3.4).

$\bar{X}_c = 6.24$ $\quad\quad$ $\bar{X}_a = 7.32$

Step 2: Compute the *t*-statistic, *t*, using the equation for unequal variances.

$$t = \frac{\left|\bar{X}_c - \bar{X}_a\right|}{\sqrt{\dfrac{s_c^2}{n_c} + \dfrac{s_a^2}{n_a}}}$$

$$t = \frac{\left|6.24 - 7.32\right|}{\sqrt{\dfrac{1.036}{10} + \dfrac{10.299}{5}}} = 0.734$$

Step 3: Determine the critical *t* value, t_{crit}, for the effective degrees of freedom, f'.

$$f' = \frac{\left(\dfrac{s_c^2}{n_c} + \dfrac{s_a^2}{n_a}\right)^2}{\left[\dfrac{\left(\dfrac{s_c^2}{n_c}\right)^2}{n_c + 1} + \dfrac{\left(\dfrac{s_a^2}{n_a}\right)^2}{n_a + 1}\right]} - 2$$

$$f' = \frac{\left(\dfrac{1.036}{10} + \dfrac{10.299}{5}\right)^2}{\left[\dfrac{\left(\dfrac{1.036}{10}\right)^2}{10 + 1} + \dfrac{\left(\dfrac{10.299}{5}\right)^2}{5 + 1}\right]} - 2 = 4.61 \rightarrow 4$$

The calculated value for effective degrees of freedom is truncated to the lower integer in this example. Truncating the calculated value for effective degrees of freedom is the most common approach. In general, rounding to a smaller value for degrees of freedom gives a larger critical value, thereby making it less likely to reject the null hypothesis of equal means.

An even more simplified approach is to use the degrees of freedom for the data set with the fewest values. In this example, that would be $n_a - 1 = 4$, which yields the same result as the effective degrees of freedom calculation. This, however, will not always be the case, and the use of the effective degrees of freedom is the preferred approach.

Note that the value for effective degrees of freedom is less than would have been used if the variances had been assumed to be equal.

From Table X2.2 for $\alpha = 0.01$ and 4 degrees of freedom, $t_{crit} = 4.604$.

Conclusion: Since 0.734 < 4.604, there is no reason to reject the assumption that the means are equal. Therefore, we assume that it is possible (but not certain) that they came from the same population. However, since the results of the *F*-test were different the agency should investigate the cause for the difference in variances.

Note X6—The difference in sample means is much greater in this example (7.32 – 6.24 = 1.08) than in the previous example (6.10 – 5.70 = 0.40). However, in the previous example it was concluded that the means were different, while in this example it was not concluded that the means were different. The larger ratio of variance values in this example is the reason that it was not possible to conclude that the means were different.

Note X7—To simplify the example the means were rounded to two decimal points and the variances to three. This can result in a significant difference in the computed result. In practice several more decimal points should be used (see Section X2.4).

X2.4. *Computer Programs for the F-Test and t-Test Calculations*

As can be seen from the example problems, the required computations can be quite complex and time consuming. This introduces the possibility of human error.

Spreadsheet programs often have built-in functions for conducting both *F*-tests and *t*-tests. These tests can be performed by anyone with a basic knowledge of how to use spreadsheet functions. A spreadsheet program that can conduct *F*-tests as well as paired *t*-tests, and two-sample *t*-tests for the cases of both equal and unequal variances can perform all necessary analyses of verification test results.

The use of spreadsheets for conducting *F*-tests and *t*-tests can be illustrated by comparing the data sets used in Example Problem 1 above. Figure X2.1 shows a spreadsheet with the contractor and agency test results as well as the results of the *F*-test and *t*-test performed by the spreadsheet program. Due to the number of decimals used in the hand calculations vs. the spreadsheet, some differences in the values exist.

Figure X2.1—Spreadsheet Results for Data from Example Problem 1

As shown in cell A24 in Figure X2.1, the spreadsheet program conducts a one-tailed *F*-test. The spreadsheet results for this program show the *F*-statistic calculated from the data, in cell B22, as well as the value for F_{crit}, in cell B24. The two data sets would be considered to likely have different variances when the calculated *F*-statistic is greater than the value of F_{crit}.

The value that is displayed in cell B23 is the probability of getting an *F*-value as large as the one for these data sets if the two data sets actually have the same variance. In other words, the lower the probability value returned by this function, the less likely it is that the two sets of data have the same variance.

The level of significance, α, is one of the input values in the spreadsheet program that calculated the results shown in Figure X2.1. To arrive for a one-sided *F*-test at the same critical values that are shown in Table X2.1, which is based on a two-sided *F*-test, the one-sided level of significance that is used must be half that for an equivalent two-sided level of significance. Specifically, since Table X2.1 is based on a two-sided α value of 0.01, the input level of significance to the spreadsheet program must be $\alpha/2 = (0.01/2) = 0.005$ to match the Table X2.1 values.

Once the results of the *F*-test are known, the *t*-test can then be conducted using the spreadsheet's *t*-test capability. As shown in Figure X2.1, this spreadsheet program presents the result for both one-tailed, cell B37, and two-tailed, cell B39, *t*-tests. The values in Table X2.2 are for two-tailed *t*-tests, and therefore compare directly with the two-tailed spreadsheet results. The two data sets would be considered to likely have different means when the calculated *t*-statistic is greater than the value of t_{crit}.

Similarly, a spreadsheet program can be used to perform the *F*-test and *t*-test on the data sets from Example Problem 2 above. This is illustrated in Figure X2.2.

The results in Figure X2.2 indicate that the variances are assumed to be not equal ($F = 9.939$, which is greater than the F_{crit} value of 7.956). This means that the unequal variance *t*-test should be used. The results in Figure X2.2 indicate that the means are assumed to be equal ($t = 0.734$, which is less than the t_{crit} value of 4.604). Due to the number of decimals used in the hand calculations vs. the spreadsheet, some differences in the values exist.

Standard Recommended Practice for

Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories

AASHTO Designation: R 18-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Recommended Practice for

Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories

AASHTO Designation: R 18-10[1]

1. SCOPE

1.1. This document contains criteria and guidelines for establishing and implementing a quality management system (QMS) for use by a construction materials laboratory (CML). These criteria may also be used by laboratory-evaluating agencies.

1.2. The criteria in this document only apply to the following testing areas: soil, aggregate, asphalt binder, cutback asphalt, emulsified asphalt, asphalt mixtures, hydraulic cement, portland cement concrete, unit masonry, metals, plastic pipe, and sprayed fire-resistive material.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 152, Flow Table for Use in Tests of Hydraulic Cement
- PP 57, Establishing Requirements for and Performing Equipment Calibrations, Standardizations, and Checks
- R 28, Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)
- T 19, Bulk Density (“Unit Weight”) and Voids in Aggregate
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 32, Sampling and Testing Brick
- T 48, Flash and Fire Points by Cleveland Open Cup
- T 49, Penetration of Bituminous Materials
- T 50, Float Test for Bituminous Materials
- T 51, Ductility of Asphalt Materials
- T 53, Softening Point of Bitumen (Ring-and-Ball Apparatus)
- T 59, Emulsified Asphalts
- T 72, Saybolt Viscosity
- T 79, Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3°C (200°F)
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 88, Particle Size Analysis of Soils
- T 89, Determining the Liquid Limit of Soils
- T 96, Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

- T 98, Fineness of Portland Cement by the Turbidimeter
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 100, Specific Gravity of Soils
- T 104, Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate
- T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)
- T 119, Slump of Hydraulic Cement Concrete
- T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 129, Normal Consistency of Hydraulic Cement
- T 131, Time of Setting of Hydraulic Cement by Vicat Needle
- T 134, Moisture-Density Relations of Soil-Cement Mixtures
- T 135, Wetting-and-Drying Test of Compacted Soil-Cement Mixtures
- T 136, Freezing-and-Thawing Tests of Compacted Soil-Cement Mixtures
- T 137, Air Content of Hydraulic Cement Mortar
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method
- T 153, Fineness of Hydraulic Cement by Air Permeability Apparatus
- T 154, Time of Setting of Hydraulic Cement Paste by Gillmore Needles
- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
- T 167, Compressive Strength of Hot Mix Asphalt
- T 170, Recovery of Asphalt from Solution by Abson Method
- T 176, Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test
- T 179, Effect of Heat and Air on Asphalt Materials (Thin-Film Oven Test)
- T 180, Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop
- T 186, Early Stiffening of Hydraulic Cement (Paste Method)
- T 190, Resistance R-Value and Expansion Pressure of Compacted Soils
- T 192, Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve
- T 193, The California Bearing Ratio
- T 196, Air Content of Freshly Mixed Concrete by the Volumetric Method
- T 201, Kinematic Viscosity of Asphalts (Bitumens)
- T 202, Viscosity of Asphalts by Vacuum Capillary Viscometer
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 228, Specific Gravity of Semi-Solid Asphalt Materials
- T 240, Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)
- T 245, Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus
- T 246, Resistance to Deformation and Cohesion of Hot Mix Asphalt (HMA) by Means of Hveem Apparatus
- T 247, Preparation of Test Specimens of Hot Mix Asphalt (HMA) by Means of California Kneading Compactor
- T 300, Force Ductility Test of Asphalt Materials
- T 301, Elastic Recovery Test of Asphalt Materials by Means of a Ductilometer
- T 308, Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method

- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor
- T 313, Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)
- T 314, Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)
- T 315, Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer

2.2. *ASTM Standards*:

- C 29, Standard Test Method for Bulk Density ("Unit Weight") and Voids in Aggregate
- C 31, Standard Practice for Making and Curing Concrete Test Specimens in the Field
- C 39, Standard Test Method for Compressive Strength of Cylindrical Concrete Specimens
- C 67, Standard Test Methods for Sampling and Testing Brick and Structural Clay Tile
- C 88, Standard Test Method for Soundness of Aggregates by Use of Sodium Sulfate or Magnesium Sulfate
- C 91, Standard Specification for Masonry Cement
- C 109, Standard Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
- C 115, Standard Test Method for Fineness of Portland Cement by the Turbidimeter
- C 128, Standard Test Method for Density, Relative Density (Specific Gravity), and Absorption of Fine Aggregate
- C 131, Standard Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine
- C 138, Standard Test Method for Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- C 143, Standard Test Method for Slump of Hydraulic-Cement Concrete
- C 173, Standard Test Method for Air Content of Freshly Mixed Concrete by the Volumetric Method
- C 185, Standard Test Method for Air Content of Hydraulic Cement Mortar
- C 187, Standard Test Method for Normal Consistency of Hydraulic Cement
- C 191, Standard Test Methods for Time of Setting of Hydraulic Cement by Vicat Needle
- C 204, Standard Test Methods for Fineness of Hydraulic Cement by Air-Permeability Apparatus
- C 230, Standard Specification for Flow Table for Use in Tests of Hydraulic Cement
- C 231, Standard Test Method for Air Content of Freshly Mixed Concrete by the Pressure Method
- C 266, Standard Test Method for Time of Setting of Hydraulic-Cement Paste by Gillmore Needles
- C 305, Standard Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
- C 430, Standard Test Method for Fineness of Hydraulic Cement by the 45-µm (No. 325) Sieve
- C 451, Standard Test Method for Early Stiffening of Hydraulic Cement (Paste Method)
- C 778, Standard Specification for Standard Sand
- D 5, Standard Test Method for Penetration of Bituminous Materials
- D 36, Standard Test Method for Softening Point of Bitumen (Ring-and-Ball Apparatus)

- D 70, Standard Test Method for Density of Semi-Solid Bituminous Materials (Pycnometer Method)
- D 88, Standard Test Method for Saybolt Viscosity
- D 92, Standard Test Method for Flash and Fire Points by Cleveland Open Cup Tester
- D 113, Standard Test Method for Ductility of Bituminous Materials
- D 139, Standard Test Method for Float Test for Bituminous Materials
- D 244, Standard Test Methods and Practices for Emulsified Asphalts
- D 422, Standard Test Method for Particle-Size Analysis of Soils
- D 558, Standard Test Methods for Moisture-Density (Unit Weight) Relations of Soil-Cement Mixtures
- D 559, Standard Test Methods for Wetting and Drying Compacted Soil-Cement Mixtures
- D 560, Standard Test Methods for Freezing and Thawing Compacted Soil-Cement Mixtures
- D 698, Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Standard Effort (12 400 ft-lbf/ft^3 (600 kN-m/m^3))
- D 854, Standard Test Methods for Specific Gravity of Soil Solids by Water Pycnometer
- D 1074, Standard Test Method for Compressive Strength of Bituminous Mixtures
- D 1557, Standard Test Methods for Laboratory Compaction Characteristics of Soil Using Modified Effort (56,000 ft-lbf/ft^3 (2,700 kN-m/m^3))
- D 1560, Standard Test Methods for Resistance to Deformation and Cohesion of Bituminous Mixtures by Means of Hveem Apparatus
- D 1561, Standard Practice for Preparation of Bituminous Mixture Test Specimens by Means of California Kneading Compactor
- D 1754, Standard Test Method for Effect of Heat and Air on Asphaltic Materials (Thin-Film Oven Test)
- D 1856, Standard Test Method for Recovery of Asphalt from Solution by Abson Method
- D 1883, Standard Test Method for CBR (California Bearing Ratio) of Laboratory-Compacted Soils
- D 2041, Standard Test Method for Theoretical Maximum Specific Gravity and Density of Bituminous Paving Mixtures
- D 2168, Standard Test Methods for Calibration of Laboratory Mechanical-Rammer Soil Compactors
- D 2170, Standard Test Method for Kinematic Viscosity of Asphalts (Bitumens)
- D 2171, Standard Test Method for Viscosity of Asphalts by Vacuum Capillary Viscometer
- D 2419, Standard Test Method for Sand Equivalent Value of Soils and Fine Aggregate
- D 2844, Standard Test Method for Resistance R-Value and Expansion Pressure of Compacted Soils
- D 2850, Standard Test Method for Unconsolidated-Undrained Triaxial Compression Test on Cohesive Soils
- D 2872, Standard Test Method for Effect of Heat and Air on a Moving Film of Asphalt (Rolling Thin-Film Oven Test)
- D 3143, Standard Test Method for Flash Point of Cutback Asphalt with Tag Open-Cup Apparatus
- D 4318, Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils
- D 4402, Standard Test Method for Viscosity Determination of Asphalt at Elevated Temperatures Using a Rotational Viscometer
- D 4753, Standard Guide for Evaluating, Selecting, and Specifying Balances and Standard Masses for Use in Soil, Rock, and Construction Materials Testing
- D 4829, Standard Test Method for Expansion Index of Soils

- D 6084, Standard Test Method for Elastic Recovery of Bituminous Materials by Ductilometer
- D 6307, Standard Test Method for Asphalt Content of Hot-Mix Asphalt by Ignition Method
- D 6521, Standard Practice for Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)
- D 6648, Standard Test Method for Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)
- D 6723, Standard Test Method for Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)
- D 6925, Standard Test Method for Preparation and Determination of the Relative Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor
- D 6926, Standard Practice for Preparation of Bituminous Specimens Using Marshall Apparatus
- D 6927, Standard Test Method for Marshall Stability and Flow of Bituminous Mixtures
- D 7000, Standard Test Method for Sweep Test of Bituminous Emulsion Surface Treatment Samples
- D 7175, Standard Test Method for Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer
- E 11, Standard Specification for Wire Cloth and Sieves for Testing Purposes
- E 77, Standard Test Method for Inspection and Verification of Thermometers

3. TERMINOLOGY

3.1. *calibration*— a process that, under specified conditions, establishes metrological traceability by determining: (1) the relation between the quantity values provided by measurement standards and the corresponding indications from a measuring instrument or system, and (2) the resulting measurement uncertainty (Note 1).

Note 1—This definition for calibration and the following definitions for check, standardization, traceability, uncertainty, and verification of calibration are based on the definitions in PP 57.

3.1.1. *Examples*—balances (measurement instrument), dynamic shear rheometer (measurement system), pycnometer (material measure).

3.1.2. *Discussion*—The purpose of calibration is to establish the traceability of a measurement. Uncertainty estimates obtained during calibration are used to judge if an instrument is suitable for its intended purpose. There is a need to re-establish traceability or recalibrate only when instrument measurements drift out of control (as determined through verification of calibration).

3.2. *check*—a specific type of inspection and/or measurement performed on equipment and materials to indicate compliance or otherwise with stated criteria.

3.2.1. *Example*—specimen molds.

3.2.2. *Discussion*—Stated criteria can be dimensional tolerances.

3.3. *maintenance*—a regularly scheduled preventive measure taken to preserve the effective working condition of test equipment.

3.4. *measurement standard*—The embodiment of the definition of a given quantity, with a stated value and measurement uncertainty, used as a reference.[2] This term is often called “reference standard.”

3.5. *metrological traceability*—the property of a result of a measurement whereby it can be related to stated references, usually national or international standards, through a documented, unbroken chain of calibrations, each contributing to the measurement uncertainty.

3.5.1. *Discussion*—There is a need for traceable measurements. Measurements, not the instrument, can be traceable. Measurement traceability is established through calibration. Measurement traceability is maintained through verification of calibration (a regular check of instrument output using a control standard).

3.6. *quality management system (QMS) (for a CML)*—the organizational structure, staff responsibilities, policies, standard operating procedures, processes, and records which assist the laboratory in achieving its quality objectives.

3.7. *standardization*—a process that determines (1) the correction to be applied to the result of a measuring instrument, measuring system, material measure, or measurement standard when its values are compared to the values realized by standards, or (2) the adjustment to be applied to a piece of equipment when its performance is compared with that of an accepted standard or process.

3.7.1. *Discussion*—Standardization in case (1) is a simplified form of calibration that estimates systematic error but does not identify random error. Standardization, therefore, does not address all of the elements of uncertainty of measurement and does not lead to traceable measurements. An example of case (2) standardization is adjusting the number of blows of a mechanically operated hammer so it applies the energy equivalent to that of a manually operated hammer.

3.8. *uncertainty*—a parameter associated with the result of a measurement that defines the range of the values that could be attributed to the measured quantity.

3.8.1. *Discussion*—The uncertainty of a measurement is required in order to establish its traceability. The uncertainty estimates obtained during calibration are used to judge if an instrument is suitable for its intended purpose.

3.9. *verification of calibration*—a process that establishes whether the results of a previously calibrated measurement instrument, measurement system, or material measure are stable.

3.9.1. *Discussion*—Verification of calibration is used to maintain the traceability of a measurement and to determine when to recalibrate. Control charts are often used to plot the results and determine whether instrument measurements have drifted out of control.

4. SIGNIFICANCE AND USE

4.1. This document provides guidance to laboratories in the establishment and implementation of a quality management system. By use of the concepts in this document, a laboratory may prepare policies, procedures, and records that describe the elements and functions of its quality management system.

4.2. This document is not intended to prescribe the methods by which a laboratory achieves the desired level of quality, but does provide acceptable approaches.

4.3. The user is cautioned that a QMS prepared by following this document can only serve a useful purpose if it describes or references procedures that are practiced on a routine basis by the laboratory. A QMS only describes the elements of the system and how they are intended to be implemented. It is not the existence but the implementation of an effective quality management system that is important.

5. MANAGEMENT REQUIREMENTS

5.1. *Quality Management System (QMS)*:

5.1.1. The laboratory shall establish, implement, and maintain a quality management system (QMS) appropriate to the scope of its activities. The QMS shall be available for use and understood by laboratory staff.

Note 2—A QMS may be documented and distributed in hard copy or electronic format.

Note 3—Examples of some QMS documents are provided in the Appendix. The laboratory may establish methods other than those shown in the Appendix to meet QMS requirements.

5.2. *Document Control*:

5.2.1. Each QMS document shall indicate its preparation date. When a document is revised, the date of revision shall be indicated on the document.

5.2.2. *Test Methods, Practices, Procedures, and Specifications*—The laboratory shall maintain copies of standards for the testing performed and shall ensure that the procedures are the most current and are readily accessible to the employees performing the testing.

5.3. *Organization*:

5.3.1. The legal name and address of the laboratory—and that of the main office or company, if different—and any other information needed to identify the organization, shall be documented.

5.3.2. The ownership and management structure of the laboratory shall be documented. Names, affiliations, and positions of principal officers and directors shall be listed.

5.3.3. The laboratory shall maintain an organization chart showing relevant internal organizational components, including positions and names, that are part of the organization. The organization chart shall clearly define relationships with other partner organizations where applicable.

5.4. *Staff*:

5.4.1. The laboratory shall maintain a position description for each technical operational position shown on the laboratory’s organization chart. Position descriptions shall identify the position and include a description of the duties, required skills, and education and experience associated with the position.

5.4.2. The laboratory shall maintain a brief biographical sketch, noting the education, work experience, licensure, certifications, and current position for each supervisory technical staff.

5.4.3. *Technical Manager*—The laboratory shall have a technical manager (however named) who has overall responsibility for the technical operations of the laboratory. In addition, the laboratory shall nominate an individual to serve in the technical manager’s absence.

5.4.4. *QMS Management*—The laboratory shall designate a person(s) having responsibility for determining whether quality management system activities are being implemented by laboratory staff. This individual(s) shall have direct access to top management (Note 4).

Note 4—This individual(s) may have other responsibilities (e.g., laboratory manager).

5.5. *Technician Training and Evaluation*:

5.5.1. The laboratory shall maintain a procedure which describes the method used to ensure that new laboratory personnel are trained to perform tests in accordance with standard procedures. In addition to the description of training methods, the document shall indicate what position or employee is responsible for the laboratory training program and the maintenance of training records (see Figure X1.1).

Note 5—There may be several different methods employed for differing levels of staff experience including (1) on-the-job apprentice training (one-on-one) for new employees with little or no experience in laboratory or inspection work; (2) formal in-house training sessions for certification, rating, or competency evaluation; and (3) training by external organizations. An individual with prior experience performing a specific test need only have competency confirmed by the laboratory (see Section 5.5.2).

5.5.2. The laboratory shall maintain a procedure describing the method used to evaluate staff competency to ensure that each test covered by the scope of this standard is performed in accordance with standard procedures. This description shall include the frequency of competency evaluations for each technician and indicate what position or employee is responsible for evaluating staff competency and maintaining records. The procedure shall ensure that each technician receives a performance evaluation for each test that technician performs (see Figure X1.2).

Note 6—Proficiency sample testing may be useful in evaluating staff competency; however, it should be used in conjunction with observation of actual testing performed.

5.5.3. The laboratory shall maintain records of technician training and competency evaluation activities. The records shall include the test method for which the technician was evaluated, the date on which competence was determined or confirmed, the name of the individual who evaluated the technician’s competency, and comments about the training or competency evaluation activity.

5.6. *Internal Audits*:

5.6.1. The laboratory shall maintain a document describing the scope of internal audits. Internal audits shall verify that the laboratory’s operations continue to comply with its policies and procedures and the requirements of this standard.

5.6.2. The document shall include the frequency of the reviews and identification of the individual(s) responsible for the review. The internal audit program shall address all elements of the quality management system and shall be conducted at least every 12 months by trained personnel independent of the activity being audited, where possible.

5.6.3. Findings from internal audits shall be recorded (see Figures X1.3 and X1.4).

5.7. *Corrective Action*:

5.7.1. The laboratory shall maintain a procedure for implementing corrective action when nonconforming work or departures from policies and procedures have been discovered (Note 7). The procedure shall identify the individual responsible for implementing corrective action and shall begin with an investigation to determine the root cause of the problem. Records of corrective action shall be maintained (see Figure X1.5).

Note 7—The corrective action procedure should be implemented for nonconformities in the following areas: internal audits; customer complaints; equipment calibrations;, standardizations; checks and maintenance; external assessments; and proficiency sample testing.

5.7.2. The laboratory shall document the method used in responding to customer complaints (see Figure X1.6). Records of customer complaints and the resulting actions shall be maintained.

5.8. *Records Retention*:

5.8.1. *Quality Management System Records*—Records pertaining to external assessments, internal audits, proficiency sample testing, technician training and evaluation, and personnel shall be retained by the laboratory for a minimum of 5 years.

5.8.2. *Technical Records*—The laboratory shall retain records of test data, test reports, equipment calibration, standardization, check, and maintenance activities for a minimum of 5 years.

Note 8—Although a 5-year retention schedule is adequate in some instances, there are many circumstances when a longer retention period may be advantageous to the laboratory. Records concerning the calibrations, standardizations, checks, and maintenance of equipment are an example. Retention schedules of this type usually require such records to be held throughout the useful life of the equipment.

6. TECHNICAL REQUIREMENTS

6.1. *Equipment*:

6.1.1. *Inventory*—The laboratory shall maintain an inventory of major sampling, testing, calibration, standardization and check equipment, and measurement standards. The list shall include, where available, the name, date placed in service, manufacturer, and model and serial number.

Note 9—An identification number assigned by the laboratory or other unique identifying information may be substituted for the model and serial number if this is the practice normally followed by the laboratory.

Note 10—Major equipment includes all equipment that is normally amortized by a laboratory, such as shakers, physical or chemical testing machines, balances, baths, ovens, microscopes, and computing equipment dedicated to testing. Equipment such as chairs, desks, and file cabinets may be excluded. Major equipment does not usually include expendable items such as miscellaneous glassware, sieves, molds, and viscometers.

6.1.2. *Equipment Calibrations, Standardizations, and Checks*:

6.1.2.1. The laboratory shall maintain a list giving a general description of equipment which requires calibration, standardization, and checks. For each item the list shall include the interval of calibration, standardization, or checks and a reference to the procedure used (Note 11) (see Figure X1.7).

Note 11—When standard procedures are used, the standard should be referenced (e.g., unit weight bucket, T 19; compression machine, T 67). When the procedure used has been prepared by the laboratory, the in-house designation should be referenced. It should be indicated if the work is performed by an outside agency.

6.1.2.2. The laboratory shall have a procedure which describes the method for ensuring that the calibration, standardization, and checks are performed for all required equipment at the specified intervals. This procedure shall include the name of the individual(s) or position(s) responsible for ensuring that these activities are performed, and procedures for handling equipment which is newly acquired, removed from service, or defective (see Figure X1.8).

6.1.2.3. The laboratory shall have detailed written procedures for all in-house calibration, standardization, and check activities not addressed in standards or operating instructions (Note 11). These procedures shall indicate the equipment required to perform the calibration, standardization, or check (see Figures X1.9 to X1.14). If a piece of laboratory testing equipment is used over a range of measurements (e.g. thermometer, dial indicator, etc.), the calibration or standardization shall include several measurements over that range.

6.1.2.4. The laboratory shall calibrate, standardize, and check all significant equipment associated with tests which the laboratory performs (Note 12). As a minimum, the applicable equipment listed in Tables A1.1 through A1.8 shall be included.

Note 12—Refer to PP 57 for guidance on performing equipment calibrations, standardizations, and checks.

6.1.2.5. *Calibration, Standardization, and Check Frequencies*—Applicable measurement equipment shall be calibrated, standardized, or checked at the intervals specified in the laboratory's QMS. The laboratory shall establish intervals according to the following guidelines:

6.1.2.5.1. The intervals specified by the laboratory shall be no greater than those indicated in Tables A1.1 through A1.8 unless such equipment is calibrated, standardized, or checked before each use or the laboratory has documented evidence to show that the conformance of the equipment to the specification requirements is stable (Notes 13, 14, and 15).

Note 13—The intervals for the calibration of measurement equipment may be extended provided that verification of calibration data obtained with frequent measurement checks using control standards indicate that equipment measurement results are stable over time. Process-control charts are commonly used to display the data.

Note 14—Equipment check intervals may be extended provided that equipment check data indicate that equipment wear is predictable over time.

Note 15—Analysis of the verification of calibration data and check data for some equipment may indicate that intervals should be decreased to ensure that the equipment consistently meets the specification requirements or is removed from service when appropriate.

6.1.2.5.2. When a maximum interval for a specific piece of measurement equipment is specified in a standard, the interval specified by the laboratory shall not exceed this interval unless the equipment is calibrated, standardized, or checked before each use.

6.1.2.6. Equipment that has been removed from service and newly acquired equipment without a manufacturer's certification shall be calibrated, standardized, or checked before being placed in service.

6.1.3. *Measurement Standards*:

6.1.3.1. The laboratory shall maintain calibration certificates that establish the traceability of measurement standards or in-house equipment used for calibrations, standardizations, and checks. The calibration certificates shall include estimates of measurement uncertainty. The QMS shall include a procedure that describes how the laboratory ensures the calibration of its measurement standards.

6.1.4. *Equipment Maintenance*:

6.1.4.1. The laboratory shall have a system in place for performing regular maintenance on any equipment or test system in which repeated use could degrade the equipment's or test system's ability to produce repeatable results.

6.1.4.2. The laboratory shall maintain a list giving a general description of equipment which requires maintenance. For each item, the list shall include the interval of maintenance and a reference to the procedure used (Note 16) (see Table A1.9 for requirements and Figure X1.17 for an example of a maintenance table).

Note 16—In most cases, the laboratory should refer to the manufacturers' instructions to determine the recommended maintenance interval and procedures. In some cases, the laboratory will need to create its own maintenance intervals and procedures based on the frequency of use and risk of equipment failure.

6.1.4.3. The laboratory shall have detailed written procedures for all in-house maintenance activities. These procedures shall indicate the equipment required to perform the maintenance and a general explanation of the work performed. If manufacturer's instructions for maintenance are available, they shall be referenced on the in-house procedure (see Figure X1.18).

6.1.4.4. The maintenance records shall contain the name of the individual that performed the maintenance, the date that the work was completed, and any comments.

6.1.4.5. The laboratory shall maintain the manufacturers' instructions for operating and maintaining equipment, where applicable.

6.1.5. *Equipment Records*—The laboratory shall maintain calibration, standardization, check, and maintenance records for all equipment specified in the QMS. Such records shall include:

6.1.5.1. Detailed results of the work performed (dimensions, mass, force, frequency, temperature, time, etc.);

6.1.5.2. Description of the equipment calibrated, standardized, checked, or maintained, including model and serial number or other acceptable identification (Note 9);

6.1.5.3. Date the work was done;

6.1.5.4. Identification of the individual who performed the work;

6.1.5.5. Identification of the calibration, standardization, check, or maintenance procedure used; and

6.1.5.6. Identification of any device used for in-house calibration, standardization, check, or maintenance, including serial numbers, laboratory numbers, or other identification.

6.2. *Sample Management*:

6.2.1. The laboratory shall have a procedure for the storage, retention, and disposal of test samples (see Figure X1.15).

Note 17—In this context, the term "storage" refers to sample placement and handling before testing. The term "retention" refers to sample placement and handling after testing.

6.2.2. The laboratory shall have a procedure for identifying test samples. The identification shall be retained throughout the life of the sample in the laboratory.

6.3. *Test Records and Reports*:

6.3.1. The laboratory shall have a document which describes methods used by the laboratory to produce test records and to prepare, check, and amend test reports. The document shall identify the individual(s) responsible for maintaining test records and reports and shall describe the distribution of test reports (see Figure X1.16).

6.3.2. *Test Records*—The laboratory shall maintain test records which contain sufficient information to permit verification of any test reports. Records pertaining to testing shall include original observations, calculations, derived data, and an identification of personnel involved in sampling and testing.

6.3.2.1. The laboratory shall prepare test reports which clearly, accurately, and unambiguously present the information specified in Table 1.

Table 1—Test Report Requirements

Identification of the report and the date issued
Description, identification, and condition of the test sample
Identification of the standard test method used
Test results and other pertinent data required by the standard test method
Identification of any test results obtained from tests performed by a subcontractor
Name of the person(s) accepting technical responsibility for the test report (if applicable)

6.3.2.2. In addition to the requirements listed in Section 6.3.2.1, the information listed in Table 2 shall be available and traceable to the test reports.

Table 2—Test Report Information

Name and address of the testing laboratory
Name and address of the client or identification of the project
Date of receipt of the test sample
Date(s) of test performance
Deviations from, additions to, or exclusions from the test method

6.3.2.3. The procedure for amending reports shall require that the previously existing report be clearly referenced when an amendment is made. The references shall establish a clear audit trail from the latest issuance or deletion to the original report and its supporting data.

6.4. *Subcontracting*—The laboratory shall maintain a document describing the policies that the laboratory follows relative to subcontracting, if it engages in such activities. These policies shall include procedures followed by the laboratory in selecting competent subcontractors and reporting the results of testing performed by subcontractors.

6.5. *Assuring the Quality of Results:*

6.6. The laboratory shall have procedures for monitoring the validity of test results. The monitoring shall be planned and may include one or more of the following:

6.6.1.1. Participation in external assessment programs (Note 17);

6.6.1.2. Participation in proficiency sample or interlaboratory comparison testing (Note 17); and

6.6.1.3. Retesting of retained items.

Note 18—The AASHTO Materials Reference Laboratory (AMRL) and the Cement and Concrete Reference Laboratory (CCRL), located in Gaithersburg, Maryland, conduct on-site assessment and proficiency sample programs which the laboratory may use.

6.6.2. *Records*—The laboratory shall retain results of the monitoring activities, including the steps taken to determine the root cause of any nonconformities and the corrective actions taken.

7. KEYWORDS

7.1. Calibration; check; construction materials testing; equipment maintenance; internal audit; quality management system; standardization.

ANNEX A1

(Mandatory Information)

Table A1.1—General Testing Equipment

Equipment	Requirement	Max. Interval (months)
Mechanical Shakers	Check Sieving Thoroughness	12
Ovens	Standardize Thermometric Device	12
Coarse Sieves (Openings ≥4.75 mm)	Check Physical Condition and Dimensions of Openings	12
Fine Sieves (Openings <4.75 mm)	Check Physical Condition	12
Specimen Molds	Check Critical Dimensions	12
General Purpose Balances and Masses	Standardize	12
Thermometer	Standardize	12
Analytical Balances and Masses	Calibrate	12
Calipers	Standardize	12
Vacuum/Pressure Measurement Devices: (Bourdon Gauges, Pressure Manometers, and Electronic Pressure Transducers)	Standardize	12
Length Measurement Devices: (Dial Indicators, LDTs, LVDTs, and Extensometers)	Standardize	12
Compression, Loading, or Tensile Testing Devices	Standardize	12

Table A1.2—Aggregate Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Unit Weight Measures	T 19/C 29	Standardize	12
Sulfate Oven	T 104/C 88	Check Rate of Evaporation	12
Sulfate Soundness Sample Containers	T 104/C 88	Check Physical Condition	12
L.A. Machine	T 96/C 131	Check RPM and Critical Dimensions	24
Steel Balls	T 96/C 131	Check Individual Weight and Charge Weight	24
Conical Mold, Tamper	T 84/C 128	Check Critical Dimensions	24

Table A1.3—Asphalt Binder/Cutback Asphalt/Emulsified Asphalt Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Saybolt Viscometers	T 59/D 244	Standardize	36
Brush Holder and Brush	D 7000	Check Critical Dimensions	12
Nylon Strip	D 7000	Check	6
Timing Devices	T 49, T 201, T 202/ D 5, D 2170, D 2171	Standardize	12
Penetrometer Needle	T 49/D 5	Check Condition and Critical Dimensions	12
Penetrometer	T 49/D 5	Standardize for Pen. Depth	12
Ductility Machine	T 51, T 300, T 301/ D 113, D 6084	Check Speed of Travel	12
TFO Shelf and RTFO Carriage	T 179, T 240/ D 1754, D 2872	Check Rotation Speed	12
Brass Rings and Assemblies	T 53/D 36	Check Critical Dimensions	12
Pycnometers	T 228/D 70	Check Physical Condition	12
Pycnometers	T 228/D 70	Standardize Volume	12
Collars and Floats	T 50/D 139	Check Critical Dimensions	12
Flow Meters	T 170, T 240/ D 1856, D 2872	Standardize	12
Flash Cups	T 48, T 79/D 92, D 3143	Check Critical Dimensions	12
Pressurized Aging Vessel	R 28/D 6521	Standardize Temperature and Pressure	6
Rotational Viscometer	T 316/D 4402	Standardize with Reference Fluid	6
Dynamic Shear Rheometer	T 315/D 7175	Standardize with Reference Fluid	6
Bending Beam Rheometer	T 313/D 6648	Calibrate Masses	12

Table A1.4—Asphalt Mixtures Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Mechanical Compactor	T 245	Standardize	36
CA Kneading Compactor	T 247/D 1561	Standardize	24
Follower, Calibration Cylinder	T 246, T 247/ D 1560, D 1561	Check Critical Dimensions	12
Manual Compaction Hammers, Breaking Heads	T 245/D 6926, D 6927	Check Critical Dimensions, Check Mass of Hammer	12
Plungers	T 167/D 1074	Check Critical Dimensions	12
Gyratory Compactor	T 312/D 6925	Standardize Ram Pressure, Frequency of Gyration, LVDT	12
Gyratory Compactor	T 312	Standardize Internal Angle of Gyration	12
Gyratory Compactor	D 6925	Standardize External or Internal Angle of Gyration	12
Ram Face, Base Plate Face	T 312/D 7115	Check Critical Dimensions	12
Ignition Oven Internal Balance	T 308/D 6307	Standardize	12

Table A1.5—Soil Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Mechanical Compactor	T 99, T 180/D 698, D 1557	Standardize	12
CA Kneading Compactor	T 190/D 2844	Standardize	24
Manual Hammer	T 99, T 180/D 698, D 1557, D 4829	Check Mass and Critical Dimensions	12
Liquid Limit Device	T 89/D 4318	Check Wear and Critical Dimensions	12
Grooving Tool	T 89/D 4318	Check Critical Dimensions	12
Hydrometers	T 88/D 422	Check Critical Dimensions	24
Straightedge	T 99, T 134, T 135, T 136, T 180/D 558, D 559, D 560, D 698, D 1557	Check Planeness of Edge	12
Weighted Foot Assembly	T 176/D 2419	Check Mass	12
CBR Annular and Slotted Weights	T 193/D 1883	Check Mass	12
CBR Penetration Piston	T 193/D 1883	Check Diameter and Length	12
Standard Metal Specimen	T 190/D 2844	Check Outside Diameter	12
Metal Follower	T 190/D 2844	Check Diameter	12
Vertical Load	D 4829	Standardize	12

Table A1.6—Portland Cement Concrete Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Unit Weight Measures	T 121/C 138	Standardize	12
Air Meters (pressure type)	T 152/C 231	Standardize	3[a]
Air Meters (volumetric type)	C 173	Standardize	12[a]
Air Meters (volumetric type)	T 196	Standardize	36[a]
Capping Material		Check Strength	3
Slump Cones	T 119/C 143	Check Critical Dimensions	12
Metallic Reusable Molds	T 22, T 23/C 31, C 39	Check Critical Dimensions	12
Single Use Molds	T 22, T 23/C 31, C 39	Check Dimensions of Each Shipment	—
Recording Thermometer	C 31, C 39	Standardize	6

[a] The individual test methods specify conditions that require restandardization, such as changes in elevation and rough handling.

Table A1.7—Hydraulic Cement Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Moist Cabinet/Water Tank Recording Thermometer(s)	T 106/C 109	Standardize	6
Storage Water	T 106/C 109	Check for Lime Saturation	6
No. 325 Sieves	T 192/C 430	Clean after 5 Determinations, Standardize after 100 Determinations	—
No. 325 Nozzle	T 192/C 430	Check Flow Rate	6
Bearing Blocks	T 106/C 109	Check Planeness	12
Wagner Turbidimeter	T 98/C 115	Standardize	6
Standard Sand		Check Each New Shipment for Conformance to C 778	—
Air-Permeability Apparatus	T 153/C 204	Standardize Using NIST 114	30
Flow Tables	M 152/C 230	Standardize Flow Results[a]	30
Air Content Measures	T 137/C 185	Standardize[a]	30
Cube Molds and Tampers	T 106/C 109	Check Critical Dimensions and Physical Condition[a]	30
Vicat Apparatus and Vicat Ring	T 129, T 131, T 186/ C 187, C 191, C 451	Check Physical Condition, Critical Dimensions, and Mass[a]	30
Gillmore Test Apparatus	T 154/C 266	Check Physical Condition, Critical Dimensions, and Mass[a]	30
Mechanical Mixing Apparatus	T 162/C 305	Check Critical Clearances and Speeds[a]	30
Water-Retention Apparatus	C 91	Check Critical Dimensions[a]	30

[a] The equipment evaluation provided by CCRL during their routine inspection satisfies this requirement.

Table A1.8—Masonry Testing Equipment

Equipment	Test Method (AASHTO/ASTM)	Requirement	Max. Interval (months)
Micrometer	T 32/C 67	Standardize	12
Air Content Measures	T 137/C 185	Standardize[a]	30
Flow Tables	M 152/C 230	Standardize Flow Results[a]	30
Water-Retention Apparatus	C 91	Check Critical Dimensions[a]	30
Water Retention	C 91	Standardize vacuum	12
Cube Molds and Tampers	T 106/C 109	Check Physical Condition and Critical Dimensions[c]	12
Flexural Bond Apparatus		Standardize	12
Mixers		Check paddle to bowl clearance	24

[a] The equipment evaluation provided by CCRL during their routine inspection satisfies this requirement.

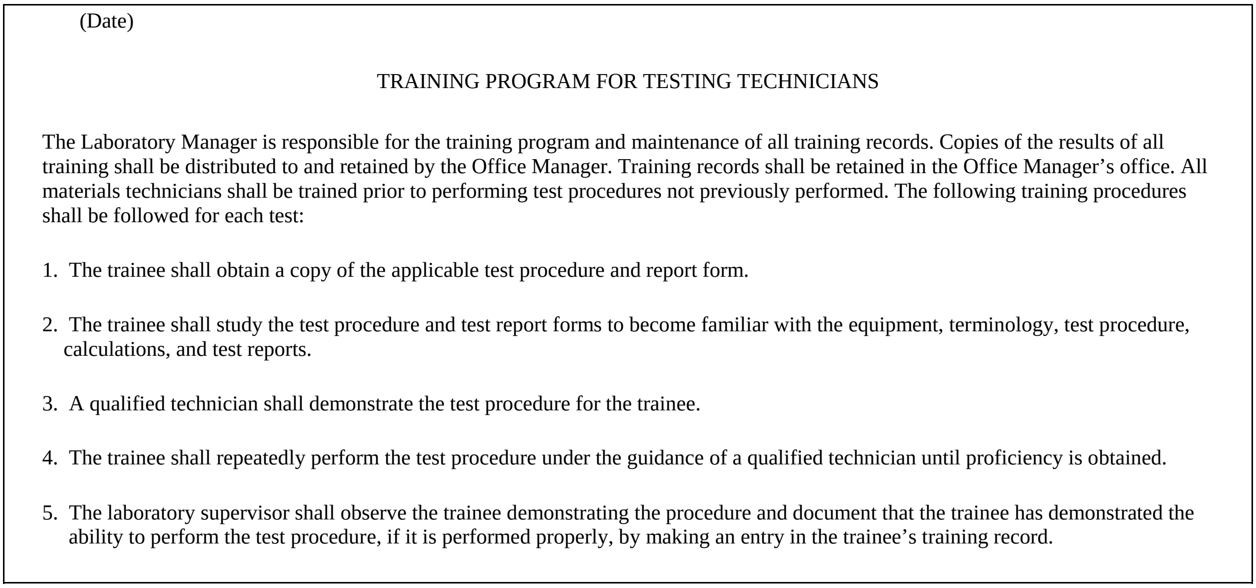
Table A1.9—Equipment Maintenance

Equipment	Test Method (AASHTO/ASTM)	Max. Interval (months)
Performance-graded binder equipment	R 28, T 240, T 313, T 314, T 315/D 2872, D 6521, D 6648, D 6723, D 7175	12
Ductilometers	T 51, T 300, T 301/D 113, D 6084	12
Mechanical Marshall compactors	T 245	12
California kneading compactors	T 190, T 247/D 1561, D 2844	12
Gyratory compactors	T 312/D 6925	12
Mechanical compactors	T 99, T 180/D 698, D 1557	12
Compression machines	Where applicable	12
Mechanical shakers	Where applicable	12

Note A1—There may be more items added to the laboratory's list of equipment that require maintenance. Maintenance activities will typically involve lubricating, tightening fittings, cleaning, replacing fluids, checking and replacing damaged or worn parts, etc. These activities will vary based on the type of equipment, how often the equipment is used, the manufacturer's recommendations, etc.

APPENDIX X1[3]

(Nonmandatory Information)



(Date)

TRAINING PROGRAM FOR TESTING TECHNICIANS

The Laboratory Manager is responsible for the training program and maintenance of all training records. Copies of the results of all training shall be distributed to and retained by the Office Manager. Training records shall be retained in the Office Manager's office. All materials technicians shall be trained prior to performing test procedures not previously performed. The following training procedures shall be followed for each test:

1. The trainee shall obtain a copy of the applicable test procedure and report form.

2. The trainee shall study the test procedure and test report forms to become familiar with the equipment, terminology, test procedure, calculations, and test reports.

3. A qualified technician shall demonstrate the test procedure for the trainee.

4. The trainee shall repeatedly perform the test procedure under the guidance of a qualified technician until proficiency is obtained.

5. The laboratory supervisor shall observe the trainee demonstrating the procedure and document that the trainee has demonstrated the ability to perform the test procedure, if it is performed properly, by making an entry in the trainee's training record.

Figure X1.1—Description of Testing Technician Training Program

(Date)

METHOD FOR REVIEWING TECHNICIAN'S COMPETENCY

Each laboratory supervisor is responsible for evaluating their test technician's competency at least once every 12 months by requiring each technician to demonstrate the AASHTO and/or ASTM test procedures for which he/she has been trained to perform. [If a technician does not routinely perform a test, it may not be necessary to evaluate his or her competency to perform the test every 12 months. However, the technician's competency shall be evaluated prior to performing the test.] Copies of the results of all competency evaluations shall be maintained by the Office Manager. Competency evaluation records shall be retained in the Office Manager's office.

For each testing technician, the supervisor shall record the test demonstrated, the date of the demonstration, and the results of the evaluation (satisfactory or unsatisfactory). In addition, the supervisor shall sign each entry on the evaluation record.

If an unsatisfactory result is recorded for a specific test, the supervisor shall review all observed deviations from the standard AASHTO or ASTM procedure with the testing technician, observe the technician re-demonstrate the test procedure and record the results as indicated above.

Figure X1.2—Method for Reviewing Test Technician's Competency

(Date)

INTERNAL AUDIT PROCEDURE

1. The Quality Manager shall review the following records, reports, and associated documentation every 12 months to ensure that established quality procedures are being followed:

a) Proficiency Sample Reports
b) On-Site Assessment Reports
c) Previous Internal Audit Findings and Corrective Actions
d) Equipment Calibration, Standardization, Check, and Maintenance Records
e) Technician Training Records
f) Technician Evaluation Records
g) Customer Feedback Records
h) Test Records and Reports
i) Quality Management System

2. After each 12-month review the Quality Manager shall discuss any deficiencies noted with appropriate staff, ensure corrective action is taken, and prepare a memorandum to the Laboratory Manager describing the items reviewed, the deficiencies identified, and the corrective action taken.

3. The Office Manager shall maintain a file containing all documents relating to quality management system review in his office.

Figure X1.3—Internal Audit Procedure

	All records adequate and/or deficiencies corrected?					
	Binder Lab	Hot Mix Lab	Soil Lab	Agg. Lab	Conc. Lab	Date Checked
Equipment Records						
Personnel Training/Competency Records						
Test Records and Reports						
Proficiency Sample Reports						
On-Site Assessment Corrective Actions						
Internal Audit Records and Corrective Actions						
Customer Feedback Records						

Have there been any changes made or updates required in the following sections of the QMS? Describe any actions taken below.

	Changes made?	QMS updated?
a) Organizational charts...		
b) Staff position descriptions...		
c) Staff biographical sketches..		
d) Staff training methods...		
e) Staff evaluation methods...		
f) Equipment inventory list..		
g) Equipment calibration/check list..		
h) Procedure describing in-house calibrations/checks...		
i) In-house equipment calibration/check procedures

PROCEDURES RELATED TO PROFICIENCY SAMPLE TESTING AND ON-SITE ASSESSMENTS

GENERAL:

It is the responsibility of the Quality Manager to review all reports pertaining to proficiency sample testing, on-site assessment, and quality management system evaluations and to bring poor results or differences to the attention of the appropriate unit supervisor. It is the responsibility of the unit supervisor to ensure that corrective action is taken and documented. (In some cases it may be necessary for the Quality Manager to take corrective action and prepare documentation relative to specific differences.)

Reports covering the results of proficiency sample testing and on-site assessment and quality management system evaluations, and memorandums summarizing investigations and any corrective action taken shall be maintained by the Quality Manager in the Quality Manager's office.

PROFICIENCY SAMPLE TESTING:
Participation:
AMRL Soil Proficiency Sample Program
AMRL Aggregate Proficiency Sample Program
CCRL Concrete Proficiency Sample Program

Identifying poor results:
Any result that is beyond 2 standard deviations from the average value.

Procedures to follow when poor results occur:
1. Determine if the Agency conducting the program correctly entered the data reported.
2. Determine if the test result obtained was properly transferred to the data sheet submitted.
3. Determine if all calculations leading to the test results obtained were correct.
4. Determine if the equipment used to perform the test meets specification requirements.
5. Determine if the procedures followed when performing the test conformed to specification requirements.
6. Take corrective action to repair or take steps to replace defective equipment or instruct the technician of the correct procedure to follow.
7. Prepare a memorandum of record summarizing the results of the investigation, identifying the cause of the poor results if determined, and describing any corrective action taken.

ON-SITE ASSESSMENTS:
Participation:
AMRL Soils Inspection
AMRL Aggregate Inspection
CCRL Portland Cement Concrete Inspection

Procedures to follow when findings are reported:
(Apparatus Deficiencies)
1. Determine if the equipment meets specification requirements.
2. If the equipment is found to be defective, take necessary steps to repair or replace it.
3. Prepare a memorandum of record summarizing the results of the investigation and any corrective action taken.

(Procedural Deficiencies)
1. Discuss each procedural deficiency with the testing technician and review the proper procedure.
2. Observe the technician perform the test properly.
3. Prepare a memorandum of record summarizing the action taken.

(Quality Management System Deficiencies)
1. The Quality Manager shall review each deficiency cited by the evaluator with the responsible employee.
2. Take appropriate action.
3. Prepare a memorandum of record summarizing the action taken.

HANDLING CUSTOMER FEEDBACK

Upon receipt of a customer complaint, the following actions shall be taken:

1. The Director of the laboratory shall be notified.
2. Complaint is brought to the attention of the Supervisor of the department or section in question.
3. Supervisor contacts the customer to verify all aspects of the complaint and establish resolution date (if necessary).
4. All reports, records, and pertinent data shall be reviewed; and all calculations are to be checked for accuracy.
5. The technician(s) performing the test is consulted by the Supervisor to determine any unusual problems or circumstances involved.
6. Supervisor reports all information gathered to the Director.
7. The Director shall formulate an appropriate reply and issue same to the complainee.

(Date)

EQUIPMENT CALIBRATION, STANDARDIZATION, CHECK, AND MAINTENANCE POLICIES AND PROCEDURES

General Policies:

1. Required equipment shall be calibrated, standardized, checked, or maintained at specified intervals following the general procedures indicated below.

2. Newly acquired equipment without a manufacturer's certification and equipment that has not been calibrated, standardized, or checked because it has been removed from service shall be calibrated or checked before being returned to service.

3. When any of the Unit's test equipment is overloaded, mishandled, giving results that are suspect, or is not meeting specification tolerances, the Unit Supervisor shall remove it from service and clearly mark it by attaching a red ribbon or tape. The equipment shall be returned to service only after appropriate repairs are made and calibration, standardization, or checks confirm the equipment functions satisfactorily or meets specification tolerances.

General Procedures:

1. The Supervisor in each Testing Unit is responsible for ensuring that calibration, standardization, checks, and maintenance activities are performed. He shall maintain a file for each piece of equipment in his unit requiring calibration, standardization, check, or maintenance. The file for each piece of equipment shall contain detailed records of calibration, standardization, check, or maintenance work performed in chronological order and shall be kept in the Supervisor's office.

2. The Supervisor in each Testing Unit shall maintain a set of 12 labeled folders in his office—one for each month of the year. Each month's folder shall contain a partially completed calibration, standardization, check, or maintenance record form for each piece of equipment requiring calibration, standardization, checks, or maintenance during the month indicated on the folder's label.

3. During the first week in each month, the Supervisor in each Testing Unit shall remove the partially completed record forms from the current month's folder and instruct the appropriate staff to perform the necessary calibration, standardization, check, or maintenance work within the next week and return the completed record forms.

4. The Supervisor shall prepare partially filled out record forms for each piece of equipment calibrated, standardized, checked, or maintained that month—identifying the equipment and the next date that calibration, standardization, check, or maintenance work is required (month and year)—and file each partially filled out form in the appropriate monthly folder.

5. The Supervisor shall file each of the completed record forms in the appropriate equipment record file in chronological order.

Figure X1.8—Policies and Procedures for Conducting Equipment Calibration, Standardization, Checks, and Maintenance

(Date) Procedure: G-2

Equipment Checked: SIEVES

Purpose:
This method provides instructions for checking the physical condition of laboratory tests sieves ranging in size from 75 mm (3 in.) to 0.075 mm (No. 200) and for measuring the openings of coarse sieves having openings greater than or equal to 4.75 mm (No. 4).

Equipment Required:

1. A caliper readable to 0.01 mm (use for 4.75-mm sieve and coarser).
2. An eye comparator with a 0.1-mm scale or a magnifier (for use with sieves finer than 4.75 mm).

Tolerance:
Sieves shall meet the physical requirements specified in AASHTO M 92 (ASTM E 11).

Procedure:

1. For sieves having openings equal to or greater than 4.75 mm, select and measure, using the calipers, the dimensions of at least four or five sieve openings in each sieve to ensure that the openings in the wire cloth conform to the requirements in Table 1 of AASHTO M 92 (ASTM E 11). Be sure to include, in the selection, any openings that appear distorted or unusual in size. Measure each of the openings as the distance between parallel wires measured at the center of each opening. Measure each opening in both the x (horizontal) and y (vertical) directions. Record the measurements for each of the selected openings. If a sieve has less than five full openings, measure all full openings.
2. For sieves smaller than 4.75 mm, inspect the sieve cloth against a uniformly illuminated background. Use the eye comparator or magnifier to examine any suspicious areas of the cloth. If obvious deviations, such as weaving defects, creases, wrinkles, or excessive foreign matter in the cloth are found, the wire cloth is unacceptable.
3. Inspect the general condition of the sieve. Check the frame and solder joints for cracks or holes. (Check for pin holes in the finer sieves.)
4. Ensure that the sieve has an appropriate label.
5. Check for tightness of the wires on each individual sieve.

Figure X1.9—Procedure for Checking Sieves

(Date) Procedure: S-1

Equipment Checked: MANUAL HAMMER (AASHTO T 99, T 180) (ASTM D 698, D 1557)

Purpose:
This method provides instructions for checking the critical dimensions of the proctor hammers.

Equipment Required:

1. Calipers readable to 0.01 mm.
2. Tape measure readable to 1 mm.
3. Balance, capacity 5 kg, readable to 1 g.

Tolerance:
Equipment shall meet the dimensional tolerances specified in the applicable test method.

Procedure:

1. Measure and record the diameter of the rammer face determined by taking two readings 90° apart using the calipers.
2. Pull up the handle, measure, and record the drop height of the hammer. Determine this height inside the guide-sleeve using the tape measure.
3. Remove the hammer from the guide-sleeve. Determine and record its mass to the nearest 1 g.
4. Measure and record the diameters of the vent holes near the end of the hammer.

Figure X1.10—Procedure for Checking Manual Compaction Hammers

(Date) Procedure: A-1

Equipment Checked: CONICAL MOLD, TAMPER (AASHTO T 84) (ASTM C 128)

Purpose:
This method provides instructions for checking the critical dimensions of the sand cone and tamper used in the above test method.

Equipment Required:

1. Calipers readable to 0.1 mm.
2. Balance, 500 g capacity, readable to 0.1 g.
3. Ruler readable to 1 mm.

Tolerance:
Equipment shall meet the dimensional tolerances specified in the test method.

Procedure:
(Cone)

1. Measure the inside diameter at the top of the cone to the nearest 1 mm by taking two readings 90° apart using the ruler and record the results.
2. Invert the cone and repeat step 1.
3. Place the cone on a flat glass surface. Measure and record the depth of the cone.
4. Using the calipers, measure the thickness of the cone to the nearest 0.1 mm by taking two readings 90° apart at the top of the cone and two readings 90° apart at the bottom of the cone and record the results.

(Tamper)

1. Measure and record the diameter of the tamping face to the nearest 1 mm by taking two readings 90° apart using the ruler.
2. Determine and record the mass of the tamper to the nearest 0.1 g.

Figure X1.11—Procedure for Checking Conical Molds and Tampers

(Date) Procedure: A-2

Equipment Checked: L. A. ABRASION MACHINE (AASHTO T 96) (ASTM C 131)

Purpose:
This method provides instructions for checking the critical dimensions and general operating condition of the L. A. abrasion machine and the mass of the spheres used as test charges.

Equipment Required:
1. Steel rule readable to 1 mm.
2. Stopwatch readable to 0.1 s.
3. Balance with a 5 kg capacity, readable to 1 g.

Tolerance:
The L. A. machine shall meet the dimensional tolerances specified in the applicable test method listed above and shall be in good operating condition. The steel spheres used to charge the L. A. machine shall meet the mass tolerances specified in the applicable test method listed above.

Procedure:
(L.A. Machine)
1. Measure and record the inside diameter of the drum at the left and right edges to the nearest 1 mm.
2. Measure and record the width and height of the opening to the nearest 1 mm.
3. Measure and record the wall thickness at the left and right edge to the nearest 1 mm.
4. Determine if the cylinder is horizontal using a steel ball to check left-to-right roll.
5. Measure and record the shelf width inside the drum to the nearest 1 mm.
6. Measure and record the distance from the shelf to the opening in the direction of rotation.
7. Using the stopwatch, determine the r/min to the nearest whole number over a 5-minute period. Record the r/min.
8. Check that the number of revolutions is 500 by looking at the counter on the machine.

(Steel Spheres)
1. Determine and record the mass of each individual sphere to the nearest 1 g.
2. Determine and record the mass of the collective charge(s) to the nearest 1 g.

Figure X1.12—Procedure for Checking L.A. Abrasion Machines

(Date) Procedure: B-3

Equipment Checked: TIMERS (AASHTO T 72, T 201, T 202) (ASTM D 88, D 2170, D 2171)

Purpose:
This procedure provides instructions for checking the accuracy of timing devices.

Inspection Equipment Required:
1. Timer, readable to 0.1 s., having a verified accuracy within the tolerance listed in above test methods.

Tolerance:
Timers shall meet the accuracy requirements specified in the applicable test methods listed above.

Procedure:
1. Hold the calibrated timer in one hand and the timer to be checked in the opposite hand.
2. Start the timers simultaneously by pressing the “start” buttons at the same time.
3. Allow the timers to run for at least 15 min. Then stop the timers simultaneously. Record the time indicated by both timers.
4. Record the difference between the two timers. Calculate and record the percent accuracy.

$$\%\ \text{accuracy} = \frac{\left(A = B\right)}{B} \times 100$$

A = Reading on lab timer (s)
B = Reading on standard timer (s)

Figure X1.13—Procedure for Checking Timing Devices

(Date) Procedure: B-4

Equipment Checked: PENETRATION APPARATUS (AASHTO T 49) (ASTM D 5)

Purpose:
This procedure provides instructions for checking the equipment used to perform the penetration test.

Equipment Required:
1. Balance, readable to 0.01 g.
2. Microscope or eyepiece, 10×.
3. Metal block, 10.0 mm high. Metal block, 25.4 mm (1 in.) high.
4. Support block, 75–87.5 mm high.
5. Ruler, readable to 1 mm.
6. Calibrated stopwatch, readable to 0.1 s.

Tolerance:
The equipment shall meet the tolerances specified in test methods AASHTO T 49 and ASTM D 5.

Procedure:
1. Remove the spindle, 50- and 100-g weights from the penetrometer. Record the weight of each to the nearest 0.01 g.
2. Weigh each needle to the nearest 0.01 g. Visually examine each needle with a microscope or eyepiece. Each needle should be straight and free of burrs. The base of each needle should be flat.
3. If an automatic timing mechanism is used on the penetrometer start the calibrated stopwatch when the plunger is released and stop the calibrated stopwatch when the plunger stops. Record the time indicated on the calibrated stopwatch to the nearest 0.1 s. If a manual device is used to release the plunger, check the accuracy of the timing device used over a 60-s interval. Record the elapsed time to the nearest 0.1 s.
4. Place the support block on the base of the penetrometer. Place the 10-mm block on the support block. Adjust the needle height so that its tip just touches the top of the 10-mm block. Remove the 10-mm block and release the needle to the support block. Adjust the instrument to measure the distance moved. Repeat step 4 using the 25.4-mm (1-in.) block. Determine dial accuracy by comparing readings with the height of the blocks.
5. Measure and record the distance from the perforated shelf to the bottom of the water bath. Measure and record the distance from the perforated shelf to the surface of the water. Measure and record the distance the thermometer is immersed in the water.
6. Observe and record the temperature of the water in the bath to the nearest 0.1°C (0.2°F).

Figure X1.14—Procedure for Checking Penetration Test Apparatus

______(Date)______

PROCESSING OF SAMPLES

IDENTIFICATION:
Each sample shall be accompanied by a sample tag indicating the sample number. This identifies the material in terms of the project, the location of use within the project, the quantity of material represented by the sample, and the material's intended use. The sample tag is kept with the sample as long as it remains in the materials laboratory.

STORAGE:
After being logged in, samples are stored in the area of the laboratory in which testing is to be done. During storage, care is taken to avoid disturbance or contamination. Any AASHTO requirements for storage (e.g., the moist storage of portland cement concrete cylinders) are followed.

RETENTION:
Samples with acceptable test results are generally discarded when testing is completed. Those with failing results are retained until review of those results is completed. At that time, the decision is made whether to discard, retest, or continue to retain the sample.

DISPOSAL:
Discarded non-hazardous materials are transported daily by materials section personnel to an appropriate area. Hazardous materials (e.g., bituminous concrete extraction solution) are stored in proper containers in an isolated area of the laboratory. Disposal by an approved disposal contractor is arranged periodically by the hazardous waste disposal officer.

Figure X1.15—Procedure for Sample Management

(Date)

TEST RECORDS

PREPARING SAMPLE LOG:

Each sample brought to the materials laboratory for testing is recorded in a log book maintained by the Laboratory Manager. The following information is recorded for each sample:

1. Sample number (this is assigned sequentially to each line of the log book).
2. Project name or contract number.
3. Description of the material.
4. Supplier of the material.
5. Location from which the sample was taken.
6. Name of person(s) who sampled the material.
7. Date of sampling.
8. Date the sample was received in the materials laboratory.
9. The word "RESAMPLE" in red ink (when applicable).
10. The date testing was completed.
11. The initials of the tester.

PREPARING AND CHECKING TEST REPORTS:

Test results are recorded on standard materials section worksheets, which are submitted to the materials lab supervisor who reviews them prior to preparing a test report. An original and two copies of the test report are prepared for review by the laboratory manager. The original test report is filed in the project folder. One copy of the test report is kept on file with the worksheets in the materials laboratory, and the other copy is sent to the project engineer for review. Test records and reports are maintained by the Office Manager.

AMENDING REPORTS:

When a report must be amended, a report form shall be filled out indicating the amended test results; the report status field "amended" on the report form shall be checked; the comment section on the report form shall state the reason for the amended report; the amended report shall be attached to the original report and processed in the normal manner; and the amended report shall be filed with the original report.

Figure X1.16—Procedures for Producing Test Records and Preparing, Checking, and Amending Test Reports

Date:_____________

MAINTENANCE INTERVALS

Equipment	Activity	Interval (months)
Compression machine	Clean, lubricate	1
Moist room	Ensure spray nozzles unclogged Check for leaks Check position of temperature recorder probe	3
Mechanical shakers	Lubricate, check for wear	3
LA abrasion machine	Lubricate	6

Figure X1.17—List of Maintenance Activities and Intervals

Date:_________ Maintenance Procedure: M-2

MECHANICAL SHAKER MAINTENANCE PROCEDURE

Equipment Needed: wrench, grease, brush

Procedure:

1. Clean all loose dust and particles from all exposed surfaces of machine
2. Check each paddle for looseness – tighten where necessary
3. Replace any paddles that are in poor condition
4. Clean and grease rotating base
5. Operate shaker without sieves in place to determine how shaker is working
6. Explore any other possible issues and resolve them

MECHANICAL SHAKER MAINTENANCE RECORD

Date	Name	Comments
1/5/08	Technician A	Replaced 2 paddles
4/3/08	Technician A	Done
7/7/08	Technician A	Screws were loose on rotating base
10/2/08	Technician B	Done
1/3/09	Technician B	Installed sound dampener on door

Figure X1.18—Mechanical Shaker Maintenance Procedure and Record

---

[1] This document is under the jurisdiction of the American Association of State Highway and Transportation Officials (AASHTO) Highway Subcommittee on Materials and is the direct responsibility of the Administrative Task Group.

[2] The definition is from the International Vocabulary of Metrology (abbreviated VIM), 3rd edition, 2008, published by the International Organization for Standardization (ISO), in the name of the eight organizations that supported its development and nominated the experts who prepared it: the Bureau International des Poids et Mesures (BIPM), the International Electrotechnical Commission (IEC), the International Federation of Clinical Chemistry (IFCC), International Laboratory Accreditation Cooperation (ILAC), ISO, the International Union of Pure and Applied Chemistry (IUPAC), the International Union of Pure and Applied Physics (IUPAP), and the International Organization of Legal Metrology (OIML). The VIM should be the first source consulted for the definitions of terms not included in this practice.

[3] The figures in this Appendix illustrate typical examples of documents, forms, and standard operating procedures that address the requirements of this practice. A laboratory may employ other methods that satisfy the intent of this practice. The figures are intended as examples of documents in a laboratory's Quality Management System. They are not intended to include all possible laboratory organizational structures or capabilities.

Standard Practice for

Procedures for Measuring Highway Noise

AASHTO Designation: R 20-99 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Procedures for Measuring Highway Noise

AASHTO Designation: R 20-99 (2008)

1. SCOPE

1.1. This standard practice is to provide guidance in acceptable procedures for measuring highway noise levels.

2. GENERAL PROVISIONS

2.1. It is recommended that the following Federal Highway Administration Report be used for field measurement of highway noise levels.

2.1.1. FHWA-PD-96-046, DOT-VNTSC-FHWA-96-5, "Measurement of Highway-Related Noise," May 1996.[1]

Standard Practice for

Quality Assurance of Standard Manufactured Materials

AASHTO Designation: R 38-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Quality Assurance of Standard Manufactured Materials

AASHTO Designation: R 38-10

1. SCOPE

1.1 This standard practice contains minimum criteria and guidelines for establishing and implementing quality assurance (QA) procedures for *standard manufactured materials* used in highway construction. The purpose of this document is to establish minimum quality control (QC) requirements for manufacturers and to provide guidelines for acceptance of standard manufactured materials by transportation agencies.

1.2 *Standard Manufactured Materials*—Materials used in transportation construction are broadly categorized according to their source and corresponding methods of production. The three principal materials categories are as follows:

- Project-produced materials,
- Fabricated structural materials, and
- Standard manufactured materials.

1.3 In order to explain the difference between these materials categories and provide a basic understanding of how QA is applied to them, each of the three primary material categories is defined below (see Section 3). Although QA procedures should be addressed for each of these material categories, the scope of this standard practice is the application of QA to standard manufactured materials.

1.4 Standard manufactured materials are standard items that are produced routinely (i.e., not for a specific project) by a manufacturer. They are generally characterized by one or more of the following conditions:

1.4.1 The materials are normally mass-produced under highly controlled and largely automated manufacturing conditions.

1.4.2 The material properties are stable and have no potential for alteration under proper transportation from the manufacturer to the project site.

1.4.3 The materials arrive at the project site in a solid, finished state and require only installation.

1.5 *Relevant Items*—This standard practice addresses those items used in transportation construction which meet the above description of standard manufactured materials. Some examples of standard manufactured materials used in transportation construction are presented in Table 1 below. The list of items in Table 1 is not all-inclusive but is intended to provide examples of typical items within each of the three principal materials categories.

Table 1—Typical Items by Materials Category

Materials Category	Example Items
Project -Produced Materials	Earthwork Subbase and Base Courses Geotechnical Items* Hot Mix Asphalt (HMA)* Portland Cement Concrete (PCC)* Field Applied Structural Coatings* Pavement Markings*
Fabricated Structural Materials	Fabricated Structural Steel and Coatings* Precast/Prestressed Concrete Structural Elements* (e.g., Precast Box Culverts, Prestressed Bridge Beams)
Standard Manufactured Materials	Binders and Cements (e.g., PG Binder, Portland Cement) Drainage or Water Systems (e.g., Ductile Iron Pipe, Corrugated Metal Pipe, PVC Pipe, Hydrants, Gates and Valves, etc.) Geotextile Fabrics Landscaping Items (e.g., Lime, Fertilizer, Seed, Mulch, Chain Link Fence, etc.) Paints and Coatings (e.g., Traffic Paints, Glass Beads, Preformed Markings, Epoxy, Zinc Galvanizing, etc.) Roadside Safety Devices (e.g., Impact Attenuators, Steel Beam Guardrail, Wood Posts, etc.) Standard Precast Concrete Items (e.g., Concrete Pipe, Concrete Manholes and Junction Boxes, Concrete Barrier, Concrete MSE Wall Panels, etc.) Standard Steel Shapes or Products (e.g., Anchor Bolts, Frames and Grates, Rebar, Stay-in-Place Forms, Sheeting and Piles, etc.) Traffic Control Devices (e.g., Electrical Conduit, Signal Heads, Signal Poles, Controllers, Signs, etc.)

* Some constituent materials incorporated are evaluated as standard manufactured materials.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- R 18, Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories

2.2 *ASTM Standards*:

- D 3665, Standard Practice for Random Sampling of Construction Materials
- E 4, Standard Practices for Force Verification of Testing Machines
- E 105, Standard Practice for Probability Sampling Of Materials

2.3 *Other Documents*:

- ISO 10013, Guidelines for Quality Management System Documentation

3. TERMINOLOGY

3.1 *Relevant Terms and Definitions*—The terms and definitions included below are provided to ensure standard application of terminology relevant to the QA of transportation construction materials, including standard manufactured materials. Where terms or definitions in this standard practice differ from the above-referenced documents, the terms included herein shall replace those contained in the above referenced documents.

3.1.1 *acceptance*—all factors used by the agency (i.e., sampling, testing, and inspection) to evaluate the degree of compliance with contract requirements and to determine the corresponding value for a given product.

3.1.2 *accredited laboratories*—laboratories that are recognized by a formal accrediting body as meeting quality system requirements, including demonstrated competence to perform standard test procedures.

3.1.3 *agency*—any organization, constituted under Federal, state, or municipal laws, that is responsible for administering contracts for highway or transportation construction.

3.1.4 *calibration*—a systematic process used to standardize measurement instruments or test equipment by determining any deviation from an established reference or standard. A correction or adjustment of the instrument or equipment may be required based on the amount of deviation from the standard.

3.1.5 *certified personnel*—personnel who are recognized by a formal certifying body as qualified to perform sampling, testing, inspection, or related procedures.

3.1.6 *control chart*—also called "statistical control chart." A graphical plot of QC measurements or test values used to identify variation in a production or placement process due to either chance causes or assignable causes.

3.1.7 *control chart limits*—also called "action limits." Statistically derived boundaries applied to a control chart for controlling material production or placement. [Control chart limits are expressed as the upper control limit (UCL) and the lower control limit (LCL). When values of the material characteristics fall within these limits, the process is "under control." When values fall outside the limits, there is an indication that some assignable cause is present causing the process to be "out of control."]

3.1.8 *dispute resolution*—the procedure used to resolve conflicts resulting from discrepancies between the agency's and contractor's results of sufficient magnitude to impact payment.

3.1.9 *engineering limits*—the absolute limiting value(s) placed on a quality characteristic beyond which the test result for an individual sample is considered to be unacceptable. [Engineering limits are established to identify material that does not provide the minimum required engineering properties. They usually have an upper engineering limit (UEL), a lower engineering limit (LEL), or both. The engineering limits may be the same as the specification limits.]

3.1.10 *fabricated structural materials*—major structural items produced specifically for an individual construction project by a material fabricator. [They are generally characterized by one or more of the following conditions: (a) The production process for the material occurs under controlled conditions at an established fabricator plant typically located within state or in another state; (b) The material properties are stable and have no potential for alteration under proper transportation from the fabricator to the project site; (c) The materials arrive at the project site in a solid state and require little or no additional work after installation.]

3.1.11 *fabricator*—a company that produces fabricated structural materials (e.g., precast/prestressed concrete structural elements, fabricated structural steel) for either the prime contractor or a subcontractor.

3.1.12 *lot*—a specific quantity of material from a single source that is assumed to be produced or placed by the same controlled process.

3.1.13 *manufacturer*—a company that manufactures and supplies standard manufactured materials for either the prime contractor, a subcontractor, or a fabricator.

3.1.14 *population*—a collection of all possible individuals, objects, or items that possess some common specified characteristic(s) that can be measured.

3.1.15 *prime (general) contractor*—the company which has the primary construction contract for an agency project and which assumes overall responsibility for completing the work.

3.1.16 *producer*—a company that produces and supplies project-produced materials (e.g., aggregates, HMA, PCC) for either the prime contractor or a subcontractor.

3.1.17 *project-produced materials*—major items produced directly for an individual construction project either by a contractor or by a material producer. [They are generally characterized by one or more of the following conditions: (a) The production process for the material occurs either at the project site or at a production plant located in close proximity to the project site; (b) The material properties are subject to potential contamination or segregation during transportation from the plant to the project site; (c) The materials arrive and are placed at the project site in a nonsolid or loose mixture state requiring subsequent mixing, compaction, finishing, or curing.]

3.1.18 *qualified laboratories*—laboratories that are capable as defined by appropriate programs established or recognized by each agency. [Accredited laboratories are considered "qualified." However, a "qualified laboratory" need not be accredited.]

3.1.19 *qualified personnel*—personnel who are capable as defined by appropriate programs established or recognized by each agency.

3.1.20 *quality*—(1) the degree of excellence of a product or service; (2) the degree to which a product or service satisfies the needs of a specific customer; (3) the degree to which a product or service conforms with a given requirement; or (4) conformance to requirements.

3.1.21 *quality assurance (QA)*—(1) all those planned and systematic actions necessary to provide confidence that a product or facility will perform satisfactorily in service; or (2) ensuring the quality of a product is what it should be. [The two primary elements of a QA program for standard manufactured materials include QC by the manufacturer and acceptance by the agency. Additional elements of a QA program for standard manufactured materials include qualified personnel, qualified laboratories, and dispute resolution procedures.]

3.1.22 *quality characteristics*—a product characteristic that is measured through testing, either for QC purposes or for conformance with acceptance requirements. [Quality characteristics are specific material properties or product requirements which are evaluated by QC and acceptance testing. Quality characteristics are normally selected because they: (a) relate to initial and long-term performance; (b) are quantifiable or measurable; and (c) can be measured with good repeatability.]

3.1.23 *quality control (QC)*—the system used by a contractor party to monitor, assess and adjust their production or placement processes to ensure that the final product will meet the specified level of quality. [QC includes sampling, testing, inspection, evaluation, and corrective action (when required) to maintain continuous control of a production or placement process.]

3.1.24 *quality measure*—any one of several mathematical tools used to quantify the level of quality of an individual quality characteristic. [Application of a quality measure to a set of test data provides an overall numeric representation of quality for a specific quality characteristic. Typical quality measures used in QA are selected because they quantify the average quality, the variability, or both. Examples of quality measures that may be used include: mean, standard deviation, percent defective (PD), percent within limits (PWL), average absolute deviation (AAD), moving average, and conformal index (CI). PWL and PD are the quality measures recommended for use in QA specifications.]

3.1.25 *quality system manual (QSM)*—a written document that describes the overall QC operating procedures of a contractor party (e.g., prime contractor, subcontractor, producer, fabricator, manufacturer). [A manufacturer's QSM documents the internal policies for achieving quality and the assignment of responsibility and accountability for QC within the manufacturer's organization. It may also describe the minimum QC requirements expected of upper- or lower-tier contractor parties who supply constituent materials or who are involved in handling or processing of the manufacturer's products.]

3.1.26 *random sampling*—a sampling procedure whereby each sample obtained from the lot has an equal probability of being selected.

3.1.27 *run chart*—also called "music bar chart." A control chart that presents individual measurements or test values for a specific quality characteristic on a vertical axis and the individual sample numbers (in consecutive order) on a horizontal axis. [Run charts plot individual sample values ($n = 1$) and usually check the measurements or test results against the specification limits or engineering limits.]

3.1.28 *sample*—(1) also called "material sample." A small quantity of material or measurement obtained from a sublot or lot. [A sample can refer to either a point of inspection (i.e., visual examination or physical measurement) or an individual material sample obtained for testing. A sample may be composed of one or more increments of equal size that have been obtained from the sampling location and combined.]; or (2) also called statistical sample. All of the samples obtained from a lot that provide information that may be used to quantify the quality of the entire lot. [The context in which the word "sample" is used determines its meaning. For example, "obtain a sample here" would mean obtain a physical quantity of material from a specific location; while "the sample size equaled nine" means that at total of nine individual material samples were obtained in a random manner and thus comprised the statistical sample of size $n = 9$. Each sample is included in the overall statistical sample for a given lot.]

3.1.29 *specification limits*—the statistically based limiting value(s) placed on a quality characteristic which are applied with a particular quality measure (such as PWL) to evaluate the quality of a lot. [Specification limits are usually composed of an upper specification limit (USL), a lower specification limit (LSL), or both. It is important to recognize that since specification limits are statistical limits, individual sample test results may fall beyond the USL or LSL and still be included in the acceptance determination. The specification limits will ultimately be used for computation of quality levels (e.g., PWL), which will be used in calculating pay factors for a lot.]

3.1.30 *standard manufactured materials*—standard items that are produced routinely (i.e., not for a specific project) by a manufacturer. [They are generally characterized by one or more of the following conditions: (a) the materials are normally mass-produced under highly controlled and largely automated manufacturing conditions; (b) the material properties are stable and have no potential for alteration under proper transportation from the manufacturer to the project site; (c) the materials arrive at the project site in a solid, finished state and require only installation.]

Note 1—Exceptions to this condition include materials such as PG binders, cements, and paints/coatings that are incorporated into either project-produced materials or fabricated structural materials.

3.1.31 *statistical control chart*—see *control chart*.

3.1.32 *statistical sample*—see *sample*.

3.1.33 *stratified random sampling*—a sampling procedure whereby samples are randomly obtained from each sublot.

3.1.34 *subcontractor*—a company which is responsible for field placement or installation of an individual item of work under contract to the prime contractor.

3.1.35 *subgroup*—a set ($n > 1$) of QC sample values from within a lot the mean or range of which are plotted on a control chart.

3.1.36 *sublot*—a subdivision of a lot.

3.1.37 *target value*—the value that is placed on a quality characteristic that represents the mean of the expected distribution of the specified population.

3.1.38 *validation*—the mathematical comparison of two independently obtained sets of data (e.g., agency acceptance data vs. manufacturer QC data) to determine whether it can be assumed they came from the same population.

4. SIGNIFICANCE AND USE

4.1 *Manufacturer Quality Control*—This document outlines minimum requirements that should be followed by manufacturers in implementing an effective QC system. It is not intended to prescribe the methods by which a manufacturer achieves the desired level of quality but instead establishes minimum guidelines and criteria for documenting and implementing QC procedures for standard manufactured materials.

4.2 *Agency Acceptance*—This document outlines recommended approaches for acceptance of standard manufactured materials by transportation agencies. It is not intended to prescribe a singular acceptance procedure for all agencies, but rather provides a uniform framework for acceptance of standard manufactured materials that takes into consideration the quality control requirements established herein.

5. QUALITY CONTROL REQUIREMENTS

5.1 Each manufacturer shall have a QC system in place to ensure the quality of their products. Quality control procedures must provide adequate assurance to agencies that the products purchased will meet relevant AASHTO, ASTM, and industry standards. The following minimum requirements for manufacturer QC shall be satisfied.

5.1.1 *Quality System Manual*—Each manufacturer shall establish and maintain a QSM. The QSM is a general document intended to outline the overall internal QC operating procedures of the manufacturer. A QSM documents the manufacturer’s policies for achieving quality and the assignment of responsibility and accountability for QC within the manufacturer organization. It also describes the minimum QC requirements expected of other manufacturers or material suppliers from whom the manufacturer obtains constituent materials incorporated in each manufactured product.

5.1.1.1 Guidelines for the preparation of QSM may be available from industry organizations that administer manufacturing facility certification programs. In addition, ISO10013 contains guidelines on the development and preparation of QSM. However, each manufacturer QSM shall meet the format and content requirements outlined below.

5.2 *QSM Format*—The manufacturer’s QSM may be maintained in an electronic format. However, one or more copies of the QSM must be maintained by the manufacturer’s QC manager in a printed and bound format (three-ring or other). The QSM shall be available to all of the manufacturer’s employees. Each document in the QSM shall indicate its preparation date, and all pages of the QSM shall be numbered. If a document is revised, the date of the revision shall be indicated on the document and recorded in a table of revisions.

5.2.1 It is the intent of this standard practice that the QSM shall address each of the items outlined below, except as agreed upon by the agency. The QSM shall be formatted to provide numbered sections for each item, in the order listed below, except as otherwise approved by the agency. The standard QSM items are as follows:

5.2.1.1 Manufacturer's quality statement;

- Written policy or mission statement

5.2.1.2 Manufacturing facility and products;

- Facility address and telephone number
- Standard manufactured materials produced

5.2.1.3 Terms and definitions;

5.2.1.4 Applicable specifications (AASHTO, ASTM, other);

5.2.1.5 QC system roles and responsibilities;

- QC organization
- QC manager
- QC technicians
- QC personnel qualification requirements
- Production personnel responsibilities for quality

5.2.1.6 QC laboratories;

- Laboratory addresses and telephone numbers
- Laboratory accreditation or qualification
- Testing equipment

5.2.1.7 Preproduction materials control;

- Constituent material types and sources of supply
- Visual inspection of constituent materials
- Control and testing of constituent materials properties
- Constituent materials storage

5.2.1.8 QC during production of standard manufactured materials;

- Lot and sublot sizes
- QC visual inspection
- Random sampling plan
- Selective sampling
- Sample identification system
- Standard QC sampling and testing methods (AASHTO, ASTM, other)
- Manufacturer-developed test procedures
- QC sample storage and retention procedures
- QC inspection and test result reporting
- Use of control charts
- Statistical analysis of test results
- Resolution of nonconforming inspection or test results

5.2.1.9 Postproduction QC activities; and

- Marking, storage, shipping, and handling of standard manufactured materials

- ■ QC records
- ■ Retention of inspection and test results and product traceability
- ■ Issuance of materials certificate of compliance (COC)

5.2.1.10 Quality audit of the manufacturing facility (as required by agency—see Section 5.13).

5.3 A model QSM outline, which includes each of the standard items above, is contained in Appendix X1 of this standard practice. The information required in each of the above QSM Sections is described below.

5.4 *Manufacturer's Quality Statement*:

5.4.1 *Written Policy or Mission Statement*—A written quality policy or quality mission statement shall be endorsed by the company's chief executive officer and shall also be available to all employees. The quality policy/mission statement shall indicate the support of top management to enforce the QC requirements contained in the QSM. The quality policy/mission statement shall contain a commitment to meeting a minimum standard of quality. A description of the QC system standards to be met shall be included.

5.5 *Manufacturing Facility and Products*:

5.5.1 *Facility Address and Telephone Number*—The QSM shall include the addresses and telephone numbers of all manufacturing facilities addressed by the QSM. The QSM shall include the telephone number and e-mail address for the QC manager and designated contact personnel.

5.5.2 *Standard Manufactured Materials Produced*—A brief listing and description of the specific products being manufactured shall be included in the QSM.

5.6 *Terms and Definitions*—The QSM should present and define any significant terms used throughout the QSM in order to establish a uniform understanding of essential concepts and to avoid potential confusion. Any terms defined in the QSM shall be consistent with the terms and definitions (see Section 3.1) included in this standard practice.

5.7 *Applicable Specifications (AASHTO, ASTM, Other)*—For all standard manufactured materials addressed under the QSM, the applicable AASHTO, ASTM, or agency specifications shall be identified. A list of the specifications should be presented (with relevant section numbers where applicable) in order to facilitate review of pertinent information.

5.8 *QCl System Roles and Responsibilities*—The personnel structure established to implement the manufacturer's quality system shall be outlined in the QSM. The specific roles and responsibilities of all QC personnel shall be documented as described below.

5.8.1 *QC Organization*—An organizational chart for the company shall be provided in the QSM. The organizational chart should indicate a clear separation between the QC personnel and production personnel. (see Figure 1.)

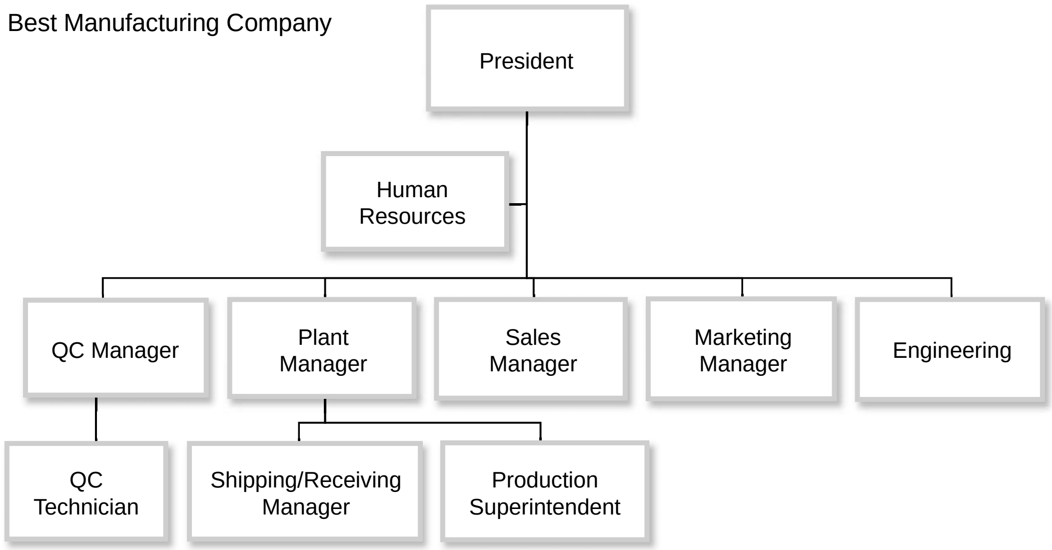

Figure 1—Sample Organization Chart

5.8.1.1 This figure illustrates a typical example of a manufacturing organization's structure and hierarchy. It is not intended to be prescriptive for the purpose of meeting the QSM requirements. Individual companies may vary in their size and arrangement; however, the effectiveness of the QC department may be significantly impacted unless the structure of the organization allows direct access to top management, independent from production responsibilities.

5.8.2 *Q C Manager*—The manufacturer shall have a QC manager who has the overall responsibility for implementing the requirements of the QSM. In addition, the manufacturer shall designate an individual with equivalent experience and qualifications to serve in the QC manager's absence. These individuals must have direct access to top management.

5.8.2.1 The QC manager shall review the QC system established to satisfy the requirements of this practice at least annually, if changes in the manufacturing process(es) occur, or whenever technical or purchaser's complaints describe a trend toward reduced quality.

5.8.3 *QC Technicians*—The manufacturer shall maintain a sufficient number of QC technicians to perform QC sampling, testing, and inspection, independent of production personnel. The technicians performing QC testing must be familiar with the tests they perform and have sufficient authority to assure that corrective actions are carried out when necessary. The quality system manual shall indicate the line of authority of QC technicians, which must demonstrate their authority to require corrective action. The QSM shall designate the qualified QC technicians at each production facility and laboratory involved in the production or testing of a product.

5.8.4 *QC Personnel Qualification Requirements*—The QSM shall contain a description of the specific knowledge, skills, qualifications, and certifications required for all personnel in the QC organization. All manufacturer QC sampling, testing, and inspection personnel shall be qualified through appropriate QC personnel qualification or certification programs. Personnel qualification/certification programs utilized may be either:

5.8.4.1 Personnel qualification/certification programs established by recognized organizations representing a particular manufacturing industry, or

5.8.4.2 Manufacturer in-house personnel qualification/certification programs acceptable to the transportation agency.

5.8.4.3 As a minimum, manufacturer in-house personnel qualification/certification programs shall require relevant experience, training, and demonstrated ability to satisfactorily perform the required inspection, testing, reporting, and documentation for the particular product manufactured.

5.8.4.4 The QSM shall describe in detail the particular qualification/certification program requirements the manufacturer will use to qualify QC personnel. Qualification/certification programs used shall include:

- Training in AASHTO, ASTM, or manufacturer test procedures,
- Demonstration of proficiency in each required test, and
- Demonstration of ability to properly document test results.

5.8.4.5 The program shall also include periodic auditing of each QC technician's ability to satisfactorily perform the required tests. The training shall include the operation of equipment, procedures to be used, calculations required, and reporting. Retraining shall be provided when an applicable method is revised. Technician training will be documented and the records pertaining to qualification/certification will be available for review.

5.8.5 *Production Personnel Responsibilities Concerning Quality*—QC should not be viewed simply as a separate activity or function within the manufacturer's organization but rather must be integrated throughout the organization. In other words, QC is not simply the responsibility of a "QC staff." It is not about relying on QC inspection and testing personnel to "make quality happen." While QC does require sampling, testing, and inspection by qualified QC personnel, quality can only be achieved by skilled workers who are properly trained to produce standard manufactured materials that conform to the specification requirements. The QSM shall describe the specific training provided to production personnel and the operating procedures implemented by these personnel to ensure the required quality of all standard manufactured materials produced.

5.9 *QC Laboratories*—Each manufacturer will maintain its own laboratory to perform QC testing. If required by the agency, the manufacturer will designate an alternate laboratory to serve a backup capacity.

5.9.1 *Laboratory Contact Information*—The QSM shall include the addresses and telephone numbers of all laboratories used by the manufacturer for QC testing. For each laboratory, the QSM shall include a contact person's name, telephone number, and e-mail address.

5.9.2 *Laboratory Accreditation or Qualification*—All manufacturer QC laboratories shall be qualified to perform the specific QC testing required for the manufactured items through an appropriate laboratory accreditation or qualification program. Laboratory accreditation or qualification must be attained through organizations or programs within one of the following three categories:

5.9.2.1 *Category I*—National laboratory accreditation programs,

5.9.2.2 *Category II*—Manufacturing industry organization programs that address laboratory qualification, or

5.9.2.3 *Category III*—Individual manufacturer laboratory qualification programs acceptable to the agency.

5.9.2.4 Examples of national laboratory accreditation programs (Category I) that address some standard manufactured materials include:

- AASHTO Accreditation Program (AAP)
- National Cooperation for Laboratory Accreditation (NACLA)
- American Association for Laboratory Accreditation (A^2LA)
- National Voluntary Laboratory Accreditation Program (NVLAP)

5.9.2.5 Examples of manufacturing industry organization programs that address laboratory qualification (Category II) for specific standard manufactured materials include:

- American Concrete Pipe Association (ACPA) Q-Cast Program
- Concrete Reinforcing Steel Institute (CRSI) Epoxy Certification Program
- National Precast Concrete Association (NPCA) Certification Program

5.9.2.6 Individual manufacturer laboratory qualification programs acceptable to the agency (Category III) must ensure that the following minimum requirements are met:

- A qualified technician shall supervise the laboratory facilities, and only qualified technicians shall perform all tests.
- The laboratory shall maintain current versions of all AASHTO, ASTM, and manufacturer test procedures for all tests performed and a current version of the company's QSM.
- The facility must adequately house and allow proper operation of all required testing equipment.
- The testing equipment shall be calibrated/verified in accordance with R 18. Testing equipment not described in R 18 shall be calibrated/verified in accordance with the manufacturer's recommendations at least once every 12 months by an appropriately qualified person.
- All laboratory equipment shall be properly maintained.
- The laboratory shall maintain records of all agency reviews and actions taken to resolve any noted deficiencies.
- Records of equipment calibration and verification will be maintained and available to the agency upon request.
- Category III laboratory programs will be reviewed and approved by the agency. Qualification will be based on the laboratory's ability to perform the required test procedures in accordance with the applicable standards, use of qualified testing technicians, calibration and verification of all testing equipment, and proper documentation. The agency may require one or more of the following before granting laboratory qualification: a demonstration of the equipment and procedures, split-sample testing with the agency, or round-robin testing.

5.9.3 *Testing Equipment*—The QSM shall contain an inventory of the major sampling, testing, and calibration equipment associated with any tests required to meet the QSM standards (Note 1). The QSM shall assign a unique identification number to each piece of testing equipment. The inventory shall include for each piece of major equipment: the name, date placed in service, manufacturer, model, and serial number (see Appendix X2, Figure X2.1).

Note 1—Major equipment includes all equipment that is normally amortized by a manufacturer, such as physical or chemical testing machines, balances, ovens, microscopes, computing equipment dedicated to testing, etc. Equipment such as chairs, desks, and file cabinets should be excluded. Major equipment does not include expendable items such as miscellaneous glassware, sieves, molds, etc.

5.9.3.1 The QSM shall contain a list giving a general description of testing equipment for performing tests covered by the scope of this standard practice which require calibration or verification. For each item listed, it shall include the interval of calibration or verification, a reference to the calibration or verification procedure used, and the location of calibration and verification records. When standard calibration procedures are used, the standard shall be referenced (e.g., compression machine, ASTM E 4). When the procedure used has been prepared by the manufacturer, the in-house designation shall be referenced. It shall be indicated whether the calibration is performed by an outside organization.

5.9.3.2 A copy of the manufacturer's instructions for use and calibration must be maintained on file. A reference to where the testing equipment inventory is located is acceptable if it is not included in the QSM.

5.9.3.3 The QSM shall describe the methods for ensuring that the calibration and verification procedures are performed for all required equipment at the specified intervals. It shall include the name of individual(s) responsible for ensuring that calibration and verification activities are performed and that procedures for handling new equipment, equipment removed from service, and out-of-calibration or defective equipment are followed. The QSM shall identify the individual(s) responsible for maintaining equipment calibration and verification records, describe the distribution of equipment calibration and verification records to management, and identify the location of resulting records.

5.10 *Pre-Production Materials Control*:

5.10.1 *Constituent Material Types and Sources of Supply*—The QSM shall list the specific types of constituent materials used for production of standard manufactured materials. All sources of supply of constituent materials shall be identified in the QSM.

5.10.2 *Visual Inspection of Constituent Materials*—All constituent materials should be visually inspected, as appropriate, prior to their use in the production of standard manufactured materials. QC procedures for visual inspection of constituent materials shall be included in the QSM.

5.10.3 *Control and Testing of Constituent Materials Properties*—The QSM shall contain a description of the specification requirements for any constituent materials received. The QSM shall contain a description of the certification and test reports delivered by the supplier(s) of the constituent materials and the location of these records. Any constituent materials that are not accepted by the manufacturer on the basis of a COC shall be tested and approved by the manufacturer prior to production of the standard manufactured material.

5.10.3.1 The QSM must include QC testing of the constituent materials used in the manufacturing process and must contain a statement that no raw materials will be used unless they have been tested and meet all AASHTO/ASTM requirements or have been shipped with a COC stating conformance with all requirements. For material having only a COC, at least one random sample must be taken from each lot of constituent materials received for preproduction QC testing to verify conformance with the specified requirements.

5.10.4 *Constituent Materials Storage*—All constituent materials should be properly stored to prevent damage, contamination, or other physical or chemical alteration prior to use in production of standard manufactured materials. QC procedures for adequate storage of constituent materials shall be described in the QSM.

5.11 *QC During Production of Standard Manufactured Materials*:

5.11.1 *Lot and Sublot Sizes*—The QSM shall describe the procedure and frequencies for inspection and selection of material samples during production. All standard manufactured materials shall be identified on a lot basis. Material lot sizes shall be established to ensure adequate QC inspection sampling and testing for the standard manufactured materials they represent. The lot size may be established by the manufacturer based upon production-run quantities or other criteria that ensure the material being evaluated within a lot is from the same material population.

5.11.1.1 QC inspection, sampling, and testing of each lot shall be established using one of the two following approaches:

- Nonstatistical lot system, or
- Statistically based lot and sublot system.
- The agency shall specify which system is to be used by the manufacturer.

5.11.1.2 Under a nonstatistical lot system, the manufacturer must provide a minimum frequency of QC inspection, sampling, and testing as specified by the agency. However, a minimum of one random sample shall be tested per lot. Lot sizes and QC inspection, sampling, and testing frequencies for each lot shall be identified in the manufacturer's QSM.

5.11.1.3 Under a statistically based lot and sublot system, each lot will be divided into a number of equally sized sublots. The use of a statistically valid sampling procedure is recommended to provide meaningful QC sampling and testing (Note 2). When a statistically based system is used, the manufacturer should select a minimum of three to five sublots per lot to ensure that the statistical sample obtained provides a meaningful representation of the lot. One random QC sample is obtained and tested from each sublot. QC inspection should also be provided for each sublot. Lot and sublot sizes shall be identified in the manufacturer's QSM when a statistically based lot and sublot system is used.

Note 2—ASTM E 105 describes procedures for determining statistically valid sample sizes and frequencies.

5.11.2 *QC Visual Inspection*—All standard manufactured materials should be visually inspected during production to ensure that the product meets the established requirements for quality. The QSM shall include QC procedures and documentation for visual inspection of each lot.

5.11.3 *Random Sampling Plan*—All manufacturer QC sampling and testing utilized in issuing a COC representing a given lot shall be performed using stratified random sampling techniques. Random sampling should be performed in accordance with ASTM D 3665. All random QC sample locations shall be properly documented. Procedures for performing and documenting QC random sampling shall be included in the QSM.

5.11.4 *Selective Sampling*—Nonrandom selective sampling may also be performed as necessary by the manufacturer to assist in controlling the production process or to assist in isolating apparent nonconforming material. Procedures for determining and documenting QC selective sampling locations shall be fully described in the QSM.

5.11.5 *Sample Identification System*—Each sample selected for QC inspection and testing (including all random and selective samples) shall be designated with a sample control number for record keeping and traceability. The test report for each sample shall identify the plant, date, shift of manufacture, production line, lot/sublot designation, and sample number. The QSM shall outline the QC sample identification system.

5.11.6 *Standard QC Sampling and Testing Methods (AASHTO, ASTM, Other)*—The QSM shall contain a description of the QC tests and verification processes utilized throughout the manufacturing process to ensure that the end product will meet the required quality level and quality limits (specification limits and engineering limits). Relevant test methods for any QC testing must be defined. Test methods should normally include AASHTO, ASTM, or other recognized industry standards. The specific quality characteristics that the test methods are being used to assess shall also be identified.

5.11.7 *Manufacturer-Developed Test Procedures*—The use of some surrogate test methods may be appropriate as part of the manufacturer's QC system. Manufacturer-developed tests shall only be used if there is no AASHTO or ASTM test method. The QSM shall include all manufacturer developed test procedures used in QC testing. All sampling and testing methods (standard and surrogate) shall be included in the QSM.

5.11.8 *QC Sample Storage and Retention Procedures*—Storage practices prior to testing should ensure that all QC samples are kept in a suitable location that protects them from damage and provides the proper environment for curing the material or maintaining the required material properties. It is recommended practice for all QC samples to be split prior to testing, in accordance with relevant sampling and testing procedures. The split-sample portion of material not used for initial testing should be retained in the original sample storage device with proper identification. The split samples should be stored in an appropriate "sample storage room" at the QC laboratory that performed the initial testing for a reasonable period (e.g., 30 to 60 days) acceptable to the agency. The QSM shall describe the procedures used for proper QC sample storage and retention.

5.11.9 *QC Inspection and Test Result Reporting*—Standard inspection report forms (IRFs) and standard test report forms (TRFs) should be used to record all QC inspection sampling and testing information. The QSM shall contain descriptions and examples of the IRFs and TRFs used by the manufacturer. The QSM shall identify the individual(s) responsible for maintaining inspection and test records and reports, shall describe the distribution of reports, and shall identify the location of resulting records. The QC IRFs and TRFs must be maintained and available for review for a minimum of 3 years.

5.11.10 *Use of Control Charts*—The manufacturer shall use statistical control charts to monitor the manufacturing process. Run charts may be used. However, control charts that plot subgroups of data must also be used. The QSM shall identify target values and ranges of operation used to set control chart limits. Control chart limits should be established for individual quality characteristics using data that define their relationship to specification limits and engineering limits.

5.11.10.1 Statistically valid control chart limits are necessary to describe threshold values reached during production of a lot when changes to the manufacturing process or other corrective action may be required to maintain the production of material within the quality limits. The QSM shall contain standard procedures for preparing and using control charts which depict the performance of the manufacturing process over time (see Appendix X3, Figure X3.1).

5.11.11 *Statistical Analysis of Test Results*—The QSM shall contain a description of the procedures used to statistically evaluate the quality of each lot using the applicable quality measure for each quality characteristic. QC personnel shall monitor QC test results for the purpose of identifying trends and to adjust production as necessary. All random QC test results should be evaluated for conformance with engineering limits and specification limits. The results of the statistical analysis of random QC test results for each lot shall be documented and included on the COC for each lot of standard manufactured materials.

5.11.12 *Resolution of Nonconforming Inspection or Test Results*—The QSM shall contain a description of the procedures used to identify and document products that do not conform to specification requirements. The identification of nonconformances may occur at any level of inspection or testing. Therefore, action at each level shall be based on standard policies described within the QSM. The QSM shall contain provisions for resolving non-conforming products or test results. Materials in a sublot that are identified as visibly deficient or that yield QC test results indicating potentially deficient material should be isolated from the lot. In the latter case, a statistically valid procedure shall be used for sampling and testing the remaining material in the sublot. The material should either be rejected (if determined to be visibly deficient) or further evaluated through selective sampling plus additional random sampling (a minimum of three random samples is recommended) and testing to ensure sufficient data is available to make a final disposition on the affected sublot.

5.11.12.1 Material in the sublot evaluated through this subsequent testing that is determined to be out-of-specification shall be labeled as defective. All nonconforming material shall be segregated in the inventory and corrected, if possible, or discarded. Procedures for marking and subsequent correcting or discarding of nonspecification material identified shall be fully described in the QSM.

5.12 *Post-Production QC Activities*:

5.12.1 *Marking, Storage, Shipping, and Handling of Standard Manufactured Materials*—The QSM shall describe a method for permanently marking the manufactured product in accordance with the requirements of any relevant AASHTO or ASTM standards. The QSM shall describe procedures for product handling, storage, and shipping to ensure that these processes will not adversely affect the material composition, characteristics, or product quality.

5.12.2 *QC Records*—All manufacturer QC inspection, sampling, and testing will be documented on standard forms developed by the manufacturer or as requested by the agency. All inspections will be documented on standard IRFs developed by the manufacturer. TRFs shall indicate the action taken to resolve nonconforming test results. The manufacturer shall maintain a complete list of documentation used to support the QSM and its processes. At a minimum, the following documentation shall be maintained:

5.12.2.1 Records of QC personnel qualifications and related training,

5.12.2.2 QC laboratory accreditation or qualification,

5.12.2.3 Testing equipment identification and verification/calibration records,

5.12.2.4 Incoming constituent material COCs and inspection and testing results,

5.12.2.5 In-process QC inspection and testing results,

5.12.2.6 Nonconforming material identification and disposition, and

5.12.2.7 Physical product dimensions or other characteristics related to agency acceptance.

5.12.3 *Retention of Inspection and Test Results and Product Traceability*—The QSM shall describe in detail the retention of all QC testing and inspection reports. They shall be available to the agency upon request. Certification and test results shall be kept on file for a period of not less than 3 years following shipment and delivery. The QC inspection and testing reports will be identified in such a way that the results for the manufactured product can be traced to the individual sublot and lot they represent.

5.12.4 *Issuance of Materials COC*—Each manufacturer will prepare for each lot of standard manufactured materials a standard COC form that meets the requirements of the agency. The COC shall include all necessary information to properly identify the material (e.g., pay item number, material number, lot number, sublot numbers) represented by the COC. Each COC is to be accompanied by a copy of all manufacturer QC inspection and test results for the corresponding lot of material.

5.13 *Quality Audit of the Manufacturing Facility*—If required by the agency, each manufacturing facility shall be audited by an independent auditing organization. Such quality audits shall be performed on an annual or other periodic basis as established by the agency. When periodic quality audits are required by the agency, the QSM shall include a description of the quality audit of each manufacturing facility producing standard manufactured materials. The quality audit shall assess the manufacturer’s compliance with each of the following QSM requirements, as a minimum:

5.13.1 Manufacturer’s quality statement,

5.13.2 Manufacturing facility and products,

5.13.3 Terms and definitions,

5.13.4 Applicable specifications,

5.13.5 Quality system roles and responsibilities,

5.13.6 QC laboratories,

5.13.7 Pre-production materials control,

5.13.8 QC during production of standard manufactured materials, and

5.13.9 Postproduction QC activities.

5.13.10 The audit findings shall be discussed with the QC manager, production manager, and top management and shall be documented in a quality audit report. Corrective actions will be taken as necessary and documented in a report prepared by the QC manager. The quality audit report shall be available for review by the agency.

6. ACCEPTANCE OF STANDARD MANUFACTURED MATERIALS

6.1 *QSM Approval*—The manufacturer's QSM shall be submitted for review and approval to each agency that is anticipated to purchase the manufacturer's product(s). The agency's approval is intended only to indicate that the QSM is in conformance with the minimum QC requirements set forth in this standard practice.

6.1.1 Once approved, the QSM provisions will remain in effect unless revisions are determined necessary by the QC manager or if revisions are requested by the agency. If any changes are made in the QSM, an updated copy of the QSM must be submitted to the agency for review and approval along with clear identification of the specific changes. Continued approval of the QSM will be based on the manufacturer's satisfactory adherence to all provisions contained in the approved QSM.

6.2 *Agency Access to Manufacturer Facilities*—The manufacturer shall sign a statement that allows state agency inspectors or their designated agents to enter any manufacturing plant or QC laboratory, unannounced, to observe the manufacturing process, review QC inspection, testing, and associated records, obtain samples for acceptance testing, or to inspect QC testing facilities, product storage, handling, and transport.

6.3 *Approach for Acceptance of Standard Manufactured Materials*—The specific procedures for acceptance of standard manufactured materials shall be determined by each agency. However, acceptance will typically be based on a COC that is supported by the QC inspection, sampling, and testing performed for the corresponding lot of standard manufactured materials in accordance with the approved QSM. If required by the agency, a copy of the manufacturer QC inspection and test results for the corresponding lot shall accompany each COC. QC test results will be reviewed by qualified agency personnel and may be used in the acceptance determination for material in a given lot. The agency may also perform acceptance inspection, sampling, and testing of products obtained from the manufacturing facility or after product delivery to the agency construction project site, in order to validate QC data.

6.4 *Acceptance Inspection, Sampling, and Testing*—The specific procedures and frequencies for acceptance inspection, sampling, and testing of standard manufactured materials shall be determined by each agency. However, acceptance inspection, sampling, and testing will typically not be performed by the agency during the manufacturing process for a given lot. As determined by the agency, acceptance sampling and testing may be performed for some quality characteristics of some materials by qualified agency personnel at the agency's laboratory on each lot delivered to the agency construction project site. The frequency of acceptance sampling and testing will typically be performed in the range of 10 to 20 percent of the manufacturer QC testing frequencies for each lot. However, this frequency may be adjusted by the agency as deemed appropriate for the particular material being tested. Field acceptance inspection of standard manufactured materials will be performed by qualified agency personnel at field placement locations on each lot at minimum frequencies determined by the agency.

6.5 *Application of Engineering Limits and Specification Limits*—The specific quality limits (specification limits and engineering limits) to be applied to each standard manufactured material shall be determined by each agency. However, the specification limits and engineering limits used will typically be in accordance with applicable AASHTO or ASTM standards or other relevant industry standards. Specification limits may be used to compute quality levels which may be used in calculating pay factors. Individual sample test results that fall beyond the engineering limits are considered to represent material that may be below an acceptable level and should be further evaluated to support an appropriate acceptance decision.

6.6 *Acceptance Documentation*—The specific procedures for documentation of the acceptance of standard manufactured materials shall be determined by each agency. However, the review by the agency of each manufacturer COC, accompanied by a copy of manufacturer QC inspection and test results, will typically be documented on a standard COC review form (COCRF) developed by the agency. Any acceptance sampling and testing performed on lots of standard manufactured materials delivered to the agency construction project site will be documented on standard TRFs developed by the agency. All agency field inspection of standard manufactured materials delivered to the agency construction project site will be documented on standard IRFs developed by the agency.

APPENDIXES

(Nonmandatory Information)

X1. MODEL QSM OUTLINE

X1.1. Manufacturer’s Quality Statement:

X1.1.1. Written Policy or Mission Statement

X1.2. Manufacturing Facility and Products:

X1.2.1. Facility Address, Telephone Number, and E-mail Contacts

X1.2.2. Standard Manufactured Materials Produced

X1.3. Terms and Definitions

X1.4. Applicable Specifications (AASHTO, ASTM, Other)

X1.5. QC System Roles and Responsibilities:

X1.5.1. QC Organization

X1.5.2. QC Manager

X1.5.3. QC Technicians

X1.5.4. QC Personnel Qualification Requirements

X1.5.5. Production Personnel responsibilities for Quality

X1.6. QC Laboratories:

X1.6.1. Laboratory Addresses, Telephone Numbers, and E-mail Contacts

X1.6.2. Laboratory Accreditation or Qualification

X1.6.3. Testing Equipment

X1.7. Preproduction Materials Control:

X1.7.1. Constituent Material Types and Sources of Supply

X1.7.2. Visual Inspection of Constituent Materials

X1.7.3. Control and Testing of Constituent Materials Properties

X1.7.4. Constituent Materials Storage

X1.8. Quality Control During Production of Standard Manufactured Materials:

X1.8.1. Lot and Sublot Sizes

X1.8.2. QC Visual Inspection

X1.8.3. Random Sampling Plan

X1.8.4. Selective Sampling

X1.8.5. Sample Identification System

X1.9. Standard QC Sampling and Testing Methods (AASHTO, ASTM, Other):

X1.9.1. Manufacturer Developed Test Procedures

X1.9.2. QC Sample Storage and Retention Procedures

X1.9.3. QC Inspection and Test Result Reporting

X1.9.4. Use of Control Charts

X1.9.5. Statistical Analysis of Test Results

X1.9.6. Resolution of Nonconforming Inspection and Test Results

X1.10. Postproduction QC Activities:

X1.10.1. Marking, Storage, Shipping, and Handling of Standard Manufactured Materials

X1.10.2. QC Records

X1.10.3. Retention of Inspection and Test Results and Product Traceability

X1.10.4. Issuance of Materials COC

X1.11. Quality Audit of the Manufacturing Facility

X2. EQUIPMENT INVENTORY AND CALIBRATION/VERIFICATION

Company: XYZ Manufacturing, Anytown, USA		
Manufacturer: A-1 Test Equipment Co.		Type: Compression Machine
Location: Bay 1, QC Test Office		Test: ASTM E 4
Model No: ABC1001	Serial No: 123456	Placed in Service: 2/4/99
Calibration/Verification Interval: Annual		Last Calibrated: 1/23/02

Standard Practice for

Developing a Quality Assurance Plan for Hot Mix Asphalt (HMA)

AASHTO Designation: R 42-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Developing a Quality Assurance Plan for Hot Mix Asphalt (HMA)

AASHTO Designation: R 42-06

1. INTRODUCTION

1.1. This standard practice presents specific details necessary to effectively control the production and placement of hot mix asphalt (HMA).

1.2. *This standard practice may involve hazardous materials, operations, and equipment. This standard practice does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard practice to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. SCOPE

2.1. This standard practice provides the necessary quality assurance plan for control, verification, and acceptance of HMA pavement. It contains requirements for both quality control and acceptance.

2.1.1. This standard practice provides framework for a quality control plan that establishes minimum requirements and activities for a contractor's quality control (QC) System related to HMA production, and placement. These requirements include a listing of the inspections and tests necessary to substantiate material and product conformance to the specifications. The primary method of field quality control employs the use of the Superpave gyratory compactor and evaluation of the volumetric properties of the mix.

2.1.2. This standard practice also provides framework for a plan that establishes acceptance requirements for an agency's assessment and acceptance of an HMA project.

2.2. The values stated in SI units are to be regarded as the standard.

4. TERMINOLOGY

4.1. The terminology used in this standard is in accordance with R 10 unless otherwise specified.

4.2. *hot mix asphalt (HMA)*—a mixture of aggregate and asphalt binder produced from an HMA plant.

4.3. *design mix formula (DMF)*—the single point target value for percent passing designated sieve sizes and volumetric properties developed in the laboratory before the start of production.

4.4. *job mix formula (JMF)*—the single point target value for percent passing designated sieve sizes and volumetric properties established after the initial production process to be used by the contractor for production quality control.

4.5. *performance-graded asphalt binder (PGAB)*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers graded to temperature regimes and performance.

4.6. *quality assurance (QA)*—planned and systematic actions necessary to provide confidence that a product is in conformance with agency plans and specifications. It contains both QC and acceptance as two separate functions.

4.7. *quality control (QC)*—planned and systematic actions and considerations to control the level of quality being produced.

4.8. *QC plan*—project-specific plan that identifies methods of sampling, testing, calibration, QC monitoring, construction controls, paving plans, process balancing, and overall operations.

4.9. *acceptance*—sampling, testing, and assessment of test results to determine whether produced material and construction operation is in conformance with agency plans and specifications.

4.10. *independent assurance program (IAP)*—program developed by the agency to evaluate personnel and equipment used in the acceptance process on a project or system-wide basis.

4.11. *agency*—state highway agency or owner of the roadway.

4.12. Definitions of many common terms relating to HMA are contained in ASTM D 8.

4.13. Definitions of terms used in reference to other Standards are as defined therein.

4.14. Definitions of terms used in mathematical expressions are as generally used in standard practice. Unique terms are defined in the section containing the first presentation of such terms.

5. SUMMARY

5.1. This standard presents a procedure containing minimum requirements for QC and QA plans applicable to the production, placement, and acceptance of HMA. It incorporates the use of other available standards, which are appropriate to the accomplishment of this task. The requirements allow tailoring to accommodate the needs of an individual agency.

6. SIGNIFICANCE AND USE

6.1. Quality cannot be tested nor inspected into an HMA pavement. It must be built in through the implementation of properly designed QC and acceptance plans. The contractor should have a properly designed quality control plan and the agency should have a properly designed acceptance plan. The design and use of the plans is a critical step toward the successful manufacture, placement, and performance of HMA pavements.

6.2. This standard is used to aid in the completion of tasks noted in Sections 6.2.1 and 6.2.2.

6.2.1. Implementation of a QC plan for a contractor(s).

6.2.2. Implementation of an acceptance plan for an agency.

6.3. QC and acceptance plans conforming to this standard practice are applicable to HMA pavement construction projects. If an inconsistency exists between the contract documents and either plan, the contract documents should govern.

7. APPARATUS

7.1. *Laboratory Requirements*:

7.1.1. Personal safety equipment required by the laboratory or OSHA for work in the HMA design and testing areas.

7.1.2. Apparatus as required by referenced standards for this standard practice.

7.1.3. All other laboratory apparatus needed to control the quality of HMA production and placement in accordance with project specifications.

7.2. *Field Requirements*:

7.2.1. Personal safety equipment required by the field organization or OSHA.

7.2.2. Field apparatus listed in standards referenced as requirements in this standard practice.

7.2.3. All other field apparatus needed to control the quality of HMA production and placement in accordance with project specifications.

7.3. Apparatus required in Sections 7.1 and 7.2 should be furnished in the quantity necessary to assure that the materials and products used can be shown to conform to the HMA specification requirements without undue delay of the production and placement process.

7.4. Additional apparatus required for use by agency representatives for verification and acceptance activities should be provided by the agency unless otherwise specified.

8. STANDARDIZATION

8.1. Agency and contractor laboratories conducting work should satisfactorily participate in the AASHTO Materials Reference Laboratory (AMRL) proficiency sample program and should also be AMRL inspected. Alternately, a non-AASHTO laboratory qualification program that meets the same requirements could be used. Inspections or tests not covered by AMRL should comply with the applicable requirements of R 18 and ASTM D 3666.

8.1.1. All apparatus should be calibrated, and the calibration verified at established intervals, relevant to AASHTO, ASTM, or agency standards.

8.2. Sampling and testing personnel should be qualified through procedures developed by the agency for obtaining samples, processing samples, inspection of work, operation of testing equipment, and test equipment validation.

8.3. Verify the calibration of the nuclear density gauge(s) using ASTM D 2950 or another system approved by the agency.

8.4. Records demonstrating compliance with the equipment, personnel, and QC requirements should be available during construction for agency review.

9. FUNCTIONS AND RESPONSIBILITIES ON HMA PROJECTS

9.1. *Agency*:

9.1.1. The agency should review and approve HMA volumetric mix designs proposed by the contractor and assess the adequacy of the contractor’s QC plans. A reasonable time for review should be specified. The agency or a representative of the agency is responsible for all acceptance testing.

9.2. *Contractor*:

9.2.1. The contractor should be responsible for the development and formulation of the DMF using M 323, R 35, and T 312 which should be submitted to the agency for approval. The contractor should be responsible for the QC of all materials during the handling, blending, mixing, and placing operations. In addition, contractor tests may be used in the acceptance decision when a contractor acceptance program is developed by the agency in accordance with Section 14.5.

10. SAMPLING

10.1. *Initial Production Samples*:

10.1.1. The contractor and the agency should obtain samples of HMA from plant-produced materials in accordance with T 168 and the applicable procedures contained in Section 12.3 and Appendix X1. Samples should be reduced to testing size in accordance with T 248 or ASTM C 702. Procedures for oven conditioning or reheating of samples should be established.

10.1.2. The contractor and the agency should select sample locations on the control strip in accordance with Section 12.3 and Appendix X1. These locations are used for in-place density testing.

10.2. *Mix Production Samples*:

10.2.1. The contractor should obtain samples for QC in accordance with T 168, using a stratified random sampling plan in accordance with Section 13.3 for determining lot sizes and Appendix X1 or ASTM D 3665 for sample location. Samples should be reduced to testing size in accordance with T 248 or ASTM C 702.

10.2.2. The agency should obtain samples for acceptance in accordance with T 168, using a stratified random sampling plan in accordance with Section 13.3 for determining lot sizes and Appendix X1 or ASTM D 3665 for sample location. Samples should be reduced to testing size in accordance with T 248 or ASTM C 702.

10.3. *Sample Locations for In-place Coring or Testing*:

10.3.1. The agency representative should select in-place sample locations in accordance with Section 13.3 for determining lot sizes, Appendix X1 for sample location, and when cores are required, ASTM D 5361 for sampling.

Note 1—In addition to the random number tables in Appendix X1, ASTM D 3665 also contains a table of random numbers, including instructions for use. R 9 and ASTM E 105, E 122, and E 141 contain additional information concerning sampling practices.

11. MATERIAL REQUIREMENTS

11.1. *Performance-Graded Asphalt Binder*:

11.1.1. PGAB should conform to the requirements of M 320.

11.1.2. Quality control of PGAB from all suppliers should be in accordance with R 26 or other programs approved by the agency.

11.2. *Aggregates*:

11.2.1. The agency should develop a testing program to ensure that aggregates meet specification requirements. The contractor’s QC plan should include, as a minimum, discussion on the proposed processing, transportation, stockpiling, and plant charging operations.

12. FIELD ADJUSTMENT OF THE DMF

12.1. *Summary*:

12.1.1. During initial plant start-up adjustments may be made during the initial lot production to assure the plant-produced HMA will meet the design requirements.

12.1.2. The contractor should be responsible for the operation of the HMA plant and the production of the HMA within the DMF limits in Table 1. The limits in Table 1 are also used to control the amount of deviation from the DMF that the contractor may use when declaring a JMF. The declared JMF should meet the requirements of M 323.

Table 1—Allowable DMF Adjustments for Initial Production

HMA Composition Property	Adjustment Limit, %
Asphalt Binder Content (P_b)	±0.4
Gradation Passing 0.150-mm and Larger Sieves	±4.0
Gradation Passing 0.075-mm Sieve	±1.5
Voids in Mineral Aggregate (VMA)	±1.0
Voids Filled with Asphalt (VFA)	±5.0

12.2. *Initial Production Lot*:

12.2.1. At the beginning of production of each mixture required in the contract, an initial production lot should be used to evaluate the DMF. The initial production lot should be divided into four sublots as specified in Table 2 depending on the mixture type. The properties of the sublots will be measured and compared to the DMF. If the deviation in air voids in any sublot exceeds ±2.0 percent or in any two sublots exceeds ±1.5 percent, the production should cease and a new DMF should be developed in accordance with Section 9.2. If the difference from the DMF for asphalt binder content in any sublot exceeds the limit shown in Table 1, the production should cease and a new DMF should be developed in accordance with Section 9.2. If the difference from the DMF for any property other than asphalt binder exceeds two times the limits shown in Table 1 or any two sublots exceed the limits shown in Table 1, the production should cease and a new DMF should be developed in accordance with Section 9.2.

Table 2—Initial Production Lots and Sublots

Nom Max Size, mm	Sublot (Mg or tons)	Lot (Mg or tons)
4.75	300	1200
9.5	400	1600
12.5	500	2000
19.0	500	2000
25.0	500	2000
37.5	500	2000

12.2.2. The last sample in the lot should be within the limits of Table 1. The initial production lot should be closed out and the Contractor should declare a JMF. The lot should be accepted with a pay factor of 1.00. For material produced outside the tolerances of Section 12.2.1 the agency should determine if the material should be left in place. The agency should require that a JMF be declared after the initial production lot. Only one initial production lot should be allowed.

12.3. *Initial Production Lot Samples*:

12.3.1. The Contractor should obtain, using the methods required by Section 10, a sample of plant-produced HMA from each sublot. Samples should be obtained from the mat behind the screed or from the haul trucks at the plant. Since the evaluation criteria are based on in-place measurements, it is recommended that QC testing be completed on road samples.

Note 2—If acceptance testing is performed on road samples, and the QC testing is based on truck samples taken at the HMA plant, the contractor should develop appropriate correlation factors.

12.3.1.1. Determine asphalt binder content and combined aggregate gradation of the HMA samples in accordance with T 164 and T 30, or T 308, or T 287 and T 30 (on cold feed material).

12.3.1.2. Determine maximum theoretical specific gravity of the HMA samples in accordance with T 209.

12.3.1.3. Compact samples of HMA according to T 312.

12.3.1.3.1. Determine bulk specific gravity, G_{mb}, in accordance with T 166, Method A.

12.3.1.3.2. Determine the air void content in accordance with R 35 at N_{ini} and N_{des} gyrations.

12.3.1.4. Determine the VMA and the VFA in accordance with R 35.

12.4. *Control Chart Initiation*:

12.4.1. A process control chart is needed to determine whether the manufacturing process is in control. Individual data points and moving averages are plotted. The individual data points indicate variability and the moving average indicates conformance to the target value. Control charts should comply with the requirements of Appendix X2.

12.4.2. When an HMA initial production lot has been produced, the contractor should establish initial control charts using single point target values from the JMF in accordance with the requirements of Appendix X3.

12.4.3. Control charts are used to graphically represent the continuous control process. They include the target value that is to be achieved for a certain material property and acceptable upper and lower limits. When a measured value is determined and plotted on the control chart, it should fall within the control limits. Mixture adjustment can be made in response to the values plotted on these control charts.

12.4.4. Control limits are established based on statistical concepts that assume the material parameter in question follows a normal distribution. Typically, the upper and lower control limits (UCL and LCL) are based on $\pm 2s$ (warning control limits) and $\pm 3s$ (action control limits), where s is the typical industry standard deviation listed in Table X3.1.

12.5. *HMA Control Strip*:

12.5.1. The Contractor should place and compact the mixture produced during the initial production lot in order to establish that the equipment and the processes planned for placement and compaction are satisfactory.

12.5.2. The final compacted thickness of the HMA control strip should be the thickness required by the pavement cross-section.

12.5.3. The control strip should be a minimum of 150 m (500 ft) long.

12.5.4. After compaction is completed, ten cores should be taken at locations selected in accordance with Appendix X1. Density of the cores will be determined in accordance with T 166.

12.5.5. The control strip will be considered acceptable when the average core density meets or exceeds contract specifications. The Agency should specify limits for the number of control strips to be allowed.

12.5.6. The Agency should determine a minimum density (e.g. 91.0 percent of T 209) above which the HMA in the control strip is allowed to remain in place and paid for with a pay factor of 1.00. For

HMA with a density less than the minimum density, the Agency should determine if the HMA should be left in place.

13. QUALITY CONTROL SYSTEM

13.1. *General Requirements*:

13.1.1. The contractor should provide and maintain a QC system that will provide reasonable assurance that all materials and products conform to the specification requirements whether manufactured or processed by the contractor or procured from suppliers or subcontractors. The contractor should perform or have performed the inspection and tests required to substantiate product conformance to the HMA design requirements, and should also perform or have performed all inspections and tests otherwise required by the project specifications. The contractor's QC procedures, inspections, and proposed testing should be documented in a written QC plan (see Appendix X3). The plan should be approved by the Agency and be available for review through the life of the contract.

13.1.2. The contractor's QC Plan should be based on tests performed to determine compliance of the HMA with the JMF. The tests should be performed on samples obtained using statistically sound, randomized sampling procedures in accordance with Section 10.

13.1.3. Typical QC HMA properties include asphalt binder content, maximum theoretical specific gravity, air voids, VMA, VFA, and percent passing key sieves in the combined gradation. Target values for these HMA properties are those from the JMF. JMF values developed from Section 12.2 are the control values. In some situations the Agency may want to require other properties such as moisture content in the HMA or bulk specific gravity of the aggregate.

13.1.4. QC testing will be based on samples from individual sublots and lots.

13.1.5. In accordance with Agency requirements, the Contractor should record the quantities of asphalt binder, aggregate, mineral filler, and fibers (if required), as well as the quantities of HMA produced, and the production temperature.

13.2. *Quality Control Components*:

13.2.1. The QC plan should be contract-specific and state how the Contractor proposes to control the materials, equipment, and operations of the project. The Agency should specify minimum information for the QC plan such as: personnel, plant operation, HMA transportation, roadway operations, and compaction operations.

13.3. *Lots and Sublots for Quality Control*:

13.3.1. The QC plan should indicate lot and sublot size for initial production and production lots.

13.3.2. Production lots will be based on HMA as delivered to the roadway. Recommended lot will be defined for 19.0-mm nominal maximum aggregate size or larger mixture designs and for 12.5-mm or smaller mixture designs. Lots will be further sub-divided into equal sublots not to exceed 1000 Mg (1000 tons) for 19.0-mm or larger mixture designs or 600 Mg (600 tons) for 12.5-mm or smaller mixture designs. Typically, four or more sublots constitute a lot. Partial sublots of 100 Mg (100 tons) or less can be added to the previous sublot. Partial sublots greater than 100 Mg (100 tons) can constitute a full sublot. Lots that contain a single sublot could be combined with the previous lot for acceptance purposes.

13.4. *Quality Control Laboratory*:

13.4.1. The HMA producer should provide and maintain a laboratory for QC testing. The laboratory should have the necessary space, equipment, and supplies for the tests to be performed. The laboratory testing equipment should meet the requirements of the test methods identified for the required sampling and testing. The agency should have the right to observe all QC testing.

13.5. *Test Equipment Calibration*:

13.5.1. The test equipment furnished by the contractor should be properly calibrated or verified and maintained in accordance with Appendix X3.2 and R 18.

13.6. *Quality Control for Plant Operations*:

13.6.1. The contractor should designate the sampling and sample reduction procedures, sampling locations, and size of samples necessary for testing. Sampling should be performed on each sublot. Sample locations should be selected randomly according to Appendix X1. The contractor may select random numbers independent of agency locations or may match the Agency locations, but samples should not be split. If contractor tests are to be used for acceptance, Section 14.5 should govern the sampling requirements.

13.6.2. The contractor should utilize QC charts that show test results for critical sieves, asphalt binder content, maximum theoretical specific gravity, air voids, VMA and VFA to identify variability in the HMA production. Target values, warning and action limits should be shown on the same charts. Details regarding QC plans and QC charts are located in Appendix X3.

13.7. *Quality Control for Roadway Operations*:

13.7.1. The contractor should control the HMA placement and compaction process to ensure compliance with the project specifications. Details regarding QC for roadway operations are located in Appendix X3.

13.8. *Documentation*:

13.8.1. The contractor should maintain adequate records of all tests. The records should indicate the test results and the nature of corrective action taken as appropriate. All charts and records documenting the contractor's QC operations and tests should be available to the agency during the performance and upon the completion of the work. The contractor should keep the test results on file for a minimum period of three years following completion of the work.

13.8.2. Test properties for the various materials and mixtures should be charted on forms or other appropriate means in accordance with the applicable requirements of the agency.

13.8.3. If production is terminated in accordance with Appendix X3.4.4 or X3.5.5, the cause and resolution should be documented.

14. HMA ACCEPTANCE PROCEDURES

14.1. *General Requirements*:

14.1.1. Acceptance sampling and testing of HMA involves stratified random sampling that is applied to a series of sublots of HMA. The objective of acceptance testing is to verify that the product meets contract specifications.

14.1.2. The agency will obtain, using the methods required by Section 10, a sample of HMA from each sublot.

14.1.3. HMA properties for acceptance typically include the asphalt binder content, air voids, VMA, and other requirements of the agency. Target values for these HMA properties should be those from the JMF. Acceptance testing also includes density on the roadway.

14.1.4. Acceptance testing will be based on independent samples from the same sublots that are used for QC and, in fact, may include different properties. Lots and sublots will be based on mixture as delivered to the roadway.

14.1.5. The method of Acceptance should be statistically based to evaluate the acceptability of the HMA. Statistically based methods, such as percent within limits using standard deviation, should be used. See Appendix X4.

14.2. *Acceptance for Mixture Properties (Air Voids, VMA, Asphalt Content)*:

14.2.1. *Point of Sampling*—The agency representative should obtain stratified random acceptance samples in accordance with Section 10.2. The samples should be obtained from the HMA behind the screed prior to initial rolling.

Note 3—If a correlation factor between samples taken from a truck at the plant and samples from the roadway behind the screed has been developed, the sample may be taken from the haul truck at the plant.

14.2.2. *Number of Samples*—One sample per sublot in accordance with Section 10.2.2.

14.2.3. *Lot Size*—Lots will be defined for 19.0 mm nominal maximum aggregate size or larger mixture designs and for 12.5 mm or smaller mixture designs. Lots will be further sub-divided into equal sublots not to exceed 1000 Mg (1000 tons) for 19.0 mm or larger mixture or 600 Mg (600 tons) for 12.5 mm or smaller mixture. Typically, four or more sublots constitute a lot. Partial sublots of 100 Mg (100 tons) or less can be added to the previous sublot. Partial sublots greater than 100 Mg (100 tons) can constitute a full sublot. Lots that contain a single sublot could be combined with the previous lot for acceptance purposes.

14.2.4. If a delay of more than four calendar days occurs in any one sublot, a partial sublot should be declared and a new sublot should start when production resumes.

14.3. *Acceptance for In-place Density, Percent Theoretical Maximum Density, (%G_{mm}):*

14.3.1. *Point of Sampling*—The agency representative should determine stratified random acceptance sample locations in accordance with Section 10.3. The locations should be determined after rolling operations are completed.

14.3.2. *Number of Tests*—Two core samples or two nondestructive in-place tests per sublot are used in accordance with Section 10.3.1.

14.3.3. *Lot Size*—Lot and sublot sizes are to be the same as the HMA lots and sublots in accordance with Section 14.2.3.

14.3.4. *Acceptance Testing*—Obtain cores in accordance with ASTM D 5361 from each location and transport the cores to a laboratory for testing. From the HMA sample in each sublot, determine the maximum specific gravity. For each core, measure the bulk specific gravity in accordance with T 166, and calculate density as a percent of theoretical maximum density. Alternately if the variability of test results is acceptable to the Agency, a calibrated nuclear density gauge can be used to determine the bulk specific gravity at each location, in accordance with ASTM D 2950, and used to calculate density as a percent of theoretical maximum density (%G_{mm}).

14.4. *Acceptance Process*:

14.4.1. The Agency will determine acceptable quality limits for HMA properties and in-place density.

14.4.2. Smoothness is also an important acceptance property. The Agency should select a method of measuring smoothness (e.g. rolling straight edge, light-weight or high-speed profilometers) and will develop specific acceptance criteria.

14.4.3. The Agency may also use subjective measures such as segregation to determine the acceptability of the HMA. The Agency may add specific criteria that may not be statistically based.

14.5. *Contractor Tests Used in the Acceptance Decision*:

14.5.1. The use of Contractor tests for project acceptance is permitted when the Agency has developed an Acceptance Program in accordance with Section 14.1.5 that includes independent verification and statistical evaluation of the Contractor's test results. Contractor and Agency sample locations will be selected independently.

14.5.2. The contractor should maintain an acceptance testing program that includes the use of a qualified laboratory and qualified testing personnel, established material sampling frequencies and testing protocols, and reporting procedures. Contractor acceptance samples should be taken from the same point of sampling as used by the Agency.

14.5.3. The Agency should establish a verification sampling and testing program that includes testing of materials by a qualified laboratory and qualified testing personnel on samples taken independently of the contractor's acceptance tests but within the same production period, quantity, area, etc. as the contractor's tests.

14.5.4. The agency should develop a statistical method of comparing the contractor's acceptance and the agency's verification tests to verify the contractor's acceptance test results, such as a comparison of means and standard deviations.

14.5.5. The agency should develop a dispute resolution system in accordance with Section 15 that addresses the disposition of discrepancies occurring between the contractor acceptance and the agency verification tests.

14.5.6. The agency's independent assurance program should include the evaluation of the contractor's qualified laboratory and qualified testing personnel.

14.6. *Pay Factors:*

14.6.1. The Agency should develop a table of pay factors, pay equations, or pay curves based on the method of acceptance.

14.7. *Documentation*:

14.7.1. The agency should maintain adequate records of all acceptance tests. The records should indicate the test results and the acceptance decisions.

14.7.2. Contractor test results that are used for acceptance should be available to the agency during the performance of the work. Test results should be submitted to the agency on forms or other appropriate means in accordance with agency requirements.

15. DISPUTE RESOLUTION

15.1. The agency should establish procedures for addressing tests that do not meet the required specification limits, for identifying dissimilar test results, for providing backup samples, and for resolving differences.

15.1.1. The definition of dissimilar is typically based on the difference between reported values for split samples as related to the number of standard deviations (d2s) for the test. The agency should use AASHTO or ASTM test procedures to determine the range of allowable results between two laboratories. Other valid procedures include statistical tests that compare means and variability of the Acceptance and verification tests results.

15.1.2. The specification should indicate the process by which a backup sample will be taken. Backup samples should be taken at the same time as the original sample.

15.1.3. The dispute resolution process should address the length of time during which an appeal can be made, who will do testing on backup samples, and how the retest values will be used to resolve the dispute.

16. KEYWORDS

16.1. Acceptance plan; acceptance testing; contractor acceptance; control charts; hot mix asphalt; percent within limits; quality assurance; quality control; stratified random sampling; Superpave.

APPENDIXES

(Nonmandatory Information)

X1. STRATIFIED RANDOM SAMPLING

X1.1. *Scope*:

X1.1.1. This method outlines the procedures for selecting sampling sites in accordance with appropriate random sampling techniques. Random sampling is the selection of a sample in such a manner that every portion to be sampled has an equal chance of being selected as the sample. It is intended that all samples, regardless of size, type, or purpose, should be selected in an unbiased manner, based entirely on chance.

X1.2. *Securing Samples*:

X1.2.1. Samples should be taken as directed by the Contractor's representative for QC purposes and the Agency representative for acceptance purposes.

X1.3. *Random Number Table*:

X1.3.1. For test results or measurements to be meaningful, it is necessary that the material to be sampled or measured be selected at random using a table of random numbers. Table X1.1 has been devised for this purpose. To use the table in selecting sample locations, proceed as follows.

X1.3.1.1. Determine the lot size and stratify the lot into a number of sublots per lot for the material being sampled.

X1.3.1.2. For each lot, use consecutive two-digit random numbers from Table X1.1. For example, if the specification requires five sublots per lot and the number 15 is randomly selected as the starting point from Column X (or Column Y) for the first lot, numbers 15–19 would be the five consecutive two-digit random numbers. For the second lot, another random starting point, number 91 for example, is selected and the numbers 91 through 95 are used for the five consecutive two-digit random numbers. The same procedure is used for additional lots.

X1.3.1.3. For samples taken from the roadway, use the decimal values in Column X and Column Y to determine the coordinates of the sample locations.

X1.3.1.4. In situations where coordinate locations do not apply (i.e., plant samples, stockpile samples, etc.), use those decimal values from Column X or Column Y.

Table X1.1—Random Positions in Decimal Fractions (Two Places)

Sequence No.	X	Y

99.	0.04	L 0.46
100.	0.29	L 0.95

Note: X = Decimal fraction of total length measured along the road from the starting point.
Y = Decimal fraction measured across the road from either outside edge towards the centerline of the paved lane.

X1.4. *Random Sample*:

X1.4.1. A random number table is a collection of random digits. The random numbers that are presented in Table X3.1 are shown in a two-place decimal format. Note that there are two columns, labeled X and Y. The numbers in either column can be used to locate a random sample when only a single dimension is required to locate the sample (e.g., time, tonnage, and units). When two dimensions are required to locate the sample, the number in the X column is used to calculate the longitudinal location, and the number in the Y column is used to calculate the transverse location. In the Y column, each number is preceded by an L or R, designating that the sample increment is to be located transversely from the left or right edge of the pavement. Figure X1.1 illustrates the procedure. An example demonstrating the use of the random sampling technique follows:

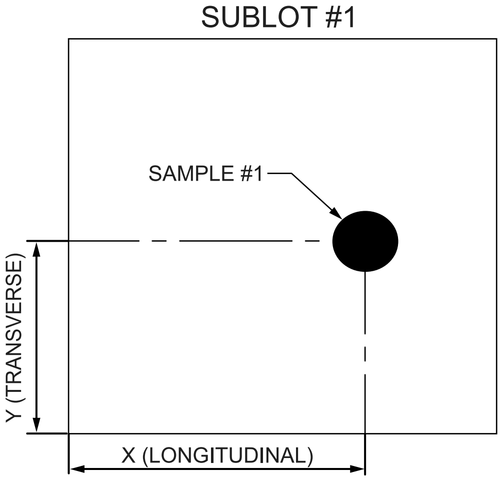

Figure X1.1—Determination of Sample Location Using Random Numbers

X1.5. *Sampling Example by Material Mass*:

X1.5.1. HMA must be sampled to determine the asphalt binder content and other mixture-related criteria. The definitions which define the lot and sublot size are located in Sections 13.3.2 and 14.2.3. The total tonnage for the example project is 21,700 Mg (tons).

X1.5.2. First, identify the lot size and then determine the number of lots, sublot size, and, finally, the point at which samples will be obtained.

X1.5.3. *Lot Size and Number of Lots*—For example, with a 19.0 mm nominal maximum aggregate size mixture, the lot size is 5,000 Mg (tons). Assuming there are 21,700 Mg (tons) of HMA required for the project, the total number of lots is:

$$\text{Number of Lots} = \frac{21{,}700\ \text{Mg (tons)}}{5{,}000\ \text{Mg (tons)/lots}} = 5\ \text{lots}$$

X1.5.4. *Sublot Size*—Based on Section 14.2.3 the sublot size is 1000 Mg (tons). The relationship between lot and sublot size is shown in Figure X1.2. The actual number and size of sublots in a lot could depend on specific conditions if partial sublots are declared during construction.

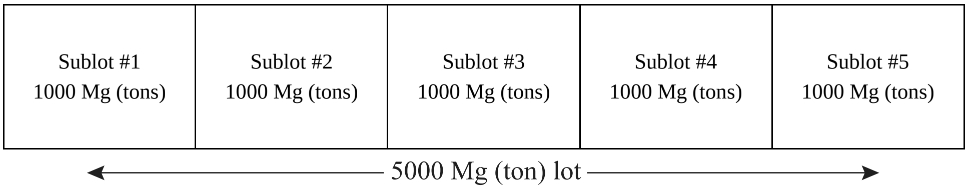

Figure X1.2—Relationship Between Lot and Sublots

X1.5.5. *Sublot Samples*—For example, for HMA property samples, the number of samples per lot is five, one per sublot. Five random numbers are selected from the table of random numbers. A block of numbers from the random number table (Table X1.1) is reproduced below.

Sequence Number	*X*	*Y*
67.	0.93	R 0.17
68.	0.40	R 0.50
69.	0.44	R 0.15
70.	0.03	L 0.60
71.	0.19	L 0.37

X1.5.6. Select random numbers from the Y column only (disregard the L or R). These numbers are 0.17, 0.50, 0.15, 0.60 and 0.37. Multiply the numbers by the size of each sublot as follows to determine the megagram (ton) to be sampled in the sublot.

Sublot	Sublot Random Number	Size Mg (ton)	Sample from Mg (ton)
1	0.17	1000	170
2	0.50	1000	500
3	0.15	1000	150
4	0.60	1000	600
5	0.37	1000	370

X1.5.6.1. The technician must obtain the first sample at approximately the 170th Mg (ton) of the first sublot. The technician must then wait until the first sublot is completed, 1000 Mg (tons), before selecting the second sample at the 500th Mg (ton) of the second sublot. The same sequence is followed for obtaining the remaining three samples.

X1.5.6.2. The sampling sequence for the lot of 5000 Mg (tons) should be:

Sublot 1: 170th Mg (ton)
Sublot 2: 1000 + 500 = 1500th Mg (ton)
Sublot 3: 2000 + 150 = 2150th Mg (ton)
Sublot 4: 3000 + 600 = 3600th Mg (ton)
Sublot 5: 4000 + 370 = 4370th Mg (ton)

Sublot sampling based on mass is illustrated in Figure X1.3.

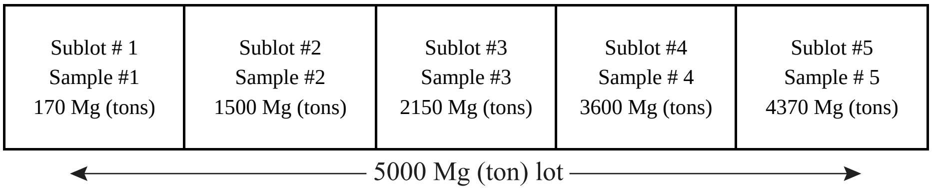

Figure X1.3—Sublot Sample

X2. STATISTICAL CONTROL CHARTS

X2.1. *Process Control*:

X2.1.1. The process control procedure recommended is the use of control charts, particularly statistical control charts. Control charts provide a means of verifying that a process is in control. It is important to understand that statistical control charts do not get or keep a process under control. The plant or construction personnel must still control the process. Control charts simply provide a visual warning mechanism to identify when the Contractor or material supplier should look for possible problems with the process.

X2.1.2. Variation of construction materials is inevitable. The purpose of control charts, then, is not to eliminate variability, but to distinguish between the inherent or chance causes of variability and a system of assignable causes. Chance causes are a part of every process and can be reduced but generally not eliminated. Assignable causes are factors that can be eliminated, thereby reducing variability. Chance causes are something that cannot be eliminated, but it may be possible to reduce their effects. The second cause of variation, assignable causes, can create major problems. However, assignable causes can be eliminated if they can be identified. Examples of assignable causes might be when the gradation for an aggregate blend goes out of specification due to a hole in one of the sieves or because the cold feed conveyor setting is incorrectly adjusted.

X2.1.3. The statistical control chart enables the contractor to distinguish between chance and assignable causes. Based upon statistical theory, construction materials, when under production control, exhibit a “bell-shaped” or normal distribution curve.

X2.1.4. The data, therefore, can be assumed to be within ±3 standard deviations (σ of the mean or target) when the process is in control and only chance causes (variability that the contractor cannot control) are acting on the system. Statistical control charts for average or means rely on the fact that, for a normal distribution, essentially all of the values fall within ±3 standard deviations from the mean. A normal distribution can be used because the distribution of sample means is normally distributed.

X2.1.5. A statistical control chart can be viewed as a normal distribution curve on its side (Figure X2.1). For a normal curve, only about 0.27 percent (1 out of 370) of the measurements should fall outside ±3 standard deviations from the average or mean. Therefore, control limits (indicating that an investigation for an assignable cause should be conducted) are set at $+3\sigma$ and -3σ.

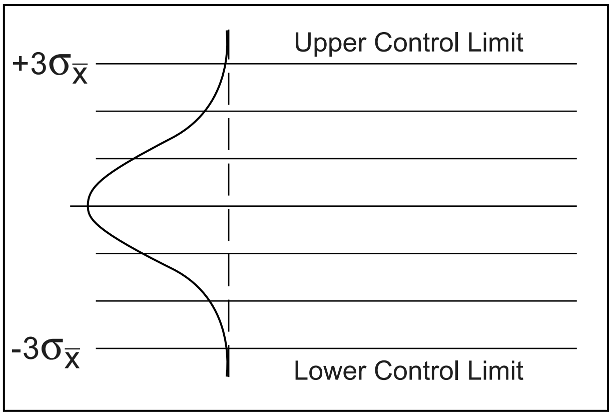

Figure X2.1—Example of a Statistical Control Chart

X2.1.6. A statistical control chart includes a target value, control limits and a series of data points that are plotted. As shown in Figure X2.2, the target value is either the production mean or design value and the control limits are established based on the standard deviation of the properties.

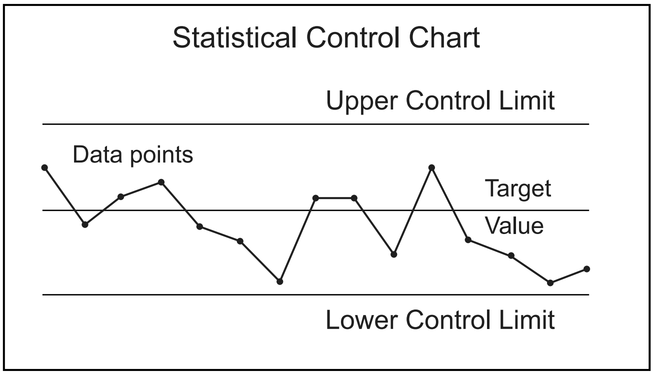

Figure X2.2—Elements of a Statistical Control Chart

X2.2. *Form of Statistical Control Charts to Be Used for HMA*:

X2.2.1. There are many forms of statistical control charts, but the form recommended in this standard practice for construction materials and processes is a control chart which shows individual test data points and a moving average. This process control chart is typically used to control the production process about the target value. Highly variable, individual test data points indicate variability in the process even though the moving average may be acceptable.

X2.2.2. For HMA the process control chart for the moving average has five reference lines that are defined as follows:

- upper action limit is the target value plus three standard deviations (Table X3.1) divided by the square root of the number of samples in the moving average. Typically five samples are used.
- upper warning limit is the target value plus two standard deviations (Table X3.1) divided by the square root of the number of samples in the moving average. Typically five samples are used.
- target value is the value of the property from the declared JMF.

- lower warning limit is the target value minus two standard deviations (Table X3.1) divided by the square root of the number of samples in the moving average. Typically five samples are used.
- lower action limit is the target value minus three standard deviations (Table X3.1) divided by the square root of the number of samples in the moving average. Typically five samples are used.

X2.2.3. Figure X2.3 shows a process control chart for asphalt binder content. The target value for asphalt binder content, 5.7 percent, is obtained from the JMF.

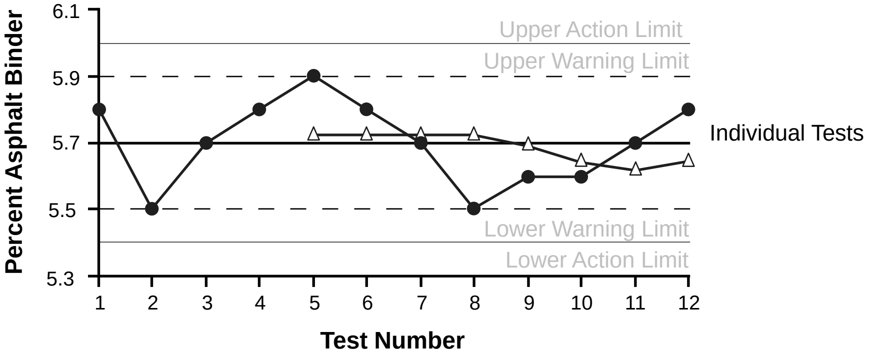

Figure X2.3—Control Chart for Asphalt Binder Content

X2.2.3.1. From Table X1.1 the standard deviation for asphalt binder content determined by extraction is 0.25 percent.

X2.2.3.2. The deviation from the target value for the warning limits for a moving average of five samples is

$$= 2 \times 0.25 / (\sqrt{5})$$

$$= 0.22$$

X2.2.3.3. The upper and lower warning limits are

UWL = 5.7 + 0.22 = 5.9

LWL = 5.7 – 0.22 = 5.5

X2.2.3.4. The deviation from the target value for the action limits for a moving average of five samples is

$$= 3 \times 0.25/(\sqrt{5})$$

$$= 0.33$$

X2.2.3.5. The upper and lower action limits are

UAL = 5.7 + 0.33 = 6.0

LAL = 5.7 – 0.33 = 5.4

X2.2.4. The individual test data points from each sublot are plotted on the chart and connected. This series of data points provides a visual indication of variability. If variability is high, the process can be refined to reduce variability. The moving average of five data points is calculated starting with the fifth data point and plotted on the chart. The moving average data points provide a visual indication of conformance with the target value. It is also possible to detect trends in the production and adjust the operation to bring the moving average closer to the target.

X2.2.5. Figure X2.4 shows a process control chart in which variability is higher than that shown in Figure X2.3. The higher variability is indicated by the individual test results. In addition, the moving average is consistently above the target. Steps should be taken to reduce variability and bring the moving average closer to the target.

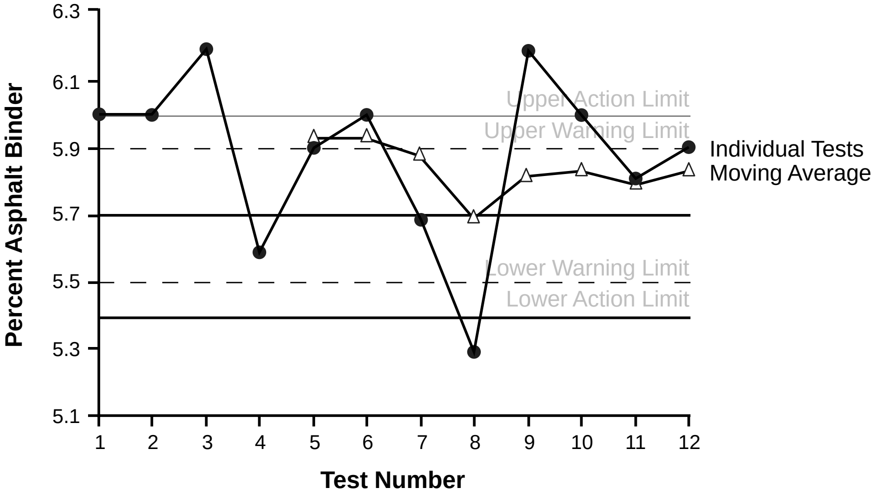

Figure X2.4—Control Chart for Asphalt Binder Content

X3. QUALITY CONTROL REQUIREMENTS FOR HOT MIX ASPHALT

X3.1. *Scope*:

X3.1.1. This appendix provides the details for contractor QC activities for HMA.

X3.2. *Test Equipment Calibration*:

X3.2.1. The equipment calibration or verification documentation should include:

X3.2.1.1. Name of the person performing the calibration or verification;

X3.2.1.2. Identification of the calibration equipment used, e.g., standard weights, proving rings, thermometers, etc;

X3.2.1.3. Last date that the calibration or verification was performed; and

X3.2.1.4. A reference to the calibration procedure used.

X3.2.1.5. Records showing the results of the calibration or verification performed.

X3.3. *Materials Sampling and Testing*:

X3.3.1. Sampling should be performed on each sublot on a random basis. The test methods and minimum frequencies of the QC tests for each HMA design should be designated. Test results should be rounded in accordance with ASTM E 29 using the rounding method.

X3.3.2. *Blended Aggregate*—A minimum of one sample should be obtained and tested for gradation in accordance with T 27 performed on each sublot on a random basis.

X3.3.2.1. *Batch Plants*—The blended aggregate gradation should be determined by calculating the combined gradation of the aggregate from each hot bin.

X3.3.2.2. *Drum Plants*—The blended aggregate gradation should be determined using aggregate samples from the cold feed belt after all materials are placed on the belt. The moisture content of the samples should be determined in accordance with T 255.

X3.3.3. *Recycled Materials*—A minimum of one sample for each 1000 kg (1000 tons) of recycled asphalt materials should be obtained and tested for asphalt binder content in accordance with T 164, gradation in accordance with T 30, and moisture content in accordance with T 255. Asphalt binder content may be determined with T 308 if a calibration factor to T 164 has been determined.

X3.3.4. *Hot Mix Asphalt*—As a minimum, samples should be obtained to determine the asphalt binder content, air voids, and VMA of the HMA. The sample should be obtained in accordance with Section 10.2. The sample should be reduced to testing size in accordance with T 248 or ASTM C 702, Method B. Place the test specimen mass into a heated mold, compact to N_{des} in accordance with T 312, and determine the bulk specific gravity in accordance with T 166. If the HMA requires reheating to achieve the compaction temperature, it should be placed in a loosely sealed, covered container. Oven temperature and time in the oven should be controlled, as defined by the Agency, to prevent a significant change in asphalt absorption and theoretical maximum specific gravity. The maximum specific gravity should be determined in accordance with T 209. One sample should be tested for moisture content in accordance with T 255, asphalt binder content in accordance with T 164 or T 308, and gradation in accordance with T 30. Alternately the asphalt binder content may be determined in accordance with T 287, in which case the gradation should be determined from the combined cold feed aggregates in accordance with T 27. The aggregate consensus properties, coarse aggregate angularity (ASTM D 5821), fine aggregate angularity (T 304), flat and elongated particles (ASTM D 4791), and sand equivalent (T 176) may be required as determined by the agency.

X3.4. *Control Charts*:

X3.4.1. The contractor should use control charts for critical sieves, asphalt binder content, maximum theoretical specific gravity, bulk specific gravity of the compacted HMA, air voids, and VMA to identify variability in the HMA production process. All test results should be recorded on the control chart the same day the tests are conducted. The charts are to be used to determine if the HMA production is in control.

X3.4.2. Target values and warning and action limits for the control charts are determined from the JMF HMA properties and plotted on the control charts. The warning and action limits are determined using typical industry standard deviations for HMA properties as shown in Table X3.1.

X3.4.3. Individual test results and the moving average of the five most current test results should be plotted. Five consecutive individual test results plotted on either side of the target value indicate an HMA composition change. If a HMA compositional change has occurred, modifications should be made to adjust the HMA property back to the target value. If a HMA compositional change has occurred in a non-pay element, the Contractor may elect to change the target value instead of adjusting the HMA property back to the target value.

X3.4.4. For a pay element, if one moving average point falls outside the warning limits, an investigation should be completed and adjustments made to bring the property back within the warning limits. The adjustment should be documented. If two consecutive moving average points fall outside the warning limit or one moving average point falls outside the action limit, production should be terminated, and a new DMF should be established in accordance with Section 9.2.1.

Note X1—In the event that one moving average point falls outside the warning limit, individual data points typically will indicate that the HMA property has been shifting over multiple sublots. If no action is taken to bring the HMA property back to the target value, a second moving average point will fall outside the limits; therefore, a new DMF is needed. In the event one moving average point falls outside the action limit, the individual data point is indicative of a major change in the HMA property. Production should cease, and an investigation should be initiated to determine the cause. If significant changes have occurred in the materials, a new DMF should be developed.

Table X3.1—Typical Industry[a] Standard Deviations for Hot Mix Asphalt Properties (Mixture Composition, Gyratory Properties and In-Place Density)[b]

HMA Composition Property		Extraction	Nuclear Gauge	Ignition Furnace	Cold Feed
Asphalt Binder Content (P_b), %		±0.25	±0.18	±0.13	—
Gradation Passing 4.75-mm and Larger Sieves, %		±3	NA	**	±3
Passing 2.36-mm to 0.150-mm Sieves, %		±2	NA	**	±2
Passing 0.075-mm Sieve, %		±0.7	NA	**	±0.7
Maximum Theoretical Specific Gravity (G_{mm})	±0.015				
Gyratory Compacted HMA Property					
Air Voids (V_a), %	±1.0				
Voids in Mineral Aggregate (VMA), %	±1.0				
Voids Filled with Asphalt (VFA), %	±5				
Bulk Specific Gravity (G_{mb})	±0.022				
In-Place Density					
Roadway Core Density (%G_{mm}), %	±1.4				

[a] Agency-specific standard deviations may be developed in lieu of the industry standard deviation.

[b] NCHRP 9-7 did not develop standard deviations for gradation of aggregate recovered from the ignition furnace; however, the standard deviation is expected to be the same as for cold feed or solvent-extracted aggregates.

X3.4.5. For a non-pay element, if one moving average point falls outside the warning limit, the contractor may elect to change the target value or adjust the property back to the target value. Mixture production should be adjusted within the limits of Table 1, Section 12.1.2. If, after making the adjustment, the mixture property remains outside the warning limit, a new DMF should be developed in accordance with Section 9.2.1.

X3.5. *Roadway Operations*:

X3.5.1. At the beginning of roadway operations the contractor should establish a rolling pattern to meet the minimum specified density. A control strip should be constructed in accordance with Section 12.5. Density will increase up to a certain point, after which a very small increase in density can be obtained with additional roller passes. At this point the density is presumed to have reached its maximum and is then considered to have peaked when additional rolling does not increase the density by more than 20 kg/m^3 (1 lb/ft^3).

X3.5.2. The contractor should use control charts for roadway density to identify variability in the HMA compaction process. All test results should be recorded on the control chart the same day the tests are conducted. The charts are to be used to determine if the HMA compaction process is in control.

X3.5.3. Target values and warning and action limits for the control charts are determined from the control strip described in Section 12.5 and plotted on the control charts. The warning and action limits are determined using typical industry standard deviations for roadway density as shown in Table X3.1.

X3.5.4. Individual test results and the moving average of the five most current test results should be plotted. If an HMA compositional change occurs and a new control strip is established, the target value would be changed.

X3.5.5. If one moving average point falls outside the warning limits, an investigation should be completed and adjustments made to bring the property back within the warning limits. The adjustment should be documented. If two consecutive moving average points fall outside the warning limit or one moving average point falls outside the action limit, the Contractor should terminate production. Prior to resuming production, the Contractor should provide the Agency with the assignable cause for the unsatisfactory density test results and develop a new control strip in accordance with Section 12.5.

X3.5.6. For purposes of QC for in-place density, lots and sublots should be in accordance with Section 13.3.2. Location of in-place sample or test sites should conform to the requirements of Appendix X1 in each sublot. The Contractor should utilize standard nondestructive industry equipment and procedures to provide suitable estimates of the in-place density.

X3.6. *Quality Control Plans*:

X3.6.1. The contractor should develop a QC plan that is expected to be specific to operations in use at any given time. The contractor should be able to make changes as required to respond to changes in the operation. A plan should not be so general as to cover all expected situations. The plan should be contract-specific and should include the following:

X3.6.1.1. Personnel including management personnel and plant and roadway technicians;

X3.6.1.2. Plant operations including stockpile management, material feed systems, HMA storage and truck loading procedures, materials and finished product sampling, and testing procedures;

X3.6.1.3. Transportation of HMA including truck types, release agents, load cover, and truck discharge procedures;

X3.6.1.4. Roadway operations including use of material transfer devices or windrow pickup machines, paver setup such as paver speed, slope and grade control, and screed extensions; and

X3.6.1.5. Compaction operations including roller type and number, roller setup (e.g. amplitude, frequency, or tire pressure), and roller speed.

X4. PERCENT WITHIN LIMITS (PWL) FOR HMA CALCULATED USING STANDARD DEVIATION

X4.1. *Scope*:

X4.1.1. This appendix provides the procedure for determination of the percent of material that is within the specification limits established for the HMA using the mean and standard deviation of the lot.

X4.2. *Significance and Use*:

X4.2.1. The PWL is a calculation used in the agency acceptance plan to determine the acceptability of materials on the project.

X4.3. *Setting of Upper and Lower Specification Limits*:

X4.3.1. Since the PWL procedure is an estimate of the population based on small sample distribution, the agency should set upper and lower specification limits relative to the desired mean and standard deviation. The mean is the target value established by the JMF and the standard deviation is one typically found from test data for the property. Proposed specification limits are evaluated for reasonableness to ensure constructability and performance. Table X4.1 provides typical industry standard deviation values.

Note X2—Agency may use historical standard deviation within the state. At a minimum the standard deviation should be no greater than the typical industry standard deviations in Table X4.1 that were developed during NCHRP 9-7.

X4.3.2. Determine the specification limits and acceptable quality level (AQL). The AQL is usually set to be 90 PWL, which means the specification limits will be ±1.645 standard deviations from the target.

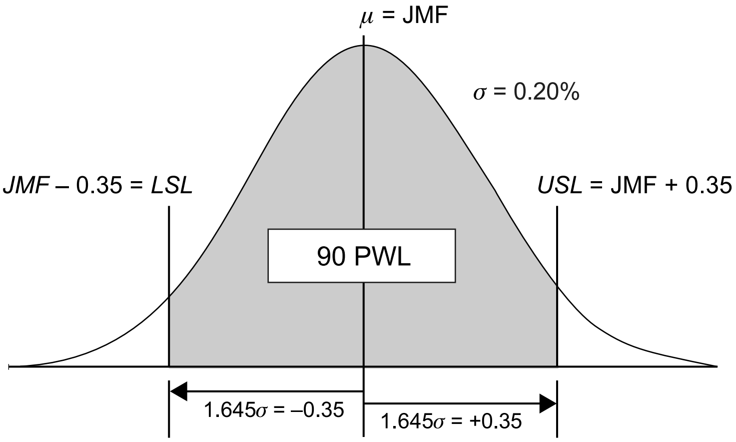

Figure X4.1—AQL Material for the Asphalt Content Example

X4.3.3. The specification limits are determined from the target JMF value and typical standard deviation. For example, if the standard deviation of asphalt binder content is 0.2 percent, HMA within the AQL would be as shown in Figure X4.1. The specification limits are: JMF ± (1.645 × 0.20) = JMF ± 0.33, rounded to ±0.35.

X4.3.4. In another example, if the Agency requires two cores per sublot and sets the specification limits for in-place density with an AQL of 90, the specification limits become 1.645 × 1.4 or ±2.3 percent. For these two examples it would be possible to produce materials within these specification limits, and the performance is expected to be satisfactory.

Table X4.1—Typical Industry Standard Deviations for HMA Properties (HMA Composition, Gyratory Properties and In-Place Density)[a]

HMA Composition Property		Extraction	Nuclear Gage	Ignition Furnace	Cold Feed
Asphalt Binder Content (P_b), %		±0.25	+ 0.18	±0.13	—
Gradation Passing 4.75-mm and Larger Sieves, %		±3	NA	b	±3
Passing 2.36-mm to 0.150-mm Sieve, %		±2	NA	b	±2
Passing 0.075-mm Sieve, %		±0.7	NA	b	±0.7
Maximum Theoretical Specific Gravity (G_{mm})	±0.015				
Gyratory-Compacted HMA Property					
Air Voids (V_a), %	±1.0				
Voids in Mineral Aggregate (VMA), %	±1.0				
Voids Filled with Asphalt (VFA), %	±5				
Bulk Specific Gravity (G_{mb})	±0.022				
In-Place Density					
Roadway Core Density (%G_{mm}), %	±1.4				

a Agency-specific standard deviations may be developed in lieu of the industry standard deviation.

b NCHRP 9-7 did not develop standard deviations for gradation of aggregate recovered from the ignition furnace; however, the standard deviation is expected to be the same as for cold feed or solvent-extracted aggregates.

X4.3.5. For air voids, VMA, and asphalt binder content, the upper and lower specification limits (USL and LSL) are calculated in Section X4.3.2. For in-place density, the LSL may be determined using a target value and offsetting three standard deviations. The target may be obtained from the control strip (Section 12.5) or may be predetermined as a desirable average density. Alternately, the LSL may be set at a predetermined value of desirable minimum density such as 92.0 percent G_{mm}.

Table X4.2—Recommended Specification Limits for HMA Properties

HMA Composition Property		Extraction	Nuclear Gage	Ignition Furnace	Cold Feed
Asphalt Binder Content (P_b), %		±0.41	±0.30	±0.21	—
Gyratory-Compacted HMA Property					
Air Voids (V_a), %	±1.6				
Voids in Mineral Aggregate (VMA), %	±1.6				
Voids Filled with Asphalt (VFA), %	±8				
In-Place Density					
Roadway Core Density (%G_{mm}), %	±2.3				

X4.4. *PWL Calculation*:

X4.4.1. Estimate the PWL in accordance with Sections X4.4.1.1 through X4.4.1.10.

X4.4.1.1. Locate *n* sampling positions in the sublot by use of Appendix X1 or other appropriate random number tables.

X4.4.1.2. Perform tests on each sample taken behind the screed (HMA properties) and each core taken from the roadway (density).

X4.4.1.3. For each test property, determine the average, $\bar{x}$, the lot measurements where n is the number of samples in the lot.

$$\bar{x} = \sum_{i=1}^{n} \frac{x_i}{n} \qquad (X4.1)$$

X4.4.1.4. For each test property, determine the standard deviation, s, of the lot.

$$s = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \bar{x})^2}{n-1}} \qquad (X4.2)$$

X4.4.1.5. For air voids, VMA, and asphalt binder content, calculate both upper and lower quality indices and the associated PWL. For in-place density, calculate the lower quality index and the associated PWL. The method to determine the quality indices follows:

X4.4.1.5.1. Determine the upper quality index, Q_U, by subtracting the average ($\bar{x}$) of the measurements from the USL and dividing the result by s.

$$Q_U = \frac{USL - \bar{x}}{s} \qquad (X4.3)$$

X4.4.1.5.2. Determine the *lower quality index*, Q_L, by subtracting the LSL from the average ($\bar{x}$) and dividing the result by s.

$$Q_L = \frac{\bar{x} - LSL}{s} \qquad (X4.4)$$

X4.4.1.6. For PWL_U, estimate the percentage of material that will fall within the upper tolerance limit by entering Table X4.3 with Q_U using the column appropriate to the total number of measurements, n.

X4.4.1.7. For PWL_L, estimate the percentage of material that will fall within the lower tolerance limit by entering Table X4.3 with Q_L using the column appropriate to the total number of measurements, n.

X4.4.1.8. For air voids, VMA, and asphalt binder content, where both upper and lower limits are used, determine the percent of material that will fall within the limits by adding the percent within the upper specification limit (PWL_U) to the percent within the lower specification limit (PWL_L), and subtracting 100 from the sum.

$$\text{Total PWL} = (PWL_U + PWL_L) - 100 \qquad (X4.5)$$

X4.4.1.9. For in-place density, determine the percent of material that will fall above the lower specification limit (PWL_L).

$$\text{Total PWL} = PWL_L \qquad (X4.6)$$

X4.5. *Example of Percent Within Limits Using Standard Deviation*

X4.5.1. Determine the PWL for air voids, where the average air voids ($\bar{x}$) of the lot is 3.7 percent, the standard deviation is 0.6 percent and the number of samples is five. The range of allowable air voids is 2.4 percent to 5.6 percent.

X4.5.2. Calculate an upper and lower quality index value (Q_U and Q_L) using the following:

$$Q_U = \left(\frac{6.1 - \bar{x}}{s}\right) = \left(\frac{5.6 - \overline{3.7}}{0.6}\right) = 3.16 \qquad (X4.7)$$

$$Q_L = \left(\frac{\bar{x} - \overline{2.4}}{s}\right) = \left(\frac{3.7 - \overline{2.4}}{0.6}\right) = 2.16 \qquad (X4.8)$$

X4.5.3. Determine an upper and lower PWL using Table X4.3 with the number of the samples and the calculated values of Q_U and Q_L.

For $n = 5$ and Q_U =4.00, the $PWL_U = 100$.

Note X3—Since the value of Q_U exceeds the highest value under the column of $n = 5$, the PWL_U equals 100.

Next, for $n = 5$ and $Q_L = 3.00$, the $PWL_L = 100$.

Then, the combined PWL_U and PWL_L is:

$$PWL = (PWL_U + PWL_L) - 100$$
$$PWL = (100 + 100) - 100 = 100$$

where:

s = sample standard deviation;
Q_L = lower quality index value;
Q_U = upper quality index value;
PWL_U = percent within limits on the upper side of the specification;
PWL_L = percent within limits on the lower side of the specification; and
PWL = total percent within limits.

Table X4.3—Quality Index Values for Estimating Percent within Limits

PWL	*n* = 3	*n* = 4	*n* = 5	*n* = 7	*n* = 10	*n* = 15

50	0.00	0.00	0.00	0.00	0.00	0.00

Notes: 1. For negative values of Q_U or Q_L, P_U or P_L is equal to 100 minus the tabular P_U or P_L.

2. If the value of Q_U or Q_L does not correspond exactly to a value in the table, use the next higher value.

X5. SAMPLE QA HMA CONSTRUCTION SPECIFICATION

X5.1. This appendix contains an example specification conforming to R 9 to develop a quality assurance plan for HMA. As such the specification contains lists of the test methods to be used, HMA design and submittal requirements, start-up and field adjustment of the mixture, QC requirements, and acceptance procedures. All of these items are included in this standard practice.

X5.2. In addition to those items listed in this standard practice, the Agency needs to add several other items to complete the specification. Among other things, these items should include:

(a) HMA producer requirements. These would be prequalification items established by the Agency for a Contractor to be eligible to supply HMA. Requirements could address plant and equipment as well as personnel and lab facilities.
(b) Specifics of QC plans for aggregate production or handling, asphalt binder control, plant operations, and roadway operations.
(c) Agency specific aggregate requirements.
(d) Special considerations for the use of recycled materials.
(e) Construction requirements such as the preparation of the surface to be overlaid, weather limitations, spreading and finishing, joints, shoulder corrugations, pavement smoothness, coring procedures, and core hole filling procedures.
(f) Pay factors.
(g) Appeal procedures.
(h) Basis of payment including bid item.

EXAMPLE SPECIFICATION

QUALITY ASSURANCE (QA) HOT MIX ASPHALT (HMA) PAVEMENT

HMA.01 DESCRIPTION

This work shall consist of one or more courses of HMA base, intermediate, or surface mixtures constructed on prepared foundations and shall be in reasonably close conformance with the lines, grades, cross-sections, dimensions, and material requirements, including tolerances, shown on the plans or indicated in the specifications.

HMA.02 QUALITY CONTROL

The HMA shall be supplied from a HMA plant in accordance with the HMA producer requirements. The HMA shall be transported and placed according to a roadway quality control plan (QCP) prepared and submitted by the contractor to the engineer at least 15 days prior to commencing HMA paving operations. The aggregate and asphalt binder materials shall be produced and controlled by separate QCPs based on either the agency approved programs or project specific criteria.

HMA Producer Requirements. The Producer takes responsibility for all aspects of the production of quality HMA in accordance with the contract requirements, and the agency monitors the producer’s production, methods of sampling, testing, calibration, verification, inspection procedures, and anticipated frequencies of each. The HMA Producer’s requirements include the following:

1. The producer’s personnel shall include a qualified technician who shall compact and analyze the HMA specimens and perform the maximum specific gravity test. The technician shall supervise all other sampling and testing of materials, the maintenance of control charts, and the maintenance of the project diary.
2. The producer shall provide and maintain a laboratory for process control testing. The laboratory shall have the necessary space, equipment, and supplies for the tests to be performed. The laboratory testing equipment shall meet the requirements of the test methods identified for the required sampling and testing, except that an electronic balance shall be provided. The gyratory compactor shall be on the agency’s list of approved Superpave

gyratory compactors. The test equipment furnished by the Producer shall be properly calibrated or verified and maintained within the limits described in the applicable test method.

3. The producer shall designate the sampling and sample reduction procedures, test methods, sampling locations, and size of samples necessary for the QC. Testing of the samples shall be completed within 48 hours of the time the sample was taken. Test values shall be reported to the nearest 0.1 percent except for the coarse aggregate angularity content and temperature of HMA which shall be reported to the nearest one percent and 1°C (2°F) respectively.
4. The producer shall detail the procedures for the management of the asphalt binder, aggregate, RAP, calibrations, HMA temperature, moisture, storage, and trucking operations to include the cleaning of the truck beds, loading, tarping, and truck unloading at the roadway.
5. The producer shall maintain control charts at the HMA plant laboratory for each DMF and JMF. All control test results shall be recorded on the control charts the same day the tests are conducted. As a minimum the charts shall be maintained until 30 test data points have been plotted. Subsequent to that time, at least 30 test data points shall be continuously displayed.
6. The producer control charts shall include the critical sieve(s) for each aggregate size from stockpile samples, critical sieve(s) for each blended aggregate, and the target mean values for the asphalt binder content, air voids, and VMA as determined from the DMF and the JMF.

QC Plan for Roadway Operations. The contractor shall identify their process to control the HMA placement and compaction processes to ensure compliance with the project specifications. As a minimum:

1. The contractor shall provide a qualified technician who shall conduct QC testing for temperature, density, and smoothness, and monitor paving operations and joint construction.
2. The QCP shall include the contractor’s methodology for balancing the operation including plant production, transportation, placement, and compaction.
3. The QCP shall also include delivery truck management, procedures for unloading the HMA and residue materials from the truck, and material transfer vehicle operations including plans for crossing bridge structures.
4. The paving plan shall include procedures for the material feed system, grade and slope controls, joint construction, HMA sampling and testing plan, temperature, rolling, density, coring, and smoothness testing.
5. The QCP shall also include documentation of all QC testing and equipment used in the HMA operations. The contractor should maintain adequate records of all tests. The records should indicate the test results and the nature of corrective action taken as appropriate. All charts and records documenting the contractor’s QC operations and tests should be available to the agency during the performance and upon the completion of the work. The contractor should keep the test results on file for a minimum period of three years following completion of the work. Test properties for the various materials and HMA should be charted on forms or other appropriate means which are in accordance with the applicable requirements of the agency.

QC Plan for Asphalt Binder Materials. QC of asphalt binder materials from all suppliers shall be in accordance with R 26 and the following:

1. The supplier shall prepare and submit a QCP that covers the manufacture, storage, shipping, and handling of all materials.
2. The supplier shall conduct testing in a laboratory that has been approved by the agency. Participation in the AMRL equipment inspection and proficiency sample programs with satisfactory ratings will be the basis for approval.
3. Specification compliance testing and complete AASHTO testing shall be accomplished at the frequency outlined in the QCP per grade of binder and at least once following feed stock changes. After initial testing, the minimum frequency for specification compliance testing shall be once per month.
4. The supplier shall furnish instructions with each grade of asphalt binder on proper storage and handling of the material.
5. The supplier shall furnish with the shipping report for each load a statement certifying that the asphalt materials have been manufactured according to R 26 and these specifications.
6. The supplier shall maintain detailed records of QC inspections, test results, and shipments for at least three years.

QC Plan for Aggregate Production. The agency should develop a testing program to ensure that aggregates meet specification requirements. The contractor's QCP should include, as a minimum, discussion on the proposed processing, transportation, stockpiling, and plant charging operations and the following:

1. The producer's personnel shall include a qualified technician who shall perform the pertinent duties during critical activities to meet the requirements of the QCP. The technician shall supervise the sampling and testing of materials, the maintenance of control charts, and the maintenance of the project diary.
2. The producer shall provide and maintain a laboratory for process control testing. The laboratory shall have the necessary space, equipment, and supplies for the tests to be performed. The laboratory testing equipment shall meet the requirements of the test methods identified for the required sampling and testing, except that an electronic balance shall be provided. The test equipment furnished by the Producer shall be properly calibrated or verified and maintained within the limits described in the applicable test method.
3. Sampling and testing of all materials that require control for aggregate gradation, decantation, deleterious, and crushed particles shall be in conformance with the AASHTO and agency requirements. Sampling shall be performed on uniform tonnage increments in an unbiased manner, and testing of the samples shall be accomplished in such time as to assure that process control is maintained. Testing shall be performed in accordance with the respective test methods unless otherwise stated by the agency.
4. The producer shall maintain control charts at the aggregate laboratory. All control test results shall be recorded on the control charts the same day the tests are conducted. As a minimum, the charts shall be maintained until 30 test data points have been plotted. Subsequent to that time, at least 30 test data points shall be continuously displayed.
5. The producer's control charts shall include the critical sieve(s) for each aggregate size from stockpile samples and critical sieve(s) for each blended aggregate.
6. The producer shall retain the QC test results for a minimum period of 3 years.

MATERIAL

HMA.03 MATERIALS

Materials shall be in accordance with the following:

Asphalt Binder	
PG Binder	AASHTO M 320
Coarse Aggregates	Agency Requirements
Fine Aggregates	Agency Requirements

HMA.04 DESIGN MIX FORMULA

A design mix formula (DMF) shall be prepared in accordance with HMA.05 and submitted in a format acceptable to the engineer one week prior to use. The DMF shall state the maximum particle size in the mixture. The DMF shall state the calibration factor, test temperature, and absorption factors to be used for the determination of asphalt binder content using the ignition oven in accordance with AASHTO T 308 or by extraction in accordance with AASHTO T 164. The DMF shall state the source, type, and dosage rate of any stabilizing additives. Approval of the DMF will be based on the ESAL and HMA designation. The engineer will assign an HMA identification number. No HMA will be accepted until the DMF has been approved.

The ESAL category identified in the pay item correlates to the following ESAL ranges:

ESAL Category	ESAL
1	< 300 000
2	300 000 to < 3 000 000
3	3 000 000 to < 10 000 000
4	10 000 000 to < 30 000 000
5	≥ 30 000 000

HMA.05 VOLUMETRIC HMA DESIGN

The DMF shall be determined for each mixture from a volumetric design by a design laboratory selected from the Agency's list of approved HMA design laboratories. A volumetric HMA design shall be performed in accordance with the respective AASHTO references as listed below.

Superpave Volumetric Mix Design	AASHTO M 323
Designing Stone Matrix Asphalt (SMA)	AASHTO MP 8
Mixture Conditioning of Hot Mix Asphalt (HMA)	AASHTO R 30
Superpave Volumetric Design for Hot Mix Asphalt (HMA)	AASHTO R 35
Theoretical Maximum Specific Gravity and Density of Bituminous Paving Mixtures	AASHTO T 209
Resistance of Compacted Asphalt Mixtures to Moisture-Induced Damage	AASHTO T 283
Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor	AASHTO T 312

The single percentage of aggregate passing each required sieve shall be within the limits of AASHTO M 323.

Dust/calculated effective asphalt binder ratio shall be from 0.6 to 1.2 when the aggregate gradation passes above the primary control sieve control point and 0.8 to 1.6 when the aggregate gradation passes below the control point. The optimum asphalt binder content for dense-graded mixtures shall produce 4.0 percent air voids at N_{des}. The design shall have at least four points, including a minimum of two points above and one point below the optimum. The maximum specific gravity of the uncompacted mixture shall be determined in accordance with AASHTO T 209.

Dense-graded mixtures shall be tested for moisture susceptibility in accordance with AASHTO T 283. The minimum tensile strength ratio (TSR) shall be 80 percent. The 150-mm (6-in.) mixture specimens shall be compacted in accordance with AASHTO T 312. If anti-stripping additives are added to the HMA to meet the minimum TSR requirements, the dosage rate shall be submitted with the DMF.

Changes in the source or types of aggregates shall require a new DMF. A new DMF shall be submitted to the engineer for approval one-week prior to use.

The HMA design compaction temperature for the specimens shall be in accordance with the asphalt binder supplier's recommendations or determined from a temperature–viscosity curve based on AASHTO T 316.

Design criteria for each HMA shall be based on the ESAL value shown in the contract documents. Air void, VMA, and VFA criteria shall be in accordance with AASHTO M 323 and R 35.

HMA.06 RECYCLED MATERIALS

Recycled materials may consist of reclaimed asphalt pavement (RAP). Reclaimed asphalt pavement shall be the product resulting from the cold milling or crushing of an existing HMA pavement. The RAP is processed so that 100 percent will pass the 50-mm (2-in.) sieve when entering the HMA plant. The coarse aggregate in the recycled materials shall pass the maximum sieve size for the HMA being produced.

Recycled materials may be used as a substitute for a portion of the new materials in accordance with AASHTO M 323. The percentages of recycled materials shall be as specified on the DMF.

HMA.07 INITIAL PRODUCTION LOT

At the beginning of production of each HMA design, an initial production lot should be used to evaluate the DMF. The initial production lot should be divided into four sublots as specified in the table below depending on the mixture type.

Initial Production Sublots and Lots

Nom Max Size	Initial Sublot Size	Initial Lot Size
4.75	300	1200
9.5	400	1600
12.5	500	2000
19.0	500	2000
25.0	500	2000
37.5	500	2000

During initial plant start-up, adjustments may be made to assure the plant-produced HMA will meet the design requirements. For the initial production lot, the contractor shall produce HMA within the limits in the table below. The DMF may be adjusted to bring the DMF into compliance with the requirements of AASHTO M 323. The maximum adjustment should be within the following limits:

Allowable DMF Adjustments for Initial Production	
HMA Composition Property	Adjustment Limit, %
Asphalt Binder Content (P_b)	±0.4
Gradation Passing 4.75-mm and Larger Sieves	±4.0
Gradation Passing 2.36-mm to 0.150-mm Sieve	±4.0
Gradation Passing 0.075-mm Sieve	±1.5
Voids in Mineral Aggregate (VMA)	±1.0
Voids Filled with Asphalt (VFA)	±5.0

By the end of the lot, the HMA should be within the limits of the above table. The initial production lot shall be closed out, and the contractor shall declare a JMF.

HMA.08 LOTS AND SUBLOTS

After the initial production lot, lots will be defined for 19.0 mm nominal maximum aggregate size or larger HMA designs and for 12.5-mm or smaller HMA designs. Lots will be further subdivided into equal sublots not to exceed 1000 Mg (1000 tons) for 19.0-mm or larger HMA designs or 600 Mg (600 tons) for 12.5-mm or smaller HMA designs. Typically, four or more sublots constitute a lot. Partial sublots of 100 Mg (100 tons) or less can be added to the previous sublot. Partial sublots greater than 100 Mg (100 tons) can constitute a full sublot. Lots that contain a single sublot could be combined with the previous lot for acceptance purposes.

HMA.09 JOB MIX FORMULA

A job mix formula (JMF) shall be developed by the Contractor. A JMF used for volumetrically accepted contracts in the current or previous calendar year that was developed to N_{des} will be allowed.

HMA.10 ACCEPTANCE OF HMA

For the initial production lots, the properties of each sublot will be measured and compared to the DMF. If the deviation in air voids in any sublot exceeds ±2 percent or in any two sublots exceeds ±1.5 percent, the production should cease, and a new DMF should be developed in accordance with HMA.05. If the deviation for asphalt binder content in any sublot exceeds the limit shown in the table below, the production should cease, and a new DMF should be developed in accordance with HMA.05. If the deviation for any property other than asphalt binder content exceeds two times the limits shown in the table below or any two sublots exceed the limits, the production should cease, and a new DMF should be developed in accordance with HMA.05.

Allowable DMF Adjustments for Initial Production	
HMA Composition Property	Deviation, %
Asphalt Binder Content (P_b)	±0.4
Gradation Passing 0.150-mm and Larger Sieves	±4.0
Gradation Passing 0.075-mm Sieve	±1.5
Voids in Mineral Aggregate (VMA)	±1.0
Voids Filled with Asphalt (VFA)	±5.0

For all lots except the initial production lot, HMA will be accepted for asphalt binder content, VMA at N_{des}, and air voids at N_{des} based on tests performed by the engineer. Acceptance testing for surface mixtures will include tests for moisture content. The engineer will randomly select a location within each sublot for sampling. An acceptance sample will consist of two plate samples with the first being at the random location and the second 0.6 m (2 ft) ahead. A backup sample consisting of two plate samples shall be located 0.6 m (2 ft) towards the center of the mat from the acceptance sample. An additional sample for moisture content shall be located 0.6 m (2 ft) back from the random sample location.

The maximum percent of moisture in the mixture shall not exceed 0.10 from plate samples. Air voids, asphalt binder content, and VMA values will be reported to the nearest 0.1 percent. Moisture and draindown test results will be rounded to the nearest 0.01 percent.

In the event that an acceptance sample is not available to represent a sublot(s), all test results of the previous sublot will be used for acceptance. If the previous sublot is not available, the subsequent sublot will be used for acceptance.

The engineer’s acceptance test results for each sublot will be available when the testing is complete. The contractor may request an appeal of the engineer's test results in accordance with HMA.21.

Determine percent within limits (PWL) and pay factors in accordance with HMA.20.

CONSTRUCTION REQUIREMENTS

HMA.11 GENERAL

Equipment for HMA operations shall be in accordance with Agency requirements.

Fuel oil, kerosene, or solvents shall not be transported in open containers on equipment. Cleaning of equipment and small tools shall not be accomplished on the pavement or shoulder areas.

Segregation, flushing, or bleeding of HMA will not be permitted. Corrective action shall be taken to prevent continuation of these conditions. Segregated, flushed, or bleeding HMA shall be removed if directed. All areas showing an excess or deficiency of asphalt binder shall be removed and replaced.

All HMA that has become loose and broken, mixed with dirt, or is in any way defective shall be removed and replaced.

HMA.12 PREPARATION OF SURFACES TO BE OVERLAID

The subgrade shall be shaped to the required grade and sections, free from all ruts, corrugations, or other irregularities, and uniformly compacted. Surfaces on which HMA is placed shall be free from objectionable or foreign materials at the time of placement.

Compacted aggregate bases and rubblized pavements shall be primed. Milled surfaces and existing surfaces shall be tacked prior to placing HMA. Contact surfaces of curbing, gutters, manholes, and other structures shall also be tacked.

HMA.13 PROCESS CONTROL

The engineer and contractor will jointly review the operations to ensure compliance with the QCP. Continuous violations of compliance with the QCP will result in suspension of paving operations.

HMA.14 WEATHER LIMITATIONS

HMA courses of less than 75 kg/m^2 (138 lb/yd^2) shall be placed only when the ambient temperature, and the temperature of the surface on which it is to be placed, is 7°C (45°F) or above. No HMA shall be placed on a frozen subgrade.

HMA.15 SPREADING AND FINISHING

The HMA shall be placed upon an approved surface by means of approved equipment. Prior to paving, the actual application rate shall be determined.

HMA courses greater than 90 kg/m^2 (165 lb/yd^2) placed under traffic shall be brought up even with each adjacent lane at the end of each workday. HMA courses less than or equal to 90 kg/m^2 (165 lb/yd^2) shall be brought forward concurrently, within practical limits, limiting the work in one lane to not more than one work day of production before moving back to bring forward the adjacent lane.

Hydraulic extensions on the paver will not be permitted for continuous paving operations. Fixed extensions or extendable screeds shall be used on courses greater than the nominal width of the paver except in areas where the paving widths vary. Hydraulic extensions may be used in tapers and added lanes less than 75 m (250 ft) in length.

Automatic slope and grade controls shall be used as outlined in the QCP.

When placing HMA with density not controlled by cores, the speed of the paver shall not exceed 15 m (50 ft) per min. Rollers shall be operated to avoid shoving of the HMA and at speeds not to exceed 4.5 km/h (3 mph). However, vibratory rollers will be limited to 4 km/h (2.5 mph).

The finished thickness of any course shall be at least two times, but not more than four times, the nominal-maximum aggregate particle size as shown on the DMF.

HMA.16 JOINTS

Longitudinal joints in the surface shall be at the lane lines of the pavement. Longitudinal joints below the surface shall be offset from previously constructed joints by approximately 150 mm (6 in.) and be located within 300 mm (12 in.) of the lane line.

Transverse joints shall be constructed by exposing a nearly vertical, full-depth face of the previous course. For areas inaccessible to rollers, other mechanical devices shall be used to achieve the required density.

If constructed under traffic, temporary transverse joints shall be feathered to provide a smooth transition to the driving surface.

HMA.17 DENSITY

Acceptance will be based on lots and sublots in accordance with HMA.08.

Density of the compacted dense-graded HMA will be determined from cores based on samples obtained from two random locations selected by the engineer within each sublot. One core shall be cut at each random location. The transverse core location will be located so that the edge of the core will be no closer than 75 mm (3 in.) from a confined edge or 150 mm (6 in.) from a non-confined edge of the course being placed. The maximum specific gravity will be determined from the sample obtained in HMA.10.

The contractor shall obtain cores in the presence of the engineer with a device that shall produce a uniform 150-mm (6-in.) diameter pavement sample. Coring shall be completed prior to the random location being covered by the next course. Surface courses shall be cored within two workdays of placement. Damaged core(s) shall be discarded and replaced with a core from a location selected by adding 0.3 m (1.0 ft) to the longitudinal location of the damaged core using the same transverse offset.

The contractor and the engineer shall mark the core to define the course to be tested. If the core indicates a course thickness of less than 2.0 times the nominal-maximum aggregate size, the core will be discarded, and a core from a new random location will be selected for testing.

The engineer will take immediate possession of the cores. If the engineer's cores are subsequently damaged, additional coring will be the responsibility of the agency. Subsequent core locations will be determined by subtracting 0.3 m (1.0 ft) from the random location using the same transverse offset.

The density for the HMA will be expressed as the percentage of maximum specific gravity (%G_{mm}) obtained by dividing the average bulk specific gravity by the maximum specific gravity for the sublot times 100. Density values (%G_{mm}) will be reported to the nearest 0.1 percent. Rounding will be in accordance with ASTM E 29 using the rounding method. The engineer will determine the bulk specific gravity of the cores (G_{mb}) in accordance with AASHTO T 166. The maximum specific gravity will be determined in accordance with AASHTO T 209. The target value for density of dense-graded mixtures of each sublot shall be 93.0 percent.

Within one workday of coring operations, the contractor shall clean, dry, and refill the core holes with HMA of similar or smaller-size particles or other approved materials.

Pay factors will be determined in accordance with HMA.20. The engineer's acceptance test results for each sublot will be available when the testing is complete.

HMA.18 SHOULDER CORRUGATIONS

Shoulder corrugations shall be in accordance with the plans.

HMA.19 PAVEMENT SMOOTHNESS

The pavement smoothness will be accepted by means of a profilograph, a 4.9 m (16 ft) long straightedge, or a 3 m (10 ft) long straightedge.

The profilograph shall be used where the following conditions are met:

1. the design speed is greater than 70 km/h (45 mph),
2. the pavement lanes are full width, 0.16 km (0.1 mi.) and or longer, and
3. the HMA is placed on a milled surface or the total application rate is 180 kg/m2 (330 lb/yd2) or greater.

The contractor shall furnish, calibrate, and operate an approved profilograph in accordance with agency requirements. The profilogram produced shall become the property of the agency. The profilograph shall remain the property of the contractor.

The 4.9 m (16 ft) long straightedge shall be used on overlays where the profilograph is not specified. The 4.9 m (16 ft) long straightedge shall be used on all full-width pavement lanes shorter than 75 m (250 ft), on tapers, within 15 m (50 ft) of bridge approaches, and within 15 m (50 ft) of an existing pavement, which is being joined.

The 3 m (10 ft) long straightedge shall be used for transverse slopes, approaches, and crossovers.

All wavelike irregularities and abrupt changes in profile caused by paving operations shall be corrected.

Each finished course of base and intermediate HMA shall be subject to approval. The pavement smoothness shall be checked on any new intermediate course located immediately below a surface course and the surface course at the locations as designated in accordance with agency requirements.

If grinding of the intermediate course is used for pavement smoothness corrections, the grinding shall not precede the surface placement by more than 30 calendar days if open to traffic.

When the 4.9-m (16-ft) straightedge is used on a surface course, the pavement variations shall be corrected to 6 mm ($^1/_4$ in.) or less. When the 3-m (10-ft) straightedge is used, the pavement variations shall be corrected to 3 mm ($^1/_8$ in.) or less.

When the profilograph is being used on a surface course, in addition to the requirements for the profile index, all areas having a high or low point deviation in excess of 8 mm (0.3 in.) shall be corrected. Courses underlying the surface courses that are exposed by corrective actions shall be milled to 25 mm (1 in.) and replaced with surface materials. The initial profile index shall be determined prior to any corrective action. The final profile index will be determined after all corrective action has been completed.

When the profilograph is being used on an intermediate course, all areas having a high or low point deviation in excess of 8 mm (0.3 in.) shall be corrected. When the 4.9-m (16-ft) or 3.0-m (10-ft) straightedge is being used on an intermediate course, all areas having a high or low point deviation in excess of 6 mm ($^1/_4$ in.) shall be corrected.

HMA.20 PAY FACTORS

For all lots except the initial production lot, the percent within limits (*PWL*) shall be estimated for each property (air voids, asphalt binder content, VMA, and in-place density) as follows:

Determine the average, $\overline{x}$, of the lot measurements, where n is the number of samples in the lot.

$$\overline{x} = \sum_{i=1}^{n} \frac{x_i}{n}$$

Determine the standard deviation, s, of the lot.

$$s = \sqrt{\frac{\sum_{i=1}^{n} (x_i - \overline{x})^2}{n-1}}$$

For air voids, asphalt binder content, and VMA, calculate the upper quality index, Q_U, by subtracting the average ($\overline{x}$) of the measurements from the upper specification limit (*USL*) and dividing the results by s. Limits are listed in the table of specification limits (see Table X1).

$$Q_U = \frac{USL - \overline{x}}{s}$$

Estimate the percentage of material that will fall within the upper tolerance limit by entering the table of quality index values with Q_U using the column appropriate to the total number of measurements, n.

For air voids, asphalt binder content, VMA, and in-place density, calculate the lower quality index, Q_L, by subtracting the lower specification limit (*LSL*) from the average ($\overline{x}$) and dividing the result by s.

$$Q_L = \frac{\overline{x} - LSL}{s}$$

Estimate the percentage of material that will fall within the lower tolerance limit by entering the table of quality index values with Q_L using the column appropriate to the total number of measurements, n.

For air voids, asphalt binder content, and VMA, where both upper and lower limits are used, determine the percent of material that will fall within the limits by adding the percent within the upper specification limit (PWL_U) to the percent within the lower specification limit (PWL_L), and subtracting 100 from the sum.

Total PWL = (PWL_U + PWL_L) – 100

For in-place density, determine the percent of material that will fall above the lower specification limit (PWL_L).

Total PWL = PWL_L

Calculate the pay factor (*PF*) for each property with the table of pay factors for different *PWL* values.

For the initial production lot, HMA accepted according to HMA.10 shall be accepted with a pay factor of 1.00. For material produced outside the tolerances of HMA.10, the agency will determine if the material should be left in place.

Table X1—Specification Limits

HMA Composition Property	Specification Limits
Mixture	
Air Voids (V_a) at N_{des}, %	2.7 to 5.3
Asphalt Binder Content by Ignition Furnace, %	±0.2 from JMF
Voids in Mineral Aggregate (VMA) at N_{des}, %	±1.3 from JMF
In-Place Density	
Roadway Core Density (%G_{mm}), %	91.7

Table X2—Quality Index Values for Estimating Percent within Limits

PWL	*n* = 3	*n* = 4	*n* = 5	*n* = 7	*n* = 10	*n* = 15
100	1.16	1.50	1.79	2.23	2.65	3.03
99	1.16	1.47	1.67	1.89	2.04	2.14
98	1.15	1.44	1.60	1.76	1.86	1.93

58	0.29	0.24	0.23	0.21	0.21	0.21
57	0.25	0.21	0.20	0.19	0.18	0.18
56	0.22	0.18	0.17	0.16	0.16	0.15
55	0.18	0.15	0.14	0.13	0.13	0.13
54	0.14	0.12	0.11	0.11	0.10	0.10
53	0.11	0.09	0.08	0.08	0.08	0.08
52	0.07	0.06	0.06	0.05	0.05	0.05
51	0.04	0.03	0.03	0.03	0.03	0.03
50	0.00	0.00	0.00	0.00	0.00	0.00

Notes: 1. For negative values of Q_U or Q_L, P_U or P_L is equal to 100 minus the tabular P_U or P_L.

2. If the value of Q_U or Q_L does not correspond exactly to a value in the table, use the next higher value.

Pay factors are calculated for each property, air voids at N_{des}, asphalt binder content, VMA at $N_{des,}$ and in-place density (%G_{mm}). The appropriate pay factor for each property is calculated as follows:

Estimated PWL greater than 78:

$$PF = 0.045(PWL) + 96.5$$

Estimated PWL greater than or equal to 42 and less than or equal to 78:

$$PF = -0.006(PWL)2 + 1.4(PWL) + 27.3$$

If the pay factor for any one of the properties is less than 75, the engineer will determine if the material will be required to be removed, other corrective action is to be taken, or left in place at a further reduced pay factor.

For all lots other than the initial production, lot a composite pay factor is determined for each lot based on test results for HMA properties and density in a weighted formula as follows:

$$CPF = 0.20(PF_{\mathrm{BINDER}}) + 0.35(PF_{\mathrm{VOIDS}}) + 0.10(PF_{\mathrm{VMA}}) + 0.35(PF_{\mathrm{DENSITY}})$$

where:

CPF = lot combined pay factor for mixture and density;
PF_{BINDER} = lot pay factor for asphalt binder content;
PF_{VOIDS} = lot pay factor for air voids at N_{des};
PF_{VMA} = lot pay factor for VMA at N_{des}; and
PF_{DENSITY} = lot pay factor for density.

The lot pay adjustment for mixture properties and density is calculated as follows.

$$q_m = L \times U \times (CPF - 100)/100$$

where:

q_m = quality assurance adjustment for mixture and density;
L = lot quantity;
U = unit price for the material, \$/Mg (\$/ton); and
CPF = combined pay factor.

The quality assurance adjustment points for smoothness will be calculated in accordance with the following:

When the pavement smoothness is tested with a profilograph, payment will be based on the final profile index ($PI_{0.0}$) in accordance with the following table:

Table X3—Adjustment for Smoothness

Design Speed Greater than 70 km/h (45 mph)	
Profile Index (*PI*0.0), mm per 0.16 km (in./0.1 mi)	Pay Factor
0 to 20 mm (0.00 to 0.80 in.)	1.06
21 to 25 mm (0.81 to 1.00 in.)	1.05
26 to 30 mm (1.01 to 1.20 in.)	1.04
31 to 35 mm (1.21 to 1.40 in.)	1.03
36 to 40 mm (1.41 to 1.60 in.)	1.02
41 to 50 mm (1.61 to 2.00 in.)	1.01
51 to 60 mm (2.01 to 2.40 in.)	1.00
61 to 65 mm (2.41 to 2.60 in.)	0.96
61 to 70 mm (2.61 to 2.80 in.)	0.92

Note: All pavements with a Profile Index ($PI_{0.0}$) greater than 70 mm (2.80 in.) shall be corrected.

A quality assurance pay factor for smoothness (PF_s) will apply to the typical section including the aggregate base, and the HMA base, intermediate, and surface courses. The quality assurance adjustment for each section will include the total area of each pavement lane excluding shoulders for a 0.16 km (0.1 mi) long section represented by the profile index calculated by the following formula:

$$q_s = (PF_s - 1.00)\sum_{i=1}^{n}\left(A \times \frac{S}{T} \times U\right)$$

where:

q_s = quality assurance adjustment for smoothness for one section;
PFs = pay factor for smoothness;
n = number of layers;
A = area of the section, m^2 (yd^2);
S = spread rate for the material, kg/m^2 (lb/yd^2);
T = conversion factor: 1000 kg/Mg (2000 lb/ton); and
U = unit price for the material, \$/Mg (\$/ton).

For the entire contract, the quality assurance adjustment for smoothness, Q_S, will be the total of the quality assurance adjustments for smoothness, q_s, on each section by the following formula:

$Q_s = \Sigma\, q_s$

Quality assurance pay factors greater than 1.00 will be applicable only to the initial measured profile index, prior to any corrective work. Quality assurance pay factors of 1.00 or less will be applied to pavement sections where corrective work has been completed.

The total quality assurance adjustments for mixture properties, density and smoothness are calculated as follows:

$q = q_m + q_S$

where:

q = total quality assurance adjustment;
q_m = quality assurance adjustment for mixture and density; and
q_S = quality assurance adjustment for smoothness.

HMA.21 APPEALS

If the QC test results do not agree with the acceptance test results, a request, along with the QC test results, may be made in writing for additional testing. Additional testing may be requested for one or more of the following tests: G_{mm}, G_{mb} of the gyratory specimens, asphalt binder content, or bulk specific gravity of the density cores. The request for the appeal for G_{mm}, G_{mb} of gyratory specimens, asphalt binder content, or bulk specific gravity of the density cores shall be submitted within seven calendar days of receipt of the Agency’s written results for that lot. The lot, sublot and specific test(s) shall be specified at the time of the appeal. Upon approval of the appeal, the engineer will perform additional testing as follows:

The backup sample(s) or new cores will be tested in accordance with the applicable test method for the test requested.

G_{mm}. The backup G_{mm} sample will be tested in accordance with AASHTO T 209, Section 9.5.1.

G_{mb} of the Gyratory Specimen. New gyratory specimens will be prepared and tested in accordance with AASHTO T 312 from the backup sample.

Asphalt Binder Content. The backup asphalt binder content sample will be prepared and tested in accordance with the test method that was used for acceptance.

Bulk Specific Gravity of the Density Core. Additional cores shall be taken within seven calendar days unless otherwise directed. Additional core locations will be determined by adding 0.3 m

(1.0 ft) longitudinally to the site of the cores tested using the same transverse offset. The appeal density cores will be tested in accordance with AASHTO T 166.

The appeal results will replace all previous test result(s) for acceptance of HMA in accordance with HMA.10 and density in accordance with HMA.17. The results will be furnished to the contractor.

HMA.22 METHOD OF MEASUREMENT

HMA will be measured by the megagram (ton) of the type specified.

HMA.23 BASIS OF PAYMENT

The accepted quantities for this work will be paid for at the contract unit price per megagram (ton) for QC/QA-HMA, of the type specified, complete in place.

Payment for furnishing, calibrating, and operating the profilograph and furnishing profile information will be made at the contract lump sum price for profilograph, HMA.

Adjustments to the contract payment with respect to mixture, density, and smoothness for mixture produced will be included in a quality assurance adjustment pay item. The unit price for this pay item will be one dollar ($1.00), and the quantity will be in units of dollars. The quantity is the total calculated in accordance with HMA.20.

Payment will be made under the following pay items:

Pay Item	Metric Pay Unit Symbol (English Pay Unit Symbol)
Profilograph, HMA	Lump Sum
QC/QA HMA. _______*	Mg (ton)
Quality Assurance Adjustment	Dollars

* Surface, Intermediate, or Base

Preparation of surfaces to be overlaid shall be included in the cost of other pay items.

Coring and refilling of the core holes shall be included in the cost of other pay items within this section.

No payment will be made for additional anti-stripping additives, appeal coring, or traffic control expenditures related to coring operations.

Corrections for pavement smoothness shall be included in the cost of other pay items within this section.

The price for profilograph, HMA, will be full compensation regardless of how often the profilograph is used or how many profilograms are produced.

Standard Specification for

Zinc-Coated Steel Wire Rope and Fittings for Highway Guardrail

AASHTO Designation: M 30-02 (2006)[1]
ASTM Designation: A 741-98

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Zinc-Coated Steel Wire Rope and Fittings for Highway Guardrail

AASHTO Designation: M 30-02 (2006)[1]

ASTM Designation: A 741-98

1. SCOPE

1.1 This specification covers 19- and 25-mm ($^{3}/_{4}$- and 1-in.) zinc-coated steel wire rope and fittings for use in the construction of highway guardrail.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 111M/M 111, Zinc (Hot-Dip Galvanized) Coatings on Iron and Steel Products
- M 120, Zinc
- M 232M/M 232, Zinc Coating (Hot-Dip) on Iron and Steel Hardware
- T 65M/T 65, Mass [Weight] of Coating on Iron and Steel Articles with Zinc or Zinc-Alloy Coatings
- T 244, Mechanical Testing of Steel Products

2.2 *ASTM Standard*:

- A 902, Standard Terminology Relating to Metallic Coated Steel Products

3. TERMINOLOGY

3.1 *Definitions*—For definitions of terms used in this specification, refer to ASTM A 902.

4. ORDERING INFORMATION

4.1 Orders for wire rope guardrail material purchased to this specification shall include the following:

4.1.1 Diameter of wire rope,

4.1.2 Type of wire rope construction,

4.1.3 Class of zinc coating required (Table 2), 4.1.4 Quantity of wire rope and length per reel, and

4.1.5 AASHTO designation and year of issue.

Note 1—A typical ordering description is as follows: 19-mm ($^3/_4$-in.) diameter, Zinc-Coated Wire Rope for Guardrail, Type 1 Construction, Class A Coating, 24.4 km (80000 lineal ft) on forty 610 m (2000 ft) reels, M 30-____.

5. MATERIAL

5.1 *Base Metal*—The base metal shall be steel made by any process and shall be of such quality that the finished wire rope and the individual zinc-coated wires shall have the properties as prescribed in this specification.

5.2 *Zinc*—The slab zinc when used for the coating shall be any grade of zinc conforming to M 120.

6. MECHANICAL REQUIREMENTS

6.1 *Breaking Strength*—The zinc-coated steel wire rope shall conform to the mechanical properties in Table 1 when tested in accordance with T 244 and employing a suitable gripping device as covered in Annex A7.3 of T 244.

6.2 *Construction*—The zinc-coated wire rope and individual wires shall conform to the dimension and construction requirements of Table 1.

Table 1—Guard Cable Requirements

Type	Diameter, min, mm (in.)	Construction (No. of Strands × No. of Wires per Strand)	Breaking Strength, min, kN (lbf)	Length of Lay of Strand, max, mm (in.)	Length of Lay of Wires in Strand, max, mm (in.)	Diameter of Coated wires in Strand, mm (in.)
I	19 ($^3/_4$)	3 by 7	110 (25000)	190 (7.5)	114 (4.5)	2.97 to 3.15 (0.117 to 0.124)
II	19 ($^3/_4$)	6 by 19[a] IWRC[b]	190 (42800)	[c]	[c]	Variable
II(a)	19 ($^3/_4$)	6 by 19[a] wire stem + core	190 (42800)	[c]	[c]	Variable
III	25 (1)	7 by 7	200 (45000)	254 (10)	114 (4.5)	2.67 to 2.95 (0.105 to 0.116)

[a] 6 by 19 classification may have from 15 to 26 wires per strand.

[b] IWRC = independent wire rope core.

[c] Length of lay as specified by manufacturer.

6.3 *Ductility of Steel*—The individual zinc-coated wires shall be capable of being wrapped two turns in a close helix at a rate not exceeding 15 turns per minute around a cylindrical steel mandrel equal to three times the nominal diameter of the wire under test without cracking or breaking of the wire.

6.4 *Mass of Zinc Coating*—The class of zinc coating shall be specified by the purchaser. The mass of the zinc coating on the individual wires for the specified class and appropriate wire size shall not be less than that specified in Table 2 when tested in accordance with the stripping test of T 65M/T 65.

Table 2—Minimum Mass of Coating

Nominal Diameter of Coated Wire		Mass of Zinc Coating, min					
		g/m^2 of Uncoated Wire Surface			oz/ft^2 of Uncoated Wire Surface		
mm	in.	Class A Coating	Class B Coating	Class C Coating	Class A Coating	Class B Coating	Class C Coating
1.02 to 1.55, incl	0.040 to 0.061, incl	122	244	366	0.40	0.80	1.20
1.58 to 2.01, incl	0.062 to 0.079, incl	152	305	458	0.50	1.00	1.50
2.03 to 2.34, incl	0.080 to 0.092, incl	183	366	549	0.60	1.20	1.80
2.36 to 2.62, incl	0.093 to 0.103, incl	214	427	641	0.70	1.40	2.10
2.64 to 3.02, incl	0.104 to 0.119, incl	244	488	732	0.80	1.60	2.40
3.05 to 3.61, incl	0.120 to 0.142, incl	259	519	778	0.85	1.70	2.55

6.5 *Adherence of Coating*—The individual zinc-coated wires shall be capable of being wrapped two turns in a close helix at a rate not exceeding 15 turns per minute around a cylindrical steel mandrel equal to three times the nominal diameter of the wire under test without the coating cracking or flaking to such an extent that any zinc can be removed by rubbing with bare fingers. Loosening or detachment during the adherence test of superficial small particles of zinc formed by mechanical polishing of the surface of zinc-coated wire shall not be considered cause for rejection.

6.6 *Appearance*—The individual wires shall be cylindrical in form, of uniform quality, and free of imperfections not consistent with good commercial practice. Each wire shall have a continuous coating of zinc of reasonably uniform thickness.

7. WIRE ROPE

7.1 The wire rope shall be right regular lay, preformed, and of the type of construction shown in Table 1. A right lay is defined as a clockwise twist away from the observer. The type of construction shall be specified by the purchaser.

8. JOINTS AND SPLICES

8.1 *Individual Wires*—The distance between joints in any two individual wires in a strand shall be not less than 457 mm (18 in.). Joints in individual wires shall be either butt-welded or brazed-lap type. Joints made by butt welding shall have all flash removed. When the brazed-lap type of joint is used, the length of the lap shall be not less than three times the diameter of the wire and the overlapping faces shall be smooth, clean, properly fluxed, and completely covered by the brazing metal. All joints shall be recoated after welding so that the joints shall have protection from corrosion equivalent to the zinc-coated wire itself.

8.2 *Strand or Rope*—Strand or rope splices may only be made when authorized in writing by the purchaser.

9. SAMPLING AND TESTING

9.1 One wire rope test specimen shall be taken from each lot. A lot shall consist of not more than 18 Mg (20 tons) of wire rope of one size and type delivered at one time.

9.2 The test specimen shall be of a length to perform conveniently all tests prescribed in this specification.

9.3 A minimum of four wire test specimens shall be cut from each size of main wires in the rope, selected at random for testing for compliance with Sections 6.2, 6.3, 6.4, and 6.5.

9.4 If an individual wire or the rope fails to meet any requirements of this specification, that reel shall be rejected and two additional tests shall be made on samples of wire rope from two different reels in the lot. If failure occurs in either of these tests, the lot of wire rope shall be rejected. The lot may be resubmitted for inspection after testing every reel for the characteristics in which the specimen failed and sorting out the defective reels.

10. INSPECTION

10.1 All tests and inspection shall be made at the place of manufacture unless otherwise specified and shall be so conducted as not to interfere unnecessarily with the operation of the works. The manufacturer shall afford the inspector representing the purchaser all reasonable facilities to satisfy him that the material being furnished is in accordance with this specification. When specified, inspection may be waived and certified copies of test reports furnished. The purchaser reserves the right to test individual wires for compliance to Sections 6.2, 6.3, 6.4, and 6.5 and the zinc-coated wire rope after fabrication.

11. PACKAGING

11.1 Current standard practice is to ship the wire rope on wooden reels. Each reel shall have the length, nominal diameter, type of strand construction, mass of rope, and name or trademark of the manufacturer plainly and indelibly marked on a strong tag, firmly attached, or this information shall be painted on the reel. The wooden reel shall be mountable so that it will revolve and the rope will run off by pulling straight ahead.

12. FITTINGS

12.1 The fittings shall be of the design called for in the plans and shall have the properties necessary to develop the strength of the wire rope.

12.2 Fittings as shown in the plans shall have a uniform coating of zinc conforming to M 111M/M 111 or M 232M/M 232, whichever applies.

13. KEYWORDS

13.1 Galvanized wire; steel wire; wire; zinc-coated carbon steel wire.

---

[1] In essential equivalence with ASTM A 741-98 except for the order of the tables.

Standard Specification for

Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement

---

AASHTO Designation: M 31M/M 31-10[1]
ASTM Designation: A 615/A 615M-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement

AASHTO Designation: M 31M/M 31-10[1]

ASTM Designation: A 615/A 615M-09

1. SCOPE

1.1. This specification covers deformed and plain carbon steel concrete reinforcement bars in cut lengths or coils. Steel bars containing alloy additions, such as with the AISI and SAE series of alloy steels, are permitted if the resulting product meets all the other requirements of this specification. The standard sizes and dimensions of deformed bars and their number designations shall be those listed in Table 1 [Table 2]. The text of this specification references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of this specification.

1.2. Bars are of three minimum yield strength levels: namely, 280 MPa [40000 psi], 420 MPa [60000 psi], and 520 MPa [75000 psi], designated as Grade 280 [40], Grade 420 [60], and Grade 520 [75], respectively.

1.3. Hot-rolled plain rounds, in sizes up to and including 63.5-mm [2 ½-in.] diameter in coils or cut lengths, when specified for dowels, spirals, and structural ties or supports, shall be furnished under this specification in Grade 280 [40], Grade 420 [60], and Grade 520 [75] (Note 2).

For ductility properties (elongation and bending), test provisions of the nearest smaller nominal diameter deformed bar size shall apply. Requirements providing for deformations and marking shall not be applicable.

1.4. Welding of the material in this specification should be approached with caution since no specific provisions have been included to enhance its weldability. When the steel is to be welded, a welding procedure suitable for the chemical composition and intended use or service should be used (Note 1).

Note 1—The use of the latest edition of ANSI/AWS D1.4 is recommended for welding reinforcing bars. This document describes the proper selection of the filler metals and preheat/interpass temperatures, as well as performance and procedure qualification requirements.

1.5. This specification is applicable for orders in either SI units (M 31M) or in inch-pound units (M 31). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 31.

Table 1—Deformed Bar Designation Numbers, Nominal Masses, Nominal Dimensions, and Deformation Requirements, SI Units

		Nominal Dimensions[a]			Deformation Requirements, mm		
Bar Designation No.[b]	Nominal Mass, kg/m	Diameter, mm	Cross-Sectional Area, mm^2	Perimeter, mm	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
10	0.560	9.5	71	29.9	6.7	0.38	3.6
13	0.994	12.7	129	39.9	8.9	0.51	4.9
16	1.552	15.9	199	49.9	11.1	0.71	6.1
19	2.235	19.1	284	59.8	13.3	0.97	7.3
22	3.042	22.2	387	69.8	15.5	1.12	8.5
25	3.973	25.4	510	79.8	17.8	1.27	9.7
29	5.060	28.7	645	90.0	20.1	1.42	10.9
32	6.404	32.3	819	101.3	22.6	1.63	12.4
36	7.907	35.8	1006	112.5	25.1	1.80	13.7
43	11.38	43.0	1452	135.1	30.1	2.16	16.5
57	20.24	57.3	2581	180.1	40.1	2.59	21.9

[a] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same mass per meter as the deformed bar.

[b] Bar designation numbers approximate the number of millimeters of the nominal diameter of the bar.

Table 2—Deformed Bar Designation Numbers, Nominal Weights, Nominal Dimensions, and Deformation Requirements

		Nominal Dimensions[a]			Deformation Requirements, in.		
Bar Designation No.[b]	Nominal Weight, lb/ft	Diameter, in.	Cross-Sectional Area, in.^{2}	Perimeter, in.	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
3	0.376	0.375	0.11	1.178	0.262	0.015	0.143
4	0.668	0.500	0.20	1.571	0.350	0.020	0.191
5	1.043	0.625	0.31	1.963	0.437	0.028	0.239
6	1.502	0.750	0.44	2.356	0.525	0.038	0.286
7	2.044	0.875	0.60	2.749	0.612	0.044	0.334
8	2.670	1.000	0.79	3.142	0.700	0.050	0.383
9	3.400	1.128	1.00	3.544	0.790	0.056	0.431
10	4.303	1.270	1.27	3.990	0.889	0.064	0.487
11	5.313	1.410	1.56	4.430	0.987	0.071	0.540
14	7.65	1.693	2.25	5.32	1.185	0.085	0.648
18	13.60	2.257	4.00	7.09	1.58	0.102	0.864

[a] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same weight per foot as the deformed bar.

[b] Bar numbers are based on the number of eighths of an inch included in the nominal diameter of the bars.

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *deformations*—transverse protrusions on a deformed bar.

3.1.2. *deformed bar*—steel bar with protrusions; a bar that is intended for use as reinforcement in reinforced concrete construction.

3.1.2.1. *Discussion*—The surface of the bar is provided with lugs or protrusions that inhibit longitudinal movement of the bar relative to the concrete surrounding the bar in such construction. The lugs or protrusions conform to the provisions of this specification.

3.1.3. *plain bar*—steel bar without protrusions.

3.1.4. *rib*—longitudinal protrusion on a deformed bar.

4. ORDERING INFORMATION

4.1. It shall be the responsibility of the purchaser to specify all requirements that are necessary for material ordered to this specification. Orders for material under this specification should include the following information:

4.1.1. Quantity (mass) [weight],

4.1.2. Name of the material (deformed and plain carbon steel bars for concrete reinforcement), 4.1.3. Size,

4.1.4. Cut length or coils,

4.1.5. Deformed or plain,

4.1.6. Grade,

4.1.7. Packaging (see Section 21),

4.1.8. AASHTO designation and year of issue, and

4.1.9. Certified mill test reports (if desired). (See Section 19.)

5. MATERIAL AND MANUFACTURE

5.1. The bars shall be rolled from properly identified heats of mold cast or strand cast steel using the electric furnace, basic-oxygen, or open-hearth process.

6. CHEMICAL REQUIREMENTS

6.1. The chemical analysis of each heat of steel shall be determined in accordance with ASTM A 751. The manufacturer shall perform the analysis on test samples taken preferably during the pouring of the heat. The percentages of carbon, manganese, phosphorus, and sulfur shall be determined. The phosphorus content thus determined shall not exceed 0.06 percent.

6.2. An analysis may be made by the purchaser from finished bars. The phosphorus content thus determined shall not exceed that specified in Section 6.1 by more than 25 percent.

7. REQUIREMENTS FOR DEFORMATIONS

7.1. Deformations shall be spaced along the bar at substantially uniform distances. The deformations on opposite sides of the bar shall be similar in size, shape, and pattern.

7.2. The deformations shall be placed with respect to the axis of the bar so that the included angle is not less than 45º. Where the line of deformations forms an included angle with the axis of the bar from 45º to 70º inclusive, the deformations shall alternately reverse in direction on each side, or those on one side shall be reversed in direction from those on the opposite side. Where the line of deformation is over 70º, a reversal in direction is not required.

7.3. The average spacing or distance between deformations on each side of the bar shall not exceed seven-tenths of the nominal diameter of the bar.

7.4. The overall length of deformations shall be such that the gap (measured as a cord) between the ends of the deformations shall not exceed 12.5 percent of the nominal perimeter of the bar. Where the ends terminate in a rib, the width of the rib shall be considered as the gap between these ends. The summation of the gaps shall not exceed 25 percent of the nominal perimeter of the bar. The nominal perimeter of the bar shall be 3.1416 times the nominal diameter.

7.5. The spacing, height, and gap of deformations shall conform to the requirements prescribed in Table 1 [Table 2].

8. MEASUREMENTS OF DEFORMATIONS

8.1. The average spacing of deformations shall be determined by measuring the length of a minimum of ten spaces and dividing that length by the number of spaces included in the measurement. The measurement shall begin from a point on a deformation at the beginning of the first space to a corresponding point on a deformation after the last included space. Spacing measurements shall not be made over a bar area containing bar marking symbols involving letters or numbers.

8.2. The average height of deformations shall be determined from measurements made on not less than two typical deformations. Determinations shall be based on three measurements per deformation, one at the center of the overall length and the other two at the quarter points of the overall length.

8.3. Insufficient height, insufficient circumferential coverage, or excessive spacing of deformations shall not constitute cause for rejection unless it has been clearly established by determinations on each lot (Note 2) tested that typical deformation height, gap, or spacing do not conform to the minimum requirements prescribed in Section 7. No rejection may be made on the basis of measurements if fewer than ten adjacent deformations on each side of the bar are measured.

Note 2—A lot is defined as all the bars of one bar number and pattern of deformation contained in an individual shipping release or shipping order.

9. TENSILE REQUIREMENTS

9.1. The material, as represented by the test specimens, shall conform to the requirements for tensile properties prescribed in Table 3 [Table 4].

Table 3—Tensile Requirements, SI Units

	Grade 280[a]	Grade 420	Grade 520[b]
Tensile strength, min MPa	420	620	690
Yield strength, min Mpa	280	420	520
Elongation in 200 mm, min %			
Bar Designation No.			
10	11	9	—
13, 16	12	9	—
19	12	9	7
22, 25	—	8	7
29, 32, 36	—	7	6
43, 57	—	7	6

[a] Grade 280 bars are furnished only in sizes 10 through 19.

[b] Grade 520 bars are furnished only in sizes 19 through 57.

Table 4—Tensile Requirements

	Grade 40[a]	Grade 60	Grade 75[b]
Tensile strength, min psi	60000	90000	100000
Yield strength, min psi	40000	60000	75000
Elongation in 8 in., min %			
Bar Designation No.			
3	11	9	—
4, 5	12	9	—
6	12	9	7
7, 8	—	8	7
9, 10, 11	—	7	6
14, 18	—	7	6

[a] Grade 40 bars are furnished only in sizes 3 through 6.

[b] Grade 75 bars are furnished only in sizes 11, 14, and 18.

9.2. The yield point or yield strength shall be determined by one of the following methods:

9.2.1. The yield point shall be determined by drop of the beam or halt of the point method as described in Section 13.1.1 of T 244.

9.2.2. Where the steel tested does not exhibit a well-defined yield point, the yield point shall be determined at extension under load using an autographic diagram method or an extensometer as described in Sections 13.1.2 and 13.1.3 of T 244.

The extension under load shall be 0.005 mm/mm [0.005 in./in.] of gauge length (0.5 percent) for Grade 280 [40] and Grade 420 [60] and shall be 0.0035 mm/mm [0.0035 in./in.] of gauge length (0.35 percent) for Grade 520 [75]. When material is furnished in coils, the test sample must be straightened prior to placing it in the jaws of the tensile machine. Straightening shall be done carefully to avoid the formation of local sharp bends and to minimize cold work. Insufficient straightening before attaching the extensometer can result in lower-than-actual yield strength readings.

9.3. The percentage of elongation shall be as prescribed in Table 3 [Table 4] when tested in accordance with Section 13.4 of T 244.

10. BENDING REQUIREMENTS

10.1. The bend-test specimen shall withstand being bent around a pin without cracking on the outside radius of the bent portion when tested in accordance with T 285. The requirements for angle of bending and sizes of pins are prescribed in Table 5 [Table 6]. When material is furnished in coils, the test sample must be straightened prior to placing it in the bend tester.

10.2. The bend test shall be made on specimens of sufficient length to ensure free bending and with apparatus which provides:

10.2.1. Continuous and uniform application of force throughout the duration of the bending operation.

10.2.2. Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate.

10.2.3. Close wrapping of the specimen around the pin during the bending operation.

10.3. It is permissible to use more severe methods of bend testing, such as placing a specimen across two pins free to rotate and applying the bending force with a fixed pin. When failures occur under more severe methods, retests shall be permitted under the bend test method prescribed in Section 10.2.

Table 5—Bend Test Requirements, SI Units

Bar Designation No.	Pin Diameter for Bend Test[a]		
	Grade 280	Grade 420	Grade 520
10, 13, 16	$3^1/_2$ *d* [b]	$3^1/_2$ *d*	—
19	5 *d*	5 *d*	5 *d*
22, 25	—	5 *d*	5 *d*
29, 32, 36	—	7 *d*	7 *d*
43, 57, (90°)	—	9 *d*	9 *d*

[a] Test bends 180 degrees unless noted otherwise.

[b] *d* = nominal diameter of specimen.

Table 6—Bend Test Requirements

Bar Designation No.	Pin Diameter for Bend Test[a]		
	Grade 40	Grade 60	Grade 75
3, 4, 5	$3^1/_2$ *d* [b]	$3^1/_2$ *d*	—
6	5 *d* [b]	5 *d*	—
7, 8	—	5 *d*	—
9, 10	—	7 *d*	—
11	—	7 *d*	7 *d*
14, 18, (90°)	—	9 *d*	9 *d*

[a] Test bends 180 degrees unless noted otherwise.

[b] *d* = nominal diameter of specimen.

11. PERMISSIBLE VARIATION IN MASS [WEIGHT]

11.1. The permissible variation shall not exceed 6 percent under nominal mass [weight], except for bars smaller than 9.5 mm [$^3/_8$ in.] plain round, the permissible variation in mass [weight] shall be computed upon the basis of the permissible variation in diameter in ASTM A 510M [ASTM A 510]. For larger bars up to and including 63.5 mm [2 ½ in.], use AASHTO M 160. Reinforcing bars are evaluated on the basis of nominal mass [weights]. In no case shall the overmass [overweight] of any bar be the cause for rejection.

11.2. The specified limit of variation shall be evaluated in accordance with ASTM E 29 (rounding method).

12. FINISH

12.1. The bar shall be free of detrimental surface imperfections.

12.2. Rust, seams, surface irregularities, or mill scale shall not be cause for rejection, provided the weight, dimensions, cross-sectional area, and tensile properties of a hand wire-brushed test specimen are not less than the requirements of this specification.

12.3. Surface imperfections other than those specified in Section 12.2 shall be considered detrimental when specimens containing such imperfections fail to conform to either tensile or bending requirements. Examples include, but are not limited to, laps, seams, scabs, slivers, cooling or casting cracks, and mill or guide marks (Notes 3 and 4).

Note 3—Reinforcing bar intended for epoxy coating application should have surfaces with a minimum of sharp edges to achieve proper cover. Particular attention should be given to bar marks and deformations, where coating difficulties are prone to occur.

Note 4—Deformed bars destined to be mechanically spliced or butt-welded may require a certain degree of roundness in order for the splices to adequately achieve strength requirements.

13. TEST SPECIMENS

13.1. All mechanical tests shall be conducted in accordance with Test Methods and Definitions T 244 including Annex A9.

13.2. Tension test specimens shall be the full section of the bar as rolled. The unit stress determinations on full-sized specimens shall be based on the nominal bar area.

13.3. The bend-test specimens shall be the full section of the bar as rolled.

14. NUMBER OF TESTS

14.1. For bar sizes No. 10 to 36 [3 to 11], inclusive, one tension test and one bend test shall be made of the largest size rolled from each heat. If, however, material from one heat differs by three or more designation numbers, one tension and one bend test shall be made from both the highest and lowest designation numbers of the deformed bars rolled.

14.2. For bar sizes No. 43 and 57 [14 and 18] bars, one tension test and one bend test shall be made of each size from each heat.

14.3. For all bar sizes, one set of dimensional property tests, including bar mass [weight] and spacing, height, and gap of deformations, shall be made of each bar size rolled from each heat.

15. RETESTS

15.1. If results of an original tension specimen fail to meet the specified minimum requirements and are within 14 MPa [2000 psi] of the required tensile strength, within 7 MPa [1000 psi] of the required yield strength, or within two percentage units of the required elongation, a retest shall be permitted on two random specimens for each original tension specimen failure from the lot. Both retest specimens shall meet the requirements of this specification.

15.2. If a bend test fails for reasons other than mechanical reasons or flaws in the specimen as described in Sections 15.4.2 and 15.4.3, a retest shall be permitted on two random specimens from the same lot. If the results of both test specimens meet the specified requirements, the lot shall be accepted. The retest shall be performed on test specimens that are at air temperature, but not less than 16ºC [60ºF].

15.3. If a mass [weight] test fails for reasons other than flaws in the specimen as described in Section 15.4.3, a retest shall be permitted on two random specimens from the same lot. Both retest specimens shall meet the requirements of this specification.

15.4. If the original test or any of the random retests fails because of reasons listed in Sections 15.4.1, 15.4.2, or 15.4.3, the test shall be considered an invalid test:

15.4.1. The elongation property of any tension test specimen is less than that specified and any part of the fracture is outside the middle half of the gauge length, indicated by scribe marks on the specimen before testing,

Note 5—Marking specimens with multiple scribes or punch marks can reduce the occurrence of fracture outside or near these marks and the need for declaring the test invalid.

15.4.2. Mechanical reasons such as failure of testing equipment or improper specimen preparation,

15.4.3. Flaws are detected in a test specimen, either before or during the performance of the test.

15.5. The original results from Sections 15.4.1, 15.4.2, or 15.4.3 shall be discarded and the test shall be repeated on a new specimen from the same lot.

16. INSPECTION

16.1. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests (except product analysis) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

16.2. *For Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein and may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification, where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

17. REJECTION

17.1. Unless otherwise specified, any rejection based on tests made in accordance with Section 6.2 shall be reported to the manufacturer within five working days from the receipt of samples by the purchaser.

17.2. Material that shows injurious defects subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

18. REHEARING

18.1. Samples tested in accordance with Section 6.2 that represent rejected material shall be preserved for 2 weeks from the date rejection is reported to the manufacturer. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

19. TEST REPORTS

19.1. When specified in the purchase order, report the following information, on a per-heat basis. Additional items may be reported as requested or desired.

19.1.1. Chemical analysis, including carbon, manganese, phosphorus, and sulfur.

19.1.2. Tensile properties.

19.1.3. Bend test.

19.2. Material Test Report, Certificate of Inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

20. MARKING

20.1. When loaded for mill shipment, bars shall be properly separated and tagged with the manufacturer's heat or test identification number.

20.2. Each producer shall identify the symbols of his marking system.

20.3. All bars produced to this specification, except plain round bars which shall be tagged for grade, shall be identified by a distinguishing set of marks legibly rolled into the surface of one side of the bar to denote, in the following order:

20.3.1. *Point of Origin*—Letter or symbol established as the producer's mill designation.

20.3.2. *Size Designation*—Arabic number corresponding to bar designation number of Table 1 [Table 2].

20.3.3. *Type of Steel*—Letter *S* indicates that the bar was produced to this specification or for Grade 420 [60] bars only; letters *S* and *W* indicate that the bar was produced to meet both Specifications M 31M/M 31 and ASTM A 706/A 706M.

20.3.4. *Minimum Yield Designation*—For Grade 420 [60] bars, either the number 4 [60] or a single continuous longitudinal line through at least five spaces offset from the center of the bar side. For Grade 520 [75] bars, either the number 5 [75] or two continuous longitudinal lines through at least five spaces offset each direction from the center of the bar. (No marking designation for Grade 280 [40] bars.)

20.3.5. It shall be permissible to substitute: a metric size bar of Grade 280 for the corresponding inch-pound size bar of Grade 40, a metric size bar of Grade 420 for the corresponding inch-pound size bar of Grade 60, and a metric size bar of Grade 520 for the corresponding inch-pound size bar of Grade 75.

21. PACKAGING

21.1. When specified in the purchase order, packaging shall be in accordance with the procedures in ASTM A 700.

21.2. *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be as specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

22. KEYWORDS

22.1. Concrete reinforcement; deformations (protrusions); steel bars.

---

[1] Agrees with ASTM A 615/A 615M-09 except for the bend testing procedure, which is referenced to T 285 and Section 9.2.2.

Standard Specification for

Steel Wire, Plain, for Concrete Reinforcement

AASHTO Designation: M 32M/M 32-09
ASTM Designation: A 82/A 82M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Wire, Plain, for Concrete Reinforcement

AASHTO Designation: M 32M/M 32-09
ASTM Designation: A 82/A 82M-07

1. SCOPE

1.1. This specification covers cold-drawn, steel wire, as drawn or galvanized, to be used as such or in fabricated form, for the reinforcement of concrete, in sizes not less than 2.03 mm [0.080 in.] nominal diameter.

1.2. Supplement S1 describes high-strength wire, which shall be furnished when specifically ordered. It shall be permissible to furnish high-strength wire in place of regular wire if mutually agreed to by the purchaser and the manufacturer.

1.3. The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard. (The inch-pound units are shown in brackets except in Table 6.)

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 55M/M 55, Steel Welded Wire Reinforcement, Plain, for Concrete
- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 641/A 641M, Standard Specification for Zinc-Coated (Galvanized) Carbon Steel Wire
- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- E 83, Standard Practice for Verification and Classification of Extensometer Systems

2.3. *Military Standard*:

- MIL-STD-129, Marking for Shipment and Storage

2.4. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

2.5. *Other Standard*:

- ACI 318, Building Code Requirements for Structural Concrete

3. ORDERING INFORMATION

3.1. It shall be the responsibility of the purchaser to specify all requirements that are necessary for the manufacture and delivery of the wire under this specification. Such requirements to be considered include, but are not limited to, the following:

3.1.1. Quantity (mass) [weight],

3.1.2. Name of material (cold-drawn steel wire for concrete reinforcement),

3.1.3. Wire size number (see Section 8),

3.1.4. Yield strength measurement (see Sections 5.1 and 11.3),

3.1.5. Packaging (see Section 15),

3.1.6. AASHTO designation and year of issue, and

3.1.7. Special requirements, if any (see Supplement S1).

Note 1—A typical ordering description is as follows: 50000 kg [100000 lb] cold-drawn steel wire for concrete reinforcement, size No. W5 in 800 kg [2000 lb] secured coils, to M 32M/M 32-___.

4. MATERIALS AND MANUFACTURE

4.1. The steel shall be made by one or more of the following processes: open-hearth, electric-furnace, or basic-oxygen.

4.2. The wire shall be cold drawn from rods that have been hot rolled from billets.

4.3. Unless otherwise specified, the wire shall be supplied uncoated. When specified as galvanized, it shall be galvanized at finish size.

5. MECHANICAL PROPERTY REQUIREMENTS

5.1. *Tension Tests*:

5.1.1. When tested as described in Methods and Definitions T 244, the material, except as specified in Section 5.1.2, shall conform to the tensile property requirements in Table 1, based on nominal area of wire.

Table 1—Tension Test Requirements

Tensile strength, min MPa [ksi]	550 [80]
Yield strength, min MPa [ksi]	485 [70]
Reduction of area, min percent	30[a]

[a] For material testing over 690 MPa [100 ksi] tensile strength, the reduction of area shall be not less than 25 percent.

5.1.2. When required by the purchaser, yield strength shall be determined as described using a Class B-1 extensometer described in ASTM E 83. The yield strength shall be determined as described in Test Methods and Definitions T 244 at an extension under load of 0.5 percent of gauge length. It shall be permissible to remove the extensometer after the yield strength has been determined. The wire shall meet the requirements of Table 1 or Table 2, whichever is applicable.

5.1.3. For material to be used in the fabrication of welded wire reinforcement, the tensile and yield strength properties shall conform to the requirements given in Table 2, based on nominal area of the wire.

Table 2—Tension Test Requirements [Material for Welded Wire Reinforcement]

	Size MW7.7 [W1.2] and Larger	Smaller Than Size MW7.7 [W1.2]
Tensile strength, min MPa [ksi]	515 [75]	485 [70]
Yield strength, min MPa [ksi]	450 [65]	385 [56]
Reduction of area, min percent	30[a]	30[a]

[a] For material testing over 690 MPa [100 ksi] tensile strength, the reduction of area shall be not less than 25 percent.

5.1.4. The material shall not exhibit a definite yield point as evidenced by a distinct drop of the beam or halt in the gauge of the testing prior to reaching ultimate tensile load.

5.2. *Bend Tests*—The bend-test specimen shall stand being bent at room temperature through 180 degrees without cracking on the outside of the bent portion, as prescribed in Table 3.

Table 3—Bend-Test Requirements

Size Number of Wire	Bend Test
MW45 [W7] and smaller	Bend around a pin the diameter of which is equal to the diameter of the specimen.
Larger than MW45 [W7]	Bend around a pin the diameter of which is equal to twice the diameter of the specimen.

5.3. *Reduction of Area Test*—The reduction of area shall be determined as described in Test Methods and Definitions T 244, and the wire shall conform to the reduction of area requirements in Table 1 and Table 2.

6. PERMISSIBLE VARIATION IN WIRE DIAMETER

6.1. The permissible variation in the diameter of the wire shall conform to the requirements in Table 4.

6.2. The difference between the maximum and minimum diameters, as measured on any given cross section of the wire, shall not exceed the tolerances listed in Table 4 for the given wire size.

Table 4—Permissible Variation in Wire Diameter

Size Number	Nominal Diameter, mm [in.]	Permissible Variation Plus and Minus, mm [in.]
Smaller than MW32 [W5]	under 6.40 [0.252]	0.08 [0.003]
MW32 [W5] to MW77 [W12], incl	6.40 [0.252] to 9.93 [0.391], incl	0.10 [0.004]
Over MW77 [W12] to MW129 [W20], incl	over 9.93 [0.391] to 12.83 [0.505], incl	0.15 [0.006]
Over MW129 [W20]	over 12.83 [0.505]	0.20 [0.008]

7. WORKMANSHIP, FINISH, AND APPEARANCE

7.1. The wire shall be free of detrimental imperfections and shall have a workmanlike finish.

7.2. Galvanized wire shall be produced as described in ASTM A 641/A 641M, regular coating.

7.3. Rust, surface seams, or surface irregularities shall not be a cause for rejection provided the requirements of Section 7.4 are met; and the minimum dimensions and mechanical properties of a hand wire-brushed test specimen are not less than the requirements of this specification.

7.4. Wire intended for welded wire reinforcement shall be sufficiently free of rust and drawing lubricant so as not to interfere with electric resistance welding.

8. GENERAL REQUIREMENTS

8.1. When wire for concrete reinforcement is ordered by size number, the relation between size number, diameter, and area shown in Table 5 and Table 6 shall apply.

Table 5—Dimensional Requirements for Plain Wire—SI Units Wire Sizes

Size Number[a]	Nominal Diameter mm [in.]	Nominal Area mm^2 [$in.^2$]
MW 5	2.52 [0.099]	5 [0.008]
MW 10	3.57 [0.140]	10 [0.016]
MW 15	4.37 [0.172]	15 [0.023]
MW 20	5.05 [0.199]	20 [0.031]
MW 25	5.64 [0.222]	25 [0.039]
MW 30	6.18 [0.243]	30 [0.047]
MW 35	6.68 [0.263]	35 [0.054]
MW 40	7.14 [0.281]	40 [0.062]
MW 45	7.57 [0.298]	45 [0.070]
MW 50	7.98 [0.314]	50 [0.078]
MW 55	8.37 [0.329]	55 [0.085]
MW 60	8.74 [0.344]	60 [0.093]
MW 65	9.10 [0.358]	65 [0.101]
MW 70	9.44 [0.372]	70 [0.109]
MW 80	10.10 [0.397]	80 [0.124]
MW 90	10.70 [0.421]	90 [0.140]
MW 100	11.30 [0.444]	100 [0.155]
MW 120	12.40 [0.487]	120 [0.186]
MW 130	12.90 [0.507]	130 [0.202]
MW 200	16.00 [0.628]	200 [0.310]
MW 290	19.20 [0.757]	290 [0.450]

[a] Table 1 represents a hard metrication of the most readily available size in the welded wire reinforcement industry. Table 5 should be used in projects that are designed using SI units. Table 6 should be used on projects designed using inch-pound units. Areas of wire should be checked with the most efficient and readily available material from producers. Other wire sizes are available, and many manufacturers can produce them in 1-mm^2 [0.0015-$in.^2$] increments.

Table 6—Dimensional Requirements for Plain Wire—Inch-Pound Units

Wire Sizes					
Size Number[a]	Nominal Diameter, in [mm.]	Nominal Area, in.^{2} [mm^2]	Size Number	Nominal Diameter, mm [in.]	Nominal Area mm^2 [in.^{2}]
W0.5	0.080 [2.03]	0.005 [3.23]	W11	0.374 [9.50]	0.110 [71.00]
W1.2	0.124 [3.14]	0.012 [7.74]	W12	0.391 [9.93]	0.120 [77.40]
W1.4	0.134 [3.39]	0.014 [9.03]	W14	0.422 [10.70]	0.140 [90.30]
W2	0.160 [4.05]	0.020 [12.90]	W16	0.451 [11.50]	0.160 [103.00]
W2.5	0.178 [4.53]	0.025 [16.10]	W18	0.479 [12.20]	0.180 [116.00]
W2.9	0.192 [4.88]	0.029 [18.70]	W20	0.505 [12.80]	0.200 [129.00]
W3.5	0.211 [5.36]	0.035 [22.60]	W22	0.529 [13.40]	0.220 [142.00]
W4	0.226 [5.73]	0.040 [25.80]	W24	0.553 [14.00]	0.240 [155.00]
W4.5	0.239 [6.08]	0.045 [29.00]	W26	0.575 [14.60]	0.260 [168.00]
W5	0.252 [6.41]	0.050 [32.30]	W28	0.597 [15.20]	0.280 [181.00]
W5.5	0.265 [6.72]	0.055 [35.50]	W30	0.618 [15.70]	0.300 [194.00]
W6	0.276 [7.02]	0.060 [38.70]	W31	0.628 [16.00]	0.310 [200.00]
W8	0.319 [8.11]	0.080 [51.60]	W45	0.757 [19.20]	0.450 [290.00]
W10	0.357 [9.06]	0.100 [64.50]			

[a] This table represents the most recently available sizes in the welded wire enforcement industry in sizes using inch-pound units. Areas of wire should be checked with the most efficient and readily available material from producers. Other wire sizes are available, and many manufacturers can produce them in 0.0015-in.^{2} increments.

9. SAMPLING

9.1. Test specimens for testing mechanical properties shall be full wire sections and shall be obtained from ends of wire coils as drawn or as galvanized. The specimens shall be of sufficient length to perform testing described in Sections 5.1 and 5.2.

9.2. If any test specimen exhibits obvious isolated imperfections that are not representative of the product, it may be discarded and another specimen substituted.

10. NUMBER OF TESTS

10.1. One tension and one bend test shall be made from each 9000 kg [10 tons] or less of each size of wire or fraction thereof in a lot, or a total of seven samples, whichever is fewer. A lot shall consist of all the coils of a single size offered for delivery at the same time.

11. INSPECTION

11.1. The inspector representing the purchaser shall have free entry at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to assure him that the material is being furnished in accordance with this specification.

11.2. Except for yield strength, all tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified. Such tests shall be so conducted as not to interfere unnecessarily with the operation of the works.

11.3. The purchaser shall have the option to require a yield strength measurement to determine compliance with yield strength requirements in Section 5.1, and shall specify that the measurement be performed by the manufacturer at the manufacturer's facilities, a recognized laboratory, or the purchaser's representative at the manufacturer's facilities. Such measurements shall be conducted without unnecessarily interfering with the manufacturing operations.

11.4. *For U.S. Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein. Except as otherwise specified in the contract, the contractor may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

12. REJECTION

12.1. Material that shows detrimental imperfections subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

12.2. Failure of any of the test specimens to comply with the requirements of this specification shall constitute grounds for rejection of the lot represented by the specimen.

12.3. Any rejection based on tests made in accordance with the specification shall be reported to the manufacturer within 2 weeks of the date of inspection or test. The material must be adequately protected and correctly identified in order that the producer may make a proper investigation.

13. REHEARING

13.1. Rejected materials shall be preserved for a period of at least 2 weeks from the date of inspection, during which time the manufacturer shall have the option to make claim for a rehearing and retesting.

13.2. The manufacturer shall have the option to resubmit the rejected lot for reinspection or retesting by inspecting or testing every coil for the property in which the test specimen failed and sorting out nonconforming coils.

14. CERTIFICATION

14.1. When specified in the purchase order or contract, the purchaser shall be furnished with the manufacturer's written certification that the material was manufactured, sampled, tested, and inspected in accordance with, and meets the requirements of, this specification. When specified in the purchase order or contract, a report of the test results shall be furnished. The certification shall include the specification number, year-date of issue, and revision letter, if any.

14.2. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document shall meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the manufacturer.

Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

15. PACKAGING AND MARKING

15.1. The size of the wire, AASHTO specification, and name or mark of the manufacturer shall be marked on a tag securely attached to each coil of wire.

15.2. Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

15.3. When specified in the contract or order, and for the direct procurement by or direct shipment to the U.S. government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for military agencies and in accordance with Fed. Std. No. 123 for civil agencies.

16. KEYWORDS

16.1. Concrete reinforcement; reinforced concrete; reinforcing steels; steel wire.

SUPPLEMENTARY REQUIREMENTS

S1. HIGH-STRENGTH WIRE

S1.1. *Scope*:

S1.1.1 This supplement delineates only those details that relate to high-strength wire and to the mechanical requirements for wire having properties generally as described in this specification.

Note S1—Building codes, for example, ACI 318, permit the use of reinforcement with a yield strength up to 550 MPa [80000 psi]. For compatibility with the codes' design provisions for high-strength reinforcement, this supplement prescribes requirements for the mechanical properties of wire that exceed the minimum values for yield strength and tensile strength in Table 1 and Table 2 of this specification.

S1.2. *Mechanical Property Requirements*:

S1.2.1 Minimum yield strength shall be specified in the purchase order in increments of 17.5 MPa [2500 psi]. When tested, the yield strength shall be determined at an extension under load of 0.0035 mm/mm [0.0035 in./in.].

Note S2—To conform to the limit on yield strength in building codes, the minimum yield strength specified in the purchase order should not be greater than 550 MPa [80000 psi].

S1.2.2 Minimum tensile strength shall be 70 MPa [10000 psi] greater than the specified minimum yield strength.

Note S3—A typical order entry line for minimum yield strength is "72500 psi minimum yield strength" or "500 MPa minimum yield strength."

S1.2.3 The minimum reduction of area shall be 30 percent. For material testing over 690 MPa [100000 psi] tensile strength, the reduction of area shall not be less than 25 percent.

S1.3. *Certification*:

S1.3.1 Certification for material produced to this supplement shall include a report of the test results for yield strength, tensile strength reduction of area, and bend tests. Frequency of testing shall conform to Section 10 of this specification or Section 12 of M 55M/M 55, as applicable.

Standard Specification for

Welded Deformed Steel Bar Mats for Concrete Reinforcement

AASHTO Designation: M 54M/M 54-07
ASTM Designation: A 184/A 184M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Welded Deformed Steel Bar Mats for Concrete Reinforcement

AASHTO Designation: M 54M/M 54-07
ASTM Designation: A 184/A 184M-06

1. SCOPE

1.1 This specification covers material in mat (or sheet) form fabricated from deformed steel bars to be used for the reinforcement of concrete. Mats consist of two layers of bars that are assembled at right angles to each other. Mats shall be assembled by welding at the intersections.

1.2 This specification is applicable to orders in either SI units (M 54M) or inch-pound units (M 54).

1.3 The values stated in either inch-pound units or SI units are to be regarded as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with this specification.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 31M/M 31, Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement

2.2 *ASTM Standard*:

- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- A 706/A 706M, Standard Specification for Low-Alloy Steel Deformed and Plain Bars for Concrete Reinforcement

2.3 *Military Standards*:

- MIL-STD-129, Marking for Shipment and Storage

2.4 *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

3. ORDERING INFORMATION

3.1 It shall be the responsibility of the purchaser to specify all requirements that are necessary for material ordered. Such requirements shall include, but are not limited to, the following:

3.1.1 Quantity,

3.1.2 Size and spacing of members in each direction,

3.1.3 Grade required 280, 420 [40, 60],

3.1.4 Type of steel as appropriate (Section 4), and

3.1.5 AASHTO M 54M/M 54 and year of issue.

Note 1—A typical ordering description is as follows: 1000 bar mats to M 54M-_____; fabricated from Grade 280 bars to M 31M-_____; 150 by 150 mm; No. 10 by 3000 mm longitudinal tip to tip, outer bars spaced 1350 mm; No. 10 by 1500 mm transverse, outer bars spaced 2850 mm. [1000 bar mats to M 54-_____; Grade 40; 6 by 6 in.; No. 4 by 120 in. longitudinal tip to tip, outer bars spaced 54 in.; No. 3 by 60 in.; transverse, outer bars spaced 114 in.].

4. MATERIAL AND MANUFACTURE

4.1 Deformed steel bars of Grades 280 [40] used in the manufacture of welded mats shall conform to M 31M [M 31]. Deformed steel bars of Grade 420 [60] used in the manufacture of welded mats shall conform to M 31M [M 31] or ASTM A 706M [A 706].

5. FABRICATION

5.1 Fabricated mats shall be composed of two layers of bars substantially parallel and perpendicular to each other.

5.1.1 Mats shall be assembled by means of welding to provide attachment at intersections.

5.1.1.1 Welds shall provide attachment at all exterior intersections and at not less than alternate interior intersections.

5.1.1.2 The separation of 5 percent or less of all welded intersections of any mat shall not be cause for rejection provided that no more than half of the welds on any one bar are separated.

5.1.1.3 Welding shall be performed in such a manner that the strength and ductility requirements of the material specification in Section 4 are met when a specimen is tested across a point of weld.

Note 2—Welding of the mat intersections has generally been performed without problems, but care should be taken when welding reinforcing bars with carbon equivalent levels above 0.55 percent, in order to prevent cracking in the weld area.

6. MECHANICAL PROPERTIES

6.1 Mats shall be capable of withstanding a static load of 670 N [150 lbf] exerted perpendicular to the plane of the mat tending to separate the bars, with no apparent loosening when applied to one intersection of connected bars.

6.2 *Number of Tests*:

6.2.1 One sample consisting of not fewer than two connections on the same transverse member shall be tested for conformance with the provisions of Sections 5.1.1.3 and 6.1 from each 7000 m^2 [75000 ft^2] of mats or fraction thereof.

6.3 *Test Methods*:

6.3.1 Tension test specimens for determining conformance with Section 5.1.1.3 shall have a welded joint located approximately at the center of the bar being tested, and the cross bar shall extend approximately 25 mm [1 in.] beyond each side. All unit stress determinations shall be based on the nominal area calculated using the nominal diameter specified.

6.3.2 Tests of connections against separation may be performed on an assembled mat by placing blocks under a deformed bar in the upper layer and applying the prescribed load upon the bar in the lower layer.

7. SIZE, DIMENSIONS, AND TOLERANCES

7.1 *Size and Spacing Dimensions*—The sizes, spacings, dimensions, and arrangement of the bar mats shall conform to the design specified by the purchaser. Bars shall extend beyond exterior intersections a distance of not less than 25 mm [1 in.]. The spacing of bars shall average that specified in the design, and the space between individual bars shall not vary more than 6 mm [$^1/_4$ in.] from that specified.

7.2 *Width and Length Tolerances*—The overall length or width of the mats shall not be more than 25 mm [1 in.] greater or less than the specified dimension.

8. FINISH AND SURFACE CONDITION

8.1 The finished mats shall be free of injurious defects in material or workmanship.

8.2 Rust, surface seams, surface irregularities, or mill scale shall not be cause for rejection provided the mass; dimensions, including height of deformation; cross-sectional area; and tensile properties of a hand wire-brushed test specimen are not less than the requirements of this specification.

9. REJECTION AND RETESTS

9.1 Fabricated mats that do not meet the requirements of this specification shall be rejected and reported to the supplier within 5 working days from the receipt of samples by the purchaser.

9.2 In case a test specimen fails to meet the provisions of Section 6.1, two additional samples shall be selected and tested. All retest specimens shall meet the requirements of this specification.

9.3 In case a test specimen fails to meet the provisions of Section 5.1.1.3, all of the remaining bars on the transverse member shall be tested and the average of all tests (including the original test) shall meet the requirements specified in Section 5.1.1.3.

10. INSPECTION AND TEST REPORTS

10.1 *Inspection*—The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's plant that concern the fabrication of the mats ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy that the mats are being furnished in accordance with this specification. All tests and inspection shall be made at the place of fabrication prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with fabricating operations. Inspection as to general workmanship shall be visual.

10.2 *Test Reports on Bar Material*—The manufacturer shall supply test reports showing that the material used in the fabrication of the mats as delivered has fulfilled the tension and bend test requirements of the specified type and grade described in Section 4. The reports shall show the manufacturer's test identification numbers, including the identity of the material.

10.3 A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 3—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI SAC X12.

10.4 *For Government Procurement Only*—Except as otherwise specified in the contract, the contractor shall be responsible for the performance of all inspection and test requirements specified herein. Except as otherwise specified in the contract, the contractor may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

11. REHEARING

11.1 Samples tested in accordance with this specification that represent rejected material shall be preserved for 2 weeks from the date rejection is reported to the manufacturer. In case of dissatisfaction with the results of the tests, the manufacturer shall have the right to make claim for a hearing within that time.

12. PACKAGING AND PACKAGE MARKING

12.1 Packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

12.2 When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for military agencies and with Fed. Std. No. 123 for civil agencies.

12.3 Each bundle of mats shall be marked with a suitable tag showing the name of the manufacturer and other markings to identify it with the order.

Standard Method of Test for

Steel Welded Wire Reinforcement, Plain, for Concrete

AASHTO Designation: M 55M/M 55-09
ASTM Designation: A 185/A 185M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Steel Welded Wire Reinforcement, Plain, for Concrete

AASHTO Designation: M 55M/M 55-09
ASTM Designation: A 185/A 185M-07

1. SCOPE

1.1. This specification covers welded wire reinforcement to be used for the reinforcement of concrete.

Note 1—Welded wire for concrete reinforcement has been described by various terms: welded wire fabric (WWF), fabric, and mesh. The wire reinforcement industry prefers the term "welded wire reinforcement" or WWR as being more representative of the range of products being manufactured. Therefore, the term "welded wire fabric" has been replaced with the term "welded wire reinforcement" in this specification and in related specifications.

1.2. This specification is applicable for orders in either SI units (M 55M) or in inch-pound units (M 55). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity but they are the applicable values when the material is ordered to M 55. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values may result in nonconformance with the specification.

2. REFERENCED DOCUMENTS

AASHTO Standard:

- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement

2.1. *ASTM Standards*:

- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- ASTM Adjuncts: Testing Jig Drawing

2.2. *Military Standard*:

- MIL-STD-129, Marking for Shipment and Storage

2.3. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipment (Civil Agencies)

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *convoluted wire*—when wire for welded reinforcement is formed into a sinusoidal wave shape, it is commonly referred to as convoluted wire. The wire is used in the manufacture of cages for certain applications of concrete pipe reinforcing.

3.1.2. *welded wire reinforcement*—as used within the scope and intent of this specification, designates a material composed of cold-drawn steel wire, as drawn or galvanized, fabricated into sheets or rolls by the process of electric-resistance welding. The finished material shall consist essentially of a series of longitudinal and transverse wires arranged substantially at right angles to each other and welded together at points of intersection.

4. ORDERING INFORMATION

4.1. It shall be the responsibility of the purchaser to specify all requirements that are necessary for the manufacture and delivery of the welded wire reinforcement under this specification. Such requirements to be considered include, but are not limited to, the following:

4.1.1. Quantity (mass or square area),

4.1.2. Name of material (welded wire reinforcement for concrete reinforcement),

4.1.3. Wire spacings and sizes,

4.1.4. Minimum yield strength if Supplement S1 of M 32M/M 32 applies.

4.1.5. Yield strength measurement. The purchaser shall have the options described in M 32M/M 32 under the Inspection section (11.3).

4.1.6. Exclusion of oversteeling, if required (Section 9.4.2),

4.1.7. Length and width of sheets or rolls,

4.1.8. Packaging (Section 16),

4.1.9. Request for outside inspection (if not requested, Section 15.1 applies), and

4.1.10. AASHTO Designation and year of issue.

Note 2—A typical ordering description is as follows: 930 m^2 welded wire reinforcement for concrete reinforcement, 100 × 300-W15 × W6 in flat sheets, 2.4 m wide × 6.1 m long, in secured lifts, to M 55M. [10000 ft^2 welded wire reinforcement for concrete reinforcement, 4 × 12 W15 × W6 in flat sheets, 96 in. wide × 240 in. long, in secured lifts, to M 55.]

5. MATERIALS

5.1. The wire used in the manufacture of welded wire reinforcement shall conform to M 32M/M 32 and its Supplement S1 if so ordered.

5.2. Welded wire reinforcement shall be furnished either in flat sheets or in rolls, as specified by the purchaser.

6. MANUFACTURE

6.1. The wires shall be assembled by automatic machines or by other suitable mechanical means that will assure accurate spacing and alignment of all members of the finished welded wire reinforcement.

6.2. Longitudinal and transverse members shall be securely connected at every intersection by a process of electrical-resistance welding, which employs the principle of fusion combined with pressure.

6.3. Wire of proper yield strength and quality when fabricated in the manner herein required shall result in a strong, serviceable, mat-type product having substantially square or rectangular openings. It shall be fabricated and finished in a workmanlike manner and shall conform to this specification.

Note 3—A variation of manufacturing includes the application of one or more longitudinal convoluted wires at one edge of reinforcement for concrete pipe reinforcing cages. This shape allows the cage ends to be expanded to a larger diameter to accommodate the bell-shaped ends of concrete pipe.

7. MECHANICAL PROPERTY REQUIREMENTS

7.1. *Tensile*—Wire for the production of welded wire reinforcement is described in M 32M/M 32. Tensile tests may be made on wire cut from the welded wire reinforcement and tested either across or between the welds; no fewer than 50 percent shall be across the welds. Tensile tests across the weld shall have the welded intersection located approximately at the center of the wire being tested and the cross wire forming the welded intersection shall extend approximately 25 mm [1 in.] beyond each side of the welded intersection.

Note 4—Tensile, reduction of area, and bend testing are normally done at the time the wire is drawn. The manufacturer's finished product shall meet the requirements of this specification and M 32M/M 32.

7.2. *Reduction of Area*—The ruptured section of the tensile specimen shall be measured to determine this property. In the case of a specimen that has been tested across a weld, the measurement shall be made only when rupture has occurred at a sufficient distance from the center of a weld to permit an accurate measurement of the fractured section. The wire shall meet the minimum reduction of area requirements of M 32M/M 32.

7.3. *Bend Test*—The wire shall withstand the bend test as described in M 32M/M 32 and shall be performed on a specimen taken from between the welds.

7.4. *Weld Shear Strength*—The weld shear strength between longitudinal and transverse wires shall be tested as described in Section 8. The minimum average shear value, in Newtons, shall not be less than 241, multiplied by the nominal area of the larger wire in square millimeters [in pounds-force shall not be less than 35000, multiplied by the nominal area of the larger wire in square inches], where the smaller wire is not less than size W1.2 and has an area of 40 percent or more of the area of the larger wire. Typical examples of the 40 percent or more wire size differential area follow:

Larger	Smaller
Size No. W20	Size No. W8
Size No. W15	Size No. W6
Size No. W10	Size No. W4

7.4.1. Reinforcement having a relationship of longitudinal and transverse wires other than those covered in Section 7.4 shall not be subject to the weld shear requirement.

7.4.2. Weld shear tests for determination of conformance to the requirements of Section 7.4 shall be conducted using a fixture as described in Section 8.

7.4.3. Four welds selected at random from the specimen described in Section 11.2 shall be tested for weld shear strength. The transverse wire of each test specimen shall extend approximately 25 mm [1 in.] on each side of the longitudinal wire. The longitudinal wire of each test specimen shall be of such length below the transverse wire so as to be adequately engaged by the grips of the testing machine. It shall be of such length above the transverse wire that its end shall be above the centerline of the upper bearing of the testing device.

7.4.4. The material shall be deemed to conform to the requirements for weld shear strength if the average of the four samples complies with the value stipulated in Section 7.4. If the average fails to meet the prescribed value, all the welds across the specimen shall then be tested. The reinforcement will be acceptable if the average of all weld shear test values across the specimen meets the prescribed minimum value.

8. WELD SHEAR TEST APPARATUS AND METHODS

8.1. As the welds in welded wire reinforcement contribute to the bonding and anchorage value of the wires in concrete, the weld acceptance tests shall be made in a weld tester that stresses the weld in a manner similar to which it is stressed in concrete. In order to accomplish this, the vertical wire in the weld tester shall be stressed in an axis close to its centerline. Also, the horizontal wire shall be held closely to the vertical wire, and in the same relative position, so as to prevent rotation of the horizontal wire. When the welded wire reinforcement is designed with different wire sizes, the larger diameter wire is the “vertical wire” when tested (see Figure 1).[1]

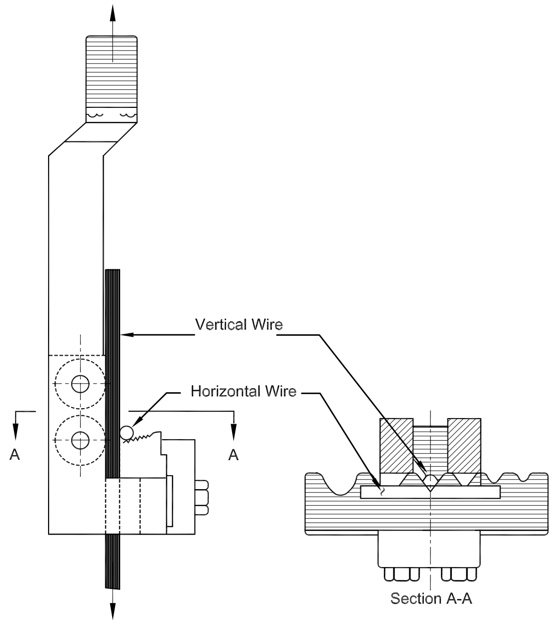

Figure 1—Welded Wire Reinforcement Weld Tester

8.2. Figure 1 shows the details of a typical weld tester together with two anvils that make it possible to test welds for wire up to 16 mm [$^5/_8$ in.] in diameter. This weld tester can be used in most tension testing machines and should be hung in a ball-and-socket arrangement at the center of the machine. This, or a similarly effective fixture designed on the same principle, is acceptable.

8.3. Test specimens should be inserted through the notch in the anvil using the smallest notch available in which the vertical wire will fit loosely. The vertical wire shall be in contact with the surface of the free rotating rollers while the horizontal wire shall be supported by the anvil on each side of the slot. The bottom jaws of the testing machine shall grip the lower end of the vertical wire and the load shall be applied at a rate of stressing not to exceed 690 MPa/min [100000 psi/min].

9. DIMENSIONS, MASS, AND PERMISSIBLE VARIATIONS

9.1. *Width*—The width of welded wire reinforcement shall be considered to be the center-to-center distance between outside longitudinal wires. The permissible variation shall not exceed 13 mm [$^1/_2$ in.] greater or less than the specified width. In case the width of flat sheets or rolls is specified as the overall width (tip-to-tip length of cross wires), the width shall not vary more than ±25 mm [±1 in.] from the specified width.

9.2. *Length*—The overall length of flat sheets, measured on any wire, may vary ±25 mm [±1 in.] or 1 percent, whichever is greater.

9.3. Overhang of the transverse wires shall not project beyond the centerline of each longitudinal edge wire more than a distance of 25 mm [1 in.] unless otherwise specified. When transverse wires are specified to project a specific length beyond the centerline of a longitudinal edge wire, the permissible variation shall not exceed 13 mm [$^1/_2$ in.] greater or less than the specified length.

9.4. The permissible variation in diameter of any wire in the finished welded wire reinforcement shall conform to the tolerances prescribed for the wire before fabrication in M 32M/M 32, with the following exceptions:

9.4.1. Because of the mechanical characteristics of fabricating welded wire reinforcement, the out-of-round requirements shall not apply;

9.4.2. Unless otherwise precluded by the purchaser in 4.1, the manufacturer will be permitted to apply oversized wire (not undersized). The size differential shall not exceed two “W” size increments on sizes W8 and smaller, and four “W” size increments on sizes larger than W8. A “W” size increment is a whole number increment, for example, W5 to W6, or W5.4 to W6.4, etc. In all cases in which such oversteeling is practiced, the producer shall identify the welded wire reinforcement with the style originally ordered.

9.5. The average spacing of wires shall be such that the total number of wires contained in a sheet or roll is equal to or greater than that determined by the specific spacing, but the center-to-center distance between individual members may vary not more than 6.4 mm [$^1/_4$ in.] from the specified spacing. It is understood that sheets of welded wire reinforcement of the specified length may not always contain an identical number of transverse wires and, therefore, may have various lengths of longitudinal overhang.

10. WORKMANSHIP, FINISH, AND APPEARANCE

10.1. Wire of proper grade and quality, when fabricated in the manner herein required, shall result in a strong, serviceable, mesh-type product having substantially square or rectangular openings. It shall be fabricated and finished in a workmanlike manner, as determined by visual inspection, and shall conform to this specification.

11. SAMPLING

11.1. Test specimens for testing mechanical properties shall be obtained by cutting from the finished welded wire reinforcement a full width section, of sufficient length to perform testing described in Sections 7.1 and 7.2.

11.2. Test specimens for determining weld shear properties shall be obtained by cutting from the finished welded wire reinforcement, a full width section of sufficient length to perform testing described in Section 7.4.

11.3. Measurements for conformance to dimensional characteristics shall be made on full sheets or rolls.

11.4. Any test specimen exhibiting obvious imperfections shall be discarded and another specimen substituted.

12. NUMBER OF TESTS

12.1. One test for conformance to tensile strength and bend requirements, and one check for conformance to dimensional characteristics shall be made for each 7000 m^2 [75000 ft^2] of welded wire reinforcement or remaining fraction thereof.

12.2. One test for conformance to weld shear strength requirement shall be made for each 28000 m^2 [300000 ft^2] or remaining fraction thereof.

13. INSPECTION AND TESTS

13.1. The inspector representing the purchaser shall have free entry at all times while work on the contract of the purchaser is being performed to all parts of the manufacturer's facilities that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to assure that the material is being furnished in accordance with this specification.

13.2. Except for yield strength, all tests and inspections shall be made at the manufacture's facilities prior to shipment, unless otherwise specified. Such tests shall be so conducted as not to interfere unnecessarily with the operation of the manufacturer's facilities.

13.3. If the purchaser considers it desirable to determine compliance with the yield strength requirements of M 32M/M 32, yield strength tests may be made in a recognized laboratory, or their representatives may make the test at the mill, if such tests do not interfere unnecessarily with the mill operations.

13.4. *For U.S. Government Procurement Only*—The purchaser shall be furnished a manufacturer's certification of conformance to M 32M/M 32 for each production date or production lot shipped. A production lot shall not exceed 28000 m^2 [300 000 ft^2], and certifications shall be traceable to specified date(s) of production marked on the product bundle prior to shipment. Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspections and test requirements specified herein. Except as otherwise specified in the contract, the contractor shall have the option to use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

14. REJECTION AND REHEARING

14.1. Unless otherwise specified, any rejection shall be reported to the manufacturer within 5 days from the time of selection of test specimens.

14.2. In case a specimen fails to meet the tension or bend test, the material shall not be rejected until two additional specimens taken from other wires in the same sheet or roll have been tested. The material shall be considered as meeting the specification in respect to any prescribed tensile property, provided the tested average for the three specimens, including the specimen originally tested, is equal to or exceeds the required minimum for the particular property in question, and provided further that none of the three specimens develops less than 80 percent of the required minimum for the tensile property in question. The material shall be considered as meeting this specification with respect to bend test requirements, provided both additional specimens satisfactorily pass the prescribed bend test.

14.3. Any material that is found not to meet the requirements of this specification subsequent to its acceptance at the manufacturer's facilities shall be subject to rejection and the manufacturer shall be promptly notified.

14.4. Welded intersections shall withstand normal shipping and handling without becoming broken, but the presence of broken welds, regardless of cause, shall not constitute cause for rejection unless the number of broken welds per sheet exceeds 1 percent of the total number of intersections in a sheet. For material furnished in rolls, not more than 1 percent of the total number of intersections in 14 m^2 [150 ft^2] of welded wire reinforcement shall be broken. Not more than one-half the permissible maximum number of broken welds shall be located on any one wire.

14.5. In the event of rejection because of failure to meet the weld shear requirements, four additional specimens shall be taken from four different sheets or rolls and tested in accordance with Section 8. If the average of all the weld shear tests performed does not meet the requirement, the material shall be rejected.

14.6. In the event of rejection because of failure to meet the requirements for dimensions, the amount of material rejected shall be limited to those individual sheets or rolls that fail to meet this specification.

14.7. Rust, surface seams, or surface irregularities will not be cause for rejection provided the minimum dimensions, cross-sectional area, and tensile properties of a hand wire-brushed test specimen are not less than the requirements of this specification.

14.8. *Rehearing*—Rejected materials shall be preserved for a period of at least 2 weeks from the date of inspection, during which time the manufacturer shall be permitted to make claim for a rehearing and retesting.

15. CERTIFICATION

15.1. If outside inspection is waived, a manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material. The certification shall include the specification number, year-date of issue and revision letter, if any.

15.2. This conformance is predicated upon testing and acceptance of wire prior to fabrication, coupled with random shear testing during production. The purchaser shall be furnished a manufacturer's certification of conformance to M 32M/M 32 for each production date or production lot shipped. A production lot shall not exceed 28000 m^2 [300 000 ft^2]. Any purchaser shall have the right to invoke any of the provisions of Section 13.4.

15.3. When Supplemental S1 of M 32M/M 32 is specified for the material, test results for yield strength, tensile strength, reduction of area, and bend tests shall be reported (S1.2.1 of M 32M/M 32).

15.4. A material test report, certificate of inspection or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the manufacturer. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 5—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI ASC X12.

16. PACKAGING AND MARKING

16.1. Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

16.2. When welded wire reinforcement is furnished in flat sheets, it shall be assembled in bundles of convenient size containing not more than 150 sheets and securely fastened together.

16.3. When welded wire reinforcement is furnished in rolls, each roll shall be secured so as to prevent unwinding during shipping and handling.

16.4. Each bundle of flat sheets and each roll shall have attached thereto a suitable tag bearing the name of the manufacturer, description of the material, M 55M/M 55, and such other information as may be specified by the purchaser.

16.5. When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for U.S. military agencies and in accordance with Fed. Std. No. 123 for U.S. government civil agencies.

17. KEYWORDS

17.1. Concrete reinforcement; reinforced concrete; reinforcing steels; steel wire; welded wire reinforcement.

Standard Specification for

Steel Strand, Uncoated Seven-Wire for Concrete Reinforcement

AASHTO Designation: M 203M/M 203-07
ASTM Designation: A 416/A 416M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Strand, Uncoated Seven-Wire for Concrete Reinforcement

AASHTO Designation: M 203M/M 203-07
ASTM Designation: A 416/A 416M-06

1. SCOPE

1.1. This specification covers two types and two grades of steel strand, uncoated seven-wire for use in pretensioned and posttensioned prestressed concrete construction. The two types of strand are low-relaxation and stress-relieved (normal-relaxation). Low-relaxation strand shall be regarded as the standard type. Stress-relieved (normal-relaxation) strand will not be furnished unless specifically ordered, or by arrangement between purchaser and supplier. Grade 1725 [250] and Grade 1860 [270] have minimum ultimate strengths of 1725 MPa [250 ksi] and 1860 MPa [270 ksi], respectively, based on the nominal area of the strand.

1.2. The values stated in either inch-pound units or SI units are to be regarded as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.3. The supplementary requirements in S1 shall be specified for 15.24-mm [0.600-in.] diameter uncoated seven-wire steel strand if needed for applications in prestressed ground anchors.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 244, Mechanical Testing of Steel Products

2.2. *ASTM Standards*:

- A 981, Standard Test Method for Evaluating Bond Strength for 15.2 mm (0.6 in.) Diameter Prestressing Steel Strand, Grade 270, Uncoated, Used in Prestressed Ground Anchors
- E 328, Standard Test Methods for Stress Relaxation for Materials and Structures

2.3. *IEEE/ASTM Standard*:

- SI 10, American National Standard for Use of the International System of Units (SI): The Modern Metric System

2.4. *Military Standards*:

- MIL-STD-129, Marking for Shipment and Storage
- MIL-STD-163, Steel Mill Products Preparation for Shipment and Storage

2.5. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *strand*—all strand shall be of the seven-wire type having a center wire enclosed tightly by six helically placed outer wires with a uniform pitch of not less than 12 and not more than 16 times the nominal diameter of the strand.

3.1.1.1. *Discussion*—The direction of lay may be either right or left hand; however, strands of different lays should not be spliced together.

4. ORDERING INFORMATION

4.1. Orders for seven-wire low-relaxation or stress-relieved (normal-relaxation) strand under this specification should include the following information:

4.1.1. Quantity (meters) [feet],

4.1.2. Diameter of strand,

4.1.3. Grade of strand,

4.1.4. Type of strand,

4.1.5. Packaging,

4.1.6. AASHTO designation and year of issue, and

4.1.7. Special requirements, if any.

Note 1—A typical ordering description is as follows: 25600 m [84000 ft], 13 mm [0.5 in.], Grade 1860 [270] low-relaxation strand, in 3600-m [12000-ft] reelless packs to M 203M/M 203-____.

5. MATERIALS AND MANUFACTURE

5.1. *Base Metal*—The base metal shall be carbon steel of such quality that when drawn to wire, fabricated into strand, and then thermally treated, it shall have the properties and characteristics prescribed in this specification.

5.2. *Wire*—The wire from which the strand is to be fabricated shall be round and have a dry-drawn finish.

Note 2—This product is a composite of seven wires and is produced to mechanical properties only; the chemical composition of all wires or any individual wire is not pertinent to this application, and heat identity is not necessarily maintained. It is possible that wire from more than one heat may be used in the manufacture of a reel or pack. Traceability is based on pack identity as maintained and reported by the manufacturer.

5.3. *Treatment*—After stranding, low-relaxation strand shall be subjected to a continuous thermal-mechanical treatment to produce the prescribed mechanical properties. For stress-relieved (normal-relaxation) strand, only thermal treatment is necessary. Temper colors that may result from the thermal operation are considered normal for the finished appearance of this strand.

6. MECHANICAL PROPERTIES

6.1. Methods of testing for mechanical properties are described in Appendix A7 of T 244. Low-relaxation strand shall also be tested as prescribed in ASTM E 328.

6.2. *Breaking Strength*—The breaking strength of the finished strand shall conform to the requirements prescribed in Table 1.

6.3. *Yield Strength*—Yield strength in kN [pounds] shall be measured at 1 percent extension under load. The minimum yield strength shall be 90 percent for low-relaxation strand and 85 percent for stress-relieved [normal-relaxation] strand of the breaking strength listed in Table 1. Initial loads for the test and minimum yield strengths are listed in Table 2.

Table 1—Breaking Strength Requirements

Strand Designation No.	Nominal Diameter of Strand, mm [in.]	Minimum Breaking Strength of Strand, kN [lbf]	Nominal Steel Area of Strand, mm^2 [in.^{2}]	Nominal Mass of Strand, g/m [lb/1000 ft]
		Grade 1725 [250]		
6	6.4 [0.250]	40.0 [9000]	23.2 [0.036]	182 [122]
8	7.9 [0.313]	64.5 [14500]	37.4 [0.058]	294 [197]
9	9.5 [0.375]	89.0 [20000]	51.6 [0.080]	405 [272]
11	11.1 [0.438]	120.1 [27000]	69.7 [0.108]	548 [367]
13	12.7 [0.500]	160.1 [36000]	92.9 [0.144]	730 [490]
15	15.2 [0.600]	240.2 [54000]	139.4 [0.216]	1094 [737]
		Grade 1860 [270]		
9	9.53 [0.375]	102.3 [23000]	54.8 [0.085]	432 [290]
11	11.11 [0.438]	137.9 [31000]	74.2 [0.115]	582 [390]
13	12.70 [0.500]	183.7 [41300]	98.7 [0.153]	775 [520]
13a	13.20 [0.520]	200.2 [45000]	107.7 [0.167]	844 [568]
14	14.29 [0.563]	230.0 [51700]	123.9 [0.192]	970 [651]
15	15.24 [0.600]	260.7 [58600]	140.0 [0.217]	1102 [740]
18	17.78 [0.700]	353.2 [79400]	189.7 [0.294]	1487 [1000]

Table 2—Yield Strength Requirements

Strand Designation No.	Nominal Diameter of Strand mm [in.]	Initial Load, kN [lbf]	Minimum Load at 1% Extension, kN [lbf] Low-Relaxation	Minimum Load at 1% Extension, kN [lbf] Normal-Relaxation
		Grade 1725 [250]		
6	6.4 [0.250]	4.0 [900]	36.0 [8100]	34.0 [7650]
8	7.9 [0.313]	6.5 [1450]	58.1 [13050]	54.7 [12300]
9	9.5 [0.375]	8.9 [2000]	80.1 [18000]	75.6 [17000]
11	11.1 [0.438]	12.0 [2700]	108.1 [24300]	102.3 [23000]
13	12.7 [0.500]	16.0 [3600]	144.1 [32400]	136.2 [30600]
15	15.2 [0.600]	24.0 [5400]	216.2 [48600]	204.2 [45900]
		Grade 1860 [270]		
9	9.53 [0.375]	10.2 [2300]	92.1 [20700]	87.0 [19550]
11	11.11 [0.438]	13.8 [3100]	124.1 [27900]	117.2 [26350]
13	12.70 [0.500]	18.4 [4130]	165.3 [37170]	156.1 [35100]
13a	13.20 [0.520]	20.0 [4500]	180.1 [40500]	170.1 [38250]
14	14.29 [0.563]	23.0 [5170]	207.0 [46530]	195.5 [43950]
15	15.24 [0.600]	26.1 [5860]	234.6 [52740]	221.5 [49800]
18	17.78 [0.700]	35.3 [7940]	318.0 [71500]	300.2 [67500]

6.3.1. The extension under load shall be measured by an extensometer calibrated with the smallest division not larger than 0.0001 mm/mm [0.0001 in./in.] of gauge length.

6.4. *Elongation*—The total elongation under load shall not be less than 3.5 percent using a gauge length of not less than 600 mm [24 in.]. It shall be permissible to determine the total elongation value by adding to the 1.0 percent yield extension the percent extension or movement between the jaws gripping the strand after yield determination. The percent is calculated on the new base length of jaw-to-jaw distance.

6.5. *Relaxation Properties*—Low-relaxation strand shall have relaxation losses of not more than 2.5 percent when initially loaded to 70 percent of specified minimum breaking strength or not more than 3.5 percent when loaded to 80 percent of specified minimum breaking strength of the strand after 1000 hours tested under the conditions listed in Sections 6.5.1 through 6.5.7.

6.5.1. If required, relaxation evidence shall be provided from the manufacturer’s records of tests on similarly dimensioned strand of the same grade.

6.5.2. The temperature of the test specimen shall be maintained at 20 ± 2ºC [68 ± 3.5ºF].

6.5.3. The test specimen shall not be subjected to loading prior to the relaxation test.

6.5.4. The initial load shall be applied uniformly over a period of not less than 3 minutes and not more than 5 minutes, and the gauge length shall be maintained constant; load-relaxation readings shall commence 1 minute after application of the total load.

6.5.5. Overstressing of the test specimen during the loading operation shall not be permitted.

6.5.6. The duration of the test shall be 1000 hours or a shorter period of at least 200 hours, provided it can be shown by records that an extrapolation of the shorter period test results to 1000 hours will provide similar relaxation values as the full 1000-hours test.

6.5.7. The test gauge length should be at least 60 times the nominal diameter. If this gauge length exceeds the capacity of the extensometer or testing machine, then it shall be permitted to substitute a gauge length of 40 times the nominal strand diameter.

7. DIMENSIONS AND PERMISSIBLE VARIATIONS

7.1. The size of the finished strand shall be expressed as the nominal diameter of the strand in millimeters [inches].

7.2. The diameter of the center wire of any strand shall be larger than the diameter of any outer wire in accordance with Table 3.

Table 3—Diameter Relation between Center and Outer Wires

Strand Designation No.	Nominal Diameter of Strand		Minimum Difference between Center Wire Diameter and Diameter of Any Outer Wire	
	mm	in.	mm	in.
Grade 1725 [250]				
6	6.4	0.250	0.025	0.001
8	7.9	0.313	0.038	0.0015
9	9.5	0.375	0.051	0.002
11	11.1	0.438	0.064	0.0025
13	12.7	0.500	0.076	0.003
15	15.2	0.600	0.102	0.004
Grade 1860 [270]				
9	9.53	0.375	0.0508	0.002
11	11.11	0.438	0.0635	0.0025
13	12.70	0.500	0.0762	0.003
13a	13.20	0.520	0.0762	0.003
14	14.29	0.563	0.0889	0.0035
15	15.24	0.600	0.1016	0.004
18	17.78	0.700	0.1143	0.0045

7.3. *Permissible Variations in Diameter*:

7.3.1. All Grade 1725 [250] strand shall conform to a size tolerance of ±0.40 mm [±0.016 in.] from the nominal diameter measured across the crowns of the wires.

7.3.2. All Grade 1860 [270] strand shall conform to a size tolerance of +0.65 mm, –0.15 mm [+0.026 in., –0.006 in.] from the nominal diameter measured across the crowns of the wire.

7.3.3. Variation in cross-sectional area and in unit stress resulting therefrom shall not be cause for rejection provided the diameter differences of the individual wires and the diameters of the strand are within the tolerances specified.

7.4. It shall be permitted to furnish, under this specification, specially dimensioned low-relaxation and stress-relieved [normal-relaxation] strands with nominal diameters up to 19 mm [0.750 in.]. The breaking strength shall be defined, and the yield strength, as defined in Section 6.3, shall not be less than 90 percent and 85 percent of the specified minimum breaking strength for low-relaxation and stress-relieved [normal-relaxation] strands, respectively. All other requirements shall apply.

8. WORKMANSHIP, FINISH, AND APPEARANCE

8.1. *Joints*:

8.1.1. There shall be no strand joints or strand splices in any length of the completed strand unless specifically permitted by the purchaser.

8.1.2. During the process of manufacture of individual wires for stranding, welding shall be permitted only prior to or at the size of the last thermal treatment, for example, patenting or control cooling. There shall be no welds in the wire after it has been drawn through the first die in the wire drawing except as provided in Section 8.1.3.

8.1.3. During fabrication of the strand, butt-welded joints are permitted in the individual wires, provided there shall not be more than one such joint in any 45-m [150-ft] section of the completed strand.

8.1.4. When specifically ordered as “Weldless,” a product free of welds shall be furnished. When “Weldless” is specified, the strand is produced as one continuous length with no welds as allowed by Section 8.1.3.

8.2. The finished strand shall be uniform in diameter and shall be free of imperfections not consistent with good commercial stranding practice.

8.3. When the strand is cut without seizings, the wire shall not fly out of position. If any wire flies out of position and can be replaced by hand, the strand will be considered satisfactory.

8.4. The strand shall not be oiled or greased. Slight rusting, provided it is not sufficient to cause pits visible to the unaided eye, shall not be cause for rejection.

Note 3—Guidance for evaluating the degree of rusting on prestressed concrete strand is presented in Sason.[1]

9. SAMPLING

9.1. Test specimens cut from either end of the strand package are permitted. Any specimen found to contain a wire joint should be discarded and a new specimen obtained.

10. NUMBER OF TESTS

10.1. One specimen for test shall be taken from each 18-Mg [20-ton] production lot of finished strand, and tested for breaking strength, yield strength, and elongation.

11. INSPECTION

11.1. If outside inspection is required, the manufacturer shall afford the inspector representing the purchaser all reasonable facilities to satisfy that the material is being furnished in accordance with this specification. All tests and inspections shall be made at the place of manufacture prior to shipment, unless otherwise agreed upon at the time of purchase, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

Note 4—The purchaser should state, at the time of order, whether outside inspection is required or waived.

12. REJECTION

12.1. Failure of any test specimen to comply with the requirements of the specification shall constitute grounds for rejection of the lot represented by the specimen.

12.2. The lot shall be resubmitted for inspection by testing a specimen from each reel or pack and sorting out nonconforming material.

12.3. In case there is a reasonable doubt in the initial testing as to the ability of the strand to meet any requirement of this specification, two additional tests shall be made on a specimen of strand from the same reel or pack, and if failure occurs in either of these tests, the strand shall be rejected.

13. CERTIFICATION

13.1. If outside inspection is waived, a manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material. The certification shall include the specification number, year-date of issue, and revision letter, if any.

13.2. The manufacturer shall, when requested in the order, furnish a representative load-elongation curve for each size and grade of strand shipped.

13.3. When the modulus of elasticity of a seven-wire strand is provided, the cross-sectional area used to compute that modulus shall also be provided. The area provided in the certification shall be the area used to calculate the modulus of elasticity.

13.4. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 5—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI ASC X12.

14. PACKAGING AND MARKING

14.1. The strand shall be furnished on reels or in reelless packs having a minimum core diameter of 610 mm [24 in.] unless otherwise specified by the purchaser. Lengths on reels or in reelless packs shall be as agreed upon at the time of purchase. The strand shall be well protected against mechanical injury in shipping as agreed upon at the time of purchase. Each reel or reelless pack shall have two strong tags securely fastened to it showing the length, size, types, grade, M 203M/M 203 or ASTM A 416, and the name or mark of the manufacturer. One tag shall be positioned where it will not be inadvertently lost during transit, such as the core of a reelless pack. The other tag shall be on the outside for easy identification.

14.2. *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

15. KEYWORDS

15.1. Prestressed concrete; seven-wire strand [tendon]; steel wire.

SUPPLEMENTARY REQUIREMENTS

Supplementary requirements shall apply only to 15.2-mm [0.600-in.] diameter strand. Grade 270 used in prestressed ground anchors or similar applications shall be specified at the time of order placement. These requirements are not applicable to strand used in prestressed concrete applications.

S1. BOND CAPACITY

S1.1. The results of bond-capacity tests performed in accordance with ASTM A 981 shall be submitted to the purchaser. The strand specimens on which tests were performed shall be from different lots and shall be representative for the strand ordered.

S1.2. The average pull force from six pull tests, performed in accordance with ASTM A 981, required to reach the 0.25-mm [0.01-in.] displacement described therein shall be at least 35.6 kN [8000 lbf] with the individual minimum test value not less than 30.2 kN [6800 lbf]. For any future retests, without changes in the manufacturing method and materials used, three tests shall be considered adequate.

S1.3. *Retests*—If the test specimens fail to satisfy Section S1.2, six additional tests shall be performed, and the results shall satisfy the acceptance criteria. Strand that failed the retest shall not be considered acceptable for the use in prestressed ground anchors.

S1.4. *Annual Test*—The pull tests shall be performed annually as a minimum or repeated when, in the opinion of the producer, a process change is made which is believed could decrease the bond capacity of the strand.

Washington, D.C. 20001

Standard Specification for

Uncoated Stress-Relieved Steel Wire for Prestressed Concrete

AASHTO Designation: M 204M/M 204-06[1]
ASTM Designation: A 421/A 421M-05

1. SCOPE

1.1. This specification covers two types of uncoated stress-relieved, round, high-carbon steel wire commonly used in prestressed linear concrete construction, as follows:

1.1.1. Type BA wire is used for applications in which cold-end deformation is used for anchoring purposes (Button Anchorage), and

1.1.2. Type WA wire is used for applications in which the ends are anchored by wedges, and no cold-end deformation of the wire is involved (Wedge Anchorage).

1.2. Supplement 1 describes low-relaxation wire and relaxation testing for that product.

1.3. This specification is applicable for orders in either SI units (M 204M) or in inch-pound units (M 204). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 204.

2.5. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

3. ORDERING INFORMATION

3.1. It shall be the responsibility of the purchaser to specify all requirements that are necessary for material ordered to this specification. Such requirements shall include, but are not limited to, the following:

3.1.1. Quantity (kg) [lb],

3.1.2. Diameter,

3.1.3. Type of anchorage (BA or WA),

3.1.4. Packaging,

3.1.5. AASHTO designation and date of issue, and

3.1.6. Special requirements, if any.

Note 1—A typical ordering description is as follows: 10,000-kg, 6.35-mm diameter wire, Type BA in approximately 450-kg, 1.5-m diameter coils, to M 204M-____. [22,000-lb, 0.250-in. diameter wire, Type BA in approximately 1000-lb, 60-in. diameter coils, to M 204-____.]

4. MANUFACTURE

4.1. *Process*—The steel shall be made by the basic-oxygen, open-hearth, or electric-furnace process.

4.2. *Internal Soundness*—A sufficient discard shall be made to ensure freedom from injurious piping and undue segregation.

4.3. *Wire*—The wire shall be cold-drawn to size and suitably stress relieved after cold drawing by a continuous heat treatment to produce the prescribed mechanical properties.

5. PHYSICAL REQUIREMENTS

5.1. *Tensile Strength*—The tensile strength of Type BA wire and Type WA wire shall conform to the requirements prescribed in Table 1, and shall be determined as prescribed in T 244, including Appendix X4.

Table 1—Tensile Strength Requirements

Nominal Diameter, mm [in.]	Minimum Tensile Strength, MPa [psi]	
	Type BA	Type WA
4.88 [0.192]	[a]	1725 [250000]
4.98 [0.196]	1655 [240000]	1725 [250000]
6.35 [0.250]	1655 [240000]	1655 [240000]
7.01 [0.276]	1620 [235000]	1620 [235000]

[a] This size is not commonly furnished in Type BA wire.

5.2. *Yield Strength*:

5.2.1. The minimum yield strength for all wire, measured by the 1 percent extension under load method, shall not be less than 85 percent of the specified minimum breaking strength.

5.2.2. The extension under load shall be measured by an extensometer calibrated with the smallest division not larger than 0.0001 mm/mm [0.0001 in./in.] of gauge length.

5.2.3. The initial load corresponding to the initial stress prescribed in Table 2 shall be applied to the specimen, at which time the extensometer is attached and adjusted to a reading of 0.001 mm/mm [0.001 in./in.] of gauge length. The load shall then be increased until the extensometer indicates an extension of 1 percent. The load for this extension shall be recorded. The stress corresponding to this load shall meet the requirements for stress at 1 percent extension prescribed in Table 2.

Table 2—Yield Strength Requirements

Nominal Diameter, mm [in.]	Initial Stress, MPa [psi]	Minimum Stress at 1% Extension, MPa [psi]	
		Type BA	Type WA
4.88 [0.192]	200 [29000]	[a]	1465 [212500]
4.98 [0.196]	200 [29000]	1407 [204000]	1465 [212500]
6.35 [0.250]	200 [29000]	1407 [204000]	1407 [204000]
7.01 [0.276]	200 [29000]	1377 [199750]	1377 [199750]

[a] This size is not commonly furnished in Type BA wire.

5.3. *Elongation*—The total elongation under load of all wire shall not be less than 4 percent when measured in a gauge length of 250 mm [10 in.].

The elongation shall be determined by an extensometer which is placed on the test specimen after a load corresponding to the initial stress prescribed in Table 2 is applied. If the fracture takes place outside of the gauge length and the elongation so measured meets the minimum requirements, no further testing shall be required. If the elongation is less than the minimum requirements, the test shall be considered an invalid test and a retest made.

6. DIAMETER AND PERMISSIBLE VARIATIONS

6.1. Wire meeting the requirements of this specification is normally ordered in the diameters shown in Table 1.

6.2. The diameter of the wire shall not vary from the nominal diameter specified by more than ±0.05 mm [±0.002 in.].

6.3. The wire shall not be out-of-round by more than 0.05 mm [0.002 in.].

7. WORKMANSHIP AND FINISH

7.1. *Cast*—A wire sample having a chord length of 1524 mm [60 in.] shall have an offset at the center of the chord of not more than 76 mm [3 in.]. This is equivalent to a chord of an arc of a circle not less than 7.6 m [25 ft] in diameter.

7.2. *Type BA Wire*—Type BA wire shall be of suitable quality to permit cold forming of buttons for anchorage. Splitting shall not be considered a cause for rejection if the button anchorage is capable of developing the minimum required tensile strength of the wire.

7.3. The wire shall be free of kinks.

7.4. The wire shall be furnished in firmly tied coils having a minimum inside diameter of 1219 mm [48 in.]. Each coil shall be of one continuous length.

7.5. There shall be no welds or joints in the finished wire. Any welds or joints made during manufacture to promote continuity of operations shall be removed.

7.6. The wire shall not be oiled or greased. Slight rusting, provided it is not sufficient to cause pits visible to the naked eye, shall not be cause for rejection.

7.7. Temper colors, which may result from the stress-relieving operations, are considered normal for the finished appearance of this strand.

8. CHEMICAL REQUIREMENTS

8.1. Variations in manufacturing processes and equipment among wire manufacturers necessitate the individual selection of an appropriate chemical composition at the discretion of the manufacturer.

8.2. Phosphorus and sulfur values shall not exceed the following:

Phosphorus	0.040 percent
Sulfur	0.050 percent

8.3. The purchaser shall have the right to make an analysis from finished wire representing each heat of steel. Samples for analysis shall be obtained by milling the wire in such a manner as to obtain a sample representative of the entire cross section. Prior to milling, the surface shall be cleaned to remove all foreign matter. All such individual determinations shall not vary from the limits shown in Section 8.2 by more than 0.008 percent.

8.4. For referee purposes, ASTM E 30-89 shall be applied.

9. SAMPLING

9.1. Unless otherwise agreed upon between the manufacturer and the purchaser, one test specimen shall be taken from each ten or fewer coils in a lot (Note 2) and tested to determine compliance with Sections 5.1, 5.2, 5.3, 6, and 7.1.

Note 2—The term “lot” means all the coils of wire of the same nominal wire size contained in an individual shipping release or shipping order.

10. INSPECTION

10.1. The purchaser shall state at the time of order whether outside inspection is required or waived. If outside inspection is required, the manufacturer shall afford the inspector representing the purchaser all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests and inspections shall be made at the place of manufacture prior to shipment, unless otherwise agreed upon at the time of purchase, and shall be so conducted as not to interfere unnecessarily with the operation of the work.

11. REJECTION

11.1. Unless otherwise specified, any rejection based on tests made in accordance with this specification shall be reported to the manufacturer within a reasonable length of time.

12. CERTIFICATION

12.1. If outside inspection is waived, a manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material.

12.2. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 3—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI ASC X12.

13. PACKAGING AND MARKING

13.1. The size of the wire, AASHTO specification number, heat number, type of wire, and name or mark of the manufacturer shall be marked on a tag securely attached to each bundle of wire.

13.2. *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. 123 for civil agencies and MIL-STD-129 for military agencies.

14. KEYWORDS

14.1. Cold-drawn wire; prestressed concrete; steel wire (tendon); stress-relieved wire.

SUPPLEMENTARY REQUIREMENTS—LOW-RELAXATION WIRE

S1. SCOPE

S1.1. This supplement delineates only those details that are peculiar to low-relaxation wire, and to the method of relaxation testing related to single wire tendons having properties generally as described in M 204M/M 204.

S2. REFERENCED DOCUMENTS

S2.1. *ASTM Standard*:

- E 328, Recommended Practice for Stress-Relaxation Tests for Materials and Structures

S3. TEST METHOD

S3.1. Low-relaxation strand shall be tested as prescribed in ASTM E 328.

S4. RELAXATION PROPERTIES

S4.1. Low-relaxation wire shall meet the physical requirements of this specification, with the added requirement that relaxation after 1000 hours under the conditions of Section S6 shall not be more than 2.5 percent when initially loaded to 70 percent of specified minimum tensile strength or not more than 3.5 percent when loaded to 80 percent of specified minimum tensile strength of the wire.

S5. YIELD STRENGTH

S5.1. Yield strength of low-relaxation wire as described in Section 5.2 shall not be less than 90 percent of the specified minimum tensile strength of the wire.

S6. CONDITIONS OF RELAXATION TEST

S6.1. If required, relaxation evidence shall be provided from the manufacturer's records of tests on similarly dimensioned wire of the same grade.

S6.2. The temperature of the test specimen shall be maintained at 20 ± 2°C [68 ± 3.5°F].

S6.3. The test specimen shall not be subjected to any loading prior to relaxation test.

S6.4. The initial load shall be applied uniformly over a period of not less than 180 seconds and not more than 300 seconds, and the gauge length shall be maintained constant; load-relaxation readings shall commence 60 seconds after application of the total load.

S6.5. Overstressing of the test specimen during the loading operation shall not be permitted.

S6.6. The duration of the test shall be 1000 hours or a shorter computed period extrapolated to 1000 hours that can be shown by records to provide similar relaxation values.

S6.7. The test gauge length shall be at least 60 times the nominal diameter.

---

[1] Agrees technically with ASTM A 421/A 421M-05 except for minor differences in wording.

Standard Specification for

Steel Welded Wire Reinforcement, Deformed, for Concrete

AASHTO Designation: M 221M/M 221-09
ASTM Designation: A 497/A 497M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Welded Wire Reinforcement, Deformed, for Concrete

AASHTO Designation: M 221M/M 221-09
ASTM Designation: A 497/A 497M-07

1. SCOPE

1.1. This specification covers welded wire reinforcement made from cold-worked drawn or rolled deformed wire, or a combination of deformed and nondeformed wires, to be used for the reinforcement of concrete.

Note 1—Welded wire for concrete reinforcement has been described by various terms: welded wire fabric (WWF), fabric, and mesh. The wire reinforcement industry prefers the term "welded wire reinforcement" (WWR) as being more representative of the range of products being manufactured. Therefore, the term "welded wire fabric" has been replaced with the term "welded wire reinforcement" in this specification and in related specifications.

1.2. This specification is applicable for orders in either SI units (M 221M) or in inch-pound units (M 221). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 221. Combining values from the two systems may result in nonconformance with the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 32M/M 32, Steel Wire, Plain, for Concrete Reinforcement
- M 225M/M 225, Steel Wire, Deformed, for Concrete Reinforcement

2.2. *ASTM Standard*:

- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment

2.3. *Military Standard*:

- MIL-STD-129, Marking for Shipment and Storage

2.4. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *convoluted wire*—when wire for welded wire reinforcement is shaped into a sinusoidal wave shape, it is commonly referred to as convoluted wire. The wire is used in the manufacture of cages for certain applications of concrete pipe reinforcing. Only nondeformed wire is normally subject to convolution.

3.1.2. *welded wire reinforcement*—as used within the scope and intent of this specification, welded wire reinforcement designates a material composed of cold-worked steel wire, fabricated into sheets or rolls by the process of electric-resistance welding. The finished material shall consist essentially of a series of longitudinal and transverse wires arranged substantially at right angles to each other, and welded together at points of intersection.

4. ORDERING INFORMATION

4.1. Orders for material to this specification should include the following information:

4.1.1. Quantity (mass or square area);

4.1.2. Name of material (deformed welded wire reinforcement for concrete reinforcement);

4.1.3. Wire spacing and sizes;

4.1.4. Minimum yield strength if Supplement S1 of M 225 applies; and minimum yield strength if wire conforming to M 32 is to be used and Supplement S1 of M 32 applies;

4.1.5. Exclusion of oversteeling, if required (Section 9.4.1);

4.1.6. Length and width of sheets or rolls;

4.1.7. Packaging (Section 16); and

4.1.8. AASHTO designation and year of issue.

Note 2—A typical ordering description is as follows: 930 m^2 welded deformed wire reinforcement for concrete reinforcement, 150 × 300-D6 × D2 in flat sheets 2.4 m wide by 6.1 m long, in secured lifts, to M 221M-____. [10000 ft^2 welded deformed wire reinforcement for concrete reinforcement, 6 × 12-D6 × D2 in flat sheets 96 in. wide by 240 in. long, in secured lifts, to M 221-___.]

5. MATERIALS

5.1. The wire used in the manufacture of welded wire reinforcement shall conform to M 225 and its Supplement S1, if so ordered, either solely or in combination with wire conforming to M 32 and its Supplement S1.

5.2. Welded wire reinforcement shall be furnished either in flat sheets, or in rolls, as specified by the purchaser.

6. MANUFACTURE

6.1. The wires shall be assembled by automatic machines or by other suitable mechanical means that will assure accurate spacing and alignment of all wires of the finished welded wire reinforcement.

6.2. Longitudinal and transverse wires shall be securely connected at every intersection by a process of electrical-resistance welding, which employs the principle of fusion combined with pressure.

6.3. Wire of proper grade and quality when fabricated in the manner herein required in this specification shall result in a strong, serviceable, mat-type product having substantially square or rectangular openings. It shall be fabricated and finished in a workmanlike manner, shall be free of injurious defects, and shall conform to this specification.

Note 3—A variation of manufacturing includes the application of one or more longitudinal convoluted wires at one edge of welded wire reinforcement for concrete pipe reinforcing cages. This shape allows the cage ends to be expanded to a larger diameter to accommodate the bell-shaped ends of concrete pipe.

7. MECHANICAL PROPERTY REQUIREMENTS

7.1. *Tensile*—Wire for the production of welded wire reinforcement, deformed, is described in M 225M/M 225. Tensile tests may be made on wire cut from the welded wire reinforcement and tested either across or between the welds; no fewer than 50 percent shall be across welds. Tensile tests across a weld shall have the welded intersection located approximately at the center of the wire being tested and the cross wire forming the welded joint shall extend approximately 25 mm [1 in.] beyond each side of the welded joint.

Note 4—Tensile and bend testing are normally done at the time wire is drawn. The manufacturer's finished product still must satisfy the mechanical properties when tested after fabrication.

7.2. *Bend Test*—The wire shall withstand the bend test as described in M 225M/M 225 and shall be performed on a specimen taken from between the welds.

7.3. *Weld Shear Strength*—The weld shear strength between longitudinal and transverse wires shall be tested as described in Section 8. The minimum average shear value in Newtons shall not be less than 241, multiplied by the nominal area of the large wire in square millimeters [or in pounds-force, shall not be less than 35000, multiplied by the nominal area of the larger wire in square inches], where the smaller wire is not less than MD25 [D4] and has an area of 40 percent or more of the area of the larger wire.

7.3.1. Welded wire reinforcement having a relationship of larger and smaller wires other than that covered in Section 7.3 shall meet an average weld shear strength requirement of not less than 3.6 kN [800 lbf] provided that the smaller wire is not smaller than MD25 [D4].

7.3.2. Weld shear tests for determination of conformance to the requirements of Section 7.3 shall be conducted using a fixture as described in Section 8.

7.3.3. Four welds selected at random from the specimen described in Section 11.2 shall be tested for weld shear strength. The transverse wire of each test specimen shall extend approximately 25 mm [1 in.] on each side of the longitudinal wire. The longitudinal wire of each test specimen shall be of such length below the transverse wire so as to be adequately engaged by the grips of the testing machine. It shall be of such length above the transverse wire that its end shall be above the center line of the upper bearing of the testing device.

7.3.4. The material shall be deemed to conform to the requirements for weld shear strength if the average of the four samples complies with the value stipulated in Section 7.3. If the average fails to meet the prescribed value, all the welds across the specimen shall then be tested. The welded wire reinforcement will be acceptable if the average of all weld shear test values across the specimen meets the prescribed minimum value.

8. WELD SHEAR TEST APPARATUS AND METHODS

8.1. As the welds in welded wire reinforcement contribute to the bonding and anchorage value of the wires in concrete, it is imperative that the weld acceptance tests be made in a jig that will stress the weld in a manner similar to which it is stressed in concrete. In order to accomplish this, the vertical wire in the jig must be stressed in an axis close to its center line. Also, the horizontal wire must be held closely to the vertical wire, and in the same relative position to prevent rotation of the horizontal wire. When the welded wire reinforcement is designed with different wire sizes, the larger diameter wire is the “vertical wire” when tested. (See Figure 1.)

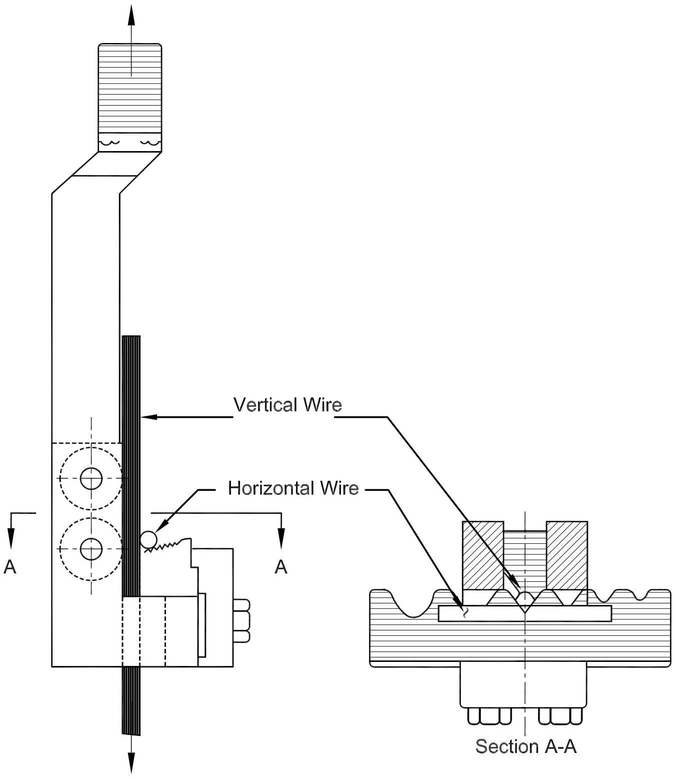

Figure 1—Welded Wire Reinforcement Weld Tester

8.2. Figure 1 shows the details of a typical testing jig together with two anvils, which make it possible to test welds for wire up to 16 mm [0.625 in.] in diameter. This testing jig can be used in most tension testing machines and should be hung in a ball-and-socket arrangement at the center of the machine. This, or a similarly effective fixture designed on the same principle, is acceptable.

8.3. Test specimens should be inserted through the notch in the anvil using the smallest notch available in which the vertical wire will fit loosely. The vertical wire shall be in contact with the surface of the free rotating rollers while the horizontal wire shall be supported by the anvil on each side of the slot. The bottom jaws of the testing machine shall grip the lower end of the vertical wire and the load shall be applied at a rate of stressing not to exceed 690 MPa/min [100 ksi/min].

9. DIMENSIONS

9.1. *Width*—The width of welded wire reinforcement shall be considered to be the center-to-center distance between outside longitudinal wires. The permissible variation shall not exceed ±13 mm [±0.5 in.] than the specified width. In case the width of flat sheets or rolls is specified as the overall width (tip-to-tip length of cross wires), the width shall not vary more than ±25 mm [±1 in.] from the specified width. When measurements involve a convoluted wire, the measurement shall be made to the approximate center of the sinusoidal wave shape.

9.2. *Length*—The overall length of flat sheets, measured on any wire, may vary ±25 mm [±1 in.], or 1 percent, whichever is greater.

9.3. Overhang of the transverse wires shall not project beyond the center line of each longitudinal edge wire more than a distance of 25 mm [1 in.], unless otherwise specified. When transverse wires are specified to project a specific length beyond the center line of a longitudinal edge wire, the permissible variation shall not exceed 13 mm [0.5 in.] greater or less than the specified length.

9.4. The permissible variation in weight of any wire in the finished welded wire reinforcement shall conform to the tolerances prescribed for the wire before fabrication, in M 225M/M 225, with the following exceptions:

9.4.1. Unless otherwise precluded by the purchaser, the manufacturer will be permitted to apply oversized wire (not undersized). The size differential shall not exceed one "D" size increment on sizes D8 and smaller, and two "D" size increments on sizes larger than D8. In all cases in which such oversteeling is practiced, the producer shall identify the welded wire reinforcement with the style originally ordered.

9.5. The average spacing of wires shall be such that the total number of wires contained in a sheet or roll is equal to or greater than that determined by the specific spacing, but the center-to-center distance between individual members may vary not more than 6.4 mm [0.25 in.] from the specified spacing. It is understood that sheets of welded wire reinforcement of the specified length may not always contain an identical number of transverse wires and, therefore, may have various lengths of longitudinal overhang.

10. WORKMANSHIP

10.1. Wire of proper grade and quality, when fabricated in the manner herein required, shall result in a strong, serviceable, mat-type product having substantially square or rectangular openings. It shall be fabricated and finished in a workmanlike manner, as determined by visual inspection, and shall conform to this specification.

11. SAMPLING

11.1. Test specimens for testing mechanical properties shall be obtained by cutting from the finished welded wire reinforcement a full-width section, of sufficient length to perform testing as described in Sections 7.1 and 7.2.

11.2. Test specimens for determining weld shear properties shall be obtained by cutting from the finished welded wire reinforcement, a full-width section of sufficient length to perform testing as described in Section 7.3.3.

11.3. Measurements for conformance to dimensional characteristics shall be made on full sheets or rolls.

11.4. If any test specimen exhibits obvious imperfections, it may be discarded and another specimen substituted.

12. NUMBER OF TESTS

12.1. One test for conformance to tensile strength and bend requirements shall be made for each 7000 m^2 [75000 ft^2] of welded wire reinforcement or remaining fraction thereof. For testing prior to fabrication, one test for each 18 Mg [20 tons] of wire shall be made.

12.2. One test for conformance to weld shear strength requirement shall be made for each 28000 m^2 [300000 ft^2] or remaining fraction thereof.

13. INSPECTION

13.1. The inspector representing the purchaser shall have free entry at all times, while work on the contract of the purchaser is being performed, to all parts of the manufacturer’s works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to assure that the material is being furnished in accordance with this specification.

13.2. Except for yield strength, all tests and inspections shall be made at the place of manufacture prior to shipment, unless otherwise specified. Such tests shall be so conducted as not to interfere unnecessarily with the operation of the works.

13.3. If the purchaser considers it desirable to determine compliance with the yield strength requirements of M 225M/M 225, yield strength tests may be made in a recognized laboratory, or their representative may make the test at the mill, if such tests do not interfere unnecessarily with the mill operations.

13.4. *For Government Procurement Only*—The purchaser shall be furnished a manufacturer’s certification of conformance to A 497/A 497M for each production date or production lot shipped. A production lot shall not exceed 28 000 m^2 [300000 ft^2], and certifications shall be traceable to specific date(s) of production marked on the product bundle prior to shipment. Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein. Except as otherwise specified in the contract, the contractor shall have the option to use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

14. REJECTION AND RETESTS

14.1. Material that does not meet the requirements of this specification may be rejected. Unless otherwise specified, any rejection shall be reported to the manufacturer within 5 days from the time of selection of test specimens.

14.2. In case a specimen fails to meet the tension or bend test, the material shall not be rejected until two additional specimens taken from other wires in the same sheet or roll have been tested. The material shall be considered as meeting the specification in respect to any prescribed tensile property, provided the tested average for the three specimens, including the specimen originally tested, is equal to or exceeds the required minimum for the particular property in question and provided further that none of the three specimens develops less than 80 percent of the required minimum for the tensile property in question. The material shall be considered as meeting this specification in respect to bend test requirements, provided both additional specimens satisfactorily pass the prescribed bend test.

14.3. Any material that is found not to meet the requirements of this specification subsequent to its acceptance at the manufacturer's facilities shall be subject to rejection and the manufacturer shall be promptly notified.

14.4. Welded joints shall withstand normal shipping and handling without becoming broken, but the presence of broken welds, regardless of cause, shall not constitute cause for rejection unless the number of broken welds per sheet exceeds 1 percent of the total number of joints in a sheet, or if the material is furnished in rolls, 1 percent of the total number of joints in 14 m^2 [150 ft^2] of welded wire reinforcement and, furthermore, provided not more than one-half the permissible maximum number of broken welds are located on any one wire.

14.5. In the event of rejection because of failure to meet the weld shear requirements, four additional specimens shall be taken from four different sheets or rolls and tested in accordance with Section 8. If the average of all the weld shear tests performed does not meet the requirement, the material shall be rejected.

14.6. In the event of rejection because of failure to meet the requirements for dimensions, the amount of material rejected shall be limited to those individual sheets or rolls that fail to meet this specification.

14.7. Rust, surface seams, or surface irregularities shall not be cause for rejection provided the minimum welded wire reinforcement dimensions, cross-sectional area, tensile properties, and weld shear strength of a hand wire-brushed test specimen are not less than the requirements for this specification. The height of deformations above the minimum height requirements (see M 225M/M 225, Table 1 and Table 2) shall not be cause for rejection.

14.8. *Rehearing*—Rejected materials shall be preserved for a period of at least 2 weeks from the date of inspection, during which time the manufacturer may make claim for a rehearing and retesting.

15. CERTIFICATION

15.1. If outside inspection is waived, a manufacturer's certification that the material has been manufactured in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material. The certification shall include the specification number, year-date of issue, and revision letter, if any.

15.2. This conformance is predicated upon testing and acceptance of wire prior to fabrication, coupled with random shear testing during production. The purchaser shall be furnished a manufacturer's certification of conformance to M 221M/M 221 for each production date or production lot shipped. A production lot shall not exceed 28 000 m^2 [300 000 ft^2]. Any purchaser shall have the right to invoke any of the provisions of Section 13.4.

15.3. When Supplement S1 of M 32M/M 32 or M 225M/M 225 is specified for the material, test results for yield strength, tensile strength, and bend tests shall be reported (S1.3.1 of M 32M/M 32, S1.3.1 of M 225M/M 225).

15.4. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 5—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI ASC X12.

16. PACKAGING AND MARKING

16.1. Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

16.2. When welded wire reinforcement is furnished in flat sheets, it shall be assembled in bundles of convenient size containing not more than 150 sheets and securely fastened together.

16.3. When welded wire reinforcement is furnished in rolls, each roll shall be secured so as to prevent unwinding during shipping and handling.

16.4. Each bundle of flat sheets and each roll shall have attached thereto a suitable tag bearing the name of the manufacturer, description of the material, M 225M/M 225, and such other information as may be specified by the purchaser.

16.5. When specified in the contract or order, and for the direct procurement by or direct shipment to the U.S. government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for U. S. military agencies and in accordance with Fed. Std. No. 123 for U. S. government civil agencies.

17. KEYWORDS

17.1. Concrete reinforcement; deformed steel wire; reinforcing steels; reinforced concrete; welded wire reinforcement.

Standard Specification for

Steel Wire, Deformed, for Concrete Reinforcement

AASHTO Designation: M 225M/M 225-09
ASTM Designation: A 496/A 496M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel Wire, Deformed, for Concrete Reinforcement

AASHTO Designation: M 225M/M 225-09
ASTM Designation: A 496/A 496M-07

1. SCOPE

1.1. This specification covers deformed steel wire that has been cold worked by drawing, rolling, or both drawing and rolling to be used as produced, or in fabricated form, for the reinforcement of concrete in sizes having nominal cross-sectional areas not less than 6.45 mm^2 [0.01 $in.^2$].

1.2. Supplement S1 describes high-strength wire, which shall be furnished when specifically ordered. It shall be permissible to furnish high-strength wire in place of regular wire if mutually agreed to by the purchaser and manufacturer.

1.3. The values stated in either SI units or inch-pound units are to be regarded separately as standard. The values stated in each system may not be exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard. The inch-pound units are shown in brackets except in Table 1.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

2.4. *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipments (Civil Agencies)

2.5. *ACI Standard*:

- ACI 318, Building Code Requirements for Structural Concrete

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *Deformed steel wire for reinforcement*—as used within the scope and intent of this specification, shall mean any cold-worked, deformed steel wire intended for use as reinforcement in concrete construction, the wire surface having deformations that (1) inhibit longitudinal movement of the wire in such construction, and (2) conform to the provisions of Section 5. It shall be permissible for the deformations to be raised or indented.

3.1.2. *Size number*—as used in this specification, refers to the numerical designation of the wire as tabulated in Table 1 and Table 2 under the column headed “Deformed Wire Size Number,” or a number indicating the nominal cross-sectional area of the deformed wire in square millimeters [hundredths of a square inch].

4. ORDERING INFORMATION

4.1. When deformed wire is ordered by size number, the dimensional requirements shall be as given in Table 1. When deformed wire is ordered to dimensions other than the sizes shown, the nominal dimensions shall be developed from the applicable unit mass per meter of the section.

4.2. It shall be the responsibility of the purchaser to specify all requirements that are necessary for the manufacture and delivery of the wire under this specification. Such requirements to be considered include, but are not limited to, the following:

4.2.1. Quantity (mass) [weight],

4.2.2. Name of material (deformed steel wire for concrete reinforcement),

4.2.3. Wire diameter (see Table 1 and Table 2),

4.2.4. Yield strength measurement (see Sections 8 and 13.3),

4.2.5. Packaging (see Section 17), and

4.2.6. AASHTO designation and year of issue.

4.2.7. Special requirements if any (see Supplement S1).

Note 1—A typical ordering description is as follows: 25,000 kg deformed steel wire for concrete reinforcement, size No. D-12, on pipe carriers, polyethylene shrouded, to M 225M-____. [50,000 lb deformed steel wire for concrete reinforcement, size No. D-12 [MD80], in 800 kg [2,000 lb] secured coils to M 225-____.

Table 1—Dimensional Requirements for Deformed Steel Wire for Concrete Reinforcement—SI Units (U.S. Customary Units)

Nominal Dimensions

[a] The number following the prefix indicates the nominal cross-sectional area of the deformed wire in square millimeters.

[b] For sizes other than those shown above, the Size Number shall be the number of one hundredths of a square inch in the nominal area of the deformed wire cross section, prefixed by the letters MD.

[c] These sizes represent the most readily available sizes in the welded wire reinforcement industry. Other wire sizes are available and many manufacturers can produce them in 1 mm^2 [0.0015 in.^{2}] increments.

[d] The nominal diameter of a deformed wire is equivalent to the diameter of a plain wire having the same mass per meter as the deformed wire.

[e] The cross-sectional area is based on the nominal diameter. The area in square millimeters [inches] is calculated by dividing the unit mass [weight] in kg/m [lb/in.] by 7×10^{-6} (mass of 1 mm^3 of steel [0.2833 weight of 1 in.^{3} of steel]) or by dividing the unit mass [weight] in kg/m [lb/ft] by 0.007849 (mass of steel 1 mm^2 and 1 m long) [3.4 (weight of steel 1 in.^{2} and 1 ft long)].

[f] The minimum average height of the deformations shall be determined from measurements made on not fewer than two typical deformations from each line of deformations on the wire. Measurements shall be made at the center of indentation as described in Section 7.7.

Table 2—Dimensional Requirements for Deformed Steel Wire for Concrete Reinforcement—U.S. Customary Units Wire Sizes[a]

D-45	1.53 [2.28]	0.757 [19.2]	0.450 [290]	2.38 [60.4]	0.285 [7.24]	0.182 [4.62]	0.0379 [0.961]

[a] In this table only, inch-pound units are regarded as standard and SI units are shown in brackets.

[b] The number following the prefix indicates the nominal cross-sectional area of the deformed wire in square inches [square millimeters].

[c] For sizes other than those shown above, the Size Number shall be the number of one-hundredths of a square inch in the nominal area of the deformed wire cross section prefixed by the letter D.

[d] These sizes represent the most readily available sizes in the welded wire reinforcement industry. Other wire sizes are available and many manufacturers can produce them in 0.0015 in.^{2} [1 mm^2] increments.

[e] The nominal diameter of a deformed wire is equivalent to the diameter of a plain wire having the same weight per foot as the deformed wire.

[f] The cross-sectional area is based on the nominal diameter. The area in square inches [millimeters] is calculated by dividing the unit weight [mass] in lb/in. [kg/mm] by 0.2833 (weight of 1 in.^{3} of steel) [7×10^{-6} (mass of 1 mm^3 of steel)], or by dividing the unit weight [mass] in lb/ft [kg/m] by 3.4 (weight of steel 1 in.^{2} and 1 ft long) [0.007849 (mass of 1 mm^2 and 1 m long)].

[g] The minimum average height of the deformations shall be determined from measurements made on not fewer than two typical deformations from each line of deformations on the wire. Measurements shall be made at the center of indentation as described in Section 6.2.

5. MATERIALS AND MANUFACTURE

5.1. The steel shall be made by one of the following processes: open hearth, electric furnace, or basic oxygen.

5.2. The deformed steel wire shall be produced from rods or bars that have been hot rolled from billets.

6. REQUIREMENTS

6.1. Deformations shall be spaced along the wire at a substantially uniform distance and shall be symmetrically dispersed around the perimeter of the section. The deformations on all longitudinal lines of the wire shall be similar in size and shape. A minimum of 25 percent of the total surface area shall be deformed by measurable deformations.

6.2. Deformed wire shall have two or more lines of deformations.

6.3. The average longitudinal spacing of deformations shall be not less than 3.5 nor more than 5.5 deformations per 25.4 mm [1 in.] in each line of deformations on the wire.

6.4. The minimum average height at the center of typical deformations based on the nominal wire diameters shown in Table 1 and Table 2 shall be as follows:

Wire Sizes	Min Avg Height of Deformations, Percent of Nominal Wire Diameter
D-3 and finer	4
Coarser than D-3 through D-10	$4^1/_2$
Coarser than D-10	5

6.5. The deformation shall be placed with respect to the axis of the wire so that the included angle is not less than 45 degrees or, if deformations are curvilinear, the angle formed by the transverse axis of the deformation and the wire axis shall be not less than 45 degrees. Where the line of deformations forms an included angle with the axis of the wire from 45 degrees to 70 degrees inclusive, the deformations shall alternately reverse in direction on each side, or those on one side shall be reversed in direction from those on the opposite side. Where the included angle is greater than 70 degrees, a reversal in direction is not required.

7. DIMENSIONS

7.1. The average spacing of deformation shall be determined by dividing a measured length of the wire specimen by the number of individual deformations in any one row of deformations on any side of the wire specimens. A measured length of the wire specimen shall be considered the distance from a point on a deformation to a corresponding point on any other deformation in the same line of deformations on the wire.

7.2. The minimum average height of deformations shall be determined from measurements made on not fewer than two typical deformations from each line of deformations on the wire. Measurements shall be made at the center of indentations.

8. MECHANICAL PROPERTY REQUIREMENTS

8.1. *Tension Tests*:

8.1.1. When tested as described in T 244, the material, except as specified in Section 8.1.2, shall conform to the tensile property requirements in Table 3 based on the nominal area of wire.

Table 3—Tension Test Requirements

	MPa [psi], Min
Tensile strength	585 [85,000]
Yield strength	515 [75,000]

8.1.2. When required by the purchaser, yield strength shall be determined using a Class B-1 extensometer as described in ASTM E 83. The yield strength shall be determined as described in T 244 and an extension of 0.5 percent of gauge length. It shall be permissible to remove the extensometer after the yield strength has been determined. The wire shall meet requirements of Table 3 or 4, whichever is applicable.

8.1.3. For material to be used in the fabrication of welded wire reinforcement, the tensile and yield strength properties shall conform to the requirements given in Table 4, based on the nominal area of the wire.

Table 4—Tension Test Requirements (Material for Welded Wire Reinforcement)

	MPa [psi], Min
Tensile strength	550 [80,000]
Yield strength	485 [70,000]

8.1.4. The material shall not exhibit a definite yield point as evidenced by a distinct drop of the beam or halt in the gauge of the testing machine prior to reaching ultimate tensile load.

8.2. *Bend Test*—The bend-test specimen shall withstand being bent at room temperature through 90 degrees without cracking on the outside of the bent portion, as prescribed in Table 5.

Table 5—Bend Test Requirements

Size Number of Wire	Bend Test
D-6 and smaller	Bend around a pin the diameter that is equal to twice the diameter of the specimen
Coarser than D-6	Bend around a pin the diameter that is equal to four times the diameter of the specimen

9. PERMISSIBLE VARIATION IN MASS [WEIGHT]

9.1. The permissible variation in mass [weight] of any deformed wire is ±6 percent of its nominal weight. The theoretical masses [weights] shown in Table 1, or similar calculations on unlisted sizes, shall be used to establish the variation.

10. WORKMANSHIP, FINISH, AND APPEARANCE

10.1. The wire shall be free of detrimental imperfections and shall have a workmanlike finish.

10.2. Rust, surface seams, or surface irregularities shall not be a cause for rejection provided the requirements of Section 10.3 are met, and the minimum dimensions and mechanical properties of a hand wire-brushed test specimen meet the requirements of this specification.

10.3. Wire intended for welded wire reinforcement shall be sufficiently free of rust and drawing lubricant, so as not to interfere with electric-resistance welding.

11. SAMPLING

11.1. Test specimens for testing mechanical properties shall be full wire sections and shall be obtained from the ends of the wire product as drawn or rolled, or both drawn and rolled. The specimens shall be of sufficient length to perform testing as described in Sections 8.1 and 8.2.

11.2. Any test specimen exhibiting obvious isolated imperfections that are not representative of the product shall be discarded and another specimen substituted.

12. NUMBER OF TESTS

12.1. One tension and one bend test shall be made from each 9,000 kg [10 tons] or less of each size of wire or fraction thereof in a lot, or a total of seven samples, whichever is fewer. A lot shall consist of all the coils of a single size offered for delivery at the same time.

13. INSPECTION

13.1. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer’s facilities that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification.

13.2. Except for yield strength, all tests and inspection shall be made at the manufacture’s facilities prior to shipment, unless otherwise specified. Such tests shall be so conducted as not to interfere unnecessarily with the operation of the manufacturer’s facilities.

13.3. The purchaser shall have the option to require a yield strength measurement to determine compliance with yield strength requirements in Section 8.1, and shall specify that the measurements be performed by the manufacturer at the manufacturer’s facilities, a recognized laboratory, or the purchaser’s representative at the manufacturer’s facilities. Such measurements shall be conducted without unnecessarily interfering with the manufacturing operations.

13.4. *For U.S. Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein. Except as otherwise specified in the contract, the contractor shall have the option to use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to ensure that material conforms to prescribed requirements.

14. REJECTION

14.1. Material that shows detrimental imperfections subsequent to its acceptance at the manufacturer's facilities shall be rejected, and the manufacturer shall be notified.

14.2. Failure of any of the test specimens to comply with the requirements of this specification shall constitute ground for rejection of the lot represented by the specimen.

14.3. Any rejection based on tests made in accordance with this specification shall be reported to the manufacturer within 2 weeks of the date of inspection or tests. The material shall be adequately protected and correctly identified such that the manufacturer is able to make a proper investigation.

15. REHEARING

15.1. Rejected materials shall be preserved for a period of at least 2 weeks from the date of inspection, during which time the manufacturer may make claim for a rehearing and retesting.

15.2. The manufacturer shall have the option to resubmit the rejected lot for reinspection or retesting by inspecting or testing every coil for the property in which the specimen failed and sorting out nonconforming coils.

16. CERTIFICATION

16.1. When specified in the purchase order or contract, the purchaser shall be furnished with the manufacturer's written certification that the material was manufactured, sampled, tested, and inspected in accordance with, and meets the requirements of, this specification. When specified in the purchase order or contract, a report of the test results shall be furnished. The certification shall include the specification number, year-date of issue, and the revision letter, if any.

16.2. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the manufacturer. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 2—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI ASC X12.

17. PACKAGING AND MARKING

17.1. The size of the wire, AASHTO designation, and name or mark of the manufacturer shall be marked on a tag securely attached to each coil of wire.

17.2. Unless otherwise specified, packaging, marking, and loading for shipment shall be in accordance with ASTM A 700.

17.3. When specified in the contract or order, and for the direct procurement by or direct shipment to the U.S. Government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for U.S. military agencies and in accordance with Fed. Std. No. 123 for U.S. Government civil agencies.

18. KEYWORDS

18.1. Concrete reinforcement; deformations (indentations); steel wire.

SUPPLEMENTARY REQUIREMENTS

S1. HIGH-STRENGTH WIRE

S1.1. *Scope*:

S1.1.1 This supplement delineates only those details that are relative to high-strength wire and to the mechanical requirements for wire having properties generally as described in this specification.

Note S1.1—Building codes, for example, ACI 318, permit the use of reinforcement with a yield strength up to 550 MPa [80,000 psi]. For compatibility with the codes' design provisions for high-strength reinforcement, this supplement prescribes requirements for the mechanical properties of wire that exceed the minimum values for yield strength and tensile strength in Table 3 and Table 4 of this specification.

S1.2. *Mechanical Property Requirements*:

S1.2.1 Minimum yield strength shall be specified in the purchase order in increments of 17.5 MPa [2500 psi]. When tested, the yield strength shall be determined at an extension under load of 0.35 percent.

Note S1.2—To conform to the limit on yield strength in building codes, the minimum yield strength specified in the purchase order should not be greater than 550 MPa [80,000 psi].

S1.2.2 Minimum tensile strength shall be 70 MPa [10,000 psi] greater than the minimum specified yield strength.

Note S1.3—A typical order entry line for minimum yield strength is, "500 MPa minimum yield strength" or "72,500 psi minimum yield strength."

S1.3. *Certification*:

S1.3.1 Certification for material produced to this supplement shall include a report of the test results for yield strength, tensile strength, and bend tests. Frequency of testing shall conform to Section 12 of this specification and Section 12 of M 221M/M 221 as applicable.

Standard Specification for

Corrosion-Resistant Coated Dowel Bars

AASHTO Designation: M 254-06

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Specification for

Corrosion-Resistant Coated Dowel Bars

AASHTO Designation: M 254-06

1. SCOPE

1.1 This specification covers the materials, manufacture, and installation of coated dowel bars to be used where corrosion-resistant performance is essential and may be used in lieu of stainless or other approved noncorrosive metals. The dowel shall consist of a steel core covered by an organic coating.

1.2 The coated dowels shall be one of the two following types:

Type A—The coating material develops sufficiently low-bond strength with concrete that a bond breaker is not required.

Type B—The coating material develops bond strength with concrete such that a bond breaker is required. The type of bond breaker used shall be as recommended by the coating manufacturer.

1.3 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 255M/M 255, Steel Bars, Carbon, Hot-Wrought, Special Quality, Mechanical Properties
- T 253, Coated Dowel Bars

2.2 *ASTM Standard*:

- G 12, Standard Test Method for Nondestructive Measurement of Film Thickness of Pipeline Coatings on Steel

2.3 *Other References*:

- FHWA-RD-74-18, "Nonmetallic Coating for Concrete Reinforcing Bars," 1974

3. GENERAL REQUIREMENTS

3.1 The coated dowels shall resist corrosion and degradation caused by roadway deicing materials and normal highway debris.

3.2 The coating shall develop low-bond strengths with portland cement concrete without a bond breaker, if Type A, or with the proper bond breaker if Type B.

3.3 The coating shall resist wear due to abrasion resulting from pavement expansion and contraction.

3.4 The coating used over the steel core shall be continuous on the lateral surface of the dowel.

3.5 Test procedures as stated herein and in T 253 shall apply to both Type A and Type B dowels.

3.6 In the event there is any change in material composition or geometrics of the joint support system, any or all parts of the dowels and assembly are subject to retesting. The frequency of qualification testing will be determined by the purchasing agency.

3.7 The processing facilities of the manufacturer and the fabricator shall be open to inspection by the agent of the purchaser at all times during the manufacturing and fabricating of the material.

3.8 A minimum of 24 dowel bars shall be made available for testing. Of these, a maximum of six bars may be in a basket assembly.

4. MATERIALS

4.1 The core material shall be made of steel meeting the requirements of M 255M/M 255. The grade shall be as specified by the purchasing agency.

4.2 The coating material shall be of organic composition with the exception of the pigment which may or may not be present and which may have an inorganic composition.

Note 1—The Type B coating material may be one of the types recommended in Report No. FHWA-RD-74-18 or other types approved by the purchasing agency.

5. DIMENSIONS

5.1 The core metal shall be 31.8-mm ($1^1/_4$-in.) diameter or as specified by the purchasing agency.

5.2 The nonabraded thickness of the Type A coating shall be 0.64 ± 0.13 mm (25 ± 5 mils). The nonabraded thickness of the Type B coating shall be 0.18 ± 0.05 mm (7 ± 2 mils).

5.3 Coating thickness shall be determined according to ASTM G 12 or by stripping the coating from the bar.

5.4 The dowels shall be supplied to lengths and in support assemblies or baskets as specified by the purchasing agency.

6. PHYSICAL REQUIREMENTS

6.1 The free ends of the dowels shall be saw cut and free of burrs and projections.

6.2 Dowel coatings shall be free from contamination, perforations, cracks, and holidays (pinholes not visually discernible). Checking for holidays shall be performed by the electric-resistance process. A 67.5-volt holiday detector shall be used, as recommended by the manufacturer of the test equipment, for the determination of holidays.

6.3 Any damage that results from welding or mechanical fixation to achieve a fixed-end condition shall not extend more than 25.4 mm (1 in.) in from the weld or point of fixation.

6.4 Welding to achieve a fixed-end condition shall be sufficiently strong to maintain dowel alignment under the forces imposed by concrete placement and construction practices.

6.5 When tested in accordance with T 253, the dowel bars shall have the following properties:

6.5.1 *Load Deflection*—The relative deflection shall not exceed 0.25 mm (0.10 in.) at the 1815-kg (4000-lb) load for any of the three specimens tested.

6.5.2 *Pullout*—The maximum pullout load shall not exceed 1360 kg (3000 lb) for any specimens, and no specimen shall show any corrosion, tears, or perforation due to the pullout and subsequent freeze-thaw testing.

6.5.3 *Abrasion*—The coating shall not have been worn away, perforated, or wrinkled, and none of the three specimens shall show depth or wear exceeding 70 percent of the original coating thickness. Thickness shall be determined according to Section 5.3 of this specification.

6.5.4 *Corrosion*—No corrosion shall be apparent on any of the specimens when viewed under five-power magnification.

6.5.5 *Chemical Resistance*—The coating shall not blister, soften, disbond, develop holidays, nor exhibit any undercutting at the drilled holes.

6.5.6 *Cathodic Disbonding*—No film failure shall take place during the first 1 hour of testing. Such film failure would be evidenced by the evolution of hydrogen gas at the cathode or appearance of corrosion products of steel at the anodes except that such hydrogen evolution or corrosion products at the intentionally cut 6.4-mm ($^1/_4$-in.) holes will not be considered as basis for rejection. However, no undercutting shall be permitted during the remainder of the test period at the intentionally cut 6.4-mm ($^1/_4$-in.) holes in either the anode or cathode.

6.5.7 *Coating Hardness*—The hardness of the coating shall exceed the Knoop Hardness Number of 16.

6.5.8 *Coating Impact Resistance*—No shattering or disbonding of the coating shall occur except at the impact area (area permanently deformed by the tup).

7. SAMPLING

7.1 A minimum of 24 dowel bars, of which up to six may be in a basket assembly, shall be furnished by the manufacturer for testing and verification of the materials and process. The specimens shall be made available to the testing laboratory 120 days prior to their first intended use. When fixed mechanical assembly is being used, a complete assembly with dowels shall be made available upon request by the purchasing agency.

8. DOCUMENTATION

8.1 Tests performed according to this specification shall be the responsibility of the manufacturers and/or coating applicator and may be performed at his laboratory or an independent laboratory approved by the purchasing agency. Upon completion of the tests, all tested specimens shall be properly labeled as to test procedure, and be made available upon request to the purchasing agency.

8.2 The laboratory facilities and procedure must be open to observation by the purchaser while tests are underway. The purchasing agency reserves the right to check any or all parts of the required tests in the agency laboratory or a laboratory of his choice.

8.3 The coated dowel manufacturer and/or coating applicator shall provide certified copies of test reports to the purchasing agency showing all test data.

8.4 For the purpose of identification, the manufacturer or applicator shall provide certification showing the generic type of coating material along with the type and percentages of pigments, diluents, fillers, flexibilizers, and other additives used.

8.5 The coated dowel manufacturer is defined as a company that produces a complete product consisting of dowel bar and coating.

8.6 The coating applicator is defined as a company that applies coatings to dowel bars.

8.7 Rechecks of the coated dowels may be made at the discretion of the purchasing agency. The purchasing agency may delete any of the above specified test procedures during rechecks of any previously approved product.

Standard Specification for

Uncoated High-Strength Steel Bars for Prestressing Concrete

AASHTO Designation: M 275M/M 275-08
ASTM Designation: A 722/A 722M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 2000

Standard Specification for

Uncoated High-Strength Steel Bars for Prestressing Concrete

AASHTO Designation: M 275M/M 275-08
ASTM Designation: A 722/A 722M-07

1. SCOPE

1.1. This specification covers uncoated high-strength steel bars intended for use in pretensioned and posttensioned prestressed concrete construction or in prestressed ground anchors. Bars are of a minimum ultimate tensile strength level of 1035 MPa [150000 psi].

1.2. Two types of bars are provided: Type I bar has a plain surface and Type II bar has surface deformations.

1.3. Supplementary requirements of an optional nature are provided. They shall apply only when specified by the purchaser.

1.4. This specification is applicable for orders in either SI units (M 275M) or in inch-pound units (M 275). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to M 275.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 244, Mechanical Testing of Steel Products
- T 285, Bend Test for Bars for Concrete Reinforcement

2.2. *ASTM Standards*:

- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- E 30-89, Test Methods for Chemical Analysis of Steel, Cast Iron, Open-Hearth Iron, and Wrought Iron

2.3. *Government Standard*:

- MIL-STD-129, Marking for Shipment and Storage

2.4. *U.S. Federal Standard*:

- Fed. Std. 123, Marking for Shipment (Civil Agencies)

3. ORDERING INFORMATION

3.1. Orders for material under this specification should include the following information:

3.1.1. Quantity (mass),

3.1.2. Name of material (uncoated high-strength bars for prestressing concrete),

3.1.3. AASHTO designation and year of issue,

3.1.4. Size and length,

3.1.5. Type,

3.1.6. Special inspection requirements, if desired (Section 12),

3.1.7. Special preparation for delivery, if desired (Section 11),

3.1.8. Load-elongation curve, if required (Section 15), and

3.1.9. Supplementary requirements, if desired.

Note 1—A typical ordering description is as follows: 50 uncoated high-strength bars for prestressing concrete to M 275M/M 275-_____; 26-mm diameter, 12.3 m long, Type II; packed in accordance with ASTM A 700; meeting supplementary bending properties. [50 uncoated high-strength bars for prestressing concrete to M 275M/M 275-____; 1-in. diameter, 40 ft, 6 in. long, Type II; packed in accordance with ASTM A 700; meeting supplementary bending properties.]

4. MATERIALS AND MANUFACTURE

4.1. The bars shall be rolled from properly identified heats of ingot cast or strand-cast steel. The standard sizes and dimensions of Type I and Type II bars shall be those listed in Table 1 and Table 2, respectively.

Table 1—Dimensions for Type I (Plain) Bar

Nominal Diameter		Nominal Weight		Nominal Area[a]	
mm	in.	kg/m	lb/ft	mm^2	$in.^2$
19	$^3/_4$	2.23	1.50	284	0.44
22	$^7/_8$	3.04	2.04	387	0.60
25	1	3.97	2.67	503	0.78
29	$1^1/_8$	5.03	3.38	639	0.99
32	$1^1/_4$	6.21	4.17	794	1.23
35	$1^3/_8$	7.52	5.05	955	1.48

[a] The nominal area is determined from the nominal diameter in inches. Values have been converted from inch-pound units to metric units.

Table 2—Dimensions for Type II (Deformed) Bar

Nominal Diameter[a]		Nominal Weight		Nominal Area[b]	
mm	in.	kg/m	lb/ft	mm^2	$in.^2$
15	$^5/_8$	1.46	0.98	181	0.28
20	$^3/_4$	2.22	1.49	271	0.42
26	1	4.48	3.01	548	0.85
32	$1^1/_4$	6.54	4.39	806	1.25
36	$1^3/_8$	8.28	5.56	1019	1.58
46	$1^3/_4$	13.54	9.10	1664	2.58
65	$2^1/_2$	27.10	18.20	3331	5.16

[a] Nominal diameters are for identification only. Values have been converted from metric to inch-pound units.

[b] The nominal area is determined from the bar weight less 3.5 percent for the ineffective weight of the deformation.

4.2. The bars shall be subjected to cold-stressing to not less than 80 percent of the minimum ultimate strength, and then shall be stress-relieved, to produce the prescribed mechanical properties.

5. CHEMICAL COMPOSITION

5.1. An analysis of each heat of steel shall be made by the manufacturer from test samples taken during the pouring of each heat.

5.1.1. Choice and use of chemical composition and alloying elements, to produce the mechanical properties of the finished bar prescribed in Section 6.2, shall be made by the manufacturer, subject to the limitations in Section 5.1.2.

5.1.2. On heat analysis, phosphorus and sulfur shall not exceed the following:

Phosphorus	0.040 percent
Sulfur	0.050 percent

5.2. A product analysis may be made by the purchaser from the finished bar representing each cast or heat of steel. The phosphorus and sulfur contents thus determined shall not exceed the limits specified in Section 5.1.2 by 0.008 percent.

5.3. ASTM E 30-89 shall be used for referee purposes.

6. MECHANICAL PROPERTIES

6.1. All testing for mechanical properties shall be performed in accordance with the requirements of T 244 Methods and Definitions.

6.2. *Tensile Properties*:

6.2.1. Finished bars shall have a minimum ultimate tensile strength of 1035 MPa [150000 psi].

6.2.2. The minimum yield strength of Type I and Type II bars shall be 85 percent and 80 percent, respectively, of the minimum ultimate tensile strength of the bars. The yield strength shall be determined by either of the methods described in T 244; however, in the extension under load method, the total strain shall be 0.7 percent, and in the offset method the offset shall be 0.2 percent.

6.2.3. The minimum elongation after rupture shall be 4.0 percent in a gauge length equal to 20 bar diameters, or 7.0 percent in a gauge length equal to 10 bar diameters.

6.3. *Test Specimens*—Tension tests shall be made using full-size bar test specimens. Machined reduced section test specimens are not permitted. All unit stress determinations shall be based on the nominal area shown in Table 1 or the effective area shown in Table 2.

6.4. *Number of Tests*—The number of tensile specimens tested shall be one from each 36 Mg [39 tons] or fraction thereof, of each size of bar rolled from each heat but not fewer than two from each heat. The specimens shall be randomly selected following the final processing operation.

6.5. *Retests*:

6.5.1. If any tensile property of any tension test specimen is less than that specified, and any part of the fracture is outside the middle third of the gauge length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

6.5.2. If the results of an original tension test fail to meet specified requirements, two additional tests shall be made on samples of bar from the same heat and bar size, and if failure occurs in either of these tests, the bar size from that heat shall be rejected.

6.5.3. If any test specimen fails because of mechanical reasons such as failure of testing equipment, it shall be discarded and another specimen taken.

6.5.4. If any test specimen develops flaws, it shall be discarded and another specimen of the same size bar from the same heat substituted.

7. REQUIREMENTS FOR DEFORMATIONS

7.1. Material furnished as Type II bar shall have deformations spaced uniformly along the length of the bar. The deformations on opposite sides of the bar shall be similar in size and shape. The average spacing or distance between deformations on both sides of the bar shall not exceed seven-tenths of the nominal diameter of the bar.

7.2. The minimum height and minimum projected area of the deformations shall conform to the requirements shown in Table 3.

Table 3—Deformation Dimensions for Type II Bar

Nominal Diameter		Deformation Dimensions					
		Maximum Average Spacing		Minimum Average Height		Minimum Projected Area[a]	
mm	in.	mm	in.	mm	in.	mm^2/mm	$in.^2/in.$
15	$^5/_8$	11.1	0.44	0.7	0.03	2.4	0.09
20	$^3/_4$	13.3	0.52	1.0	0.04	3.4	0.13
26	1	17.8	0.70	1.3	0.05	4.4	0.17
32	$1^1/_4$	22.5	0.89	1.6	0.06	5.4	0.21
36	$1^3/_8$	25.1	0.99	1.8	0.07	6.1	0.24
46	$1^3/_4$	30.1	1.19	2.2	0.09	7.3	0.29
65	$2^1/_2$	44.5	1.75	2.9	0.11	9.7	0.38

[a] Calculated from equation, minimum projected area = $0.75\pi d\ h/s$ where:
d = nominal diameter,
h = minimum average height, and
s = maximum average spacing.

7.3. *Mechanical Coupling*—For those bars having deformations arranged in a manner to permit coupling of the bars with a screw-on type of coupler, it shall be the responsibility of the finished-bar manufacturer to demonstrate that a bar cut at any point along its length may be coupled to any other length of bar and that a coupled joint supports the minimum specified ultimate tensile strength of the coupled bars. The coupler type shall be provided or designed by the finished-bar manufacturer.

8. MEASUREMENTS OF DEFORMATIONS

8.1. The average spacing of deformations shall be determined by dividing a measured length of the bar specimen by the number of individual deformations and fractional parts of deformations on any one side of the bar specimen. A measured length of the bar specimen shall be considered the distance from a point on a deformation to a corresponding point on any other deformation on the same side of the bar.

8.2. The average height of deformations shall be determined from measurements made on not fewer than two typical deformations. Determinations shall be based on three measurements per deformation: one at the center of the overall length, and the other two at the quarter points of the overall length.

8.3. To indicate adequately the conformity to the dimensional requirements, measurements shall be taken at random from one bar from each 30 Mg [33 tons] of each lot or fraction thereof.

8.4. Insufficient height, insufficient projected area, or excessive spacing of deformations shall not constitute cause for rejection unless it has been clearly established by determinations on each lot that typical deformation height or spacing does not conform to the minimum requirements prescribed in Section 7. No rejection shall be made on the basis of measurements if fewer than ten adjacent deformations on each side of the bar are measured.

Note 2—The term “lot” shall mean all bars of the same nominal mass per linear meter [weight per linear foot] contained in an individual shipping release or shipping order.

9. PERMISSIBLE VARIATION IN SIZE OR MASS

9.1. For Type I bars, the permissible variation from the nominal diameter specified in Table 1 shall not exceed +0.75, –0.25 mm [+0.030, –0.010 in.].

9.2. For Type II bars, the permissible variation from the nominal mass specified in Table 2 shall not exceed +3 percent, –2 percent.

10. FINISH

10.1. The bars shall be free of defects injurious to the mechanical properties and shall have a workmanlike finish.

11. DELIVERY

11.1. Packaging and loading for shipment shall be in accordance with ASTM A 700.

11.2. When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, marking for shipment, in addition to requirements specified in the contract or order, shall be in accordance with MIL-STD-129 for military agencies and with Fed. Std. No. 123 for civil agencies.

11.3. Unless otherwise specified in the contract or order, bars shall be grouped by size. Each bundle or lift shall be tagged, showing the heat number, bar size, specification number (M 275M/M 275), and the identity of the finished bar manufacturer. The tags shall display the following statement "High Strength Prestressing Bars." Both ends of each bar shall be painted yellow.

12. INSPECTION

12.1. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests (except product analysis) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

12.2. If specified in the purchase order, the purchaser shall reserve the right to perform any of the inspections set forth in the specification where such inspections are deemed necessary to assure that the material furnished conforms to prescribed requirements.

12.3. If outside inspection is waived, the finished-bar manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material.

13. REJECTION

13.1. Unless otherwise specified, any rejection based on tests made in accordance with Section 5.2 shall be reported to the manufacturer within five working days from the receipt of samples by the purchaser.

13.2. Material that shows injurious defects subsequent to its acceptance at the manufacturer's works shall be subject to rejection, and the manufacturer shall be notified.

14. REHEARING

14.1. Samples tested in accordance with Section 5.2 that represent rejected material shall be preserved for 2 weeks from the date rejection is reported to the manufacturer. In case of dissatisfaction with the results of the tests, the manufacturer shall be permitted to make claim for a rehearing within that time.

15. CERTIFICATION

15.1. If outside inspection is waived, a manufacturer's certification that the material has been tested in accordance with and meets the requirements of this specification shall be the basis of acceptance of the material. The certification shall include the specification number, year-date of issue, and revision letter, if any.

15.2. The manufacturer shall, when required in the order, furnish a representative load-elongation curve for each size and type of bar shipped.

15.3. A modulus of elasticity value of 205 GPa (29700000 psi) shall be used for the purpose of elongation calculation for Type II bars.

Note 3—Experience has shown that plotted load-elongation curves from mill tests on Type II bars vary excessively and are not sufficiently reliable for use in calculating modulus of elasticity values.

15.4. A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) shall be regarded as having the same validity as a counter part printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any existing EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 4—The industry definition as invoked here is: EDI is the computer-to-computer exchange of business information in a standard format such as ANSI SAC X12.

16. KEYWORDS

16.1. High-strength steel bars; prestressed concrete; posttensioning; deformed bars; plain bars.

SUPPLEMENTARY REQUIREMENTS

The following supplementary requirements shall apply only when specified in the purchase order or contract.

S1. BENDING PROPERTIES

S1.1. The bend-test specimens shall withstand being bent, at ambient temperature, but in no case less than 15°C [59°F], around a pin without cracking on the outside of the bent portion. The requirements for degree of bending and sizes of pins are prescribed in Table 4.

Table 4—Supplementary Bend Test Requirements

Nominal Bar Diameters		Diameter of Pin for 135° Bend[a]
mm	in.	
15	$^5/_8$	$d = 6t$
20	$^3/_4$	$d = 6t$
26	1	$d = 6t$
32	$1^1/_4$	$d = 8t$
36	$1^3/_8$	$d = 8t$
46	$1^3/_4$	$d = 10t$
65	$2^1/_2$	$d = 10t$

[a] d = diameter of pin around which specimen is bent.
t = nominal diameter of bar.

S1.2. The bend test shall be made on full-sized specimens of sufficient length to ensure free bending and with apparatus that provides the following:

S1.2.1 Continuous and uniform application of force throughout the duration of the bending operation.

S1.2.2 Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate or bending about a central pin on a simple span with end supports free to rotate.

S1.2.3 Close wrapping of the specimen around the pin during the bending operation.

S1.3. Other methods of bend testing shall be permitted, but failures due to such methods shall not constitute a basis for rejection.

S1.4. The number of bend-test specimens shall be one from each 20 Mg [22 tons], or fraction thereof, of each size of bar rolled from each heat, but not fewer than two from each heat. The specimens shall be randomly selected following the final processing operation.

S1.5. If a bend test fails for reasons other than mechanical reasons or flaws in the specimen as described in Sections 6.5.3 and 6.5.4, a retest shall be permitted on two random specimens from the quantity of the finished bar product for each bar size in S1.4. If the results of both test specimens meet the specified requirements, the bars shall be accepted. The retest shall be performed on test specimens that are at air temperature, but not less than 15°C [59°F].

S2. REDUCTION OF AREA

S2.1. The minimum reduction of area from the effective area shall be 20 percent for Type I plain bars.

S3. CHEMICAL REQUIREMENTS

S3.1. The chemical composition determined as specified in Section 5.1 shall be reported to the purchaser or his representative.

Standard Specification for

Epoxy-Coated Reinforcing Bars: Materials and Coating Requirements

---

AASHTO Designation: M 284M/M 284-09
ASTM Designation: A 775/A 775M-07b

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Epoxy-Coated Reinforcing Bars: Materials and Coating Requirements

AASHTO Designation: M 284M/M 284-09
ASTM Designation: A 775/A 775M-07b

AASHTO M 284M/M 284-09 is identical to ASTM A 775/A 775M-07b except for the following provision:

1. Add the following to the last sentence of ASTM A 775/A 775M-07b Section 11.4:

   The coating thickness after curing on sheared or cut ends shall be 175 to 450 µm (7 to 18 mils). The patching material used to repair the sheared or cut ends shall not extend beyond 75 mm (3 in.) from the sheared or cut end.

Standard Specification for

Epoxy-Coated Reinforcing Bars: Handling Requirements for Fabrication and Job Site

---

AASHTO Designation: M 317M/M 317-03 (2007)
ASTM Designation: D 3963/D 3963M-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Epoxy-Coated Reinforcing Bars: Handling Requirements for Fabrication and Job Site

AASHTO Designation: M 317M/M 317-03 (2007)

ASTM Designation: D 3963/D 3963M-01

AASHTO M 317M/M 317-03 (2007) is identical to ASTM D 3963/D 3963M-01.

Standard Specification for

Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement

AASHTO Designation: M 322M/M 322-10
ASTM Designation: A 996/A 996M-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement

AASHTO Designation: M 322M/M 322-10
ASTM Designation: A 996/A 996M-09

1. SCOPE

1.1 This specification covers rail-steel and axle-steel bars for concrete reinforcement. Three types of product are included, designated with a “rail symbol” and an “R” for bars made of rail-steel and with an “A” for bars made of axle-steel. The standard sizes and dimensions of deformed bars and their number designations are given in Table 1. All sizes and grades of all types may not be readily available; manufacturers should be consulted to verify availability.

1.2 The text of this specification references notes and footnotes that provide explanatory material. These notes and footnotes, excluding those in tables and figures, shall not be considered as requirements of the specification.

1.3 Type “rail symbol” and Type R are of two minimum yield levels, namely 350 MPa [50 000 psi] and 420 MPa [60 000 psi] designated as Grade 350 [50] and Grade 420 [60], respectively. Type A is of two minimum yield levels, namely 300 MPa [40 000 psi] and 420 MPa [60 000 psi] designated Grade 300 [40] and Grade 420 [60].

1.4 The weldability of the steel is not a requirement of this specification.

1.5 This specification is applicable for orders in either SI units (M 322M) or inch-pound units (M 322).

1.6 The values stated in either SI units or inch-pound units are to be regarded as standard. Within the text, the inch-pound units are shown in brackets. The values stated must be used independently of the other. Combining values from the two systems may result in nonconformance with the specification.

1.7 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Table 1—Deformed Bar Designation Numbers, Nominal Masses [Weights], Nominal Dimensions, and Deformation Requirements

		Nominal Dimensions[a]			Deformation Requirements, mm		
Bar Designation No.	Nominal Mass [Weight], kg/m [lb/ft]	Diameter, mm [in.]	Cross-Sectional Area, mm^2 [$in.^2$]	Perimeter, mm [in.]	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
10 [3]	0.560 [0.376]	9.5 [0.375]	71 [0.11]	29.9 [1.178]	6.7 [0.262]	0.38 [0.015]	3.6 [0.143]
13 [4]	0.994 [0.668]	12.7 [0.500]	129 [0.20]	39.9 [1.571]	8.9 [0.350]	0.51 [0.020]	4.9 [0.191]
16 [5]	1.552 [1.043]	15.9 [0.625]	199 [0.31]	49.9 [1.963]	11.1 [0.437]	0.71 [0.028]	6.1 [0.239]
19 [6]	2.235 [1.502]	19.1 [0.750]	284 [0.44]	59.8 [2.356]	13.3 [0.525]	0.97 [0.038]	7.3 [0.286]
22 [7]	3.042 [2.044]	22.2 [0.875]	387 [0.60]	69.8 [2.749]	15.5 [0.612]	1.12 [0.044]	8.5 [0.334]
25 [8]	3.973 [2.670]	25.4 [1.000]	510 [0.79]	79.8 [3.142]	17.8 [0.700]	1.27 [0.050]	9.7 [0.383]

[a] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same mass [weight] per meter [foot] as the deformed bar.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- T 244, Mechanical Testing of Steel Products

2.2 *ASTM Standards*:

- A 700, Standard Practices for Packaging, Marking, and Loading Methods for Steel Products for Shipment
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

2.3 *Military Standards*:

- MIL-STD-129, Marking for Shipment and Storage
- MIL-STD-163, Steel Mill Products Preparation for Shipment and Storage

2.4 *Federal Standard*:

- Fed. Std. No. 123, Marking for Shipment (Civil Agencies)

3. TERMINOLOGY

3.1 *Description of Terms Specific to This Standard*:

3.1.1 *deformations*—transverse protrusions on a deformed bar.

3.1.2 *deformed bar*—steel bar with transverse protrusions; a bar that is intended for use as reinforcement in reinforced concrete construction.

3.1.2.1 *Discussion*—The surface of the bar is provided with lugs or protrusions that inhibit longitudinal movement of the bar relative to the concrete surrounding the bar in such construction. The lugs or protrusions conform to the provisions of this specification.

3.1.3 *rib*—longitudinal protrusion on a deformed bar.

4. ORDERING INFORMATION

4.1 It shall be the responsibility of the purchaser to specify all requirements that are necessary for material ordered to this specification. Such requirements shall include, but are not limited to, the following:

4.1.1 Quantity (mass) [weight],

4.1.2 Name of material (rail-steel or axle-steel deformed bars for concrete reinforcement),

4.1.3 Type,

4.1.4 Size,

4.1.5 Grade,

4.1.6 Packaging (see Section 20),

4.1.7 AASHTO designation and year of issue, and

4.1.8 Certified mill test reports (if desired). (See Section 18.)

5. MATERIAL AND MANUFACTURE

5.1 The bars shall be rolled from standard section Tee-rails or from carbon-steel axles for railway cars and locomotives. No other materials, such as those known by the terms “rerolled, rail-steel equivalent, and rail-steel quality,” shall be substituted.

6. CARBON DETERMINATION

6.1 For axle-steel product, the manufacturer shall make a determination for the carbon content of each axle received for manufacture into reinforcing bars. Based on these carbon determinations, all steel axles shall be stocked for subsequent rolling in separated lots by carbon range. The ranges of carbon shall be determined by the manufacturer as those best suited to meet the mechanical requirements.

6.2 When requested by the purchaser, the manufacturer shall report the carbon range for each lot of bars furnished.

7. REQUIREMENTS OF DEFORMATIONS

7.1 Deformations shall be spaced along the bar at substantially uniform distances. The deformations on opposite sides of the bar shall be similar in size, shape, and pattern.

7.2 The deformations shall be placed with respect to the axis of the bar so that the include angle is not less than 45 degrees. Where the line of deformations forms an include angle with the axis of the bar from 45 degrees to 70 degrees inclusive, the deformations shall alternately reverse in direction from those on the opposite side. Where the line of deformation is greater than 70 degrees, a reversal in direction shall not be required.

7.3 The average spacing or distance between deformations on each side of the bar shall not exceed seven-tenths of the nominal diameter of the bar.

7.4 The overall length of deformations shall be such that the gap between the ends of the deformations shall not exceed 12.5 percent of the nominal perimeter of the bar. Where the ends terminate in a rib, the width of the rib shall be considered as the gap between these ends. The summation of the gaps shall not exceed 25 percent of the nominal perimeter of the bar. Furthermore, the summation of gaps shall not exceed 25 percent of the nominal perimeter of the bar. The nominal perimeter of the bar shall be 3.1416 times the nominal diameter.

7.5 The spacing, height, and gap of deformations shall conform to the requirements prescribed in Table 1.

8. MEASUREMENTS OF DEFORMATIONS

8.1 The average spacing of deformations shall be determined by measuring the length of a minimum of ten spaces and dividing that length by the number of spaces included in the measurement. The measurement shall begin from a point on a deformation at the beginning of the first space to a corresponding point on a deformation after the last included space. Spacing measurements shall not be made over a bar area containing bar marking symbols involving letters or numbers.

8.2 The average height of deformations shall be determined from measurements made on not fewer than two typical deformations. Determinations shall be based on three measurements per deformation, one at the center of the overall length and the other two at the quarter points of the overall length.

8.3 Insufficient height, insufficient circumferential coverage, or excessive spacing of deformations shall not constitute cause for rejection unless it has been clearly established by determinations on each lot (Note 1) tested that typical deformation height, gap, or spacing do not conform to the minimum requirements prescribed in Section 7. No rejection may be made on the basis of measurements if fewer than ten adjacent deformations on each side of the bar are measured.

Note 1—As used within the intent of Sections 8.3 and 14.1, the term “lot” shall mean all the bars of one bar number and pattern of deformations contained in an individual shipping release or shipping order.

9. TENSILE REQUIREMENTS

9.1 The material, as represented by the test specimens, shall conform to the requirements for tensile properties prescribed in Table 2.

9.2 The yield point or yield strength shall be determined by one of the following methods:

9.2.1 The yield point shall be determined by the drop of the beam or halt in the gauge of the testing machine.

9.2.2 Where the steel tested does not exhibit a well-defined yield point, the yield strength shall be determined by the offset method (0.2 percent offset), as described in T 244 (Section 13.2.1).

9.3 The percentage of elongation shall be as prescribed in Table 2.

Table 2—Tensile Requirements

	Grade[a] 300 [40]	Grade 350 [50]	Grade 420 [60]	
Tensile strength, min, MPa [psi]	500 [70 000]	550 [80 000]	600 [90 000]	
Yield strength, min, MPa [psi]	300 [40 000]	350 [50 000]	400 [60 000]	
Elongation in 200 mm [8 in.], min, percent Bar Designation No.:			Rail Symbol and Type R	Type A
10 [3]	11	6	6	8
13, 16, 19 [4, 5, 6]	12	7	6	8
22 [7]	11	6	5	8
25 [8]	10	5	4.5	7

[a] Sizes 10 through 19 may not be readily available; manufacturers should be consulted to verify availability.

10. BENDING REQUIREMENTS

10.1 The bend-test specimen shall withstand being bent around a pin without cracking on the outside of the bent portion. The requirements for degree of bending and sizes of pins are prescribed in Table 3.

Table 3—Bend-Test Requirements

Bar Designation No.	Pin Diameter for Bend Tests[a]		
	Type Rail Symbol	Type R	Type A
10, 13, 16 [3, 4, 5]	6*d*[b]	$3\,{}^{1}/_{2}d$	$3\,{}^{1}/_{2}d$
19, 22, 25 [6, 7, 8]	6*d*	5*d*	5*d*

[a] Test bends 180°.

[b] *d* = nominal diameter of specimen.

10.2 The bend test shall be made on specimens of sufficient length to ensure free bending and with an apparatus that provides the following:

10.2.1 Continuous and uniform application of force throughout the duration of the bending operation;

10.2.2 Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate;

10.2.3 Close wrapping of the specimen around the pin during the bending operation.

10.3 It shall be permissible to use other acceptable, more severe methods of bend testing, such as placing a specimen across two pins free to rotate and applying the bending force with a fixed pin. When failures occur under more severe methods, retests shall be permitted under the bend-test method prescribed in Section 10.2.

11. PERMISSIBLE VARIATION IN MASS [WEIGHT]

11.1 Deformed reinforcing bars shall be evaluated on the basis of nominal mass [weight]. The mass [weight] determined using the measured mass [weight] of the test specimen and rounding in accordance with ASTM E 29 shall be at least 94 percent of the applicable mass [weight] per unit length prescribed in Table 1. In no case shall excess mass [overweight] of any deformed bar be cause for rejection.

12. FINISH

12.1.1 The bars shall be free of detrimental surface imperfections.

12.1.2 Rust, seams, surface irregularities, or mill scale shall not be cause for rejection, provided the mass [weight], dimensions, cross-sectional area, and tensile properties of a hand wire-brushed test are not less than the requirements of this specification.

12.1.3 Surface imperfections or flaws other than those specified in Section 12.1.2 shall be considered detrimental when specimens containing such imperfections fail to conform to either tensile or bending requirements. Examples include, but are not limited to, laps, seams, slivers, cooling or casting cracks, and mill or guide marks.

13. TEST SPECIMENS

13.1 All mechanical tests shall be conducted in accordance with T 244, including Annex A9.

13.2 Tension test specimens shall be the full section of bar as rolled.

13.3 The unit stress determinations on full-sized specimens shall be based on the nominal bar area.

13.4 The bend-test specimens shall be the full section of the bar as rolled.

14. NUMBER OF TESTS

14.1 For bar sizes No. 10 to No. 25 [No. 3 to No. 8] inclusive, one tension test and one bend test shall be made from each lot (Note 1) of 9 Mg [10 tons] or fraction thereof. Each lot of rails (“rail symbol” or “R”) shall not vary more than 5 kg/m [10 lb/yd] of nominal mass [weight]. Each lot of axles (Type A) shall be assorted in groups as specified in Section 6.

15. RETESTS

15.1 If results of an original tension specimen fail to meet the specified minimum requirements and are within 14 MPa [2000 psi] of the required tensile strength, within 7 MPa [1000 psi] of the required yield point, or within two percentage points of the required elongation, a retest shall be permitted on two random specimens for each original tension specimen failure from the lot. Both retest specimens shall meet the requirements of this specification.

15.2 If a bend test fails for reasons other than mechanical reasons or flaws in the specimen as described in Sections 15.4.2 and 15.4.3, a retest shall be permitted on two random specimens from the same lot. Both retest specimens shall meet the requirements of this specification. The retest shall be performed on test specimens that are at air temperature, but not less than 16°C [60°F].

15.3 If a weight [mass] test fails for reasons other than flaws in the specimen as described in Section 15.4.3, a retest shall be permitted on two random specimens from the same lot. Both retest specimens shall meet the requirements of this specification.

15.4 If the original test or any of the random retests fails because of any reasons listed in Sections 15.4.1, 15.4.2 or 15.4.3, the test shall be considered an invalid test. The results shall be discarded and the test shall be repeated on a specimen from the same lot.

15.4.1 The elongation property of any tension test specimen is less than that specified, and any part of the fracture is outside the middle half of the gauge length, as indicated by scribe marks on the specimen before testing.

15.4.2 Mechanical reasons such as failure of testing equipment or improper specimen preparation.

15.4.3 Flaws are detected in a test specimen, either before or during the performance of the test.

Note 2—Marking specimens with multiple scribe or punch marks can reduce the occurrence of fracture outside or near these marks and the need for declaring the test invalid.

16. INSPECTION

16.1 The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

16.2 *For Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein and shall be permitted to use one's own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

17. REJECTION

17.1 Material that shows injurious defects subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

18. TEST REPORTS

18.1 When specified in the purchase order, report the following information on a per-lot basis. Additional items may be reported as requested or desired.

18.1.1 Carbon level—Type A only,

18.1.2 Tensile properties,

18.1.3 Bend test.

18.2 A material test report, certificate of inspection, or similar document printed from or used in electronic form from an electronic data interchange (EDI) transmission shall be regarded as having the same validity as a counterpart printed in the certifier's facility. The content of the EDI transmitted document must meet the requirements of the invoked AASHTO standard(s) and conform to any EDI agreement between the purchaser and the supplier. Notwithstanding the absence of a signature, the organization submitting the EDI transmission is responsible for the content of the report.

Note 3—The industry definition invoked here is: EDI is the computer to computer exchange of business information in a standard format such as ANSI ASC X12.

19. MARKING

19.1 When loaded for mill shipment, bars shall be properly separated and tagged with the manufacturer's test identification number.

19.2 Each manufacturer shall identify the symbols of his marking system.

19.3 All bars produced to this specification shall be identified by a distinguishing set of marks legibly rolled into the surface of one side of the bar to denote in the following order:

19.3.1 *Point of Origin*—letter or symbol established as the manufacturer's mill designation;

19.3.2 *Size Designation*—Arabic number corresponding to bar designation number of Table 1;

19.3.3 *Type of Steel*—rail symbol, letter R or letter A, indicating that the bar was produced from rail or axle steel;

19.3.4 *Minimum Yield Designation*—for Grade 420 [60] bars, either the number 4 [60] or a single continuous longitudinal line through at least five spaces offset from the center of the bar side. (There is no marking designation for Grade 350 [50] or Grade 300 [40] bars.)

19.3.5 It shall be permissible to substitute bars having sizes and grades in SI units for bars ordered to the corresponding sizes and grades in inch-pound units.

20. PACKAGING

20.1 When specified in the purchase order, packaging shall be in accordance with the procedures in ASTM A 700.

20.2 *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be as specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

21. KEYWORDS

21.1 Concrete reinforcement; deformations (protrusions); steel bars.

Standard Specification for

Materials for Embankments and Subgrades

AASHTO Designation: M 57-80 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Materials for Embankments and Subgrades

AASHTO Designation: M 57-80 (2008)

1. SCOPE

1.1 This specification covers materials for use in the construction of embankments and subgrades.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 145, Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes
- M 146, Terms Relating to Subgrade, Soil-Aggregate, and Fill Materials
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test
- T 88, Particle Size Analysis of Soils
- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop
- T 180, Moisture-Density Relations of Soils Using a 4.54-kg (10-lb) Rammer and a 457-mm (18-in.) Drop
- T 191, Density of Soil In-Place by the Sand-Cone Method
- T 224, Correction for Coarse Particles in the Soil Compaction Test
- T 310, In-Place Density and Moisture Content of Soil and Soil-Aggregate by Nuclear Methods (Shallow Depth)

3. DEFINITIONS

3.1 Definitions of these materials are given in M 146.

4. GENERAL REQUIREMENTS

4.1 Materials shall be free from detrimental quantities of organic material, such as leaves, grass, roots, and sewage.

4.2 Materials obtained from cuts or borrow areas shall conform to one of the following requirements:

Note 1—See M 145.

4.2.1 *In Embankments*—Materials classified in the A-1, A-2-4, A-2-5, or A-3 groups as in M 145 shall be used when available and shall be compacted to the depth specified to not less than 95 percent of the maximum density per T 99. If material of this character is not available and materials from the A-2-6, A-2-7, A-4, A-5, A-6, or A-7 groups must be used, special attention should be given to the design and construction of the embankment. Materials from these groups shall be compacted to not less than 95 percent of the maximum density and within two percentage points of the optimum moisture content per T 99.

4.2.2 *In Subgrades*—Materials classified in the A-1, A-2-4, A-2-5, or A-3, groups as shown in M 145 shall be used when available and shall be compacted to the depth specified to not less than 95 percent of the maximum density per T 99. Materials in the A-2-6, A-2-7, A-4, A-5, A-6, or A-7 groups may be used if compacted to the depth specified to not less than 95 percent of the maximum density and within two percentage points of the optimum moisture content per T 99.

4.3 Local shale may be used in embankment or subgrade construction if the condition of existing pavements and embankments indicate satisfactory results. Appropriate special specifications shall be prepared for such material.

5. DENSITY REQUIREMENTS

5.1 Density percentage requirements may be specified in terms of T 180, if the resultant density and optimum moisture content are comparable with T 99 under the above conditions.

6. METHODS OF TESTING

6.1 Methods of testing materials for embankments and subgrades shall be in accordance with the standard methods of the American Association of State Highway and Transportation Officials. (See Table 1.)

Table 1—AASHTO Standard Methods

Soil preparation (dry method)	T 87
Soil preparation (wet method)	T 146
Material passing 75-µm (No. 200) sieve	T 11
Sieve analysis	T 27
Mechanical analysis of soils	T 88
Liquid limit	T 89
Plastic limit	T 90
Moisture-density relationship [2.5-kg (5.5-lb) rammer]	T 99
Moisture-density relationship [4.54-kg (10-lb) rammer]	T 180
Density of soil in place	T 191, T 233
Moisture in place by nuclear methods	T 310
Coarse particle correction	T 224

Note 2—Use either T 88 or T 11 and T 27 to determine the particle size distribution as a basis for classification.

Standard Specification for

Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes

AASHTO Designation: M 145-91 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes

AASHTO Designation: M 145-91 (2008)

1. SCOPE

1.1 This recommended practice describes a procedure for classifying soils into seven groups based on laboratory determination of particle size distribution, liquid limit, and plasticity index. Evaluation of soils within each group is made by means of a "group index," which is a value calculated from an empirical formula. The group classification, including group index, should be useful in determining the relative quality of the soil material for use in earthwork structures, particularly embankments, subgrades, subbases, and bases. However, for the detailed design of important structures, additional data concerning strength or performance characteristics of the soil under field conditions will usually be required.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test
- T 88, Particle Size Analysis of Soils
- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 146, Wet Preparation of Disturbed Soil Samples for Test

2.2 *ASTM Standard*:

- D 1140, Standard Test Methods for Amount of Material in Soils Finer Than the No. 200 (75-µm) Sieve

Note 1—Either T 88, or T 11 and T 27, or ASTM D 1140 will be used to determine the particle size distribution of soils or soil-aggregate mixtures as a basis for classification.

3. CLASSIFICATION

3.1 The classification is made by using the test limits and group index values shown in Table 1. If a more detailed classification is desired, a further subdivision of the groups shown in Table 1 may be made. An example of the classification with subgroups such as those shown in Table 1 may be made. An example of the classification with such subgroups is shown in Table 2. The liquid limit and plasticity index ranges for the A-4, A-5, A-6, and A-7 soil groups are shown graphically in Figure 2.

Table 1—Classification of Soils and Soil-Aggregate Mixtures

General Classification	Granular Materials (35 Percent or Less Passing 75 µm)			Silt-Clay Materials (More Than 35 Percent Passing 75 µm)			
Group Classification	A-1	A-3[a]	A-2	A-4	A-5	A-6	A-7
Sieve analysis, percent passing:							
2.00 mm (No. 10)	—	—	—	—	—	—	—
0.425 mm (No. 40)	50 max	51 min	—	—	—	—	—
75 µm (No. 200)	25 max	10 max	35 max	36 min	36 min	36 min	36 min
Characteristics of fraction passing 0.425 mm (No. 40)							
Liquid limit	—			40 max	41 min	40 max	41 min
Plasticity index	6 max	NP	[b]	10 max	10 max	11 min	11 min
General rating as subgrade	Excellent to Good			Fair to Poor			

[a] The placing of A-3 before A-2 is necessary in the "left to right elimination process" and does not indicate superiority of A-3 over A-2.

[b] See Table 2 for values.

Table 2—Classification of Soils and Soil-Aggregate Mixtures

General Classification	Granular Materials (35 Percent or Less Passing 75 µm)							Silt-Clay Materials (More Than 35 Percent Passing 75 µm)			
	A-1			A-2							A-7
Group Classification	A-1-a	A-1-b	A-3	A-2-4	A-2-5	A-2-6	A-2-7	A-4	A-5	A-6	A-7-5, A-7-6
Sieve analysis, percent passing:											
2.00 mm (No. 10)	50 max	—	—	—	—	—	—	—	—	—	—
0.425 mm (No. 40)	30 max	50 max	51 min	—	—	—	—	—	—	—	—
75 µm (No. 200)	15 max	25 max	10 max	35 max	35 max	35 max	35 max	36 min	36 min	36 min	36 min
Characteristics of fraction passing 0.425 mm (No. 40)											
Liquid limit	—		—	40 max	41 min	40 max	41 min	40 max	41 min	40 max	41 min
Plasticity index	6 max		NP	10 max	10 max	11 min	11 min	10 max	10 max	11 min	11 min[a]
Usual types of significant constituent materials	Stone fragments, gravel and sand		Fine sand	Silty or clayey gravel and sand				Silty soils		Clayey soils	
General rating as subgrade	Excellent to Good							Fair to Poor			

[a] Plasticity index of A-7-5 subgroup is equal to or less than *LL* − 30. Plasticity index of A-7-6 subgroup is greater than *LL* − 30. (See Figure 2.)

3.2 *Classification Procedure*—With required test data available, proceed from left to right in Table 1 or Table 2 and the correct group will be found by process of elimination. The first group from the left into which the test data will fit is the correct classification. All limiting test values are shown as whole numbers. If fractional numbers appear on test reports, convert to nearest whole number for purposes of classification. Group index values should always be shown in parentheses after group symbol as: A-2-6(3), A-4(5), A-6(12), A-7-5(17), etc.

4. DEFINITIONS OF GRAVEL, SAND, AND SILT-CLAY

4.1 The terms “gravel,” “coarse sand,” and “silt-clay,” as determinable from the minimum test data required in this classification arrangement and as used in subsequent word descriptions, are defined as follows:

4.1.1 *gravel*—material passing sieve with 75-mm (3-in.) square openings and retained on the 2.00-mm (No. 10) sieve.

4.1.2 *coarse sand*—material passing the 2.00-mm (No. 10) sieve and retained on the 0.425-mm (No. 40) sieve.

4.1.3 *fine sand*—material passing the 0.425-mm (No. 40) sieve and retained on the 75-µm (No. 200) sieve.

4.1.4 *silt clay (combined silt and clay)*—material passing the 75-µm (No. 200) sieve.

4.1.5 Boulders and cobbles (retained on 75-mm (3-in.) sieve) should be excluded from the portion of the sample to which the classification is applied, but the percentage of such material, if any, in the sample should be recorded.

4.1.6 The term “silty” is applied to fine material having plasticity index of 10 or less and the term “clayey” is applied to fine material having plasticity index of 11 or greater.

5. DESCRIPTION OF CLASSIFICATION GROUPS

5.1 *Granular Materials*—Containing 35 percent or less passing 75-µm (No. 200) sieve, Note 2.

5.1.1 *Group A-1*—The typical material of this group is a well-graded mixture of stone fragments or gravel, coarse sand, fine sand, and a nonplastic or feebly plastic soil binder. However, this group also includes stone fragments, gravel, coarse sand, volcanic cinders, etc. without soil binder.

5.1.1.1 *Subgroup A-1-a* includes those materials consisting predominantly of stone fragments or gravel, either with or without a well-graded binder of fine material.

5.1.1.2 *Subgroup A-1-b* includes those materials consisting predominantly of coarse sand, either with or without a well-graded soil binder.

5.1.2 *Group A-3*—The typical material of this group is fine beach sand or fine desert blow sand without silty or clay fines or with a very small amount of nonplastic silt. The group includes also stream-deposited mixtures of poorly graded fine sand and limited amounts of coarse sand and gravel.

5.1.3 *Group A-2*—This group includes a wide variety of "granular" materials that are borderline between the materials falling in Groups A-1 and A-3 and silt-clay materials of Groups A-4, A-5, A-6, and A-7. It includes all materials containing 35 percent or less passing the 75-µm (No. 200) sieve that cannot be classified as A-1 or A-3 due to fines content or plasticity or both, in excess of the limitations for those groups.

5.1.3.1 Subgroups A-2-4 and A-2-5 include various granular materials containing 35 percent or less passing the 75-µm (No. 200) sieve and with a minus 0.425-mm (No. 40) portion having the characteristics of the A-4 and A-5 groups. These groups include such materials as gravel and coarse sand with silt contents or plasticity indexes in excess of the limitations of Group A-1, and fine sand with nonplastic silt content in excess of the limitations of Group A-3.

5.1.3.2 Subgroups A-2-6 and A-2-7 include materials similar to those described under Subgroups A-2-4 and A-2-5 except that the fine portion contains plastic clay having the characteristics of the A-6 or A-7 group.

Note 2—Classification of materials in the various groups applies only to the fraction passing the 75-mm (3-in.) sieve. Therefore, any specifications regarding the use of A-1, A-2, or A-3 materials in construction should state whether boulders retained on the 75-mm (3-in.) sieve are permitted.

5.2 *Silt-Clay Materials*—Containing more than 35 percent passing the 75-µm (No. 200) sieve.

5.2.1 *Group A-4*—The typical material of this group is a nonplastic or moderately plastic silty soil usually having the 75 percent or more passing the 75-µm (No. 200) sieve. The group includes also mixtures of fine silty soil and up to 64 percent of sand and gravel retained on 75-µm (No. 200) sieve.

5.2.2 *Group A-5*—The typical material of this group is similar to that described under Group A-4, except that it is usually of diatomaceous or micaceous character and may be highly elastic as indicated by the high liquid limit.

5.2.3 *Group A-6*—The typical material of this group is a plastic clay soil usually having 75 percent or more passing the 75-µm (No. 200) sieve. The group includes also mixtures of fine clayey soil and up to 64 percent of sand and gravel retained on the 75-µm (No. 200) sieve. Materials of this group usually have high-volume change between wet and dry states.

5.2.4 *Group A-7*—The typical material of this group is similar to that described under Group A-6, except that it has the high liquid limits characteristic of the A-5 group and may be elastic as well as subject to high-volume change.

5.2.4.1 Subgroup A-7-5 includes those materials with moderate plasticity indexes in relation to liquid limit and which may be highly elastic as well as subject to considerable volume change.

5.2.4.2 Subgroup A-7-6 includes those materials with high plasticity indexes in relation to liquid limit and which are subject to extremely high-volume change.

Note 3—Highly organic soils (peat or muck) may be classified in an A-8 group. Classification of these materials is based on visual inspection, and is not dependent on percentage passing the 75-µm (No. 200) sieve, liquid limit, or plasticity index. The material is composed primarily of partially decayed organic matter, generally has a fibrous texture, dark brown or black color, and an odor of decay.

These organic materials are unsuitable for use in embankments and subgrades. They are highly compressible and have low strength.

6. GROUP INDEX

6.1 The group index is calculated from the following formula:

Group index = $(F - 35)\,[0.2 + 0.005\,(LL - 40)] + 0.01\,(F - 15)\,(PI - 10)$

where:

F = percentage passing 75-µm (No. 200) sieve, expressed as a whole number. This percentage is based only on the material passing the 75-mm (3-in.) sieve.

LL = liquid limit, and

PI = plasticity index.

6.1.1 When the calculated group index is negative, the group index shall be reported as zero.

6.1.2 The group index should be reported to the nearest whole number.

6.2 Figure 1 may be used in estimating the group index, by determining the partial group index due to liquid limit and that due to plasticity index, then obtaining the total of the two partial group indexes.

6.3 When calculating the group index of A-2-6 and A-2-7 subgroups, only the PI portion of the formula (or of Figure 1) shall be used.

6.4 The following are examples of calculations of the group index:

6.4.1 Assume that an A-6 material has 55 percent passing the 75-µm (No. 200) sieve, liquid limit of 40, and plasticity index of 25. Then,

Group index = $(55 - 35)\,[0.2 + 0.005\,(40 - 40)] + 0.01\,(55 - 15)\,(25 - 10) = 4.0 + 6.0 = 10$

6.4.2 Assume that an A-7 material has 80 percent passing the 75-µm (No. 200) sieve, liquid limit of 90, and plasticity index of 50. Then,

Group index = $(80 - 35)\,[0.2 + 0.005\,(90 - 40)] + 0.01\,(80 - 15)\,(50 - 10) = 20.3 + 26.0$, or 46.3

6.4.3 Assume that an A-4 material has 60 percent passing the 75-µm (No. 200) sieve, liquid limit of 25, and plasticity index of 1. Then,

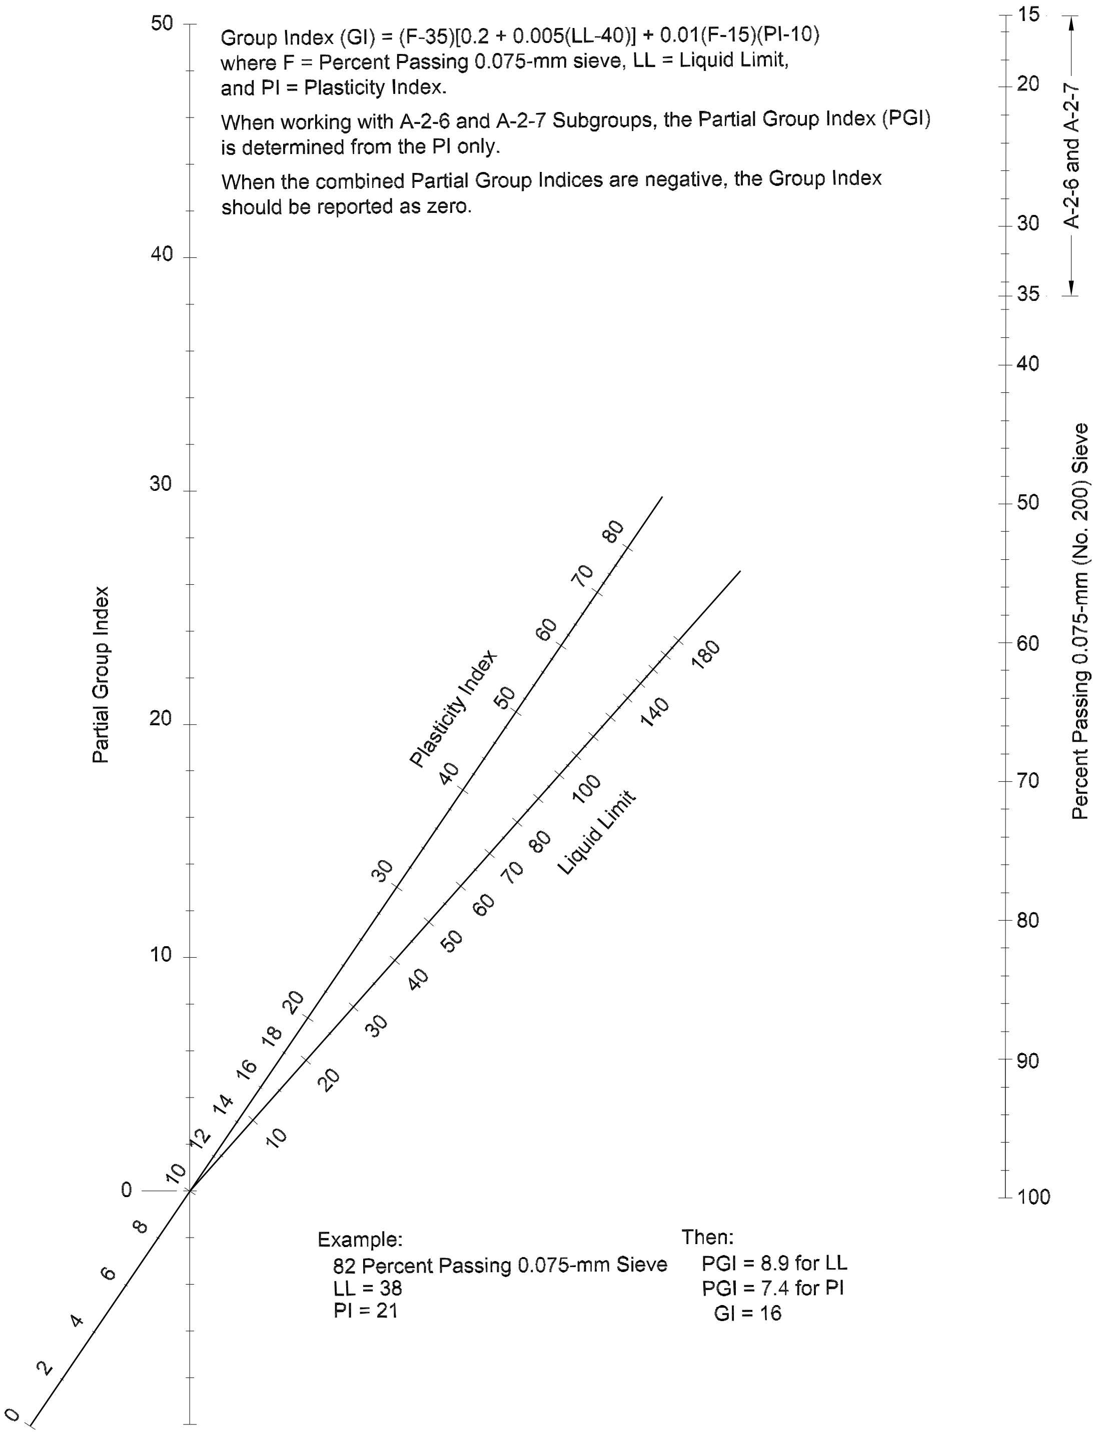
Group index = $(60 - 35)\,[0.2 + 0.005\,(25 - 40)] + 0.01\,(60 - 15)\,(1 - 10) = 25 \times (0.2 - 0.075) + 0.01\,(45)\,(-9) = 3.1 - 4.1 = -1.0$

Report as zero.

6.4.4 Assume that an A-2-7 material has 30 percent passing the 75-µm (No. 200) sieve, liquid limit of 50, and plasticity index of 30. Then,

Group index = $0.01\,(30 - 15)\,(30 - 10) = 3.0$ or 3

(Note that only the PI portion of formula was used.)



Group Index (GI) = (F-35)[0.2 + 0.005(LL-40)] + 0.01(F-15)(PI-10)
where F = Percent Passing 0.075-mm sieve, LL = Liquid Limit,
and PI = Plasticity Index.

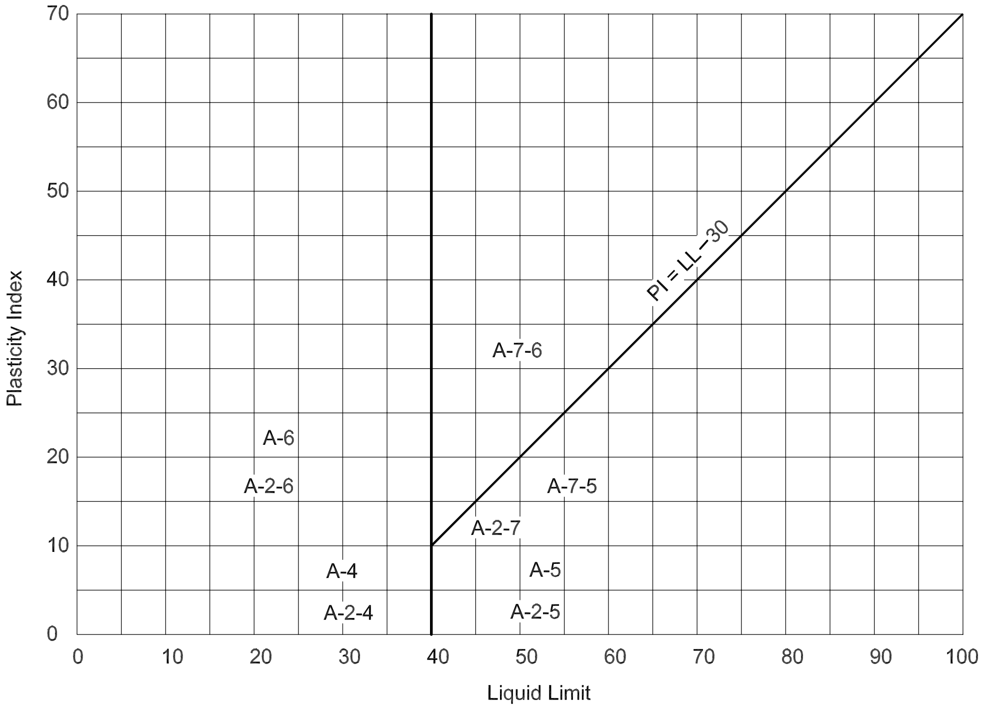
When working with A-2-6 and A-2-7 Subgroups, the Partial Group Index (PGI) is determined from the PI only.

When the combined Partial Group Indices are negative, the Group Index should be reported as zero.

Example:
82 Percent Passing 0.075-mm Sieve
LL = 38
PI = 21

Then:
PGI = 8.9 for LL
PGI = 7.4 for PI
GI = 16

Figure 1—Group Index Chart



Note: A-2 Soils contain less than 35 percent finer than the 75-µm (No. 200) sieve.

Figure 2—Liquid Limit and Plasticity Index Ranges for Silt-Clay Materials

7. BASIS FOR GROUP INDEX FORMULA

7.1 The empirical group index formula devised for approximately within-group evaluation of the "clayey granular materials" and the "silt-clay materials" is based on the following assumptions:

7.1.1 Materials falling within Groups A-1-a, A-1-b, A-2-4, A-2-5, and A-3 are satisfactory as subgrade when properly drained and compacted under moderate thickness pavement (base and/or surface course) of a type suitable for the traffic to be carried, or can be made satisfactory by additions of small amounts of natural or artificial binders.

7.1.2 Materials falling within the "clayey granular" Groups A-2-6 and A-2-7 and the "silt-clay" Groups A-4, A-5, A-6, and A-7 will range in quality as subgrade from the approximate equivalent of the good A-2-4 and A-2-5 subgrades to fair and poor subgrades requiring a layer of subbase material or an increased thickness of base course over that required under Section 7.1.1 in order to furnish adequate support for traffic loads.

7.1.3 The assumed critical minimum percentage passing the 75-µm (No. 200) sieve is 35 neglecting plasticity, and 15 as affected by plasticity indexes greater than 10.

7.1.4 Liquid limits of 40 and above are assumed to be critical.

7.1.5 Plasticity indexes of 10 and above are assumed to be critical.

7.1.6 For soils that are nonplastic and when the liquid limit cannot be determined, the group index shall be considered zero.

7.2 There is no upper limit of group index value obtained by use of the formula. The adopted critical values of percentage passing the 75-µm (No. 200) sieve, liquid limit and plasticity index, are based on an evaluation of subgrade, subbase, and base course materials by several highway organizations that use the tests involved in this classification system.

7.3 Under average conditions of good drainage and thorough compaction, the supporting value of a material as subgrade may be assumed as an inverse ratio to its group index; that is, a group index of zero indicates a "good" subgrade material and a group index of 20 or greater indicates a "very poor" subgrade material.

Standard Specification for

Terms Relating to Subgrade, Soil-Aggregate, and Fill Materials

AASHTO Designation: M 146-91 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Terms Relating to Subgrade, Soil-Aggregate, and Fill Materials

AASHTO Designation: M 146-91 (2008)

1. SCOPE

1.1 These definitions cover terms used in descriptions and specifications of materials occurring as or employed in the construction of subgrades, soil-aggregate base and surface courses, and fills.

1.2 The values stated in SI units are to be regarded as the standard.

2. DEFINITIONS OF ROCK AND SOIL

2.1 *rock*—natural solid mineral matter occurring in large masses or fragments.

2.2 *soil*—sediments or other unconsolidated accumulations of solid particles produced by the physical and chemical disintegration of rocks, and which may or may not contain organic matter.

2.3 *broken rock*—angular fragments of rock which will be retained on a 75-mm (3-in.) sieve.

2.4 *cobble (cobblestone)*—a rock fragment, usually rounded or semi-rounded, with an average dimension between 75 and 305 mm (3 and 12 in.).

2.5 *boulder*—a rock fragment, usually rounded by weathering or abrasion, with an average dimension of 305 mm (12 in.) or more.

3. DEFINITIONS OF SOIL-AGGREGATE AND ITS COMPONENTS

3.1 *soil-aggregate (dense-graded aggregate)*—natural or prepared mixtures consisting predominately of stone, gravel or sand and containing silt-clay (minus 75-μm (No. 200) material).

3.2 *binder (soil binder)*—portion of soil passing 0.425-mm (No. 40) sieve.

3.3 *stone*—crushed or naturally angular particles of rock that will pass a 75-mm (3-in.) sieve and be retained on a 2.00-mm (No. 10) sieve.

3.3.1 *coarse stone*—stone passing the 75-mm (3-in.) sieve and retained on the 25.0-mm (1-in.) sieve.

3.3.2 *medium stone*—stone passing the 25.0-mm (1-in.) sieve and retained on the 9.5-mm ($^{3}/_{8}$-in.) sieve.

3.3.3 *fine stone*—stone passing the 9.5-mm ($^{3}/_{8}$-in.) sieve and retained on the 2.00-mm (No. 10) sieve.

3.4 *gravel*—rounded particles of rock that will pass a 75-mm (3-in.) sieve and be retained on a 2.00-mm (No. 10) sieve.

3.4.1 *coarse gravel*—gravel passing the 75-mm (3-in.) sieve and retained on the 25.0-mm (1-in.) sieve.

3.4.2 *medium gravel*—gravel passing the 25.0-mm (1-in.) sieve and retained on the 9.5-mm ($^3/_8$-in.) sieve.

3.4.3 *fine gravel*—gravel passing the 9.5-mm ($^3/_8$-in.) sieve and retained on the 2.00-mm (No. 10) sieve.

3.5 *sand*—granular material resulting from the disintegration, grinding, or crushing of rock and which will pass the 2.00-mm (No. 10) sieve and be retained on the 75-µm (No. 200) sieve.

3.5.1 *coarse sand*—sand passing the 2.00-mm (No. 10) sieve and retained on the 0.425-mm (No. 40) sieve.

3.5.2 *fine sand*—sand passing the 0.425-mm (No. 40) sieve and retained on the 75-µm (No. 200) sieve.

3.6 *silt-clay (minus 75-µm (No. 200) material)*—fine soil particles which will pass the 75-µm (No. 200) sieve.

3.6.1 *silt fraction*—material passing the 75-µm (No. 200) sieve and larger than 0.002 mm.

3.6.2 *clay fraction*—material smaller than 0.002 mm.

3.6.3 *colloids*—material smaller than 0.001 mm.

4. DEFINITIONS OF PAVEMENT SUBSTRUCTURE COMPONENTS

4.1 *embankment foundation*—the material on which an embankment is placed.

4.2 *embankment (fill)*—a raised structure of soil, soil-aggregate, or rock.

4.3 *subgrade (basement soil)*—the prepared and compacted soil immediately below the pavement system and extending to such depth as will affect the structural design.

4.4 *subbase*—the layer used in the pavement system between the subgrade and the base course.

4.5 *base*—the layer used in a pavement system to reinforce and protect the subgrade or subbase.

Standard Specification for

Materials for Aggregate and Soil-Aggregate Subbase, Base, and Surface Courses

AASHTO Designation: M 147-65 (2008)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Specification for

Materials for Aggregate and Soil-Aggregate Subbase, Base, and Surface Courses

AASHTO Designation: M 147-65 (2008)

1. SCOPE

1.1 This specification covers the quality and grading of sand-clay mixtures; gravel, stone, or slag screenings; or sand, crusher run coarse aggregate consisting of gravel, crushed stone, or slag with or without soil mortar or any combination of these materials for use in the construction of subbase, base and surface courses. The requirements are intended to cover only materials having normal or average specific gravity, absorption, and gradation characteristics. Where other materials are to be used, appropriate limits suitable to their use must be specified.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:
- M 144, Calcium Chloride
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 87, Dry Preparation of Disturbed Soil and Soil-Aggregate Samples for Test
- T 88, Particle Size Analysis of Soils
- T 89, Determining the Liquid Limit of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 96, Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine
- T 146, Wet Preparation of Disturbed Soil Samples for Test

3. GENERAL REQUIREMENTS

3.1 *Coarse Aggregate*:

3.1.1 Coarse aggregate retained on the 2.00-mm (No. 10) sieve shall consist of hard, durable particles or fragments of stone, gravel, or slag. Materials that break up when alternately frozen and thawed or wetted and dried shall not be used.

3.1.2 Coarse aggregate shall have a percentage of wear, by the Los Angeles test, T 96, of not more than 50.

Note 1—A higher or lower percentage of wear may be specified by the engineer, depending upon the materials available for the work.

3.2 *Fine Aggregate*:

3.2.1 Fine aggregate passing the 2.00-mm (No. 10) sieve shall consist of natural or crushed sand, and fine mineral particles passing the 75-µm (No. 200) sieve.

3.2.2 The fraction passing the 75-µm (No. 200) sieve shall not be greater than two-thirds of the fraction passing the 0.425-mm (No. 40) sieve. The fraction passing the 0.425-mm sieve shall have a liquid limit not greater than 25 and a plasticity index not greater than 6.

3.3 All material shall be free from vegetable matter and lumps or balls of clay. The soil-aggregate material shall conform to the grading requirements of Table 1. The grading requirements for composite aggregate material will be specified by the engineer.

Table 1—Grading Requirements for Soil-Aggregate Materials

Sieve Designation		Mass Percentage Passing					
Standard, mm	Alternate	Grading A	Grading B	Grading C	Grading D	Grading E	Grading F
50.0	2 in.	100	100	—	—	—	—
25.0	1 in.	—	75–95	100	100	100	100
9.5	$^{3}/_{8}$ in.	30–65	40–75	50–85	60–100	—	—
4.75	No. 4	25–55	30–60	35–65	50–85	55–100	70–100
2.00	No. 10	15–40	20–45	25–50	40–70	40–100	55–100
0.425	No. 40	8–20	15–30	15–30	25–45	20–50	30–70
0.075	No. 200	2–8	5–20	5–15	5–20	6–20	8–25

4. SUBBASE MATERIALS

4.1 Materials for subbase shall conform to the requirements of Sections 3 and 4 for Gradings A, B, C, D, E, or F. The type and grading desired shall be specified.

Note 2—Where local experience has shown that lower percentages passing the 75-µm (No. 200) sieve than are required in Table 1 are necessary for subbase materials in order to prevent damage by frost action, the engineer should specify such lower percentages.

5. BASE COURSE MATERIALS

5.1 Materials for base course shall conform to the requirements of Section 3 for Gradings A, B, C, D, E, or F. The grading desired shall be specified.

Note 3—Where local experience has shown that lower percentages passing the 75-µm (No. 200) sieve than are required in Table 1 are necessary for base course materials in order to prevent damage by frost action, the engineer should specify such lower percentages.

6. SURFACE COURSE MATERIALS

6.1 Materials for surface course shall conform to the requirements of Sections 3 and 4 for Gradings C, D, E, or F. The gradings desired shall be specified.

Note 4—Where it is planned that the soil aggregate surface course is to be maintained for several years without bituminous surface treatment or other superimposed impervious surfacing, the engineer should specify a minimum of eight percent passing 75-µm (No. 200) sieve in lieu of the minimum percentages shown in Table 1 for Grading C, D, or E, and should specify a maximum liquid limit of 35 and plasticity index range of four to nine in lieu of the limits given in Section 3.2.2.

7. MOISTURE CONTENT

7.1 All materials shall contain moisture equal to or slightly below the optimum necessary to insure that the design density requirements are obtained when materials are compacted.

8. ADMIXTURE

8.1 Calcium chloride used for the control of moisture shall meet the requirements of M 144.

9. METHODS OF SAMPLING AND TESTING

9.1 Sampling and testing shall be in accordance with the following standard methods of the American Association of State Highway and Transportation Officials:

- Sampling, T 2
- Sieve analysis, T 27 or T 88
- Preparing samples, T 87
- Liquid limit, T 89
- Plastic limit and plasticity index, T 90
- Percentage of wear, T 96
- Passing 75-µm (No. 200 sieve), T 11

Standard Specification for

Lime for Soil Stabilization

AASHTO Designation: M 216-05 (2009)
ASTM Designation: C 977-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Lime for Soil Stabilization

AASHTO Designation: M 216-05 (2009)

ASTM Designation: C 977-03

---

1. SCOPE

1.1. This specification pertains to quicklime and hydrated lime, either high calcium, dolomitic, or magnesian lime, for use in stabilization of soils. (See Note 2.)

Note 1—Quicklime and hydrated lime act upon clay soils and may render such soils suitable for highway construction and for other load-bearing applications. In most cases, lime causes finely divided clay particles to agglomerate into coarser particles, which improves load-bearing properties and subsequently the lime-treated soil hardens by chemical reaction.

Note 2—No attempt is made to present requirements for by-product lime, commercial lime slurry, etc. Specification requirements for these materials could be better determined on a local basis.

1.2. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

---

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 25, Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime
- C 50, Standard Practice for Sampling, Sample Preparation, Packaging, and Marking of Lime and Limestone Products
- C 51, Standard Terminology Relating to Lime and Limestone (as used by the Industry)
- C 110, Standard Test Methods for Physical Testing of Quicklime, Hydrated Lime, and Limestone
- D 6276, Standard Test Method for Using pH to Estimate the Soil-Lime Proportion Requirement for Soil Stabilization

---

3. CHEMICAL COMPOSITION

3.1. Unless otherwise specified, for definitions of terms used in this specification, refer to Definitions of Terms, ASTM C 51.

3.2. Quicklime and hydrated lime for soil stabilization shall conform to the following chemical composition:

Calcium and magnesium oxides (on a non-volatile basis, minimum percent)	90.0
Carbon dioxide (taken at point of manufacture, maximum percent)	5.0
Free moisture (taken at point of manufacture maximum percent)	2.0

4. PHYSICAL PROPERTIES

4.1. Hydrated lime shall have not more than three percent retained on a No. 30 (0.590-mm) sieve and not more than 25 percent retained on a No. 200 (0.075-mm) sieve.

4.2. *Quicklime*:

4.2.1. *Particle Size of Quicklime*—Quicklime shall all pass a 1.0-in. (25.4-mm) sieve.

4.2.2. Quicklime for soil stabilization shall have a temperature rise of a minimum of 30°C in 20 minutes as measured by ASTM C 110.

4.2.3. *Residue of Quicklime*—Quicklime for soil stabilization shall have not more than 10 percent residue measured by ASTM C 110.

5. FIELD APPLICATIONS

5.1. When quicklimes are used, ensure that thorough mixing of the lime and soil is accomplished and all lime pebbles have been hydrated with additional water and distributed uniformly throughout the soil. There shall be no lime pebbles present before the compaction operation starts. Check by turning soil with a spade at representative intervals and inspect for visible lime pebbles. Care should be exercised on initial dry applications to minimize environmental dusting.

5.2. For hydrated limes, additional water shall be added to the lime-soil mixture to facilitate mixing and uniform distribution of the hydrated lime in the soil layer. There shall be no lime clumps present before the compaction operation starts. Check by turning soil with a spade at representative intervals and inspect for visible lime clumps. Care should be exercised on initial dry applications to minimize environmental dusting.[1]

6. TEST METHOD

6.1. The chemical analysis of quicklime and hydrated lime shall be conducted in accordance with ASTM C 25. (See Appendix X1.)

6.2. The particle size of hydrated lime shall be determined in accordance with the sieve analysis of hydrated lime in accordance with ASTM C 110.

6.3. The appendix to this specification contains a nonmandatory test to approximate the lime-soil proportion for stabilization. A more detailed version of this test appears in ASTM D 6276.

7. SAMPLING, INSPECTION, PACKAGING, AND MARKING

7.1. The sampling, inspection, rejection, retesting, packaging, and marking shall be done in accordance with ASTM C 50.

8. KEYWORDS

8.1. Highway construction; hydrated lime; lime-treated soils; load-bearing; quicklime; soil stabilization.

APPENDIX

(Nonmandatory Information)

X1. METHOD FOR DETERMINING STABILIZATION ABILITY OF LIME

X1.1. This test method usually provides a lime-soil proportion for stabilization. It gives an indication whether the soil in question can be stabilized. For most stabilization work, the results of this test should be verified by performance tests in a soil laboratory.

X1.2. Air dry a sufficient quantity of the soil to be tested and screen through a No. 40 (425-µm) sieve. Store in a closed container to maintain uniform moisture. Determine the mass, to the nearest 0.1 g, a series of 20-g samples of soil and place in separate 150-mL containers with water-tight lids.

X1.3. In the case of quicklime, rapidly crush the lime to pass a No. 6 (3.35-mm) sieve.

X1.4. Determine the mass, to the nearest 0.01 g, a series of quantities of lime equivalent to 2, 3, 4, 5, and 6 percent of the soil sample.

X1.5. Add the lime quantity to the soil sample, mark the container with the appropriate percentage, and mix the dry contents thoroughly.

X1.6. Add the 100 mL of 70ºF carbon dioxide-free distilled water or, if possible, 70ºF actual water to be used on the job to each container of soil and lime. Seal with screw-cap lid and mix the three components by shaking the bottles. Shake each bottle for 30 seconds every 10 minutes for one hour. After one hour, shake vigorously and transfer part of the slurry into a beaker. Measure the pH with a low-sodium error glass electrode (previously standardized to pH 12.45 with an agitated calcium hydroxide slurry). Record the pH reading for each mixture.

X1.7. If the pH readings are 12.40 or higher, the lowest percentage that gives a pH of 12.40 is the percent required to stabilize the soil. If the pH readings do not go beyond pH of 12.30 and two percentages give this reading, the lowest percent to give a pH of 12.30 is the percent required to stabilize the soil. If the highest pH reading is a pH of 12.30 and only the highest percentage lime used gives a pH of 12.30, additional testing is required using higher percentages of lime.

---

Standard Specification for

Geotextile Specification for Highway Applications

AASHTO Designation: M 288-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Geotextile Specification for Highway Applications

AASHTO Designation: M 288-06

1. SCOPE

1.1. This is a materials specification covering geotextile fabrics for use in subsurface drainage, separation, stabilization, erosion control, temporary silt fence, and paving fabrics. This is a material purchasing specification and design review of use is recommended.

1.2. This specification sets forth a set of physical, mechanical, and endurance properties that must be met or exceeded by the geotextile being manufactured.

1.3. In the context of quality systems and management, this specification represents a manufacturing quality control (MQC) document. However, its general use is essentially as a recommended design document.

1.4. This specification is intended to assure both good quality and performance of geotextiles used as listed in Section 1.1, but is possibly not adequate for the complete specification in a specific situation. Additional tests, or more restrictive values for the tests indicated, may be necessary under conditions of a particular application.

1.5. This specification is based on geotextile survivability from installation stresses. Designers should be aware that the classes in this specification reflect this basic premise. Refer to Appendix X1 of this specification for geotextile construction guidelines.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 88, Particle Size Analysis of Soils
- T 90, Determining the Plastic Limit and Plasticity Index of Soils
- T 99, Moisture-Density Relations of Soils Using a 2.5-kg (5.5-lb) Rammer and a 305-mm (12-in.) Drop

2.2. *ASTM Standards*:[1]

- D 123, Standard Terminology Relating to Textiles
- D 276, Standard Test Methods for Identification of Fibers in Textiles
- D 4354, Standard Practice for Sampling of Geosynthetics for Testing
- D 4355, Standard Test Method for Deterioration of Geotextiles from Exposure to Light, Moisture and Heat in a Xenon Arc Type Apparatus
- D 4439, Standard Terminology for Geosynthetics
- D 4491, Standard Test Methods for Water Permeability of Geotextiles by Permittivity

- D 4533, Standard Test Method for Trapezoid Tearing Strength of Geotextiles
- D 4632, Standard Test Method for Grab Breaking Load and Elongation of Geotextiles
- D 4751, Standard Test Method for Determining Apparent Opening Size of a Geotextile
- D 4759, Standard Practice for Determining the Specification Conformance of Geosynthetics
- D 4873, Standard Guide for Identification, Storage, and Handling of Geosynthetic Rolls and Samples
- D 5141, Standard Test Method for Determining Filtering Efficiency and Flow Rate of the Filtration Component of a Sediment Retention Device Using Site-Specific Soil
- D 5261, Standard Test Method for Measuring Mass per Unit Area of Geotextiles
- D 6140, Standard Test Method to Determine Asphalt Retention of Paving Fabrics Used in Asphalt Paving for Full-Width Applications
- D 6241, Standard Test Method for Static Puncture Strength of Geotextiles and Geotextile-Related Products Using a 50-mm Probe

3. DEFINITIONS

3.1. *Formulation*—The mixture of a unique combination of ingredients identified by type, properties, and quantity. For nonwoven geotextiles, a formulation is defined as the exact percentages and types of resin(s), additives, and/or carbon black.

3.2. *Manufacturing Quality Control (MQC)*—A planned system of inspections that is used to directly monitor and control the manufacture of a material that is factory originated. Manufacturing Quality Control is normally performed by the manufacturer of geosynthetic materials and is necessary to ensure minimum (or maximum) specified values in the manufactured product. Manufacturing Quality Control refers to measures taken by the manufacturer to determine compliance with the requirements for materials and workmanship as stated in certification documents and contract specifications [ref. EPA/600/R-93/182].

3.3. *Minimum Average Roll Value (MARV)*—For geosynthetics, a MQC tool used to allow manufacturers to establish published values such that the user/purchaser will have a 97.7 percent confidence that the property in question will meet published values. For normally distributed data, MARV is calculated as the typical value minus two standard deviations from documented quality control test results for a defined population from one specific test method associated with one specific property.

3.4. *Minimum Value*—The lowest sample value from documented MQC test results for a defined population from one test method associated with one specific property.

3.5. *Maximum Value*—The highest sample value from documented MQC test results for a defined population from one test method associated with one specific property.

4. PHYSICAL REQUIREMENTS

4.1. Fibers used in the manufacture of geotextiles, and the threads used in joining geotextiles by sewing, shall consist of long-chain synthetic polymers, composed of at least 95 percent by weight of polyolefins or polyesters. They shall be formed into a stable network such that the filaments or yarns retain their dimensional stability relative to each other, including selvages.

4.2. Geotextiles used for subsurface drainage, separation, stabilization, and permanent erosion control applications shall conform to the physical requirements of Section 8. Geotextiles used for temporary silt fence shall conform to the physical requirements of Section 9 and geotextiles used as paving fabrics shall conform to the physical requirements of Section 10.

4.3. All property values, with the exception of apparent opening size (AOS), in these specifications represent MARV in the weakest principal direction (i.e., average test results of any roll in a lot sampled for conformance or quality assurance testing shall meet or exceed the minimum values provided herein). Values for AOS represent MARV.

5. CERTIFICATION

5.1. The contractor shall provide to the engineer a certificate stating the name of the manufacturer, product name, style number, chemical composition of the filaments or yarns, and other pertinent information to fully describe the geotextile.

5.2. The manufacturer is responsible for establishing and maintaining a quality control program to assure compliance with the requirements of the specification. Documentation describing the quality control program shall be made available upon request.

5.3. The manufacturer's certificate shall state that the furnished geotextile meets MARV requirements of the specification as evaluated under the manufacturer's quality control program. A person having legal authority to bind the manufacturer shall attest to the certificate.

5.4. Either mislabeling or misrepresentation of materials shall be reason to reject those geotextile products.

6. SAMPLING, TESTING, AND ACCEPTANCE

6.1. Geotextiles shall be subject to sampling and testing to verify conformance with this specification. Sampling shall be in accordance with the most current ASTM D 4354, using the section titled, "Procedure for Sampling for Purchaser's Specification Conformance Testing." In the absence of purchaser's testing, verification may be based on manufacturer's certifications as a result of testing by the manufacturer of quality assurance samples obtained using the procedure for sampling for manufacturer's quality assurance (MQA) testing. A lot size shall be considered to be the shipment quantity of the given product or a truckload of the given product, whichever is smaller.

6.2. Testing shall be performed in accordance with the methods referenced in this specification for the indicated application. The number of specimens to test per sample is specified by each test method. Geotextile product acceptance shall be based on ASTM D 4759. Product acceptance is determined by comparing the average test results of all specimens within a given sample to the specification MARV. Refer to ASTM D 4759 for more details regarding geotextile acceptance procedures.

7. SHIPMENT AND STORAGE

7.1. The labeling, shipment, and storage of geotextiles shall follow ASTM D 4873. Product labels shall clearly show the manufacturer or supplier name, style name, and roll number. Each shipping document shall include a notation certifying that the material is in accordance with the manufacturer's certificate.

7.2. Each geotextile roll shall be wrapped with a material that will protect the geotextile, including the ends of the roll, from damage due to shipment, water, sunlight, and contaminants. The protective wrapping shall be maintained during periods of shipment and storage.

7.3. During storage, geotextile rolls shall be elevated off the ground and adequately covered to protect them from the following: site construction damage; precipitation; extended ultraviolet radiation, including sunlight; chemicals that are strong acids or strong bases; flames, including welding sparks; temperatures in excess of 71ºC (160ºF); and any other environmental condition that may damage the physical property values of the geotextile.

---

8. GEOTEXTILE PROPERTY REQUIREMENTS FOR SUBSURFACE DRAINAGE, SEPARATION, STABILIZATION, AND PERMANENT EROSION CONTROL

8.1. *General Requirements*:

8.1.1. Table 1 provides strength properties for three geotextile classes. The geotextile shall conform to the properties of Table 1 based on the geotextile class required in Table 2, 3, 4, 5, or 6 for the indicated application.

8.1.2. All numeric values in Table 1 represent MARV in the weaker principal direction. The geotextile properties required for each class are dependent upon geotextile elongation. When sewn seams are required, the seam strength, as measured in accordance with ASTM D 4632, shall be equal to or greater than 90 percent of the specified grab strength.

8.2. *Subsurface Drainage Requirements*:

8.2.1. *Description*—This specification is applicable to placing a geotextile against a soil to allow for long-term passage of water into a subsurface drain system retaining the *in situ* soil. The primary function of the geotextile in subsurface drainage applications is filtration. Geotextile filtration properties are a function of the *in situ* soil gradation, plasticity, and hydraulic conditions.

8.2.2. *Geotextile Requirements*—The geotextile shall meet the requirements of Table 2. Woven slit film geotextiles (i.e., geotextiles made from yarns of a flat, tape-like character) will not be allowed. All numeric values in Table 2, except AOS, represent MARV in the weaker principal direction. Values of AOS represent maximum average roll values.

Table 1—Geotextile Strength Property Requirements

			Geotextile Class[a,b]					
			Class 1		Class 2		Class 3	
	Test Methods	Units	Elongation <50%[c]	Elongation ≥50%[c]	Elongation <50%[c]	Elongation ≥50%[c]	Elongation <50%[c]	Elongation ≥50%[c]
Grab strength	ASTM D 4632	*N*	1400	900	1100	700	800	500
Sewn seam strength[d]	ASTM D 4632	*N*	1260	810	990	630	720	450
Tear strength	ASTM D 4533	*N*	500	350	400[e]	250	300	180
Puncture strength	ASTM D 6241	*N*	2750	1925	2200	1375	1650	990
Permittivity	ASTM D 4491	sec^{-1}	Minimum property values for permittivity, AOS, and UV stability are based on geotextile application. Refer to Table 2 for subsurface drainage, Table 3 and Table 4 for separation, Table 5 for stabilization, and Table 6 for permanent erosion control.					
Apparent opening size	ASTM D 4751	mm						
Ultraviolet stability (retained strength)	ASTM D 4355	%						

[a] Required geotextile class is designated in Table 2, 3, 4, 5, or 6 for the indicated application. The severity of installation conditions for the application generally dictates the required geotextile class. Class 1 is specified for more severe or harsh installation conditions where there is a greater potential for geotextile damage, and Classes 2 and 3 are specified for less severe conditions.

[b] All numeric values represent MARV in the weaker principal direction. (See Section 8.1.2.)

[c] As measured in accordance with ASTM D 4632.

[d] When sewn seams are required. Refer to Appendix for overlap seam requirements.

[e] The required MARV tear strength for woven monofilament geotextiles is 250 N.

Table 2—Subsurface Drainage Geotextile Requirements

			Requirements, Percent in Situ Soil Passing 0.075 mm[a]		
	Test Methods	Units	<15	15 to 50	>50
Geotextile class			Class 2 from Table 1[b]		
Permittivity[c,d]	ASTM D 4491	sec–1	0.5	0.2	0.1
Apparent opening size[c,d]	ASTM D 4751	mm	0.43 max avg roll value	0.25 max avg roll value	0.22[e] max avg roll value
Ultraviolet stability (retained strength)	ASTM D 4355	%	50% after 500 h of exposure		

[a] Based on grain size analysis of in situ soil in accordance with T 88.

[b] Default geotextile selection. The engineer may specify a Class 3 geotextile from Table 1 for trench drain applications based on one or more of the following:

1. The engineer has found Class 3 geotextiles to have sufficient survivability based on field experience.
2. The engineer has found Class 3 geotextiles to have sufficient survivability based on laboratory testing and visual inspection of a geotextile sample removed from a field test section constructed under anticipated field conditions.
3. Subsurface drain depth is less than 2 m; drain aggregate diameter is less than 30 mm; and compaction requirement is less than 95 percent of T 99.

[c] These default filtration property values are based on the predominant particle sizes of in situ soil. In addition to the default permittivity value, the engineer may require geotextile permeability and/or performance testing based on engineering design for drainage systems in problematic soil environments.

[d] Site specific geotextile design should be performed especially if one or more of the following problematic soil environments are encountered: unstable or highly erodible soils such as non-cohesive silts; gap graded soils; alternating sand/silt laminated soils; dispersive clays; and/or rock flour.

[e] For cohesive soils with a plasticity index greater than seven, geotextile maximum average roll value for apparent opening size is 0.30 mm.

8.2.3. The property values in Table 2 represent default values that provide sufficient geotextile survivability under most construction conditions. Note *b* of Table 2 provides for a reduction in the minimum property requirements when sufficient survivability information is available. The engineer may also specify properties different from those listed in Table 2 based on engineering design experience.

8.3. *Separation Requirements*:

8.3.1. *Description*—This specification is applicable to the use of a geotextile to prevent mixing of a subgrade soil and an aggregate cover material (subbase, base, select embankment, etc.). This specification may also apply to situations other than beneath pavements where separation of two dissimilar materials is required, but where water seepage through the geotextile is not a critical function.

8.3.2. The separation application is appropriate for pavement structures constructed over soils with a California Bearing Ratio equal to or greater than 3 (CBR ≥ 3) (shear strength greater than approximately 90 kPa). It is appropriate for unsaturated subgrade soils. The primary function of a geotextile in this application is separation.

8.3.3. *Geotextile Requirements*—The geotextile shall meet the requirements of Table 3. All numeric values in Table 3 except AOS represent MARV in the weakest principal direction. Values for AOS represent maximum average roll values.

Table 3—Separation Geotextile Property Requirements

	Test Methods	Units	Requirements
Geotextile class			See Table 4
Permittivity	ASTM D 4491	sec–1	0.02[a]
Apparent opening size	ASTM D 4751	mm	0.60 max avg roll value
Ultraviolet stability (retained strength)	ASTM D 4355	%	50% after 500 h of exposure

[a] Default value. Permittivity of the geotextile should be greater than that of the soil ($\Psi_g > \Psi_s$). The engineer may also require the permeability of the geotextile to be greater than that of the soil ($^{kg > ks}$).

Table 4—Required Degree of Survivability as a Function of Subgrade Conditions, Construction Equipment, and Lift Thickness (Class 1, 2, and 3 properties are given in Table 1; Class 1 + properties are higher than Class 1, but not defined at this time and, if used, must be specified by the purchaser)[a]

	Low ground-pressure equipment ≤25 kPa (3.6 psi)	Medium ground-pressure equipment > 25 to ≤50 kPa (>3.6 to ≤ 7.3 psi)	High ground-pressure equipment >50 kPa (>7.3 psi)
Subgrade has been cleared of all obstacles except grass, weeds, leaves, and fine wood debris. Surface is smooth and level so that any shallow depressions and humps do not exceed 450 mm (18 in.) in depth or height. All larger depressions are filled. Alternatively, a smooth working table may be placed.	Low (Class 3)	Moderate (Class 2)	High (Class 1)
Subgrade has been cleared of obstacles larger than small to moderate-sized tree limbs and rocks. Tree trunks and stumps should be removed or covered with a partial working table. Depressions and humps should not exceed 450 mm (18 in.) in depth or height. Larger depressions should be filled.	Moderate (Class 2)	High (Class 1)	Very High (Class 1+)
Minimal site preparation is required. Trees may be felled, delimbed, and left in place. Stumps should be cut to project not more than ±150 mm (±6 in.) above subgrade. Geotextile may be draped directly over the tree trunks, stumps, large depressions and humps, holes, stream channels, and large boulders. Items should be removed only if placing the geotextile and cover material over them will distort the finished road surface.	High (Class 1)	Very high (Class 1+)	Not recommended

[a] Recommendations are for 150 to 300 mm (6 to 12 in.) initial lift thickness. For other initial lift thicknesses:
300 to 450 mm (12 to 18 in.): reduce survivability requirement one level;
450 to 600 mm (18 to 24 in.): reduce survivability requirement two levels;
>600 mm (24 in.): reduce survivability requirement three levels
For special construction techniques such as prerutting, increase the geotextile survivability requirement one level. Placement of excessive initial cover material thickness may cause bearing failure of the soft subgrade.

8.3.4. The property values in Table 3 represent default values that provide for sufficient geotextile survivability under most construction conditions. The engineer may also specify properties different from those listed in Table 3 based on engineering design and experience.

8.4. *Stabilization Requirements*:

8.4.1. *Description*—This specification is applicable to the use of a geotextile in wet, saturated conditions to provide the coincident functions of separation and filtration. In some installations, the geotextile can also provide the function of reinforcement. Stabilization is applicable to pavement structures constructed over soils with a California Bearing Ratio between one and three ($1 < \text{CBR} > 3$) (shear strength between approximately 30 kPa and 90 kPa).

8.4.2. The stabilization application is appropriate for subgrade soils that are saturated due to a high groundwater table or due to prolonged periods of wet weather. This specification is not appropriate for embankment reinforcement where stress conditions may cause global subgrade foundation or stability failure. Reinforcement of the pavement section is a site specific design issue.

8.4.3. *Geotextile Requirements*—The geotextile shall meet the requirements of Table 5. All numeric values in Table 5 except AOS represent MARV in the weakest principal direction. Values for AOS represent maximum average roll values.

Table 5—Stabilization Geotextile Property Requirements

	Test Methods	Units	Requirements
Geotextile class			Class 1 from Table 1[a]
Permittivity	ASTM D 4491	sec–1	0.05[b]
Apparent opening size	ASTM D 4751	mm	0.43 max avg roll value
Ultraviolet stability (retained strength)	ASTM D 4355	%	50% after 500 h of exposure

[a] Default geotextile selection. The engineer may specify a Class 2 or 3 geotextile from Table 1 based on one or more of the following:

1. The engineer has found the class of geotextile to have sufficient survivability based on field experience.
2. The engineer has found the class of geotextile to have sufficient survivability based on laboratory testing and visual inspection of a geotextile sample removed from a field test section constructed under anticipated field conditions.

[b] Default value. Permittivity of the geotextile should be greater than that of the soil ($\Psi_g > \Psi_s$). The engineer may also require the permeability of the geotextile to be greater than that of the soil ($^{kg > ks}$).

8.4.4. The property values in Table 5 represent default values that provide for sufficient geotextile survivability under most construction conditions. Note 2 of Table 5 provides for a reduction in the minimum property requirements when sufficient survivability information is available. The engineer may also specify properties different from those listed in Table 5 based on engineering design and experience.

8.5. *Permanent Erosion Control*:

8.5.1. *Description*—This specification is applicable to the use of a geotextile between energy absorbing armor systems and the *in situ* soil to prevent soil loss resulting in excessive scour and to prevent hydraulic uplift pressures causing instability of the permanent erosion control system. This specification does not apply to other types of geosynthetic soil erosion control materials such as turf reinforcement mats.

8.5.2. The primary function the geotextile serves in permanent erosion control applications is filtration. Geotextile filtration properties are a function of hydraulic conditions and, *in situ* soil gradation, density, and plasticity.

8.5.3. *Geotextile Requirements*—The geotextile shall meet the requirements of Table 6. Woven slit film geotextiles (i.e., geotextiles made from yarns of a flat, tape-like character) will not be allowed. All numeric values in Table 6 except AOS represent MARV in the weaker principal direction. Values for AOS represent maximum average roll values.

8.5.4. The property values in Table 6 represent default values that provide for sufficient geotextile survivability under conditions similar to or less severe than those described under Note *b* of Table 6. Note *c* of Table 6 provides for a reduction in the minimum property requirements when sufficient survivability information is available or when the potential for construction damage is reduced. The engineer may also specify properties different from those listed in Table 6 based on engineering design and experience.

Table 6—Permanent Erosion Control Geotextile Requirements

			Requirements, Percent in Situ Soil Passing 0.075 mm[a]		
	Test Methods	Units	<15	15 to 50	>50
Geotextile class:					
Woven monofilament geotextiles				Class 2 from Table 1[b]	
All other geotextiles				Class 1 from Table 1[b,c]	
Permittivity[a,d]	ASTM D 4491	sec–1	0.7	0.2	0.1
Apparent opening size [c,d, e]	ASTM D 4751	mm	0.43 max avg roll value	0.25 max avg roll value	0.22[e] max avg roll value
Ultraviolet stability (retained strength)	ASTM D 4355	%		50% after 500 h of exposure	

[a] Based on grain size analysis of *in situ* soil in accordance with T 88.

[b] As a general guideline, the default geotextile selection is appropriate for conditions of equal or less severity than either of the following:

1. Armor layer stone weights do not exceed 100 kg, stone drop height is less than 1 m, and no aggregate bedding layer is required.
2. Armor layer stone weighs more than 100 kg, stone drop height is less than 1 m, and the geotextile is protected by a 150-mm thick aggregate bedding layer designed to be compatible with the armor layer. More severe applications require an assessment of geotextile survivability based on a field trial section and may require a geotextile with strength properties.

[c] The engineer may specify a Class 2 geotextile from Table 1 based on one or more of the following:

1. The engineer has found Class 2 geotextiles to have sufficient survivability based on field experience.
2. The engineer has found Class 2 geotextiles to have sufficient survivability based on laboratory testing and visual inspection of a geotextile sample removed from a field test section constructed under anticipated field conditions.
3. Armor layer stone weighs less than 100 kg, stone drop height is less than 1 m, and the geotextile is protected by a 150-mm thick aggregate bedding layer designed to be compatible with the armor layer.
4. Armor layer stone weights do not exceed 100 kg, and stone is placed with a zero drop height.

[d] These default filtration property values are based on the predominant particle sizes of *in situ* soil. In addition to the default permittivity value, the engineer may require geotextile permeability and/or performance testing based on engineering design for drainage systems in problematic soil environments.

[e] See the following:

1. Site specific geotextile design should be performed especially if one or more of the following problematic soil environments are encountered: unstable or highly erodible soils such as non-cohesive silts; gap graded soils; alternating sand/silt laminated soils; and /or rock flour.
2. For cohesive soils with a plasticity index greater than seven, geotextile maximum average roll value for apparent opening size is 0.30 mm.

9. TEMPORARY SILT FENCE REQUIREMENTS

9.1. *Description*—This specification is applicable to the use of a geotextile as a vertical, permeable interceptor designed to remove suspended soil from overland water flow. The function of a temporary silt fence is to filter and allow settlement of soil particles from sediment-laden water. The purpose is to prevent the eroded soil from being transported off the construction site by water runoff.

9.2. *Geotextile Requirements*—The geotextile used for temporary silt fence may or may not be supported between posts with wire or polymeric mesh. The temporary silt fence geotextile shall meet the requirements of Table 7. All numeric values in Table 7 except AOS represent MARV. Values for AOS represent maximum average roll values.

9.3. Field monitoring shall be performed to verify that the armor system placement does not damage the geotextile. The minimum height above ground for all silt fences shall be 750 mm. Minimum embedment depth of geotextile shall be 150 mm. Refer to Appendix X1 for more detailed installation requirements.

Table 7—Temporary Silt Fence Property Requirements

				Requirements, Unsupported Silt Fence	
	Test Methods	Units	Supported Silt Fence[a]	Geotextile Elongation ≥50%[b]	Geotextile Elongation <50%[b]
Maximum post spacing			1.2 m	1.2 m	2 m
Grab strength	ASTM D 4632	*N*			
Machine direction			400	550	550
X-Machine direction			400	450	450
Permittivity[c]	ASTM D 4491	sec–1	0.05	0.05	0.05
Apparent opening size	ASTM D 4751	mm	0.60 max avg roll value	0.60 max avg roll value	0.60 max avg roll value
Ultraviolet stability (retained strength)	ASTM D 4355	%	70% after 500 h of exposure	70% after 500 h of exposure	

[a] Silt fence support shall consist of 14-gauge steel wire with a mesh spacing of 150 mm by 150 mm or prefabricated polymeric mesh of equivalent strength.

[b] As measured in accordance with ASTM D 4632.

[c] These default filtration property values are based on empirical evidence with a variety of sediments. For environmentally sensitive areas, a review of previous experience and/or site or regionally specific geotextile tests should be performed by the agency to confirm suitability of these requirements.

10. PAVING FABRIC REQUIREMENTS

10.1. *Description*—This specification is applicable to the use of a paving fabric, saturated with asphalt cement, between pavement layers. The function of the paving fabric is to act as a waterproofing and stress relieving membrane within the pavement structure. This specification is not intended to describe fabric membrane systems specifically designed for pavement joints and localized (spot) repairs.

10.2. *Paving Fabric Requirements*—The paving fabric shall meet the requirements of Table 8. All numeric values in Table 8 represent MARV in the weaker principal direction.

Table 8—Paving Fabric Property Requirements[a]

	Test Methods	Units	Requirements
Grab strength	ASTM D 4632	*N*	450
Ultimate elongation	ASTM D 4632	%	≥50
Mass per unit area	ASTM D 5261	gm/m^2	140
Asphalt retention	ASTM D 6140	1/m^2	[b] [c]
Melting point	ASTM D 276	°C	150

[a] All numeric values represent MARV in the weaker principal direction. (Refer to Section 10.2.)

[b] Asphalt required to saturate paving fabric only. Asphalt retention must be provided in manufacturer certification. (Refer to Section 5.) Value does not indicate the asphalt application rate required for construction. Refer to Appendix for discussion of asphalt application rate.

[c] Product asphalt retention property must meet the MARV value provided by the manufacturer certification. (Refer to Section 5.)

APPENDIX

(Nonmandatory Information)

X1. CONSTRUCTION/INSTALLATION GUIDELINES

X1.1. *General*:

X1.1.1. This Appendix is intended for use in conjunction with M 288 for Geotextiles. The specification details materials properties for geotextiles used in drainage, erosion control, separation/stabilization, silt fences, and pavement overlay application. The material properties are only one factor in a successful installation involving geotextiles. Proper construction and installation techniques are essential in order to ensure that the intended function of the geotextile is fulfilled.

X1.1.2. *Geotextile Identification, Packaging, and Storage*:

X1.1.2.1. Refer to ASTM D 4873.

X1.1.3. *Geotextile Exposure Following Placement*:

X1.1.3.1. Atmospheric exposure of geotextiles to the elements following lay down shall be a maximum of 14 days to minimize damage potential.

X1.1.4. *Seaming*:

X1.1.4.1. If a sewn seam is to be used for the seaming of the geotextile, the thread used shall consist of high strength polypropylene, or polyester. Nylon thread shall not be used. For erosion control applications, the thread shall also be resistant to ultraviolet radiation. The thread shall be of contrasting color to that of the geotextile itself.

X1.1.4.2. For seams that are sewn in the field, the contractor shall provide at least a 2-meter length of sewn seam for sampling by the engineer before the geotextile is installed. For seams that are sewn in the factory, the engineer shall obtain samples of the factory seams at random from any roll of geotextile that is used on the project.

X1.1.4.2.1. For seams that are field sewn, the seams sewn for sampling shall be sewn using the same equipment and procedures as will be used for the production seams. If seams are sewn in both the machine and cross machine direction, samples of seams from both directions shall be provided.

X1.1.4.2.2. The contractor shall submit the seam assembly description along with the sample of the seam. The description shall include the seam type, stitch type, sewing thread, and stitch density.

X1.2. *Drainage Geotextiles*[2] (See Sections 8.1 and 8.2.)

X1.2.1. *Construction*:

X1.2.1.1. Trench excavation shall be done in accordance with details of the project plans. In all instances excavation shall be done in such a way so as to prevent large voids from occurring in the sides and bottom of the trench. The graded surface shall be smooth and free of debris.

X1.2.1.2. In the placement of the geotextile for drainage applications, the geotextile shall be placed loosely with no wrinkles or folds, and with no void spaces between the geotextile and the ground surface. Successive sheets of geotextiles shall be overlapped a minimum of 300 mm, with the upstream sheet overlapping the downstream sheet.

X1.2.1.2.1. In trenches equal to or greater than 300 mm in width, after placing the drainage aggregate, the geotextile shall be folded over the top of the backfill material in a manner to produce a minimum overlap of 300 mm. In trenches less than 300 mm but greater than 100 mm wide, the overlap shall be equal to the width of the trench. Where the trench is less than 100 mm the geotextile overlap shall be sewn or otherwise bonded. All seams shall be subject to the approval of the engineer.

X1.2.1.2.2. Should the geotextile be damaged during installation or drainage aggregate placement, a geotextile patch shall be placed over the damaged area extending beyond the damaged area a distance of 300 mm, or the specified seam overlap, whichever is greater.

X1.2.1.3. Placement of drainage aggregate should proceed immediately following placement of the geotextile. The geotextile should be covered with a minimum of 300 mm of loosely placed aggregate prior to compaction. If a perforated collector pipe is to be installed in the trench, a bedding layer of drainage aggregate should be placed below the pipe, with the remainder of the aggregate placed to the minimum required construction depth.

X1.2.1.3.1. The aggregate should be compacted with vibratory equipment to a minimum of 95 percent Standard AASHTO density unless the trench is required for structural support. If higher compactive effort is required, a Class 1 geotextile as per Table 1 of the M 288 is needed.

X1.2.1.4. Figures X1.1 through X1.3 illustrate various geotextile drainage application details.

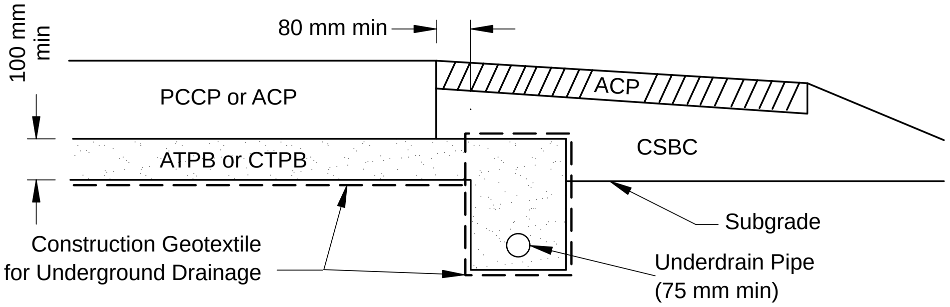

Figure X1.1—Geotextile Drain Requirements for Permeable Bases

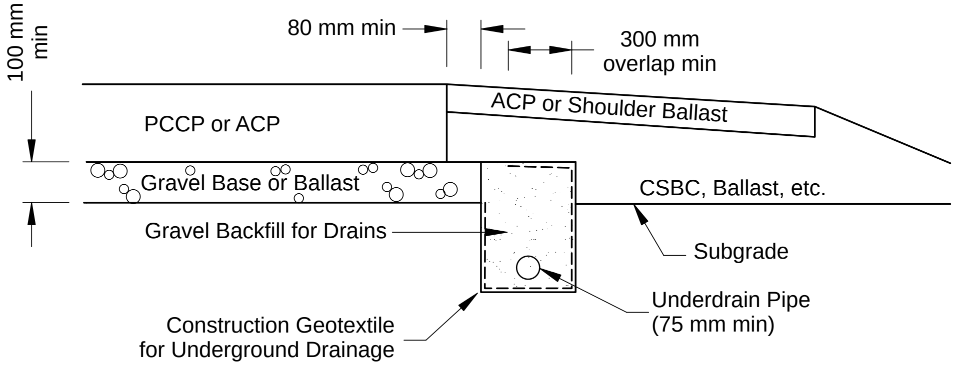

Figure X1.2—Geotextile Wrapped Longitudinal Edge Drain

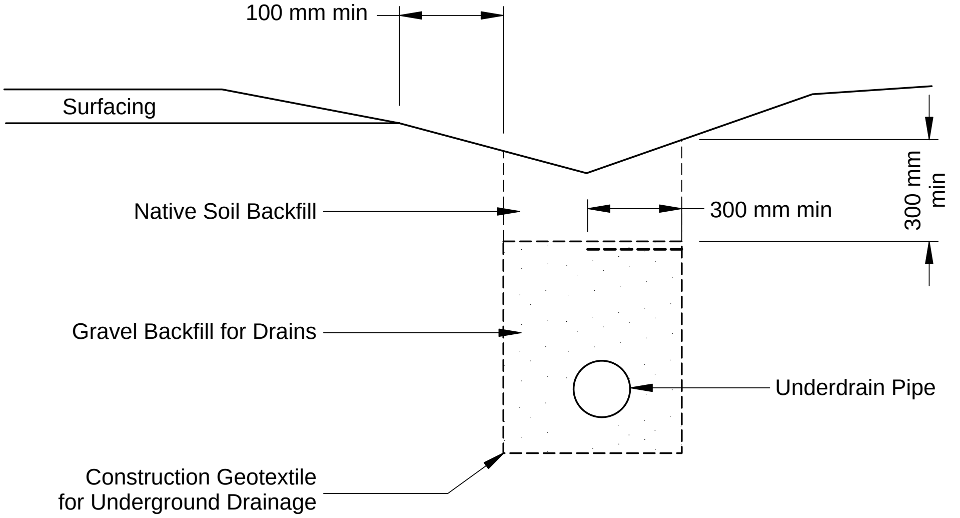

Figure X1.3—Geotextile Wrapped Pavement Under Drain

X1.3. *Separation/Stabilization Geotextiles* (See Sections 8.1, 8.3, and 8.4.):

X1.3.1. *Construction*:

X1.3.1.1. The installation site shall be prepared by clearing, grubbing, and excavation or filling the area to the design grade. This includes removal of topsoil and vegetation.

Note X1—Soft spots and unsuitable areas will be identified during site preparation or subsequent proof rolling. These areas shall be excavated and backfilled with select material and compacted using normal procedures.

X1.3.1.2. The geotextile shall be laid smooth without wrinkles or folds on the prepared subgrade in the direction of construction traffic. Adjacent geotextile rolls shall be overlapped, sewn or joined as required in the plans. Overlaps shall be in the direction as shown on the plans. See Table X1.1 for overlap requirements.

Table X1.1—Overlap Requirements

Soil CBR	Minimum Overlap
Greater than 3	300–450 mm
1–3	0.6–1 m
0.5–1	1 m or sewn
Less than 0.5	Sewn
All roll ends	1 m or sewn

X1.3.1.2.1. On curves, the geotextile may be folded or cut to conform to the curves. The fold or overlap shall be in the direction of construction and held in place by pins, staples, or piles of fill or rock.

X1.3.1.2.2. Prior to covering, the geotextile shall be inspected to ensure that the geotextile has not been damaged (i.e., holes, tears, rips) during installation. The inspection shall be done by the engineer or the engineer's designated representative. It is recommended that the designated representative be a certified inspector.

Damaged geotextiles, as identified by the engineer, shall be repaired immediately. Cover the damaged area with a geotextile patch that extends an amount equal to the required overlap beyond the damaged area.

X1.3.1.3. The subbase shall be placed by end dumping onto the geotextile from the edge of the geotextile, or over previously placed subbase aggregate. Construction vehicles shall not be allowed directly on the geotextile. The subbase shall be placed such that at least the minimum specified lift thickness shall be between the geotextile and equipment tires or tracks at all times. Turning of vehicles shall not be permitted on the first lift above the geotextile.

Note X2—On subgrades having a CBR value of less than one, the subbase aggregate should be spread in its full thickness as soon as possible after dumping to minimize the potential of localized subgrade failure due to overloading of the subgrade.

X1.3.1.3.1. Any ruts occurring during construction shall be filled with additional subbase material, and compacted to the specified density.

X1.3.1.3.2. If placement of the backfill material causes damage to the geotextile, the damaged area shall be repaired as previously described in Section A3.1.2.1. The placement procedures shall then be modified to eliminate further damage from taking place (i.e., increase initial lift thickness, decrease equipment loads, etc.).

Note X3—In stabilization applications, the use of vibratory compaction equipment is not recommended with the initial lift of subbase material, as it may cause damage to the geotextile.

X1.4. *Erosion Control Geotextiles* (See Section 8.5.):

X1.4.1. *Construction*:

X1.4.1.1. The geotextile shall be placed in intimate contact with the soils without wrinkles or folds and anchored on a smooth graded surface approved by the engineer. The geotextile shall be placed in such a manner that placement of the overlying materials will not excessively stretch so as to tear the geotextile. Anchoring of the terminal ends of the geotextile shall be accomplished through the use of key trenches or aprons at the crest and toe of slope. Refer to Figures X1.4 through X1.7 for construction details.

Note X4—In certain applications to expedite construction, 450-mm anchoring pins placed on 600- to 1800-mm centers, depending on the slope of the covered area, have been used successfully.

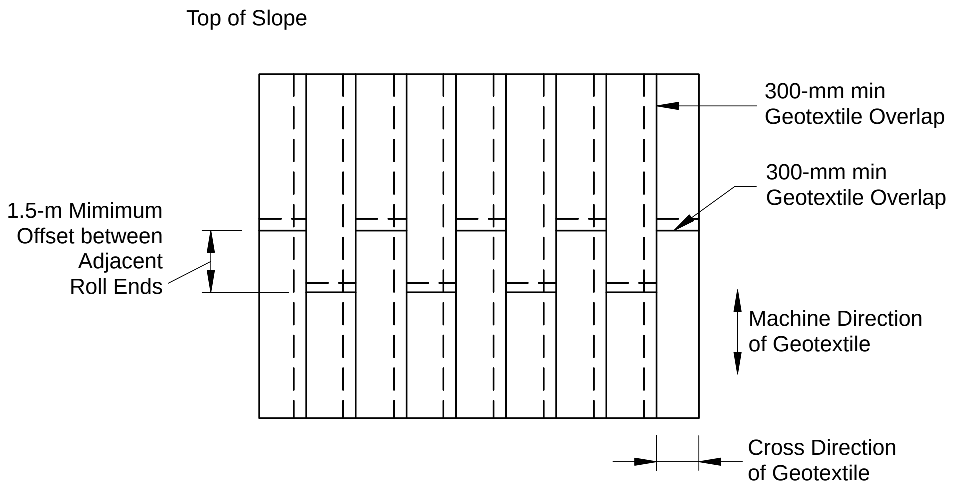

Figure X1.4—Method of Placing Geotextile for Protection of Cut and Fill Slopes

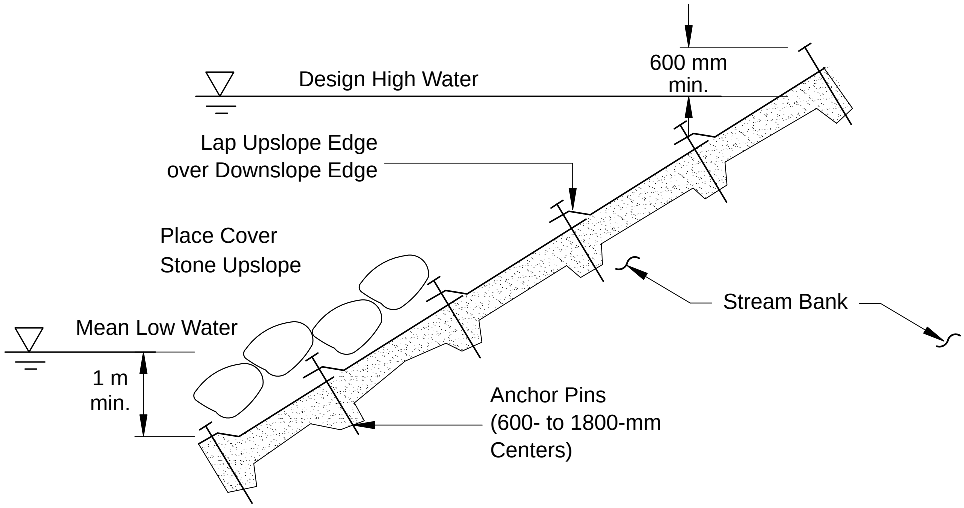

Figure X1.5—Cross Section of Slopes with Riprap

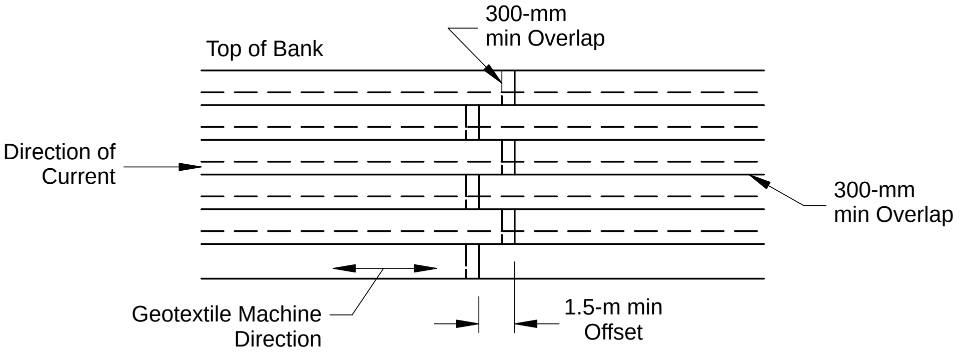

Figure X1.6—Geotextile Placement Scheme for Streambank Protection

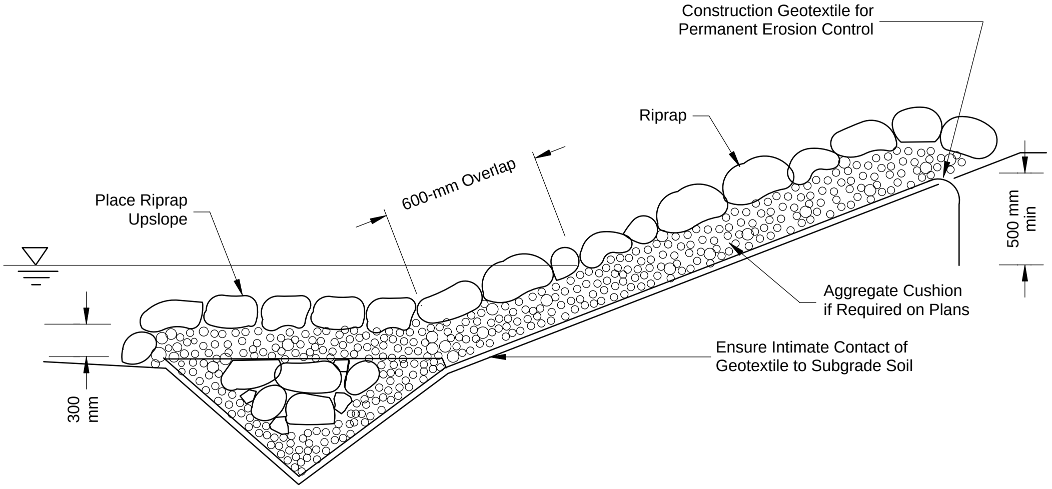

Figure X1.7—Key Detail at Top and Toe of Slope for Geotextiles Used for Permanent Erosion Control

X1.4.1.1.1. The geotextile shall be placed with the machine direction parallel to the direction of water flow, which is normally parallel to the slope for erosion control runoff and wave action (Figure X1.4), and parallel to the stream or channel in the case of streambank and channel protection (Figure X1.6). Adjacent geotextile sheets shall be joined by either sewing or overlapping. Overlapped seams of roll ends shall be a minimum of 300 mm except where placed under water. In such instances the overlap shall be a minimum of 1 m. Overlaps of adjacent rolls shall be a minimum of 300 mm in all instances.

Note X5—When overlapping, successive sheets of the geotextile shall be overlapped upstream over downstream, and/or upslope over downslope. In cases where wave action or multidirectional flow is anticipated, all seams perpendicular to the direction of flow shall be sewn.

X1.4.1.1.2. Care shall be taken during installation so as to avoid damage occurring to the geotextile as a result of the installation process. Should the geotextile be damaged during installation, a geotextile patch shall be placed over the damaged area extending 1 m beyond the perimeter of the damage.

X1.4.1.2. The armor system placement shall begin at the toe and proceed up the slope. Placement shall take place so as to avoid stretching and subsequent tearing of the geotextile. Riprap and heavy stone filling shall not be dropped from a height of more than 300 mm. Stone with a mass of more than 100 kg shall not be allowed to roll down the slope.

X1.4.1.2.1. Slope protection and smaller sizes of stone filling shall not be dropped from a height exceeding 1 m, or a demonstration provided showing that the placement procedures will not damage the geotextile. In underwater applications, the geotextile and backfill material shall be placed the same day. All void spaces in the armor stone shall be backfilled with small stone to ensure full coverage.

X1.4.1.2.2. Following placement of the armor stone, grading of the slope shall not be permitted if the grading results in movement of the stone directly above the geotextile.

X1.4.1.3. Field monitoring shall be performed to verify that the armor system placement does not damage the geotextile.

X1.4.1.3.1. Any geotextile damaged during backfill placement shall be replaced as directed by the engineer at the contractor's expense.

X1.5. *Silt Fence Geotextiles* (See Section 9.):

X1.5.1. *Related Material Requirements*:

X1.5.1.1. Wood, steel, or synthetic support posts having a minimum length of 1 m plus the burial depth may be used. They shall be of sufficient strength to resist damage during installation and to support the applied loads due to material build up behind the silt fence.

Note X6—It has been found that hardwood posts having dimensions of at least 30 mm × 30 mm, No. 2 Southern Pine at least 65 mm × 65 mm, or steel posts of U, T, L, or C shape, weighing 600 g per 300 mm have performed satisfactorily.

X1.5.1.2. Wire or polymer support fence shall be at least 750 mm high and strong enough to support applied loads. Polymer support fences shall meet the same ultraviolet degradation requirements as the geotextile.

Note X7—Wire support fences having at least six horizontal wires and being at least 14-gauge wire have performed satisfactorily. Vertical wires should be a maximum of 150 mm apart.

X1.5.2. *Construction*:

X1.5.2.1. The geotextile at the bottom of the fence shall be buried in a "J" configuration to a minimum depth of 150 mm in a trench so that no flow can pass under the silt fence. The trench shall be backfilled and the soil compacted over the geotextile.

X1.5.2.1.1. The geotextile shall be spliced together with a sewn seam only at a support post, or two sections of fence may be overlapped instead.

X1.5.2.1.2. The contractor must demonstrate to the satisfaction of the engineer that the geotextile can withstand the anticipated sediment loading.

X1.5.2.1.3. See Figure X1.8 for details.

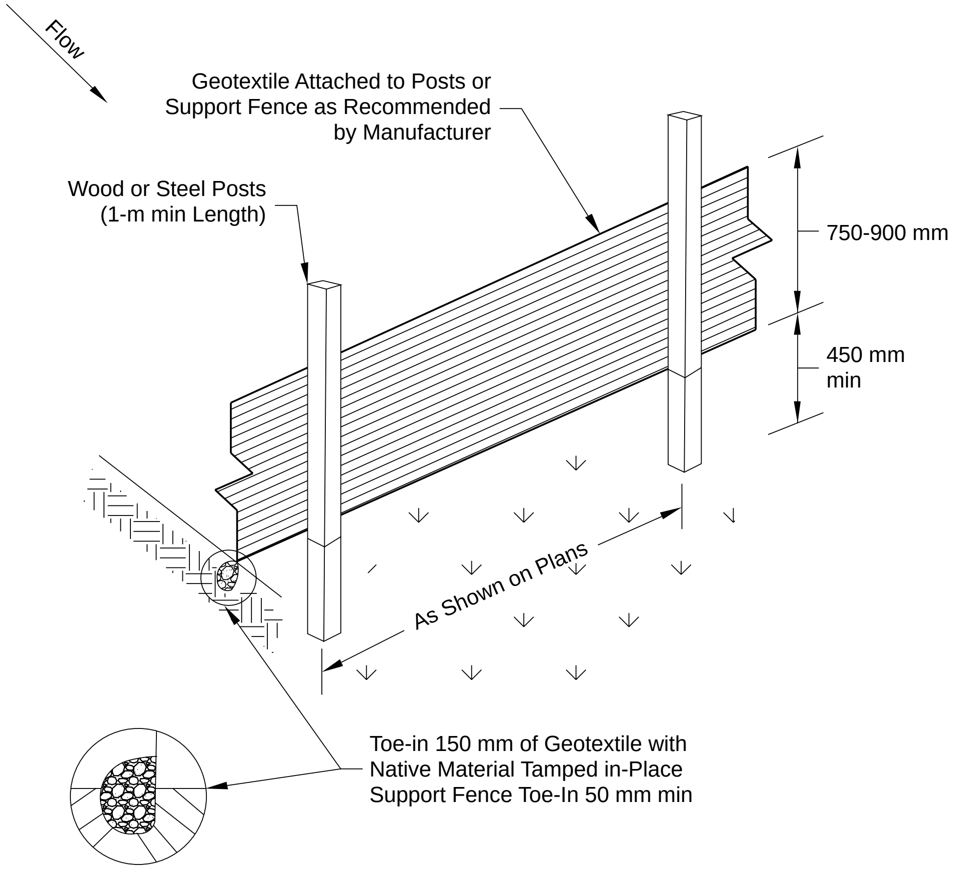

Figure X1.8—Typical Silt Fence Detail

X1.5.2.2. The posts shall be placed at spacing as shown on the project plans. Posts should be driven or placed a minimum of 500 mm into the ground. Depth shall be increased to 600 mm if fence is placed on a slope of 3:1 or greater.

Note X8—Where 500-mm depth is impossible to attain, the posts should be adequately secured to prevent overturning of the fence due to sediment loading.

X1.5.2.3. The support fence shall be fastened securely to the upslope side of the fence post. The support fence shall extend from the ground surface to the top of the geotextile.

X1.5.2.4. When self-supported fence is used, the geotextile shall be securely fastened to fence posts.

X1.5.2.5. Silt fences should be continuous and transverse to the flow. The silt fence should follow the contours of the site as closely as possible. The fence shall also be placed such that the water cannot run off around the end of the fence.

X1.5.2.5.1. The silt fence should be limited to handle an area equivalent to 90 square meters per 3 m of fence. Caution should be used where the site slope is greater than 1:1, and water flow rates exceed 3 L per second per 3 m of fence.

X1.5.3. *Maintenance*:

X1.5.3.1. The contractor shall inspect all temporary silt fences immediately after each rainfall and at least daily during prolonged rainfall. The contractor shall immediately correct any deficiencies.

X1.5.3.1.1. The contractor shall also make a daily review of the location of silt fences in areas where construction activities have altered the natural contour and drainage runoff to ensure that the silt fences are properly located for effectiveness. Where deficiencies exist as determined by the engineer, additional silt fence shall be installed as directed by the engineer.

X1.5.3.1.2. Damaged or otherwise ineffective silt fences shall be repaired or replaced promptly.

X1.5.3.2. Either sediment deposits shall be removed when the deposit reaches half the height of the fence, or a second silt fence shall be installed as directed by the engineer.

X1.5.3.3. The silt fence shall remain in place until the engineer directs it be removed. Upon removal, the contractor shall remove and dispose of any excess sediment accumulations, dress the area to give it a pleasing appearance, and cover with vegetation all bare areas in accordance with contract requirements.

X1.5.3.3.1. Removed silt fence may be used at other locations provided the geotextile and other material requirements continue to be met to the satisfaction of the engineer.

X1.6. *Paving Fabrics* (See Section 10.):

X1.6.1. *Materials*:

X1.6.1.1. The sealant material used to impregnate and seal the paving fabric, as well as bond it to both the base pavement and overlay, shall be a paving grade asphalt recommended by the paving fabric manufacturer, and approved by the engineer.

X1.6.1.1.1. Uncut asphalt cements are the preferred sealant; however, cationic and anionic emulsions may be used provided the precautions outlined in Section A6.3.3 are followed. Cutbacks and emulsions that contain solvents shall not be used.

X1.6.1.1.2. The grade of asphalt cement specified for hot mix design in each geographic location is generally the most acceptable material.

X1.6.1.2. Washed concrete sand may be spread over asphalt saturated paving fabric to facilitate movement of equipment during construction or to prevent tearing or delamination of the paving fabric. Hot mix broadcast in front of construction vehicle tires may also be used to serve this purpose. If sand is applied, excess quantities shall be removed from the paving fabric prior to placing the surface course.

X1.6.1.2.1. Sand is not usually required. However, ambient temperatures are occasionally sufficiently high to cause bleed-through of the asphalt sealant resulting in undesirable paving fabric adhesion to construction vehicle tires.

X1.6.2. *Equipment*:

X1.6.2.1. The asphalt distributor shall be capable of spraying the asphalt sealant at the prescribed uniform application rate. No streaking, skipping, or dripping will be permitted. The distributor shall also be equipped with a hand spray having a single nozzle and positive shut-off valve.

X1.6.2.2. Mechanical or manual lay down equipment shall be capable of laying the paving fabric smoothly.

X1.6.2.3. The following miscellaneous equipment shall be provided: stiff bristle brooms or squeegees to smooth the paving fabric; scissors or blades to cut the paving fabric; brushes for applying asphalt sealant to paving fabric overlaps.

X1.6.2.4. Pneumatic rolling equipment to smooth the paving fabric into the sealant and sanding equipment may be required for certain jobs. Rolling is especially required on jobs where thin lifts or chip seals are being placed. Rolling helps ensure paving fabric bond to the adjoining pavement layers in the absence of heat and weight associated with thicker lifts of asphaltic pavement.

X1.6.3. *Construction*:

X1.6.3.1. Neither the asphalt sealant nor the paving fabric shall be placed when the engineer deems weather conditions unsuitable. Air and pavement temperatures shall be sufficient to allow the asphalt sealant to hold the paving fabric in place. For asphalt cements, air temperature shall be 10ºC and rising. For asphalt emulsions, air temperature shall be 15ºC and rising.

X1.6.3.2. The surface on which the paving fabric is to be placed shall be reasonably free of dirt, water, vegetation, or other debris. Cracks exceeding 3 mm in width shall be filled with suitable crack filler. Potholes shall be properly repaired as directed by the engineer. Fillers shall be allowed to cure prior to paving fabric placement.

X1.6.3.3. The specified rate of asphalt sealant application must be sufficient to satisfy the asphalt retention properties of the paving fabric, and bond the paving fabric and overlay to the old pavement.

Note X9—When emulsions are used, the application rate must be increased to offset water content of the emulsion.

X1.6.3.3.1. Application of the sealant shall be by distributor spray bar, with hand spraying kept to a minimum. Temperature of the asphalt sealant shall be sufficiently high to permit uniform spray pattern. For asphalt cements, the minimum temperature shall be 145ºC. To avoid damage to the paving fabric, however, the distributor tank temperatures shall not exceed 160ºC.

X1.6.3.3.2. Spray patterns for asphalt emulsions are improved by heating. Temperatures in the 55ºC to 70ºC range are desirable. A temperature of 70ºC shall not be exceeded since higher temperatures may break the emulsion.

X1.6.3.3.3. The target width of asphalt sealant application shall be the paving fabric width plus 150 mm. The asphalt sealant shall not be applied any farther in advance of paving fabric placement than the distance the contractor can maintain free of traffic.

X1.6.3.3.4. Asphalt spills shall be cleaned from the road surface to avoid flushing and paving fabric movement.

X1.6.3.3.5. When asphalt emulsions are used, the emulsion shall be cured prior to placing the paving fabric and final wearing surface. This means essentially no moisture remaining.

X1.6.3.4. The paving fabric shall be placed onto the asphalt sealant with minimum wrinkling prior to the time the asphalt has cooled and lost tackiness. As directed by the engineer, wrinkles or folds in excess of 25 mm shall be slit and laid flat.

X1.6.3.4.1. Brooming and/or pneumatic rolling will be required to maximize paving fabric contact with the pavement surface.

X1.6.3.4.2. Overlap of paving fabric joints shall be sufficient to ensure full closure of the joint, but should not exceed 150 mm. Transverse joints shall be lapped in the direction of paving to prevent edge pickup by the paver. A second application of asphalt sealant to the paving fabric overlaps will be required if the engineer judges additional asphalt sealant is needed to ensure proper bonding of the double paving fabric layer.

X1.6.3.4.3. Removal and replacement of paving fabric that is damaged will be the responsibility of the contractor.

Note X10—The problems associated with wrinkles are related to thickness of the asphalt lift being placed over the paving fabric. When wrinkles are large enough to be folded over, there usually is not enough asphalt available from the tack coat to satisfy the requirement of multiple layers of paving fabric. Therefore, wrinkles should be slit and laid flat. Sufficient asphalt sealant should be sprayed on the top of the paving fabric to satisfy the requirement of the lapped paving fabric.

Note X11—In overlapping adjacent rolls of paving fabric, it is desirable to keep the lapped dimension as small as possible and still provide a positive overlap. If the lapped dimension becomes too large, the problem of inadequate tack to satisfy the two lifts of paving fabric and the old pavement may occur. If this problem does occur, then additional asphaltic sealant should be added to the lapped areas. In the application of the additional sealant, care should be taken not to apply too much since excess will cause flushing.

X1.6.3.4.4. Trafficking the paving fabric will be permitted for emergency and construction vehicles only.

X1.6.3.5. Placement of the hot mix overlay should closely follow paving fabric laydown. The temperature of the mix shall not exceed 160ºC. In the event asphalt bleeds through the paving fabric causing construction problems before the overlay is placed, the affected areas shall be blotted by spreading sand. To avoid movement of, or damage to, the seal-coat saturated paving fabric, turning of the paver and other vehicles shall be gradual and kept to a minimum.

X1.6.3.6. Prior to placing a seal coat (or thin overlay such as an open graded friction course), lightly sand the paving fabric at a spread rate of 0.65 to 1 kg/m^2, and pneumatically roll the paving fabric tightly into the sealant.

ADVISORY

It is recommended that, for safety considerations, trafficking of the paving fabric should not be allowed. However, if the contracting agency elects to allow trafficking, the following verbiage is recommended:

"If approved by the engineer, the seal-coat saturated paving fabric may be opened to traffic for 24 to 48 hours prior to installing the surface course. Warning signs shall be placed which advise the motorist that the surface may be slippery when wet. The signs shall also post the appropriate safe speed. Excess sand shall be broomed from the surface prior to placing the overlay. If, in the judgment of the engineer, the fabric surface appears dry and lacks tackiness following exposure to traffic, a light tack coat shall be applied prior to the overlay."

[2] Geotextiles used as sheet drains are not included in the discussions in this section.

Standard Specification for

Glass Cullet Use for Soil-Aggregate Base Course

AASHTO Designation: M 318-02 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Glass Cullet Use for Soil-Aggregate Base Course

AASHTO Designation: M 318-02 (2006)

1. SCOPE

1.1. This specification covers processed glass cullet intended for use as a granular road base material. When properly processed and mixed with natural or crushed aggregate, hauled to and properly spread and compacted on a prepared grade to appropriate density standards, glass cullet can be expected to provide adequate stability and load support for use as road or highway bases. Material described in this specification is not intended to be used in treated or stabilized pavement layers. This specification is intended for use in conjunction with M 147 or with the requirements of the local jurisdiction specifying the properties of natural or crushed aggregate used in the base course. It is not intended for use in base courses in locations where surfacing will not be placed over the base.

Note 1—The engineer is advised to provide appropriate construction specifications to ensure that sufficient compaction is achieved so that further densification of the completed pavement from traffic loadings will be insignificant. The method requires compaction of the material at a suitable moisture content on a firm foundation of a short control strip by means of vibratory or other proven effective rollers or tampers, until no further increase in density results. Compaction requirements should ensure that the average density of the final base course is an appropriate percentage of the maximum density obtained for the control strip; for base courses, achieving on average 98 percent of the maximum control strip density is suggested.

1.2. The values stated in SI units are to be regarded as the standard. The English unit equivalents shown in parentheses may be appropriate, except with regard to sieve sizes and aggregate size as determined by the use of testing sieves, in which case the standard SI designation shown is the standard as required by M 92.

2. DEFINITIONS

2.1. The definitions of base course and other soil-aggregate terms are given in M 146. The term glass cullet as used in this specification refers to a crushed glass container material that is screened and graded for potential use as a substitute material for soil-aggregate base course.

3.2. *ASTM Standards*:

- D 2940, Standard Specification for Graded Aggregate Material For Bases or Subbases for Highways or Airports
- D 4791, Standard Test Method for Flat Particles, Elongated Particles, or Flat and Elongated Particles in Coarse Aggregate

4. ORDERING INFORMATION

4.1. The purchaser or specifier shall include the following information in the purchase order or contract documents:

4.1.1. Reference to this specification, including year;

4.1.2. Grading to be furnished for the granular base;

4.1.3. The percentage of glass cullet by mass in the granular base;

4.1.4. The optimum moisture content and maximum density of the granular base; and

4.1.5. Exceptions or additions to this specification.

5. PHYSICAL PROPERTIES AND DELETERIOUS SUBSTANCES IN GLASS CULLET

5.1. Glass cullet shall consist of broken food and beverage containers. China dishes, ceramics, or plate glass shall be limited to a maximum of 5 percent by mass of glass cullet. Refer to Appendix X1 for further discussion of this topic.

5.2. Glass cullet shall be crushed and screened if necessary so that 100 percent of the glass cullet material passes the 9.5-mm ($^3/_8$-in.) sieve.

5.3. Glass cullet shall be free of odor.

5.4. Container tops, paper, labels, food residue, foil, wood, and other deleterious materials shall be limited to a maximum of 1 percent by mass of the glass cullet, of which no more than 0.05 percent by mass of paper shall be permitted. Extraneous soil-like materials shall be limited to a maximum of 2 percent by mass of the glass cullet. Refer to Appendix X3 for a discussion of methods to determine these percentages. Glass cullet shall be free of TV or other cathode ray tubes, fluorescent light bulbs, and any toxic or hazardous materials as defined by the state or local jurisdiction, which the supplier shall certify.

5.5. Glass cullet material shall be processed so as to limit the quantity of shard-like particles to less than 1 percent by mass as measured by ASTM Standard D 4791. Refer to Appendix X4 for further discussion of this topic.

6. SOIL-AGGREGATE MATERIALS AND GLASS CONTENT

6.1. Glass cullet shall be combined with soil-aggregate material to form a blended material conforming to the requirements of M 147, ASTM D 2940, or the requirements of the specifying jurisdiction.

6.2. The supplier shall be permitted to use up to 20 percent by mass of glass cullet in composite glass cullet/soil-aggregate mixtures.

6.3. If the engineer wishes to use a combination of materials that exceeds the glass percentage limit indicated above, then reference should be made to the evaluation methods described in Appendix X2.

6.4. The supplier shall ensure that composite material is uniformly blended.

7. METHODS OF SAMPLING AND TESTING

7.1. Glass cullet soil-aggregate composite shall be sampled and tested in accordance with the following standard methods of the American Association of State Highway and Transportation Officials, except as otherwise provided in this specification:

7.1.1. T 2, Sampling;

7.1.2. T 11, Elutriation;

7.1.3. T 27, Grading;

7.1.4. T 87, Sample Preparation;

7.1.5. T 88, Particle Size Analysis;

7.1.6. T 99, Moisture-Density Relationship;

7.1.7. T 180, Moisture-Density Relationship.

APPENDIXES

(Nonmandatory Information)

X1. CHINA DISHES, CERAMICS, PLATE GLASS, OR GLASS PRODUCTS IN EXCESS OF 5 PERCENT OF THE CONTAINER GLASS CULLET WEIGHT

X1.1. If products such as non-beverage container glass, glass-like products, or ceramics are processed to the specified glass cullet gradations presented above, there is no technical evidence to suggest that their use at levels in excess of 5 percent by mass of the container glass cullet will have an adverse effect on the properties of a granular base. Insofar as these glass products are introduced in percentages less than or equal to 5 percent by mass of the total glass cullet content, little impact is expected. If the engineer wishes to use higher percentages of non-beverage container glass that meets all other requirements of this specification in the base course material, then one of the following laboratory tests or field evaluation tests and acceptance criteria is recommended:

X1.1.1. *Validation by Use of California Bearing Ratio Testing*—The supplier should compare California Bearing Ratio test results (T 193) obtained from a control sample (consisting of natural soil-aggregate material normally used to comply with granular base specifications) and from the composite blend of glass product and natural soil-aggregate proposed for use on the project.

X1.1.2. *Validation by Use of Resilient Modulus Testing*—The supplier should compare Resilient Modulus test results (T 292 and T 307) obtained from a control sample (consisting of natural soil-aggregate material normally used to comply with granular base specifications) and from the composite blend of glass product and natural soil-aggregate proposed for use on the project. Three tests for each condition shall be performed and the values averaged.

X1.1.3. *California Bearing Ratio and Resilient Modulus Criteria*—If the California Bearing Ratio value for the glass product/natural soil-aggregate combination is equal to or greater than that for the control material, and if the average Resilient Modulus value for the glass product/natural soil-aggregate combination is equal to or greater than the average value for the control material alone, then the higher percentage non-container glass product aggregate may be permitted subject to further validation by field validation as defined in Section X1.1.4.

X1.1.4. *Validation by Field Demonstration Application*—The supplier shall show by construction of a test strip or introducing historical data that will demonstrate that higher percentages of non-beverage container glass than those recommended in these specifications do not adversely affect the granular base design and performance by establishing periodic performance reviews (not less than annually) of the field application until such time that the engineer is satisfied with the results.

X2. GLASS CULLET IN EXCESS OF 20 PERCENT BY MASS OF THE COMPOSITE BLEND

X2.1. Experience has shown that the use of less than 20 percent by mass of glass cullet in soil-aggregates produces an efficient combination where the properties of the combination are substantially equivalent to the natural soil-aggregate material alone. Little is known of the performance of combinations of greater than 20 percent by mass of glass cullet aggregate. If the engineer wishes to use higher percentages of glass cullet in the base course material, then the following performance acceptance criteria is recommended:

X2.1.1. *Validation by Use of California Bearing Ratio Testing*—The supplier should compare California Bearing Ratio test results conducted on a control sample consisting of natural soil-aggregate material normally used to comply with granular base specifications to the composite blend of glass cullet and natural soil-aggregate the supplier wishes to use on the project.

X2.1.2. *Validation by Use of Resilient Modulus Testing*—The supplier should compare the results of Resilient Modulus testing on a control sample consisting of natural soil-aggregate material normally used to meet granular base specifications to the natural soil-aggregate material plus the percentage of glass cullet material that the supplier wishes to use on the project. Three tests for each condition shall be performed and the values averaged.

X2.1.3. *California Bearing Ratio and Resilient Modulus Criteria*—If the California Bearing Ratio value for the glass cullet/natural soil-aggregate combination is equal to or greater than that for the control material, and if the average Resilient Modulus value for the glass cullet/natural soil-aggregate combination is equal to or greater than the average value for the control material alone, then the higher percentage glass cullet combination may be permitted subject to further validation by field application as defined in Section X2.1.4.

X2.1.4. *Validation during Field Application*—The supplier shall show by constructing a test strip or introducing historical data that will demonstrate that such higher percentages of glass aggregate than recommended in these specifications does not adversely affect the granular base design and performance by establishing periodic performance reviews of the field application until such time that the engineer is satisfied with the results.

X3. DETERMINATION OF PERCENTAGES OF DELETERIOUS MATERIALS

X3.1. It is recommended that percentages of deleterious materials be determined on a mass basis as described below or some equivalent alternative. In the mass method approach, a representative sample of the glass cullet is taken and dried to constant mass. The sample is then visually segregated into four categories: (1) glass, (2) paper, (3) other deleterious materials, and (4) soils. The percentage of each component may be determined by dividing the mass of the component by the mass of the total sample. Each value would then be multiplied by 100 to yield a percentage. The values so determined can be rounded to the nearest 0.1 percent.

X4. GLASS CULLET PROCESSING AND SAFETY

X4.1. The nature of crushed glass is such that certain crushing processes may generate particles that are elongated or exceptionally sharp, posing a potential safety hazard. Proper processing, which includes glass crushing, can produce a somewhat well-rounded glass particle that can be safely handled. As a result, it is recommended that glass used in granular base applications should be processed so that glass particles retained on a 4.75-mm (No. 4) sieve should not contain more than 1 percent by mass of particles so flat, elongated, or both that the ratio between the maximum and minimum dimensions of a circumscribing rectangular prism exceeds 5:1. Such an evaluation can be performed in accordance with ASTM D 4791. These requirements are intended to ensure that the processed glass cullet will have a minimal amount (less than 1 percent) of long, narrow glass particles that may pose a safety hazard. More stringent requirements may be needed. The ratio is not to be used as a criterion for the evaluation of the engineering properties of glass cullet.

Standard Specification for

Reclaimed Concrete Aggregate for Unbound Soil-Aggregate Base Course

AASHTO Designation: M 319-02 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Reclaimed Concrete Aggregate for Unbound Soil-Aggregate Base Course

AASHTO Designation: M 319-02 (2006)

1. SCOPE

1.1 This specification covers the use of reclaimed concrete aggregate as an unbound granular base course material. When properly processed, hauled, spread, and compacted on a prepared grade to appropriate density standards, reclaimed concrete aggregate used alone or blended with natural or crushed aggregate can be expected to provide adequate stability and load support for use as road or highway base courses. The approach presented in this specification is suitable for the satisfactory installation of a reclaimed concrete aggregate base course. However, local experience, practices, or materials that have been successfully applied may be used in lieu of this specification. This specification is not intended for use in base courses in locations where surfacing will not be placed over the base course.

1.2 Since reclaimed concrete aggregate is a recycled material, various state and local jurisdiction laws and regulations may be applicable. The user of this specification is cautioned to contact state and local environmental and other local regulators to determine what requirements are appropriate.

1.3 The values stated in SI units are to be regarded as the standard. The English unit equivalents shown in parentheses may be appropriate, except with regard to sieve sizes and aggregate size as determined by the use of testing sieves, in which case the standard SI designation shown is the standard, as required by M 92.

Note 1—The engineer is cautioned to provide appropriate construction specifications to ensure compaction to an extent that further densification of the compacted pavement from traffic loadings will be insignificant. At the time of placement, the reclaimed concrete aggregate material shall contain moisture approximately equal to the optimum moisture content necessary to make certain that the design density requirements are obtained when the material is compacted. Reclaimed concrete aggregate can be expected to exhibit higher absorption than natural aggregate materials. Accordingly, the engineer should expect to experience moderately higher optimum moisture content values than would be expected with natural aggregate materials. The reclaimed concrete aggregate shall be compacted using vibratory or other proven effective rollers or tampers to achieve the required density results. Further discussion of compaction issues is presented in Appendix X1.

Note 2—The engineer should be aware of the highly alkaline nature of reclaimed concrete aggregate, the relatively high degree of solubility of these alkaline materials, and the potential increase in pH that could occur in waters percolating through a reclaimed concrete aggregate base. Depending on the sensitivity of local soils, surface waters, and groundwater to the presence of alkaline material, the engineer should set appropriate limits on the proximity of placement of reclaimed concrete aggregate relative to groundwater and surface waters. Additionally, the presence of water percolating through reclaimed concrete aggregate will induce a corrosive solution with a pH of approximately 11 to 12. Therefore, reclaimed concrete aggregate shall not be used in the vicinity of metal culverts, such as aluminum culverts, that are sensitive to highly alkaline environments.

Note 3—The engineer is cautioned to prevent, or minimize when possible, the use of reclaimed concrete aggregate over a geotextile drainage layer, gravel drain fields, drain field piping, or open soil-lined stormwater retention or detention facilities. Soluble minerals rich in calcium salts and calcium hydroxide can be hydraulically transported from the reclaimed concrete aggregate material. When this occurs and the reclaimed concrete aggregate is located above such porous drainage systems, there is a tendency for the referenced minerals to precipitate out of solution and bind the drainage structure. The mineral deposits formed are sometimes referred to as tufa-like or portlandite deposits. Over time the permeability of the drainage system can be reduced. Further discussion of this topic and recommended drainage evaluation procedures are presented in Appendix X2.

Note 4—The engineer should be aware that reclaimed concrete aggregate used as base course could, with time, gain strength and exhibit a corresponding loss of permeability in the base course layer. This is due to residual cementitious reactions in the concrete material. If the base course is intended for use as a drainage layer, then the fine portion of the reclaimed concrete aggregate should be removed or modified to reduce the potential for this occurrence.

Note 5—The engineer is cautioned that some reclaimed concrete aggregate materials will yield high soundness loss values when subjected to conventional sulfate soundness testing methods, and such testing methods may not be suitable for reclaimed concrete aggregate soundness testing. Further discussion of this topic is presented in Section 6.3 and Appendix X3.

Note 6—The engineer is cautioned to ensure that reclaimed concrete source materials are not contaminated with extraneous solid waste or hazardous materials. Methods and criteria for examining and approving reclaimed concrete materials prior to use should be established by the specifying jurisdiction. This provision is further addressed in Section 7.3.

- LS-614, Freezing and Thawing of Coarse Aggregate (Ontario Ministry of Transportation)

3. DEFINITIONS

3.1 The definitions of base course and other soil aggregate terms are given in M 146. For use in this specification, base course shall mean the uppermost unbound granular layer of the pavement structure. The definition for reclaimed concrete aggregate as used in this specification is a manufactured aggregate material that is derived from the crushing, processing, and classification of portland cement concrete construction debris recovered from roadways, sidewalks, buildings, bridges, and other sources.

4. ORDERING INFORMATION

4.1 The purchaser or specifier shall include the following information in the purchase order or contract documents:

4.1.1 Reference to this specification, including year;

4.1.2 Grading to be furnished for the granular base;

4.1.3 Soundness testing requirements; and

4.1.4 Exceptions or additions to this specification.

5. GRADING AND PROPORTIONS

5.1 Reclaimed concrete aggregate or reclaimed concrete aggregate combined with other approved natural or man-made aggregate materials shall comply with the gradation requirements of M 147, ASTM D 2940, or the requirements of the specifying jurisdiction.

5.2 If the contractor/supplier wishes to use combinations of reclaimed concrete aggregate or reclaimed concrete aggregates with other approved aggregate materials, a request shall be made to the engineer for approval. The percentage of materials shall be established as part of a pre-submitted blended aggregate combination. In cases where the contractor/supplier wishes to change the approved combination, a special request for approval shall be made to the engineer. At the engineer’s discretion, revised density acceptance testing shall be required.

5.3 When the engineer permits the contractor/supplier to combine reclaimed concrete aggregate with other approved aggregates, this shall be accomplished by mechanical interlock blending or belt blending to ensure uniform mixing. The contractor/supplier may use other methods of blending if it can be demonstrated to the engineer that the alternate blending method will prevent segregation.

6. PHYSICAL PROPERTIES

6.1 Reclaimed concrete aggregate shall consist of crushed concrete material and natural aggregate particles, derived from the crushing of portland cement concrete, that are hard, durable fragments of stone, gravel, slag, crushed concrete, or sand.

6.2 Reclaimed concrete aggregate shall be limited in plastic soils such that the minus 0.425-mm (No. 40) sieve material when tested for liquid limit (T 89) shall not be greater than 30 and the plasticity index (T 90) shall not be greater than four, and/or, at the discretion of the engineer, the sand equivalent value (T 176) of the minus 0.425-mm (No. 40) sieve material shall be a minimum of 25 percent.

6.3 Reclaimed concrete aggregate shall have a percentage of wear by the Los Angeles abrasion test (T 96) of not more than 50 percent.

6.4 Reclaimed concrete aggregate soundness testing shall be required at the discretion of the engineer. Appendix X3 lists permissible alternative soundness test methods and acceptance criteria. (See Note 5.)

7. DELETERIOUS SUBSTANCES

7.1 Reclaimed concrete aggregate shall contain not more than 5 percent bituminous concrete materials by mass. (See Note 7.)

7.2 Reclaimed concrete aggregate shall contain not more than 5 percent brick by mass. (See Note 7.)

7.3 Reclaimed concrete aggregate material shall be free of all materials that fall under the category of solid waste or hazardous materials as defined by the state or local jurisdiction. (See Note 8.)

7.4 Reclaimed concrete aggregate shall be substantially free of wood, metal, plaster, and gypsum board, when these materials are not classified as solid waste as defined in Section 7.3. (See Notes 8 and 9.)

Note 7—If the engineer wishes to specify reclaimed concrete aggregate material where the percentages of bituminous concrete and/or brick exceed those shown above, an evaluation method for approving higher percentages is presented in Appendix X4.

Note 8—The engineer may select stockpiling as an approach to assist in qualitatively identifying the presence of deleterious materials. Stockpiling can also be used as a means to qualitatively assess the uniformity of the material. When such an approach is used, the stockpile may represent all or part of the material to be used on a project and should be constructed in a manner that will minimize segregation and permit a complete visual examination of the material.

Note 9—Substantially free, in the context of this specification, shall mean percentages of undesirable materials that are less than the following: wood—0.1 percent maximum; metals—0.1 percent maximum; plaster and gypsum board—0.1 percent maximum. At the engineer's discretion these respective quantities may be adjusted if, in the engineer's opinion, such adjustment will not impact the performance of the base course.

8. METHODS OF SAMPLING AND TESTING

8.1 Sample and test the aggregate in accordance with the following standard methods of the American Association of State Highway and Transportation Officials, except as otherwise provided in this specification:

8.1.1 T 2, Sampling;

8.1.2 T 11, Elutriation;

8.1.3 T 27, Grading;

8.1.4 T 87, Sample Preparation;

8.1.5 T 88, Particle Size Analysis;

8.1.6 T 89, Liquid Limit;

8.1.7 T 90, Plastic Limit and Plasticity Index;

8.1.8 T 96, L.A. Abrasion;

8.1.9 T 104, Aggregate; and/or

8.1.10 T 176, Sand Equivalent Test.

APPENDIXES

(Nonmandatory Information)

X1. DENSITY CONTROL METHODS FOR RECLAIMED CONCRETE MATERIALS

X1.1. The traditional method to control density is to perform a proctor test and compare in-place density values with the maximum dry density. Procedural methods have also been used and are based on the performance of standard compaction techniques performed for a designated number of passes, and are usually based on the experience of the specifying agency. In this second approach, once the required numbers of passes are made, the lift is accepted. Both of the previously referenced methods have been successfully applied to reclaimed concrete materials. If reclaimed concrete from different sources is used on a specific job site, however, or if the reclaimed concrete is blended with other natural or manufactured aggregates, density control problems may result. An alternate compaction control method to account for variations in the specific gravity of reclaimed concrete aggregate is presented below.

X1.2. This alternative field control method allows for variations in source materials and automatically adjusts for those changes to ensure maximum compaction of the reclaimed concrete material in the field. In overview, the procedure involves the use of a variable acceptance criteria for compaction based on testing on each designated lot and sublot on a project site. The compaction equipment and compaction practices shall be approved by the engineer. After placing the initial lot at approximately its optimum moisture content as determined in the laboratory, the acceptance degree of compaction is established by measuring the density of the compacted material between each pass of the compaction equipment and continuing such equipment passes until there is no longer an increase in the density. The lift density established in this manner then becomes the acceptance criteria and the lift has met that value and is accepted. All subsequent lots and sublots are placed at or near the moisture content of the first lot and tested in a similar manner. The following is a step-by-step description of this test method.

X1.2.1. *Lot and Sublot Description and Size*—For purposes of control of the compaction of reclaimed concrete aggregate for base course, the base material shall be divided into lots, each of which shall represent approximately 5,000 square meters (5,980 square yards) of base course, or the amount that is placed in one day, whichever is less. When more than one shift is performed on a given day, the engineer may use each shift to define a lot. Each lot will be further subdivided into four sub-lots of approximately 1,250 square meters (1,490 square yards) each or for smaller lots into four sub-lots of approximate equal size.

X1.2.2. After the initial sublot is laid down and moisture is added to achieve a moisture content approximately at the optimum moisture content as determined in the laboratory, a testing plan shall be defined for the measurement of in-place density in at least four different locations in each sublot. The sublot will be compacted and tested for density after each pass. After each of the four locations is tested, the lift shall be compacted with one or more additional passes. After each compaction pass, in-place density testing will again be performed. This sequence shall continue until there is no significant increase or decrease in the density of the lift as the result of an additional pass. In-place density testing shall be performed using an approved testing method. For reasons of this specification, the term “compaction pass” shall mean the passing of the compaction equipment over the entire lot surface one complete time.

X1.2.3. When the compaction described in the Section X1.2 has been achieved, the base course lot shall be considered to be compacted adequately. Such testing shall be ongoing until the project is completed.

X2. TUFA-LIKE DEPOSITS

X2.1. Portland cement concrete contains, among other minerals, a mix of complex calcium salts and calcium hydroxide that can be highly soluble. Once in solution, these minerals will remain so until the conditions of solubility change. This may occur as the result of the evaporation of water, thus resulting in the minerals having a solubility concentration above the solubility constant for that mineral, if temperature conditions change or in the presence of other compounds, such as carbon dioxide, that may react with these minerals to promote precipitation. The resulting mineral deposits are commonly referred to as tufa-like or portlandite deposits. Such deposits may affect the permeability of the geotextiles, gravel drain fields, drain field piping, or open soil-lined stormwater retention or detention facilities placed downgradient of the reclaimed concrete aggregate base. If the supplier wishes to use reclaimed concrete aggregate in the vicinity of geotextiles or fine-grained drainage layers, the following evaluation and acceptance criteria are recommended.

X2.1.1. Validation of geotextile or fine-grained drainage layer permeability by field experience. The supplier may submit evidence to the engineer that the same reclaimed concrete aggregate material has performed satisfactorily with the same geotextile or fine-grained drainage layer to be used on the project for a period of at least 3 years with no perceptible reduction in the permeability of the geotextile.

X2.1.2. Validation of geotextile or fine-grained drainage layer clogging potential by use of comparative permeability testing. The effect of tufa-like deposition on the permeability of geotextiles or fine-grained drainage layers may be determined by use of ASTM D 5101. To determine the potential for geotextile or fine-grained drainage-layer clogging using this method, a control sample (e.g., natural aggregates and geotextile or fine-grained drainage layer) and the reclaimed concrete aggregate and geotextile or fine-grained drainage layer should be tested and compared. During this test the permeability of the natural aggregate-geotextile or fine-grained drainage-layer combination and the reclaimed concrete aggregate-geotextile or fine-grained drainage-layer combination should be recorded after less than 1 week of flow through testing, as described in the ASTM specification, and after 12 weeks of flow through testing. The degree to which reclaimed concrete aggregate might impact a geotextile or fine-grained drainage layer can be assessed by comparing the results of reclaimed concrete aggregate testing and that of a control material to determine the relative impact of using reclaimed concrete aggregate above a geotextile or fine-grained drainage layer. A reduction in permeability by 10 percent or more over the 12-week time period of the reclaimed concrete aggregate sample relative to the control sample would suggest a measurable impact.

X3. SOUNDNESS TESTING OF RECLAIMED CONCRETE AGGREGATE

X3.1. Reclaimed concrete aggregate can be susceptible to sulfate attack when it is tested for soundness using sodium sulfate or magnesium sulfate solution, resulting in high loss values, particularly when sodium sulfate solution is used. Sulfate solution test methods (T 104) may be applied if local experience has found these methods to be satisfactory; however, alternative approaches are available if sulfate solution testing is found to exhibit high-loss values.

X3.2. Alternative test approaches include the following:

X3.2.1. *The No-Test Alternative*—This approach accepts the reclaimed concrete aggregate based on the other quality measures and waives the soundness requirements.

X3.2.2. *AASHTO T 103*—This approach uses a freeze-thaw procedure in water with 25 freeze-thaw cycles and a maximum allowable loss of 20 percent.

X3.2.3. *New York State DOT, Test Method NY 703-08*—This approach uses a test sample saturated in a 3 percent sodium chloride brine solution and a maximum allowable loss of 20 percent.

X3.2.4. *Ontario Ministry of Transportation (MOT), Test Method LS-614*—This approach uses a 3 percent sodium chloride brine solution with five freeze-thaw cycles and a maximum allowable loss of 20 percent.

X4. PROVISIONS FOR USING EXCESS BITUMINOUS CONCRETE OR BRICK

X4.1. If the engineer wishes to use higher percentages of bituminous concrete or brick in the base course material, permitted in Sections 7.2 and 7.3, respectively, of this specification, then one or more of the following performance acceptance criteria is recommended:

X4.1.1. *Validation by Use of California Bearing Ratio (T 193) Testing*—The engineer should compare California Bearing Ratio test results conducted on a control sample, consisting of reclaimed concrete aggregate material that complies with granular base specifications, to the blend of reclaimed concrete aggregate that contains the higher percentage of bituminous concrete and/or brick the supplier wishes to use on the project. If the California Bearing Ratio value for the reclaimed concrete aggregate and bituminous concrete and/or brick combination is equal to or greater than that for the control material, then the higher percentage of bituminous concrete and/or brick combination may be used.

X4.1.2. *Validation by Use of Resilient Modulus (T 307) Testing*—The engineer should compare the results of Resilient Modulus testing on a control sample, consisting of reclaimed concrete aggregate material that complies with the granular base specifications, to the reclaimed concrete aggregate material plus the percentage of bituminous concrete aggregate or brick material that the supplier wishes to use on the project. Three tests for each condition shall be performed and the values averaged. If the average Resilient Modulus value for the reclaimed concrete aggregate and bituminous concrete and/or brick combination is equal to or greater than the average value for the control material alone, then the higher percentage of bituminous concrete and/or brick combination may be used.

X4.1.3. *Validation by Field Application*—The engineer shall show by constructing a test strip or introducing historical data that incorporating percentages of bituminous concrete and/or brick into reclaimed concrete aggregate that are higher than permitted in this specification does not adversely affect the performance of the granular base.

Standard Practice for

Conducting Geotechnical Subsurface Investigations

AASHTO Designation: R 13-03 (2007)[1]
ASTM Designation: D 420-98 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249

Standard Practice for

Conducting Geotechnical Subsurface Investigations

AASHTO Designation: R 13-03 (2007)[1]
ASTM Designation: D 420-98 (2003)

INTRODUCTION

Investigation and identification of subsurface materials and conducting subsurface investigations involve complex techniques that may be accomplished by many different procedures and may be variously interpreted. These studies are frequently site specific and are influenced by geological and geographical settings; by the purpose of the investigation; by the design requirements for the project proposed; and by the background, training, and experience of the investigator.

This standard practice for soil, rock, and groundwater investigation based on standard procedures will provide a more consistent, uniform, and rational methodology for site evaluations. An acceptable and consistent investigation, sampling, testing, and evaluation program will determine subsurface site conditions and thereby provide the information needed to bring about safer and more cost-effective transportation facilities.

1. SCOPE

1.1. This standard practice identifies recognized methods by which soil, rock, and groundwater conditions may be determined. The objective of the investigation should be to identify and locate, both horizontally and vertically, significant soil and rock types and groundwater conditions present within a given site area and to establish the characteristics of the subsurface materials by sampling and *in situ* testing. Laboratory testing of soil and rock samples is governed by other AASHTO and ASTM standards.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not propose to address all safety concerns associated with its usage. It is the duty and responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Note 1—The values stated in SI units are to be regarded as the standard.

3. SIGNIFICANCE AND USE

3.1. An adequate soil, rock, and groundwater subsurface investigation provides pertinent information for decision making on one or more of the following subjects:

3.1.1. Location of the proposed construction both vertically and horizontally;

3.1.2. Location and preliminary evaluation of suitable borrow and other local sources of construction material;

3.1.3. Need for special excavating and dewatering techniques;

3.1.4. Investigations of stability in natural slopes and cuts, and embankment foundation stability;

3.1.5. Conceptual selection of embankment types and hydraulic barrier requirements;

3.1.6. Conceptual selection of alternate foundation types and elevations of the corresponding suitable bearing strata;

3.1.7. Development of additional detailed subsurface investigations for specific structures or facilities;

3.1.8. Need for and type of subgrade or embankment foundation treatment or drainage;

3.1.9. Selection of roadway or area pavement type;

3.1.10. Need to identify areas requiring special environmental protection; and/or

3.1.11. Need to identify potential hazardous locations and types of hazardous materials.

3.2. The investigation may require the collection of sufficiently large soil and rock samples of such quality to allow adequate testing to determine the soil or rock classification or mineralogic type, or both, as well as other engineering properties pertinent to the proposed design.

3.3. This standard practice is not meant to be an inflexible description of investigation requirements. Other techniques may be applied as appropriate.

4. RECONNAISSANCE OF PROJECT AREA

4.1. Available technical data from the literature or from personal communication should be reviewed before any field program is started. This includes, but is not limited to, topographic maps, air photos, satellite imagery, geologic maps, statewide or county soil surveys and mineral resource surveys, and engineering soil maps covering the proposed project area. Reports of subsurface investigations of nearby or adjacent projects should be studied.

Note 2—While some older maps and reports may be obsolete and of limited value in light of current knowledge, a comparison of the old with the new will often reveal valuable unexpected information.

4.1.1. The United States Geological Survey and the geological surveys of the various states are the principal sources of geologic maps and reports on mineral resources and groundwater.

4.1.2. United States Department of Agriculture Natural Resources Conservation Service soil survey reports, where available and recent, should enable the engineer to estimate the range in soil profile characteristics to depths of 1.5 or 2.0 m (5 or 6 ft) for each soil mapped.

Note 3—Each soil type has a distinctive soil profile due to age, parent material, relief, climatic condition, and biological activity. Consideration of these factors can assist in identifying the various soil types, each requiring special engineering considerations and treatment. Similar engineering soil properties are often found where similar soil profile characteristics exist. Changes in soil properties in adjacent areas often indicate changes in parent material or relief.

4.2. In areas where descriptive data are limited by inadequate geologic or soils maps, the soil and rock in open cuts in the vicinity of the proposed project should be studied and various soil and rock profiles noted. Field notes of such studies should include data outlined in Section 10.6.

4.3. Where a preliminary map covering the area of the project is desired, it can be prepared on maps compiled from aerial photography that show the ground conditions. The distribution of the predominant soil and rock deposits likely to be encountered during the investigation may be shown using data obtained from geologic maps, landform analysis, and limited ground reconnaissance. Experienced air photo interpreters can deduce much subsurface data from a study of black and white, color, and infrared photographs because similar soil or rock conditions, or both, usually have similar patterns of appearance in regions of similar climate or vegetation.

Note 4—This preliminary map may be expanded into a detailed engineering map by locating all test holes, pits, and sampling stations and by revising boundaries as determined from the detailed subsurface survey.

4.4. In areas where documentary information is insufficient, some knowledge of subsurface conditions can be obtained from land owners, local well drillers, and representatives of the local construction industry.

4.5. Review of past land use (tax maps, fire insurance records, etc.) or changes to local contours, or both, may indicate the possible presence of buried materials that may result in remediative efforts.

5. EXPLORATION PLAN

5.1. Available project design and performance requirements must be reviewed prior to final development of the exploration plan. Preliminary exploration should be planned to indicate the areas of conditions needing further investigation. A complete subsurface soil, rock, and groundwater investigation should encompass the following activities:

5.1.1. Review of available information on the geologic history, rock, soil, and groundwater conditions occurring at the proposed location and in the immediate vicinity of the site;

5.1.2. Interpretation of aerial photography and other remote sensing data;

5.1.3. Field reconnaissance for identification of surficial geologic conditions, mapping of stratigraphic exposures and outcrops, and examination of the performance of existing structures;

5.1.4. On-site investigation of the surface and subsurface materials by geophysical surveys, borings, or test pits;

5.1.5. Recovery of representative disturbed samples for laboratory classification tests of soil, rock, and local construction material. These should be supplemented by undisturbed specimens suitable for the determination of those engineering properties pertinent to the investigation;

5.1.6. Identification of the position of the groundwater table, or water tables, if there is perched groundwater, or of the piezometric surfaces if there is artesian groundwater. The variability of these positions in both short and long time frames should be considered. Color mottling of the soil strata may be indicative of long-term seasonal high groundwater positions;

5.1.7. Identification and assessment of the location of suitable foundation material, either bedrock or satisfactory load-bearing soils;

5.1.8. Field identification of soil sediments and rock, with particular reference to type and degree of decomposition (for example, saprolite, karst, decomposing or slaking shales), the depths of their occurrence, and the types and locations of their structural discontinuities;

5.1.9. Evaluation of the performance of existing installations, relative to their foundation material and environment in the immediate vicinity of the proposed site; and

5.1.10. Determination of the possible presence of buried hazardous material that may result in remediation efforts.

---

6. EQUIPMENT AND PROCEDURES FOR USE IN EXPLORATION

6.1. The type of equipment required for a subsurface investigation depends upon various factors including the type of subsurface material, the depth of exploration, the nature of the terrain, and the intended use of the data.

6.2. Hand augers, hole diggers, shovels, and push tube samplers are suitable for exploration of surficial soils to depths of 1 to 5 m (3 to 15 ft). Driven probe rods, without sampling, can indicate obstructions by refusal for similar depth of exploration.

6.3. Earth excavation equipment such as backhoes, draglines, and drilled pier augers (screw or bucket) may be used to allow *in situ* examination of soil deposits and sampling of materials containing very large particles. The engineer should be aware of the possibility of permanent disturbance of potential bearing strata by unbalanced pore pressure in test excavations.

6.4. Power augers and rotary drills with appropriate drill tools suitable for soil investigation and sampling.

6.5. Well drilling equipment may be suitable for deep geologic exploration. Normally samples are in the form of sand-sized cuttings captured from the return flow, but coring devices are available.

6.6. *In situ* instrumentation for settlement and ground movement.

6.7. Small tools or aids such as geology picks, binoculars, magnifying glass, acid, etc.

---

7. GEOPHYSICAL EXPLORATION

7.1. Geophysical or remote sensing techniques may assist in mapping the areal extent of geological formations and for evaluating variations in soil and rock properties.

7.1.1. Satellite and aircraft spectral mapping tools such as LANDSAT may be used to find and map the areal extent of subsurface materials and geologic structure. Interpretation of aircraft photographs and satellite imagery may locate and identify significant geologic features that may be indicative of faults and fractures. Some ground control is generally required to verify information derived from remote sensing data.

7.2. Geophysical survey methods can be used to supplement borehole and outcrop data and to interpolate between holes. Seismic, ground penetrating radar, and electrical resistivity methods can be particularly valuable when distinct differences in the properties of contiguous subsurface materials are indicated.

7.3. Shallow seismic refraction/reflection and ground penetrating radar techniques can be used to map soil horizons and depth profiles, water tables, and depth to bedrock in many situations, but depth penetration and resolution vary with local conditions. Electromagnetic induction, electrical resistivity, and induced polarization (or complex resistivity) techniques may be used to map variations in water content, clay horizons, stratification, and depth to aquifer/bedrock. Other geophysical techniques such as gravity, magnetic, and shallow ground temperature methods may be useful under certain specific conditions. Deep seismic and electrical methods are routinely used for mapping stratigraphy and structure of rock in conjunction with logs. Cross-hole shear wave velocity measurements may provide soil and rock parameters for dynamic analyses.

7.3.1. The seismic refraction method may be especially useful in determining depth to, or rippability of, rock in locations where successively denser strata are encountered.

7.3.2. The seismic reflection method may be useful for delineating geological units at depths below 3 m (10 ft). It is not constrained by layers of low seismic velocity and is especially useful in areas of rapid stratigraphic change.

7.3.3. The electrical resistivity method may be similarly useful in determining depth to rock and anomalies in the stratigraphic profile, in evaluating stratified formations where a denser stratum overlies a less dense stratum, and in location of prospective sand-gravel or other sources of borrow material. Resistivity parameters also are required for the design of grounding systems and cathodic protection for buried structures.

7.3.4. The ground penetrating radar method may be useful in defining soil and rock layers and man-made structures in the depth range of 0.3 to 10 m (1 to 30 ft).

7.3.5. Airborne thermal infrared line scanning is useful in locating seepage areas on hills and earthen water impounding structures.

Note 5—Geophysical investigations can be a useful guide in determining boring or test hole locations. If at all possible, the interpretation of geophysical studies should be verified by borings or test excavations.

8. SAMPLING

8.1. Obtain samples that adequately represent each subsurface material that is significant to the project design and construction. The size and type of sample required is dependent upon the tests to be performed, the relative amount of coarse particles present, and the limitations of the test equipment to be used.

Note 6—The size of disturbed or bulk samples for routine tests may vary at the discretion of the geotechnical investigator, but the following quantities are suggested as suitable for most materials:

- *Visual classification*—50 g to 500 g (2 oz to 1 lb)
- *Soil constants and particle size analysis of nongravelly soil*—500 g to 2.5 kg (1 lb to 5 lb)
- *Soil compaction tests and sieve analysis of gravelly soils*—20 kg to 40 kg (40 lb to 80 lb)
- *Aggregate manufacture or aggregate properties tests*—50 kg to 200 kg (100 lb to 400 lb)

8.2. Accurately identify each sample with the boring, test hole, or test pit number and depth below reference ground surface from which it was taken. Place a waterproof identification tag inside the container, securely close the container, protect it to withstand rough handling, and mark it with proper identification on the outside. Keep samples for natural water content determination in sealed containers to prevent moisture loss. When drying of samples may affect classification or engineering properties test results, protect them to minimize moisture loss. ASTM D 4220 and D 5079 address the transportation of samples from field to laboratory.

8.3. Recommended AASHTO and ASTM procedures for sampling are as follows:

8.3.1. AASHTO T 2 describes the sampling of coarse and fine aggregates for the preliminary investigation of a potential source of supply.

8.3.2. AASHTO T 306 describes the use of augers in soil investigations and sampling where disturbed soil samples can be used. Depths of auger investigations are limited by groundwater conditions, soil characteristics, and equipment used.

8.3.3. AASHTO T 206 describes a procedure to obtain representative soil samples for identification and classification laboratory tests and to measure the resistance of the soil to penetration by a standardized sampler. ASTM D 6066 describes a procedure to be used in testing loose sands below the water table for liquefaction studies or when a high level of care is required in drilling these soils.

8.3.4. AASHTO T 207 describes a procedure to recover relatively undisturbed soil samples suitable for laboratory testing.

8.3.5. AASHTO T 225 describes a procedure to recover intact samples of rock and certain soils too hard to sample by T 206 or T 207.

8.3.6. ASTM D 3550 describes a procedure to recover moderately disturbed, representative samples of soil for classification testing and in some cases shear or consolidation testing.

9. CLASSIFICATION OF EARTH MATERIALS

9.1. Identify samples of soil and rock after submission to the laboratory for identification and classification tests in accordance with one or more of the following AASHTO and ASTM standards:

9.1.1. ASTM C 294, Standard Descriptive Nomenclature for Constituents of Concrete Aggregates.

9.1.2. ASTM D 2487, Standard Practice for Classification of Soils for Engineering Purposes.

9.1.3. AASHTO M 145, Classification of Soils and Soil-Aggregate Mixtures for Highway Construction Purposes.

9.1.4. ASTM D 2488, Standard Practice for Description and Identification of Soils (Visual-Manual Procedure).

9.1.5. ASTM D 4083, Standard Practice for Description of Frozen Soils (Visual-Manual Procedure).

10. DETERMINATION OF SUBSURFACE CONDITIONS

10.1. Subsurface conditions are positively defined only at the individual test pit, hole, boring, or open cut examined. Conditions between observation points may be significantly different from those encountered in the exploration. A stratigraphic profile can be developed by detailed investigations only where determinations of a continuous relationship of the depths and locations of various types of soil and rock can be inferred. This phase of the investigation may be implemented by plotting logs of soil and rock exposures in walls of excavations or cut areas and by plotting logs of the test borings. Then one may interpolate between and extrapolate a reasonable distance beyond these logs. The spacing of these investigations should depend on the geologic complexity of the project area and on the importance of soil and rock continuity to the project design. Exploration should be deep enough to identify all strata that might be significantly affected by the proposed use of the site and to develop the engineering data required to allow analysis of the items listed in Section 3 for each project.

Note 7—Plans for a program of intrusive subsurface investigation should consider possible requirements for permits for installation and proper closure of boreholes and wells at the completion of the investigation.

10.2. The depth of exploratory borings or test pits for roadbeds, airport paving, or vehicle parking areas should be to at least 1.5 m (5 ft) below the proposed subgrade elevation. Special circumstances may increase this depth. Borings for structures, excavations, or embankments should extend below the level of significant stress or groundwater influence from the proposed load as determined by a subsurface stress analysis.

10.3. When project construction or performance of the facility may be affected by either pervious water-bearing materials or impervious materials that can block internal drainage, borings should extend sufficiently to determine those engineering and hydrogeologic properties relevant to the project design.

10.4. In all borrow areas, the borings or test pits should be sufficient in number and depth to outline the required quantities of material meeting the specified quality requirements.

10.5. Where frost penetration or seasonal dessication may be significant in the behavior of soil and rock, borings should extend well below the depth from finished grade of the anticipated active zone.

10.6. Exploration records shall be kept in a systematic manner for each project. Such records shall include:

10.6.1. Description of each site or area investigated. Each test hole, boring, test pit, or geophysical test site shall be clearly located (horizontally and vertically) with reference to some established coordinate system, datum, or permanent monument.

10.6.2. Logs of each test hole, boring, test pit, or cut surface exposure shall show clearly the field description and location of each material and any water encountered, either by symbol or word description.

Note 8—Color photographs of rock cores, soil samples, and exposed strata may be of considerable value. Each photograph should include an identifying number or symbol, a date, and reference scale.

10.6.3. Identification of all soils based on AASHTO M 145, ASTM D 2488, D 2607, or D 4083 or such other identification/classification system that meets agency policy and requirements. Identification of rock materials based on ASTM C 119 or C 294. Classification of soil and rock materials is discussed in Section 9.

10.6.4. Record of location and description of seepage and water-bearing zones and piezometric elevations found in each test hole, boring, or test pit.

10.6.5. Record of the precise location of *in situ* test results, such as the penetration resistance or vane shear tests, plate load tests, or other *in situ* tests for engineering properties of soils or rock.

10.6.6. Percentage of core recovery and rock quality designation in core drilling as outlined in Section 8.3.5.

10.6.7. Graphical presentation of field and laboratory data and their interpretation facilitates comprehensive understanding of subsurface conditions.

11. *IN SITU* TESTING

11.1. *In situ* testing is useful for: (a) measurement of soil parameters in their undisturbed condition with all of the restraining or loading effects, or both, of the surrounding soil or rock mass active; and (b) for rapid or closely spaced measurements, or both, of earth properties without the necessity of sampling.

11.2. Recommended AASHTO and ASTM procedures for *in situ* sampling and testing are as follows:

11.2.1. AASHTO T 206 describes a penetration test that has been correlated by many authors with various strength properties of soils.

11.2.2. AASHTO T 235 describes the estimation of the bearing capacity of soil in place by means of field loading tests. The results can be useful for design of spread footings based on static loading conditions. The load test should be performed in conjunction with other field tests, generally in accordance with T 206 or ASTM D 3441 or D 1586 to allow a determination of the applicability of the results.

11.2.3. AASHTO T 223 describes a procedure to measure the *in situ* unit shear resistance of cohesive soils by rotation of a four-bladed vane in a horizontal plane.

11.2.4. ASTM D 3385 describes a procedure for field measurement of the infiltration rate of soils. Water under a constant head is allowed to seep into the top surface of a fixed soil area and the volume rate of inflow into a known volume of soil is measured.

11.2.5. ASTM D 3441 describes the determination of the end bearing and side friction components of the resistance to penetration of a conical penetrometer into a soil mass.

11.2.6. ASTM D 4403 describes the application of various types of extensometers used in the field of rock mechanics.

11.2.7. ASTM D 4429 describes the field determination of the California Bearing Ratio for soil surfaces *in situ* to be used in the design of pavement systems.

11.2.8. ASTM D 4719 describes an *in situ* stress-strain test performed on the walls of a borehole in soil.

11.2.9. *In situ* instrumentation to measure movement such as inclinometers, settlement plates, tiltmeters, etc.

11.3. Corrosion potential should be checked for pH, resistivity, and bacterial potentials where potentially unacceptable changes or damages may occur.

12. INTERPRETATION OF RESULTS

12.1. Interpret the results of an investigation in terms of actual findings and make every effort to collect and include all field and laboratory data from previous investigations in the same area. Extrapolation of data into local areas not surveyed and tested should be made only for conceptual studies. Such extrapolation can be done only where geologically uniform stratigraphic and structural relationships are known to exist on the basis of other data. Cross sections may be developed as part of the site characterization if required to demonstrate the site conditions.

12.1.1. Cross sections included with the presentation of basic data from the investigation should be limited to the ground surface profile and the factual subsurface data obtained at specific exploration locations. Stratigraphic units between the locations of intrusive explorations should only be indicated if supported by continuous geophysical studies.

12.1.2. Cross sections showing interpretations of stratigraphic units and other conditions between intrusive explorations but without support of continuous geophysical profiles should be presented in an interpretive report appendix or in a separate interpretive report. The interpretive cross sections must be accompanied by notes describing anomalies or otherwise significant variations in the site conditions that should be anticipated for the intended design or construction activities.

Note 9—Additional exploration should be considered if there is not sufficient knowledge to develop interpretive cross sections, with realistic descriptions of anticipated variations in subsurface conditions, to meet project requirements.

12.2. Subject to the restrictions imposed by state licensing law, recommendations for design parameters can be made only by professional engineers and geologists specializing in the field of geotechnical engineering and familiar with the purpose, conditions, and requirements of the study. Soil mechanics, rock mechanics, and geomorphological concepts must be combined with a knowledge of geotechnical engineering or hydrogeology to make a complete application of the results of the soil, rock, and groundwater investigation. Complete design recommendations may require a more detailed study than that envisioned by this standard practice.

12.3. Delineate subsurface profiles only from actual geophysical, test hole, test pit, or cut-surface data. Interpolation between locations should be made on the basis of available geologic knowledge of the area and should be clearly identified. The use of geophysical techniques as discussed in Section 7.2 is a valuable aid in such interpolation. Geophysical survey data should be identified separately from sample data or *in situ* test data.

13. REPORT

13.1. The report of a subsurface investigation should include:

13.1.1. The location of the area investigated in terms pertinent to the project. This may include sketch maps or aerial photos on which the test pits, boreholes, and sample areas are located, as well as geomorphological data relevant to the determination of the various soil and rock types. Such data include elevation contours, streambeds, sink holes, cliffs, etc. Where feasible, include in the report a geologic map and/or an agronomic soils map of the area investigated.

13.1.2. A description of the investigation procedures, including all borings and test hole logs, graphic presentation of all compaction, consolidation, or load test data tabulation of all laboratory test results, and graphical interpretations of the geophysical measurements.

13.1.3. Cross sections delineating the extent of the stratigraphic units and note anomalies or otherwise significant conditions.

13.1.4. A summary of the findings obtained under Sections 4, 10, and 12, using subhead titles for the respective sections and appropriate recommendations and disclaimers for the use of the report.

14. PRECISION AND BIAS

14.1. This standard provides qualitative data only; hence, precision and bias are not applicable.

15. KEYWORDS

15.1. Explorations; feasibility studies; field investigations; foundation investigations; geological investigations; geophysical investigation; groundwater; hydrologic investigations; maps; preliminary investigations; reconnaissance surveys; sampling; site investigations; soil surveys; subsurface investigations.

16. REFERENCES

Note 10—There is a vast literature on subsurface investigations ranging from (1) references on the identification, characterization, and measurement of a single site-specific attribute of a soil or rock to (2) references showing how to make broad inferences of surficial and subsurface conditions of very large areas of terrain by interpretation of high altitude photography or satellite imagery. The following listed references are a sample of the technical literature in the subject area of subsurface investigations.

A special note should be made with respect to Reference 16.1. This manual is a comprehensive and exhaustive treatment of the methodology of conducting subsurface investigations for transportation facilities. The manual gives very detailed explanations of the various techniques of subsurface investigations along with hundreds of figures, diagrams, tables, photographs, and references. The manual was authorized by the American Association of State Highway and Transportation Officials in direct response to requests by the Association's Subcommittee on Materials and Subcommittee on Bridges and Structures.

[1] This standard practice is similar to and technically equivalent to ASTM D 420-98 (2003).

Standard Practice for

Drilling for Subsurface Investigations Unexpectedly Encountering Suspected Hazardous Material

AASHTO Designation: R 21-96 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Drilling for Subsurface Investigations Unexpectedly Encountering Suspected Hazardous Material

AASHTO Designation: R 21-96 (2009)

1. SCOPE

1.1. This practice is intended to help protect drillers in the event they unexpectedly encounter suspected hazardous materials while performing subsurface investigations. This is accomplished by training the drillers, identifying precautions to minimize risks of contamination, and establishing a procedure to follow if suspected hazardous material is encountered.[1]

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard and Publication*:

- R 13, Conducting Geotechnical Subsurface Investigations
- *Hazardous Waste Guide for Project Development*

2.2. *ASTM Standard*:

- D 420, Standard Guide to Site Characterization for Engineering, Design, and Construction Purposes

3. SIGNIFICANCE AND USE

3.1. There are three basic types of sites. One type is a known hazardous waste site. These sites contain hazardous waste, and have been formally labeled. This includes all Superfund sites and CERCLA (Comprehensive Environmental Response, Compensation, and Liability Act of 1980, 42 U.S.C. Section 9601–9657) sites. The second type is the nonhazardous site. These sites have no hazardous material at all. The third type, which is the subject of this practice, is one that contains unknown and unanticipated hazardous waste. This practice is intended to help drillers in situations in which they have no advance warning that they will encounter hazardous material.

4. HAZARDOUS MATERIAL IDENTIFICATION

4.1. The first and most important step drillers must take in protecting themselves from contamination is identifying the presence of suspected hazardous material. Proper identification depends on awareness, and knowledge of what to look for. All drillers on staff should be trained how to use their senses and observe their surroundings for clues indicating the presence of hazardous or explosive material.

5. MINIMIZING CONTAMINATION RISK

5.1. Drillers shall take routine precautions to minimize the risk of contamination through proper protective gear, good work habits, and good hygiene. Contaminants enter the body through skin absorption, cuts in the skin, inhalation, ingestion, and skin penetration (radioactivity).

5.1.1. *Proper Protection*—Drillers shall use skin protection (gloves, long-sleeved shirts) and work boots.

5.1.2. *Work Habits*—Drillers shall follow good work habits, including (1) avoiding skin contact with soil and drilling fluid, (2) minimizing the risk of inhaling contaminants by using drilling fluid, and (3) cleaning all equipment and tools before leaving the job site to avoid spreading contamination. (When mud and soil dry out, contaminants can become airborne.)

5.1.3. *Hygiene*—Drillers shall clean off boots, gloves, clothes, etc. before entering a vehicle to avoid spreading contamination beyond the job site and shall wash hands before eating, drinking, smoking, or making skin contact.

6. PROCEDURE

6.1. AASHTO R 13 and ASTM D 420 describe procedures that govern the investigation and site assessment process. Drillers shall take the following precautions in addition to the precautions described in these standards if they encounter hazardous material.

6.1.1. *Assess the Risk*—Determine whether the risk is one of contamination or explosion. Natural gas and some petroleum byproducts are explosive in very high concentrations.

6.1.2. *Contamination*—If the risk is of contamination only, any driller not properly trained should cease drilling and leave the site. Drillers who have successfully completed a 40-hour course in Hazardous Materials Training shall secure the site, while avoiding skin contact, ingestion, and inhalation. After securing the site, the responsible party shall make the necessary notifications. All contaminated material should be handled, contained, and disposed of according to current, established procedures.

6.1.3. *Explosion*—If there is a risk of explosion, the drillers shall leave the site and let the hole vent. If the smell remains or gets stronger, the drillers shall use an explosion risk meter, if they are properly trained and certified (Note 1) to assess the actual risk of explosion. If the risk is significant, the drillers shall properly decommission the hole in accordance with state regulations and proceed to the next location.

Note 1—Drillers must be trained and certified to use the explosion risk meter. The decision to proceed should be made by a responsible, qualified party, with input from the drillers.

7. KEYWORDS

7.1. Driller protection; hazardous material; subsurface exploration.

Standard Practice for

Decommissioning Geotechnical Exploratory Boreholes

AASHTO Designation: R 22-97 (2005)

INTRODUCTION

The preservation of groundwater resources is a very important issue in the design, construction, and maintenance of the highway infrastructure system. Most projects require some type of on-site subsurface geotechnical investigation to properly design the facilities. These investigations typically involve progressing smaller diameter (<200 mm) exploratory boreholes up to depths of approximately 60 m. In some instances, cone penetrometers or instrumentation devices such as piezometers, monitoring wells, and vane shear tests are used to obtain subsurface information. By progressing exploratory boreholes which may penetrate the water table, a conduit for surface and subsurface aquifer cross contamination may be introduced. In situations in which the investigation may lead to the contamination of groundwater resources, it would be prudent to properly abandon the borehole.

Construction of a borehole seal during decommissioning can add significantly to the time, material, and labor costs of geotechnical exploratory boreholes. Some states have regulations that mandate that all geotechnical exploratory boreholes must be sealed. When that is the case, this standard practice is of limited use, and the reader should consult references pertaining to borehole sealing. If borehole sealing mandates are not in effect, this standard practice may provide some guidelines regarding which boreholes should be sealed, as well as the procedures involved in this determination.

1. SCOPE

1.1 *Types of Boreholes*—This standard practice addresses the permanent decommissioning (closure) of the following types of geotechnical exploratory boreholes. It is specifically intended to address the closure in situations in which hazardous material or solid wastes are determined not to be present.[1] Included in the list of geotechnical exploratory boreholes are:

1.1.1 Boreholes progressed with temporary casing for obtaining soil, rock, and groundwater information;

1.1.2 Uncased boreholes progressed for obtaining soil, rock, and groundwater information using drilling mud or open-hole techniques;

1.1.3 Hollow-stem flight auger boreholes;

1.1.4 Observation wells for monitoring groundwater conditions;

1.1.5 Instrumentation boreholes (i.e., piezometers, Borros points, etc.);

1.1.6 Cone penetrometer boreholes; and

1.1.7 Soil characterization tests (vane shear, dilatometer, etc.).

1.2 *Intent of Practice*—This practice describes the overall process of decommissioning the holes and, as such, includes a systematic approach to completing the process. The typical steps entail an evaluation of the specific site characteristics and potential problems, a review of available decommissioning options including the null option if applicable, selection of an appropriate sealant, and a method of sealing. Specific requirements for the quality control and performance of the sealed borehole are addressed. Record-keeping requirements are noted.

1.3 *Safety—This standard practice does not propose to address all safety concerns associated with its usage. It is the duty and responsibility of the user of this practice to establish appropriate safety and health practices and determine the applicability of other state regulatory limitations prior to use.*

- NCHRP Project 21-4, *Sealing Geotechnical Exploratory Holes to Protect the Subsurface Environment*

3. SUMMARY OF GUIDE

3.1 Presently there are numerous state agencies and private contractors who install geotechnical exploratory boreholes for the state transportation programs. Within these agencies, various state regulations and decommissioning procedures are in place. No national or international standards exist for abandoning geotechnical boreholes. This standard practice attempts to provide members of the transportation industry with guidelines and references to follow in evaluating the need for sealing, different sealant materials, methods for sealing, and the associated record keeping for the process.

4. SIGNIFICANCE AND USE

4.1 This standard practice is intended to provide technical information and is not intended to supplant any Federal, state, or municipal regulations which may be in effect in a particular area. For a summary of practices of state transportation departments, see National Cooperative Highway Research Program Report NCHRP Project 21-4, *Sealing Geotechnical Exploratory Holes to Protect the Subsurface Environment*, August 1995.

5. MATERIALS

5.1 See NCHRP Report 378, *Recommended Guidelines for Sealing Geotechnical Exploratory Holes*, Chapter Six.

6. PROCEDURE

6.1 Reaching the decision regarding the appropriate type of decommissioning procedure for geotechnical exploratory boreholes is a complex task. Among other factors, the person making the decision must understand the hydrogeology of the area, be aware of any known aquifers in the vicinity, know where various groundwater levels exist, and know the depth and diameter of the borehole. From a practical point of view, the decision regarding the correct type of decommissioning must be studied prior to performing the actual field work.

6.2 The decommissioning process can be broken down into two major processes, backfilling or sealing. These two processes are defined as follows:

6.2.1 *Backfilling*—The practice of placing native soil cuttings or other materials in the hole as a part of the restoration process. This is largely an uncontrolled process and may only inadvertently produce a seal.

6.2.2 *Sealing*—The knowledgeable and conscientious practice of constructing a permanent hydraulic barrier in the hole. This is a carefully controlled practice of hole decommissioning.[2]

6.3 The information for making the decision regarding when a geotechnical exploratory borehole should be sealed must be gathered from a broad spectrum of available resources. The first step to follow in reaching a decision is to perform a review of the existing site data. Data can be collected from a number of sources, including but not limited to:

(a) Geologic reports,
(b) Topographic maps,
(c) Previous borings in the area,
(d) Water well records,
(e) Aquifer maps,
(f) Hazardous site maps,
(g) Survey of industry (pollutant potential),
(h) Survey of existing or proposed landfills, and
(i) State environmental protection agencies.

Making a final decision may require input from various people skilled in different disciplines, such as hydrogeology, geology, drilling, geotechnical engineering, and highway design.

6.4 The goal in decommissioning any hole is to leave, as far as possible, the hydrologic conditions in an unaltered state. This is particularly important where a public water supply is obtained from groundwater in an area. To determine whether this is the case, maps of aquifers used for public water supplies can be obtained from state and local public health agencies and state environmental protection agencies. The need for aquifer protection is as great for private water companies as it is for water supply systems under municipal control.

6.5 A review of geologic reports, water well records, and previous borings can help define where confined aquifers or multiple aquifers are present. Confined aquifers, which are sometimes called artesian aquifers, require special consideration for borehole decommissioning. The confined aquifer is overlain by an impervious layer such as clay or glacial till. When a borehole penetrates the confining layer and enters the underlying aquifer, it is introducing a vertical pathway for aqueous constituents to enter the aquifer. Moreover, the material comprising the confining layer is likely to remain open after the removal of drill rods or casing, so that the avenue for possible contaminants will not be self-sealing. Multiple aquifers are similar to confined aquifers, in that several waterbearing strata of aquifer material are separated by confining impermeable strata. The determination as to whether the medium to be drilled is a confined or multiple aquifer should be made before drilling, or in the field by qualified personnel.

6.6 After information is compiled from the aforementioned sources, it is necessary to make the decision as to whether backfilling or sealing is the most appropriate action. Some boreholes will encounter conditions that mandate sealing in order to safeguard the groundwater resources of the area.

6.6.1 Any boreholes that encounter methane gas should be sealed as quickly as possible. Methane is a naturally occurring explosive gas which may be tapped at relatively shallow depths, and can present a public safety hazard if it is allowed to vent indefinitely from a borehole.

6.6.2 As mentioned earlier, confined aquifers and multiple aquifers are unique geologic conditions, and they require sealing. It is especially important to seal a flowing artesian condition because the groundwater will carry fine material with it as it flows out of the ground, and this may cause future subsidence. Confined aquifers that do not flow to the surface should be sealed as well because of the possibility of cross-contamination of separate and discrete hydrogeologic units.

6.6.3 Boreholes drilled in areas where groundwater is the source of documented large public water supplies should be sealed.

6.6.4 In a heavily populated urban or suburban area, the possibility of future contamination of groundwater is increased because of the density of potential spill sites such as gas stations, landfills, dry cleaning stores, and chemical factories. Boreholes that encounter groundwater in these areas should be sealed.

6.6.5 Boreholes that are drilled in environmentally sensitive areas should be sealed. An example of this would be a piezometer installed in a wetland as part of an environmental impact study.

6.7 Some boreholes do not require sealing, but should be backfilled after use. If backfilling the borehole with native cuttings is justified, care should be taken to compact the upper portion of the native material in the hole to minimize any future subsidence. With any borehole, an open hole should at least be backfilled and not left open, because of the possibility of a hazard to pedestrians and others.

6.7.1 Boreholes that do not encounter groundwater require backfilling, but not sealing, because they do not disturb the hydrologic regime.

6.7.2 If a borehole is located entirely in granular material, it does not require sealing even if groundwater is encountered. After removal of the drilling equipment, granular material will collapse on itself, and the previously existing hydrogeologic conditions will be restored.

6.7.3 If a borehole is located entirely within material of low permeability, backfilling is adequate for decommissioning. An example of this would be a borehole drilled through clay or dense glacial till over shale rock. None of these materials would be considered an aquifer.

6.8 The procedures for properly sealing a borehole are presented in Chapter 7 through Chapter 10 of NCHRP Report 378, *Recommended Guidelines for Sealing Geotechnical Exploratory Holes.*

Note 1—The hole reentry method for sealing penetration holes (Chapter 10) can be used only if the hole remains open on its own after removal of tools.

6.9 It is important that the quality of workmanship and the skills of the drilling personnel who perform the sealing operation are guaranteed. Individual states should determine procedures to qualify personnel for this activity, such as a certification process.

7. RECORD KEEPING

7.1 Proper record-keeping practice is addressed in Chapter 11 of the NCHRP Report 378.

8. INVENTORY OF SEALED BOREHOLES

8.1 In addition to maintaining the sealing records identified in Section 7 of this practice, the borehole should be located using a suitable coordinate system wherever possible. With the advances in Global Positioning technologies and the incorporation of GIS application, complete records and locations of sealed boreholes will provide valuable information to the various state agencies charged with protecting valuable groundwater resources.

10. ADDITIONAL APPLICATIONS

10.1 The focus of this standard practice is limited to geotechnical exploratory holes. This practice also contains information that may pertain to other activities performed by the transportation industry that result in a vertical conduit being introduced into the ground in an area where protection of groundwater is a consideration.

APPENDIX

(Nonmandatory information)

X1. TERMINOLOGY

X1.1.1. *abandonment*—see *decommissioning*.

X1.1.2. *aquifer*—a geologic formation, group of formations, or part of a formation capable of yielding a significant amount of groundwater to wells or springs.[3]

X1.1.3. *artesian*—groundwater which is under sufficient hydrostatic head to rise above the aquifer containing it. A flowing artesian condition is when water flows up to the surface through a drillhole.

X1.1.4. *artesian well*—a well tapping an aquifer bounded above and below by impermeable beds or beds of distinctly lower permeability than the aquifer itself. The water will rise in the well above the point of initial penetration (above the bottom of the confining or impermeable layer overlying the aquifer). This term includes both flowing and non-flowing wells.[3]

X1.1.5. *backfilling*—the practice of placing native soil cuttings or other materials in the hole as part of the restoration process. This is largely an uncontrolled process and may only inadvertently produce a seal.[4]

X1.1.6. *confined aquifer*—an aquifer that is overlain by a confining bed, which has significantly lower permeability than the aquifer.

X1.1.7. *decommissioning*—the engineered closure of a geotechnical exploratory hole sealed with plugging materials. This term also includes the planning and documenting of all associated activities.

X1.1.8. *geotechnical exploratory borehole*—any temporary cased or uncased borehole completed primarily for the purpose of obtaining geologic or geotechnical data about subsurface soil or rock conditions, and/or for determining groundwater levels. This definition includes all *in situ* testing borings, instrumented boreholes, piezometers, and observation wells.[5]

X1.1.9. *grout*—a fluid mixture of cement, bentonite, and water used to seal the annular space around or between well casings, or to fill and seal abandoned wells or boreholes.[3]

X1.1.10. *monitoring well*—a well designed to obtain a representative groundwater sample and/or to measure the water level elevation over the screened interval.[3]

X1.1.11. *observation well*—a well designed to measure the depth to the water table. An observation well is screened across the water table and usually is installed in unconfined aquifers.[3]

X1.1.12. *permeability*—the ease with which a porous material allows liquid or gaseous fluids to flow through it. For water, this is usually expressed in units of centimeters per second and is termed hydraulic conductivity. Soils and synthetic liners with a permeability for water of 1×10^{-7} cm/sec or less may be considered impermeable.[3]

X1.1.13. *piezometer well*—a well designed to measure the hydraulic potential (water level elevation) at a specific point in the subsurface. A piezometer has a short screen that is positioned entirely beneath the water table.[3]

X1.1.14. *pressure grouting*—a method of forcing grout into specific portions of a well for sealing purposes.[3]

X1.1.15. *public water supply*—any water supply, including source, treatment, storage, transmission, and distribution facilities through which water is furnished for human consumption or other domestic use to any community, collection, or number of individuals, excluding water supplies serving one single family residence.[3]

X1.1.16. *sealing*—the knowledgeable and conscientious practice of constructing a permanent hydraulic barrier in the hole. This is a carefully controlled practice of hole decommissioning.[4]

X1.1.17. *static water level*—the vertical distance from the surface of the ground to the water level in a well when the water level is not affected by pumping or free flow.[3]

X1.1.18. *tremie tube*—a small diameter pipe used to place grout, filter pack material, or other well construction materials in a well.[3]

X1.1.19. *unconfined aquifer*—an aquifer in which there are no confining beds between the zone of saturation and the surface. Also known as a water table aquifer.

X1.1.20. *unconsolidated formation*—any naturally occurring, loosely cemented, or poorly indurated earth material including such materials as uncompacted gravel, sand, silt, and clay. Alluvium, soil, and overburden are terms frequently used to describe such formations.[3]

Standard Practice for

Assessment of Corrosion of Steel Piling for Non-Marine Applications

AASHTO Designation: R 27-01 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Assessment of Corrosion of Steel Piling for Non-Marine Applications

AASHTO Designation: R 27-01 (2006)

1. SCOPE

1.1. This standard practice is focused on corrosion of steel piling for non-marine soil applications.

1.2. This standard practice is divided into two parts: Part I—Environmental Conditions Causing Corrosion of Steel Piling, and Part II—Corrosion Considerations for New and Existing Piling.

1.2.1. Part I of the standard practice describes the current knowledge of the mechanism of underground corrosion to aid the reader in better understanding the controlling factors and identifies the known factors that cause corrosion of piling in non-marine applications.

1.2.2. Part II of the standard practice describes procedures that should be followed to assess the soil corrosivity at a specific site and offers guidance in the selection of corrosion mitigation procedures for new piling installations. Methods are described to evaluate the present condition of existing steel piling. Guidance is provided in the continued use of existing steel piling or reuse of steel piling in new or rehabilitated structures.

1.3. This standard practice does not preclude testing and test methods used to assess design parameters for the placement or continued use of piling.

1.4. Test methods not currently available as AASHTO or ASTM Methods are included in the Appendices of the NCHRP Report 408 (Beavers 1997).

1.5. *This standard practice may involve hazardous materials, operations, and equipment. This standard practice does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

3. SIGNIFICANCE AND USE

3.1. This standard practice identifies the factors that cause corrosion of steel piles subjected to subsurface, non-marine environment in underground conditions. It provides procedures to assess the corrosion potential of the piles and offers recommendations on the ways to mitigate the corrosion. By determining the existing condition, the remaining life of the piles can be predicted.

PART I—ENVIRONMENTAL CONDITIONS CAUSING CORROSION OF STEEL PILING

4. MECHANISM OF UNDERGROUND CORROSION

4.1. Corrosion of structural steel in soils is electrochemical in nature. When steel corrodes, the iron atoms in the steel undergo oxidation and lose electrons (Equation 1). Other components in the soil are reduced and gain the lost electrons (some combination of Equations 2, 3, and 4). The electrochemical reaction associated with oxidation is the anodic reaction and the electrochemical reaction associated with reduction is the cathodic reaction. The sites where the anodic and cathodic reactions take place are termed the anode and cathode, respectively. The combination of the anode and the cathode, coupled with current flow between the two, is called a corrosion cell.

4.2. Figure 1 is a schematic of a corrosion cell. As shown in Figure 1, the electrons produced by the oxidation reaction flow from the anode to the cathode in the steel where they are consumed by the reduction reaction. Note that the direction of current flow is opposite to the direction of electron flow since, by definition, current is the flow of positive charge. In the soil, current must flow from the anode to the cathode to maintain charge neutrality. Current flow in the soil is carried by ions, moving through the water in pore spaces between the soil particles.

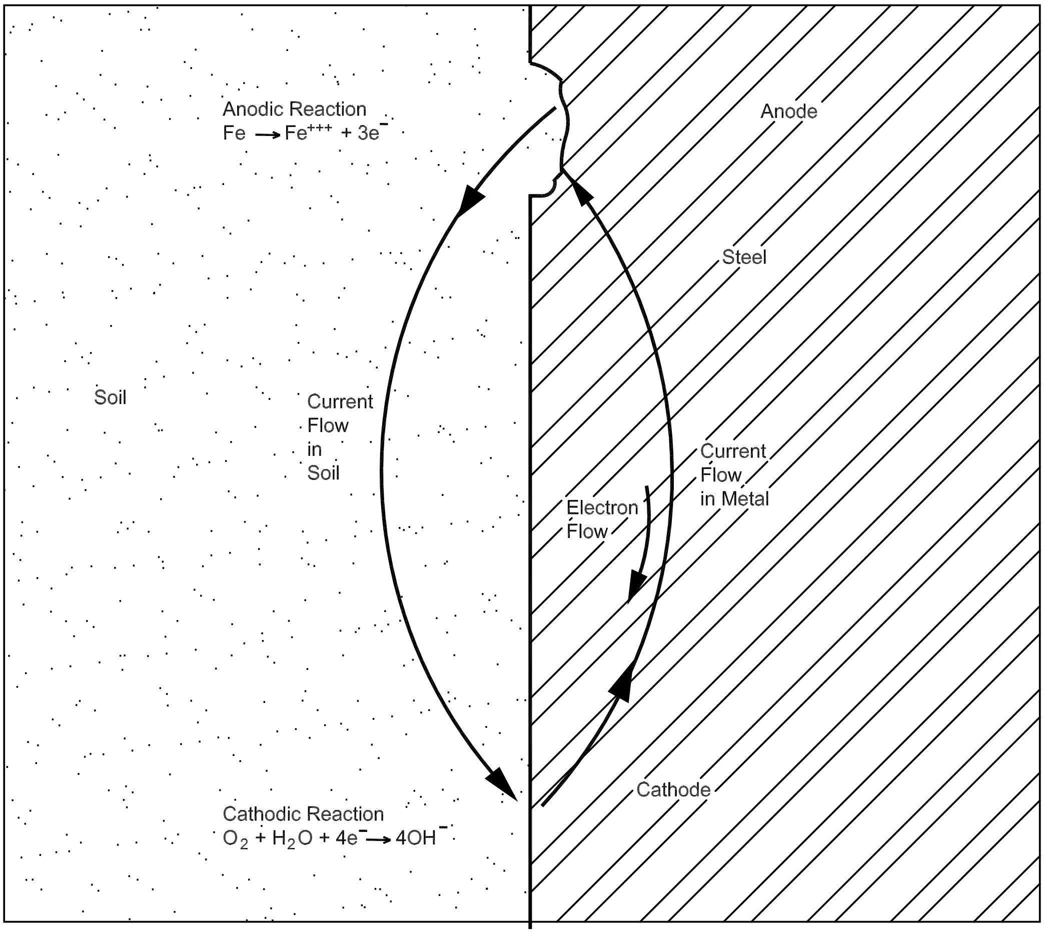

Figure 1—Schematic of a Corrosion Cell

4.3. Oxygen reduction (Equation 2) usually controls the rate of corrosion of steel in soils. This reaction is, in turn, controlled by the rate of movement of oxygen through the soil and water to the steel surface. In the absence of oxygen, reduction of water (Equation 3) can occur. However, this is normally slow enough to cause no significant corrosion damage to steel. Hydrogen ion reduction (Equation 4) occurs when the soil is very acidic and can significantly contribute to the rate of corrosion of steel in such soils. The iron ions produced by oxidation of the steel can eventually react with components in the soil to form corrosion products. For example, Equation 5 shows the iron ions reacting with water to produce rust. Other corrosion-related products are formed on the surface of the metal by the reduction reactions. These products include hydroxide ions (Equations 2 and 3) and hydrogen gas (Equations 3 and 4).

4.3.1. *Oxidation of Iron*:

$$Fe \rightarrow Fe^{+++} + 3e^{-} \qquad (1)$$

4.3.2. *Oxygen Reduction*:

$$O_2 + 2H_2O + 4e^{-} \rightarrow 4OH^{-} \qquad (2)$$

4.3.3. *Water Reduction*:

$$2H_2O + 2e^{-} \rightarrow H_2 + 2OH^{-} \qquad (3)$$

4.3.4. *Hydrogen Ion Reduction*:

$$2H^+ + 2e^- \rightarrow H_2 \qquad (4)$$

4.3.5. *Formation of Rust*:

$$2Fe^{+++} + 3H_2O \rightarrow Fe_2O_3 + 6H^+ \qquad (5)$$

4.4. If the anodes and cathodes are very close to each other and evenly distributed on the steel surface, uniform corrosion of the steel occurs. On most underground steel structures, rates of uniform corrosion are low and rarely cause service failures. The most notable exception is where the soil pH is below 4.

4.5. Where the anode and cathode sites are well separated on a steel surface, a "macrocell" is formed. Severe corrosion and resulting service failures can occur when the anode in a macrocell is confined to a relatively small area of the steel. In this instance, the form of corrosion is frequently referred to as pitting. Once macrocells are started on a steel surface, the products of the electrochemical reactions generally cause the macrocell to continue. For example, the reduction reactions cause an increase in the pH at the cathode. Steels form protective films in elevated pH environments, reducing the rate of corrosion. On the other hand, the reactions at the anode reduce the pH. The acidic environment created at the anode causes protective oxide films on the steel to break down, increasing the corrosion rate. As the pH at the anode decreases, the reduction of hydrogen ions may occur locally, further increasing the rate of attack.

4.6. One of the common macrocells on piling in soils is caused by variation in oxygen concentration over the steel surface. Oxygen macrocells frequently develop in stratified soils. Anodes are formed where the oxygen concentration is low, such as in clay soils, and cathodes are formed where the oxygen concentration is high, such as in sandy soils. The water table is another area where oxygen macrocells usually develop. A macrocell also may develop where there is variation in the chloride content of the soil, such as along roads with saltwater run-off. In this macrocell, anodes form in regions of high-chloride concentration.

4.7. Other factors that affect the rate of oxygen macrocell corrosion include the relative surface area of the anode and the cathode, soil resistivity, and microbiological activity. Where the cathode is large and the anode is small, a large current is concentrated at the anode, leading to high rates of corrosion at the anode. Soil corrosivity generally increases with decreasing soil resistivity. Where the soil resistance is high, a high current flow between the anode and cathode cannot occur due to the high voltage (IR) drop in the high resistance soil path. Microbiological activity, or the presence of welds or inclusions in the steel, can also aggravate macrocell corrosion by aiding in the creation of the anodic sites. Further discussion of the effects of resistivity and other parameters on corrosion is given in the NCHRP Report 408.

4.8. Piling and other underground structures also can undergo accelerated corrosion as a result of stray current flow in the soil. Sources of stray current include cathodic protection systems for other structures, direct current (DC) electric transit systems, mining activity, and high voltage DC electric power lines. DC electric current, flowing parallel to a structure, will jump onto that structure if that structure has a lower resistance in the direction of the current flow than the soil. The structure is cathodically protected where the current jumps onto the structure and corrosion is accelerated where the current leaves the structure. Stray current corrosion is most commonly observed on structures that have large dimensions in one horizontal direction, such as pipelines. Sheet piling and other piling that are electrically continuous also can experience stray current corrosion.

4.9. To summarize, corrosion of structural steel in soils is electrochemical in nature and is caused by the presence of oxygen and moisture in the soil. Corrosion is most likely to occur at or above the water table in disturbed stratified soils having low resistivity. For example, fill soils containing man-made materials such as cinders, slag, or ash are known to cause significant corrosion of steel piles. Stray electrical currents flowing in the ground, from sources such as transit systems, also can contribute to corrosion of structural steels in soils.

PART II—CORROSION CONSIDERATIONS FOR NEW AND EXISTING PILING

5. SUMMARY OF APPROACH

5.1. A preliminary investigation (Phase I Site Assessment) is performed to obtain pertinent available information on the surface and subsurface conditions at the site. Information obtained in this investigation may include the position of the piling or pile cap with respect to the groundwater table, the soil characteristics, and the presence of contaminants in the soil. This information is used to determine whether a further (Phase II) assessment is required. In general, a Phase II site investigation is required unless:

5.1.1. The piling or pile cap is or will be below the water table at all times or,

5.1.2. The Phase I site assessment provides the necessary information outlined in the Phase II site investigation to establish the corrosivity of the site.

5.1.3. In cases where there are multiple sites that require investigation, priority should be given to those sites known to contain corrosive materials such as slag, cinders, ash, or other man-made products.

5.2. In the Phase II Site Investigation, continuous soil sampling is performed to a depth of 1 meter below the minimum water table. The testing protocol outlined in Figure 2 is used for analyzing the soil samples. For homogeneous soils, testing is performed every 60 to 90 cm, while testing is performed on each distinct soil layer for inhomogeneous soils. This testing is limited to resistivity, pH, and particle size.

5.3. The flow chart shown in Figure 3 is used, in conjunction with the results of the soil analyses, to determine the likelihood of significant uniform or macrocell corrosion. As shown in the figure, neither form of corrosion is likely to occur at a significant rate if the saturated soil resistivity is greater than approximately 2000 ohm-cm. Depending on the homogeneity, particle size, and pH of the soil, one or both forms of corrosion may occur at a significant rate if the saturated soil resistivity is below 2000 ohm-cm.

5.4. The need for corrosion monitoring, corrosion mitigation, or pile repair or replacement is determined using the flow chart shown in Figure 4. No further testing or analysis is required if the results of the soil analyses indicate there is a low probability of significant uniform or macrocell corrosion. Corrosion monitoring is recommended where one or both forms of corrosion may occur at a significant rate. This corrosion monitoring will establish the rate of corrosion such that a remaining life assessment can be performed. Corrosion mitigation is recommended if the predicted remaining life is less than the design life. Corrosion mitigation is recommended in cases where corrosive soils are present and there is insufficient time for proper corrosion monitoring. Pile repair or replacement is required if there is no predicted remaining life. If the predicted remaining life is much less than the design life, the pile should be excavated and examined to better define the existing condition and the need for repair, replacement, or corrosion mitigation.

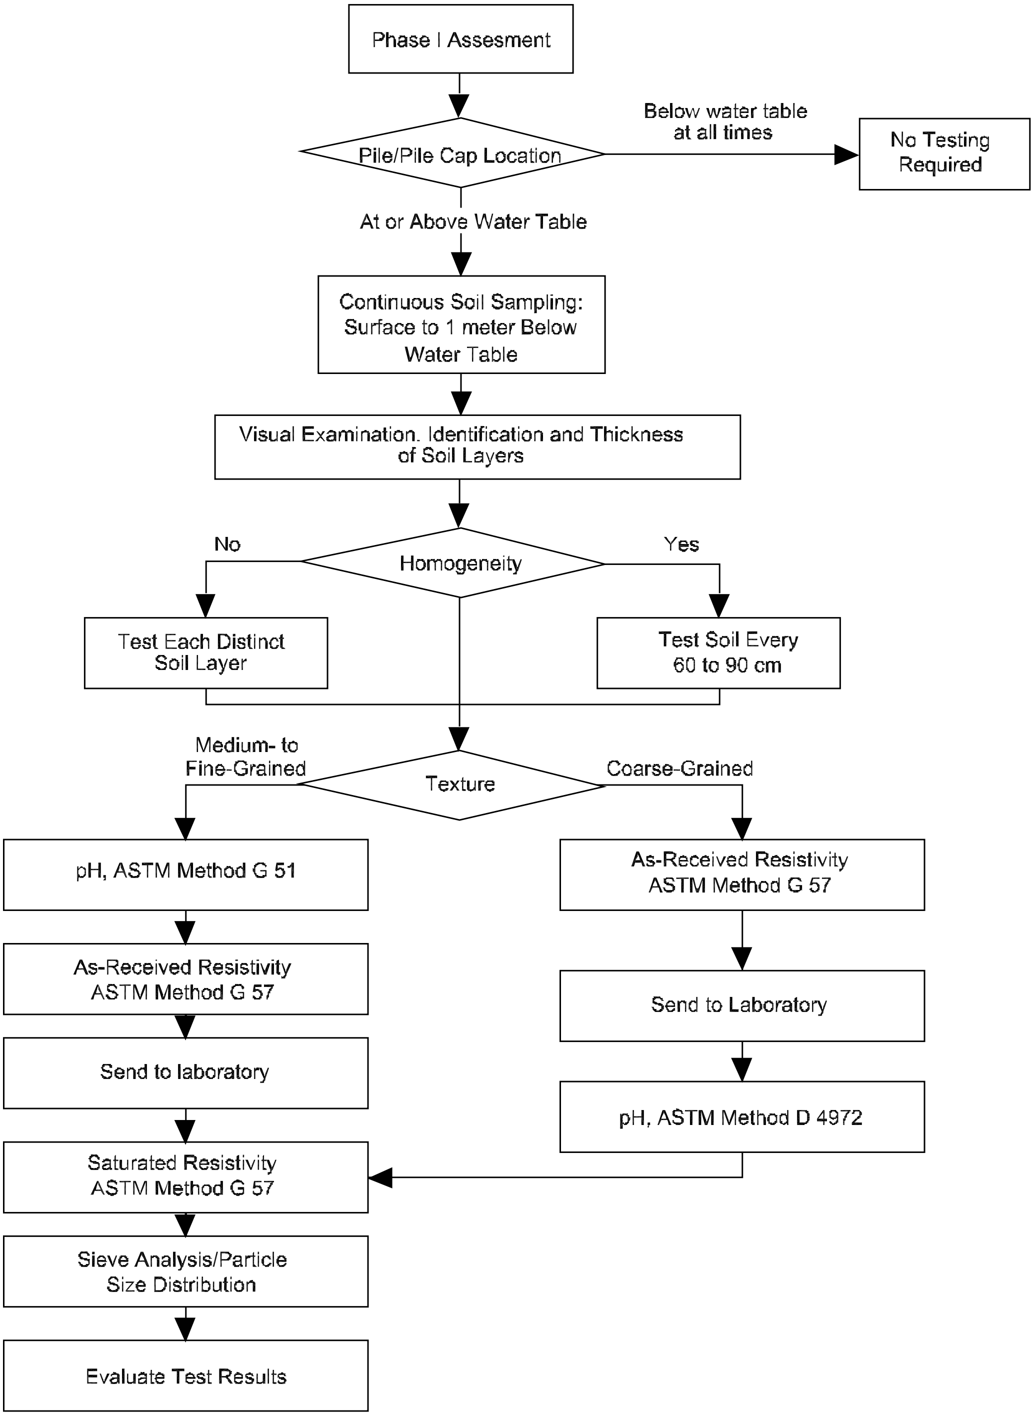

Figure 2—Phase II Site Sampling and Testing Protocol

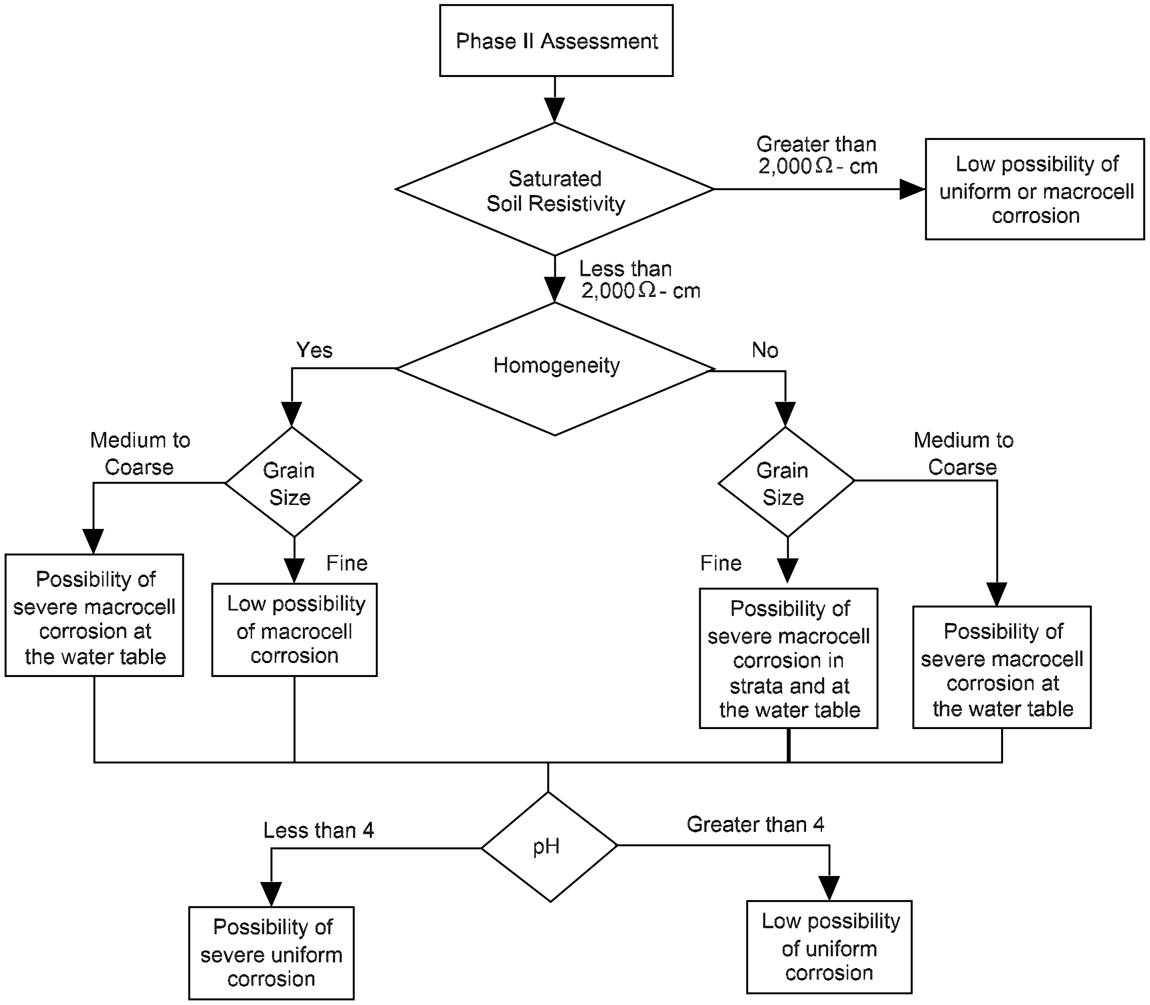

Figure 3—Determination of the Possibility for General and/or Macrocell Corrosion Based on Soil Analysis

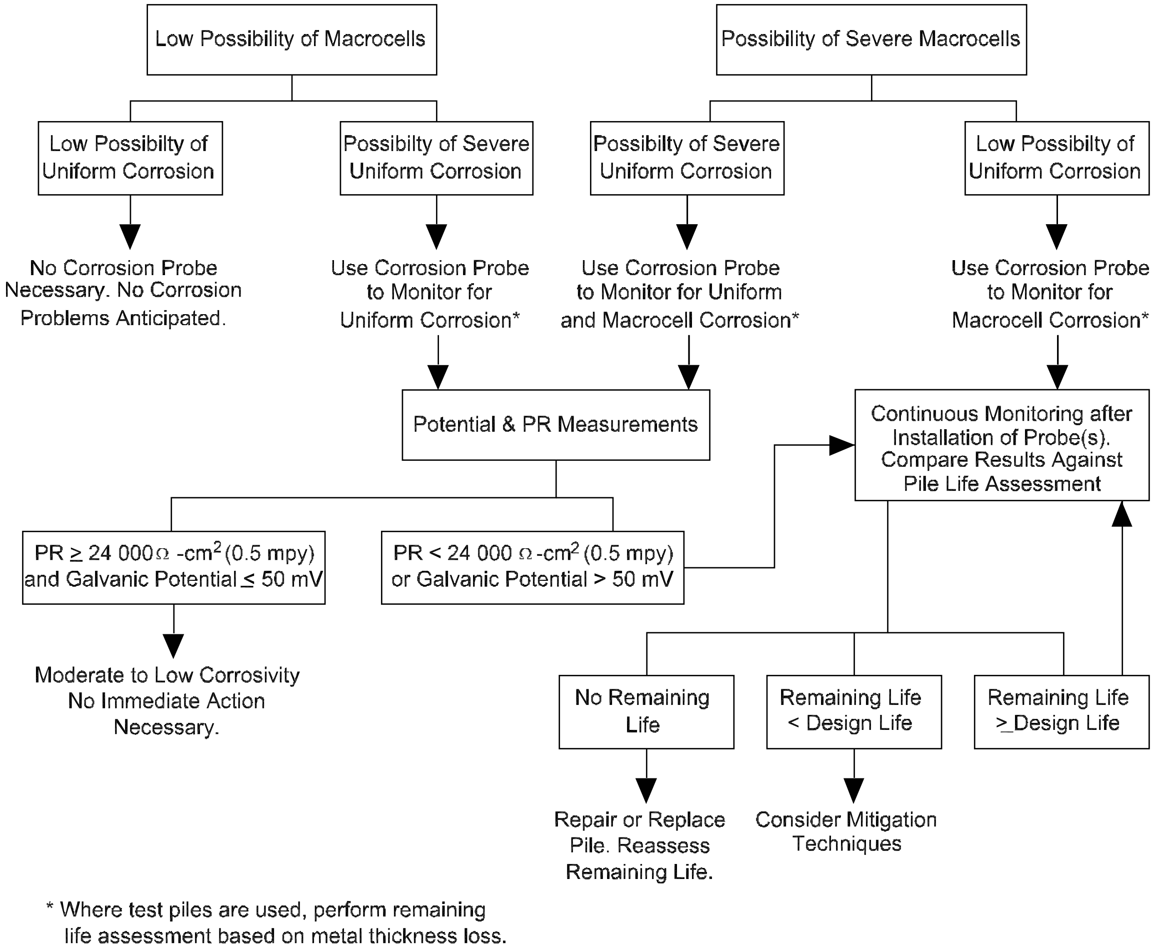

Figure 4—Determination of the Necessity for Electrochemical Testing, Corrosion Monitoring, and Mitigation

6. PHASE I (PRELIMINARY ASSESSMENT)

6.1. The purpose of the Phase I Site Assessment is to obtain pertinent available information on the surface and subsurface conditions to aid in the assessment of soil corrosivity. Information may be available on (1) the position of the pile or pile cap in relation to the groundwater table, (2) the presence of environmental contaminants, (3) characteristics of the soil and rock at the site, and (4) location, fluctuation, and chemistry of the groundwater.

6.2. Possible sources of relevant information for the Phase I Assessment include (1) local and U.S. Geological Survey, (2) USDA Soil Conservation Service, and (3) U.S. and State DOTs.

6.3. All data gathered from the Phase I Assessment should be forwarded to the engineer in charge of the project. These data should be used to determine if a Phase II Site Investigation is required. A Phase II Site Investigation is required unless:

6.3.1. The piling or pile cap is or will be below the water table at all times or,

6.3.2. The Phase I Site Assessment provides the necessary information outlined in the Phase II Site Investigation to establish the corrosivity of the site.

6.3.3. In cases where there are multiple sites that require investigation, priority should be given to those sites known to contain corrosive materials such as slag, cinders, ash, or other man-made products.

7. PHASE II (SITE INVESTIGATION)

7.1. The purpose of the Phase II Site Investigation is to obtain information on soil properties to assess the potential for corrosion of buried steel piles at the site. Figure 2 shows the site sampling and testing protocol.

7.2. *Soil Collection*:

7.2.1. The following quantities of soil are suggested as the minimum sample size suitable for most materials:

Table 1—Minimum Sample Sizes

Test	Total Size	–4.75 mm
Particle Size	50 to 500 g	—
pH	100 g	40 g
Resistivity	2000 g	1800 g

7.2.2. A soil sample with minimal disturbance is preferred for the corrosivity assessment. The following test methods are applicable: T 206, T 207, T 251, and T 255.

7.2.2.1. Continuous samples are preferred, if possible.

7.2.2.2. A 7.6-cm (3-in.) split spoon is an excellent sampling technique in that it provides a non-disturbed, continuous sample of sufficient quantity for the required analyses.

7.2.2.3. Air is the preferred drilling fluid if drilling fluids must be used.

7.2.2.4. If thin-walled tubes are used and the sample is contained for more than 72 hours, the coating in the tube should NOT be oil or any other material that may contaminate the soil sample.

7.2.3. Disturbed samples may be obtained by hand auger or test pit/excavation in the event that a minimally disturbed sample cannot be obtained. Applicable methods include T 203.

7.2.4. Representative samples should be collected, as indicated in Figure 2, to a depth of 1 meter below the water table.

7.2.5. Soil pH and resistivity measurements should be performed in the field (if possible) using ASTM G 51 and G 57, respectively.

7.2.5.1. For determination of pH of coarse-grained soils (gravels), where a stable reading cannot be obtained with ASTM G 51, ASTM D 4972 should be performed in the laboratory. For comparison with ASTM G 51 data, the pH value should be reduced by 0.5 to 1.0 units.

7.3. *Soil Handling*:

7.3.1. *Preserving and Transporting*—The intent, precautions, and procedures of ASTM D 4220 (Group B) are applicable to this practice. Soil samples should be handled in such a way as to preserve moisture and maintain the orientation and integrity of the soil sample. All samples should be placed in sealed glass jars as soon as possible to preserve natural moisture and exclude oxygen. The jars should be clearly labeled as to location, depth, and method of sampling. Ship samples to the laboratory within 1 to 2 days.

7.4. *Laboratory Soil Testing*:

7.4.1. *Sample Reduction*—Sample reduction procedures, if necessary, should not be performed until visual observation is made to describe the soil, thickness, and relationship of the various soil layers. Resistivity and pH should always be determined on the as-received sample prior to sample reduction if not previously determined in the field.

7.4.2. *Description and Identification:*

7.4.2.1. Soil samples should be visually examined in the as-received condition to determine uniformity/homogeneity and particle size.

7.4.2.2. A log of the various soil layers should be recorded and include description, identification, and thickness measurements of the soil layers.

7.4.2.3. Applicable methods include ASTM D 2488 and D 2487. The Unified Soil Classification System (USCS) should be used to classify soil.

7.4.2.4. For non-homogeneous soils, laboratory analyses should be performed on portions of each distinct layer from the surface to a depth of 1 meter below the water table.

7.4.2.5. For homogeneous soils, laboratory analyses should be performed on samples from approximately 60- to 90-cm intervals.

7.4.3. *Resistivity:*

7.4.3.1. The ASTM G 57, Wenner Four-Pin technique, should be used for all soil resistivity measurements.

7.4.3.2. Resistivity measurement should be made using soil finer than 4.75-mm (No. 4) sieve in the as-received condition prior to performing any other soil testing while the natural moisture is still present. Resistivity should also be performed on saturated soil.

7.4.3.3. For saturated measurements, place soil in a glass or plastic jar and saturate with distilled or deionized water. Mix thoroughly, cover, and let sit overnight (at least 14 hours) prior to measurement.

7.4.4. *pH*—Soil pH measurements should be performed in the laboratory using ASTM G 51 if not previously determined in the field. ASTM D 4972 should be used for primarily coarse-grained soils.

7.4.5. *Sulfate:*

7.4.5.1. The ASTM D 516 procedure is applicable.

7.4.5.2. The sulfate calibration curve described in ASTM D 516 may be expanded to accommodate samples whose sulfate concentration is greater than 40 mg/L.

7.4.6. *Chloride*:

7.4.6.1. The chloride concentration shall be determined by either the Mohr method (silver nitrate titration) or by an ion selective electrode. The ASTM D 512 procedure is applicable.

7.4.6.2. If the Mohr Method is used, the pH of the sample (or diluted sample) must be in the range of 6.0 to 8.5. Dilute sulfuric acid or sodium hydroxide may be used to adjust the pH.

7.4.6.3. See T 291 for a list of ions known to interfere with the analysis of chloride.

8. REPORT

8.1. *Report the following information*:

8.1.1. Date, time, depth, and method of sampling;

8.1.2. Sample identification—location and depth;

8.1.3. Position (depth) of the groundwater table;

8.1.4. Test methodology if several methods are applicable; and

8.1.5. All units in metric, followed by English units in parentheses.

9. TEST RESULTS DECISION MATRIX

9.1. All data gathered should be forwarded to the engineer in charge of the project for analysis.

9.2. The flow chart shown in Figure 3 is used to determine the possibility of uniform and or macrocell corrosion based on the soil analysis.

9.3. The flow charts cannot encompass all possibilities for corrosion of steel piling at a given site. Other factors that may contribute to corrosivity at a given site include the presence of chemical contamination, stray DC currents in the soil, and the presence of high concentrations of microbes.

9.3.1. A qualified corrosion specialist should be consulted where it is suspected that these or other unusual conditions that could contribute to corrosion of structural steel piling are present.

9.3.2. Sulfate reducing bacteria are more likely to be present where high-sulfate levels are detected.

9.4. The guidelines provided in the flow charts are not meant to supersede any local, state, or federal requirements.

10. CORROSION PROBES

10.1. The flow chart shown in Figure 4 is used to determine whether corrosion monitoring is required at the site, based on the possibility of uniform and/or macrocell corrosion.

10.1.1. A corrosion probe that is capable of monitoring uniform corrosion (e.g., a polarization resistance (PR) probe or a simple test pile) should be used at sites where soil data indicate a moderate-to-high possibility for uniform corrosion.

Note 1—A test pile is a pile that is removed after a specified exposure period and examined for loss of thickness.

10.1.2. A corrosion probe that is capable of monitoring macrocell corrosion (e.g., a galvanic current probe or test pile) should be used at sites where soil data indicate a moderate-to-high possibility of macrocell corrosion.

10.1.3. A qualified corrosion specialist should be consulted to assist in probe selection and field corrosion rate measurements.

10.2. Corrosion mitigation is recommended in cases where corrosive soils are present and there is insufficient time for proper corrosion monitoring.

10.3. Install probe through the most corrosive soil layers based on the soil analyses. The corrosion probe should be installed in soil as near as possible to the steel pile for long-term corrosion monitoring of new piling, if necessary.

10.3.1. The frequency of measurements and test duration should be established by the person(s) conducting the tests on a site-specific basis.

10.3.2. Procedures for making galvanic current and PR measurements are given in Appendices M and N, respectively, in the NCHRP Report 408.

10.4. Data gathered from the electrochemical measurements should be used to help assess the remaining life of the steel piling, as described below.

11. ESTIMATION OF SERVICE LIFE

11.1. Remaining service life of piles can be estimated if three factors are known. These are: present condition of the piles, rate of degradation of those piles, and the criterion used for the pile failures.

11.2. In establishing the existing condition of piles, two conditions apply:

11.2.1. For new piles, the existing condition is the installed condition.

11.2.2. For existing piles, the condition can be established by excavation and evaluation, or it can be estimated based on the maximum corrosion rate measured electrochemically and the time the pile has been in the ground.

Note 2—The estimated service life, based on the electrochemical measurements, is much less than the design life.

11.3. Estimate rate of piling degradation by (1) direct measurement of dimensional loss of the pile (or test pile) and the time the pile (or test pile) has been in the ground, or (2) the electrochemical corrosion rate measurements.

11.4. Establish remaining service life based on criterion for pile failure.

11.4.1. Failure of steel piling, from a corrosion standpoint, is an average loss equal to 50 percent of the original cross-sectional area.

11.4.2. When using the corrosion rate measurements to calculate sectional loss of an H or sheet pile, be sure to consider metal loss from all sides of the pile.

11.4.3. The section-loss criteria should be used in addition to existing federal, state, and local criterion to determine pile failure.

11.5. The flow chart in Figure 4 shows how the results of the remaining life calculation are used to make decisions with regard to repair, replacement, the application of mitigation techniques, or continued corrosion monitoring of a pile.

11.6. Procedures for excavation and exposure of piling and further details on methods of estimating service life of unprotected bare steel piling are given in Appendix S of the NCHRP Report 408.

12. APPLICATION OF CORROSION MITIGATION

12.1. As shown in Figure 4, corrosion mitigation is recommended where the estimated remaining life is less than the design life.

12.1.1. Possible choices for corrosion mitigation of new piling include the following: cathodic protection, coatings, encasement of pile, remove/replace corrosive fill, alter pile design (for example a thicker cross section), or alternative material of construction for the pile.

12.1.2. Possible choices for corrosion mitigation of existing piling include cathodic protection or remove/replace corrosive fill.

13. KEYWORDS

13.1. Corrosion; corrosion probes; direct current; electrochemical reaction; macrocell; microbiological activity; remaining life; soil resistivity; steel piling.

Standard Practice for

Compost for Erosion/Sediment Control (Filter Berms and Filter Socks)

AASHTO Designation: R 51-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Compost for Erosion/Sediment Control (Filter Berms and Filter Socks)

AASHTO Designation: R 51-10[1]

1. SCOPE

1.1. This specification covers compost produced from various organic by-products for use as a filter berm media for erosion/sediment control. The technique described in this specification is primarily used for temporary erosion/sediment control applications where perimeter controls are required or necessary.

1.2. This technique is appropriate for slopes up to a 2:1 grade (horizontal distance:vertical distance) and on level surfaces and should only be used in areas that have sheet flow drainage patterns (not areas that receive concentrated flows).

1.3. The filter sock technology is appropriate for areas outlined in Section 1.2 as well as areas of high sheet flow erosion, around inlets, and in other disturbed areas of construction sites requiring sediment control. Unlike filter berms, the filter sock technology may be used in areas that have concentrated flow drainage patterns, up to 10 gallons per minute per linear foot of filter sock.

3. GENERAL DESCRIPTION

3.1. Compost is the product resulting from the controlled biological decomposition of organic material, occurring under aerobic conditions, that has been sanitized through the generation of heat and stabilized to the point that it is appropriate for its particular application. Active composting is typically characterized by a high-temperature phase that sanitizes the product and allows a high rate of decomposition, followed by a lower temperature phase that allows the product to stabilize while still decomposing at a slower rate. Compost should possess no objectionable odors or substances toxic to plants and shall not resemble the raw material from which it was derived. Compost contains plant nutrients but is typically not characterized as a fertilizer.

3.2. Compost may be derived from a variety of feedstocks, including agricultural, forestry, food, or industrial residuals; biosolids (treated sewage sludge); leaf and yard trimmings; manure; tree wood; or source-separated or mixed solid waste.

3.3. Proper thermophilic composting, meeting the U.S. Environmental Protection Agency’s definition for a “process to further reduce pathogens” (PFRP), will effectively reduce populations of human and plant pathogens, as well as destroy noxious weed seeds and propagules.

3.4. Compost is typically characterized as a finely screened and stabilized product that is used as a soil amendment. However, most composts also contain a wood-based fraction (e.g., bark, ground brush and tree wood, wood chips, etc.) that is typically removed before use as a soil amendment. This coarser, woody fraction of compost plays an important role when compost is used in erosion and sediment control. It is even possible to add fresh, ground bark or composted, properly sized wood-based materials to a compost product, as necessary, to improve its efficacy in this application.

3.5. Compost products acceptable for this application must meet the chemical, physical, and biological parameters outlined in Section 4.

4. CHEMICAL, PHYSICAL, AND BIOLOGICAL PARAMETERS

4.1. Compost products specified for use in this application must meet the criteria specified in Table 1. The products’ parameters will vary based on whether vegetation will be established on the filter berm or if it will be self-contained in a filter sock.

4.2. Only compost products that meet all applicable state and federal regulations pertaining to their production and distribution may be used in this application. Approved compost products must meet related state and federal chemical contaminant (e.g., heavy metals, pesticides, etc.) and pathogen limits pertaining to the feedstocks (source materials) in which they were derived.

Table 1—Filter Berm Media Parameters

Parameters[a,b]	Reported as (Units of Measure)	Filter Berm to Be Vegetated	Filter Berm to Be Left Unvegetated	Filter Sock Media
pH[c]	pH units	5.0–8.5	N/A	5.0–8.5
Soluble Salt Concentration[c] (electrical conductivity)	dS/m (mmhos/cm)	Max 5	N/A	N/A
Moisture Content	%, wet weight basis	30–60	30–60	< 60
Organic Matter Content	%, dry weight basis	25–65	25–100	25–100
Particle Size	% passing a selected mesh size, dry weight basis	3 in. (75 mm), 100% passing 1 in. (25 mm), 90% to 100% passing $^{3}/_{4}$ in. (19 mm), 70% to 100% passing $^{1}/_{4}$ in. (6.4 mm), 30% to 75% passing (no more than 60% passing $^{1}/_{4}$ in. (6.4 mm) in high rainfall/flow rate situations) Max particle length of 6 in. (152 mm)	3 in. (75 mm), 100% passing 1 in. (25 mm), 90% to 100% passing $^{3}/_{4}$ in. (19 mm), 70% to 100% passing $^{1}/_{4}$ in. (6.4 mm), 30% to 75% passing (no more than 50% passing $^{1}/_{4}$ in. (6.4 mm) in high rainfall/flow rate situations) Max particle length of 6 in. (152 mm)	2 in. (50 mm), 99% to 100% passing $^{3}/_{8}$ in. (10 mm), 30% to 50% passing (or 50% to 70% retained) Maximum particle length of 2 in. (50 mm)
Stability/Maturity[d]				
Carbon Dioxide Evolution Rate	mg CO_2-C per g OM per day	< 8	N/A	N/A
Physical Contaminants (man-made inerts)	%, dry weight basis	< 1	< 1	< 1

[a] Recommended test methodologies are provided in *Test Methods for the Examination of Composting and Compost* (TMECC, The U.S. Composting Council).

[b] Landscape Architects and Project (Field) Engineers may modify the allowable compost specification ranges based on specific field conditions and plant requirements.

[c] Each specific plant species requires a specific pH range. Each plant also has a salinity tolerance rating, and maximum tolerable quantities are known. When specifying the establishment of any plant or turf species, it is important to understand their pH and soluble salt requirements, and how they relate to the compost in use.

[d] Stability/Maturity rating is an area of compost science that is still evolving, and as such, other various test methods could be considered. Also, never base compost quality conclusions on the result of a single stability/maturity test.

4.3. Very coarse (woody) composts that contain less than 30 percent of fine particles (1 mm in size) should be avoided if optimum reductions in total suspended solids (TSS) is desired or if the berm is to be seeded.

4.4. In regions subject to higher rates of precipitation and/or greater rainfall intensity, larger compost filter berms or filter socks should be used. In these particular regions, coarser compost products are preferred as the filter berm must allow for an improved water percolation rate.

Design Note: Engineers should inquire as to the flow rate per linear foot of filter sock in order to ensure drainage rate of tool being used is in accordance with total watershed management plan. Required flow through rates are outlined in Table 2.

Table 2—Suggested Compost Filter Sock Flow Through Rates

Annual Rainfall/Flow Rate	Flow Rates
Low	4–6 gallons/minute
Average	6–10 gallons/minute
High	>10 gallons/minute

Note 1—Specifying the use of compost products that are certified by the U.S. Composting Council's Seal of Testing Assurance (STA) Program (www.compostingcouncil.org) will allow for the acquisition of products that are analyzed on a routine basis using the specified test methods. STA participants are also required to provide a standard product label to all customers, allowing easy comparison to other products.

5. FIELD APPLICATIONS

5.1. The following steps shall be taken for the proper installation of compost as a filter berm or filter sock media for erosion/sediment control on both level and sloped areas. Either device should be placed as prescribed on the engineering plans.

5.2. *Filter Berms*:

5.2.1. Parallel to the base of the slope, or around the perimeter of affected areas, construct a trapezoidal berm at the dimensions specified in Table 3. In general, when compost filter berms are used to control erosion/sediment near or on a slope, the base of the berm should be twice the height of the berm.

5.2.2. Compost shall be applied to the dimensions specified in Table 3.

Table 3—Compost Filter Berm Dimensions

Annual Rainfall/Flow Rate	Total Precipitation and Rainfall Erosivity Index	Dimensions for the Compost Filter Berm (Height by Width)
Low	1–25 in., 20–90	1 ft by 2 ft–1$^1/_2$ ft by 3 ft (30 cm by 60 cm–45 cm by 90 cm)
Average	26–50 in., 91–200	1 ft by 2 ft–1$^1/_2$ ft by 3 ft (30 cm by 60 cm–45 cm by 90 cm)
High	51 in. and above, 201 and above	1$^1/_2$ ft by 3 ft–2 ft by 4 ft (45 cm by 90 cm–60 cm by 120 cm)

5.2.3. Compost filter berm dimensions should be modified based on specific site (e.g., soil characteristics and existing vegetation) and climatic conditions, as well as particular project-related requirements. The severity of slope grade, as well as slope length, will also influence the size of the berm.

5.2.4. In regions subject to higher rates of precipitation or rainfall intensity, or both, as well as spring snow melt, larger berms should be used. In these regions, and on sites possessing severe grades or long slope lengths, berms possessing a larger dimension may be used. Berms may be placed at the top and the base of the slope, a series of berms may be constructed down the profile of the slope (15–25 ft apart), or berms may be used in conjunction with a compost blanket (surface applied compost). In these particular regions as well as regions subject to wind erosion, coarser compost products are also preferred for use in filter berm construction.

5.2.5. In regions subject to lower rates of precipitation and/or rainfall intensity, smaller berms may be used. However, the minimum filter berm dimensions shall be 1 ft (30 cm) high by 2 ft (60 cm) wide.

Note 2—Specific regions may receive higher rainfall rates, but this rainfall is received through low-intensity rainfall events (e.g., the Northwestern United States). These regions may use smaller berms.

5.2.6. Larger berms should also be used where required to be in place and functioning for more than 1 year.

5.2.7. Compost shall be uniformly applied using an approved spreader unit, such as a pneumatic blower, specialized berm machine, etc. When applied, the compost should be directed at the soil surface, compacting (settling) and shaping the berm to some degree. The filter berm may also be applied by hand when approved by the Project Engineer or Landscape /Designer.

5.2.8. On highly unstable soils, use compost filter berms in conjunction with appropriate structural measures. If used in conjunction with a silt fence, the silt fence fabric shall be laid on the soil surface with the lip facing the slope. The compost filter berm shall be constructed at the uphill base of the silt fence and over the entire fence fabric lip.

5.2.9. Seeding the berm may be done, if desired, in conjunction with pneumatic blowing, or following berm construction with a hydraulic seeding unit, or by hand.

5.3. *Filter Socks*:

5.3.1. Filter socks shall either be made on site or delivered to the jobsite. The filter sock shall be produced from a 5-mil-thick continuous high density polyethylene (HDPE) filament, woven into a tubular mesh netting material with openings in the knitted mesh of $^{3}/_{8}$ in. (10 mm). This shall then be filled with compost meeting the specifications outlined in Table 1 to the diameter of the sock. Filter sock netting materials are also available in biodegradable plastics for areas where removal and disposal are not planned. Filter socks contain the compost, allowing filtration to occur even during peak storm events and concentrated flows.

5.3.2. Filter socks will be placed at locations indicated on plans as directed by the Engineer. Filter socks should be installed parallel to the base of the slope or other affected area, perpendicular to sheet flow. In extreme conditions (i.e., 2:1 slopes), or when sheet flow flows to the area from a parcel above the work zone, a second sock shall be constructed at the top of the slope in order to dissipate flows.

5.3.3. At locations where greater than a 200-ft-long section of ground is to be treated with a filter sock, the sock lengths should be sleeved. After one sock section (200 ft) is filled and tied off (knotted) or zip tied, the second sock section shall be pulled over the first (1–2 ft) and “sleeved” creating an overlap. Once overlapped, the second section is filled with compost starting at the sleeved area to create a seamless appearance. The socks may be staked at the overlapped area (where the sleeve is) to keep the sections together. Sleeving at the joints is necessary because it reduces the opportunity for water to penetrate the joint when installed in the field.

5.3.4. In general, a 12-in. diameter filter sock will replace a normal (24-in.) silt fence, and an 18-in. diameter filter sock will replace a “super silt” (36-in.) silt fence reinforced with steel posts.

5.3.5. If the filter sock is to be left as a permanent filter or part of the natural landscape, it may be seeded at time of installation for establishment of permanent vegetation. The Engineer shall specify seed requirements.

5.3.6. Filter socks may be used in direct flow situations perpendicular to runoff channels not exceeding 3 ft (90 cm) in depth. Normally, 8-in. filter socks should be used. Be sure to stake the filter sock perpendicular to water flow, at a minimum interval of 10 linear feet, using 2-in. (5-cm) wooden stakes. The stakes should be projected through the center of the filter sock and into the soil 1 ft (30 cm) deep and leaving 3–4 in. (7.5–10 cm) protruding above the filter sock.

6. TEST METHODS

6.1. The chemical, physical, and biological analysis of the compost shall be determined in accordance with the *Test Methods for the Examination of Composting and Compost* (TMECC), jointly published by the U.S. Department of Agriculture and the U.S. Composting Council (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). (See Appendix X1.)

6.2. ASTM D 2977 shall be used to determine gradation of the compost.

7. SAMPLING, INSPECTION, PACKING, AND MARKING

7.1. The sampling, testing, packing, and marking of compost samples shall be done in accordance with TMECC 02.01-B (Selection of Sampling Locations for Windrows and Piles).

8. KEYWORDS

8.1. Compost; compost logs; compost socks; compost tubes; compost wattles; erosion control; filter berm; filter logs; filter socks; filter tubes; sediment control; sheet flow.

APPENDIXES

(Nonmandatory Information)

X1. METHODS FOR THE SAMPLING AND CHARACTERIZATION OF COMPOST

X1.1. Sampling procedures to be used for purposes of this specification (and the Seal of Testing Assurance Program) are as provided in 02.01 Field Sampling of Compost Materials, 02.01-B Selection of Sampling Locations for Windrows and Piles of the *Test Methods for the Examination of Composting and Compost* (TMECC), Chapter 2, Section One, Sample Collection and Laboratory Preparation, jointly published by the USDA and USCC (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). The sample collection section is available online at http://tmecc.org/tmecc/.

X1.2. Test Methods to be used for purposes of this specification are as provided in the *Test Methods for the Examination of Composting and Compost* (TMECC), jointly published by the USDA and USCC (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). A list of such methods is provided in the table below and online at http://tmecc.org/tmecc/.

Table X1.1—Test Methods for Compost Characterization

Compost Parameters	Reported as	Test Method	Test Method Name
pH		TMECC 04.11-A	Electrometric pH Determinations for Compost. 1:5 Slurry Method.
Soluble salts	dS/m (mmhos/cm)	TMECC 04.10-A	Electrical Conductivity for Compost. 1:5 Slurry Method (Mass Basis).

Standard Practice for

Compost for Erosion/Sediment Control (Compost Blankets)

AASHTO Designation: R 52-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Compost for Erosion/Sediment Control (Compost Blankets)

AASHTO Designation: R 52-10[1]

1. SCOPE

1.1. This specification covers compost produced from various organic by-products for use as a surface mulch for erosion/sediment control on sloped areas. This technique may be used for both temporary and permanent erosion/sediment control applications.

1.2. This technique is appropriate for slopes up to a 2:1 grade (horizontal distance:vertical distance) and should only be used in areas that have sheet flow drainage patterns (not areas that receive concentrated flows). This technique may also be used on up to 1:1 slopes with proper consideration to length of slope and compost application rates (depth).

3. GENERAL DESCRIPTION

3.1. Compost is the product resulting from the controlled biological decomposition of organic material, occurring under aerobic conditions, which has been sanitized through the generation of heat and stabilized to the point that it is appropriate for its particular application. Active composting is typically characterized by a high-temperature phase that sanitizes the product and allows a high rate of decomposition, followed by a lower temperature phase that allows the product to stabilize while still decomposing at a slower rate. Compost should possess no objectionable odors or substances toxic to plants and shall not resemble the raw material from which it was derived. Compost contains plant nutrients but is typically not characterized as a fertilizer.

3.2. Compost may be derived from a variety of feedstocks, including agricultural, forestry, food, or industrial residuals; biosolids (treated sewage sludge); leaf and yard trimmings; manure; tree wood; or source-separated or mixed solid waste.

3.3. Proper thermophilic composting, meeting the U.S. Environmental Protection Agency's definition for a "process to further reduce pathogens" (PFRP), will effectively reduce populations of human and plant pathogens, as well as destroy noxious weed seeds and propagules.

3.4. Compost is typically characterized as a finely screened and stabilized product that is used as a soil amendment. However, most composts also contain a wood-based fraction (e.g., bark, ground brush and tree wood, wood chips, etc.) that is typically removed before use as a soil amendment. This coarser, woody fraction of compost plays an important role when compost is used in erosion and sediment control. It is even possible to add fresh, ground bark or composted, properly sized wood-based material to a compost product, as necessary, to improve its efficacy in this application.

3.5. Compost products acceptable for this application must meet the chemical, physical, and biological parameters outlined in Section 4.

4. CHEMICAL, PHYSICAL, AND BIOLOGICAL PARAMETERS

4.1. Compost products specified for use in this application are described in Table 1. The products' parameters will vary based on whether vegetation will be established on the treated slope.

4.2. Only compost products that meet all applicable state and federal regulations pertaining to its production and distribution may be used in this application. Approved compost products must meet related state and federal chemical contaminant (e.g., heavy metals, pesticides, etc.) and pathogen limit standards pertaining to the feedstocks (source materials) in which they were derived.

Table 1—Compost Blanket Parameters

Parameters[a,b]	Reported as (Units of Measure)	Surface Mulch to Be Vegetated	Surface Mulch to Be Left Unvegetated
pH[c]	pH units	5.0–8.5	N/A
Soluble Salt Concentration[c] (electrical conductivity)	dS/m (mmhos/cm)	Max 5	Max 5
Moisture Content	%, wet weight basis	30–60	30–60
Organic Matter Content	%, dry weight basis	25–65	25–100
Particle Size	% passing a selected mesh size, dry weight basis	3 in. (75 mm), 100% passing 1 in. (25 mm), 90% to 100% passing $^3/_4$ in. (19 mm), 65% to 100% passing $^1/_4$ in. (6.4 mm), 0% to 75% passing Max particle length of 6 in. (152 mm)	3 in. (75 mm), 100% passing 1 in. (25 mm), 90% to 100% passing $^3/_4$ in. (19 mm), 65% to 100% passing $^1/_4$ in. (6.4 mm), 0% to 75% passing Max particle length of 6 in. (152 mm)
Stability/Maturity[d]			
Carbon Dioxide Evolution Rate	mg CO_2-C per g OM per day	<8	N/A
Physical Contaminants (man-made inerts)	%, dry weight basis	<1	< 1

[a] Recommended test methodologies are provided in *Test Methods for the Examination of Composting and Compost* (TMECC, The U.S. Composting Council).

[b] Landscape Architects and Project (Field) Engineers may modify the allowable compost specification ranges based on specific field conditions and plant requirements.

[c] Each specific plant species requires a specific pH range. Each plant also has a salinity tolerance rating, and maximum tolerable quantities are known. When specifying the establishment of any plant or turf species, it is important to understand their pH and soluble salt requirements, and how they relate to the compost in use.

[d] Stability/Maturity rating is an area of compost science that is still evolving, and as such, other various test methods could be considered. Also, never base compost quality conclusions on the result of a single stability/maturity test.

4.3. Very coarse compost should be avoided if the slope is to be landscaped or seeded as it will make planting and crop establishment more difficult.

4.4. In regions subject to higher rates of precipitation and/or rainfall intensity, higher compost application rates should be used. In these particular regions, as well as regions subject to wind erosion, coarser compost products are preferred.

Note 1—Specifying the use of compost products that are certified by the U.S. Composting Council's Seal of Testing Assurance (STA) Program (www.compostingcouncil.org) will allow for the acquisition of products that are analyzed on a routine basis, using the specified test methods. STA participants are also required to provide a standard product label to all customers, allowing easy comparison to other products.

Where water quality is an issue, or in areas in proximity to sensitive water bodies, the appropriate compost product should be used and vegetating the compost blanket should be considered.

5. FIELD APPLICATIONS

5.1. The following steps shall be taken for the proper installation of compost as a soil blanket for erosion/sediment control on sloped areas.

5.1.1. Slightly roughen (scarify) slopes and remove large clods, rocks, stumps, roots larger than two in. in diameter, and debris on slopes where vegetation is to be established. This soil preparation step may be eliminated where approved by the Project Engineer or Landscape Architect/Designer, or where seeding or planting is not planned. Where practical, track (compact) perpendicular to contours on the slope using a bulldozer before applying compost as a soil blanket.

5.1.2. Apply compost at the rates specified in Table 2.

Table 2—Compost Blanket Application Rates

Annual Rainfall/Flow Rate	Total Precipitation and Rainfall Erosivity Index	Application Rate for Vegetated Compost Surface Mulch[a]	Application Rate for Unvegetated Compost Surface Mulch
Low	1–25 in., 20–90	$\frac{1}{2}$–$\frac{3}{4}$ in. (12.5–19 mm)	1–1$\frac{1}{2}$ in. (25–37.5 mm)
Average	26–50 in., 91–200	$\frac{3}{4}$–1 in. (19–25 mm)	1$\frac{1}{2}$–2 in. (37.5–50 mm)
High	51 in. and above, 201 and above	1–2 in. (25–50 mm)	2–4 in. (50–100 mm)

[a] These lower application rates should only be used in conjunction with seeding and for compost blankets applied during the prescribed planting season for the particular region.

5.1.2.1. Compost blanket application rates should be modified based on specific site (e.g., soil characteristics and existing vegetation) and climatic conditions as well as particular project-related requirements. The severity of slope grade, as well as slope length, will also influence compost application rates.

5.1.2.2. In regions subject to higher rates of precipitation and/or rainfall intensity, higher compost application rates should be used. In these regions, as well as those with spring snow melt and on sites possessing severe grades or long slope lengths, the compost blanket may be used in conjunction with a compost filter berm. The filter berm may be 1–2 ft (30 cm–60 cm) high by 2–4 ft (60 cm–120 cm) wide, and may be placed at the top or base (or both) of the slope. In these particular regions, as well as regions subject to wind erosion, coarser compost products may be preferred.

5.1.2.3. In regions subject to lower rates of precipitation or rainfall intensity, or both, lower compost application rates may be used.

Note 2—Specific regions may receive higher rainfall rates, but this rainfall is received through low-intensity rainfall events (e.g., the Northwestern United States). These regions may use lower compost application rates.

5.1.3. Compost shall be uniformly applied using an approved spreader unit, such as a bulldozer, side discharge manure spreader, etc. Alternatively, apply compost using a pneumatic (blower) unit, or other unit that propels the product directly at the soil surface, thereby preventing water from moving between the soil-compost interface. Thorough watering may be used to improve settling of the compost. Apply compost layer approximately 3 ft (90 cm) over the top of the slope, or overlap it into existing vegetation.

5.1.4. On highly unstable soils, use compost in conjunction with appropriate structural measures.

5.1.5. Dry or hydraulic seeding may be completed following compost application, as required, or during the compost application itself, where a pneumatic unit is used to apply the compost.

6. TEST METHODS

6.1. The chemical, physical, and biological analysis of the compost shall be determined in accordance with the *Test Methods for the Examination of Composting and Compost* (TMECC), jointly published by the U.S. Department of Agriculture and the U.S. Composting Council (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). (See Appendix X1.)

6.2. ASTM D 2977 shall be used to determine compost gradation.

7. SAMPLING, INSPECTION, PACKING, AND MARKING

7.1. The sampling, testing, packing, and marking of compost samples shall be done in accordance with TMECC 02.01-B (Selection of Sampling Locations for Windrows and Piles).

8. KEYWORDS

8.1. Compost; erosion control; sediment control; sheet flow; slope stabilization.

APPENDIXES

(Nonmandatory Information)

X1. METHODS FOR THE SAMPLING AND CHARACTERIZATION OF COMPOST

X1.1. Sampling procedures to be used for purposes of this specification (and the Seal of Testing Assurance program) are as provided in 02.01 Field Sampling of Compost Materials, 02.01-B Selection of Sampling Locations for Windrows and Piles of the *Test Methods for the Examination of Composting and Compost* (TMECC), Chapter 2, Section One, Sample Collection and Laboratory Preparation, jointly published by the USDA and USCC (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). The sample collection section is available online at http://tmecc.org/tmecc/.

X1.2. Test Methods to be used for purposes of this specification are as provided in the *Test Methods for the Examination of Composting and Compost* (TMECC), jointly published by the USDA and USCC (2002 publishing as a part of the USDA National Resource Conservation Technical Bulletin Series). A list of such methods is provided in the table below and online at http://tmecc.org/tmecc/.

Table X1.1—Test Methods for Compost Characterization

Compost Parameters	Reported as	Test Method	Test Method Name
pH	pH units	TMECC 04.11-A	Electrometric pH Determinations for Compost. 1:5 Slurry Method.
Soluble salts	dS/m (mmhos/cm)	TMECC 04.10-A	Electrical Conductivity for Compost. 1:5 Slurry Method (Mass Basis).
Primary plant nutrients:	%, as-is (wet) and dry weight basis		
Nitrogen	Total N	TMECC 04.02-D	Nitrogen. Total Nitrogen by Combustion.
Phosphorus	P_2O_5	TMECC 04.03-A	Phosphorus. Total Phosphorus.
Potassium	K_2O	TMECC 04.04-A	Potassium. Total Potassium.
Calcium	Ca	TMECC 04.04-Ca	Secondary and Micro-Nutrient Content. Calcium.
Magnesium	Mg	TMECC 04.04-Mg	Secondary and Micro-Nutrient Content. Magnesium.
Moisture content	%, wet weight basis	TMECC 03.09-A	Total Solids and Moisture at 70 ± 5°C.
Organic matter content	%, dry weight basis	TMECC 05.07-A	Matter Method. Loss on Ignition Organic Matter Method.
Particle size	Screen size passing through	TMECC 02.12-B	Laboratory Sample Preparation. Sample Sieving for Aggregate Size Classification.
Stability (respirometry)	mg CO_2-C per g TS per day mg CO_2-C per g OM per day	TMECC 05.08-B	Respirometry. Carbon Dioxide Evolution Rate.
Maturity (Bioassay)		TMECC 05.05-A	Biological Assays. Seedling Emergence and Relative Growth.
Percent Emergence	% (average)		
Relative Seedling Vigor	% (average)		

X2. ADDITIONAL INFORMATION—WEBSITES

X2.1. For additional information on regional precipitation rates or rainfall erosivity indexes go online at http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/regional_monitoring/us_12-month_precip.shtml or http://topsoil.nserl.purdue.edu/nserlweb/weppmain.

X2.2. Find U.S. Composting Council Seal of Testing Assurance Program documents at http://tmecc.org/sta/ or www.compostingcouncil/programs/sta.org.

Standard Specification for

Wire-Cloth Sieves for Testing Purposes

AASHTO Designation: M 92-10
ASTM Designation: E 11-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Wire-Cloth Sieves for Testing Purposes

AASHTO Designation: M 92-10
ASTM Designation: E 11-09

AASHTO M 92-10 is identical to ASTM E 11-09.

Standard Specification for

Flow Table for Use in Tests of Hydraulic Cement

AASHTO Designation: M 152M/M 152-06[1]
ASTM Designation: C 230/C 230M-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Flow Table for Use in Tests of Hydraulic Cement

AASHTO Designation: M 152M/M 152-06[1]
ASTM Designation: C 230/C 230M-03

1. SCOPE

1.1. This specification covers requirements for the flow table and accessory apparatus (Note 1) used in making flow tests for consistency of mortars in tests of hydraulic cement.

Note 1—To help clarify the design of the flow table and accessory apparatus see the drawing in Figure 1 [Figure 2]. This drawing is for informational purposes only.

1.2. The values stated in either SI units or inch-pound units shall be regarded separately as standard. The values stated are not exact equivalents; therefore, each system must be used independently of the other. It is permissible to use an inch-pound caliper and mold with an SI flow table or an SI caliper and mold with an inch-pound flow table. It is not permissible to mix an SI mold with an inch-pound caliper or an inch-pound mold with an SI caliper.

2. FLOW TABLE AND FRAME

2.1. The flow table apparatus shall consist of an integrally cast rigid iron frame and a circular rigid tabletop 255.0 ± 2.5 mm [10 ± 0.1 in.] in diameter, with a shaft attached perpendicular to the tabletop by means of a screw thread. The tabletop and shaft with contact shoulder shall be mounted on a frame in such a manner that it can be raised and dropped vertically through the specified height of 12.7 ± 0.13 mm [0.500 ± 0.005 in.] for new tables and 12.7 ± 0.38 mm [0.500 ± 0.015 in.] for tables in use, by means of a rotated cam. The tabletop shall have a fine machined plane surface, free of blowholes and surface defects. The top shall be scribed with eight equidistant lines 68 mm [$2^5/_8$ in.] long, extending from the outside circumference toward the center of the table. Each line shall end with a scribed arc, 6 mm [$^1/_4$ in.] long, whose center point is the center of the table top with a radius of 59.5 mm [$2^3/_8$ in.]. The scribe lines shall be made with a 60-degree tool to a depth of 0.25 mm [0.01 in.]. The tabletop shall be of cast brass or bronze having a Rockwell hardness number not less than 25 HRB with an edge thickness of 7.5 mm [0.3 in.], and shall have six integral radial stiffening ribs. The tabletop and attached shaft shall have a mass of 4.08 ± 0.05 kg [9 ± 0.1 lb] and the mass shall be symmetrical around the center of the shaft.

2.2. The cam and vertical shaft shall be of medium carbon machinery steel, hardened where indicated in Figure 1 or Figure 2. The shaft shall be straight and the difference between the diameter of the shaft and the diameter of the bore of the frame shall be not less than 0.05 mm [0.002 in.] and not more than 0.08 mm [0.003 in.] for new tables and shall be maintained at 0.05 to 0.25 mm [0.002 to 0.010 in.] for tables in use. The end of the shaft shall not fall upon the cam at the end of the drop, but shall make contact with the cam not less than 120 degrees from the point of drop. The face of the cam shall be a smooth spiraled curve of uniformly increasing radius from 13 to 32 mm [$^1/_2$ to $1^1/_4$ in.] in 360 degrees and there shall be no appreciable jar as the shaft comes into contact with the cam. The cam shall be so located and the contact faces of the cam and shaft shall be such that the table does not rotate more than one revolution in 25 drops. The surfaces of the frame and of the table which come into contact at the end of the drop shall be maintained smooth, plane, and horizontal and parallel with the upper surface of the table and shall make continuous contact over a full 360 degrees.

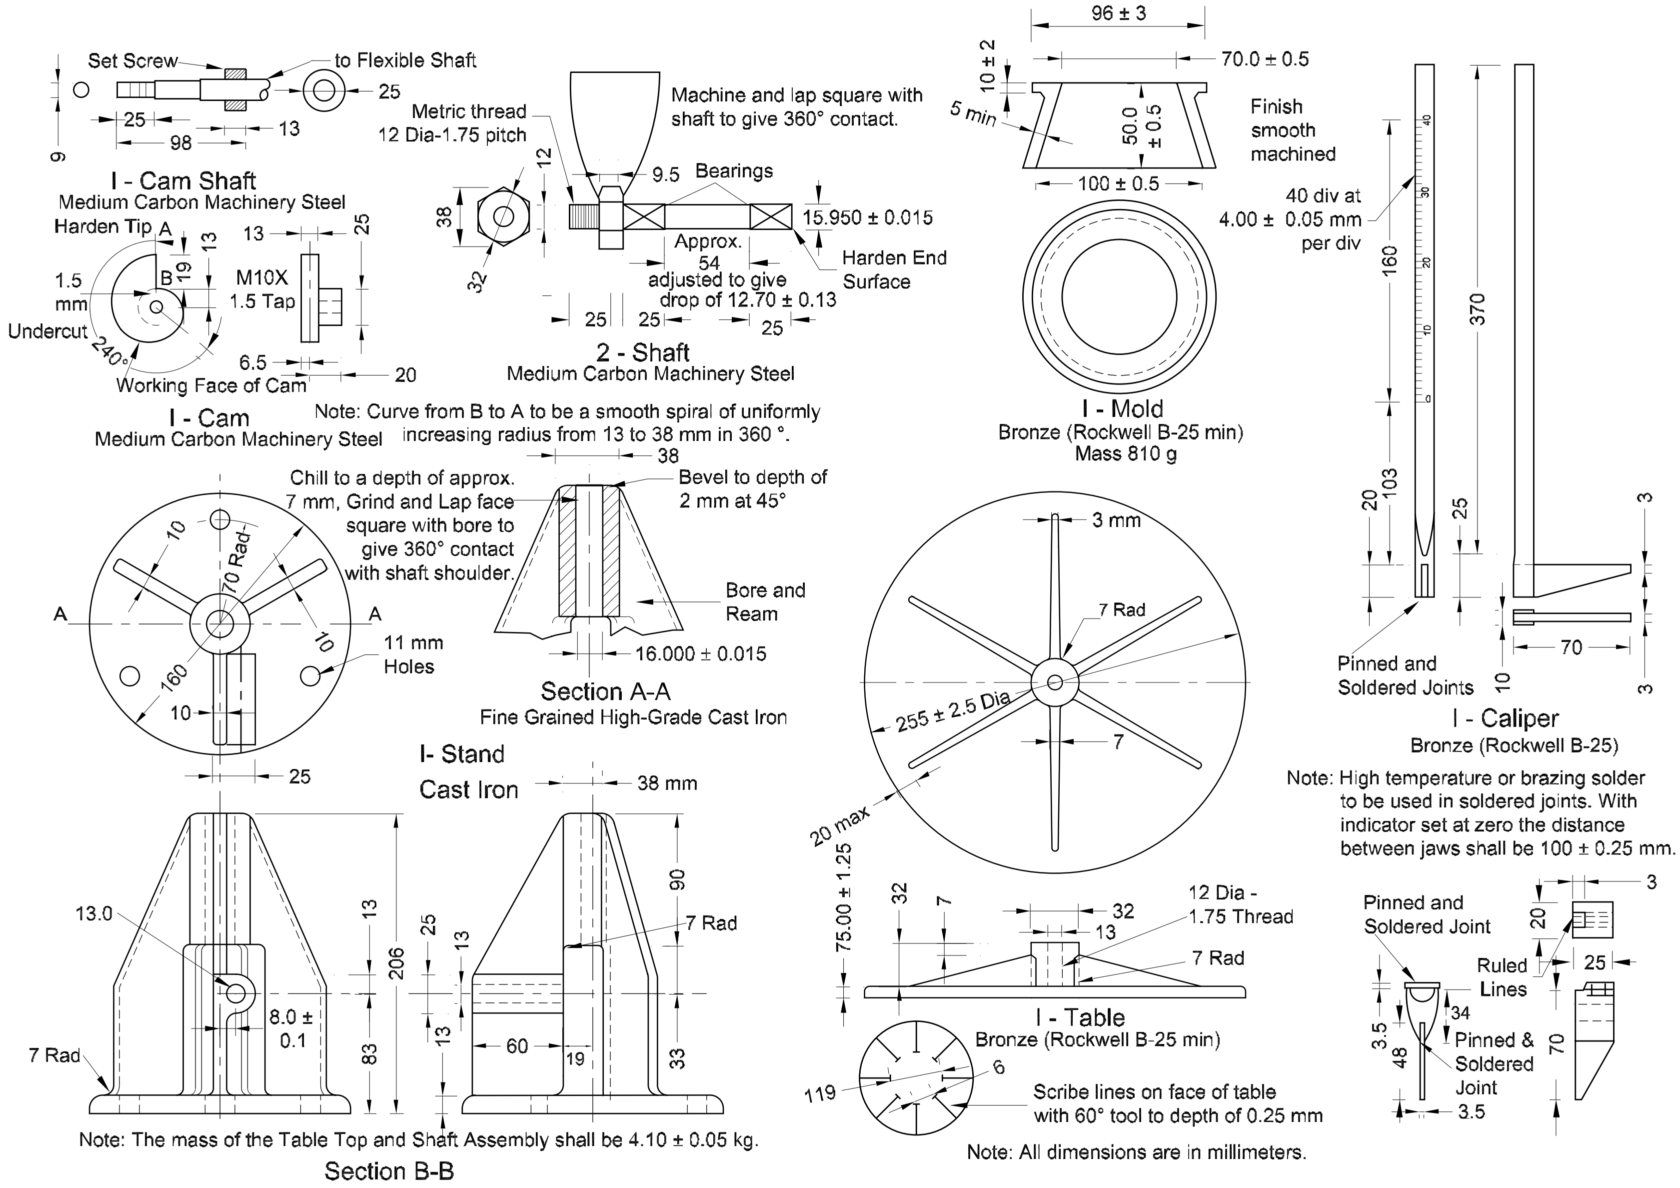
2.3. The supporting frame of the flow table shall be integrally cast of fine-grained, high-grade cast iron. The frame casting shall have three integral stiffening ribs extending the full height of the frame and located 120 degrees apart. The top of the frame shall be chilled to a depth of approximately 6.0 mm [$^1/_4$ in.] and the face shall be ground and lapped square with the bore to give 360 degrees contact with the shaft shoulder. The underside of the base of the frame shall be ground to secure complete contact with the steel plate beneath.

2.4. The flow table shall be driven by a motor (Note 2), connected to the cam shaft through an enclosed worm gear speed reducer and flexible coupling. The speed of the camshaft shall be approximately 100 rpm. The motor drive mechanism shall not be fastened or mounted on the table base plate or frame.

Note 2—A 40 W ($^1/_{20}$ hp) motor has been found adequate.

2.5. The performance of a flow table shall be considered satisfactory if in calibration tests, the table gives a flow value that does not differ by more than five percentage points from flow values obtained with suitable calibration materials.[2] (See Note 3.)

Note 3—Some causes of and solutions to unsatisfactory performance of the flow table may be found in the section on flow tables in the ASTM *Manual of Cement Testing*.



Note: Curve from B to A to be a smooth spiral of uniformly increasing radius from 13 to 38 mm in 360 °.

Note: High temperature or brazing solder to be used in soldered joints. With indicator set at zero the distance between jaws shall be 100 ± 0.25 mm.

Scribe lines on face of table with 60° tool to depth of 0.25 mm

Note: The mass of the Table Top and Shaft Assembly shall be 4.10 ± 0.05 kg.

Note: All dimensions are in millimeters.

Figure 1—Flow Table and Accessory Apparatus (SI Units)

3. FLOW TABLE MOUNTING

3.1. The flow table frame shall be tightly bolted to a cast iron or steel plate at least 25 mm [1 in.] thick and 250 mm [10 in.] square. The top surface of this plate shall be machined to a smooth plane surface. The plate shall be anchored to the top of a concrete pedestal by four 13-mm [$^1/_2$-in.] bolts that pass through the plate and are imbedded at least 150 mm [6 in.] in the pedestal. The pedestal shall be cast inverted on the base plate. A positive contact between the base plate and the pedestal shall be obtained at all points. No nuts or other such leveling devices shall be used between the plate and the pedestal. Leveling shall be effected by suitable means under the base of the pedestal.

3.2. The pedestal shall be 250 to 275 mm [10 to 11 in.] square at the top, and 375 to 400 mm [15 to 16 in.] square at the bottom, 625 to 750 mm [25 to 30 in.] in height, and shall be of monolithic construction cast from concrete having a density of at least 2240 kg/m^3 [140 lb/ft^3]. A stable gasket cork padding, 13 mm [$^1/_2$ in.] thick and the same size as the pedestal bottom or four pieces of padding 13 mm [$^1/_2$ in.] thick and approximately 100 mm [4 in.] square, shall be inserted under the pedestal of the four corners, respectively. The flow table shall be checked frequently for levelness of the tabletop, stability of the pedestal and tightness of bolts and nuts in the table base and the pedestal table. (A torque of 27 N·m [20 lb·ft] is recommended when tightening those fastenings.)

3.3. The tabletop, after the frame has been mounted on the pedestal, shall be level along two diameters at right angles to each other, in both the raised and lowered positions.

4. FLOW TABLE LUBRICATION

4.1. The vertical shaft of the table shall be kept clean and shall be lightly lubricated (See Note 4) with a light oil (SAE-10). Oil shall not be present between the contact faces of the tabletop and the supporting frame. Oil on the cam face will lessen wear and promote smoothness of operation. The table should be raised and permitted to drop a dozen or more times just prior to use if it has not been operated for some time.

Note 4—It has been demonstrated that an absence of lubrication on the table shaft will significantly reduce the flow reading.

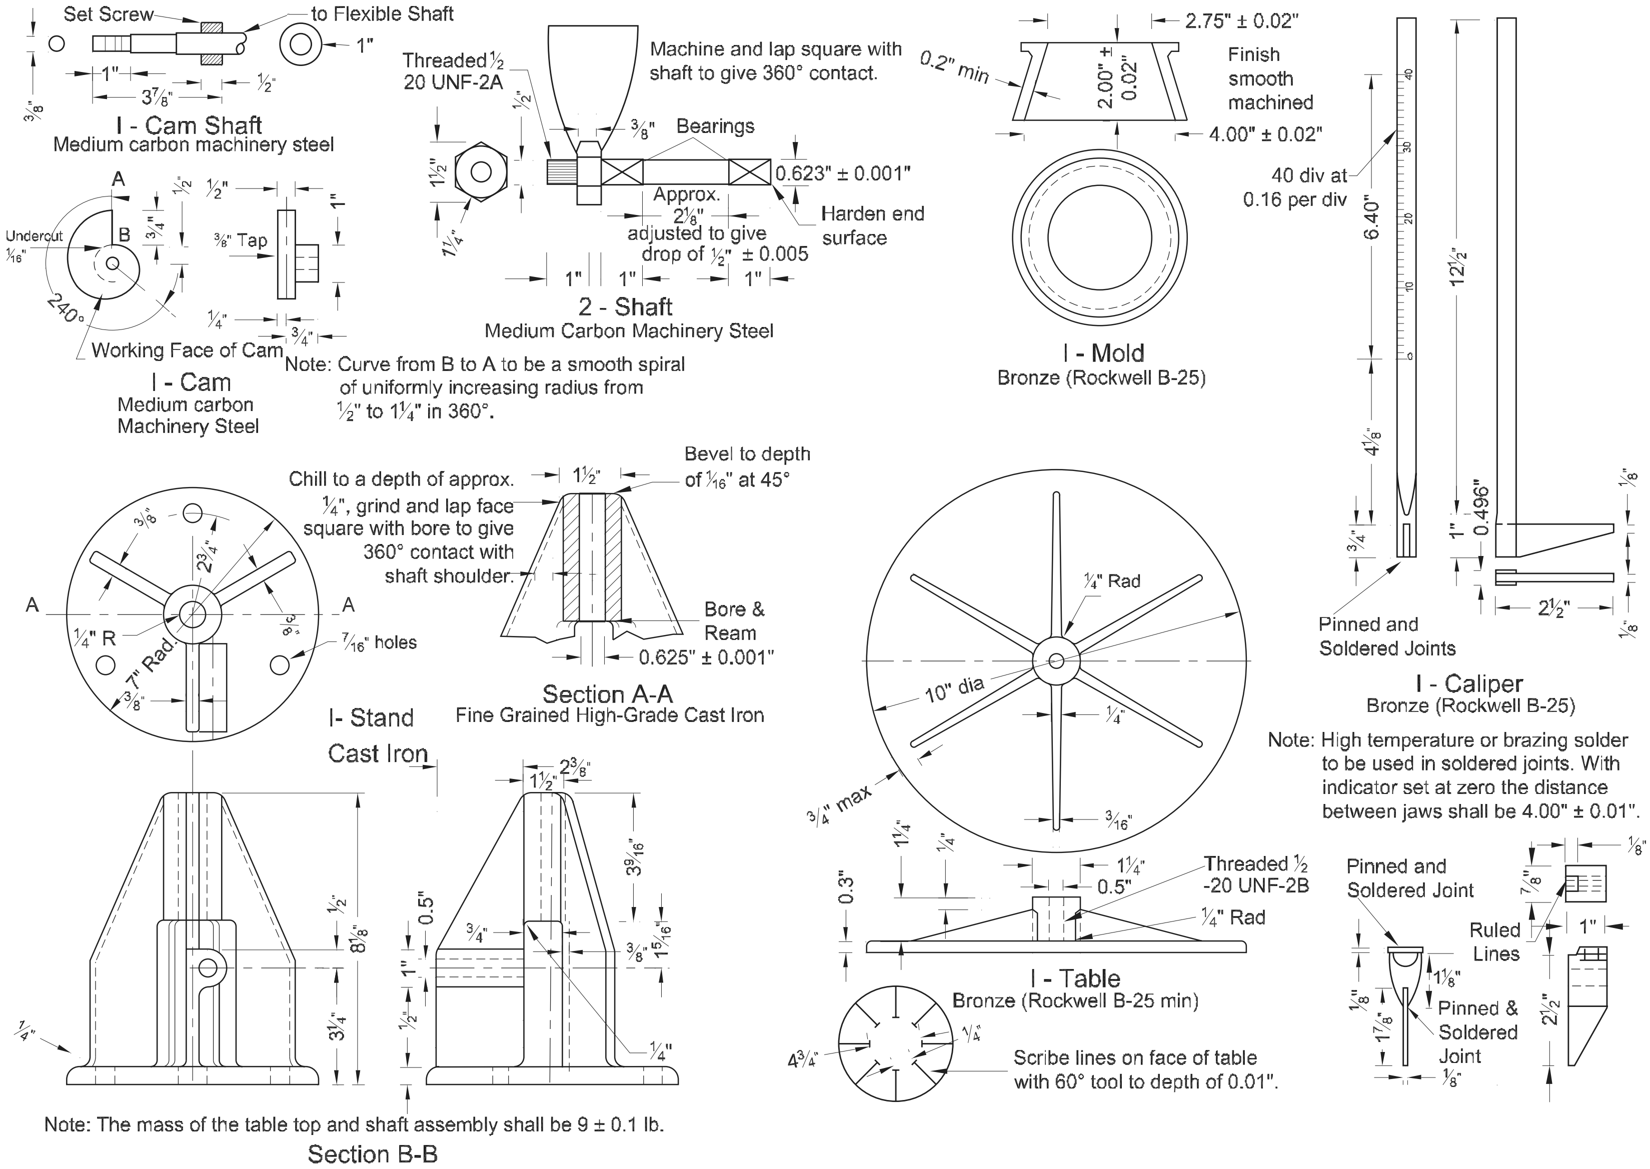


Figure 2—Flow Table and Accessory Apparatus (U.S. Customary Units)

5. MOLD AND CALIPER

5.1. The conical mold for casting the flow specimen shall be of cast bronze or brass, constructed as shown in Figure 1 or Figure 2. The Rockwell hardness number of the metal shall be not less than 25 HRB. The height of the mold shall be 50.0 ± 0.5 mm [2.00 ± 0.02 in.]. The diameter of the top opening shall be 70.0 ± 0.5 mm [2.75 ± 0.02 in.] for new molds and 70.0 + 1.3 and –0.5 mm [2.75 + 0.05 and –0.02 in.] for molds in use. The diameter of the bottom opening shall be 100.0 ± 0.5 mm [4.00 ± 0.02 in.] for new molds and 100.0 + 1.3 and –0.5 mm [4.00 + 0.05 and –0.02 in.] for molds in use.

The surfaces of the base and top shall be parallel and at right angles to the vertical axis of the cone. The mold shall have a minimum wall thickness of 5 mm [0.2 in.]. The outside of the top edge of the mold shall be shaped so as to provide an integral collar for convenient lifting of the mold. All surfaces shall be machined to a smooth finish. A circular shield approximately 255 mm [10 in.] in diameter, with a center opening approximately 100 mm [4 in.] in diameter, made of nonabsorbing material not attacked by the cement, shall be used with the flow mold to prevent mortar from spilling on the tabletop.

5.2. A caliper consisting of one fixed jaw and one jaw movable along a permanent scale, conforming to the design and dimensions shown in Figure 1 or Figure 2 (Note 5), shall be provided for measuring the diameter of the mortar after it has been spread by the operation of the table. The scale shall be machine divided into 40 increments with 4.0 mm [0.16 in.] between divisions with major division lines every five divisions and the increment number every 10 divisions (Note 5). The construction and accuracy of the instrument shall be such that the distance between the jaws shall be 100 ± 0.25 mm [4 ± 0.01 in.] when the indicator is set at zero.

Note 5—The caliper shown in Figure 1 or Figure 2 is graduated to indicate one-fourth of the actual flow percentage, so that the readings of four measurements on the caliper may be added to give the flow value without the necessity of calculating the average of four individual measurements of the total flow.

---

[1] Except for the use of SI units this method agrees with ASTM C 230-03.

[2] Such a material may be obtained from the Cement and Concrete Reference Laboratory at the National Institute of Standards and Technology, Washington, DC 20234.

Standard Specification for

Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

AASHTO Designation: M 201-08
ASTM Designation: C 511-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes

AASHTO Designation: M 201-08
ASTM Designation: C 511-06

1. SCOPE

1.1. This specification includes requirements for mixing rooms where paste and mortar specimens are prepared; and for moist cabinets, moist rooms, and water storage tanks where paste, mortar and concrete test specimens are stored.

1.2. Values in SI units shall be obtained by measurement in SI units or by appropriate conversion, using the Rules for Conversion and Rounding given in IEEE/ASTM SI 10, of measurements made in other units.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- C 51, Standard Terminology Relating to Lime and Limestone (as used by the Industry)
- E 77, Standard Test Method for Inspection and Verification of Thermometers

2.2. *IEEE/ASTM Standard*:

- SI 10, American National Standard for use of the International System of Units (SI): The Modern Metric System

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *mixing room, n*—a room with controlled temperature and relative humidity where cement paste and mortar specimens are prepared.

3.1.2. *moist cabinet, n*—a compartmented storage facility of moderate dimensions with controlled temperature and relative humidity.

3.1.3. *moist room, n*—a “walk-in” storage facility with controlled temperature and relative humidity, commonly called a fog room when the prescribed relative humidity is achieved by the atomization of water.

4. REQUIREMENTS FOR CEMENT MIXING ROOMS

4.1. The temperature of the air in the vicinity of the mixing slab, molds, and base plates shall be maintained at 23.0 ± 4.0ºC and at a relative humidity of not less than 50 percent.

4.2. The temperature of the mixing water used to prepare cement paste and mortar specimens shall be 23.0 ± 2.0ºC.

5. TEMPERATURE MEASURING DEVICES

5.1. *Reference Temperature Measuring Devices*—used to verify the temperature recorder must be accurate and readable to 0.5ºC. A copy of the certificate or report that verifies the accuracy shall be available in the laboratory.

Note 1—The ice-point method described in ASTM E 77 may be used to ensure that no damage to the reference thermometer has occurred during shipping.

5.2. *Temperature Recorder*—shall record temperatures every 15 minutes or less and shall be accurate and readable to 1 ºC. The data from the recorder shall be evaluated at a minimum of once each week. A record of this evaluation documenting the date checked, a confirmation that the data are within the required temperature range, and the name of the individual performing this evaluation shall be maintained in the laboratory. (Note 2)

Note 2—This requirement may be satisfied by an initialed and dated temperature recorder chart. Brief changes in the temperature due to door openings should be ignored.

5.2.1. The temperature recorder shall be verified at least every 6 months or whenever there is a question of accuracy.

5.2.1.1. For moist cabinets and rooms, position the reference temperature measuring device in a readable position in air as near as practical to the temperature recorder probe. Keep the door closed for at least 5 min prior to taking readings. Record the temperature readings of both the temperature recorder and the reference temperature measuring device. When taking these readings, the reference temperature measuring device shall remain in the moist cabinet or room and read immediately upon opening the door.

5.2.1.2. For water storage tanks, position the reference temperature measuring device in a readable position in water as near as practical to the temperature recorder probe. Without removing the reference temperature measuring device from the water, record the temperature readings of both the temperature recorder and the reference temperature measuring device after the temperatures have stabilized.

5.2.1.3. Verify the accuracy of the temperature recorder by comparing the reading of the temperature recorder with that of the reference temperature measuring device during the normal operation of the moist cabinet, moist room, or water storage tanks. If the difference between the temperature readings is greater than 1ºC, the temperature recorder shall be adjusted to within 0.5ºC of the reference temperature-measuring device.

6. REQUIREMENTS FOR MOIST CABINETS AND MOIST ROOMS

6.1. *General*—The atmosphere in a moist cabinet or moist room shall have a temperature of 23.0 ± 2.0°C and a relative humidity of not less than 95 percent. The moisture in the atmosphere shall be saturated to the degree needed to ensure that the exposed surfaces of all specimens in storage will both look moist and feel moist at all times. All moist cabinets and moist rooms shall be equipped with a temperature recorder. The use of humidity recording devices is optional. Shelves on which fresh specimens are placed shall be level.

6.1.1. The air in a moist cabinet or moist room must be nearly saturated with moisture in order to provide specified storage conditions. In many cases, saturation is below optimum during periods when specimens are being placed in or removed from storage. Measurements of relative humidity should not be made at such obviously inopportune times.

6.1.2. The air temperature inside the moist cabinet or moist room shall be controlled with provisions made for heating or cooling, or both, as may be necessary. This shall be accomplished in one of two ways:

6.1.2.1. Thermostatically control the air temperature within the moist cabinet or moist room when surrounding space is not conditioned. In this case the sensing element for the controls shall be located inside the moist cabinet or moist room.

6.1.2.2. Thermostatically control the space surrounding the moist cabinet or moist room and manually control the temperature within the moist cabinet or moist room.

6.1.3. In either of the preceding cases, the laboratory shall demonstrate the ability of the controls to maintain the required temperature in the moist cabinet or moist room over an extended period of time. Data from the temperature recorder that indicate that the temperatures are within the temperature limits specified in 6.1 shall be required as evidence of this ability.

6.2. *Moist Cabinets*—A moist cabinet shall be constructed of durable materials and the doors shall be tightfitting. The specified relative humidity shall be maintained by the use of one or more fog sprays, water sprays, or curtains of water on the inner walls that are so directed that the discharge will collect in a pool at or near the bottom of the moist storage section.

6.3. *Moist Rooms*:

6.3.1. *General*—The walls of a moist room shall be constructed of durable materials, and all openings shall be provided with tight-fitting doors or windows (Note 3). The specified relative humidity may be maintained in any convenient and suitable manner (Note 4).

Note 3—Well-insulated walls will substantially help maintain necessary conditions.

Note 4—A fog spray found suitable for this purpose is shown in Figure 1.

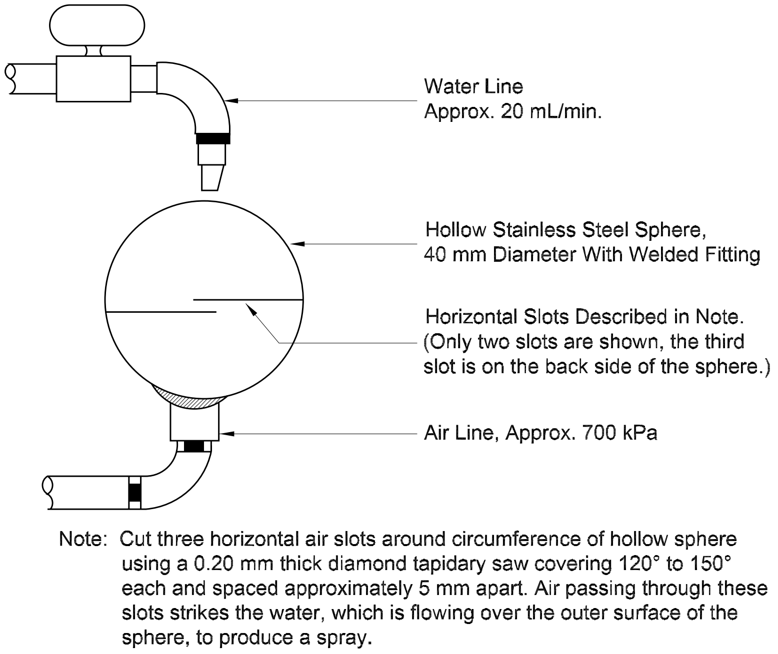

Figure 1—Example of a Fog Spray for Maintaining Relative Humidity in Moist Rooms (Full Scale)[1]

6.3.2. *Moist Rooms Used in Cement Testing*—Durable shelving that is properly shielded to prevent droplets of water from falling on the surfaces of freshly molded specimens shall be available within each moist room.

6.3.3. *Moist Rooms Used in Concrete Testing*—Atmospheric conditions within each moist room shall be such that test specimens in storage shall have free water maintained on their entire surface area at all times. Specimens shall not be exposed to dripping or running water.

7. REQUIREMENT FOR WATER STORAGE TANKS

7.1. *General*—Tanks shall be constructed of non-corroding materials. Provision for automatic control of water temperature at 23.0 ± 2.0ºC shall be made where a tank is located in a room not having temperature controlled within that range and in any other instance where difficulty in maintaining temperatures within the specified range is encountered. With the exception of water storage tanks located in a moist room or moist cabinet, all water storage tanks shall be equipped with a temperature recorder with its sensing element in the storage water. For the purpose of temperature recording, a group of water storage tanks may be considered one tank if the following three conditions are met: (1) all the tanks are interconnected with tubing that allows the water to flow between the tanks, (2) some means of circulation is provided between tanks, and (3) temperature variation between the tanks must not exceed 1.0ºC when checked and recorded weekly. The water in a storage tank shall be saturated with calcium hydroxide to prevent leaching of calcium hydroxide from the specimens (Note 5). Water not saturated with calcium hydroxide (high-calcium hydrated lime) may affect test results due to leaching of lime from the test specimens and shall not be used in storage tanks. To maintain saturation with calcium hydroxide, excess calcium hydroxide shall be present. For the purposes of lime saturation to prevent leaching, lime means high-calcium hydrated lime, not calcium carbonate (limestone) (see ASTM C 51). The water in the storage tank shall be thoroughly stirred at intervals not to exceed one month to help replace calcium ions that have depleted. Tanks shall be cleaned and refilled with water containing 3 g/L of calcium hydroxide at intervals not to exceed 24 months (Note 6).

Note 5—pH is not a reliable indicator of lime saturation in storage tank water since severe reductions in dissolved calcium ions can occur before pH values are significantly reduced.

Note 6—The 3 g/L level is intended to provide a quantity of calcium hydroxide approximately two times that required for initial saturation.

7.2. Do not use continuously running fresh water or demineralized water in storage tanks because it may affect test results due to excessive leaching. A closed system, circulating the saturated limewater between or among storage tanks, may be used.

8. KEYWORDS

8.1. Cement paste; concrete; mixing rooms; moist cabinets; moist rooms; mortar; water storage tanks.

---

[1] One spray will supply sufficient water to supply moisture to a space of 25 m^3. Hollow spheres available through McMaster Carr Supply Co., P.O. Box 4355, Chicago, IL 60680-4355.

Standard Specification for

Weighing Devices Used in the Testing of Materials

AASHTO Designation: M 231-95 (2006)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Specification for

Weighing Devices Used in the Testing of Materials

AASHTO Designation: M 231-95 (2006)

1. SCOPE

1.1 This specification covers requirements for scales and balances, and the loose standard masses used with balances, used in the testing of construction materials.

1.2 The requirements included are descriptive of the balances required by a number of AASHTO test methods. The general-purpose balances described herein may not be sufficiently accurate for certain tests, especially where a high degree of accuracy is required at large capacities. In such instances, the requirements for the balance should be included in the test method.

1.3 The requirements included herein are not sufficiently descriptive to be used as purchase specifications without amplification by the potential purchaser.

1.4 The values stated in SI units are to be regarded as the standard.

2. CLASSIFICATION

2.1 Weighing devices are divided into two classes of analytical balances, designated A and B, and five classes of general purpose scales or balances, designated G1, G2, G5, G20, and G100, based on readability.

2.2 Standard masses classified as Class 1, 2, 3, and 4, listed in ASTM E 617, may be used with the analytical balances. Standard masses listed in Table 2, Section 2.23 of *NIST Handbook 44* (1992 Edition) may be used with general-purpose balances.

3. TERMINOLOGY

3.1 *acceptance tolerance*—the maximum permissible deviation from correct indication for new standard masses or balances, and standard masses or balances having received major servicing. Usually equal to one-half of the maintenance tolerance.

3.2 *accuracy*—maximum permissible deviation of indications of a balance or scale from the true value within applicable tolerances.

3.3 *balance*—an instrument for determining mass, in its simplest form having a beam supported exactly in the middle having two pans of equal mass suspended from its extremities. Generally, weighing devices of a relatively high degree of accuracy used for determinations of mass in the laboratory.

3.4 *direct-reading balance*—a balance on which the mass of applied loads of various magnitudes is either automatically indicated, or is indicated by means of a calibrated weighbeam, throughout all or a portion of the range of the balance.

3.5 *equal-arm balance*—a balance having a beam supported exactly in the middle, having two pans suspended from its extremities, in which the mass of unknown quantity on one pan is compared with a set of standards of mass in the other pan. There may or may not be a weighbeam.

3.6 *general-purpose masses*—standard masses used for general mass determination, generally being less accurate than standard analytical masses.

3.7 *maintenance tolerance*—maximum permissible deviation from correct indication for masses or balances in service.

3.8 *off-center loading*—application of a load to the pan of a balance or scale at a point displaced from the center of the support axis of the load-receiving element.

3.9 *readability*—the smallest unit of mass that can be read without estimation over the given range of measurement either directly or by use of a vernier or micrometer.

3.10 *scale*—an instrument or machine used for mass determination, usually embodying a system of multiplying levers. Generally considered to have a lesser degree of accuracy than balances.

3.11 *sensitivity*—mass required to produce a discernible movement in the indicating system of the balance or scale.

3.12 *sensitivity requirement*—the minimum change in the position of rest of the indicating element of a scale or balance in response to a specified change in test load on the load-receiving element of the scale or balance.

3.13 *simple balance*—a balance designed primarily for use in conjunction with a set of standard masses. There may or may not be a weighbeam.

3.14 *standard analytical masses*—working standards of mass used for analytical work, having relatively small tolerances from the stated values.

4. REQUIREMENTS

4.1 *Analytical Balances*—Analytical balances of the class specified shall conform to the requirements of Table 1. These requirements apply both to balances with built-in masses and balances used with separate masses. The class for standard masses is suggested to provide the required accuracy (Note 1).

Table 1—Standard Analytical Balances

Balance Class	Accuracy	Sensitivity	Readability[a]	Class of Standard Masses[b]	Capacity[c]
A	0.0002 g	0.0001 g	0.0001 g	1, 2, or 3	200 g
B	0.002 g	0.001 g	0.001 g	3	200 g

[a] Readability of markings on direct reading balances.

[b] Class suggested for use with simple balances.

[c] Maximum capacity generally available with balances of the accuracy and sensitivity indicated for the class. Varies depending on the manufacturer, and whether direct reading or simple balance.

Note 1—The tolerances for standard masses are such that a single mass deviating by the full tolerance may cause the balance to exceed the accuracy requirement. In general, an individual mass will deviate only slightly from the stated value, and groups of masses will have some with a positive variation and some with a negative variation, which will tend to be compensating.

4.2 *General Purpose Balances and Scales*—General purpose weighing devices shall conform to the accuracy, readability, and sensitivity indicated in Table 2. Within any interval equal to 10 percent of the capacity of the balance, the difference in the load indications shall be accurate to within 0.1 percent of the difference in masses (Note 2). The device shall not be loaded in excess of its nominal or stated capacity.

Table 2—General Purpose Balances and Scales

Class	Readability and Sensitivity	Accuracy[a]
G 1	0.01 g	0.02 g or 0.1 percent
G 2	0.1 g	0.2 g or 0.1 percent
G 5	1 g	2 g or 0.1 percent
G 20	5 g	5 g or 0.1 percent
G 100	20 g	20 g or 0.1 percent

[a] Accuracy equal to the mass stated or 0.1 percent of the test load, whichever is greater, throughout the range of use.

Note 2—This requirement is to ensure linear performance of balance or scale. It is recommended that it be checked at five or more points throughout its range.

4.2.1 The balance selected for use is based on the accuracy, readability, sensitivity, and capacity required for the test being performed. Subportions of the sample are to be weighed to at least the accuracy indicated by the device required for the total sample (Note 3).

Note 3—Balances have considerable variation in quality. Less expensive balances may be unable to provide the required accuracy for the full range of the capacity of the device, especially if subjected to rough field usage.

4.2.2 Balances indicating in the Avoirdupois system (pounds and ounces), or separate masses used with such devices, shall meet levels of accuracy, readability, and sensitivity equivalent to those shown in Table 2 for balances and Table 4 for masses.

4.3 *Balance Condition*—The physical design and condition of a balance shall be such that the balance will meet the requirements of Sections 4.1 and 4.2.

4.3.1 Repeated determinations of the mass of a test load shall yield load indications that agree with each other within the sensitivity specification for the balance.

4.3.2 Mechanisms for adding or subtracting built-in internal masses shall function smoothly.

4.3.3 Dials and mass increment indicators shall display clearly the readings they were designed to show.

4.3.4 The accuracy requirement shall be met for any point of application of a test load on the balance pan or other mass receiving element.

4.4 *Masses*—Masses shall be selected so that the requirements for accuracy, sensitivity, and/or readability specified in Sections 4.1 and 4.2 are met when the masses are used with the appropriate balance.

4.4.1 *Standard Analytical Balances*—Analytical masses for use with equal arm balances should be Class 1, 2, 3, or 4, as appropriate for the accuracy of the balance with which they are to be used. The requirements for these masses are described in ASTM E 617. Applicable tolerances are shown in Table 3. Class 1 and 2 masses are reference masses, generally used for verification of masses of lesser classes, although Class 2 masses are used as working masses for high precision mass determinations. Classes 3 and 4 are considered to be working masses (Note 1).

Table 3—Tolerances for Standard Analytical Masses

	Acceptance Tolerances					
	Class 1[a]		Class 2[b]			
	Tolerance		Tolerance		Class 3[c]	Class 4[c]
Denomination	Individual, mg	Group, mg	Individual, mg	Group, mg	Tolerance, mg	Tolerance, mg
1000 g	2.5		5.0		10.0	20.0
500 g	1.2		2.5		5.0	10.0
300 g	0.75	1.35	1.5	2.7	3.0	6.0
200 g	0.50		1.0		2.0	4.0
100 g	0.25		0.50		1.0	2.0
50 g	0.12		0.25		0.60	1.2
30 g	0.074	0.16	0.15	0.29	0.45	0.90
20 g	0.074		0.10		0.35	0.70
10 g	0.050		0.074		0.25	0.50
5 g	0.034		0.054		0.18	0.36
3 g	0.034		0.054		0.15	0.30
2 g	0.034	0.065	0.054	0.105	0.13	0.26
1 g	0.034		0.054		0.10	0.20
500 mg	0.010		0.025		0.080	0.16
300 mg	0.010		0.025		0.070	0.14
200 mg	0.010	0.020	0.025	0.055	0.060	0.12
100 mg	0.010		0.025		0.050	0.10
50 mg	0.010		0.014		0.042	0.085
30 mg	0.010		0.014		0.038	0.075
20 mg	0.010	0.020	0.014	0.034	0.035	0.070
10 mg	0.010		0.014		0.030	0.060
5 mg	0.010		0.014		0.028	0.055
3 mg	0.010		0.014		0.026	0.052
2 mg	0.010	0.020	0.014	0.034	0.025	0.050
1 mg	0.010		0.014		0.025	0.050

[a] Maintenance tolerances same as acceptance tolerances.

[b] Maintenance tolerances for standard masses below 100 mg are the same as acceptance tolerances. For standard masses 100 mg and above, the maintenance tolerances are twice the acceptance tolerances.

[c] Maintenance tolerances are twice the acceptance tolerances.

4.4.2 *General Purpose Masses*—General purpose masses for use with equal arm balances should conform to the requirements of *NIST Handbook 44* (1992 Edition), Table 2, Section 2.23, Weights. Masses for use with single pan balances shall have sufficient accuracy so that the balances meet the requirements for such devices. Applicable tolerances are shown in Table 4.

Table 4—Tolerances for General Purpose Masses

Denomination	Maintenance Tolerance[a]	Denomination	Maintenance Tolerance[a]
20 kg	1500 mg	30 g	30 mg
10 kg	1000 mg	20 g	20 mg
5 kg	800 mg	10 g	15 mg
3 kg	500 mg	5 g	10 mg
2 kg	400 mg	3 g	8 mg
1 kg	250 mg	2 g	6 mg
500 g	175 mg	1 g	4 mg
300 g	150 mg	500 mg	3.0 mg
200 g	100 mg	300 mg	2.0 mg
100 g	70 mg	200 mg	1.5 mg
50 g	40 mg	100 mg	1.0 mg

[a] Acceptance tolerances on new masses are one-half the maintenance tolerances.

Standard Specification for

Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests

AASHTO Designation: M 261-96 (2009)[1]
ASTM Designation: E 501-08

American Association of State Highway and Transportation Officials
444 North Capitol Street NW, Suite 249
Washington, DC 20001

Standard Specification for

Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests

AASHTO Designation: M 261-96 (2009)[1]
ASTM Designation: E 501-08

1. SCOPE

1.1 This specification covers the general requirements for the standard rib tire for pavement friction testing. The tire covered by this specification is only for use in evaluation of tire-pavement friction.

1.2 Terminology in this specification is consistent with ASTM E 867.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- T 242, Frictional Properties of Paved Surfaces Using a Full-Scale Tire

2.2 *ASTM Standards*:

- D 297, Standard Test Methods for Rubber Products—Chemical Analysis
- D 412, Standard Test Methods for Vulcanized Rubber and Thermoplastic Elastomers—Tension
- D 1054, Standard Test Method for Rubber Property—Resilience Using a Goodyear-Healey Rebound Pendulum
- D 1765, Standard Classification System for Carbon Blacks Used in Rubber Products
- D 2240, Standard Test Method for Rubber Property—Durometer Hardness
- D 3182, Standard Practice for Rubber—Materials, Equipment, and Procedures for Mixing Standard Compounds and Preparing Standard Vulcanized Sheets
- E 501, Standard Specification for Standard Rib Tire for Pavement Skid-Resistance Tests
- E 867, Standard Terminology Relating to Vehicle-Pavement Systems

3. MATERIALS AND MANUFACTURE

3.1 The individual standard tires shall conform to the design standards of Section 6. Dimensions, masses, and permissible variations are given in Section 6 and in Figure 1.

3.2 Tread compounding, fabric processing, and all steps in tire manufacturing shall be certified to ensure that the specifications are met.

3.3 A small raised guideline shall be molded on the tire shoulder area to provide a rapid visual check as to whether the maximum wear level for testing has been reached. Tires should be removed from service as recommended in Section 11.5. The marking on the tire should include the following information:

- G78-15,
- Standard Pavement Test Tire—Not for General Highway Use,
- ASTM E 501,
- (Manufacturer’s Name or Trademark),
- Directional arrow on side of tire,
- Rim: 15 × 6JJ.

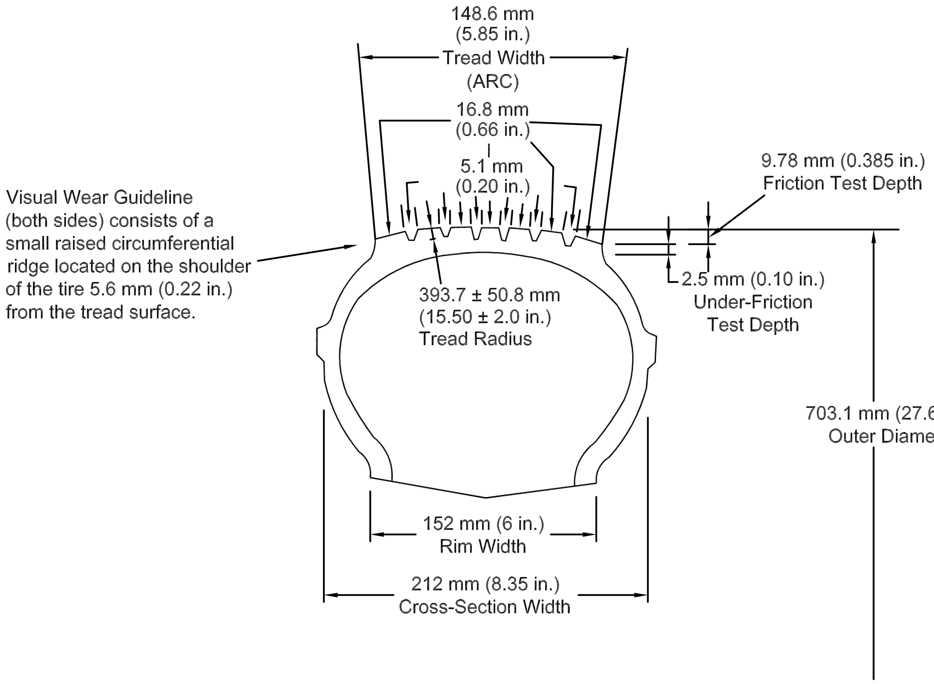

Figure 1—Tire Section, Including Inflated Tire Dimensions

4. MATERIAL REQUIREMENTS

4.1 The compounding requirements for the tread compound are given in Table 1.

Table 1—Compounding of Tread Rubber[a]

Material	Parts per Hundred of Rubber (PPHR)
SBR 1712[b]	89.38
BR-1208[c]	35.00
N339[d]	75.00
High aromatic oil	22.12
Zinc oxide	3.00
Stearic acid	2.00
6PPD[e]	2.00
Paraffin wax	2.00
Sulfur	1.80
TBBS[f]	1.10
DPG[g]	0.10

[a] ASTM D 3182

[b] Styrene-butadiene rubber (23.5 percent styrene) 37.5 parts of high-aromatic oil

[c] High cis-polybutadiene

[d] N339 Carbon Black. See ASTM D 1765.

[e] Dimethyl butylphenyl phenylenediamine

[f] Butyl benzothiazole sulfenamide

[g] Diphenyl guanidine

4.2 *Fabric*—The fabric shall be polyester body or carcass plies and fiberglass belt plies.

Note 1—Certain proprietary products have been specified since exact duplication of properties of the finished tire may not be achieved with other similar products. This inclusion does not in any way comprise a recommendation for these proprietary products, nor against similar products of other manufacturers, nor does it imply any superiority over any such similar products.

5. PHYSICAL REQUIREMENTS

5.1 The physical and mechanical test requirements are given in Table 2.

Table 2—Physical Requirements of Tread Compound

Tensile sheet cure at 150˚C (302˚F), min	30
300 percent modulus, MPa (psi) (ASTM D 412)	6.9 ± 1.4 (1000 ± 200)
Tire tread durometer (ASTM D 2240)	58 ± 2
Specific gravity (ASTM 297)	1.13 ± 0.02
Tensile strength, min, MPa (psi) (ASTM D 412)	13.8 (2000)
Elongation, min, percent (ASTM D 412)	500

6. DIMENSIONS, MASSES, AND PERMISSIBLE VARIATIONS

6.1 *General*—Details of dimensions are listed as follow and are shown in Figure 1. Where tolerances are not specified, tire dimensions are subject to manufacturers' normal tolerances.

6.1.1 *Construction*—The tire shall be a size G78-15 tubeless type, belted bias construction (two body plies plus two belt plies). The tread width shall be 149 mm (5.85 in.) and the cross-sectional tread radius shall be 394 mm ± 51 mm (15.50 in. ± 2.0 in.). The tire shall have a recommended cross-section width of 212 mm (8.35 in.) and a recommended section height of 161 mm (6.34 in.) when mounted on a Tire and Rim Association 15 × 6 (381 × 152 mm) JJ rim. The cured crown angles shall be 33 ± 2 degrees for the body plies, and 27 ± 2 degrees for the belt plies.

6.1.2 *Ribs*—The tire shall have seven plain ribs of 16.8 mm (0.66 in.) width each. Both sides of the shoulder ribs shall be parallel from the tread surface down to a depth equal to the wear guideline.

6.1.3 *Grooves*—The tire shall have six straight grooves of 5.1-mm (0.20-in.) width each. Each groove shall be parallel to the radius of the tread radius arc and shall have a full radius at the bottom of the groove. Each groove shall have a uniform friction test depth of 9.8 mm (0.385 in.) maximum and shall have an under-tread thickness of 2.5 mm (0.10 in.).

6.1.4 *Wear Indicators*—There shall be six rows of tread wear indicators spaced uniformly around the tire circumference and directly across the full tread width in all six grooves. These tread wear indicators shall be 1.6 mm (0.063 in.) deep and approximately 12.7 mm (0.50 in.) long. A visual wear guideline shall be located on the shoulder of the tire 5.6 mm (0.22 in.) from the tread surface as shown in Figure 1.

7. WORKMANSHIP

7.1 Tires shall be free of defects in workmanship and material.

8. TEST METHODS

8.1 *Tensile Sheet Cures*—ASTM D 3182.

8.2 *Modulus (300 percent)*—ASTM D 412.

8.3 *Tensile Sheet Durometer*—ASTM D 2240, using a Type A Shore durometer.

8.4 *Specific Gravity*—ASTM D 297.

8.5 *Tensile Strength*—ASTM D 412.

8.6 *Elongation*—ASTM D 412.

8.7 *Tire Tread Durometer*—ASTM D 2240.

8.7.1 Use a Type A durometer 12.7-mm (0.5-in.) diameter presser foot. Shore, code XAHAF is recommended.

8.7.2 The durometer shall be calibrated at a reading of 60 hardness.

8.7.3 Condition the tire and durometer to equilibrium at 23 ± 2ºC (73.4 ± 3.6ºF) before determining tread hardness.

8.7.4 The tire tread hardness is to be determined by averaging at least one set of six readings. A set is one reading taken in the center of each rib, excluding the center rib. It is recommended that additional sets of readings be taken around the tread circumference.

8.7.5 Apply presser foot to the tire tread as rapidly as possible without shock, keeping the foot parallel to the tread surface. Apply just sufficient pressure to obtain firm contact between presser foot and tire tread surface. Read the durometer scale within 1 second after presser foot is in contact with the tire tread, but after initial maximum transient, which may occur immediately after contact is made.

9. CERTIFICATION

9.1 Tires are to be inflated and measured prior to shipment. Upon request, the manufacturer shall furnish the purchaser certification that the test tire meets this specification.

9.2 All tires under certification shall be subject to the manufacturer's normal variation.

10. PACKAGING AND PRESERVATION

10.1 The tires should be kept dry under ordinary atmospheric conditions in subdued light, 21 ± 14ºC (70 ± 25 F). Tires should not be stored near electric motors, welders, or other ozone-generating equipment.

11. RECOMMENDATIONS FOR TIRE USE AND OPERATIONAL REQUIREMENTS

11.1 The tire is for pavement friction testing only and is not designed for general highway service. Necessary transport of test equipment should be on commercial tires.

11.2 A new tire break-in of 320 km (200 miles) minimum should be made on tires by the purchaser before using the tire for testing.

11.3 The tire shall be operated with not less than 165 kPa (24 psi) inflation.

11.4 The recommended static test load on the tire shall be 4825 N (1085 lbf) with loading to a maximum of 6150 N (1380 lbf) permissible, at 165 kPa (24 psi) inflation.

11.5 Tire should be mounted so that it is rotated in the direction of the arrow on the side of the tire.

11.6 When irregular wear or damage results from tests or when the remaining groove depth in any groove is 4.2 mm (0.165 in.) or less, the use of the tire as a standard test tire shall be discontinued.

11.7 **Caution**—Measured friction force or friction number may be influenced by tire tread depth and/or hardness. The magnitude of this dependence is a function of the water depth, pavement characteristics, test speed, and tire-aging effects.

12. KEYWORDS

12.1 Friction; pavement; rib tire.

---

[1] Except for terminology, figures, and the use of SI units, this specification agrees with ASTM E 501-08.

Standard Specification for

Smooth-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests

5. PHYSICAL REQUIREMENTS

5.1 The physical and mechanical test requirements are given in Table 2.

Table 2—Physical Requirements of Tread Compound

Tensile sheet cure at 150˚C (302˚F), min	30
300 percent modulus, MPa (psi) (ASTM D 412)	6.9 ± 1.4 (1000 ± 200)
Tire tread durometer (ASTM D 2240)	58 ± 2
Specific gravity (ASTM D 297)	1.13 ± 0.02
Tensile strength, min, MPa (psi) (ASTM D 412)	13.8 (2000)
Elongation, min, percent (ASTM D 412)	500

6. DIMENSIONS, MASSES, AND PERMISSIBLE VARIATIONS

6.1 *General*—Details of dimensions are shown in Figure 1. Where tolerances are not specified, tire dimensions are subject to manufacturer's normal tolerances.

6.1.1 *Design and Construction*—The tire shall be a size G78-15 tubeless type, belted bias construction (two-body plies plus two-belt plies). The tread width shall be 149 mm (5.85 in.) and the cross-sectional tread radius shall be 394 ± 51 mm (15.50 ± 2.0 in.). The tread shall have a thickness of 9.8 mm (0.385 in.) and an under-tread thickness of 2.5 mm (0.10 in.). The tire shall have a recommended cross-section width of 212 mm (8.35 in.) and a recommended section height of

161 mm (6.34 in.) when mounted on a Tire and Rim Association 15 by 6 (381 by 152 mm) JJ rim. The cured crown angles shall be 33 ± 2 degrees for the body plies, and 27 ± 2 degrees for the belt plies.

6.1.2 *Wear Indicators*—A visual wear guideline shall be located on the shoulder of the tire 5.6 mm (0.22 in.) from the tread surface as shown in Figure 1.

7. WORKMANSHIP

7.1 Tires shall be free of defects in workmanship and materials.

8. TEST METHODS

8.1 *Tensile Sheet Cures*—ASTM D 3182.

8.2 *Modulus (300 percent)*—ASTM D 412.

8.3 *Tensile Sheet Durometer*—ASTM D 2240, using a Type A Shore durometer.

8.4 *Specific Gravity*—ASTM D 297.

8.5 *Tensile Strength*—ASTM D 412.

8.6 *Elongation*—ASTM D 412.

8.7 *Tire-Tread Durometer*—ASTM D 2240 in addition to the following procedures.

8.7.1 Use a Type A durometer 12.7-mm (0.5-in.) diameter presser foot. (Shore Code XAHAF is recommended.)

8.7.2 The durometer shall be calibrated at a reading of 60 hardness.

8.7.3 Condition the tire and durometer to equilibrium at 23 ± 2ºC (73.4 ± 3.6ºF) before determining tread hardness.

8.7.4 The tire tread hardness is to be determined by averaging at least one set of six readings. A set should consist of readings taken at equally spaced intervals across the tread. It is recommended that additional sets of readings be taken around the tread circumference.

8.7.5 Apply presser foot to the tire tread as rapidly as possible without shock, keeping the foot parallel to the tread surface. Apply just sufficient pressure to obtain firm contact between the presser foot and the tire tread surface. Read the durometer scale within 1 second after the presser foot is in contact with the tire tread, but after initial maximum transient, which may occur immediately after contact is made.

9. CERTIFICATION

9.1 Tires are to be inflated and measured prior to shipment. Upon request, the manufacturer shall furnish the purchaser certification that the test tire meets this specification.

9.2 All tires under certification shall be subject to the manufacturers' normal variation.

10. PRESERVATION

10.1 Tires shall be kept dry under ordinary atmospheric conditions in subdued light, 21 ± 14ºC (70 ± 25ºF). Tires should not be stored near electric motors, welders, or other ozone generating equipment.

11. RECOMMENDATIONS FOR TIRE USE AND OPERATIONAL REQUIREMENTS

11.1 The tire is intended for pavement friction testing only and is not designed for general highway service. Commercial tires should be used for necessary transporting of test equipment.

11.2 A new tire break-in of 320 km (200 miles) minimum should be made on tires by the purchaser before using the tire for testing.

11.3 The tire shall be operated with not less than 165 kPa (24 psi) inflation.

11.4 The recommended static test load on the tire shall be 4825 N (1085 lbf), with loading to a maximum of 6150 N (1380 lbf) permissible, at 165 kPa (24 psi) inflation.

11.5 Tire should be mounted so that it is rotated in the direction of the arrow on the side of the tire.

11.6 When irregular wear or damage results from tests or when the tire is worn to the wear line, the use of the tire as a standard test tire shall be discontinued.

11.7 **Caution**—Measured friction force or friction number may be influenced by tire tread hardness. The magnitude of this dependence is a function of the water depth, pavement characteristics, test speed, and tire-aging effects.

12. KEYWORDS

12.1 Friction; friction force; friction number; pavement; tire-pavement.

---

[1] Except for terminology, figures, and the use of SI units, this specification agrees with ASTM E 524-08.

Standard Practice for

Calibrating the Load Cell and Deflection Sensors for a Falling Weight Deflectometer

AASHTO Designation: R 32-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Calibrating the Load Cell and Deflection Sensors for a Falling Weight Deflectometer

AASHTO Designation: R 32-09

1. SCOPE

1.1 This standard practice covers the annual calibration of the load cell and the deflection sensors and the monthly relative calibration of the deflection sensors of a falling weight deflectometer (FWD). It is used to establish calibration factors for correcting FWD measurements.

1.2 This procedure is not applicable to the calibration of cyclic loading and other types of pavement deflection testing equipment.

1.3 Annual calibration is performed at least once per year or as soon as possible after a deflection sensor or a load cell has been replaced on the FWD. It shall be performed by a certified technician.

1.4 Monthly relative calibration is performed on the deflection sensors at least once per month and immediately after a deflection sensor is replaced. A certified technician is not required.

1.5 The procedure results in calibration factors that are entered into the FWD software as multipliers. When the FWD measurements are multiplied by the calibration factors, the result is a set of measurements that have been corrected to agree with the calibration instrumentation.

1.6 Calibration procedures may vary slightly among FWD types. This procedure can be used for all types of FWDs with minor modifications within the limits of the reference calibration equipment.

1.7 This procedure has been automated in the software package *WinFWDCal*. It is required that the computer program be used to carry out the procedure.

1.8 To use this procedure, the FWD computer must be capable of electronic data transfer.

1.9 Data files for all types of FWDs can be read by the *WinFWDCal* software. The PDDX file format (see Section 3.1.9) is required for data input. FWD data files that are in native format can be converted to PDDX format using *PDDXconvert*, which is both an integral component in *WinFWDCal* and a stand-alone utility.

1.10 The values stated in SI units are to be regarded as standard. Imperial units given in parentheses are for information purposes only.

1.11 *This standard practice may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the* *user of this standard practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards:*

- R 33, Calibrating the Reference Load Cell Used for Reference Calibrations for Falling Weight Deflectometer

2.2 *Other document:*

- FHWA-HRT-07-040, FWD Calibration Center and Operational Improvements: Redevelopment of the Calibration Protocol and Equipment

3. TERMINOLOGY

3.1 *Definition of Terms Specific to this Standard*:

3.1.1 *certified technician*—an individual who has demonstrated proficiency at performing FWD calibrations during an annual quality assurance review and been issued a certificate of compliance. The certification procedure is described in detail in Report No. FHWA-HRT-07-040.

3.1.2 *data acquisition system*—the signal conditioner, data acquisition board, data acquisition software, computer, and cabling. It is connected to either the reference load cell or the accelerometer.

3.1.3 *FWD deflection sensor*—device used to measure the deflection response for a given load (e.g., geophones, accelerometers, or other devices).

3.1.4 *FWD load cell*—device located under the loading mechanism in an FWD that measures the load response of the FWD system.

3.1.5 *drop sequence*—the sequence of load levels with replicate drops at each load level used during reference calibration.

3.1.6 *final gain factor*—calibration factor for the load or deflection sensor at the end of the calibration procedure. The final calibration is entered into the FWD operating program as the final step in the calibration process.

3.1.7 *initial gain factor*—calibration factor for the load or deflection sensor that was present in the FWD operating program before the start of calibration.

3.1.8 *interim gain factor*—calibration factor for the deflection sensor resulting from averaging all trials of reference calibration.

3.1.9 *Pavement Deflection Data Exchange (PDDX)*—the file format required by *WinFWDCal*. This format is described in Report No. FHWA-HRT-07-040.

3.1.10 *reference calibration*—term used to describe the calibration of either the FWD load cell or deflection sensors against a separate reference measuring system. For load cell calibration, the reference system is a custom-made reference load cell; and for deflection sensors, it is a precision accelerometer.

3.1.11 *reference gain factor*—calibration factor determined by one trial during reference calibration.

3.1.12 *relative calibration*—term used to describe a calibration procedure in which the deflection sensors are calibrated relative to one another. No outside reference system is used.

3.1.13 *relative gain factor*—calibration factor determined by one trial during relative calibration.

3.1.14 *WinFWDCal*—the software required for data acquisition and data analysis for FWD calibration.

4. SUMMARY OF METHOD

4.1 In annual calibration, the deflection sensors and load cell from the FWD are first calibrated against independently calibrated reference devices. This calibration process, which is called “reference calibration,” can be performed at a regional calibration center or any other properly equipped location. Information on the location of these centers is available.[1]

4.1.1 The FWD load cell is calibrated against a custom-made reference load cell, which enables the FWD load cell to be calibrated without being removed from the testing equipment.

4.1.2 The FWD deflection sensors are removed from their holders on the FWD and mounted in a rigid stand where they are calibrated against a precision accelerometer (with the accelerometer signal being double integrated by *WinFWDCal*). The sensors are stacked vertically in the stand, one above another, so that all sensors, including the accelerometer, are subjected to the same pavement deflection.

4.1.3 Next, the calibration of the FWD deflection sensors is further refined by comparing them to each other in a process referred to as “relative calibration.” As such, it serves as the final step in the annual calibration process. In annual calibration, the same sensor stand is used for both reference and relative calibration.

4.2 Monthly relative calibration uses a relative calibration stand supplied by the FWD manufacturer. It is a quick means to periodically verify that the sensors are functioning properly and consistently. Monthly relative calibration assumes that the overall mean deflection, as determined from simultaneous measurements by the full set of deflection sensors, yields an accurate estimate of the true deflection. This assumption requires that the deflection sensors must have first been subjected to the annual calibration procedure.

4.2.1 The relative calibration procedure used for monthly relative calibration is different from that used for annual calibration.

4.3 Acceptance criteria for annual calibration and monthly relative calibration, based upon the repeatability of the calibration factors, are identified in the calibration procedure. If accepted, the new gain factors shall be entered into the FWD operating program.

5. SIGNIFICANCE AND USE

5.1 Calibration of both the load cell and the deflection sensors provides a means of comparison of results from different FWD types and manufacturers.

5.2 Calibration ensures consistency in the data collection among various agency FWDs.

---

6. APPARATUS

6.1 *Facilities*—Indoor space with easy access for FWD and towing vehicle, a level floor large enough so that the FWD trailer and the towing vehicle can sit level during the test, a reasonably constant temperature (between 10 and 38°C) and humidity (40 to 90 percent, noncondensing), heated, but not necessarily air-conditioned, and good security for the calibration equipment.

6.1.1 *Test Pad*—4- by 5-m (12- by 15-ft) slab with a 2.5-m (8-ft) wide clear zone around perimeter (for maneuvering FWDs and the reference data acquisition system) having a smooth, crack-free portland cement concrete surface.

Note 1—While an isolated test pad is recommended, it is not required, provided that all other facilities requirements, especially the minimum slab deflection requirement and sufficient slab damping, are achieved. The slab dimensions (4 by 5 m) are suggested, and other dimensions may be satisfactory.

Note 2—A modest amount of hairline cracking is permissible. Should the test pad develop cracks which are visibly open (1.5 mm (0.06 in.) or more), it shall be replaced.

6.1.1.1 The test pad should be isolated (by impregnated felt bond breaker, sawed and caulked joint, or similar means) from the surrounding floor area.

6.1.1.2 The test pad shall have a slab deflection of at least 300 microns (12 mils) due to 70-kN (16,000-lb) load at the position of the deflection sensor calibration stand when the FWD is in the specified position for calibration.

Note 3—Fatigue calculations indicate that acceptable fatigue life can be achieved with a 125-mm (5-in.) thick portland cement concrete slab resting on a 200-mm (8-in.) open-graded crushed stone base. A layer of filter fabric shall be placed below the base to protect it from intrusion of subgrade fines. To achieve adequate deflections, the subgrade modulus shall be less than 80 MPa (12,000 psi) with bedrock deeper than 7 to 9 m (25 to 30 ft). Where bedrock exists at depths of 4 to 8 m (15 to 25 ft), a subgrade modulus of 50 MPa (7500 psi) or less will be needed. Test pads located where bedrock is less than 4 m (15 ft) deep are likely to be very sensitive to minor variations in subgrade moisture, and hence are not advisable.

Note 4—If deflections in this range cannot be achieved, then it may be necessary to relocate the FWD to a different pavement. In general, a concrete pavement on a relatively weak subgrade will yield the required deflection amplitude.

6.1.1.3 The sensor holder shall be located not closer than 150 mm (6 in.) from the edge of the test pad, but it is not required, nor is it possible, that the test pad shall deflect uniformly across the entire area of the pad.

6.2 *Equipment*—The following equipment is needed in the calibration facility:

Note 5—Drawings of each of the special items of equipment, cabling diagrams, and the data acquisition software, *WinFWDCal* and *PDDXconvert*, are available.[1]

6.2.1 *Signal Conditioner*—Measurements Group Inc. Vishay Model 2310 signal conditioner[2] with power cable and stabilizer bar.

6.2.2 *Data Acquisition Board (DAQ)*—Keithley Model KUSB-3108 data acquisition board.[3]

6.2.3 *Connecting Cables*—Vishay to accelerometer, Vishay to load cell, Vishay to DAQ, and DAQ to computer USB port.

6.2.4 *Computer*—A laptop or desktop computer capable of running Windows *XP* or higher software, having at least four USB ports.

6.2.5 *Reference Load Cell*—Custom-built reference load cell (300-mm diameter) calibrated annually to 106 kN (24,000 lb) capacity.

6.2.6 *Reference Accelerometer*—Silicon Designs Model 2220-005 ± 5 g accelerometer mounted in a custom-built aluminum box housing.

6.2.7 *Accelerometer Calibration Platform*—Custom-built aluminum platform capable of being leveled. Used for daily calibration of the accelerometer and for storage of the accelerometer when it is not in use.

6.2.8 *Data Acquisition Software*—*WinFWDCal* and *PDDXconvert*.

6.2.9 *Deflection Sensor Calibration Stands*—Custom-built welded aluminum stands with shelves for ten deflection sensors and one reference accelerometer. One design is used with geophones and another with seismometers. Used for annual calibration.

6.2.10 *Ball-joint Anchor*—Custom-built hardware, bolted to the floor or test pad, for coupling the deflection sensor calibration stand to the pavement.

6.2.11 *Relative Calibration Stand*—Provided by the FWD manufacturer with as many positions as the number of active deflection sensors. Used for monthly relative calibration.

7. FALLING WEIGHT DEFLECTOMETER SET UP

7.1 The FWD shall be in good operating condition prior to performing reference calibration. Particular attention shall be paid to cleaning the deflection sensor bases, where appropriate, to ensure that they seat properly in the sensor stand. Also, verify that the FWD load plate is firmly attached to the load cell and the swivel (if so equipped) is well lubricated. All electrical connectors shall be inspected and, if necessary, cleaned and firmly seated.

7.2 During set up, FWD-specific information will need to be transferred electronically from the FWD computer files to the calibration computer. The *WinFWDCal* software will provide guidance to accomplish this.

7.3 If the FWD is trailer-mounted, the trailer shall remain attached to the towing vehicle throughout the entire calibration period.

7.4 The FWD shall be at room temperature and should be set up as it is used under normal operating procedures.

7.5 Before beginning any calibration work, and throughout the entire calibration period, there shall be no data filters in operation in the FWD operating program. Verify that all smoothing or filtering has been turned off.

7.6 A series of warm-up drops shall be performed immediately prior to beginning calibration.

7.7 The drop sequence used for calibration shall be determined in a two-step process.

7.7.1 The FWD owner shall specify the load levels to be used during calibration. A minimum of three and a maximum of four load levels shall be specified. The highest load level shall not exceed 80 kN (18 000 lb) ± 10 percent.

Note 6—Heavy weight deflectometers (HWD) can achieve the target load levels by taking off all of the removable weights.

7.7.2 With the accelerometer in the sensor stand and the stand mounted in the ball-joint anchor, use the *WinFWDCal* software to determine the minimum number of replicate drops. More than the minimum number of drops may be used, not to exceed ten drops per load level.

7.7.3 Program the drop sequence in the FWD computer, progressing from the lowest to the highest load level. Provide for a pause after each drop or manually control the FWD. The same number of drops shall be used at each load level. The same drop sequence shall be used for both load and deflection sensor calibration.

7.7.4 If three load levels are used, the minimum number of drops in the sequence shall be 18 and the maximum number shall be 30. For four load levels, the minimum number of drops shall be 20 and the maximum shall be 40.

8. LOAD CELL CALIBRATION SET UP

8.1 If the reference load cell has not been calibrated within the past 12 months, then it shall be recalibrated in accordance with R 33.

8.2 Hook up the cables and warm up the electronics for at least 30 minutes before beginning a calibration.

8.3 Zero the signal conditioner with the load plate high, so that there is no external load on the reference load cell. For accurate results, it is critically important that the reference load cell be zeroed with the FWD load plate in the raised position. The signal conditioner excitation and gain must be set exactly to the levels at which the reference load cell was calibrated. The software will provide guidance to accomplish this.

8.4 Position the FWD so that the load plate is near the center of the calibration test pad, or on any other stiff, smooth concrete surface. Sweep the area beneath the load plate to assure there will be no sand or other loose debris under the reference load cell.

8.5 Position the reference load cell beneath the FWD load plate, making sure that the three guides are aligned around the plate. Verify that the load plate sits squarely on the load cell and on the pavement.

Note 7—After applying three seating drops, it should not be possible to slide a piece of paper under the load plate anywhere around the perimeter of the plate or under any of the support feet of the reference load cell.

9. DEFLECTION SENSOR CALIBRATION SET UP

9.1 Hook up the cables and warm up the electronics for at least 30 minutes before beginning a calibration.

9.2 The signal conditioner excitation and gain must be set exactly to the specified levels. The software will provide guidance to accomplish this.

9.3 Calibrate the accelerometer, mounted in an aluminum box, using the calibration platform. The platform shall be carefully adjusted using the bubble level to assure that the accelerometer is aligned with Earth's gravity field. The accelerometer shall be calibrated in both +1 g and –1 g fields by inverting the box briefly. The *WinFWDCal* software will provide on-screen instructions. The calibration shall be repeated after 4 hours.

Note 8—Care must be taken to avoid dropping the accelerometer box during the calibration process because the shock may damage the accelerometer.

9.4 Position the FWD so the load plate is as close as possible to the ball-joint anchor.

9.5 Connect the sensor stand to the ball-joint anchor and tighten all bolts securely. Slippage between the stand and the base, or between the base and the concrete test pad, shall not be allowed. The ball joint shall rotate with slight friction. It is important that the FWD shall not come in contact with the sensor stand during the calibration.

9.6 Attach the accelerometer box in position in the sensor stand.

9.7 Remove the FWD deflection sensors from the FWD and position them in the sensor stand in accordance with the *WinFWDCal* on-screen instructions.

Note 9—For monthly relative calibration, the sensor stand supplied by the FWD manufacturer shall be used; only Section 9.7 is needed; and the procedure in Section 12 shall be used.

10. ANNUAL DEFLECTION SENSOR CALIBRATION PROCEDURE

10.1 *Reference Calibration*—Deflection sensor reference calibration consists of performing two trials, in which all of the sensors are calibrated simultaneously in the sensor stand. The position of the sensors in the stand is inverted between the trials. Spare deflection sensors shall not be calibrated unless they have separate, dedicated signal conditioning channels in the FWD microprocessor.

10.1.1 The reference calibration drop sequence established during set up (Section 7.7) shall be used. The load plate shall not be raised at any time during the sequence.

10.1.2 Perform the drop sequence for the first reference calibration trial. Review and accept or reject the data for each drop. The *WinFWDCal* software will graphically display the deflection-time data after each drop.

10.1.3 At the conclusion of the drop sequence, transfer the FWD data electronically to the calibration computer and review the results. For each sensor, *WinFWDCal* will regress the FWD output (independent variable) versus the reference deflection sensor (dependent variable) forced through zero. The slope of the regression line for each sensor, when multiplied times the initial gain factor, gives the reference gain factor.

10.1.4 The slope for an individual sensor is acceptable if its reported standard error is not more than 0.0020. The trial is acceptable if the standard errors for all sensors are not more than 0.0020.

10.1.5 If the first trial is acceptable, continue with the second trial. Repeat Section 10.1. Invert the sensors in the stand before the second trial according to the diagram displayed by *WinFWDCal*.

10.2 *Interim Gain Factor Acceptance Criteria*—Evaluate the data as follows:

10.2.1 After two trials have been accepted, *WinFWDCal* will calculate the average reference gain factor for each sensor and display the results as the interim gain factors (one gain factor for each sensor).

10.2.2 *WinFWDCal* will calculate the difference in the reference gain factors for each sensor between the two trials and the root-mean-square (RMS) difference for all sensors. If the RMS difference is no more than 0.003, then the reference calibration test is complete.

10.2.3 If the RMS difference is greater than 0.003, this indicates that some sensors may not be sufficiently repeatable. Two more reference calibration trials shall be performed. Repeat Section 10.1. *WinFWDCal* will calculate the standard deviations of the reference gain factors for each sensor for the four trials. If each of the standard deviations is no more than 0.003, then the reference calibration test is complete.

10.2.4 The average of the four reference gain factors for each sensor shall be reported as the interim gain factors.

10.3 *Relative Calibration*—Reference calibration is followed by relative calibration, using the same sensor stand. Two trials are performed. For each trial, 40 drops shall be applied from the highest drop height used in reference calibration. The sensors shall not be repositioned in the sensor stand before the first trial.

Note 10—The *WinFWDCal* software will adjust the FWD data collected in the relative calibration using the interim calibration factors internally. Do *not* enter the interim factors in the FWD operating program before performing relative calibration.

10.3.1 Perform the drop sequence for the first relative calibration trial.

10.3.2 At the conclusion of the drop sequence, transfer the FWD data electronically to the calibration computer and review the results. For each sensor, *WinFWDCal* will calculate the means ratio. The means ratio multiplied times the interim gain factor gives the relative gain factor.

10.3.3 *WinFWDCal* does an analysis of variance (ANOVA) for the data and reports the standard error. The trial is acceptable if the standard error is not more than 3 microns (0.12 mils).

Note 11—The *WinFWDCal* software will display a plot of the data for the 40 drops. The graph should be scanned to detect outliers (for instance, a loose sensor in the stand).

10.3.4 If the standard error is greater than 3 microns (0.12 mils) the trial shall be rejected. Repeat Section 10.3. (Do not reposition the sensors in the sensor stand.) If acceptable results cannot be obtained after four trials, no further effort shall be made to calibrate the deflection sensors.

Note 12—The reason why the standard error exceeds 3 microns should be investigated and corrected, if possible, before repeating the procedure.

10.3.5 If the first trial is acceptable, continue with the second trial. Repeat Section 10.3. Invert the sensors in the stand before the second trial according to the diagram displayed by *WinFWDCal*.

10.4 After two trials have been accepted, *WinFWDCal* will calculate the average relative gain factor for each sensor, and report the results as the final gain factors.

11. ANNUAL LOAD CELL CALIBRATION PROCEDURE

11.1 *Reference Calibration*—Reference load cell calibration consists of at least two trials.

11.1.1 The reference calibration drop sequence established during set up (Section 7.7) shall be used. The load plate shall not be raised at any time during the sequence.

11.1.2 Perform the drop sequence for the first reference calibration trial. Review and accept or reject the data for each drop. The *WinFWDCal* software will graphically display the deflection-time data after each drop.

11.1.3 At the conclusion of the drop sequence, transfer the FWD data electronically to the calibration computer and review the results. For each sensor, *WinFWDCal* will regress the FWD output (independent variable) versus the reference load cell (dependent variable) forced through zero. The slope of the regression line for each sensor, when multiplied times the initial gain factor, gives the reference gain factor.

11.1.4 The slope for the trial is acceptable if its reported standard error is not more than 0.0020.

11.1.5 If the first trial is acceptable, continue with the second trial. Repeat Section 11.1.

11.1.6 After two trials have been accepted, *WinFWDCal* will calculate the average reference gain factor and report the results as the final gain factor. If the range of the two reference gain factors is not more than 0.003, then the final gain factor shall be accepted. The reference calibration test is complete.

11.1.7 If the results are outside the allowable range, a third reference calibration trial shall be performed. Repeat Section 11.1.

11.1.8 If the standard deviation of the gain factors for three acceptable trials is not more than 0.003, then the results of the three trials shall be averaged and reported as the final gain factor for the load cell. The reference calibration test is complete.

11.1.9 If the standard deviation exceeds 0.003, the reference load cell calibration procedure shall be repeated (one more trial), yielding a fourth gain factor.

Note 13—The reason why the standard deviation exceeds 0.003 should be investigated and corrected, if possible, before repeating the procedure.

11.1.10 If the standard deviation of all calibrations (four acceptable trials) is not more than 0.003, the average of all four results shall be reported as the final gain factor for the load cell, and the reference calibration test is complete. If acceptable results cannot be obtained after four trials, no further effort shall be made to calibrate the load cell.

12. ANNUAL CALIBRATION ACCEPTANCE AND CERTIFICATION

12.1 *Evaluation and Acceptance of Final Gain Factors*—The *WinFWDCal* software will perform the needed calculations. Evaluate the data as follows:

12.1.1 The final gain factors from this calibration shall be compared to the corresponding gain factors from the previous calibration (i.e., the initial gain factors). There shall be no more than a 1 percent difference, either higher or lower, for each individual deflection sensor and for the load cell. If this criterion is satisfied, then final gain factor for the sensor shall be accepted. If this criterion is not satisfied for a sensor, then evaluate it according to the next criterion.

12.1.2 The final gain factor for the sensor shall fall within a range of 0.980 to 1.020. If this criterion is satisfied, then the final gain factor for the sensor shall be accepted. If this criterion is not satisfied for the sensor, then evaluate it according to the next criterion.

12.1.3 If a historical record of previous calibrations for the sensor is available for a period of 4 years or more, and there are at least three previous calibration results over this period of time, then the time rate of change of the final gain factor for the sensor shall be no more than 0.1 percent per year. If this criterion is satisfied, then the final gain factor for the sensor shall be accepted.

12.2 *Certificate of Calibration*—If the final calibration results meet the acceptance criteria for all sensors, a certificate of calibration listing the final gain factors for the load cell and each deflection sensor shall be issued by *WinFWDCal*.

12.2.1 The final gain factors shall be entered into the FWD operating program.

13. MONTHLY RELATIVE CALIBRATION PROCEDURE

13.1 Monthly relative calibration can serve one of two purposes. With regular use, it is a means to verify that the deflection sensors are functioning properly and consistently. It can also be used to replace a damaged sensor, providing a gain factor for the replacement sensor for short-term use until an annual calibration can be done.

Note 14—Monthly relative calibration uses a calibration stand provided by the FWD manufacturer. The deflection sensors are stacked vertically in the stand, one above another, so that all sensors are subjected to the same pavement deflection. Position in the stand may have an effect on the deflection readings. To compensate for this, the sensors are rotated through all positions in the stand. *This rotation procedure is different from the relative calibration procedure done for annual calibration.*

Note 15—Monthly relative calibration relies on collecting a large number of data that can be averaged to reduce the significance of random measurement errors. Deflections in excess of 500 microns (20 mils) are needed for the results to be accurate. *WinFWDCal* does the statistical data analysis to compute adjustment ratios and final gain factors from the data. Since a large number of drops are involved, the properties of the pavement materials may change due to compaction or liquefaction during the procedure. However, all of the sensors are equally affected, so as long as the effect is not too extreme, the adjustment ratios are still accurate.

13.1.1 Some FWDs have fewer than or more than seven active deflection sensors. If they do, these procedures shall be modified to calibrate the actual number of active sensors in use on the FWD. Any number of sensors will work as long as the calibration stand will accept them.

13.1.2 Remove all of the deflection sensors from their holders on the FWD. Make sure that the sensors are labeled (e.g., from one to seven) with respect to their normal position on the FWD. The center sensor shall be defined as D1 for this procedure.

13.1.3 Position the deflection sensors in the stand for the first set.

13.1.4 The sensor stand shall be held in a vertical position. Mark the location where it rests so that it can be relocated precisely on the same spot. This should be done by gluing a washer to the pavement or by chipping a small divot in the pavement with a chisel or a screwdriver.

13.1.5 Select the FWD drop height and the distance from the loading plate to the sensor stand to yield deflections near 500 microns ± 100 microns (20 mils ± 4 mils).

Note 16—If deflections in this range cannot be achieved, choose another location. A concrete pavement on a relatively weak subgrade will usually yield the required deflection. This procedure may be carried out at any location that satisfies the deflection requirement.

13.1.6 Warm up the FWD and condition the test point by repeating a sequence of ten drops until the loads and deflections that are registered are nearly uniform. The deflections in a sequence of ten drops should not show a steadily increasing or decreasing trend.

13.1.7 Lower the FWD loading plate. Do *not* raise the loading plate or move the FWD during the relative calibration testing. This will assure a constant distance between the center of the load plate and the base of the sensor stand.

13.1.8 For each set, make two seating drops (no data recorded) followed by five replicate drops (for which data are recorded) while holding the stand in a vertical position.

13.1.9 At the end of each set, rotate the sensors in the stand. The general progression is for the sensors to move from the bottom toward the top of the stand. With a nine-sensor FWD, a total of 45 drops shall be recorded (nine sets of five replicate drops for each set). With a seven-sensor FWD, 35 drops shall be recorded.

13.2 *Relative Calibration Data Analysis*—Follow the *WinFWDCal* on-screen instructions for set up of the procedure. Transfer the FWD data file electronically to the *WinFWDCal* software program for analysis. Options are provided in the software to indicate whether a normal data analysis or a special analysis for sensor replacement is required.

13.3 *Adjustment of Calibration Factors: Normal Analysis*—Normal analysis is used when no sensor is being replaced.

13.3.1 The *WinFWDCal* software will report the adjustment ratios and the gain factors for each deflection sensor. Adjustment of the gain factors in the FWD operating system shall be made only when those changes are both significant and verified to be necessary. The following guidelines shall be used to evaluate the need for adjustment of the gain factors:

13.3.1.1 If all of the adjustment ratios are between 0.997 and 1.003 inclusive, they are not statistically significantly different from a ratio of 1.000. The calculated adjustments are trivial. The calibration test is complete, and no change of the gain factors shall be made.

13.3.1.2 When the adjustment ratios for one or more sensors fall outside of the range 0.997 to 1.003, a second relative calibration trial shall be performed. Repeat Section 13.1. If the gain factors for each sensor in both trials agree within 0.003, the need for the adjustment has been verified. The gains shall be adjusted for *all* sensors. The gain factors for each sensor for the two trials shall be averaged and entered in the FWD operating system. The calibration test is complete.

13.3.1.3 If, for one or more sensors, the difference in the gains for the two trials is greater than 0.003, reject the first two trials and perform two more trials. If the second attempt also exceeds the allowable difference, the annual calibration procedure (Section 10) shall be performed as soon as possible.

13.4 *Adjustment of Calibration Factors: Sensor Replacement*—When replacing a damaged deflection sensor, the monthly calibration procedure should be used to determine a gain factor for the replacement sensor. The calculations are done by the *WinFWDCal* software, and a gain factor is reported only for the replacement sensor.

13.4.1 Two relative calibration trials shall be performed. If the two gain factors for the replacement sensor agree within 0.003, then the gain factors for the two trials shall be averaged and entered in the FWD operating system. The calibration test is complete.

13.4.2 If the difference is greater than 0.003, two more relative calibration trials shall be performed. Repeat Section 13.1. *WinFWDCal* will report the average gain factor from the four trials and the standard deviation. If the standard deviation is not more than 0.003, then the average gain factor shall be entered in the FWD operating system. The calibration test is complete.

13.4.3 If the standard deviation of the four trials is more than 0.003, no further effort shall be made to calibrate the replacement sensor. The annual calibration procedure (Section 10) shall be performed as soon as possible.

14. REPORT

14.1 *The calibration certificate shall report the following information*:

14.1.1 Calibration date;

14.1.2 Listing of the original load cell serial number and gain factor;

14.1.3 Listing of the original deflection sensor positions, serial numbers, and gain factors;

14.1.4 Final load cell gain factor; and

14.1.5 Final deflection sensor gain factors for each sensor.

15. PRECISION AND BIAS

15.1 *Load Cell Calibration*:

15.1.1 Seventeen load cell calibration trials were done in 2006 by three FWD calibration operators using a Dynatest FWD. No difference between operators was found. The overall standard deviation of the final calibration factor was 0.00152. The 95th percentile repeatability using a Student's *t-test* uses a multiplier of 2.11.

For this example, the precision and bias statement would read:

Precision and Bias Statement for Dynatest Load Cell Calibration:

The 95 percent repeatability of the final gain factor: 0.321 percent.
No reproducibility statement is available at this time.
There is no bias expected in the final gain factor.

15.2 *Geophone Calibration*:

15.2.1 Nine geophone calibration trials were done in 2006 by three FWD calibration operators using a Dynatest FWD. No difference between operators was found. The overall pooled standard deviation of the final calibration factors for all nine geophones was 0.00245. By using the pooled standard deviation, the normal distribution multiplier of 1.96 may be used.

For this example, the precision and bias statement would read:

Precision and Bias Statement for Dynatest Geophone Calibration:

The 95 percent repeatability of the final gain factor: 0.480 percent.
No reproducibility statement is available at this time.
There is no bias expected in the final gain factor.

Standard Practice for

Calibrating the Reference Load Cell Used for Reference Calibrations for Falling Weight Deflectometer

AASHTO Designation: R 33-03 (2008)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Calibrating the Reference Load Cell Used for Reference Calibrations for Falling Weight Deflectometer

AASHTO Designation: R 33-03 (2008)[1]

1. SCOPE

1.1. The reference load cell is a precision instrument that requires regular and thorough calibration.

1.2. It is essential that the reference load cell be calibrated using a testing machine that is properly maintained and accurately calibrated.

1.3. The reference load cell and its cable and the associated signal conditioner are considered a *system* of instruments which are to be calibrated together and used together.

1.4. *This standard practice may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- R 32, Calibrating the Load Cell and Deflection Sensors for a Falling Weight Deflectometer

2.2. *ASTM Standard*:

- E 74, Standard Practice of Calibration of Force-Measuring Instruments for Verifying the Force Indication of Testing Machines

3. SUMMARY OF METHOD

3.1. The reference load cell system is calibrated against a recently calibrated universal testing machine.

3.2. The reference load cell system is conditioned in the testing machine by loading it three times to 1.2 times the highest load to be measured by the falling weight deflectometer (FWD) (for a typical FWD 100 kN (20 000 lb)).

3.3. Loads are applied at a rate of 5 kN (1000 lb) per minute and read from both the load cell system and the testing machine.

3.4. Develop a polynomial regression equation with an estimated standard error of less than 20 N (50 lb) and a coefficient of determination of better than 0.98. A third- to fifth-degree polynomial will provide these limits.

3.5. The regression coefficients are entered into the data acquisition software used for the reference load cell system.

4. SIGNIFICANCE AND USE

4.1. In order to be confident in the calibration factors derived in the FWD load cell calibration, the reference load cell must be calibrated against known loads.

5. TERMINOLOGY

5.1. *Description of Terms Specific to This Standard*:

5.1.1. *reference load cell*—custom-built calibration device used to calibrate the in-place load cell on the FWD.

5.1.2. *reference load cell system*—system composed of the reference load cell, its cables, and the associated signal conditioners. This system must be maintained for use in the FWD load cell calibrations.

6. APPARATUS

6.1. *Testing Machine*—A static testing machine, hydraulic or screw-powered, with a load capacity of at least 200 kN (50 000 lb) or 2.5 times the maximum load to be measured by the FWD should be used for the reference load cell calibration. The high capacity of the testing machine assures that the test frame will be adequately rigid. The testing machine shall have several load ranges, among them a range slightly higher than 1.2 times the maximum load to be measured by the FWD. Care must be taken to avoid overloading the reference load cell during its calibration.

Note 1—Alternatively, a servo-controlled, closed-loop testing system such as an MTS machine with a capacity of 200 kN (50 000 lb) or 2.5 times the maximum load to be measured by the FWD can be used for this purpose. Newer digital systems can provide the accuracy required for this purpose.

6.2. *Signal Conditioner*—The signal conditioner should be sanctioned by the manufacturer of the calibration load cell.

6.3. *Data Acquisition Board*—A data acquisition board with resolution of 16 bit or better should be used for calibration.

6.4. *Triggering System*—An adequate software- or hardware-driven, digital or analog triggering system should be used to synchronize the signals from the data acquisition boards.

7. PREPARATION OF APPARATUS

7.1. The testing machine shall be calibrated according to ASTM E 74 or the manufacturer's recommendation within 12 months prior to conducting this procedure. The device(s) used to calibrate the universal testing machine shall be certified to be traceable to the National Institute of

Standards and Technology (NIST) calibration(s). The certificate of calibration provided for the testing machine shall be used to develop an adjustment algorithm that will correct the indicated load on the testing machine to the NIST load.

7.2. The data acquisition board should be calibrated as per recommendation of the manufacturer.

7.3. The signal conditioner amplifier shall be balanced according to the procedure described in the manufacturer's instruction manual. With the signal input terminals shorted together, at a gain of 100, the AC noise on the ±10-volt output shall be 1 millivolt or less.

7.4. Inspect the reference load cell carefully before calibration. Verify that the cable and the connectors are making proper contact.

7.4.1. Make a continuity check to verify that there are no breaks in the wires. Verify that the Allen screws on the load cell are tight.

Note 2—The load cells are typically torqued to a level suggested by the manufacturer and set with Locktite during assembly. *These screws shall not be loosened unless it is absolutely necessary*. If any of the screws are loosened, they shall be removed one at a time and their threads cleaned. Locktite shall be reapplied to their threads, and they shall be torqued to the specified level.

7.4.2. It is of utmost importance to utilize the software and associated hardware provided by the appropriate agencies in accordance with their instructions. Special attention should be paid to setting up the signal conditioning gains, filters, and input and output voltages precisely as recommended by the responsible agency. The Federal Highway Administration Long-Term Pavement Performance Program has developed several programs that can be used as guidelines.

8. PROCEDURE

8.1. Attach the cable from the signal conditioner to the reference load cell and turn on the signal conditioner.

8.2. Warm up the testing machine for at least 15 minutes.

8.3. Carefully align and center the system under the upper loading block of the testing machine.

8.4. Apply a nominal load of 100 kN (20 000 lb) or 1.2 times the maximum load to be measured by the FWD to the reference load cell three times, unloading after each repetition. Apply the load at a rate in the range of 20 kN to 100 kN (5000 lb to 20 000 lb) per minute. With the servo-valve closed-loop systems, apply three pulses of about 100 kN (20 000 lb) or 1.2 times the maximum load to be measured by the FWD.

8.5. Apply load at a rate no faster than 5 kN (1000 lb) per minute. Either manually or digitally, record the load from the calibration load cell and the voltage output (or number of bits) from the load cell being verified. Take readings at 5-kN (1000-lb) intervals up to a maximum load of 100 kN (20 000 lb) or 1.2 times the maximum load to be measured by the FWD. While releasing the load, record a reading at 50 kN (10 000 lb) and at zero load.

If a servo-valve, closed-loop hydraulic system is used, apply pulses with duration of 100 msec or less at 5-kN (10 000-lb) increments to a maximum load of 100 kN (20 000 lb) or 1.2 times the maximum load to be measured by the FWD. Repeat the process at least three times at each load level.

9. CALCULATIONS

9.1. Using a spreadsheet program, enter the results of the calibrations as follows:

9.1.1. In one column, enter the loads registered by the testing machine (i.e., 0, 5, 10, etc.).

9.1.2. If necessary, correct these loads to the NIST traceable loads, based on the certificate of calibration for the testing machine.

9.1.3. Also subtract the tare weight of the upper bearing block from the loads, if applicable.

9.1.4. In another column, enter the voltage output of the load cell being verified. If the number of bits on the data acquisition board is registered, convert them to voltage.

9.2. Conduct a polynomial-regression analysis between the corrected calibration load cell (as the Y variable) versus voltage output from the load cell being verified (as the X variable).

9.2.1. Evaluate the polynomial solution according to the following criteria:

9.2.1.1. The standard error of the Y estimate should be less than ±20 N (50 lb).

9.2.1.2. The coefficient of determination should be greater than 0.98.

Note 3—To optimize the fitting process, start with a first-degree polynomial (i.e., a line) and increase the number of polynomial terms until the two criteria above are met. If the two criteria cannot be met up to a fifth-degree polynomial, either repeat the calibration process or contact the manufacturer of the reference calibration set up for assistance.

9.3. The regression coefficients shall be recorded and entered in the data acquisition program.

10. REPORT

10.1. *Report the following information*:

10.1.1. Date of the calibration, and

10.1.2. The regression coefficients from Section 9.3.

11. FREQUENCY OF CALIBRATION

11.1. Calibration of the reference load cell shall be performed at least once per year. It shall also be performed immediately after any changes to the set up of the calibration load system.

12. PRECISION AND ACCURACY

12.1. No precision or accuracy statements are available at this time.

---

Standard Practice for

Installing, Monitoring, and Processing Data of the Traveling Type Slope Inclinometer

AASHTO Designation: R 45-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Installing, Monitoring, and Processing Data of the Traveling Type Slope Inclinometer

AASHTO Designation: R 45-08

1. SCOPE

1.1. This practice provides instructions for installation, monitoring, and data reduction for the *traveling type* slope inclinometer for use with guide casing. A slope inclinometer is a precision instrument that measures lateral displacement of a guide casing resulting from the movement of earth, concrete, or other masses. This type of instrument can be used to detect and monitor movements in earth- and rock-fill dams, highway embankments and foundations, excavation slopes, sheet pile bulkheads, concrete retaining walls, and other structures. Since the instrument is waterproof, it can be used on projects where normal measurements would not be feasible, such as the displacement of the lower portion of a pipe pile. The data, which are well suited for computer reduction, can be used to interpret shear zones in landslide areas and as a basis for predicting impending shear failures or structural failures based on the amount and rate of lateral deformation occurring.

1.2. The practice is divided into the following parts:

1.2.1. Part I, Installing Slope Inclinometer Guide Casing;

1.2.2. Part II, Monitoring Slope Inclinometer Guide Casing; and

1.2.3. Part III, Data Computations and Analysis.

1.3. The values stated in SI units are to be regarded as the standard.

PART I—INSTALLING SLOPE INCLINOMETER GUIDE CASING

2. APPARATUS

2.1. *Drilling Equipment*:

2.1.1. Drill rig capable of drilling a hole with diameter large enough to accommodate the particular size slope inclinometer casing used and allow for adequate backfilling. The depth of the hole needed varies with the particular installation, locale, and/or discretion of the engineer. Normally, a drill rig capable of drilling a 203-mm (8-in.) diameter hole to the desired installation depth may be used. A smaller drill rig may be used for shallow depth installations.

2.2. *Guide Casing*:

2.2.1. Guide casing, usually round extruded plastic, with four equally spaced longitudinal grooves on the inside of the casing compatible with the particular torpedo sensor used. However, some casing may not be grooved because the torpedo sensor maintains proper orientation by use of locking metal orientation rods. Some inclinometers may be used in square steel casing with the torpedo sensor guide wheels tracking in opposite corners of the casing. The casing comes in assorted diameters and may come in any convenient length, such as 1.52- or 3.05-m (5- or 10-ft) sections.

2.3. *Couplings*:

2.3.1. The couplings may be extruded plastic with four equally spaced grooves and usually come in 152-mm (6-in.) lengths. In cases where settlement is expected, longer couplings may be used to join the sections of casing. The resulting gap between casing sections allows the casing to telescope together as compression of the surrounding materials occurs. Alternately, a coupling mechanism may be included as part of the guide casing.

2.4. *Installation Tools*:

2.4.1. Inclinometer guide casing installation tools specified by the manufacturer, normally consisting of hacksaw, casing clamp, casing anchor (recommended), tape measure, and a device for marking casing grooves such as a felt tip marker or file. A special wheel groove alignment tool, duct or masking tape, and solvent cement may be needed for plastic casing. A vibrator and/or grout pump may be used for backfill compaction and placement if necessary.

2.5. *Plugs*:

2.5.1. Plugs compatible with the particular guide casing are used for protecting the top and bottom of the casing from mud and debris. A conical plug may be used to ease insertion of the casing into a rough-sided hole.

2.6. *Protective Device (Optional)*:

2.6.1. Hole cover or other protective device to minimize vandalism and large enough (152 mm (6 in.)) to allow the cable clamp-guide wheel assembly to be installed on top of the casing. A metal pipe with either a threaded cap or hinged lid with hasp and lock may be used. For protection from impacts by construction traffic, bollards or barriers may be installed.

3. DRILLING AND HOLE PREPARATION

3.1. The size of the drill hole should be large enough to accommodate the particular size casing used and depends on the particular installation, locale, materials encountered, depth of the hole, available backfill materials, or the discretion of the engineer. Larger holes facilitate backfilling. Minimum diameter may be only sufficient to accommodate the casing used. This is applicable in cases where the material may close quickly. Normally, the drill hole may be approximately two times the outside diameter of the casing or a minimum of 127 to 152 mm (5 to 6 in.). The hole should be as vertical as possible (vertical inclination should be less than 3 degrees), and drilled several meters (at least 3 m, or as directed by the engineer) into stable material below or beyond the anticipated zone of movement. Usually, the borehole should extend into rock or soil to achieve sufficient rigidity to provide the fixity of the inclinometer. The bottom 3 m (or as directed by the engineer) of the inclinometer casing should be embedded below the lowest possible failure plane and should extend into hard or very dense material to assure that the future readings do not show any movement at the bottom of the inclinometer casing.

3.2. The hole usually should be cleaned by flushing with water or blowing compressed air before attempting to install the inclinometer casing. Depending on the installation, sometimes it is necessary to leave drilling mud (if it is used) in the borehole to control caving, thereby allowing proper backfill.

3.3. Any means of accomplishing a boring is satisfactory as long as it is suitable to the engineer and conditions at the site. If the ground is firm and the hole will remain open without steel casing, then either a dry hole (drilled with a continuous flight auger) or a water-filled hole (drilled with a chopping bit or a rotary bit and using water to flush out the cuttings) is satisfactory.

3.3.1. Hollow stem augers may be used with success because the augers can be pulled after installation of the slope inclinometer casing. If the hole is likely to squeeze in because of soft soils or cave because of sand, drilling mud may be used and left in the hole upon completion of the boring.

3.3.2. If drilling mud is used, some difficulty may be encountered in making the inclinometer casing go down completely in the hole, but this may be remedied by filling the casing with water or other physical means.

3.4. Steel or any other type of casing may be used if justified to prevent the hole from caving. Usually, steel flush joint drill casing may be used. The steel casing should be a diameter large enough to allow backfill material to be placed in the annular space between the steel casing and outside of the slope inclinometer casing. The backfill material then can be shoveled or poured in small amounts while at the same time pulling the steel casing in small increments. Care should be taken so that the backfill material does not lock the steel casing to the slope inclinometer casing. In extremely difficult cases, steel casing may be left in place upon completion of the boring. However, steel casing tends to thicken any zones of movement. Care should be taken to maintain proper orientation of the slope inclinometer casing while backfilling.

3.5. Inclinometers may be installed in structures and retaining walls to monitor performance and stability. Casing may be incorporated into the structure design or installed after construction by drilling or coring. To prevent damage, casing designed for installation during construction may be placed inside a construction casing, which is grouted into place.

4. INCLINOMETER CASING INSTALLATION

4.1. Any type of soil inclinometer casing may be used as long as it meets the slope inclinometer manufacturer’s requirements and is compatible with the particular sensor torpedo used. Usually, plastic casing is used in most installations; however, steel or other types of casing may be used under certain conditions such as embedment in concrete structures.

Orientation of the casing tracking grooves should be properly maintained throughout installation. The grooves should be oriented parallel and perpendicular to the anticipated direction of movement or at the discretion of the engineer. However, groove orientation of the casings in different holes should be consistent to avoid confusion. The installation may be expedited if the casing is preassembled and coupled together in units of 3.05 to 7.62 m (10 to 25 ft) each.

The following is a brief explanation of the installation techniques for typical casing; reference should be made to the manufacturer’s instruction manual for a more detailed explanation. Refer to Figure 1.

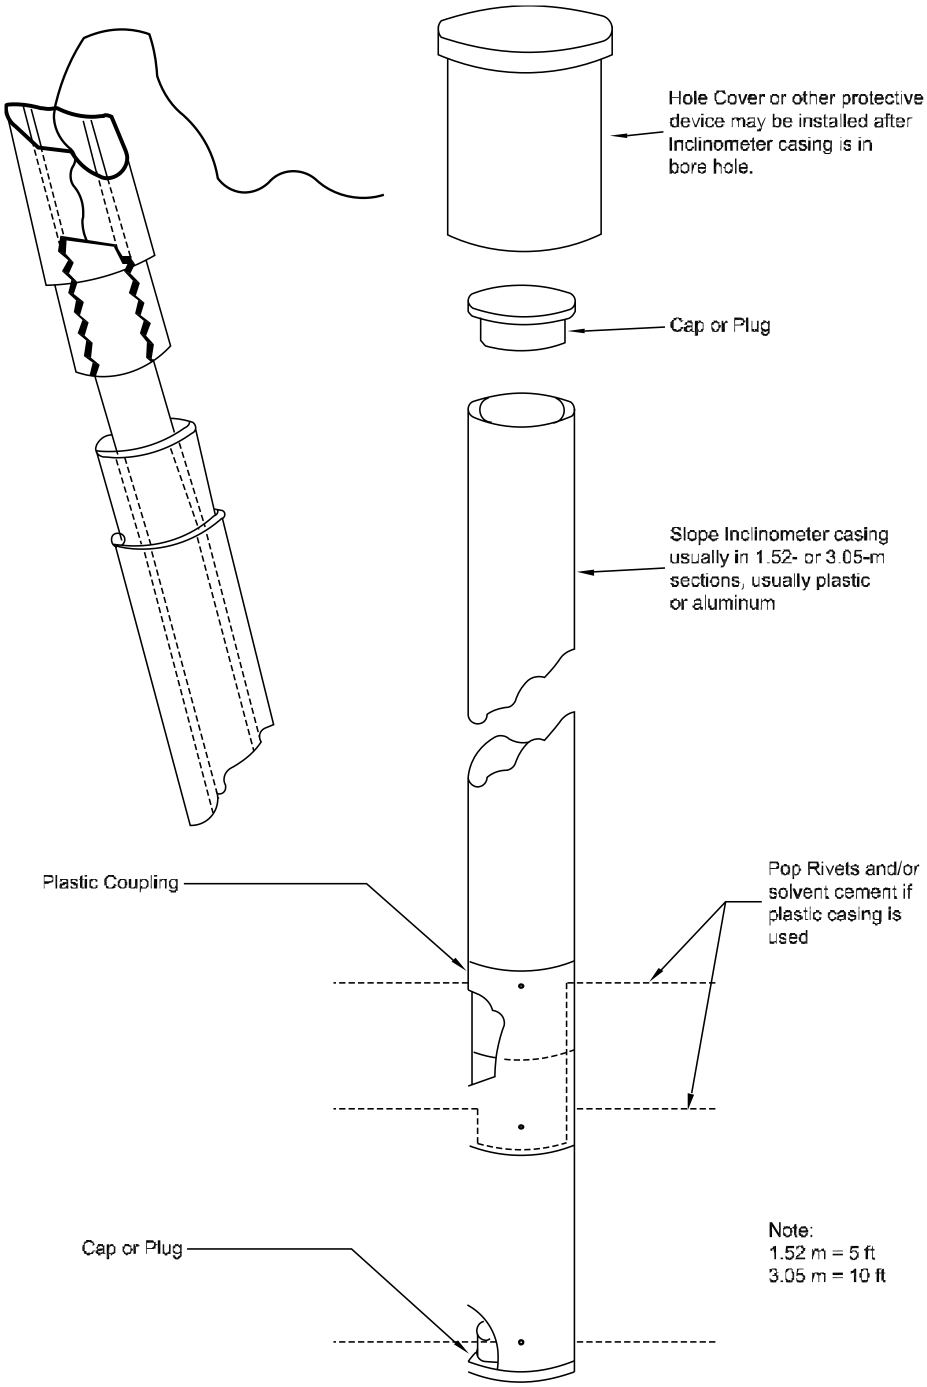

Figure 1—Typical Assembly of Slope Inclinometer Casing

4.2. *Casing*:

4.2.1. Attach a plug to the bottom section of casing by using solvent cement, pop rivets, self-locking devices provided with the casing, or other manufactured supplied coupling. If required, attach a plastic coupling to the top end of casing with solvent cement, pop rivets, self-locking devices provided with the casing, or other supplied coupling.

4.2.2. Lower the first section of casing into the boring with the plug on the lower end and the coupling attached to the top. A casing clamp should be attached approximately 0.3 to 0.6 m (1 to 2 ft) from the top of the casing.

4.2.3. Each end of the casing may be marked with a scribe line or felt tip marker to prevent rivets, if used, from being placed in the instrument tracking grooves. Either solvent cement compatible with the casing, self-locking devices, pop rivets, and/or other manufactured supplied coupling may be used to join the casing and couplings. Any combination of these methods may be used for extremely deep installations.

4.2.4. The two sections are carefully attached together, thus lining up the tracking grooves. The casing ends should be butted together. The two sections may be attached with pop rivets, solvent cement, self-locking device, and/or other manufactured supplied coupling. Casing clamps may be used to prevent the casing from falling into the hole. Lower and attach another section of casing and repeat the previous procedure until the casing rests on the bottom of the hole. Cut off any excess casing to a desirable height with a hacksaw. The predetermined orientation of the instrument tracking grooves should be properly maintained. Installation procedures are the same for telescoping couplings except special fasteners are usually used to automatically align the grooves. If telescoping couplings are used, the casing should not be allowed to rest on the bottom of the borehole, where the weight of the casing would cause the sections to telescope together. Pop rivets or any similar products may be used to prevent the telescoping couplings from collapsing during installation. Pop rivets should not be placed directly in the alignment of the casing's grove. One to two aluminum rivets are recommended (or as directed by the engineer) to prevent the casing from collapsing. The rivets shall be installed about $^1/_2$ in. from the edge of the section body (with telescoping sleeves extended to accommodate settlement). A typical telescoping coupler allows 6 inches of compression or extension.

4.3. The couplings of the casing may or may not be watertight. If the boring is filled with drilling mud, the mud may enter the casing as it is installed. Likewise, the injection of grout to fill the annular space around the casing may result in grout entering the casing.

4.3.1. In such instances, the casing should be flushed with clean water before the grout has hardened. A stiff brush may also be lowered down the casing during washing to ensure that the longitudinal grooves are clean. Inflow of mud or grout may be lessened by waxing, gluing, or taping all joints.

4.4. If sand or gravel is used as the backfill material and groundwater measurements are desired from the installation, small holes or slots may be drilled into the bottom section of inclinometer casing.

5. BACKFILLING THE INCLINOMETER CASING

5.1. The quality and extent of backfilling the slope inclinometer casing depends on the particular installation, groundwater conditions, type of backfill materials, or discretion of the engineer. Best results are obtained if care is taken in backfilling to eliminate any voids, bridging, or settlement in the backfill material. An air impelled or other type vibrator may be used to alleviate bridging. Backfill materials should be of similar shear strength to the *in situ* materials.

5.2. A cap may be placed over the top end of the casing prior to backfilling to prevent any backfill materials falling into the casing.

5.3. *Dry Sand*:

5.3.1. Dry sand may be used when the boring is dry, relatively shallow, and of a fairly small diameter, about 127 to 203 mm (5 to 8 in.). The sand should be clean, dry, and of uniform size, if possible. Standard Ottawa sand is ideal; washed concrete sand is acceptable. The sand may be densified by vibrations, shoveled, or poured slowly through a wire screen to eliminate bridging. Sometimes, sand may settle later and produce both vertical and horizontal deformations of the casing, which are not the result of ground movements. Water may be used to backfill the hole to eliminate any voids or bridging and densify the sand.

5.4. *Pea Gravel*:

5.4.1. Any gravel suitable to the engineer may be used. Pea gravel [9.5 mm (or $^3/_8$ in.)] or No. 9 crushed limestone chips are examples. The gravel may be shoveled slowly in small increments to eliminate any bridging that might occur. Gravel may be used in deeper boreholes where groundwater measurements would be desirable.

5.5. *Cement Grout Backfill*:

5.5.1. A very desirable backfill material is cement grout. This may consist of a lean cement grout, a clay cement grout, or a thixotropic drill mud. A mixture of three bags [22.7 kg/bag (50 lb/bag)], hydrated lime to one bag [42.6 kg/bag (94 lb/bag)] Portland cement, or a mixture of Portland cement with 15 percent Bentonite by volume may be considered good grout mixes. Another simple economical mix is to use ready-mixed “mortar mix” with sufficient water to allow it to be poured into the borehole. The grout mix shall mimic the installation ground conditions. The grout may be poured around the casing from the ground surface (if the borehole stays open and dry) or it may be injected through a small-diameter pipe lowered in the annular space between the casing and the boring. The grout pipe should be 6 to 12 in. from the bottom of the borehole to prevent it from plugging up.

5.5.2. If outer steel casing or hollow stem augers was installed in the hole, it should be pulled before the grout sets. Cement grout backfill is not desirable when groundwater measurements are required. The steel casing or hollow stem auger should be pulled straight up to prevent any spiraling of the inclinometer casing. As each section of the steel casing or hollow stem auger is pulled out of the ground, additional grout should be placed to top off the borehole preventing unwanted cave-ins.

5.6. If needed, install the hole cover or other protective device over the top of the casing prior to completion of backfilling. Then backfill around and inside the hole cover, leaving enough casing exposed to allow room for the clamp-guide wheel assembly.

5.7. If needed, buoyancy of the casing may be overcome by applying weight to the casing by filling the casing with water. If necessary, a down force applied from the bottom such as a steel pipe or drill rod may be used to hold the casing in place.

5.8. Pertinent identification information, including hole location and depth, may be permanently marked on the inside of the hole cover lid. Depending on the situation, the initial readings should be deferred at least 24 hours to allow the backfill to settle and the casing to stabilize. After the casing and hole cover have been installed and backfilled, it may be desirable to reference the casing guide grooves to magnetic north so that subsequent readings are made on the same grooves.

PART II—MONITORING SLOPE INCLINOMETER GUIDE CASING

6. APPARATUS

6.1. *Slope Inclinometer Instrument*:

6.1.1. Readout unit, sensor torpedo, and interconnecting cable.

6.2. Guide wheel clamp assembly.

6.3. Optional casing extension with coupling attached.

6.4. Occasionally, problems are encountered in twisting the casing after installation. This twist is due either to irregularities in the manufacturing processes of the casing or by rotation of the joints during placement. Several types of instruments are commercially available to measure the spiral, which can be compensated for during displacement calculations.

7. INSTRUMENTS

7.1. Various types of instruments are commercially available. The inclinometer torpedo sensor generally has a two-wheel assembly, each of which consists of a rigid wheel for guidance and a spring-loaded wheel for orientation. These wheel assemblies are located near each end of the inclinometer. The configuration produces a voltage output, which is measured at the ground surface with a readout unit. Some units are capable of storing required data, which can be downloaded onto a computer for data reduction and analysis.

Note 1—Because of their reliability and popularity, brief descriptions and explanations will be given for the accelerometer-type torpedo sensor slope inclinometers. Most manufacturers recommend obtaining readings from the bottom progressing to the top for each complete survey. Refer to Figure 2.

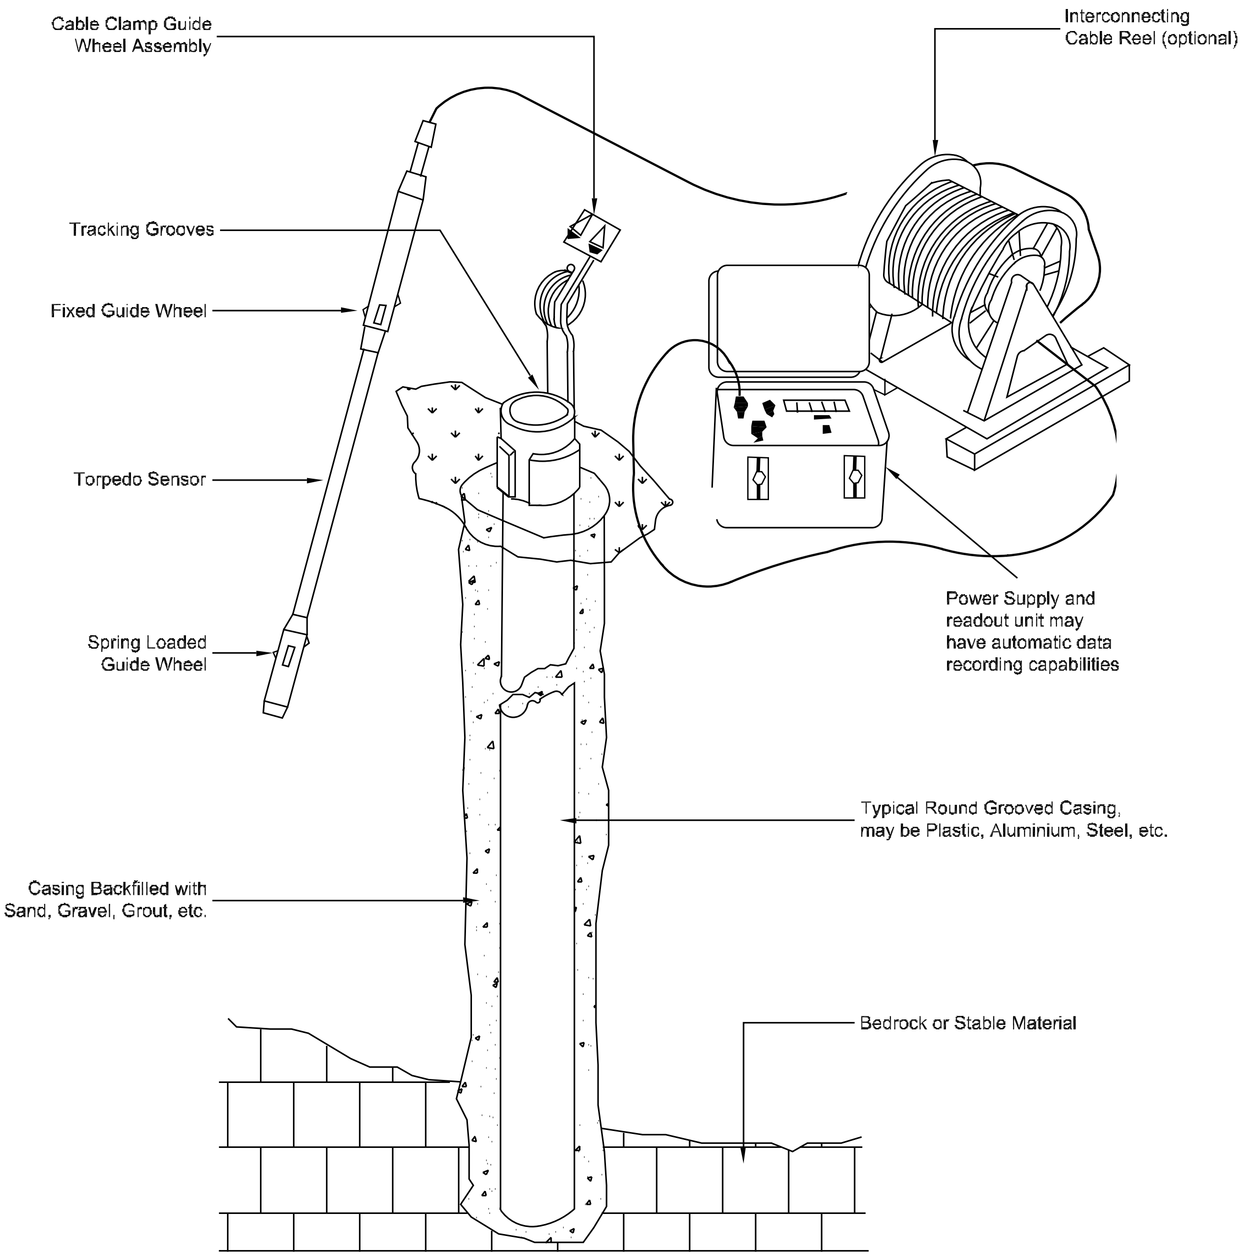

Figure 2—Typical Slope Inclinometer Installation and Monitoring Equipment

8. MONITORING WITH THE ACCELEROMETER-TYPE SENSOR

8.1. *Description*:

8.1.1. The accelerometer-type inclinometer sensor differs somewhat from the typical instrument in that it usually has a smaller outside diameter between the two-wheel assemblies. Separated by a distance of usually 610 mm (24 in.), each assembly may consist of two fixed wheels, 90 degrees apart, and a spring-loaded wheel on the opposite side of the probe (135 degrees from either of the fixed wheels). Sometimes only one fixed wheel and one spring-loaded wheel mounted 180 degrees apart are used in each assembly. The lower wheel assembly is free to rotate approximately 5 degrees to accommodate irregularities in the casing. The angle of inclination is determined from a readout unit that may relate a geometric function of the angle of inclination to a current obtained from one or two servo-accelerometers in the probe. The data is normally stored on a computer chip in the readout device to allow for upload to a computer for data reduction and analysis.

8.2. *Operation*:

8.2.1. The operating technique starts with a visual check of the O-ring seal to ensure water tightness in the cable connector after the components are assembled. A quick calibration to ensure that the unit is functional is completed by placing the probe into the borehole in a specified groove, taking a reading, and then placing the probe in the opposite groove and taking a reading. Disregarding the sign, the two readings should be within 20 dial units of each other. After this check, the probe is lowered to the bottom of the borehole to begin incremental readings. Care should be taken not to bump the inclinometer probe at the bottom of the casing. The probe should be allowed time to equilibrate for about 5 minutes at the bottom of the casing before taking the first set of readings. Through the use of a switch on the readout unit, readings can be taken both in the plane through the spring-loaded wheel and perpendicular to it, thus reducing the number of times the inclinometer must traverse the casing. To reduce irregularities, a second series of readings is taken with the probe rotated 180 degrees from the first position.

8.3. *Maintenance*:

8.3.1. Certain maintenance must be performed to keep the unit operable. The connector between the inclinometer and the electrical cable should be kept free of water and dirt (as for all electrical contacts). The condition of the O-ring in the connector should be checked regularly since water-filled casings create large pressure heads acting against it. Three power sources are usually permitted: (a) internal battery, (b) external battery, and (c) a/c power. The internal batteries are usually a rechargeable type that must be replaced periodically. Any additional recommendations by the equipment manufacturer should also be followed.

PART III—DATA COMPUTATIONS AND ANALYSIS

9. PROCEDURES

9.1. The casing is usually assumed to be vertical for the first set of readings. All subsequent readings are compared to this initial or index set of readings.

9.2. Refer to the individual manufacturer's operating manual for recording data, and data reduction. The procedure of data reduction recommended by most manufacturers involves a summation of readings in opposite direction and then multiplication by a calibration factor to obtain the deflection of the casing from vertical. Subsequent readings are compared to initial readings to obtain change of inclination at any depth.

10. DATA SHEET

10.1. The typical data sheet usually contains columns for the individual readings, the initial difference, the subsequent reading difference, the change, and accumulated change. Refer to the manufacturer's operation manual.

11. PLOTTING DATA

11.1. The slope inclinometer movement is usually plotted as a time plot of the accumulated deflection versus depth. The computer program can be used efficiently to plot rate, magnitude, depth, and direction of movement, although the data is easily plotted by hand. Follow the manufacturer's operating manual for instructions.

Standard Specification for

Preservatives and Pressure Treatment Processes for Timber

AASHTO Designation: M 133-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Preservatives and Pressure Treatment Processes for Timber

AASHTO Designation: M 133-10

---

1. SCOPE

1.1. This specification covers the wood preservatives, the preservative treatment processes, the results of treatment, the inspection and testing of preservatives and of treatment, and the identification of properly treated timber.

---

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

2.4. *International Code Council–Evaluation Service, Inc. (ICC–ES)*:

- AC326, Acceptance Criteria for Proprietary Wood Preservative Systems–Common Requirements for Treatment Process, Test Methods and Performance

3. GENERAL REQUIREMENTS

3.1. Standards of the American Wood-Preservers' Association (AWPA) and specified commercial standards are incorporated herein by reference. Attention is called to the fact that all preservatives are not equally effective on all species of wood or under all conditions of exposure. The engineer preparing the plans and specifications should select the type of preservatives, retentions, and species best suited for his purpose and conditions.

3.2. International Code Council Evaluation Service, Inc. (ICC-ES) requirements and specified commercial standards are incorporated herein by reference. Treated wood product reports issued by the ICC-ES as Evaluation Service Reports (ESRs) must be current as posted on the ICC-ES website www.icc-es.org and in compliance with AC326. The treated wood product's report must allow for the end-use that is required by the project specifications.

4. TIMBER QUALITY

4.1. The properties of the timber selected for preservative treatment shall conform to the requirements of M 168.

5. PRESERVATIVE QUALITY

5.1. The following named preservatives are acceptable in this specification. The properties shall be those set forth in the referenced AWPA Standards:

5.1.1. *Creosote*—P 1/P 13.

5.1.2. *Creosote-Coal Tar Solution*—P 2.

5.1.3. *Creosote-Petroleum Solution*—P 3.

5.1.4. *Petroleum for Blending with Creosote*—P 4.

5.1.5. *Pentachlorophenol*—P 8.

5.1.6. *Solvents Used in Pentachlorophenol Solutions*—P 9.

5.1.7. *Acid Copper Chromate*—P 5.

5.1.8. *Ammoniacal Copper Zinc Arsenate*—P 5.

5.1.9. *Chromated Copper Arsenate, Type C*—P 5.

5.1.10. *Ammoniacal Copper Quat, Type B*—P 5.

5.1.11. *Copper Naphthenate*—P 8.

5.1.12. *Alkali Copper Quat, Type C*—P 5.

5.1.13. *Copper Azole, Type A (CBA-A)—P 5.*

5.1.14. *Copper Azole, Type B (CA-B)*—P 5.

5.1.15. *Alkaline Copper Quat, Type D*—P 5.

5.1.16. *Copper Azole, Type C (CA-C)*—P 5.

5.1.17. *Propiconazole Tebuconazole Imidacloprid (PTI)*—P 5.

5.2. The following preservative systems are acceptable by means of a published and current ICC-ES Report (ESR) and are in compliance with AC326.

5.2.1. Micronized Copper Quaternary.

5.2.2. Micronized Copper Azole.

5.2.3. Dispersed Copper Azole Type C (μCA-C).

6. PRESERVATIVE TREATMENT PROCESSES AND RESULTS

6.1. Wood products shall be treated in accordance with the ICC-ES Evaluation Report or AWPA Standard U1–Use Category System: User Specification for Treated Wood. A Use Category appropriate for the application shall be established in accordance with Standard U1 Sections 2 and 3. Specific requirement for various commodities can then be found in Section 6.

6.1.1. *Sawn Products*—U1, Section 6, Commodity Specification A (Includes all sawn posts and lumber).

6.1.2. *Round Timber Piling*—U1, Section 6, Commodity Specification E.

6.1.3. *Round Poles*—U1, Section 6, Commodity Specification D (16 feet or longer).

6.1.4. *Round Posts*—U1, Section 6, Commodity Specification B (Less than 16 feet long).

6.1.5. *Wood Composites*—U1, Section 6, Commodity Specification F (includes plywood).

6.2. Field treatment of cuts, holes and injuries to treated wood products shall be in accordance with AWPA Standard M4.

7. INSPECTION AND MARKING

7.1. Treatment shall conform to the quality requirements described in the ICC-ES Evaluation Report or AWPA M3–Standard Quality Control Procedures for Wood Preserving Plants. The wood treater shall apply to each piece of treated timber a legible brand, mark or tag indicating the name of the treater and the specification symbol or specification requirements to which the treatment conforms. Acceptable symbols of compliance shall be similar to brands listed in AWPA M6, or as provided for in the plans or special provisions.

7.2. The engineer shall be provided adequate facilities and free access to the necessary parts of the treating plant for inspection of material, workmanship, and treating processes, to determine that the contract requirements are met. Inspection of the treatment and products shall conform to the requirements of AWPA M2–*Standard for Inspection of Wood Products Treated with Preservatives*. The engineer reserves the right to retest all materials after delivery to the job site and to reject all materials that do not meet the requirements of the contract. Reinspection at the job site may include assay to determine retention of preservatives and extraction and analysis of preservative to determine its quality.

8. METHODS OF SAMPLING AND TESTING

8.1. The sampling and testing of wood preservatives shall be in accordance with the following standard methods of the American Association of State Highway and Transportation Officials (AASHTO), the American Society for Testing Materials (ASTM), and the American Wood-Preservers' Association (AWPA):

8.1.1. *Sampling Wood Preservatives*—AWPA A4.

8.1.2. *Specific Gravity at 38/15.5°C of Creosote Solution*—AWPA A1.

8.1.3. *Water in Creosote*—AWPA A1.

8.1.4. *Insoluble Matter in Creosote*—AWPA A1.

8.1.5. *Distillation of Creosote*—AASHTO T 62; AWPA A1.

8.1.6. *Tar Acids in Creosote and Creosote-Coal Tar Solutions*—ASTM D 453.

8.1.7. *Specific Gravity of Petroleum*—ASTM D 287.

8.1.8. *Flash Point of Petroleum (Pensky-Martens)*—AASHTO T 73.

8.1.9. *Viscosity, Saybolt*—AASHTO T 72.

8.1.10. *Analysis of Water-Borne Preservatives*—AWPA A2.

8.1.11. *Analysis of Oil-Borne Preservatives*—AWPA A5.

8.1.12. *Chromium, Copper, Arsenic and Zinc in Water-borne Preservatives by X-ray*—AWPA A9, by ICP—AWPA A21, by AA—AWPA A11.

8.1.13. *Naphthenic Acid in Copper Naphthenate*—AWPA A13.

8.1.14. *Water-Extractable Copper in Copper Naphthenate*—AWPA A14

8.1.15. *Quaternary Compounds in ACQ Preservative or Micronized Copper Quaternary*—AWPA A18 or A37.

8.1.16. *Propiconazole and Tebuconazole in Waterborne Preservatives by HPLC*—AWPA A28.

8.1.17. *Azoles in Waterborne Preservatives and Wood by Gas Chromatography (GC)*—AWPA A31.

8.1.18. *Imidacloprid in Waterborne Preservatives and Wood by HPLC*—AWPA A43.
Wood Densities for Preservative Retention Calculations—AWPA A12.

8.1.19. *Standard for Wet Ashing Procedures for Preparing Wood for Chemical Analysis*—AWPA A7.

Standard Specification for

Wood Products

AASHTO Designation: M 168-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Wood Products

AASHTO Designation: M 168-07

1. SCOPE

1.1. This specification provides a compilation of specifications covering commercial grades and species of lumber and other wood products for highway construction as indicated below. More detailed requirements will be found in the various specifications cited for specific products.

1.1.1. Lumber,

1.1.2. Structural-Glued Laminated Timber,

1.1.3. Piling,

1.1.4. Posts, and

1.1.5. Structural Composite Lumber.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

3. DEFINITIONS

3.1. *board*—lumber that is less than 38 mm standard (2 in. nominal) thickness and greater than 38 mm standard (2 in. nominal) width. Boards less than 140 mm standard (6 in. nominal) width are sometimes called strips.

3.2. *dimension*—lumber with a thickness from 38 mm standard (2 in. nominal) up to but not including 114 mm standard (5 in. nominal) and a width of greater than 38 mm standard (2 in. nominal).

3.3. *dressed lumber*—lumber that has been planed (surfaced).

3.4. *factory and shop lumber*—lumber intended to be cut up for use in further manufacture. It is graded on the percentage of the area that will produce a limited number of cuttings of a specified minimum size and quality.

3.5. *lumber grade*—quality designation of lumber established in accordance with established grading rules developed and adopted by grading rules-writing agencies, which is certified by either the American Lumber Standards Committee Board of Review or a nationally recognized equivalent system.

3.6. *grading rules-writing agency*—organizations that write and publish grading rules for lumber based upon NIST PS 20 guidelines and that are accredited by the American Lumber Standard Committee Board of Review or nationally recognized equivalent system.

3.7. *hardwood*—generally, one of the commercial species groups or one of the botanical groups of trees that have vessels or pores and broad leaves, in contrast to the conifers or softwoods. The term has no reference to actual hardness of the wood.

3.8. *heartwood*—the wood extending from the pith to the sapwood, the cells of which no longer participate in the life process of the tree. Heartwood may contain phenolic compounds, gums, resins, and other materials that usually make it darker and more decay resistant than sapwood.

3.9. *lumber*—the product of the saw and planing mill for which manufacturing is limited to sawing, resawing, passing lengthwise through a standard planing machine, crosscutting to length, and matching. Lumber may be made from either softwood or hardwood.

3.10. *nominal size*—as applied to timber or lumber, the size by which it is known and sold in the market (often differs from actual size).

3.11. *rough lumber*—lumber that has not been dressed (surfaced) but has been sawed, edged, and trimmed.

3.12. *softwood (conifers)*—generally, one of the botanical groups of trees that have a needlelike or scalelike leaves.

3.13. *structural composite lumber*—lumber that is a reconstituted (manufactured) lumber product for structural applications, which is either laminated veneer lumber or parallel strand lumber bonded with an exterior adhesive.

3.14. *structural-glued laminated timber*—an engineered, stress-rated product of a timber laminating plant, comprising assemblies of specially selected and prepared wood laminations securely bonded together with adhesives. The grain of all laminations is approximately parallel longitudinally. The laminations may be composed of pieces end joined to form any length, of pieces placed or bonded edge to edge to make any width, or of pieces bent to curved form during bonding.

3.15. *stress graded lumber*—lumber that has been graded based upon grading rules developed, adopted, and published by grading rules-writing agencies that have been certified by the American Lumber Standards Committee Board of Review or equivalent system; or lumber having assigned working stresses and modulus of elasticity values in accordance with accepted basic principles of strength grading, and the provisions on NIST Voluntary Product Standard PS 20.

3.16. *structural lumber*—lumber that is intended for use where allowable properties are required. The structural lumber grade is based on the strength or stiffness of the piece as related to anticipated use.

3.17. *timber*—lumber that is standard 114 mm (nominal 5 in.) or more in the least dimension.

3.18. *yard lumber*—a little-used term for lumber of all sizes and patterns that is intended for general building purposes having no design property requirements.

3.19. *worked lumber*—lumber that has been dressed, matched, shiplapped, and/or patterned.

4. CLASSIFICATION

4.1. *Species of Wood*:

4.1.1. The standard commercial and botanical names of the species of wood recognized in the specification are as described in ASTM D 1165.

4.1.1.1. Some species may be covered under more than one set of grading rules. In such cases, the applicable grading rules shall be as specified in the contract.

4.1.1.2. Some grading rules provide for the inclusion of additional species under the established commercial name of the lumber.

4.1.2. *Limitation of Use*:

4.1.2.1. Wood for structural purposes shall not be used in exposed permanent structures without pressure impregnation of a preservative in accordance with M 133.

4.1.2.2. The heartwood of the following species is high in decay resistance and, when specified, may be used without preservative treatment:

Softwoods	Hardwoods
Bold Cypress, old growth	Chestnut
Cedar	Locust, Black
Juniper	Oak, White
Redwood, old growth	Osage, Orange
Yew, Pacific	Walnut, Black

4.2. *Hardwoods*:

4.2.1. *Grading*—Lumber from hardwood species shall be graded in accordance with grading rules that conform to the basic provision of NIST PS 20 and that are developed, adopted, and published by grading rules-writing agencies that are certified by the American Lumber Standards Committee Board of Review or nationally recognized equivalent system.

4.2.1.1. Hardwood lumber, which is intended for structural use with design stress, shall be stress graded lumber that is graded in conformance with nationally accepted standards such that the lumber will meet the required stress values listed in Section 13.2 Division I of the *AASHTO Standard Specification for Highway Bridges* or in Section 8.4 of the *AASHTO LRFD Bridge Design Specifications*.

4.2.2. *Classification*—Hardwood lumber shall be classified and stress graded marked according to the use, manufacturing, and size classification listed in NIST PS 20 as outlined below.

4.2.2.1. Use classification shall be Yard Lumber, Structural Lumber, and Factory and Shop Lumber.

4.2.2.2. Manufacturing classification shall be Rough Lumber, Dressed (Surfaced) Lumber, and Worked Lumber.

4.2.2.3. Size classification shall be Nominal Size Designations of Boards, Dimension, and Timbers; Rough Dry Sizes; and Dressed Sizes.

4.2.3. *Stress Grading*—As appropriate, either ASTM D 245, ASTM D 1990, ASTM D 2555, or ASTM D 6570 and/or other equivalent nationally recognized technical standards shall be used to develop working stress and modulus of elasticity values for Stress Graded Structural Lumber.

4.2.3.1. Design values developed by grading rules agencies may be used provided they were developed in accordance with nationally accepted standards. The purchaser may request a report from the rules writing agency explaining how the design values of working stress and modulus of elasticity were derived.

4.3. *Softwoods*:

4.3.1. *Grading*—Lumber from softwood species shall be graded in accordance with grading rules that conform to the basic provisions of NIST PS 20 and are developed, adopted, and published by grading rules-writing agencies that are certified by the American Lumber Standards Committee Board of Review or a nationally recognized equivalent system.

4.3.1.1. Softwood lumber, which is intended for structural use with design stress, shall be stress graded lumber that is graded in conformance with nationally accepted standards such that the lumber will meet the required stress values listed in Section 13.2 Division I of the *AASHTO Standard Specifications for Highway Bridges* or in Section 8.4 of the *AASHTO LRFD Bridge Design Specifications.*

4.3.2. *Classification*—Softwood lumber shall be classified and stress-grade marked according to the use, manufacturing, and size classifications listed in NIST PS 20 as outlined below.

4.3.2.1. Use classifications shall be Yard Lumber, Structural Lumber, and Factory and Shop Lumber.

4.3.2.2. Manufacturing classifications shall be Rough Lumber, Dressed (Surfaced) Lumber, and Worked Lumber.

4.3.2.3. Size classifications shall be Nominal Size Designations of Boards, Dimension, and Timbers; Rough Dry Sizes; and Dressed Sizes.

4.3.3. *Stress Grading*—As appropriate, either ASTM D 425, ASTM D 1990, ASTM D 2555, or ASTM D 6570 and/or other equivalent nationally recognized technical standards shall be used to develop working stress and modulus of elasticity values for Stress Graded Structural Lumber.

4.3.3.1. Design values developed by grading rules agencies may be used provided they were developed in accordance with nationally accepted standards. The engineer may request a report from the rules-writing agency explaining how the design values of working stress and modulus of elasticity were derived.

4.4. *Structural Composite Lumber*:

4.4.1. The ASTM D 5456 or equivalent nationally recognized standard shall be used to develop working stresses and modulus values for Structural Composite Lumber; however, the values shall not be less than the minimum values as specified by the *AASHTO Standard Specifications for Highway Bridges* or *AASHTO LRFD Bridge Design Specifications.*

4.5. *Structural Glued-Laminated Timber*:

4.5.1. ASTM D 3737 or equivalent nationally recognized standard shall be used to develop working stresses and modulus values for Structural Glued-Laminated Lumber; however, the values shall not be less than the minimum values as specified by the *AASHTO Standard Specification for Highway Bridges* or the *AASHTO LRFD Bridge Design Specifications*.

5. PRODUCTS

5.1. *Lumber*:

5.1.1. All lumber shall conform with the applicable softwood or hardwood lumber grading standards. The following requirements shall be specified in the purchase order:

5.1.1.1. The nominal dimensions: thickness, width, and length of each item required;

5.1.1.2. The grade required or the stress-grade rating of lumber required, including any special requirements, such as provisions for heartwood content, freedom from wane, seasoning condition, etc.;

5.1.1.3. Manufacturing classification such as rough, dressed, or worked lumber;

5.1.1.4. The allowable species according to standard commercial name;

5.1.1.5. The name of the agency that will be responsible for grading, inspecting, and grade marking the lumber;

5.1.1.6. The year of issue of the applicable grading rules; and

5.1.1.7. Preservative treatment required.

5.2. *Structural-Glued Laminated Timber*:

5.2.1. Requirements for the dimensions, grade combinations, lumber for laminating, appearance grades, adhesives, and laminating of structural-glued laminated timber as well as inspection and test procedures, marking, and the certification by a qualified inspection and testing agency shall be in conformance with ANSI/AITC A 190.1. Species, grade, and design values for Structural-Glued Laminated Timber shall conform to the *AASHTO Standard Specifications for Highway Bridges* or *AASHTO LRFD Bridge Design Specifications*.

5.3. *Piling*:

5.3.1. Round timber piles shall conform to ASTM D 25.

5.4. *Posts*:

5.4.1. Posts shall be of sound wood, free of decay, excessive knots, and insect attack and shall otherwise conform to the provisions of this specification.

5.4.1.1. *Fence Posts*—Posts shall be preservative-treated in accordance with Section 4.1.2 except where the contract plans permit use of decay-resistant varieties. Posts to be driven shall be machine-pointed prior to treatment.

5.4.1.2. *Guardrail Posts*—Guardrail posts shall be a stress grade of 8.2 MPa (1200 psi) or more, conforming to the applicable standards contained in AASHTO-ARTBA-AGC, *A Standardized*

Guide to Highway Barrier Hardware. When a preservative is required, framing and boring shall be completed prior to treatment in accordance with M 133.

5.4.1.3. *Sign Posts*—Rectangular posts shall be surfaced four sides (S4S), conforming to the provisions of this specification. When a preservative is required, framing and boring shall be completed prior to the treatment in accordance with M 133.

5.5. *Structural Composite Lumber*:

5.5.1. Requirements for grade, adhesives, and laminating of Structural Composite Lumber as well as inspection and test procedures, marking and the certification by a qualified inspection and testing agency shall be in conformance with ASTM D 5456. Species, grades, and design values for Structural Composite Lumber shall conform to the *AASHTO Standard Specifications for Highway Bridges* or the *AASHTO LRFD Bridge Design Specifications*.

As an aid to the user of this volume, the following tabulation shows equivalencies between AASHTO and ASTM specifications. Where an asterisk (*) follows the ASTM number, there is a difference between the two specifications. These differences are explained in the endnote accompanying each individual specification.

AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS

EXECUTIVE COMMITTEE
2009–2010

President: Larry L. “Butch” Brown, Sr., Mississippi
Vice President: Susan Martinovich, P.E., Nevada
Secretary/Treasurer: Carlos Braceras, Utah

Regional Representatives:

Region I	Joseph Marie, Connecticut, One-Year Term Gabe Klein, District of Columbia, Two-Year Term
Region II	Dan Flowers, Arkansas, One-Year Term Mike Hancock, Kentucky, Two-Year Term
Region III	Nancy J. Richardson, Iowa, One-Year Term Thomas K. Sorel, Minnesota, Two-Year Term
Region IV	Paula Hammond, Washington, One-Year Term Amadeo Saenz, Jr., Texas, Two-Year Term

Immediate Past President: Allen Biehler, P.E., Pennsylvania
Executive Director: John C. Horsley, Washington, DC

AMERICAN ASSOCIATION OF STATE HIGHWAY AND TRANSPORTATION OFFICIALS

HIGHWAY SUBCOMMITTEE ON MATERIALS

2009–2010

Grant Levi, NORTH DAKOTA, Chairman
Mark Felag, RHODE ISLAND, Vice Chairman
Jack Springer, FHWA, Secretary

ALABAMA
Larry Lockett, Materials and Tests Engineer, Alabama Department of Transportation
3700 Fairground Road
Montgomery, AL 36110

Lynn Wolfe, Testing Engineer

ALASKA
Michael San Angelo, State Materials Chief Materials Engineer, Alaska Department of Transportation and Public Facilities
5800 E. Tudor Road
Anchorage, AK 99507-1286

R. Scott Gartin, State Quality Assurance Engineer

ARIZONA
James Delton, Assistant State Engineer, Materials Group, Arizona Department of Transportation
1221 North 21st Avenue
Phoenix, AZ 85007

Paul Burch, Quality Assurance Engineer

Julie Kliewer, District Engineer, Phoenix Construction

ARKANSAS
Michael Benson, Engineer of Materials Division, Arkansas State Highway and Transportation Department
P.O. Box 2261
Little Rock, AR 72203

Emanuel Banks, Assistant Chief Engineer, Operations

Ralph J. Hall, Assistant to the Director

CALIFORNIA
Phil Stolarski, Division of Materials Engineering and Testing Services, California Department of Transportation
5900 Folsom Boulevard
Sacramento, CA 95819-4612

COLORADO
Jim Zufall, Materials and Geotechnical Branch Manager, Colorado Department of Transportation
4670 Holly Street, Unit A
Denver, CO 80216-6408

CONNECTICUT
Ravi V. Chandran, Director of Research and Materials, Connecticut Department of Transportation
280 West Street
Rocky Hill, CT 06067-3502

Wayne Blair, Assistant Director of Materials Testing

DELAWARE
James T. Pappas, III, Chief Materials and Research Engineer, Delaware Department of Transportation
P.O. Box 778
Dover, DE 19903-0778

Maureen Kelley, Geotechnical Engineer

DISTRICT OF COLUMBIA
Wasi U. Khan, Chief, QA/QC Materials Division, District of Columbia Department of Transportation
2000 14th Street, N.W., Room N-401
Washington, DC 20009

FLORIDA
Thomas O. Malerk, Director, Office of Materials, Florida Department of Transportation
5007 N.E. 39th Avenue
Gainesville, FL 32609-2604

GEORGIA
Georgene M. Geary, State Materials and Research Administrator, Georgia Department of Transportation
15 Kennedy Drive
Forest Park, GA 30297

Richard Douds, Office of Materials and Research

Donald Wishon, Project Review Engineer

HAWAII
JoAnne Nakamura, Bituminous Engineer, Materials Testing and Research Branch, Hawaii Department of Transportation
2530 Likelike Highway
Honolulu, HI 96819

Gerry Carnate, Structural Materials Engineer

IDAHO
Jeff Miles, Materials Engineer, Idaho Transportation Department
P.O. Box 7129
Boise, ID 83707-1129

ILLINOIS
David L. Lippert, Chief of Materials and Physical Research, Illinois Department of Transportation
126 E. Ash Street
Springfield, IL 62704-4766

Matt Mueller, Engineer of Tests

INDIANA
Ronald P. Walker, Chief, Division of Materials and Tests, Indiana Department of Transportation
120 S. Shortridge Road
Indianapolis, IN 46219

IOWA
James Berger, Director, Office of Materials, Iowa Department of Transportation
800 Lincoln Way
Ames, IA 50010

KANSAS
Richard E. Kreider Jr., Chief, Bureau of Materials and Research, Kansas Department of Transportation
Dwight D. Eisenhower State Office Building, 700 S.W. Harrison Street
Topeka, KS 66603-3754

KENTUCKY
William Broyles, Director, Division
of Materials, Kentucky
Transportation Cabinet
1227 Wilkinson Boulevard
Frankfort, KY 40601-1226

Allen H. Myers, Asphalt Branch
Manager

LOUISIANA
Luanna Cambas, Materials Engineer
Administrator, Louisiana Department
of Transportation and Development
5080 Florida Boulevard
Baton Rouge, LA 70806

MAINE
Bruce A. Yeaton, Testing Engineer,
Maine Department of Transportation
16 State House Station
Augusta, ME 04333-0016

MARYLAND
Timothy E. Smith, Director, Office of
Materials and Technology, Maryland
State Highway Administration
7450 Traffic Drive, Building #4
Hanover, MD 21076

Woodrow L. Hood, Materials
Management Division Chief

Mark Wolcott, Deputy Director, Office
of Materials Technology

MASSACHUSETTS
John E. Grieco, Director of Research
and Materials, Massachusetts
Department of Transportation,
400 D Street
South Boston, MA 02110

MICHIGAN
John F. Staton, Materials Engineer,
Construction and Technology Division,
Michigan Department of Transportation
8885 Ricks Road,
P.O. Box 30049
Lansing, MI 48909

MINNESOTA
Keith L. Shannon, Director, Office of
Materials and Road Research,
Minnesota Department
of Transportation
1400 Gervais Avenue, Mailstop 645
Maplewood, MN 55109

Curt Turgeon, Pavement Engineer

MISSISSIPPI
James A. Williams, State Materials
Engineer, Mississippi Department of

Revisions for 30th Edition of Standard Specifications for Transportation Materials and Methods of Sampling and Testing—Part 1

The balloted technical changes listed below are also indicated in the specifications by a change bar in the left margin. Non-balloted editorial changes do not receive the change bar.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
M 20-70 (2004)	Penetration-Graded Asphalt Cement	2b	Deleted in 2009.
M 31M/M 31-10	Deformed and Plain Carbon-Steel Bars for Concrete Reinforcement	4g	Revised to maintain equivalency with ASTM A 615/A 615M-09.
M 43-05 (2009)	Sizes of Aggregate for Road and Bridge Construction	1c	Reconfirmed in 2009.
M 91-10	Sewer and Manhole Brick (Made from Clay or Shale)	4a	Updated to agree with ASTM C 32-09.
M 92-10	Wire-Cloth Sieves for Testing Purposes	1b	Updated to agree with ASTM E 11-09.
M 114-10	Building Brick (Solid Masonry Units Made from Clay or Shale)	4a	Updated to agree with ASTM C 62-08.
M 133-10	Preservatives and Pressure Treatment Processes for Timber	4c	Revised to include additional preservatives.
M 148-05	Liquid Membrane-Forming Compounds for Curing Concrete	3b	Discontinued in 2009.
M 156-97 (2009)	Requirements for Mixing Plants for Hot-Mixed, Hot-Laid Bituminous Paving Mixtures	2c	Reconfirmed in 2009.
M 160M/M 160-08	General Requirements for Steel Plates, Shapes, Sheet Piling, and Bars for Structural Use	4f	Discontinued in 2009.
M 164-05 (2008)	High-Strength Bolts for Structural Steel Joints	4f	Discontinued in 2009.
M 164M-06	High-Strength Bolts for Structural Steel Joints [Metric]	4f	Discontinued in 2009.
M 170-10	Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe	4a	Revised.
M 170M-10	Reinforced Concrete Culvert, Storm Drain, and Sewer Pipe [Metric]	4a	Revised.
M 171-05	Sheet Materials for Curing Concrete	3b	Discontinued in 2009.
M 175M/M 175-05 (2009)	Perforated Concrete Pipe	4a	Reconfirmed in 2009.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
M 181-10	Chain-Link Fence	4d	Revised.
M 182-05 (2009)	Burlap Cloth Made from Jute or Kenaf and Cotton Mats	3b	Reconfirmed in 2009.
M 198-10	Joints for Concrete Pipe, Manholes, and Precast Box Sections Using Preformed Flexible Joint Sealants	4a	Updated to agree with ASTM C 990-09.
M 199M/M 199-10	Precast Reinforced Concrete Manhole Sections	4a	Revised.
M 206M/M 206-10	Reinforced Concrete Arch Culvert, Storm Drain, and Sewer Pipe	4a	Revised.
M 207M/M 207-10	Reinforced Concrete Elliptical Culvert, Storm Drain, and Sewer Pipe	4a	Revised.
M 208-01 (2009)	Cationic Emulsified Asphalt	2a	Reconfirmed in 2009.
M 210-10	Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete	3a	Revised to agree with ASTM C 490-08.
M 213-01 (2010)	Preformed Expansion Joint Fillers for Concrete Paving and Structural Construction (Nonextruding and Resilient Bituminous Types)	4e	Reconfirmed in 2010.
M 216-05 (2009)	Lime for Soil Stabilization	3a	Reconfirmed in 2009.
M 232M/M 232-10	Zinc Coating (Hot-Dip) on Iron and Steel Hardware	4h	Revised to maintain equivalency with ASTM A 153/A 153M-09.
M 237-96 (2009)	Epoxy Resin Adhesives for Bonding Traffic Markers to Hardened Portland Cement and Asphalt Concrete	4c	Reconfirmed in 2009.
M 240-10	Blended Hydraulic Cement	3a	Revised to agree with ASTM C 595-09.
M 253-05 (2008)	Structural Bolts, Alloy Steel, Heat-Treated, 150 ksi Minimum Tensile Strength	4f	Discontinued in 2009.
M 253M-05	High-Strength Steel Bolts, Classes 10.9 and 10.9.3, for Structural Steel Joints [Metric]	4f	Discontinued in 2009.
M 261-96 (2009)	Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests	5a	Reconfirmed with editorial corrections in 2009.
M 262-10	Concrete Pipe and Related Products	4a	Revised.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
M 268-10	Retroreflective Sheeting for Flat and Vertical Traffic Control Applications	4d	Revised extensively.
M 270M/M 270-10	Structural Steel for Bridges	4f	Revised to maintain equivalency with ASTM A 709/A 709M-09a.
M 286-96 (2009)	Smooth-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests	5a	Reconfirmed with editorial corrections in 2009.
M 291M-07	Carbon and Alloy Steel Nuts [Metric]	4f	Discontinued in 2009.
M 292M/M 292-10	Carbon and Alloy Steel Nuts for Bolts for High-Pressure or High-Temperature Service, or Both	4f	Revised to maintain equivalency with ASTM A 194/A 194M-09.
M 293-10	Hardened Steel Washers	4f	Revised to maintain equivalency with ASTM F 436-09.
M 293M-06	Hardened Steel Washers [Metric]	4f	Discontinued in 2009.
M 294-10	Corrugated Polyethylene Pipe, 300- to 1500-mm (12- to 60-in.) Diameter	4b	Revised, based on NCHRP Report 631.
M 297-10	Preformed Polychloroprene Elastomeric Joint Seals for Bridges	4e	Revised to maintain equivalency with ASTM D 3542-08.
M 298-10	Coatings of Zinc Mechanically Deposited on Iron and Steel	4h	Updated to agree with ASTM B 695-04 (2009).
M 299-10	Coatings of Cadmium Mechanically Deposited	4h	Updated to agree with ASTM B 696-00 (2009).
M 304-10	Poly(Vinyl Chloride) (PVC) Profile Wall Drain Pipe and Fittings Based on Controlled Inside Diameter	4b	Revised, based on NCHRP Report 631.
M 306-10	Drainage, Sewer, Utility, and Related Castings	4h	Revised according to task force recommendations.
M 320-10	Performance-Graded Asphalt Binder	2b	Revised extensively.
M 322M/M 322-10	Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement	4g	Revised to maintain equivalency with ASTM A 996/A 996M-09.

Designation Number	Title	Technical Section Number	2009 Ballot Revision
M 328-10	Inertial Profiler	5a	Revised and adopted MP 11-08 as M 328-10.
R 4-97 (2009)	Statistical Procedures	5c	Reconfirmed in 2009.
R 9-05 (2009)	Acceptance Sampling Plans for Highway Construction	5c	Reconfirmed in 2009.
R 18-10	Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories	AMRL	Revised extensively.
R 25-00 (2009)	Technician Training and Qualification Programs	5c	Reconfirmed in 2009.
R 26-01 (2009)	Certifying Suppliers of Performance-Graded Asphalt Binders	2b	Reconfirmed in 2009.
R 38-10	Quality Assurance of Standard Manufactured Materials	5c	Revised to reference R 18.
R 40-10	Measuring Pavement Profile Using a Rod and Level	5a	Revised.
R 48-10	Determining Rut Depth in Pavements	5a	Revised.
R 51-10	Compost for Erosion/Sediment Control (Filter Berms and Filter Socks)	1a	Revised and adopted MP 9 as R 51-10.
R 52-10	Compost for Erosion/Sediment Control (Compost Blankets)	1a	Revised and adopted MP 10 as R 52-10.
R 53-10	Qualification of Deformed and Plain Reinforcing Steel Bar, Welded Wire, and Wire Producing Mills	4g	Adopted PP 45-07 as R 53-10.
R 54-10	Accepting Pavement Ride Quality When Measured Using Inertial Profiling Systems	5a	Revised and adopted MP 17 as R 54-10.
R 55-10	Quantifying Cracks in Asphalt Pavement Surfaces	5a	Revised and adopted PP 44-01 (2008) as R 55-10.
R 56-10	Certification of Inertial Profiling Systems	5a	Revised and adopted PP 49-08 as R 56-10.
R 57-10	Operating Inertial Profiling Systems	5a	Revised and adopted PP 50-07 as R 57-10.

Standard Method of Test for

Sampling of Aggregates

AASHTO Designation: T 2-91 (2006)
ASTM Designation: D 75-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling of Aggregates

AASHTO Designation: T 2-91 (2006)
ASTM Designation: D 75-03

AASHTO T 2-91 (2006) is identical to ASTM D 75-03 except that all references to ASTM C 702 contained in ASTM D 75-03 shall be replaced with T 248 in T 2.

Standard Method of Test for

Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing

AASHTO Designation: T 11-05 (2009)[1]
ASTM Designation: C 117-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing

AASHTO Designation: T 11-05 (2009)[1]
ASTM Designation: C 117-04

1. SCOPE

1.1. This test method covers determination of the amount of material finer than a 75-µm (No. 200) sieve in aggregate by washing. Clay particles and other aggregate particles that are dispersed by the wash water, as well as water-soluble materials, will be removed from the aggregate during the test.

1.2. Two procedures are included, one using only water for the washing operation, and the other including a wetting agent to assist the loosening of the material finer than the 75-µm (No. 200) sieve from the coarser material. Unless otherwise specified, Procedure A (water only) shall be used.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standards*:
- C 117, Standard Test Method for Materials Finer than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SUMMARY OF METHOD

3.1. A sample of the aggregate is washed in a prescribed manner, using either plain water or water containing a wetting agent, as specified. The decanted wash water, containing suspended and dissolved material, is passed through a 75-µm (No. 200) sieve. The loss in mass resulting from the wash treatment is calculated as mass percent of the original sample and is reported as the percentage of material finer than a 75-µm (No. 200) sieve by washing.

4. SIGNIFICANCE AND USE

4.1. Material finer than the 75-µm (No. 200) sieve can be separated from larger particles much more efficiently and completely by wet sieving than through the use of dry sieving. Therefore, when accurate determinations of material finer than 75 µm in fine or coarse aggregate are desired, this test method is used on the sample prior to dry sieving in accordance with T 27. The results of this test method are included in the calculation in T 27, and the total amount of material finer than 75 µm by washing, plus that obtained by dry sieving the same sample, is reported with the results of T 27. Usually the additional amount of material finer than 75 µm obtained in the dry-sieving process is a small amount. If it is large, the efficiency of the washing operation should be checked. A large amount of material could also be an indication of the degradation of the aggregate.

4.2. Plain water is adequate to separate the material finer than 75 µm from the coarser material with most aggregates. In some cases, the finer material is adhering to the larger particles, such as some clay coatings and coatings on aggregates that have been extracted from bituminous mixtures. In these cases, the fine material will be separated more readily with a wetting agent in the water.

5. APPARATUS AND MATERIALS

5.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

5.2. *Sieves*—A nest of two sieves, the lower being a 75-µm (No. 200) sieve and the upper being a sieve with openings in the range of 2.36-mm (No. 8) to 1.18-mm (No. 16), both conforming to the requirement of M 92.

5.3. *Container*—A pan or vessel of a size sufficient to contain the sample covered with water and to permit vigorous agitation without loss of any part of the sample or water.

5.4. *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5ºC (230 ± 9ºF).

5.5. *Wetting Agent*—Any dispersing agent, such as liquid dishwashing detergents, that will promote separation of the fine materials.

Note 1—The use of a mechanical apparatus to perform the washing operation is not precluded, provided the results are consistent with those obtained using manual operations. The use of some mechanical washing equipment with some samples may cause degradation of the sample.

6. SAMPLING

6.1. Sample the aggregate in accordance with T 2. If the same test sample is to be tested for sieve analysis according to T 27, comply with the applicable requirements of that method.

6.2. Thoroughly mix the sample of aggregate to be tested and reduce the quantity to an amount suitable for testing using the applicable methods described in T 248. If the same test sample is to be tested according to T 27, the minimum mass shall be as described in the applicable sections of that method. Otherwise, the mass of the test sample, after drying, shall conform with the following:

Nominal Maximum Size	Minimum Mass, g
4.75 mm (No. 4) or smaller	300
9.5 mm ($^3/_8$ in.)	1000
19.0 mm ($^3/_4$ in.)	2500
37.5 mm (1$^1/_2$ in.) or larger	5000

The test sample shall be the end result of the reduction. Reduction to an exact predetermined mass shall not be permitted. If the nominal maximum size of the aggregate to be tested is not listed above, the next larger size listed shall be used to determine sample size.

7. SELECTION OF PROCEDURE

7.1. Procedure A shall be used, unless otherwise specified by the specification with which the test results are to be compared, or when directed by the agency for which the work is performed.

8. PROCEDURE A—WASHING WITH PLAIN WATER

8.1. Dry the test sample to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF). Determine the mass to the nearest 0.1 percent of the mass of the test sample.

8.2. If the applicable specification requires that the amount passing the 75-µm (No. 200) sieve shall be determined on a portion of the sample passing a sieve smaller than the nominal maximum size of the aggregate, separate the sample on the designated sieve and determine the mass of the material passing the designated sieve to 0.1 percent of the mass of this portion of the test sample. Use this mass as the original dry mass of the test sample in Section 10.1.

Note 2—Some specifications for aggregates with a nominal maximum size of 50 mm or greater, for example, provide a limit for material passing the 75-µm (No. 200) sieve determined on that portion of the sample passing the 25.0-mm sieve. Such procedures are necessary since it is impractical to wash samples of the size required when the same test sample is to be used for sieve analysis by T 27.

8.3. After drying and determining the mass, place the test sample in the container and add sufficient water to cover it. No detergent, dispersing agent, or other substance shall be added to the water. Agitate the sample with sufficient vigor to result in complete separation of all particles finer than the 75-µm (No. 200) sieve from the coarser particles, and to bring the fine material into suspension. The use of a large spoon or other similar tool to stir and agitate the aggregate in the wash water has been found satisfactory. Immediately pour the wash water containing the suspended and dissolved solids over the nested sieves, arranged with the coarser sieve on top. Take care to avoid, as much as feasible, the decantation of coarser particles of the sample.

8.4. Add a second charge of water to the sample in the container, agitate, and decant as before. Repeat this operation until the wash water is clear.

Note 3—If mechanical washing equipment is used, the charging of water, agitating, and decanting may be a continuous operation.

Note 4—A spray nozzle or a piece of rubber tubing attached to a water faucet may be used to rinse any of the material that may have fallen onto the sieves. The velocity of water, which may be increased by pinching the tubing or by use of a nozzle, should not be sufficient to cause any splashing of the sample over the sides of the sieve.

8.5. Return all material retained on the nested sieves by flushing to the washed sample. Dry the washed aggregate to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF) and determine the mass to the nearest 0.1 percent of the original mass of the sample.

Note 5—Following the washing of the sample and flushing any materials retained on the 75-µm (No. 200) sieve back into the container, no water should be decanted from the container except through the 75-µm sieve, to avoid loss of material. Excess water from flushing should be evaporated from the sample in the drying process.

9. PROCEDURE B—WASHING USING A WETTING AGENT

9.1. Prepare the sample in the same manner as for Procedure A.

9.2. After drying and determining the mass, place the test sample in the container. Add sufficient water to cover the sample, and add wetting agent to the water (Note 6). Agitate the sample with sufficient vigor to result in complete separation of all particles finer than the 75-µm (No. 200) sieve from the coarser particles, and to bring the fine material into suspension. The use of a large spoon or other similar tool to stir and agitate the aggregate in the wash water has been found satisfactory. Immediately pour the wash water containing the suspended and dissolved solids over the nested sieves, arranged with the coarser sieve on top. Take care to avoid, as much as feasible, the decantation of coarser particles of the sample.

Note 6—There should be enough wetting agent to produce a small amount of suds when the sample is agitated. The quantity will depend on the hardness of the water and the quality of the detergent. Excessive suds may overflow the sieves and carry some material with them.

9.3. Add a second charge of water (without wetting agent) to the sample in the container, agitate, and decant as before. Repeat this operation until the wash water is clear.

9.4. Complete the test as for Procedure A.

10. CALCULATION

10.1. Calculate the amount of material passing a 75-µm (No. 200) sieve by washing as follows:

$$A = \left[(B - C) / B \right] \times 100 \qquad (1)$$

where:

A = percentage of material finer than a 75-µm (No. 200) sieve by washing;

B = original dry mass of sample, g; and

C = dry mass of sample after washing, g.

11. REPORT

11.1. Report the percentage of material finer than the 75-µm (No. 200) sieve by washing to the nearest 0.1 percent, except if the result is 10 percent or more, report the percentage to the nearest whole number.

11.2. Include a statement as to which procedure was used.

12. PRECISION AND BIAS

12.1. *Precision*—The estimates of precision of this test method listed in Table 1 are based on results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by this test method and ASTM C 117. The significant differences between the methods at the time the data were acquired is that T 11 required, and ASTM C 117 prohibited, the use of a wetting agent. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

Table 1—Precision

	Standard Deviation (1s),[a] percent	Acceptable Range of Two Results (d2s),[a] percent
Coarse aggregate:[b]		
Single-operator precision	0.10	0.28
Multilaboratory precision	0.22	0.62
Fine aggregate:[c]		
Single-operator precision	0.15	0.43
Multilaboratory precision	0.29	0.82

[a] These numbers represent the (1s) and (d2s) limits as described in ASTM C 670.

[b] Precision estimates are based on aggregates having a nominal maximum size of 19.0 mm ($^3/_4$ in.) with less than 1.5 percent finer than the 75-μm (No. 200) sieve.

[c] Precision estimates are based on fine aggregates having 1.0 to 3.0 percent finer than the 75-μm (No. 200) sieve.

12.1.1. The precision values for fine aggregate in Table 1 are based on nominal 500-g test samples. Revision of this test method in 1996 permits the fine aggregate test sample size to 300-g minimum. Analysis of results of testing of 300-g and 500-g test samples from Aggregate Proficiency Test Samples 99 and 100 (Samples 99 and 100 were essentially identical) produced the precision values in Table 2, which indicates only minor differences due to test sample size.

Table 2—Precision Data for 300-g and 500-g Test Samples

Fine Aggregate Proficiency Sample				Within Laboratory		Between Laboratory	
Test Result	Sample Size	No. Labs	Avg	1s	d2s	1s	d2s
AASHTO T 11/ASTM C 117 (Total material passing the	500 g	270	1.23	0.08	0.24	0.23	0.66
No. 200 sieve by washing, percent)	300 g	264	1.20	0.10	0.29	0.24	0.68

Note 7—The values for fine aggregate in Table 1 will be revised to reflect the 300-g test sample size when a sufficient number of Aggregate Proficiency Tests have been conducted using that sample size to provide reliable data.

12.2. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is made.

13. KEYWORDS

13.1. Aggregate; size analysis; wash loss; 75μm (No. 200) sieve.

---

[1] Except for Sections 5.1 and 6.2, and Note 4, this test method is identical with ASTM C 117-04.

Standard Method of Test for

Bulk Density ("Unit Weight") and Voids in Aggregate

AASHTO Designation: T 19M/T 19-09
ASTM Designation: C 29/C 29M-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bulk Density ("Unit Weight") and Voids in Aggregate

AASHTO Designation: T 19M/T 19-09
ASTM Designation: C 29/C 29M-07

1. SCOPE

1.1. This test method covers the determination of bulk density ("unit weight") of aggregate in a compacted or loose condition, and calculated voids between particles in fine, coarse, or mixed aggregates based on the same determination. This test method is applicable to aggregates not exceeding 125 mm (5 in.) in nominal maximum size.

Note 1—Unit weight is the traditional terminology used to describe the property determined by this test method, which is weight per unit volume (more correctly, mass per unit volume or density).

1.2. The values stated in either inch-pound units or acceptable metric units are to be regarded separately as standard, as appropriate for a specification with which this test method is used. An exception is with regard to sieve sizes and nominal size of aggregate, in which the metric values are the standard as stated in M 92. Within the text, inch–pound units are shown in brackets. The values stated in each system may not be exact equivalents; therefore, each system must be used independently of the other, without combining values in any way.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *definitions*—definitions are in accordance with ASTM C 125 unless otherwise indicated.

3.1.1. *bulk density, n*—of aggregate, the mass of a unit volume of bulk aggregate material, in which the volume includes the volume of the individual particles and the volume of the voids between the particles. Expressed in kg/m^3(lb/ft^3).

3.1.1.1. *discussion*—units of mass are the kilogram (kg), the pound (lb), or units derived from these. Mass may also be visualized as equivalent to inertia, or the resistance offered by a body to change of motion (acceleration). Masses are compared by weighing the bodies, which amounts to comparing the forces of gravitation acting on them. ASTM D 123.

3.1.2. *unit weight, n*—weight (mass) per unit volume. (Deprecated term—used preferred term bulk density.)

3.1.2.1. *discussion*—the term weight means the force of gravity acting on the mass.

3.1.3. *weight, n*—the force exerted on a body by gravity. (See also mass.)

3.1.3.1. *discussion*—weight is equal to the mass of the body multiplied by the acceleration due to gravity. Weight may be expressed in absolute units (newtons, poundals) or in gravitational units (kgf, lbf), for example: on the surface of the earth, a body with a mass of 1 kg has a weight of 1 kgf (approximately 9.81 N), or a body with a mass of 1 lb has a weight of 1 lbf (approximately 4.45 N or 32.2 poundals). Since weight is equal to mass times the acceleration due to gravity, the weight of a body will vary with the location where the weight is determined, while the mass of the body remains constant. On the surface of the earth, the force of gravity imparts to a body that is free to fall an acceleration of approximately 9.81 m/s^2 (32.2 ft/s^2). ASTM D 123.

3.2. *Descriptions of Terms*:

3.2.1. *voids, n*—in unit volume of aggregate, the space between particles in an aggregate mass not occupied by solid mineral matter.

3.2.1.1. *discussion*—voids within particles, either permeable or impermeable, are not included in voids as determined by T 19M/T 19.

4. SIGNIFICANCE AND USE

4.1. This test method is often used to determine bulk density values that are necessary for use for many methods of selecting proportions for concrete mixtures.

4.2. The bulk density also may be used for determining mass/volume relationships for conversions in purchase agreements. However, the relationship between degree of compaction of aggregates in a hauling unit or stockpile and that achieved in this method is unknown. Further, aggregates in hauling units and stockpiles usually contain absorbed and surface moisture (the latter affecting bulking), while this method determines the bulk density on a dry basis.

4.3. A procedure is included for computing the percentage of voids between the aggregate particles based on the bulk density determined by this method.

5. APPARATUS

5.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

5.2. *Tamping Rod*—A round, straight steel rod, 16 mm ($^5/_8$ in.) in diameter and approximately 600 mm (24 in.) in length, having one end rounded to a hemispherical tip of the same diameter as the rod.

5.3. *Measure*—A cylindrical metal measure, preferably provided with handles. It shall be watertight, with the top and bottom true and even, and sufficiently rigid to retain its form under rough usage. The measure should have a height approximately equal to the diameter, but in no case shall the height be less than 80 percent nor more than 150 percent of the diameter. The capacity of the measure shall conform to the limits in Table 1 for the aggregate size to be tested. The thickness of metal in the measure shall be as described in Table 2. The top rim shall be smooth and plane within 0.25 mm (0.01 in.) and shall be parallel to the bottom within 0.5º (Note 2). The interior wall of the measure shall be a smooth and continuous surface.

Table 1—Capacity of Measures

Nominal Maximum Size of Aggregate		Capacity of Measure[a]	
mm	in.	L (m^3)	ft^3
12.5	$^1/_2$	2.8 (0.0028)	$^1/_{10}$
25.0	1	9.3 (0.0093)	$^1/_3$
37.5	$1^1/_2$	14 (0.014)	$^1/_2$
75	3	28 (0.028)	1
100	4	70 (0.070)	$2^1/_2$
125	5	100 (0.100)	$3^1/_2$

[a] The indicated size of measure shall be used to test aggregates of a nominal maximum size equal to or smaller than that listed. The actual volume of the measure shall be at least 95 percent of the nominal volume listed.

Note 2—The top rim is satisfactorily plane if a 0.25 mm (0.01 in.) feeler gauge cannot be inserted between the rim and a piece of 6 mm ($^1/_4$ in.) or thicker plate glass laid over the measure. The top and bottom are satisfactorily parallel if the slope between pieces of plate glass in contact with the top and bottom does not exceed 0.87 percent in any direction.

5.3.1. If the measure also is to be used for testing for bulk density of freshly mixed concrete according to T 121, the measure shall be made of steel or other suitable metal not readily subject to attack by cement. Reactive materials, such as aluminum alloys are permitted, where as a consequence of an initial reaction, a surface film is formed which protects the metal against further corrosion.

5.3.2. Measures larger than nominal 28-L (1-ft^3) capacity shall be made of steel for rigidity, or the minimum thicknesses of metal listed in Table 2 should be suitably increased.

Table 2—Requirements for Measures

Capacity of Measure	Thickness of Metal, Min Bottom	Thickness of Metal, Min Upper $1^1/_2$ in. or 38 mm of Wall[a]	Thickness of Metal, Min Remainder of Wall
Less than 11 L	5.0 mm	2.5 mm	2.5 mm
11 to 42 L, incl	5.0 mm	5.0 mm	3.0 mm
Over 42 to 80 L, incl	10.0 mm	6.4 mm	3.8 mm
Over 80 to 133 L, incl	13.0 mm	7.6 mm	5.0 mm
Less than 0.4 ft^3	0.20 in.	0.10 in.	0.10 in.
0.4 ft^3 to 1.5 ft^3, incl	0.20 in.	0.20 in.	0.12 in.
Over 1.5 to 2.8 ft^3, incl	0.40 in.	0.25 in.	0.15 in.
Over 2.8 to 4.0 ft^3, incl	0.50 in.	0.30 in.	0.20 in.

[a] The added thickness in the upper portion of the wall may be obtained by placing a reinforcing band around the top of the measure.

5.4. *Shovel or Scoop*—A shovel or scoop of convenient size for filling the measure with aggregate.

5.5. *Calibration Equipment*

5.5.1. *Plate Glass*—A piece of plate glass, preferably at least 6 mm ($^1/_4$ in.) thick and at least 25 mm (1 in.) larger than the diameter of the measure to be calibrated.

5.5.2. *Grease*—A supply of water insoluble grease.

Note 3—Petrolatum, vacuum grease, water pump grease, or chassis grease are examples of suitable material used to form a seal between the glass plate and measure.

5.5.3. *Thermometer*—A thermometer having a range of at least 10 to 32°C (50 to 90°F) and that is readable to at least 0.5 °C (1 °F).

5.5.4. *Balance*—A balance as described in Section 5.1.

6. SAMPLING

6.1. Obtain the sample in accordance with T 2, and reduce to test sample size in accordance with T 248.

7. SAMPLE

7.1. The size of sample shall be approximately 125 to 200 percent of the quantity required to fill the measure and shall be handled in a manner to avoid segregation. Dry the sample of aggregate to constant mass, preferably in an oven at 110 ± 5ºC (230 ± 9ºF).

8. CALIBRATION OF MEASURE

8.1. Measures shall be recalibrated at least once a year or whenever there is reason to question the accuracy of the calibration.

8.2. Place a thin layer of grease on the rim of the measure to prevent leakage of water from the measure.

8.3. Determine the mass of the plate glass and measure to the nearest 0.05 kg (0.1 lb).

8.4. Fill the measure with water that is at room temperature and cover with the plate glass in such a way as to eliminate bubbles and excess water. Remove any water that may have overflowed onto the measure or plate glass.

8.5. Determine the mass of the water, plate glass, and measure to the nearest 0.05 kg (0.1 lb).

8.6. Measure the temperature of the water to the nearest 0.5 °C (1 °F) and determine its density from Table 3, interpolating if necessary.

Table 3—Density of Water

Temperature			
°C	°F	kg/m^3	lb/ft^3
15.6	60	999.01	62.366
18.3	65	998.54	62.336
21.1	70	997.97	62.301
(23.0)	(73.4)	(997.54)	(62.274)
23.9	75	997.32	62.261
26.7	80	996.59	62.216
29.4	85	995.83	62.166

8.7. Calculate the volume, V, of the measure. Alternatively, calculate the factor, F, for the measure.

$$V = (B - C)/D \qquad (1)$$

$$F = D/(B - C) \qquad (2)$$

where:

V = volume of the measure, m^3 (ft^3)

B = mass of the water, plate glass, and measure, kg (lb)

C = mass of the plate glass and measure, kg (lb)

D = density of the water for the measured kg/m^3 (lb/ft^3), and

F = factor for the measure, 1/m^3 (1/ft^3)

Note 4—For the calculation of bulk density, the volume of the measure in acceptable metric units should be expressed in cubic meters, or the factor as 1/m^3. However, for convenience the size of the measure may be expressed in liters (equal to m^3/1000).

.

9. SELECTION OF PROCEDURE

9.1. The shoveling procedure for loose bulk density shall be used only when specifically stipulated. Otherwise, the compact bulk density shall be determined by the rodding procedure for aggregates having a nominal maximum size of 37.5 mm ($1^1/_2$ in.) or less, or by the jigging procedure for aggregates having a nominal maximum size greater than 37.5 mm ($1^1/_2$ in.) and not exceeding 125 mm (5 in.).

10. RODDING PROCEDURE

10.1. Fill the measure one-third full and level the surface with the fingers. Rod the layer of aggregate with 25 strokes of the tamping rod evenly distributed over the surface. Fill the measure two-thirds full and again level and rod as above. Finally, fill the measure to overflowing and rod again in the manner previously mentioned. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

10.2. In rodding the first layer, do not allow the rod to strike the bottom of the measure forcibly. In rodding the second and third layers, use vigorous effort, but not more force than to cause the tamping rod to penetrate to the previous layer of aggregate.

Note 5—In rodding the larger sizes of coarse aggregate, it may not be possible to penetrate the layer being consolidated, especially with angular aggregates. The intent of the procedure will be accomplished if vigorous effort is used.

10.3. Determine the mass of the measure plus contents, and the mass of the measure alone and record the values to the nearest 0.05 kg (0.1 lb).

11. JIGGING PROCEDURE

11.1. Fill the measure in three approximately equal layers as described in Section 10.1, compacting each layer by placing the measure on a firm base, such as a cement-concrete floor, raising the opposite sides alternately about 50 mm (2 in.), and allowing the measure to drop in such a manner as to hit with a sharp, slapping blow. The aggregate particles, by this procedure, will arrange themselves in a densely compacted condition. Compact each layer by dropping the measure 50 times in the manner described, 25 times on each side. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

11.2. Determine the mass of the measure plus contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg (0.1 lb).

12. SHOVELING PROCEDURE

12.1. Fill the measure to overflowing by means of a shovel or scoop, discharging the aggregate from a height not to exceed 50 mm (2 in.) above the top of the measure. Exercise care to prevent, so far as possible, segregation of the particle sizes of which the sample is composed. Level the surface of the aggregate with the fingers or a straightedge in such a way that any slight projections of the larger pieces of the coarse aggregate approximately balance the larger voids in the surface below the top of the measure.

12.2. Determine the mass of the measure plus contents, and the mass of the measure alone, and record the values to the nearest 0.05 kg (0.1 lb).

13. CALCULATION OF RESULTS

13.1. *Bulk Density*—Calculate the bulk density for the rodding, jigging, or shoveling procedure as follows:

$$M = (G - T)/V \tag{3}$$

or,

$$M = (G - T) \times F \tag{4}$$

where:

M = bulk density of aggregate, kg/m^3 (lb/ft^3);
G = mass of aggregate plus the measure, kg (lb);
T = mass of the measure, kg (lb);
V = volume of measure, m^3 (ft^3); and
F = factor for measure, m^{-3} (ft^{-3}).

13.1.1. The bulk density determined by this method is for aggregate in an oven-dry condition. If the bulk density in terms of saturated-surface-dry (SSD) condition is desired, use the exact procedure in this method, and then calculate the SSD bulk density by the following formula:

$$M_{SSD} = M[1 + (A/100)] \tag{5}$$

where:

M_{SSD} = bulk density in SSD condition, kg/m^3 (lb/ft^3); and
A = absorption, percent, determined in accordance with T 84 or T 85.

13.2. *Void Content*—Calculate the void content in the aggregate using the bulk density determined by either the rodding, jigging, or shoveling procedure, as follows:

$$\text{Voids \%} = \frac{100[(S \times W) - M]}{S \times W} \tag{6}$$

where:

M = bulk density of aggregate, kg/m^3 (lb/ft^3);
S = bulk specific gravity (dry basis) as determined in accordance with T 84 or T 85; and
W = density of water, 998 kg/m^3 (62.3 lb/ft^3).

14. REPORT

14.1. Report the results for bulk density to the nearest 10 kg/m^3 (1 lb/ft^3) as follows:

14.1.1. Bulk density by rodding,

14.1.2. Bulk density by jigging, or

14.1.3. Loose bulk density.

14.2. Report the results for void content to the nearest one percent as follows:

14.2.1. Voids in aggregate compacted by rodding, percent, 14.2.2. Voids in aggregate compacted by jigging, percent, or

14.2.3. Voids in loose aggregate, percent.

14.3. Indicate the procedure used.

---

15. PRECISION AND BIAS

15.1. The following estimates of precision for this method are based on results from the AASHTO Materials Reference Laboratory (AMRL) Proficiency Sample Program, with testing conducted by this method and ASTM C 29. There are no significant differences between the two methods. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

15.2. *Coarse Aggregate (bulk density)*:

15.2.1. *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 (0.88 lb/ft^3) (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 (2.5 lb/ft^3) (d2s).

15.2.2. *Multi-Laboratory Precision*—The multi-laboratory standard deviation has been found to be 30 kg/m^3 (1.87 lb/ft^3) (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 85 kg/m^3 (5.3 lb/ft^3) (d2s).

15.2.3. These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for bulk density by rodding of normal-weight aggregates having a nominal maximum aggregate size of 25.0 mm (1 in.), and using a 14-L ($^1/_2$-ft^3) measure.

15.3. *Fine Aggregate (bulk density)*:

15.3.1. *Single-Operator Precision*—The single-operator standard deviation has been found to be 14 kg/m^3 (0.88 lb/ft^3) (1s). Therefore, results of two properly conducted tests by the same operator on similar material should not differ by more than 40 kg/m^3 (2.5 lb/ft^3) (d2s).

15.3.2. *Multi-Laboratory Precision*—The multi-laboratory standard deviation has been found to be 44 kg/m^3 (2.76 lb/ft^3) (1s). Therefore, results of two properly conducted tests from two different laboratories on similar material should not differ by more than 125 kg/m^3 (7.8 lb/ft^3) (d2s).

15.3.3. These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670. The precision estimates were obtained from the analysis of AMRL proficiency sample data for loose bulk density from laboratories using a 2.8-L ($^1/_{10}$-ft^3) measure.

15.4. No precision data on void content are available. However as the void content in aggregate is calculated from bulk density and bulk specific gravity, the precision of the voids content reflects the precision of these measured parameters given in Sections 15.2 and 15.3 of this method and in T 84 and T 85.

15.5. *Bias*—The procedure in this test method for measuring bulk density and void content has no bias because the values for bulk density and void content can be defined only in terms of a test method.

Standard Method of Test for

Organic Impurities in Fine Aggregates for Concrete

AASHTO Designation: T 21-05 (2009)[1]
ASTM Designation: C 40-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Organic Impurities in Fine Aggregates for Concrete

AASHTO Designation: T 21-05 (2009)[1]

ASTM Designation: C 40-04

1. SCOPE

1.1. This test method covers two procedures for an approximate determination of the presence of injurious organic compounds in fine aggregates that are to be used in hydraulic cement mortar or concrete. One procedure uses a standard color solution and the other uses a glass color standard.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 2, Sampling of Aggregates
- T 71, Effect of Organic Impurities in Fine Aggregate on Strength of Mortar
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standard*:

- D 1544, Standard Test Method for Color of Transparent Liquids (Gardner Color Scale)

3. SIGNIFICANCE AND USE

3.1. This test method is of significance in making a preliminary determination of the acceptability of fine aggregates with respect to the requirements of M 6.

3.2. The principal value of this test method is to furnish a warning that organic impurities may be present. When a sample subjected to this test produces a color darker than the standard color, it is advisable to perform the test for the effect of organic impurities on the strength of mortar in accordance with T 71.

4. APPARATUS

4.1. *Glass Bottles*—Colorless glass graduated bottles, approximately 240 to 470-mL (8 to 16-oz) nominal capacity, equipped with watertight stoppers or caps, not soluble in the specified reagents. In no case shall the maximum outside dimension of the bottles, measured along the line of sight used for the color comparison, be greater than 60 mm (2.5 in.) or less than 40 mm (1.5 in.). The graduations on the bottles shall be in milliliters or ounces (U.S. fluid), except that unmarked bottles may be calibrated and scribed with graduations by the user. In such case, graduation marks are required at only three points as follows:

4.1.1. *Standard Color Solution Level*—75 mL, ($2^1/_2$ oz) (U.S. fluid);

4.1.2. *Fine Aggregate Level*—130 mL, ($4^1/_2$ oz) (U.S. fluid); and

4.1.3. *NaOH Solution Level*—200 mL, (7 oz) (U.S. fluid).

4.2. *Glass Color Standard*:

4.2.1. Glass standard colors shall be used as described in Table 1 of ASTM D 1544.

Note 1—A suitable instrument consists of five glass color standards mounted in a plastic holder. Only the glass identified as Gardner Color Standard No. 11 is to be used as the Glass Color Standard in Section 9.2.

5. REAGENT AND STANDARD COLOR SOLUTION

5.1. *Reagent Sodium Hydroxide Solution (3 percent)*—Dissolve 3 parts by mass of sodium hydroxide (NaOH) in 97 parts of water.

5.2. *Standard Color Solution*—Dissolve reagent grade potassium dichromate ($K_2Cr_2O_7$) in concentrated sulfuric acid (sp gr 1.84) at the rate of 0.250 g/100 mL of acid. The solution must be freshly made for the color comparison using gentle heat if necessary to effect solution. Preparation of the reference standard color solution is unnecessary when the Glass Color Standard procedure is used to determine the color value.

6. SAMPLING

6.1. The sample shall be selected in general accordance with T 2.

7. TEST SAMPLE

7.1. Obtain a test sample of fine aggregate of about 450 grams (approximately 1 pound) in accordance with T 248. Sample drying prior to testing, if necessary, shall be done by air drying only.

8. PROCEDURE

8.1. Fill a glass bottle to the 130-mL (approximately $4^1/_2$-fluid oz) level with the sample of the fine aggregate to be tested.

8.2. Add a three-percent NaOH solution in water until the volume of the fine aggregate and liquid, indicated after shaking, is 200 mL (approximately 7 fluid oz).

8.3. Stopper the bottle, shake vigorously, and then allow to stand for 24 hours.

9. DETERMINATION OF COLOR VALUE

9.1. *Standard Color Solution Procedure*—At the end of the 24-hour standing period, fill a glass bottle to the 75-mL (approximately $2^1/_2$-fluid oz) level with the fresh standard color solution, prepared not longer than two hours previously, as prescribed in Section 5.2. Hold the bottle with the test sample and the bottle with the standard color solution side by side and compare the color of light transmitted through the supernatant liquid above the test sample with the color of light transmitted through the standard color solution. Record whether it is lighter, darker, or of equal color to that of the reference standard.

9.2. *Glass Color Standard Procedure*—To define more precisely the color of the liquid of the test sample, five glass standard colors may be used as described in Table 1 of ASTM D 1544, using the following colors:

Gardener Color Standard No.	Organic Plate No.
5	1
8	2
11	3 (standard)
14	4
16	5

The comparison procedure described in Section 9.1 shall be used, except that the organic plate number which is nearest the color of the supernatant liquid above the test specimen shall be reported. When using this procedure it is not necessary to prepare the standard color solution.

10. INTERPRETATION OF RESULTS

10.1. If the color of the supernatant liquid is darker than that of the standard color solution or the glass color standard organic plate No. 3 (Gardner Color Standard No. 11), the fine aggregate under test shall be considered to possibly contain injurious organic compounds, and further tests should be made before approving the fine aggregate for use in concrete.

11. PRECISION AND BIAS

11.1. Since this test produces no numerical values, determination of the precision and bias is not necessary.

---

[1] This method agrees with ASTM C 40-04, except for shifting of text between Sections 9.2 and 5.2.

Standard Method of Test for

Sieve Analysis of Fine and Coarse Aggregates

AASHTO Designation: T 27-06[1]
ASTM Designation: C 136-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sieve Analysis of Fine and Coarse Aggregates

AASHTO Designation: T 27-06[1]
ASTM Designation: C 136-05

1. SCOPE

1.1. This method covers the determination of the particle size distribution of fine and coarse aggregates by sieving.

1.2. Some specifications for aggregates, which reference this method, contain grading requirements including both coarse and fine fractions. Instructions are included for sieve analysis of such aggregates.

1.3. The values stated in SI units are to be regarded as the standard. The values in parentheses are provided for information purposes only.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory regulations prior to use*.

3. TERMINOLOGY

3.1. *Definitions*—For definitions of terms used in this standard, refer to ASTM C 125.

4. SUMMARY OF METHOD

4.1. A sample of dry aggregate of known mass is separated through a series of sieves of progressively smaller openings for determination of particle size distribution.

5. SIGNIFICANCE AND USE

5.1. This method is used primarily to determine the grading of materials proposed for use as aggregates or being used as aggregates. The results are used to determine compliance of the particle size distribution with applicable specification requirements and to provide necessary data for control of the production of various aggregate products and mixtures containing aggregates. The data may also be useful in developing relationships concerning porosity and packing.

5.2. Accurate determination of material finer than the 75-μm (No. 200) sieve cannot be achieved by use of this method alone. Test Method T 11 for material finer than the 75-μm (No. 200) sieve by washing should be employed.

6. APPARATUS

6.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

6.2. *Sieves*—The sieve cloth shall be mounted on substantial frames constructed in a manner that will prevent loss of material during sieving. The sieve cloth and standard sieve frames shall conform to the requirements of M 92. Nonstandard sieve frames shall conform to the requirements of M 92 as applicable.

Note 1—It is recommended that sieves mounted in frames larger than standard 203.2 mm (8 in.) diameter be used for testing coarse aggregate to reduce the possibility of overloading the sieves. See Section 8.3.

6.3. *Mechanical Sieve Shaker*—A mechanical sieving device, if used, shall create motion of the sieves to cause the particles to bounce, tumble, or otherwise turn so as to present different orientations to the sieving surface. The sieving action shall be such that the criterion for adequacy of sieving described in Section 8.4 is met in a reasonable time period.

Note 2—Use of a mechanical sieve shaker is recommended when the size of the sample is 20 kg (44 lb) or greater, and may be used for smaller samples, including fine aggregate. Excessive time (more than approximately 10 minutes) to achieve adequate sieving may result in degradation of the sample. The same mechanical sieve shaker may not be practical for all sizes of samples, since the large sieving area needed for practical sieving of a large nominal size coarse aggregate very likely could result in loss of a portion of the sample if used for a smaller sample of coarse aggregate or fine aggregate.

6.4. *Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110 ± 5ºC (230 ± 9ºF).

7. SAMPLING

7.1. Sample the aggregate in accordance with T 2. The mass of the field sample shall be the mass shown in T 2 or four times the mass required in Sections 7.4 and 7.5 (except as modified in Section 7.6), whichever is greater.

7.2. Thoroughly mix the sample and reduce it to an amount suitable for testing using the applicable procedures described in T 248. The sample for test shall be the approximate mass desired when dry and shall be the end result of the reduction. Reduction to an exact predetermined mass shall not be permitted.

Note 3—Where sieve analysis, including determination of material finer than the 75-µm (No. 200) sieve, is the only testing proposed, the size of the sample may be reduced in the field to avoid shipping excessive quantities of extra material to the laboratory.

7.3. *Fine Aggregate*—The size of the test sample of aggregate, after drying, shall be 300 g minimum.

7.4. *Coarse Aggregate*—The mass of the test sample of coarse aggregate shall conform with the following:

Nominal Maximum Size Square Openings, mm (in.)	Minimum Mass of Test Sample, kg (lb)
9.5 ($^3/_8$)	1 (2)
12.5 ($^1/_2$)	2 (4)
19.0 ($^3/_4$)	5 (11)
25.0 (1)	10 (22)
37.5 (1$^1/_2$)	15 (33)
50 (2)	20 (44)
63 (2$^1/_2$)	35 (77)
75 (3)	60 (130)
90 (3$^1/_2$)	100 (220)
100 (4)	150 (330)
125 (5)	300 (660)

7.5. *Coarse and Fine Aggregates Mixtures*—The mass of the test sample of coarse and fine aggregate mixtures shall be the same as for coarse aggregate in Section 7.4.

7.6. *Samples of Large-Size Coarse Aggregate*—The size of sample required for aggregate with 50-mm (2-in.) nominal maximum size or larger is such as to preclude convenient sample reduction and testing as a unit except with large mechanical splitters and sieve shakers. As an option when such equipment is not available, instead of combining and mixing sample increments and then reducing the field sample to testing size, conduct the sieve analysis on a number of approximately equal sample increments such that the total mass tested conforms to the requirements of Section 7.4.

7.7. In the event that the amount of material finer than the 75-µm (No. 200) sieve is to be determined by T 11, use the procedure described in Section 7.7.1 or 7.7.2, whichever is applicable.

7.7.1. For aggregates with a nominal maximum size of 12.5 mm ($^1/_2$ in.) or less, use the same test sample for testing by T 11 and this method. First test the sample in accordance with T 11 through the final drying operation, then dry sieve the sample as stipulated in Sections 8.2 through 8.7 of this method.

7.7.2. For aggregates with a nominal maximum size greater than 12.5 mm ($^1/_2$ in.), a single test sample may be used as described in Section 7.7.1 or separate test samples may be used for T 11 and this method.

7.7.3. Where the specification requires determination of the total amount of material finer than the 75-µm (No. 200) sieve by washing and dry sieving, use the procedure described in Section 7.7.1.

8. PROCEDURE

8.1. If the test sample has not been subjected to testing by T 11, dry it to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF) and determine the mass of it to the nearest 0.1 percent of the total original dry sample mass.

Note 4—For control purposes, particularly where rapid results are desired, it is generally not necessary to dry coarse aggregate for the sieve analysis test. The results are little affected by the moisture content unless (1) the nominal maximum size is smaller than about 12.5 mm ($^1/_2$ in.), (2) the coarse aggregate contains appreciable material finer than 4.75 mm (No. 4), or (3) the coarse aggregate is highly absorptive (a lightweight aggregate, for example). Also, samples may be dried at the higher temperature associated with the use of hot plates without affecting results, provided steam escapes without generating pressures sufficient to fracture the particles, and temperatures are not so great as to cause chemical breakdown of the aggregate.

8.2. Select sieves with suitable openings to furnish the information required by the specifications covering the material to be tested. Use additional sieves as desired or necessary to provide other information, such as fineness modulus, or to regulate the amount of material on a sieve. Nest the sieves in order of decreasing size of opening from top to bottom and place the sample, or portion of the sample if it is to be sieved in more than one increment, on the top sieve. Agitate the sieves by hand or by mechanical apparatus for a sufficient period, established by trial or checked by measurement on the actual test sample, to meet the criterion for adequacy of sieving described in Section 8.4.

8.3. Limit the quantity of material on a given sieve so that all particles have opportunity to reach sieve openings a number of times during the sieving operation. For sieves with openings smaller than 4.75-mm (No. 4), the quantity retained on any sieve at the completion of the sieving operation shall not exceed 7 kg/m^2 (4 g/in.^{2}) of sieving surface area (Note 5). For sieves with openings 4.75 mm (No. 4) and larger, the quantity retained in kg shall not exceed the product of 2.5 × (sieve opening, mm × (effective sieving area, m^2)). This quantity is shown in Table 1 for five sieve-frame dimensions in common use. In no case shall the quantity retained be so great as to cause permanent deformation of the sieve cloth.

8.3.1. Prevent an overload of material on an individual sieve by one or a combination of the following methods:

8.3.1.1. Insert an additional sieve with opening size intermediate between the sieve that may be overloaded and the sieve immediately above that sieve in the original set of sieves.

8.3.1.2. Split the sample into two or more portions, sieving each portion individually. Combine the masses of the several portions retained on a specific sieve before calculating the percentage of the sample on the sieve.

8.3.1.3. Use sieves having a larger frame size and providing greater sieving area.

Note 5—The 7 kg/m^2 amounts to 200 g for the usual 203.2-mm (8-in.) diameter sieve (with effective sieving surface diameter of 190.5 mm (7.5 in.)).

8.3.1.4. In the case of coarse and fine aggregate mixtures, the portion of the sample finer than the 4.75-mm (No. 4) sieve may be distributed among two or more sets of sieves to prevent overloading of individual sieves.

8.3.1.5. Alternatively, the portion finer than the 4.75-mm (No. 4) sieve may be reduced in size using a mechanical splitter according to T 248. If this procedure is followed, compute the mass of each size increment of the original sample as follows:

$$A = \frac{W_1}{W_2} \times B \qquad (1)$$

where:

A = mass of size increment on total sample basis,

W_1 = mass of fraction finer than 4.75-mm (No. 4) sieve in total sample,

W_2 = mass of reduced portion of material finer than 4.75-mm (No. 4) sieve actually sieved, and

B = mass of size increment in reduced portion sieved.

Table 1—Maximum Allowable Quantity of Material Retained on a Sieve, kg

Sieve Opening Size	Nominal Dimensions of Sieve[a]				
	203.2-mm, dia[b]	254-mm, dia[b]	304.8-mm, dia[b]	350 by 350, mm	372 by 580, mm
	Sieving Area, m^2				
	0.0285	0.0457	0.0670	0.1225	0.2158
125 mm (5 in.)	[c]	[c]	[c]	[c]	67.4
100 mm (4 in.)	[c]	[c]	[c]	30.6	53.9
90 mm (3 $^{1}/_{2}$ in.)	[c]	[c]	15.1	27.6	48.5
75 mm (3 in.)	[c]	8.6	12.6	23.0	40.5
63 mm (2 $^{1}/_{2}$ in.)	[c]	7.2	10.6	19.3	34.0
50 mm (2 in.)	3.6	5.7	8.4	15.3	27.0
37.5 mm (1 $^{1}/_{2}$ in.)	2.7	4.3	6.3	11.5	20.2
25.0 mm (1 in.)	1.8	2.9	4.2	7.7	13.5
19.0 mm ($^{3}/_{4}$ in.)	1.4	2.2	3.2	5.8	10.2
12.5 mm ($^{1}/_{2}$ in.)	0.89	1.4	2.1	3.8	6.7
9.5 mm ($^{3}/_{8}$ in.)	0.67	1.1	1.6	2.9	5.1
4.75 mm (No. 4)	0.33	0.54	0.80	1.5	2.6

[a] Sieve frame dimensions in inch units: 8.0-in. diameter; 10.0-in. diameter; 12.0-in. diameter; 13.8 by 13.8 in. (14 by 14 in. nominal); 14.6 by 22.8 in. (16 by 24 in. nominal).

[b] The sieve area for round sieve is based on an effective diameter 12.7 mm ($^{1}/_{2}$ in.) less than the nominal frame diameter, because M 92 permits the sealer between the sieve cloth and the frame to extend 6.35 mm ($^{1}/_{4}$ in.) over the sieve cloth. Thus the effective sieving diameter for a 203.2-mm (8.0-in.) diameter sieve frame is 190.5 mm (7.5 in.). Sieves produced by some manufacturers do not infringe on the sieve cloth by the full 6.35 mm ($^{1}/_{4}$ in.).

[c] Sieves indicated have less than five full openings and should not be used for sieve testing.

8.4. Continue sieving for a sufficient period and in such manner that, after completion, not more than 0.5 percent by mass of the total sample passes any sieve during 1 minute of continuous hand sieving performed as follows: Hold the individual sieve, provided with a snug-fitting pan and cover, in a slightly inclined position in one hand. Strike the side of the sieve sharply and with an upward motion against the heel of the other hand at the rate of about 150 times per minute, turn the sieve about one-sixth of a revolution at intervals of about 25 strokes. In determining sufficiency of sieving for sizes larger than the 4.75-mm (No. 4) sieve, limit the material on the sieve to a single layer of particles. If the size of the mounted testing sieves makes the described sieving motion impractical, use 203.2-mm (8-in.) diameter sieves to verify the sufficiency of sieving.

8.5. Unless a mechanical sieve shaker is used, hand sieve particles obtained on the 75 mm (3 in.) by determining the smallest sieve opening through which each particle will pass by rotating the particles, if necessary, in order to determine whether they will pass through a particular opening; however, do not force particles to pass through an opening.

8.6. Determine the mass of each size increment on a scale or balance conforming to the requirements specified in Section 6.1 to the nearest 0.1 percent of the total original dry sample mass. The total mass of the material after sieving should check closely with original mass of sample placed on the sieves. If the amounts differ by more than 0.3 percent, based on the original dry sample mass, the results should not be used for acceptance purposes.

8.7. If the sample has previously been tested by T 11, add the mass finer than the 75-µm (No. 200) sieve determined by that method to the mass passing the 75-µm (No. 200) sieve by dry sieving of the same sample in this method.

9. CALCULATION

9.1. Calculate percentages passing, total percentages retained, or percentages in various size fractions to the nearest 0.1 percent on the basis of the total mass of the initial dry sample. If the same test sample was first tested by T 11, include the mass of material finer than 75-µm (No. 200) sieve by washing in the sieve analysis calculation; and use the total dry sample mass prior to washing in T 11 as the basis for calculating all the percentages.

9.1.1. When sample increments are tested as provided in Section 7.6, total the masses of the portion of the increments retained on each sieve, and use these masses to calculate the percentage as in Section 9.1.

9.2. Calculate the fineness modulus, when required, by adding the total percentages of material in the sample that is coarser than each of the following sieves (cumulative percentages retained), and dividing the sum by 100; 150 µm (No. 100), 300 µm (No. 50), 600 µm (No. 30), 1.18 mm (No. 16), 2.36 mm (No. 8), 4.75 mm (No. 4), 9.5 mm ($^3/_8$ in.), 19.0 mm ($^3/_4$ in.), 37.5 mm ($1^1/_2$ in.), and larger, increasing the ratio of 2 to 1.

10. REPORT

10.1. Depending upon the form of the specifications for use of the material under test, the report shall include one of the following:

10.1.1. Total percentage of material passing each sieve, or

10.1.2. Total percentage of material retained on each sieve, or

10.1.3. Percentage of material retained between consecutive sieves.

10.2. Report percentages to the nearest whole number, except if the percentage passing the 75-µm (No. 200) sieve is less than 10 percent, it shall be reported to the nearest 0.1 percent.

10.3. Report the fineness modulus, when required, to the nearest 0.01.

11. PRECISION AND BIAS

11.1. *Precision*—The estimates of precision for this test method are listed in Table 2. The estimates are based on the results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by T 27 and ASTM C 136. The data are based on the analyses of the test results from 65 to 233 laboratories that tested 18 pairs of coarse aggregate proficiency test samples and test results from 74 to 222 laboratories that tested 17 pairs of fine aggregate proficiency test samples (Samples No. 21 through 90). The values in the table are given for different ranges of total percentage of aggregate passing a sieve.

Table 2—Estimates of Precision

	Total Percentage of Material Passing		Standard Deviation (1s), Percent[a]	Acceptable Range of Two Results (d2s), Percent[a]
Coarse Aggregate:b	100	≥95	0.32	0.9
Single-operator precision	<95	≥85	0.81	2.3
	<85	≥80	1.34	3.8
	<80	≥60	2.25	6.4
	<60	≥20	1.32	3.7
	<20	≥15	0.95	2.7
	<15	≥10	1.00	2.8
	<10	≥5	0.75	2.1
	<5	≥2	0.53	1.5
	<2	0	0.27	0.8
Multilaboratory precision	100	≥95	0.35	1.0
	<95	≥85	1.37	3.9
	<85	≥80	1.92	5.4
	<80	≥60	2.82	8.0
	<60	≥20	1.97	5.6
	<20	≥15	1.60	4.5
	<15	≥10	1.48	4.2
	<10	≥5	1.22	3.4
	<5	≥2	1.04	3.0
	<2	0	0.45	1.3
Fine Aggregate:				
Single-operator precision	100	≥95	0.26	0.7
	<95	≥60	0.55	1.6
	<60	≥20	0.83	2.4
	<20	≥15	0.54	1.5
	<15	≥10	0.36	1.0
	<10	≥2	0.37	1.1
	<2	0	0.14	0.4
Multilaboratory precision	100	≥95	0.23	0.6
	<95	≥60	0.77	2.2
	<60	≥20	1.41	4.0
	<20	≥15	1.10	3.1
	<15	≥10	0.73	2.1
	<10	≥2	0.65	1.8
	<2	0	0.31	0.9

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

[b] The precision estimates are based on aggregates with nominal maximum size of 19.0 mm ($^{3}/_{4}$ in.).

11.1.1. The precision values for Fine Aggregate in Table 2 are based on nominal 500-g test samples. Revision of ASTM C 136 in 1994 permitted the fine aggregate test sample size to be 300 g minimum. Analysis of results of testing of 300-g and 500-g test samples from Aggregate Proficiency Test Samples 99 and 100 (Samples 99 and 100 were essentially identical) produced the precision values in Table 3, which indicate only minor differences due to test sample size.

Note 6—The values for Fine Aggregate in Table 2 will be revised to reflect the 300-g test sample size when a sufficient number of Aggregate Proficiency Tests have been conducted using that sample size to provide reliable data.

Table 3—Precision Data for 300-g and 500-g Fine Aggregate Test Samples

Fine Aggregate Proficiency Sample Test Result	Sample Size	Number of Labs	Average	Within Laboratory 1s	Within Laboratory d2s	Among Laboratories 1s	Among Laboratories d2s
AASHTO T 27/ASTM C 136:							
Total material passing the 4.75-mm (No. 4) sieve (%)	500 g	285	99.992	0.027	0.066	0.037	0.104
	300 g	276	99.990	0.021	0.060	0.042	0.117
Total material passing the 2.36-mm (No. 8) sieve (%)	500 g	281	84.10	0.43	1.21	0.63	1.76
	300 g	274	84.32	0.39	1.09	0.69	1.92
Total material passing the 1.18-mm (No. 16) sieve (%)	500 g	286	70.11	0.53	1.49	0.75	2.10
	300 g	272	70.00	0.62	1.74	0.76	2.12
Total material passing the 600-µm (No. 30) sieve (%)	500 g	287	48.54	0.75	2.10	1.33	3.73
	300 g	276	48.44	0.87	2.44	1.36	3.79
Total material passing the 300-µm (No. 50) sieve (%)	500 g	286	13.52	0.42	1.17	0.98	2.73
	300 g	275	13.51	0.45	1.25	0.99	2.76
Total material passing the 150-µm (No. 100) sieve (%)	500 g	287	2.55	0.15	0.42	0.37	1.03
	300 g	270	2.52	0.18	0.52	0.32	0.89
Total material passing the 75-µm (No. 200) sieve (%)	500 g	278	1.32	0.11	0.32	0.31	0.85
	300 g	266	1.30	0.14	0.39	0.31	0.85

11.2. *Bias*—Since there is no accepted reference material suitable for determining the bias in this test method, no statement on bias is made.

Standard Method of Test for

Mechanical Analysis of Extracted Aggregate

AASHTO Designation: T 30-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mechanical Analysis of Extracted Aggregate

AASHTO Designation: T 30-10

1. SCOPE

1.1 This method covers a procedure for the determination of the particle-size distribution of fine and coarse aggregates extracted from hot mix asphalt (HMA), using sieves with square openings.

1.2 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 164, Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)
- T 255, Total Evaporable Moisture Content of Aggregate by Drying
- T 308, Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method

2.2 *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SIGNIFICANCE AND USE

3.1 This method is used to determine the grading of aggregates extracted from HMA. The results are used to determine compliance of the particle-size distribution with applicable specification requirements and to provide necessary data for control of the production of various aggregates to be used in HMA.

4. APPARATUS

4.1 The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to M 231.

4.2 *Sieves*—The sieve cloth shall be mounted on substantial frames constructed in a manner that will prevent loss of material during sieving. The sieve cloth and standard sieve frames shall conform to the requirements of M 92. Nonstandard sieve frames shall conform to the requirements of M 92 as applicable.

4.3 *Mechanical Sieve Shaker*—A mechanical sieving device, if used, shall create motion of the sieves to cause the particles to bounce, tumble, or otherwise turn so as to present different orientations to the sieving surface. The sieving action shall be such that the criterion for adequacy of sieving described in Section 6.7 is met in a reasonable time period.

Note 1—Use of a mechanical sieve shaker is recommended when the size of the sample is 20 kg (44 lb) or greater, and may be used for smaller samples, including fine aggregate. Excessive time (more than approximately 10 min) to achieve adequate sieving may result in degradation of the sample. The same mechanical sieve shaker may not be practical for all sizes of samples, since the large sieving area needed for practical sieving of a large nominal size coarse aggregate very likely could result in loss of a portion of the sample if used for a smaller size of coarse aggregate or fine aggregate.

4.4 *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5ºC (230 ± 9ºF).

4.5 *Wetting Agent*—Any dispersing agent, such as Calgon, Joy, or other detergent that will promote separation of the fine materials.

4.6 *Containers and Utensils*—A pan or vessel of a size sufficient to contain the sample covered with water and to permit vigorous agitation without loss of any part of the sample or water.

5. SAMPLE

5.1 The sample shall consist of the entire lot or sample of aggregate obtained according to T 164 or T 308 from which the binder material has been extracted.

6. PROCEDURE

6.1 *Sample*:

6.1.1 The sample shall be dried, if necessary, until further drying at 110 ± 5ºC (230 ± 9ºF) does not alter the mass by more than 0.1 percent, the precision of weighing. The total mass of aggregate in the HMA being tested is the sum of the mass of the dried aggregates and the mineral matter contained in the extracted asphalt binder. The latter is to be taken as the sum of the mass of ash in the extract and the increase in mass of the filter element as determined in T 164.

6.1.2 Determine and record the mass of the sample to the nearest 0.1 g. This mass shall agree with the mass of aggregate remaining after ignition (M_f from T 308) within 0.1 percent of M_f for an aggregate sample obtained from T 308. If the variation exceeds 0.1 percent, the results of this test should not be used for acceptance purposes.

6.2 The test sample shall be placed in a container and covered with water. Add a sufficient amount of wetting agent to assure a thorough separation of the material finer than the 75-µm (No. 200) sieve from the coarser particles. There should be enough wetting agent to produce a small amount of suds when the sample is agitated. The quantity will depend on the hardness of the water, the quality of the detergent, and the agitation process. Excessive suds may overflow the sieves and carry some material with them. The contents of the container shall be agitated vigorously and the wash water immediately poured over a nest of two sieves consisting of a 2.00- or 1.18-mm (No. 10 or No. 16) sieve superimposed on a 75-µm (No. 200) sieve. The use of a large spoon to stir and agitate the aggregate in the wash water has been found to be satisfactory.

The use of a mechanical apparatus to perform the washing operation is allowable, providing mechanical wash does not degrade the sample. When mechanical washing equipment is used, the introduction of water, agitating, and decanting may be a continuous operation. Use care not to overflow or overload the 75-µm (No. 200) sieve.

6.3 The agitation shall be sufficiently vigorous to result in the complete separation of all particles finer than the 75-µm (No. 200) sieve from the coarse particles and bring them into suspension in order that they may be removed by decantation of the wash water. Care should be taken to avoid, as much as possible, the decantation of the coarse particles of the sample. The operation shall be repeated until the wash water is clear.

6.4 All material retained on the nested sieves shall be returned to the container. The washed aggregate in the container shall be dried to constant mass per T 255, and weighed to the nearest 0.1 percent.

6.5 The aggregate shall then be sieved over sieves of various sizes required by the specification covering the HMA, including the 75-µm (No. 200) sieve. Nest the sieves in order of decreasing size of opening from top to bottom and place the sample on the top sieve. Agitate the sieves by a mechanical apparatus for a sufficient period, established by trial or checked by measurement on the actual test sample, to meet the criterion for adequacy of sieving described in Section 6.7.

6.6 Limit the quantity of material on a given sieve so that all particles have opportunity to reach sieve openings a number of times during the sieving operation. For sieves with openings smaller than 4.75 mm (No. 4), the mass retained on any sieve at the completion of the sieving operation shall not exceed 6 kg/m^2 (4 g/in.^{2}) of sieving surface. For sieves with openings 4.75 mm (No. 4) and larger, the mass in kg shall not exceed the product of 2.5 × (sieve opening in mm) × (the sieving surface area in m^2). In no case shall the mass be so great as to cause permanent deformation of the sieve cloth.

Note 2—The 6 kg/m^2 (4 g/in.^{2}) amounts to 200 g for the usual 203-mm (8-in.) diameter sieve. The amount of material retained on a sieve may be regulated by (1) the introduction of a sieve with larger openings immediately above the given sieve or (2) testing the sample in a number of increments.

6.7 Continue sieving for a sufficient period and in such manner that, after completion, not more than 0.5 percent by mass of the total sample passes any sieve during 60 s of continuous hand-sieving performed as follows: Hold the individual sieve, provided with a snug-fitting pan and cover, in a slightly inclined position in one hand. Strike the side of the sieve sharply and with an upward motion against the heel of the other hand at the rate of about 150 times per minute, turning the sieve about one sixth of a revolution at intervals of about 25 strokes. In determining the adequacy of sieving for sizes larger than the 4.75-mm (No. 4) sieve, limit the material on the sieve to a single layer of particles. If the size of the mounted testing sieves makes the described sieving motion impractical, use 203-mm (8-in.) diameter sieves to verify the adequacy of sieving.

7. CALCULATIONS

7.1 The mass of material passing each sieve and retained on the next and the amount passing the 75-µm (No. 200) sieve shall be recorded. The summation of these various masses must check the dried mass after washing within 0.2 percent of the total mass. The mass of dry material passing the 75-µm (No. 200) sieve by dry sieving shall be added to the mass removed by washing, and if applicable, the mass of mineral matter in the asphalt binder, in order to obtain the total passing the 75-µm (No. 200) sieve. The masses of fractions retained on the various sieves and the total passing the 75-µm (No. 200) sieve shall be converted to percentages by dividing each by the total mass of aggregate in the HMA from Section 6.1.

7.2 For aggregate samples obtained from T 308, apply the aggregate correction factor, as required in T 308, to obtain the final total passing percentages.

8. REPORT

8.1 The results of the sieve analysis shall be reported as follows: (a) total percentages passing each sieve; or (b) total percentages retained on each sieve; or (c) percentages retained between consecutive sieves, depending upon the form of the specifications for the use of the material being tested. Percentages shall be reported to the nearest whole number, except for the percentage passing the 75-μm (No. 200) sieve, which shall be reported to the nearest 0.1 percent.

9. PRECISION AND BIAS

9.1 *Precision*—The estimates of precision for this test method are listed in Table 1. The estimates are based on the results from the AASHTO Materials Reference Laboratory Proficiency Sample Program, with testing conducted by T 30. The data are based on the analyses of the test results from 47 to 190 laboratories that tested 17 pairs of proficiency test samples (Samples No. 1 through 34). The values in the table are given for different ranges of total percentage of aggregate passing a sieve.

Table 1—Precision

	Total Percentage of Material Passing a Sieve	Standard Deviation (1s) Percent[a]	Acceptable Range of Two Results—(d2s) Percent[a]
Extracted aggregate:[b]			
Single-Operator Precision	95 to 100	0.49	1.4
	40 to 94	1.06	3.0
	25 to 39	0.65	1.8
	10 to 24	0.46	1.3
	5to 9	0.29	0.8
	2 to 4	0.21	0.6
	0 to 1	0.17	0.5
Multilaboratory Precision	95 to 100	0.57	1.6
	40 to 94	1.24	3.5
	25 to 39	0.84	2.4
	10 to 24	0.81	2.3
	5 to 9	0.56	1.6
	2 to 4	0.43	1.2
	0 to 1	0.32	0.9

[a] These numbers represent, respectively, the (1s) and (d2s) limits described in ASTM C 670.

[b] The precision estimates are based on aggregates with nominal maximum sizes of 19.0 mm ($^3/_4$ in.) to 9.5 mm ($^3/_8$ in.).

9.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

Standard Method of Test for

Sieve Analysis of Mineral Filler for Hot Mix Asphalt (HMA)

AASHTO Designation: T 37-07[1]
ASTM Designation: D 546-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sieve Analysis of Mineral Filler for Hot Mix Asphalt (HMA)

AASHTO Designation: T 37-07[1]
ASTM Designation: D 546-05

1. SCOPE

1.1. This method of test covers the sieve analysis of mineral fillers used in hot mix asphalt (HMA).

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 17, Mineral Filler for Bituminous Paving Mixtures
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 88, Particle Size Analysis of Soils
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SIGNIFICANCE AND USE

3.1. The method is used to determine compliance of mineral fillers with the grading requirements of M 17.

4. APPARATUS

4.1. *Weighing Device*, conforming to the requirements of M 231, Class G 2.

4.2. *Sieves*, conforming to M 92, square-hole, woven wire cloth, with nominal opening sizes of 75-µm (No. 200), 300-µm (No. 50), and 600-µm (No. 30) sieves.

4.3. *Oven*—An oven of sufficient size, capable of maintaining a uniform temperature of 110 ± 5ºC (230 ± 9ºF).

5. TEST SAMPLE

5.1. Obtain the sample for test in accordance with the requirements of M 17 and reduce to testing size in accordance with T 248. Use a minimum of 100 g of dry material for each sieve analysis.

6. PROCEDURE

6.1. Dry the test sample to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF) and determine the mass to the nearest 0.1 g.

6.2. After drying and determining the mass, place the dry test sample on the 600-µm (No. 30) sieve, which shall be nested above the 300-µm (No. 50) and 75-µm (No. 200) sieves. Wash the material by means of a stream of water from a faucet (Note 1). Continue the washing until the water coming through the 75-µm (No. 200) sieve is clear (Note 2). Remove the material retained on each of the three sieves into individual pans, washing the sieves as necessary to remove all material. If desired, excess water may be decanted from the pans prior to drying (Note 3). Dry the residue from each sieve to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF) (Note 4). Calculate the mass of material retained on each sieve as a percentage of the original sample.

Note 1—A spray nozzle or a piece of rubber tubing attached to a water faucet may be used for the washing. The velocity of the water, which may be increased by pinching the tubing, must be controlled to prevent loss of any sample by splashing over the sides of the sieves.

Note 2—Take care to avoid accumulation of water on the 75-µm (No. 200) sieve, because it may become clogged and the operation cannot be completed within a reasonable period.

Note 3—If excess water is decanted from the pan containing the washed aggregate prior to drying, care should be taken to avoid the loss of fines. The excess water should be decanted through a 75-µm (No. 200) sieve and any material on the sieve should be returned to the sample with minimal washing.

Note 4—Some material passes the 75-µm (No. 200) sieve on dry sieving that did not pass during the washing operation. When desired, additional information may be obtained by dry sieving the portion of the sample retained on the 75-µm (No. 200) sieve, in accordance with T 88.

7. REPORT

7.1. Report the results of the sieve analysis as the total percentage passing each sieve, expressed to the nearest 0.5 percent.

8. PRECISION AND BIAS

8.1. *Precision*—The estimates of precision for this test method are shown in Table 1. They are based on results of an interlaboratory testing program where replicable samples of four different mineral fillers were tested in 20 laboratories using this test method. The materials tested ranged from a coarse mineral filler, that had about 93 percent passing the 600-µm (No. 30) sieve and 51 percent passing the 75-µm (No. 200) sieve, to finer mineral fillers that had about 99 percent passing the 300-µm (No. 50) sieve and 95 percent passing the 75-µm (No. 200) sieve.

Table 1—Average Precision

Precision	Test Result Value, Percent in Size Fraction[a]	Standard Deviation, (1s), Percent[b]	Acceptable Range of Test Results, (d2s), Percent[c]
Single operator	Less than 2	0.14	0.5[c]
	More than 2	0.7	2.0
Multilaboratory	Less than 2	0.17	0.5
	More than 2	1.0	2.8

[a] The percent between consecutive sieves, or percent retained on the largest sieve, 600-µm (No. 30), or percent passing the smallest sieve, 75-µm (No. 200).

[b] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

[c] The minimum d2s is 0.5 percent in this case since results of the test are expressed to the nearest 0.5 percent.

8.2. *Bias*—Research to determine the bias of this test method has not been conducted. Therefore, no statement on bias is made.

---

[1] Except for the title, requirements for the weighing device, precision of weighing, and SI units, this method essentially corresponds to ASTM D 546-05.

Standard Method of Test for

Effect of Organic Impurities in Fine Aggregate on Strength of Mortar

---

AASHTO Designation: T 71-08[1]
ASTM Designation: C 87-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Effect of Organic Impurities in Fine Aggregate on Strength of Mortar

AASHTO Designation: T 71-08[1]
ASTM Designation: C 87-04

1. SCOPE

1.1. This test method covers the determination of the effect on mortar strength of the organic impurities in fine aggregate, whose presence is indicated by tests with T 21. Comparison is made between compressive strengths of mortar made with washed and unwashed fine aggregate.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 152M/M 152, Flow Table for Use in Tests of Hydraulic Cement
- M 231, Weighing Devices Used in the Testing of Materials

- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SIGNIFICANCE AND USE

3.1. This test method is of significance in making a final determination of the acceptability of fine aggregates with respect to the requirements of M 6 concerning organic impurities.

3.2. This test method is only applicable to those samples which, when tested in accordance with T 21, have produced a supernatant liquid with a color darker than that of the reference standard color Plate No. 3 or color solution.

4. BASIS FOR COMPARISON

4.1. The fine aggregate that produced a color darker than the standard in T 21 shall be compared in mortar, as described in this test method, with a sample of the same aggregate that has been washed in a solution of sodium hydroxide followed by thorough rinsing in water. The washing shall be repeated a sufficient number of times until the supernatant liquid obtained in T 21 has a color lighter than standard (Note 1).

4.2. Unless otherwise specified or permitted, strength comparisons shall be made at seven days in accordance with the following conditions:

4.2.1. Mix three batches of mortar with the aggregate washed in sodium hydroxide and three batches with the unwashed aggregate on the same day. All batches shall have the same quantity of fine aggregate. Mix the batches for the two conditions alternately.

4.2.2. Mold three 50-mm or 2-in. cubes from each batch.

4.2.3. Test the three cubes from each batch at the age specified.

Note 1—T 21 describes a standard procedure and an alternative procedure for the determination of color value. In the standard procedure, there is a single reference standard color. In the alternative procedure, five glass color standards are used. The reference standard color is equivalent to color Plate No. 3.

5. SAMPLING AND SAMPLE PREPARATION

5.1. Sample portions of fine aggregate for this test shall be obtained from the same sample used for T 21. Needed reduction of samples to obtain test portions shall be in accordance with T 248.

5.2. Secure an additional field sample if needed from the aggregate supply in accordance with T 2.

5.3. In the event that the fine aggregate being used includes particles so large that the adjustment bracket (as described in T 162) cannot provide adequate clearance, the oversized particles shall be removed by sieving on the 4.75-mm (No. 4) or 2.36-mm (No. 8) sieve. If this procedure is employed, the report shall so state and shall indicate the percentage of material so removed.

Note 2—**Caution**: The clearances between the paddle and the bowl specified in T 162 are suitable when using the standard mortar made with graded sand. To permit the mixer to operate freely and to avoid serious damage to the paddle and bowl when coarser aggregates are used, it may be necessary to set the clearance adjustment bracket to provide greater clearances than specified. A clearance of approximately 4.0 mm is required in T 162; a clearance of approximately 5.0 mm has been found to be satisfactory for this method when used with fine aggregate from which the material retained on the 4.75-mm (No. 4) sieve has been removed.

5.4. Split the fine aggregate to be used for these tests into two approximately equal portions, using Test Method T 248. Set one portion aside to be used in the unwashed condition. The second portion is to be washed before use.

5.5. *Preparing Washed Fine Aggregate*:

5.5.1. Perform the washing and the rinsing of the fine aggregate with care to minimize the loss of fines, so that the aggregate after washing and rinsing has a fineness modulus within 0.10 of that of the unwashed aggregate.

5.5.2. *Establishing a Standard for Thoroughness of Rinsing*—Place a small amount of the water to be used for washing and rinsing in a clean, clear container, and determine the pH of the water by use of pH paper, pH meter, or add a drop of phenolphthalein to the wash water and retain for later comparison.

5.5.3. *Washing the Aggregate*—Place sufficient quantity of fine aggregate for three batches in a suitable container, flood with the sodium hydroxide solution, and agitate thoroughly with a spoon or trowel. At the end of the washing and after allowing the fines to settle, siphon off as much of the sodium hydroxide as possible, without removing any of the aggregate fines. Aggregates containing particles that float may be elutriated onto a No. 200 sieve to capture any floating particles.

5.5.4. *Rinsing the Aggregate*—Add a large quantity of water to the washed aggregate, agitate, allow to stand for fines to settle, and then siphon off the rinse water. Repeat this operation several times, until the water used for rinsing has a pH equal to or lower than the pH of the water prior to contact with the fine aggregate. If phenolphthalein was used as an indicator, the color of the wash water is to equal or lighter in color than the solution prepared in Section 5.5.2.

5.5.5. *Verifying Removal of Organic Impurities*—Repeat the Test Method T 21 procedure to determine if the washing has removed sufficient organic impurities to produce a satisfactory result (color lighter than the standard). If the fine aggregate continues to produce an unsatisfactory result (color darker than the standard), repeat the washing and rinsing procedure (described in Sections 5.5.3 and 5.5.4) as many times as necessary until a satisfactory result is obtained by Test Method T 21.

6. REAGENTS AND MATERIALS

6.1. Portland cement shall be Type I or Type II, meeting the requirements of M 85.

6.2. *Sodium Hydroxide Solution (3 percent)*—Dissolve three parts by mass of sodium hydroxide (NaOH) in 97 parts water.

6.3. *Phenolphthalein*—Dissolve 1 g of reagent grade phenolphthalein in 1 L of 95 percent reagent grade ethyl alcohol.

7. APPARATUS

7.1. *Flow Table, Flow Mold, and Caliper*, as described in M 152M/M 152.

7.2. *Tamper, Trowel, Cube Molds, and Testing Machine*, as described in T 106.

7.3. *Mixer, Bowl, and Paddle*, as described in T 162.

7.4. *Balance*, conforming to M 231 for Class G 5.

7.5. *pH paper*, 0–14.

7.6. *pH meter*, capable of reading 0.1 pH units or better.

8. TEMPERATURE

8.1. The temperature of the mixing water, moist closet, and storage tank shall be maintained at 23.0 ± 1.7ºC (73.4 ± 3ºF).

9. PREPARATION OF MORTAR

9.1. *Number of Test Batches*—Prepare three batches of mortar using the washed aggregates and three batches of mortar using the unwashed aggregate, on the same day. Mix the batches, alternating between the washed and the unwashed aggregate.

9.2. Use water and cement in quantities that will yield a water–cement ratio of 0.6 by mass. It has been found that 600 g of cement and 360 mL of water will usually be adequate for a six-cube batch.

Note 3—Use of cement, water, and an appropriate amount of aggregate for a six-cube batch, or larger, is recommended to assure uniform mixing of the mortar.

9.3. Using fine aggregate that has been brought to a saturated surface dry condition as described in T 84, prepare a quantity of aggregate estimated to provide slightly more than needed to produce a batch of the desired consistency.

Note 4—If the absorption has been determined in accordance with T 84, the aggregate may be prepared for test by adding to a known mass of dry aggregate the amount of water it will absorb, mixing thoroughly, and permitting the aggregate to stand in a covered pan for 60 minutes before use. The washed and unwashed aggregate may be presumed to have the same absorption.

Note 5—The mass of the prepared aggregate should be determined so that the amount actually used in a batch may be calculated as described in Section 10.1.3. Experience indicates that the quantity of fine aggregate used in a six-cube batch will range from approximately 1200 g for fine-graded material to approximately 2200 g for coarse-graded material.

9.3.1. The mortar shall be proportioned to produce a consistency of 110 ± 5 in 25 drops of the flow table, as determined by the flow test described in T 106.

9.4. Prepare the mortar in a mechanical mixer in accordance with the procedure for mixing mortars described in T 162, as modified below.

Note 6—Unwashed aggregate should be used in the initial batch, so that washed aggregate is not wasted in case the batch must be discarded.

9.4.1. During the period from 30 to 60 seconds from the start of mixing, and while still mixing at slow speed, slowly add a measured quantity of aggregate estimated to provide the proper consistency.

9.4.2. During the final 1 minute of mixing at medium speed, if the flow appears to be too high, additional aggregate may be added after the first 30 seconds of this mixing period. To do so, stop the mixer briefly, add the aggregate, and then complete the additional 30 seconds of mixing.

10. PROCEDURE

10.1. Make a determination of the flow as described in T 106.

10.1.1. Should the flow be too great, return the mortar to the mixing bowl, add additional aggregate, mix for 30 seconds at medium speed, and make another determination of the flow. If more than two trials must be made to obtain a flow of 110 ± 5, consider the mortar as a trial mortar, and prepare test specimens from a new batch.

10.1.2. If the mortar is too dry, discard the batch.
