10.1.3. Determine the quantity of aggregate used by subtracting the mass of the portion remaining after mixing from the mass of the initial sample. Use this quantity of aggregate in all subsequent batches for the aggregate under test.

10.2. *Molding Test Specimens*—Immediately following completion of a flow test indicating acceptable consistency, return the mortar from the flow table to the mixing bowl, scrape down the bowl, and then remix the entire batch 15 seconds at medium speed. Upon completion of mixing, shake the excess mortar from the paddle into the bowl. Place the mortar in cube molds in two layers in accordance with the procedures described in T 106.

10.3. For subsequent batches, use washed and unwashed aggregate alternately and the quantity of aggregate determined in Section 10.1.3. Follow the procedure for mixing mortars described in T 162. Following the final 1-minute mixing in T 162, do not perform a flow test but instead allow the mortar to stand in the mixing bowl 90 seconds without covering. During the last 15 seconds of this interval, quickly scrape down into the batch any mortar that may have collected on the side of the bowl. Then remix for 15 seconds at medium speed. Upon completion of mixing, shake the excess mortar from the paddle into the mixing bowl. Place the mortar in the cube molds in two layers in accordance with the procedure described in T 106.

10.4. Store the test specimens and determine compressive strength in accordance with T 106.

11. CALCULATION AND REPORT

11.1. Calculate the compressive strength of each specimen by dividing the maximum load it carried during the test by the cross-sectional area. Average the strengths of the three specimens from each batch. Calculate three-strength ratios by dividing the average strength for a batch containing unwashed aggregate by the average strength for the corresponding (in respective order of mixing) batch containing washed aggregate.

11.2. Report the average of the three ratios, expressed as a percentage, as the relative strength for the aggregate under test.

11.3. If the fine aggregate was sieved to remove particles coarser than the 4.75-mm (No. 4) sieve (as described in Section 5.3), so state in the report and indicate the quantity of material removed as a percentage of the original sample mass.

12. PRECISION AND BIAS

12.1. The following precision statement is applicable when a test result is the average ratio, as defined by this test method, of three pairs of mortar batch strength tests with all the batches mixed on the same day and tested at the same age.

12.2. The single laboratory coefficient of variation has been determined to be 5.4 percent (Note 7). Therefore, results of two properly conducted tests in the same laboratory should not differ from each other by more than 15.3 percent (Note 7) of their average. The maximum range (difference between highest and lowest) of the three individual ratios used in calculating the average should not exceed 17 percent (Note 8).

Note 7—These numbers represent, respectively, the (1s percent) and (d2s percent) limits as described in ASTM C 670.

Note 8—Calculated as described in the section on precision of individual measurements averaged to obtain a test result in ASTM C 670.

---

[1] This method is similar to but not technically identical to ASTM C 87-04.

Standard Method of Test for

Specific Gravity and Absorption of Fine Aggregate

AASHTO Designation: T 84-10[1]
ASTM Designation: C 128-07a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity and Absorption of Fine Aggregate

AASHTO Designation: T 84-10[1]
ASTM Designation: C 128-07a

---

1. SCOPE

1.1. This method covers the determination of bulk and apparent specific gravity, 23/23ºC (73.4/73.4ºF), and absorption of fine aggregate.

1.2. This method determines (after 15 hours in water) the bulk specific gravity and the apparent specific gravity, the bulk specific gravity on the basis of mass of saturated surface-dry aggregate, and the absorption.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *absorption*—the increase in the mass of aggregate due to water in the pores of the material, but not including water adhering to the outside surface of the particles, expressed as a percentage of the dry mass. The aggregate is considered "dry" when it has been maintained at a temperature of 110 ± 5ºC for sufficient time to remove all uncombined water by reaching a constant mass.

3.1.2. *specific gravity*—the ratio of the mass (or weight in air) of a unit volume of a material to the mass of the same volume of gas-free distilled water at stated temperatures. Values are dimensionless.

3.1.2.1. *apparent specific gravity*—the ratio of the weight in air of a unit volume of the impermeable portion of aggregate at a stated temperature to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

3.1.2.2. *bulk specific gravity*—the ratio of the weight in air of a unit volume of aggregate (including the permeable and impermeable voids in the particles, but not including the voids between particles) at a stated temperature to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

3.1.2.3. *bulk specific gravity (SSD)*—the ratio of the mass in air of a unit volume of aggregate, including the mass of water within the voids filled to the extent achieved by submerging in water for approximately 15 hours (but not including the voids between particles) at a stated temperature, compared to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

---

4. SIGNIFICANCE AND USE

4.1. Bulk specific gravity is the characteristic generally used for calculation of the volume occupied by the aggregate in various mixtures containing aggregate including portland cement concrete, bituminous concrete, and other mixtures that are proportioned or analyzed on an absolute volume basis. Bulk specific gravity is also used in the computation of voids in aggregate in T 19M/T 19. Bulk specific gravity determined on the saturated surface-dry basis is used if the aggregate is wet, that is, if its absorption has been satisfied. Conversely, the bulk specific gravity determined on the oven-dry basis is used for computations when the aggregate is dry or assumed to be dry.

4.2. Apparent specific gravity pertains to the relative density of the solid material making up the constituent particles not including the pore space within the particles that is accessible to water. This value is not widely used in construction aggregate technology.

4.3. Absorption values are used to calculate the change in the mass of an aggregate due to water absorbed in the pore spaces within the constituent particles, compared to the dry condition, when it is deemed that the aggregate has been in contact with water long enough to satisfy most of the absorption potential. The laboratory standard for absorption is that obtained after submerging dry aggregate for approximately 15 hours in water. Aggregates mined from below the water table may have a higher absorption when used, if not allowed to dry. Conversely, some aggregates when used may contain an amount of absorbed moisture less than the 15 hours soaked condition: For an aggregate that has been in contact with water and that has free moisture on the particle surfaces, the percentage of free moisture can be determined by deducting the absorption from the total moisture content determined by T 255 by drying.

5. APPARATUS

5.1. *Balance*, conforming to the requirements of M 231, Class G 2.

5.2. *Pycnometer*—A flask or other suitable container into which the fine aggregate test sample can be readily introduced and in which the volume content can be reproduced with ±100 mm^3. The volume of the container filled to mark shall be at least 50 percent greater than the space required to accommodate the test sample. A volumetric flask of 500-mL capacity or a fruit jar fitted with a pycnometer top is satisfactory for a 500-g test sample of most fine aggregates. A Le Chatelier flask as described in T 133 is satisfactory for an approximately 55-g test sample.

5.3. *Mold*—A metal mold in the form of a frustum of a cone with dimensions as follows: 40 ± 3 mm inside diameter at the top, 90 ± 3 mm inside diameter at the bottom, and 75 ± 3 mm in height, with the metal having a minimum thickness of 0.8 mm.

5.4. *Tamper*—A metal tamper having a mass of 340 ± 15 g and having a flat circular tamping face 25 ± 3 mm in diameter.

6. SAMPLING

6.1. Sampling shall be accomplished in general accordance with T 2.

7. PREPARATION OF TEST SPECIMEN

7.1. Obtain approximately one kilogram of the fine aggregate from the sample using the applicable procedures described in T 248.

7.1.1. Dry it in a suitable pan or vessel to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF). Allow it to cool to comfortable handling temperature, cover with water, either by immersion or by the addition of at least 6 percent moisture to the fine aggregate and permit to stand for 15 to 19 hours.

7.1.2. As an alternative to Section 7.1.1, where the absorption and specific gravity values are to be used in proportioning concrete mixtures with aggregates used in their naturally moist condition, the requirement for initial drying to constant mass may be eliminated and, if the surfaces of the particles have been kept wet, the 15-hour soaking may also be eliminated.

Note 1—Values for absorption and for specific gravity in the saturated surface-dry condition may be significantly higher for aggregate not oven dried before soaking than for the same aggregate treated in accordance with Section 7.1.1.

7.2. Decant excess water with care to avoid loss of fines, spread the sample on a flat, nonabsorbent surface exposed to a gently moving current of warm air, and stir frequently to secure homogeneous drying. If desired, mechanical aids such as tumbling or stirring may be employed to assist in achieving the saturated surface-dry condition. As the material begins to dry sufficiently, it may be necessary to work it with the hands in a rubbing motion to break up any conglomerations, lumps, or balls of material that develop. Continue this operation until the test specimen approaches a free-flowing condition. Follow the procedure in Section 7.2.1 to determine whether or not surface moisture is present on the constituent fine aggregate particles. It is intended that the first trial of the cone test will be made with some surface water in the specimen. Continue drying with constant stirring, and if necessary, work the material with a hand-rubbing motion, and test at frequent intervals until the test indicates that the specimen has reached a surface-dry condition. If the first trial of the surface moisture test indicates that moisture is not present on the surface, it has been dried past the saturated surface-dry condition. In this case, thoroughly mix a few milliliters of water with the fine aggregate and permit the specimen to stand in a covered container for 30 minutes. Then resume the process of drying and testing at frequent intervals for the onset of the surface-dry condition.

7.2.1. *Cone Test for Surface Moisture*—Hold the mold firmly on a smooth nonabsorbent surface with the large diameter down. Place a portion of the partially dried fine aggregate loosely in the mold by filling until overflow occurs and heaping additional material above the top of the mold by holding it with the cupped fingers of the hand holding the mold. Lightly tamp the fine aggregate into the mold with 25 light drops of the tamper. Each drop should start about 5 mm (0.2 in.) above the top surface of the fine aggregate. Permit the tamper to fall freely under gravitational attraction on each drop. Adjust the starting height to the new surface elevation after each drop and distribute the drops over the surface. Remove loose sand from the base and lift the mold vertically. If surface moisture is still present, the fine aggregate will retain the molded shape. When the fine aggregate slumps slightly, it indicates that it has reached a surface-dry condition. Some angular fine aggregate or material with a high proportion of fines may not slump in the cone test upon reaching a surface-dry condition. This may be the case if fines become airborne upon dropping a handful of the sand from the cone test 100 to 150 mm onto a surface. For these materials, the saturated surface-dry condition should be considered as the point that one side of the fine aggregate slumps slightly upon removing the mold.

Note 2—The following criteria have also been used on materials that do not readily slump:

1. *Provisional Cone Test*—Fill the cone mold as described in Section 7.2.1 except only use 10 drops of the tamper. Add more fine aggregate and use 10 drops of the tamper again. Then add material two more times using three and two drops of the tamper, respectively. Level off the material even with the top of the mold; remove loose material from the base; and lift the mold vertically.
2. *Provisional Surface Test*—If airborne fines are noted when the fine aggregate is such that it will not slump when it is at a moisture condition, add more moisture to the sand, and at the onset of the surface-dry condition, with the hand lightly pat approximately 100 g of the material on a flat, dry, clean, dark, or dull nonabsorbent surface such as a sheet of rubber, a worn oxidized, galvanized, or steel surface, or a black-painted metal surface. After one to three seconds, remove the fine aggregate. If noticeable moisture shows on the test surface for more than one to two seconds, then surface moisture is considered to be present on the fine aggregate.
3. Colorimetric procedures described by Kandhal and Lee, *Highway Research Record No. 307*, p. 44.
4. For reaching the saturated surface-dry condition on a single-size material that slumps when wet, hard-finish paper towels can be used to surface dry the material until the point is just reached where the paper towel does not appear to be picking up moisture from the surfaces of the fine aggregate particles.

8. PROCEDURE

8.1. Make and record all mass determinations to 0.1 g.

8.2. Partially fill the pycnometer with water. Immediately introduce into the pycnometer 500 ± 10 g of saturated surface-dry fine aggregate prepared as described in Section 7, and fill with additional water to approximately 90 percent of capacity. Manually roll, invert, and agitate or use a combination of these actions to eliminate all air bubbles in the pycnometer (Note 3). Accomplish mechanical agitation by external vibration of the pycnometer in a manner that will not degrade the sample. A level of agitation adjusted to just set individual particles in motion is sufficient to promote de-airing without degradation. A mechanical agitator shall be considered acceptable for use if comparison tests for each six-month period of use show variations less than the acceptable range of two results (d2s) indicated in Table 1 from results of manual agitation on the same material. Adjust its temperature to 23.0 ± 1.7ºC (73.4 ± 3ºF), if necessary by immersion in circulating water, and bring the water level in the pycnometer to its calibrated capacity. Determine total mass of the pycnometer, specimen, and water.

Note 3—It normally takes about 15 to 20 minutes to eliminate air bubbles by manual methods. Dipping the tip of a paper towel into the pycnometer has been found to be useful in dispersing the foam that sometimes builds up when eliminating the air bubbles, or adding a few drops of isopropyl alcohol, after removal of air bubbles and just prior to bringing the water level to its calibrated capacity, has also been found useful in dispersing foam on the water surface. Do not use isopropyl alcohol when using the alternative method described in Section 8.2.1.

Table 1—Precision

	Standard Deviation (1s)[a]	Acceptable Range of Two Results (d2s)[a]
Single-operator precision:		
Bulk specific gravity (dry)	0.011	0.032
Bulk specific gravity (SSD)	0.0095	0.027
Apparent specific gravity	0.0095	0.027
Absorption,[b] percent	0.11	0.31
Multilaboratory precision:		
Bulk specific gravity (dry)	0.023	0.066
Bulk specific gravity (SSD)	0.020	0.056
Apparent specific gravity	0.020	0.056
Absorption,[b] percent	0.23	0.66

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670. The precision estimates were obtained from the analysis of combined AASHTO Materials Reference Laboratory reference sample data from laboratories using 15- to 19-hour saturation times and other laboratories using 24 ± 4 hours of saturation time. Testing was performed on aggregates of normal specific gravities, and started with aggregates in the oven-dry condition.

[b] Precision estimates are based on aggregates with absorptions of less than 1 percent and may differ for manufactured fine aggregates having absorption values greater than 1 percent.

8.2.1. *Alternative to Determining the Mass in Section 8.2*—The quantity of added water necessary to fill the pycnometer at the required temperature may be determined volumetrically using a buret accurate to 0.15 mL. Compute the total mass of the pycnometer, specimen, and water as follows:

$$C = 0.9975\,V_a + S + W \qquad (1)$$

where:

C = mass of pycnometer with specimen and water to calibration mark, g;
V_a = volume of water added to pycnometer, mL;
S = mass of saturated surface-dry specimen, g; and
W = mass of the pycnometer empty, g.

8.2.2. *Alternative to the Procedure in Section 8.2*—Use a Le Chatelier flask initially filled with water to a point on the stem between the 0 and the 1-mL mark. Record this initial reading with the flask and contents within the temperature range of 23.0 ± 1.7ºC (73.4 ± 3ºF). Add 55 ± 5 g of fine aggregate in the saturated surface-dry condition (or other mass as necessary to result in raising the water level to some point on the upper series of graduation). After all fine aggregate has been introduced, place the stopper in the flask and roll the flask in an inclined position, or gently whirl it in a horizontal circle so as to dislodge all entrapped air, continuing until no further bubbles rise to the surface (Note 4). Take a final reading with the flask and contents within 1ºC (1.8ºF) of the original temperature.

Note 4—When using the Le Chatelier flask method, slowly adding a small measured amount (not to exceed 1 mL) of isopropyl alcohol, after removal of air bubbles, has been found useful in dispersing foam appearing on the water surface. The volume of alcohol used must be subtracted from the final reading (R_2).

8.3. Remove the fine aggregate from the pycnometer, dry to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF), cool in air at room temperature for 1.0 ± 0.5 hours and determine the mass.

Note 5—In lieu of drying and determining the mass of the sample which has been removed from the pycnometer, a second portion of the saturated surface-dry sample may be used to determine the oven-dry mass. This sample must be obtained at the same time and be within 0.2 grams of the mass of the sample which is introduced into the pycnometer.

8.3.1. If the Le Chatelier flask method is used, a separate sample portion is needed for the determination of absorption. Weigh a separate 500 ± 10 g portion of the saturated surface-dry fine aggregate, dry to constant mass, and reweigh. This sample must be obtained at the same time as the sample that is introduced into the Le Chatelier flask.

8.4. Determine the mass of the pycnometer filled to its calibration capacity with water at 23.0 ± 1.7ºC (73.4 ± 3ºF).

8.4.1. *Alternative to Determining the Mass in Section 8.4*—The quantity of water necessary to fill the empty pycnometer at the required temperature may be determined volumetrically using a buret accurate to 0.15 mL. Calculate the mass of the pycnometer filled with water as follows:

$$B = 0.9975\,V + W \qquad (2)$$

where:

B = mass of flask filled with water, g;
V = volume of flask, mL; and
W = mass of the flask empty, g.

9. BULK SPECIFIC GRAVITY

9.1. Calculate the bulk specific gravity, 23/23ºC (73.4/73.4ºF) as follows:

$$\text{Bulk sp gr} = A/\left(B + S - C\right) \qquad (3)$$

where:

A = mass of oven-dry specimen in air, g;
B = mass of pycnometer filled with water, g;
S = mass of saturated surface-dry specimen, g; and
C = mass of pycnometer with specimen and water to calibration mark, g.

9.1.1. If the Le Chatelier flask method was used, calculate the bulk specific gravity, 23/23ºC, as follows:

$$\text{Bulk sp gr} = \frac{S_1\left(A/S\right)}{0.9975\left(R_2 - R_1\right)} \qquad (4)$$

where:

S_1 = mass of saturated surface-dry specimen used in Le Chatelier flask, g;

R_2 = final reading of water level in Le Chatelier flask; and

R_1 = initial reading of water level in Le Chatelier flask.

10. BULK SPECIFIC GRAVITY (SATURATED SURFACE-DRY BASIS)

10.1. Calculate the bulk specific gravity, 23/23ºC (73.4/73.4ºF), on the basis of mass of saturated surface-dry aggregate as follows:

$$\text{Bulk sp gr}\left(\text{saturated surface-dry basis}\right) = S/(B+S-C) \qquad (5)$$

10.1.1. If the Le Chatelier flask method was used, calculate the bulk specific gravity, 23/23ºC, on the basis of saturated surface-dry aggregate as follows:

$$\text{Bulk sp gr}\left(\text{saturated surface-dry basis}\right) = \frac{S_1}{0.9975\left(R_2 - R_1\right)} \qquad (6)$$

11. APPARENT SPECIFIC GRAVITY

11.1. Calculate the apparent specific gravity, 23/23ºC (73.4/73.4ºF) as follows:

$$\text{Apparent sp gr} = A/\left(B+A-C\right) \qquad (7)$$

12. ABSORPTION

12.1. Calculate the percentage of absorption as follows:

$$\text{Absorption, percent} = \left[\left(S-A\right)/A\right] \times 100 \qquad (8)$$

13. REPORT

13.1. Report specific gravity results to the nearest 0.001 (Fine Aggregate meeting M 6 requirements may be reported to the nearest 0.01) and absorption to the nearest 0.1 percent. The Appendix gives mathematical interrelationships among the three types of specific gravities and absorption. These may be useful in checking the consistency of reported data or calculating a value that was not reported by using other reported data.

13.2. If the fine aggregate was tested in a naturally moist condition other than the oven dried and 15-hour soaked condition, report the source of the sample and the procedures used to prevent drying prior to testing.

14. PRECISION AND BIAS

14.1. The estimates of precision of this test method (listed in Table 1) are based on results from the AASHTO Materials Reference Laboratory Reference Sample Program, with testing conducted by this test method and ASTM C 128. The significant difference between the methods is that ASTM C 128 requires a saturation period of 24 ± 4 hours, and T 84 requires a saturation period of 15 to 19 hours. This difference has been found to have an insignificant effect on the precision indices. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

14.2. Since there is no accepted reference material suitable for determining the bias for the procedure in T 84 for measuring specific gravity and absorption of fine aggregate, no statement on bias is being made.

APPENDIX

(Nonmandatory Information)

X1. POTENTIAL DIFFERENCES IN BULK SPECIFIC GRAVITY AND ABSORPTION DUE TO PRESENCE OF MATERIAL FINER THAN 75 μm (No. 200)

X1.1. It has been found that there may be significant differences in bulk specific gravity and absorption between fine aggregate samples tested with the material finer than 75 μm (No. 200) present and not present in the samples. Samples from which the material finer than 75 μm is not removed usually give a higher absorption and a lower bulk specific gravity compared with testing the same fine aggregate from which the material finer than 75 μm is removed following the procedures of Test Method T 11. Samples with material finer than 75 μm may build up a coating around the coarser fine aggregate particles during the surface drying process. The resultant specific gravity and absorption that is subsequently measured is that of the agglomerated and coated particles and not that of the parent material. The difference in absorption and specific gravity determined between samples from which the material finer than 75 μm have not been removed and samples from which the material finer than 75 μm have been removed depends on both the amount of the material finer than 75 μm present and the nature of the material. When the material finer than 75 μm is less than about 4 percent by mass, the difference in specific gravity between washed and unwashed samples is less than 0.03. When the material finer than 75 μm is greater than about 8 percent by mass, the difference in specific gravity obtained between washed and unwashed samples may be as great as 0.13.

X1.2. The material finer than 75 μm, which is removed, can be assumed to have the same specific gravity as the fine aggregate. Alternatively, the specific gravity of the material finer than 75 μm may be further evaluated using T 100; however, this test determines the apparent specific gravity and not the bulk specific gravity.

X2. INTERRELATIONSHIPS BETWEEN SPECIFIC GRAVITIES AND ABSORPTION AS DEFINED IN T 84 AND T 85

X2.1. Let:

S_d = bulk specific gravity (dry-basis),
S_s = bulk specific gravity (SSD-basis),
S_a = apparent specific gravity, and
A = absorption in percent.

Then:

$$S_s = (1 + A/100)\,S_d \tag{X1.1}$$

$$S_a = \frac{1}{\frac{1}{S_d} - \frac{A}{100}} = \frac{S_d}{1 - \frac{AS_d}{100}} \tag{X1.2}$$

Or:

$$S_a = \frac{1}{\frac{1 + A/100}{S_s} - \frac{A}{100}} = \frac{S_s}{1 - \frac{A}{100}(S_s - 1)} \tag{X1.3}$$

$$A = \left(\frac{S_s}{S_d} - 1\right)100 \tag{X1.4}$$

$$A = \left(\frac{S_a - S_s}{S_a(S_s - 1)}\right)100 \tag{X1.5}$$

---

[1] This method is technically equivalent to ASTM C 128-07a.

Standard Method of Test for

Specific Gravity and Absorption of Coarse Aggregate

AASHTO Designation: T 85-10[1]
ASTM Designation: C 127-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity and Absorption of Coarse Aggregate

AASHTO Designation: T 85-10[1]
ASTM Designation: C 127-04

1. SCOPE

1.1. This method covers the determination of specific gravity and absorption of coarse aggregate. The specific gravity may be expressed as bulk specific gravity, bulk specific gravity (saturated-surface-dry (SSD)), or apparent specific gravity. The bulk specific gravity (SSD) and absorption are based on aggregate after 15 hours soaking in water. This method is not intended to be used with lightweight aggregates.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *absorption*—the increase in the mass of aggregate due to water in the pores of the material, but not including water adhering to the outside surface of the particles, expressed as a percentage of the dry mass. The aggregate is considered "dry" when it has been maintained at a temperature of 110 ± 5ºC for sufficient time to remove all uncombined water by reaching a constant mass.

3.1.2. *specific gravity*—the ratio of the mass (or weight in air) of a unit volume of a material to the mass of the same volume of gas-free distilled water at stated temperatures. Values are dimensionless.

3.1.2.1. *apparent specific gravity*—the ratio of the weight in air of a unit volume of the impermeable portion of aggregate at a stated temperature to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

3.1.2.2. *bulk specific gravity*—the ratio of the weight in air of a unit volume of aggregate (including the permeable and impermeable voids in the particles, but not including the voids between particles) at a stated temperature to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

3.1.2.3. *bulk specific gravity (SSD)*—the ratio of the mass in air of a unit volume of aggregate, including the mass of water within the voids filled to the extent achieved by submerging in water for approximately 15 hours (but not including the voids between particles) at a stated temperature, compared to the weight in air of an equal volume of gas-free distilled water at a stated temperature.

4. SUMMARY OF METHOD

4.1. A sample of aggregate is immersed in water for approximately 15 hours to essentially fill the pores. It is then removed from the water, the water dried from the surface of the particles, and weighed. Subsequently the sample is weighed while submerged in water. Finally the sample is oven-dried and weighed a third time. Using the mass and weight measurements thus obtained and formulas in the method, it is possible to calculate three types of specific gravity and absorption.

5. SIGNIFICANCE AND USE

5.1. Bulk specific gravity is the characteristic generally used for calculation of the volume occupied by the aggregate in various mixtures containing aggregate, including portland cement concrete, bituminous concrete, and other mixtures that are proportioned or analyzed on an absolute volume basis. Bulk specific gravity is also used in the computation of voids in aggregate in T 19M/T 19. Bulk specific gravity (SSD) is used if the aggregate is wet, that is, if its absorption has been satisfied. Conversely, the bulk specific gravity (oven-dry) is used for computations when the aggregate is dry or assumed to be dry.

5.2. Apparent specific gravity pertains to the relative density of the solid material making up the constituent particles not including the pore space within the particles which is accessible to water.

5.3. Absorption values are used to calculate the change in the mass of an aggregate due to water absorbed in the pore spaces within the constituent particles, compared to the dry condition, when it is deemed that the aggregate has been in contact with water long enough to satisfy most of the absorption potential. The laboratory standard for absorption is that obtained after submerging dry aggregate for approximately 15 hours in water. Aggregates mined from below the water table may have a higher absorption, when used, if not allowed to dry. Conversely, some aggregates when used may contain an amount of absorbed moisture less than the 15-hour soaked condition. For an aggregate that has been in contact with water and that has free moisture on the particle surfaces, the percentage of free moisture can be determined by deducting the absorption from the total moisture content determined by T 255.

5.4. The general procedures described in this method are suitable for determining the absorption of aggregates that have had conditioning other than the 15-hour soak, such as boiling water or vacuum saturation. The values obtained for absorption by other methods will be different than the values obtained by the prescribed 15-hour soak, as will the bulk specific gravity (SSD).

5.5. The pores in lightweight aggregates may or may not become essentially filled with water after immersion for 15 hours. In fact, many such aggregates can remain immersed in water for several days without satisfying most of the aggregates' absorption potential. Therefore, this method is not intended for use with lightweight aggregate.

6. APPARATUS

6.1. *Balance*—Conforming to the requirements of M 231, Class G 5. The balance shall be equipped with suitable apparatus for suspending the sample container in water from the center of the weighing platform or pan of the balance.

6.2. *Sample Container*—A wire basket of 3.35 mm (No. 6) or finer mesh, or a bucket of approximately equal breadth and height, with a capacity of 4 to 7 L for 37.5-mm ($1^1/_2$-in.) nominal maximum size aggregate or smaller, and a larger container as needed for testing larger maximum size aggregate. The container shall be constructed so as to prevent trapping air when the container is submerged.

6.3. *Water Tank*—A watertight tank into which the sample and container are placed for complete immersion while suspended below the balance, equipped with an overflow outlet for maintaining a constant water level.

6.4. *Suspended Apparatus*—Wire suspending the container shall be of the smallest practical size to minimize any possible effects of a variable immersed length.

6.5. *Sieves*—A 4.75-mm (No. 4) sieve or other sizes as needed (Sections 7.2, 7.3, and 7.4), conforming to M 92.

7. SAMPLING

7.1. Sample the aggregate in accordance with T 2.

7.2. Thoroughly mix the sample of aggregate and reduce it to the approximate quantity needed using the applicable procedures in T 248. Reject all material passing a 4.75-mm (No. 4) sieve by dry sieving and thoroughly washing to remove dust or other coatings from the surface. If the coarse aggregate contains a substantial quantity of material finer than the 4.75-mm (No. 4) sieve (such as for Size No. 8 and 9 aggregates in M 43), use the 2.36-mm (No. 8) sieve in place of the 4.75-mm (No. 4) sieve. Alternatively, separate the material finer than the 4.75-mm (No. 4) sieve and test the finer material according to T 84.

7.3. The minimum mass of test sample to be used is given below. In many instances it may be desirable to test a coarse aggregate in several separate size fractions; and if the sample contains more than 15 percent retained on the 37.5-mm ($1^1/_2$-in.) sieve, test the material larger than 37.5 mm in one or more size fractions separately from the smaller size fractions. When an aggregate is tested in separate size fractions, the minimum mass of test sample for each fraction shall be the difference between the masses prescribed for the maximum and minimum sizes of the fraction.

Nominal Maximum Size, mm (in.)	Minimum Mass of Test Sample, kg (lb)
12.5 ($^1/_2$) or less	2 (4.4)
19.0 ($^3/_4$)	3 (6.6)
25.0 (1)	4 (8.8)
37.5 ($1^1/_2$)	5 (11)
50 (2)	8 (18)
63 ($2^1/_2$)	12 (26)
75 (3)	18 (40)
90 ($3^1/_2$)	25 (55)
100 (4)	40 (88)
112 ($4^1/_2$)	50 (110)
125 (5)	75 (165)
150 (6)	125 (276)

7.4. If the sample is tested in two or more size fractions, determine the grading of the sample in accordance with T 27, including the sieves used for separating the size fractions for the determinations in this method. In calculating the percentage of material in each size fraction, ignore the quantity of material finer than the 4.75-mm (No. 4) sieve or 2.36-mm (No. 8) sieve when that sieve is used in accordance with Section 7.2.

8. PROCEDURE

8.1. Dry the test sample to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF), cool in air at room temperature for 1 to 3 hours for test samples of 37.5 mm ($1^1/_2$-in.) nominal maximum size, or longer for larger sizes until the aggregate has cooled to a temperature that is comfortable to handle (approximately 50ºC). Subsequently immerse the aggregate in water at room temperature for a period of 15 to 19 hours.

Note 1—When testing coarse aggregate of large nominal maximum size requiring large test samples, it may be more convenient to perform the test on two or more subsamples, and the values obtained combined for the computation described in Section 9.

8.2. Where the absorption and specific gravity values are to be used in proportioning concrete mixtures in which the aggregates will be in their naturally moist condition, the requirement for initial drying to constant mass may be eliminated, and, if the surfaces of the particles in the sample have been kept continuously wet until test, the 15-hour soaking may also be eliminated.

Note 2—Values for absorption and bulk specific gravity (SSD) may be significantly higher for aggregate not oven dried before soaking than for the same aggregate treated in accordance with Section 8.1. This is especially true of particles larger than 75 mm (3 in.) since the water may not be able to penetrate the pores to the center of the particle in the prescribed soaking period.

8.3. Remove the test sample from the water and roll it in a large absorbent cloth until all visible films of water are removed. Wipe the larger particles individually. A moving stream of air may be used to assist in the drying operation. Take care to avoid evaporation of water from aggregate pores during the operation of surface-drying. Determine the mass of the test sample in the saturated surface-dry condition. Record this and all subsequent masses to the nearest 1.0 g or 0.1 percent of the sample mass, whichever is greater.

8.4. After determining the mass, immediately place the saturated-surface-dry test sample in the sample container and determine its mass in water at 23.0 ± 1.7ºC (73.4 ± 3ºF), having a density of 997 ± 2 kg/m^3. Take care to remove all entrapped air before determining the mass by shaking the container while immersed.

Note 3—The container should be immersed to a depth sufficient to cover it and the test sample during mass determination. Wire suspending the container should be of the smallest practical size to minimize any possible effects of a variable immersed length.

8.5. Dry the test sample to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF), cool in air at room temperature 1 to 3 hours, or until the aggregate has cooled to a temperature that is comfortable to handle (approximately 50ºC), and determine the mass. Use this weight for A in the calculations in Section 9.

9. CALCULATIONS

9.1. *Specific Gravity*:

9.1.1. *Bulk Specific Gravity*—Calculate the bulk specific gravity, 23/23ºC (73.4/73.4ºF), as follows:

$$\text{Bulk sp gr} = A/(B-C) \tag{1}$$

where:

A = mass of oven-dry test sample in air, g;

B = mass of saturated-surface-dry test sample in air, g; and

C = mass of saturated test sample in water, g.

9.1.2. *Bulk Specific Gravity (Saturated-Surface-Dry)*—Calculate the bulk specific gravity, 23/23ºC (73.4/73.4ºF), on the basis of mass of saturated-surface-dry aggregate as follows:

$$\text{Bulk sp gr}\,(\text{saturated - surface - dry}) = B/(B-C) \tag{2}$$

9.1.3. *Apparent Specific Gravity*—Calculate the apparent specific gravity, 23/23ºC (73.4/73.4ºF), as follows:

$$\text{Apparent sp gr} = A/(A-C) \tag{3}$$

9.2. *Average Specific Gravity Values*—When the sample is tested in separate size fractions, the average value for bulk specific gravity, bulk specific gravity (SSD), or apparent specific gravity can be computed as the weighted average of the values as computed in accordance with Section 9.1 using the following equation:

$$G = \frac{1}{\frac{P_1}{100\,G_1} + \frac{P_2}{100\,G_2} + \cdots \frac{P_n}{100\,G_n}} \tag{4}$$

where:

G = average specific gravity (All forms of expression of specific gravity can be averaged in this manner.);

$P_1, P_2 \ldots P_n$ = mass percentages of each size fraction present in the original sample; and

$G_1, G_2 \ldots G_n$ = appropriate specific gravity values for each size fraction depending on the type of specific gravity being averaged.

Note 4—Some users of this method may wish to express the results in terms of density. Density may be determined by multiplying the bulk specific gravity, bulk specific gravity (SSD), or apparent specific gravity by the density of water (997.5 kg/m^3 or 0.9975 Mg/m^3 or 62.27 lb/ft^3 at 23ºC). Some authorities recommend using the density of water at 4ºC (1000 kg/m^3 or 1.000 Mg/m^3 or 62.43 lb/ft^3) as being sufficiently accurate. The density terminology corresponding to bulk specific gravity, bulk specific gravity (SSD), and apparent specific gravity has not been standardized.

9.3. *Absorption*—Calculate the percentage of absorption, as follows:

$$\text{Absorption, percent} = [(B - A)/A] \times 100 \tag{5}$$

9.4. *Average Absorption Value*—When the sample is tested in separate size fractions, the average absorption value is the average of the values as computed in Section 9.3, weighted in proportion to the mass percentages of the size fractions in the original sample as follows:

$$A = (P_1 A_1/100) + (P_2 A_2/100) + \cdots (P_n A_n/100) \tag{6}$$

where:

A = average absorption, percent;

$P_1, P_2 \ldots P_n$ = mass percentages of each size fraction present in the original sample; and

$A_1, A_2 \ldots A_n$ = absorption percentages for each size fraction.

10. REPORT

10.1. Report specific gravity results to the nearest 0.001(Coarse Aggregate meeting M 80 requirements may be reported to the nearest 0.01), and indicate the type of specific gravity, whether bulk, bulk (saturated-surface-dry), or apparent.

10.2. Report the absorption result to the nearest 0.1 percent.

10.3. If the specific gravity and absorption values were determined without first drying the aggregate, as permitted in Section 8.2, it shall be noted in the report.

11. PRECISION AND BIAS

11.1. The estimates of precision of this test method listed in Table 1 are based on results from the AASHTO Materials Reference Laboratory Reference Sample Program, with testing conducted by this test method and ASTM C 127. The significant difference between the methods is that ASTM C 127 requires a saturation period of 24 ± 4 hours, while T 85 requires a saturation period of 15 hours minimum. This difference has been found to have insignificant effect on the precision indices. The data are based on the analyses of more than 100 paired test results from 40 to 100 laboratories.

Table 1—Precision

	Standard Deviation (1s)[a]	Acceptable Range of Two Results (d2s)[a]
Single-operator precision:		
Bulk specific gravity (dry)	0.009	0.025
Bulk specific gravity (SSD)	0.007	0.020
Apparent specific gravity	0.007	0.020
Absorption,[b] percent	0.088	0.25
Multilaboratory precision:		
Bulk specific gravity (dry)	0.013	0.038
Bulk specific gravity (SSD)	0.011	0.032
Apparent specific gravity	0.011	0.032
Absorption,[b] percent	0.145	0.41

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670. The precision estimates were obtained from the analysis of combined AASHTO Materials Reference Laboratory reference sample data from laboratories using 15-hour minimum saturation times and other laboratories using 24 ± 4-hour saturation time. Testing was performed on aggregates of normal specific gravities and started with aggregates in the oven-dry condition.

[b] Precision estimates are based on aggregates with absorptions of less than 2 percent.

11.2. *Bias*—Since there is no accepted reference material for determining the bias for the procedure in this test method, no statement on bias is being made.

APPENDIXES

(Nonmandatory Information)

X1. DEVELOPMENT OF EQUATIONS

X1.1. The derivation of the equation is apparent from the following simplified cases using two solids. Solid 1 has a mass W_1 in grams and a volume V_1 in milliliters; its specific gravity (G_1) is therefore W_1/V_1. Solid 2 has a mass W_2 and volume V_2, and $G_2 = W_2/V_2$. If the two solids are considered together, the specific gravity of the combination is the total mass in grams divided by the total volume in milliliters:

$$G = (W_1 + W_2)/(V_1 + V_2) \qquad (X1.1)$$

Manipulation of this equation yields the following:

$$G = \frac{1}{\dfrac{V_1 + V_2}{W_1 + W_2}} = \frac{1}{\dfrac{V_1}{W_1 + W_2} + \dfrac{V_2}{W_1 + W_2}} \qquad (X1.2)$$

$$G = \frac{1}{\dfrac{W_1}{W_1 + W_2}\left(\dfrac{V_1}{W_1}\right) + \dfrac{W_2}{W_1 + W_2}\left(\dfrac{V_2}{W_2}\right)} \qquad (X1.3)$$

However, the mass fractions of the two solids are:

$$W_1/(W_1 + W_2) = P_1/100 \qquad (X1.4)$$

and:

$$W_2/(W_1+W_2)=P_2/100 \qquad (X1.5)$$

and:

$$1/G_1=V_1/W_1 \text{ and } 1/G_2=V_2/W_2 \qquad (X1.6)$$

therefore:

$$G=1/[(P_1/100)(1/G_1)+(P_2/100)(1/G_2)] \qquad (X1.7)$$

An example of the computation is given in Table X1.1.

Table X1.1—Example Calculation of Average Values of Specific Gravity and Absorption for a Coarse Aggregate Tested in Separate Sizes

Size Fraction, mm (in.)	Percent in Original Sample	Bulk Specific Gravity (SSD)[a]	Sample Mass Used in Test, g	Absorption, percent
4.75 to 12.5 (No. 4 to $^1/_2$)	44	2.72	2213.0	0.4
12.5 to 37.5 ($^1/_2$ to $1^1/_2$)	35	2.56	5462.5	2.5
37.5 to 63 ($1^1/_2$ to $2^1/_2$)	21	2.54	12593.0	3.0

[a] Average Specific Gravity (SSD)

$$G_{SSD}=\frac{1}{\dfrac{0.44}{2.72}+\dfrac{0.35}{2.56}+\dfrac{0.21}{2.54}}=2.62 \qquad (X1.8)$$

Average Absorption:

$$A=(0.44)\ (0.4)+(0.35)\ (2.5)+(0.21)\ (3.0)=1.7\% \qquad (X1.9)$$

X2. INTERRELATIONSHIPS BETWEEN SPECIFIC GRAVITIES AND ABSORPTION AS DEFINED IN METHODS T 85 AND T 84

X2.1. Let:

S_d = bulk specific gravity (dry basis),

S_s = bulk specific gravity (SSD basis),

S_a = apparent specific gravity, and

A = absorption in percent.

Then:

$$S_s=(1+A/100)\,S_d \qquad (X2.1)$$

$$S_a=\frac{1}{\dfrac{1}{S_d}-\dfrac{A}{100}}=\frac{S_d}{1-\dfrac{AS_d}{100}} \qquad (X2.2)$$

$$S_d = \frac{1}{\frac{1 + A/100}{S_s} - \frac{A}{100}} \qquad (X2.3)$$

$$= \frac{S_s}{1 - \left(\frac{A}{100}\left(S_s - 1\right)\right)}$$

$$A = \left(\frac{S_s}{S_d} - 1\right)100 \qquad (X2.4)$$

$$A = \left(\frac{S_a - S_s}{S_a\left(S_s - 1\right)}\right)100 \qquad (X2.5)$$

---

[1] This method is technically equivalent to ASTM C 127-04.

Standard Method of Test for

Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

AASHTO Designation: T 96-02 (2006)
ASTM Designation: C 131-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine

AASHTO Designation: T 96-02 (2006)
ASTM Designation: C 131-01

AASHTO T 96-02 (2006) is identical to ASTM C 131-01 except for the following provisions:

1. All references to the ASTM standards contained in ASTM C 131-01, listed in the following table, shall be replaced with the corresponding AASHTO standard.

Referenced Standards

ASTM	AASHTO
C 136	T 27
C 702	T 248
D 75	T 2
E 11	M 92

2. Add a new Section after Section 3.1 of ASTM C 131-01 as follows:

   3.2 DESCRIPTION OF TERMS

   Constant Mass—Test samples dried at a temperature of 110 ± 5ºC (230 ± 9ºF) to a condition such that it will not lose more than 0.1 percent moisture after an additional 2 hours of drying at 110 ± 5ºC (230 ± 9ºF). Such a condition of dryness can be verified by determining the mass of the sample before and after successive 2 hours of drying periods. In lieu of such a determination, samples may be considered to have reached constant mass when they have been dried at a temperature of 110 ± 5ºC (230 ± 9ºF) for an equal or longer period than that previously found adequate for producing the desired constant mass condition under equal or heavier loading conditions of the oven.

3. Add the phrase to the first sentence in Section 6.1 of ASTM C 131-01 as follows:

   …machine "equipped with a counter and" conforming…

   Also replace the seventh sentence of this section as follows:

   "A removable steel shelf shall extend along the length of the cylinder to within 5 mm (0.2 in.) of the full inside length of the cylinder, project inward 89 ± 2 mm (3.5 ± 0.1 in.) and shall be mounted on the interior cylindrical surface of the cylinder, or on the inside surface of the cover, in such a way that a plane centered between the large faces coincides with an axial plane."

   Also the third from the last sentence of Section 6.1 of ASTM C 131-01 is not included in AASHTO T 96-02 (2006).

4. Changes to Figure 1 of ASTM C 131-01 are as follows:

a. The phrase "NOT LESS THAN 1270 mm MEASURED ON OUTSIDE OF DRUM" is not included in AASHTO T 96-02 (2006).

b. The steel wall thickness shall be changed from "12.7 mm THICK" to "12.7 ± 3.2 mm ($^1/_2$ ± $^1/_8$ in.) THICK."

5. Add the following note after Note 2 in ASTM C 131-01:

   "NOTE—Due to its mass, the location of the shelf relative to the opening influences the "at rest" position of the opening. The shelf location should be chosen to provide a convenient position of the opening to facilitate the loading of aggregate and spheres and to avoid impact of the charge on the cover."

6. Add the following new section after Section 6.3 of ASTM C 131-01:

   "*Oven*—The oven shall be capable of maintaining a uniform temperature of 110 ± 5ºC (230 ± 9ºF)."

7. Replace Section 6.3 of ASTM C 131-01 with the following:

   "*Balance*—The balance shall conform to AASHTO M 231, Class G 5."

Standard Method of Test for

Soundness of Aggregates by Freezing and Thawing

AASHTO Designation: T 103-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Soundness of Aggregates by Freezing and Thawing

AASHTO Designation: T 103-08

1. SCOPE

1.1. This method describes three procedures to be followed in testing aggregates to determine their resistance to disintegration by freezing and thawing. It furnishes information helpful in judging the soundness of aggregates subjected to weathering, particularly when adequate information is not available from service records of the behavior of the aggregate.

1.2. The following applies to all specified limits in this standard: For the purpose of determining conformance with these specifications, an observed value or a calculated value shall be rounded off "to the nearest unit" in the last right-hand place of figures used in expressing the limiting value, in accordance with the rounding-off of E 29.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 27, Sieve Analysis of Fine and Coarse Aggregates

2.2. *ASTM Standard*:

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. APPARATUS

3.1. *The apparatus shall consist of the following*:

3.1.1. *Freezing Equipment*—No specific requirements for the type or size of the freezing equipment are given as many laboratories have adequate equipment but variable in type and size. The freezing and thawing apparatus shall consist of a suitable chamber or chambers in which the sample may be subjected to the specified freezing and thawing cycle, together with the necessary refrigerating and heating equipment and controls to produce continuously and automatically, reproducible cycles within the specified temperature requirements. In the event that the equipment does not operate automatically, provision shall be made for either its continuous manual operation on a 24-hour-a-day basis or for the storage of all samples in a thawed condition when the equipment is not in operation. All equipment shall be capable of being operated at a temperature not higher than

–26º ± 3°C (–15º ± 5.4ºF) to 21°C ± 3°C (70°F ± 5.4°F) at any point in the freezing chamber. The equipment shall be equipped with an automatic temperature-recording device with an approximate temperature range of –40ºC (–40ºF) to 50ºC (122ºF), readable and accurate to 0.5ºC (1ºF).

3.1.2. *Sample Containers*—The sample containers shall be of plastic, rubber, or other materials suitable for the procedure to be followed. The containers shall be flexible to not cause undue stress on the aggregate being tested in water in the freezing cycle. The sample containers shall be of sufficient size to hold required sample and solution as well as being compatible with the freeze/thaw apparatus.

3.1.3. *Sieves*—The sieves used shall meet the requirements of M 92.

3.1.4. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

3.1.5. *Drying Oven*—The drying oven shall provide a free circulation of air through the oven and shall be capable of maintaining a temperature of 110º ± 5ºC (230º ± 9ºF).

3.1.6. *Temperature–Measuring Equipment*—Shall consist of thermometers, resistance thermometers, or thermocouples, capable of measuring the temperature at various points within the testing chamber and at the centers of each sample container. The thermometers, resistance thermometers, or thermocouples shall have an approximate range from –26ºC to 50ºC (–15° to 120ºF), readable and accurate to 0.5ºC (1ºF).

4. SAMPLES

4.1. *Fine Aggregate*—Fine aggregate for the test shall be passed through a 9.5-mm ($^3/_8$-in.) sieve. The sample shall be of such size that it will yield a minimum 100 g of each of the following sieves:

Table 1—Sieve Size

Passing Sieve	Retained on Sieve
9.5 mm ($^3/_8$ in.)	4.75 mm (No. 4)
4.75 mm (No. 4)	2.36 mm (No. 8)
2.36 mm (No. 8)	1.18 mm (No. 16)
1.18 mm (No. 16)	600 µm (No. 30)
600 µm (No. 30)	300 µm (No. 50)

4.1.1. Should the sample contain less than five percent of any of the sizes specified in Section 4.1., that size shall not be tested.

4.2. *Coarse Aggregate*—Coarse aggregate for the test shall consist of +4.75-mm (No. 4) sieve size material. The sample shall be of such a size that it will yield the following minimum:

Table 2—Grading Requirements

Fraction Size Range (Note 1)	Mass, g
Larger sizes by 25.0-mm (1-in.) spread in sieve size, each fraction	7000 ± 1000
63-mm to 50-mm ($2^1/_2$-in. to 2-in.) material	3000 ± 300
50-mm to 37.5-mm (2- in. to $1^1/_2$-in.) material	2000 ± 200
37.5-mm to 25.0-mm ($1^1/_2$-in. to 1-in.) material	1000 ± 50
25.0-mm to 19.0-mm (1-in. to $^3/_4$-in.) material	700 ± 30
19.0-mm to 12.5-mm ($^3/_4$-in. to $^1/_2$-in.) material	670 ± 10
12.5-mm to 9.5-mm ($^1/_2$-in. to $^3/_8$-in.) material	330 ± 5
9.5-mm to 4.75-mm ($^3/_8$-in. to No. 4) material	300 ± 5

Note 1—The number and size range of fraction sizes, which are shown in Table 2, may be changed to reduce the number of size fractions being tested; however, the total sample mass for the number of size fractions being tested should equal the sample mass for the size as shown in Table 2.

4.3. Should the samples contain less than 5 percent of the sizes specified in Section 4.1 or 4.2, that size shall not be tested. For the purpose of calculating the test results, it shall be considered to have the same loss in treatment as the average of the next smaller and the next larger size. If one of these sizes is absent, it shall be considered to have the same loss as the next larger or next smaller size, whichever is present. When the 19- to 9.5-mm ($^3/_4$- to $^3/_8$-in.), 37.5- to 19.0-mm ($^3/_4$- to $1^1/_2$-in.), or 63- to 37.5-mm ($2^1/_2$- to $1^1/_2$-in.) test samples specified in Section 4.2 cannot be prepared due to absence of one of the two sizes of aggregate shown for each, the size available shall be used to prepare the sample tested.

4.4. When a sample to be tested with more than 10 percent coarser than the 9.5-mm ($^3/_8$-in.) sieve and, also, more than 10 percent finer than the 4.75-mm (No. 4) sieve, the sample shall be divided into a minus 4.75-mm fraction and a plus 4.75-mm fraction. The resulting fractions shall be tested in accordance with the procedures for fine aggregate and coarse aggregate, respectively. Report the results separately for the fine aggregate fraction and the coarse aggregate fraction, giving the percentages of the coarse and fine size fractions in the initial grading.

Table 3—Grading Requirements

Size (Square-Opening Sieves)	Mass, g
9.5 mm to 4.75 mm ($^3/_8$ in. to No. 4)	300 ± 5
19.0 mm to 9.5 mm ($^3/_4$ in. to $^3/_8$ in.)	1000 ± 10
Consisting of:	
12.5-mm to 9.5-mm ($^1/_2$-in. to $^3/_8$-in.) material	330 ± 5
19.0-mm to 12.5-mm ($^3/_4$-in. to $^1/_2$-in.) material	670 ± 10
37.5-mm to 19.0-mm ($1^1/_2$-in. to $^3/_4$-in.) material	1500 ± 50
Consisting of:	
25.0-mm to 19.0-mm (1-in. to $^3/_4$-in.) material	500 ± 30
37.5-mm to 25.0-mm ($1^1/_2$-in. to 1-in.) material	1000 ± 50
63-mm to 37.5-mm ($2^1/_2$-in. to $1^1/_2$-in.) material	5000 ± 300
Consisting of:	
50-mm to 37.5-mm (2-in. to $1^1/_2$-in.) material	2000 ± 200
63-mm to 50-mm ($2^1/_2$-in. to 2-in.) material	3000 ± 300
Larger sizes by 25.0-mm (1-in.) spread in sieve size, each fraction	7000 ± 1000

5. PREPARATION OF TEST SAMPLE

5.1. *Fine Aggregate*—The sample shall be thoroughly washed on a 150-µm (No. 100) sieve and dried to constant mass at a temperature of 110 ± 5ºC (230º ± 9ºF). The sample shall be separated into the different sizes by sieving, as follows:

5.1.1. Separate each fraction of mineral aggregate by sieving over required nest of the standard sieves specified in Section 4.1. From the fractions obtained in this manner select samples of sufficient size to yield 100 g after sieving to refusal per AASHTO T 27. Fine aggregate sticking in the meshes of the sieves shall not be used in preparing the samples. Samples consisting of 100 g shall be weighed out of each of the separated fractions after final sieving and placed in separate containers for the test.

5.2. *Coarse Aggregate*—The sample of coarse aggregate shall be thoroughly washed and dried to constant mass at a temperature of 110º ± 5ºC (230º ± 9ºF). It shall be separated into the different sizes shown in Section 4.2 by sieving to refusal per AASHTO T 27. The proper mass of sample for each fraction shall be weighed out and placed in separate containers for the test. In the case of fractions coarser than the 19.0-mm ($^3/_4$-in.) sieve, the number of particles shall be counted.

5.3. *Ledge Rock*—For testing ledge rock, the sample shall be prepared by breaking it into fragments reasonably uniform in size and shape and having a mass of approximately 100 g each. The test sample shall have a mass of 5000 g ± 100 g. The sample shall be thoroughly washed and dried previous to test as described in Section 5.2.

Table 4—Suggested Form for Recording Test Data (with Illustrative Test Values)

Sieve Size			Grading of Original Sample, Percent	Mass of Test Fractions Before Test, g	Percentage Passing Designated Sieve After Test	Weighted Percentage Loss
			Soundness Test of Fine Aggregate			
Minus 150 µm			5			
300 µm to 150 µm			12			
600 µm to 300 µm			26	100	4.2	1.1
1.18 mm to 600 µm			25	100	4.8	1.2
2.36 mm to 1.18 mm			17	100	8.0	1.4
4.75 mm to 2.36 mm			11	100	11.2	1.2
9.5 mm to 4.75 mm			4		11.2[a]	0.4
Totals			100			5
			Soundness Test of Coarse Aggregate			
63 mm to 50 mm	2825 g	63 to 37.5 mm	20	4783	4.8	1.0
50 mm to 37.5 mm	1958 g					
37.5 mm to 25.0 mm	1012 g	37.5 to 19.0 mm	45	1525	8.0	3.6
25.0 mm to 19.0 mm	513 g					
19.0 mm to 12.5 mm	675 g	19.0 to 9.5 mm	23	1008	9.6	2.2
12.5 mm to 9.5 mm	333 g					
9.5 mm to 4.75 mm			12	298	11.2	1.3
Totals			100			8

[a] The percentage loss (11.2 percent) of the next smaller size is used as the percentage loss for this size, since this size contains less than 5 percent of the original sample as received. See Section 4.3.

6. PROCEDURES

6.1. *Procedure A—Total Immersion*:

6.1.1. Each sample fraction obtained per Section 5 shall be placed in a freeze/thaw container. Sufficient quantity of water, 3 percent NaCl and water solution, or 0.5 percent methyl alcohol and water solution shall be added to the sample container to completely immerse the sample in the solution. Allow the immersed sample to soak for 24 ± 4 hours at a temperature of 23° ± 3°C (73° ± 5°F) prior to the start of the freeze cycle.

6.1.2. Each sample fraction container shall be placed in the freeze apparatus. A thermometer or thermocouple shall be placed in the center of one of the samples. The sample shall be cooled until the temperature at the center of the sample reaches –23° ± 3°C (–9° ± 5°F). The temperature shall be held for a minimum 2 hours prior to the start of the thaw cycle. Upon completion of a freeze cycle, the temperature at the center of the sample shall be raised to 21° ± 3°C (70° ± 5°F). The temperature shall be held for a minimum 30 minutes.

6.2. *Procedure B—Partial Immersion in Alcohol–Water Solution*:

6.2.1. In this procedure, the samples shall be placed in a vacuum chamber and saturated by subjecting them to an air pressure of not over 3.4 kPa (25.4 mm of mercury), and breaking the vacuum with a sufficient amount of a 0.5 percent (by mass) solution of ethyl alcohol in water to completely cover the samples. The samples shall be left in the solution for 15 minutes.

6.2.2. The samples shall then be removed from the vacuum chamber. Coarse aggregates shall be placed one layer deep in shallow pans containing 6.4 mm ($^1/_4$ in.) of the alcohol–water solution and frozen in this condition. Samples of fine aggregate can most conveniently be handled by placing them in 250-µm (No. 60) or finer wire cloth sieves which in turn are held in shallow trays, and the samples frozen in a surface-wet condition.

6.2.3. Samples shall be frozen and thawed as required in Procedure A.

6.3. *Procedure C—Partial Immersion in Water*:

6.3.1. This procedure is the same as Procedure B except that water is used instead of the alcohol–water solution.

7. CYCLES

7.1. Alternate freezing and thawing shall be repeated until the required number of cycles is obtained. One test cycle consists of one freeze cycle and one thaw cycle. Repeat the procedure of alternate freezing and thawing for 25 cycles. Aggregate type and history may require additional cycles to accurately evaluate aggregate performance. One complete cycle shall not exceed 24 hours. If the test is interrupted, the sample shall remain covered in a thawed state until testing is resumed. The sample shall remain immersed during the test.

Some authorities have required 50, 16, and 25 cycles for Procedures A, B, and C, respectively.

8. QUANTITATIVE EXAMINATION

8.1. *The quantitative examination shall be made as follows*:

8.1.1. After the completion of the final cycle, each sample shall be dried to constant mass at 110º ± 5ºC (230º ± 9ºF) weighed, and except in the case of fine aggregate or ledge rock, sieved over the sieve shown for the appropriate size of particle in Table 4. The material retained on the sieve shall be weighed and the mass recorded. Larger sizes by 25-mm spread in sieve size shall be sieved over the original retaining sieve to determine their loss. The material retained on each sieve shall be weighed and the mass recorded.

Table 5—Sieve Size

Size of Aggregate	Sieve Used to Determine Loss
63 mm to 37.5 mm ($2_1/_2$ to $1^1/_2$ in.)	31.5 mm ($1^1/_4$ in.)
37.5 mm to 19.0 mm ($1^1/_2$ to $^3/_4$ in.)	16.0 mm ($^5/_8$ in.)
19.0 mm to 9.5 mm ($^3/_4$ to $^3/_8$ in.)	8.0 mm ($^5/_{16}$ in.)
9.5 mm to 4.75 mm ($^3/_8$ in. to No. 4)	4.0 mm (No. 5)

8.1.2. Samples of fine aggregate shall be sieved over the original retaining sieve to determine their loss. The material retained on each sieve shall be weighed and the mass recorded.

8.1.3. In the case of ledge rock, the loss in mass shall be determined by subtracting from the original mass of the sample the final mass of all fragments that have not broken into three or more pieces.

9. REPORT

9.1. *The report shall include the following data*:

Note 2—Table 4 in Section 5, shown with test values inserted for purpose of illustration, is a suggested form for recording test data. The test values shown might be appropriate for any procedure, depending on the quality of the aggregates.

9.1.1. Mass of each fraction of each sample before test.

9.1.2. Except in the case of ledge rock, the actual loss of each fraction of the sample expressed as a percentage of the original mass of the fraction.

9.1.3. Weighted average calculated from the percentage of loss for each fraction, based on the grading of the sample as received for examination or, preferably, on the average grading of the material from that portion of the supply of which the sample is representative. In these calculations, sizes finer than the 300-μm (No. 50) sieve shall be assumed to have zero-percent loss.

9.1.4. For an aggregate containing appreciable amounts of both fine and coarse material tested as two separate samples as required in Section 4.4, compute the weighted average losses separately for the minus 4.75-mm and plus 4.75-mm fractions based on recomputed gradings considering the fine fraction as 100 percent and the coarse fraction as 100 percent. Report the results separately giving the percentage of the minus 4.75-mm and plus 4.75-mm material in the initial grading.

9.1.5. In the case of ledge rock, the loss as determined in Section 8.1.3 shall be reported as a percentage of the original mass.

9.1.6. If considered desirable or when requested, the type of failure of the discrete particles in the sample shall be reported.

9.1.7. Procedure used.

9.1.8. For Procedure A, solution used.

Standard Method of Test for

Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate

AASHTO Designation: T 104-99 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Soundness of Aggregate by Use of Sodium Sulfate or Magnesium Sulfate

AASHTO Designation: T 104-99 (2007)

1. SCOPE

1.1. This method covers the procedure to be followed in testing aggregates to determine their resistance to disintegration by saturated solutions of sodium sulfate or magnesium sulfate. This is accomplished by repeated immersion in saturated solutions of sodium or magnesium sulfate followed by oven drying to partially or completely dehydrate the salt precipitated in permeable pore spaces. The internal expansive force, derived from the rehydration of the salt upon re-immersion, simulates the expansion of water on freezing. This test method furnishes information helpful in judging the soundness of aggregates subject to weathering action, particularly when adequate information is not available from service records of the material exposed to actual weathering conditions. Attention is called to the fact that test results by the use of the two salts differ considerably and care must be exercised in fixing proper limits in any specifications that may include requirements for these tests.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 27, Sieve Analysis of Fine and Coarse Aggregates

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 100, Standard Specification for ASTM Hydrometers

3. APPARATUS

3.1. *Sieves*—With square openings of the following sizes conforming to M 92, for sieving the samples in accordance with Sections 5, 6, and 8:

4.75 mm	(No. 4)	63 mm	($2^1/_2$ in.)
4.00 mm	(No. 5)	50 mm	(2 in.)
2.36 mm	(No. 8)	37.5 mm	($1^1/_2$ in.)
1.18 mm	(No. 16)	31.5 mm	($1^1/_4$ in.)
600 µm	(No. 30)	25.0 mm	(1 in.)
300 µm	(No. 50)	19.0 mm	($^3/_4$ in.)
150 µm	(No. 100)	16.0 mm	($^5/_8$ in.)
		12.5 mm	($^1/_2$ in.)
		9.5 mm	($^3/_8$ in.)
		8.0 mm	($^5/_{16}$ in.)

3.2. *Containers for Samples*—Sieves 203.2 mm (8 in.) in diameter for each separate size fractions of aggregate during test. Used, out-of-tolerance sieves according to M 92, in acceptable condition, may be used as containers (Note 1).

3.2.1. *Coarse Aggregate*—2.36-mm (No. 8) Size.

3.2.2. *Fine Aggregate*—250-µm (No. 60) Size.

Note 1—Sieves 203.2 mm (8 in.) in diameter may be substituted with containers which permit free access of solution to the sample and drainage of the solution from the sample without loss of aggregate. Substitution with such containers may affect results. Referee testing, comparison testing, or testing of aggregate to be used in critical applications must be performed using sieves 203.2 mm (8 in.) in diameter.

3.3. *Apparatus for Immersing Samples in Solution (optional)*—When necessary, apparatus for holding the sieves containing the sample for immersing into the solution shall be constructed in such a manner to permit free access of the solution to the sample and drainage of the solution from the sample.

3.4. *Temperature Regulation*—Suitable means for regulating the temperature of the samples during immersion in the sodium sulfate or magnesium sulfate solution shall be provided.

3.5. *Thermometer*—A thermometer covering the recommended temperature range for solutions during test and readable to 0.1ºC (0.2ºF).

3.6. *Temperature Recorder*—A unit capable of recording solution temperature a minimum of once every 10 minutes for the duration of the test with an accuracy of 0.3ºC (0.5ºF).

3.7. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

3.8. *Drying Oven*—The oven shall be capable of being heated continuously at 110º ± 5ºC (230º ± 9ºF) and the rate of evaporation, at this range of temperature, shall be at least 25 g/h for 4 hours, during which period the doors of the oven shall be kept closed. This rate shall be determined by the loss of water from 1-liter Griffin low-form beakers, each initially containing 500 g of water at a temperature of 21º ± 2ºC (70º ± 3ºF), placed at each corner and the center of each shelf of the oven. The evaporation requirement is to apply to all test locations when the oven is empty except for the beakers of water.

3.9. *Specific Gravity Measurement*—Hydrometers conforming to the requirements of ASTM E 100, or a suitable combination of graduated glassware and balance, capable of measuring the solution specific gravity within ±0.001.

4. SPECIAL SOLUTIONS REQUIRED

4.1. Prepare the solution for immersion of test samples from either sodium or magnesium sulfate in accordance with Section 4.1.1 or 4.1.2 (Note 2). The volume of the solution shall be at least five times the solid volume of all samples immersed at any one time.

Note 2—Some aggregates containing carbonates of calcium or magnesium are attacked chemically by fresh sulfate solution, resulting in erroneously high-measured losses. If this condition is encountered or is suspected, repeat the test using a filtered solution that has been used previously to test the same type of carbonate rock, provided that the solution meets the requirements of Sections 4.1.1 and 4.1.2 for specific gravity.

4.1.1. *Sodium Sulfate Solution*—Prepare a saturated solution of sodium sulfate by dissolving a reagent grade of the salt in water (Note 5) at a temperature of 25ºC (77ºF) minimum. Add sufficient salt (Note 3) of the anhydrous (Na_2SO_4) form to ensure not only saturation but also the presence of excess crystals when the solution is ready for use in the tests. Thoroughly stir the mixture during the addition of the salt and stir the solution at frequent intervals until used. To reduce evaporation and prevent contamination, keep the solution covered at all times when access is not needed. Allow the solution to cool to 20.3 to 21.9ºC (68.5 to 71.5ºF). Again stir, and allow the solution to remain at the designated temperature for at least 48 hours before use. Prior to each use, break up the salt cake, if any, in the container, stir the solution thoroughly, and determine the specific gravity of the solution. When used, the solution shall have a specific gravity not less than 1.154 nor more than 1.171. Discard a discolored solution, or filter it and check for specific gravity.

Note 3—For the solution, 215 g of anhydrous salt per liter of water are sufficient for saturation at 22ºC (71.6ºF). However, since this salt is not completely stable and since it is desirable that an excess of crystals be present, the use of not less than 225 g of the anhydrous salt per liter of water is recommended.

4.1.2. *Magnesium Sulfate Solution*—Prepare a saturated solution of magnesium sulfate by dissolving a reagent grade of the salt in water (Note 5) at a minimum temperature of 25ºC (77ºF) (Note 4). Add sufficient salt (Note 4) of either the anhydrous ($MgSO_4$) or the crystalline ($MgSO_4 \cdot 7H_2O$) (Epsom salt) form, to ensure saturation and the presence of excess crystals when the solution is ready for use in the tests. Thoroughly stir the mixture during the addition of the salt and stir the solution at frequent intervals until used. To reduce evaporation and prevent contamination, keep the solution covered at all times when access is not needed. Allow the solution to cool to 20.3 to 21.9ºC (68.5 to 71.5ºF). Again stir, and allow the solution to remain at the designated temperature for at least 48 hours before use. Prior to each use, break up the salt cake, if any, in the container, stir the solution thoroughly, and determine the specific gravity of the solution. When used, the solution shall have a specific gravity not less than 1.297 nor more than 1.306. Discard a discolored solution, or filter it and check for specific gravity.

Note 4—For the solution, 350 g of anhydrous salt or 1230 g of the heptahydrate per liter of water are sufficient for saturation at 23ºC (73.4ºF). However, since these salts are not completely stable, with the hydrous salt being the more stable of the two, and since it is desirable that an excess of crystals be present, it is recommended that the heptahydrate salt be used and in an amount of not less than 1400 g/L of water.

When preparing the saturated solution of magnesium sulfate, the salt crystals will dissolve more readily if the crystals are added in small amounts and the water temperature is higher than 35ºC (95ºF) due to the chemical cooling effect during preparation.

Note 5—Distilled water shall be used in referee or comparison testing.

4.2. *Barium Chloride Solution*—A 0.2 molar solution of barium chloride (41.6 g of $BaCl_2$ per liter of solution) to determine the presence of sodium or magnesium sulfate in the wash water.

5. SAMPLES

5.1. *Fine Aggregate*—Fine aggregate for the test shall be passed through a 9.5-mm ($^3/_8$-in.) sieve. The sample shall be of such size that it will yield not less than 100 g of each of the following sizes, expressed in terms of the following sieves:

Passing Sieve	Retained on Sieve
9.5 mm ($^3/_8$ in.)	4.75 mm (No. 4)
4.75 mm (No. 4)	2.36 mm (No. 8)
2.36 mm (No. 8)	1.18 mm (No. 16)
1.18 mm (No. 16)	600 µm (No. 30)
600 µm (No. 30)	300 µm (No. 50)

5.1.1. Should the sample contain less than 5 percent of any of the sizes specified in Section 5.1, that size shall not be tested.

5.2. *Coarse Aggregate*—Coarse aggregate for the test shall consist of material from which the sizes finer than the 4.75-mm (No. 4) sieve have been removed. The sample shall be of such a size that it will yield the amounts indicated in Table 1.

Table 1—Coarse Aggregate Sample

Sieve Size	Mass, g
63 mm to 37.5 mm ($2^1/_2$ in. to $1^1/_2$ in.)	5000 ± 300
Consisting of:	
50-mm to 37.5-mm (2-in. to $1^1/_2$-in.) material	2000 ± 200
63-mm to 50-mm ($2^1/_2$-in. to 2-in.) material	3000 ± 300
37.5 mm to 19.0 mm ($1^1/_2$ in. to $^3/_4$ in.)	1500 ± 50
Consisting of:	
25.0-mm to 19.0-mm (1-in. to $^3/_4$ -in.) material	500 ± 30
37.5-mm to 25.0-mm ($1^1/_2$-in. to 1-in.) material	1000 ± 50
19.0 mm to 9.5 mm ($^3/_4$ in. to $^3/_8$ in.)	1000 ± 10
Consisting of:	
12.5-mm to 9.5-mm ($^1/_2$-in. to $^3/_8$-in.) material	330 ± 5
19.0-mm to 12.5-mm ($^3/_4$-in. to $^1/_2$-in.) material	670 ± 10
9.5 mm to 4.75 mm ($^3/_8$ in. to No. 4)	300 ± 5

5.2.1. Should the sample contain less than 5 percent of any of the sizes specified in Section 5.2, that size shall not be tested. When a combination of sizes is specified for the test portion and one of the sizes specified is less than 5 percent of the sample, reduce the test portion by the applicable mass specified in Section 5.2 for the size not available.

5.2.2. When testing large rock (broken stone, ledge rock, cobbles, and boulders for use as riprap, channel lining, etc.), obtain the test portion by crushing, splitting, or sawing the larger sample pieces. Test only those pieces in the 37.5 to 19.0 mm ($1^1/_2$ to $^3/_4$ in.) and 63 to 37.5 mm ($2^1/_2$ to $1^1/_2$ in.) size fractions when size reduction is by crushing or splitting. Test pieces in the 63 to 37.5 mm ($2^1/_2$ to $1^1/_2$ in.) size fraction when size reduction is by sawing.

Note 6—When the rock contains bedding planes, crushing or splitting will usually cause the rock to break on those bedding planes. Sawing will usually leave the bedding planes intact, and thus more likely to split the particles due to growth of the salt crystals in the soundness test.

5.2.3. When testing large rock (to evaluate a potential source) which will be subsequently crushed to produce aggregate, obtain the test portion by crushing the larger sample pieces. Test pieces only in those sizes that will be included in the produced aggregate, but ignoring any material finer than 4.75-mm (No. 4) sieve or coarser than 63-mm ($2^1/_2$-in.) sieve.

5.2.4. When the finished aggregate material will contain particles coarser than 63 mm ($2^1/_2$ in.), such as aggregate for use in mass concrete, crush the material coarser than 63 mm ($2^1/_2$ in.) and distribute the material among that in the range of 63-mm ($2^1/_2$ in.) to 4.75-mm (No. 4) sieves. Discard material finer than 4.75-mm (No. 4) sieve.

5.3. When an aggregate to be tested contains appreciable amounts of both fine and coarse material, having a grading with more than 10 percent coarser than the 9.5-mm ($^3/_8$-in.) sieve and, also, more than 10 percent finer than the 4.75-mm (No. 4) sieve, test separate samples of the minus 4.75 mm (No. 4) fraction and the plus 4.75 mm (No. 4) fraction in accordance with the procedures for fine aggregate and coarse aggregate, respectively. Report the results separately for the fine aggregate fraction and the coarse aggregate fraction, giving the percentages of the coarse and fine size fractions in the initial grading.

6. PREPARATION OF TEST SAMPLE

6.1. *Fine Aggregate*—Thoroughly wash the sample of fine aggregate on a 300-µm (No. 50) sieve, dry to constant mass at 110º ± 5ºC (230º ± 9ºF), and separate into the different sizes by sieving, as follows: Make a rough separation of the graded sample by means of a nest of the standard sieves specified in Section 5.1. From the fractions obtained in this manner, select samples of sufficient size to yield 100 g after sieving to refusal. (In general, a 110-g sample will be sufficient.) Do not use fine aggregate sticking in the meshes of the sieves in preparing the samples. Weigh samples consisting of 100 ± 0.1 g out of each of the separated fractions after final sieving, record the masses of the test samples, and place in separate containers for the test.

6.2. *Coarse Aggregate*—Thoroughly wash and dry the sample of coarse aggregate to constant mass at 110º ± 5ºC (230º ± 9ºF) and separate it into the different sizes shown in Section 5.2 by sieving to refusal. Weigh out quantities of the different sizes within the tolerances of Section 5.2 and combine them to the designated total mass (Note 7). Record the masses of the test samples and their fractional components. In the case of sizes larger than 19.0 mm ($^3/_4$ in.), record the number of particles in the test samples.

Note 7—The fractional components of each sample may be placed in separate containers if so desired but is not required. If separate containers are used, the two sizes must be combined for the calculations for Section 8.1.2 (Table 2).

Table 2—Suggested Form for Recording Test Data (with Illustrative Test Values)

Sieve Size			Grading of Original Sample, Percent	Mass of Test Fractions Before Test, g	Percentage Passing Designated Sieve After Test	Weighted Percentage Loss
			Soundness Test of Fine Aggregate			
Minus 150 µm			5			
300 µm to 150 µm			12			
600 µm to 300 µm			26	100	4.2	1.1
1.18 mm to 600 µm			25	100	4.8	1.2
2.36 mm to 1.18 mm			17	100	8.0	1.4
4.75 mm to 2.36 mm			11	100	11.2	1.2

[a] The percentage loss (11.2 percent) of the next smaller size is used as the percentage loss for this size, since this size contains less than 5 percent of the original sample as received. See Section 10.1.3.4.

7. PROCEDURE

7.1. *Storage of Samples in Solution*—Immerse the samples in the prepared solution of sodium sulfate or magnesium sulfate for not less than 16 hours nor more than 18 hours in such a manner that the solution covers them to a depth of at least 12.5 mm ($^{1}/_{2}$ in.) (Note 8). Cover the containers to reduce evaporation and prevent the accidental addition of extraneous substances. Maintain the samples immersed in the solution at a temperature of 20.3 to 21.9ºC (68.5 to 71.5ºF) for the immersion period.

Note 8—Suitably weighted wire grids placed over the sample in the containers will permit this coverage to be achieved with very light-weight aggregates.

7.2. *Drying Samples after Immersion*—After the immersion period, remove the aggregate sample from the solution, permit it to drain for 15 ± 5 minutes, and place in the drying oven. The temperature of the oven shall have been brought previously to 110º ± 5ºC (230º ± 9ºF). Dry the samples at the specified temperature until constant mass has been achieved. Establish the time required to attain constant mass as follows: with the oven containing the maximum sample load expected, check the mass losses of test samples by removing and weighing them without cooling, at intervals of 2 to 4 hours; make enough checks to establish required drying time for the least favorable oven location (Section 3.6) and sample condition (Note 9). Constant mass will be considered to have been achieved when mass loss is less than 0.1 percent of sample mass in 4 hours of drying. After constant mass has been achieved, allow the samples to cool to 20 to 25ºC (68 to 77ºF) (Note 10), when they shall again be immersed in the prepared solution as described in Section 7.1. Cooling may be aided by the use of an air conditioner or fan. Temperature of the material shall be checked by thermometer or other acceptable means before placing the material in the soaking solution.

Note 9—Drying time required to reach constant mass may vary considerably for several reasons. Efficiency of drying will be reduced as cycles accumulate because of salt adhering to particles and, in some cases, because of increase in surface area due to breakdown. The different size fractions of aggregate will have differing drying rates. The smaller sizes will tend to dry more slowly because of their larger surface area and restricted interparticle voids, but this tendency may be altered by the effects of container size and shape.

Note 10—Experience has shown that sample temperatures significantly different than the solution temperature of 21.1ºC (70.0ºF) may change the temperature of the solution temporarily, thereby causing a change in salt saturation even though the solution returns to 21.1ºC (70.0ºF) for most of the soaking period. This may cause erroneous results.

7.3. *Number of Cycles*—Repeat the process of alternate immersion and drying until the required number of cycles is obtained. Preferably, the test shall be performed continuously until the specified number of cycles is obtained. However, if the test must be interrupted, leave the samples in the oven, at 110º ± 5ºC (230º ± 9ºF) until the testing can be resumed.

7.4. Review the temperature record from the recording unit. Verify solution temperature limits were not exceeded.

8. QUANTITATIVE EXAMINATION

8.1. *Make the quantitative examination as follows*:

8.1.1. After the completion of the final cycle and after the sample has cooled, wash the sample free from the sodium sulfate or magnesium sulfate. Wash by circulating water at 43º ± 6ºC (110º ± 10ºF) through the samples in their containers by introducing hot water near the bottom and allowing the water to pass through the samples and overflow. The thoroughness of washing shall be checked by obtaining a sample of rinse water after it has passed through the samples and checked with 0.2 molar barium chloride. Further washing is required if sample becomes cloudy upon addition of the barium chloride solution. In areas where the water gives a reaction with barium chloride other analytical means shall be used to assure thoroughness of washing. In the washing operation, the samples shall not be subjected to impact or abrasion that may tend to break up particles.

8.1.2. After the sodium sulfate or magnesium sulfate has been removed, dry each fraction of the sample to constant mass at 110º ± 5ºC (230º ± 9ºF). Sieve the fine aggregate over the same sieve on which it was retained before the test, and sieve the coarse aggregate over the sieve shown below for the appropriate size of particle. For fine aggregate, the method and duration of sieving shall be the same as were used in preparing the test samples. For coarse aggregate, sieving shall be by hand, with agitation sufficient only to assure that all undersize material passes the designated sieve. No extra manipulation shall be employed to break up particles or cause them to pass the sieves. Determine the mass of the material retained on each sieve and record each amount. The difference between each of these amounts and the initial mass of the fraction of the sample tested is the loss in the test and is to be expressed as a percentage of the initial mass for use in Table 2.

Size of Aggregate	Sieve Used to Determine Loss
63 mm to 37.5 mm ($2^1/_2$ to $1^1/_2$ in.)	31.5 mm ($1^1/_4$ in.)
37.5 mm to 19.0 mm ($1^1/_2$ to $^3/_4$ in.)	16.0 mm ($^5/_8$ in.)
19.0 mm to 9.5 mm ($^3/_4$ to $^3/_8$ in.)	8.0 mm ($^5/_{16}$ in.)
9.5 mm to 4.75 mm ($^3/_8$ in. to No. 4)	4.0 mm (No. 5)

9. QUALITATIVE EXAMINATION

9.1. *Make a qualitative examination of test samples coarser than 19.0 mm ($^3/_4$ in.) as follows (Note 11)*:

9.1.1. Separate the particles of each test sample into groups according to the action produced by the test (Note 11).

9.1.2. Record the number of particles showing each type of distress.

Note 11—Many types of action may be expected. In general, they may be classified as disintegration, splitting, crumbling, cracking, flaking, etc. While only particles larger than 19.0 mm ($^3/_4$ in.) in size are required to be examined qualitatively, it is recommended that examination of the smaller sizes be made in order to determine whether there is any evidence of excessive splitting.

10. REPORT

10.1. *The report shall include the following data (Note 12)*:

10.1.1. Mass of each fraction of each sample before test.

10.1.2. Material from each fraction of the sample finer than the sieve designated in Section 8.1.2 for sieving after test, expressed as a percentage of the original mass of the fraction.

10.1.3. Weighted average calculated from the percentage of loss for each fraction, based on the grading of the sample as received for examination determined by using T 27 or, preferably, on the average grading of the material from that portion of the supply of which the sample is representative except that:

10.1.3.1. For fine aggregates with less than 10 percent coarser than the 9.5-mm ($^3/_8$-in.) sieve, assume sizes finer than the 300-μm (No. 50) sieve to have zero-percent loss and sizes coarser than the 9.5-mm ($^3/_8$-in.) sieve to have the same loss as the next smaller size for which test data are available.

10.1.3.2. For coarse aggregate with less than 10 percent finer than the 4.75-mm (No. 4) sieve, assume sizes finer than the 4.75-mm (No. 4) sieve to have the same loss as the next larger size for which test data are available.

10.1.3.3. For an aggregate containing appreciable amounts of both fine and coarse material tested as two separate samples as required in Section 5.3, compute the weighted average losses separately for the minus 4.75-mm (No. 4) and plus 4.75-mm (No. 4) fractions based on recomputed gradings considering the fine fraction as 100 percent and the coarse fraction as 100 percent. Report the results separately giving the percentage of the minus 4.75-mm (No. 4) and plus 4.75-mm (No. 4) material in the initial grading.

10.1.3.4. For the purpose of calculating the weighted average, consider any size in Section 5.1 or 5.2 that contain less than 5 percent of the sample to have the same loss as the average of the next smaller and the next larger size, or if one of these sizes is absent, to have the same loss as the next larger or next smaller size, whichever is present.

10.1.3.5. For large rock tested according to Section 5.2.2 the weighted average (if more than one size fraction is tested) shall be the arithmetic mean of the loss on the fractions tested.

10.1.3.6. For large rock tested according to Sections 5.2.3 or 5.2.4, the weighted average shall be based on a sample grading conforming to the middle of the specification to which the aggregate will be produced, or the actual grading as produced. If the specification grading includes fractions larger than 63-mm ($2^1/_2$ in.) sieve, assume such sizes have the same percentage loss as the 63 to 37.5 mm ($2^1/_2$ to $1^1/_2$ in.) fraction.

10.1.4. Report the weighted percentage loss to the nearest whole number.

10.1.5. In the case of particles coarser than 19.0 mm ($^3/_4$ in.) before test: (1) the number of particles in each fraction before test, and (2) the number of particles affected, classified as to number disintegrating, splitting, crumbling, cracking, flaking, etc., as shown in Table 3.

Table 3—Suggested Form for Qualitative Examination (with Illustrative Test Values)

Qualitative Examination of Coarse Sizes									
	Particles Exhibiting Distress								Total No. of Particles before Test
	Splitting		Crumbling		Cracking		Flaking		
Sieve Size	No.	Percent	No.	Percent	No.	Percent	No.	Percent	
63 mm to 37.5 mm	2	7	—	—	2	7	—	—	29
37.5 mm to 19.0 mm	5	—	—	2	—	—	—	—	50

10.1.6. Kind of solution (sodium or magnesium sulfate) and whether the solution was freshly prepared or previously used.

10.1.7. Method of producing particles for test, when reduced from large pieces as described in Sections 5.2.2, 5.2.3, or 5.2.4.

Note 12—Table 2, shown with test values inserted for purpose of illustration, is a suggested form for recording test data. The test values shown might be appropriate for either salt, depending on the quality of the aggregate.

11. PRECISION

11.1. For coarse aggregate with weighted average sulfate soundness losses in the ranges of 6 to 16 percent for sodium and 9 to 20 percent for magnesium, the precision indexes are as indicated, in Table 4 (Note 13).

Table 4—Precision Indexes

	Coefficient of Variation (1s%), percent[a]	Difference between Two Tests (d2s%), percent of average[a]
Multilaboratory:		
Sodium sulfate	41	116
Magnesium sulfate	25	71
Single-Operator:		
Sodium sulfate	24	68
Magnesium sulfate	11	31

[a] These numbers represent, respectively, the (1s%) and (d2s%) limits as described in ASTM C 670.

Note 13—The values in the precision statement are based on testing according to this method prior to revision in 1991. The revisions in 1991 are believed to improve the precision of the method.

Standard Method of Test for

Clay Lumps and Friable Particles in Aggregate

AASHTO Designation: T 112-00 (2008)[1]
ASTM Designation: C 142-97

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Clay Lumps and Friable Particles in Aggregate

AASHTO Designation: T 112-00 (2008)[1]
ASTM Designation: C 142-97

1. SCOPE

1.1. This method covers the approximate determination of clay lumps and friable particles in natural aggregates.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing

3. SIGNIFICANCE AND USE

3.1. This test method is of primary significance in determining the acceptability of aggregate with respect to the requirements of M 6 and M 80.

4. APPARATUS

4.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

4.2. *Containers*—Rust-resistant containers of a size and shape that will permit the spreading of the sample on the bottom in a thin layer.

4.3. *Sieves*—Sieves conforming to M 92.

4.4. *Oven*—An oven providing free circulation of air and capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF).

5. SAMPLES

5.1. Aggregate for this test shall consist of the material remaining after completion of T 11. To provide the quantities designated in Sections 5.3 and 5.4, it may be necessary to combine material from more than one test by T 11.

5.2. Dry the aggregate to substantially constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF).

5.3. Test samples of fine aggregate shall consist of the particles coarser than a 1.18-mm (No. 16) sieve and shall have a mass not less than 25 g.

5.4. Separate the test samples of coarse aggregate into different sizes, using the following sieves: 4.75 mm (No. 4), 9.5 mm ($^3/_8$ in.), 19.0 mm ($^3/_4$ in.), and 37.5 mm ($1^1/_2$ in.). The test sample shall weigh not less than indicated in the following table:

Size of Particles Making Up Test Sample	Weight of Test Sample, Min, g
4.75 to 9.5 mm (No. 4 to $^3/_8$ in.)	1000
9.5 to 19.0 mm ($^3/_8$ to $^3/_4$ in.)	2000
19.0 to 37.5 mm ($^3/_4$ to $1^1/_2$ in.)	3000
Over 37.5 mm ($1^1/_2$ in.)	5000

5.5. If the grading of the original sample provides less than 5 percent of any of the sizes indicated in Section 5.4, do not test that size.

5.6. In the case of aggregate which is composed of substantial amounts of both fine and coarse aggregate sizes, separate the material into two sizes at the 4.75-mm (No. 4) sieve, and prepare the samples of fine and coarse aggregate in accordance with Sections 5.3 and 5.4. Any aggregate containing 50 percent or more material retained on the 4.75-mm (No. 4) sieve is considered to be coarse aggregate.

Note 1—In most cases, only the plus 4.75-mm (No. 4) fraction of coarse aggregate needs to be evaluated by this test method, regardless of the amount of minus 4.75-mm (No. 4) material present. However, the amount of 1.18-mm (No. 16) to 4.75-mm (No. 4) material present shall be included in the weight of the test sample in Section 7.1 when calculating the percent of clay lumps and friable particles.

6. PROCEDURE

6.1. Determine the mass of the test sample to the accuracy specified in Section 4.1 and spread it in a thin layer on the bottom of the container, cover it with distilled water and soak it for a period of 24 ± 4 hours. Roll and squeeze particles individually between the thumb and forefinger to attempt to break the particle into smaller sizes. Do not use the fingernails to break up particles, or press particles against a hard surface or each other. Classify any particles that can be broken with the fingers into fines removable by wet sieving as clay lumps or friable particles. After all discernible clay lumps and friable particles have been broken, separate the undersized material from the remainder of the sample by wet sieving over the sieve prescribed in Table 1.

Table 1—Procedure

Size of Particles Making Up Sample	Size of Sieve for Removing Residue of Clay Lumps and Friable Particles
Fine aggregate (retained on 1.18-mm (No. 16) sieve)	850 µm (No. 20)
4.75 to 9.5 mm (No. 4 to $^3/_8$ in.)	2.36 mm (No .8)
9.5 to 19.0 mm ($^3/_8$ to $^3/_4$ in.)	4.75 mm (No. 4)
19.0 to 37.5 mm ($^3/_4$ to $1^1/_2$ in.)	4.75 mm (No. 4)
Over 37.5 mm ($1^1/_2$ in.)	4.75 mm (No. 4)

6.2. Perform the wet sieving by passing water over the sample through the sieve while manually agitating the sieve, until all undersize material has been removed.

6.3. Remove the retained particles carefully from the sieve, dry to substantially constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF), allow to cool, and determine the mass to the accuracy specified in Section 4.1.

7. CALCULATION

7.1. Calculate the percent of clay lumps and friable particles in fine aggregate or individual sizes of coarse aggregate as follows:

$$P = \left[\left(M - R \right) / M \right] \times 100 \qquad (1)$$

where:

P = percent of clay lumps and friable particles;

M = mass of test sample (for fine aggregate the mass of the portion coarser than the 1.18-mm (No. 16) sieve as described in Section 5.3); and

R = mass of particles retained on designated sieve, as determined in accordance with Section 6.3.

7.2. For coarse aggregates, the percent of clay lumps and friable particles shall be an average based on the percent of clay lumps and friable particles in each sieve-size fraction weighted in accordance with the grading of the original sample before separation, or, preferably, the average grading of the supply represented by the sample. For the purpose of calculating the weighted average when the sample contains less than 5 percent of the material in a given size, that size shall be considered to contain the same percent of clay lumps and friable particles as the next larger or next smaller size, whichever is present.

8. PRECISION AND BIAS

8.1. *Precision*—The estimate of the precision of this test method is provisional and is based on samples of one fine aggregate that was tested by 10 different operators at nine different laboratories. For that sample, the average "percent of clay lumps and friable particles" in the aggregate was 1.2 percent, and the standard deviation was 0.6 percent. Based on this standard deviation, the acceptable range of two test results on samples from the same aggregate sent to different laboratories is 1.7 percent.

8.2. *Bias*—Since there is no acceptable reference material for determining the bias for the procedure in this test method, no statement is being made.

---

[1] Except for Sections 4.1 and 5.6, this method is identical to ASTM C 142-97.

Standard Method of Test for

Lightweight Pieces in Aggregate

AASHTO Designation: T 113-06[1]
ASTM Designation: C 123-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Lightweight Pieces in Aggregate

AASHTO Designation: T 113-06[1]

ASTM Designation: C 123-03

1. SCOPE

1.1. This method covers the determination of the percentage of lightweight pieces in aggregate by means of sink-float separation in a heavy liquid of suitable specific gravity.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard involves hazardous materials, operations, or equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For a specific hazard statement, see Note 1.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 2, Sampling of Aggregates
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 248, Reducing Samples of Aggregate to Testing Size

2.2. *ASTM Standards*:

- D 3665, Standard Practice for Random Sampling of Construction Materials
- E 100, Standard Specification for ASTM Hydrometers

3. SIGNIFICANCE AND USE

3.1. This method is used to determine conformance with provisions of M 6 and M 80 pertaining to the amount of lightweight material in fine and coarse aggregates. A heavy liquid with a specific gravity of 2.0 is used to separate particles, which may be classified as coal or lignite. Heavier liquids are used to check the percentages of other lightweight pieces, such as chert having a specific gravity less than 2.40.

3.2. The method is useful in identifying porous aggregate particles in research activities or in petrographic analyses.

4. APPARATUS

4.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

4.2. *Containers* suitable for drying the aggregate sample, and containers suitable for holding the heavy liquid during the sink-float separation.

4.3. *Skimmer*—A piece of 300-µm (No. 50) sieve cloth, conforming to M 92, of suitable size and shape for separating the floating pieces from the heavy liquid.

4.4. *Hot Plate or Oven*—Of appropriate size capable of maintaining a uniform temperature of 110 ± 5°C (230 ± 9°F).

4.5. *Sieves*—300-µm (No. 50) and 4.75-mm (No. 4) conforming to M 92.

4.6. *Specific Gravity Measurement*—A hydrometer conforming to the requirements of Section 5 through 11 of ASTM E 100 or a suitable combination of graduated glassware and balance, capable of measuring the liquid specific gravity within ± 0.01.

5. HEAVY LIQUID

5.1. The heavy liquid shall consist of one of the following: (See Note 1.)

5.1.1. A solution of zinc chloride in water (for materials having a specific gravity less than 2.0).

5.1.2. A mixture of kerosene with 1,1,2,2 tetrabromoethane, proportioned to produce desired specific gravities (1,1,2,2-tetrabromoethane has a specific gravity of about 2.95).

5.1.3. A solution of zinc bromide in water (for materials having a specific gravity less than 2.6).

5.2. The specific gravity of the heavy liquid shall be maintained within ± 0.01 of the specified value at all times during the test.

Note 1—**Caution**: The chemicals listed in Section 5.1.2 are toxic, both by absorption through the skin and by inhalation. They shall be used only in a hood (preferably of the down-draft type) or out-of-doors, and care shall be taken to avoid inhalation or contact with the eyes or skin. There is no particular hazard from the fumes of zinc chloride solution (Section 5.1.1) or zinc bromide solution (Section 5.1.3), but goggles and gloves shall be worn to prevent contact with the eyes or skin.

1,1,2,2-tetrabromoethene is highly toxic and extremely dangerous to use and when heated emits highly toxic fumes of bromine, hydrogen bromide, and carbonyl bromide. It should be handled only by personnel trained and qualified in its use. Its storage should be in a secured location, away from noncompatible chemicals.

6. SAMPLING

6.1. Secure a field sample of the aggregate in accordance with T 2 and ASTM D 3665. Reduce the sample to test portion size in accordance with T 248.

6.2. Dry the test portion to constant mass at a temperature of 110 ± 5°C (230 ± 9°F) before testing. The minimum size of the test specimen shall be as follows:

Nominal Maximum Size of Aggregate (Square-Opening Sieves)	Minimum Mass of Sample, g
4.75 mm (No. 4)	200
9.5 mm ($^3/_8$ in.)	1500
19.0 mm ($^3/_4$ in.)	3000
37.5 mm ($1^1/_2$ in.)	5000
75 mm (3 in.)	10000

If the nominal maximum size of the aggregate to be tested is not listed above, the next largest size shall be used to determine the sample size.

7. PROCEDURE

7.1. *Fine Aggregate*—Allow the dried test specimen of fine aggregate to cool to room temperature and then sieve over a 300-µm (No. 50) sieve until less than 1 percent of the retained material passes the sieve in 1 minute of continuous sieving. Determine the mass of the material coarser than the 300-µm sieve to the nearest 0.1 g and bring this material to a saturated-surface-dry condition (Note 2) by means of the procedure specified in T 84 (Section 7.1.1), then introduce it into the heavy liquid (Note 1) in a suitable container. The volume of liquid shall be at least three times the absolute volume of the aggregate. Pour the liquid, including the floating pieces, into a second container, passing it through the skimmer, taking care that only the floating pieces are poured off with the liquid and that none of the fine aggregate which sinks is decanted onto the skimmer. Return to the first container the liquid that has been collected in the second container and, after further agitation of the sample by stirring, repeat the decanting process just described until the specimen is free of floating pieces. Wash the decanted pieces contained on the skimmer in an appropriate solvent to remove the heavy liquid. Alcohol is appropriate for 1.1.2.2-tetrabromoethane and water for the zinc chloride and zinc bromide solutions. After the decanted pieces have been washed allow them to dry (Section 7.1.2). Brush the dry decanted pieces from the skimmer onto the balance pan and determine the mass to the nearest 0.1 g. If more precise determination is required, the decanted particles shall be dried to constant mass at 110 ± 5°C to determine the value of W_1 used for the calculation in Section 8.1. (See Section 7.1.3.)

7.1.1. If the absorption as determined in accordance with T 84 is known, the fine aggregate is permitted to be prepared for test by adding to a known mass of dry sand the amount of water it will absorb, mixing thoroughly, and permitting the sand to stand in a covered pan for 30 minutes before use.

7.1.2. Drying shall take place in the hood or out-of-doors if other than zinc chloride or zinc bromide is used. An oven or hot plate is permitted to be used to accelerate the drying providing that it is done in the hood or that the oven is forced-air ventilated and that a temperature of 115°C is not exceeded.

7.1.3. Normally the discrepancy between oven-dry mass and saturated surface-dry mass of the decanted particles will not significantly affect the calculated percentage of lightweight pieces.

7.2. *Coarse Aggregate*—Allow the dried test specimen of coarse aggregate to cool to room temperature and sieve over a 4.75-mm sieve. Determine the mass of the material coarser than the No. 4 sieve to the nearest 1 g, and bring to a saturated surface-dry condition (Note 2) by means of the procedure specified in T 85; then introduce it into the heavy liquid in a suitable container. The volume of liquid shall be at least three times the absolute volume of the aggregate. Using the skimmer, remove the pieces that float to the surface, and save them. Repeatedly agitate the remaining pieces, and remove the floating pieces until no additional pieces rise to the surface. Wash the pieces that are skimmed off in an appropriate solvent to remove the heavy liquid (see Section 7.1). After the heavy liquid has been removed, allow the pieces to dry (Section 7.1.2). Determine the mass of the decanted pieces to the nearest 1 g. If a more precise determination is required, dry the particles to constant mass at 110 ± 5°C to determine the value of W_1 used for the calculation in Section 8.1. (See Section 7.1.3.)

Note 2—If material undergoes degradation in water, the material does not have to be brought to a saturated surface-dry condition.

8. CALCULATION

8.1. *Calculate the percentage of lightweight pieces (pieces floating on the heavy liquid) as follows*:

For fine aggregate:

$$L = \left(W_1/W_2\right) \times 100 \tag{1}$$

For coarse aggregate:

$$L = \left(W_1/W_3\right) \times 100 \tag{2}$$

where:

L = percentage of lightweight pieces,

W_1 = dry mass of pieces that float,

W_2 = dry mass of portion of specimen coarser than 300-µm (No. 50) sieve, and

W_3 = dry mass of portion of specimen coarser than the 4.75-mm (No. 4) sieve.

9. REPORT

9.1. *The report shall include the following*:

9.1.1. Identification of the aggregate as to source, type, and nominal maximum size.

9.1.2. Type and specific gravity of heavy liquid used for the test.

9.1.3. Percentage of lightweight pieces calculated to nearest 0.1 percent.

10. PRECISION AND BIAS

10.1. *Precision*—No interlaboratory or intralaboratory studies have been conducted using this test method to determine precision indices. The committee is seeking pertinent data from users of the test method.

10.2. *Bias*—Bias of the test method may be estimated by running separate specific gravity and absorption determinations on individual pieces of the separate sink, or float fractions, or both.

---

[1] This test method is technically equivalent with ASTM C 123-03.

Standard Method of Test for

Aggregate Durability Index

AASHTO Designation: T 210-10[1]
ASTM Designation: D 3744-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Aggregate Durability Index

AASHTO Designation: T 210-10[1]
ASTM Designation: D 3744-03

1. SCOPE

1.1. This method describes the procedure for determining the durability of aggregates. The durability index is a value indicating the relative resistance of an aggregate to produce detrimental claylike fines when subjected to the prescribed mechanical methods of degradation.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

3. SUMMARY OF METHOD

3.1. This method was developed to permit prequalification of aggregates proposed for use in the construction of transportation facilities. Basically, the test establishes an aggregate's resistance to generating fines when agitated in the presence of water. Separate and different test procedures are used to evaluate the coarse and the fine portions of a material.

3.2. A sample of coarse aggregate is prepared to a specific grading and then washed in a mechanical washing vessel for a 2-minute agitation time. After discarding the minus 4.75-mm (No. 4) material, the washed test sample is dried and prepared to the final test grading.

3.3. The coarse aggregate test sample is then agitated in the mechanical washing vessel for a period of 10 minutes. A representative portion of the resulting wash water and minus 75-µm (No. 200) size fines are collected and mixed with a stock calcium chloride solution and placed in a plastic cylinder. After a 20-minute sedimentation time, the level of the sediment column is read. The height of the sediment value is then used to calculate the durability index of the coarse aggregate (D_c).

3.4. The fine aggregate sample is prepared by washing a specific quantity of the material in the mechanical washing vessel for a 2-minute agitation period. All minus 75-µm (No. 200) size material is washed from the sample through a 75-µm (No. 200) sieve and discarded. The plus 75-µm (No. 200) fraction is dried.

3.5. The fine aggregate test sample is tested by T 176 except for a modification to the duration of the shaking time. The mechanical shaker method is required. A shaking time of 10 minutes instead of 45 seconds is used.

3.6. This method includes procedures for testing aggregates exhibiting a wide range in specific gravity, including lightweight and porous coarse aggregates, and also procedures for testing small maximum size aggregate that is too fine to test as a coarse aggregate and too coarse to consider as a fine aggregate, such as a pea gravel or a very coarse sand.

3.7. The durability index for coarse aggregate (D_c) or for fine aggregate (D_f) is calculated, as applicable, by appropriate equations presented in the method. The durability index of a well-graded aggregate containing both coarse and fine fractions is defined as the lowest of the two values, D_c or D_f, obtained by the test. This value is recommended to be the controlling value for specification purposes.

4. SIGNIFICANCE AND USE

4.1. This test assigns an empirical value to the relative amount, fineness, and character of claylike material that may be generated in an aggregate when subjected to mechanical degradation.

4.2. The procedure has been used in limited geographical areas of the United States and the results have been correlated with aggregate performance in various construction applications, including: aggregate base, permeable material for backfill, fine concrete aggregate, and riprap for rock slope protection.[2,3]

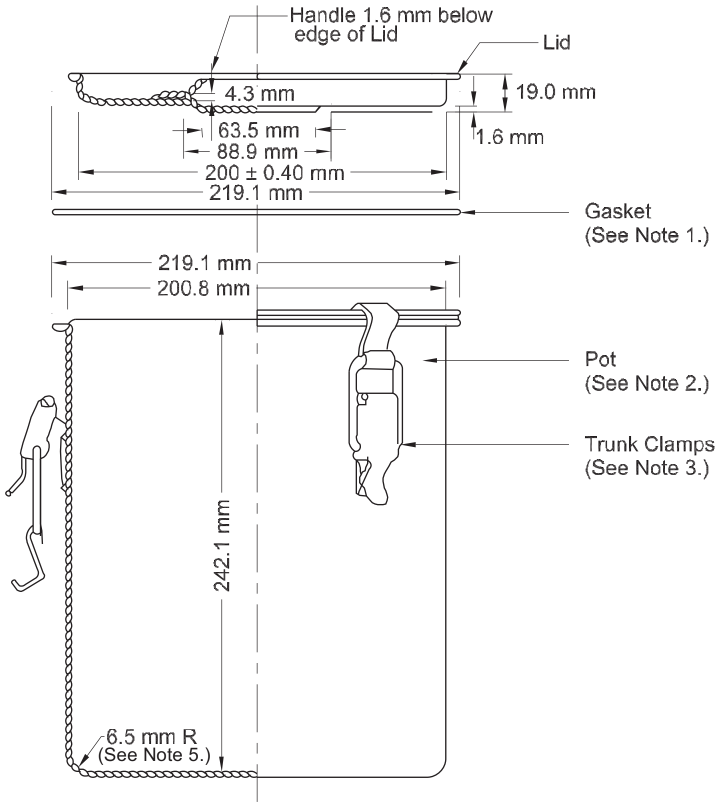
4.3. A minimum durability index is permitted to be specified to prohibit the use of an aggregate that is prone to degradation and will result in generation of claylike fines in various construction applications.

4.4. This method provides a rapid test for evaluation of the quality of a new aggregate source. Research has indicated it may also be suitable for use instead of the sodium sulfate soundness test for evaluating the durability characteristics of fine aggregate for use in portland-cement concrete, thereby reducing the need for time-consuming and expensive soundness tests.[2]

4.5. Although the application of this method has been limited to aggregates for specific construction uses, the possibility exists for expanding the application of this method to control the quality of aggregates used in other areas of construction, such as aggregates for use in bituminous paving mixtures, coarse aggregate for use in portland-cement concrete, and aggregate for use as railroad ballast.

5. APPARATUS

5.1. *Mechanical Washing Vessel (Pot)*—A flat-bottomed, straight-sided cylindrical vessel conforming to the specifications and dimensions shown in Figure 1.



Dimensional Equivalents

mm	in.	mm	in.	mm	in.
242.1	$9^{17}/_{32}$	199.2	$7^{27}/_{32}$	6.4	$^1/_4$
219.1	$8^5/_8$	88.9	$3^1/_2$	1.6	$^1/_{16}$
216.3	$8^{33}/_{64}$	63.5	$2^1/_2$	0.8	$^1/_{32}$
200.8	$7^{29}/_{32}$	19.0	$^3/_4$	0.40	$^1/_{64}$
200.0	$7^7/_8$	14.3	$^9/_{16}$		

Notes:

1. The gasket will be 3.2-mm ($^1/_8$-in.) neoprene rubber, having an inside diameter of 199.23 ± 0.40 mm ($7\ ^{27}/_{32} \pm {}^1/_{64}$ in.) and an outside diameter of 216.30 ± 0.40 mm ($8\ ^{33}/_{64} \pm {}^1/_{64}$ in.).
2. The pot shall be a flat bottom, straight-sided, cylindrical vessel with a capacity of approximately 4 L (2 gal). The top edge shall be flared outward to form a seal for the gasket and lid.
3. Three trunk clamps are required and shall be placed at one-third intervals. The clamps shall be attached to the pot by rivets or welds so that the pot remains watertight. When fitted with the 3.2-mm ($^1/_8$-in.) gasket and clamped in place, the lid shall form a watertight seal with the flared edge of the pot.
4. The vessel shall be 0.9-mm (20-gauge) stainless steel, unless otherwise noted. All dimensions shall be within ± 0.8 mm ($\pm\ ^1/_{32}$ in.), unless otherwise noted.
5. The bottom side inside radius shall be no larger than 6.4 mm ($^1/_4$ in.) with an allowable tolerance of –0.8 mm ($-^1/_{32}$ in.).

Figure 1—Mechanical Washing Vessel

5.2. *Collection Pan*—A round pan at least 250 mm (10 in.) in diameter and at least 100 mm (4 in.) deep, suitable to collect the wash water from the washed sample. The pan shall have vertical or nearly vertical sides and shall be equipped as necessary to hold the wire mesh of a 203-mm (8-in.) diameter sieve at least 76 mm (3 in.) above the bottom. An adaptor that will not allow loss of fines or wash water may be used to nest the sieve with the container, or the sieve may be nested with a blank sieve frame resting in the bottom of the pan.

5.3. *Agitator*—A mechanical device designed to hold the wash vessel in an upright position while subjecting it to a lateral reciprocating motion at a rate of 285 ± 10 complete cycles per minute. The reciprocating motion shall be produced by means of an eccentric in the base of the carrier and the length of the stroke shall be 44.5 ± 0.6 mm (1.75 ± 0.025 in.). The clearance between the cam and follower of the eccentric shall be 0.25 to 1.02 mm (0.001 to 0.004 in.).

5.4. All equipment required to perform T 176.

5.5. *Sieves*—The sieves shall conform to M 92.

5.6. *Balance*, conforming to the requirements of M 231, Class G 2.

6. REAGENTS AND MATERIALS

6.1. *Calcium Chloride Solutions*—Use stock and working calcium chloride solutions as specified in Section 7 of T 176.

6.2. *Water*—Use distilled or demineralized water for the normal performance of this method. The test results are likely to be affected by certain minerals dissolved in water. However, if it is determined that local tap water is of such purity that it does not affect the test results, the use of tap water is permissible in place of distilled or demineralized water. For referee purposes, distilled or demineralized water shall be used for all steps in the test.

7. TEMPERATURE CONTROL

7.1. This test is normally performed without strict temperature control; however, for referee purposes, retest the material with the temperature of the distilled or demineralized water and the working calcium chloride solution at 22 ± 3°C (72 ± 5°F).

8. SAMPLING

8.1. Obtain samples of the aggregate to be tested in accordance with T 2.

9. INITIAL SAMPLE PREPARATION

9.1. Dry aggregate samples sufficiently to permit a complete separation on the 4.75-mm (No. 4) sieve and to develop a free-flowing condition in the portion passing the sieve. Perform drying by any method that does not heat the aggregate in excess of 60°C (140°F) or cause degradation of the particles. The use of sunlight, ovens, or forced drafts of warm air are the most common drying methods.

9.2. If the sample contains an appreciable amount of clay, turn the aggregate frequently during the drying process to obtain even drying throughout and prevent the formation of hard clay lumps.

9.3. Break up any hard clods and remove coatings of fines from the coarse aggregate particles by any means that will not appreciably reduce the natural individual particle sizes.

9.4. Determine the sample grading by sieving in accordance with T 27 on the 19.0-, 12.5-, 9.5-, 4.75-, 2.36-, and 1.18-mm ($^3/_4$-, $^1/_2$-, $^3/_8$-in. and Nos. 4, 8, and 16) sieves. Discard any material that is retained on the 19.0-mm ($^3/_4$-in.) sieve.

9.5. Determine the test procedures to be used for establishing the durability index of the aggregate based upon the grading of the aggregate as determined in Section 9.4.

9.5.1. If less than 10 percent of the aggregate passes the 4.75-mm (No. 4) sieve, test coarse aggregate (Procedure A) only.

9.5.2. If less than 10 percent of the aggregate is coarser than the 4.75-mm (No. 4) sieve, test fine aggregate (Procedure B) only.

9.5.3. When both coarse and fine aggregate fractions are each present in quantities equal to or greater than 10 percent and if the percent passing the 1.18-mm (No. 16) sieve is greater than 10 percent, use both Procedures A and B on the appropriate aggregate sizes. If the percent passing the 1.18-mm (No. 16) sieve is less than or equal to 10 percent, use Procedure A or Procedure C.

9.5.4. If most of the aggregate (75 to 80 percent) is retained between the 9.5- and 1.18-mm ($^3/_8$-in. and No. 16) sieves, use Procedure C only.

PROCEDURE A—COARSE AGGREGATE

10. TEST SAMPLE PREPARATION

10.1. Prepare a 2550 ± 25 g (air-dry) preliminary test sample using the grading given below:

Aggregate Size	Air Dry Mass, g
19.0 to 12.5 mm ($^3/_4$ to $^1/_2$ in.)	1070 ± 10
12.5 to 9.5 mm ($^1/_2$ to $^3/_8$ in.)	570 ± 10
9.5 to 4.75 mm ($^3/_8$ in. to No. 4)	910 ± 5
	2550 ± 25

For materials with less than 10 percent in any of the fractions specified in the above table, prepare the test specimen using the actual calculated percentage for the deficient fraction and proportionally increase the weights of the remaining fractions to obtain the 2550-gram test specimen.

Example 1—Less than 10 percent of $^3/_4$- to $^1/_2$ in. (19.0- to 12.5-mm) material in aggregate.

Aggregate Sieve Size	Percent Each Size	Calculations	Air Dry Weight, g
19.0 to 12.5 mm ($^3/_4$ in. to $^1/_2$ in.)	6	0.06 × 2550	153 ± 10
12.5 to 9.5 mm ($^1/_2$ in. to $^3/_8$ in.)	36	$\frac{570\ (2550 - 153)}{570 + 910}$	923 ± 10
9.5 to 4.75 mm ($^3/_8$ in. to No. 4)	58	$\frac{910\ (2550 - 153)}{570 + 910}$	1474 ± 5
Totals	100		2550 ± 25

Example 2—Less than 10 percent of $^3/_4$- to $^1/_2$-in. (19.0- to 12.5 mm) and $^1/_2$- × $^3/_8$-in. (12.5- to 9.5-mm) material in aggregate.

Aggregate Sieve Size	Percent Each Size	Calculations	Air Dry Weight, g
19.0 to 12.5 mm ($^3/_4$ in. to $^1/_2$ in.)	4	0.04 × 2550	102 ± 10
12.5 to 9.5 mm ($^1/_2$ in. to $^3/_8$ in.)	7	0.07 × 2550	179 ± 10
9.5 to 4.75 mm ($^3/_8$ in. to No. 4)	89	2550 – (102 + 179)	2269 ± 5
Totals	100		2550 ± 25

Example 3—No $^3/_4$- to $^1/_2$-in. (19.0- to 12.5-mm) material in aggregate.

Aggregate Sieve Size	Percent Each Size	Calculations	Air Dry Weight, g
19.0 to 12.5 mm ($^3/_4$ in. to $^1/_2$ in.)	None present	0 × 2550	0
12.5 to 9.5 mm ($^1/_2$ in. to $^3/_8$ in.)	39	$\frac{570\ (2550 - 0)}{570 + 910}$	982 ± 10
9.5 to 4.75 mm ($^3/_8$ in. to No. 4)	61	$\frac{910\ (2550 - 0)}{570 + 910}$	1568 ± 10
Totals	100		2550 ± 25

Remainder of 10.1 does not change.

Dry the preliminary test sample to constant mass at a temperature of 110 ± 5°C (230 ± 9°F), allow to cool, and determine the mass. Record the resulting mass, *W*.

Note 1—If an adjustment of the test specimen mass or volume of wash and test water (Section 10.3), or both, is not required, it is not necessary to oven-dry the test sample prior to the initial wash.

10.2. Place the preliminary test sample in the mechanical washing vessel, and add 1000 ± 5 mL of distilled or demineralized water.

Note 2—Sections 10.3 through 10.3.4 are only necessary if the preliminary test sample is not completely inundated after the specified amount of water is added to the washing vessel pot.

10.3. Because of the low-specific gravity or high-absorption rate, or both, of some aggregates, the proportions of aggregate to water will not provide the intended interparticle abrasion. Testing of these materials will require adjustment of the test specimen mass or volume of both wash and test water, or both.

10.3.1. Wash all materials that are not completely inundated when 1000 mL of water are added to the test sample and test with adjusted sample masses and water volumes.

10.3.2. Determine the bulk, oven-dry specific gravity, and percentage of absorption of the aggregate in accordance with T 85.

10.3.3. Adjust the total mass of the test sample using the following equation:

Adjusted sample mass,

$$g = \frac{\text{Specific Gravity of Aggregate}}{2.65} \times W \tag{1}$$

Adjust the mass of material in each size fraction proportionally to the masses specified in Section 10.7.

10.3.4. Adjust the volume of test water using the following equation:

$$\text{Adjusted Water} = 1000 + (A \times W) - 50 \tag{2}$$

where:

A = absorption of aggregate, percent (expressed as a decimal fraction); and

W = mass of oven-dried test sample, g.

10.4. Clamp the vessel lid in place, and secure the vessel in the agitator. Begin agitation after a time of 60 ± 10 seconds has elapsed from the introduction of the wash water. Agitate the vessel for 120 ± 5 seconds.

10.5. After the 2-minute agitation time is completed, remove the vessel from the agitator, unclamp the lid and pour the contents onto a 4.75-mm (No. 4) sieve. Rinse any remaining fines from the vessel onto the sieve and direct water (from a flexible hose attached to a faucet) onto the aggregate until the water passing through the sieve comes out clear.

10.6. Dry the fraction retained on the 4.75-mm (No. 4) sieve to constant mass at a temperature of 110 ± 5°C (230 ± 9°F) and determine the mass. If the loss in mass due to washing in accordance with Sections 10.2, 10.3, 10.4, and 10.5 is equal to or less than 75 g, a test sample suitable for further testing has been prepared and the procedures in Sections 10.7 through 10.12 are omitted. If the loss in mass exceeds 75 g, the preliminary test sample is permitted to be retained and used if a second sample is washed by the same procedure and the two samples are combined according to the specified masses to provide the desired test sample.

10.7. Determine the grading to be used in preparing the preliminary test sample as follows: If each of the aggregate sizes listed in the following table represents 10 percent or more of the 19.0-mm to 4.75-mm ($^3/_4$-in. to No. 4) portion, as determined from the masses recorded in Section 9.4, use the oven-dry masses of material specified below for preparing the preliminary test sample.

Aggregate Size	Air Dry Mass, g
19.0 to 12.5 mm ($^3/_4$ in. to $^1/_2$ in.)	1050 ± 10
12.5 to 9.5 mm ($^1/_2$ in. to $^3/_8$ in.)	550 ± 10
9.5 to 4.75 mm ($^3/_8$ in. to No. 4)	900 ± 5
	2500 ± 25

Note 3—For materials with less than 10 percent in any of the fractions specified in the above table, prepare the test specimen using the actual calculated percentage for the deficient fraction and proportionally increase weights of the remaining fractions using the method shown in Section 10.1.

10.8. Prepare a 2500 g preliminary test sample using the prescribed grading. Dry the test sample to constant mass at a temperature of 110 ± 5°C (230 ± 9°F).

10.9. Mechanically wash the preliminary sample in the same manner as prescribed in Sections 10.2, 10.3, 10.4, and 10.5.

10.10. Repeat Sections 10.8 and 10.9, if necessary, to obtain sufficient material to yield a washed test sample of 2500 ± 25 g and contain each size fraction in the quantity specified in Section 10.7.

10.11. After allowing the oven-dried material to cool, separate the washed coarse aggregate on the 12.5-, 9.5-, and 4.75-mm ($^1/_2$-, $^3/_8$-in., and No. 4) sieves. Discard the material passing the 4.75-mm (No. 4) sieve.

10.12. Prepare the washed test sample using the masses specified in Section 10.7 from representative portions of each size of washed material. Occasionally a third preliminary test sample is needed to obtain the required mass of material of a specific size.

11. PROCEDURE FOR COARSE AGGREGATE

11.1. Place the plastic cylinder (sand equivalent test cylinder as required in T 176) on a work table, which will not be subjected to vibrations during the performance of the sedimentation phase of the test. Pour 7 mL (0.24 oz) of the stock calcium chloride solution into the cylinder. Place a 4.75-mm and 75-µm (Nos. 4 and 200) sieve on the pan or vessel provided to collect the wash water with 4.75-mm sieve on top. The 4.75-mm sieve serves only to protect the 75-µm sieve.

11.2. Place the washed test sample (as prepared in Section 10) in the mechanical washing vessel. Then add the amount of distilled or demineralized water as determined in Section 10.3, clamp the lid in place, and secure the vessel in the agitator. Begin agitation after a period of 60 seconds has elapsed from the introduction of the wash water. Agitate the vessel for 600 ± 15 seconds.

11.3. Immediately following the agitation period, take the vessel from the agitator and remove the lid. Agitate the contents of the vessel by moving the upright vessel vigorously in a horizontal circular motion five or six times in order to bring the fines into suspension. Immediately pour the contents of the vessel into the nested 4.75-mm and 75-µm (Nos. 4 and 200) sieves placed in the pan provided to collect the wash water. Discard the material retained on the 4.75-mm sieve. Collect all wash water and passing 75-µm material in the collecting pan. To assure that all material finer than 75-µm sieve is washed through the sieve, take the following steps:

11.3.1. As the wash water is draining through the 75-µm (No. 200) sieve, apply a jarring action to the sieve by lightly bumping the side of the sieve frame with the heel of a hand.

11.3.2. When a concentration of the material is retained on the 75-µm (No. 200) sieve, rerinse the fine material by pouring the wash water through the sieve again. To rerinse the material:

11.3.2.1. Allow the wash water to stand undisturbed in the collection pan for a few moments to permit the heavier particles to settle to the bottom.

11.3.2.2. Pour the upper portion of the wash water into another container.

11.3.2.3. Pour the wash water back through the 75-µm (No. 200) sieve and again collect all wash water and passing 75-µm material in the collection pan.

11.3.2.4. Repeat the rinsing procedure as necessary until all of the minus 75-µm (No. 200) material has been washed through the sieve.

11.4. Add distilled or demineralized water to bring the volume of dirty wash water to 1000 ± 5 mL. Then transfer the wash water to a vessel suitable for stirring and pouring.

11.5. Place a funnel in the graduated plastic cylinder. Stir the wash water by hand to bring the fines into suspension. While the water is still turbulent, pour enough of the wash water into the cylinder to bring the level of the liquid to the 381-mm (15-in.) mark.

11.6. Remove the funnel, place the stopper in the end of the cylinder, and prepare to mix the contents immediately.

11.7. Mix the contents of the cylinder by alternately turning the cylinder upside down and right side up, allowing the bubble to completely traverse the length of the cylinder 20 times in approximately 35 seconds.

11.8. At the completion of the mixing process, place the cylinder on the work table and remove the stopper. Allow the cylinder to stand undisturbed for 1200 ± 15 seconds. Then immediately read and record the height of the sediment column to the nearest 2.5 mm (0.1 in.).

Note 4—There are two unusual conditions that may be encountered in this phase of the test procedure. One is that a clearly defined line of demarcation may not form between the sediment and the liquid above it in the specified 20-minute period. If this should occur in a test in which distilled or demineralized water is used, allow the cylinder to stand undisturbed until the clear demarcation line does form; then immediately read and record the height of the column of sediment and the total sedimentation time. If this should occur in a test in which tap water is used, discontinue the test and retest using an untested portion of the sample with distilled or demineralized water. The second unusual condition is that the liquid immediately above the line of demarcation may still be darkly clouded at the end of 20 minutes and the demarcation line, although distinct, may appear to be in the sediment column itself. As for the first case, if tap water was used, rerun the test using a new sample with distilled or demineralized water; otherwise read and record this line of demarcation at the end of the specified 20-minute sedimentation period as usual.

PROCEDURE B—FINE AGGREGATE

12. TEST SAMPLE PREPARATION

12.1. Split or quarter a representative portion from the material passing the 4.75-mm (No. 4) sieve of sufficient mass to obtain an oven-dry mass of 500 ± 25 g.

12.2. Dry the preliminary test sample to constant mass at a temperature of 110 ± 5°C (230 ± 9°F). Cool to room temperature.

12.3. Place the preliminary test sample in the mechanical washing vessel, add 1000 ± 5 mL of distilled or demineralized water, and clamp the vessel lid in place. Secure the vessel in the agitator in sufficient time to begin agitation after 600 ± 30 seconds have elapsed from the introduction of the wash water. Agitate the vessel for a period of 120 ± 5 seconds.

12.4. After the 2-minute agitation period is completed, remove the vessel from the agitator, unclamp the lid, and carefully pour the contents into the protected 75-µm (No. 200) sieve described in Section 11.1. Rinse any remaining fines from the vessel onto the sieve. Direct the water (from flexible hose attached to a faucet) onto the aggregate until the water passing through the sieve comes out clear.

12.5. If necessary, flood clayey or silty samples prior to pouring them over the sieve to prevent clogging the 75-µm (No. 200) sieve. Flood by adding water to the vessel following the agitation period. Use repeated flooding as necessary before all of the contents of the vessel can be poured over the sieve.

12.6. Following the rinsing, transfer the material from the sieve to a drying pan, and dry to constant mass at a temperature of 110 ± 5°C (230 ± 9°F). It is necessary to wash the material from the 75-µm (No. 200) sieve in order to transfer the retained material to a drying pan. Leave the pan in a slanted position until the free water that drains to the lower side becomes clear; then pour off this clear water. Use large shallow pans and spread the sample as thin as possible to speed drying.

12.7. After allowing the oven-dried material to cool, split or quarter a sufficient amount of the washed material to fill the 85-mL (3-oz) measuring tin to overflowing. While filling the tin measure, tap the bottom edge of the tin on a work table or other hard surface to cause consolidation of the material and allow the maximum amount to be placed in the measuring tin. After filling and consolidation is complete, strike off to level using a straightedge. Use extreme care in this procedure to obtain a truly representative sample.

Note 5—The use of a sample splitter meeting the requirements of T 248 is considered preferable.

13. PROCEDURE FOR FINE AGGREGATE

13.1. Conduct a sand equivalent test in accordance with T 176, except use a mechanical shaker to continuously shake the cylinder and contents for 600 ± 15 seconds.

PROCEDURE C—AGGREGATES TOO FINE TO BE TESTED AS COARSE AGGREGATE AND TOO COARSE TO BE TESTED AS FINE AGGREGATE

14. TEST SAMPLE PREPARATION

14.1. Procedure C has been developed to test aggregates, such as pea gravel, and other aggregates contained primarily between the 9.5- and 1.18-mm ($^3/_8$-in. and No. 16) sieves. Such aggregates are too fine to be tested as coarse aggregate and too coarse to be tested as sand.

14.2. Prepare a test sample using the procedure in Section 12.

15. PROCEDURE

15.1. Fill the plastic cylinder to the 102.0 ± 2.5 mm (4 ± 0.1 in.) level with distilled or demineralized water. Pour the prepared test specimen into the cylinder using a funnel to avoid spillage. Tap the bottom of the cylinder sharply with the heel of the hand, as necessary, to release air bubbles and promote thorough wetting. Allow to stand undisturbed for 10 ± 1 minutes.

15.2. Stopper the cylinder, loosen the material from the bottom, and place the cylinder in the mechanical sand equivalent shaker. Start the timer and allow the machine to shake the cylinder and contents for 30 ± 1 minute.

15.3. At the end of the shaking period, remove the cylinder from the shaker and transfer the water and passing 75-µm (No. 200) material to another cylinder containing 7 mL (0.24 oz) of stock calcium chloride solution as follows:

15.3.1. Nest the 2.36-mm and 75-µm (Nos. 8 and 200) sieves into a funnel that empties into the second cylinder. Hold the mouth of the inverted cylinder over the nested sieves and remove the stopper, permitting the sample and water to pour onto the sieves. Rinse the remaining fines from the inverted cylinder onto the sieves with a small amount of fresh distilled water. Rinse the material retained on the sieves with additional fresh distilled water to assure that all minus 75-µm (No. 200) material passes through the sieve. Take care not to fill the cylinder above the 380-mm (15-in.) mark. Allow time for the water to drain through the sieves and then add enough fresh distilled water to bring the level of the liquid to the 380-mm (15-in.) mark. Stopper the cylinder and mix the contents by inverting 20 times in 35 seconds.

15.4. Allow the cylinder to stand undisturbed for 1200 ± 15 seconds from the time of completion of mixing, then read the top of the clay suspension to the nearest 2.5 mm (0.1 in.).

CALCULATION

16. PROCEDURE A—COARSE AGGREGATE

16.1. Compute the durability index of the coarse aggregate to the nearest whole number using the following equation:

$$D_c = 30.3 + 20.8 \cot\left(0.29 + 0.0059\,H\right) \qquad (3)$$

where:

D_c = durability index;

H = height of sediment, mm, and the quantity (0.29 – 0.0059 H) is in radians.

16.2. Solutions of Equation 3 are given in Table 1.

Table 1—Durability Index of Coarse Aggregate

Sediment Height		D_c	Sediment Height		D_c	Sediment Height		D_c	Sediment Height		D_c	Sediment Height		D_c
mm	in.		mm	in.		mm	in.		mm	in.		mm	in.

												381.0	15.0	0

Note: $D_c = 30.3 + 20.8 \cot (0.29 + 0.0059\,H)$[a].

[a] H is measured in mm.

17. PROCEDURE B—FINE AGGREGATE

17.1. Calculate the durability index of the fine aggregate to the nearest 0.1 using the following equation:

$$D_f = \frac{\text{Sand Reading}}{\text{Clay Reading}} \times 100 \qquad (4)$$

17.2. If the calculated durability index is not a whole number, report it as the next higher whole number. For example, if the clay reading was recorded as 203.2 mm (8.0 in.) and the sand reading was recorded as 83.8 mm (3.3 in.), the calculated durability index would be: D_f = (83.8/203.2) × 100 or 41.2; report as 42.

17.3. If it is desired to average a series of values, average the whole number values as determined in Section 17.2. If the average of these values is not a whole number, round it to the next higher whole number as shown in the following example:

Example—Calculated D_f values are 41.2, 43.8, and 40.9, which, when rounded to the next higher whole number, become 42, 44, and 41. The average of these values is then determined: (42 + 44 + 41)/3 = 42.3; and reported as 43.

18. PROCEDURE C—AGGREGATES TOO FINE TO BE TESTED AS COARSE AGGREGATE AND TOO COARSE TO BE TESTED AS FINE AGGREGATE

18.1. Calculate the durability index in accordance with Section 16.

PRECAUTIONS

19. PRECAUTIONS

19.1. Perform the test in a location free of vibrations, because vibrations may cause the suspended material to settle at a greater rate than normal.

19.2. Do not expose the plastic cylinders to direct sunlight any longer than is necessary.

19.3. Frequently check the play between the cam and eccentric on the agitator by grasping one of the hanger rods and attempting to move the sieve base. If any play is noticed, replace the cam or bearing, or both.

19.4. Lubricate the agitator at least once every three months.

REPORT

20. REPORT

20.1. Report the "as-received" sieve analysis of the aggregate subjected to testing, the sieve analysis of the coarse sample used, and the sieve analysis of the fine sample used. Report the calculated durability index (D_c or D_f) with an indication as to whether Procedure A, B, or C was used.

20.2. Include a statement as to whether or not strict temperature control was maintained, and whether tap, distilled, or demineralized water was used.

PRECISION AND ACCURACY

21. PRECISION AND ACCURACY

21.1. Criteria for judging the acceptability of the durability index values determined by this method are very limited. The data that are tabulated herein were developed by one state agency in the western United States on materials common to that geographical area. The criteria were established by performing 48 individual tests on each of six different aggregates, two of which were coarse aggregates and four of which were fine aggregates. Two tests by two operators in 12 laboratories were performed on each material.

21.2. An indication of the precision of this method of test is presented in Table 2. The single-operator standard deviation and the multilaboratory standard deviation for both the durability index of coarse aggregate (D_c) and the durability index of fine aggregate (D_f) increases as the index decreases.

Table 2—Precision[a]

Coarse Aggregate[b]			Fine Aggregate[c]		
Durability Index	Standard Deviation	Acceptable range of two results	Durability Index	Standard Deviation	Acceptable range of two results
Single-Operator Precision			Single-Operator Precision		
60	3.58	10.1	50	2.40	6.8
65	3.07	8.7	55	2.24	6.3
70	2.56	7.2	60	2.08	5.9
75	2.04	5.8	65	1.92	5.4
80	1.53	4.3	70	1.76	5.0
85	1.01	2.9	75	1.61	4.5
Multilaboratory Precision			Multilaboratory Precision		
60	4.35	12.3	50	5.11	14.4
65	3.72	10.5	55	4.77	13.5
70	3.10	8.8	60	4.43	12.5
75	2.47	7.0	65	4.10	11.6
80	1.85	5.2	70	3.76	10.6
85	1.22	3.5	75	3.42	9.7

[a] These values represent the 1s and d2s limits described in ASTM C 670.

[b] Data for two materials.

[c] Data for four materials.

21.3. The maximum single-operator standard deviation has been found to be 3.58. Therefore, the results of two properly conducted tests by the same operator on the same material are not expected to differ by more than 10.1.

21.4. The maximum multilaboratory standard deviation has been found to be 5.11. Therefore, the results of two properly conducted tests from two different laboratories on samples of the same aggregate are not expected to differ by more than 14.4.

21.5. *Bias*—No information is presented on the bias of the procedure in this test method for measuring the durability index, because no material having an accepted reference value is available.

Standard Method of Test for

Reducing Samples of Aggregate to Testing Size

AASHTO Designation: T 248-02 (2006)[1]
ASTM Designation: C 702-98 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Reducing Samples of Aggregate to Testing Size

AASHTO Designation: T 248-02 (2006)[1]
ASTM Designation: C 702-98 (2003)

1. SCOPE

1.1. These methods cover the reduction of large samples of aggregate to the appropriate size for testing employing techniques that are intended to minimize variations in measured characteristics between the test samples so selected and the large sample.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 2, Sampling of Aggregates
- T 84, Specific Gravity and Absorption of Fine Aggregate

2.2. *ASTM Standard*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates

3. TERMINOLOGY

3.1. *definitions*—the terms used in this standard are defined in ASTM C 125.

4. SIGNIFICANCE AND USE

4.1. Specifications for aggregates require sampling portions of the material for testing. Other factors being equal, larger samples will tend to be more representative of the total supply. These methods provide for reducing the large sample obtained in the field or produced in the laboratory to a convenient size for conducting a number of tests to describe the material and measure its quality in a manner that the smaller test sample portion is most likely to be a representation of the larger sample, and thus of the total supply. The individual test methods provide for minimum masses of material to be tested.

4.2. Under certain circumstances, reduction in size of the large sample prior to testing is not recommended. Substantial differences between the selected test samples sometimes cannot be avoided, as for example, in the case of an aggregate having relatively few large-sized particles in the sample. The laws of chance dictate that these few particles may be unequally distributed among the reduced-size test samples. Similarly, if the test sample is being examined for certain contaminants occurring as a few discrete fragments in only small percentages, caution should be used in interpreting results from the reduced-size test sample. Chance inclusion or exclusion of only one or two particles in the selected test sample may importantly influence interpretation of the characteristics of the original sample. In these cases, the entire original sample should be tested.

4.3. Failure to carefully follow the procedures in these methods could result in providing a nonrepresentative sample to be used in subsequent testing.

5. SELECTION OF METHOD

5.1. *Fine Aggregate*—Samples of fine aggregate that are drier than the saturated-surface-dry condition (Note 1) shall be reduced in size by a mechanical splitter according to Method A. Samples having free moisture on the particle surfaces may be reduced in size by quartering according to Method B, or by treating as a miniature stockpile as described in Method C.

5.1.1. If the use of Method B or Method C is desired, and the sample does not have free moisture on the particle surfaces, the sample may be moistened to achieve this condition, thoroughly mixed, and then the sample reduction performed.

Note 1—The method of determining the saturated-surface-dry condition is described in T 84. As a quick approximation, if the fine aggregate will retain its shape when molded in the hand, it may be considered to be wetter than saturated-surface-dry.

5.1.2. If use of Method A is desired and the sample has free moisture on the particle surfaces, the entire sample may be dried to at least the surface-dry condition, using temperatures that do not exceed those specified for any of the tests contemplated, and then the sample reduction performed. Alternatively, if the moist sample is very large, a preliminary split may be made using a mechanical splitter having wide chute openings 38 mm ($1^1/_2$ in.) or more to reduce the sample to not less than 5000 g. The portion so obtained is then dried, and reduction to test sample size is completed using Method A.

5.2. *Coarse Aggregates and Mixtures of Coarse and Fine Aggregates*—Reduce the sample using a mechanical splitter in accordance with Method A (preferred method) or by quartering in accordance with Method B. The miniature stockpile Method C is not permitted for coarse aggregates or mixtures of coarse and fine aggregates.

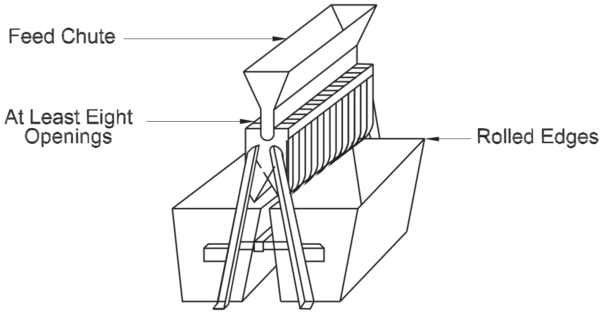
6. SAMPLING

6.1. The samples of aggregate obtained in the field shall be taken in accordance with T 2, or as required by individual test methods. When tests for sieve analysis only are contemplated, the size of field sample listed in T 2 is usually adequate. When additional tests are to be conducted, the user shall determine that the initial size of the field sample is adequate to accomplish all intended tests. Similar procedures shall be used for aggregate produced in the laboratory.

METHOD A—MECHANICAL SPLITTER

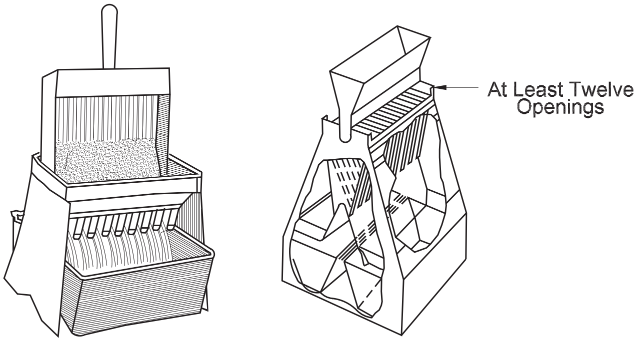
7. APPARATUS

7.1. *Sample Splitter*—Sample splitters shall have an even number of equal width chutes, but not less than a total of eight for coarse aggregate, or 12 for fine aggregate, which discharge alternatively to each side of the splitter. For coarse aggregate and mixed aggregate the minimum width of the individual chutes shall be approximately 50 percent larger than the largest particles in the sample to be split (Note 2). For dry fine aggregate in which the entire sample will pass the 9.5-mm ($^3/_8$-in.) sieve, the minimum width of the individual chutes shall be at least 50 percent larger than the largest particles in the sample and the maximum width shall be 19 mm ($^3/_4$ in.). The splitter shall be equipped with two receptacles to hold the two halves of the sample following splitting. It shall also be equipped with a hopper or straightedged pan, which has a width equal to or slightly less than the overall width of the assembly of chutes, by which the sample may be fed at a controlled rate to the chutes. The splitter and accessory equipment shall be so designed that the sample will flow smoothly without restriction or loss of material (Figure 1).



Riffle Sample Splitter

(a) Large Sample Splitter for Coarse Aggregate



(b) Small Sample Splitters for Fine Aggregate

Note: (a) may be constructed as either closed or open type. Closed type is preferred.

Figure 1—Sample Splitters (Riffles)

Note 2—Mechanical splitters are commonly available in sizes adequate for coarse aggregate having the largest particle not over 37.5 mm ($1^1/_2$ in.).

8. PROCEDURE

8.1. Place the original sample in the hopper or pan and uniformly distribute it from edge to edge, so that when it is introduced into the chutes, approximately equal amounts will flow through each chute. The rate at which the sample is introduced shall be such as to allow free flowing through the chutes into the receptacles below. Reintroduce the portion of the sample in one of the receptacles into the splitter as many times as necessary to reduce the sample to the size specified for the intended test. The portion of the material collected in the other receptacle may be reserved for reduction in size for other tests.

METHOD B—QUARTERING

9. APPARATUS

9.1. Apparatus shall consist of a straightedge; straightedged scoop, shovel, or trowel; a broom or brush; and a canvas blanket approximately 2 by 2.5 m (6 by 8 ft).

10. PROCEDURE

10.1. Use either the procedure described in Section 10.1.1 or 10.1.2, or a combination of both.

10.1.1. Place the original sample on a hard, clean, level surface where there will be neither loss of material nor the accidental addition of foreign material. Mix the material thoroughly by turning the entire sample over three times. With the last turning, shovel the entire sample into a conical pile by depositing each shovelful on top of the preceding one. Carefully flatten the conical pile to a uniform thickness and diameter by pressing down the apex with a shovel so that each quarter sector of the resulting pile will contain the material originally in it. The diameter should be approximately four to eight times the thickness. Divide the flattened mass into four equal quarters with a shovel or trowel and remove two diagonally opposite quarters, including all fine material, and brush the cleared spaces clean. Successively mix and quarter the remaining material until the sample is reduced to the desired size (Figure 2).

10.1.2. As an alternative to the procedure in Section 10.1.1 when the floor surface is uneven, the field sample may be placed on a canvas blanket and mixed with a shovel as described in Section 10.1.1, or by alternatively lifting each corner of the canvas and pulling it over the sample toward the diagonally opposite corner causing the material to be rolled. Flatten the pile as described in Section 10.1.1. Divide the sample as described in Section 10.1.1, or, if the surface beneath the blanket is uneven, insert a stick or pipe beneath the blanket and under the center of the pile, then lift both ends of the stick, dividing the sample into two equal parts. Remove the stick leaving a fold of the blanket between the divided portions. Insert the stick under the center of the pile at right angles to the first division and again lift both ends of the stick, dividing the sample into four equal parts. Remove two diagonally opposite quarters, being careful to clean the fines from the blanket. Successively mix and quarter the remaining material until the sample is reduced to the desired size (Figure 3).

Figure 3—Quartering on a Canvas Blanket

METHOD C—MINIATURE STOCKPILE SAMPLING (DAMP FINE AGGREGATE ONLY)

11. APPARATUS

11.1. Apparatus shall consist of a straightedge; straightedged scoop, shovel, or trowel for mixing the aggregate; and either a small sampling thief, small scoop, or spoon for sampling.

12. PROCEDURE

12.1. Place the original sample of damp fine aggregate on a hard, clean, level surface where there will be neither loss of material nor the accidental addition of foreign material. Mix the material thoroughly by turning the entire sample over three times. With the last turning, shovel the entire sample into a conical pile by depositing each shovelful on top of the preceding one. If desired, the conical pile may be flattened to a uniform thickness and diameter by pressing the apex with a shovel so that each quarter sector of the resulting pile will contain the material originally in it. Obtain a sample for each test by selecting at least five increments of material at random locations from the miniature stockpile, using any of the sampling devices described in Section 11.1.

---

[1] Technically equivalent but not identical to ASTM C 702-98 (2003).

Standard Method of Test for

Total Evaporable Moisture Content of Aggregate by Drying

AASHTO Designation: T 255-00 (2008)[1]
ASTM Designation: C 566-97 (2004)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Total Evaporable Moisture Content of Aggregate by Drying

AASHTO Designation: T 255-00 (2008)[1]
ASTM Designation: C 566-97 (2004)

1. SCOPE

1.1. This test method covers the determination of the percentage of evaporable moisture in a sample of aggregate by drying both surface moisture and moisture in the pores of the aggregate. Some aggregate may contain water that is chemically combined with the minerals in the aggregate. Such water is not evaporable and is not included in the percentage determined by this test method.

1.2. The values stated in SI units are to be regarded as the standard. The values stated in parentheses are provided for information only.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For specific precautionary statements, see Sections 5.3.1, 7.2.1, and 7.3.1.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials

- T 2, Sampling of Aggregates
- T 19M/T 19, Bulk Density (“Unit Weight”) and Voids in Aggregate
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate

2.2. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. For definitions of terms used in this test method, refer to ASTM C 125.

4. SIGNIFICANCE AND USE

4.1. This test method is sufficiently accurate for usual purposes such as adjusting batch quantities of ingredients for concrete. It will generally measure the moisture in the test sample more reliably than the sample can be made to represent the aggregate supply. In rare cases where aggregate itself is altered by heat, or where more refined measurement is required, the test should be conducted using a ventilated, controlled-temperature oven.

4.2. Large particles of coarse aggregate, especially those larger than 50 mm (2 in.), will require greater time for the moisture to travel from the interior of the particle to the surface. The user of this test method should determine by trial if rapid drying methods provide sufficient accuracy for the intended use when drying large-size particles.

5. APPARATUS

5.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

5.2. *Source of Heat*—A ventilated oven capable of maintaining the temperature surrounding the sample at 110 ± 5ºC (230 ± 9ºF). Where close control of the temperature is not required (see Section 4.1), other suitable sources of heat may be used, such as an electric or gas hot plate, electric heat lamps, or a ventilated microwave oven.

5.3. *Sample Container*—A container not affected by the heat, and of sufficient volume to contain the sample without danger of spilling, and of such shape that the depth of sample will not exceed one-fifth of the least lateral dimension.

5.3.1. **Precaution**—When a microwave oven is used, the container shall be nonmetallic.

Note 1—Except for testing large samples, an ordinary frying pan is suitable for use with a hot plate, or any shallow flat-bottomed metal pan with heat lamps or oven. Note precaution in Section 5.3.1.

5.4. *Stirrer*—A metal spoon or spatula of convenient size.

6. SAMPLE

6.1. Sampling shall generally be accomplished in accordance with T 2, except the sample size may be as stated in Table 1.

Table 1—Sample Size for Aggregate

Nominal Maximum Size of Aggregate, mm (in.)[a]	Mass of Normal Weight Aggregate Sample, Min., kg[b]
4.75 (0.187) (No. 4)	0.5
9.5 ($^3/_8$)	1.5
12.5 ($^1/_2$)	2
19.0 ($^3/_4$)	3
25.0 (1)	4
37.5 ($1^1/_2$)	6
50 (2)	8
63 ($2^1/_2$)	10
75 (3)	13
90 ($3^1/_2$)	16
100 (4)	25
150 (6)	50

[a] Based on sieves meeting M 92.

[b] Determine the minimum sample mass for lightweight aggregate by multiplying the value listed by the dry-loose unit mass of the aggregate in kg/m3 (determined using T 19M/T 19) and dividing by 1600.

6.2. Secure a sample of the aggregate representative of the moisture content in the supply being tested and having a mass not less than the amount listed in Table 1. Protect the sample against loss of moisture prior to determining the mass.

7. PROCEDURE

7.1. Determine the mass of the sample to the nearest 0.1 percent.

7.2. Dry the sample thoroughly in the sample container by means of the selected source of heat, exercising care to avoid loss of any particles. Very rapid heating may cause some particles to explode, resulting in loss of particles. Use a controlled temperature oven when excessive heat may alter the character of the aggregate, or where more precise measurement is required. If a source of heat other than the controlled temperature oven is used, stir the sample during drying to accelerate the operation and avoid localized overheating. When using a microwave oven, stirring of the sample is optional.

7.2.1. **Caution**—When using a microwave oven, occasionally minerals are present in aggregates that may cause the material to overheat and explode. If this occurs, it can damage the microwave oven.

7.3. When a hot plate is used, drying can be expedited by the following procedure. Add sufficient anhydrous denatured alcohol to cover the moist sample. Stir and allow suspended material to settle. Decant as much of the alcohol as possible without losing any of the sample. Ignite the remaining alcohol and allow it to burn off during drying over the hot plate.

7.3.1. **Warning**—Exercise care to control the ignition operation to prevent injury or damage from the burning alcohol.

7.4. The sample is thoroughly dry when further heating causes, or would cause, less than 0.1 percent additional loss in mass.

7.5. Determine the mass of the dried sample to the nearest 0.1 percent after it has cooled sufficiently not to damage the balance.

8. CALCULATION

8.1. Calculate total evaporable moisture content as follows:

$$p = 100(W - D)/D \qquad (1)$$

where:

p = total evaporable moisture content of sample, percent;
W = mass of original sample, g; and
D = mass of dried sample, g.

8.2. Surface moisture content is equal to the difference between the total evaporable moisture content and the absorption, with all values based on the mass of a dry sample. Absorption may be determined in accordance with T 85, Test for Specific Gravity and Absorption of Coarse Aggregate, or T 84, Test for Specific Gravity and Absorption of Fine Aggregate.

9. PRECISION AND BIAS

9.1. *Precision*:

9.1.1. The within-laboratory single operator standard deviation for moisture content of aggregates has been found to be 0.28 percent (Note 2). Therefore, results of two properly conducted tests by the same operator in the same laboratory on the same type of aggregate sample should not differ by more than 0.79 percent (Note 2) from each other.

9.1.2. The between-laboratory standard deviation for moisture content of aggregates has been found to be 0.28 percent (Note 2). Therefore, results of properly conducted tests from two laboratories on the same aggregate sample should not differ by more than 0.79 percent (Note 2) from each other.

9.1.3. Test data used to derive the above precision indices were obtained from samples dried to a constant mass in a drying oven maintained at 110 ± 5ºC. When other drying procedures are used, the precision of the results may be significantly different than that indicated above.

Note 2—These numbers represent, respectively, the 1s and d2s limits as described in ASTM C 670.

9.2. *Bias*:

9.2.1. When experimental results are compared with known values from accurately compounded specimens, the following has been derived.

9.2.1.1. The bias of moisture tests on one aggregate material has been found to have a mean of +0.06 percent. The bias of individual test values from the same aggregate material has been found with 95 percent confidence to lie between –0.07 percent and +0.20 percent.

9.2.1.2. The bias of moisture tests on a second aggregate material has been found to have a mean of less than +0.01 percent. The bias of individual test values from the same aggregate material has been found with 95 percent confidence to lie between –0.14 percent and +0.14 percent.

9.2.1.3. The bias of moisture tests overall on both aggregate materials has been found to have a mean of +0.03 percent. The bias of individual test values overall from both aggregate materials has been found with 95 percent confidence to lie between –0.12 percent and +0.18 percent.

9.2.2. Test data used to derive the above bias statement were obtained from samples dried to a constant mass in a drying oven maintained at 110 ± 5ºC. When other drying procedures are used, the bias of the results may be significantly different than that indicated above.

Note 3—These precision and bias statements were derived from aggregate moisture data provided by 17 laboratories participating in the SHRP Soil Moisture Proficiency Sample Program, which is fully described in the National Research Council Report SHRP-P-619. The samples tested that relate to these statements were well-graded mixtures of fine and coarse aggregate with moisture contents ranging from air dry to saturated surface dry.

10. KEYWORDS

10.1. Aggregate; drying; moisture content.

---

[1] This method is technically equivalent with ASTM C 566-97 (2004), except for the balance statement in Section 5.1.

Standard Method of Test for

Accelerated Polishing of Aggregates Using the British Wheel

AASHTO Designation: T 279-96 (2006)
ASTM Designation: D 3319-90

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Accelerated Polishing of Aggregates Using the British Wheel

AASHTO Designation: T 279-96 (2006)
ASTM Designation: D 3319-90

1. SCOPE

1.1. This method covers a laboratory procedure by which an estimate may be made of the extent to which different coarse aggregates may polish.

1.2. The values stated in SI units are regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the users of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 261, Rib-Tread Standard Tire for Special-Purpose Pavement Frictional-Property Tests
- T 2, Sampling of Aggregates
- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)
- T 278, Surface Frictional Properties Using the British Pendulum Tester

2.2. *ASTM Standards*:

- C 778, Standard Specification for Standard Sand
- D 75, Standard Practice for Sampling Aggregates
- D 1415, Standard Test Method for Rubber Property—International Hardness [1]
- E 303, Standard Test Method for Measuring Surface Frictional Properties Using the British Pendulum Tester

3. SIGNIFICANCE AND USE

3.1. This test method simulates the polishing action of vehicular traffic on coarse aggregates used in bituminous pavements.

3.2. A polish value is determined that may be used to rate or classify coarse aggregates for their ability to resist polishing under traffic.

4. TERMINOLOGY

4.1. *Definitions*:

4.1.1. *initial friction value*—the initial British Pendulum Tester readings on the test specimens before they are polished in the accelerated polishing machine.

4.1.2. *polish value (PV)*—a measure of the state of polish reached by a test specimen subjected to accelerated polishing using the materials, equipment, and procedures described in this method. The measurement is made using the British Pendulum Tester as described in Section 5.3 and T 278.

5. APPARATUS

5.1. *Accelerated Polishing Machine*[2]—An accelerated polishing machine, also known as the British Wheel, and based upon a 1958 design by the Road Research Laboratory of Great Britain. This machine shall be mounted on a firm, rigid, and level base. The equipment shall include the following:

5.1.1. *Cylindrical Wheel*—Hereafter referred to as the road wheel, and having a flat surface periphery and of such size and shape as to permit 14 specimens described below to be clamped onto the periphery to form a continuous surface of aggregate particles, 44.5 mm ($1^3/_4$ in.) wide and 406.4 mm (16 in.) in diameter.

5.1.2. A means of rotating the road wheel about its own axis at a speed of 320 ± 5 rpm.

5.1.3. A means of bringing the surface of a rubber-tired wheel 203.2 mm (8 in.) in diameter and 50.8 mm (2 in.) wide to bear on the aggregate specimens mounted on the surface of the road wheel with a total load of 391.44 ± 4.45 N (88 ± 1 lbf). The tire shall be treated, if necessary, to obtain a true running surface. The tire shall be free to rotate about on its own axis, which shall be parallel to the axis of the road wheel. The plane of rotation of the tire shall coincide with that of the road wheel. Before a new tire is used on a test, it should be conditioned by a preliminary run of 6 hours with a 150-grit silicon carbide using dummy specimens (extra or used) on the road wheel.

5.1.3.1. *Alternate Tire No. 1*—An industrial 8 × 2 pneumatic smooth-tread hand-truck tire (Note 1). The tire rubber hardness shall be 55 ± 5 IRHD measured in accordance with ASTM D 1415. The tire shall be inflated to a pressure of 310.26 ± 13.79 kPa (45 ± 2 psi).

Note 1—This is the tire originally supplied with the Accelerated Polishing Machine[2] and known by the tire manufacturer's designation Dunlop® RLI 8 × 2. Dunlop discontinued manufacturing this tire in February 1979. It is retained as an alternate in this test method for those users who may still have a supply and in the event that Dunlop should resume manufacturing it in the future.

5.1.3.2. *Alternate Tire No. 2*—An industrial 8-in. OD × 4-in. ID (2.80 × 4), 4 NHS-4 ply, cross-hatch pattern tread hand-truck tire (Note 2). The tire shall be inflated to a pressure of 241.32 ± 13.79 kPa (35 ± 2 psi).

Note 2—When it became known that the Dunlop® tire (Section 5.1.3.1) was no longer being manufactured, the necessity of finding a replacement tire for the test method was evident. A search and study by the Texas State Department of Highways and Public Transportation culminated in finding this tire, a Goodyear® Industrial All Weather Hand-Truck tire size 2.80 × 4 (Goodyear Product Code 202-008-002), to give polish values equal to those obtained with the Dunlop® tire.[3] A suitable inner-tube such as Goodyear® G250-4 (Product Code 199-010-700) is necessary. It was also found necessary to modify the 4-in. wheel furnished with the Accelerated Polish Machine to facilitate mounting the Goodyear® tire. Approximately 0.10 in. should be removed from the wheel diameter and a larger hole provided for the valve stem. This did not affect mounting and use of the Dunlop® tire.

5.1.4. A means to feed the 150-grit silicon carbide abrasive at the rate given in Section 8.5. The grit shall be fed continuously and with a uniform distribution across the width of the specimens. The grit shall be applied directly onto the road wheel surface ahead of the point of contact with the rubber-tired wheel.

5.1.5. A means to feed the water at the rate given in Section 8.5 in such a way that the water is spread continuously and uniformly over the surface of the road wheel ahead of the point of contact with the rubber-tired wheel.

5.2. *Metal Molds*—A number of accurately machined metal molds for preparing specimens. The specimen formed is 88.9 by 44.45 by 16.0 mm (3.5 by 1.75 by 0.63 in.) and shall be curved to fit on a surface having a 203.2-mm (8-in.) radius of curvature.

5.3. *British Pendulum Tester*—A friction measuring device. The British Pendulum Tester used shall conform to T 278.

5.3.1. The slider contact path shall be 76.2 ± 1.6 mm (3 ± $^1/_{16}$ in.).

5.3.2. The slider width shall be 31.8 mm ($1^1/_4$ in.).

5.3.3. The rubber that is bonded to the slider shall be 6.4 by 25.4 by 31.8 mm ($^1/_4$ by 1 by $1^1/_4$ in.).

5.3.4. The rubber shall meet the requirements of M 261.

5.3.5. The zero adjustment shall be checked before and after testing the specimens and as often as the operator deems necessary.

5.3.6. The calibration procedures of T 278 shall be used. However, after calibration, the small slider shall be inserted.

6. MATERIALS AND SUPPLIES

6.1. *Water*—A supply of tap water for use where water is required for any purpose in this method.

6.2. *Fine Sand*—A supply of fine sand for sifting into the interstices of the aggregate prior to placing of the bonding material. Standard sand conforming to the requirements of ASTM C 778 has been found suitable for this purpose.

6.3. *Mold-Release Agent*—The use of a mold-release agent is optional. A mold-release agent may be used to prevent bonding between the mold and the bonding material. Silicon release agent and paste wax, as used for automobiles and floors, have been found suitable. The user should use care to prevent this agent from being absorbed by the aggregate as it could affect the measured polish value.

6.4. *Silicon Carbide Grit*—A supply of silicon carbide grit (150-grit size) to be used as the polishing agent. Grit should be checked for gradation using 150-µm (No. 100), 75-µm (No. 200) sieves and separated and recombined if necessary to maintain a uniform gradation for all testing.

6.5. *Bonding Agent*—A supply of polyester resin and catalyst (or another suitable bonding material, such as an epoxy resin) having a pot life of 20 to 30 minutes and a curing time of 3 to 6 hours. This bonding agent shall not be so fluid as to flow through the fine sand.

6.5.1. An optional bonding agent may be used to eliminate use of the fine sand. This bonding agent must be quite viscous so that it will not flow completely around the aggregate particles and become part of the surface of the test specimen. Examples of suitable materials are given in Appendix X1.

6.5.2. Follow the manufacturer's precautions concerning storage and use of resin and catalyst.

6.6. *Coarse Aggregate*—Approximately a 0.014 m^3 ($^1/_2$ ft^3) supply of coarse aggregate to be tested and sampled in accordance with T 2. The aggregate shall be normal plant-run, but laboratory-crushed material may be tested, if so identified.

7. TEST AND CONTROL SPECIMENS

7.1. At least five test specimens for each coarse aggregate shall be tested. (See Section 10.2.)

7.2. Laboratories evaluating only a few coarse aggregates each year shall include standard laboratory control specimens in each run. Two sets containing five test specimens each will allow the inclusion of four control specimens. With an accumulation of polish value history, the control specimens may be eliminated. This will allow an increase in the number of the coarse aggregate test specimens for the two sets.

7.3. The aggregate to be tested shall pass the 12.7-mm ($^1/_2$-in.) sieve and shall be retained on a 9.53-mm ($^3/_8$-in.) sieve.

Note 3—Aggregate gradation may be varied to meet the needs of the user if reported with the test results. However, aggregates larger than 12.7 mm ($^1/_2$ in.) may not be accommodated by the mold, and aggregates smaller than 9.53 mm ($^3/_8$ in.) may not be adequately bonded in the specimen molding process to be retained for the duration of the test.

7.4. Thoroughly wash and dry the aggregate to be tested at 100 to 110ºC to essentially constant mass.

7.5. Coat the mold with mold-release agent.

7.6. Each specimen shall contain a single layer of dry aggregate placed by hand as densely as possible with a flat surface down to cover the bottom 89.9 by 44.45 mm (3.5 by 1.75 in.) surface of the mold.

Note 4—Particles selected should be representative of the material to be evaluated. Flat, elongated, or unusually shaped particles can cause difficulty in placement and bonding. Misleading polish values can result from inadequate surface area for polishing.

7.7. Fill the interstices between the aggregate with the fine sand, described in Section 6.2, from one-fourth to one-half of the aggregate depth.

7.7.1. An optional method eliminates the sand by using a viscous polyester resin. This material is described in Section 6.5.

7.8. Prepare the bonding agent described in Section 6.5 and in accordance with the manufacturer's instructions. The consistency of the bonding agent shall be such that it will flow freely between the aggregate particles but not so thin as to impregnate the sand or to bond this sand to the specimen surface, later preventing its removal. An ideal consistency would be such that the bonding agent must be forced into the voids between the aggregate particles by gentle hand pressure with a spatula.

7.8.1. The optional bonding agent requires a heavier consistency such that it will not flow except with the aid of a spatula.

7.9. Fill the prepared mold to overflow with the bonding material.

Note 5—Care should be used to ensure that the bonding agent is not allowed to penetrate near the aggregate surface to be polished in such a way that the rubber slider may contact it.

7.10. When the bonding material has stiffened sufficiently, strike off the excess material even with the curved sides of the mold.

7.11. When the bonding material has cured properly (3 to 6 hours) remove the specimen from the mold.

7.12. If sand was used, remove all free and excess sand from the face of the specimen.

7.13. If warping prevents proper placement on the road wheel, dress the bottom of the test specimens with a grinding wheel or belt sander to ensure proper fit. Respirators shall be used to prevent breathing the dust.

8. PROCEDURE

8.1. Determine the initial friction value of each prepared test specimen in accordance with T 278 using the slider specified in Section 5.3. Take all readings from the permanent scale.

8.2. Clamp 14 specimens around the periphery of the road wheel (using rubber O-rings near the edge of the specimens) to form a continuous strip of particles upon which the pneumatic-tired wheel shall ride freely without bumping or slipping.

8.3. Maintain the temperature of the specimens, water, and apparatus at 23.9 ± 2.8ºC (75 ± 5ºF) during the entire time of the test.

8.4. Bring the road wheel to a speed of 320 + 5 rpm, and bring the pneumatic-tired wheel to bear on the surface of the specimen with a total load of 391.44 ± 4.45 N (88 ± 1 lbf).

8.5. Feed the No. 150 silicon carbide grit at a rate of 6 ± 2 g/min for the desired testing time (Note 6). Feed the water at the rate of 50 to 75 mL per minute.

Note 6—Aggregates should be subjected to a polishing action of 10 hours, unless maximum polish is achieved in a shorter time. Maximum polish is achieved when no change is detected on successive measurements.

8.6. Remove the specimens from the road wheel and wash thoroughly to remove grit.

8.7. After cleaning, test each specimen to determine the polish value in accordance with T 278 using the slider specified in Section 5.3. Take all readings from the permanent scale.

8.8. If control specimens are used, determine adjustments to the polish value by comparing the polish value obtained for control specimens to the established value for the control aggregate as follows:

PV adjusted = PV Control (Standard)/PV Control (run) – PV Specimen (run)

8.9. If the rate of polish is desired, repeat the procedure in Sections 8.2 to 8.7 at regular intervals of machine time such as 1, 2, 4, 6, 8, and 10 hours.

9. REPORT

9.1. *Report the following information as is appropriate to the needs of the user*:

9.1.1. Identification of the coarse aggregate tested (and the control aggregate, if used) including gradation of aggregate,

9.1.2. Initial friction value for specimens containing aggregates to be evaluated and for control specimens, if used,

9.1.3. Polish values for specimens containing aggregates evaluated and for control specimens, if used,

9.1.4. Length of time and interim polish value of specimens tested for rate-of-polish determination,

9.1.5. Temperature during testing period, and

9.1.6. Dates of testing period.

10. PRECISION AND BIAS

10.1. The only measurement in this method that may be evaluated for precision and bias is the polish value. Refer to Section 7, Precision and Bias, of T 278 for information on precision and number of test specimens.

10.2. If no control specimen is used, it is recommended that seven specimens of the aggregate to be evaluated be tested in order to reduce random testing errors and to increase the confidence level of the test.

APPENDIX

(Nonmandatory Information)

X1. SUITABLE BONDING AGENT

X1.1. The formulation in Table X1.1 entitled “Polyester Bonding Agent” is a polyester bonding agent that has been found to successfully eliminate the need for sand as described in Section 7.

Table X1.1—Polyester Bonding Agent

Parts by Weight	Component	Supplier
100	Polylite 32-773 Polyester Resin[a]	Reichhold Chemical Co.
30	Wollastonite NYAD 400 Extender Pigment[b]	Interpace Corp.[b]
5 to 6	Santocel Z Silica Aerogel,[c]	Monsanto Chemical Co.
	Aerosil 200,[d] or Cab-O-Sil	Degussa, Inc.
	M-5 Colloidal Silica[e]	Godfrey L. Cabot, Inc.
0.5	6 percent Cobalt Naphthenate Solution[a]	Reichhold Chemical Co.

[a] Available from Reichhold Chemical Co., 523 N. Broadway, White Plains, NY 10603.
[b] Available from Interpace Corp., Customer Service Division, Willsboro, NY 12996.
[c] Available from Monsanto Chemical Co., 800 N. Lindberg Blvd, St. Louis, MO 63166.
[d] Available from Degussa, Inc., Route 46 at Hollister Rd., Teterboro, NJ 07608.
[e] Available from Cabot Corp., Cab-O-sil Division, Tuscole, IL 61953.

X1.2. Prepare the grout as follows:

X1.2.1. Add the Wollastonite NYAD 400 to the polyester resin and disperse with a laboratory model Cowles Disperser or similar equipment that will give a good, uniform mix. Then add the Santocel Z or Cab-O-Sil M-5 and grind in with the Cowles Dispenser until a good gel is obtained. The amount of gelling agent may be varied depending upon the stiffness desired. The thixotropy or gel can also be increased by stirring in glycerine at a maximum of 0.1 part by mass following dispersal of the gelling agent. Stir in the cobalt naphthenate.

X1.2.2. Just prior to use, add approximately 0.7 percent mass of 60 percent methyl ethyl ketone peroxide catalyst to the basic polyester grout and stir well. The amount of catalyst may also be varied depending upon the pot life or working time and the speed of cure desired.

X1.3. The working time of a 200-g batch of the catalyzed material is 15 to 20 minutes at 25ºC (77ºF). The cast specimens will cure adequately in 12 hours at 25ºC (77ºF) to perform the accelerated polish test.

Note X1—Other formulations may also be suitable and easily obtained locally. One such material is Preco, Gold Label, Non-Sagging Resin and Powder.[4]

Standard Method of Test for

Uncompacted Void Content of Fine Aggregate

AASHTO Designation: T 304-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Uncompacted Void Content of Fine Aggregate

AASHTO Designation: T 304-08

1. SCOPE

1.1. This method describes the determination of the loose uncompacted void content of a sample of fine aggregate. When measured on any aggregate of a known grading, void content provides an indication of that aggregate's angularity, sphericity, and surface texture compared with other fine aggregates tested in the same grading. When void content is measured on an as-received fine aggregate grading, it can be an indicator of the effect of the fine aggregate on the workability of a mixture in which it may be used.

1.2. Three procedures are included for the measurement of void content. Two use graded fine aggregate (standard grading or as-received grading), and the other uses several individual size fractions for void content determinations:

1.2.1. *Standard Graded Sample (Method A)*—This method uses a standard fine aggregate grading that is obtained by combining individual sieve fractions from a typical fine aggregate sieve analysis. See the section on Preparation of Test Samples for the Grading.

1.2.2. *Individual Size Fractions (Method B)*—This method uses each of three fine aggregate size fractions: (a) 2.36-mm (No. 8) to 1.18-mm (No. 16); (b) 1.18-mm (No. 16) to 600-µm (No. 30); and (c) 600-µm (No. 30) to 300 µm (No. 50). For this method, each size is tested separately.

1.2.3. *As-Received Grading (Method C)*—This method uses that portion of the fine aggregate finer than a 4.75-mm (No. 4) sieve.

1.2.4. See the section on Significance and Use for Guidance on the method to be used.

1.3. The values stated in SI units shall be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. Terms used in this standard are defined in ASTM C 125 or ACI 116R.

4. SUMMARY OF TEST METHOD

4.1. A nominal 100-mL calibrated cylindrical measure is filled with fine aggregate of prescribed grading by allowing the sample to flow through a funnel from a fixed height into the measure. The fine aggregate is struck off, and its mass is determined by weighing. Uncompacted void content is calculated as the difference between the volume of the cylindrical measure and the absolute volume of the fine aggregate collected in the measure. Uncompacted void content is calculated using the bulk dry specific gravity of the fine aggregate. Two runs are made on each sample and the results are averaged.

4.1.1. For a graded sample (Method A or Method C) the percent void content is determined directly, and the average value from two runs is reported.

4.1.2. For the individual size fractions (Method B), the mean percent void content is calculated using the results from tests of each of the three individual size fractions.

5. SIGNIFICANCE AND USE

5.1. Methods A and B provide percent void content determined under standardized conditions that depend on the particle shape and texture of a fine aggregate. An increase in void content by these procedures indicates greater angularity, less sphericity, or rougher surface texture, or some combination of the three factors. A decrease in void content results is associated with more rounded, spherical, smooth surfaced fine aggregate, or a combination of these factors.

5.2. Method C measures the uncompacted void content of the minus 4.75-mm (No. 4) portion of the as-received material. This void content depends on grading as well as particle shape and texture.

5.3. The void content determined on the standard graded sample (Method A) is not directly comparable with the average void content of the three individual size fractions from the same sample tested separately (Method B). A sample consisting of single size particles will have a higher void content than a graded sample. Therefore, use either one method or the other as a comparative measure of shape and texture, and identify which method has been used to obtain the reported data. Method C does not provide an indication of shape and texture directly if the grading from sample to sample changes.

5.3.1. The standard graded sample (Method A) is most useful as a quick test that indicates the particle shape properties of a graded fine aggregate. Typically, the material used to make up the standard graded sample can be obtained from the remaining size fractions after performing a single sieve analysis of the fine aggregate.

5.3.2. Obtaining and testing individual size fractions (Method B) is more time consuming and requires a larger initial sample than using the graded sample. However, Method B provides additional information concerning the shape and texture characteristics of individual sizes.

5.3.3. Testing samples in the as-received grading (Method C) may be useful in selecting proportions of components used in a variety of mixtures. In general, high void content suggests that the material could be improved by providing additional fines in the fine aggregate or more cementitious material may be needed to fill voids between particles.

5.3.4. The bulk dry specific gravity of the fine aggregate is used in calculating the void content. The effectiveness of these methods of determining void content and its relationship to particle shape and texture depends on the bulk specific gravity of the various size fractions being equal, or nearly so. The void content is actually a function of the volume of each size fraction. If the type of rock or minerals, or its porosity, in any of the size fractions varies markedly it may be necessary to determine the specific gravity of the size fractions used in the test.

5.4. Void content information from Methods A, B, or C will be useful as an indicator of properties such as: the mixing water demand of hydraulic cement concrete; flowability, pumpability, or workability factors when formulating grouts or mortars; or, in bituminous concrete, the effect of the fine aggregate on stability and voids in the mineral aggregate; or the stability of the fine aggregate portion of a base course aggregate.

---

6. APPARATUS

6.1. *Cylindrical Measure*—A right cylinder of approximately 100 mL capacity having an inside diameter of approximately 39 mm and an inside height of approximately 86 mm made of drawn copper water tube meeting ASTM Specification B 88 Type M, or B 88 M Type C. The bottom of the measure shall be metal at least 6 mm thick, shall be firmly sealed to the tubing, and shall be provided with means for aligning the axis of the cylinder with that of the funnel. (See Figure 1.)

6.2. *Funnel*—The lateral surface of the right frustum of a cone sloped 60 ± 4º from the horizontal with an opening of 12.7 ± 0.6 mm diameter. The funnel section shall be a piece of metal, smooth on the inside and at least 38 mm high. It shall have a volume of at least 200 mL or shall be provided with a supplemental glass or metal container to provide the required volume. (See Figure 2.)

Note 1—Pycnometer top C9455 sold by Hogentogler and Co., Inc., 9515 Gerwig, Columbia, MD 21046, 410-381-2390 is satisfactory for the funnel section, except that the size of the opening has to be enlarged and any burrs or lips that are apparent should be removed by light filing or sanding before use. This pycnometer top must be used with a suitable glass jar with the bottom removed (Figure 2).

6.3. *Funnel Stand*—A three- or four-legged support capable of holding the funnel firmly in position with the axis of the funnel colinear (within a 4-degree angle and a displacement of 2 mm) with the axis of the cylindrical measure. The funnel opening shall be 115 ± 2 mm above the top of the cylinder. A suitable arrangement is shown in Figure 2.

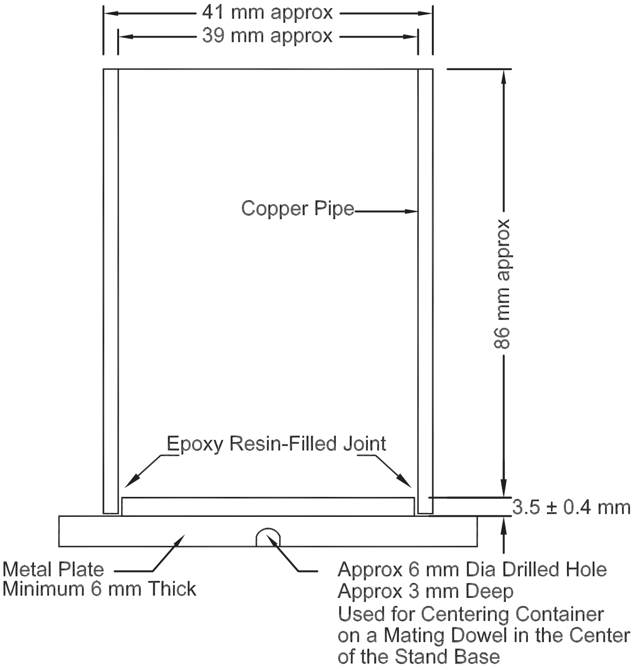

Figure 1—Nominal 100-mL Cylindrical Measure

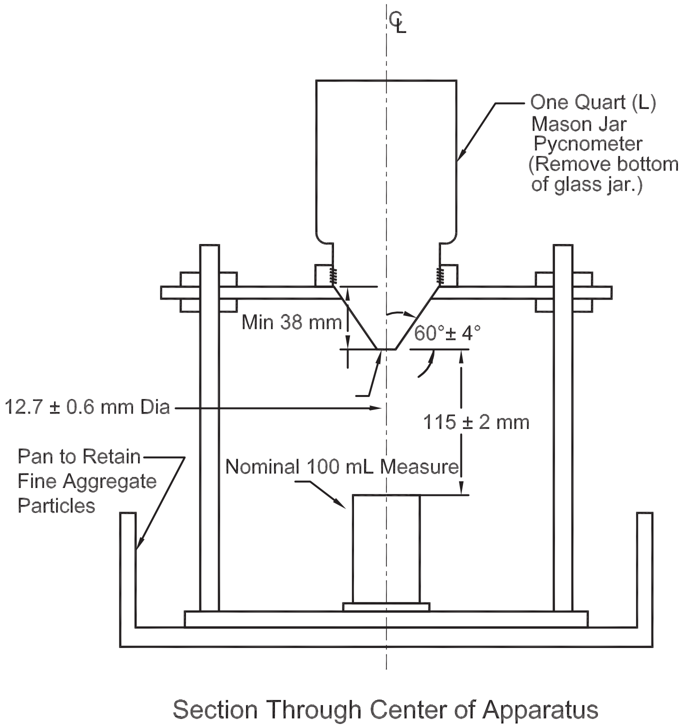

Figure 2—Suitable Funnel Stand Apparatus with Cylindrical Measure in Place

6.4. *Glass Plate*—A square glass plate approximately 60 mm by 60 mm with a minimum 4-mm thickness used to calibrate the cylindrical measure.

6.5. *Pan*—A metal or plastic pan of sufficient size to contain the funnel stand and to prevent loss of material. The purpose of the pan is to catch and retain fine aggregate particles that overflow the measure during filling and strike off.

6.6. Metal spatula with a blade approximately 100 mm long, and at least 20 mm wide, with straight edges. The end shall be cut at a right angle to the edges. The straight edge of the spatula blade is used to strike off the fine aggregate.

6.7. Scale or balance accurate and readable to ±0.1 g within the range of use, capable of weighing the cylindrical measure and its contents.

7. SAMPLING

7.1. The sample(s) used for this test shall be obtained using T 2 and T 248, or from sieve analysis samples used for T 27, or from aggregate extracted from a bituminous concrete specimen. For Methods A and B, the sample is washed over a 150-µm (No. 100) or 75-µm (No. 200) sieve in accordance with T 11 and then dried and sieved into separate size fractions according to T 27 procedures. Maintain the necessary size fractions obtained from one (or more) sieve analysis in a dry condition in separate containers for each size. For Method C, dry a split of the as-received sample in accordance with the drying procedure in T 27.

8. CALIBRATION OF CYLINDRICAL MEASURE

8.1. Apply a light coat of grease to the top edge of the dry, empty cylindrical measure. Weigh the measure, grease, and glass plate. Fill the measure with freshly boiled, deionized water at a temperature of 18 to 24ºC. Record the temperature of the water. Place the glass plate on the measure, being sure that no air bubbles remain. Dry the outer surfaces of the measure and determine the combined mass of measure, glass plate, grease, and water by weighing. Following the final weighing, remove the grease, and determine the mass of the clean, dry, empty measure for subsequent tests.

8.2. Calculate the volume of the measure as follows:

$$V = 1000\ \frac{M}{D} \tag{1}$$

where:

V = volume of cylinder, mL;

M = net mass of water, g; and

D = density of water (See table in T 19M/T 19 for density at the temperature used.), kg/m^3.

Determine the volume to the nearest 0.1 mL.

Note 2—If the volume of the measure is greater than 100.0 mL, it may be desirable to grind the upper edge of the cylinder until the volume is exactly 100.0 mL, to simplify subsequent calculations.

9. PREPARATION OF TEST SAMPLES

9.1. *Method A—Standard Graded Sample*—Weigh out and combine the following quantities of fine aggregate, which has been dried and sieved in accordance with T 27.

Individual Size Fraction	Mass, g
2.36 mm (No. 8) to 1.18 mm (No. 16)	44
1.18 mm (No. 16) to 600 µm (No. 30)	57
600 µm (No. 30) to 300 µm (No. 50)	72
300 µm (No. 50) to 150 µm (No. 100)	17
	190

The tolerance on each of these amounts is ±0.2 g.

9.2. *Method B—Individual Size Fractions*—Prepare a separate 190-g sample of fine aggregate, dried and sieved in accordance with T 27, for each of the following size fractions:

Individual Size Fraction	Mass, g
2.36 mm (No. 8) to 1.18 mm (No. 16)	190
1.18 mm (No. 16) to 600 µm (No. 30)	190
600 µm (No. 30) to 300 µm (No. 50)	190

The tolerance on each of these amounts is ±1 g. Do not mix these samples together. Each size is tested separately.

9.3. *Method C—As-Received Grading*—Pass the sample (dried in accordance with T 27) through a 4.75-mm (No. 4) sieve. Obtain a 190 ± 1-g sample of the material passing the 4.75-mm (No. 4) sieve for test.

9.4. *Specific Gravity of Fine Aggregate*—If the bulk dry specific gravity of fine aggregate from the source is unknown, determine it on the minus 4.75-mm (No. 4) material according to T 84. Use this value in subsequent calculations unless some size fractions differ by more than 0.05 from the specific gravity typical of the complete sample, in which case the specific gravity of the fraction (or fractions) being tested must be determined. An indicator of differences in specific gravity of various particle sizes is a comparison of specific gravities run on the fine aggregate in different gradings. Specific gravity can be run on gradings with and without specific size fractions of interest. If specific gravity differences exceed 0.05, determine the specific gravity of the individual 2.36-mm (No. 8) to 150-µm (No. 100) sizes for use with Method A or the individual size fractions for use with Method B either by direct measurement or by calculation using the specific gravity data on gradings with and without the size fraction of interest. A difference in specific gravity of 0.05 will change the calculated void content about one percent.

10. PROCEDURE

10.1. Mix each test sample with the spatula until it appears to be homogeneous. Position the jar and funnel section in the stand and center the cylindrical measure as shown in Figure 2. Use a finger to block the opening of the funnel. Pour the test sample into the funnel. Level the material in the funnel with the spatula. Remove the finger and allow the sample to fall freely into the cylindrical measure.

10.2. After the funnel empties, strike-off excess heaped fine aggregate from the cylindrical measure by a rapid single pass of the spatula with the width of the blade vertical, keeping the straight part of its edge horizontal and in light contact with the top of the measure. Until this operation is complete, exercise care to avoid vibration or any disturbance that could cause compaction of the fine aggregate in the cylindrical measure (Note 3). Brush adhering grains from the outside of the container and determine the mass of the cylindrical measure and contents to the nearest 0.1 g. Retain all fine aggregate particles for a second test run.

Note 3—After strike-off, the cylindrical measure may be tapped lightly to compact the sample to make it easier to transfer the container to scale or balance without spilling any of the sample.

10.3. Recombine the sample from the retaining pan and cylindrical measure and repeat the procedure. The results of two runs are averaged. See the Calculation section.

10.4. Record the mass of the empty measure. Also, for each run, record the mass of the measure and fine aggregate.

11. CALCULATION

11.1. Calculate the uncompacted voids for each determination as follows:

$$U = \frac{V - (F/G)}{V} \times 100 \qquad (2)$$

where:

V = volume of cylindrical measure, mL;

F = net mass, g, of fine aggregate in measure (gross mass minus the mass of the empty measure);

G = bulk dry specific gravity of fine aggregate; and

U = uncompacted voids, percent, in the material.

11.2. *For the Standard Graded Sample* (Method A), calculate the average uncompacted voids for the two determinations and report the result as U_s.

11.3. *For the Individual Size Fractions* (Method B), calculate:

11.3.1. First, the average uncompacted voids for the determination made on each of the three size-fraction samples:

U_1 = uncompacted voids, 2.36 mm (No. 8) to 1.18 mm (No. 16), percent;

U_2 = uncompacted voids, 1.18 mm (No. 16) to 600 μm (No. 30), percent; and

U_3 = uncompacted voids, 600 μm (No. 30) to 300 μm (No. 50), percent.

11.3.2. Second, the mean uncompacted voids (U_m) including the results for all three sizes:

$$U_m = (U_1 + U_2 + U_3)/3 \qquad (3)$$

11.4. *For the As-Received Grading* (Method C), calculate the average uncompacted voids for the two determinations and report the result as U_R.

12. REPORT

12.1. *For the Standard-Graded Sample* (Method A), report:

12.1.1. The Uncompacted Voids (U_s) in percent to the nearest one-tenth of a percent (0.1 percent).

12.1.2. The specific gravity value used in the calculations.

12.2. *For the Individual-Size Fractions* (Method B), report the following percent voids to the nearest one-tenth of a percent (0.1 percent):

12.2.1. Uncompacted Voids for Size Fractions: (a) 2.36 mm (No. 8) to 1.18 mm (No. 16) (U_1); (b) 1.18 mm (No. 16) to 600 μm (No. 30) (U_2); and (c) 600 μm (No. 30) to 300 μm (No. 50) (U_3).

12.2.2. Mean Uncompacted Voids (U_m).

12.2.3. Specific gravity value(s) used in the calculations, and whether the specific gravity value(s) were determined on a graded sample or the individual size fractions used in the test.

12.3. *For the As-Received Sample* (Method C), report:

12.3.1. The uncompacted voids (U_R) in percent to the nearest one-tenth of a percent (0.1 percent).

12.3.2. The specific gravity value used in the calculation.

13. PRECISION AND BIAS

13.1. *Precision*:

13.1.1. The single-operator standard deviation has been found to be 0.13 percent voids (1s), using the graded standard silica sand as described in ASTM C 778. Therefore, results of two properly conducted tests by the same operator on similar samples should not differ by more than 0.37 percent (d2s).

13.1.2. The multilaboratory standard deviation has been found to be 0.33 percent (1s) using the standard fine aggregate as described in ASTM C 778. Therefore, results of two properly conducted tests by different laboratories on similar samples should not differ by more than 0.93 percent (d2s).

13.1.3. The above statements pertain to void contents determined on "graded standard sand" as described in ASTM C 778, which is considered rounded, and is graded from 600 μm (No. 30) to 150 μm (No. 100), and may not be typical of other fine aggregates. Additional precision data are needed for tests of fine aggregates having different levels of angularity and texture tested in accordance with this test method.

13.2. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedures in this test method, bias has not been determined.

14. KEYWORDS

14.1. Angularity; fine aggregate; particle shape; sand; surface texture; void content.

Standard Method of Test for

Uncompacted Void Content of Coarse Aggregate (As Influenced by Particle Shape, Surface Texture, and Grading)

AASHTO Designation: T 326-05 (2009)[1]

1. SCOPE

1.1. This method describes the determination of the loose uncompacted void content of a sample of coarse aggregate. When measured on any aggregate of a known grading, void content provides an indication of the aggregate's angularity, sphericity, and surface texture compared with other coarse aggregates tested in the same grading.

1.2. Three procedures are included for the measurement of void content. Two use graded coarse aggregate (standard grading or as-received grading), and the other uses several individual size fractions for void content determinations:

1.2.1. *Standard Graded Sample (Method A)*—This method uses a standard coarse aggregate grading that is obtained by combining individual sieve fractions from the maximum density curve drawn from the maximum coarse aggregate size. See the section on Preparation of Test Samples for the grading.

1.2.2. *Individual Size Fractions (Method B)*—This method uses each of three coarse aggregate size fractions: (a) 19 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.); (b) 12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.); (c) 9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4). For this method, each size is tested separately.

1.2.3. *As-Received Grading (Method C)*—This method uses that portion of the coarse aggregate retained on the 4.75-mm (No. 4) sieve.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulation limitations prior to its use.*

3. SUMMARY OF TEST METHODS

3.1. A calibrated cylindrical measure is filled with coarse aggregate of prescribed grading by allowing the sample to flow through a funnel from a fixed height into the measure. The coarse aggregate is struck off, and its mass is determined by weighing. Uncompacted void content is calculated as the difference between the volume of the cylindrical measure and the absolute volume of the coarse aggregate collected in the measure. Uncompacted void content is calculated using the bulk dry specific gravity of the coarse aggregate as received without special grading except as noted in Section 4.3.1. Two runs are made on each sample and the results are averaged.

3.1.1. For a graded sample (Test Method A or C) the percent void content is determined directly, and the average value from two runs is reported.

3.1.2. For the individual size fractions (Test Method B), the mean percent void content is calculated using the results from tests of each of the three individual size fractions.

4. SIGNIFICANCE AND USE

4.1. Methods A and B provide percent void content determined under standardized conditions, which depends on the particle shape and texture of a coarse aggregate. An increase in void content by these procedures indicates greater angularity, less sphericity, or rougher surface texture, or some combination of the three factors. A decrease in void content results is associated with more rounded, spherical, or smooth-surfaced coarse aggregates, or a combination of these factors.

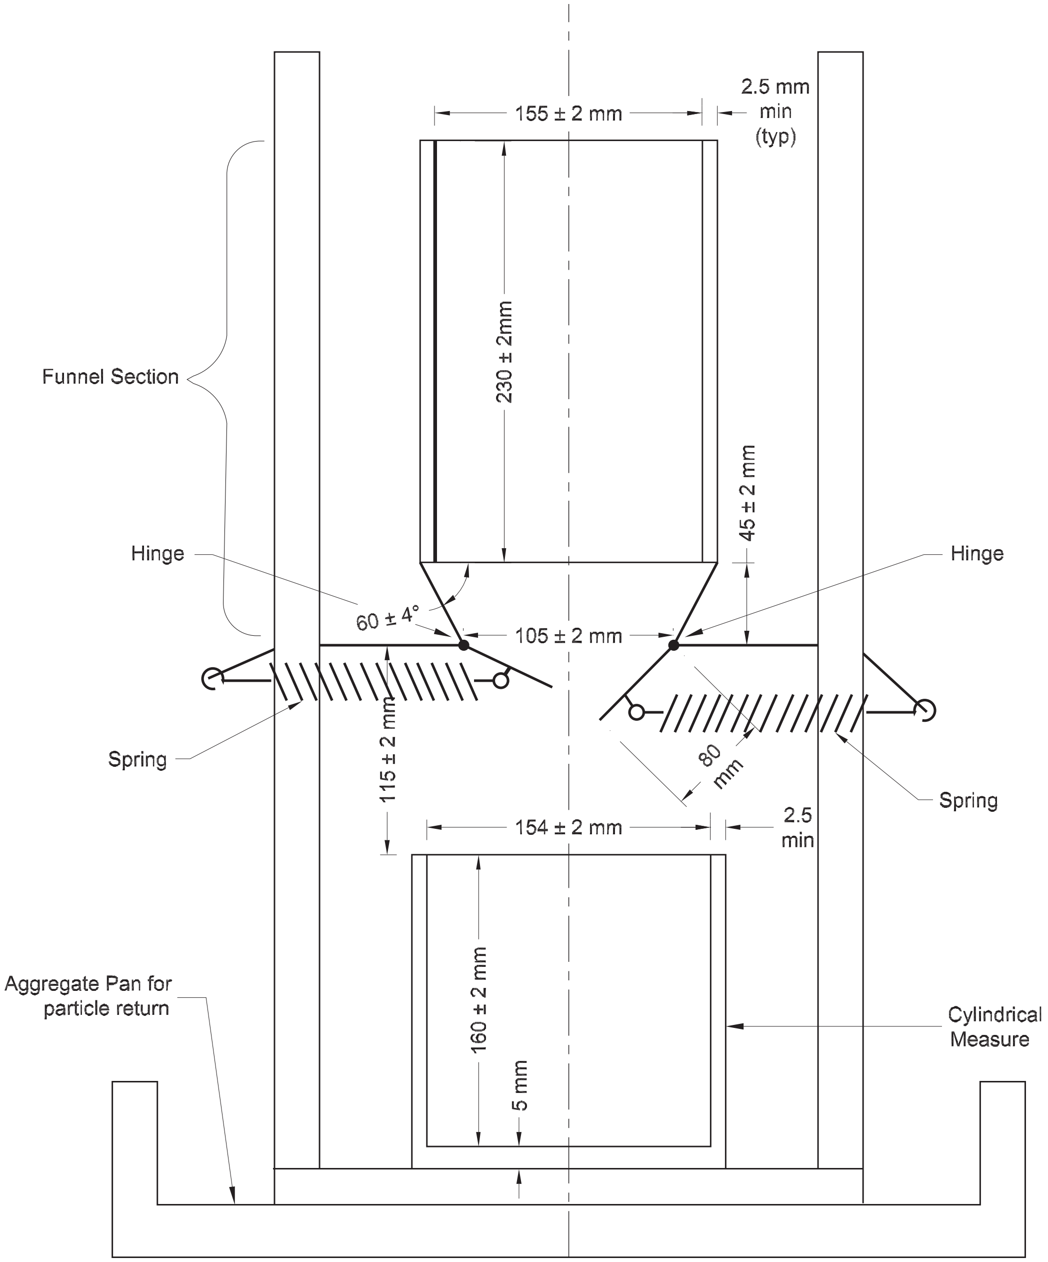
4.2. Method C measures the uncompacted void content of the fraction retained on a 4.75-mm (No. 4) sieve of the as-received material. This void content depends on grading as well as particle shape and texture.

4.3. The void content determined on the standard graded sample (Method A) is not directly comparable with the average void content of the three individual size fractions from the same sample tested separately (Method B). A sample consisting of single size particles will have a higher void content than a graded sample. Therefore, use either one method or the other as a comparative measure of shape and texture, and identify which method has been used to obtain the reported data. Method C does not provide an indication of shape and texture directly if the grading from sample to sample changes.

4.3.1. The bulk dry specific gravity of the coarse aggregate determined by T 85 is used in calculating the void content. The effectiveness of these methods of determining void content and its relationship to particle shape and texture depends on the bulk specific gravity of various size fractions being equal, or nearly so. The void content is actually a function of the volume of each size fraction. If the type of rock or minerals, or its porosity, in any of the size fractions varies markedly, it may be necessary to determine the specific gravity of the size fractions used in the test.

5. APPARATUS

5.1. *Cylindrical Measure*—A cylindrical metal measure shall be watertight, with the top and bottom true and even, preferably machined to accurate dimensions on the inside and sufficiently rigid to retain its form under rough usage. The top rim shall be smooth and plane within 0.25 mm and shall be parallel to the bottom within 0.5 degrees. The inside diameter shall be 154 ± 2 mm and the inside height shall be 160 ± 2 mm. See Figure 1 for nominal dimensions.



Note: Figure is not to scale.

Figure 1—Test Apparatus

5.2. *Funnel*—The lateral surface of the right frustum of a cone sloped 60 ± 4 degrees from the horizontal with an opening of 105 ± 2-mm diameter. The funnel section shall be a piece of metal, smooth on the inside. It shall have a volume of at least two times the volume of the cylindrical measure or shall be provided with a supplemental metal container to provide the required volume. (See Figure 1.)

5.3. *Funnel Stand*—A support capable of holding the funnel firmly in position with the axis of the funnel colinear (within a four degree angle and a displacement of 2 mm) with the axis of the cylindrical measure. The funnel opening shall be 115 ± 2 mm above the top of the cylinder.

5.4. *Glass Plate*—A square glass plate approximately 170 mm × 170 mm with a minimum thickness of 4 mm used to calibrate the cylindrical measure.

5.5. *Pan*—A metal or glass pan of sufficient size to contain the funnel stand and to prevent loss of material. The purpose of the pan is to catch and retain aggregate particles that overflow the measure during filling and strike off.

5.6. *Flat Metal Straightedge*—A flat metal straightedge of 300 ± 5 mm length, 40 ± 2 mm in width and 3 mm thickness is used to strike off the top of the container.

5.7. *Scale* or balance conforming to M 231 and capable of weighing the cylindrical measure and its contents.

6. SAMPLING

6.1. The samples used for this test shall be obtained using T 2 and T 248, or from sieve analysis samples used for T 27. For Methods A and B, the sample is washed over a 75-µm (No. 200) sieve in accordance with T 11 and then dried and sieved into separate size fractions according to T 27. Maintain the necessary size fractions obtained from one (or more) sieve analysis in a dry condition in separate containers for each size. For Method C, dry and split the as-received sample in accordance with T 27 drying procedure.

7. CALIBRATION OF CYLINDRICAL MEASURE

7.1. Apply a light coat of grease to the top edge of the dry, empty cylindrical measure. Weigh the measure, grease, and glass plate. Fill the measure with freshly boiled, deionized water at a temperature of 18 to 24°C. Record the temperature of the water. Place the glass plate on the measure, being sure that no air bubbles remain. Dry the outer surfaces of the measure and determine the combined mass of measure, glass plate, grease, and water by weighing. Following the final weighing, remove the grease, and determine the mass of the clean, dry, empty measure for subsequent tests.

7.2. Calculate the volume of measure as follows:

$$V = 1000\left(M/D\right) \qquad (1)$$

where:

V = volume of cylinder, mL;

M = net mass of water, g; and

D = density of water (see Table 3 in T 19M/T 19 for density at the temperature used), kg/m^3.

Determine the volume to the nearest 0.1 mL.

8. PREPARATION OF TEST SAMPLES

8.1. *Method A—Standard Graded Sample*—weigh and combine the following quantities of coarse aggregate (based on the maximum size of the aggregate) which has been dried and sieved in accordance with T 27. (See Table 1.) The total sample weight should be 5000 g ± 10 g.

Table 1—Standard Gradations for Method A

Maximum Size of Aggregate	Sieve Size (mm)	Mass, g
19 mm	19 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.)	1740
	12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.)	1090
	9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4)	2170
12.5 mm	12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.)	1970
	9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4)	3030

8.2. *Method B—Individual Size Fractions*—Prepare a separate 5000 g sample of coarse aggregate, dried and sieved in accordance with T 27, for each of the following size fractions (see Table 2):

Table 2—Size Fractions for Method B

Sieve Size (mm)	Mass, g
19 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.)	5000
12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.)	5000
9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4)	5000

8.3. *Method C—As-Received Grading*—Pass the sample (dried in accordance with T 27) over a 4.75-mm (No. 4) sieve. Obtain a 5000 g ± 10 g sample of the material. The tolerance on each of the amounts in Table 2 is 10 g. Do not mix these samples together. Each size is tested separately.

8.4. *Specific Gravity of Coarse Aggregate*—If the bulk dry specific gravity of coarse aggregate from the source is unknown, determine it on the plus 4.75 mm (No. 4) sample according to T 85.

9. PROCEDURE

9.1. Mix each sample until it appears to be homogeneous. Center the cylindrical measure under the funnel section as shown in Figure 1. Close the doors at the bottom of the funnel section and latch them shut. Pour the test sample into the funnel section. Hold the doors shut with one finger and open the latch on the doors. Remove the finger from the doors, allowing the doors to swing open and the aggregate to fall freely into the cylindrical measure.

Note 1—A latch may be placed on the doors for the convenience of the operator or the operator may hold the doors closed with a finger during the filling of the funnel section, in which case the latch on the doors would not be necessary.

9.2. After the funnel empties, strike off excess heaped aggregate from the cylindrical measure. Until this operation is complete, exercise care to avoid vibration or any disturbance that could cause compaction of the coarse aggregate in the cylindrical measure. Remove any aggregate that may have fallen on the outside of the container and determine the mass of the cylindrical measure and contents to the nearest 0.1 g. Retain all aggregate particles for a second test run.

9.3. Recombine the sample from the retaining pan and cylindrical measure and repeat the procedure. The results of two runs are averaged. (See Section 10.)

9.4. Record the mass of the empty measure. Also, for each run, record the mass of the measure and coarse aggregate.

10. CALCULATION

10.1. Calculate uncompacted voids for each determination as follows:

$$U = \frac{V - \left(F / G\right)}{V} \times 100 \qquad (2)$$

where:

V = volume of cylindrical measure, mL;

F = net mass, g, of coarse aggregate in measure (gross mass minus the mass of the empty measure);

G = bulk dry specific gravity of coarse aggregate; and

U = uncompacted voids, percent, in the material.

10.2. For the Standard Graded Sample (Method A), calculate the average uncompacted voids for the two determinations and report the result as U_s.

10.3. For the Individual Size Fractions (Method B), calculate:

10.3.1. First, the average uncompacted voids for the determination made on each of the three size-fraction samples:

U_1 = uncompacted voids, 19 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.), percent;

U_2 = uncompacted voids, 12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.), percent; and

U_3 = uncompacted voids, 9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4), percent.

10.3.2. Second, the mean uncompacted voids (U_m) including the results for all three sizes:

$$U_m = (U_1 + U_2 + U_3)/3 \qquad (3)$$

10.4. For the As-Received Grading (Method C), calculate the average uncompacted voids for the two determinations and report the results as U_R.

11. REPORT

11.1. For the Standard Graded Sample (Method A), report the following:

11.1.1. The Uncompacted Voids (U_s) in percent to the nearest one-tenth of a percent.

11.1.2. The specific gravity value used in the calculation.

11.2. For the Individual Size Fractions (Method B), report the following percent voids to the nearest one tenth of a percent:

11.2.1. Uncompacted Voids for Size Fraction:

11.2.1.1. 19 mm ($^3/_4$ in.) to 12.5 mm ($^1/_2$ in.) (U_1).

11.2.1.2. 12.5 mm ($^1/_2$ in.) to 9.5 mm ($^3/_8$ in.) (U_2).

11.2.1.3. 9.5 mm ($^3/_8$ in.) to 4.75 mm (No. 4) (U_3).

11.2.2. Mean Uncompacted Voids (U_m).

11.2.3. Specific gravity value(s) used in the calculations, and whether the specific gravity value(s) were determined on a graded sample or the individual size fractions used in the test.

11.3. For the As-Received Sample (Method C), report the following:

11.3.1. The Uncompacted Voids (U_R) in percent to the nearest one-tenth of a percent.

11.3.2. The specific gravity value used in the calculation.

12. PRECISION AND BIAS

12.1. *Precision*—No precision has been established.

12.2. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedures in these test methods, bias has not been determined.

13. KEYWORDS

13.1. Angularity; coarse aggregate; particle shape; surface texture; void content.

AASHTO Designation: T 327-09[1]
ASTM Designation: D 6928-03

1. SCOPE

1.1. This method covers a procedure for testing coarse aggregate for resistance to abrasion using the Micro-Deval apparatus.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. The text of this method references notes and footnotes which provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the test method.

1.4. *This procedure may involve hazardous materials, operations, and equipment. This procedure does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitation prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 27, Sieve Analysis of Fine and Coarse Aggregates

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SUMMARY OF TEST METHOD

3.1. The Micro-Deval Test is a measure of abrasion resistance and durability of mineral aggregates resulting from a combination of actions including abrasion and grinding with steel balls in the presence of water. A sample with standard grading is initially soaked in water for not less than 1 hour. The sample is then placed in a jar mill with 2.0 liters of water and an abrasive charge consisting of 5000 grams of 9.5-mm diameter steel balls. The jar, aggregate, water, and charge are revolved at 100 rpm for 2 hours depending on the particle size. The sample is then washed and oven-dried. The loss is the amount of material passing the 1.18-mm sieve, expressed as a percent by mass of the original sample.

4. SIGNIFICANCE AND USE

4.1. The Micro-Deval abrasion test is a test of coarse aggregates to determine abrasion loss in the presence of water and an abrasive charge. Many aggregates are more susceptible to abrasion when wet than dry, and the use of water in this test incorporates this reduction in resistance in degradation, in contrast to some other tests that are conducted on dry aggregate. The test results are helpful in evaluating the toughness/abrasion resistance of coarse aggregate subject to abrasion when adequate information is not available from service records.

4.2. The Micro-Deval abrasion test is a useful test for detecting changes in properties of aggregate produced from an aggregate source as part of a quality control or quality assurance process.

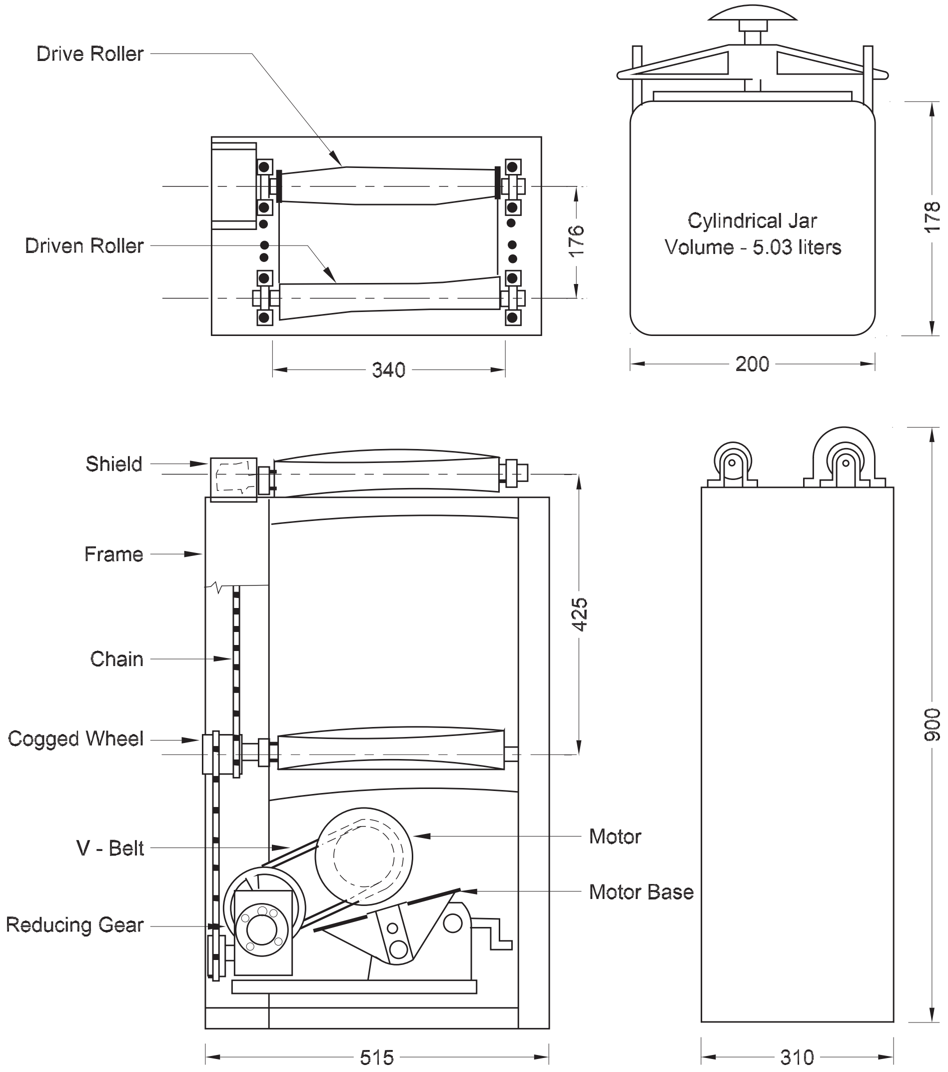
5. TERMINOLOGY

5.1. *constant mass*—test samples dried at a temperature of 110 ± 5°C to a condition such that it will not lose more than 0.1 percent moisture after 2 hours of drying. Such a condition of dryness can be verified by weighing the sample before and after successive 2 hours drying periods. In lieu of such a determination, samples may be considered to have reached constant mass when they have been dried at a temperature of 110 ± 5°C for an equal or longer period than that previously found adequate for producing the desired constant mass condition under equal or heavier loading conditions of the oven.

6. APPARATUS

6.1. *Micro-Deval Abrasion Machine*—A jar rolling mill capable of running at 100 ± 5 rpm (Figure 1).

Note 1—Micro-Deval abrasion machine fitted with a counter may be used if the test is conducted on the basis of number of revolutions (Section 9.4).



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 1—Micro-Deval Abrasion Machine and Container

6.2. *Containers*—Stainless steel Micro-Deval abrasion jars having a 5-L capacity with a rubber ring in the rotary locking cover; an external diameter of 194 to 202 mm, and an internal height of 170 to 177 mm. The inside and outside surfaces of the jars shall be smooth and have no observable ridges or indentations (Figure 1).

6.3. *Abrasion Charge*—Magnetic stainless steel balls are required. These shall have a diameter of 9.5 ± 0.5 mm. Each jar requires a charge of 5000 ± 5 g of balls.

6.4. *Sieves*—Sieves with square openings, and of the following sizes conforming to M 92 specifications: 19.0 mm, 16.0 mm, 12.5 mm, 9.5 mm, 6.3 mm, 4.75 mm, 1.18 mm.

6.5. *Oven*—The oven shall be capable of maintaining a temperature of 110 ± 5°C.

6.6. *Balance*—A balance or scale accurate to 1.0 g.

7. REFERENCE AGGREGATE

7.1. *Laboratory Reference Aggregate*—A supply of standard "Brechin Quarry No. 2" coarse aggregate available from the Soils and Aggregates Section, Materials Engineering and Research Office, Ministry of Transportation, 1201 Wilson Avenue, Downsview, Ontario, Canada M3M 1J8.

7.2. *Calibration Aggregate*—An adequate supply of aggregate, established by the laboratory to use for calibration of the test method (see Section 11.1).

8. TEST SAMPLE

8.1. The test sample shall be washed and oven-dried at 110 ± 5°C to constant mass, separated into individual size fractions in accordance with T 27, and recombined to meet the grading as shown in Section 8.2.

8.2. Aggregate for the test shall normally consist of material passing the 19.0-mm sieve, retained on the 9.5-mm sieve. An oven-dried sample of 1500 ± 5 g shall be prepared as in Table 1 (suggested revisions to Micro-Deval Test Method, July 13, 1998, AASHTO Technical Subcommittee 1c).

Table 1—Preparation of an Oven-Dried Sample of 19.0 mm

Passing	Retained	Mass
19.0 mm	16.0 mm	375 g
16.0 mm	12.5 mm	375 g
12.5 mm	9.5 mm	750 g

8.3. In a case where the nominal maximum size of the coarse aggregate is 12.5 mm or less, a sample of 1500 ± 5 g shall be prepared as in Table 2:

Table 2—Preparation of an Oven-Dried Sample of Less Than 16.0 mm

Passing	Retained	Mass
12.5 mm	9.5 mm	750 g
9.5 mm	6.3 mm	375 g
6.3 mm	4.75 mm	375 g

8.4. In a case where the nominal maximum size of the coarse aggregate is 9.5 mm or less, a sample 1500 ± 5 g shall be prepared as in Table 3:

Table 3—Preparing an Oven-Dried Sample of Less Than 12.5 mm

Passing	Retained	Mass
9.5 mm	6.3 mm	750 g
6.3 mm	4.75 mm	750 g

9. TEST PROCEDURE

9.1. Prepare a representative 1500 ± 5 g sample. Determine the Mass "A" and record to the nearest 1.0 g.

9.2. Immerse the sample in 2.0 ± 0.05 liters of tap water at a temperature of 20 ± 5°C for a minimum of 1 hour either in the Micro-Deval container or some other suitable container.

9.3. Place the sample in the Micro-Deval abrasion container with 5000 ± 5 g of steel balls and the water used in Section 9.2 to saturate the sample. Install the cover and place the Micro-Deval container on the machine.

9.4. Run the machine at 100 ± 5 rpm for 12,000 ± 100 revolutions for the grading shown in Section 8.2; for 10,500 ± 100 revolutions for the grading shown in Section 8.3; and for 9,500 ± 100 revolutions for the grading shown in Section 8.4.

Note 2—Some equipment is not capable of measuring the total number of revolutions of the drum. If desired, instead of using revolutions, time can be used as follows:

Run the machine at 100 ± 5 rpm for 120 ± 1 minutes for the grading shown in Section 8.2. For the grading shown in Section 8.3, run the machine for 105 ± 1 minutes. For the grading shown in Section 8.4, run the machine for 95 ± 1 minutes.

9.5. Carefully pour the sample and steel balls over a 4.75-mm sieve superimposed on a 1.18-mm sieve. Take care to remove the entire sample from the stainless steel jar. Wash and manipulate the retained material on the sieve with water using a hand held water hose and the hand until the washings are clear and all material smaller than 1.18 mm passes that sieve. Remove the stainless steel balls using a magnet or other suitable means. Discard material smaller than 1.18 mm.

9.6. Combine the material retained on the 4.75-mm and 1.18-mm sieves, being careful not to lose any material.

9.7. Oven-dry the sample to constant mass at 110 ± 5°C.

9.8. Weigh the sample to the nearest 1.0 g. Record the Mass "B."

10. CALCULATIONS

10.1. Calculate the Micro-Deval abrasion loss, as follows, to the nearest 0.1 percent.

$$\text{Percent Loss} = (A - B)/A \times 100 \quad (1)$$

where:

A = mass, as determined in Section 9.1; and

B = mass, as determined in Section 9.8.

11. USE OF THE CALIBRATION AGGREGATE

11.1. *Calibration Aggregate*—The laboratory will establish an adequate supply of material to use for calibration of the test method. A suitable material with a loss of between 15 and 25 percent shall be established. From this material, 10 samples shall be taken randomly and tested. At the same time, 10 samples of reference aggregate from Brechin Quarry No. 2 (see Section 7.1) shall also be tested. Provided the mean loss and variation of the Brechin Quarry No. 2 aggregate is within allowed tolerance of Section 11.1.1, the mean value obtained with the supply of the in-house calibration aggregate shall be used thereafter. At any time a new supply is required, the calibration procedure shall be conducted.

11.1.1. The mean loss of the Brechin Quarry No. 2 reference aggregate (see Section 7.1) in multilaboratory study of the Micro-Deval Test is 19.1 percent. For continued acceptance of data, individual reference material test data must fall within the range 17.5 to 20.7 percent loss for 95 percent of the time.

11.1.2. When test data of the calibration aggregate is outside the limits, an investigation as to the probable cause shall be conducted. The equipment shall be re-calibrated and the testing technique re-examined to detect nonconformance with the test procedure.

11.2. Every 10 samples, but at least every week in which a sample is tested, a sample of the calibration aggregate shall be tested. The material shall be taken from a stock supply and prepared according to Section 8. When 20 samples of calibration material have been tested, and the results show satisfactory variation, the frequency of testing may be changed to a minimum of one sample every month.

11.3. *Trend Chart Use*—The percent loss of the last 20 samples of calibration material shall be plotted on a trend chart in order to monitor the variation in results (Figure 2).

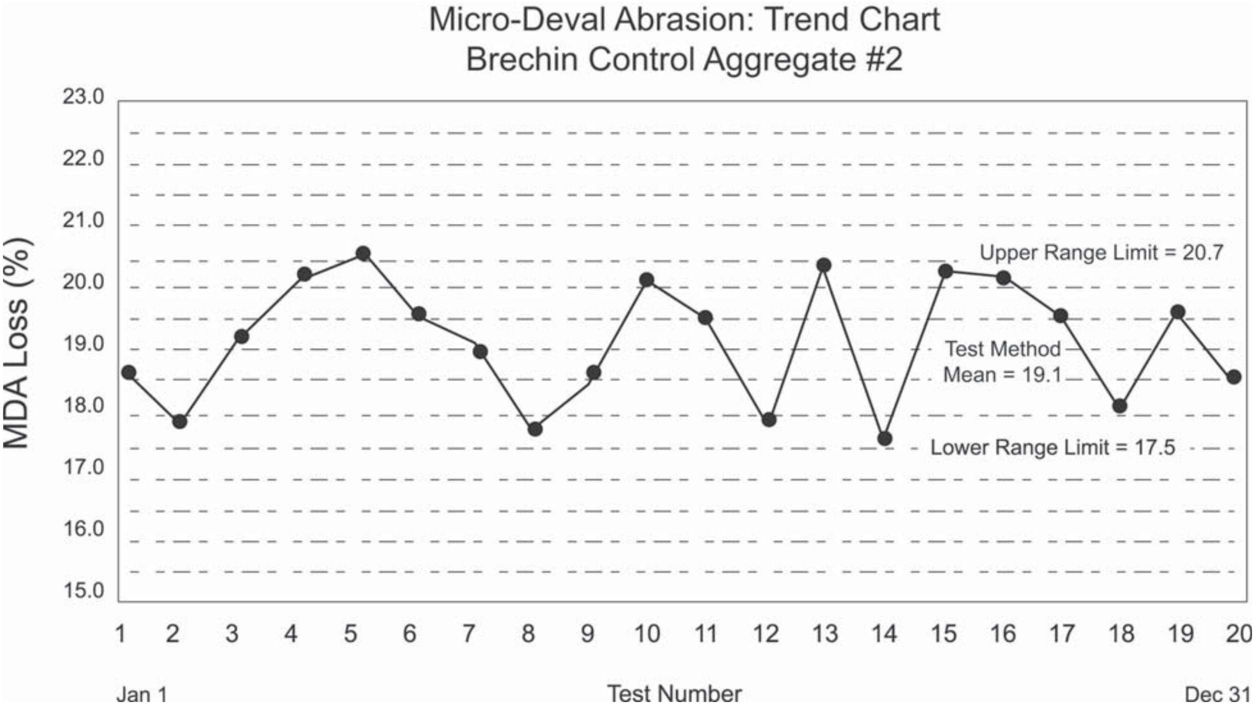


Figure 2—Micro-Deval Abrasion Trend Chart for Brechin Quarry No. 2 Aggregates Sample

12. REPORT

12.1. *The report shall include the following*:

12.1.1. The maximum size of the aggregate tested and the grading used;

12.1.2. The percent loss of the test sample to one decimal place;

12.1.3. The percent loss of the calibration aggregate, tested closest to the time at which the aggregate was tested, to the nearest 0.1 percent; and

12.1.4. The percent loss of the last 20 samples of calibration material on a trend chart.

13. PRECISION AND BIAS

13.1. *Precision*—The multilaboratory precision has been found to vary over the range of values obtained in this test. The figures given in Column 2 are the coefficients of variation that have been found to be appropriate for the materials described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests on the same sample expressed as a percent of their mean, 95 percent of the time.

Table 4—Multilaboratory Precision

Aggregate Abrasion Loss, Percent	Coefficient of Variation, Percent of Mean[a]	Acceptable Range of Two Results, Percent of Mean[a]
5	10.0	28
12	6.4	18
17	5.6	16
21	5.3	15

[a] These numbers represent, respectively, the (1s percent) and (d2s percent) limits as described in ASTM C 670.

13.2. *Bias*—The procedure in this test method for measuring resistance to abrasion has no bias because the resistance to abrasion can only be defined in terms of the test method.

14. KEYWORDS

14.1. Abrasion resistance; coarse aggregate; Micro-Deval.

APPENDIX

(Nonmandatory Information)

X1. INTERPRETATION OF TEST RESULTS

X1.1. In studies of the performance of aggregates in this test (Rogers 1998; Kandhal and Parker 1997), the limits in Table X1.1 have been found useful for separating aggregates of satisfactory performance from those of fair or poor performance.

Table X1.1—Limits of Satisfactory Performance of Aggregates

Application	Maximum Micro-Deval Abrasion Loss, %
Granular subbase	30[a]
Granular base	25[a]
Open graded base course	17[a]
Asphalt concrete base course and secondary surface course	21[a]
Asphalt concrete surface course	17[a] 18[b]

Standard Method of Test for

The Qualitative Detection of Harmful Clays of the Smectite Group in Aggregates Using Methylene Blue

AASHTO Designation: T 330-07[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

The Qualitative Detection of Harmful Clays of the Smectite Group in Aggregates Using Methylene Blue

AASHTO Designation: T 330-07[1]

1. SCOPE

1.1. The purpose of this standard is to identify the presence of harmful clays of the smectite group (poor minus 75-µm material) and to provide an indication of the surface activity of the aggregate.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 231, Weighing Devices Used in the Testing of Materials

3. SUMMARY OF TEST METHOD

3.1. Methylene Blue solution is titrated in increments into distilled water containing sample material passing the 75-µm (No. 200) sieve in increments. A small amount of water containing the sample material and titrated Methylene Blue is removed via a glass rod and dropped onto filter paper. When the clay fraction of the sample aggregate can no longer absorb more Methylene Blue, a blue ring is formed on the filter paper.

4. SIGNIFICANCE AND USE

4.1. The Methylene Blue Value determined by this standard can be used to estimate the amount of harmful clays and organic matter present in an aggregate. A high value for Methylene Blue Value indicates a large amount of clay or organic material present in the sample.

Note 1—Research (Aschenbrener, 1992) has developed the following relationship of methylene blue values and anticipated hot mix asphalt pavement performance as related to moisture susceptibility. (See Table 1.)

Table 1—Expected Performance of Methylene Blue

Methylene Blue (mg/g)	Expected Performance
≤6	Excellent
7–12	Marginally acceptable
13–19	Problems/possible failures
≥20	Failure

5. APPARATUS

5.1. Amber-colored burette of at least 50-mL capacity with 0.1-mL graduations.

5.2. Magnetic mixer with stir bar.

5.3. Balance complying with M 231, Class G1.

5.4. Glass rod of approximately 250-mm (10-in.) length and approximately 8-mm (0.3-in.) diameter.

5.5. Timer or stopwatch.

5.6. Pan and 75-µm (No. 200) sieve.

5.7. Volumetric flask of 1000-mL capacity.

5.8. Whatman No. 2 filter paper.

5.9. Three 500-mL griffin beakers.

5.10. Methylene Blue, reagent grade-dated and stored for no more than four months in a brown bottle wrapped with foil in a dark cabinet at lab temperature.

Note 2—One gram of Methylene Blue is dissolved in enough distilled water to produce 200 mL of solution, with each one mL of solution containing 5 mg of Methylene Blue.

5.11. Distilled water at lab temperature.

5.12. Oven capable of maintaining 110 ± 5°C (230 ± 9°F).

Note 3—For the purposes of this procedure, lab temperature is defined as 15–25°C (60–77°F).

6. SAMPLE PREPARATION

6.1. This test shall be performed on a sample of material passing the 75-µm (No. 200) sieve, taken from the washed portion of a representative sample of individual or combined material (as required). The material shall be washed through the 75-µm (No. 200) sieve and collected in a clean container. This container shall be large enough to hold several gallons of water and material passing the 75-µm (No. 200) sieve. Allow the material to settle and remove the excess water. The portion passing the 75-µm (No. 200) sieve is collected, transferred to a smaller container, and dried for testing. The collected material is mixed thoroughly prior to testing. The minimum oven-dry mass of the collected material shall be at least 30 g to ensure enough material for a possible retest.

7. PROCEDURE

7.1. Place 10.0 g (±0.05 g) of the minus 75-µm (No. 200) material that has been dried to constant mass in a 500-mL griffin beaker.

7.2. Add 30 mL of distilled water and stir with the mixer to make a slurry.

7.3. With the slurry still mixing, fill the burette with the Methylene Blue solution, add 0.5 mL of the solution to the slurry, and stir for 1 minute.

7.4. Remove a drop of the slurry, using the glass stirring rod, and place on the filter paper.

7.5. Observe the appearance of the drop on the filter paper. The end point is indicated by the formation of a light blue halo around the drop. Continue adding the Methylene Blue solution to the slurry in 0.5-mL increments with 1-minute stirring after each addition, then testing, until the end point is reached.

7.6. After the end point is reached, continue stirring for 5 minutes and retest.

Note 4—With experience, the person performing the test can reach the end point more quickly by skipping early increments.

8. CALCULATION

8.1. *Example*:

$$M = CV/W \qquad (1)$$

where:

M = Methylene Blue Value in mg of solution per g of the minus 75-µm (No. 200) material;

C = mg of Methylene Blue/mL of solution;

V = mL of Methylene Blue solution required for titration; and

W = grams of dry material.

8.2. The calculation may be simplified by inserting the mg of Methylene Blue per mL of solution and the grams of dry material.

$$M = (5 \times V)/10 \qquad (2)$$

$$M = 0.5V \qquad (3)$$

9. REPORT

9.1. *The report shall include the following*:

9.1.1. Type and source of the material tested; and

9.1.2. Methylene Blue value to the nearest 0.1 mg/g.

10. PRECISION AND BIAS

10.1. *Precision*—No precision has been established for this test.

10.2. *Bias*—No bias can be established because no reference material is available for this test.

11. KEYWORDS

11.1. Clay and organic material; fine aggregate; methylene blue; moisture susceptibility.

Standard Method of Test for

Determining the Percentage of Fracture in Coarse Aggregate

AASHTO Designation: T 335-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Percentage of Fracture in Coarse Aggregate

AASHTO Designation: T 335-09[1]

1. SCOPE

1.1. This test method covers the determination of the percentage, by mass, of a coarse aggregate sample that consists of fractured particles meeting specified requirements.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3. The text of the standard reference notes provides explanatory material. These notes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 248, Reducing Samples of Aggregate to Testing Size
- T 255, Total Evaporable Moisture Content of Aggregate by Drying

3. SUMMARY OF TEST METHOD

3.1. A sample of aggregate is separated using the designated size of screen conforming to the specification controlling the determination of coarse and fine aggregate. The coarse aggregate particles are visually evaluated to determine their conformance to the defined fracture. The percentage of conforming particles, by mass, is determined for comparison to standard specifications.

4. APPARATUS

4.1. *Balance*—Meeting the requirements of M 231 for general-purpose balance required for the principal sample mass being tested.

4.2. *Sieves*—Meeting the requirements of M 92.

4.3. *Splitter*—Meeting the requirements of T 248.

5. TERMINOLOGY

5.1. *fractured face*—an angular, rough, or broken surface of an aggregate particle created by crushing, or by other means. A face is considered a "fractured face" whenever one-half or more of the projected area, when viewed normal to that face, is fractured with sharp and well-defined edges (this excludes small nicks).

5.2. *fractured particle*—a particle of aggregate having at least the minimum number of fractured faces specified (usually one or two).

6. SAMPLING

6.1. Sample the aggregate in accordance with T 2 and reduce the sample in accordance with T 248.

7. SAMPLE PREPARATION

7.1. Where the specifications list only a total fracture percentage, the sample shall be prepared in accordance with Method 1. When the specifications require that the fracture be counted and reported on each sieve, the sample shall be prepared in accordance with Method 2.

7.2. *Method 1—Combined Fracture Determination*:

7.2.1. Dry the sample sufficiently to obtain a clean separation of fine and coarse material in the sieving operation. Sieve the sample in accordance with T 27 over the 4.75-mm (No. 4) sieve, or the appropriate sieve listed in the agency specifications for this material.

Note 1—Where necessary, wash the sample over the sieve or sieves designated for the determination of fractured particles to remove any remaining fine material and dry the sample to a constant mass in accordance with T 255.

7.2.2. Reduce the sample using a splitter in accordance with T 248 to the appropriate size for test. This size of test sample should be slightly larger in mass than that shown in Table 1 to account for additional loss of fines after washing.

Table 1—Sample Size (Method 1, Combined Sieve Fracture)

Nominal Maximum Particle Size	Minimum Sample Mass Retained 4.75-mm (No. 4) Sieve
37.5 mm ($1^1/_2$ in.)	2500 g (6 lb)
25.0 mm (1 in.)	1500 g (3.5 lb)
19.0 mm ($^3/_4$ in.)	1000 g (2.2 lb)
12.5 mm ($^1/_2$ in.)	700 g (1.5 lb)
9.5 mm ($^3/_8$ in.)	400 g (0.9 lb)
4.75 mm (No. 4)	200 g (0.5 lb)

7.3. *Method 2—Individual Sieve Fracture Determination*:

7.3.1. Dry the sample sufficiently to obtain a clean separation of fine and coarse material in the sieving operation. A washed sample from the gradation determination (T 11 and T 27) may be used. If not, sieve the sample in accordance with T 27 over the appropriate sieves listed in the specifications for this material. Select a representative portion from each sieve by splitting or quartering in accordance with T 248 to the appropriate size for testing. This size of test sample for each sieve should be at least as large as shown in Table 2.

Table 2—Sample Size (Method 2, Individual Sieve Fracture)

Nominal Maximum Particle Size	Minimum Sample Mass Retained 4.75-mm (No. 4) Sieve
31.5 mm ($1^1/_4$ in.)	1500 g (3.5 lb)
25.0 mm (1 in.)	1000 g (2.2 lb)
19.0 mm ($^3/_4$ in.)	700 g (1.5 lb)
16.0 mm ($^5/_8$ in.)	500 g (1.0 lb)
12.5 mm ($^1/_2$ in.)	300 g (0.7 lb)
9.5 mm ($^3/_8$ in.)	200 g (0.5 lb)
6.3 mm ($^1/_4$ in.)	100 g (0.2 lb)
4.75 mm (No. 4)	100 g (0.2 lb)
2.36 mm (No. 8)	25 g (0.1 lb)
2.00 mm (No. 10)	25 g (0.1 lb)

Note 2—Where necessary, wash the sample over the sieve or sieves designated for the determination of fractured particles to remove any remaining fine material and dry the sample to a constant mass in accordance with T 255.

Note 3—If fracture is determined on a sample obtained for gradation, use the mass retained on the individual sieves unless less than 5 percent of the total mass is retained on that sieve. In that case, place the material with that retained on the next smaller sieve size. If a smaller specification sieve does not exist, this material shall not be included in the fracture determination.

8. PROCEDURE

8.1. Spread the dried, cooled test sample on a clean flat surface large enough to permit careful inspection of each particle. To verify that a particle meets the fracture criteria, hold the aggregate particle so that the face is viewed directly. (See Section 5.1.)

8.2. To aid in making the fracture determination, separate the sample into three categories: (1) fractured particles meeting the above criteria, (2) particles not meeting specification criteria, and (3) questionable or borderline particles.

8.3. Determine the mass of particles in the fractured category, the mass of questionable particles, and the mass of the unfractured particles.

8.4. If on any of the determinations more than 15 percent of the total mass of the sample is placed in the questionable category, repeat the determination until no more than 15 percent is present in that category.

9. REPORT

9.1. *Report the following information*:

9.1.1. Calculate the mass percentage of fracture faces to the nearest 1 percent as follows:

$$P = [(F + Q/2)/(F + Q + N)] \times 100 \qquad (1)$$

where:

P = percentage of fracture,
F = mass of fractured particles,
Q = mass of questionable or borderline particles, and
N = mass of unfractured particles.

10. PRECISION AND BIAS

10.1. No precision data is available using this method.

Standard Method of Test for

Sampling Bituminous Materials

AASHTO Designation: T 40-02 (2006)
ASTM Designation: D 140-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling Bituminous Materials

AASHTO Designation: T 40-02 (2006)
ASTM Designation: D 140-01

AASHTO T 40-02 (2006) is identical to ASTM D 140-01 except for the following provisions:

1. Insert an additional sentence in Section 1.1 as follows:

   Samples may be taken from tanks, stockpiles, vehicles, or containers used for the storage or shipping of bituminous materials.
2. Section 5 is not included.
3. Replace Section 6.1.2 with the following:

   6.1.2 From bulk storage, 1 L (1 qt) for each sampling valve, or
4. Replace Sections 7.1.1, 7.1.2, and 7.1.3 with the following:

   7.1.1 Containers for liquid bituminous material samples, except emulsions, shall be double-seal friction-top cans, square cans with screw tops, or small-mouth cans with screw caps.

   7.1.2 Containers for anionic emulsified asphalt samples shall be wide-mouth jars or bottles made of glass or plastic.

   7.1.3 Containers for cationic emulsified asphalt samples shall be wide-mouth jars or bottles made of plastic or wide-mouth cans with screw caps.
5. Add a note at the end of Section 7.1 as follows:

   Note—Wide-mouth jars or bottles made of glass may be permitted if previous experience has shown them to be satisfactory.
6. Replace Section 8.5 with the following:

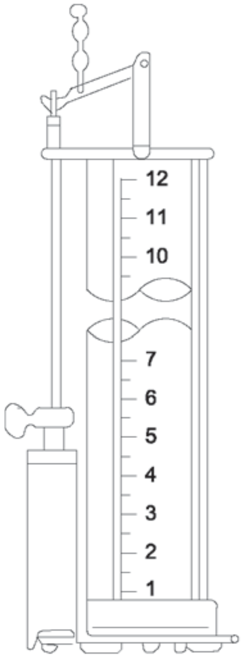
   8.5 Transferring samples from one container to another shall be avoided if possible, as the characteristics of the materials could be altered during transfer, and there is a possibility of contamination.
7. Replace Section 9.1 with the following:

   9.1 *Bulk Storage Tanks Not Equipped with Mechanical Agitators (Liquid Materials or Materials Made Liquid by Heating)*—Samples shall be obtained by one of the three following methods:
8. Replace Section 9.1.1 with the following:

   9.1.1 *Tank Tap Method*—Using valves or taps at the top, middle, and lower locations of the tank, draw a 1- to 4-L (1-qt to 1-gal) sample from each location after clearing the line by drawing and discarding a minimum of 4 L (1 gal) of the material.
9. Sections 9.1.1.1 and 9.1.1.2 are not included.

10. Replace Section 9.1.2 with the following:

    9.1.2 *Thief Sampler Method* (not suitable for asphalt cements)—Samples shall be taken at the top, middle, and lower levels of the tank by lowering a thief sampler into the material. A satisfactory type with instructions for use is shown in Figure 2.



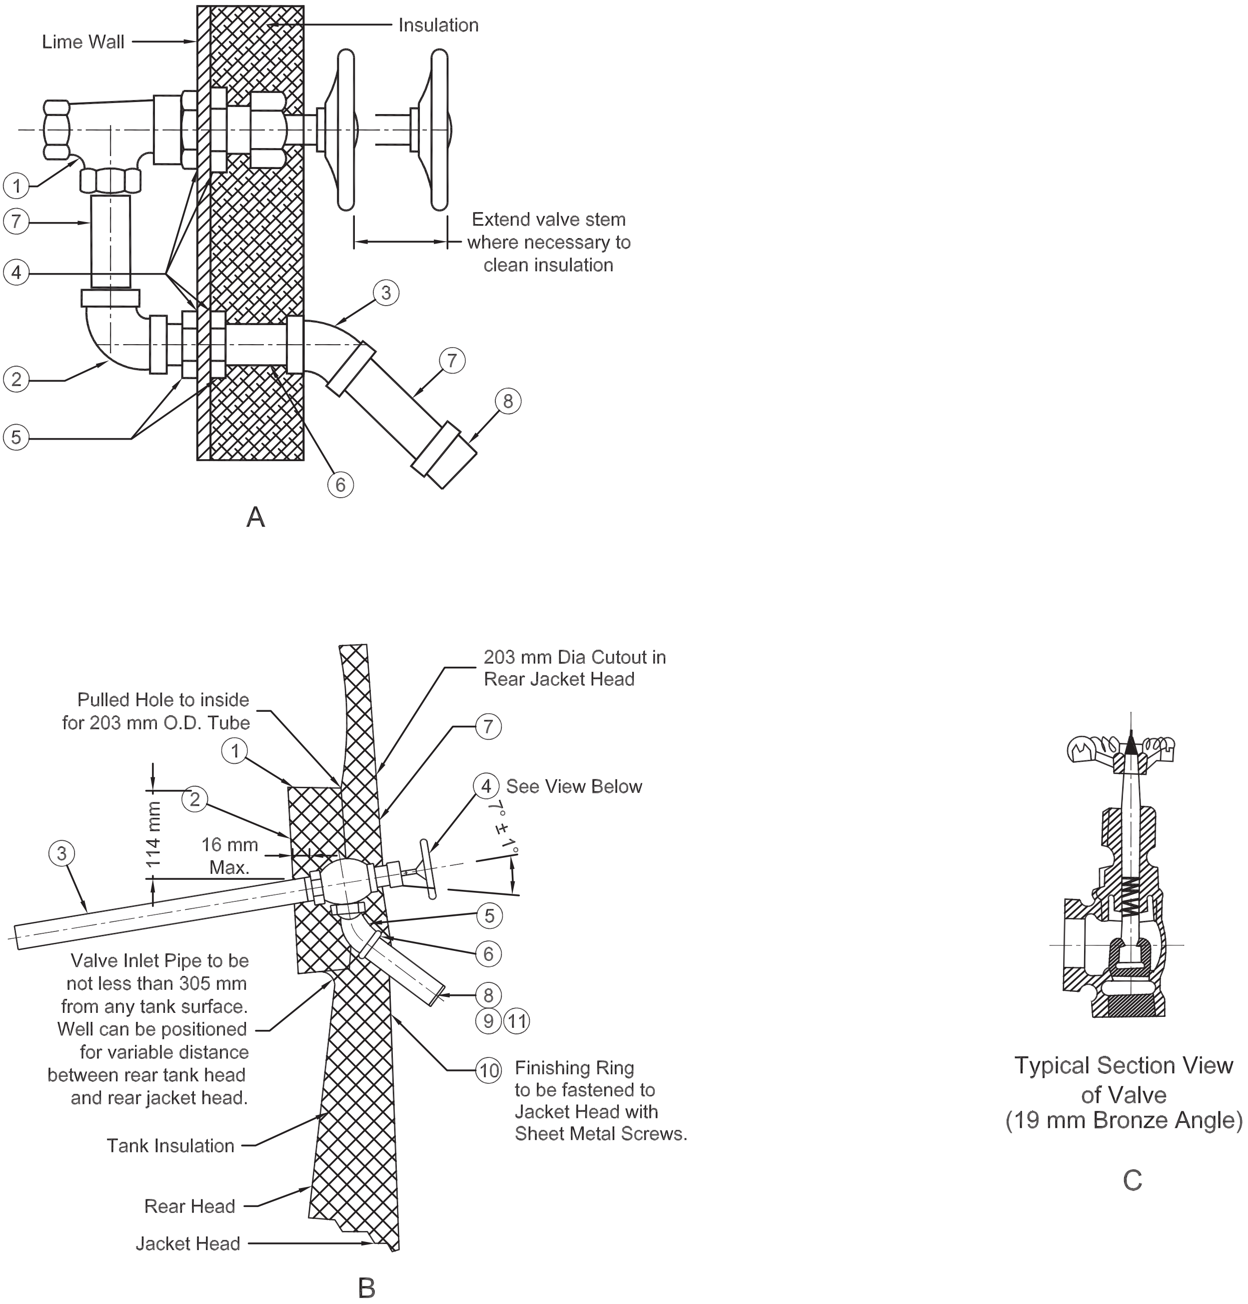
Note: This type of sampler is lowered into the tank with the bottom valve open (there is no top closure). When the desired depth is reached, the lowering chain is given a snap tug which closes the bottom valve. The sampler is then withdrawn from the tank and the contents transferred to the sample container. This sampler may be used for repetitive sampling in the same tank.

Figure 2—Thief Sampler

11. Note 3 contained in Section 9.1.2 is not included.
12. Replace Section 10.1 with the following:

    10.1 Each delivery vehicle or distributor shall be equipped with a sampling valve similar in design to those shown in Figure 1. It shall be installed at least 305 mm (1 ft) from the shell and clearly labeled as a “Sampling Valve.” Before the sample is taken from the sample valve, a minimum of 4 L (1 gal) shall be drawn from the sample valve and discarded.
13. Insert an additional section between Sections 10.1 and 10.2 as follows:

    When permitted by the purchaser, the following methods may be used to obtain representative samples.
14. Replace Figure 1 with the following figure:



Typical Section View of Valve (19 mm Bronze Angle)

Figure 1—Typical Submerged Asphalt Sampling Devices

Dimensional Equivalents

16 mm	19 mm	25 mm	76 mm	89 mm	102 mm	114 mm	203 mm	305 mm	330 mm

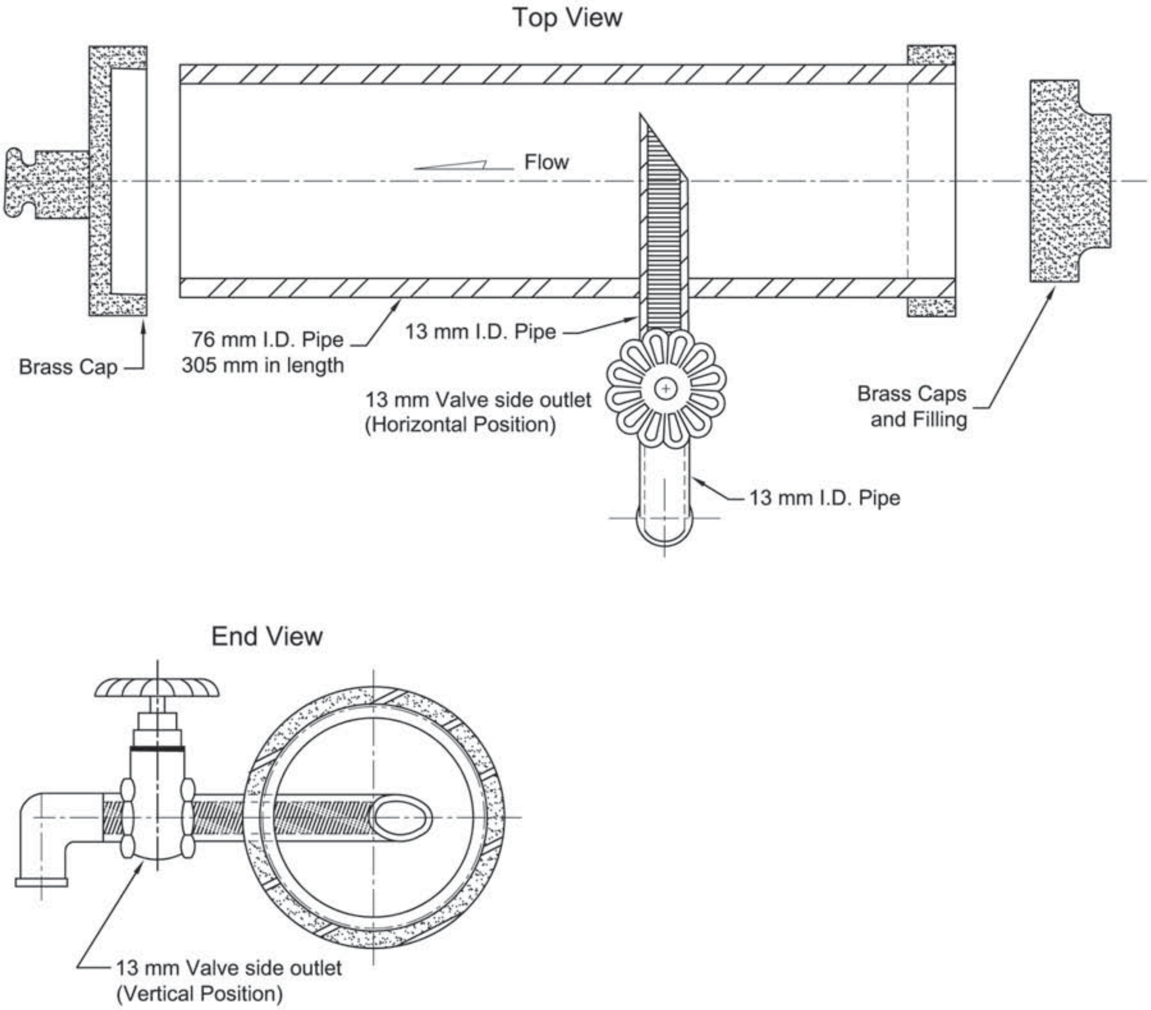
15. Replace Figure 5 with the following figure:



Dimensional Equivalents

13 mm	76 mm	305 mm
$^1/_2$ in.	3 in.	12 in.

Notes:
1. The outlet valve may be attached in either a horizontal or vertical position; the vertical position is preferred.
2. This device is to be furnished by the asphalt plant operator and should remain in the custody of the inspector until the completion of the job.
3. The device is to be inserted in the discharge line between the unloading pipe and the hose.
4. If the transport operator so elects, the 13-mm outlet assembly may be permanently attached to the outlet pipe, as near to the end as is practicable.
5. Drain off sufficient material through the spigot prior to taking a sample to ensure removal of any contaminants.
6. The sample should be taken after one-third and not more than two-thirds of the load has been removed. Take the sample slowly to ensure it is representative of the material being unloaded.

Figure 5—Typical Device for Sampling of Liquid Asphalt from Transports

Standard Method of Test for

Solubility of Bituminous Materials

AASHTO Designation: T 44-03 (2007)[1]
ASTM Designation: D 2042-01

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Solubility of Bituminous Materials

AASHTO Designation: T 44-03 (2007)[1]
ASTM Designation: D 2042-01

1. SCOPE

1.1. This method covers the determination of the degree of solubility in trichloroethylene or 1,1,1 trichloroethane of asphalt materials having little or no mineral matter. The portion that is soluble in trichloroethylene or 1,1,1 trichloroethane represents the active cementing constituents.

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests

3. SUMMARY OF METHOD

3.1. The sample is dissolved in trichloroethylene or 1,1,1 trichloroethane and filtered through a filter mat. The insoluble material is washed, dried, and weighed.

4. APPARATUS AND MATERIALS

4.1. The assembly of the filtering apparatus is illustrated in Figure 1. Details of the component parts are as follows:

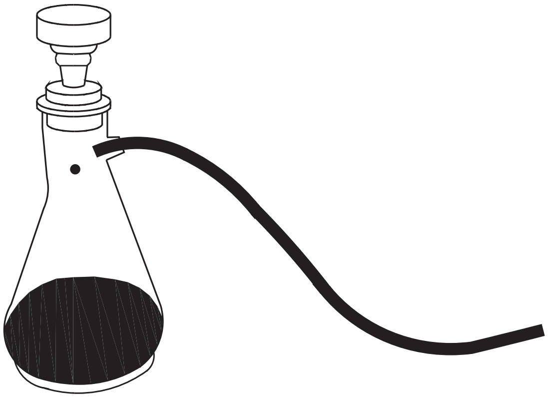


Figure 1—Filtering Apparatus Assembly

4.1.1. *Gooch Crucible*—glazed inside and outside with the exception of outside bottom surface. The approximate dimensions shall be a diameter of 44 mm at top, tapering to 36 mm at bottom, and a depth of 24 to 28 mm.

4.1.2. *Glass Fiber Pad*—32, 35, or 37 mm in diameter.[2]

4.1.3. *Filter Flask*—heavy-wall, with side tube, 250-mL capacity or larger.

4.1.4. *Filter Tube*—40 to 42 mm inside diameter.

4.1.5. *Rubber Tubing or Adapter*—for holding the Gooch crucible on the filter tube.

Note 1—Other suitable assemblies permitting vacuum filtration with a Gooch crucible may be used.

4.2. *Erlenmeyer Flask*—125 mL, or other suitable container.

4.3. *Oven*—capable of maintaining a temperature of 110 ± 5ºC (230 ± 9ºF).

4.4. *Desiccator*—of suitable size, charged with an effective desiccant.

4.5. *Analytical Balance*—Class A conforming to the requirements of AASHTO Specification M 231.

5. SOLVENT

5.1. Technical grade, Type I, tricholorethylene or technical grade 1,1,1 tricholorethane.

6. SAFETY PRECAUTIONS

6.1. Trichloroethylene and 1,1,1 trichloroethane are toxic materials and strict adherence to instructions in Material Safety Data Sheets are to be followed. *Caution*: Trichloroethylene and 1,1,1 trichloroethane in the presence of heat and moisture may form acids that are extremely corrosive.

7. PREPARATION OF GOOCH CRUCIBLE

7.1. Assemble the filtering apparatus as shown in Figure 1. Place filter pad into the Gooch crucible, moisten the pad with solvent, and seat firmly in the bottom of the crucible with light suction. Dry the crucible and contents at 110 ± 5ºC (230 ± 9ºF) for at least 20 minutes. Cool the crucible and contents in a desiccator for at least 20 minutes and determine the mass. Repeat this procedure until constant mass (±0.3 mg) is obtained. Store in a desiccator until ready for use.

8. SAMPLE PREPARATION

8.1. If the sample is not fluid, heat the sample with care to prevent local overheating until it has become sufficiently fluid to pour, occasionally stirring the sample to aid heat transfer and to assure uniformity. Avoid the entrapment of air.

9. PROCEDURE

9.1. Note safety precautions in Section 6. Transfer approximately 2 g of the sample into a tared 125-mL Erlenmeyer flask or other suitable container. Allow the container and its contents to cool to ambient temperatures and determine the mass to the nearest 1 mg. Add 100 mL of the trichloroethylene or 1,1,1 trichloroethane to the container, stopper flask and agitate as necessary until the sample is dissolved and no undissolved material adheres to the container. Check for undissolved material after a period of at least 15 minutes.

Normally the temperature at which this test is run is not critical, and it may be performed at the laboratory air temperature. For referee tests, however, the flask and sample in solution shall be placed in a water bath maintained at 37.8 ± 0.25ºC (100 ± 0.5ºF) for one hour before filtering.

9.2. Place the previously prepared and tared Gooch crucible in the filtering tube.

Wet the filter pad with a small portion of clean solvent and decant the solution through the filter pad of the crucible with light suction.

When the insoluble matter is appreciable, retain as much of it as possible in the container until the solution has drained through the filter pad. Wash the container with a small amount of solvent and, using a stream of solvent from a wash bottle, transfer all insoluble matter to the crucible. Use a "policeman" if necessary to remove any insoluble matter adhering to the container, rinse the policeman and the container, thoroughly wash the insoluble matter in the crucible with solvent until the filtrate is substantially colorless, then apply strong suction to remove the remaining solvent. Remove the crucible from the tube and wash the bottom free of any dissolved matter. Dry the crucible and contents at 110 ± 5ºC (230 ± 9ºF) for at least 20 minutes. Cool the crucible and contents in a desiccator for at least 20 minutes and determine the mass. Repeat this procedure until constant mass (±0.3 mg) is obtained.

Fiberglass filter pads should be used only one time.

10. CALCULATIONS AND REPORT

10.1. Calculate either the total percentage of insoluble matter or the percentage of the sample soluble in the solvent used as follows:

$$\text{Insoluble, percent} = \frac{C - A}{B} \times 100 \qquad (1)$$

$$\text{Soluble, percent} = \left(\frac{B - (C - A)}{B} \right) \times 100 \qquad (2)$$

where:

A = mass of crucible and filter;

B = total mass of sample; and

C = mass of crucible, filter, and insoluble material.

10.1.1. Report the percentage of insoluble material to the nearest 0.1 percent.

11. PRECISION

11.1. Estimates of standard deviations for this procedure and the criteria for judging the acceptability of results (95 percent confidence level) are indicated in Table 1.

Table 1—Standard Deviations

	Standard Deviations			
	Within-Laboratory Variability[a]		Between-Laboratory Variability[a]	
	Standard Deviation[b]	Repeatability[c]	Standard Deviation[b]	Reproducibility[d]
Asphalts solubility more than 99 percent (trichloroethylene or 1,1,1 trichloroethane)	0.035	0.10	0.090	0.26

[a] For definition of terms and recommended use of precision indexes, see the Recommended Practice for Use of the Terms Precision and Accuracy as Applied to Measurement of a Property of a Material (ASTM E 177).

[b] The standard deviations shown represent the estimated standard deviation of the measurement process for the stated conditions. They are calculated by multiplying the standard deviations of the applicable data by the factor:

$$1 + \frac{1}{4(N-1)}$$

where N is the number of tests in the set of data.

[c] Two results obtained by an operator on the same sample should be considered suspect if they differ by more than the stated amount. As defined in Recommended Practice E 177, this is the difference two-sigma limits for single-laboratory-operator-machine-multiday precision.

[d] Two results obtained by operators in different laboratories should be considered suspect if they differ by more than the stated amount. As defined in Recommended Practice E 177, this is the "difference two-sigma" limits for multilaboratory-operator-machine-day precision.

The estimates of standard deviation are based on the following:

	Asphalts
Materials	4
Replications	3
Solvents	4
Laboratories	26
Degrees of freedom:	
Within-laboratory variability	159
Between-laboratory variability	81
Standard deviation(s) of data:	
Within-laboratory variation	0.035
Between-laboratory variation	0.090

11.2. AASHTO Materials Reference Laboratory (AMRL) data for T 44 and ASTM D 2042 were analyzed in 2001. These data represent approximately 13,200 repetitions of the test conducted on 132 samples having solubility values between 99.5 percent and 100 percent. For samples within this range, the analysis suggests the following precision values are appropriate:

Multilaboratory Standard Deviation (1s) = 0.01 + (0.75 × % Insoluble)
Single-Operator Standard Deviation (1s) = 0.01 + (0.25 × % Insoluble)

---

[1] Similar, but not technically identical to ASTM D 2042-01.

[2] Whatman Grade 934 AH glass microfiber filter pad, available from Reeves Angel & Co., Clifton, NJ, has been found suitable.

Standard Method of Test for

Flash and Fire Points by Cleveland Open Cup

AASHTO Designation: T 48-06
ASTM Designation: D 92-05a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Flash and Fire Points by Cleveland Open Cup

AASHTO Designation: T 48-06
ASTM Designation: D 92-05a

AASHTO T 48-06 is identical to ASTM D 92-05a except for the following provisions:

1. All references to the ASTM standards listed in the following table shall be replaced with the corresponding AASHTO standard:

Referenced Standards

ASTM	AASHTO
D 93	T 73
D 140	T 40
D 1310	T 79

2. Add the following reference to Section 2.1:

   C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. Replace the dimensions in Figure 1 with the following:

	Millimeters		Inches	
	Min	Max	Min	Max
A—Diameter	3.8	5.4	0.15	0.21
C—Diameter	1.6	5.0	0.06	0.20
D	5.0		0.20	
E	6.4, approximately		0.25, approximately	

4. Replace the dimensions in Figure 2 with the following:

	Millimeters		Inches	
	Min	Max	Min	Max
A	6.4, nominal		0.25, nominal	
C	6.4, nominal		0.25, nominal	
D—Diameter	54.5	56.5	2.15	2.22
F—Diameter	150, nominal		6, nominal	

5. Replace the dimensions in Figure 3 with the dimensions below. Do not include a dimension "G" as shown in Figure 3. However, include a dimension for the thickness of the flange of the test cup that is not included in Figure 3. This dimension for the thickness of the flange shall be designated "K" with the dimensional requirements as in the following table:

	Millimeters		Inches	
	Min	Max	Min	Max
B	62.5	64.0	2.46	2.52
C	2.8	3.6	0.11	0.14
D—Radius	4, approximately		0.16, approximately	
H	2.8	3.6	0.11	0.14
J	97	101	3.8	4.0
K	1.8	3.4	0.07	0.13

6. Add the following sentence after the first sentence in Section 11.1.1:

   To aid in this operation, a Filling Level Gauge (A1.7) may be used.

7. Add an additional note that immediately follows Section 11.1.1 as follows:

   Note—The sample cup may be filled away from the apparatus provided the thermometer is preset with the cup in place and the sample level is correct at the beginning of the test. A shim 6.4-mm (0.25-in.) thick is useful in obtaining the correction distance from the bottom of the bulb to the bottom of the cup.

8. Replace the first sentence of Section 11.1.3 with the following:

   Light the test flame, and adjust it to a diameter of 3.8 to 5.4 mm (0.15 to 0.21 in.).

9. Replace Section 11.1.4 with the following:

   11.1.4 Apply heat initially at such a rate that the temperature indicated by the temperature-measuring device increases 10 to 20ºC (18 to 36ºF)/min. When the test specimen temperature is approximately 56ºC (100ºF) below the expected flash point, decrease the heat so that the rate of temperature rise during the last 28ºC (50ºF) before the flash point is 4 to 7ºC (7 to 13ºF)/min.

10. Replace the fourth sentence of Section 11.1.5 with the following:

    The center of the test flame must move in a horizontal plane not more than 2.5 mm (0.10 in.) above the plane of the upper edge of the cup and pass in one direction only.

11. Replace the last sentence of Section 11.1.9 with the following:

    Continue heating the test specimen at 4 to 7ºC (7 to 13ºF)/min and testing the material every 2ºC (5ºF) as described in Section 11.1.5 until the flash point is obtained.

12. Replace Section 14 with the following:

    14. **Precision and Bias**

    14.1 *Precision*—Criteria for judging the acceptability of test results for the flash point of asphalt binders obtained by this method are given in Table 1. Criteria for judging the acceptability of fire point test results can be found in ASTM D 92.

    14.1.1 *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results exceeds the values given in Table 1, Column 3.

    14.1.2 *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 1 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results exceeds the values given in Table 1, Column 3.

Table 1—Precision Estimates

Condition	Acceptable Standard Deviation (1s)[a]	Range of Two Results (d2s)[a]
Single-Operator Precision:		
Flash Point (°C)	3	8
Multilaboratory Precision:		
Flash Point (°C)	10	28

[a] These values represent the 1s and d2s limits described in ASTM Practice C 670.

Note: The precision estimates for Flash Point given in Table 1 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 98 to 148 laboratories for each of the eight pairs of samples. The analysis included four binder grades: PG 52-34, PG 64-16, PG 64-22, and PG 70-22. Average flash points ranged from 268.5 to 353.5°C. The details of the analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

14.2 *Bias*—The procedure of this test method has no bias because flash point and fire point can only be defined in terms of this test method.

13. Replace Section A1.3 with the following:

    A1.3 *Ignition Source Applicator*—The device for applying the test flame may be of any suitable design, but the tip shall be 1.6 to 5.0 mm (0.06 to 0.20 in.) in diameter at the end and the orifice shall have an approximate diameter of 0.8 mm (0.031 in.). The device for applying the test flame shall be so mounted to permit automatic duplication of the sweep of the test flame, the radius of swing being not less than 150 mm (6 in.) and the center of the orifice moving in a plane not more than 2.5 mm (0.10 in.) above the cup. A bead having a diameter of 3.8 to 5.4 mm (0.15 to 0.21 in.) shall be mounted in a convenient position on the apparatus so the size of the test flame can be compared to it.

14. Add an additional Section A1.7 after Section A1.6 as follows:

    A1.7 *Filling Level Gauge*—A device to aid in the proper adjustment of the sample level in the cup. It may be made of suitable metal with at least one projection, but preferably two for adjusting the sample level in the test cup to 9 to 10 mm (0.35 to 0.39 in.) below the top edge of the cup. A hole 0.8 mm (0.031 in.) in diameter, the center of which is located not more than 2.5 mm (0.10 in.) above the bottom edge of the gauge, shall be provided for use in checking the center position of the orifice of the test flame applicator with respect to the rim of the cup. (Figure 4 shows a suitable version.)

15. Add a Figure 4 after Section A1.7.

	Millimeters	Inches	
A	100	4	Nominal
B	20	¾	Nominal
C	3.2	⅛	Nominal
D	30	1¼	Nominal
E	9–10	0.35–0.39	
F	0.8 Dia (2.5 mm above bottom edge)	1/32 Dia (0.10 in. above bottom edge)	Nominal Maximum
G	10	⅜	Nominal

Figure 4—Filling Level Gauge

Standard Method of Test for

Penetration of Bituminous Materials

AASHTO Designation: T 49-07
ASTM Designation: D 5-06$^{\in 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Penetration of Bituminous Materials

AASHTO Designation: T 49-07
ASTM Designation: D 5-06$^{\epsilon 1}$

AASHTO T 49-07 is identical to ASTM D 5-06$^{\epsilon 1}$ except for the following provisions:

1. Replace all references to ASTM D 36 with AASHTO T 53.
2. Add the following to Section 2:
   2.4 *AASHTO Standard*:
   R 16, Regulatory Information for Chemicals Used in AASHTO Tests
3. Replace the last sentence of Section 6.1 with the following:
   The weight of the spindle shall be checked.

Standard Method of Test for

Float Test for Bituminous Materials

AASHTO Designation: T 50-09
ASTM Designation: D 139-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Float Test for Bituminous Materials

AASHTO Designation: T 50-09
ASTM Designation: D 139-07

AASHTO T 50-09 is identical to ASTM D 139-07 except as follows:

1. Insert a new section immediately before Section 2.1 to contain the following:

   All references to the ASTM standards listed in the following table shall be replaced with the corresponding AASHTO standard.

Referenced Standards

ASTM	AASHTO
D 244	T 59
D 6997	T 59

2. Add two new sentences at the end of Section 7.3 to contain the following:

   "The residue may also be poured from the still directly into a tin or small container which shall be maintained at the proper temperature for pouring. The temperature of the residue shall be verified during pouring by inserting the 30 AWG gauge thermocouple probe into the residue while it is poured out of the container into the collar."

Standard Method of Test for

Ductility of Asphalt Materials

AASHTO Designation: T 51-09
ASTM Designation: D 113-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Ductility of Asphalt Materials

AASHTO Designation: T 51-09

ASTM Designation: D 113-07

AASHTO T 51-09 is identical to ASTM D 113-07 except for the following provisions:

1. Replace all references to the ASTM standards listed in the following table with the corresponding AASHTO standard:

Referenced Standards

ASTM	AASHTO
D 5	T 49
D 1754	T 179
D 2872	T 240
E 11	M 92

2. Add the following sentences to Section 4.2:

   The volume of water shall be not less than 10 L. The depth of water shall not be less than 50 mm and such that the mold can be immersed to a depth of 25 mm. The water in the bath shall be substantially free from oil and slime or other organic growth.

3. Add the following sentence to Section 4.4:

   If a thermometer conforming to ASTM E 1 is used, calibrate the thermometer according to ASTM E 77.

4. Replace 4.5 with the following:

   4.5 *Release Agent* —Mixtures of glycerin and dextrin or talc (3 g of glycerin to about 5 g of dextrin or talc has been used satisfactorily), Dow-Corning Silicone Stop-Cock Grease, or a mixture of castor oil and Versamid 900 [100:1 mixture by weight heated to 204 to 232ºC (400 to 450ºF) and stirred until homogeneous] have been proven suitable. Other release agents may be used provided results obtained are comparable to those obtained when using one of the above.

5. Delete Note 2, which recommends sieving some samples.

Standard Method of Test for

Softening Point of Bitumen (Ring-and-Ball Apparatus)

AASHTO Designation: T 53-09
ASTM Designation: D 36-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Softening Point of Bitumen (Ring-and-Ball Apparatus)

AASHTO Designation: T 53-09
ASTM Designation: D 36-06

AASHTO T 53-09 is identical to ASTM D 36-06 except for the following provisions:

1. Replace all references to the ASTM standards listed in the following table with the corresponding AASHTO standard:

Referenced Standards

ASTM	AASHTO
D 92	T 48
D 140	T 40

2. Replace Section 5.2 with the following:

   Pouring Plate—A flat, smooth brass plate.

3. Add an additional subsection to Section 5.7 that reads as follows:

   An ASTM Wide Range Softening Point Thermometer, having a range from –1 to +175°C or 30 to 350°F and conforming to the requirements for Thermometer 113C or 113F as prescribed in ASTM E 1. As an alternative, other thermometric devices may be used provided they: (1) have a maximum scale error no greater than that of the thermometer specified in ASTM E 1, and (2) are capable of indicating temperature within 0.5°C (1.0°F).

4. Replace the last sentence of Section 5.7.1 with the following:

   As an alternative, other thermometric devices may be used provided they: (1) have a maximum scale error no greater than that of the thermometer specified in ASTM E 1, and (2) are capable of indicating temperature within 0.2°C (0.5°F).

5. Replace the last sentence of Section 5.7.2 with the following:

   As an alternative, other thermometric devices may be used provided they: (1) have a maximum scale error no greater than that of the thermometer specified in ASTM E 1, and (2) are capable of indicating temperature within 0.5°C (1.0°F).

6. Delete the final two sentences of Section 5.7.3.
7. Replace Figure 1 with the figure on the next page.
8. Replace the first sentence of Section 6.1.3 with the following:

   Ethylene Glycol, with a boiling point between 193 and 204°C (379 and 399°F).

9. Replace the first sentence of Section 9.1.1 with the following:

   Freshly boiled distilled water for softening points between 30 and 80°C (86 and 176°F); use Thermometer 15C or 15F or an alternative thermometric device as specified in Section 5.7.1.

10. Replace the first sentence of Section 9.1.2 with the following:

    USP glycerin for softening points above 80°C (176°F) and up to 157°C (315°F); use Thermometer 16C or 16F or an alternative thermometric device as specified in Section 5.7.2.

11. Replace the first sentence of Section 9.1.3 with the following:

    Ethylene glycol for softening points between 30 and 110°C (86 and 230°F); use Thermometer 113C or 113F, or an alternative thermometric device as specified in Section 5.7.2.

12. Replace Section 11.1 with the following:

    When using Thermometer 15C or 15F, or an alternative thermometric device as specified in Section 5.7.1, report the mean or corrected mean of the temperatures recorded in Section 9.6 to the nearest 0.2°C (0.5°F) as the softening point.

13. Replace Section 11.2 with the following:

    When using Thermometer 16C, 16F, 113C, or 113F, or an alternative thermometric device as specified in Section 5.7.2, report the mean or corrected mean of the temperatures recorded in Section 9.6 to the nearest 0.5°C (1.0°F) as the softening point.

Standard Method of Test for

Water in Petroleum Products and Bituminous Materials by Distillation

AASHTO Designation: T 55-02 (2006)
ASTM Designation: D 95-05$^{\epsilon 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Water in Petroleum Products and Bituminous Materials by Distillation

AASHTO Designation: T 55-02 (2006)

ASTM Designation: D 95-05$^{\in 1}$

AASHTO T 55-02 (2006) is identical to ASTM D 95-05$^{\in 1}$ except that all references to the ASTM standards contained in ASTM D 95-05$^{\in 1}$, listed in the following table, shall be replaced with the corresponding AASHTO standard:

Standard Method of Test for
Emulsified Asphalts

AASHTO Designation: T 59-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Emulsified Asphalts

AASHTO Designation: T 59-09

1. SCOPE

1.1 These test methods, given under the headings titled Composition, Consistency, Stability, Examination of Residue, Identification Tests, Coating Tests on Emulsified Asphalts, and Density of Emulsified Asphalts, cover the examination of Emulsified Asphalt composed principally of a semisolid or liquid asphalt base, water, and an emulsifying agent. The methods cover the following tests:

Test	Section(s)
Composition:	
Water Content	4
Residue and Oil Distillate by Distillation	5
Emulsified Asphalt Residue by Evaporation	6
Particle Charge of Cationic Emulsified Asphalts	7
Consistency:	
Viscosity (Saybolt Furol)	8
Stability:	
Demulsibility	9
Settlement	10
Cement Mixing	11
Sieve Test	12
Coating Test	13
Miscibility with Water	14
Freezing Test	15
Coating Ability and Water Resistance	16
Storage Stability of Emulsified Asphalt	17
Examination of Residue	18 to 25
Identification Tests:	
Identification Test for Cationic Rapid-Setting (CRS) Emulsified Asphalts	26
Identification Test for Cationic Slow-Setting (CSS) Emulsified Asphalts	27
Coating Tests on Emulsified Asphalts:	
Field Coating Test	28
Emulsified Asphalt/Job Aggregate Coating Test	29
Density of Emulsified Asphalts:	
Test to Determine Mass per Liter (Gallon)	30

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. SAMPLE CONDITIONING FOR TESTING

3.1 All emulsified asphalt with viscosity requirements of 50°C (122°F) should be heated to 50 ± 3°C (122 ± 5°F) in the original sample container in a 71°C (160°F) water bath or oven. The container should be vented to relieve pressure. After the sample reaches 50 ± 3°C (122 ± 5°F), stir the sample to achieve homogeneity.

COMPOSITION

4. WATER CONTENT

4.1 *Scope*:

4.1.1 This test method covers the procedure for determining the water content of emulsified asphalt by reflux distillation using a water trap.

4.2 *Significance and Use*:

4.2.1 This test method measures the amount of water present in the emulsified asphalt, as distinguished from either asphalt material or petroleum solvent.

4.3 *Apparatus and Materials*:

4.3.1 *Metal Distillation Pot*—The metal distillation pot [Figure 1(a)] shall be a vertical cylindrical vessel, preferably made of copper, having a faced flange at the top to which the head is tightly attached by means of a clamp. The head shall be made of metal, preferably brass or copper, and shall be provided with a tubulation 25.4 mm (1 in.) in inside diameter.

4.3.2 *Glass Distillation Pot*—The glass distillation pot [Figure 1(b)] shall be a short-neck, round-bottom flask, made of well-annealed glass, and having an approximate capacity of 500 mL.

4.3.3 *Heat Source*—The heat source used with the metal distillation pot shall be a ring gas burner of 100-mm (4-in.) inside diameter or an electric mantle heater. The heat source for the glass distillation pot shall be either an ordinary gas burner or electric heater.

4.3.4 *Condenser*—The condenser shall be a water-cooled, reflux glass-tube type, having a jacket not less than 400 mm ($15^3/_4$ in.) in length, with an inner tube 9.5 to 12.7 mm ($^3/_8$ to $^1/_2$ in.) in outside diameter. The end of the condenser shall be ground to an angle of 30 ± 5° from the vertical axis of the condenser.

4.3.5 *Trap*—The trap shall be made of annealed glass constructed in accordance with Figure 1(c) and graduated in 0.10-mL divisions from 0 to 2 mL and in 0.20-mL divisions from 2 to 25 mL.

4.3.6 *Solvent*—Xylol or other petroleum distillate conforming to the following distillation requirements: 98 percent distills between 120 and 250°C (248 and 482°F). This distillation shall be conducted in accordance with ASTM D 86.

4.3.7 *Balance*—Conforming to the requirements of M 231, Class G 2.

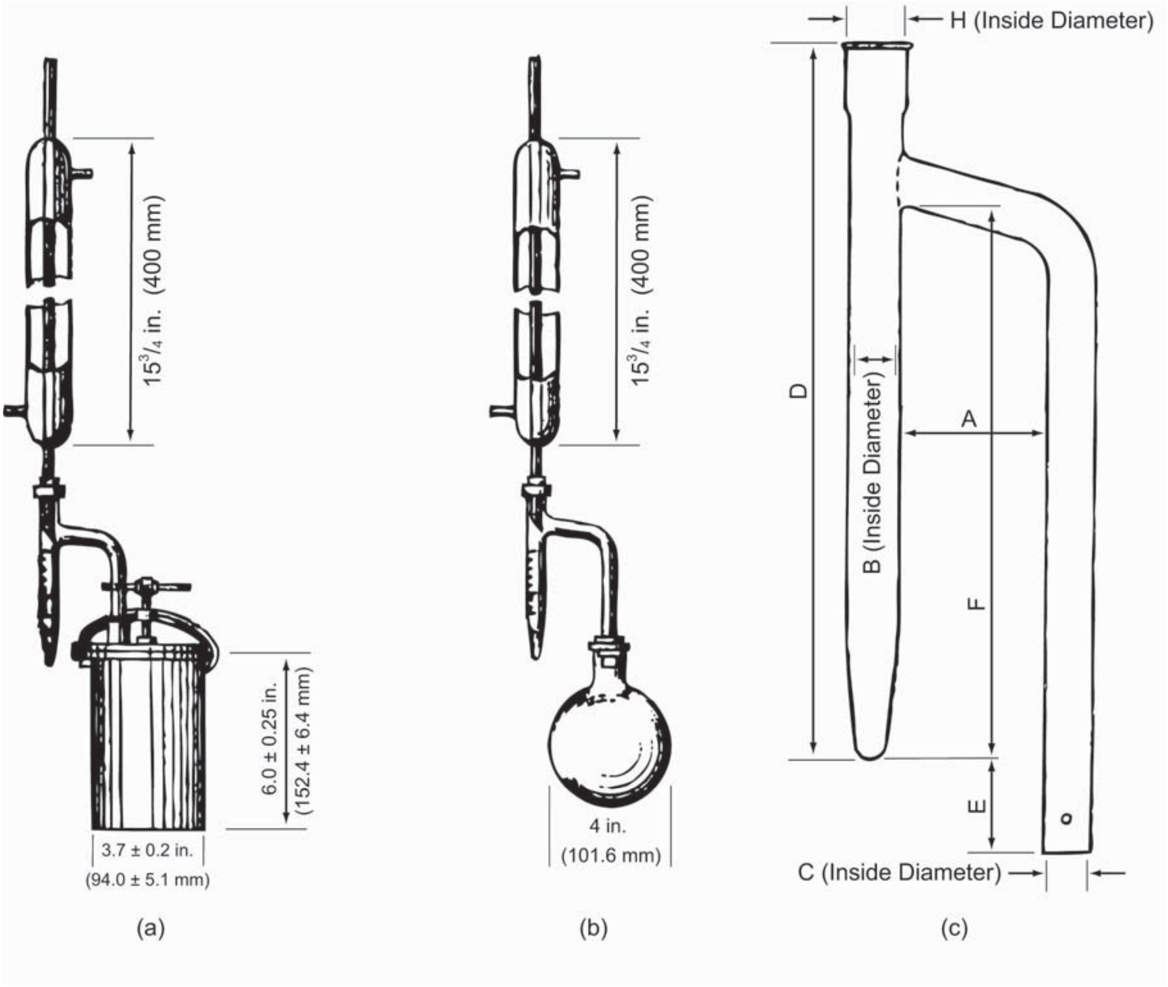
4.4 *Sample*:

4.4.1 Obtain a representative sample of the material as specified in T 40.

Note 1—The difficulties in obtaining representative samples for this determination are unusually great, so the importance of proper sampling cannot be too strongly emphasized.

4.5 *Procedure*:

4.5.1 When the material to be tested contains 25 percent or less water, place 100 ± 0.1 g of the sample in the distillation pot. When the material contains more than 25 percent water, use a 50 ± 0.1-g sample. Thoroughly mix the sample to be tested with 200 mL of solvent by swirling, taking proper care to avoid any loss of material.



Metric Equivalents

A = 45 to 55 mm (1.8 to 2.2 in.)
B = 14 to 16 mm (0.55 to 0.62 in.)
C = 12 to 16 mm (0.47 to 0.62 in.)
D = 235 to 255 mm (9.3 to 10.0 in.)
E = 25 to 38 mm (1.0 to 1.5 in.)
F = 186 to 194 mm (7.3 to 7.6 in.)
H = 18 to 19 mm (0.71 to 0.75 in.)

Figure 1—Apparatus for Determining Water Content

4.5.2 Connect the distillation pot, trap, and condenser by means of tight-fitting corks as shown in Figure 1(a) or 1(b). Adjust the end of the condenser in the trap to a position which will allow the end to be submerged to a depth of not more than 1 mm (0.04 in.) below the surface of the liquid in the trap after distillation conditions have been established. When using the metal distillation pot, insert a heavy paper gasket, moistened with the solvent, between the lid and flange before attaching the clamp. Insert a loose cotton plug in the top of the condenser tube to prevent condensation of atmospheric moisture.

4.5.3 When the ring burner is used with the metal distillation pot, place it about 75 mm (3 in.) above the bottom of the distillation pot at the beginning of the distillation, and gradually lower it as the distillation proceeds. Regulate the heat so that the condensate falls from the end of the condenser at a rate of 2 to 5 drops per second. Continue the distillation at the specified rate until no water is visible on any part of the apparatus and a constant volume of water is obtained in the trap (V_{wt}).

Remove any persistent ring of condensed water in the condenser tube by increasing the rate of distillation for a few minutes.

4.6 *Calculation and Report*:

4.6.1 Calculate the water content as follows:

$$\text{Water Content, \%} = (V_{wt}/M_s) \times 100 \qquad (1)$$

where:

V_{wt} = volume of water in the trap, mL; and

M_s = original mass of the sample, g.

4.6.2 Report the result as "water mass percent."

4.7 *Precision and Bias*:

4.7.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

4.7.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Water Content, mass %	Repeatability, mass %
30 to 50	0.8

4.7.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Water Content, mass %	Reproducibility, mass %
30 to 50	2.0

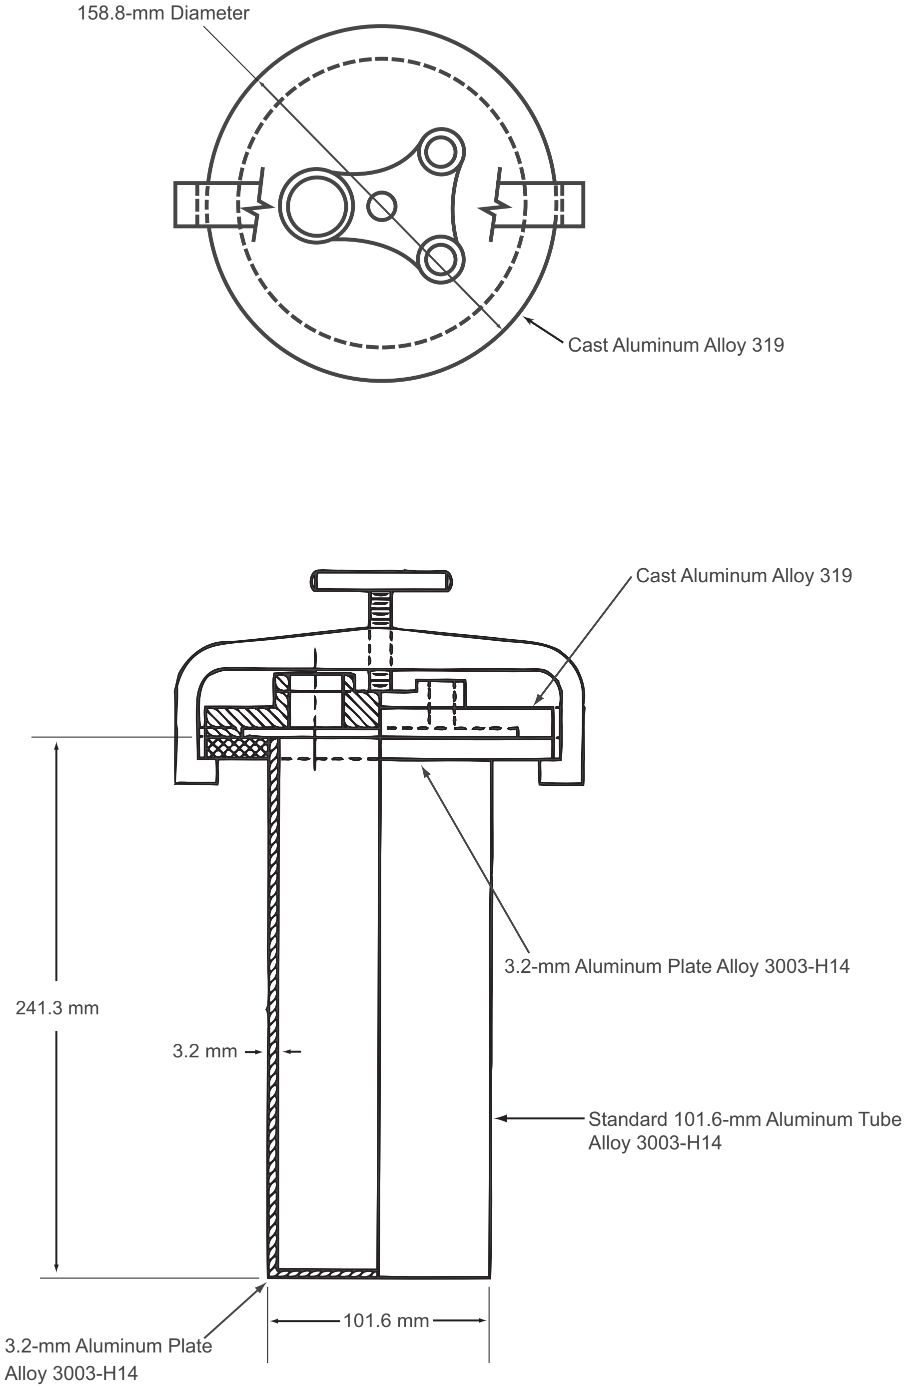
5. RESIDUE AND OIL DISTILLATE BY DISTILLATION

5.1 *Scope*:

5.1.1 This test method covers the quantitative determination of residue and oil distillate in emulsified asphalt composed principally of a semisolid or liquid asphalt base, water, and an emulsifying agent.

5.2 *Significance and Use*:

5.2.1 This test method can be used for quantitative determination of residue and oil distillate in emulsified asphalt for specification acceptance, service evaluation, control, and research. This method can also be used to obtain residue and oil distillate for further testing.



Metric Equivalents	
in.	mm
$^1/_8$	3.2
4	101.6
$6^1/_4$	158.8
$9^1/_2$	241.3

NOTE—The distillation pot cover may be machined from Rolled Aluminum Plate Alloy 3003-H14.

Figure 2—Example of an Aluminum-Alloy Distillation Pot

5.3 *Apparatus*:

5.3.1 *Aluminum-Alloy Distillation Pot*[1]*and Heat Source*—Approximately 240 mm ($9^1/_2$ in.) in height by 95 mm ($3^3/_4$ in.) in inside diameter (Figure 2) with one 121-mm ($4^3/_4$ -in.) inside diameter ring burner,[2] having holes on the inner periphery and having three spacers to ensure centering of the burner around the distillation pot (Figure 3).

Note 2—Residue by distillation results obtained with iron stills in accordance with T 59-65 are acceptable. Similarly, results obtained with a 127-mm (5-in.) ring burner as in subsequent issues of T 59 are acceptable.

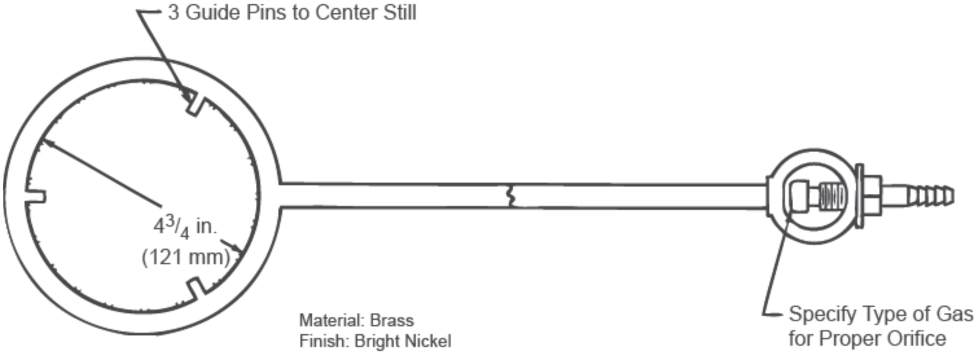


Figure 3—Ring Burner with 121-mm ($4^3/_4$-in.) Inside Diameter

5.3.2 *Connection Apparatus*—Consisting of a glass connecting tube, tin shield, and water-cooled glass condenser of the West or Leibig type with a borosilicate glass or metal jacket and a suitable adapter between the condenser and a 100-mL graduated cylinder, all with dimensions as shown in Figure 4.

5.3.3 *Graduated Cylinder*—100-mL capacity with graduation intervals of 1.0 mL.

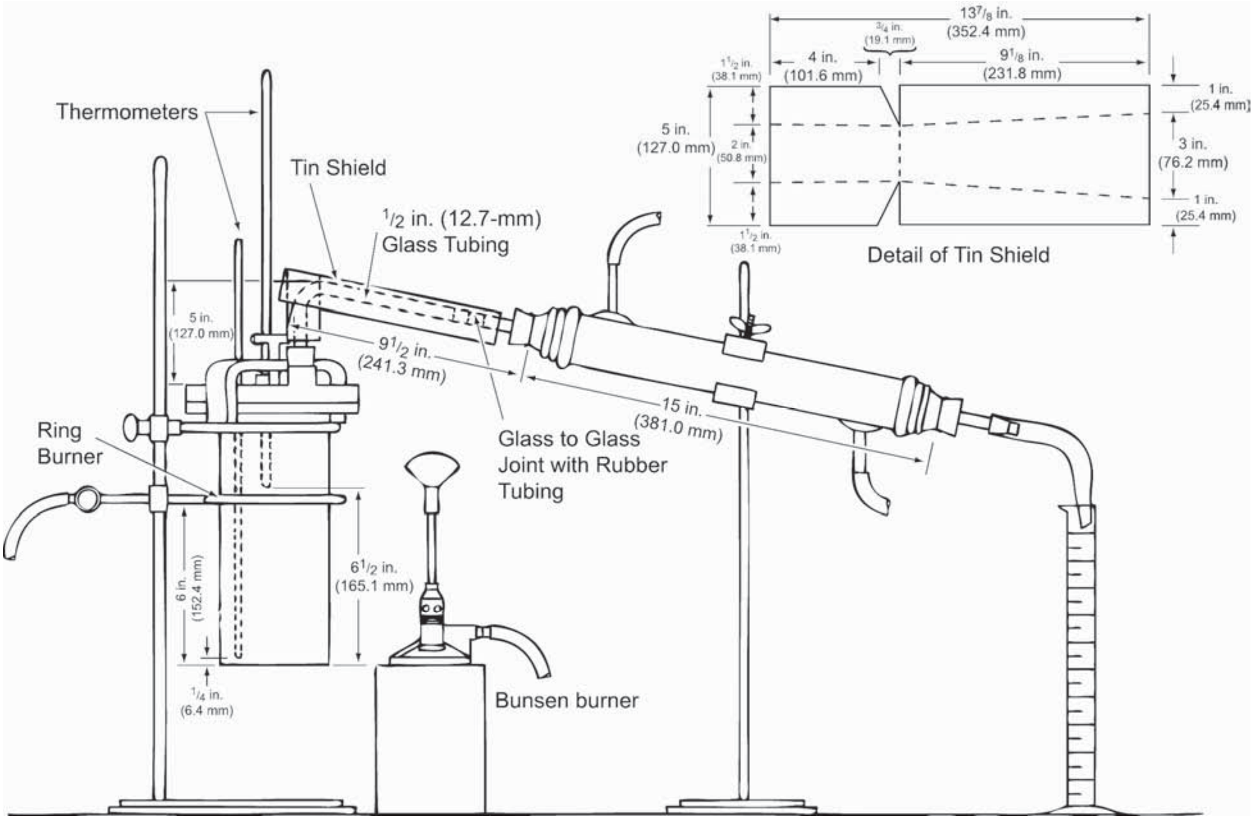
5.3.4 *Thermometers*—Two ASTM Low-Distillation Thermometers, graduated either in Celsius or Fahrenheit degrees as specified, having a range from –2 to +300°C or 30 to 580°F, respectively, and conforming to the requirements for Thermometer 7C or 7F as prescribed in ASTM E 1.

Note 3—For details of the assembly of the apparatus for the distillation test, see Figure 4.

5.3.5 *Balance*—Conforming to the requirements of M 231, Class G 2.

5.3.6 *Sieve*—A 0.300-mm (No. 50) sieve conforming to M 92.

5.3.7 *Bunsen Burner.*



Metric Equivalents															
mm	6.5	13	19	25	38	51	76	102	127	152	165	232	241	352	381
in.	$^1/_4$	$^1/_2$	$^3/_4$	1	$1^1/_2$	2	3	4	5	6	$6^1/_2$	$9^1/_8$	$9^1/_2$	$13^7/_8$	15

Figure 4—Apparatus Assembly for Distillation Test of Emulsified Asphalt

5.4 *Procedure*:

5.4.1 Determine the mass of the aluminum-alloy distillation pot (including the lid, clamp, cork, thermometers, and gaskets, if a gasket is used.) Pour 200 ± 0.1 g of a representative sample of the emulsified asphalt into the distillation pot.

5.4.2 Use a gasket of oiled paper between the distillation pot and its cover, or grind the joint to a tight fit. Securely clamp the cover on the distillation pot.

5.4.3 Insert a thermometer through a cork, in each of the small holes provided in the cover. Adjust these thermometers so that the end of the bulb of one is approximately 6 mm ($^1/_4$ in.) from the bottom of the distillation pot and the bulb of the other is approximately 165 mm ($6^1/_2$ in.) from the bottom of the distillation pot.

5.4.4 Place the ring burner around the distillation pot about 150 mm (6 in.) from the bottom of the distillation pot. Apply heat by lighting this burner and adjusting it to a low flame. Also apply just enough heat from a burner to the connecting tube to prevent condensation of water in this tube.

5.4.5 Move the ring burner approximately level with the bottom of the distillation pot when the temperature on the lower thermometer is approximately 215°C (420°F). Increase the temperature to 260 ± 5°C (500 ± 10°F), as read on the lower thermometer, maintaining it at this temperature for 15 minutes. Complete the total distillation in 60 ± 15 minutes from the first application of heat.

Note 4—The location of the burner at the start of the test is flexible. It may be raised to decrease the chance of "foam-over" or lowered to the middle of the distillation pot for emulsified asphalt containing no solvent. A sudden change in the temperature reading of the upper thermometer indicates foam on the bulb. Remove heat until the foaming ceases. (The ring burner may be gradually lowered as the distillation proceeds to ensure that the time requirements of this test are satisfied.)

5.4.6 Immediately at the expiration of the heating period, determine the mass of the distillation pot and accessories again as described in Section 5.4.1. Calculate and report the percentage of residue by distillation according to Equation 2. Record the volume of oil distillate to the nearest $^1/_2$ mL (V_{od}). Calculate and report the oil distillate as a volume percentage of the total emulsified asphalt according to Equation 3. Save this oil distillate if identification is desired.

Note 5—The mass of the aluminum-alloy distillation pot at room temperature (Section 5.4.1) is 1.5 g higher than at 260°C (500°F). Correct for this error by adding 1.5 g to the gross mass obtained in Section 5.4.6 prior to calculating the percentage of residue by distillation (M_{pr} as provided in Equation 2.)

5.4.7 Remove the cover from the distillation pot; stir, and immediately pour appropriate portions of the residue into a 236-mL (8-oz) tin or other suitable molds and containers for performing the required tests. Handle or condition molds and containers for the desired examination of the residue as described in Sections 20 to 25, and proceed as required by the appropriate method from the points that follow the pouring stage. If there is foreign matter in the residue, the material shall be poured through a 300-µm (No. 50) sieve prior to pouring it into the test molds and containers.

5.5 *Calculation and Report*:

5.5.1 Calculate the percentage of residue in the sample as follows:

$$P_{or} = (M_{pr} - M_p)/2 \qquad (2)$$

where:

P_{or} = percentage of oil residue;

M_{pr} = mass of the distillation pot, accessories, and residue after the test (+ 1.5 g), g; and

M_p = mass of the distillation pot and accessories before the test, g.

5.5.2 Calculate the percentage of oil distillate as follows:

$$P_{od} = V_{od}/2 \qquad (3)$$

where:

P_{od} = percentage of oil distillate (by volume of emulsified asphalt); and

V_{od} = volume of oil distillate, to the nearest 0.5 mL.

5.5.3 Report both the percentage of asphalt residue and percentage of asphalt distillate to the nearest 0.1 percent.

5.6 *Precision and Bias*:

5.6.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

5.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Residue by Distillation, mass %	Repeatability, mass %
50 to 70	1.0

5.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Residue by Distillation, mass %	Reproducibility, mass %
50 to 70	2.0

6. EMULSIFIED ASPHALT RESIDUE BY EVAPORATION

6.1 *Scope*:

6.1.1 This test method covers the quantitative determination of emulsified asphalt residue in emulsified asphalt composed principally of a semisolid or liquid asphalt base, water, and an emulsifying agent.

6.2 *Significance and Use*:

6.2.1 The test may be used to indicate compositional characteristics of emulsified asphalt. Evaporation residue may also be subjected to other characterization tests outlined under the "examination of residue" portions of this method (Sections 20 to 25). However, properties of the residue from the evaporation procedure may differ from those from the distillation residue (see Section 6.4.2.1).

6.3 *Apparatus*:

6.3.1 *Beakers*—Low form, l000-mL capacity, made of glass or metal, or a container of similar capacity.

6.3.2 *Glass Rods*—With flame-polished ends, approximately 6 mm ($^1/_4$ in.) in diameter and 180 mm (7 in.) in length.

6.3.3 *Balance*—Conforming to the requirements of M 231, Class G 2.

6.3.4 *Oven*—Conforming to ASTM E 145, Type lB.

6.3.5 *Sieve*—A 0.300-mm (No. 50) sieve conforming to M 92.

6.4 *Procedure*:

6.4.1 Determine the mass of each beaker containing a glass rod to the nearest 0.1 g (M_{br}). Pour 50 ± 0.1g of thoroughly mixed emulsified asphalt into each of four beakers. Place the beakers containing the rods and sample in the oven, the temperature of which has been adjusted to 163 ± 3°C (325 ± 5°F), for 2 hours. At the end of this period, remove each beaker, and stir the residue thoroughly. Replace the beakers in the oven for 1 hour; then remove the beakers from the oven. Allow them to cool to room temperature, and determine the mass of each beaker (containing a rod and the residue from the sample). Designate this mass as M_{brr}.

Note 6—Care must be taken to prevent the loss of asphalt from the beaker through foaming or spattering. Also, the placing of the beakers and emulsified asphalt samples in the oven and bringing the oven and sample to a temperature of 163°C (325°F) together is permissible. If preferred, preliminary evaporation of water may be accomplished by careful heating on a hot plate, followed by oven heating at 163°C (325°F) for 1 hour.

6.4.2 When tests on the residue from the emulsified asphalt are required, replace the beakers in the oven until the asphalt residue is sufficiently fluid to pass through a 0.300-mm (No. 50) sieve (usually requiring 15 to 30 minutes). Pour the residue through the 0.300-mm (No. 50) sieve into suitable containers and molds for performing such tests as desired, as described in Sections 20 to 25.

6.4.2.1 The method for residue by evaporation described in Section 6 tends to give an asphalt residue lower in penetration and ductility than the distillation method described in Section 5. Material may be accepted but shall not be rejected as failing to meet specifications containing requirements for determination of residue by distillation on data obtained by evaporation. If residue by evaporation fails to meet the requirements for properties specified for residue by distillation, the tests shall be repeated using the distillation method.

6.5 *Calculation and Report*:

6.5.1 Calculate the percentage of residue for each beaker as follows:

$$\text{Residue, \%} = 2(M_{brr} - M_{br}) \qquad (4)$$

where:

M_{brr} = mass of the beaker, rod, and residue, g; and

M_{br} = tare mass of the beaker and rod, g.

6.5.2 Report the percentage of residue by evaporation as the average of the four results.

6.6 *Precision and Bias*:

6.6.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

6.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Residue by Evaporation, mass %	Repeatability, mass %
50 to 70	0.4

6.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Residue by Evaporation, mass %	Reproducibility, mass %
50 to 70	0.8

7. PARTICLE CHARGE OF CATIONIC EMULSIFIED ASPHALTS

7.1 *Scope*:

7.1.1 This test method is used to identify cationic emulsified asphalt. Positively charged particles are classified as cationic.

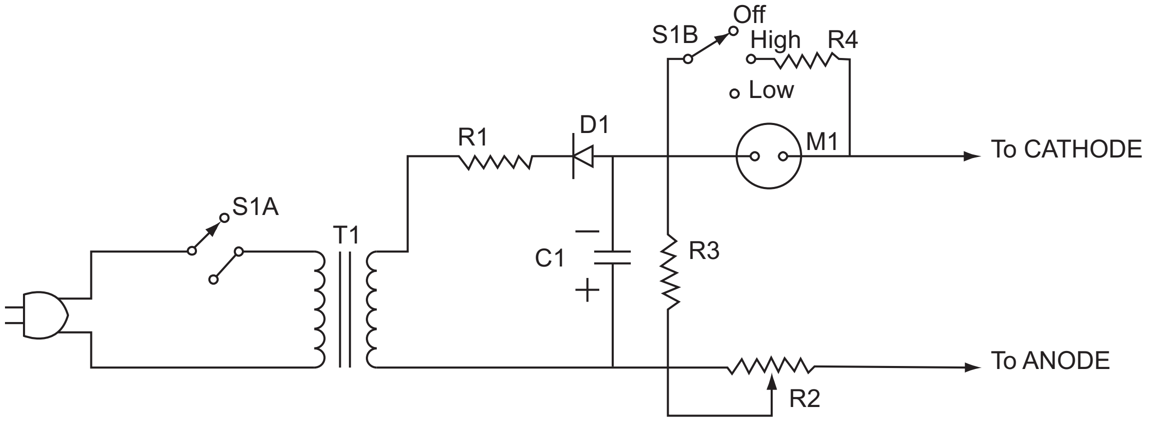
7.2 *Significance and Use*:

7.2.1 Cationic emulsified asphalt is identified by the migration of the particles to a negatively charged electrode (cathode) by means of a direct current.

7.3 *Apparatus*:

7.3.1 *Current Source*—Consisting of 12-V DC, a milliammeter, and a variable resistor (Figures 5 and 6).

Figure 5—Particle Charge Tester



C1—500-µF 25-V capacitor
D1—silicon diode
M1—0- to 10-mA milliammeter
R1—47 Ω, 1-W resistor
R2—5000 Ω potentiometer
R3—6800 Ω $^1/_4$W resistor
R4—meter shunt (determined by type of meter used)
S1—2-pole, 3-position rotary switch
T1—12.6-V filament transformer

Figure 6—Particle Charge Tester Circuit Diagram

7.3.2 *Electrodes*—Two stainless steel plates, 25.4 mm by 101.6 mm (1 in. by 4 in.) insulated from each other and rigidly held parallel 12.7 mm ($^1/_2$ in.) apart (Figure 7).

7.3.3 *Insulator*—Polytetraflouroethylene resin square rod, virgin electrical grade, 12.7 mm ($^1/_2$ in.) thick (see Figure 7). An insulator made from other suitable material may be used.

7.3.4 *Beaker*—250 mL capacity.

7.3.5 *Glass Rod*—101.6 mm (4 in.) long and 6.35 mm ($^1/_4$ in.) thick or other suitable material or device that is capable of insulating and suspending the electrode assembly in the emulsified asphalt.

7.3.6 *Water Bath*—Capable of maintaining the required testing temperature within the limits specified.

7.3.7 *Thermometer*—ASTM No. 19C or 19F conforming to the requirements of ASTM E 1.

7.3.8 *Timer*—Graduated in 0.1 second and accurate within 0.1 percent when tested over a 15-minute interval.

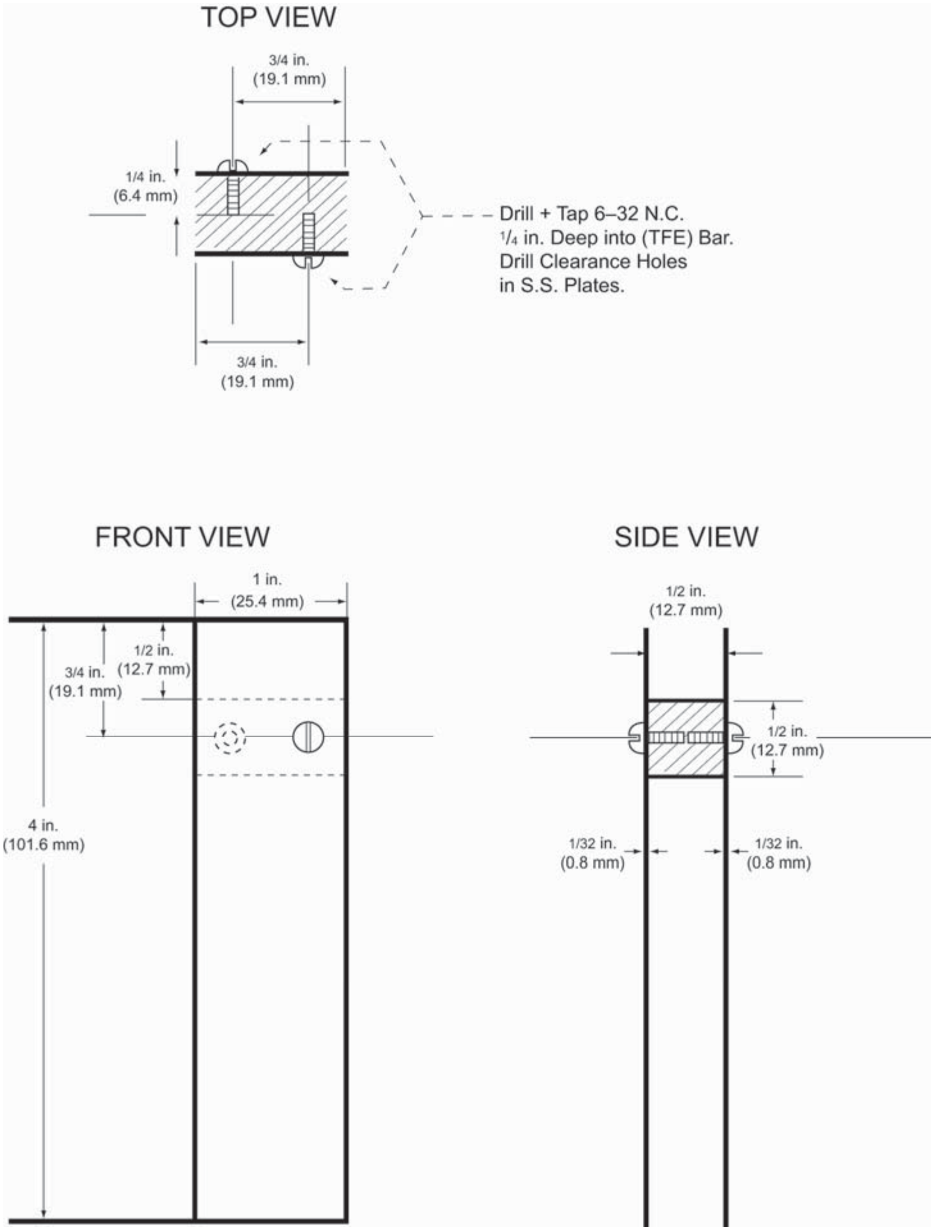


Figure 7—Insulator

7.4 *Procedure*:

7.4.1 Heat the emulsified asphalt to be tested to 50 ± 3°C (122 ± 5°F) in a 71 ± 3°C (160 ± 5°F) water bath. Stir the emulsified asphalt thoroughly to ensure uniformity of temperature.

7.4.2 Pour the emulsified asphalt to be tested into the 250-mL beaker to a height that will allow the electrodes to be suspended 25.4 mm (1 in.) in the emulsified asphalt. To facilitate suspension of the electrodes, insert the glass rod or equivalent between the two electrodes under the insulator. Place the ends of the glass rod or equivalent on the two opposite top edges of the beaker. An apparatus capable of manual height adjustment to insulate and suspend the electrode assembly in the emulsified asphalt may be used if desired.

7.4.3 Connect the electrodes, properly cleaned according to Section 7.4.3.1, to the DC source.

7.4.3.1 New electrodes and electrodes to be reused should be cleaned in the following sequence:

1. Wash with distilled water;
2. Wash with a suitable asphalt solvent;
3. Wash with isopropyl or ethyl alcohol; and
4. Wash with distilled water.

7.4.4 Adjust the current to a minimum of 8 mA with the variable resistor, and start timing with a suitable timing device.

Note 7—Higher current levels may be specified, but the current used shall be reported.

7.4.5 When the current drops to 2 mA or at the end of 30 minutes, whichever occurs first, disconnect the current source, and gently wash the electrodes with a smooth, thin stream of distilled water.

7.4.6 Observe the asphalt deposit on the electrodes. A cationic emulsified asphalt will deposit a discernible amount of asphalt on the cathode (negative electrode) while the anode (positive electrode) will be relatively clean. Any evidence of a clearly discernible asphalt deposit on the cathode when compared with the anode is considered to be passing. If the particle charge test does not produce conclusive results for cationic slow-setting (CSS) emulsified asphalt, proceed to Section 27.

7.5 *Report*:

7.5.1 Report the following information:

7.5.1.1 Level of current used; and

7.5.1.2 Whether the tested emulsified asphalt passes or fails as defined in Section 7.4.6.

7.6 *Precision and Bias*:

7.6.1 This test method, requiring subjective evaluation of test results and reporting of only two possible conditions, does not lend itself readily to a conventional statistical round-robin exercise. At present, there is no precision and bias statement for this test method.

CONSISTENCY

8. VISCOSITY (SAYBOLT FUROL)

8.1 *Scope*:

8.1.1 This test method utilizes the Saybolt Furol viscometer to measure the consistency of emulsified asphalt. It is applicable to all the emulsified asphalt specified in M 140, M 208, and M 316.

8.2 *Significance and Use*:

8.2.1 Viscosity has significance in the use of emulsified asphalt because it is a property that affects utility. When used in application types of construction, the material must be thin enough to be uniformly applied through the spray bar of a distributor, yet thick enough so that it will not flow from the crown or grade of the road. For mixing-grade emulsified asphalt, the viscosity may affect the mixability and resulting thickness of film on the aggregate. The viscosity of emulsified asphalt may be affected by shear. Therefore, strict adherence to this test procedure is necessary to achieve precision.

8.3 *Apparatus*:

8.3.1 *Viscometer*—A Saybolt Furol viscometer conforming to the requirements specified in T 72.

8.3.2 *Sieve*—An 0.850-mm (No. 20) sieve or a 20-mesh strainer of wire cloth, framed or unframed.

8.3.3 *Thermometers*—ASTM No. l7C or 17F for tests at 25°C (77°F) and ASTM No. l9C or l9F for tests at 50°C (l22°F), conforming to the requirements of ASTM E 1.

8.3.4 *Water Bath*—Capable of maintaining the required testing temperature within the limits specified in T 72.

8.3.5 *Beaker*—Glass beaker, 400-mL capacity

8.3.6 *Timer*—Graduated in 0.1 second and accurate within 0.1 percent when tested over a 15-minute interval.

8.4 *Procedure*:

8.4.1 *Tests at 25°C (77°F)*—Stir the sample thoroughly without incorporating bubbles, and pour it into a 118-mL (4-oz) bottle. Place the bottle in the water bath at 25°C (77°F) for 30 minutes and mix the sample in the bottle by inverting it several times, slowly enough to prevent bubble formation. Pour the sample into the viscometer through the 0.850-mm (No. 20) sieve or 20-mesh strainer, allowing a small portion to flow through the outlet tube to waste. Place the cork in position; fill the viscometer, and without stirring the sample again, determine the viscosity as prescribed in T 72.

8.4.2 *Tests at 50°C (122°F)*—Clean and dry the viscometer and insert the cork. Heat the emulsified asphalt sample to 50 ± 3°C (122 ± 5°F) in a 71 ± 3°C (160 ± 5°F) water bath or oven. Stir the sample thoroughly without incorporating bubbles, and then pour approximately 100 mL into a 400-mL glass beaker. Immerse the bottom of the beaker containing the emulsified asphalt approximately 50.8 mm (2 in.) below the level of a 71 ± 3°C (160 ± 5°F) water bath. Hold the beaker upright and stir the emulsified asphalt with a wide circular motion at a rate of 60 r/min with the thermometer to obtain uniform temperature distribution. Avoid incorporation of bubbles. Heat the emulsified asphalt in the water bath to 51.4 ± 0.3°C (124.5 ± 0.5°F). Immediately pour the emulsified asphalt through the 0.850-mm (No. 20) sieve or 20-mesh strainer into the viscometer until it is above the overflow rim. Stir the emulsified asphalt in the viscometer at 60 r/min with the thermometer until the test temperature is attained, avoiding bubble formation. Adjust the bath temperature until the emulsified asphalt temperature remains constant for 1 minute at 50 ± 0.05°C (122 ± 0.1°F). Withdraw the thermometer. Quickly remove the excess emulsified asphalt from the gallery with a suction pipet. Determine the viscosity as described in T 72. Report the results to the nearest 1 second.

Note 8—While the Saybolt Furol viscometer is not used for petroleum products and lubricants when the time of flow is less than 25 seconds, this instrument is satisfactory for testing emulsified asphalt when the time of flow is not less than 20 seconds.

8.5 *Precision and Bias*:

8.5.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

8.5.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Test Temperature, °C (F)	Viscosity, s	Repeatability, % of the mean
25 (77)	20 to 100	5
50 (122)	75 to 400	9.6

8.5.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Test Temperature, °C (F)	Viscosity, s	Reproducibility, % of the mean
25 (77)	20 to 100	15
50 (122)	75 to 400	21

STABILITY

9. DEMULSIBILITY

9.1 *Scope*:

9.1.1 This test method, applicable to anionic and cationic emulsified asphalt of the rapid-setting (RS) and medium-setting (MS) types, measures the chemical breaking of the emulsified asphalt.

9.2 *Significance and Use*:

9.2.1 This test method is used to identify or classify an emulsified asphalt as an RS or MS type by measuring the amount of available asphalt that is broken from the emulsified asphalt by utilizing specified amounts and concentrations of calcium chloride solution for anionic emulsified asphalt and dioctyl sodium sulfosuccinate for cationic emulsified asphalt.

9.3 *Apparatus and Reagents*:

9.3.1 *Wire Cloth*—Three pieces of 1.40-mm (No. 14) wire cloth approximately 125 mm (5 in.) square, unframed, having wire diameters and openings that conform to M 92.

9.3.2 *Beakers*—Three metal beakers of 600-mL capacity each.

9.3.3 *Rods*—Three metal rods with rounded ends, approximately 8 mm ($^5/_{16}$ in.) in diameter.

9.3.4 *Buret*—A 50-mL glass buret graduated in 0.1-mL intervals.

9.3.5 *Calcium Chloride Solution (1.11 g/L)*—Dissolve 1.11 g of calcium chloride ($CaCL_2$) in distilled water and dilute it to 1 L. The 1.11 g/L calcium chloride solution shall be standardized to be a 0.02 ± 0.001-N solution of calcium chloride in water. Although this solution will remain stable, it shall be stored in an airtight container when not in use.

9.3.6 *Calcium Chloride Solution (5.55 g/L)*—Dissolve 5.55 g of $CaCl_2$, in distilled water, and dilute it to 1 L. The 5.55 g/L calcium chloride solution shall be standardized to be a 0.1 ± 0.001-N solution of calcium chloride in water. Although this solution will remain stable, it shall be stored in an airtight container when not in use.

9.3.7 *Dioctyl Sodium Sulfosuccinate Solution (0.8 percent)*—Dissolve 8.00 g of dioctyl sodium sulfosuccinate in 992 mL of distilled water. This solution will degrade over time; it shall be stored in a dark glass, airtight container in a cool, dark location when not in use. This solution shall not be used for testing purposes if more than 90 days have elapsed since it was prepared.

9.3.8 *Balance*—Conforming to the requirements of M 231, Class G 2.

9.3.9 *Oven*—Capable of maintaining a temperature of 163 ± 3°C (325 ± 5°F).

9.3.10 *Timer*—Graduated in 0.1 second and accurate within 0.1 percent when tested over a 15-minute interval.

9.4 *Procedure*:

9.4.1 Determine the percentage of residue by distillation as described in Section 5.

9.4.2 Record the mass of each assembly of beaker, rod, and wire cloth.

9.4.3 Pour 100 ± 0.1 g of the emulsified asphalt into each of three 600-mL beakers in the assemblies. Heat the sample of emulsified asphalt and proper reagent to a temperature of 25 ± 0.5°C (77 ± 1.0°F).

9.4.4 Over a period of approximately 2 minutes, add to each beaker, from a buret, one of the following:

9.4.4.1 35 mL of $CaCl_2$ solution (1.11 g/L) for anionic RS emulsified asphalt:

9.4.4.2 50 mL of $CaC1_2$ solution (5.55 g/L) for MS or mixing-type emulsified asphalt; or

9.4.4.3 35 mL of dioctyl sodium sulfosuccinate solution (0.8 percent) for cationic RS emulsified asphalt.

9.4.5 While adding the $CaC1_2$ solution in Section 9.4.4.1, 9.4.4.2, or 9.4.4.3, stir the contents of the beaker continuously and vigorously, kneading any lumps against the sides of the beaker to ensure thorough mixing of the reagent with the emulsified asphalt.

9.4.6 Continue kneading any lumps for an additional 2 minutes after all of the solution has been added.

9.4.7 Decant the mixture of any unbroken emulsified asphalt and reagent onto the wire cloth. Rinse the beaker containing the sample and metal rod with distilled water, pouring the rinse water through the wire cloth. Knead and break up all lumps, and continue washing the beaker, rod, and wire cloth until the rinse water drains clear.

9.4.8 Place the wire cloth containing the asphalt residue in the beaker with the metal rod. Place the assembly in a 163 ± 3°C (325 ± 5°F) drying oven for 1 hour. Preliminary heating at lower temperatures to prevent spattering is permissible. Allow the beaker and contents to cool, and determine the mass. Repeat the heating and mass determination until successive masses differ by no more than 0.1 g.

9.5 *Calculation*:

9.5.1 Subtract the tare mass of the beaker, rod, and wire cloth from the mass of the dried assembly to obtain the demulsibility residue. Calculate the demulsibility as follows:

$$\text{Demulsibility, \%} = (M_{der}/M_{dir}) \times 100 \qquad (5)$$

where:

M_{der} = average mass of demulsibility residue from the three tests of each sample of emulsified asphalt, g (Section 9.4.8); and

M_{dir} = mass of residue by distillation in 100 g of the emulsified asphalt, g (Section 9.4.1).

9.6 *Precision and Bias*:

9.6.1 The following criteria should be used for judging the acceptability of results of tests on RS emulsified asphalt (95 percent probability):

Note 9—Precision does not apply when using dioctyl sodium sulfosuccinate solution in the testing of cationic emulsified asphalt for demulsibility.

9.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Demulsibility, mass %	Repeatability, % of the mean
30 to 100	5

9.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Demulsibility, mass %	Reproducibility, % of the mean
30 to l00	30

10. SETTLEMENT

10.1 *Scope*:

10.1.1 This test method measures the settlement of emulsified asphalt that occurs in a cylindrical container.

10.2 *Significance and Use*:

10.2.1 This test method is a measure of the uniformity of emulsified asphalt dispersion in storage over a period of time.

10.3 *Apparatus*:

10.3.1 *Cylinders*—Two 500-mL glass cylinders, with pressed or molded glass bases and cork or glass stoppers, having an outside diameter of 50 ± 5 mm (2 ± 0.2 in.). The cylinders should have 5-mL graduations.

Note 10—Cylinders with side arms may be used so that samples can be withdrawn without the use of pipets.

10.3.2 *Glass Pipet*—A 60-mL siphon glass-tube pipet of optional form.

10.3.3 *Balance*—Conforming to the requirements of M 231, Class G 2.

10.3.4 *Beakers*—Low form, 1000-mL capacity, made of glass or metal, or a container of similar capacity.

10.4 *Procedure*:

10.4.1 Place a 500-mL representative sample in each of the two glass cylinders. Stopper the cylinders and allow them to stand undisturbed at laboratory air temperature for 5 days. After standing for this period, remove approximately the top 55 mL of emulsified asphalt by means of a pipet or siphon without disturbing the balance. Mix each portion thoroughly. Pour 50 g of each sample into separate 1000-mL beakers, and determine the asphalt residue by evaporation in accordance with Section 6.

10.4.2 After removal of the top portion of the sample, siphon off approximately the next 390 mL from each of the cylinders. Thoroughly mix the emulsified asphalt remaining in the cylinders, and pour 50 g into separate 1000-mL beakers. Determine the asphalt residue by evaporation of these samples in accordance with Section 6.

Note 11—If the emulsified asphalt contains appreciable amounts of oil distillate as determined by distillation (see Section 5), the settlement value may be calculated from the difference in the percentage of water content between the top and bottom portion of the samples as determined by the procedure described in Section 4.

Note 12—If cylinders with side arms are used, siphoning is not required. Obtain a 55-mL sample from the upper arm. Drain off 390 mL from the lower arm.

10.5 *Calculation and Report*:

10.5.1 Calculate the settlement for each cylinder as follows:

$$\text{Settlement, \% (5 days)} = P_{rb} - P_{rt} \qquad (6)$$

where:

P_{rb} = the percentage of residue from the top portion of the sample; and

P_{rt} = the percentage of residue from the bottom portion of the sample.

Note 13—If the settlement values between the two cylinders differ by more than the stated repeatability, the result is considered suspect and the test shall be repeated. If for individual cylinders the percent residue of both the top and bottom samples is less than the percent residue of the emulsified asphalt, the result is considered suspect and the test shall be repeated. If for individual cylinders the percent residue of both the top and bottom portion of the samples is greater than the percent residue of the emulsified asphalt, the result is considered suspect, and the test shall be repeated.

10.5.2 Report the settlement as the average of the two individual cylinder results.

10.6 *Precision and Bias*:

10.6.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

10.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Settlement, mass %	Repeatability
0 to 1.0	0.4 mass %
Above 1.0	5% of the mean

10.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Settlement, mass %	Reproducibility
0 to 1.0	0.8 mass %
Above 1.0	10% of the mean

11. CEMENT MIXING

11.1 *Scope*:

11.1.1 This test method is a mixing test used to identify or classify a slow-setting, SS or CSS, type of emulsified asphalt.

11.2 *Significance and Use*:

11.2.1 The result of this test indicates the ability of an SS emulsified asphalt to mix with a finely divided, high surface area material (i.e., high early strength, Type III, portland cement) without breaking the emulsified asphalt.

11.3 *Apparatus and Material*:

11.3.1 *Sieves*—A 0.180-mm (No. 80) sieve and a 76.2-mm (3-in.) diameter 1.40-mm (No. 14) sieve, made of wire cloth conforming to M 92.

11.3.2 *Dish*—A round-bottom iron dish or kitchen saucepan of approximately 500-mL capacity.

11.3.3 *Stirring Rod*—A steel rod with rounded ends, approximately 13 mm ($^1/_2$ in.) in diameter.

11.3.4 *Graduate*—A l00-mL graduated cylinder.

11.3.5 *Balance*—Conforming to the requirements of M 231, Class G 2.

11.3.6 *Oven*—Conforming to ASTM E 145, Type 1B.

11.3.7 *Cement*:

11.3.7.1 High-early-strength portland cement conforming to the requirements for Type III portland cement in M 85 and having a minimum specific surface area of 1900 cm^2/g (928 ft^2/lb) as measured by the Wagner Turbidimeter.

11.4 *Procedure*:

11.4.1 Dilute the emulsified asphalt with distilled water to a residue of 55 percent, as determined by distillation or by evaporation for 3 h at 163°C (325°F), according to Section 5 or 6 as appropriate.

11.4.2 Sieve a portion of the cement through the 0.180-mm (No. 80) sieve. Add 50 ± 0.1 g of the cement passing the 0.180-mm (No. 80) sieve into the dish.

11.4.3 Ensure the ingredients and apparatus are at a temperature of approximately 25°C (77°F) before mixing. Add 100 mL of the diluted emulsified asphalt to the cement and stir the mixture at once with the steel rod, using a circular motion at a rate of 60 r/pm. At the end of the 1-min mixing period, add 150 mL of distilled water, and continue stirring for 3 min.

11.4.4 Pour the mixture through a weighed 1.40-mm (No. 14) sieve. Use repeated washings to completely remove the material from the mixing bowl. Pour these washings over the sieve, and rinse the sieve using distilled water held at a height of approximately 150 mm (6 in.) until the water running through the sieve is clear. Place the sieve in a shallow pan; heat it at 163°C (325°F) in an oven, and determine the mass. Repeat the heating and mass determination until successive masses differ by no more than 0.1 g.

11.5 *Calculation and Report*:

11.5.1 Calculate the mass of the sample retained on the sieve and in the pan as follows:

$$\text{Mass retained} = M_{spr} - M_{sp} \qquad (7)$$

where:

M_{spr} = mass of the sieve, pan, and residue, g; and

M_{sp} = mass of the sieve and pan, g.

11.5.2 Report the mass, in grams, of the material retained on the sieve and in the pan as the percentage of break in the cement mixing test.

11.6 *Precision and Bias*:

11.6.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

11.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Cement Mixing, mass %	Repeatability, mass %
0 to 2	0.2

11.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Cement Mixing, mass %	Reproducibility, mass %
0 to 2	0.4

12. SIEVE TEST

12.1 *Scope*:

12.1.1 This test method measures the degree to which an emulsified asphalt may contain particles of asphalt or other discreet solids retained on a 0.850 mm (No. 20) mesh sieve.

12.2 *Significance and Use*:

12.2.1 The retention of an excessive amount of particles on the sieve indicates that problems may occur in handling and application of the material. Particles of asphalt retained on the sieve often are caused by agglomeration of the dispersed phase. Storage, pumping, handling, and temperature can all contribute to the formation of particles. Contamination from the tank, transport, or hose is another factor affecting particle formation.

12.3 *Apparatus and Reagents*:

12.3.1 *Sieve*—A sieve having a 76.2-mm (3-in.) frame and an 0.850-mm (No. 20) wire sieve cloth conforming to M 92.

12.3.2 *Pan*—A tin box cover or shallow metal pan of appropriate size to fit over the bottom of the standard sieve.

12.3.3 *Sodium Oleate Solution (2 percent)*—Dissolve 20 g of pure sodium oleate in distilled water and dilute it to 1 L.

Note 14—Replace sodium oleate solution with distilled water when testing cationic emulsified asphalt.

12.3.4 *Balances*—Conforming to the requirements of M 231, Class G 5 for determining the mass of the emulsified asphalt, and M 231, Class G 2 for determining the mass of the sieve and residue.

12.3.5 *Oven*—Capable of maintaining a temperature of 105 ± 5°C (220 ± 9°F).

12.3.6 *Desiccator*.

12.3.7 *Oven or Water Bath*—Capable of maintaining a temperature of 50 ± 3°C (122 ±5°F), if it is necessary to heat the emulsified asphalt before testing.

12.4 *Procedure*:

12.4.1 The temperature at which the sieve test should be performed is related to the viscosity of the emulsified asphalt. For those materials whose viscosity is 100 seconds or less at 25°C (77°F), perform the test at room temperature. For those materials whose viscosity is more than 100 seconds at 25°C (77°F) and those whose viscosity is specified at 50°C (122°F), use a test temperature of 50 ± 3°C (122 ± 5°F). If heating is necessary, the emulsified asphalt may be placed in a closed container in an oven or water bath, followed by stirring to achieve homogeneity.

12.4.2 Record the mass of the sieve and pan and wet the wire cloth with the 2-percent sodium oleate solution. Transfer 1000 g of the emulsified asphalt into a suitable container, and pour it through the sieve. Wash the container and residue on the sieve with the sodium oleate solution until the washings run clear. Place the pan under the sieve and heat them for 2 h in a 105°C (220°F) drying oven. Cool them in a desiccator, and determine the mass of the sieve, pan, and residue.

12.5 *Calculation*:

12.5.1 Calculate the percentage of sample retained on the sieve as follows:

Sample retained, % = $(M_{spr} - M_{sp})/10$ (8)

where:

M_{spr} = mass of the sieve, pan, and residue, g; and
M_{sp} = mass of the sieve and pan, g.

12.6 *Precision*:

12.6.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

12.6.1.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Sieve Test, mass %	Repeatability, mass %
0 to 0.1	0.03

12.6.1.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Sieve Test, mass %	Reproducibility, mass %
0 to 0.1	0.08

13. COATING TEST

13.1 *Scope*:

13.1.1 This test method is applicable to those emulsified asphalts intended for use by mixing with aggregate. It is not applicable to RS types or diluted materials used for tack coats, priming or mulch treatments.

13.2 *Significance and Use*:

13.2.1 The intent of the coating test is to ensure that a given mixing-grade emulsified asphalt is adequately stable emulsified asphalt and otherwise possesses the ability to mix with a reference stone for the prescribed time and coat it uniformly and thoroughly.

13.3 *Apparatus and Material*:

13.3.1 *Sieves*—19.0-mm ($^{3}/_{4}$-in.) and 6.4-mm ($^{1}/_{4}$-in.) sieves conforming to M 92.

13.3.2 *Spatula*—A steel spatula or its equivalent, having a blade approximately 200 mm (8 in.) in length.

13.3.3 *Dish*—A round-bottom iron dish or a kitchen saucepan, of approximately 1-L (1-qt) capacity.

13.3.4 *Stone*—A supply of reference stone (hard limestone, trap rock, or other similar type) which has been washed with water and dried before using. All stone shall pass through a 19.0-mm ($^{1}/_{4}$-in.) screen and not more than 5 percent shall pass through the 6.4-mm ($^{1}/_{4}$-in.) screen.

Note 15—Each laboratory shall select its own reference stone supply, the source of which is not apt to change; this policy is to avoid rapid changes in the character of reference stone used in any one laboratory.

13.3.5 *Balance*—Conforming to the requirements of M 231, Class G 2.

13.4 *Procedure*:

13.4.1 Add 465 ± 0.1 g of stone into the dish. Add 35 ± 0.1 g of the emulsified asphalt to the stone in the dish, and mix vigorously with the spatula for 3 minutes.

13.4.2 Record whether or not there is appreciable separation of the asphalt base from the water in the emulsified asphalt, and whether or not the stone is uniformly and thoroughly coated with the emulsified asphalt.

14. MISCIBILITY WITH WATER

14.1 *Scope*:

14.1.1 This test may be applied to all MS and SS emulsified asphalts. It is not applicable to RS types.

14.2 *Significance and Use*:

14.2.1 It is sometimes desirable to dilute an emulsified asphalt in the field with water. This test is designed to ascertain if this operation may be completed safely without breaking the emulsified asphalt.

14.3 *Apparatus:*

14.3.1 *Breaker*—Glass beaker of 400-mL capacity.

14.4 *Procedure*:

14.4.1 Gradually add 150 mL of distilled water, with constant stirring, to 50 mL of the emulsified asphalt in a 400-mL glass beaker. The temperature should be between 21 and 25°C (70 and 77°F). Allow the mixture to stand for 2 hours; then examine it for any appreciable coagulation of the asphalt portion of the emulsified asphalt. Such coagulation indicates that the emulsified asphalt has broken.

14.5 *Report:*

14.5.1 Report whether or not the emulsified asphalt breaks as defined in Section 14.4.1.

15. FREEZING TEST

15.1 *Scope*:

15.1.1 Emulsified asphalt is normally damaged by freezing temperatures, but specially formulated materials are expected to pass this test.

15.2 *Significance and Use*:

15.2.1 Certain agencies, who desire to use, store, or transport emulsified asphalt under less-than-ideal weather conditions, may require that the product remain homogeneous (unbroken) after being subjected to temperatures of –17.8°C (0°F).

15.3 *Apparatus*:

15.3.1 *Container*—Metal container, 500-mL capacity, with a sealable lid.

15.3.2 *Freezer*—Capable of maintaining a temperature of –17.8 ± 0.5°C (0 ± 1°F).

15.4 *Procedure*:

15.4.1 Place approximately 400 g of the emulsified asphalt in a clean container, such as a 500-mL (1-Pt) press-top can.

15.4.2 Expose the emulsified asphalt in the closed container to an air temperature of –17.8 ± 0.5°C (0 ± 1°F) for a minimum of 12 hours.

15.4.3 At the expiration of the freezing period, permit the emulsified asphalt to thaw by exposure of the container to ambient temperature.

15.4.4 Repeat the freezing and thawing periods in Section 15.4.2 and 15.4.3 until the emulsified asphalt is subjected to three cycles of freezing and thawing.

15.4.5 After the third cycle, the emulsified asphalt may be homogeneous or may have separated into distinct layers which cannot be rendered homogeneous by stirring at ambient temperature.

15.5 *Report*:

15.5.1 Report the result of this test as either “Homogeneous” or “Broken” depending on the condition of the material as defined in Section 15.4.5.

16. COATING ABILITY AND WATER RESISTANCE

16.1 *Scope*:

16.1.1 This test method is intended to aid in the identification of emulsified asphalt suitable for mixing with coarse-graded calcareous aggregates.

Note 16—Aggregates other than limestone may be used provided calcium carbonate is omitted throughout the test method. Laboratory washing and air-drying of such aggregates shall also be omitted.

16.2 *Significance and Use*:

16.2.1 This test method covers the determination of the ability of an emulsified asphalt to (1) coat an aggregate thoroughly; (2) withstand a mixing action while remaining as a film on the aggregate; and (3) resist the washing action of water after completion of the mixing.

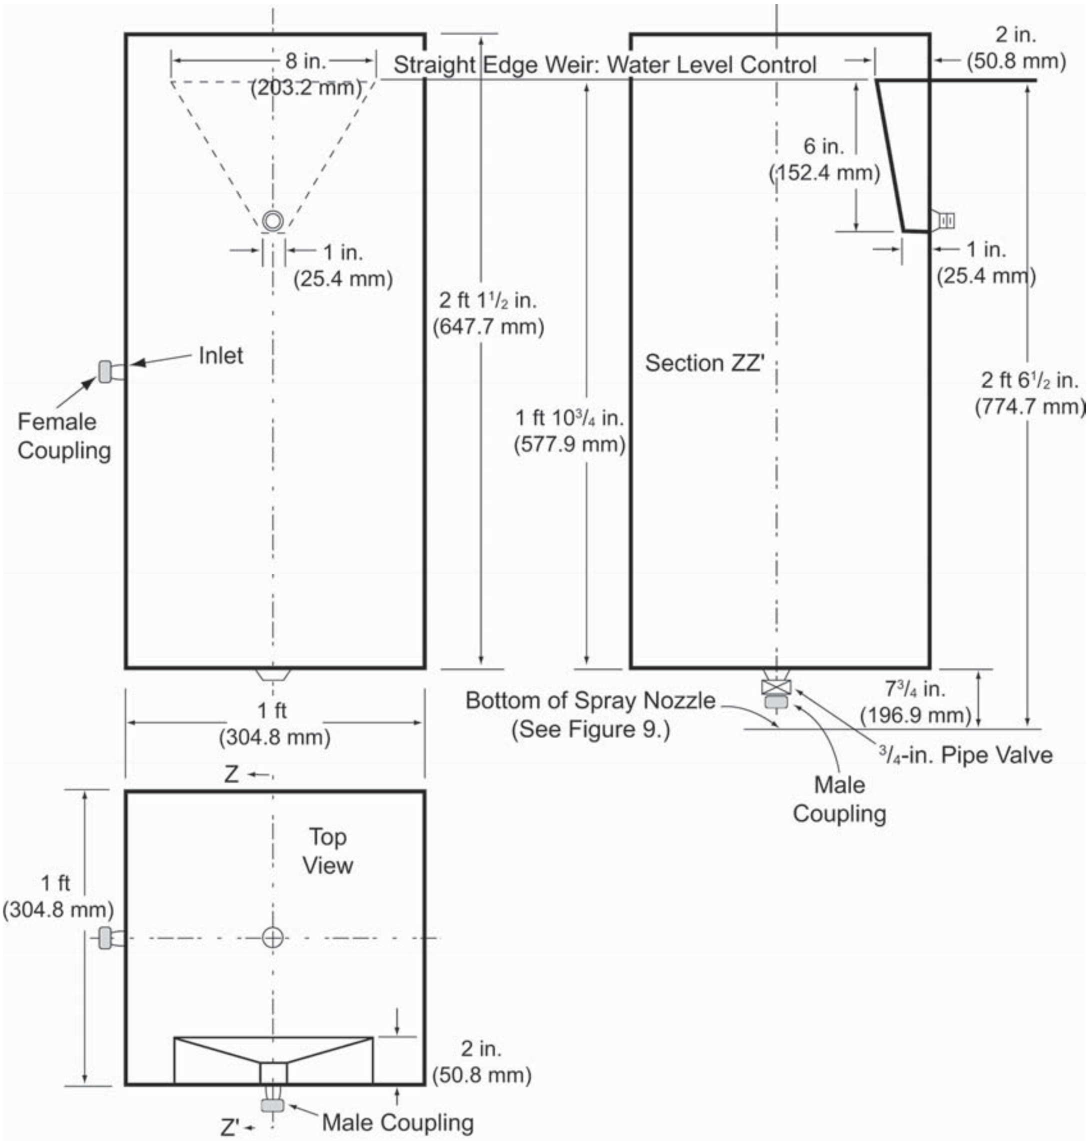
16.3 *Apparatus:*

16.3.1 *Mixing Pan*—An enameled kitchen saucepan with handle, of approximately 3-L (3-qt) capacity.

16.3.2 *Spatula*—A steel spatula or its equivalent, having a blade approximately 200 mm (8 in.) in length.

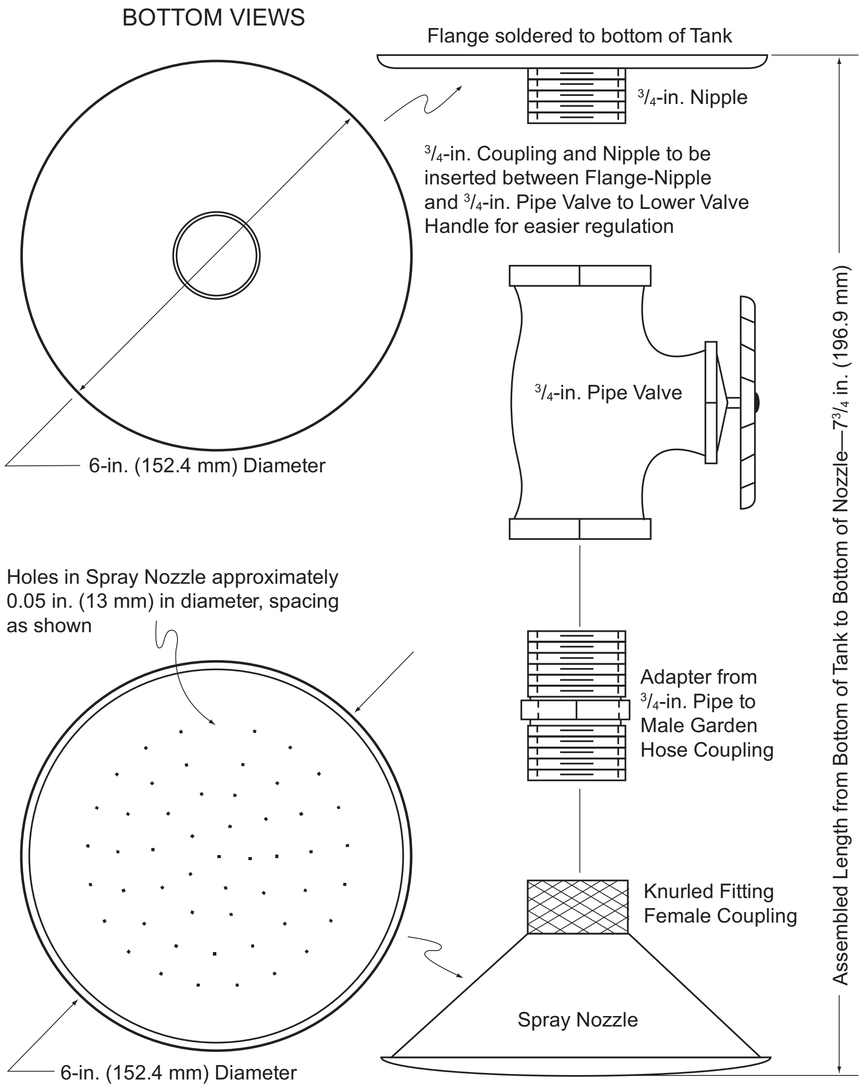
16.3.3 *Sieves*—19.0-mm ($^3/_4$-in.) and 4.75- mm (No. 4) sieves conforming to M 92.

16.3.4 *Constant-Head Water-Spraying Apparatus*—An apparatus for applying tap water in a spray under a constant head of 774.7 mm (2.54 ft) (Figures 8 and 9). The water shall issue from the apparatus in a low-velocity spray.



NOTE—Use galvanized steel sheeting for the tank. All joints and fitting attachments shall be soldered and shall be watertight. All couplings shall be standard brass garden hose fittings. The 19.0-mm ($^3/_4$-in.) pipe valve shall be placed as close as possible to the bottom of the tank, allowing space to shut off the valve. The tank shall be placed on a suitable stand, so that the distance from the bottom of the spray head to the top of the test sample is 919.4 ± 25.4 mm (3 ft ± 1 in.).

Figure 8—Constant-Head Flow Tank



NOTE 1—A Speakman, Model 235S, all brass, fixed shower head has been found acceptable.

NOTE 2—Existing 101.6-mm (4-in.) diameter shower heads may continue to be used.

Figure 9—Valve and Nozzle Assembly for Constant-Head Flow Tank

16.3.5 *Thermometer*—An ASTM Low Softening Point Thermometer 15C (or 15F), having a range from –2 to 80°C (or 30 to 180°F) and conforming to the requirements in ASTM E 1.

16.3.6 *Balance*—Conforming to the requirements of M 231, Class G 2.

16.3.7 *Pipet*—10-mL capacity.

16.4 *Materials*:

16.4.1 *Aggregate*—Reference aggregate shall be a laboratory-washed and air-dried limestone aggregate graded to pass the 19.0-mm ($^3/_4$-in.) sieve and be retained on the 4.75-mm (No. 4) sieve.[3] (Note 15)

16.4.2 *Calcium Carbonate*—Chemically pure, precipitated calcium carbonate ($CaCO_3$) shall be used as a dust to be mixed with the reference aggregate.

16.4.3 *Water*—Tap water with a hardness not over 250 ppm $CaCO_3$ for spraying over the sample.

16.4.4 *Absorbent Paper*.

16.5 *Procedure for Tests with Dry Aggregate*:

16.5.1 Conduct the test at 23.9 ± 5.5°C (75 ± 10°F).

16.5.2 Add 461 g of the air-dried, graded reference aggregate in the mixing pan.

16.5.3 Add 4.0 g of $CaCO_3$ dust in the mixing pan, and mix it with the 461 g of aggregate for approximately 1 minute with a spatula to obtain a uniform film of dust on the aggregate particles.

Note 17—The total mass of aggregate and dust shall equal 465 g. If no calcium carbonate is included, the mass of aggregate alone shall be 465 g.

16.5.4 Add 35 g of the emulsified asphalt into the aggregate in the pan and mix vigorously with the spatula for 5 minutes using a tossing action created by a back-and-forth motion in an elliptical path of the mixing blade. At the end of the mixing period, tilt the pan and permit any excess emulsified asphalt not on the aggregate to drain from the pan.

16.5.5 Remove approximately one half of the mixture from the pan and place it on absorbent paper to evaluate the coating.

16.5.6 Immediately spray the mixture remaining in the pan with tap water from the constant-head water-spraying apparatus to cover the mixture. The distance from the spray head to the sample shall be 305 ± 75 mm (12 ± 3 in.). Then carefully pour off the water. Continue spraying and pouring off the water until the overflow water runs clear. Carefully drain the water in the pan. Transfer the mixture from the mixing pan onto absorbent paper for evaluation of coating retention.

16.5.7 Evaluate the mixture immediately by visual estimation as to the total aggregate surface area that is coated with asphalt.

16.5.8 Repeat the evaluation by visual estimation of the coating of aggregate surface area with asphalt after the mixture has been air-dried in the laboratory at room temperature. A fan may be used for drying if desired.

16.6 *Procedure for Tests with Wet Aggregate*:

16.6.1 Proceed in accordance with Section 16.5.1 to 16.5.3.

16.6.2 Pipet 9.3 mL of water into the aggregate and $CaCO_3$ dust mixture in the mixing pan and mix thoroughly to obtain uniform wetting.

16.6.3 Continue in accordance with Section 16.5.4 to 16.5.8.

16.7 *Interpretation of Results*:

16.7.1 Evaluate and report the following information for tests with both dry and wet aggregate:

16.7.1.1 At the end of the mixing period, record the coating of the total aggregate surface area with emulsified asphalt as “good,” “fair,” or “poor, ” where a rating of “good” means fully coated with emulsified asphalt (exclusive of pinholes and sharp edges of the aggregate), a rating of “fair” applies to the condition of more area of coated than uncoated, and a rating of “poor” applies to the condition of more area uncoated than coated.

16.7.1.2 After spraying with water, record the coating of the total aggregate surface area with the asphalt as “good,” “fair,” or “poor,” according to the definitions for those terms in Section 16.7.1.1.

16.7.1.3 After air-drying in the laboratory, record the coating of the total aggregate surface area by the asphalt as good, fair, or poor.

Note 18—Comments about the results of the test may be included in the evaluation.

17. STORAGE STABILITY OF EMULSIFIED ASPHALT

17.1 *Scope*:

17.1.1 This test method relates to the ability of emulsified asphalt to remain as a uniform dispersion during storage. It is applicable to emulsified asphalt composed principally of a semisolid or liquid asphalt base, water, and an emulsifying agent.

17.2 *Summary of Test Method*:

17.2.1 This test method determines the difference in percent residue of samples taken from the top and bottom of material placed in undisturbed simulated storage for 24 hours. The result is expressed as the average of the two individual values obtained by determining the difference between the percent residue of the top and bottom samples for each storage cylinder.

17.3 *Significance and Use*:

17.3.1 This test method is useful for determining the storage stability of emulsified asphalt in a comparatively short amount of time. It is a measure of the permanence of the dispersion as related to time, but it is not to be construed to have significance as a measure of other stability aspects involved in use of emulsified asphalt.

17.4 *Apparatus*:

17.4.1 *Cylinders*—Two 500-mL glass cylinders, with pressed or molded glass bases and cork or glass stoppers, having an outside diameter of 50 ± 5 mm (2 ± 0.2 in.), and having 5-mL graduations. (Note 12)

17.4.2 *Glass Pipet*—A 60-mL siphon glass-tube pipet of optional form.

17.4.3 *Balance*—Conforming to the requirements of M 231, Class G 2.

17.4.4 *Beakers*—Low form, 1000-mL capacity, made of glass or metal, or a container of similar capacity.

17.4.5 *Oven*—Conforming to ASTM E 145, Type lB.

17.5 *Procedure*:

17.5.1 Heat the emulsified asphalt to room temperature, 21 to 27°C (70 to 80°F). Place a 500-mL representative sample in each of the two glass cylinders. Stopper the cylinders and allow them to stand undisturbed at laboratory air temperature, 21 to 27°C (70 to 80°F), for 24 hours. After standing for this period, remove approximately 55 mL from the top of the emulsified asphalt by means of the pipet or siphon without disturbing the balance (Note 12). Thoroughly mix each portion.

17.5.2 Pour 50 ± 0.1 g of each sample into separate l000-mL beakers; the mass of each beaker shall previously have been determined with a 6-mm ($^{1}/_{4}$-in.) diameter by 178-mm (7-in.) glass rod. Adjust the temperature of the oven to 163 ± 2.8°C (325 ± 5°F). Place the beakers containing the rods and sample in the oven for 2 hours. At the end of this period, remove each beaker and thoroughly stir the residue. Place the beakers in the oven for 1 hour (Note 6). Remove the beakers from the oven and allow them to cool to room temperature. Determine the mass of each beaker with the rods.

17.5.3 After removal of the top portion of the sample, siphon off approximately the next 390 mL from each of the cylinders. Thoroughly mix the emulsified asphalt remaining in the cylinders and pour 50 g into separate 1000-mL beakers. Determine the asphalt residue of these samples in accordance with Section 17.5.2.

17.6 *Calculation and Report*:

17.6.1 Calculate and report the storage stability in accordance with Section 10.5 and observe Note 13.

17.7 *Precision and Bias*:

17.7.1 *Repeatability*—The repeatability standard deviation is 0.2 percent. The average difference between two results, obtained by the same operator with the same equipment, but not concurrently, will be approximately 0.2 percent. Two such values should be considered suspect (95 percent confidence level) if they differ by more than 0.5 percent.

17.7.2 *Reproducibility*—The reproducibility standard deviation is 0.2 percent. The average difference between two results obtained by operators in different laboratories will be approximately 0.3 percent. Two such values should be considered suspect (95 percent confidence level) if they differ by more than 0.6 percent.

Note 19—If this test method is performed using only one cylinder instead of two for each determination as specified in the method, then the following precision criteria should be used:

	Repeatability, %
Standard deviation	0.2
Average difference	0.3
Suspect criterion	0.5

	Reproducibility, %
Standard deviation	0.2
Average difference	0.3
Suspect criterion	0.6

EXAMINATION OF RESIDUE

18. SCOPE

18.1 Tests for specific gravity, ash content, solubility in trichloroethylene, penetration, ductility, and the float test are suggested for examination of the emulsified asphalt residue obtained by distillation (Section 5) or evaporation.

19. SIGNIFICANCE AND USE

19.1 The suggested procedures are used to characterize and evaluate the properties of emulsified asphalt residues.

20. SPECIFIC GRAVITY

20.1 Determine the specific gravity on a representative portion of the residue in accordance with T 228 or ASTM D 3289.

21. ASH CONTENT

21.1 Determine the ash content on a representative portion of the residue in accordance with the rapid routine method of ash determination, as described in ASTM D 128.

22. SOLUBILITY IN TRICHLOROETHYLENE

22.1 Determine the solubility in trichloroethylene on a representative portion of the residue in accordance with T 44.

23. PENETRATION

23.1 Determine the penetration on a representative portion of the residue in accordance with T 49.

23.2 *Precision*—The following criteria should be used for judging the acceptability of results (95 percent probability):

23.2.1 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Penetration of Residue, range	Repeatability, points
80 to 200	15

23.2.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Penetration of Residue, range	Reproducibility, points
80 to 200	30

24. DUCTILITY

24.1 Determine the ductility on a representative portion of the residue in accordance with T 51.

25. FLOAT TEST

25.1 Perform the float test on a representative portion of the residue in accordance with T 50, except revise Section 7.2 of ASTM D 139 as follows:

25.1.1 Pour the residue into the collar at or near 260°C (500°F) preferably, directly from the distillation pot. If the residue has been allowed to cool below 260°C (500°F), reheat it to 260°C (500°F) with stirring and pour into the collar.

IDENTIFICATION TESTS

26. IDENTIFICATION TEST FOR CATIONIC RAPID-SETTING (CRS) EMULSIFIED ASPHALTS

26.1 *Scope*:

26.1.1 This test method covers a procedure for identifying CRS emulsified asphalt. The inability to coat a specific silica sand distinguishes CRS emulsified asphalt from MS and SS cationic grades.

26.2 *Significance and Use*:

26.2.1 This test method is based upon the rapid asphalt deposition properties of CRS emulsified asphalt as a function of sand surface area and surface charge. The test method differs from the usual coating test because the material passes the requirement when it fails to coat the specified silica sand.

26.2.2 Impurities in the silica sand often prevent the emulsified asphalt from passing the test. Washing the sand to remove impurities prior to the test is required. Impurities affecting test results are normally due to the presence of iron (Fe^+) and organic dewatering agents that can alter the sand surface charge.

26.3 *Apparatus*:

26.3.1 *Mixing Bowl*—Metal or porcelain saucepan, $2^1/_2$ to 3 L ($2^1/_2$ to 3 qt), equipped with a handle.

26.3.2 *Washing Container*—Beaker made from borosilicate glass, 1000-mL capacity.

26.3.3 *Stainless Steel Spatula or Glass Rod.*

26.3.4 *Oven*—Convection or forced-draft, capable of maintaining 120 to 150°C (248 to 302°F).

26.3.5 *Balance*—Conforming to the requirements of M 231, Class G 2.

26.3.6 *Drying Pan*—Stainless steel or glass, 150 mm (6 in.) by 225 mm (9 in.) or larger.

26.3.7 *Graduated Cylinder*—Made from borosilicate glass, 500-mL capacity.

26.3.8 *Thermometer*—ASTM No. 67C or 67F as specified in ASTM E 1.

26.3.9 *Eye Protection*—Suitable safety glasses or other appropriate eye protection.

26.3.10 *Hand Protection*—Sufficiently acid and alcohol resistant.

26.3.11 *Timer*—Graduated in 0.1 second and accurate within 0.1 percent when tested over a 15-minute interval.

26.4 *Material*:

26.4.1 *Hydrochloric Acid*—Reagent, 36.5 to 38.0 percent.

26.4.2 *Isopropyl Alcohol*—Reagent, 100 percent.

26.4.3 *Distilled Water*.

26.4.4 *Absorbent Paper*.

26.4.5 *Silica Sand*—F-95, whole grain, with a gradation similar to that in the table below.[4]

TYPICAL GRADATION

U.S. Sieve No.	30	40	50	70	100	140	200	270
Millimeters	0.850	0.425	0.300	0.212	0.150	0.106	0.075	0.053
% Passing	100	99	97	89	56	17	2	Trace

26.5 Emulsified Asphalt Sample.

26.5.1 Obtain a representative sample of the CRS emulsified asphalt for testing in accordance with T 40.

26.6 *Sand Preparation*:

26.6.1 Prepare 400 mL of 5-percent hydrochloric acid, by volume, in isopropyl alcohol by mixing 20 mL of hydrochloric acid into a blend of 80 mL of distilled water and 300 mL of isopropyl alcohol in a 500-mL graduated cylinder.

26.6.2 Add 500 g of the F-95 silica sand into a 1000-mL beaker. Add 400 mL of the “5-percent hydrochloric acid in isopropyl alcohol/water” mixture into the beaker containing the silica sand, and stir for 5 minutes with a stainless steel spatula or glass rod.

26.6.3 Decant the acid/alcohol/water mixture carefully without a loss of sand.

26.6.4 Wash the sand with at least 400 mL of hot distilled water, 50 to 70°C (122 to 158°F) and stir for approximately 1 minute. Decant the water without a loss of sand. Repeat water-washing the sand two more times.

26.6.5 Scrape the washed sand onto the drying pan (avoiding as much loss of sand as possible) and spread the sand over the surface of the drying pan. Place the pan with the sand in an oven and dry it to a constant mass at a temperature of 120 to 150°C (248 to 302°F).

26.6.6 Allow the sand to cool and transfer the dry sand to a suitable container. Mix the sand for approximately 30 seconds to obtain uniformity.

26.7 *Procedure*:

26.7.1 Perform the following operations at 25 ± 5°C (77 ± 9°F).

26.7.2 Add 465 g of the washed silica sand blend into a mixing bowl. Add 35 g of the emulsified asphalt to be tested and mix vigorously with a spatula for approximately 2 minutes using a combined stirring and kneading action. At the end of the mixing period, tilt the bowl, and allow any excess emulsified asphalt, which is not coating the sand, to drain from the bowl.

26.7.3 Place the mix on absorbent paper. Visually estimate the amount of uncoated and coated area in the mixture.

Note 20—Visual estimation is less accurate at moderate levels of coating than at the two extremes. If the results are inconclusive, the washing and mixing procedure should be repeated.

26.8 *Interpretation of Results*:

26.8.1 From the visual estimation of the amount of uncoated area and coated area in the mixture, record the coating of the total sand surface area by the emulsified asphalt. More uncoated area than coated area shall be considered as a passing rating for identification of CRS emulsified asphalt. (Note 20)

26.9 *Precision and Bias*:

26.10 This test method, which requires a subjective evaluation of test results and reports only two possible conditions, does not lend itself readily to a statistical round-robin exercise. Development of a procedure to quantitatively determine the comparative coating will be considered.

27. IDENTIFICATION TEST FOR CATIONIC SLOW-SETTING (CSS) EMULSIFIED ASPHALTS

27.1 *Scope*:

27.1.1 This test method is intended to identify a CSS grade of emulsified asphalts if the results of the particle charge test are inconclusive (Section 7.4.6).

27.2 *Summary of Test Method*:

27.2.1 A specified amount of washed and dried silica sand is hand-mixed with a specified amount of emulsified asphalt. The mixing time should extend until the aggregate is completely coated. The amount of CSS-grade emulsified asphalt in the mix should yield a total mix asphalt content of about 5.0 percent. The sample is spread out and allowed to air-cure for 24 hours. The retained coating, after boiling, is then determined.

27.3 *Significance and Use*:

27.3.1 The conditions of the test are designed to identify the ability of a CSS grade of emulsified asphalt from M 208 to properly mix, coat, and adhere to a specified silica sand.

27.3.2 This test method is intended to confirm the adhesive properties that exist between a cationic emulsified asphalt and silica sand and the ability of the sample to remain coated after being submerged in boiling water.

27.4 *Apparatus and Material*:

27.4.1 *Heat Source*—Hot plate or bunsen burner. The use of a bunsen burner will necessitate the placement of an interfacial material between the flame and beaker.

27.4.2 *Screen*—No. 20 mesh folded into a circular configuration with the edges folded downward; or a strip of 0.850-mm (No. 20) mesh screen, 25.4 mm by 355.6 mm (1 in. by 14 in.) in length, and a circular screen of the circumference of the 1000-mL beaker. Bend the strip into a circle and insert it in the bottom of the beaker. Place the circular screen on top of the strip.

27.4.3 *Beaker*—l000-mL capacity.

27.4.4 Paper Napkin.

27.4.5 *20–30 Standard Ottawa Silica Sand*—As described in ASTM C 778 and washed to remove impurities prior to testing.[4]

27.4.6 *Spatula*—A steel spatula or its equivalent, having a blade of 203.2 mm (8 in.) in length.

27.4.7 *Mixing Container*—400-mL capacity, glass or stainless steel beaker or bowl.

27.4.8 *Beaker Tongs.*

27.4.9 *Eye Protection*—Suitable safety glasses with a side shield or any other appropriate eye protection.

27.4.10 *Hand Protection*—Heat-resistant gloves.

27.4.11 *Balance*—Conforming to the requirements of M 231, Class G 2.

27.4.12 *Distilled Water.*

27.5 *Procedure*:

27.5.1 Weigh 150 g of dry silica sand into the mixing container.

27.5.2 Add 12 g of the emulsified asphalt and immediately begin to mix vigorously for 20 to 60 seconds or until silica sand is completely coated.

Note 21—Water may be added to facilitate mixing; 1.0 percent is generally sufficient.

27.5.3 The sample should be spread onto a paper napkin in such a manner as to facilitate curing. Allow the sample to air-cure for 24 hours. Remove the sample from the paper napkin and break it into several pieces; observe whether the sample is completely cured. If the sample is not completely cured, allow additional curing time.

27.5.4 Boil about 500 mL of distilled water in a 1000-mL beaker containing 0.850-mm (No. 20) mesh screen shelf. Place the coated silica sand in the boiling water on top of the screen.

27.5.5 Boil for 10 minutes and then decant the water.

27.5.6 Spread the sample on a level surface and observe the coating of the mix.

27.6 *Report*:

27.6.1 From the visual examination of the amount of coated and uncoated areas in the mixture, record the retained coating, after boiling, of the total sand surface area. If the coating is in excess of 50 percent, the emulsified asphalt should be considered as having a passing rating for classification of CSS emulsified asphalt.

27.7 *Precision and Bias*:

27.7.1 This test method, which requires a subjective evaluation of test results and reports only two possible conditions, does not lend itself readily to a statistical round-robin exercise. At present, there is no precision and bias statement for this test method.

COATING TESTS ON EMULSIFIED ASPHALTS

28. FIELD COATING TEST

28.1 *Scope*:

28.1.1 This is a quick field method to ascertain the compatibility of emulsified asphalt with the job aggregate.

28.2 *Significance and Use*:

28.2.1 This test method is used at the project site to determine (1) the ability of the emulsified asphalt to coat the job aggregate; (2) the ability of the emulsified asphalt to withstand mixing; and (3) the water resistance of the aggregate coated with emulsified asphalt.

28.3 *Summary of Test Method*:

28.3.1 A measured amount of the job aggregate is hand-mixed with a measured amount of the emulsified asphalt supplied to the job. The ability of the emulsified asphalt to remain as a coating during a 5-minute mixing cycle is observed. The resistance offered by the coating to washing off is determined by repeated filling of a container of coated aggregate with water and emptying.

28.4 *Apparatus*:

28.4.1 *Metal Containers*—$^{1}/_{2}$-L (1-Pt) capacity (friction-top pint cans).

28.4.2 *Metal Porcelain Saucepan*—2$^{1}/_{2}$- to 3-L (2$^{1}/_{2}$- to 3-qt), equipped with a handle.

28.4.3 *Dispensing Graduate*—50-mL capacity, preferably plastic.

28.4.4 *Serving Spoon*—Long-handled.

28.4.5 *Sieve*—A 19-mm ($^{3}/_{4}$-in.) sieve, made of wire cloth and conforming to M 92.

28.4.6 *Timer* —Graduated in 0.1 second and accurate within 0.1 percent when tossed over a 15-minute interval.

28.4.7 *Newspapers*.

28.5 *Procedure*:

28.5.1 Remove the rim from the $^{1}/_{2}$-L (1-Pt) can.

28.5.2 Fill the can level with the job aggregate, discarding any sizes above 19 mm ($^{3}/_{4}$ in.).

28.5.3 Measure out 50 mL of emulsified asphalt.

28.5.4 Transfer the aggregate and the emulsified asphalt into the saucepan.

28.5.5 Hand-mix vigorously for 5 minutes with the spoon.

28.5.6 Observe (1) whether the stone is fully coated with the emulsified asphalt and rate the coating as “good,” “fair,” or “poor,” using the ratings as defined in Section 16.7.1.1; and (2) the presence, if any, of free water, which denotes breakdown of the emulsified asphalt.

28.5.7 Refill the $^{1}/_{2}$-L (1-Pt) can with the coated stone.

28.5.8 Set the can of coated stone upright in the saucepan.

28.5.9 Fill the can with water and pour if off. Repeat this step five times.

28.5.10 Transfer the contents of the can onto newspapers. Repeat the observations made in Section 28.5.6 and record the ratings.

28.6 *Report*:

28.6.1 Report the observations made in Sections 28.5.6 and 28.5.10 as the results from this test.

28.7 *Precision and Bias*:

28.7.1 The usual methods of analysis for precision cannot be applied to this test method because it is not fully quantitative.

29. EMULSIFIED ASPHALT/JOB AGGREGATE COATING TEST

29.1 *Scope*:

29.1.1 This test method may be used to identify the ability of SS grades of emulsified asphalt to mix with and coat a dense and fine-graded job aggregate. It is a laboratory test method for screening emulsified asphalt candidates for mixing with and coating job aggregates and is not to be construed as a mix design test method.

29.2 *Significance and Use*:

29.2.1 The conditions of the test are designed to identify the ability of emulsified asphalt, SS grades (CSS from M 208 and SS from M 140), to mix with and coat dense-graded and fine-graded job aggregate.

29.3 *Summary of Test Method*:

29.3.1 A specified amount of dry job aggregate is hand-mixed with a specified amount of water in order to "pre-wet" the aggregate. The wetted aggregate is then hand-mixed with a specified amount of emulsified asphalt of known asphalt content, until the maximum coating of the job aggregate is obtained. (Mix time is usually 15 to 120 seconds) The ability of the emulsified asphalt to mix with the job aggregate is determined by using various amounts of water and emulsified asphalt until a maximum coating of the job aggregate is obtained. This coating is rated as "good," "fair," or "poor."

29.4 *Apparatus*:

29.4.1 *Containers*—A 1000-mL glass beaker, a 1.0-L (l-qt) friction-top metal can, or 1000-mL stainless steel beaker or bowl.

29.4.2 *Mixing Tool*—A steel spatula or its equivalent, having a blade approximately 203.2 mm (8 in.) in length.

29.4.3 *Balance*—Conforming to the requirements of M 231, Class G 2.

29.5 *Procedure*:

29.5.1 Add 300 g of dry job aggregate into the container. Add and record the amount of water necessary to "pre-wet" the aggregate (based on the dry mass of the aggregate). Immediately begin to mix vigorously for 1 minute or until all aggregate surfaces subjectively appear to be wetted (as a guide, use 2 to 8 percent water for dense-graded aggregate and 4 to 12 percent water for fine-graded aggregate). The natural moisture in a job aggregate may be used in the test if the moisture content is predetermined. Additional water may then be added, if necessary, to obtain the desired level of water to be used for "pre-wetting" the aggregate.

29.5.2 Add and record the amount of emulsified asphalt (of known asphalt residue content) necessary to coat the aggregate. Immediately begin to mix vigorously, scraping the sides and bottom of the container, for 15 to 120 seconds or until the maximum coating has been attained (as a guide, based on the dry mass of the aggregate, use 3 to 7 percent asphalt residue for dense-graded aggregate and

4 to 8 percent residue for fine-graded aggregate). For example: 8 percent emulsified asphalt in 60 percent solids would be equivalent to 4.8 percent asphalt residue in the mix.

29.5.3 If the mix appears to be too dry and insufficiently coated, repeat Section 29.5.1 or 29.5.2, using an increased amount of water or emulsified asphalt, or both. If the mix appears to be too wet from excessive water or emulsified asphalt, or both, repeat Section 29.5.1 or 29.5.2, using less water or emulsified asphalt, or both.

29.5.4 For each job aggregate mix, observe and record the amount of water used to "pre-wet" the aggregate and asphalt residue from the emulsified asphalt, and note the one mix that provides the best aggregate coating.

29.5.5 Rate the best coating as "good," "fair," or "poor," using the ratings as defined in Section 16.7.1.1.

29.6 *Report*:

29.6.1 Report the amount of water used to "pre-wet" the aggregate and residual asphalt needed for the best aggregate coating obtainable.

29.6.2 Report the maximum coating achieved as "good," "fair," or "poor" in accordance with Section 16.7.

29.7 *Precision and Bias*:

29.7.1 The usual methods of analysis for precision cannot be applied to this test method because it is not fully quantitative.

DENSITY OF EMULSIFIED ASPHALTS

30. TEST TO DETERMINE MASS PER LITER (GALLON)

30.1 *Scope*:

30.1.1 This test method is used to determine the mass per liter (gallon) of emulsified asphalt used in highway construction. This density is computed by determining the mass of emulsified asphalt contained in a standard measure of known volume.

Note 22—The calculation of Imperial Gallon Weight may be made by using proper conversion factors.

30.2 *Significance and Use*:

30.2.1 This test method provides a controlled laboratory test for the determination of quantitative volumes of emulsified asphalt for use in bills-of-lading, invoicing, and application rates.

30.3 *Apparatus*:

30.3.1 *Mass-per-Gallon Cup*—Stainless steel measure of known standard volume (83.2 mL).

30.3.2 *Balance*—Conforming to the requirements of M 231, Class G 2.

30.3.3 *Water Bath*—Capable of maintaining a constant temperature of 25 ± 0.5°C (77 ± 1°F).

30.3.4 *Timer*—Graduated in 0.1 second and accurate within 0.1 percent when tested over a 15-minute interval.

30.3.5 *Sieve*—A 0.850-mm (No. 20) sieve, made of wire cloth and conforming to M 92.

30.4 *Procedure*:

30.4.1 Stir the emulsified asphalt sample and place it in a constant-temperature water bath maintained at 25 ± 0.5°C (77 ± 1°F) for approximately 1 hour.

30.4.2 Place the measure and its cap on the balance, and zero the balance.

30.4.3 Remove the emulsified asphalt sample from the bath and stir it, using care to avoid trapping air in the sample. If necessary, strain it through an 850-mm (No. 20) sieve to remove any skin or film that might be present in the emulsified asphalt.

30.4.4 Bring the measure to approximately 25°C (77°F) and pour the emulsified asphalt into the measure, filling it completely.

30.4.5 Start placing the cap onto the measure, and remove, with a clean dry rag or paper, the excess emulsified asphalt oozing through the orifice in the cap.

30.4.6 When the cap is tightly placed on the measure, clean the measure carefully, and determine the mass on the tared balance to the nearest 0.01 g. Record this mass.

30.5 *Calculation*:

30.5.1 Calculate the mass per liter of emulsified asphalt as follows:

$$D_e = M_e \times 11.98 \tag{9}$$

where:

D_e = density of the emulsified asphalt, g/L; and

M_e = mass of the emulsified asphalt in the measure, g.

30.5.2 When desired, calculate the mass per gallon of emulsified asphalt as follows:

$$D_e = M_e/10 \tag{10}$$

where:

D_e = density of the emulsified asphalt, lb/gal; and

M_e = mass of the emulsified asphalt in the measure, g.

30.6 *Report*:

30.6.1 Report the density of emulsified asphalts in grams per liter (pounds per gallon) to the nearest 5 g (0.01 lb) at 25°C (77°F).

30.7 *Precision and Bias*:

30.7.1.1 The following criteria should be used for judging the acceptability of results (95 percent probability):

30.7.1.2 Duplicate results by the same operator should not be considered suspect unless they differ by more than the following amount:

Density	Repeatability
Grams per liter at 25°C (77°F)	0.019
Pounds per gallon at 25°C (77°F)	0.019

30.7.2 The results submitted by each of two laboratories should not be considered suspect unless they differ by more than the following amount:

Density	Reproducibility
Grams per liter at 25°C (77°F)	0.034
Pounds per gallon at 25°C (77°F)	0.034

Note 23—Mass per liter (gallon) at 25°C (77°F) may be translated to mass per liter (gallon) at 15.6°C (60°F) by using a multiplier of 1.00475.

31. KEYWORDS

31.1 Asphalt residue; cationic; coating; demulsibility; distillation; emulsified asphalt; evaporation; medium-setting; miscibility; particle charge; rapid-setting; settlement; slow-setting; storage stability; viscosity; water content.

Standard Method of Test for

Saybolt Viscosity

AASHTO Designation: T 72-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Saybolt Viscosity

AASHTO Designation: T 72-10

1. SCOPE

1.1 This test method covers the empirical procedures for determining the Saybolt Universal or Saybolt Furol viscosities of petroleum products at specified temperatures between 21 and 99°C (70 and 210°F). A special procedure for waxy products is indicated.

Note 1—T 201 and ASTM D 445 are preferred for the determination of kinematic viscosity. These methods require smaller samples and less time, and provide greater accuracy. Kinematic viscosities may be converted to Saybolt viscosities by use of the tables in ASTM D 2161. It is recommended that viscosity indexes be calculated from kinematic rather than Saybolt viscosities.

1.2 The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *Furol*—an acronym of "Fuel and road oils".

3.1.2 *Saybolt Furol viscosity*—the corrected efflux time in seconds of 60 mL (2 oz) of sample flowing through a calibrated Furol orifice under specified conditions. The viscosity value is reported in "Saybolt Furol seconds," abbreviated "SFS," at a specified temperature.

3.1.3 *Saybolt Universal viscosity*—the corrected efflux time in seconds of 60 mL (2 oz) of sample flowing through a calibrated Universal orifice under specified conditions. The viscosity value is reported in "Saybolt Universal seconds," abbreviated "SUS," at a specified temperature.

4. SUMMARY OF TEST METHOD

4.1 The efflux time in seconds of 60 mL of sample, flowing through a calibrated orifice, is measured under carefully controlled conditions. This time is corrected by an orifice factor and reported as the viscosity of the sample at that temperature.

5. SIGNIFICANCE AND USE

5.1 This test method is useful in characterizing certain petroleum products, as one element in establishing uniformity of shipments and sources of supply.

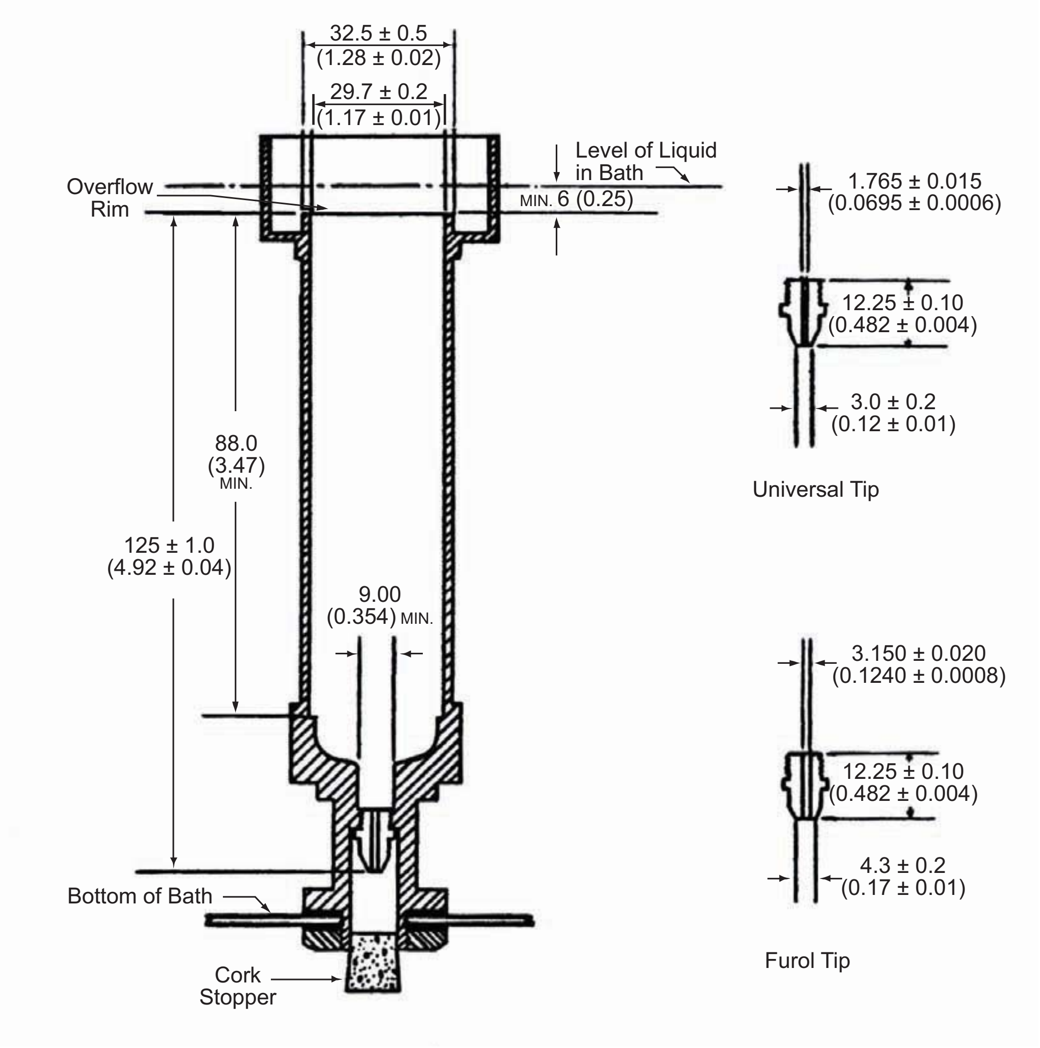
5.2 See ASTM D 117 for applicability to mineral oils used as electrical insulating oils.

5.3 The Saybolt Furol viscosity is approximately one tenth of the Saybolt Universal viscosity and is recommended for characterization of petroleum products such as fuel oils and other residual materials having Saybolt Universal viscosities greater than 1000 s.

5.4 Determination of the Saybolt Furol viscosity of asphalt materials at higher temperatures is covered by ASTM E 102.

6. APPARATUS

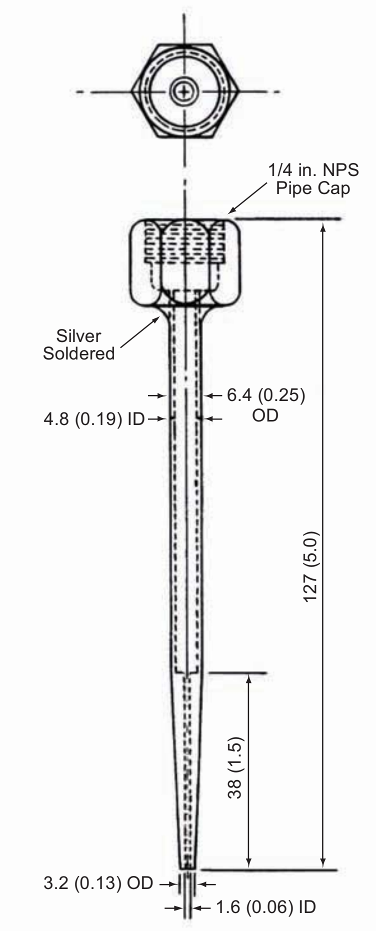
6.1 Saybolt Viscometer and Bath, as shown in Figure 1 and described in Annex A2.



Note—All dimensions are in millimeters (inches).

Figure 1—Saybolt Viscometer with Universal and Furol Orifice

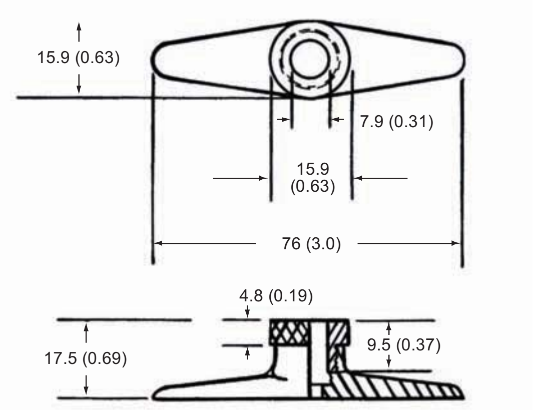
6.2 Withdrawal Tube, as shown in Figure 2, or other suitable device.



Note—All dimensions are in millimeters (inches).

Figure 2—Withdrawal Tube for Use with Saybolt Viscometer

6.3 *Thermometer Support*—One suitable design is shown in Figure 3.



Note—All dimensions are in millimeters (inches).

Figure 3—Thermometer Support

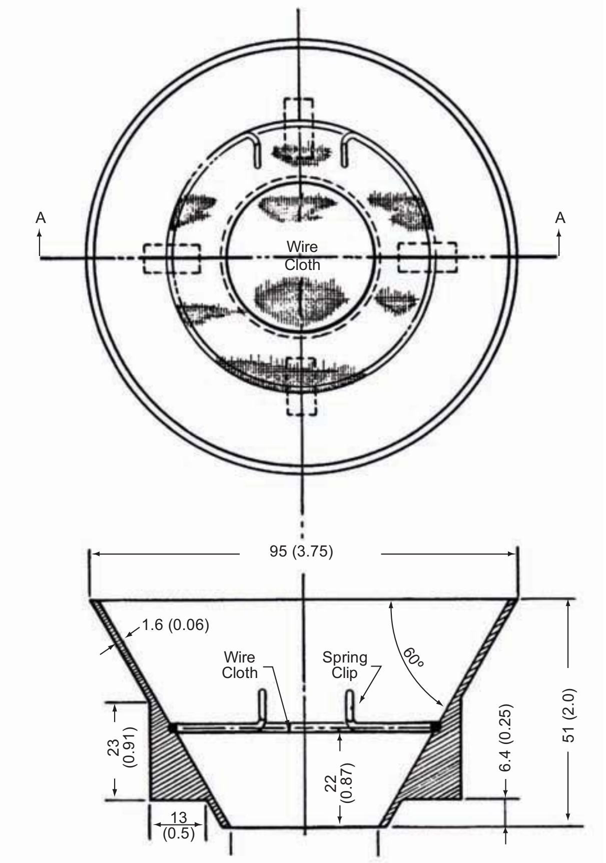
6.4 Saybolt Viscosity Thermometers, as listed in Table 1, for reading the temperature of the sample. Each thermometer shall conform to the requirements listed in ASTM E 1 for that ASTM Thermometer Number.

Table 1—ASTM Saybolt Viscosity Thermometers

Standard Test Temperature, °C (°F)	ASTM Thermometer Number	Thermometer	
		Range, °C (°F)	Subdivisions, °C (°F)
21.1 (70)	17C (17F)	19 to 27 (66 to 80)	0.1 (0.2)
25.0 (77)	17C (17F)	19 to 27 (66 to 80)	0.1 (0.2)
37.8 (100)	18C (18F)	34 to 42 (94 to 108)	0.1 (0.2)
50.0 (122)	19C (19F)	49 to 57 (120 to 134)	0.1 (0.2)
54.4 (130)	19C (19F)	49 to 57 (120 to 134)	0.1 (0.2)
60.0 (140)	20C (20F)	57 to 65 (134 to 148)	0.1 (0.2)
82.2 (180)	21C (21F)	79 to 87 (174 to 188)	0.1 (0.2)
98.9 (210)	22C (22F)	95 to 103 (204 to 218)	0.1 (0.2)

6.5 *Bath Thermometers*—Saybolt Viscosity thermometers, or any other temperature-indicating devices of equivalent accuracy.

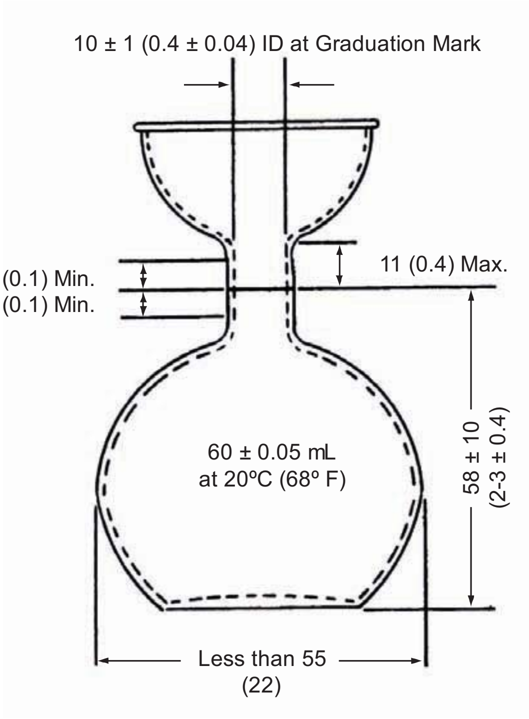
6.6 Filter Funnel, as shown in Figure 4, equipped with interchangeable 0.850-mm (No. 20), 0.150-mm (No. 100), and 0.075-mm (No. 200) wire-cloth inserts meeting the requirements of ASTM E 11 with respect to the wire cloth. Filter funnels of a suitable alternate design may be used.



Note—All dimensions are in millimeters (inches).

Figure 4—Filter Funnel for Use with Saybolt Viscometer

6.7 Receiving Flask, as shown in Figure 5.



Note—All dimensions are in millimeters (inches).

Figure 5—Receiving Flask

6.8 Timer, graduated in tenths of a second, and accurate to 0.1 percent when tested over a 60-min interval. Electric timers are acceptable if operated on a controlled-frequency circuit.

6.9 125-mL (4.2-oz.) Erlenmeyer flask

7. SAMPLING

7.1 Sample the material in accordance with T 40, as appropriate.

8. PREPARATION OF APPARATUS

8.1 Use a Universal orifice or tip for lubricants and distillates with efflux times greater than 32 s to give the desired accuracy. Liquids with efflux times greater than 1000 s are not conveniently tested with this orifice.

8.2 Use a Furol orifice or tip for residual materials with efflux times greater than 25 s to give the desired accuracy (see also Section 5.3).

8.3 Clean the viscometer thoroughly with an appropriate solvent of low toxicity; then remove all solvent from the viscometer and its gallery. Clean the receiving flask in the same manner.

Note 2—The plunger commonly supplied with the viscometer should never be used for cleaning as this might damage the overflow rim and walls of the viscometer.

8.4 Set up the viscometer and bath in an area where they will not be exposed to drafts or rapid changes in air temperature and dust or vapors that might contaminate a sample.

8.5 Place the receiving flask (Figure 5) beneath the viscometer so that the graduation mark on the flask is from 100 to 130 mm (4 to 5 in.) below the bottom of the viscometer tube and so that the stream of oil will just strike the neck of the flask.

8.6 Fill the bath to at least 6 mm ($^1/_4$ in.) above the overflow rim of the viscometer with an appropriate bath medium selected from Table 2.

8.7 Provide adequate stirring and thermal control for the bath so that the temperature of a test sample in the viscometer will not vary more than ±0.05°C (±0.09°F) after reaching the selected test temperature.

8.8 Do not make viscosity measurements at temperatures below the dew point of the room's atmosphere.

8.9 For calibration and referee tests, keep the room temperature between 20 and 30°C (68 and 86°F), and record the actual temperature. However, room temperatures up to 38°C (100°F) will not introduce errors in excess of 1 percent.

Table 2—Bath Media

Standard Test Temperature, °C (°F)	Bath Medium	Max Temp Differential,[a] °C (°F)	Bath Temperature Control Functional Precision, °C (°F)
21.1 (70)	water	± 0.05 (0.09)	± 0.05 (0.09)
25.0 (77)	water	± 0.05 (0.09)	± 0.05 (0.09)
37.8 (100)	water, or oil of 50 to 70 SUS viscosity at 37.8°C (100°F)	± 0.15 (0.27)	± 0.05 (0.09)
50.0 (122)	water, or oil of 120 to 150 SUS viscosity at 37.8°C (100°F)	± 0.20 (0.36)	± 0.05 (0.09)
54.4 (130)	water, or oil of 120 to 150 SUS viscosity at 37.8°C (100°F)	± 0.30 (0.54)	± 0.05 (0.09)
60.0 (140)	water, or oil of 120 to 150 SUS viscosity at 37.8°C (100°F)	± 0.50 (0.90)	± 0.05 (0.09)
82.2 (180)	water, or oil of 300 to 370 SUS viscosity at 37.8°C (100°F)	± 0.80 (1.40)	± 0.05 (0.09)
98.9 (210)	oil of 330 to 370 SUS viscosity at 37.8°C (100°F)	± 1.10 (2.0)	± 0.05 (0.09)

[a] Maximum permissible difference between bath and sample temperatures at the time of the test.

9. CALIBRATION AND STANDARDIZATION

9.1 Calibrate the Saybolt Universal viscometer at intervals of not more than three years by measuring the efflux time at 37.8°C (100°F) of an appropriate viscosity oil standard, following the procedure given in Section 10. See Annex A2 for viscosity oil standards available.

9.2 The efflux time of the viscosity oil standard shall equal the certified Saybolt viscosity value. If the efflux time differs from the certified value by more than 0.2 percent, calculate a correction factor, F, for the viscometer as follows:

$$F = V/t \quad (1)$$

where:

V = Certified Saybolt viscosity of the standard; and

t = Measured efflux time at 37.8°C (100°F), s.

Note 3—If the calibration is based on a viscosity oil standard having an efflux time between 200 and 600 s, the correction factor applies to all viscosity levels at all temperatures.

9.3 Calibrate the Saybolt Furol viscometer at 50°C (122°F) as discussed in Section 9.1, using a viscosity oil standard having a minimum efflux time of 90 s.

9.4 Viscometers or orifices requiring corrections greater than 1.0 percent shall not be used in referee testing.

10. PROCEDURE

10.1 Establish and control the bath temperature at the selected test temperature.

10.1.1 Standard test temperatures for measuring Saybolt Universal viscosities are 21.1, 37.8, 54.4, and 98.9°C (70, 100, 130, and 210°F).

10.1.2 Standard test temperatures for measuring Saybolt Furol viscosities are 25.0, 37.8, 50.0, and 98.9°C (77, 100, 122, and 210°F).

10.1.3 Other standard test temperatures in use include 60.0 and 82.2°C (140 and 180°F).

10.2 Insert a cork stopper into the air chamber at the bottom of the viscometer; a small chain or cord may be attached to the cork to facilitate rapid removal. The cork shall fit tightly enough to prevent the escape of air, as evidenced by the absence of oil on the cork when it is withdrawn as described in Section 10.9.

10.3 If the selected test temperature is above room temperature, the test may be expedited by preheating the sample in its original container to not more than 1.7°C (3.0°F) above the test temperature.

10.4 Stir the sample well; then strain it through a wire cloth of appropriate mesh directly into the viscometer until the level is above the overflow rim. The wire cloth shall be 0.150-mm (No. 100) mesh except as noted in T 59.

10.5 For liquid asphalt materials having highly volatile components, such as rapid-curing and medium-curing cutbacks, preheating the material in an open container shall not be permitted. The material shall be poured at room temperature into the viscometer, or if the material is too viscous to pour conveniently at room temperature, it shall be warmed sufficiently by placing the sample in the original container in a water bath at 50°C (122°F) for a few minutes prior to pouring. The step that requires filtering through a wire cloth shall be omitted for liquid asphalt materials containing highly volatile components. For tests on these materials above room temperature, greater temperature differentials than indicated in Table 2 will be permitted during the heating period, but the bath temperature must be adjusted within the prescribed limits prior to the final minute of stirring (during which the temperature of the sample remains constant).

10.6 The viscosities of steam-refined cylinder oils, black lubricating oils, residual fuel oils, and similar waxy products can be affected by their thermal histories. Use the following preheating procedure with such products to obtain uniform results at temperatures below 93°C (200°F):

10.6.1 Heat the sample in its original container to about 50°C (122°F), while stirring and shaking it to dissolve and blend waxy materials. Probe the bottom of the container with a stirring rod to ensure that all waxy materials are in solution, and then mix the solution well.

10.6.2 Pour about 100 mL into a 125-mL (4.2-oz) Erlenmeyer flask. Stopper the flask loosely with a cork or rubber stopper.

10.6.3 Immerse the flask in a bath of boiling water for 30 min.

10.6.4 Mix the solution well and remove the sample from the boiling water bath. Wipe the outside of the flask dry, and strain the sample through the 0.075-mm (No. 200) wire cloth in the filter funnel directly into the viscometer until the level is above the overflow rim. Complete the viscosity test within 1 h after reheating.

10.7 Stir the sample in the viscometer with the appropriate viscosity thermometer equipped with the thermometer support (Figure 3). Use a circular motion at 30 to 50 r/min in a horizontal plane. When the sample temperature remains constant within 0.05°C (0.09°F) of the test temperature during 1 min of continuous stirring, remove the thermometer.

Note 4—Never attempt to adjust the temperature by immersing hot or cold bodies in the sample. Such thermal treatment might affect the sample and the precision of the test.

10.8 Immediately place the tip of the withdrawal tube (Figure 2) in the gallery at one point, and apply suction to remove oil until its level in the gallery is below the overflow rim. Do not touch the overflow rim with the withdrawal tube in order to avoid reducing the effective liquid head of the sample.

10.9 Ensure that the receiving flask is in proper position. Then snap the cork from the viscometer, and start the timer at the same instant. A small chain or cord may be attached to the cork to facilitate rapid removal.

10.10 Stop the timer the instant the bottom of the oil meniscus reaches the graduation mark on the receiving flask. Record the efflux time in seconds to the nearest 0.1 s.

11. CALCULATION AND REPORT

11.1 Multiply the efflux time by the correction factor for the viscometer determined in Section 9.2.

11.2 Report the corrected efflux time as the Saybolt Universal or Saybolt Furol viscosity of the oil at the temperature at which the test was performed.

11.2.1 Report the viscosity values to the nearest whole second.

12. PRECISION AND BIAS

12.1 *Results should not differ from the mean by more than the following (see Note 5)*:

12.1.1 Repeatability (one operator and apparatus)—1 percent.

12.1.2 Reproducibility (different operators and apparatus)—2 percent.

Note 5—For petroleum products, the precision and bias are based on data from ASTM E 102.

13. KEYWORDS

13.1 Asphalt materials; kinematic; Saybolt; viscosity.

ANNEXES

(Mandatory Information)

A1. SAYBOLT VISCOMETER AND ACCESSORIES

A1.1. *Viscometer*—The viscometer, illustrated in Figure 1, shall be constructed entirely of corrosion-resistant metal, conforming to the dimensional requirements shown in Figure 1. The orifice tip, Universal or Furol, may be constructed as a replaceable unit in the viscometer. Provide a nut at the lower end of the viscometer for fastening it in the bath. Mount the viscometer vertically in the bath, and test the alignment with a spirit level on the plane of the gallery rim. Provide a cork or other suitable means to prevent the flow of material until the start of the test; a small chain or cord may be attached to the cork to facilitate rapid removal.

A1.2. *Bath*—The bath serves both as a support to hold the viscometer in a vertical position as well as the container for the bath medium. Equip the bath with effective insulation and with an efficient stirring device. Provide the bath with a coil for heating and cooling and with thermostatically controlled heaters capable of maintaining the bath within the functional precision given in Table 2. The coil should be located at least 75 mm (3 in.) from the viscometer. Provide a means for maintaining the bath medium at least 6 mm (0.25 in.) above the overflow rim. The bath media are given in Table 2.

A2. VISCOSITY STANDARDS

A2.1. *Saybolt Viscosity Standards*—Certified Saybolt viscosity oil standards conforming to ASTM requirements are established by Saybolt viscosity values by cooperative determinations of kinematic viscosity values. The kinematic values are converted to Saybolt Universal and Saybolt Furol viscosity values by means of conversion tables given in ASTM D 2161. The approximate Saybolt viscosities are shown in Table A2-1.

Table A2-1—Saybolt Viscosity Oil Standards [a]

Note—All values are nominal and will vary by lot.

Viscosity Oil Standard	At 37.8°C (100°F)		At 98.9°C (210°F)		At 50°C (122°F)	
	SUS	mm^2/s	SUS	mm^2/s	SUS	mm^2/s
S3	36	3.0	—	—	—	—
S6	46	6.0	—	—	—	—
S20	100	20	—	—	—	—
N26	130	27	—	—	—	—
N35	170	35	—	—	—	—

N250	1300	280	140	29	—	—
N350	1570	340	160	32	—	—
N415	2180	470	200	41	—	—
S600	—	—	240	50	120	310
S2000	—	—	360	72	—	—

Note: All values are nominal and will vary by lot.

[a] These viscosity oil standards are available in 0.5-L (16.9-oz) containers from the Cannon Instrument Co., 2139 High Tech Rd., State College, PA 16803.

A2.2. *Standards Conforming to ASTM Saybolt Viscosity Standards*—The viscosity standards may also be used for routine calibrations at other temperatures as shown in Table A2-1. Other reference liquids, suitable for routine calibrations, may be established by selecting stable oils covering the desired range and determining their viscosities in a viscometer calibrated with a standard conforming to ASTM requirements.

A2.3. *Routine Calibrations*—The viscosity standards may also be used for routine calibrations at other temperatures as shown in Table A2-1.

Standard Method of Test for

Distillation of Cutback Asphaltic (Bituminous) Products

AASHTO Designation: T 78-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Distillation of Cutback Asphaltic (Bituminous) Products

AASHTO Designation: T 78-10

1. SCOPE

1.1 This test method covers a distillation test for cut-back asphalt products.

1.2 The values given in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

3. SUMMARY OF METHOD

3.1 Two hundred milliliters (6.8-oz) of the sample are distilled in a 500-mL (16.9-oz) flask, at a controlled rate, to a temperature in the liquid of 360°C (680°F), and the volumes of distillate obtained at specified temperatures are measured. The residue from the distillation, and also the distillate itself, may be tested as required.

4. SIGNIFICANCE AND USE

4.1 This procedure measures the amount of the more volatile constituents in cut-back asphalt products. The properties of the residue after distillation are not necessarily characteristic of the asphalt used in the original mixture, nor of the residue which may be left at any particular time after field application of the cut-back asphalt product. The presence of silicone in the cut-back asphalt product may affect the distillation residue by retarding the loss of volatile material after the residue has been poured into the residue container.

5. APPARATUS

5.1 *Distillation Flask*—500-mL (16.9-oz) side-arm type, having the dimensions shown in Figure 1.

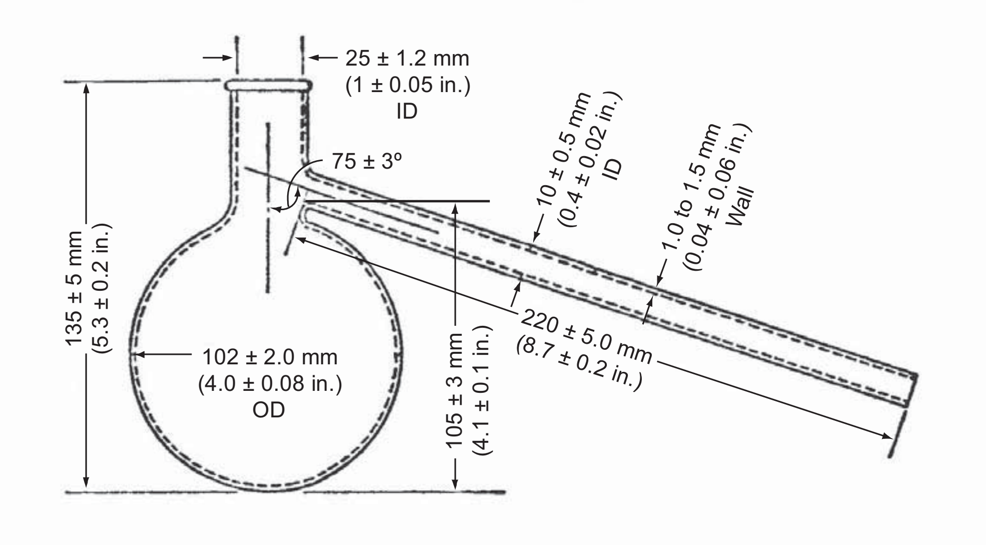

Figure 1—Distillation Flask

5.2 *Condenser*—Standard glass-jacketed, of nominal jacket length from 200 to 300 mm (7.9 to 11.8 in.) and overall tube length of 450 ± 10 mm (17.7 ± 0.4 in.) (see Figure 2).

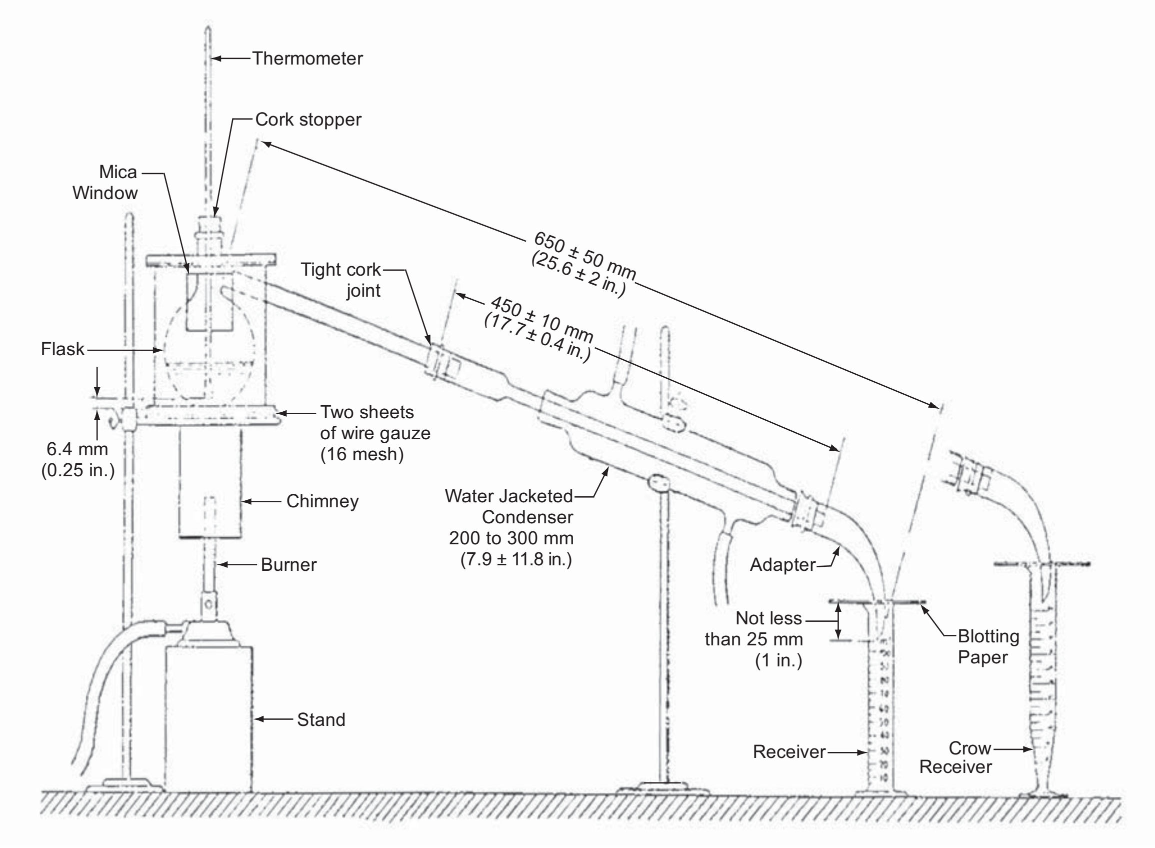

Figure 2—Distillation Apparatus

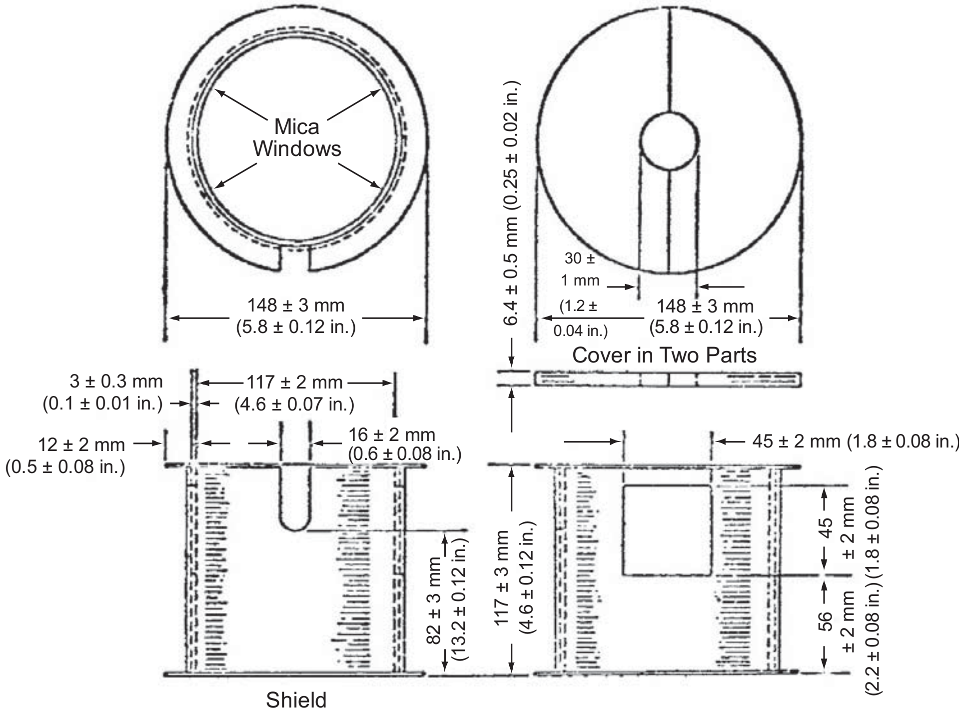
5.3 *Shield*—Steel, lined with 3-mm (0.1-in.) fireproof insulation and fitted with transparent mica windows, of the form and dimensions shown in Figure 3, used to protect the flask from air currents and to reduce radiation. The cover (top) shall be made in two parts of 6.4-mm (0.25-in.) fireproof insulation.



Flanged Open-End Cylinder made of 22-gauge galvanized iron with 3-mm (0.1-in.) fireproof lining riveted to metal

Two Mica Windows are provided at right angles to the end slot.

Figure 3—Shield

5.4 *Adapter*—Heavy-wall [1-mm (0.04-in.)] glass, with a reinforced top, having an angle of approximately 105 degrees. The inside diameter at the large end shall be approximately 18 mm (0.7 in.), and at the small end, not less than 5 mm (0.2 in.). The lower surface of the adapter shall be on a smooth descending curve from the larger end to the smaller. The inside line of the outlet end shall be vertical, and the outlet shall be cut or ground (not fire-polished) at an angle of 45 ± 5 degrees to the inside line. Figure 2 indicates the appropriate location of the adapter in the distillation apparatus.

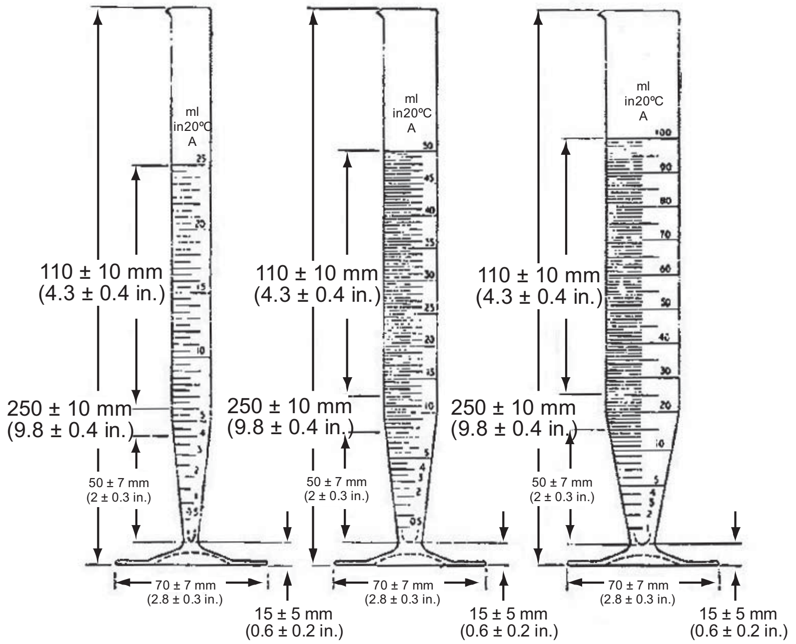
5.5 *Shield and Flask Support*—Two 15-cm^2 (2.3-in.^{2}) sheets of 1.18-mm (No. 16)-mesh Chromel wire gauze on a tripod or ring.

5.6 *Heat Source*:

5.6.1 Adjustable Tirrill-type gas burner or equivalent.

5.6.2 An electric heater equipped with a transformer capable of controlling from 0 to 750 W. The shield and support shall be a refractory with an opening of 79 mm (3.1 in.), with the upper surface beveled to 86 mm (3.4 in.) to accommodate the specified 500-mL (16.9-oz) flask. When the flask is placed on the refractory, there should be a distance of approximately 3 mm (0.1 in.) between the bottom of the flask and the heating elements.

5.7 *Receiver*—A standard 100-mL (3.4-oz) graduated cylinder conforming to the dimensions of ASTM E 133, or a 100-mL (3.4-oz) Crow receiver as shown in Figure 4.



Note—All dimensions are in millimeters (inches).

Figure 4—Crow Receivers of 25- (0.8-), 50- (1.7-), and 100-mL (3.4-oz) Capacity

Note 1—Receivers of smaller capacity having 0.1-mL (0.003-oz) divisions may be used when low volumes of total distillate are expected and the added accuracy required.

5.8 *Residue Container*—A seamless metal container with a slip-on cover of 75 ± 5 mm (3.0 ± 0.2 in.) in diameter and 55 ± 5 mm (2.2 ± 0.2 in.) in height.

5.8.1 **Caution**—Provide a cover suitable in size and material to extinguish a flame in the residue container if the residue flames after pouring.

5.9 *Thermometer*—ASTM high-distillation thermometers having a range from –6 to 400°C (20 to 760°F) and conforming to the requirements for Thermometer 8C (8F) as prescribed in ASTM E 1, or IP Thermometer 6C conforming to IP Specifications for Standard Thermometers, or an equivalent thermometric device that has been calibrated in accordance with ASTM E 220. ASTM 8C Thermometers shall be used for referee testing.

5.10 *Balance*—Conforming to the requirements of M 231, Class G 2.

5.11 Thermometers as specified in IP Standards.

5.12 Crow Receiver as specified in British Standards 658:1989.

6. SAMPLING

6.1 Stir the sample thoroughly, warming it if necessary, to ensure homogeneity before removal of a portion for analysis.

6.2 If sufficient water is present to cause foaming or bumping, dehydrate a sample of not less than 250 mL (8.5-oz) by heating it in a distillation flask sufficiently large to prevent foaming over into the side-arm. When foaming has ceased, stop the distillation. If any light oil has distilled over, separate and pour this material back into the flask when the contents have cooled just sufficiently to prevent the loss of volatile oil. Mix the contents of the flask thoroughly before removal of a portion for analysis. An alternative procedure is described in ASTM D 370.

7. PREPARATION OF APPARATUS

7.1 Calculate the mass of 200 mL (6.8-oz) of the sample from the specific gravity of the material at 15.6/15.6°C. Add this amount ± 0.5 g into the 500-mL (16.9-oz) flask.

7.2 Place the flask in the shield supported by two sheets of gauze on a tripod or ring. Connect the condenser tube to the tubulature of the flask with a tight cork joint. Clamp the condenser so that the axis of the bulb of the flask through the center of its neck is vertical. Adjust the adapter over the end of the condenser tube so that the distance from the neck of the flask to the outlet of the adapter is 650 ± 50 mm (25.6 ± 2.0 in.) (see Figure 3).

7.3 Insert the thermometer through a tightly fitting cork in the neck of the flask so that the bulb of the thermometer rests on the bottom of the flask. Raise the thermometer 6 mm (0.25 in.) from the bottom of the flask using the scale divisions on the thermometer to estimate the 6-mm (0.25-in.) distance above the top of the cork.

7.4 Protect the burner by a suitable shield or chimney. Place the receiver so that the adapter extends at least 25 mm (1 in.) but not below the 100-mL (3.4-oz) mark. Cover the graduate closely with a piece of blotting paper, or similar material, suitably weighted, which has been cut to fit the adapter snugly.

7.5 The flask, condenser tube, adapter, and receiver shall be clean and dry before starting the distillation. Place the seamless residue container on its cover in an area free from drafts.

7.6 Pass cold water through the condenser jacket. Use warm water, if necessary, to prevent formation of solid condensate in the condenser tube.

8. PROCEDURE

8.1 Correct, to the nearest 1°C (2°F), the temperatures to be observed in the distillation for barometric pressure in millimeters of mercury. If the prevailing barometric pressure in millimeters of mercury is known, correct the temperature to be observed with the factors shown in Table 1. Do not correct for the emergent stem of the thermometer if used. See the example corrections that follow.

Correction = (Observed pressure in mm Hg – 760) × Correction per mm Hg

Correction per mm Hg = $^{1}/_{10}$ the correction per 10 mm Hg given in Table 1

Example:

Barometric Pressure = 748 mm Hg

Nominal Observation Temperature = 260°C (500°F)

Celsius Correction = (748 – 760) × (0.632/10) = –0.758

Corrected Temperature = 260 – 0.758 = 259°C (rounded to nearest 1°C)

Fahrenheit Correction = (748 – 760) × (1.138/10) = –1.366

Corrected Temperature = 500 – 1.366 = 498°F (rounded to nearest 2°F)

Note 2—Table 1 covers a wide range of temperatures from 160 to 360°C (320 to 680°F) and is preferred for worldwide specifications other than ASTM or IP specifications.

Table 1—Factors for Calculating Temperature Corrections

Nominal Temperature, °C (°F)	Correction per 10 mm Hg Difference in Pressure,[a] °C (°F)
160 (320)	0.514 (0.925)
175 (347)	0.531 (0.957)
190 (374)	0.549 (0.989)
225 (437)	0.591 (1.063)
250 (482)	0.620 (1.116)
260 (500)	0.632 (1.138)
275 (527)	0.650 (1.170)
300 (572)	0.680 (1.223)
315.6 (600)	0.698 (1.257)
325 (617)	0.709 (1.277)
360 (680)	0.751 (1.351)

[a] To be subtracted when the barometric pressure is below 760 mm Hg; to be added when the barometric pressure is above 760 mm Hg.

8.2 Apply heat so that the first drop of distillate falls from the end of the flask side-arm in 5 to 15 min. Conduct the distillation so as to maintain the following drop rates (count the drop count to be made at the tip of the adapter):

- 50 to 70 drops per minute up to 260°C (500°F)
- 20 to 70 drops per minute between 260 and 316°C (500 and 600°F)
- Not over 10 min to complete distillation from 316 to 360°C (600 to 680°F)

Note 3—Some cut-back asphalt products yield either no distillate or very little distillate over portions of the temperature range up to 316°C (600°F). In this case, it becomes impractical to maintain the distillation rates above. For such cases the intent of the method shall be met if the rate of temperature rise exceeds 5°C (9°F)/min.

8.2.1 Record the volumes of distillate to the nearest 0.5 mL (0.02-oz) in the receiver at the corrected temperatures. If the volume of distillate recovered is critical, use receivers graduated in 0.1-mL (0.003-oz) divisions and immersed in a transparent bath maintained at 15.6 ± 3°C (60 ± 5°F).

8.3 When the temperature reaches the corrected temperature of 360°C (680°F), discontinue the heat, and remove the flask and thermometer. With the flask in a pouring position, remove the thermometer, and immediately pour the contents into the residue container. The total time from discontinuing the heat to starting the pour shall not exceed 30 s. When pouring, the side-arm should be substantially horizontal to prevent condensate in the side-arm from returning to the residue.

Note 4—The formation of skin on the surface of a residue during cooling entraps vapors which will condense and cause higher penetration results when they are stirred back into the sample. If skin begins to form during cooling, it should be gently pushed aside. This operation can be done with a spatula with a minimum of disturbance to the sample.

8.4 Allow the condenser and any distillates trapped in the condenser neck to drain into the receiver, and record the total volume of distillate collected as total distillate up to 360°C (680°F).

8.5 When the residue has cooled until the point that fuming just ceases, stir it thoroughly, and, when the material reaches 135 ± 5°C (275 ± 9°F), pour the residue into the appropriate receptacles for testing properties such as penetration, viscosity, or softening point. Proceed as required by the appropriate method from the point that follows the pouring stage.

8.6 If desired, the distillate, or the combined distillates from several tests, may be submitted to a further distillation, in accordance with IP 123 or ASTM D 86, or when the distillate is of coal-tar origin, Method C.O.3.

9. CALCULATION AND REPORT

9.1 *Asphalt Residue*—Calculate the percent residue to the nearest 0.1 as follows:

$$R = [(200 - TD/200] \times 100$$

where:

R = residue content, in volume percent, and

TD = total distillate recovered up to 360°C (680°F), mL.

9.1.1 Report the percent volume by difference as the residue from distillation up to 360°C (680°F).

9.2 *Total Distillate*—Calculate the percent total distillate to the nearest 0.1 as follows:

$$TD\% = TD/200 \times 100$$

9.2.1 Report the volume percent as the total distillate up to 360°C (680°F).

9.3 *Distillate Fractions*:

9.3.1 Determine the percentages by volume of the original sample by dividing the observed volume (in milliliters) of the fraction by 2. Report the volume percent to the nearest 0.1as follows:

- Up to 190°C (374°F)
- Up to 225°C (437°F)
- Up to 260°C (500°F)
- Up to 316°C (600°F)

9.3.2 Determine the percentages by volume of total distillate by dividing the observed volume (in milliliters) of the fraction by the milliliters recovered up to 360°C (680°F) and multiplying by 100. Report the distillate, volume percent of total distillate to 360°C (680°F), to the nearest 0.1 as follows:

- Up to 190°C (374°F)
- Up to 225°C (437°F)
- Up to 260°C (500°F)
- Up to 316°C (600°F)

9.4 Where penetration, viscosity, or other tests have been performed, report the results with reference to this test method as well as to any other method used.

9.4.1 *Example*—Penetration by T 49 of residue obtained from T 78.

10. PRECISION AND BIAS

10.1 *The following criteria shall be used for judging the acceptability of results (95 percent probability)*:

10.1.1 *Repeatability*—Duplicate values by the same operator shall not be considered suspect unless the determined percentages differ by more than 1.0 "volume percent" of the original sample.

10.1.2 *Reproducibility*—The values reported by each of two laboratories shall not be considered suspect unless the reported percentages differ by more than the following:

Distillation fractions, volume percent of the original sample:

Up to 175°C (347°F)	3.5
Above 175°C (347°F)	2.0
Residue, volume percentage by difference from the original sample	2.0

10.2 Criteria for judging variability of test results on the distillation residue have not been determined.

11. KEYWORDS

11.1 Cut-back asphalt; distillate; residue.

Standard Method of Test for

Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3°C (200°F)

AASHTO Designation: T 79-96 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Flash Point with Tag Open-Cup Apparatus for Use with Material Having a Flash Point Less Than 93.3°C (200°F)

AASHTO Designation: T 79-96 (2008)

1. SCOPE

1.1. This method covers the procedure for the determination of flash points by the tag open-cup apparatus of cutback asphalts having flash points of less than 93.3ºC (200ºF).

The sample is placed in the tester and heated at a slow and constant rate. A small test flame is passed at a uniform rate in a level plane across the cup at specified intervals. The flash point is the lowest temperature at which application of the test flame causes the vapor at the surface of the liquid to flash.

Note 1—Specifications commonly designate the Cleveland Open-Cup method (AASHTO T 48) for asphalt binders and cutback asphalts having flash points above 79.5ºC (175ºF).

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This test may involve hazardous materials, operations, and equipment. This test does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 48, Flash and Fire Points by Cleveland Open Cup

2.2. *ASTM Standard*:

- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. APPARATUS

3.1. *Tag Open-Cup Tester*—This apparatus consists of a glass test cup, copper water bath, thermometer holder, small gas burner, ignition taper, liquid leveling device, and draft shield. The apparatus is described in detail in Appendix X1.

3.2. *Thermometer*—A Pensky-Martens, low-range thermometer capable of measuring –5 to 110ºC (20 to 230ºF) and conforming to the requirements for an ASTM Thermometer No. 9C (9F) as prescribed in ASTM E 1 shall be used.

4. BATH MEDIA

4.1. Water for flash points up to 79.5ºC (175ºF).

4.2. Water-glycol solution (1:1) for flash points above 79.5ºC (175ºF).

5. ASSEMBLY AND PREPARATION OF APPARATUS

5.1. The tag open-cup tester shall be placed in a firm and level position on a solid, vibration-free table in a draft-free hood or flash room, or well toward the back of a draft shield such as that described in Section X1.1.7. The top of the tester shall be shielded from strong light so that the flash may be easily seen. A room temperature of 25 ± 5ºC (77 ± 9ºF) should be maintained throughout the test.

5.2. Adjust the horizontal and vertical positions of the ignition taper so that the jet passes on the circumference of a circle having a radius of 152 mm (6 in.) and in a level plane, 3.2 mm ($^1/_8$ in.) above the upper edge of the cup as measured from the center of the orifice. The jet should pass across the center of the cup. These adjustments should be made only when required, as usually the apparatus is used continuously for a series of tests.

Note 2—The leveling device is used as a gauge to adjust the height of the taper.

6. PROCEDURE

6.1. Place the glass test cup in the metal bath, and adjust the thermometer holder so that the thermometer is supported firmly in a vertical position halfway between the center and edge of the cup and on a line passing through the center of the cup and the pivot of the taper. Place the thermometer so that the bottom of the bulb is 6.4 mm ($^1/_4$ in.) above the inner bottom of the cup.

6.2. Fill the metal bath with water or water-glycol solution having a temperature at least 16.5ºC (30ºF) below the probable flash point of the material to be tested. Cool tap water is satisfactory in most instances when water is used, and may be introduced into the chamber between the bath and sample cups until a slight overflow is noted at the overflow spout. The bath should be filled to a level approximately 3.2 mm ($^1/_8$ in.) from the top of the bath when the test cup is in place.

6.3. Rest the metal leveling device on the rim of the cup, and fill the cup with material to be tested until the level of material just touches the pointers of the leveling device [this level should be approximately 3.2 mm ($^1/_8$ in.) below the rim of the cup].

Note 3—The test sample should be at least 10ºC (18ºF) below the anticipated flash point.

6.4. Light the ignition taper, and adjust the test flame to approximately the same size as the comparison bead or the reference hole in the leveling device, but in no case greater than 4 mm ($^5/_{32}$ in.).

6.5. Apply heat to the bath so that the temperature of the sample rises at the rate of 1.0 ± 0.3ºC (2.0 ± 0.5ºF) per minute.

6.6. At 10 to 15ºC (18 to 27ºF) below the anticipated flash point, adjust the sample level in the test cup (a syringe or medicine dropper provides a convenient means of removing material from the cup). At successive 1ºC (2ºF) intervals, pass the ignition taper across the sample in a continuous motion so that the time consumed for each pass is 1 second. The center of the test flame must move in a plane, 3.2 mm ($^1/_8$ in.) above the upper edge of the cup passing in one direction first, then in the opposite direction at the next successive temperature.

6.7. Record, as the flash point, the temperature read on the thermometer at the time the test flame application causes a distinct flash in the interior of the test cup.

7. REPORT

7.1. Report the lowest temperature, in degrees Celsius or Fahrenheit, at which the initial flash is noted as the Tag Open-Cup Flash Point.

APPENDIX

(Nonmandatory information)

X1. APPARATUS

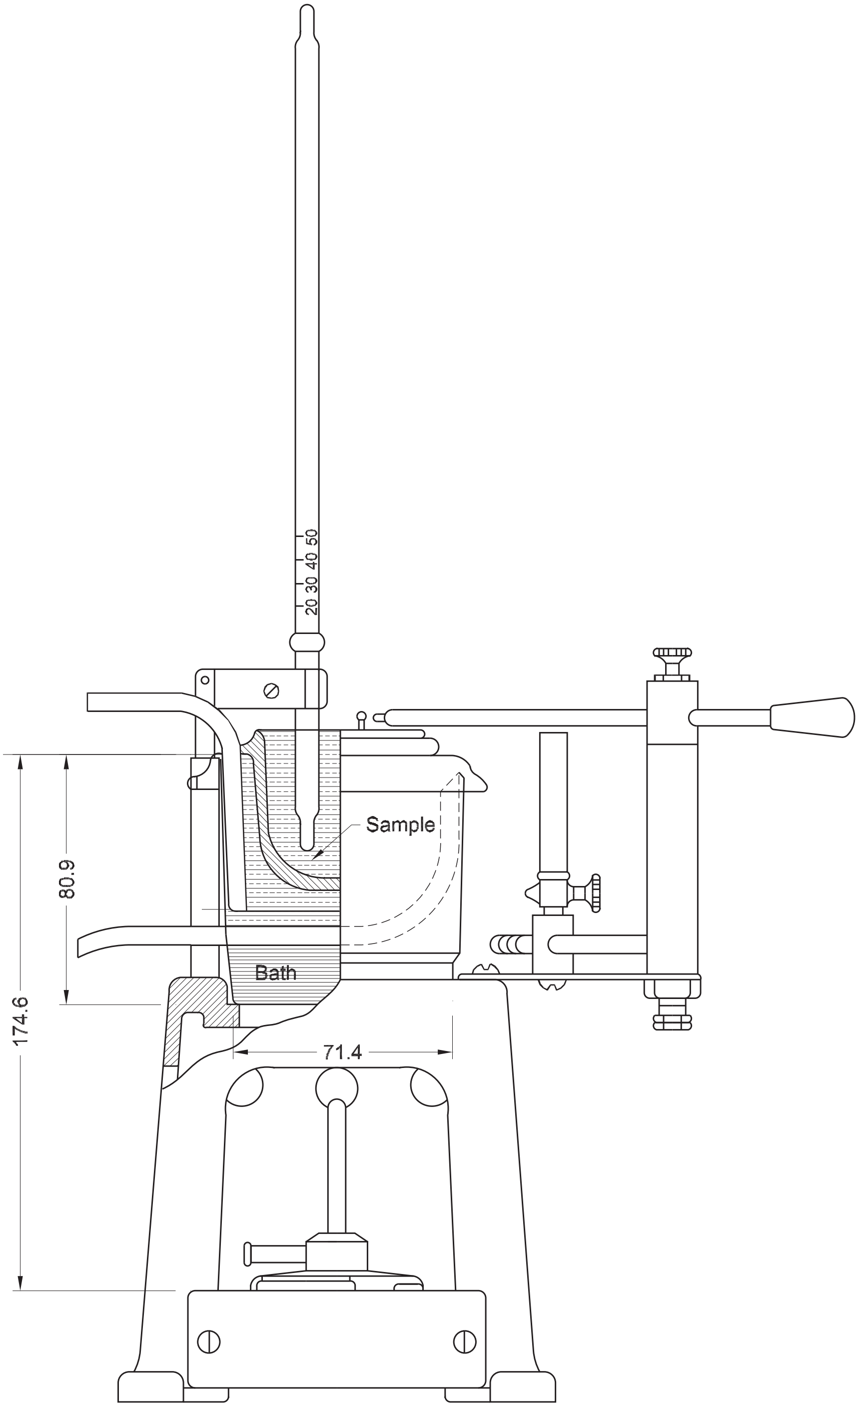
X1.1. The Tag Open-Cup Tester is shown in Figure X1.1. It consists of the following parts, which must conform to the dimensions shown, and have the additional characteristics as noted:

X1.1.1. *Copper Bath*—Equipped with a constant-level overflow so placed as to maintain the bath liquid level 3.2 mm ($^1/_8$ in.) below the ridge of the glass cup.

X1.1.2. *Thermometer Holder*—Supplied with the tester as shown in Figure X1.1. It shall support the thermometer firmly in a vertical position.

X1.1.3. *Glass Test Cup* (Figure X1.2)—Of molded clear glass, annealed, heat-resistant, and free from surface defects.

X1.1.4. *Filling Level Gauge* (Figure X1.3)—For proper adjustment of the liquid level in the cup. This device shall be made of suitable metal at least 3.2 mm ($^1/_8$ in.) thick, with two projections for adjusting the liquid level in the glass cup to 3.18 ± 0.25 mm (0.125 ± 0.01 in.) below the top edge or rim of the cup. Also, the holes in the leveling device may be used to adjust the size of the test flame and for gauging the height of the taper above the edge of the cup.



Dimensional Equivalents

Millimeters	Inches
71.4	2 $^{13}/_{16}$
80.9	3 $^{3}/_{16}$
174.6	6 $^{7}/_{8}$

Note: All dimensions are shown in millimeters unless otherwise noted.

Figure X1.1—Tag Open-Cup Tester

	Millimeters	Inches
A	51.6 ± 1.6	2.03 ± 0.063
B	38.1 ± 1.6	1.50 ± 0.063
C	7.9 ± 0.8	0.31 ± 0.031
D Outside diameter	55.1 ± 1.9	2.17 ± 0.075
E Outside diameter	50.8 ± 1.6	2.00 ± 0.063

Figure X1.3—Filling Level Gauge

X1.1.5. *"Micro" or Small Gas Burner*—Of suitable dimensions for heating the bath. A screw clamp may be used to help regulate the gas. A small electric heater controlled by a variable power transformer may be used.

X1.1.6. *Ignition Taper*—A small, straight, blowpipe-type gas burner. The tip of the taper should be approximately 1.6 mm ($^1/_{16}$ in.) in diameter. The ignition taper should be maintained in a fixed horizontal plane above the test cup by means of a swivel device so that the test flame passes on the circumference of a circle having a radius of at least 152 mm (6 in.). A comparison bead, 4.0 mm ($^5/_{32}$ in.) in diameter, may be mounted in a convenient spot. If mounted on the ignition taper, a portion of the tip of the taper, 1.6 mm ($^1/_{16}$ in.) in diameter, shall extend at least 3 mm ($^1/_8$ in.) beyond the bead.

X1.1.7. *Draft Shield*—A suitable shield may be made of two rectangular sheets of noncombustible material, 610 by 710 mm (24 by 28 in.), fastened together along the 710 mm (28 in.) side, preferably by hinges. A triangular sheet, 610 by 610 by 860 mm (24 by 24 by 34 in.), is fastened by hinges to one of the lateral sheets to form a top when the shield is open. The interior of the draft shield shall be painted a flat black.

Standard Method of Test for

Spot Test of Asphaltic Materials

AASHTO Designation: T 102-09

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Spot Test of Asphaltic Materials

AASHTO Designation: T 102-09

1. SCOPE

1.1. This method of test is applicable only to asphaltic products derived from petroleum and should not be applied to natural asphalts containing nonbituminous matter insoluble in xylene.

1.2. Materials, which by use of standard solvent are classed as positive, may be further tested to determine their degree of positiveness by means of their "xylene equivalent." The xylene equivalent shall be the lowest percentage by volume of xylene in a solvent composed of xylene and standard naphtha or xylene and normal heptane, as specified, which produces a "negative spot" for the material in question. These shall be known as the naphtha-xylene equivalent and heptane-xylene equivalent, respectively. The percentage of xylene in the solvents shall be stated in even 5.0 percent increments. When neither xylene equivalent is specified, the standard naphtha only shall be used as the solvent.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 81, Cutback Asphalt (Rapid-Curing Type)
- M 82, Cutback Asphalt (Medium-Curing Type)
- M 226, Viscosity-Graded Asphalt Cement
- M 231, Weighing Devices Used in the Testing of Materials
- T 40, Sampling Bituminous Materials
- T 78, Distillation of Cutback Asphaltic (Bituminous) Products

2.2. *ASTM Standards*:
- D 86, Standard Test Method for Distillation of Petroleum Products at Atmospheric Pressure
- D 611, Standard Test Methods for Aniline Point and Mixed Aniline Point of Petroleum Products and Hydrocarbon Solvents
- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. SIGNIFICANCE

3.1. The spot test is used to determine if an asphaltic material has been overheated during processing. A "positive" result indicates that an asphaltic material has been overheated. A "negative" result indicates that the materials have not been overheated.

3.2. The spot test has been used as an indicator of the compatibility of the components of an asphalt binder, with a negative spot indicating good compatibility and a positive spot indicating poor compatibility.

3.3. The spot test is an optional test for asphaltic materials as specified in M 81, M 82, and M 226.

4. APPARATUS

4.1. *Flask*—50-mL capacity, either Florence boiling flask or wide-mouth flat-bottom soxhlet extraction flask approximately 45 mm ($1^3/_4$ in.) in diameter by 60 mm ($2^3/_8$ in.) high.

4.2. *Stopper*—cork or rubber stopper for flask provided with a 200-mm (8-in.) length of 6.4 mm ($^1/_4$ in.) glass tubing.

4.3. *Filter Paper*—Whatman No. 50. (The 70-mm size is sufficient.)

4.4. *Glass Plate*—A smooth, clear glass plate shall first be cleaned with trichloroethylene, then washed with soap and water, wiped dry, cleaned with a suitable glass-cleaning preparation, and wiped dry and free from dust and lint. After this cleaning treatment, a drop of the asphalt mixture when applied to the glass should flow out evenly to form a smoothly bounded elliptical stain. If the stain is jagged and uneven in outline, the glass should again be cleaned with a suitable glass-cleaning liquid until a drop of the asphalt mixture flows out as described.

4.5. Pipette or burette with 0.1-mL graduations.

4.6. *Thermometer*—ASTM Precision Thermometer 64C (64F) conforming to requirements of ASTM E 1.

4.7. *Balance*—balance having sufficient capacity and conforming to M 231, Class G 1.

4.8. *Water bath*—maintained at temperature of 32.0º ± 0.5ºC (89.6º ± 1.0ºF).

5. MATERIALS

5.1. The standard naphtha shall be a straight run overhead distillate free from cracked products of any kind and shall conform to the requirements as indicated in Table 1.

Table 1—Naphtha

Gravity A.P.I.	49–50
Distillation:	
Initial boiling point	Above 149°C (300°F)
50 percent over	168–179°C (335–355°F)
End point	Below 210°C (410°F)
Aniline number	59 to 63°C (138 to 145°F)

5.1.1. The aniline number of the solvent shall be determined according to ASTM D 611.

Note 1—Naphtha conforming with these requirements may be obtained under the name of Skelly Solve "S" from Barton Solvents Inc., 201 S. Cedar, Valley Center, KS.

5.2. Xylene shall be chemically pure xylene showing a boiling range of 137 to 140ºC (278.6 to 284ºF) when distilled in accordance with ASTM D 86.

5.3. Normal heptane shall conform to the requirements as indicated in Table 2 (Note 2).

Table 2—Heptane

ASTM Motor Octane Number	0.0 ± 0.2
Density at 20°C, g/mL	0.68375 ± 0.00015

Increase from 20 to 80 percent recovery, °C	0.20 maximum

[a] Determined by means of Method of Test for Measurements of Freezing Points of High-Purity Compounds for Evaluation of Purity (ASTM D 1015).

[b] For equipment and methods used, see Research Paper RP 2079, *Journal of Research*, National Bureau of Standards, Vol. 44, pp. 309-310.

Note 2—Normal heptane meeting this specification may be obtained from the following sources:

- Enjay Col, Inc., 15 West 51st Street, New York, NY.
- Phillips Petroleum Co., Chemical Products Department, Bartlesville, OK.
- Westvaco Chlorine Products Corporation, 405 Lexington Avenue, New York, NY.
- Standard Oil Development Co., Linden, NJ.

6. SAMPLING

6.1. For asphalt cements, perform the test on the original material. For cutback asphalts, perform the test upon the residue from the distillation test T 78.

7. PROCEDURE

7.1. Place a 2.00 ± 0.02 g sample in the flask. If it does not flow readily at room temperature, carefully heat the flask until the sample can be spread in a thin film covering the bottom of the lower portion of the flask. Then allow the flask to cool to room temperature.

7.2. With the pipette or burette, place 10.2 mL of the specified solvent in the flask. Quickly insert the stopper with its 200-mm (8-in.) length of tubing into the neck of the flask, and swirl the flask with a rapid circular motion for 5 seconds. The flask shall then be immersed to its neck in a bath of gently boiling water for 55 seconds.

7.3. Remove the flask from the bath and swirl for 5 seconds. Each minute thereafter alternately immerse the flask for 55 seconds and remove and swirl for 5 seconds until complete dispersion has taken place.

7.4. After complete dispersion as judged by tilting the flask, lower the end of the glass tube shall below the level of the solution. Allow the flask to cool for 30 minutes at room temperature.

7.5. Warm the asphalt-solvent mixture for 15 minutes in a water bath maintained at 32.0 ± 0.5ºC (89.6 ± 1.0ºF). Thoroughly stir the asphalt-solvent mixture. By means of a clean stirring rod, place a drop of the warm mixture on the Whatman No. 50 filter paper. After 5 minutes, examine the spot by holding the paper at arm's length with the plane of the paper at approximately a right angle to the line of vision with a good light source (preferably diffused daylight) at the observer's back. If the drop forms a brown or yellowish-brown circular stain, with a darker solid or annular nucleus in the center, report the test as "positive."

7.6. If the drop forms a uniformly brown circular stain, set the asphalt-solvent mixture aside in its tightly stoppered flask at room temperature in a subdued light to be retested 24 hours after the first examination. Warm the mixture to 32.0 ± 0.5ºC (89.6 ± 1.0ºF) for 15 minutes as before. Vigorously stir until uniform. Place a drop of the asphalt-solvent mixture on filter paper. If the drop from the 24-hour-old mixture still forms a uniformly brown circular stain, report the test as "negative"; but if a darker solid or annular nucleus, as described in the Section 7.5, now forms in the center of the stain, report the test as "positive."

8. PROCEDURE IN DISPUTED CASES

8.1. In case of dispute, repeat the entire test. Make up any loss in mass of solvent during dispersion by adding additional solvent, and after dispersion is complete, keep the flask in subdued light at 25.0º± 1.7ºC (77º ± 3ºF) until the 24-hour tests are made. Warm the asphalt-solvent mixture for 15 minutes to 32.0 ± 0.5ºC (89.6 ± 1ºF), then place a drop of the mixture on a filter paper. If the appearance of the drop on the filter paper made with the 24-hour-old mixture is still in dispute, run the test on the glass plate as specified below.

8.2. Place a drop of the 24-hour-old mixture on the glass plate held at an angle of 45 degrees with the horizontal. If, as the drop flows out, a dull matted streak develops in the center of its path, report the test as "positive."

8.3. If a drop of the 24-hour-old mixture flows out to a uniform, clear, glossy brown film, without the central streak as described in the Section 8.2, report the test as "negative."

9. PROCEDURE FOR XYLENE EQUIVALENTS

9.1. The method used in testing for "xylene equivalents" is the same as specified in Section 7 except that the solvent shall be composed either of xylene and the standard naphtha or of xylene and normal heptane as specified.

9.2. To determine the xylene equivalent, disperse two or more samples of the asphalt to be examined in the prescribed mixed solvent. Vary the percentage of xylene by successive 5 percent (volume) increments until two asphalt solutions have been found, one of which shows a positive spot while the next (in which the solvent contains 5 percent more xylene) shows a negative spot. Report the xylene equivalent by the xylene percentage in the two solvents used in these two solutions; for example, as "10–15 percent naphtha-xylene equivalent" or "20–25 percent heptane-xylene equivalent."

9.3. When acceptance of material is based on a specified xylene equivalent, the exact lowest percentage of xylene that produces a "negative spot" need not be determined. The sample may be tested with solvent composed of the specified percentages of xylene and standard naphtha or xylene and normal heptane as required, and any material which shows negative for this solvent shall be reported as being less than the particular xylene equivalent which has been designated; for example, “less than 20 percent naphtha-xylene equivalent” or “less than 25 percent heptane-xylene equivalent.”

10. REPORT

10.1. This report shall include the following:

10.1.1. Identification of sample.

10.1.2. Solvent used in testing.

10.1.3. “Positive” or “Negative” result.

10.1.4. If performed, the xylene equivalent.

11. PRECISION AND BIAS

11.1. *Precision*—The research required to develop precision estimates has not been conducted.

11.2. *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

12. KEYWORDS

12.1. Asphalt, spot test, xylene equivalent

Standard Method of Test for

Moisture or Volatile Distillates in Hot Mix Asphalt (HMA)

AASHTO Designation: T 110-03 (2007)[1]
ASTM Designation: D 1461-85 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Moisture or Volatile Distillates in Hot Mix Asphalt (HMA)

AASHTO Designation: T 110-03 (2007)[1]
ASTM Designation: D 1461-85 (2006)

1. SCOPE

1.1. This method is intended for the determination, by direct measurement, of moisture or volatile fractions of the bitumen in hot mix asphalt (HMA).

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 168, Sampling Bituminous Paving Mixtures

3. SIGNIFICANCE AND USE

3.1. This method is used for determining either the amount of moisture or the amount of volatile petroleum distillates in HMA.

4. APPARATUS

4.1. *Metal Still*—A vertical cylindrical still, as illustrated in Figure 1, having a faced flange at the top to which the head is tightly attached by means of a clamp. The head shall be of metal and provided with a tubulation 25.4 mm (1 in.) in inside diameter.

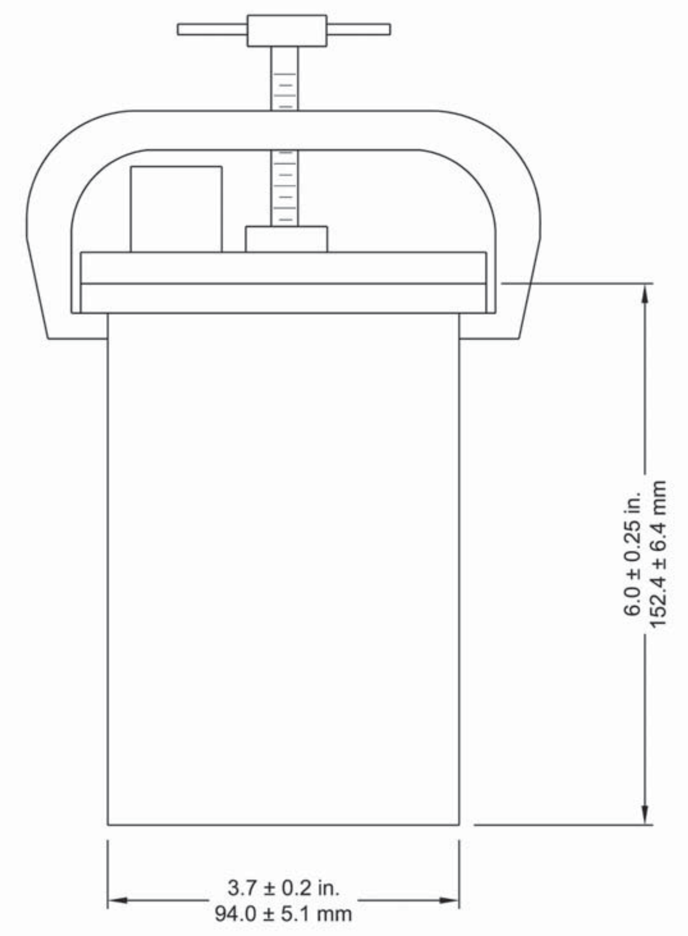

Figure 1—Metal Still

Note 1—Still diameters of up to 127 mm (5 in.) may be used if required to accommodate larger samples.

4.2. *Condenser*, of the water-cooled reflux glass-tube type, having a condenser jacket not less than 400 mm ($15^3/_4$ in.) long, with an inner tube 9.5 to 12.7 mm ($^3/_8$ to $^1/_2$ in.) in outside diameter. The end of the condenser inserted in the receiver shall be ground off at an angle of 30 degrees from the vertical axis of the condenser or otherwise configured to fit the receiver. For mixtures with very volatile solvents, it may be necessary to supplement this water-cooled condenser with a second water-cooled condenser of approximately the same dimensions.

4.3. *Receiver*, of well-annealed glass, of one of the following types depending upon the purpose of the test:

4.3.1. For determination of water in HMA, a glass receiver of 10- or 25-mL capacity shall be used. The receiver shall be graduated in 0.1-mL divisions with a ±0.05-mL maximum error below 1-mL and in 0.2-mL divisions with a ±0.1-mL maximum error above 1 mL as specified in Table 1 and Figures 2, 3, 4, and 5. Receivers with tapered or ball-bottom vapor tube ends require adaptors for connection to the metal still.

4.3.2. For determination of the volatile fractions of the HMA, the receiver shall conform to the dimensions shown in Figure 6.

Table 1—Description of Receivers

Style	Description			Figure	Size of Receiver, mL	Range, mL	Smallest Scale Division, mL	Maximum Scale Error, mL
	Top of Graduated Tube	Bottom of Graduated Tube	Bottom of Vapor Tube					
						0 to 1.0	0.1	0.05
A	§ joint	conical	§ joint	2	10	Over 1.0 to 10.0	0.2	0.1
B	§ joint	conical	§ joint	3				
C	§ joint	conical	plain	4		0 to 1.0	0.1	0.05
D	plain	conical	plain	5	25	Over 1.0 to 25	0.2	0.1
					5	0 to 5.0	0.1	0.05
E	§ joint	round	§ joint	6	10	0 to 10.0	0.1	0.1

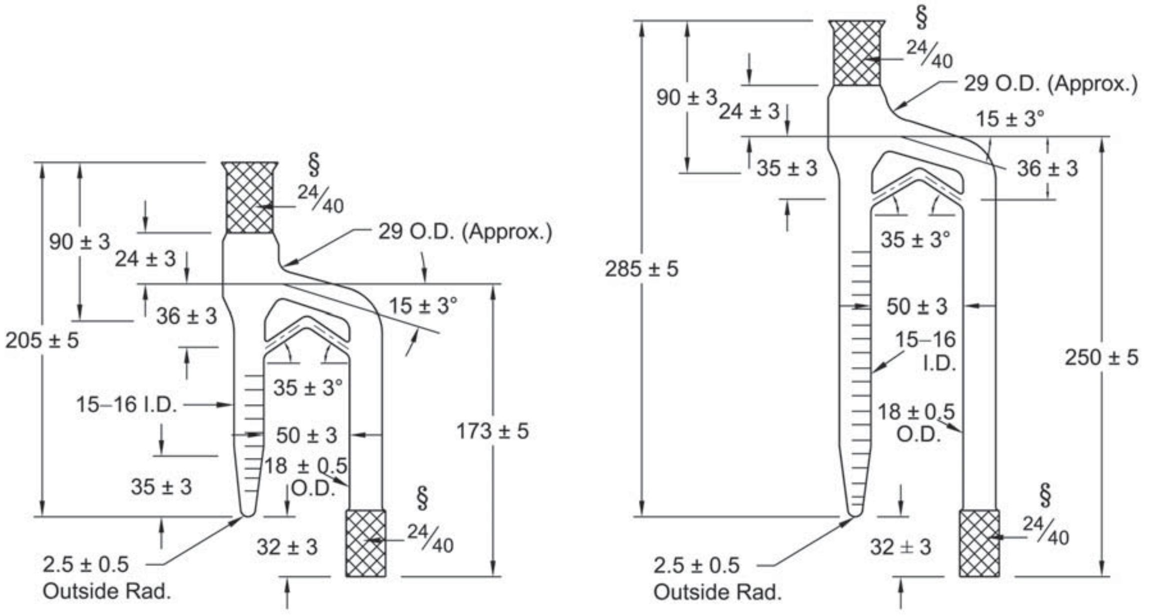
4.4. *Solvent*—For general use, an aromatic solvent is preferred since it has high solvency and dispersing power for most asphalt materials. Xylene, or a blend of 20 percent toluene and 80 percent xylene, is recommended. For asphalts and similar petroleum products, a petroleum distillate, five percent boiling between 90 and 100ºC (194 and 212ºF), and 90 percent distilling below 210ºC (410ºF), may be used. For coal tar, water-gas tar, and similar materials, an aromatic solvent must be used.

4.5. *Heating Device*—Any satisfactory source of heat capable of maintaining a rate of distillation of 85 to 95 drops per minute.

5. SAMPLING

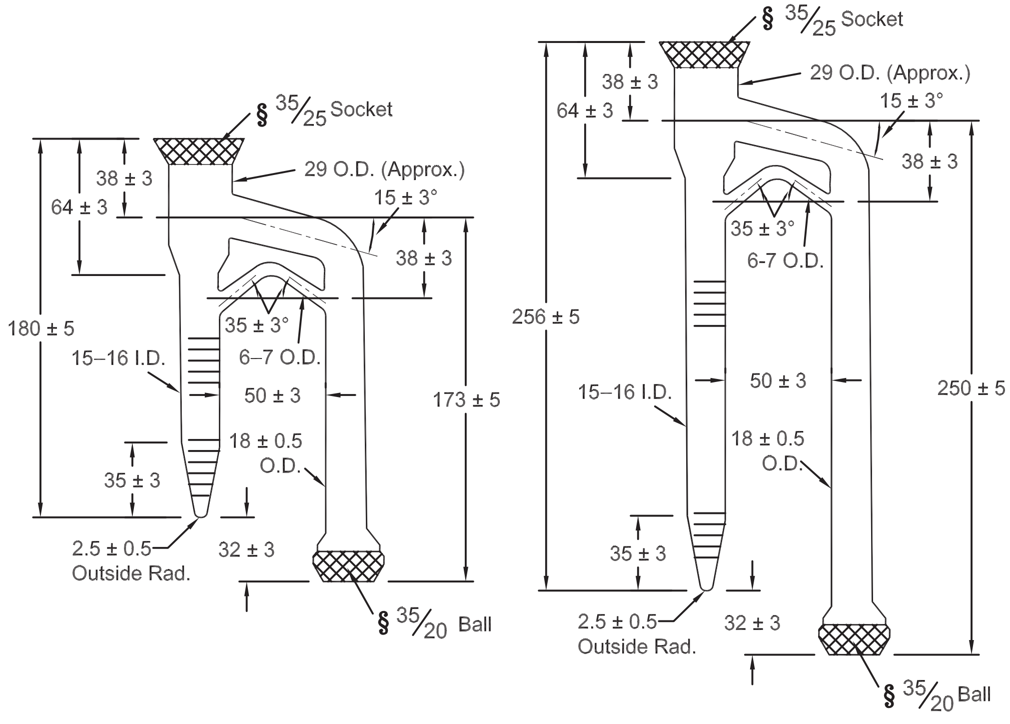
5.1. Sampling shall be performed in accordance with T 168.

5.2. The sample shall be representative of the material and of such size as practical to fill the container in which it is transported to the laboratory. For duplicate tests, a 2-L ($^1/_2$-gal) friction-top tin pail full of material would be satisfactory.



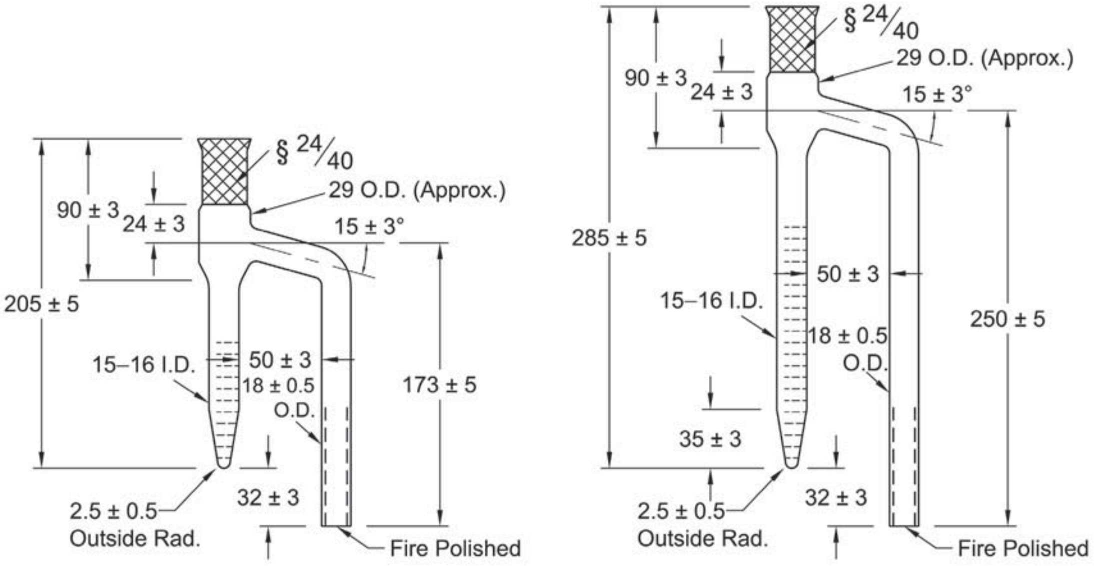
Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Receivers (Style A)



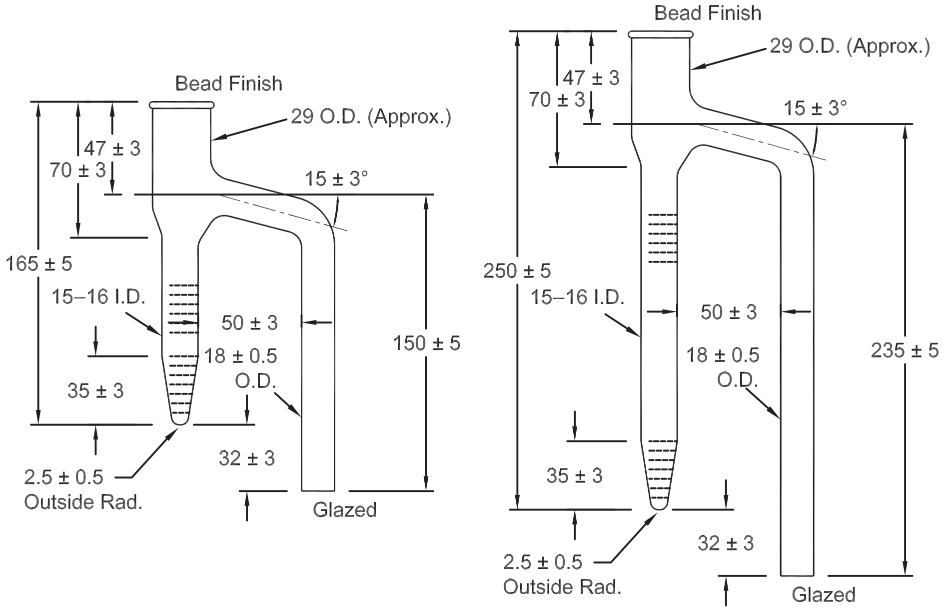
Note: All dimensions shown in millimeters unless otherwise noted.

Figure 3—Receivers (Style B)



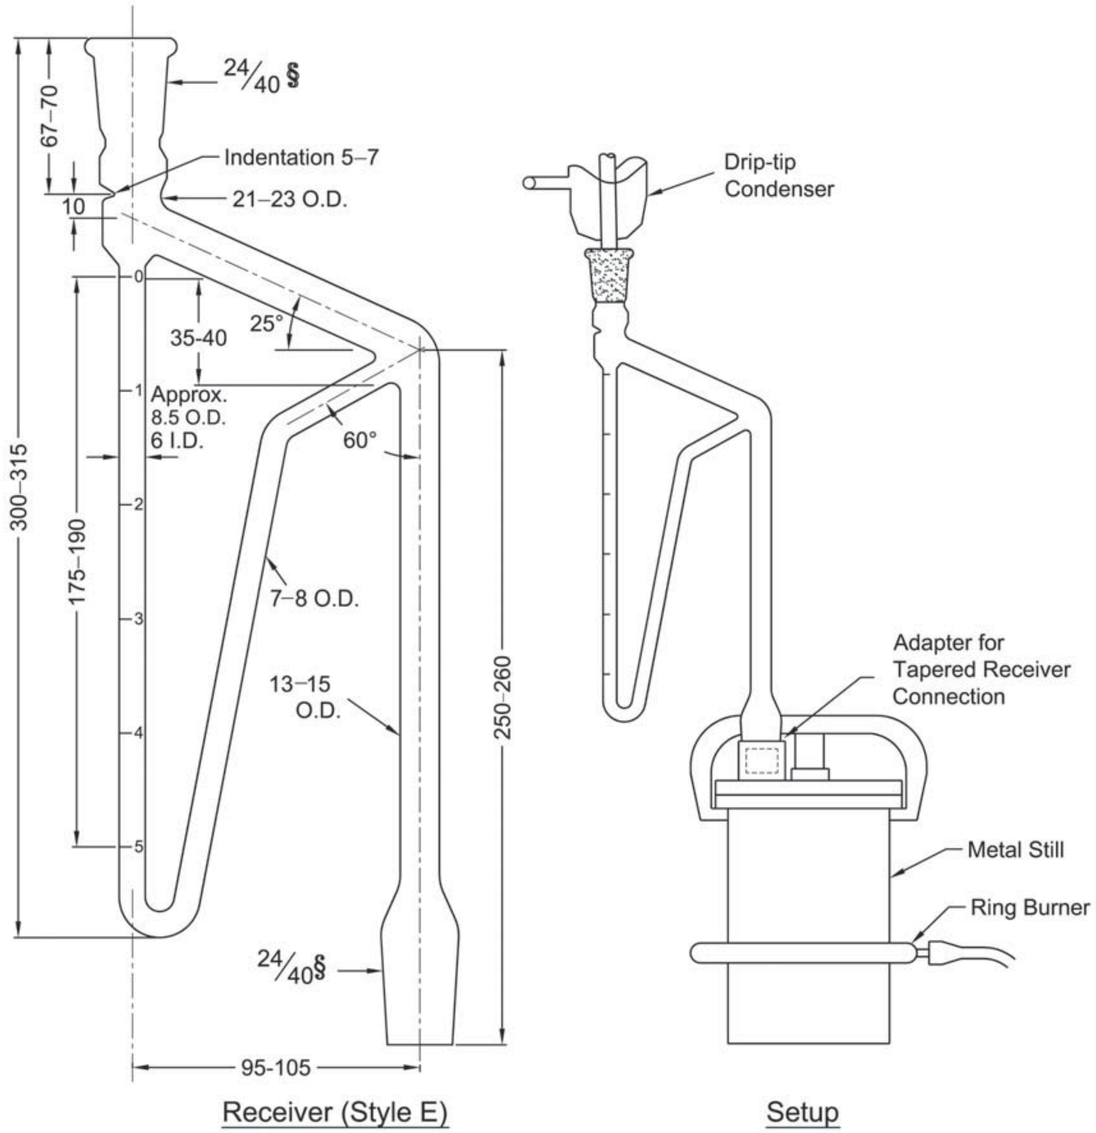
Note: All dimensions shown in millimeters unless otherwise noted.

Figure 4—Receivers (Style C)



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 5—Receivers (Style D)



Receiver (Style E)

Setup

Note: All dimensions are shown in millimeters unless otherwise noted.

Figure 6—Apparatus for Determining Volatile Distillates

6. TEST SPECIMEN AND SAMPLE

6.1. Thoroughly mix the sample, and weigh out an amount estimated to yield a percentage of moisture or diluent within the capacity of the receiver calibration. Keep the remainder of the sample in its tightly covered container. The weighed sample should not be less than 500 g for normal mixtures. Thoroughly break up this sample to avoid large lumps, and place it in the still.

7. PROCEDURE FOR DETERMINATION OF MOISTURE

7.1. After the sample has been placed in the still, add 200 mL of the solvent, and quickly stir it into the sample.

7.2. Assemble the components of the apparatus as illustrated in Figure 7, choosing the receiver in accordance with the expected water content of the sample and making all connections vapor-and liquid-tight. Insert a gasket of heavy paper, moistened with water, between the still body and cover. The condenser tube and receiver must be chemically clean to assure free drainage of water into the bottom of the trap. Insert a loose cotton plug in the top of the condenser to prevent condensation of atmospheric moisture inside it. Circulate cold water through the jacket of the condenser.

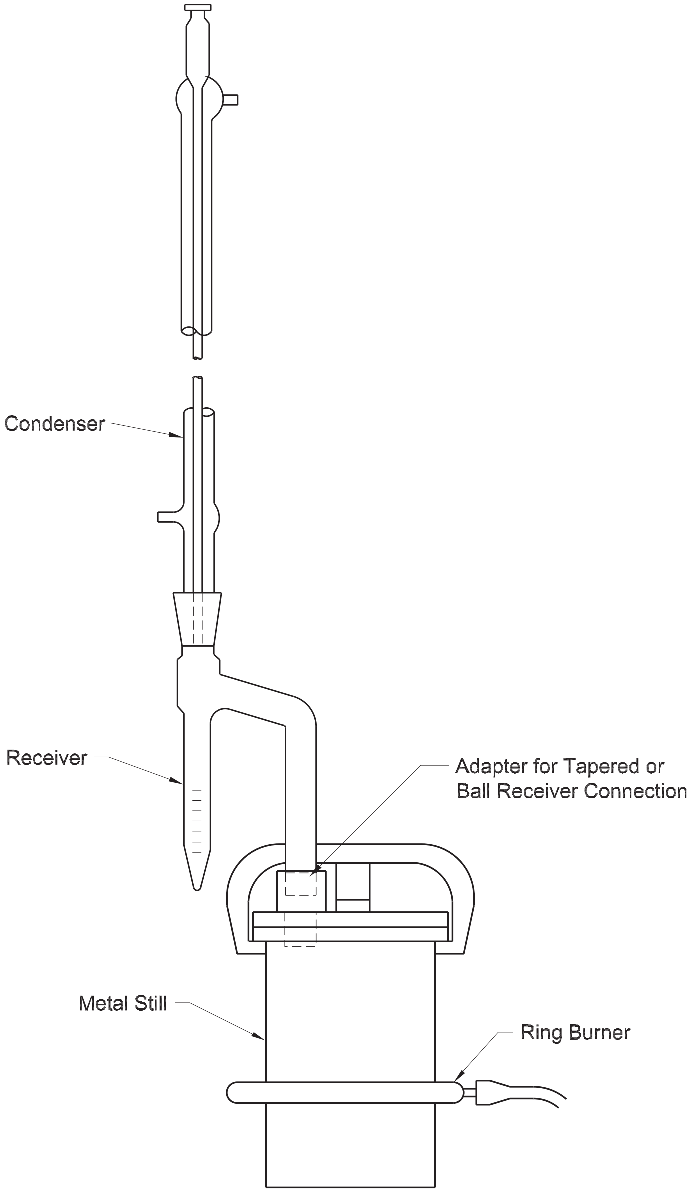


Figure 7—Typical Assembly for Determining Moisture Content

7.3. Apply heat at such a rate that refluxing will start within 5 to 10 minutes, after the heat has been applied, and the condensed solvent will drip into the receiver at a rate of 85 to 95 drops per minute. Continue the distillation until three successive readings of the receiver at 15-minute intervals show no increase in the amount of water being condensed, except that in no case shall distillation continue for more than 1.5 hours.

7.4. Allow the contents of the receiver to reach room temperature, and read the volume of water in the receiver to the nearest scale division. Record the volume of water, and calculate the percentage by mass of the sample taken as described in Section 9.1.

8. PROCEDURE FOR DETERMINATION OF VOLATILE DISTILLATES

8.1. After the sample has been placed in the still, add 350 mL of water and approximately 3 g of sodium carbonate (Na_2CO_3), and quickly stir it into the sample. Firmly attach the still cover, and assemble the receiver and condenser in the manner prescribed in Section 7.2, except that the gasket should be moistened with a solvent and the trap used shall be the dilution trap specified in Section 4.3.2.

8.2. Apply heat at such a rate that the water and solvent will begin to reflux in 5 to 10 minutes after the heat has been applied and will drip from the condenser at the rate of 85 to 95 drops per minute. In case the sample contains a large amount of very volatile solvent, it may be necessary to add a second water-cooled condenser above the first one or reduce the rate of distillation somewhat to prevent escape of the solvent.

8.3. Continue distillation until three successive readings of the upper and lower levels of the diluent at 15-minute intervals show no increase in the quantity being collected. Then remove the source of heat, and allow the apparatus to stand for 0.5 hour to permit the solvent to cool and separate.

8.4. Record the volume of diluent in the receiver to the nearest scale division, and calculate the percentage by mass of the sample taken as described in Section 9.2. Use the specific gravity of the diluent at 25ºC (77ºF).

Note 2—Assume the specific gravity of diluent based on knowledge of diluent type or values in the range of 0.85 to 0.90. This range only defines volatiles that are obtained at the maximum test temperature.

9. CALCULATION

9.1. Calculate the moisture content as follows:

$$\text{Moisture, \%} = \frac{A}{B} \times 100 \qquad (1)$$

where:

A = the volume of water in the receiver (mL), and

B = the mass of the sample (g).

9.2. Calculate the volatile distillate as follows:

$$\text{Volatile Distillates, \%} = C \times \frac{D}{E} \times 100 \qquad (2)$$

where:

C = the volume of diluent in the receiver (mL),

D = the specific gravity of the diluent at 25ºC (77°F), and

E = the mass of the sample (g).

10. REPORT

10.1. Report the moisture content as the mass percent of water content in accordance with Section 9.1.

10.2. Report the volatile distillates as the mass percent of diluent content in accordance with Section 9.2.

11. PRECISION

11.1. *Precision for Determination of Moisture*—The following criteria should be used for judging the acceptability of results (95 percent probability) when using the 10-mL or 25-mL receivers.

11.1.1. *Repeatability*—Duplicate determinations of water by the same operator should be considered suspect if they differ by more than the following amounts:

Water Collected	
0–1.0 mL	0.1 mL
1.1–25 mL	0.1 mL or 2% of the mean, whichever is greater

11.1.2. *Reproducibility*—The results submitted by each of two laboratories should be considered suspect if they differ by more than the following amounts:

Water Collected	
0–1.0 mL	0.2 mL
1.1–25 mL	0.2 mL or 10% of the mean, whichever is greater

11.2. *Precision for Determination of Volatile Distillates*—The precision of this method is obtained by statistical examination or interlaboratory test results as follows:

11.2.1. *Repeatability*—Duplicate determinations of volatile distillates by the same operator should be considered suspect if they differ by more than 0.6-volume percent.

11.2.2. *Reproducibility*—The results submitted by each of two laboratories should be considered suspect if they differ by more than 1.4-volume percent.

---

[1] Similar but not identical to ASTM D 1461-85 (2006).

Standard Method of Test for

Mineral Matter or Ash in Asphalt Materials

AASHTO Designation: T 111-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Mineral Matter or Ash in Asphalt Materials

AASHTO Designation: T 111-10

1. SCOPE

1.1. This method of test is intended for the determination of mineral matter in solid, semisolid, or liquid asphalt.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 44, Solubility of Bituminous Materials
- T 55, Water in Petroleum Products and Bituminous Materials by Distillation
- T 170, Recovery of Asphalt from Solution by Abson Method

3. SIGNIFICANCE

3.1. This method of test is used to determine the amount of mineral material (ash content) in an asphalt sample by means of ignition. According to T 170, ash content testing is required for recovered asphalt residue.

3.2. Testing for solubility of asphalt (T 44) may be used for the determination of mineral matter provided all the insoluble material has been transferred to the Gooch crucible used in T 44.

4. APPARATUS

4.1. The apparatus required shall consist of the following:

4.1.1. *Crucible*—with cover and a capacity of 50 to 100 mL—either platinum, porcelain, or fused silica.

4.1.2. *Gas burner*.

4.1.3. *Analytical balance*—conforming to M 231, Class B.

4.1.4. *Desiccator*—with ground glass cover.

4.1.5. *Muffle furnace*—capable of igniting the residue to a dull red heat [500 to 600°C (930 to 1110°F)].

5. PREPARATION OF SAMPLE

5.1. If the sample contains more than 2.0 percent water, it shall be dehydrated by distillation in accordance with T 55, before testing. If the material is hard and brittle, it may be ground and dried at a temperature below the volatilization temperature of the asphalt.

6. PROCEDURE

6.1. Determine the mass of a sample of the material (2 to 5 g) to the nearest 0.001 g in a tared crucible. Heat the sample slowly to drive off the combustible material without spattering until the asphalt is ignited. Then continue heating only enough to maintain combustion. When all readily volatile material is burned, ignite all free carbon in a muffle furnace until all carbonaceous matter has disappeared.

6.2. Cool the residue in the desiccator, and determine the mass to the nearest 0.001 g. Repeat heating in the muffle furnace until a constant mass of the residue is obtained.

6.3. When carbonate materials are present, moisten the ash with a few drops of ammonium carbonate solution. Dry the sample in an oven at 100 ± 10ºC (212 ± 18ºF). After the sample is dry, place it in the muffle furnace, and heat to a dull red for a few minutes. Cool the residue in the desiccator, and determine the mass to the nearest 0.001 g.

7. CALCULATIONS

7.1. The mass of mineral matter (ash) divided by the mass of the original sample and multiplied by 100 gives the percentage of mineral matter (ash content).

8. REPORT

8.1. This report shall include the following:

8.1.1. Identification of sample.

8.1.2. The percentage of mineral matter (ash content) to the nearest 0.1 percent.

9. PRECISION AND BIAS

9.1. *Precision*—The research required to develop precision estimates has not been conducted.

9.2. *Bias*—The research required to establish the bias has not been conducted.

10. KEYWORDS

10.1. Ash, mineral matter, asphalt.

Standard Method of Test for

Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)

AASHTO Designation: T 164-10[1]
ASTM Designation: D 2172-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)

AASHTO Designation: T 164-10[1]
ASTM Designation: D 2172-05

1. SCOPE

1.1. These methods cover the quantitative determination of asphalt binder in hot mix asphalt (HMA) and HMA pavement samples. Aggregate obtained by these methods may be used for sieve analysis using T 30.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Specific hazards are given in Section 8.

Note 1—The results obtained by these methods may be affected by the age of the material tested, with older samples tending to yield slightly lower asphalt binder contents. Best quantitative results are obtained when the test is made on HMA mixtures and pavements shortly after their preparation. It is difficult to remove all the asphalt binder when some aggregates are used; some solvent may remain within the mineral matter affecting the measured asphalt binder content.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 30, Mechanical Analysis of Extracted Aggregate
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 110, Moisture or Volatile Distillates in Hot Mix Asphalt (HMA)
- T 168, Sampling Bituminous Paving Mixtures
- T 170, Recovery of Asphalt from Solution by Abson Method
- T 228, Specific Gravity of Semi-Solid Asphalt Materials
- T 329, Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 604, Standard Specification for Diatomaceous Silica Pigment (Withdrawn 2003)

- D 2111, Standard Test Methods for Specific Gravity and Density of Halogenated Organic Solvents and Their Admixtures
- D 4080, Standard Specification for Trichloroethylene, Technical and Vapor-Degreasing Grade
- D 6368, Standard Specification for Vapor-Degreasing Solvents Based on normal-Propyl Bromide and Technical Grade normal-Propyl Bromide

3. TERMINOLOGY

3.1. *nominal maximum size (of aggregate)*—One size larger than the first sieve that retains more than 10 percent aggregate.

3.2. *constant mass*—shall be defined as the mass at which further drying does not alter the mass by more than 0.05 percent when weighed at 2-h intervals.

4. SUMMARY OF TEST METHODS

4.1. The HMA is extracted with trichloroethylene, *normal*-propyl bromide, or methylene chloride, using the extraction equipment applicable to the particular method. Terpene extractant may be used in Method A or E. The asphalt binder content is calculated by differences from the mass of the extracted aggregate, moisture content, and mineral matter in the extract. The asphalt binder content is expressed as a mass percent of moisture-free mixtures.

5. SIGNIFICANCE AND USE

5.1. All of the methods can be used for quantitative determinations of asphalt binder in HMA mixtures and pavement samples for specification acceptance, service evaluation, quality control, and research. Each method prescribes the solvents and any other reagents that can be used in the method. T 170 requires that Method A or E (Note 2) and reagent grade trichloroethylene be used when asphalt binder is recovered from solution.

Note 2—The vacuum extractor, Section 22.1.1, can be modified by a vacuum trap attached to the top of the "end point" sight tube to collect the extract to allow its use for recoveries (Figure 4b).

6. APPARATUS

6.1. *Oven*—capable of maintaining the temperature at 110 ± 5ºC (230 ± 9ºF), for warming the sample.

6.2. *Oven*—capable of maintaining the temperature at 149 to 163ºC (300 to 325ºF), for drying the sample if the moisture content is not determined.

6.3. *Pan*—flat, of appropriate size.

6.4. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231.

6.5. *Cylinders*—graduated, 1000 or 2000-mL capacity.

7. REAGENTS

7.1. *Methylene Chloride*, technical grade. *Caution*—see Section 8.

7.2. *normal-propyl Bromide*, conforming to ASTM D 6368—see Section 8.

7.3. *Trichloroethylene*, reagent grade (Note 3) or conforming to ASTM D 4080—see Section 8.

7.4. *Terpene*—Extractant, shall be non-halogenated, non-toxic, and shall readily dissolve asphalt binder from HMA and place it into solution. This extractant shall be easily rinsed from the remaining aggregate without forming a gel, and the extractant rinsed from the aggregate shall pass readily through the diatomaceous earth and the filter.

Note 3—Reagent grade trichloroethylene may be required when asphalt binder is recovered from the solution. (See T 170, Note 1.)

Note 4—Only vented ovens should be used when terpene extractants are used.

8. PRECAUTIONS

8.1. The solvents listed in Section 7 should be used only under a hood or with an effective surface exhaust system in a well-ventilated area, since they are all toxic to some degree as described in R 16. Trichloroethylene, methylene chloride, and normal-propyl bromide in the presence of heat and moisture may form acids that are extremely corrosive to certain metals, particularly when subject to contact over lengthy periods of time. Proper precautions should be taken to not allow these solvents to remain in small quantities in the effluent tanks of aluminum vacuum extractors.

8.2. Trichloroethylene stored in a steel container and in continuous contact with moisture may decompose by dehydrohalogenation to form unsaturated hydrocarbon liquids and hydrogen chloride. Steel drums containing trichloroethylene should be stored in a cool, dry location, kept tightly sealed and opened as infrequently as possible. Trichloroethylene should be transferred from the drums to clean, dry, brown glass bottles for laboratory use. The hydrogen chloride in decomposed trichloroethylene may harden an asphalt during the extraction and Abson recovery test (T 170).

8.3. All local, State, and Federal regulations must be followed with when hauling, using, storing, and discarding extractants and rinse water. These requirements include fire ordinances as well as wastewater treatment regulations. The Materials Safety Data Sheet should be followed closely to avoid fires and explosions. Storage of extractant-soaked rags should be prohibited.

9. SAMPLING

9.1. Obtain samples in accordance with T 168.

9.2. *Preparation of Test Specimens*:

9.2.1. If the HMA is not sufficiently soft to separate with a spatula or trowel, place it in a large, flat pan, and warm it in a 110 ± 5ºC (230 ± 9ºF) oven only until it can be handled or separated. Split or quarter the material until the mass of material required for the test is obtained.

9.2.2. The size of the test sample shall be governed by the nominal maximum aggregate size of the HMA and conform to the mass requirement shown in Table 1 (Note 5).

Table 1—Size of Sample

Nominal Maximum Aggregate Size		Minimum Mass of Sample, kg
Mm	in.	
4.75	No. 4	0.5
9.5	$^{3}/_{8}$ in.	1
12.5	$^{1}/_{2}$ in.	1.5
19.0	$^{3}/_{4}$ in.	2
25.0	1 in.	3
37.5	$1^{1}/_{2}$ in.	4

Note 5—When the mass of the test specimen exceeds the capacity of the equipment used (for a particular method), the test specimen may be divided into suitable increments, tested, and the results appropriately combined for calculation of asphalt binder content (Section 13).

9.2.3. Unless the HMA sample is free of moisture (Note 7), a test specimen is required for the determination of moisture (Section 10) in the HMA. Take this test specimen from the remaining sample in the HMA immediately after obtaining the extraction test specimen.

Note 6—If the extraction test is only being performed to recover asphalt binder from the HMA and the percent asphalt binder is not being determined, it is unnecessary to determine the moisture content of the HMA.

Table 2—Dimensional Equivalents

mm	in.	mm	in.	mm	in.
0.8	$^{1}/_{32}$	42.9	$1^{11}/_{16}$	155.6	$6^{1}/_{8}$
1.6	$^{1}/_{16}$	44.5	$1^{3}/_{4}$	157.2	$6^{3}/_{16}$
2.0	$^{5}/_{64}$	47.6	$1^{7}/_{8}$	158.8	$6^{1}/_{4}$
3.2	$^{1}/_{8}$	50.8	2	163.5	$6^{7}/_{16}$
4.0	$^{5}/_{32}$	55.6	$2^{3}/_{16}$	165.1	$6^{1}/_{2}$

10. MOISTURE CONTENT

10.1. When required, determine the moisture content of the mixture (Section 9.2.3) in accordance with the procedure described in T 110 or T 329.

Note 7—If recovery of asphalt binder from the solution obtained from the extraction test is not required, the entire test specimen may be dried in an oven at a temperature of 105 to 165ºC (221 to 329ºF) to constant mass prior to extraction, instead of determining the moisture content.

10.2. Calculate the mass of water (W_2, Section 13) in the extraction test portion by multiplying mass percent water (Section 10.1) by the mass of the extraction test portion (W_1, Section 13).

TEST METHOD A

11. APPARATUS

11.1. In addition to the apparatus listed in Section 6, the following apparatus is required for Method A:

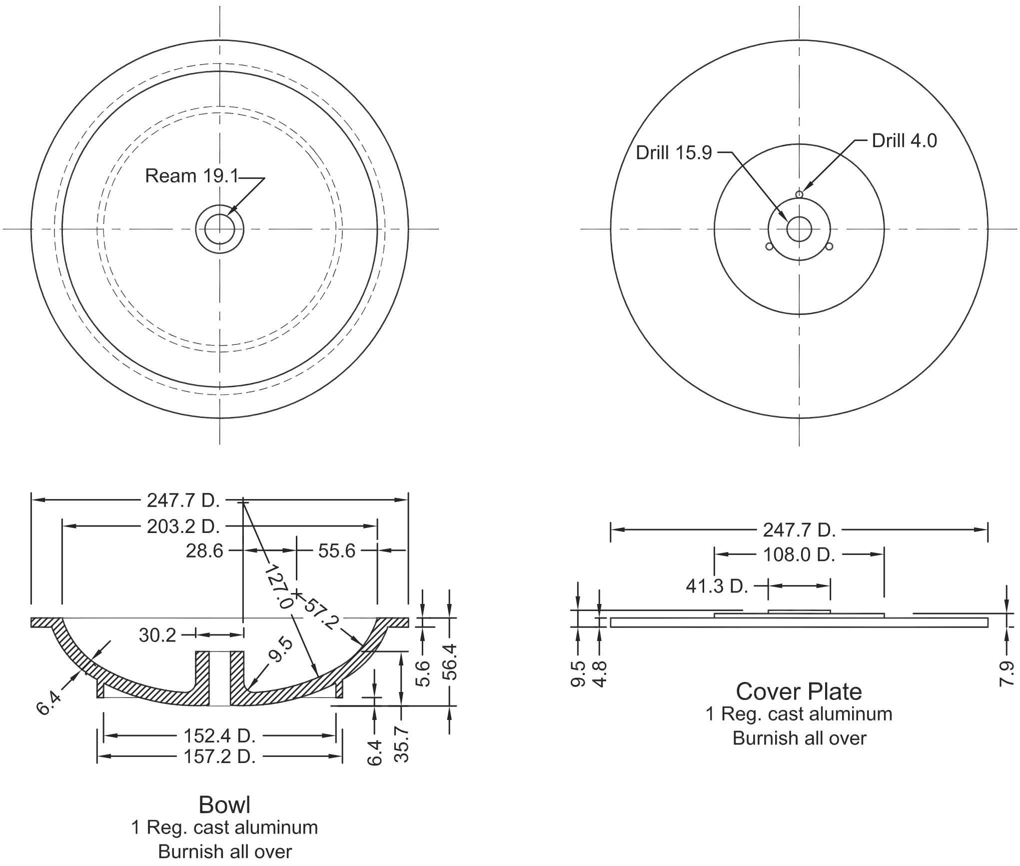
11.1.1. *Extraction Apparatus*, consisting of a bowl approximating that shown in Figure 1 and an apparatus in which the bowl may be revolved at controlled variable speeds up to 3600 r/min. The speed may be controlled manually or with a preset speed control. The apparatus should be provided with a container for catching the solvent discharged from the bowl and a drain for removing the solvent. The apparatus preferably shall be provided with explosion-proof features and installed in a hood or an effective surface exhaust system to provide ventilation.

Note 8—Similar apparatus of larger size may be used.

11.1.2. *Filter Rings*, felt or paper, to fit the rim of the bowl.

11.1.3. *Low-Ash Paper Filter Rings* may be used in place of the felt filter ring (Section 11.1.2). Such filter rings shall consist of low-ash filter paper stock, 1.27 ± 0.13 mm (0.05 ± 0.005 in.) thick. The nominal base weight of the paper shall be 150 ± 14 kg (330 ± 30 lb) for a ream [500 sheets, 635 by 965 mm (25 by 38 in.)]. The ash content of the paper should not exceed 0.2 percent (approximately 0.034 g per ring).

Note 9—Where terpene extractants are used, the gears and shaft should be lubricated frequently.



Note: See Table 2 for dimensional equivalents. All dimensions shown in millimeters unless otherwise noted.

Figure 1—Extraction Unit Bowl (Method A)

12. PROCEDURE

12.1. Determine the moisture content of the material in accordance with Section 10.

12.2. Place the test portion into a bowl.

12.3. Cover the test portion in the bowl with trichloroethylene, methylene chloride, *normal*-propyl bromide, or terpene extractant, and allow sufficient time for the solvent to disintegrate the test portion (not more than 1 h). Place the bowl containing the test portion and the solvent in the extraction apparatus. Dry the filter ring to a constant mass in an oven at 110 ± 5ºC (230 ± 9ºF), and fit it around the edge of the bowl. Clamp the cover on the bowl tightly, and place an appropriate container under the drain to collect the extract.

12.4. Start the centrifuge revolving slowly, and gradually increase the speed to a maximum of 3600 r/min until solvent ceases to flow from the drain. Allow the machine to stop; add 200 mL (or more as appropriate for the mass of the sample) of trichloroethylene, methylene chloride, *normal*-propyl bromide, or terpene extractant, and repeat the procedure. Use sufficient solvent additions (not less than three) until the extract is not darker than a light straw color. Collect the extract and the washings in an appropriate container for mineral matter determination.

12.5. Carefully transfer the filter ring and all of the aggregate in the centrifuge bowl into a tared metal pan. Dry in air under a hood until the fumes dissipate, and then to a constant mass in an oven at 110 ± 5ºC (230 ± 9ºF) (Notes 10 and 11). The mass of the extracted aggregate (W_3) is equal to the mass of the contents in the pan minus the initial dry mass of the filter ring. Brush off mineral matter adhering to the surface of the filter ring, and add it to the extracted aggregate for further testing.

Note 10—The filter and aggregate may be left inside the centrifuge bowl and dried to constant mass in an oven at 110 ± 5ºC (230 ± 9ºF) and the mass determined.

Note 11—The filter ring may be dried separately to constant mass in an oven at 110 ± 5ºC (230 ± 9ºF) provided that care is taken not to lose any of the fine material clinging to the filter. If this procedure is used, the aggregate may then be dried to constant mass either in an oven or on a hot plate at 110 ± 5ºC (230 ± 9ºF).

12.5.1. Use the following alternative procedure when low-ash filter rings are used. Place the aggregate and filter rings in a clean metal pan. Dry as specified above. Carefully fold the dried filter ring and stand it on the aggregate. Burn the filter ring. Determine the mass of the extracted aggregate in the pan (W_3).

Note 12—Since dry aggregate absorbs moisture when exposed to air containing moisture, determine the mass of the extracted aggregate immediately after cooling to a suitable temperature.

12.6. Determine the amount of mineral matter in the extract by one of the procedures specified in Annex A1.

13. CALCULATION OF ASPHALT BINDER CONTENT

$$\mathit{Asphalt\ Binder\ Content},\ \% = \frac{(W_1 - W_2) - (W_3 + W_4)}{W_1 - W_2} \times 100 \qquad (1)$$

where:

W_1 = mass of test portion;

W_2 = mass of water in test portion;

W_3 = mass of extracted mineral aggregate; and

W_4 = mass of mineral matter in the extract.

Note 13—When ashless filter rings are not used, add the increase in mass of the felt ring to W_4.

Note 14—When it is desired to express the asphalt binder content as a mass percent of the moisture-free aggregate, substitute the mass $W_3 + W_4$ for the mass $W_1 - W_2$ in the divisor of Equation 1.

TEST METHOD B

14. APPARATUS

14.1. In addition to the apparatus listed in Section 6, the following apparatus is required for Test Method B:

14.1.1. *Extraction Apparatus*—similar to that shown in Figure 2.

Figure 2—Extraction Apparatus (Method B)

14.1.1.1. *Glass Jar*—cylindrical, plain, made of heat-resistant glass. The jar shall be free of cracks, scratches, or other evidence of flaws that might cause breakage during heating.

14.1.1.2. *Cylindrical Metal Frames*—one or two. The lower frame shall have legs of sufficient length to support the frame, including the apex of the metal cone and paper cone liner above the solvent level. When two frames are used, the upper frame shall have legs of sufficient length to support the metal cone and paper cone liner at or above the top rim of the lower frame. The legs of the upper frame shall fit securely in the top rim of the lower frame. A bail handle may be provided on the inside of the top rim of each frame for convenient handling. The metal used in fabricating the frames shall be essentially unreactive to the solvents used in the test.

14.1.1.3. *Condenser*—fabricated with a truncated hemispherical condensing surface and a truncated conical top. Other suitable geometric shapes may also be used provided they accomplish the condensing and flow functions intended. The material used in fabricating the condenser shall be essentially unreactive to water and to the solvent used and shall be provided with a suitable water inlet and outlet.

14.1.1.4. *Filter Paper*—medium-grade, fast-filtering. The diameter of the paper shall be such that when folded in accordance with the directions given below, it shall completely line the metal cones in the frames.

14.1.1.5. *Thermal Distributing Protective Pad*—approximately 3 mm (0.1 in.) thick for use as insulation between the glass jar and hot plates.

14.1.1.6. *Electric Hot Plate*—thermostatically controlled, of sufficient dimensions and heat capacity to permit refluxing of the solvent as described in Section 16.2.5.

15. PREPARATION OF TEST PORTION

15.1. Prepare a test portion for moisture determination and extraction in accordance with the procedure described in Section 9.

16. PROCEDURE

16.1. *Moisture*:

16.1.1. Determine the moisture content of the HMA (Section 9.2.3) in accordance with the method described in Section 10.

16.2. *Extraction*:

16.2.1. Dry one sheet of filter paper for each frame used to a constant mass in an oven at 110 ± 5ºC (230 ± 9ºF). Fold each paper on its diameter; fold the ends over, and spread it open to form a proper size to fit inside the metal cones.

16.2.2. Determine the mass of each frame with its filter paper liner to the nearest 0.5 g. Record the mass of each frame.

16.2.3. Place the test portion in the frame(s). If two frames are used, distribute the test portion approximately equally between the two. The top of the test portion must be below the upper edge of the paper liner. Determine the mass of each loaded frame separately to the nearest 0.5 g. Again, record the mass.

16.2.4. Use one of the solvents (Note 15) specified in Section 7.1, 7.2, or 7.3. Pour the solvent into the glass cylinder, and place the bottom frame into it. The solvent level should be below the apex of the one in the lower frame. If two frames are used, place the upper frame in the lower frame, fitting its legs into the holes in the upper rim of the lower frame.

Note 15—Sufficient denatured ethyl alcohol may be poured over the test portion(s) to wet the filter paper. A mixture of 20 percent denatured alcohol and 80 percent trichloroethylene has proven to be a better solvent for some aggregates.

16.2.5. If required, place the thermal insulating pad on the hot plate and then the cylinder on the pad. Cover the condenser. Circulate a gentle, steady stream of cool water through the condenser. Adjust the temperature of the hot plate so that the solvent will boil gently and a steady stream of condensed solvent flows into the cone. If necessary, adjust the temperature of the hot plate to maintain the solvent stream at a rate necessary to keep the test portions in the cone(s) completely covered with condensed solvent. Take care not to allow condensed solvent to overflow the filter cone(s). Continue the refluxing until the solvent flowing from the lower cone is a light straw color (when viewed against a white background). At this point, turn off the hot plate, and allow the apparatus to cool enough to handle; turn off the condenser, and remove it from the cylinder.

16.2.6. Remove the frame assembly from the cylinder. Allow it to dry in air (hood), and then dry it to a constant mass in an oven at 110 ± 5ºC (230 ± 9ºF) (Note 9).

16.2.7. Determine the mineral matter in the extraction solution by one of the procedures specified in Annex A1.

17. CALCULATION OF ASPHALT BINDER CONTENT

17.1. Calculate the percentage of asphalt binder in the test portion in accordance with the procedure described in Section 13.

TEST METHOD D

18. APPARATUS

18.1. In addition to the apparatus listed in Section 6, the following apparatus is required for Test Method D:

18.1.1. *Extraction Apparatus*—As shown in Figure 3, consisting of an extraction kettle of metal or borosilicate glass, fitted with a perforated basket and a condenser top. The underside of the condenser shall be covered with numerous rounded knobs to distribute the condenser solvent uniformly over the surface of the sample. The suspension of the basket shall be arranged to support the basket 13 mm ($^1/_2$ in.) above the bottom of the kettle, for immersion of the test portion in the solvent, and at least 75 mm (3 in.) above the bottom of the kettle for refluxing (Note 8).

18.1.2. *Cloth Filter Sacks*—with an elastic hem for lining the basket.

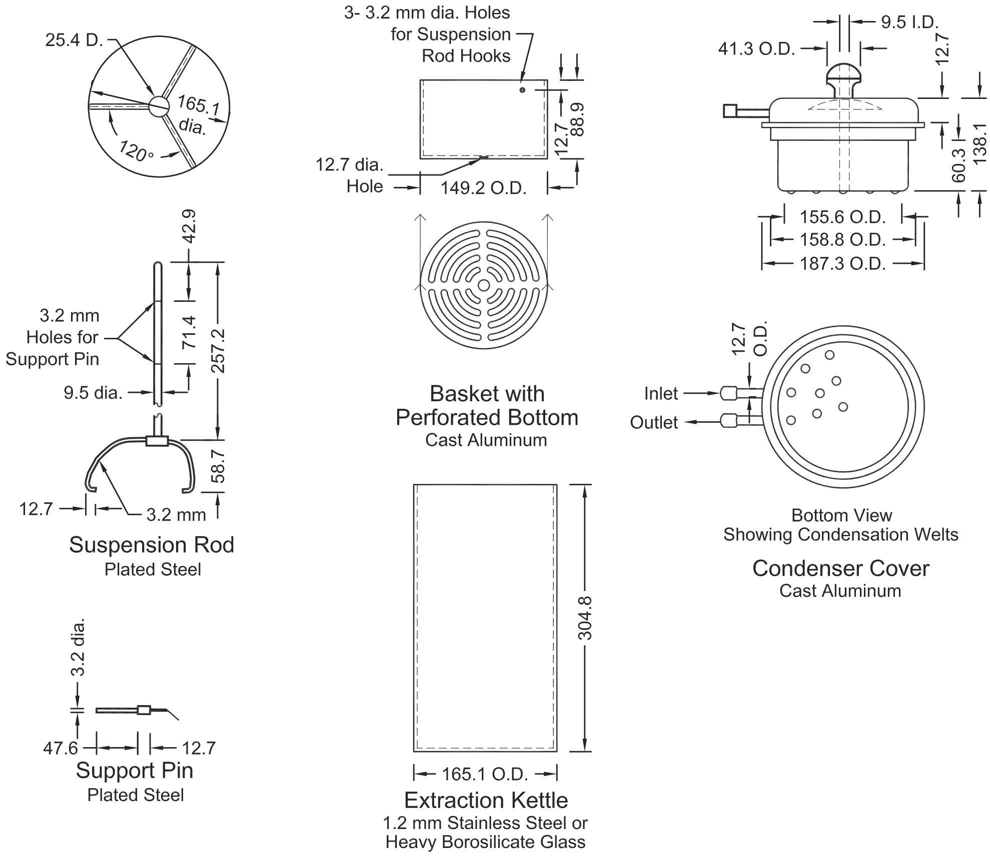


Figure 3—Extractor Unit (Method D)

19. PREPARATION OF TEST PORTIONS

19.1. Prepare test portions for moisture determination and extraction in accordance with the procedure described in Section 9.

20. PROCEDURE

20.1. *Moisture*:

20.1.1. Determine the moisture content of the HMA (Section 9.2.3) in accordance with the method described in Section 10.

20.2. *Extraction*:

20.2.1. Insert a filter sack in the extraction basket, and determine the mass with the tare pan to determine the total tare mass. Place the test portion in the filter sack, and determine the total mass. Calculate the mass of the test portion.

20.2.2. Attach the suspension rod to the loaded basket, and set the assembly into the extraction kettle. Pour approximately 600 mL of solvent (Section 7.1, 7.2, or 7.3) over the test portion. Set the condenser cover in place on the kettle. Provide a flow of cold water through the condenser lid. Raise the basket to immersion level, for example 13 mm ($^1/_2$ in.) above the bottom of kettle, by inserting the support pin through the upper hole of the suspension rod. Place the extractor on the hot plate, and adjust the heating rate so that solvent is maintained at a gentle boil, avoiding vigorous boiling which might wash fines over the sides of the basket.

20.2.3. Continue heating with the test portion in the immersion position for 15 to 30 min, and then raise the basket to refluxing level. Increase the heat, and maintain active boiling until solvent dripping from the basket appears to be a light straw color when viewed against a white background. If a stainless steel kettle is used, lift out the basket and the condenser cover assembly for examination of the solvent.

20.2.4. Remove the extractor from the hot plate, and allow it to cool for several minutes. Lift out the basket and condenser assembly. Cover the kettle; remove the filter sack, and distribute its contents into the tared pan in which the mass of the test portion was originally determined. Place the filter sack on top of the recovered aggregate. Dry on a steam bath and then in an oven at 110 ± 5ºC (230 ± 9ºF) to constant mass. Transfer the extract solution to a 1000-mL graduate. Wash the extractor clean with solvent, and add the washings to the extract solution.

20.2.5. Determine the mineral matter in the extract solution by one of the procedures specified in Annex A1.

21. CALCULATION OF ASPHALT BINDER CONTENT

21.1. Calculate the percentage of asphalt binder in the test portion in accordance with the procedure described in Section 13.

TEST METHOD E

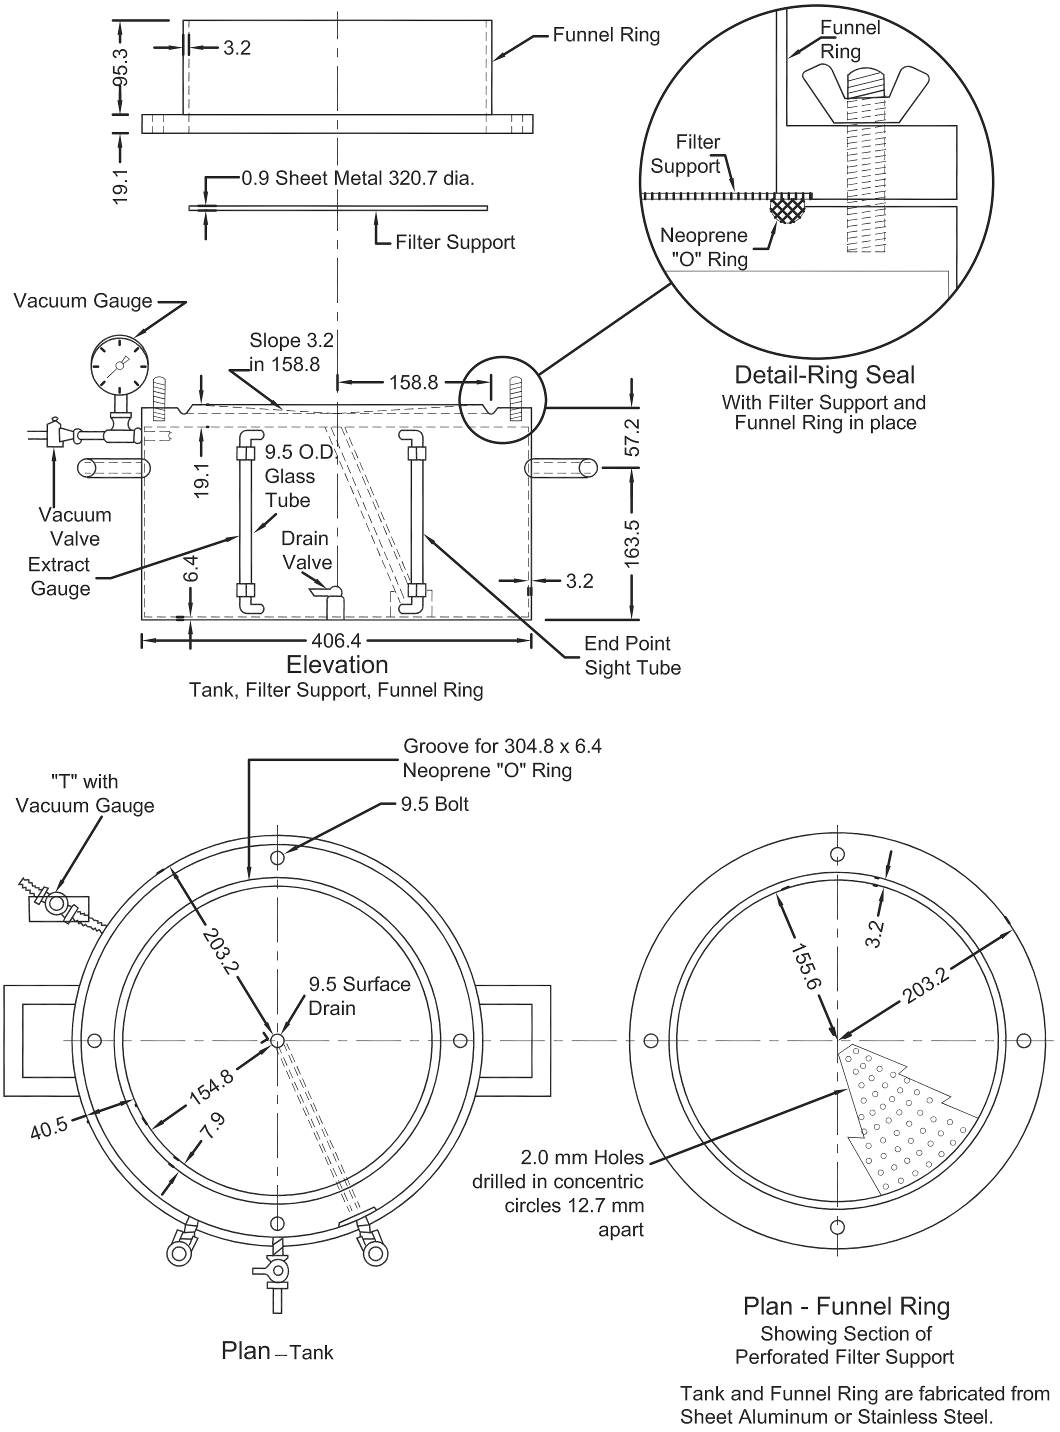
22. APPARATUS

22.1. In addition to the apparatus listed in Section 6, the following apparatus is required for Test Method E:

22.1.1. *Vacuum Extractor*—complete with the vacuum pump, gasket, rubber tubing, filter paper, support plate, and funnel ring. The dimensional equivalents and apparatus shown in Table 3, and Figures 4a, 4b, and 4c and similar designs are suitable.

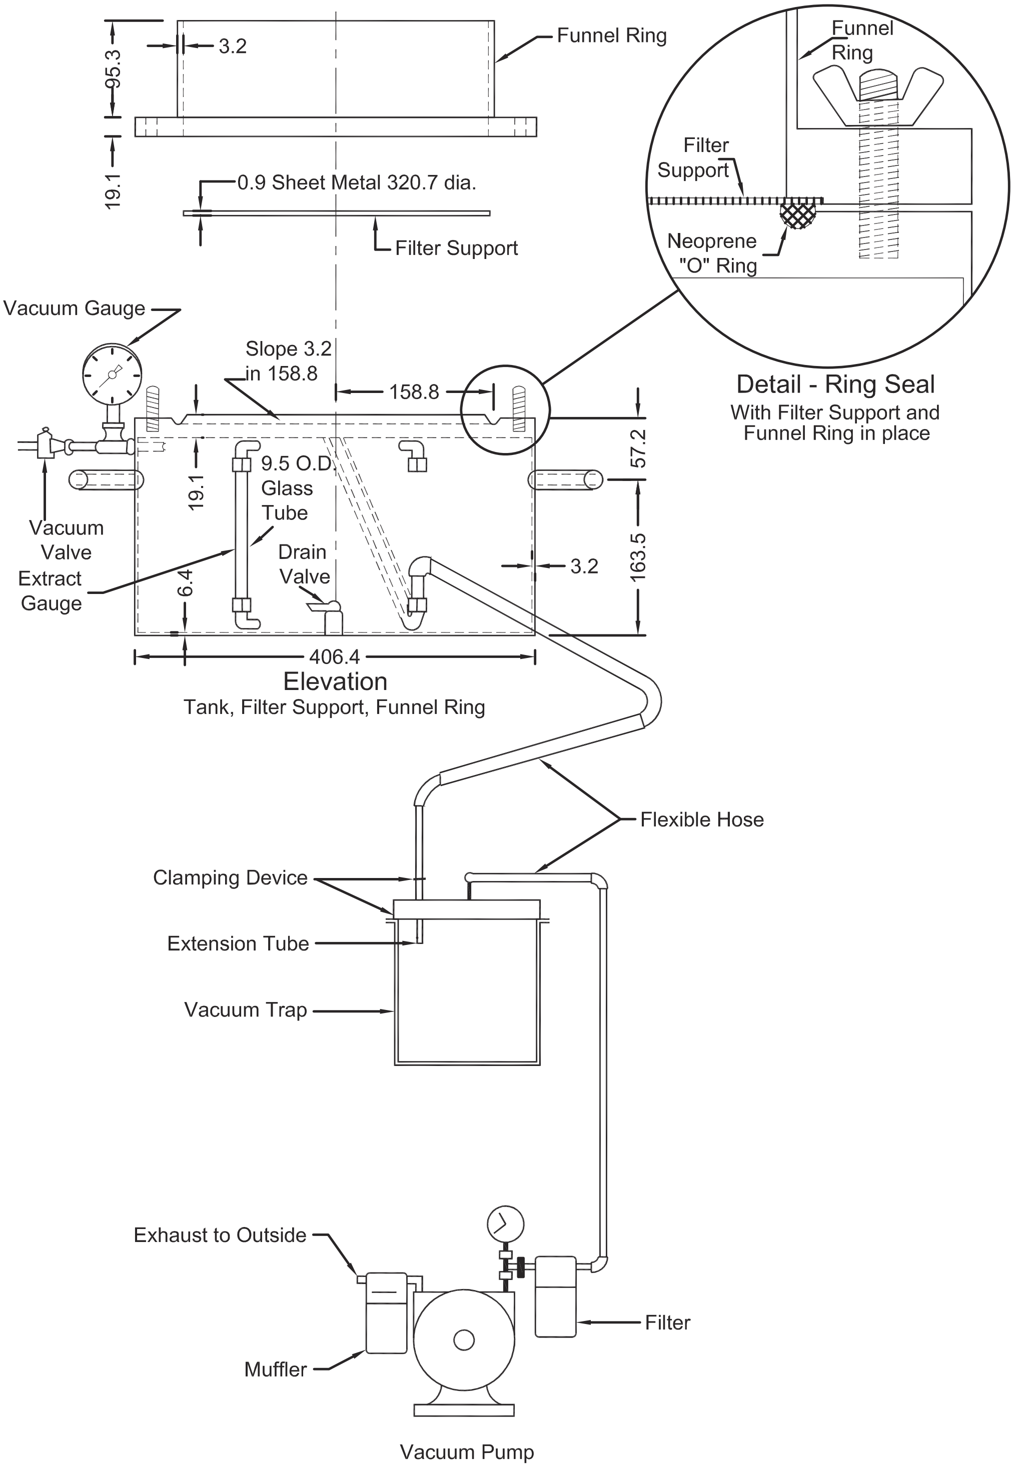
Table 3—Dimensional Equivalents

in.	mm	in.	Mm
16	406	$2^1/_4$	57
$12^5/_8$	321	$1^{19}/_{32}$	40
12	305	$^3/_4$	19
8	203	$^1/_2$	12.7
$6^7/_{16}$	164	$^3/_8$	9.5
$6^1/_4$	159	$^1/_4$	6.4
$6^1/_8$	156	$^3/_{64}$	1.19
$6^3/_{32}$	155	0.060	1.52
$3^3/_4$	95		



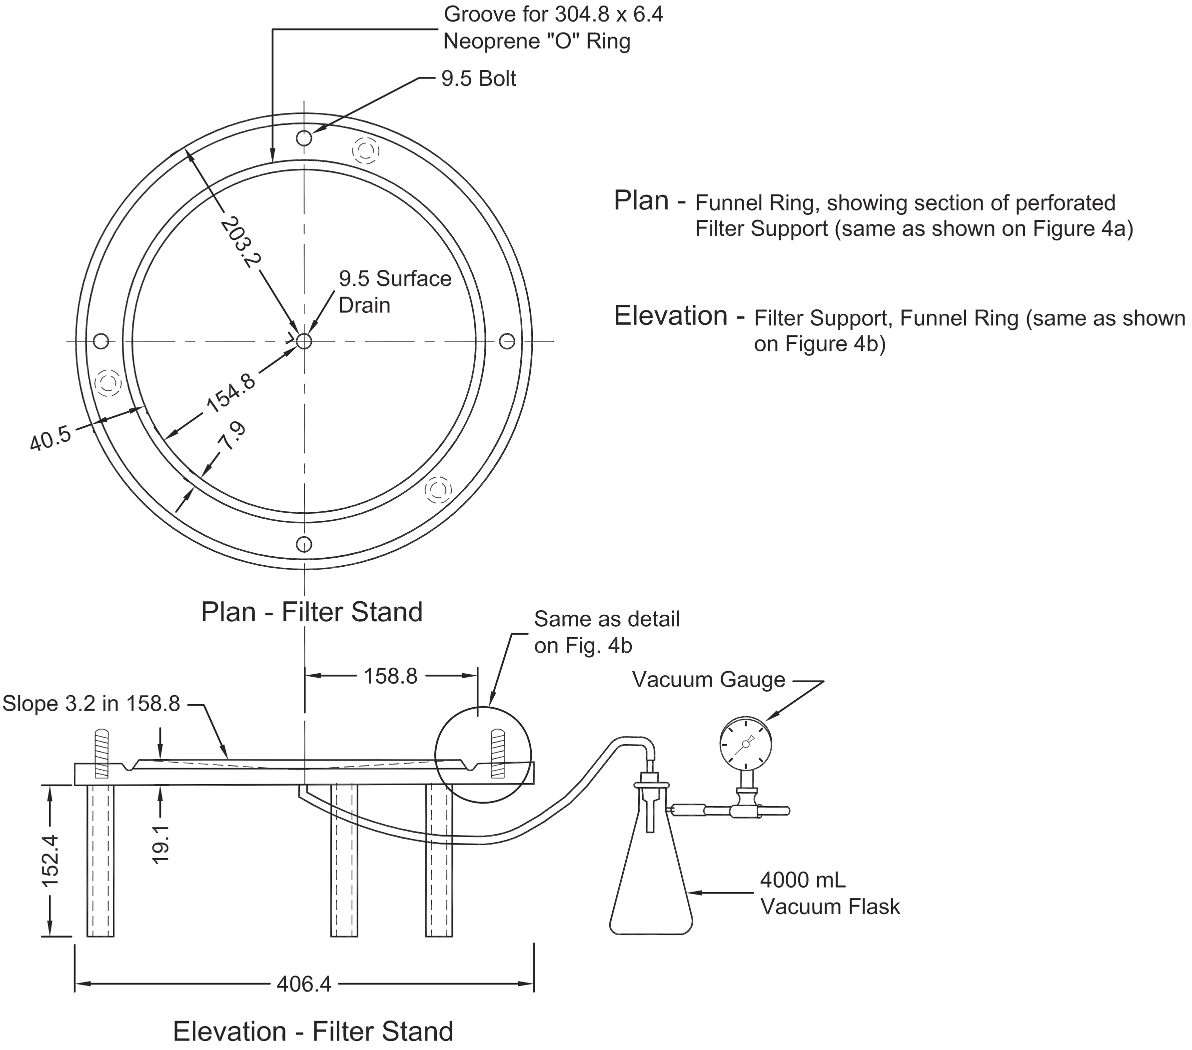
Note: See Table 3 for dimensional equivalents. All dimensions shown in millimeters unless otherwise noted.

Figure 4a—Vacuum Extractor



Note: All dimensions are shown in millimeters unless otherwise noted.

Figure 4b—Vacuum Extractor



Note: All dimensions are shown in millimeters unless otherwise noted.

Figure 4c—Vacuum Extractor

22.1.2. *Filter Paper*, medium-grade, fast-filtering, 330 mm (13 in.) in diameter.

22.1.3. *Sample Container*, 3.8-L (4-qt) capacity or greater.

22.1.4. *Erlenmeyer Flasks*, glass, two, having a capacity of 4000 mL each.

22.1.5. *Graduate*, glass, having a capacity of 500 mL.

22.1.6. *Wash Bottle*, plastic, having a capacity of 500 mL.

22.1.7. *Dial Thermometer*, having a range from 10 to 82ºC (50 to 180ºF).

22.1.8. *Mixing Spoon*.

22.1.9. *Spatula*.

22.1.10. *Stiff Bristled Brush*.

22.1.11. *Erlenmeyer Flask*, glass, having a capacity of 1000 mL.

22.1.12. *Watch Glass*, having a diameter of approximately 100-mm (4-in.) diameter.

22.1.13. *Metal Tongs*, 150 to 200 mm (6 to 8 in.) long.

22.1.14. 1.18-mm (No. 16) and 75-µm (No. 200) Sieves, 305 mm (12 in.) in Diameter (optional).

Note 16—Use apparatus and materials listed under Sections 22.1.11, 22.1.12, 22.1.13, 23.1, and 23.2 only with HMA that is hard to filter, as in Method E-II.

22.1.15. *Stainless Steel Beaker*.

23. REAGENTS AND MATERIALS

23.1. Diatomaceous Silica Filtering Aid conforming to Type B of ASTM D 604.[2]

23.2. *Ethyl Alcohol*, denatured (optional).

23.3. *Methylene Chloride* (Note 17).

Note 17—Any of the other solvents listed in Section 7 may be substituted for methylene chloride.

24. PREPARATION OF TEST PORTIONS

24.1. Prepare test portions for moisture determination and extraction in accordance with the procedure described in Section 9.

25. PROCEDURE

25.1. Determine the moisture content of the HMA (Section 9.2.3) in accordance with the method described in Section 10.

25.2. *Extraction*:

25.2.1. Place the extraction test portion into the tared stainless steel beaker, and determine the mass (Note 18).

25.2.2. If the test portion is above 54ºC (130ºF), allow it to cool to a temperature less than 54ºC (130ºF). When sufficiently cool, pour 200 mL of denatured alcohol, if needed, over the specimen (Note 18). Add approximately 700 mL of extractant, and stir until the asphalt binder is visually in solution (Note 19).

Note 18—Alcohol should not be needed with terpene extractants.

Note 19—If equipment is available, an ultrasonic cleaning tank may be used instead of the beaker (Section 25.2.1) in which to bring the asphalt binder into solution (Section 25.2.2).

25.2.3. Dry the filter paper (more than one filter paper may be used) to constant mass in an oven at 110 ± 5ºC (230 ± 9ºF), and place the filter paper on the extractor, taking care to center the filter paper and tighten the wing nuts "finger tight" (Note 20).

Note 20—Experience has shown that clogging of the filter may be reduced by decanting the extract solution through nested 1.18-mm (No. 16) and 75-µm (No. 200) sieves onto the filter. When sieves are used, the solution will be decanted onto the 1.18-mm (No. 16) sieve instead of the filter.

25.2.4. Start the vacuum pump and slowly decant extract solution from the sample container onto the filter. When all solution has been removed from the filter paper, the vacuum pump may be stopped or left running.

25.2.5. Cover the sample remaining in the container with extractant, up to 700 mL. Stir gently until the asphalt binder and aggregate fines appear to be in suspension (or start the ultrasonic cleaner if used). Repeat the step in Section 25.2.4.

25.2.6. Repeat Section 25.2.5 until the solution is a light straw color and the aggregate is visually clean. The flow of solvent may be slowed for color observation by partially opening the vacuum valve and reducing the vacuum. If terpene extractant is used, pour all of the extractant onto the filter, and allow the vacuum to continue until the fluid has passed through the filter. Repeat Sections 25.2.5 and 25.2.4, using water preferably above 43°C (110°F), as many times as necessary to remove the terpene residue from the aggregate and render the rinse water clear. Operate the vacuum pump for a few minutes after the last wash to aid in drying the test portion. Scrape the aggregate away from the side of the funnel ring toward the center of the filter to avoid loss when the ring is removed. Also wash the sides of the funnel ring to remove any fines. Stop the vacuum pump and remove the ring, brush the clinging aggregate into the tared drying pan. Carefully pick up the filter paper and aggregate by holding the paper on opposite sides and raising it straight up. Transfer the aggregate on the filter paper to the tared drying pan, and brush the clinging aggregate from the filter into the pan. Alternatively, the filter paper and aggregate may be contained separately in tared pans or the aggregate may be contained in a tared pan and the filter paper placed on top of it. In either case, use care to assure that all traces of aggregate in the test sample are transferred to the drying pan(s).

25.2.7. Dry the extracted aggregate and filter to a constant mass in an oven at 110 ± 5ºC (230 ± 9ºF) (Note 21).

Note 21—See the alternate procedure in Section 12.5.1 when low-ash filter paper is used.

25.2.8. Determine the mass of the filter and aggregate in the pan(s), and record it. Subtract the mass of the filter and pan to determine the mass of the extracted aggregate.

25.2.9. Determine the mineral matter in the extract solution by one of the procedures specified in Annex A1 (Note 22).

Note 22—Sections 25.2.9 and 25.2.15 may be omitted when this method is used only for control of asphalt binder content during HMA production (plant control).

TEST METHOD E-II

25.2.10. To extract a slow-filtering HMA mixture efficiently, prepare the test portion as described in Sections 25.2.1 and 25.2.2.

25.2.11. Dry the filter paper to constant mass in an oven at 110 ± 5ºC (230 ± 9ºF), and place the filter paper on the extractor, taking care to center the filter paper and tighten the wing nuts "finger tight" (Note 20).

25.2.12. Weigh between 50 and 200 g of oven-dried diatomaceous silica filtering aid into a 1000-mL Erlenmeyer flask; record the mass, and then add 500 mL of extractant. Swirl until the diatomaceous silica is completely in suspension.

25.2.13. Immediately pour the diatomaceous silica and extractant over the filter. Two pre-dried filters separated by an additional 50 to 100 g of diatomaceous earth may be used to retain the minus 75-µm (No. 200) material, if desired, to facilitate improved flow of the liquid. Start the vacuum pump, and let it run until the pad formed by the diatomaceous silica is surface dry and begins to crack slightly (Note 23).

Note 23—Some diatomaceous silica may be washed through the filter and included in the mineral matter determination of Section 25.2.15. Blank tests are recommended to determine the amount of diatomaceous silica, if any, lost through the filter. An appropriate correction will be required in the mineral matter mass.

25.2.14. Place the watch glass in the extractor, and slowly decant the extractant from the container over the watch glass (Note 24). Stop the vacuum pump when all the solution has been removed from the filter. Repeat as in Section 25.2.5, except decant the solution onto the watch glass. Complete the procedure as in Section 25.2.6. Also wash the watch glass with extractant to remove any fines onto the filter.

Note 24—When nested sieves are used, the watch glass may be omitted.

25.2.15. Determine the amount of mineral matter in the extract solution by one of the procedures specified in Annex A1 (Note 22).

26. CALCULATION OF ASPHALT BINDER CONTENT (APPLICABLE TO BOTH METHOD E-I AND METHOD E-II)

26.1. Calculate the percentage of asphalt binder in the test portion in accordance with the procedure described in Section 13.

27. PRECISION AND BIAS

27.1. The single-laboratory standard deviation has been found to be 0.18 percent. Therefore, results of two properly conducted tests by the same operator on the same batch should not differ by more than 0.52 percent. These values become 0.21 and 0.58, respectively, when extractant containing 85 percent terpene is used (Notes 25 and 26).

27.2. The multilaboratory standard deviation has been found to be 0.29 percent. Therefore, the results of two properly conducted tests from two different laboratories on samples from the same batch should not differ by more than 0.81 percent. These values become 0.29 and 0.83, respectively, when extractant containing 85 percent terpene is used (Notes 25 and 26).

Note 25—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

Note 26—These precision statements are based on one pair of reference samples with 59 laboratories participating and three laboratory results deleted as outlying observations. The reference samples contained aggregate with 98 percent passing the 9.5-mm ($^3/_8$-in.) screen. All test methods were used in the interlaboratory test program.

ANNEX

(Mandatory Information)

A1. DETERMINING THE AMOUNT OF MINERAL MATTER IN THE EXTRACT

A1.1. *Ashing Method*:

A1.1.1. *Apparatus*:

A1.1.1.1. *Ignition Dish*—at least 125 mL in capacity.

A1.1.1.2. Ignition Furnace or Bunsen Burner.

A1.1.1.3. Steam bath or hot plate.

A1.1.1.4. Desiccator.

A1.1.1.5. *Analytical Balance*—conforming to the requirements of M 231, Class B.

A1.1.1.6. *Cylinder*—100 mL in capacity.

A1.1.2. *Reagents*:

A1.1.2.1. *Ammonium Carbonate Solution*—Saturated solution of reagent-grade ammonium carbonate [$(NH_4)_2CO_2$]

A1.1.3. *Procedure*:

A1.1.3.1. Determine either the volume or mass of the total extract (W_1). Condition the ignition dish in an ignition furnace or over a bunsen burner; cool it in a desiccator, and determine the mass of the ignition dish to the nearest 0.001 g. Agitate the extract thoroughly, and immediately measure 100 mL or 100 g into the ignition dish. Evaporate to dryness on a steam bath or hot plate. Ash the residue at a dull red heat [500 to 600ºC (932 to 1112ºF)] and cool it. Determine the mass of the ash, and add 5 mL of saturated ammonium carbonate solution per gram of ash. Digest at room temperature for 1 h. Dry in an oven at 110 ± 5ºC (230 ± 9ºF) to constant mass; cool in a desiccator, and determine the mass to the nearest 0.001 g (G).

A1.1.3.2. Calculate the mass of mineral matter in the total volume of extract (W_4) as follows:

$$W_4 = G\,(W_1/100) \tag{A1.1}$$

where:

G = ash remaining in the ignition dish to nearest 0.001 g; and

W_1 = total volume, mL (or total mass, g) of extract.

A1.2. *Centrifuge Method*:

A1.2.1. *Apparatus*:

A1.2.1.1. Any suitable high-speed (3000 r/min or higher) centrifuge of the continuous-flow type.[3]

A1.2.1.2. *Balance*—conforming to the requirements of M 231, Class G 1.

A1.2.1.3. Funnel or Steam Hood.

A1.2.2. *Procedure*:

A1.2.2.1. Determine the mass of a clean, empty centrifuge cup (or bowl) to the nearest 0.01 g, and place it in the centrifuge. Position a container at the appropriate spout to catch the effluent from the centrifuging operation. Transfer all of the extract (from Method A, B, D, or E as appropriate) to an appropriate (feed) container suitably equipped with a feed control (valve or clamp, etc.). To ensure quantitative transfer of the extract to the feed container, the receptacle containing the extract should be washed several times with small amounts of clean solvent and the washings added to the feed container. Start the centrifuge, and allow it to reach a constant operational speed (e.g., 9000 r/min for the SMM type and 20000 + r/min for the Sharples type). Open the feed line, and feed the extract into the centrifuge at a rate of 100 to 150 mL/min. After all the extract has passed through the centrifuge, wash the feed mechanism (with the centrifuge still running) with several increments of clean solvent, allowing each increment to run through the centrifuge until the effluent is essentially colorless.

A1.2.2.2. Allow the centrifuge to stop, and remove the cup (or bowl). Clean the outside with fresh solvent. Allow the residual solvent to evaporate in a funnel or steam hood, and then dry the container in an oven controlled at 110 ± 5ºC (230 ± 9ºF). Cool the container and redetermine the mass to the nearest 0.01 g immediately. The increase in mass is the mass of mineral matter, W_4 (Section 13), in the extract.

A1.3. *Volumetric Method*:

A1.3.1. *Apparatus*:

A1.3.1.1. Flask.

A1.3.1.2. *Water Bath*—capable of controlling temperature to ±0.1ºC (±0.2ºF).

A1.3.1.3. *Balance*—conforming to the requirements of M 231, Class G 2.

A1.3.2. *Procedure*:

A1.3.2.1. Place the extract in a previously tared and calibrated flask. Place the flask in a constant-temperature bath controlled to ±0.1ºC (±0.2ºF), and allow it to reach the temperature at which the flask was calibrated. When the desired temperature has been reached, fill the flask with solvent at the same temperature. Bring the level of the liquid in the flask up to the neck; insert the stopper, making sure the liquid overflows the capillary, and remove the flask from the bath. Wipe the flask dry; determine the mass to the nearest 0.1 g, and record this mass as the mass of flask plus extract, M_2.

Note A1—Instead of using a controlled temperature bath, the temperature of the extract may be measured and the necessary corrections to the volume of the flask and the density of the asphalt binder and solvent made.

A1.3.2.2. Calculate the volume of asphalt and fines in the extract as follows:

$$V_1 = V_2 - \frac{\left(M_1 - M_2\right)}{G_1} \qquad (A1.2)$$

where:

V_1 = volume of asphalt and fines in the extract, mL;

V_2 = volume of the flask, mL;

M_1 = mass of the contents of the flask, g;

M_2 = mass of the asphalt binder and fines in the extract (or mass of the total sample minus the mass of the extracted aggregate), g; and

G_1 = specific gravity of the solvent determined to the nearest 0.001 in accordance with ASTM D 2111.

A1.3.2.3. Calculate the mass of fines in the extract as follows:

$$M_3 = K\left(M_2 - G_3V_1\right) \qquad (A1.3)$$

where:

M_3 = mass of fines in the extract, g;

G_2 = specific gravity of fines as determined in accordance with T 84;

G_3 = specific gravity of asphalt binder as determined in accordance with T 228;

$K = \frac{G_2}{G_2 - G_3}$;

V_1 = as given in Section A1.3.2.2; and

M_2 = as given in Section A1.3.2.2.

---

[1] This method is similar to ASTM D 2172-05.

[2] Celite 110, manufactured by Johns-Manville, has been found satisfactory for this purpose; however, all filtering aids should be presieved through a 75-µm (No. 200) sieve when the gradation test on the aggregate is to be performed.

[3] The Sharples Supercentrifuge and the SMM continuous-flow centrifuge have been found suitable for this method.

Standard Method of Test for

Effect of Water on Compressive Strength of Compacted Bituminous Mixtures

AASHTO Designation: T 165-02 (2006)
ASTM Designation: D 1075-96

American Association of State Highway and Transportation Officials

Standard Method of Test for

Effect of Water on Compressive Strength of Compacted Bituminous Mixtures

AASHTO Designation: T 165-02 (2006)
ASTM Designation: D 1075-96

The AASHTO equivalent of this test method has been discontinued. Please refer to ASTM D 1075-96 for information formerly contained in this standard.

Standard Method of Test for

Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens

AASHTO Designation: T 166-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens

AASHTO Designation: T 166-10

1. SCOPE

1.1. This method of test covers the determination of bulk specific gravity of specimens of compacted hot mix asphalt (HMA).

1.2. This method should not be used with samples that contain open or interconnecting voids or absorb more than 2.0 percent of water by volume, as determined in Sections 7.2 or 10.2 herein.

1.3. The bulk specific gravity of the compacted HMA may be used in calculating the unit mass of the mixture.

1.4. The values stated in SI units are to be regarded as the standard.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 275, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Paraffin-Coated Specimens

2.2. *ASTM Standard:*

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *bulk specific gravity (of solids)*—the ratio of the mass in air of a unit volume of a permeable material (including both permeable and impermeable voids normal to the material) at a stated temperature to the mass in air of equal density of an equal volume of gas-free distilled water at a stated temperature. The form of the expression shall be:

Bulk specific gravity at x/y °C (1)

where:

x = temperature of the material; and
y = temperature of the water.

3.1.2. *constant mass*—shall be defined as the mass at which further drying does not alter the mass by more than 0.05 percent when weighed at 2-h intervals.

4. TEST SPECIMENS

4.1. Test specimens may be either laboratory-compacted HMA or sampled from HMA pavements.

4.2. *Size of Specimens*—It is recommended that: (1) the diameter of cylindrically compacted or cored specimens, or the length of the sides of sawed specimens, be at least equal to four times the maximum size of the aggregate; and (2) the thickness of specimens be at least one and one half times the maximum size of the aggregate.

4.3. Specimens shall be taken from pavements with a core drill, diamond or carborundum saw, or by other suitable means.

4.4. Care shall be taken to avoid distortion, bending, or cracking of specimens during and after the removal from the pavement or mold. Specimens shall be stored in a safe, cool place.

4.5. Specimens shall be free from foreign materials such as seal coat, tack coat, foundation material, soil, paper, or foil.

4.6. If desired, specimens may be separated from other pavement layers by sawing or other suitable means. Care should be exercised to ensure sawing does not damage the specimens.

METHOD A

5. APPARATUS

5.1. *Weighing Device*—The weighing device shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231. The weighing device shall be equipped with a suitable suspension apparatus and holder to permit weighing the specimen while suspended from the center of the scale pan of the weighing device.

5.2. *Suspension Apparatus*—The wire suspending the container shall be the smallest practical size to minimize any possible effects of a variable immersed length. The suspension apparatus shall be constructed to enable the container to be immersed to a depth sufficient to cover it and the test sample during weighing. Care should be exercised to ensure no trapped air bubbles exist under the specimen.

5.3. *Water Bath*—For immersing the specimen in water while suspended under the weighing device, equipped with an overflow outlet for maintaining a constant water level.

6. PROCEDURE

6.1. Dry the specimen to a constant mass at a temperature of 52 ± 3°C (125 ± 5°F). Samples saturated with water shall initially be dried overnight and then weighed at 2-h drying intervals. Recently compacted laboratory samples, which have not been exposed to moisture, do not require drying.

6.2. Cool the specimen to room temperature at 25 ± 5°C (77 ± 9°F), and record the dry mass as *A* (Note 1). Immerse each specimen in water bath at 25 ± 1°C (77 ± 1.8°F) for 4 ± 1 min, and record the immersed mass as *C*. Remove the specimen from the water, damp-dry the specimen by blotting with a damp towel as quickly as possible (not to exceed 5 s), and determine the surface-dry mass as *B*. Any water that seeps from the specimen during the weighing operation is considered part of the saturated specimen. Each specimen shall be immersed and weighed individually.

Note 1—If desired, the sequence of testing operations may be changed to expedite the test results. For example, first the immersed mass *C* can be taken, then the surface-dry mass *B*, and finally the dry mass *A*.

Note 2—Terry cloth has been found to work well for an absorbent cloth. Damp is considered to be when no water can be wrung from the towel.

7. CALCULATION

7.1. Calculate the bulk specific gravity of the specimen as follows:

$$\text{Bulk Specific Gravity} = \frac{A}{B - C} \qquad (2)$$

where:

A = mass of the specimen in air, g;
B = mass of the surface-dry specimen in air, g; and
C = mass of the specimen in water, g.

7.2. Calculate the percent of water absorbed by the specimen (on a volume basis) as follows:

$$\text{Percent of Water Absorbed by Volume} = \frac{B - A}{B - C} \times 100 \qquad (3)$$

7.3. If the percent of water absorbed by the specimen as calculated in Section 6.2 exceeds 2.0 percent, use T 275 to determine the bulk specific gravity.

METHOD B

8. APPARATUS

8.1. *Weighing Device*—The weighing device shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231.

8.2. *Water Bath*—For immersing the specimen in water.

8.3. *Thermometer*—ASTM 17C (17F), having a range of 19 to 27°C (66 to 80°F), graduated in 0.1°C (0.2°F) subdivisions.

8.4. *Volumeter*[1]—Calibrated to 1200 mL, or an appropriate capacity depending on the size of the test sample. The volumeter shall have a tapered lid with a capillary bore.

9. PROCEDURE

9.1. Dry the specimen to a constant mass at a temperature of 52 ± 3°C (125 ± 5°F). Samples saturated with water shall initially be dried overnight and then weighed at 2-h drying intervals. Recently compacted laboratory samples, which have not been exposed to moisture, do not require drying.

9.2. Cool the specimen to room temperature at 25 ± 5°C (77 ± 9°F), and record the dry mass as *A* (Note 1). Immerse the specimen in the water bath at 25 ± 1°C (77 ± 1.8°F), and let it saturate for at least 10 min. At the end of the 10-min period, fill a calibrated volumeter with distilled water at 25 ± 1°C (77 ± 1.8°F), and weigh the volumeter. Designate this mass as *D*. Remove the saturated specimen from the water bath and damp-dry the specimen by blotting with a damp towel (Note 2) as quickly as possible (not to exceed 5 s). Weigh the specimen, and record the surface-dry mass as *B*. Any water that seeps from the specimen during the weighing operation is considered part of the saturated specimen.

9.3. Place the specimen into the volumeter, and let it stand for at least 60 s. Bring the temperature of the water to 25 ± 1°C (77 ± 1.8°F), and cover the volumeter, making certain that some water escapes through the capillary bore of the tapered lid. Wipe the outside of the volumeter dry with a dry, absorbent cloth, and weigh the volumeter and its contents (Note 3). Record this weight as *E*.

Note 3—If desired, the sequence of testing operations can be changed to expedite the test results. For example, first the mass of the saturated, damp-dry specimen *B* can be taken. Then the volumeter containing the saturated specimen and water *E* can be weighed. The dry mass of the specimen *A* can be determined last.

Note 4—Method B is not acceptable for specimens that have more than 6 percent air voids.

10. CALCULATIONS

10.1. Calculate the bulk specific gravity of the specimen as follows:

$$\text{Bulk Specific Gravity} = \frac{A}{B + D - E} \qquad (4)$$

where:

A = mass of the dry specimen, g;
B = mass of the surface-dry specimen, g;
D = mass of the volumeter filled with water at 25 ± 1°C (77 ± 1.8°F), g; and
E = mass of the volumeter filled with the specimen and water at 25 ± 1°C (77 ± 1.8°F), g.

10.2. Calculate the percent of water absorbed by the specimen (on a volume basis) as follows:

$$\text{Percent of Water Absorbed by Volume} = \frac{B - A}{B + D - E} \times 100 \qquad (5)$$

10.3. If the percent of water absorbed by the specimen as calculated in Section 10.2 exceeds 2.0 percent, use T 275 to determine the bulk specific gravity.

METHOD C (RAPID TEST)

11. PROCEDURE

11.1. This procedure can be used for testing specimens which are not required to be saved and which contain a substantial amount of moisture. Specimens obtained by coring or sawing can be tested the same day by this method.

11.2. The testing procedure shall be the same as given in Sections 6 or 9 except for the sequence of operations. The dry mass *A* of the specimen is determined last as follows.

11.3. Place the specimen in a large, flat-bottom drying pan of known mass. Place the pan and specimen in an oven at 110 ± 5°C (230 ± 9°F). Leave the specimen in the oven until it can be easily separated to the point where the particles of the fine aggregate-asphalt portion are not larger than 6.3 mm ($^1/_4$ in.). Place the separated specimen in an oven at 110 ± 5°C (230 ± 9°F), and dry to a constant mass.

11.4. Cool the pan and specimen to room temperature at 25 ± 5°C (77 ± 9°F). Determine the mass of the pan and specimen; subtract the mass of the pan, and record as the dry mass *A*.

12. CALCULATIONS

12.1. Calculate the bulk specific gravity as given in Sections 7.1 or 10.1.

13. REPORT

13.1. The report shall include the following:

13.1.1. The method used (*A*, *B*, or *C*).

13.1.2. Bulk Specific Gravity reported to the nearest thousandth.

13.1.3. Absorption reported to the nearest hundredth.

14. PRECISION

Table 1—Precision Estimates for AASHTO T 166

Condition of Test	Standard Deviation (1s)[a]	Acceptable Range of Two Results (d2s)[a]
Single-operator precision	0.002	0.006
Multilaboratory precision	0.006	0.017

[a] These values represent the 1s and 2ds limits described in ASTM C 670.

Note: Based on interlaboratory study described in NCHRP Research Report 9-26 Phase 2 involving 150-mm diameter specimens, 20 laboratories, three materials (9.5-mm, 12.5-mm, and 19.0-mm mixtures), and two replicates.

---

[1] Suitable aluminum volumeters of different sizes are available from Pine Instrument Co., 101 Industrial Drive, Grove City, PA 16127; and Rainhart Co., 604 Williams St., Austin, TX 78765.

Standard Method of Test for

Compressive Strength of Hot Mix Asphalt

AASHTO Designation: T 167-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Compressive Strength of Hot Mix Asphalt

AASHTO Designation: T 167-10

1. SCOPE

1.1. This test method provides a method for measuring the compressive strength of compacted asphalt mixtures. It is for use with specimens weighed, batched, mixed, and fabricated in the laboratory, as well as for mixtures manufactured in a hot mix plant.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information only.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.3. *Federal Specification*:

- Standard Specifications for Construction of Roads and Bridges on Federal Highway Projects

3. SIGNIFICANCE AND USE

3.1. The compressive strength of specimens prepared and tested by this test method along with density and voids properties are used for laboratory mix design of asphalt mixtures.

3.1.1. This test method also describes methods that can be used for molding, curing, and testing of specimens being evaluated by ASTM D 1075.

3.1.2. When used in conjunction with other mixture physical properties, the compressive strength may contribute to the overall mixture characterization and is one factor determining its suitability for use under given loading conditions and environment as a highway paving material.

3.2. Typical values of minimum compressive strengths for design of asphalt mixtures by this test method for different traffic densities are given in Table 402-1 of the “Standard Specifications for Construction of Roads and Bridges on Federal Highway Projects, 2003.” Some state departments of transportation and Federal agencies have specific requirements of their own based on their experience with this test method. The agencies should be consulted for their specific requirements if work is to meet their standards.

3.3. Reheated field mixtures are permissible in this test method, but the resulting compressive strengths will be higher than for newly prepared mixtures due to the change in the binder viscosity, an element of the compressive strength as measured under these loading conditions and temperature (Note 4).

4. APPARATUS

4.1. *Molds and Plungers*—Molds and plungers shall be as follows:

4.1.1. The molding cylinder shall have sufficient height to allow fabrication of a 101.6 by 101.6 mm (4 by 4 in.) specimen. It shall have an inside diameter of 101.60 to 101.73 mm (4.000 to 4.005 in.) and a nominal wall thickness of 6.4 mm ($^1/_4$ in.).

4.1.2. The mold plungers shall pass through the mold freely and shall have a diameter within 1.27 mm (0.050 in.) of the mold’s inside diameter. The plungers may be solid, hollow, or other structure as long as the ends are at least 12.7 mm ($^1/_2$ in.) thick and are at a right angle to the mold wall. The bottom plunger must be within 50 ± 4 mm (2 ± $^1/_8$ in.) high, but the top plunger may be any suitable height.

4.1.3. *Specimens Other Than 101.6 by 101.6 mm (4 by 4 in.)*—Molds and plungers for fabricating these size specimens may be used in accordance with Section 6.

4.2. *Supports*—Temporary supports shall be provided to raise the molding cylinder 25.4 mm (1 in.) during the molding operation. Steel bars 25.4 mm (1 in.) square are suitable.

4.3. *Testing Machine*—The testing machine must be of any type of sufficient capacity that will provide a range of accurately controllable rates of vertical deformation. Since the rate of vertical deformation for the compression test is specified as 0.05 mm/min·mm (0.05 in./min·in.) of specimen height, and it may be necessary to test specimens ranging in size from 50.8 by 50.8 mm

(2 by 2 in.) to perhaps 203.2 by 203.2 mm (8 by 8 in.) in order to maintain the specified minimum ratio of specimen diameter to particle size, the testing machine should have a range of controlled speeds covering at least 2.5 mm (0.1 in.)/min for 50.8-mm (2-in.) specimens to 10.2 mm (0.4 in.)/min for 203.2-mm (8-in.) specimens. The testing machine shall conform to the requirements of ASTM E 4. The testing machine shall be equipped with two steel bearing blocks with hardened faces, one of which is spherically seated and the other plain. The spherically seated block shall be mounted to bear on the upper surface of the test specimen and the plain block shall rest on the platen of the testing machine to form a seat for the specimen. The bearing faces of the plates shall have a diameter slightly greater than that of the largest specimens to be tested. The bearing faces, when new, shall not depart from a true plane by more than 0.0127 mm (0.0005 in.) at any point and shall be maintained within a permissible variation limit of 0.025 mm (0.001 in.). In the spherically seated block, the center of the sphere shall coincide with the center of the bearing face. The movable portion of this block shall be held closely in the spherical seat, but the design shall be such that the bearing face can be rotated freely and tilted through small angles in any direction.

4.4. *Oven*—The oven used in the preparation of materials or reheating of mixtures shall be controllable within ±3°C (±5°F) of any specified temperature above ambient up to 200°C (392°F).

4.5. *Hot Plate*—A small hot plate equipped with a rheostat shall be provided for supplying sufficient heat under the mixing bowl to maintain the aggregate and asphalt material at the desired temperature during mixing.

4.6. *Hot Water Bath or Oven*—A water bath or oven sufficiently large to hold three sets of 101.6-mm (4-in.) molds and plungers. If the water bath does not have an internal temperature control, a hot plate of sufficient capacity with a control to maintain the water bath at a temperature just under the boiling point will be required. The oven shall be capable of maintaining a temperature of 93.3 to 135°C (200 to 275°F).

4.7. *Air Bath*—The air bath shall be thermostatically controlled and shall maintain the air temperature for storing the specimens at 25 ± 0.5°C (77 ± 1.0°F) immediately prior to performing the compression test.

4.8. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

4.9. *Mixing Machine*—Mechanical mixing is preferable to hand mixing. Any type of mixer may be used, provided it can maintain the mixture at the required mixing temperature and will produce a well-coated, homogeneous mixture of the required size in 2 minutes or less, and further provided that it is of such design that fouling of the blades will be minimized and each individual batch can be retrieved in essentially its entirety, including asphalt and fines. Hand mixing is allowable, if necessary, but for hot mixtures the time required to obtain satisfactory coating is often excessive, and generally the test results are less uniform than when machine mixing is employed.

4.10. *Spatulas*—A flexible spatula for scraping the mixing bowl and a stiff spatula for spading the specimen in the mold.

5. PREPARATION OF TEST MIXTURES

5.1. Limit the size of the individual batches to the amount required for one test specimen.

5.2. Mix an initial batch for the purpose of "buttering" the mixing bowl and stirrers. Empty this batch after mixing and clean the sides of the bowl and stirrers of mixture residue by scraping with a small limber spatula. Do not wipe with cloth or wash clean with solvent, except when a change is to be made in the asphalt binder or at the end of a run.

5.3. Mold a trial specimen in order to determine the correct weight of materials to produce a specimen of the desired height. Use the initial or "buttering" batch for this purpose, if desired.

5.4. Aggregate ingredient samples shall be obtained in accordance with T 2 and reduced to the appropriate size by T 248. When preparing aggregates for batching, each reduced ingredient sample shall be separated into the desired size fractions in accordance with T 27. Agency practice will specify which sieves should be used to derive the desired fractions.

5.4.1. The Mixture Design, Job Mix Formula, or other control shall be used to combine the appropriate weight of each size from each ingredient aggregate to obtain the appropriate gradation and batch weight, and to determine the appropriate weight of asphalt binder to use for each specimen.

5.5. A representative sample of asphalt binder shall be obtained in accordance with T 40 from a representative stock of the material.

5.5.1. For unmodified asphalt binders, the temperature versus kinematic viscosity relationship for the asphalt binder involved dictates the temperature that should be used for preparing the hot mix asphalt test specimens. The mixing temperature is typically the temperature that yields 170 ± 20 centistokes of viscosity. The compacting temperature is typically the temperature that yields 280 ± 30 centistokes of viscosity. Mixing and compacting temperatures may be provided by the asphalt binder manufacturer (Note 1). Aggregate is heated no hotter than 28°C (50°F) above the mixing temperature to allow for dry mixing prior to adding the asphalt binder.

Note 1—Modified asphalt binders may not adhere to the equi-viscous ranges noted in Section 5.5.1. The user should refer to the asphalt binder manufacturer to establish appropriate mixing and compaction temperature ranges. In no case should the mixing temperature exceed 175°C (350°F).

5.5.2. The mixing and compacting temperatures are normally available from the asphalt binder supplier; however, it may be determined by testing the asphalt binder for kinematic viscosity (T 201) at two temperatures and plotting a graph showing the temperature and corresponding viscosity for each of the two points. Temperatures of 135°C (275°F) and 163°C (325°F) are convenient for asphalt binder grade PG 64-22; however, lower temperatures may be more appropriate for less viscous grades.

5.5.3. The graph paper may be a single or double cycle semi-log paper with the log axis (y) ranging from 100 to 1000 centistokes and the linear (x) axis established to cover the above two temperatures. Greater precision is derived by selecting ranges that utilize most of the page. General descriptions of the graph paper can be observed in ASTM D 2493 and ASTM D 341.

5.6. *Laboratory-Mixed Material*—Preheat the bowl and batch of aggregate in an oven meeting the requirements of Section 4.4 to a temperature that complies with the aggregate temperature in Section 5.5. This will result in an acceptable temperature after dry mixing. With the bowl of aggregate resting on a balance, quickly pour the prescribed weight of hot asphalt binder onto the hot aggregate and immediately mix the asphalt binder into the aggregate (Section 4.9). If mixing by hand, this can be done with a large spoon by rolling the material from perimeter toward the center to maximize aggregate and asphalt contact and minimize asphalt contact with the bowl. The mixing should be completed within 90 to 120 seconds, during which time the temperature should have dropped to about 3 to 5°C (5 to 9°F) above the compacting temperature. As soon as the material has been thoroughly mixed and has reached temperature within the specified range, charge the mold and compact the specimen.

Note 2—If the countertop is metal, an insulator such as paper may be used to reduce the rate of cooling.

5.6.1. When mixing is complete, the temperature of the mixture must be at least 3°C (5°F) above the compacting temperature; otherwise, discard the mixture and repeat mixing procedures according to Section 5.6, taking precautions to maintain temperature.

Note 3—Reheating may result in increased aging of the asphalt binder. Depending on the particular asphalt binder being tested, this can result in significantly higher-strength values.

Note 4—Laboratory samples prepared according to this test method may produce different test results, such as compressive strength values and percent air voids, when compared to results obtained from reheated plant-mixed field samples due to the effect of additional cure time and the absorption of asphalt binder by the aggregate in the field sample.

5.7. *Plant-Mixed Material*—Plant mixed hot mix asphalt shall be sampled in accordance with AASHTO T 168 and reduced to slightly more than the amount needed to fabricate the specimen. The size reduction shall be in accordance with AASHTO T 248, Method B. Adjust the weight of the reduced sample to the required weight by removing and discarding a small amount of the mixture. Care must be exercised to discard both fine and coarse particles to maintain the proper gradations.

5.7.1. Place the weighed sample into an appropriate container and heat in an oven to the mixing temperature provided in Section 5.5 for the asphalt represented in the mixture. Thoroughly mix the mixture until the temperature is 3 to 5ºC (5 to 9ºF) above the compacting temperature. This will result in the mixture being at the compacting temperature when compacting begins.

5.7.2. Compacting may commence immediately, or the material may be placed into an oven for a short time to allow more efficient handling of multiple plant-mixed samples; however, a sample should not remain in the oven for more than 1 hour.

6. TEST SPECIMENS

6.1. Generally, the test specimens shall be cylinders 101.6 mm (4.0 in.) in diameter and 101.6 ± 2.5 mm (4.0 ± 0.1 in.) in height. It is recognized that the size of test specimens has an influence on the results of the compressive strength test. Cylindrical specimens of dimensions other than 101.6 mm (4.0 in.) diameter are allowable, provided that:

6.1.1. The height shall be equal to the diameter within ±2.5 percent;

6.1.2. The diameter shall be not less than four times the nominal diameter of the largest aggregate particles;

6.1.3. The diameter shall be not less than 50.8 mm (2 in.); and

6.1.4. The unit rate of deformation shall be kept constant during the compression test (Section 8).

7. MOLDING AND CURING TEST SPECIMENS

7.1. Wipe the molds and plungers with a clean cloth that has a few drops of oil on it. Place approximately one half of the mixture (Laboratory-manufactured material according to Section 5.6, or reheated Plant-mixed material according to Section 5.7) in the molding cylinder which, together with the top and bottom plunger, has been preheated for at least 1 hour in the water bath maintained at a temperature just under the boiling point or preheated for at least 2 hours in an oven maintained at a temperature between 93.3 and 135°C (200 and 275°F). With the bottom plunger in place and the molding cylinder supported temporarily on the two steel support bars, spade the mixture vigorously 25 times with a heated spatula, with 15 of the blows being delivered around the perimeter of the mold to reduce honeycombing, and the remaining ten at random over the mixture.

7.2. Quickly transfer the remaining half of the mixture to the molding cylinder and repeat a similar spading action. Penetrate the mixture with the spatula as deeply as possible. A spatula having a slightly curved cross section has been used to advantage by some laboratories. The top of the mixture must be slightly rounded or cone-shaped to aid in firm seating of the upper plunger.

7.3. Compress the mixture between the top and bottom plungers under an initial load of about 1 MPa (150 psi) to set the mixture against the sides of the mold. Remove the support bars to permit full double–plunger action and apply the entire molding load of 20.7 MPa (3000 psi) for 2 minutes. When specimens are to be tested in accordance with ASTM 1075 for loss of strength resulting from the action of water, the standard molding load of 20.7 MPa (3000 psi) may be increased or decreased to achieve a target air void percentage or percent density.

Note 5—Based on the specified area of the plunger used with a 101.6-mm (4-in) molding cylinder, 1 MPa (150 psi) is approximately 8.2 kN (1850 lb) and 20.7 MPa (3000 psi) is approximately 168 kN (37 700 lb).

Note 6—Alternate methods of compaction may be utilized provided approximately 7 percent air voids are achieved.

7.4. Remove the specimen from the mold with an ejection device that provides a smooth, uniform rate of travel for the ejection head.

7.5. After removal from the mold, oven-cure specimens for 24 hours at 60°C (140°F). In case specimens are to be stored dry for more than 24 hours from completion of oven curing to compression testing, protect them from exposure to the air by sealing them in closely fitting, airtight containers.

8. PROCEDURE

8.1. Allow the test specimens to cool at room temperature for at least 2 hours after removal from the curing oven; then determine the bulk specific gravity of each specimen in accordance with T 166.

8.2. Bring the test specimens to the test temperature 25 ± 1°C (77 ± 1.8°F) by storing them in an air bath maintained at the test temperature for not less than 4 hours.

8.3. Test the specimens in axial compression without lateral support at a uniform rate of vertical deformation of 0.05 mm/min·mm (or 0.05 in./min·in.) of height. For specimens 101.6 mm (4 in.) in height, use a rate of 5.08 mm/min (0.2 in./min). Specimen failure is defined as the maximum load experienced by the specimen during the compression process.

8.4. The theoretical specific gravity and density shall be determined by T 209, or by any other method deemed appropriate by the agency involved. If T 209 is used, a sample of the mixture prepared but not molded, and compacted may be used.

8.5. Calculate the percent air voids in each specimen in accordance with T 269.

9. REPORT

9.1. *Report the following information*:

9.1.1. The bulk specific gravity, theoretical maximum specific gravity, density, and percent air voids of the specimens;

9.1.2. The compressive strength in kilopascals (lb/in.^{2}), determined by dividing the maximum vertical load obtained during deformation at the rate specified in Section 8 by the original cross-sectional area of the test specimen. Not fewer than three specimens shall be prepared for each asphalt increment, and the average of the three shall be reported as the compressive strength; and

9.1.3. The nominal height and diameter of the test specimens.

9.1.4. The compaction method utilized.

10. PRECISION AND BIAS

10.1. *Single-Operator Precision*—The single-operator standard deviation of a single test result (where the test result is, as defined in this test method, the average of a minimum of three separate compressive strengths) has been found to be 145 kPa (21 psi) (Note 7). Therefore, results of two properly conducted tests (each consisting of the average of a minimum of three individual compressive strengths) in the same laboratory on the same material by the same operator should not differ by more than 407 kPa (59 psi) (Note 7), and the range (difference between highest and lowest) of the individual measurements used in calculating the average should not exceed 841 kPa (122 psi) (Note 8).

Note 6—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

Note 7—Calculated as described in ASTM C 670.

10.2. *Multilaboratory Precision*—The multilaboratory standard deviation of a single test result (where the test result is, as defined in this test method, the average of a minimum of three separate compressive strengths) has been found to be 372 kPa (54 psi) (Note 7.) Therefore, results of two properly conducted tests (each consisting of the average of a minimum of three individual compressive strengths) in different laboratories on the same material should not differ by more than 1055 kPa (153 psi).

Note 8—The precision statements given are applicable only to the static compaction method.

10.3. This test method has no bias because the compressive strength of asphalt mixtures is defined only in terms of the test method.

11. KEYWORDS

11.1. Asphalt paving mixtures; compression testing; compressive strength.

Standard Method of Test for

Sampling Bituminous Paving Mixtures

AASHTO Designation: T 168-03 (2007)
ASTM Designation: D 979-01 (2006)$^{\in 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling Bituminous Paving Mixtures

AASHTO Designation: T 168-03 (2007)

ASTM Designation: D 979-01 (2006)$^{\in 1}$

AASHTO T 168-03 (2007) is identical to ASTM D 979-01 (2006)$^{\in 1}$ except for the following provisions:

1. All references to the ASTM standards listed in the following table, shall be replaced with the corresponding AASHTO standard:

Referenced Standard	
ASTM	AASHTO
C 702	T 248

2. Insert an additional section between Sections 4.1.1 and 4.1.2 containing the following:

   Care shall be taken in sampling to avoid segregation of coarse aggregate and asphalt mortar. Care shall be taken also to prevent contamination by dust or other foreign matter.

3. Insert new Sections 5.2.3.3, 5.2.3.4 and 5.2.3.5 after Section 5.2.3.2 as follows:

   5.2.3.3 If the mixture is in a windrow (cold mix), random samples of the windrow at intervals of not more than 150 m (500 ft) shall be secured and tested separately. Samples of the windrow shall be secured by flattening it at one point into a layer of approximately 0.3 m (1 ft) thick and coring this layer at three or more random points to obtain the required sample size as shown in Table 1.

   5.2.3.4 If the mix has been bladed into a relatively uniform layer, samples shall be secured at intervals of not more than 150 m (500 ft).

   5.2.3.5 Samples from a stockpile shall be obtained by combining equal quantities of the mixture taken from holes dug into points near the top, middle, and bottom of the stockpile. Reduction of the sample to the required size shall be as described in Section 5.3.2.

4. Insert an additional section between Sections 6.2.3 and 6.2.4 containing the following:

   Lot number.

Standard Method of Test for

Recovery of Asphalt Binder from Solution by Abson Method

AASHTO Designation: T 170-00 (2009)[1]
ASTM Designation: D 1856-95a (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Recovery of Asphalt Binder from Solution by Abson Method

AASHTO Designation: T 170-00 (2009)[1]
ASTM Designation: D 1856-95a (2003)

1. SCOPE

This method covers the recovery, by the Abson Method, of asphalt binder from a previously conducted extraction with reagent-grade trichloroethylene or reagent-grade methylene chloride (Note 1). The asphalt binder is recovered with properties substantially the same as those it possessed in the asphalt mixture and in quantity sufficient for further testing.

Note 1—Trichloroethylene conforming to ASTM D 4080 or technical grade methylene chloride may be used, but it is recommended that for each new supply of the solvent, a blank should be run on an asphalt binder of known properties. In case of dispute, reagent grade should be used.

Blank Determinations—Introduce about 70 g of asphalt binder into a 2000-mL flask (68-oz); add about 800 mL (27 oz) of solvent to dissolve the asphalt, allow the solution to stand for about 4 h; concentrate the solution by distillation to about 200 mL (6.8 oz) and then recover the asphalt binder. Total elapsed time from when the solvent is added to the time the recovery test is completed is about 7 h.

1.1 The values stated in SI units are to be regarded as the standard.

1.2 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- T 111, Mineral Matter or Ash in Asphalt Materials
- T 164, Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)

2.2 *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 96, Standard Test Methods for Water and Sediment in Crude Oil by Centrifuge Method (Field Procedure) (Withdrawn 2000)

- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. SUMMARY OF METHOD

3.1 The solution of solvent and asphalt binder from a prior extraction is distilled under prescribed conditions to a point where most of the solvent has been distilled, at which time carbon dioxide gas is introduced into the distillation process to remove all traces of the extraction solvent. The recovered asphalt binder (distillation residue) can then be subjected to further testing as required.

4. SIGNIFICANCE AND USE

4.1 The asphalt binder should be extracted from the asphalt mixture in accordance with Method A or E (Note 2) of T 164, as there is some experimental evidence that the recovered asphalt binder may have slightly lower penetration values when recovered from solutions obtained from hot extraction methods.

Note 2—Equipment in Method E of T 164 can be modified by a vacuum trap attached to the top of the "end point" site tube to collect the extract to allow its use for recoveries.

5. APPARATUS

5.1 *Centrifuge*—Batch unit capable of exerting a minimum centrifugal force of 770 times gravity or a continuous unit capable of exerting a minimum force of 3000 times gravity. The apparatus specified in ASTM D 96 may also be used.[2]

5.2 *Centrifuge Tubes*—A supply of 250- to 500-mL (8.5- to 16.9-oz) wide-mouth bottles, or centrifuge tubes as shown in Figure 1 or 2 of ASTM D 96.

5.3 *Distillation Assembly*—As shown in Figure 1 and consisting of the following items:

5.3.1 *Extraction Flasks*—A 250- to 500-mL (8.5- to 16.9-oz) wide-mouth, heat-resistant flask for distillation and a suitable flask for the receiver.

5.3.2 *Glass Tubing*—Heat-resistant glass tubing, having a 10-mm (0.4-in.) inside diameter and a goose-neck-shaped delivery tube (as shown in Figure 1) for connecting the flask to the condenser.

5.3.3 *Inlet Aeration Tube*—At least 180 mm (7 in.) in length having a 6-mm ($^1/_4$ in.) outside diameter with a 10-mm (0.4-in.) bulb containing six staggered holes approximately 1.5 mm (0.06 in.) in diameter.[3]

5.3.4 *Electric Heating Mantle*—With a variable transformer, oil bath, or fluidized sand bath, to fit a 250- to 500-mL (8.5- to 16.9-oz) flask.

5.3.5 *Water-Jacketed Condenser*—Allihn type, with a 200-mm (7.9-in.) minimum jacket length or equivalent.

5.3.6 *Thermometer*—An ASTM Low Distillation Thermometer 7ºC (7ºF), having a range of –2 to 300ºC (28 to 572ºF), and conforming to the requirements in ASTM E 1.

5.3.7 *Gas Flow Meter*—As shown in Figure 1, or any type capable of indicating a gas flow of up to 1000 mL/min.[4]

5.3.8 *Corks*—No. 20, drilled as shown in Figure 1.

5.3.9 *Flexible Elastometric Tubing*—resistant to chlorinated solvents, having a sufficient length and size to connect the aeration tube to a flowmeter, and equipped with a pinch clamp or stopcock to close the aeration tube prior to introducing carbon dioxide.

5.3.10 *Separatory Funnel* [5]—(alternative procedure, see Subsection 9.3.1), 125-mL (4.2 oz) capacity or larger.

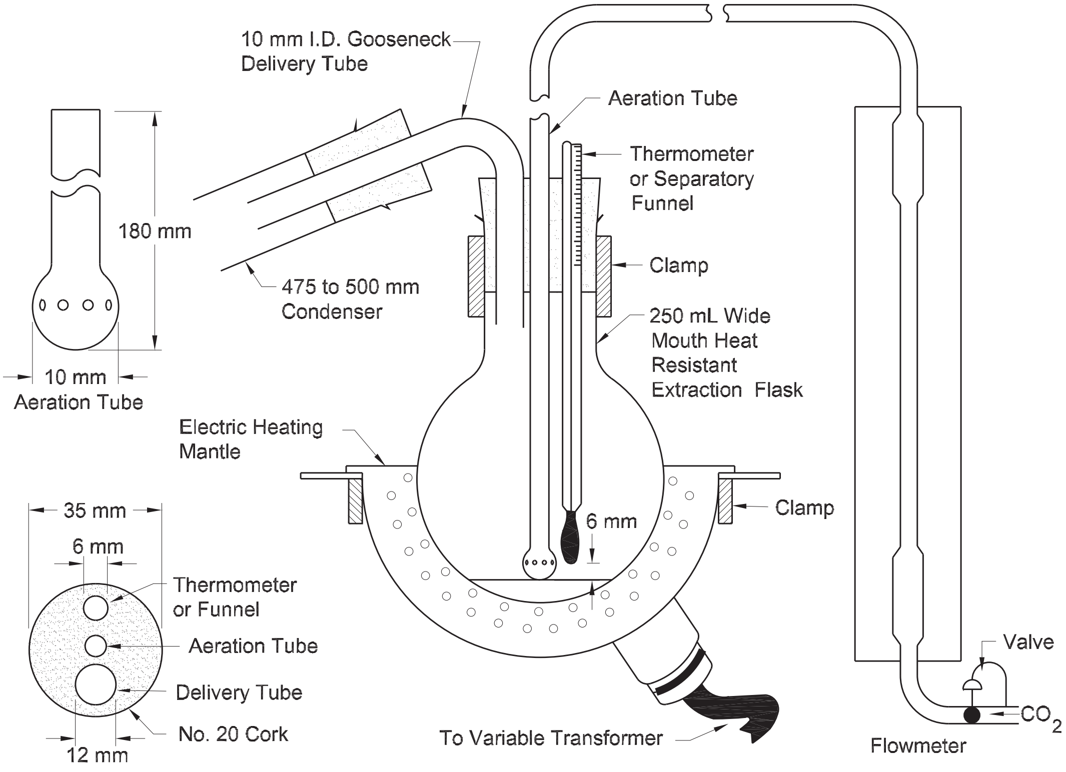

Figure 1—Distillation Assembly for Asphalt Recovery

6. REAGENTS AND MATERIALS

6.1 *Carbon Dioxide Gas*—A pressurized tank, with a pressure-reducing valve, or other convenient source.

6.2 The solvent for extracting the asphalt binder from the mixture should be reagent-grade trichloroethylene or reagent-grade methylene chloride. Other solvents may affect the asphalt binder and change its properties significantly from that as it exists in the mixture (Note 1.)

7. PRECAUTIONS

7.1 **Caution**—The solvents listed in Section 6.2 should be used only under a hood, or with an effective surface exhaust system in a well-ventilated area, since they are toxic to some degree as indicated in R 16.

8. SAMPLE

8.1 The sample shall consist of a solution, from previous extraction by Method A or E of T 164, of a sample of sufficient mass to result in approximately 75 to 100 g of recovered asphalt binder. More or less quantities of asphalt binder may be recovered; however, the properties of the recovered asphalt binder may not be in agreement with those recovered from a quantity of 75 to 100 g. In case of a dispute, 75 to 100 g should be recovered.

8.2 During the extraction process, it is important that all of the asphalt binder in the mixture be extracted, as there could be some selective solvency of the asphalt binder, and the harder, more viscous components of the asphalt binder might be left in the mixture if the extraction is not carried to completion.

8.3 Since heavy petroleum distillates such as mineral spirits or kerosene will affect the properties of the recovered asphalt binder, it is important to avoid the use of such solvents in cleaning the extraction and recovery apparatus and use only trichloroethylene or methylene chloride for cleaning. Residues of heavy petroleum solvents on the equipment may contaminate the recovered asphalt binder and affect its test properties. It is also necessary to use new filter rings, clean felt pads, or other uncontaminated filtering media in the extraction process to avoid contamination from a previous extraction.

8.4 Generally, the asphalt binder in mixtures will progressively harden when exposed to air, particularly if the mixtures are in a loose condition. Therefore, it is important to protect asphalt mixtures from exposure to air and preferably to store them in airtight containers at a temperature below 0ºC (32ºF) until they can be tested. When samples of asphalt mixture are warmed for preparing representative portions for extraction tests in accordance with Method A or E (Note 2) of T 164, they should be placed in an oven in covered containers and heated to a maximum temperature of 110ºC (230ºF) for the minimum time necessary to obtain workability, but no longer than 30 min. If the samples have been stored at a low temperature, they should be allowed to reach room temperature before placing them in the oven.

9. PROCEDURE

9.1 The entire procedure, from the start of the extraction to the final recovery, must be completed within 8 h.

9.2 Centrifuge the solution from the previous extraction for a minimum of 30 min at 770 times gravity in 250- to 500-mL (8.5- to 16.9-oz) wide-mouth bottles or centrifuge tubes in the batch apparatus specified. If a continuous centrifuge is used, the extract solution shall be charged at a rate not to exceed 150 mL/min (5.1 oz/min), while the unit is operating at a speed calculated to produce a centrifugal force of not less than 3000 times gravity.

9.3 Concentrate the solution to approximately 200 to 300 mL (6.8 to 10.1 oz) by any primary distillation operation using a flask large enough to hold all the solution from the extraction. Transfer the residue from the primary distillation flask, using several washes of solvent to rinse all of the residue into the 250- to 500-mL (8.5- to 16.9-oz) distillation flask. Assemble the apparatus as shown in Figure 1, and introduce carbon dioxide gas at a low rate (approximately 100 mL/min) to provide agitation and prevent foaming. Continue the distillation until the temperature reaches 157 to 160ºC (315 to 320ºF); at that point increase the carbon dioxide gas flow to approximately 900 mL/minute. Maintain this gas flow rate for 10 min while also maintaining the temperature of the residue in the flask at 160 to 166ºC (320 to 330ºF). The setting of the variable transformer for obtaining this temperature can be established by a few trial runs; generally a higher setting can be used for the main distillation. Reduce the setting when most of the solvent has been vaporized. In place of the electric heating mantle, an oil bath or a fluidized sand bath may be substituted in which the temperature during the introduction of the carbon dioxide gas is maintained 8 to 14ºC (15 to 25ºF) higher than the inside temperature. If, after 10 min, dripping of condensed solvent from the delivery tube is still occurring, maintain the gas flow and temperature until 5 min after the dripping ceases in order to flush solvent vapors from the flask. In no case shall the time of flow of carbon dioxide gas be less than 15 minutes. At the end of this period, discontinue the gas flow and heat.

9.3.1 *Alternative Procedure*—Assemble the apparatus as shown in Figure 1 with the separatory funnel in the thermometer hole in the cork. As an alternative, the separatory funnel may be inserted in a separate hole drilled in the cork stopper. Raise the aeration tube so that the bulb is above the surface of the solution. Fill the separatory funnel with the centrifuged solution, and open the stopcock to fill the flask approximately one half full of solution. Apply low heat to the flask, and start distillation. At this time, lower the aeration tube so that the bulb is in contact with the bottom of the flask, and introduce carbon dioxide gas at a low rate (approximately 100 mL/min) to provide agitation and prevent foaming. Adjust the funnel stopcock to introduce fresh solvent at a rate that will keep the flask approximately one half full during distillation, adding additional solution to the funnel until all of the solution has been introduced into the distillation flask. Wash the solution container and funnel with fresh solvent to transfer all asphalt binder into the distillation flask. If the separatory funnel has not been inserted into a separate hole drilled in the cork stopper, remove the separatory funnel, and insert the thermometer. When the temperature reaches 157 to 160ºC (315 to 320ºF), increase the carbon dioxide gas flow to approximately 900 mL/minute. Maintain this gas flow rate for 10 min while also maintaining the temperature of the residue in the flask at 160 to 166ºC (320 to 330ºF). If, after 10 min, dripping of condensed solvent from the delivery tube is still occurring, maintain the gas flow and temperature until 5 minutes after the dripping ceases in order to flush solvent vapors from the flask. In no case shall the time of flow of carbon dioxide gas be less than 15 min. At the end of this period, discontinue the gas flow and heat.

9.4 If the residue in the flask is highly viscous at 163ºC (325ºF), so that dispersion of the carbon dioxide in the residue is restricted and the recovered asphalt binder is expected to have a penetration at 25ºC (77ºF) of less than 30, maintain the carbon dioxide gas flow and temperature for 20 to 22 min, which includes the initial 15 min.

9.5 The recovered asphalt binder can be heated to reliquefy, and portions taken for testing. Testing may include dynamic shear, bending beam, direct tension, rotational viscosity, penetration, softening point, ductility, ash content, and kinematic and absolute viscosity determinations as required. Ash content determinations shall be conducted on all recovered asphalt binder in accordance with T 111 and reported with other test data on the recovered asphalt binder. Ash contents of recovered asphalt binder greater than 1 percent may affect the accuracy of the penetration, ductility, softening point, or viscosity tests.

Note 3—Determination of the mass of recovered asphalt binder serves as a check to assure that all of the solvent has been removed when this mass is compared with the mass of extracted asphalt binder as determined by T 164. The mass of the recovered asphalt binder should be corrected for the ash content determined.

10. PRECISION AND BIAS

10.1 *Precision*—Data from the AMRL proficiency sample database from 1974 to 1992 was analyzed to develop estimates of test precision. [6] The results of the analysis are summarized below. The grades of asphalt binders included in the analysis consisted of AC-5, AC-10, AC-15, AC-20, AC-30, AC-

40, AR-2000, and AR-4000. The precision estimates provided apply to unaged asphalt binder having physical test properties within the following ranges:

■ Penetration at 25°C (77°F)	29 to 181
■ Kinematic viscosity at 135°C (275°F), cSt	200 to 720
■ Viscosity at 60°C (140°F), P	520 to 5320

10.1.1 *Single-Operator Precision*—The figures given in Column 2 of the table below are the coefficients of variation that have been found to be appropriate for the tests and conditions described in Column 1 of the same table. When performed by the same operator on the same sample in the same laboratory using the same apparatus, the difference in the results of two properly conducted tests, expressed as a percent of their mean, shall not exceed the figures given in Column 3 of the following table.

Test Index	Coefficient of Variation (Percent of Mean) [7]	Acceptable Range of Two Results (Percent of Mean)[7]
Single-Operator Precision:		
Penetration at 25°C (77°F)	11	30
Kinematic viscosity at 135°C (275°F), cSt	9	26
Viscosity at 60°C (140°F), P	18	51

10.1.2 *Multilaboratory Precision*—The figures given in Column 2 of the table below are the coefficients of variation that have been found to be appropriate for the tests and conditions described in Column 1 of the same table. When performed by different operators in different laboratories, the difference in the results of two properly conducted tests on the same material, expressed as a percent of their mean, shall not exceed the figures given in Column 3 of the following table.

Test Index	Coefficient of Variation (Percent of Mean)[7]	Acceptable Range of Two Results (Percent of Mean)[7]
Multilaboratory Precision:		
Penetration at 25°C (77°F)	21	58
Kinematic viscosity at 135°C (275°F), cSt	16	46
Viscosity at 60°C (140°F), P	33	93

10.2 *Bias*—Since there are no data at this time to prepare a bias statement, no statement on bias is made.

---

[1] Similar, but not technically identical to ASTM D 1856-95a (2003).
[2] An "International" No. 2 Centrifuge operating at 1900 r/min or an "SMM Continuous Centrifuge," exerting a force of 3000 times gravity at 9000 r/min, has been found satisfactory for this purpose.

Standard Method of Test for

Effect of Heat and Air on Asphalt Materials (Thin-Film Oven Test)

AASHTO Designation: T 179-05 (2009)[1]
ASTM Designation: D 1754-97 (2002)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Effect of Heat and Air on Asphalt Materials (Thin-Film Oven Test)

AASHTO Designation: T 179-05 (2009)[1]
ASTM Designation: D 1754-97 (2002)

1. SCOPE

1.1. This method covers the determination of the effect of heat and air on a film of semisolid asphaltic materials. The effects of this treatment are determined from measurements of selected asphalt properties before and after the test.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 49, Penetration of Bituminous Materials
- T 51, Ductility of Asphalt Materials
- T 201, Kinematic Viscosity of Asphalts (Bitumens)
- T 202, Viscosity of Asphalts by Vacuum Capillary Viscometer

2.2. *ASTM Standards*:

- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers
- E 145, Standard Specification for Gravity-Convection and Forced-Ventilation Ovens

3. SUMMARY OF METHOD

3.1. A film of asphaltic material is heated in an oven for 5 hours at 163ºC (325ºF). The effects of heat and air are determined from changes occurring in physical properties measured before and after the oven treatment. An optional procedure is provided for determining the change in sample mass.

3.2. Precision values for the method have been developed for viscosity, viscosity change, penetration change, and mass change; precision for other properties is undefined.

4. SIGNIFICANCE

4.1. This method indicates approximate change in properties of asphalt during conventional hot-mixing at about 150ºC (300ºF) as indicated by viscosity, penetration, or ductility measurements. It yields a residue that approximates the asphalt condition as incorporated in the pavement. If the mixing temperature differs appreciably from the 150ºC (300ºF) level, more or less effect on properties will occur.

5. APPARATUS

5.1. *Oven*—The oven shall be electrically heated and shall conform to the performance requirements of ASTM E 145, for Gravity-Convection and Forced-Ventilation Ovens Type IB (Gravity-Convection), for operating temperatures up to 180ºC (356ºF). During the tests for compliance to ASTM E 145 requirements, the oven shelf, properly centered as described in Section 5.1.2, shall be in place and rotating.

5.1.1. *Construction*—The oven shall be rectangular with minimum interior dimensions (exclusive of space occupied by the heating element) of 330 mm (13 in.) in each direction. (See Note 1.) The oven shall have, in front, a tightly fitted hinged door, which shall provide a clear opening substantially the same as the interior height and width of the oven. The door may contain a window with dimensions of at least 100 by 100 mm (4 by 4 in.) and with two sheets of glass separated by an air space, through which a vertical thermometer, located as specified in Section 5.2, may be read without opening the door; or the oven may be provided with an inner glass door, through which the thermometer may be observed on opening the outer door momentarily. The oven shall be adequately ventilated by convection currents of air and for this purpose shall be provided with openings for the entrance of air and for the exit of heated air and vapors. Openings may be of any size and arrangement provided the requirements of ASTM E 145, Type 1B are met.

5.1.2. *Rotating Shelf*—The oven shall be provided with a metal circular shelf having a minimum diameter of 250 mm (9.8 in.) (Note 1). The shelf construction shall be such that it provides a flat surface for support of the containers without blocking all air circulation through the shelf when the containers are in place. The shelf shall be suspended by a vertical shaft and centered with respect to the horizontal interior dimensions of the oven and shall be provided with a mechanical means of rotating it at the rate of 5.5 ± 1.0 r/min. The shelf shall be vertically located as close to the center of the oven as permitted by compliance with the requirements of Section 5.2 regarding thermometer placement. The shelf shall be constructed or marked in such a way that the sample containers can be placed in the same position during each test. There shall be a minimum of two and a maximum of six sample container positions. Each sample container position shall be symmetrical with respect to the shaft and to any holes in the shelf. The number of sample container positions shall be the maximum that will fit on the shelf without violating the above requirements and without excessive overhang.

Note 1—Minimum size ovens accommodate two containers. For routine or control operations, larger ovens, having proportionately larger shelves to accommodate a greater number of containers, may be advantageous and are suitable, provided the requirements of ASTM E 145, Type 1B are met. Under no circumstances should more than one shelf, properly centered, be used in an oven.

5.1.3. *Recovery Time*—When the oven obtains a temperature of 163ºC (325ºF) and two sample pans are introduced, the oven shall be capable of returning to 162ºC (323ºF) within 15 minutes.

5.2. *Thermometer*—An ASTM Loss on Heat Thermometer having a range of 155 to 170ºC and conforming to the requirements for Thermometer 13C, as prescribed in ASTM E 1. The thermometer shall be supported from the shaft of the circular shelf in a vertical position at a point equidistant from the center and outer edge of the shelf. The bottom of the thermometer bulb shall be approximately 6.4 mm ($^1/_4$ in.) above the top of the shelf.

5.3. *Container*—A cylindrical pan 140 mm ($5^1/_2$ in.) in inside diameter and 9.5 mm ($^3/_8$ in.) deep with a flat bottom. Fifty milliliters of the sample in this size container gives a film thickness of 3.2 mm ($^1/_8$ in.). Pans shall be made of stainless steel and should have a metal thickness of approximately 0.635 mm (0.025 in.).

Note 2—Pans have a tendency to become warped or bent with use. Although tests indicate that a small amount of warping does not significantly affect results, frequent inspection to eliminate badly warped or damaged pans is advisable. The indicated metal thicknesses are those found to provide adequate rigidity without excessive weight. Stainless steel pans manufactured from 0.6 mm (No. 24) stainless sheet-gauge steel comply with the recommended thickness. Pans made from 0.5 mm (No. 26) stainless sheet-gauge metal are also acceptable but have a greater tendency to warp during use. However, in no case shall the thickness of the metal be less than 0.381 mm (0.015 in.).

5.4. *Balances*—If the loss on heating is desired, a Class B balance conforming to the requirements of M 231 is required. If only the residue is desired, a Class G 2 balance conforming to M 231 may be used.

6. PREPARATION OF SAMPLES

6.1. Place sufficient material for the test in a suitable container and heat to a fluid condition. Extreme care should be taken so that there is no local overheating of the sample and that the highest temperature reached does not exceed 150°C (302°F). Stir the sample with a general purpose thermometer during the heating period, but avoid incorporating air bubbles in the sample. Weigh 50.0 ± 0.5 g into each of two or more tared sample pans meeting the requirements of Section 5.3 (Note 3).

Note 3—When tests on the residue other than penetration and ductility are desired, more than two containers may be needed to provide sufficient material for test.

6.2. At the same time, pour a portion of the sample into the containers specified for measurement of original asphalt properties. Complete these tests by appropriate AASHTO test methods.

6.3. If the quantitative value of the loss or gain in sample mass is desired, cool the samples for the oven test to room temperature and determine the mass of each sample separately to the nearest 0.001 g. If the change in mass is not required, allow the samples to cool to approximately room temperature before placing in the oven as directed in Section 7.3.

7. PROCEDURE

7.1. Level the oven so that the shelf rotates in a horizontal plane. Extreme care should be taken so that there is no local overheating of the sample and that the highest temperature reached does not exceed 150°C (302°F). Determine the temperature of the oven by means of the specified thermometer (Section 5.2).

7.2. Place an empty sample container in each of the predetermined sample container positions on the rotating shelf. Adjust the temperature control so the specified thermometer (Section 5.2) reads 163 ± 1°C (325 ± 2°F) when the oven is at equilibrium. Once the adjustment is complete, the empty sample containers may be removed at the discretion of the operator. However, the temperature control shall not be readjusted once any sample containers are removed.

Note 4—Removing sample containers will affect convection patterns in the oven and may cause the thermometer reading to change from the desired level. This phenomenon is normal and occurs because the thermometer is not in the same location as the temperature control sensor. Replacing the containers should cause the thermometer to return to the original level.

7.3. With the oven at 163ºC (325ºF), quickly place the containers with the sample on the circular shelf. Fill any vacant positions with empty sample containers, so that every sample container position is occupied. Close the oven door, and start rotating the shelf. Maintain the temperature at 163 ± 1ºC (325 ± 2ºF) for 5 hours after the sample has been introduced and the oven has again reached that temperature. The 5-hour period shall start when the temperature reaches 162ºC (323ºF) and in no case shall the total time that a sample is in the oven be more than 5.25 hours. At the conclusion of the heating period, remove the samples from the oven. If the change in mass is not being determined, proceed in accordance with Section 7.5. If the change in mass is being determined, cool to room temperature, determine the mass to the nearest 0.001 g, and calculate the change in mass on the basis of the asphalt in each container. When complete tests cannot be made in the same day, and if the loss or gain in the sample mass is being determined, determine the mass of the residues and store them overnight before reheating. If the change in mass is not being determined, transfer the residue to the 240-mL (8-oz) container as described in Section 7.4 before storing overnight.

Note 5—Materials having different mass-change characteristics should not generally be tested at the same time due to the possibility of cross-absorption.

Note 6—This test method does not prohibit placing an asphalt sample in the position under the thermometer. However, it is recommended that this position not be used for a sample, and that an empty pan remain in this position in order to minimize the risk associated with thermometer breakage.

7.4. After weighing the containers with the residues, place them on refractory board(s). Put the board(s) and the containers on the circular shelf of the oven maintained at 163ºC (325ºF). Close the oven and rotate the shelf for 15 ± 2 minutes, remove the samples and board(s), and immediately proceed as described in Section 7.5.

7.5. Pour the samples into a 240-mL (8-oz) ointment tin. Remove substantially all of the material from the 140-mm ($5^1/_2$-in.) pans by scraping with a suitable spatula or putty knife. Stir the combined residues thoroughly, placing the 240-mL (8-oz) container on a hot plate to maintain the material in a fluid condition if necessary. Pour the material into the proper containers or molds for the penetration, ductility, or other tests if required. Complete the tests on residue by appropriate AASHTO test methods within 72 hours of performing this test.

Note 7—The pans may be removed from the oven and scraped one at a time provided that each pan remains in the oven the required 15 ± 2 minutes.

8. REPORT

8.1. Report the values of the original asphalt properties measured in Section 6.2 and the residue property values as measured in Section 7.5. Viscosity change may also be expressed as the ratio of the residual asphalt viscosity to the original asphalt viscosity. Penetration change is evaluated as the penetration of the residue expressed as the percentage of the original penetration.

8.2. Report ductility or other test results in accordance with the appropriate AASHTO Methods of Test.

8.3. When determined, report the average change in mass of the material in all the containers used in the test as mass percent of the original material. A mass loss shall be reported as a negative number, while a mass gain shall be reported as a positive number.

Note 8—This test can result in either a mass loss or a mass gain. During the test, volatile components evaporate (causing a decrease in mass), while oxygen reacts with the sample (causing an increase in mass). The combined effect determines whether the sample has an overall mass gain or overall mass loss. Samples with a very low percentage of volatile components will usually exhibit a mass gain, while samples with a high percentage of volatile components will usually exhibit a mass loss.

9. PRECISION

9.1. Criteria for judging the acceptability of the viscosity at 60ºC (140ºF) and 135ºC (275ºF), viscosity ratio at 60ºC (140ºF), change in penetration at 25ºC (77ºF), and mass change test results obtained by this method are given in Table 1.

Table 1—Precision

Material and Type Index	Standard Deviation (1s)	Acceptable Range of Two Results (d2s)	Coefficient of Variation (Percent of Mean) (1s%)	Acceptable Range of Two Results (Percent of Mean) (d2s%)
Single-operator precision:				
Percentage of retained penetration	1.43	4.0	—	—
Change in mass percentage:				
Not more than 0.4% (max)	0.014	0.04	—	—
Greater than 0.4%	—	—	2.9	8.0
Viscosity at 60˚C (140˚F)	—	—	3.3	9.3
Viscosity at 135˚C (275˚F)	—	—	2.0	5.7
Viscosity Ratio at 60˚C (140˚F):[a]	—	—	5.6	16.0
Multilaboratory precision:[b]				
Percentage of retained penetration	2.90	8.0	—	—
Change in mass percentage:				
Not more than 0.4% (max)	0.055	0.16	—	—
Greater than 0.4%	—	—	14.0	40.0
Viscosity at 60˚C (140˚F)	—	—	11.6	33.0
Viscosity at 135˚C (275˚F)	—	—	6.4	18.0
Viscosity Ratio at 60˚C (140˚F):[a]	—	—	9.1	26.0

[a] Viscosity Ratio is the ratio of the viscosity at 60˚C (140˚F) after test to the viscosity at 60˚C (140˚F) before test.

[b] Multilaboratory precision is applicable to asphalt cements having viscosity ratios lower than 3.0. Precision for ratios greater than 3.0 have not been established.

9.1.1. The figures given in Column 2 are the standard deviations that have been found to be appropriate for the materials and conditions of test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests. The figures given in Column 4 are the coefficients of variation that have been found to be appropriate for the materials and conditions of test described in Column 1. The figures given in Column 5 are the limits that should not be exceeded by the difference between the results of two properly conducted tests expressed as a percent of their means.

9.2. Criteria for judging variability of other test results are not available at the present time.

[1] Similar but not identical to ASTM D 1754-97 (2002).

Standard Method of Test for

Determining Degree of Particle Coating of Asphalt Mixtures

AASHTO Designation: T 195-67 (2007)
ASTM Designation: D 2489-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Degree of Particle Coating of Asphalt Mixtures

AASHTO Designation: T 195-67 (2007)
ASTM Designation: D 2489-02

1. SCOPE

1.1. This method covers the determination of the degree of particle coating in an asphalt mix on the basis of the percentage of coarse aggregate particles that are completely coated. Determination of the percentage of coated particles for varying mixing times may be used to establish the least mixing time required to produce satisfactory coating of the aggregate for a given set of conditions. This test method applies to mixtures containing aggregate of a nominal maximum aggregate size less than 38 mm ($1^1/_2$ in.).

1.2. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 92, Wire-Cloth Sieves for Testing Purposes
- T 168, Sampling Bituminous Paving Mixtures

3. APPARATUS

3.1. *Sieves*—9.5-mm ($^3/_8$-in.) and 4.75-mm (No. 4) sieves conforming to M 92.

3.2. *Stopwatch*—For checking the actual mixing time.

3.3. *Thermometer*—With a range from 10 to 204.4ºC (50 to 400ºF).

3.4. *Sample Shovel*.

3.5. *Sample Trays*.

4. SAMPLING

4.1. *Batch Plant*—Permit the plant to operate at an established mixing time per batch (timed by a stopwatch).

4.2. *Continuous Plant*—Establish a mixing time by use of the following formula:

$$\frac{\text{Pug Mill Contents, kg (lb)}}{\text{Pug Mill Output, kg/s (lb/s)}} \qquad (1)$$

4.3. Samples should be taken at the asphalt mixing plant, immediately after discharge from the pug mill, from three alternate truckloads of mixture. (See T 168.)

4.4. The amount of material required to perform the test is approximately 2.3 to 3.6 kg (5 to 8 lb).

5. PROCEDURE

5.1. Sieve each material immediately, while it is still hot, on a 9.5-mm ($^3/_8$-in.) sieve for materials with a maximum size larger than 9.5 mm ($^3/_8$ in.). For materials with a maximum size of 9.5 mm ($^3/_8$ in.) or less, use a 4.75-mm (No. 4) sieve. Take a sample large enough to yield between 200 and 500 coarse particles retained on the 9.5-mm ($^3/_8$-in.) or 4.75-mm (No. 4) sieve. Do not overload the sieves. If necessary, sieve the sample in two or three operations. Shaking should be reduced to a minimum to prevent recoating of uncoated particles.

5.2. Place the particles on a clean surface in a one-particle layer, and start counting immediately.

5.3. Very carefully examine each particle under direct sunlight, fluorescent light, or similar light conditions. If even a tiny speck of uncoated stone is noted, classify the particle as "partially uncoated." If completely coated, classify the particle as "completely coated."

6. CALCULATION

6.1. The required computation is as follows:

$$\text{Percent of Coated Particles} = \frac{\text{No. of Completely Coated Particles} \times 100}{\text{Total No. of Particles}} \qquad (2)$$

7. REPORT

7.1. *Report the following information*:

7.1.1. Type of plant—batch or continuous.

7.1.2. Type of mix.

7.1.3. Mixing time to the nearest 0.5 min.

7.1.4. Mixing temperature to the nearest 5°C (9°F).

7.1.5. Percent of coated particles to the nearest 0.1 percent.

8. PRECISION AND BIAS

8.1. *Precision*—No precision data is available at this time.

8.2. *Bias*—Since there are no accepted reference materials suitable for determining the bias of this test method, no statement of bias is presented.

9. KEYWORDS

9.1. Asphalt; asphalt mixing plant; coating; mixing time; pug mill.

AASHTO T 200-79 (2006) is identical to ASTM E 70-97 (2002).

Standard Method of Test for

Kinematic Viscosity of Asphalts (Bitumens)

AASHTO Designation: T 201-10
ASTM Designation: D 2170-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Kinematic Viscosity of Asphalts (Bitumens)

AASHTO Designation: T 201-10
ASTM Designation: D 2170-07

AASHTO T 201-10 is identical to ASTM D 2170-07 except for the following provisions:

1. All references to ASTM D 92 shall be replaced with AASHTO T 48. Add reference to R 16, Regulatory Information for Chemicals Used in AASHTO Tests.
2. Delete the 1 in front of cm^2/s in the fourth sentence of Section 3.1.2.
3. Replace the last two sentences in Section 6.3 with the following:

   The efficiency of the stirring and the balance between heat losses and heat input must be such that the temperature of the bath medium does not vary by more than ±0.1ºC (±0.2ºF) over the length of the viscometer, or from viscometer to viscometer in the various bath positions.
4. Replace Section 8.2 with the following:

   8.2 Maintain the bath at the test temperature within ±0.1ºC (±0.2ºF). Apply the necessary corrections, if any, to all thermometer readings.
5. Add a last sentence to Section A2.3.3.1 as follows:

   When the sample travels through capillary R and fills bulb A approximately half full, arrest its flow by placing a stopper in tube L.
6. Add a last sentence to Section A2.3.3.3 as follows:

   This 15-minute period is part of and not in addition to the equilibration time of Section A2.3.4.
7. Revise the second sentence of Section A2.3.5 to read as follows:

   For the Zeitfuchs cross-arm viscometer, apply slight vacuum to tube M (or pressure to tube N) to cause…

Standard Method of Test for

Viscosity of Asphalts by Vacuum Capillary Viscometer

AASHTO Designation: T 202-10
ASTM Designation: D 2171-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Viscosity of Asphalts by Vacuum Capillary Viscometer

AASHTO Designation: T 202-10
ASTM Designation: D 2171-07

AASHTO T 202-10 is identical to ASTM D 2171-07 except for the following provisions:

1. The following reference is added:

   R 16, Regulatory Information for Chemicals Used in AASHTO Tests.
2. Replace the last sentence in Section 6.3 with the following:

   The efficiency of the stirring and the balance between heat loss and heat input must be such that the temperature of the bath medium does not vary by more than ±0.1ºC (±0.2ºF) over the length of the viscometer, or from viscometer to viscometer in the various bath positions.
3. Replace Section 8.1.1 with the following:

   8.1.1 Maintain the bath at the test temperature within ±0.1ºC (±0.2ºF). Apply the necessary corrections, if any, to all thermometer readings.
4. In Table X1.1, change the viscosity range for Viscometer Size Number 12 to "36 to 800 Pa•s (360 to 8000 P)."
5. In Table X3.1, change the approximate calibration factor for Viscometer Size Number 25, Bulb D from ".007" to "0.07", and change the title to "Standard Viscometer Sizes, Capillary Radii, Approximate Calibration Factors, *K*, and Viscosity Ranges for Modified Koppers Vacuum Capillary Viscometer."
6. Replace Section X4.3.1.7 with the following:

   X4.3.1.7 Calculate the calibration factor, *K*, for each bulb as follows:

   $$K = \eta / t \qquad (X4.1)$$

   where:

   K = viscometer bulb calibration factor at 40.0 kPa (300 mm Hg), Pa•s/s;
   η = viscosity of viscosity standard at calibration temperature, Pa•s; and
   t = flow time, s.

7. Replace Table X4.1 with the following table:

	Approximate Viscosity, Pa•s		
Viscosity Standard	At 25°C (77°F)	At 40°C (104°F)	At 60°C (140°F)
N30000[a]	80	—	4.7
N190000[a]	520	140	33
N270000[a]	5300	—	340
S30000[a]	80	21	—

[a] Available in 1-pint containers. Purchase orders should be addressed to Cannon Instrument Co., P.O. Box 16, State College, PA 16801 or see website, www.cannoninstrument.com. Shipment will be made as specified or by best means.

Standard Method of Test for

Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)

AASHTO Designation: T 209-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)

AASHTO Designation: T 209-10

1. SCOPE

1.1. This test method covers the determination of the theoretical maximum specific gravity and density of uncompacted hot mix asphalt (HMA) at 25°C (77°F).

Note 1—The precision of the method is best when the procedure is performed on samples that contain aggregates that are completely coated. In order to assure complete coating, it is desirable to perform the method on samples that are close to the optimum asphalt binder content.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- PP 57, Establishing Requirements for and Performing Equipment Calibrations, Standardizations, and Checks
- R 47, Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size
- T 168, Sampling Bituminous Paving Mixtures

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 4311, Standard Practice for Determining Asphalt Volume Correction to a Base Temperature

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *density, as determined by this test method*—the mass of a cubic meter of the material at 25°C (77°F) in SI units, or the mass of a cubic foot of the material at 25°C (77°F) in inch–pound units.

3.1.2. *residual pressure, as employed by this test method*—the pressure in a vacuum vessel when vacuum is applied.

3.1.3. *specific gravity, as determined by this test method*—the ratio of a given mass of material at 25°C (77°F) to the mass of an equal volume of water at the same temperature.

4. SUMMARY OF TEST METHOD

4.1. A weighed sample of oven-dry HMA in the loose condition is placed in a tared vacuum container Sufficient water at a temperature of 25 ± 0.5°C (77 ± 0.9°F) is added to completely submerge the sample. Vacuum is applied for 15 ± 2 min to gradually reduce the residual pressure in the vacuum container to 3.7 ± 0.3 kPa (27.5 ± 2.5 mm Hg). At the end of the vacuum period, the vacuum is gradually released. The volume of the HMA sample is obtained either by immersing the vacuum container with the sample into a water bath and determining the mass (Section 13.1) or by filling the vacuum container level full of water and determining the mass in air (Section 13.2). At the time of weighing, the temperature is measured as well as the mass. From the mass and volume measurements, the specific gravity or density at 25°C (77°F) is calculated. If the temperature employed is different than 25°C (77°F), an appropriate correction is applied.

5. SIGNIFICANCE AND USE

5.1. The theoretical maximum specific gravities and densities of HMA are intrinsic properties whose values are influenced by the composition of the mixtures in terms of types and amounts of aggregates and asphalt materials.

5.1.1. These properties are used to calculate percent air voids in compacted HMA.

5.1.2. These properties provide target values for the compaction of HMA.

5.1.3. These properties are essential when calculating the amount of asphalt binder absorbed by the internal porosity of the individual aggregate particles in HMA.

6. APPARATUS

6.1. Follow the procedures for performing equipment calibrations, standardizations, and checks found in PP 57.

6.2. *Vacuum Container*:

6.2.1. The vacuum containers described must be capable of withstanding the full vacuum applied, and each must be equipped with the fittings and other accessories required by the test procedure being employed. The opening in the container leading to the vacuum pump shall be covered by a piece of 0.075-mm (No. 200) wire mesh to minimize the loss of fine material.

6.2.2. The capacity of the vacuum container should be between 2000 and 10,000 mL and depends on the minimum sample size requirements given in Section 7.2. Avoid using a small sample in a large container.

6.2.3. *Vacuum Bowl*—Either a metal or plastic bowl with a diameter of approximately 180 to 260 mm (7 to 10 in.) and a bowl height of at least 160 mm (6.3 in.) equipped with a transparent cover fitted with a rubber gasket and a connection for the vacuum line.

6.2.4. *Vacuum Flask for Mass Determination in Air Only (Section 13.2)*—A thick-walled volumetric glass flask and a rubber stopper with a connection for the vacuum line.

6.2.5. *Pycnometer for Mass Determination in Air Only*—A glass, metal, or plastic pycnometer.

6.3. *Balance*—A balance conforming to the requirements of AASHTO M 231, Class G 2. The balance shall be standardized at least every 12 months.

6.3.1. For the mass determination-in-water method (Section 13.1), the balance shall be equipped with a suitable apparatus and holder to permit determining the mass of the sample while suspended below the balance. The wire suspending the holder shall be the smallest practical size to minimize any possible effects of a variable immersed length.

6.4. *Vacuum Pump or Water Aspirator*—Capable of evacuating air from the vacuum container to a residual pressure of 4.0 kPa (30 mm Hg).

6.4.1. When a vacuum pump is used, a suitable trap of one or more filter flasks, or equivalent, shall be installed between the vacuum vessel and vacuum source to reduce the amount of water vapor entering the vacuum pump.

6.5. *Vacuum Measurement Device*—Residual pressure manometer[1] or vacuum gauge to be connected directly to the vacuum vessel and capable of measuring residual pressure down to 4.0 kPa (30 mm Hg) or less (preferably to zero). The gauge shall be standardized at least annually and be accurate to 0.1 kPa (1 mm Hg.). It shall be connected at the end of the vacuum line using an appropriate tube and either a "T" connector on the top of the vessel or a separate opening (from the vacuum line) in the top of the vessel to attach the hose. To avoid damage, the manometer shall not be situated on top of the vessel.

Note 2—A residual pressure of 4.0 kPa (30 mm Hg) absolute pressure is approximately equivalent to a 97 kPa (730 mm Hg) reading on a vacuum gauge at sea level.

Note 3—Residual pressure in the vacuum container, measured in millimeters of mercury, is the difference in the height of mercury in the Torricellian vacuum leg of the manometer and the height of mercury in the other leg of the manometer that is attached to the vacuum container.

Note 4—An example of a correct arrangement of the testing equipment is shown in Figure 1. In the figure, the purpose of the train of small filter flasks is to trap water vapor from the vacuum container that otherwise would enter the oil in the vacuum pump and decrease the pump's ability to provide adequate vacuum. Insertion of a valve to isolate the line to each vacuum chamber can reduce wear on the bleeder valve atop each chamber and assist in tracing sealing leaks.

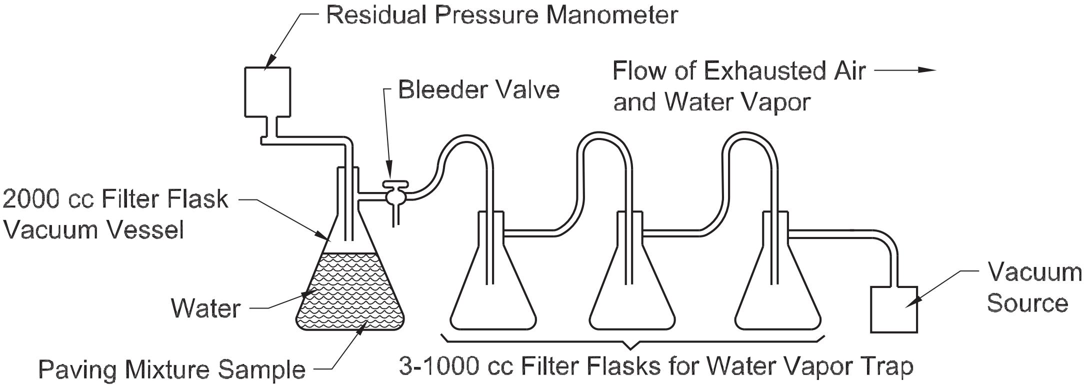

Figure 1—Example of Correct Arrangement of Testing Apparatus

6.6. *Bleeder Valve*—attached to the vacuum train to facilitate adjustment of the vacuum being applied to the vacuum container.

6.7. *Thermometric Device (Mass Determination in Air)*—A liquid-in-glass thermometer or other thermometric device, accurate to 0.5°C (1°F), of suitable range with subdivisions of 0.5°C (1°F). The thermometric device shall be standardized at the test temperature at least every 12 months.

6.8. *Water Bath*:

6.8.1. For vacuum bowls, a water bath capable of maintaining a constant temperature between 20 and 30°C (68 and 86°F) is required. (See Appendix X for a method for correcting the theoretical maximum specific gravity to 25°C (77°F) when measurements are made at temperatures other than 25°C (77°F).

6.8.2. *Thermometric Device (Mass Determination in Water)*—A liquid-in-glass thermometer or other thermometric device, accurate to 0.5°C (1°F) shall be used to measure the temperature of the water bath. The thermometric device shall be standardized at least every 12 months.

6.8.3. When using the mass determination-in-water technique (Section 13.1), the water bath must be suitable for immersion of the suspended container with its deaerated sample.

6.9. *Drying Oven*—A thermostatically controlled drying oven capable of maintaining a temperature of 135 ± 5°C (275 ± 9°F) or 105 ± 5°C (221 ± 9°F).

6.9.1. *Thermometric Device*—A liquid-in-glass thermometer or other thermometric device accurate to 3°C (5°F) shall be used to measure the temperature of the oven. The thermometric device shall be standardized at least every 12 months.

6.10. *Protective Gloves*—used when handling glass equipment under vacuum.

7. SAMPLING

7.1. Obtain the sample in accordance with T 168.

7.2. The size of the sample shall conform to the following requirements. Samples larger than the capacity of the container may be tested a portion at a time.

Table 1—Minimum Sample Sizes

Nominal Maximum Aggregate Size, mm	Minimum Sample Size, g
37.5 or greater	4000
19 to 25	2500
12.5 or smaller	1500

8. STANDARDIZATION OF FLASKS, BOWLS, AND PYCNOMETERS

8.1. For the mass determination-in-water method (Section 13.1), standardize the vacuum bowls for temperature correction by determining the mass of each container when immersed in water over the range of water bath temperatures likely to be encountered in service (Figure 2).

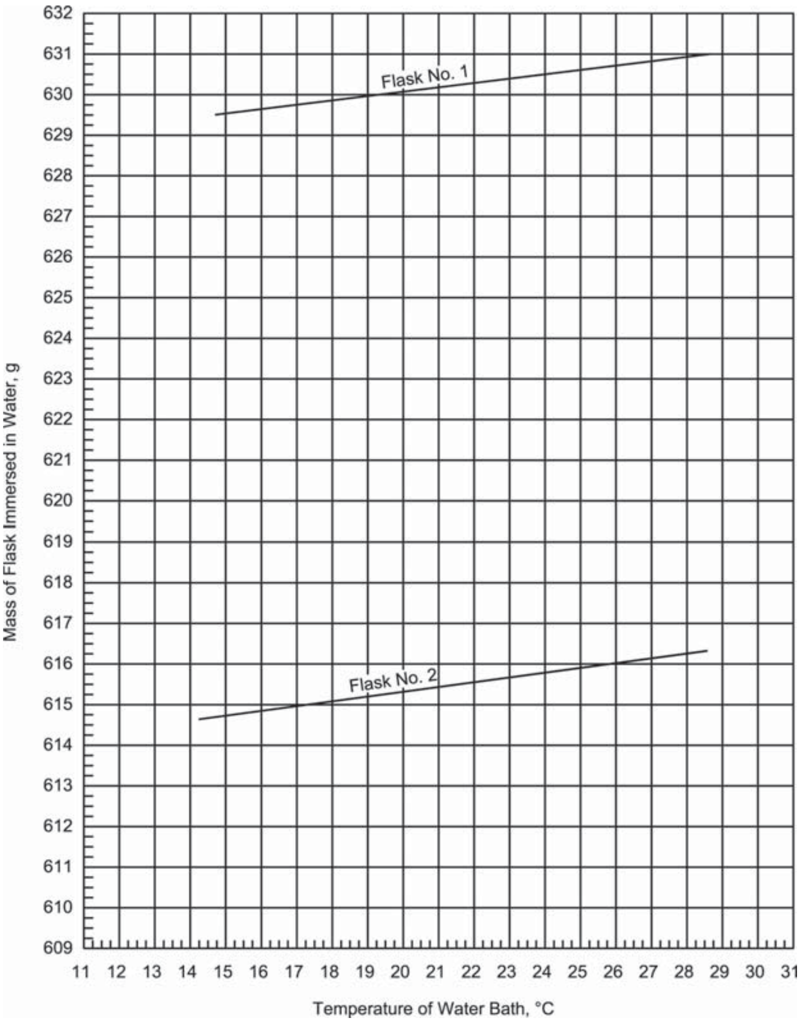

Figure 2—Example Standardization Curve for Volumetric Flask

8.2. For the mass determination-in-air method (Section 13.2), standardize the volumetric flasks or pycnometers for temperature correction by determining the mass of the container when filled with water over the range of water bath temperatures likely to be encountered in service (Figure 3). When standardized at 25 ± 0.5°C (77 ± 0.9°F) designate this mass as *D*. Accurate filling may be ensured by the use of a glass cover plate.

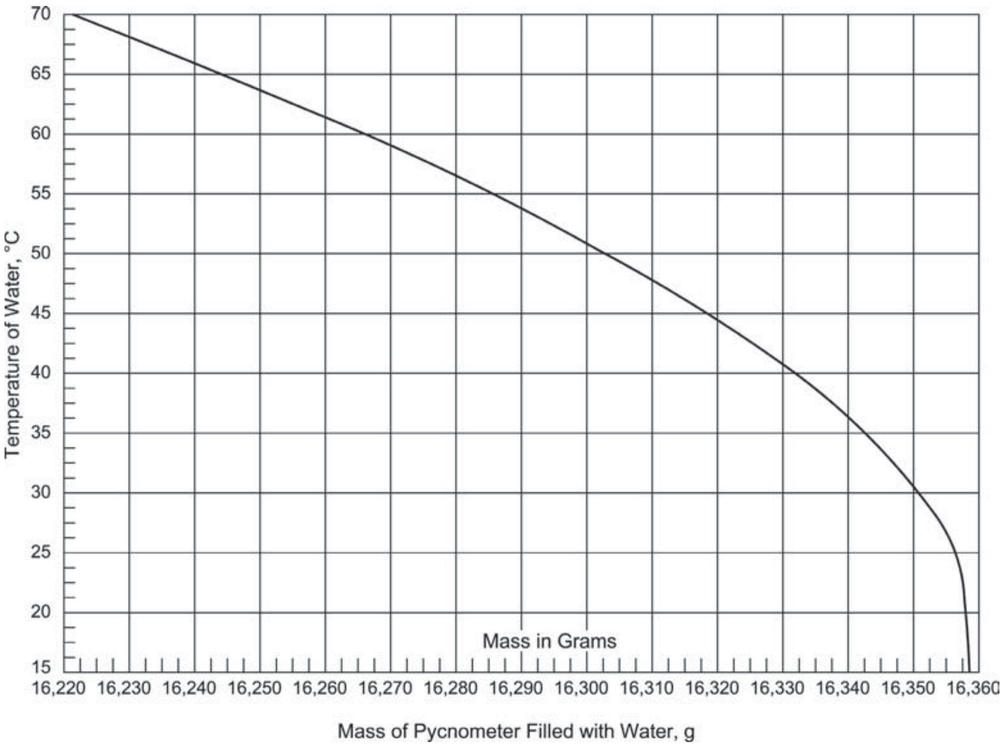

Figure 3—Example Standardization Curve for Pycnometer

8.3. Standardize the large-size plastic pycnometer by accurately determining the mass of water required to fill it over a range of temperature from about 20 to 65°C (70 to 150°F), and construct a standardization curve of mass versus temperature as shown in Figure 3. Care should be taken to follow exactly the same procedure in standardization as in conducting a test.

8.3.1. The following filling procedure may be used for the model with a latched lid and vented stopper. The domed lid is latched in place and the pycnometer nearly filled with water. Leave about 50 mm (2 in.) empty. The release of air bubbles may be facilitated by applying vacuum and by dropping first one side then the other of the pycnometer about 10 mm ($^1/_2$ in.) above a hard, flat surface. This vacuum application and bubble release procedure should take about 10 min so that the temperature equilibrium between the shell and the water approximates that attained when performing a test. The final amount of water is then gently poured in until the level is about halfway up the neck. Any air bubbles caught against the dome that cannot be released by jarring or by swirling the water may be "pricked" or pushed to the surface with a bent wire or other suitable device. Insert the vented stopper using only enough force to just seat the stopper and immediately wipe the excess water off the top.

8.3.2. For the models with a quick-disconnect vacuum line and unlatched lid, the filling procedure is as follows. With the inlet valve closed, apply a vacuum of about 30 kPa (225 mm Hg). Open the inlet valve slowly letting water in until the level reaches 25 mm (1 in.) below the top of the dome and close the valve. Continue applying vacuum and release the bubbles by jarring and rapping the vessel with a rubber mallet. Slowly open the inlet valve and allow more water in until the water overflows into the aspirator (vacuum) line and then close the valve. This vacuum application and bubble release procedure should take about 10 min so that the temperature equilibrium between the shell and the water approximates that attained when performing a test. Disconnect the vacuum line by pulling it out at the quick-disconnect joint below the gauge.

8.3.3. Wipe the outside of the pycnometer dry, determine the mass of the full pycnometer and measure the water temperature.

Note 5—The shape of the standardization curve is a function of two opposing factors that can be rationally defined. As the temperature is increased, the container itself expands (adding mass—"Pycnometer" line in Figure 4) and the density of the contained water decreases (resulting in loss of mass—"Water" line in Figure 4). These relationships are shown in Figure 4 for a typical large-size pycnometer. The "Water" curve may be constructed by multiplying the volume at 25°C (77°F) by the difference between the density of water at 25°C (77°F), which is 0.9970, and the density of water at the standardization temperature (see Equation 1).

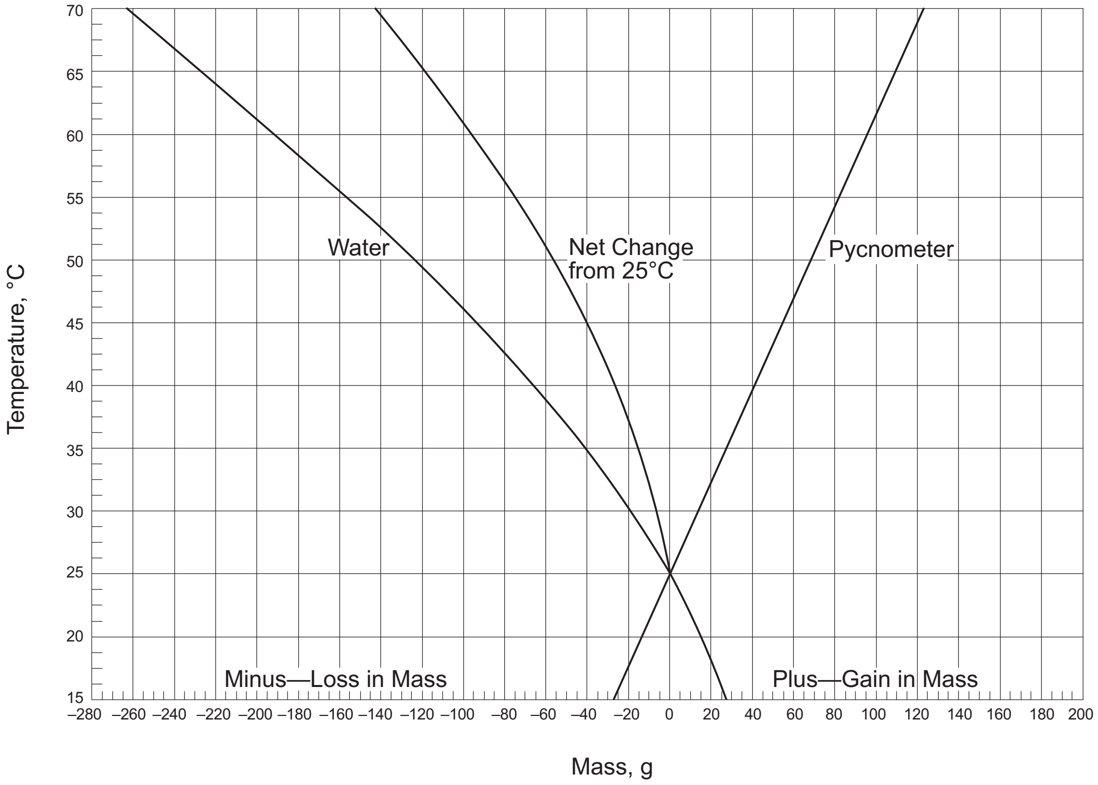

Figure 4—Effect of Change in Density of Water and Volume of Pycnometer with Change in Temperature

$$\text{Difference Due to Water Expansion} = V_{25}(0.9970 - dw)$$

$$\text{Since } V_{25} = W_{25} / 0.9970$$

$$V_{25}(0.9970 - dw) \text{ reduces to } W_{25}\left(1 - \frac{dw}{0.9970}\right) \qquad (1)$$

where:

V_{25} = volume of water to fill a container at 25°C (77°F), cm$^{3;}$

W_{25} = mass of water to fill a container at 25°C (77°F), g; and

dw = density of water at the standardization temperature, Mg/m^3.

The rate of change in capacity of the container due to thermal expansion of the pycnometer itself is essentially constant over the temperature range from 20 to 65°C (70 to 150°F). Thus, the "Pycnometer" line in Figure 4 can be drawn through the 0 at 25°C (77°F) point knowing only the slope of the straight line relationship. The slope can be established by averaging at least five standardization mass determinations at some elevated temperature, adding the loss due to water expansion and subtracting the mass at 25°C (77°F), W_{25}, to give the gain in capacity due to expansion of the container. The difference in mass divided by the difference in temperature is the slope of the "Pycnometer" line. For a polycarbonate pycnometer of about 13,500-mL capacity, the slope thus established was 2.75 g/°C (1.53 g/°F). This value is believed to be typical and reasonably constant.

The bending of the standardization curve (Figure 3) due to these offsetting thermal factors thus minimizes experimental error due to temperature effects in the normal working range, 25°C (77°F), for both the volumetric flask and the pycnometer containers. Defining the standardization curve makes it possible to correct for temperature, rather than "bringing the container and sample to temperature" thereby eliminating the cost of a water bath and making it feasible to improve accuracy by testing larger samples and to materially reduce the testing time.

8.4. While standardization of the flask or either pycnometer need to be performed only once, the standardization should be checked occasionally, particularly at 25°C (77°F). The equipment must be kept clean and free from any accumulation that would change the mass if the volume standardization is to remain constant. Care should be taken to use only neutral solvents, especially with plastic containers; glass vessels should not be subjected to high vacuum if they are scratched or damaged.

9. SAMPLE PREPARATION

9.1. Separate the particles of the HMA sample by hand, taking care to avoid fracturing the aggregate, so that the particles of the fine aggregate portion are not larger than 6.3 mm ($^1/_4$ in.). If an HMA sample is not sufficiently soft to be separated manually, place it in a pan, and warm it in an oven until it can be separated as described.

9.2. Samples prepared in a laboratory shall be conditioned and dried in an oven at 135 ± 5°C (275 ± 9°F) for a minimum of 2 h or as appropriate to match the mix design procedure being used. Longer drying time may be necessary for the sample to achieve a constant mass (mass repeats within 0.1 percent). HMA which has not been prepared in a laboratory with oven-dried aggregates shall be dried to a constant mass at a temperature of 105 ± 5°C (221 ± 9°F). This drying and conditioning operation shall be combined with any warming described in Section 9.1.

Note 6—The minimum 2 h time in the oven is specified as the short-term conditioning time for laboratory-prepared specimens. The short-term conditioning at the specified temperature is especially important when absorptive aggregates are used. This short-term conditioning will ensure the computation of realistic values for the amount of asphalt absorbed by the aggregate and void properties of the mix. Plant-produced HMA should not be short-term conditioned since absorption takes place during production.

9.3. Cool the sample to room temperature, and place it in a tared and standardized flask, bowl or pycnometer. The sample is to be placed directly into a vacuum container. A container within a container is not to be used. Determine the mass and designate the net mass of the sample as *A*. Add sufficient water at a temperature of approximately 25°C (77°F) to cover the sample completely.

Note 7—The release of entrapped air may be facilitated by the addition of a suitable wetting agent such as Aerosol OT in concentration of 0.001 percent or 0.2 g in 20 L of water. This solution is then diluted by about 20:1 to make a wetting agent of which 5 to 10 mL may be added to the apparatus.

TEST METHOD A—MECHANICAL AGITATION

10. APPARATUS

10.1. In addition to the apparatus listed in Section 6, the following apparatus is required for Method A:

10.1.1. *Mechanical Shaker*—Shaker for removing air from asphalt mix.

11. PROCEDURE

11.1. Remove air trapped in the sample by applying gradually increased vacuum until the residual pressure manometer reads 3.7 ± 0.3 kPa (27.5 ± 2.5 mm Hg). Maintain this residual pressure for 15 ± 2 min. Agitate the container and contents using the mechanical device during the vacuum period. Glass vessels should be shaken on a resilient surface such as a rubber or plastic mat, and not on a hard surface, so as to avoid excessive impact while under vacuum.

11.2. At the end of the vacuum period, release the vacuum by increasing the pressure at a rate not to exceed 8 kPa (60 mm Hg) per second and proceed with one of the mass determination methods in Section 13.

TEST METHOD B—MANUAL AGITATION

12. PROCEDURE

12.1. Remove air trapped in the sample by applying gradually increased vacuum until the residual pressure manometer reads 3.7 ± 0.3 kPa (27.5 ± 2.5 mm Hg). Maintain this residual pressure for 15 ± 2 min. Agitate the container and contents during the vacuum period by vigorously shaking at intervals of about 2 min. Glass vessels should be shaken on a resilient surface such as a rubber or plastic mat, and not on a hard surface, so as to avoid excessive impact while under vacuum.

12.2. At the end of the vacuum period, release the vacuum by increasing the pressure at a rate not to exceed 8 kPa (60 mm Hg) per second and proceed with one of the mass determination methods in Section 13.

13. MASS DETERMINATION

13.1. *Mass Determination in Water*—Suspend the container and contents in the water bath and determine the mass after a 10 ± 1 min immersion. Measure the water bath temperature, and if different from 25 ± 1°C (77 ± 2°F), correct the mass to 25°C (77°F) using the standardization temperature adjustment developed in Section 8.1. Designate the mass of the sample in water at 25°C (77°F) as C.

Note 8—Instead of using a chart like Figure 2 to establish the mass correction for the temperature of the vacuum vessel submerged by itself in the water bath, this correction can be easily established by rapidly and completely emptying the vacuum container immediately following the final mass determination, and then without delay, determining the mass of the vessel by itself when totally submerged in the water bath.

13.2. *Mass Determination in Air*—Fill the flask or any one of the pycnometers with water and adjust the contents to a temperature of 25 ± 1°C (77 ± 2°F). Determine the mass of the container and contents, completely filled, in accordance with Section 8.2 within 10 ± 1 min after completing Section 11.1 or 12.1. Designate this mass as E.

Note 9—See Appendix X1 for correcting the theoretical maximum specific gravity when measurements are made at temperatures other than 25°C (77°F).

14. CALCULATION

14.1. Calculate the theoretical maximum specific gravity of the sample at 25°C (77°F) as follows:

14.1.1. *Mass Determination in Water*:

$$\text{Theoretical Maximum Specific Gravity} = \frac{A}{A - C} \qquad (2)$$

where:

A = mass of the oven-dry sample in air, g; and

C = mass of the water displaced by the sample at 25°C (77°F), g.

14.1.2. *Mass Determination in Air*:

$$\text{Theoretical Maximum Specific Gravity} = \frac{A}{A + D - E} \qquad (3)$$

where:

A = mass of the oven-dry sample in air, g;

D = mass of the container filled with water at 25°C (77°F), g; and

E = mass of the container filled with the sample and water at 25°C (77°F), g.

14.1.3. *Large-Size Plastic Pycnometer Determinations*:

14.1.3.1. If the test temperature is between 22.2 and 26.7°C (72 and 80°F), Equation 3 may be used to calculate specific gravity within a minor amount of error due to thermal effects (0.001 points or less).

14.1.3.2. If the test temperature differs significantly from 25°C (77°F), correct for thermal effects as follows:

$$\text{Specific Gravity} = \frac{A}{(A+F)-(G+H)} \times \frac{dw}{0.9970} \qquad (4)$$

where:

A = mass of the oven-dry sample in air, g;

F = mass of the pycnometer filled with water at the test temperature (Figure 3), g;

G = mass of the pycnometer filled with water and the sample at the test temperature, g;

H = correction for thermal expansion of asphalt (Figure 5), g;

dw = density of water at the test temperature, Curve D in Figure 6, Mg/m^3; and

0.9970 = density of water at 25°C (77°F), Mg/m^3.

The ratio (*dw*/0.9970) is Curve R in Figure 6.

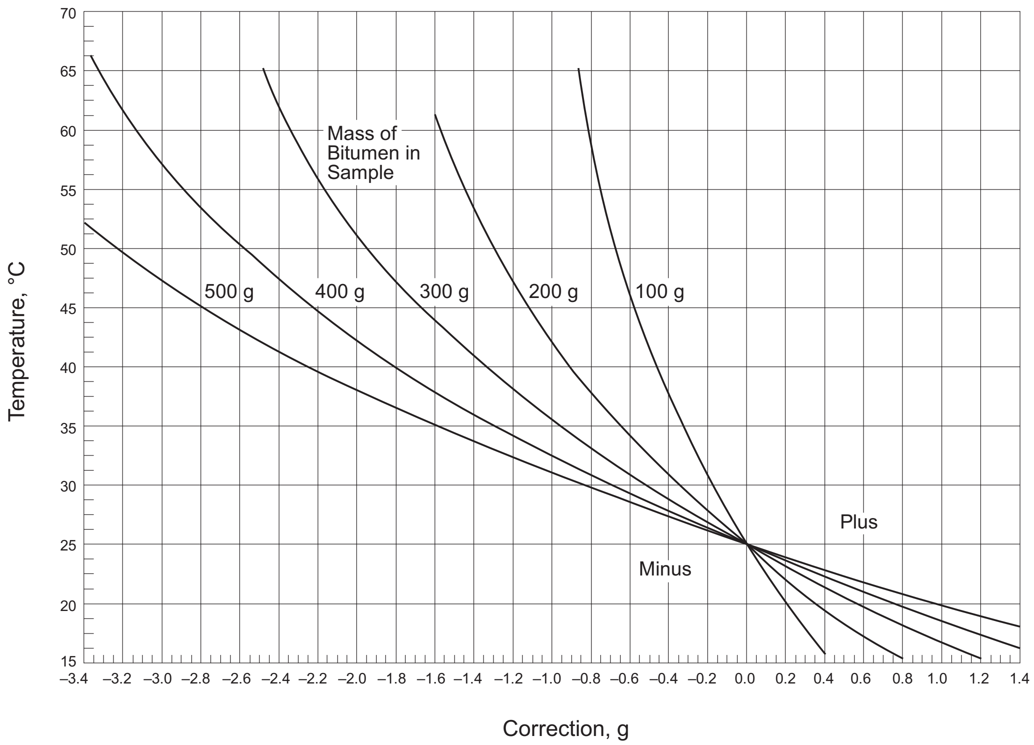

Figure 5—Correction Curves for Expansion of Asphalt, *H*, in Equation 4

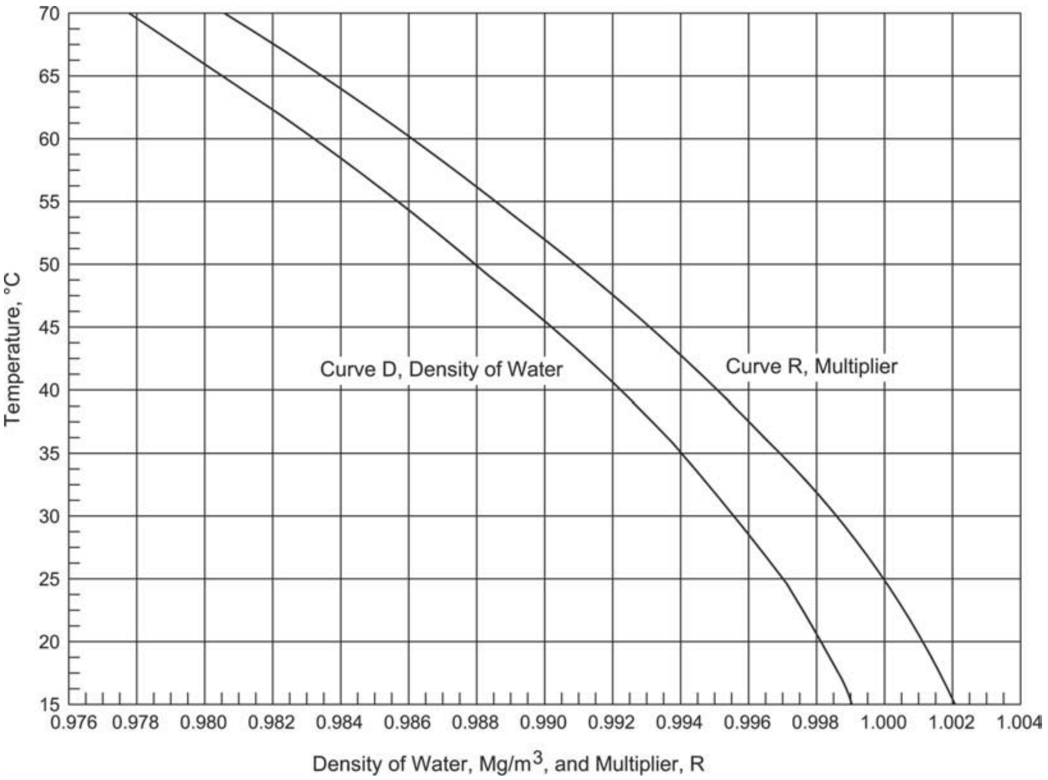

Figure 6—Curves D and R for Equation 4

Note 10—This general procedure for correcting for thermal effects should also be applicable to corresponding measurements made with other suitable containers.

Note 11—When samples are tested a portion at a time, differences between the maximum specific gravities for each portion should be within the precision statements listed in Section 17. If the values are within the precision statements, the specific gravities for each portion shall be averaged. If the values are outside the precision statements, the test shall be performed again.

14.2. *Theoretical maximum density at 25°C (77°F)*:

14.2.1. Calculate the corresponding theoretical maximum density at 25°C (77°F) as follows:

Theoretical maximum density at 25°C (77°F) = theoretical maximum specific gravity × 997.1 kg/m^3 in SI units, or

Theoretical maximum density at 25°C (77°F) = theoretical maximum specific gravity × 62.245 lb/ft^3 in inch–pound units.

where:

The density of water at 25°C (77°F) = 997.1 kg/m^3 in SI units or 62.245 lb/ft^3 in inch–pound units.

15. SUPPLEMENTAL PROCEDURE FOR MIXTURES CONTAINING POROUS AGGREGATE

Note 12—Experiments indicate that this supplemental procedure has an insignificant effect on the test results if the HMA contains individual aggregate with a water absorption below 1.5 percent.

15.1. If the pores of the aggregates are not thoroughly sealed by an asphalt film, they may become saturated with water during the application of vacuum. To determine if this condition has occurred, proceed as follows after completing Section 13.1 or 13.2. Drain the water from the sample. To prevent the loss of fine particles, decant the water through a towel held over the top of the container. Break several large pieces of aggregate and examine the broken surfaces for wetness.

15.2. If the aggregate has absorbed water, spread the sample before an electric fan to remove the surface moisture. Determine the mass at 15 min intervals, and when the loss in mass is less than 0.05 percent for this interval, the sample may be considered to be surface dry. This procedure requires about 2 h and shall be accompanied by intermittent stirring of the sample. Break conglomerations of HMA by hand. Take care to prevent loss of the HMA particles.

15.3. To calculate the specific gravity of the sample, substitute the final surface-dry mass determined in Section 15.2 for *A* in the denominator of Equation 2 or 3 as appropriate.

16. REPORT

16.1. *Report the following information*:

16.1.1. Specific gravity and density of the HMA to the nearest 0.001 for specific gravity or nearest 1 kg/m^3 (0.1 lb/ft^3) for density as follows: sp gr 25/25°C (77/77°F) or density at 25°C (77°F),

16.1.2. Type of HMA,

16.1.3. Size of the sample,

16.1.4. Number of samples,

16.1.5. Type of container, and

16.1.6. Type of procedure.

17. PRECISION

17.1. Criteria for judging the acceptability of specific gravity test results obtained by this test method are given in the following table:

Table 2—Precision Estimates

Test and Type Index	Standard Deviation (1s)	Acceptable Range of Two Results (d2s)
Test results obtained without use of Section 15		
Method A [a]		
Single-operator precision	0.0051	0.014
Multilaboratory precision	0.0084	0.024
Method B [b]		
Single-operator precision	0.0064	0.018
Multilaboratory precision	0.0103	0.029

[a] Basis of estimate: 1 replicate, 1 material, 344 laboratories.

[b] Basis of estimate: 1 replicate, 1 material, 134 laboratories.

17.2. The figures given in Column 2 are the standard deviations that have been found to be appropriate for the conditions of the test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests. Multi-laboratory precision has not been verified for 4500-mL or larger pycnometers.

17.3. The values in Column 3 are the acceptable range for two tests. When more than two results are being evaluated, the range given in Column 3 must be increased. Multiply the standard deviation(s) in Column 2 by the multiplier given in Table 1 of ASTM C 670 for the number of actual tests.

Example for three tests: 0.004 × 3.3 = 0.013.

Additional guidance and background is given in ASTM C 670.

APPENDIX

(Nonmandatory Information)

X1. THEORETICAL MAXIMUM SPECIFIC GRAVITY FOR LOOSE HMA

X1.1. *Scope*:

X1.1.1. This appendix has two objectives:

X1.1.1.1. To indicate a method for correcting the theoretical maximum specific gravity to 25°C (77°F) when measurements are made at temperatures other than 25°C (77°F).

X1.1.1.2. To indicate the range of temperature in °C above or below 25°C (77°F) within which no temperature correction is required, because the measured theoretical maximum specific gravity values are shown to be 0.0004 or less away from the value determined at 25°C (77°F).

X1.2. *Indicated Values*:

X1.2.1. The following example values are indicated for the theoretical maximum specific gravity of a loose HMA sample:

X1.2.1.1. Mass of the loose HMA sample = 1251.3 g.

X1.2.1.2. Volume of the loose HMA sample at 25°C (77°F) = 492.77 mL.

X1.2.1.3. Asphalt binder content = 5.0 percent of total mix.

X1.2.1.4. Specific gravity of the asphalt at 25°C (77°F) = 1.029.

X1.2.1.5. Combined bulk specific gravity of the aggregate = 2.714.

X1.2.1.6. Cubical coefficient of expansion of the asphalt binder at 20°C (68°F) = 6.2×10^{-4} mL/mL/°C (ASTM D 4311).

X1.2.1.7. Cubical coefficient of expansion of the aggregate at 20°C (68°F) = 2.2×10^{-5} mL/mL/°C.[2]

X1.3. *Basis of Calculation for One Gram of Loose HMA at 20°C (68°F)*:

X1.3.1. Mass of the asphalt binder = 0.05 g.

X1.3.2. Volume of the asphalt binder = 0.05/1.029 = 0.0486 mL.

X1.3.3. Mass of the aggregate = 0.95 g.

X1.3.4. Volume of the aggregate = 0.95/ 2.714 = 0.3500 mL.

X1.3.5. Volume of the asphalt binder plus aggregate in one gram of loose HMA at 20°C (68°F) = 0.0486 + 0.3500 = 0.3986 mL.

X1.4. *Basis of Calculation for Volume Change of One Gram of Loose HMA for1°C (2°F) from 20°C (68°F)*:

X1.4.1. Volume change for the asphalt binder = $6.2 \times 10^{-}4 \times 0.0486 = 0.3013 \times 10^{-4}$ mL = 3.0130×10^{-5} mL.

X1.4.2. Volume change for the aggregate = $2.2 \times 10^{-5} \times 0.3500 = 0.77 \times 10^{-5}$ mL.

X1.4.3. Volume change for of one gram of loose HMA for 1°C (2°F) change in temperature from 20°C (68°F) = $3.0130 \times 10^{-5} + 0.7700 \times 10^{-5} = 3.7830 \times 10^{-5}$ mL.

X1.5. *Volume Correction*:

X1.5.1. For a difference in water temperature of 1°C (2°F) above or below 20°C (68°F), a correction to the volume of water displaced by one gram of loose HMA can be made by the following equation:

$$\text{Correction} = \Delta T \times K_T \times V_T \text{ mL} \qquad (X1.1)$$

where:

ΔT = 1°C (2°F),

K_T = volume change of 1 g of loose HMA for a 1°C (2°F) change in temperature above or below 20°C (68°F) = 3.7830×10^{-5} mL, and

V_T = volume of water for a corresponding 1251.3-g mass of loose HMA at a test temperature of 20°C (68°F) = 492.77 mL.

Substituting these values into the equation gives the following:

Correction = $1 \times 3.7830 \times 10^{-5} \times 492.77 = 0.01864$ mL/g at 20°C (68°F).

X1.6. Table X1.1 illustrates an example of the influence of temperature corrections. For a measured volume and a given mass of HMA tested at specific temperatures, this table relates these influences to the specific gravity of the HMA.

Table X1.1—Influence of Temperature Corrections to a Measured Volume at 20°C of a Given Mass of Loose Paving Mixture, to Provide the Required Theoretical Maximum Specific Gravity at 25°C

Temperature, °C	Volume of HMA at 20°C (68°F), mL	Volume Correction for Temp Change	Corrected Volume of HMA at 20°C (68°F), mL	Mass of HMA, g	Specific Gravity of HMA
1	*2*	*3*	*4 = 2 + 3*	*5*	*6 = 5/4*
31	492.77	0.2046	492.975	1251.3	2.5383
30[a]	492.77	0.1860	492.956	1251.3	2.5384
29[a]	492.77	0.1674	492.937	1251.3	2.5385
28[a]	492.77	0.1488	492.919	1251.3	2.5386
27[a]	492.77	0.1302	492.900	1251.3	2.5386
26[a]	492.77	0.1116	492.882	1251.3	2.5387
25[a]	492.77	0.0930	492.863	1251.3	2.5388
24[a]	492.77	0.0744	492.844	1251.3	2.5389
23[a]	492.77	0.0558	492.826	1251.3	2.5390
22[a]	492.77	0.0372	492.807	1251.3	2.5391
21[a]	492.77	0.0186	492.789	1251.3	2.5392
20	492.77	0.0000	492.772	1251.3	2.5393
19	492.77	–0.0186	492.751	1251.3	2.5394

[a] Range less than 0.0005.

Notes: Strictly speaking, the above table shows that the specific gravity for this particular mix, as measured at 20°C (68°F), just fails to meet the corrected theoretical maximum specific gravity at 25°C (77°F), 2.5388 versus 2.5393, that is, by 0.0005, and that a temperature correction would be required.
If the measurement for volume had been made at 21°C (70°F), the table indicates that no temperature correction would have been necessary, because the measurement at 21°C (70°F) would have satisfied the theoretical maximum specific gravity at 25°C (77°F), 2.5388 versus 2.5392, a difference of less than 0.0005.

Standard Method of Test for

Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method

AASHTO Designation: T 227-02 (2006)
ASTM Designation: D 1298-99 (2005)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method

AASHTO Designation: T 227-02 (2006)
ASTM Designation: D 1298-99 (2005)

AASHTO T 227-02 (2006) is identical to ASTM D 1298-99 (2005) except for the following provision:

1. Insert a note after Section 5.2 containing the following:

   Note: This method may be used for the determination of the specific gravity of tars by use of an additional appropriate hydrometer.

Standard Method of Test for

Specific Gravity of Semi-Solid Asphalt Materials

AASHTO Designation: T 228-09
ASTM Designation: D 70-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity of Semi-Solid Asphalt Materials

AASHTO Designation: T 228-09
ASTM Designation: D 70-08

AASHTO T 228-09 is identical to ASTM D 70-08 except for the following provisions:

1. Replace all references to the ASTM standards listed in the following table with the corresponding AASHTO standards:

Referenced Standards

ASTM	AASHTO
D 140	T 40
D 3142	T 295

2. Add the following to Section 2:

   2.3 *AASHTO Standard*:

   M 231, Weighing Devices Used in the Testing of Materials

3. Add the following sentence to Note 2:

   The terms “relative density” and “specific gravity” are used interchangeably in this standard.

4. Replace Section 6.4 with the following:

   6.4 *Balance*—conforming to the requirements of M 231, Class B.

5. Replace Section 11.2 with the following:

   11.2 Fill the pycnometer with freshly boiled distilled or deionized water at test temperature and place the stopper in the pycnometer. Do not allow any air bubbles to remain in the pycnometer. Place the filled pycnometer in the beaker.

6. Replace the last sentence in Section 12.1 with the following:

   “Do not heat for more than 60 minutes over a flame or hot plate or for more than two hours in an oven, and avoid incorporating air bubbles in the sample.”

7. Replace Section 12.3 with the following:

   12.3 Fill the pycnometer with freshly boiled distilled or deionized water at the test temperature and place the stopper in the pycnometer. Do not allow any air bubbles to remain in the pycnometer. Place the filled pycnometer in the beaker.

8. Replace Section 15 with the following:

   15. **Precision and Bias**

   15.1 *Precision*—Criteria for judging the acceptability of the relative density results obtained by this method are given in Table 1.

   15.1.1 *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results exceeds the values given in Table 1, Column 3.

15.1.2 *Multilaboratory Precision (Reproducibility)*—The figures in Column 4 of Table 1 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results exceeds the values given in Table 1, Column 5.

Table 1—Precision Estimates

	Single-Operator		Multilaboratory	
Condition	Standard Deviation (1s)[a]	Acceptable Range of Two Results (d2s)[a]	Standard Deviation (1s)[a]	Acceptable Range of Two Results (d2s)[a]
Asphalt:				
Specific Gravity (15.6°C)	0.0011	0.0032	0.0018	0.0051
Specific Gravity (25°C)	0.0008[b]	0.0021[b]	0.0013[b]	0.0035[b]
Soft Tar Pitch:				
Specific Gravity (15.6°C)	0.0013	0.0038	0.0029	0.0083
Specific Gravity (25°C)	0.00083	0.0023	0.0017	0.0048

[a] These values represent the 1s and d2s limits described in ASTM Practice C 670.

[b] The precision estimates denoted by the superscript “b” are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 104 to 121 laboratories for each of the eight pairs of samples. The analysis included four binder grades: PG 52-34, PG 64-16, PG 64-22, and PG 70-22. Average specific gravities in the analysis ranged from 1.0058 to 1.0428. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Note: Values in Table 1 not marked with a superscript “b” are precision estimates retained from ASTM D 70-03, Section 14, Table 1. These values were not part of the scope of the AMRL research activities described with the superscript “b”.

15.2 *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

Standard Method of Test for

Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)

AASHTO Designation: T 240-09[1]
ASTM Designation: D 2872-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)

AASHTO Designation: T 240-09[1]
ASTM Designation: D 2872-04

1. SCOPE

1.1. This test is used to measure the effect of heat and air on a moving film of asphalt binder and to provide residue for additional testing. The effects of this treatment are determined from measurements of the properties of the asphalt binder before and after the test.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- M 320, Performance-Graded Asphalt Binder
- R 16, Regulatory Information for Chemicals Used in AASHTO Tests
- R 18, Establishing and Implementing a Quality Management System for Construction Materials Testing Laboratories

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers
- E 220, Standard Test Method for Calibration of Thermocouples by Comparison Techniques
- E 644, Standard Test Methods for Testing Industrial Resistance Thermometers

3. SUMMARY OF TEST METHOD

3.1. A moving film of asphaltic material is heated in an oven for 85 minutes at 163°C (325°F). The effects of heat and air are determined from changes in physical test values as measured before and after the oven treatment. The residue from this test is also used for additional testing as required in M 320. An optional procedure is provided for determining the change in sample mass.

3.2. Precision values for this test method have been developed for viscosity at 60°C (140°F), ductility at 15.6°C (60°F), and mass change.

4. SIGNIFICANCE AND USE

4.1. This method indicates the approximate change in properties of asphalt binder during conventional batch plant mixing at about 150°C (302°F) as indicated by viscosity and other rheological measurements. The residue from this test is also used to determine the conformance of an asphalt binder to M 320. It yields a residue which approximates the condition of the asphalt binder immediately after the pavement is constructed. If the mixing temperature differs appreciably from 150°C (302°F), more or less effect on the properties will occur. This method can also be used to determine mass change, which is a measure of asphalt binder volatility and mass changes resulting from oxidation.

5. APPARATUS

5.1. *Oven*—A double-walled electrically heated convection type with inside dimensions as follows: a height of 381 mm (15 in.), a width of 483 mm (19 in.), and a depth (with door closed) of 445 ± 13 mm ($17^1/_2 \pm {}^1/_2$ in.). The door shall contain a symmetrically located window with dimensions of 305- to 330-mm (12- to 13-in.) wide by 203- to 229-mm (8- to 9-in.) high. The window shall contain two sheets of heat-resistant glass separated by an air space. The window should permit an unobstructed view of the interior of the oven. The heating element shall be located below the oven floor and shall be adequate to maintain the required temperature. The oven shall be vented at the top and bottom. The bottom vents shall be located symmetrically to supply incoming air around the heating elements. They shall have an open area of 15.0 ± 0.7 cm^2 (2.31 ± 0.11 $in.^2$). The top vents shall be symmetrically arranged in the upper part of the oven and have an open area of 9.3 ± 0.45 cm^2 (1.45 ± 0.07 $in.^2$).

5.1.1. The oven shall have an air plenum covering the side walls and ceiling, the air space being 38 mm ($1^1/_2$ in.) deep from the walls and ceiling. At a midpoint in the width of the oven and 152 mm (6 in.) from the face of the circular metal carriage to its axis, a squirrel cage-type fan 133.4 mm ($5^1/_4$ in.) outside diameter by 73 mm ($2^7/_8$ in.) wide shall be turned at 1725 r/min by an externally mounted motor. The squirrel cage fan shall be set so that the fan turns in an opposite direction to its vanes. The air flow characteristics of the fan-plenum system shall be suctioned from the floor of the oven through the wall plenums with the air exiting through the fan. Figures 1 and 2 show details of this fan-plenum system.

5.1.2. The oven shall be equipped with a proportional temperature controller capable of maintaining a temperature of 163 ± 1.0°C (325 ± 1.8°F). The sensing element of the controller may be placed at any location that enables the oven to maintain temperature control as specified in this standard. The temperature controller shall be capable of bringing the fully loaded oven back to the test temperature within a 10-minute period after insertion of the samples in a preheated oven.

5.1.3. A thermometer shall be hung from or affixed to a mounting in the ceiling which is 51 mm (2 in.) from the right side of the oven at a midpoint in the depth of the oven so that the bulb of the thermometer or the tip of the sensor of the alternative thermometric device is within 25 mm (1 in.) of an imaginary line level to the shaft of the circular metal carriage.

5.1.4. The oven shall be provided with a 305-mm (12-in.) diameter vertical circular carriage—see Figure 2 for details. This carriage shall be provided with suitable openings and clips for firmly holding eight glass containers—see Figure 3—in a horizontal position. The vertical carriage shall be mechanically driven through a 19-mm ($^3/_4$-in.) diameter shaft at a speed of 15 ± 0.2 r/min.

5.1.5. The oven shall be equipped with an air jet positioned to blow heated air into each container at its lowest point of travel. The air jet shall have an outlet orifice 1.02 mm (0.04 in.) in diameter (No. 60 drill) connected to a 7.6-m (25-ft) length of 7.9-mm ($^5/_{16}$-in.) O.D. refrigeration copper tubing. This tubing shall be coiled to lie flat on the bottom of the oven and lead to a source of fresh-dried, dust-free, regulated air. The tubing in the bottom of the oven shall be exposed to the plenum of the oven and shall not be covered by aluminum foil or other material.

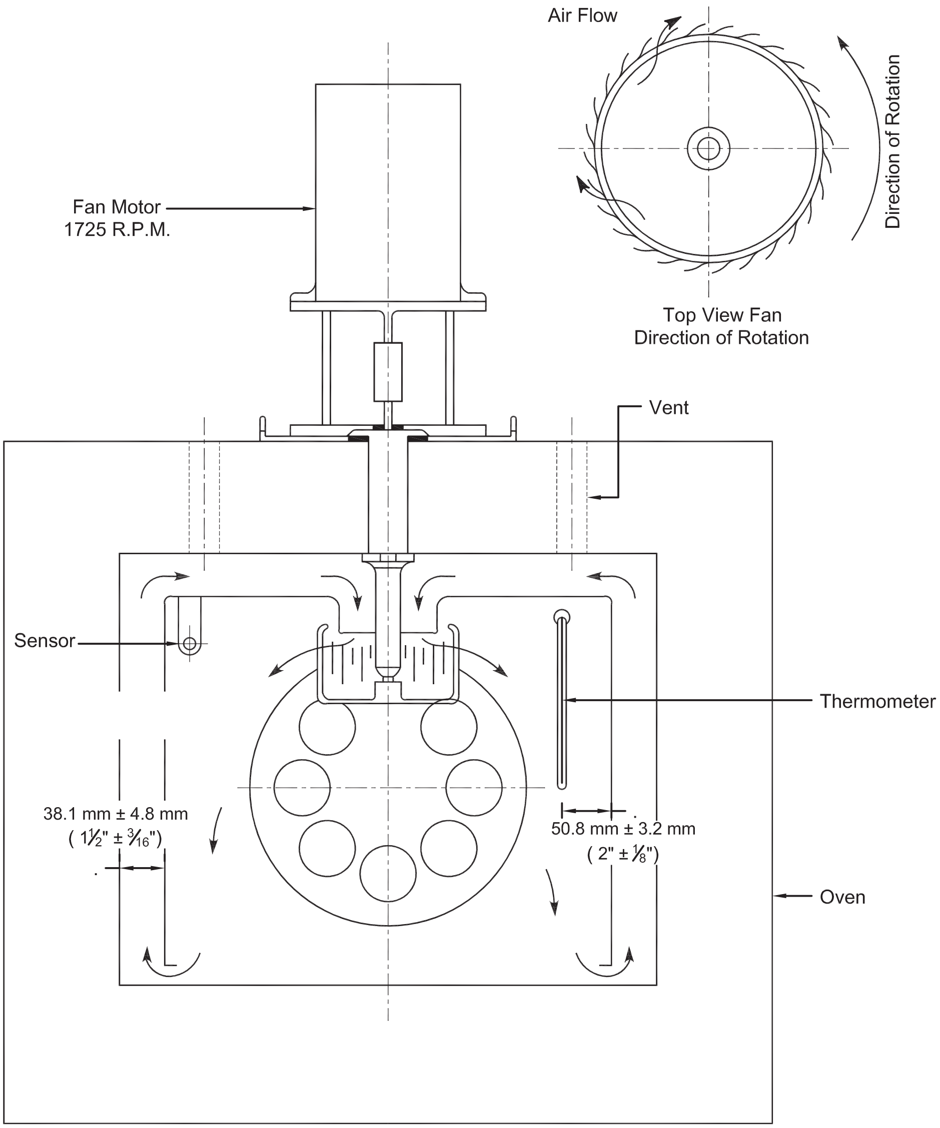

Figure 1—Schematic of Air Flow Front View

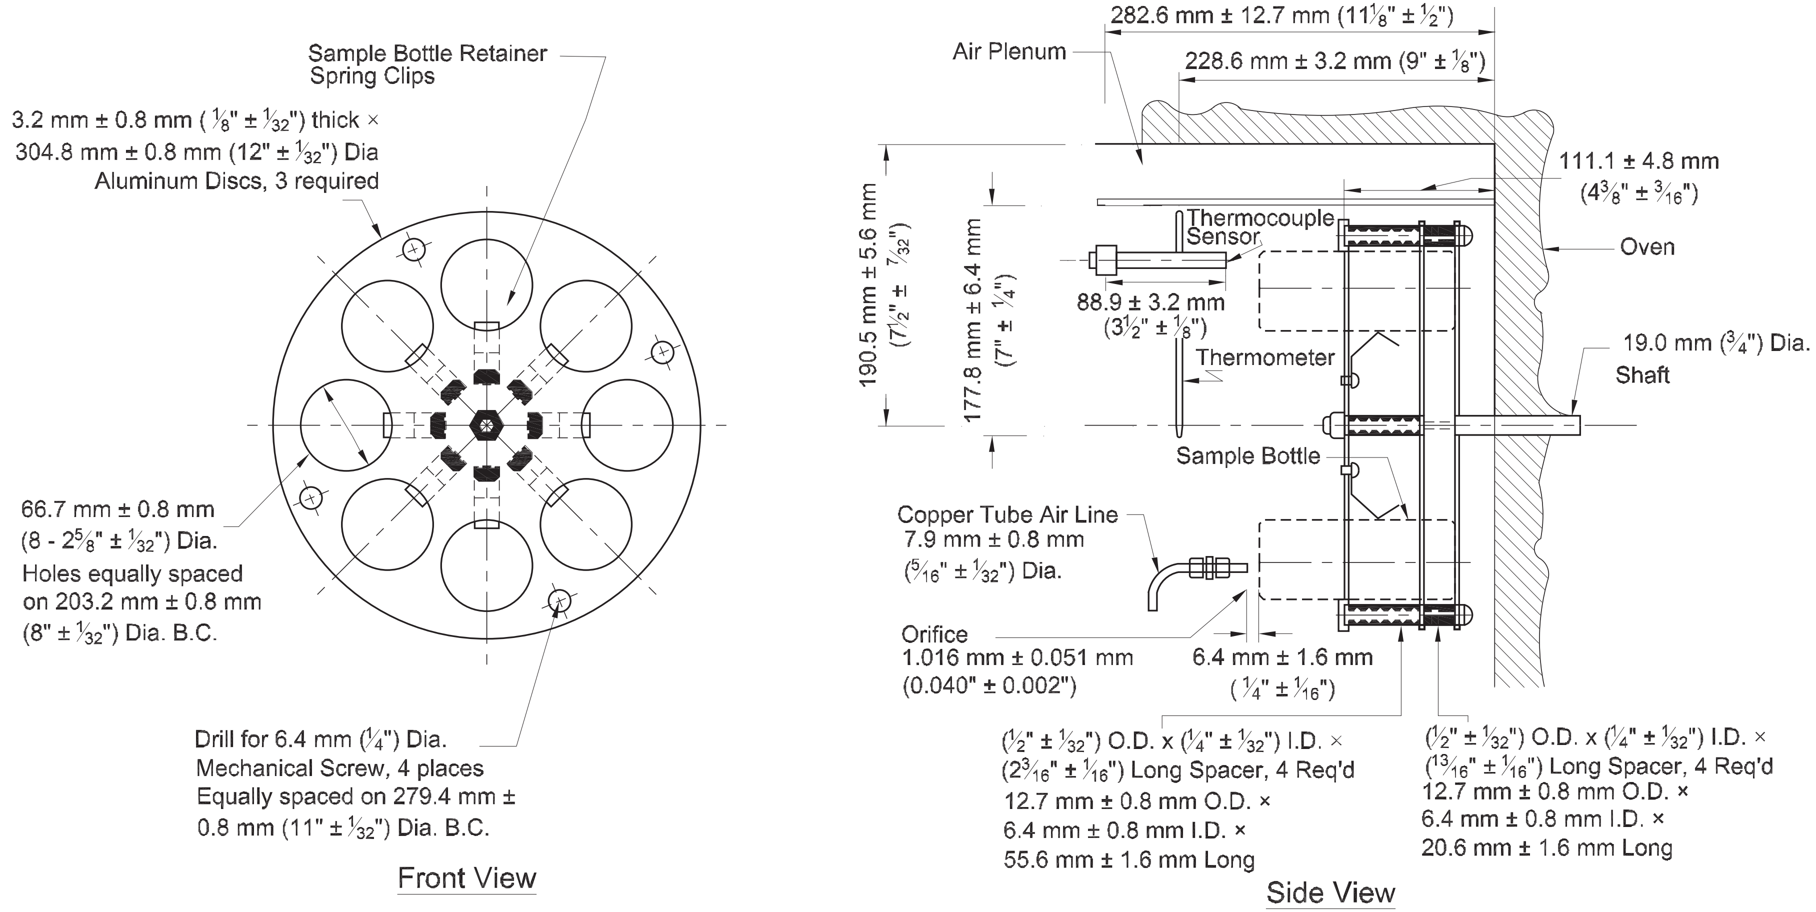

Figure 2—Circular Metal Carriage

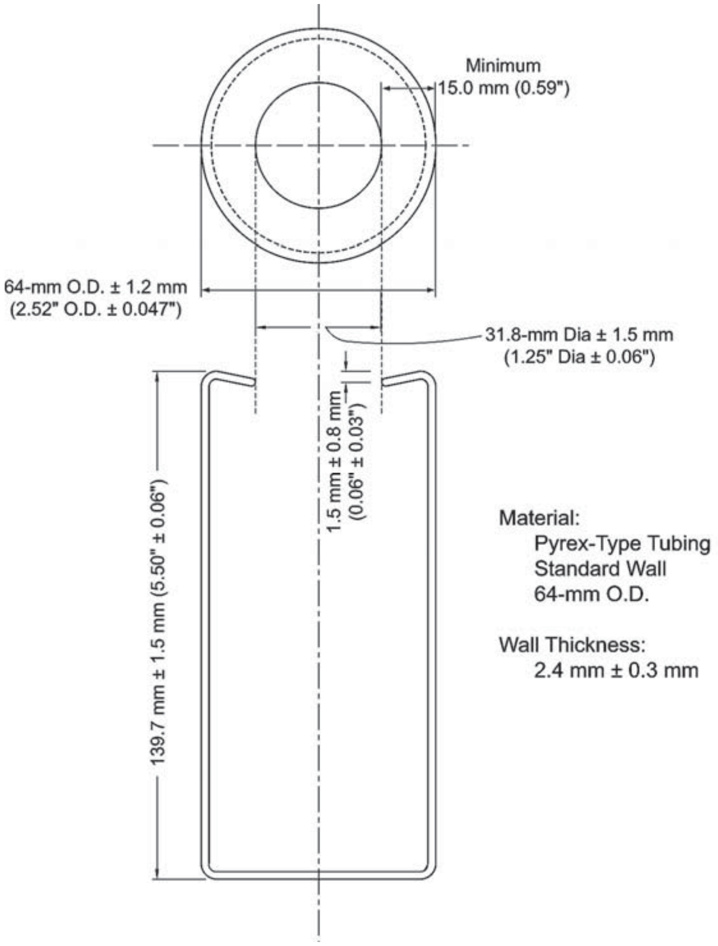

Figure 3—Sample Container

Note 1—Activated Silica Gel treated with an indicator is a satisfactory desiccant for the dried air.

5.2. *Flowmeter*—The flowmeter may be any suitable type capable of measuring the airflow at a rate of 4000 ± 100 mL/min. The flowmeter shall be located downstream of all regulating devices and upstream of the copper coil. The flowmeter shall be positioned so it is maintained at approximately room temperature. The flow meter shall be standardized at least every 12 months using a wet-test meter or other method. This standardization shall be based on airflow exiting the air jet and shall be conducted with the oven off and at room temperature.

5.3. *Thermometer*—An ASTM 13C (13F) thermometer as prescribed in (ASTM E 1 with an accuracy of 0.2°C (0.5°F). The thermometer shall be calibrated according to the requirements specified in R 18. This thermometer shall be used to make all temperature measurements required by this method. In order to reduce the risks associated with thermometer breakage, the thermometer may be fully or partially encapsulated in an optically transparent polymer sheath having a maximum thickness of 0.25 mm (0.01 in.). If a sheath is used, it shall be installed such that there is substantial mechanical contact with the thermometer. The thermometer shall be standardized after installation of the sheath.

5.3.1. The test thermometer may be replaced with an alternative thermometric device, provided the following requirements are met:

5.3.1.1. The thermometric device shall be mounted in the same position as the test thermometer it replaces.

5.3.1.2. The thermometric device shall (1) have a maximum scale error no greater than that of the test thermometer it replaces, and (2) be capable of indicating temperature within 0.1°C (0.2°F).

5.3.1.3. The thermometric device shall be standardized at the interval specified in R 18. Guidance for performing the standardization is given in ASTM E 220 or E 644.

5.4. *Container*—The container in which the asphalt binder is to be tested shall be of heat-resistant glass, with a smooth interior, conforming to the dimensions shown in Figure 3. Glass may be treated (e.g., frosted) on its exterior for handling purposes.

5.5. *Balance*—If the loss on heating is desired, a Class B balance conforming to the requirements of M 231 is required. If only the residue is desired, a Class G 2 balance conforming to M 231 may be used. The balance shall be standardized according to the requirements specified in R 18.

5.6. *Cooling Rack*—A wire or sheet metal rack, constructed of stainless steel or aluminum, which allows the sample containers to cool in a horizontal position. The rack shall be constructed in a way that allows air to flow freely around each container with at least 25-mm (1-in.) clearance between containers, and at least 25-mm (1-in.) clearance between the containers and any solid surface.

5.7. *Electronic Level (Optional)*—A precision level for measuring the levelness of the support provided by the circular openings in the metal carriage. The length shall be at least 125 mm (5 in.), and the width shall be 30 ± 3 mm (1.2 ± 0.1 in.). The bearing surface of the level shall be ground flat. Resolution, accuracy, and repeatability shall be ±0.1°. The level shall have a hold button freeze so that the level can be read after removing the level from the carriage.

Note 2—An SPI Tronic Digital Level PRO 360 or its equivalent has been found suitable for this purpose. The device may be purchased through local or mail order suppliers of machine tools.

6. PREPARATION OF OVEN

6.1. Position the air outlet orifice so that it is 6.4 mm ($^1/_4$ in.) from the opening of the glass container. The orifice shall also be so positioned that the jet blows horizontally into the center of the container opening when the rotating container is at its lowest position.

6.2. Position the thermometer specified in Section 5.3 so that the end of the bulb of the thermometer is within 25 mm (1 in.) of an imaginary line level to the center of the shaft holding the revolving carriage. If an alternative thermometric device is used, position it as specified in Section 5.3 so that the tip of the sensor is within 25 mm (1 in.) and level to the center of the shaft holding the revolving carriage.

6.3. Adjust the oven so that the horizontal axes of the glass containers, when in position in the carriage, are level to within ±1.0°. This shall be accomplished by checking the carriage, not by checking the level of the oven. A recommended procedure for ensuring that the containers are level to 1.0°is given in the Appendix. Alternative procedures may be used to ensure that the carriage is level to ±1.0. Check for wear in the bearing every 6 months and when the levelness of the carriage is checked.

Note 3—The bearing that supports the metal carriage is subject to wear, and excessive wear is known to allow the carriage to tilt. This affects the levelness of the containers and creates the potential for binder to creep from the bottles.

6.4. Start the fan. The fan shall remain on when the oven heater is on and the oven door is closed. The fan may be stopped when the oven door is opened. Stopping the fan may be accomplished manually, with an electronic door interlock, or through other means.

6.5. Preheat the oven for a minimum of 2 hours prior to testing, with the temperature controller adjusted to the setting that will be used during the test. This setting shall be selected such that when the oven is fully loaded and the air is on, the oven will equilibrate at 163.0 ± 1.0°C (325 ± 1.8°F), as indicated by the test thermometer.

Note 4—Because the presence of sample containers affects the temperature distribution in the oven, containers must be present in the oven when the controller setting is determined. The use of empty containers is acceptable for this purpose.

7. PROCEDURE

7.1. The sample as received shall be free of water. Heat the sample in its container with a loosely fitted cover in an oven not to exceed 163°C (325°F) for the minimum time necessary to ensure that the sample is completely fluid. Manually stir the sample but avoid incorporating air bubbles.

7.2. Pour 35 ± 0.5 g of the sample into each of the number of glass containers required to provide sufficient material for the tests that are to be performed on the residue.

7.3. Immediately after pouring the sample into a glass container, turn the container to a horizontal position. Rotate the container slowly for at least one full rotation, and attempt to precoat its cylindrical surface. It is not necessary to precoat the open end of the container, and care should be taken to prevent the sample from flowing out of the container during this step. Ensure that the asphalt binder does not coat the central part of the open end of the container. Place the container horizontally in a clean cooling rack that is maintained in a draft-free, room-temperature location away from ovens or other sources of heat.

Note 5—Complete precoating of the cylindrical surface may not be possible for highly modified binders.

Note 6—For maximum precision in determining mass change, the cooling rack should be in a location which is the same temperature and humidity as the balance used for measuring the mass of the containers.

Note 7—Static electricity may cause unstable mass measurements, due in part to the characteristics of the glass sample containers. This problem can be minimized by mounting a passive ion source inside the balance draft shield.

7.4. Allow the glass containers to cool in the cooling rack for at least 60 minutes but no more than 180 minutes before placing the containers in the oven.

7.5. When mass change is being determined, use two separate containers for this determination. After cooling, determine the mass of these containers using an analytical balance having a resolution of 0.001 g or better. Separately place each container vertically on the balance and record the mass to the full resolution of the balance.

7.6. With the oven at operating temperature and the airflow set at 4000 ± 300 mL/min, arrange the containers holding the asphalt binder in the carriage so that the carriage is balanced. Fill any unused spaces in the carriage with empty containers. Close the door, and rotate the carriage assembly at a rate of 15 ± 0.2 r/min. Maintain the glass containers in the oven with the air flowing and the carriage rotating for 85 minutes. The test temperature of 163 ± 1.0°C (325 ± 1.8°F) shall be reached within the first 10 minutes—otherwise discontinue the test.

7.7. At the conclusion of the testing period, remove any containers for mass change determination, and place them horizontally in the cooling rack. Then remove each remaining container, one at a time, and transfer its contents to a collection container having a capacity at least 30 percent greater than the total expected volume of residue. This transfer shall be accomplished by first pouring out any residue which will flow freely from the container, and then scraping out as much of the remaining residue as practical. While the residue is being removed from each container, the oven door shall remain closed, with the heater power on, the air on, and the remaining samples rotating in the carriage. The final container shall be removed from the oven within 5 minutes of removal of the initial container.

Note 8—Any scraping tool may be used, as long as an average of 90 percent or more of the residue is removed from the sample containers. It has been determined that circumferential scraping tends to be more effective than lengthwise scraping.

7.8. After removing the residue from each of the containers, gently stir the residue in the collection container to homogenize the residue without introducing air into it.

7.9. If the mass change is being determined, allow the designated containers to cool on the cooling rack for at least 60 minutes but not more than 180 minutes. After cooling, determine the mass of these containers using an analytical balance having a resolution of 0.001 g or better. Separately place each container vertically on the balance, and record the mass to the full resolution of the balance.

7.9.1. Make a note on the report if any sample appears to have flowed out of the container. If mass has flowed from the container, do not use the container for mass change determination. The results from one container may be used to determine mass change if mass has flowed from the container. If only one container is used to determine mass change, note it on the report. Use two containers for referee purposes.

Note 9—Some labs have reported problems with the asphalt binder flowing from the container during the test. If this occurs, check the levelness of the circular openings in the carriage and the dimensions of the container. Containers with a small annular ring appear to be particularly susceptible to this problem. Containers that do not comply with the dimensional requirements should be removed from service.

Note 10—To improve mass change precision, the containers used for determining mass change should only be handled with clean gloves or tongs. Transfer to the balance should be done with tongs to prevent contamination and temperature changes which could distort the mass measurement.

8. REPORT

8.1. Report the results from the RTFO test in terms of the physical changes in the asphalt binder brought about by this method. These values are obtained by performing appropriate tests on the asphalt binder before and after the RTFO test.

Note 11—Physical test results required for M 320 are reported as part of the test methods specified in M 320, not as part of this test method.

8.2. When determined, report the average mass change of the material in the two containers as a mass percent of the original material. Report this calculated result to the nearest 0.001 percent. A mass loss shall be reported as a negative number, while a mass gain shall be reported as a positive number.

Note 12—This test can result in either a mass loss or a mass gain. During the test, volatile components and reaction products (primarily water) evaporate (causing a decrease in mass) while oxygen reacts with the sample (causing an increase in mass). The combined effect determines whether the sample has an overall mass gain or an overall mass loss. Samples with a very low percentage of volatile components will usually exhibit a mass gain, while samples with a high percentage of volatile components will usually exhibit a mass loss.

8.3. Report asphalt binder loss from any of the mass change containers. Report if mass change is based on one container.

9. PRECISION AND BIAS

9.1. Criteria for judging the acceptability of the viscosity at 60°C (140°F) and the ductility at 15.6°C (60°F) test results on the residue after heating are given in Table 1. The values given in Column 2 are the standard deviations that have been found to be appropriate for the materials and conditions of test described in Column 1. The values given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests. The values given in Column 4 are the coefficients of variation that have been found to be appropriate for the materials and conditions of test described in Column 1. The values given in Column 5 are the limits that should not be exceeded by the difference between the results of two properly conducted tests expressed as a percent of their mean.

Table 1—Precision of Test on Residue

Test Methods	Standard Deviation (1s)	Acceptable Range of Two Results (d2s)	Coefficient of Variation (Percent of Mean) (1s%)	Acceptable Range of Two Results (Percent of Mean) (d2s%)
Single-operator precision:				
Viscosity at 60°C (140°F)	—	—	2.3	6.5
Ductility at 15.6°C (60°F)[a]	3 cm	9 cm	—	—
Multilaboratory precision:				
Viscosity at 60°C (140°F)	—	—	4.2	11.9
Ductility at 15.6°C (60°F)	6 cm	16 cm	—	—

[a] This is based on the analysis of data resulting from tests by 16 laboratories on two asphalt binders ranging from 13 to 30 cm.

9.2. *Precision for Change in Mass*—Criteria for judging the acceptability of change in mass results obtained by this method are given in Tables 2 and 3. Table 2 should be consulted as the final qualifier for precision purposes. Table 3 has been added for the convenience of the user.

9.3. *Single-Operator Precision (Repeatability)*—The equation in Column 2 of Table 2 indicates that the standard deviation of the test results (1s) can be expressed as a function of the mass change (X) for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results exceeds the value determined by multiplying the 1s estimate determined in Column 2 for the average value of the two results by a factor of 2.83. This is shown in Table 2, Column 3.

9.4. *Multilaboratory Precision (Reproducibility)*—The equation in Column 2 of Table 2 indicates that the standard deviation of the test results (1s) can be expressed as a function of the mass change (X) for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results exceeds the value determined by multiplying the 1s estimate determined in Column 2 for the average value of the two results by a factor of 2.83. This is shown in Table 2, Column 3.

Table 2—Precision Estimates

Condition	Standard Deviation (1s)[a,b]	Acceptable Range of Two Test Results (d2s)[a,b,c]
Single Operator Precision:		
Mass Loss (%)	1s = 0.0061 + 0.0363(X)	d2s = (0.0061 + 0.0363(X_{avg})) × (2.83)
Multilaboratory Precision:		
Mass Loss (%)	1s = 0.00153 + 0.1365(X)	d2s = (0.00153 + 0.1365(X_{avg})) × (2.83)

[a] These values represent the 1s and d2s limits described in ASTM Practice C 670.

[b] X and X_{avg} should be entered into equations as positive numbers.

[c] The value X_{avg} represents the average value of two test results.

Note 13—The precision estimates given in Table 2 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 166 to 191 laboratories for each of the eight pairs of samples. The analysis included five binder grades: PG 52-34, PG 64-16, PG 64-22, PG 70-22, and PG 76-22 (SBS modified). The samples used in the analysis had an average mass loss ranging from –0.05 to –0.51 percent. The equations for precision estimates are reliable only in situations when the change in mass is negative. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Table 3—Stratified Estimates of Precision

Condition	Standard Deviation (1s)[a]	Acceptable Range of Two Test Results (d2s)[a]
Single Operator Precision:		
Mass Loss (%)		
0.0 to 0.1%	0.0079	0.0224
0.1 to 0.2%	0.0115	0.0327
0.2 to 0.3%	0.0152	0.0429
0.3 to 0.4%	0.0188	0.0532
0.4 to 0.5%	0.0224	0.0635
Multilaboratory Precision:		
Mass Loss (%)		
0.0 to 0.1%	0.0084	0.0236
0.1 to 0.2%	0.0220	0.0623
0.2 to 0.3%	0.0357	0.1009
0.3 to 0.4%	0.0493	0.1395
0.4 to 0.5%	0.0630	0.1781

[a] The values represented in this table are the 1s and d2s limits described as stratified values. Table 2 of this standard should be consulted as the final qualifier for precision purposes.

9.5. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

APPENDIX

(Nonmandatory Information)

X1. RECOMMENDED PROCEDURE FOR DETERMINING THE LEVELNESS OF THE CARRIAGE'S OPENINGS

X1.1 Verify the accuracy and sensitivity of the electronic level as follows:

X1.1.1 *Accuracy*—Place a square glass plate on a rigid bench top and place the level in the center of the glass plate in a direction parallel to one of the sides. If necessary, shim the glass plate so that it does not rock when pressed at its corners. Observe the position of the bubble and shim one edge of the glass plate until the bubble is centered between the markings on the vial. Take a reading. Rotate the level end-for-end and again observe the position of the bubble and take a reading. The readings should not differ by more than 0.2°.

X1.1.2. *Sensitivity*—With the level in the center of the glass plate and parallel to one of the edges, shim one end of the level and observe the change in position of the bubble. The shim shall be of sufficient thickness to raise the level by 0.20° (0.5 mm in 140 mm [0.020 in. in 5.25 in.]). The addition of the shim shall cause a distinct and observable change in the position of the bubble. If the shift in the position of the bubble is not observable the level lacks adequate sensitivity and shall be replaced.

X1.2. Check the bearing that supports the carriage for wear. If there is any noticeable movement of the carriage when it is manually rotated in an upward motion, replace the bearing before proceeding.

X1.3. Rotate the carriage so that one of the openings is at 90° clockwise from the vertical direction (3 o'clock position). Insert the level into the opening, capture the reading, remove the level, and record the angle to the nearest 0.1°. Rotate the carriage by 180° in a clockwise direction and repeat the measurement.

X1.4. The readings for each position should be 0.0° ± 01.0°. Shim the underside of the oven until the requirements are met.

X1.5. Repeat the process for the other openings. All readings should be 0.0° ± 01.0°. If this requirement cannot be met consult the manufacturer.

---

[1] Similar, but not technically identical to ASTM D 2872-04. The differences between standards are as follows:

- In Section 5.1.2, the required tolerance for the temperature of the oven is ± 1.0°C (± 1.8°F) in T 240 and ± 0.5°C (± 1.0°F) in the ASTM method.
- The position of the orifice is $^1/_4 \pm ^1/_{16}$ in. in Figure 2 of T 240 and is $^1/_4 \pm ^1/_8$ in. in Section 6.1 of the ASTM method.
- In Section 5.3.1, the T 240 requirements for the alternative thermometric device differ from the ASTM method.
- In Section 5.2, T 240 has requirements for the tolerance and standardization of the flowmeter.
- In Section 5.4, T 240 allows exterior frosting of the glass container.
- In Section 5.7, T 240 has optional electronic level.
- In Section 6.3, T 240 requirements for leveling and checking the bearing differ from the ASTM method.
- In Section 7.9.1, T 240 has detailed procedure in the event that mass flows out of the container.
- In Section 6.5, the RTFO is required to be preheated for at least 2 hours in T 240 and for at least 16 hours in the ASTM method.
- In Section 7.1, the maximum temperature of the oven for preparation of the sample is 163°C (325°F) in T 240 and 150°C (302°F) in the ASTM method.
- The Appendix is in T 240 but not in the ASTM method.

Standard Method of Test for

Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus

AASHTO Designation: T 245-97 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus

AASHTO Designation: T 245-97 (2008)

1. SCOPE

1.1. This method covers the measurement of the resistance to plastic flow of cylindrical specimens of bituminous paving mixture loaded on the lateral surface by means of the Marshall apparatus. This method is for use with mixtures containing asphalt cement, asphalt cutback or tar, and aggregate up to 25.4-mm (1-in.) maximum size.

2. APPARATUS

2.1. *Specimen Mold Assembly*—Mold cylinders 101.6 mm (4 in.) in diameter by 76.2 mm (3 in.) in height, base plates, and extension collars shall conform to the details shown in Figure 1. Three mold cylinders are recommended.

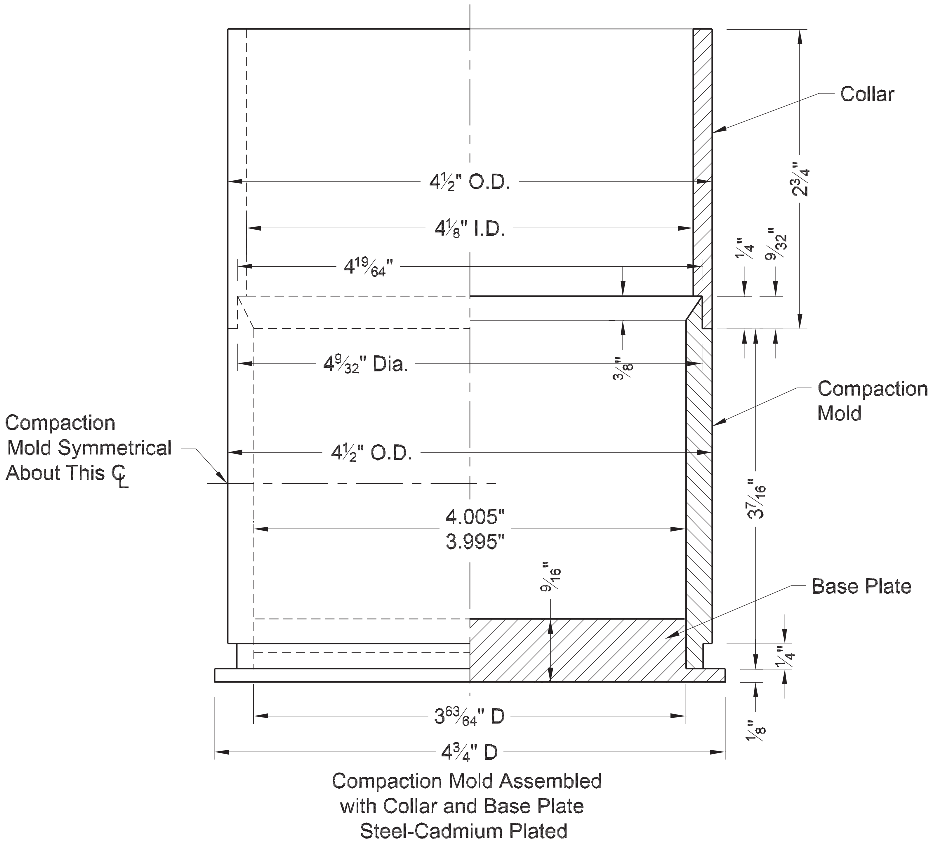

Figure 1—Compaction Mold

Table 1—Table of Equivalents for Figures 1 and 3

12.7	$^{1}/_{2}$	44.4	$1^{3}/_{4}$	101.47	3.995	158.8	$6^{1}/_{4}$
14.3	$^{9}/_{16}$	50.8	2	101.6	4	193.7	$7^{5}/_{8}$
15.9	$^{5}/_{8}$	57.2	$2^{1}/_{4}$	101.73	4.005	685.8	27

2.2. *Specimen Extractor*, steel, in the form of a disk with a diameter not less than 100 mm (3.95 in.) and 12.7 mm ($^{1}/_{2}$ in.) thick for extracting the compacted specimen from the specimen mold with the use of the mold collar. A suitable bar is required to transfer the load from the ring dynamometer adapter to the extension collar while extracting the specimen.

2.3. *Compaction Hammer*—The compaction hammer (Figure 2) shall have a flat, circular tamping face and a 4536 ± 9 g (10 ± 0.02 lb) sliding weight (including safety finger guard if so equipped) with a free fall of 457.2 ± 1.524 mm (18 ± 0.06 in.).

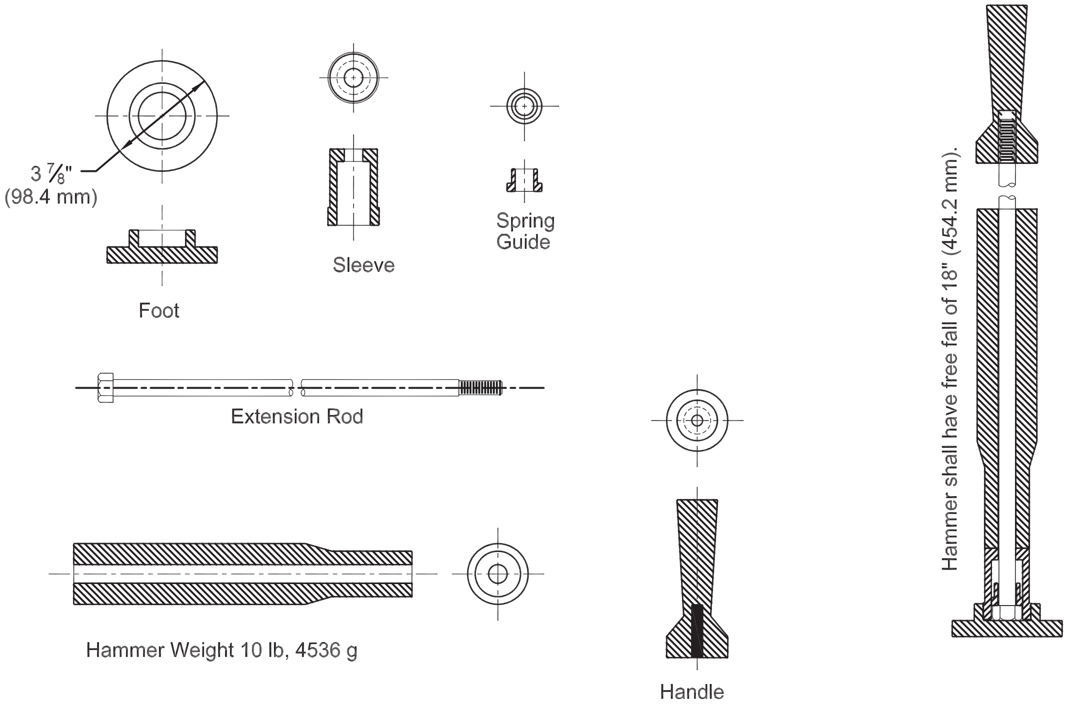

Figure 2—Compaction Hammer

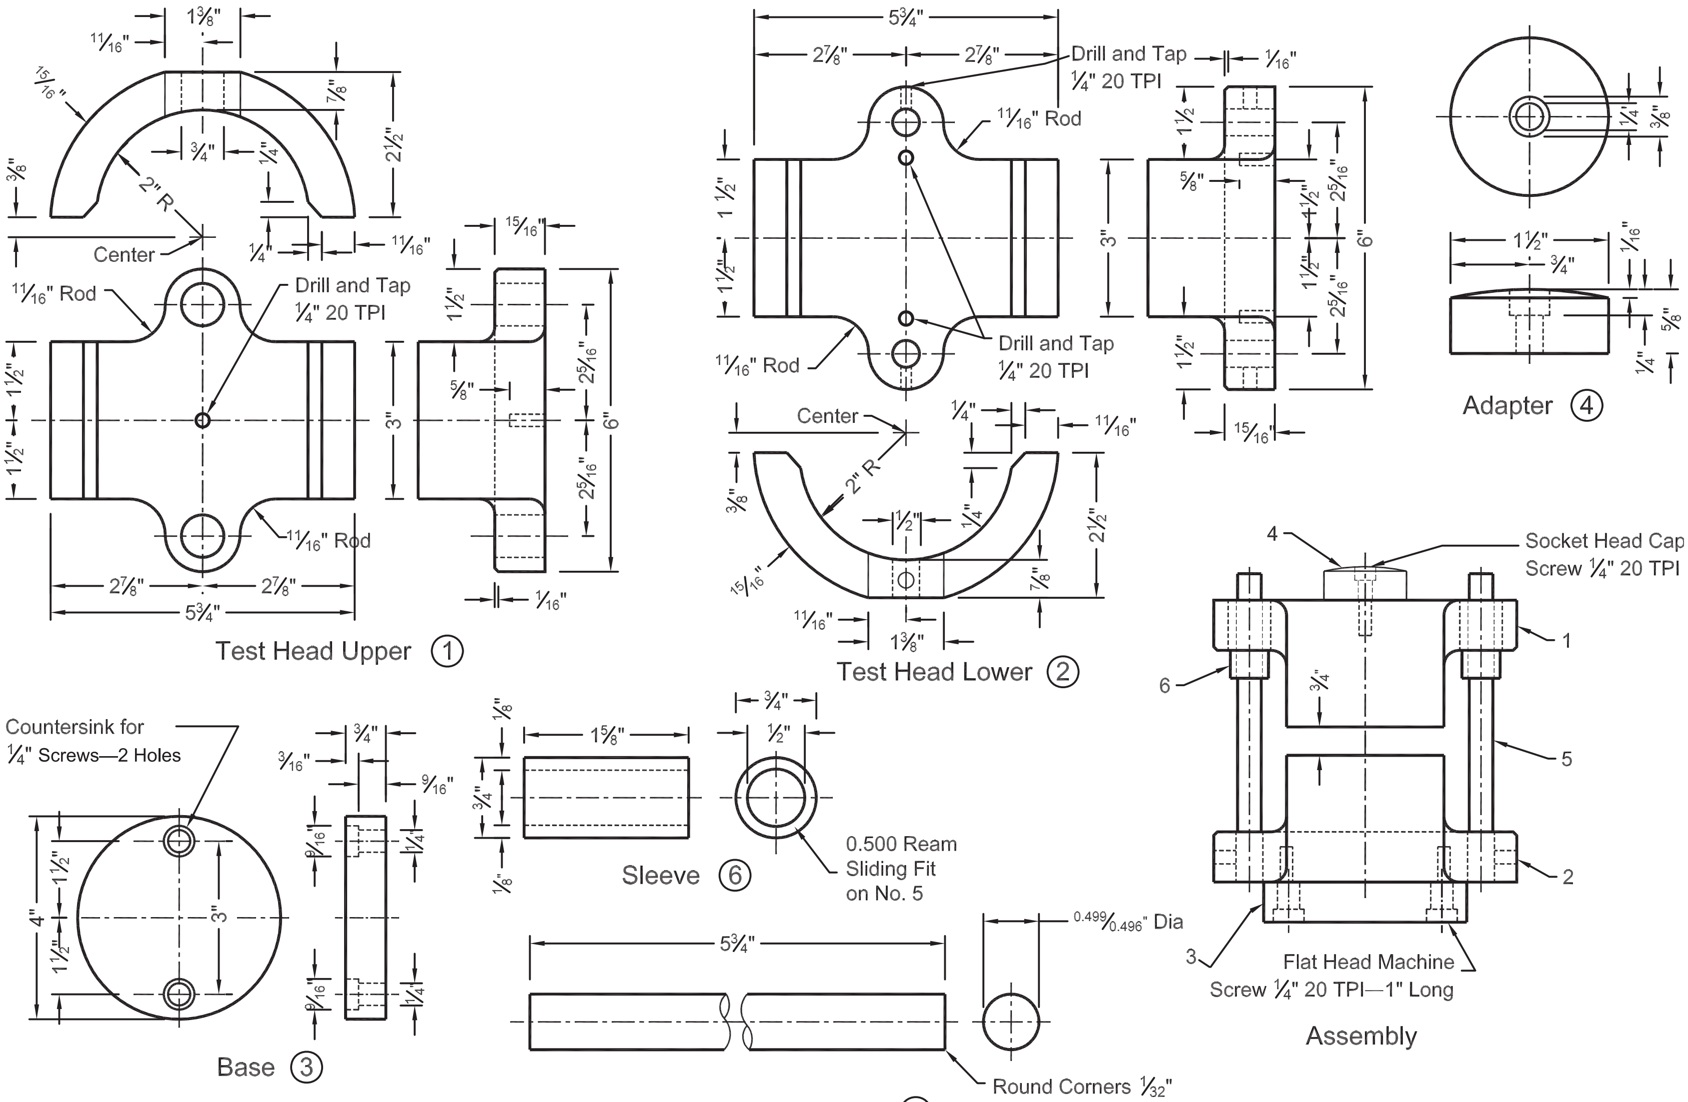
Note 1—The compaction hammer may be equipped with a finger safety guard as shown in Figure 2.

Note 2—Instead of a hand-operated hammer, and associated equipment described in Sections 2.3, 2.4, and 2.5, a mechanically operated hammer may be used provided it has been calibrated to give results comparable with the hand-operated hammer.

2.4. *Compaction Pedestal*—The compaction pedestal shall consist of a 203.2 by 203.2- by 457.2-mm (8- by 8- by 18-in.) wooden post capped with a 304.8- by 304.8- by 25.4-mm (12- by 12- by 1-in.) steel plate. The wooden post shall be oak, pine, or other wood having an average dry weight of 0.67 to 0.77 g/cm^3 (42 to 48 lb/ft^3). The wooden post shall be secured by four angle brackets to a solid concrete slab. The steel cap shall be firmly fastened to the post. The pedestal assembly shall be installed so that the post is plumb and the cap is level.

2.5. *Specimen Mold Holder*—mounted on the compaction pedestal so as to center the compaction mold over the center of the post. It shall hold the compaction mold, collar, and base plate securely in position during compaction of the specimen.

2.6. *Breaking Head*—(Figure 3) shall consist of upper and lower cylindrical segments or test heads having an inside radius of curvature of 50.8 mm (2 in.) accurately machined. The lower segment shall be mounted on a base having two perpendicular guide rods or posts extending upward. Guide sleeves in the upper segment shall be in such a position as to direct the two segments together without appreciable binding or loose motion on the guide rods.



(Table of Equivalents Same as for Figure 1)

Figure 3—Breaking Head

2.7. *Loading Jack*—The loading jack (Figure 4) shall consist of a screw jack mounted in a testing frame and shall produce a uniform vertical movement of 50.8 mm (2 in.)/min. An electric motor may be attached to the jacking mechanism.

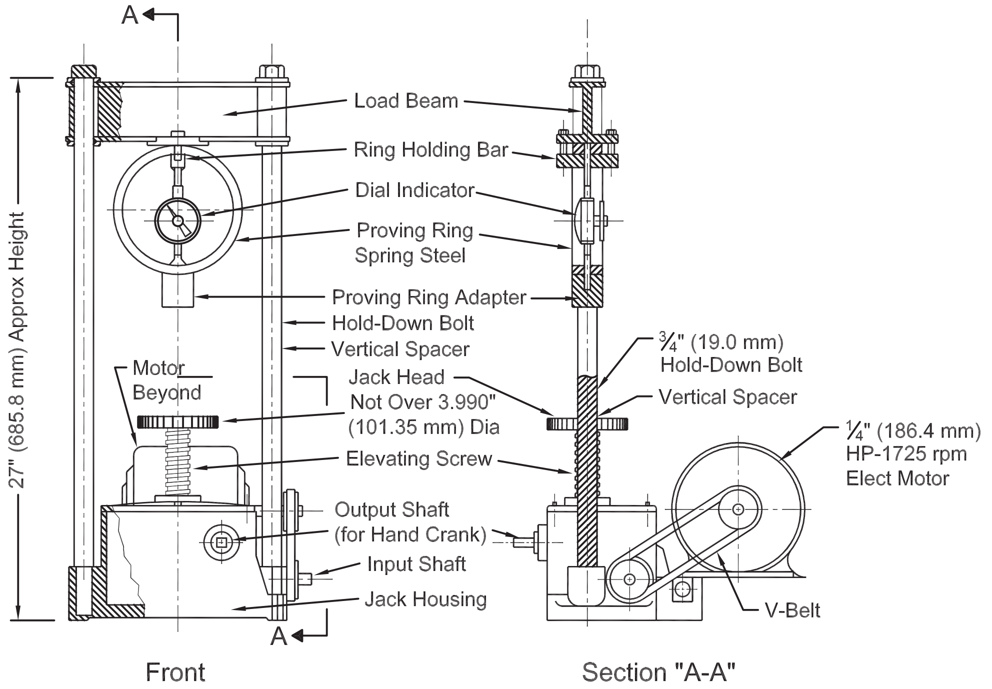


Figure 4—Compression Testing Machine

Note 3—Instead of the loading jack, a mechanical or hydraulic testing machine may be used provided the rate of movement can be maintained at 50.8 mm (2 in.)/min while the load is applied.

2.8. *Ring Dynamometer Assembly*—One-ring dynamometer (Figure 4) of 22.2 kN (5000 lbf) capacity and sensitivity of 44.5 N (10 lbf) up to 4.45 kN (1000 lbf) and 111.2N (25 lbf) between 4.45 and 22.2 kN (1000 and 5000 lbf) shall be equipped with a micrometer dial. The micrometer dial shall be graduated in 0.0025 mm (0.0001 in.). Upper and lower ring dynamometer attachments are required for fastening the ring dynamometer to the testing frame and transmitting the load to the breaking head.

Note 4—Instead of the ring dynamometer assembly, any suitable load-measuring device may be used provided the capacity and sensitivity meet the above requirements.

2.9. *Flowmeter*—The flowmeter shall consist of a guide sleeve and a gauge. The activating pin of the gauge shall slide inside the guide sleeve with a slight amount of frictional resistance. The guide sleeve shall slide freely over the guide rod of the breaking head. The flowmeter gauge shall be adjusted to zero when placed in position on the breaking head when each individual test specimen is inserted between the breaking head segments. Graduations of the flowmeter gauge shall be in 0.25-mm (0.01-in.) divisions.

Note 5—Instead of the flowmeter, a micrometer dial or stress-strain recorder graduated in 0.25 mm (0.01 in.) may be used to measure flow.

2.10. *Ovens or Hot Plates*—Ovens or hot plates shall be provided for heating aggregates, bituminous material, specimen molds, compaction hammers, and other equipment to the required mixing and molding temperatures. It is recommended that the heating units be thermostatically controlled so as to maintain the required temperature within 2.8ºC (5ºF). Suitable shields, baffle plates, or sand baths shall be used on the surfaces of the hot plates to minimize localized overheating.

2.11. *Heating Device*—A small hot plate with continuously variable heating rate, a sand bath, infrared lamp, or other suitable device shall be available for supplying sufficient heat under the mixing bowl to maintain the aggregate and bituminous material at the desired temperature during mixing. If a hot plate is used, a wire mesh or similar material shall be placed on the hot plate to prevent direct contact between the hot plate and mixing bowl.

2.12. *Mixing Apparatus*—Mechanical mixing is recommended. Any type of mechanical mixer may be used provided it can be maintained at the required mixing temperature and will produce a well-coated, homogeneous mixture of the required amount in the allowable time, and further provided that essentially all of the batch can be recovered. A metal pan or bowl of sufficient capacity and hand mixing may also be used.

2.13. *Water Bath*—The water bath shall be at least 152.4 mm (6 in.) deep and shall be thermostatically controlled so as to maintain the bath at 60 ± 1ºC (140 ± 2ºF) or 37.8 ± 1ºC (100 ± 2ºF). The tank shall have a perforated false bottom or be equipped with a shelf for supporting specimens 50.8 mm (2 in.) above the bottom of the bath.

2.14. *Air Bath*—The air bath for asphalt cutback mixtures shall be thermostatically controlled and shall maintain the air temperature at 25 ± 1ºC (77º ± 2ºF).

2.15. *Miscellaneous Equipment*:

2.15.1. *Containers for Heating Aggregates*— flat-bottom metal pans or other suitable containers.

2.15.2. *Containers for Heating Bituminous Material*—either gill-type tins, beakers, pouring pots, or saucepans may be used.

2.15.3. *Mixing Tool*—either a steel trowel (garden type) or spatula, for spading, and hand mixing.

2.15.4. *Thermometers*—for determining temperatures of aggregates, bitumen, and bituminous mixtures. Armored-glass, dial type, or digital thermometers with metal stems are recommended. A range from 9.9 to 204ºC (50 to 400ºF), with sensitivity of 2.8ºC (5ºF) is required.

2.15.5. Thermometers for water and air baths sensitive to 0.2ºC (0.4ºF) with a range sufficient to determine the specified bath temperature.

2.15.6. *Balance*—2-kg capacity, sensitive to 0.1 g, for weighing molded specimens.

2.15.7. *Balance*—5-kg capacity, sensitive to 1.0 g, for batching mixtures.

2.15.8. *Gloves*—for handling hot equipment.

2.15.9. *Rubber Gloves*—for removing specimens from water bath.

2.15.10. *Marking Crayons*—for identifying specimens.

2.15.11. *Scoop*—flat bottom, for batching aggregates.

2.15.12. *Spoon*—large, for placing the mixture in the specimen molds.

3. TEST SPECIMENS

3.1. *Number of Specimens*—Prepare at least three specimens for each combination of aggregates and bitumen content.

3.2. *Preparation of Aggregates*—Dry aggregates to constant mass at 105 to 110ºC (221 to 230ºF) and separate the aggregates by dry-sieving into the desired size fractions.[1] The following size fractions are recommended:

- 25.0 to 19.0 mm (1 to $^3/_4$ in.)
- 19.0 to 9.5 mm ($^3/_4$ to $^3/_8$ in.)
- 9.5 mm to 4.75 mm ($^3/_8$ in. to No. 4)
- 4.75 mm to 2.36 mm (No. 4 to No. 8)
- Passing 2.36 mm (No. 8)

3.3. *Determination of Mixing and Compacting Temperatures*:

3.3.1. The temperatures to which the asphalt cement and asphalt cutback must be heated to produce a viscosity of 170 ± 20 cSt shall be the mixing temperature.

3.3.2. The temperature to which asphalt cement must be heated to produce a viscosity of 280 ± 30 cSt shall be the compacting temperature.

3.3.3. From a composition chart for the asphalt cutback used, determine from its viscosity at 60ºC (140ºF) the percentage of solvent by mass. Also determine from the chart the viscosity at 60ºC (140ºF) of the asphalt cutback after it has lost 50 percent of its solvent. The temperature determined from the viscosity temperature chart to which the asphalt cutback must be heated to produce a viscosity of 280 ± 30 cSt after a loss of 50 percent of the original solvent content shall be the compacting temperature.

3.3.4. The temperature to which tar must be heated to produce Engler specific viscosities of 25 ± 3 and 40 ± 5 shall be, respectively, the mixing and compacting temperature.

3.4. *Preparation of Mixtures*:

3.4.1. An initial batch shall be mixed for the purpose of "buttering" the mixture bowl and stirrers. This batch shall be emptied after mixing and the sides of the bowl and stirrers shall be cleaned of mixture residue by scraping with a small limber spatula but shall not be wiped with cloth or washed clean with solvent, except when a change is to be made in the binder or at the end of a run.

3.4.2. Weigh into separate pans for each test specimen the amount of each size fraction required to produce a batch that will result in a compacted specimen 63.5 ± 1.27 mm (2.5 ± 0.05 in.) in height (about 1200 g). Mix the aggregate in each pan and place the pans on a hot plate or in the oven and heat to a temperature not exceeding the mixing temperature established in Section 3.3 by more than approximately 28ºC (50ºF) for asphalt cement and tar mixes at 14ºC (25ºF) for cutback asphalt mixes. Heat, to the established mixing temperature, just sufficient bituminous material for the batch in a separate container. Charge the mixing bowl with the heated aggregate. Form a crater in the dry-blended aggregate and weigh the preheated required amount of bituminous material into the mixture. For mixes prepared with cutback asphalt, introduce the mixing blade in the mixing bowl and determine the total mass of the mix components plus bowl and blade before proceeding with mixing. Care must be exercised to prevent loss of the mix during mixing and subsequent handling. At this point, the temperature of the aggregate and bituminous material shall be within the limits of the mixing temperature established in Section 3.3. Mix the aggregate and bituminous material rapidly until thoroughly coated. To maintain proper mixing temperature, one of the methods described in Section 2.11 may be used.

3.4.3. Following mixing, cure asphalt cutback mixtures in a ventilated oven maintained at approximately 11.1ºC (20ºF) above the compaction temperature. Curing is to be continued in the mixing bowl until the precalculated weight of 50 percent solvent loss or more has been obtained. The mix may be stirred in a mixing bowl during curing to accelerate the solvent loss. However, care should be exercised to prevent loss of the mix. Weigh the mix during curing in successive intervals of 15 minutes initially and less than 10-minute intervals as the weight of the mix at 50 percent solvent loss is approached.

3.5. *Compaction of Specimens*:

3.5.1. Thoroughly clean the specimen mold assembly and the face of the compaction hammer and heat them either in boiling water, on the hot plate, or in an oven, to a temperature between 93.3 and 148.9ºC (200 and 300ºF). Place a piece of filter paper or paper toweling cut to size in the bottom of the mold before the mixture is introduced. Place the entire batch in the mold, spade the mixture vigorously with a heated spatula or trowel 15 times around the perimeter and 10 times over the interior. Remove the collar and smooth the surface of the mix with a trowel to a slightly rounded shape. Temperatures of the mixtures immediately prior to compaction shall be within the limits of the compacting temperature established in Section 3.3.

3.5.2. Replace the collar, then place a piece of filter paper or paper toweling cut to size on top of the mixture and place the mold assembly on the compaction pedestal in the mold holder, and unless otherwise specified, apply 50 or 75 blows with the compaction hammer with a free fall in 457.2 mm (18 in.). Hold the axis of the compaction hammer perpendicular to the base of the mold assembly during compaction. Remove the base plate and collar, and reverse and reassemble the mold. Apply the same number of compaction blows to the face of the reversed specimen. After compaction, remove the base plate and place the sample extractor on the end of the specimen. Place the assembly with the extension collar up in the testing machine, apply pressure to the collar by means of the load transfer bar, and force the specimen into the extension collar. Lift the collar from the specimen. Carefully transfer the specimen to a smooth, flat surface and allow it to stand overnight at room temperature. Weigh, measure, and test the specimen.

Note 6—In general, specimens shall be cooled as specified in Section 3.5.2. When more rapid cooling is desired, table fans may be used. Mixtures that lack sufficient cohesion to result in the required cylindrical shape on removal from the mold immediately after compaction may be cooled in the mold in air until sufficient cohesion has developed to result in the proper cylindrical shape.

4. PROCEDURE

4.1. Bring the specimens prepared with asphalt cement or tar to the specified temperature by immersing in the water bath 30 to 40 minutes or placing in the oven for two hours. Maintain the bath or oven temperature at 60 ± 1ºC (140 ± 1.8ºF) for the asphalt cement specimens and 37.8 ± 1ºC (100 ± 1.8ºF) for tar specimens. Bring the specimens prepared with asphalt cutback to the specified temperature by placing them in the air bath for a minimum of two hours. Maintain the air bath temperature at 25 ± 1ºC (77 ± 1.8ºF). Thoroughly clean the guide rods and the inside surfaces of the test heads prior to making the test, and lubricate the guide rods so that the upper test head slides freely over them. The testing-head temperature shall be maintained between 21.1 to 37.8ºC

(70 to 100ºF) using a water bath when required. Remove the specimen from the water bath, oven, or air bath, and place in the lower segment of the breaking head. Place the upper segment of the breaking head on the specimen, and place the complete assembly in position on the testing machine. Place the flowmeter, where used, in position over one of the guide rods and adjust the flowmeter to zero while holding the sleeve firmly against the upper segment of the breaking head. Hold the flowmeter sleeve firmly against the upper segment of the breaking head while the test load is being applied.

4.2. Apply the load to the specimen by means of the constant rate of movement of the loadjack or testing-machine head of 50.8 mm (2 in.) per minute until the maximum load is reached and the load decreases as indicated by the dial. Record the maximum load noted on the testing machine or converted from the maximum micrometer dial reading. Release the flowmeter sleeve or note the micrometer dial reading, where used, the instant the maximum load begins to decrease. Note and record the indicated flow value or equivalent units in twenty-five hundredths of a millimeter (hundredths of an inch) if a micrometer dial is used to measure the flow. The elapsed time for the test from removal of the test specimen from the water bath to the maximum load determination shall not exceed 30 seconds.

Note 7—For core specimens, correct the load when thickness is other than 63.5 mm ($2^1/_2$ in.) by using the proper multiplying factor from Table 2.

---

5. REPORT

5.1. *The report shall include the following information*:

5.1.1. Type of sample tested (laboratory sample or pavement core specimen);

Note 8—For core specimens, the height of each test specimen in millimeters (or inches) shall be reported.

5.1.2. Average maximum load in pounds-force (or newtons) of at least three specimens, corrected when required;

5.1.3. Average flow value, in hundredths of an inch, twenty-five hundredths of a millimeter, of three specimens; and

5.1.4. Test temperature.

Table 2—Stability Correlation Ratios[a,b]

Volume of Specimen, cm^3	Approximate Thickness of Specimen, in.	mm	Correlation Ratio
200 to 213	1	25.4	5.56
214 to 225	$1^{1}/_{16}$	27.0	5.00
226 to 237	$1^{1}/_{8}$	28.6	4.55
238 to 250	$1^{3}/_{16}$	30.2	4.17
251 to 264	$1^{1}/_{4}$	31.8	3.85
265 to 276	$1^{5}/_{16}$	33.3	3.57
277 to 289	$1^{3}/_{8}$	34.9	3.33
290 to 301	$1^{7}/_{16}$	36.5	3.03
302 to 316	$1^{1}/_{2}$	38.1	2.78
317 to 328	$1^{9}/_{16}$	39.7	2.50
329 to 340	$1^{5}/_{8}$	41.3	2.27
341 to 353	$1^{11}/_{16}$	42.9	2.08
354 to 367	$1^{3}/_{4}$	44.4	1.92
368 to 379	$1^{13}/_{16}$	46.0	1.79
380 to 392	$1^{7}/_{8}$	47.6	1.67
393 to 405	$1^{15}/_{16}$	49.2	1.56
406 to 420	2	50.8	1.47
421 to 431	$2^{1}/_{16}$	52.4	1.39
432 to 443	$2^{1}/_{8}$	54.0	1.32
444 to 456	$2^{3}/_{16}$	55.6	1.25
457 to 470	$2^{1}/_{4}$	57.2	1.19
471 to 482	$2^{5}/_{16}$	58.7	1.14
483 to 495	$2^{3}/_{8}$	60.3	1.09
496 to 508	$2^{7}/_{16}$	61.9	1.04
509 to 522	$2^{1}/_{2}$	63.5	1.00
523 to 535	$2^{9}/_{16}$	65.1	0.96
536 to 546	$2^{5}/_{8}$	66.7	0.93
547 to 559	$2^{11}/_{16}$	68.3	0.89
560 to 573	$2^{3}/_{4}$	69.9	0.86
574 to 585	$2^{13}/_{16}$	71.4	0.83
586 to 598	$2^{7}/_{8}$	73.0	0.81
599 to 610	$2^{15}/_{16}$	74.6	0.78
611 to 625	3	76.2	0.76

[a] The measured stability of a specimen multiplied by the ratio for the thickness of the specimen equals the corrected stability for a 63.5 mm ($2^{1}/_{2}$-in.) specimen.

[b] Volume-thickness relationship is based on a specimen diameter of 101.6 mm (4 in.).

---

[1] Detailed requirements for these sieves are given in M 92, Wire-Cloth Sieves for Testing Purposes.

Standard Method of Test for

Resistance to Deformation and Cohesion of Hot Mix Asphalt (HMA) by Means of Hveem Apparatus

AASHTO Designation: T 246-10[1]
ASTM Designation: D 1560-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance to Deformation and Cohesion of Hot Mix Asphalt (HMA) by Means of Hveem Apparatus

AASHTO Designation: T 246-10[1]
ASTM Designation: D 1560-09

1. SCOPE

1.1. These methods cover the determination of (1) the resistance to deformation of compacted HMA mixtures by measuring the lateral pressure developed from applying a vertical load by means of the Hveem stabilometer; and (2) the cohesion of compacted bituminous mixtures by measuring the forces required to break or bend the sample as a cantilever beam by means of the Hveem cohesiometer.[2]

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 247, Preparation of Test Specimens of Hot Mix Asphalt (HMA) by Means of California Kneading Compactor
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

RESISTANCE TO DEFORMATION

3. APPARATUS

3.1. *Stabilometer*—The Hveem stabilometer (Figures 1 and 2) is a triaxial testing device consisting essentially of a rubber sleeve within a metal cylinder containing a liquid which registers the horizontal pressure developed by a compacted test specimen as a vertical load is applied.

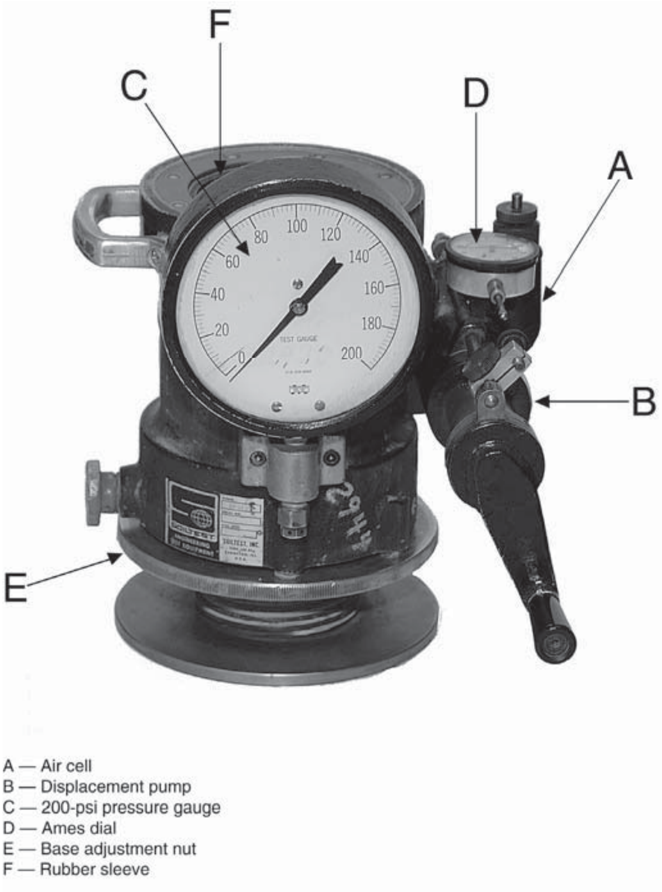

Figure 1—Hveem Stabilometer

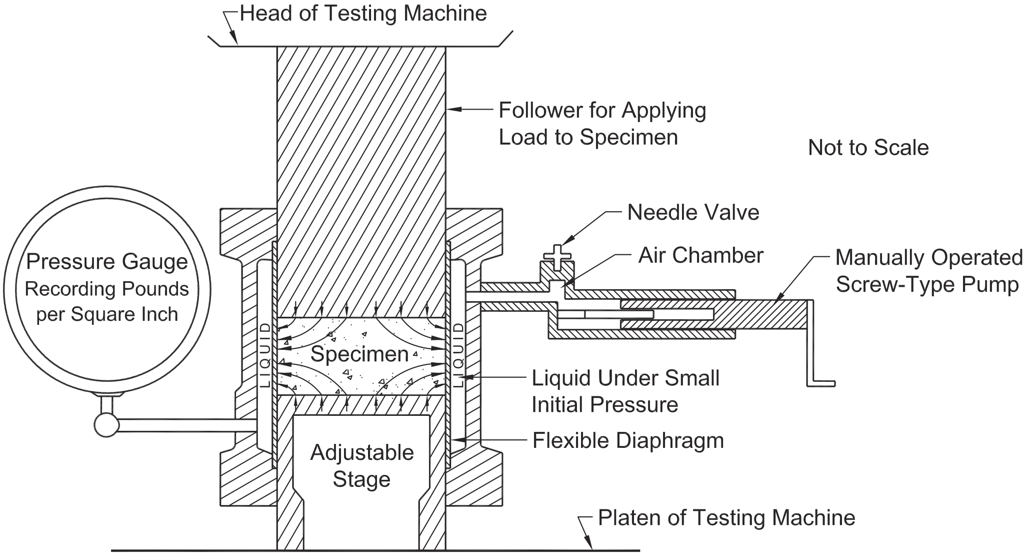

Notes: 1. The specimen is given lateral support by the flexible sidewall, which transmits horizontal pressure to the liquid.
2. The magnitude of the pressure can be read on the gauge.

Figure 2—Diagrammatic Sketch of the Hveem Stabilometer (Not to Scale)

3.2. *Testing Machine*—A compression testing machine having a minimum capacity of 44.5 kN (10 000 lbf). Figure 3 shows the assembly of the stabilometer in a testing machine. The 222-kN (50 000-lbf) capacity compression testing machine specified in T 247 is normally used to perform the stabilometer test.

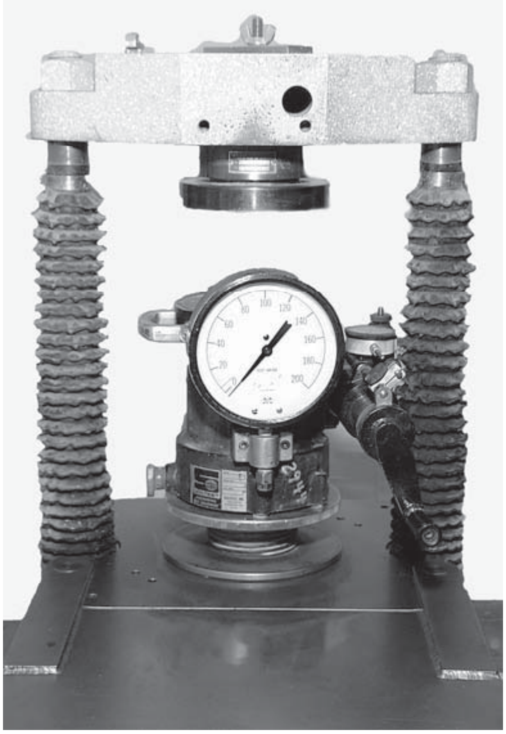

Figure 3—Hveem Stabilometer Mounted in the Testing Machine

3.3. *Test Specimen Push-Out Device*—A lever device, attached to the press, to push the specimen out of the mold. (See Figure 4.) Other acceptable apparatus may be used.

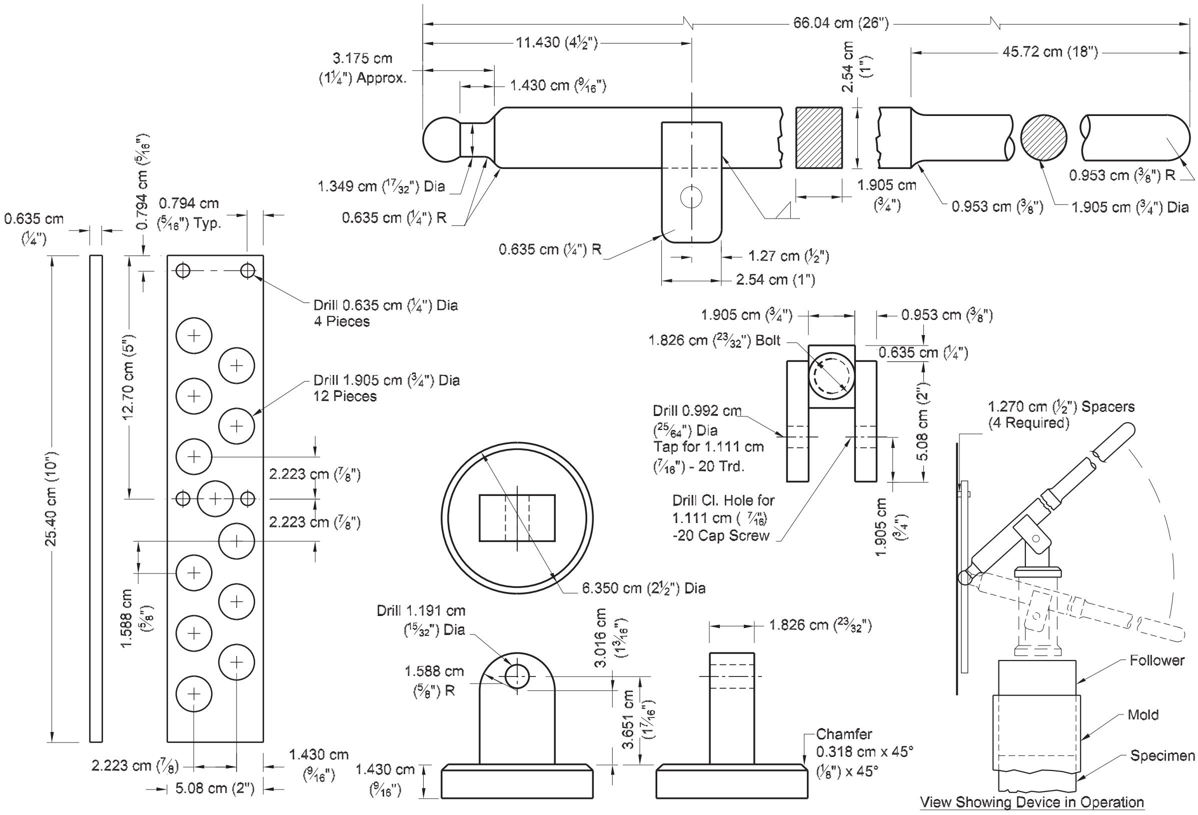

Figure 4—Detailed Drawings of the Test Specimen Push-Out Device

3.4. *Oven*—An oven capable of maintaining a temperature of 60 ± 3ºC (140 ± 5ºF).

3.5. *Calibration Cylinder*—A hollow metal cylinder, 101.6 ± 0.13 mm (4 ± 0.005 in.) in outside diameter by 140 ± 25 mm ($5^1/_2$ ± 1 in.) high (for calibration purposes).

3.6. *Rubber Bulb*—for introducing air into the stabilometer.

3.7. *Follower*—One solid wall metal follower, 101.2 mm (3.985 in.) in diameter by 140 mm ($5^1/_2$ in.) high (see Figures 5 and 6).

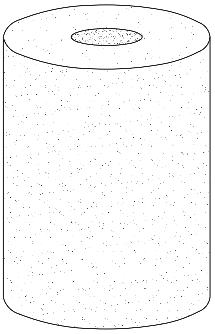

Figure 5—Specimen Follower

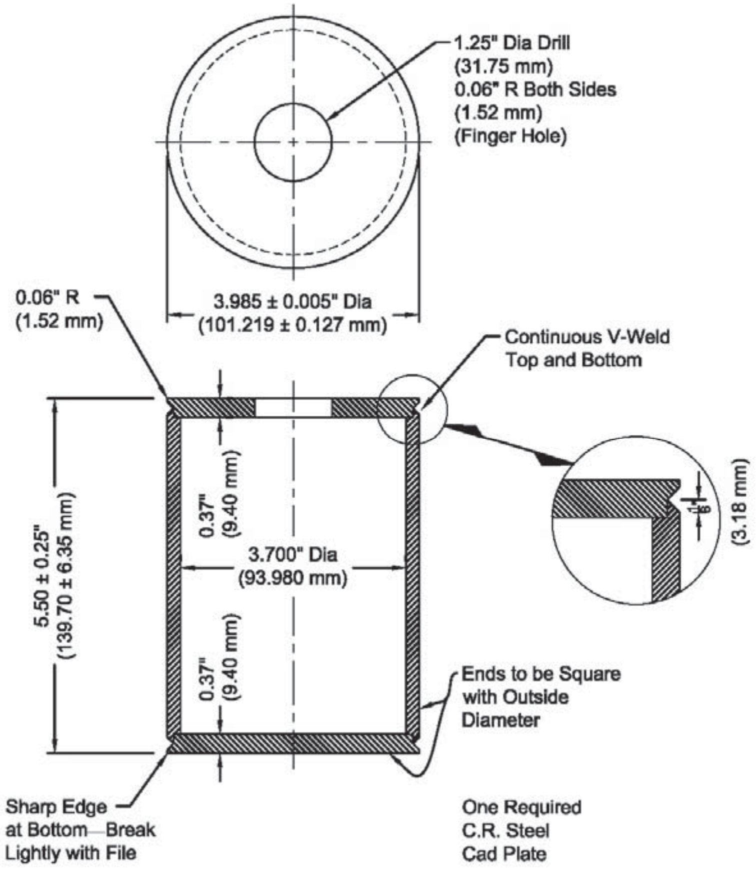

Figure 6—Detail Drawing of the Specimen Follower

---

4. TEST SPECIMENS

4.1. *Size of Specimens*—Test specimens shall be 102 mm (4 in.) in diameter. The height of the test specimens should be 64 ± 3 mm (2.5 ± 0.1 in.). However, if this height cannot be obtained, the stabilometer value shall be corrected as indicated by Figure 9.

4.2. *Compaction of Specimens*—Test specimens shall be formed and compacted in accordance with T 247; or compacted into a 4-in. diameter mold using a Superpave gyratory compactor, gyratory shear compactor, or other types of compactors.

Note 1—Specimens compacted by different means may not have similar stabilometer or cohesiometer values.

5. ADJUSTMENT OF STABILOMETER

5.1. Adjust the stabilometer base so that the distance from the bottom of the upper tapered ring (Figure 1) to the top of the base is 89 mm (3.5 in.).

5.2. Adjust the amount of air in the air cell so that when the liquid pressure is increased from 34.5 to 689 kPa (5 to 100 psi) by turning the pump handle at the approximate rate of two turns per second, the turns indicator will indicate 2.00 ± 0.05 turns with the metal calibration cylinder in the stabilometer chamber.

5.3. With the stabilometer and stage base in position on the platen, adjust the testing machine so that the load will be applied at the rate of 1.3 mm (0.05 in.)/min.

6. PROCEDURE

6.1. Bring the specimen to a temperature of 60 ± 3ºC (140 ± 5ºF).

Note 2—Bring the specimen to room temperature in the case where it is desired to test with whatever moisture may be present in the mixture.

6.2. Transfer the compacted specimen from the mold to the stabilometer by means of the push-out device described in Section 2.3. Make sure that the specimen goes into the stabilometer straight, with the tamped end up, and that it is firmly seated level on the base. Place the 140-mm ($5^1/_2$-in.) follower on top of the specimen and turn the displacement pump until a horizontal pressure of exactly 34.5 kPa (5 psi) is recorded on the stabilometer gauge. If the testing machine has a spherically seated type of upper head, the locking shims used during the fabrication of the test specimen must be removed prior to performing the stabilometer test. Start the vertical movement of the press (speed of 1.3 mm (0.05 in.)/min) and record the stabilometer gauge readings when the vertical load is 2.23, 4.45, 8.90, 13.4, 17.8, 22.3, and 26.7 kN (500, 1000, 2000, 3000, 4000, 5000, and 6000 lbf). Stop the vertical movement of the press when the total load reaches 26.7 kN (6000 lbf). Immediately reduce the vertical load to 4.45 kN (1000 lbf) and then adjust the horizontal pressure to 34.5 kPa (5 psi). This will result in a further reduction of the vertical load in less than 4.45 kN (1000 lbf). This is normal and no compensation need be made. Measure the number of turns of the pump handle required to raise the horizontal pressure from 34.5 to 689 kPa (5 to 100 psi) with the specimen in place. Turn the pump handle at approximately two turns per second when applying this pressure. The number of turns measured is the displacement reading, *D*. In measuring the displacement, the vertical load will increase and at times exceed 4.45 kN (1000 lbf). As before, these changes in load are characteristic and no adjustment or compensation is required.

7. CALCULATIONS

7.1. Determine the stabilometer value of the specimen as follows:

$$S = \frac{22.2}{\left[P_h \bullet D / \left(P_v - P_h\right)\right] + 0.222} \quad (1)$$

where:

S = stabilometer value;

P_h = horizontal pressure, for corresponding P_v in kPa (or psi);

D = displacement on specimen; and

P_v = vertical pressure (typically 2800 kPa (400 psi)).

8. REPORT

8.1. The report shall include the following:

8.1.1. Stabilometer value,

8.1.2. Test temperature, and

8.1.3. Bitumen content.

COHESION

Note 3—Cohesion testing is optional and is not required to determine Hveem Stability.

9. APPARATUS

9.1. *Cohesiometer*—A Hveem cohesiometer, as shown in Figures 7 and 8.[3]

9.2. *Steel Shot*—2000 g of steel shot, size No. 10, all passing a 2-mm (No. 10) sieve and retained on a 1.4-mm (No. 14) sieve.

9.3. *Oven*—An oven capable of maintaining a temperature of 60 ± 1ºC (140 ± 2ºF).[3]

9.4. *Balance*—A balance having a capacity of 5 kg and sensitive to 1 g or less.

Note 3—Other materials may be used, provided a rate of loading is achieved which is equivalent to that obtained when using steel shot.

10. TEST SPECIMENS

10.1. *Preparation of Specimen*—The test specimen will normally be the compacted specimen used after completion of the stabilometer test. If the sample is taken from a compressed pavement slab by means other than coring, it should be cut to size with a suitable saw.

10.2. *Size of Specimens*—The cohesiometer is designed to test specimens up to 127 mm (5 in.) in width and from 25 mm (1 in.) to 76 mm (3 in.) high.

11. PROCEDURE

11.1. Place the specimen to be tested in the oven and allow to stand until the temperature is 60 ± 1ºC (140 ± 2ºF) throughout (this normally will require a minimum of 2 h).

11.2. Preheat the cohesiometer to 60 ± 1ºC (140 ± 2ºF). Clamp the test specimen firmly in the cohesiometer, being certain that it is well centered with the top plates parallel with the surface of the specimen. Tighten the clamp nuts until snug using the fingers only. Delay starting the test until the temperature within the cohesiometer cabinet returns to 60 ± 1ºC (140 ± 2ºF). Allow the shot to flow into the receiver at the end of the lever arm at a rate of flow of 1800 ± 20 g/min. Stop the flow of shot when the specimen breaks or when the lever arm deflects 13 mm ($^1/_2$ in.) from the horizontal, if that occurs before the specimen breaks. Determine and record the mass of shot to the nearest gram.

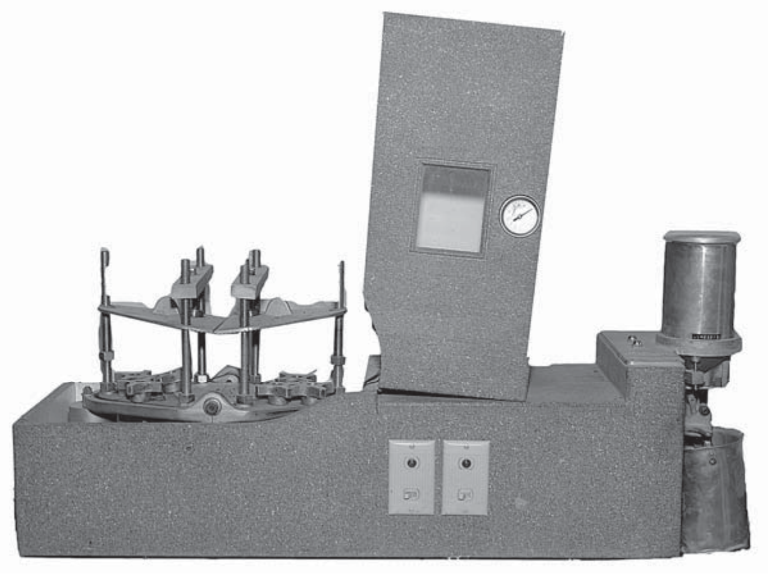

Figure 7—Hveem Cohesiometer

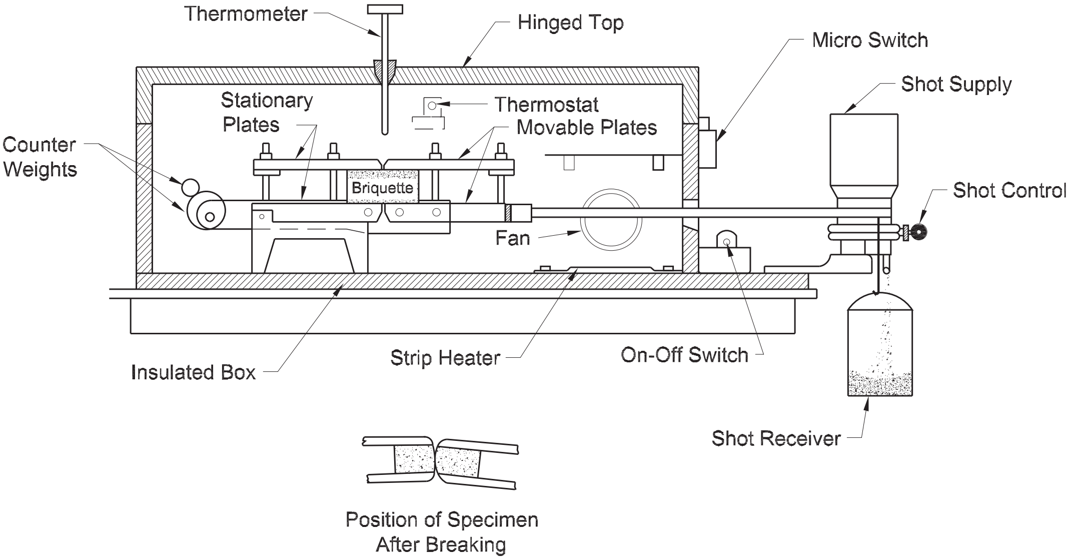

Figure 8—Detailed Drawing of the Hveem Cohesiometer

Chart for Correcting Stabilometer Values
to Specimen Height of 2.50" (64 mm)

Height Correction should be made using
the Table and Chart below.

Example: Overall Height of 2.74" (69 mm)
Select Correction Curve "B"
Stabilometer Value Uncorrected = 35
Stabilometer Value Corrected = 38

Overall Specimen Ht	Correction Curve
2.80" to 3.00" (71 mm to 76 mm)	A
2.60" to 2.79" (66 mm to 70 mm)	B
2.40" to 2.59" (61 mm to 65 mm)	C
2.20" to 2.39" (56 mm to 60 mm)	D
2.00" to 2.19" (51 mm to 55 mm)	E

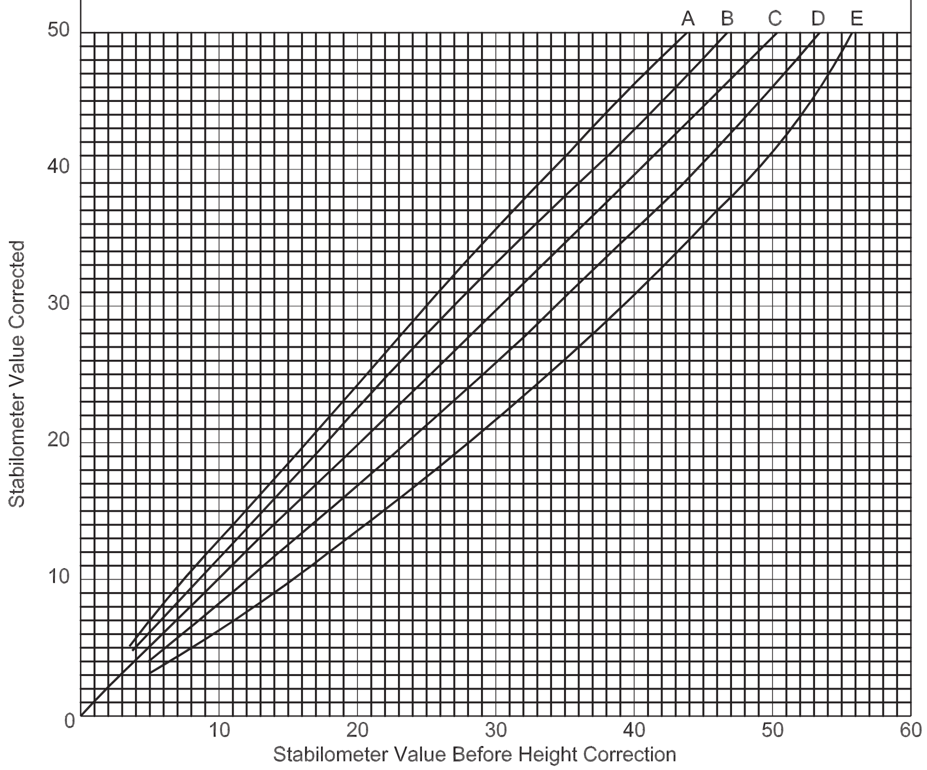

Figure 9—Chart for Correcting Stabilometer Values to Specimen Height of 2.5 in. (64 mm)

12. CALCULATIONS

12.1. Calculate the cohesiometer values as follows:

U.S. Customary Units:

$$C = L/W\left(0.20H + 0.044H^2\right) \qquad (2)$$

Metric Units:

$$C = L/W\left(0.0310H + 0.00269H^2\right) \tag{3}$$

where:

C = cohesiometer value, g/25 mm (1 in.) of width corrected to 76 mm (3 in.) height;
L = weight of shot, g;
W = diameter, or width of specimen, cm (or in.); and
H = height of specimen, cm (or in.).

13. REPORT

13.1. The report shall include the following:

13.1.1. Cohesiometer value,

13.1.2. Test temperature, and

13.1.3. Bitumen content.

---

[1] Except for the allowable tolerances of the calibration cylinder in Section 2.5, this method is the same as ASTM D 1560-09.

[2] A more detailed description of the procedures for performing the tests is available on request from the California Division of Highways, Transportation Laboratory, 5900 Folsom Blvd., Sacramento, CA 95819. Also available is a procedure containing details regarding the operation and calibration of the stabilometer and the replacement of the stabilometer diaphragm.

[3] Detailed working drawings of the apparatus illustrated in Figure 8 are available at nominal cost from the American Society for Testing and Materials, 100 Barr Harbor Dr., West Conshohocken, PA 19428-2959. Request Adjunct No. 12-415600-10.

Standard Method of Test for

Preparation of Test Specimens of Hot Mix Asphalt (HMA) by Means of California Kneading Compactor

AASHTO Designation: T 247-10
ASTM Designation: D 1561-92

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Preparation of Test Specimens of Hot Mix Asphalt (HMA) by Means of California Kneading Compactor

AASHTO Designation: T 247-10
ASTM Designation: D 1561-92

1. SCOPE

1.1. The method covers the compaction of test specimens of hot mix asphalt (HMA) by means of a mechanical compactor that imparts a kneading action to the test specimens by a series of individual impressions made with a ram.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 30, Mixture Conditioning of Hot Mix Asphalt (HMA)
- T 246, Resistance to Deformation and Cohesion of Hot Mix Asphalt (HMA) by Means of Hveem Apparatus
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer

3. APPARATUS

3.1. *California Kneading Compactor*—Mechanical kneading compactor, as shown in Figure 1,[1] for consolidating test specimens.

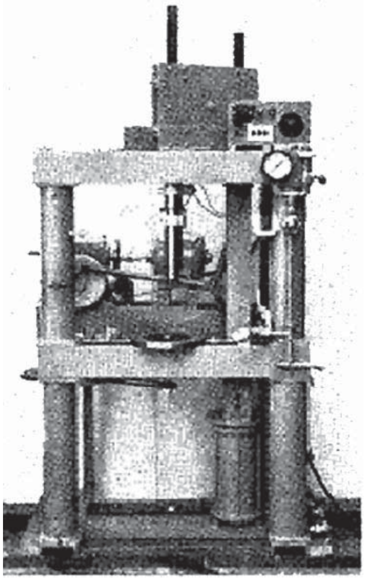

Figure 1—California Kneading Compactor

Note 1—Kneading compactors, which on standardization develop a trace curve similar to that of the California kneading compactor, shall be considered acceptable under this test method. Optionally, any kneading compactor capable of fabricating specimens that will provide stabilometer values equivalent to those obtained from the California kneading compactor shall be acceptable for use under this test method. The supplier has the responsibility of furnishing those substantiating data for his device.

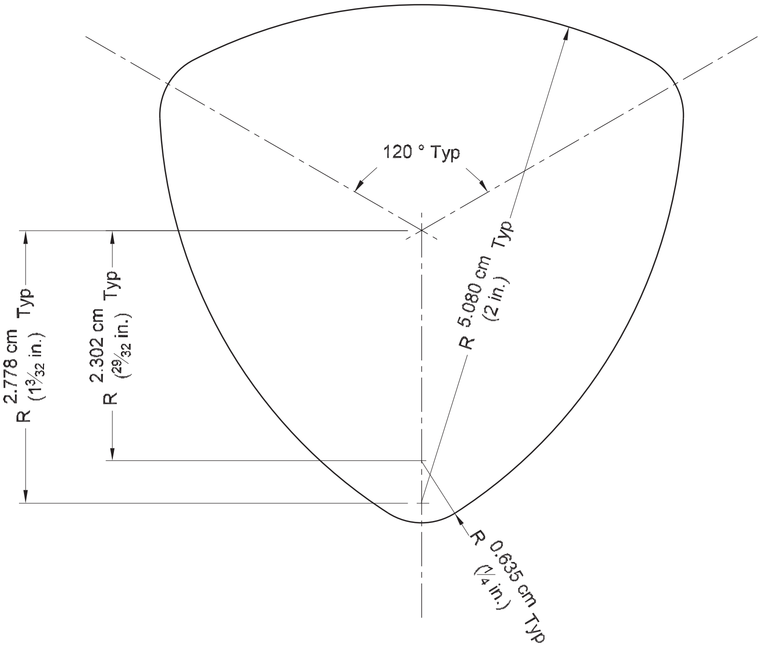
Note 2—Curves are considered within standardization when they show the same peak pressure and dwell time in load time trace obtained in the calibration procedure.

Note 3—This compactor shall be considered in standardization when the peak momentary load applied to a test specimen is held within 5 percent of the intended foot pressure (within the range from 2.4 to 3.4 MPa (350 to 500 psi)).

Note 4—The stabilometer values from replicate specimens fabricated by T 247 and tested in accordance with T 246 shall fall within a range of three units for all dense-graded HMA mixtures containing aggregates not larger than 12.5 mm ($^1/_2$ in.) and within a range of four units for coarser-graded HMA mixtures containing up to 25.0-mm (1-in.) maximum-sized aggregates.

3.2. *Compactor Foot*—A ram having a face shaped as shown in Figure 2, and having an area of approximately 20.059 cm^2 (3.1 in.^{2}).

3.3. *Mold Holder, Funnel, and Feeder Trough*, as shown in Figure 3.



Dimensional Limits, cm (in.)

	Min	Max
Distance Across Foot 3 Measurements 120° Apart	5.189 (2.042)	5.289 (2.082)

Figure 2—Face of Compactor Ram

Figure 3—Funnel, Feeder Trough, and Mold Assembly of the California Kneading Compactor

3.4. *Molds*—Molding cylinders for 101.60 ± 0.13 mm (4.000 ± 0.005 in.) in inside diameter by 127 mm (5 in.) in height. A minimum of three such compaction molds is recommended.

3.5. *Rod*—Round-nose steel rod, 9.5 mm ($^3/_8$ in.) in diameter by 406 mm (16 in.) long.

3.6. *Paper Disks*—Heavy paper disks, 102 mm (4 in.) in diameter.

3.7. *Shim*—Steel shim, 6.4 mm ($^1/_4$ in.) thick, 19 mm ($^3/_4$ in.) wide, and 64 mm ($2^1/_2$ in.) long.

3.8. *Metal Followers*—Two metal followers, 101.2 ± 0.11 mm (3.985 ± 0.005 in.) in diameter; one 140 mm (5.5 in.) high, the other 38.1 mm (1.5 in.) high.

3.9. *Testing Machine*—A compression testing machine having a minimum capacity of 222 kN (50 000 lbf).

3.10. *Ovens*—Electric ovens capable of maintaining temperatures of 60 ± 3ºC (140 ± 5ºF) and 110 ± 3ºC (230 ± 5ºF).

3.11. *Balance*—A balance having a capacity of 5 kg or more and sensitive to 1.0 g or less for determining the mass of the mixture.

3.12. *Measuring Device*—A device for measuring the height of the specimen to the nearest 0.3 mm (0.01 in.).

3.13. *Sample Mixing Apparatus*—Suitable equipment is required for mixing the aggregate and the asphalt binder. Hand mixing is permissible but mechanical mixing is recommended.[2]

3.14. *Sample Splitter*—Riffle-type.

3.15. *Miscellaneous Apparatus*—Thermometers, trowels, spatulas, scoops, gloves, and metal pans.

Note 5—**Caution:** rough interior of molds can cause a difference in test results.

4. TEST SPECIMENS

4.1. *Selection of Binder Content for Specimens*—Determine the theoretical or estimated optimum amount of bitumen for the aggregate (Note 6). On normal materials, conduct laboratory tests for a minimum of three binder contents, one above, one below, and one at the theoretical or estimated optimum content. The incremental change of binder content should be 0.5 percent. For extremely critical mixes, lower the incremental change of binder content to 0.3 percent, and increase the number of tests to a minimum of five. Conversely, for highly absorptive aggregates, increase the incremental change of binder content to 1.0 percent, and reduce the number of tests to three. Express the percentage of the binder as a percentage of the dry weight of the aggregate.

Note 6—The optimum amount of binder for the aggregate may be determined by the method commonly employed by the laboratory. A method that has been found suitable is the centrifuge kerosene equivalent method.

4.2. *Preparation of Aggregates*—Obtain a sieve analysis and specific gravity determination on the fine and coarse aggregate (aggregate shall be separated by means of a 4.75-mm (No. 4) sieve). Separate the aggregate into the various size fractions necessary for accurately recombining into test mixtures conforming to specified grading requirements.

4.3. *Preparation of Mixtures*—Combine the moisture-free aggregates into batches weighing 1200 g. (Every effort should be made to fabricate test specimens 64 ± 3 mm (2.5 ± 0.1 in.) in height.) The mixing temperature range is defined as the range of temperatures where the unaged binder has a viscosity of 0.17 ± 0.02 Pa·s when measured in accordance with T 316. Charge the mixing bowl with the heated aggregate from one pan and dry-mix thoroughly. Form a crater in the dry-blended aggregate, and weigh the required amount of binder into the mix. Immediately initiate mixing. Mix the aggregate and binder as quickly and thoroughly as possible to yield HMA having a uniform distribution of binder. As an option, mechanical mixing may be used.

Note 7—Modified binders may not adhere to the equiviscosity requirements noted, and the manufacturer's recommendations should be used to determine mixing and compaction temperatures.

5. PROCEDURE

5.1. *Temperatures*—After completing the mixture preparation, perform the required mixture conditioning in accordance with R 30.

5.2. *Molding Specimens*—The mixture and molds shall be brought to compaction temperature prior to molding operations. Place the compaction mold in position in the mold holder, and insert a paper disk, 102 mm (4 in.) in diameter, to cover the base plate of the mold holder. Place a steel shim under the edge of the mold temporarily in order for the base plate of the mold holder to act as a free-fitting plunger during the compaction operation. Weigh out the required amount of HMA mixture for one specimen at the specified temperature and place it in the insulated feeder trough, which shall have been preheated to the approximate compaction temperature for the HMA mixture. Spread the HMA mixture uniformly on the feeder trough to ensure uniformity when transferring it to the mold. By means of a paddle of suitable dimensions to fit the cross-section of the trough, push one half of the mixture into the mold. Preheat the round-nose rod. Rod the one-half portion of the HMA mixture 20 times in the center of mass and 20 times around the edge by means of the round-nose rod. Transfer the remainder of the sample to the mold and repeat the rodding procedure. Place the mold and assembly into position on the California kneading compactor. By means of the variable transformer controlling the heater, maintain the compactor foot sufficiently hot to prevent the HMA mixture from adhering to it. Apply approximately 20 tamping blows at a pressure of 1.7 MPa (250 psi). The number of tamping blows will vary, depending upon the type of the HMA mixture, the purpose being to form the HMA mixture into a semi-compacted condition so that it will not be unduly disturbed by the full pressure of 3.4 MPa (500 psi). After semi-compaction has been accomplished, remove the shim and release the mold-tightening screw sufficiently to permit free "up and down" movement of the mold. Increase the compactor foot pressure to 3.4 MPa (500 psi), and apply 150 tamping blows to complete compaction.

Note 8—When testing referee samples for the purpose of qualifying a compactor, use only material for the test specimens that will compact under the maximum foot pressure prescribed in Section 4.2 without visible movement, distortion, or penetration of the compactor foot.

Note 9—In some instances where sandy or unstable material is involved, it may not be possible to accomplish the compaction in the kneading compactor because of undue movement of the mixture under the compactor foot. In these instances, use a 178-kN (40,000 lbf) static load (for a 102-mm (4-in.) diameter specimen) applied by the double plunger method in which a free-fitting plunger is placed on both the bottom and top of the test specimen. Apply the load at the rate of 1.3 mm (0.05 in.)/min, and hold for 30 ± 5 s.

5.3. *Application of Static Load*—After compaction in the California kneading compactor, place the mold and the specimen in an oven at 60ºC (140ºF) for 1.5 h prior to applying the static "leveling off" load:

5.4. The "leveling off" load shall consist of the application of a static load of 6.9 MPa (1000 psi) in a compression testing machine. Apply the load by the double plunger method in which metal followers are employed as free-fitting plungers on the top and bottom of the specimen. After releasing the “leveling off” load, measure the height of the specimen to the nearest 0.25 mm (0.01 in.); record the measurement, and return the specimen in the mold to the 60ºC (140ºF) oven in order to retain temperature for testing. Complete testing of the specimens according to T 246 within 3 h of returning the specimens to the oven.

Note 10—A push-out device for removing the specimen is described in T 246. The temperature of the specimen and the method of transfer from the mold to the stabilometer are given in Section 5.2 of T 246.

6. REPORT

6.1. *The report shall include the following*:

6.1.1. Height of the specimen, and

6.1.2. Temperature of compaction in the California kneading compactor.

Standard Method of Test for

Percent Air Voids in Compacted Dense and Open Asphalt Mixtures

---

AASHTO Designation: T 269-97 (2007)[1]
ASTM Designation: D 3203-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Percent Air Voids in Compacted Dense and Open Asphalt Mixtures

AASHTO Designation: T 269-97 (2007)[1]
ASTM Designation: D 3203-05

1. SCOPE

1.1. This method covers determination of the percent air voids in compacted dense and open asphalt mixtures.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 275, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Paraffin-Coated Specimens
- T 331, Bulk Specific Gravity and Density of Compacted Hot Mix Asphalt (HMA) Using Automatic Vacuum Sealing Method

2.2. *ASTM Standards*:

- D 3549, Standard Test Method for Thickness or Height of Compacted Bituminous Paving Mixture Specimens
- D 4460, Standard Practice for Calculating Precision Limits Where Values are Calculated from Other Test Methods
- E 1547, Standard Terminology Relating to Industrial and Specialty Chemicals

3. TERMINOLOGY

3.1. The terms *specific gravity* and *density* used in this test method are in accordance with ASTM E 1547.

3.2. *Definitions*:

3.2.1. *air voids*—the pockets of air between the asphalt-coated aggregate particles in a compacted asphalt mixture.

3.2.2. *dense asphalt mixture*—asphalt mixtures in which the air voids are less than 10 percent when compacted.

3.2.3. *open asphalt mixture*—asphalt mixtures in which the air voids are 10 percent or more when compacted.

3.2.3.1. For borderline cases, an asphalt mixture shall be designated an open asphalt mixture if the calculated percent air voids, based on either Section 6.1 or 6.2, is 10 percent or more.

4. SIGNIFICANCE AND USE

4.1. The percent air voids in an asphalt mixture is used as one of the criteria in the design methods and for evaluation of the compaction achieved on asphalt paving projects.

5. SAMPLING

5.1. Samples for testing shall consist of specimens from laboratory-molded mixtures or cores from field-compacted mixtures.

6. PROCEDURE

6.1. For dense asphalt mixtures, determine the bulk specific gravity of the compacted mixture either by T 166, T 275 or T 331. Determine the theoretical maximum specific gravity in accordance with T 209 on a comparable asphalt mixture to avoid the influence of differences in gradation, asphalt content, etc.

6.2. For open asphalt mixtures, determine the density of a regularly shaped specimen of compacted mixture from its dry mass (in grams) and its volume (in cubic centimeters). Obtain the height of the specimen by ASTM D 3549. Measure the diameter of the specimen at four locations, and average the measurements. Calculate the volume of the specimen based on the average height and diameter measurement. Convert the density to bulk specific gravity by dividing by 0.99707 g/cm^3 or 997 kg/m^3, the density of water at 25ºC (77ºF). Determine the theoretical maximum specific gravity in accordance with T 209 on a comparable asphalt mixture to avoid the influence of differences in gradation, asphalt content, etc.

For reference purposes, determine both the bulk specific gravity and the theoretical maximum specific gravity on portions of the same sample of compacted asphalt mixture.

7. CALCULATIONS

7.1. Calculate the percent air voids in a compacted asphalt mixture as follows:

$$\text{Percent Air Voids} = 100(1 - A/B) \qquad (1)$$

where:

A = the bulk specific gravity, and

B = the theoretical maximum specific gravity.

7.2. Report the percent air voids to one decimal place.

8. PRECISION AND BIAS

8.1. The precision of this test method depends on the precision of test methods for bulk specific gravity and theoretical maximum specific gravity. It is computed by a procedure described in ASTM D 4460. Since the computation for percent air voids in Section 7.1 involves the quotient of bulk specific gravity divided by the theoretical maximum specific gravity, the quotient formula is used:

$$\sigma_{x/y} = \sqrt{\frac{\overline{y}^2\ \sigma_x^2 + \overline{x}^2\ \sigma_y^2}{\overline{y}^4}} \qquad (2)$$

where:

$\sigma_{x/y}$ = the standard deviation for determining the precision limits of test results for a standard based on the quotient of two test results from two other standards,

$\overline{x}$ = the mean (average) value of the x standard (bulk specific gravity) test results,

$\overline{y}$ = the mean (average) value of the y standard (theoretical maximum specific gravity) test results,

σ_x = the standard deviation from the precision statement of the x standard, and

σ_y = the standard deviation from the precision statement of the y standard.

Note 1—The x standard (T 166, T 275, or T 331) is used to compute bulk specific gravity, and the y standard (T 209) is used to compute theoretical maximum specific gravity.

8.2. Criteria for judging the acceptability of percent air voids test results that are obtained by using T 275 and T 209 for nonporous aggregates are:

Test and Type Index	Standard Deviation	Acceptable Range of Two Results
Single-Operator Precision	0.32	0.91
Multilaboratory Precision	—	—

8.3. Criteria for judging the acceptability of percent air voids test results that are obtained by using T 166 and T 209 for nonporous aggregates are:

Test and Type Index	Standard Deviation	Acceptable Range of Two Results
Single-Operator Precision	0.51	1.44
Multilaboratory Precision	1.09	3.08

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE CALCULATION OF PRECISION

X1.1. *Assume the following precision data*:

Bulk Specific Gravity, x
When the average x = 2.423 and the standard deviation of x = 0.007.

Theoretical Maximum Specific Gravity, *y*
When the average $y = 2.523$ and the standard deviation of $y = 0.004$.

Then using Equation 2:

$$\sigma_{x/y} = \sqrt{\frac{(2.523)^2 (0.007)^2 + (2.423)^2 (0.004)^2}{(2.523)^4}} = 0.00316 \qquad (X1.1)$$

This value is in terms of air voids; therefore, the value should be multiplied by 100 to convert it into a percentage. Therefore:

$$\sigma_{x/y} = 0.0032(100) = 0.32\% \qquad (X1.2)$$

---

[1] Similar, but not technically identical to ASTM D 3203-05.

Standard Method of Test for

Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Paraffin-Coated Specimens

AASHTO Designation: T 275-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Paraffin-Coated Specimens

AASHTO Designation: T 275-07

1. SCOPE

1.1. This method of test covers the determination of bulk specific gravity of specimens of compacted hot mix asphalt (HMA).

1.2. *Definition*:

1.2.1. *Bulk Specific Gravity (of solids)*—the ratio of the mass in air of a unit volume of a permeable material (including both permeable and impermeable voids normal to the material) at a stated temperature to the mass in air of equal density of an equal volume of gas-free distilled water at a stated temperature. The form of the expression shall be:

Bulk specific gravity at x, y°C

where:

x = temperature of the material, and

y = temperature of the water.

1.3. This method should be used with samples that contain open or interconnecting voids or absorb more than 2.0 percent of water by volume, as determined by T 166.

1.4. The bulk specific gravity of the compacted HMA may be used in calculating the unit mass of the mixture.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt Using Saturated Surface-Dry Specimens

3. TEST SPECIMENS

3.1. Test specimens may be either laboratory-compacted HMA or sampled from HMA pavements. The mixtures may be surface or wearing course, binder or leveling course, or hot mix base.

3.2. *Size of Specimens*—It is recommended that: (1) the diameter of cylindrically compacted or cored specimens, or the length of the sides of sawed specimens, be at least equal to four times the maximum size of the aggregate; and (2) the thickness of specimens be at least one and one-half times the maximum size of the aggregate.

3.3. Specimens shall be taken from pavements with a core drill, diamond or carborundum saw, or by other suitable means.

3.4. Care shall be taken to avoid distortion, bending, or cracking of specimens during and after the removal from pavement or mold. Specimens shall be stored in a safe, cool place.

3.5. Specimens shall be free from foreign materials such as seal coat, tack coat, foundation material, soil, paper, or foil.

3.6. If desired, specimens may be separated from other pavement layers by sawing or other suitable means.

METHOD A

4. APPARATUS

4.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231. The balance shall be equipped with a suitable suspension apparatus and holder to permit weighing the specimen while suspended from the center of the scale pan of the balance.

4.2. *Suspension Apparatus*—The wire suspending the container shall be the smallest practical size to minimize any possible effects of a variable immersed length. The suspension apparatus shall be constructed to enable the container to be immersed to a depth sufficient to cover it and the test sample during weighing.

4.3. *Water Bath*—For immersing the specimen in water while suspended under the balance, equipped with an overflow outlet for maintaining a constant water level, and thermostatically controlled so as to maintain the bath at 25 ± 0.5ºC (77 ± 0.9ºF).

5. PROCEDURE

5.1. *Mass of Uncoated Specimens*—Weigh the specimen after it has been dried to a constant mass. Designate this mass as *A*. Constant mass shall be defined as the mass at which further drying at 52 ± 3ºC (125 ± 5ºF) does not alter the mass by 0.05 percent. The sample shall initially be dried overnight at 52 ± 3ºC (125 ± 5ºF) and then weighed at 2-h drying intervals.

5.2. *Mass of Coated Specimen in Air*—Coat the test specimen on all surfaces with melted paraffin sufficiently thick to seal all surface voids. Allow the coating to cool in air at room temperature at 25 ± 5ºC (77 ± 9ºF) for at least 30 min and then weigh the specimen. Designate this mass as *D*.

Note 1—If it is desired to utilize the specimen for further tests that require the removal of the paraffin coating, the specimen may be dusted with powdered talc prior to coating.

Note 2—Application of the paraffin may be accomplished by chilling the specimen in a refrigerating unit to a temperature of approximately 4.5ºC (40ºF) for at least 30 min and then dipping the specimen in warm paraffin (5.5ºC (10ºF) above the melting point). It may be necessary to brush the surface of the paraffin with added hot paraffin in order to fill any pinpoint holes.

5.3. *Mass of Coated Specimen in Water*—Weigh the coated specimen in a water bath at 25 ± 1ºC (77 ± 1.8ºF). Designate this mass as *E*.

5.4. *Specific Gravity of Paraffin*—Determine the specific gravity of the paraffin at 25 ± 1ºC (77 ± 1.8ºF), if unknown, and designate this value as *F*.

6. CALCULATION

6.1. Calculate the bulk specific gravity of the specimen as follows: round and report the value to the nearest three decimal places.

$$\text{Bulk Specific Gravity} = \frac{A}{D - E - \left(\frac{D - A}{F}\right)} \qquad (1)$$

where:

A = mass of the dry specimen in air, g;

D = mass of the dry specimen plus paraffin coating in air, g;

E = mass of the dry specimen plus paraffin coating in water, g; and

F = specific gravity of the paraffin at 25 ± 1ºC (77 ± 1.8ºF).

METHOD B

7. APPARATUS

7.1. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

7.2. *Water Bath*—Thermostatically controlled, so as to maintain the bath at 25 ± 0.5ºC (77 ± 0.9ºF).

7.3. *Thermometer*—ASTM 17C (17F), having a range of 19 to 27ºC (66 to 80ºF), graduated in 0.1ºC (0.2ºF) subdivisions.

7.4. *Volumeter*[1]—Calibrated to 1200 mL or appropriate capacity depending on the size of the test sample. The volumeter shall have a tapered lid with a capillary bore.

8. PROCEDURE

8.1. Dry the specimen to a constant mass (See Section 5.1). Cool the specimen to room temperature at 25 ± 5ºC (77 ± 9ºF), and record the dry mass. Designate this mass as *C*.

8.2. Coat the specimen on all surfaces with melted paraffin until sufficiently thick to seal all surface voids. Allow the coating to cool in air at 25 ± 0.5ºC (77 ± 0.9ºF) for at least 30 min, and then weigh the specimen (Notes 1 and 2). Designate this mass as *C*.

8.3. Fill a calibrated volumeter with distilled water at 25 ± 1ºC (77 ± 1.8ºF), and weigh the volumeter. Designate this mass as *D*.

8.4. Place the coated specimen into the volumeter and cover the volumeter, making certain that some water escapes through the capillary bore in the tapered lid. Wipe the outside of the volumeter dry with a dry absorbent cloth and weigh the volumeter and its contents. Designate this mass as *E*.

8.5. Determine the specific gravity of the paraffin at 25 ± 1ºC (77 ± 1.8ºF), if unknown, and designate this value as *F*.

9. CALCULATIONS

9.1. Calculate the bulk specific gravity of the specimen as follows: round and report the value to the nearest three decimal places.

$$\text{Bulk Specific Gravity} = \frac{A}{D - \left[E - C + \left(\frac{C - A}{F}\right)\right]} \qquad (2)$$

where:

A = mass of the dry specimen in air, g

C = mass of the dry specimen plus paraffin coating in air, g

D = mass of the volumeter filled with water at 25 ± 1ºC (77 ± 1.8ºF), g

E = mass of the volumeter filled with the paraffin-coated specimen and water at 25 ± 1ºC (77 ± 1.8ºF), g, and

F = specific gravity of the paraffin at 25 ± 1ºC (77 ± 1.8ºF).

10. PRECISION

10.1. Duplicate specific gravity results by the same operator should not be considered suspect unless they differ by more than 0.02.

---

Standard Method of Test for

Resistance of Compacted Hot Mix Asphalt (HMA) to Moisture-Induced Damage

---

AASHTO Designation: T 283-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance of Compacted Hot Mix Asphalt (HMA) to Moisture-Induced Damage

AASHTO Designation: T 283-07

1. SCOPE

1.1. This method covers preparation of specimens and the measurement of the change of diametral tensile strength resulting from the effects of water saturation and accelerated water conditioning, with a freeze-thaw cycle, of compacted HMA. The results may be used to predict long-term stripping susceptibility of the HMA and evaluate liquid anti-stripping additives that are added to the asphalt binder or pulverulent solids, such as hydrated lime or portland cement, which are added to the mineral aggregate.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- D 3549, Standard Test Method for Thickness or Height of Compacted Bituminous Paving Mixture Specimens

---

3. SIGNIFICANCE AND USE

3.1. As noted in the scope, this method is intended to evaluate the effects of saturation and accelerated water conditioning, with a freeze-thaw cycle, of compacted HMA. This method can be used to test: (a) HMA in conjunction with mixture design testing (lab-mixed, lab-compacted); (b) HMA produced at mixing plants (field-mixed, lab-compacted); and (c) HMA cores obtained from completed pavements of any age (field-mixed, field-compacted).

3.2. Numerical indices of retained indirect-tensile properties are obtained by comparing the properties of laboratory specimens subjected to moisture and freeze-thaw conditioning with the similar properties of dry specimens.

---

4. SUMMARY OF METHOD

4.1. Test specimens for each set of mix conditions, such as those prepared with untreated asphalt binder, asphalt binder treated with anti-stripping agent, or aggregate treated with lime, are prepared. Each set of specimens is divided into subsets. One subset is tested in dry condition for indirect-tensile strength. The other subset is subjected to vacuum saturation and a freeze cycle, followed by a warm-water soaking cycle, before being tested for indirect-tensile strength. Numerical indices of retained indirect-tensile strength properties are calculated from the test data obtained by the two subsets: dry and conditioned.

---

5. APPARATUS

5.1. Equipment for preparing and compacting specimens from one of the following: T 245, T 247, T 312, or ASTM D 3387.

5.2. Equipment for determining the theoretical maximum specific gravity (G_{mm}) of the HMA from T 209 or ASTM D 2041.

5.3. Balance and water bath from T 166.

5.4. Water bath capable of maintaining a temperature of 60 ± 1ºC (140 ± 1.82ºF).

5.5. Freezer maintained at –18 ± 3ºC (0 ± 5ºF).

5.6. A supply of plastic film for wrapping specimens; heavy-duty, leakproof plastic bags to enclose the saturated specimens; and masking tape.

5.7. 10-mL graduated cylinder.

5.8. Pans having a surface area of 48 400 to 129 000 mm^2 (75 to 200 in.^2) in the bottom and a depth of approximately 25 mm (1 in.).

5.9. Forced-draft oven, thermostatically controlled, capable of maintaining any desired temperature setting from room temperature to 176ºC (350ºF) within ±3ºC (±5ºF).

5.10. Loading jack and ring dynamometer from T 245, or a mechanical or hydraulic testing machine from T 167, to provide a range of accurately controllable rates of vertical deformation, including 50 mm/min (2 in./min).

5.11. Steel loading strips with a concave surface having a radius of curvature equal to the nominal radius of the test specimen. For specimens 100 mm (4 in.) in diameter, the loading strips shall be 12.7 mm (0.5 in.) wide, and for specimens 150 mm (6 in.) in diameter, the loading strips shall be 19.05 mm (0.75 in.) wide. The length of the loading strips shall exceed the thickness of the specimens. The edges of the loading strips shall be rounded to the appropriate radius of curvature by grinding.

6. PREPARATION OF LABORATORY-MIXED, LABORATORY-COMPACTED SPECIMENS

6.1. Make at least six specimens for each test, half to be tested dry and the other half to be tested after partial saturation and moisture conditioning with a freeze-thaw cycle (Note 1).

Note 1—It is recommended that two additional specimens for the set be prepared. These specimens can then be used to establish compaction procedures as given in Section 6.5 or 7.4 and the vacuum saturation technique as given in Section 10.3.

6.2. Specimens 100 mm (4 in.) in diameter by 63.5 ± 2.5 mm (2.5 ± 0.1 in.) thick, or 150 mm (6 in.) in diameter by 95 ± 5 mm (3.75 ± 0.20 in.) thick are used. Specimens 150 mm (6 in.) in diameter by 95 ± 5 mm (3.75 ± 0.20 in.) thick should be used if aggregate larger than 25 mm (1 in.) is present in the mixture.

6.3. Prepare mixtures in batches large enough to make at least three specimens or, alternatively, prepare a batch large enough to just make one specimen at a time. If preparing a multi-specimen batch, split the batch into single-specimen quantities before placing in the oven.

6.4. After mixing, the mixture shall be placed in a pan having a surface area of 48 400 to 129 000 mm^2 (75 to 200 in.^2) in the bottom and a depth of approximately 25 mm (1 in.) and cooled at room temperature for 2 ± 0.5 h. Then, the mixture shall be placed in a 60 ± 3ºC (140 ± 5ºF) oven for 16 ± 1 h for curing. The pans should be placed on spacers to allow air circulation under the pan if the shelves are not perforated.

6.5. After curing, place the mixture in an oven for 2 h ± 10 min at the compaction temperature ±3ºC (5ºF) prior to compaction. Compact the specimens according to one of the following methods: T 245, T 247, T 312, or ASTM D 3387. The mixture shall be compacted to 7.0 ± 0.5 percent air voids. This level of voids can be obtained by adjusting the number of blows in T 245; adjusting foot pressure, number of tamps, leveling load, or some combination in T 247; or adjusting the number of revolutions in T 312 or ASTM D 3387. The exact procedure must be determined experimentally for each mixture before compacting the specimens for each set (Note 2).

Note 2—Due to the elevated void content and potential instability of the specimens, ensure each specimen is adequately cool and stable prior to removal from the mold.

6.6. After removal from the molds, the specimens shall be stored for 24 ± 3 h at room temperature.

7. PREPARATION OF FIELD-MIXED, LABORATORY-COMPACTED SPECIMENS

7.1. Make at least six specimens for each test, half to be tested dry and the other half to be tested after partial saturation and moisture conditioning with a freeze-thaw cycle (Note 1).

7.2. Specimens 100 mm (4 in.) in diameter by 63.5 ± 2.5 mm (2.5 ± 0.1 in.) thick, or 150 mm (6 in.) in diameter by 95 ± 5 mm (3.75 ± 0.20 in.) thick are used. Specimens 150 mm (6 in.) in diameter by 95 ± 5 mm (3.75 ± 0.20 in.) thick should be used if aggregate larger than 25 mm (1 in.) is present in the mixture.

7.3. Field-mixed asphalt mixtures shall be sampled in accordance with ASTM D 979.

7.4. No loose-mix curing as described in Section 6.4 shall be performed on the field-mixed samples. After sampling, divide the sample to obtain the desired size in accordance with R 49. Next, place the mixture in an oven until it reaches the compaction temperature ±3ºC (5ºF). Then, compact the specimen according to one of the following methods: T 245, T 247, T 312, or ASTM D 3387. The mixture shall be compacted to 7.0 ± 0.5 percent air voids. This level of voids can be obtained by adjusting the number of blows in T 245; adjusting foot pressure, number of tamps, leveling load, or some combination in T 247; or adjusting the number of revolutions in T 312 or ASTM D 3387. The exact procedure must be determined experimentally for each mixture before compacting the specimens for each set (Note 2).

7.5. After removal from the molds, the specimens shall be stored for 24 ± 3 h at room temperature.

8. PREPARATION OF FIELD-MIXED, FIELD-COMPACTED SPECIMENS (CORES)

8.1. Select locations on the completed pavement to be sampled, and obtain cores. When testing pavement layers with a thickness less than or equal to 63.5 mm (2.5 in.), use 100-mm (4-in.) diameter cores. Otherwise, use either 100-mm (4-in.) or 150-mm (6-in.) diameter cores. The number of cores shall be at least six for each set of mix conditions.

8.2. Separate the core layers as necessary by sawing them or by other suitable means, and store the layers to be tested at room temperature until they are dry.

8.3. No loose-mix curing (Section 6.4) or compacted-mix curing (Section 6.6) shall be performed on the field-mixed, field-compacted specimens (cores).

9. EVALUATION AND GROUPING OF SPECIMENS

9.1. After curing or heating mixture samples for the theoretical maximum specific gravity (G_{mm}) test as described in Sections 6.4 and 6.5, or Section 7.4 as appropriate, determine the G_{mm} of those samples by T 209 or ASTM D 2041.

9.2. Determine each specimen thickness (t) in accordance with ASTM D 3549.

9.3. Record each specimen diameter (D) as defined in Section 6.2, 7.2, or 8.1, as appropriate.

9.4. Determine each bulk specific gravity (G_{mb}) by Method A of T 166. Express the volume (E) of the specimens, or the saturated, surface-dry mass minus the mass in water, in cubic centimeters.

9.5. Calculate the percentage of air voids (P_a) in accordance with T 269.

9.6. Separate the specimens into two subsets, of at least three specimens each, so that the average air voids of the two subsets are approximately equal.

For those specimens to be subjected to vacuum saturation, a freeze cycle, and a warm-water soaking cycle, calculate the volume of air voids (V_a) in cubic centimeters using the following equation:

$$V_a = \frac{P_a E}{100} \tag{1}$$

where:

V_a = volume of air voids, cm^3;

P_a = air voids, percent; and

E = volume of the specimen, cm^3.

Note 3—A data sheet that is convenient for use with this test method is shown as Table 1.

10. PRECONDITIONING OF TEST SPECIMENS

10.1. One subset will be tested dry, and the other will be partially vacuum-saturated, subjected to freezing, and soaked in warm water before testing.

10.2. The dry subset will be stored at room temperature as described in Section 6.6 or Section 7.5, as appropriate. At the end of the curing period from Section 6.6 or 7.5, as appropriate, the specimens shall be wrapped with plastic or placed in a heavy-duty, leakproof plastic bag. The specimens shall then be placed in a 25 ± 0.5ºC (77 ± 1ºF) water bath for 2 h ± 10 min with a minimum 25 mm (1 in.) of water above their surface. Then, test the specimens as described in Section 11.

10.3. *The other subset shall be conditioned as follows*:

10.3.1. Place the specimen in the vacuum container supported a minimum of 25 mm (1 in.) above the container bottom by a perforated spacer. Fill the container with potable water at room temperature so that the specimens have at least 25 mm (1 in.) of water above their surface. Apply a vacuum of 13 to 67 kPa absolute pressure (10 to 26 in. Hg partial pressure) for a short time (approximately 5 to 10 minutes). Remove the vacuum and leave the specimen submerged in water for a short time (approximately 5 to 10 minutes).

10.3.2. Determine the mass of the saturated, surface-dry specimen after partial vacuum saturation (B') by Method A of T 166.

10.3.3. Calculate the volume of absorbed water (J') in cubic centimeters by use of the following equation:

$$J' = B' - A \tag{2}$$

where:

J' = volume of absorbed water, cm^3;

B' = mass of the saturated, surface-dry specimen after partial vacuum saturation, g; and

A = mass of the dry specimen in air, g (Section 9.4).

10.3.4. Determine the degree of saturation (S') by comparing the volume of absorbed water (J') with the volume of air voids (V_a) from Section 9.6 using the following equation:

$$S' = \frac{100J'}{V_a} \tag{3}$$

where:

S' = degree of saturation, percent.

10.3.5. If the degree of saturation is between 70 and 80 percent, proceed to Section 10.3.7.

10.3.6. If the degree of saturation is less than 70 percent, repeat the procedure beginning with Section 10.3.1 using more vacuum and/or time. If the degree of saturation is more than 80 percent, the specimen has been damaged and must be discarded. In this case, repeat the procedure on the next specimen beginning with Section 10.3.1 using less vacuum and/or time.

10.3.7. Cover each of the vacuum-saturated specimens tightly with a plastic film (Saran Wrap® brand or equivalent). Place each wrapped specimen in a plastic bag containing 10 ± 0. 5 mL of water and seal the bag. Place the plastic bags containing the specimens in a freezer at a temperature of –18 ± 3°C (0 ± 5°F) for a minimum of 16 hours. Remove the specimens from the freezer.

10.3.8. Place the specimens in a bath containing potable water at 60 ± 1°C (140 ± 2°F) for 24 ± 1 h. The specimens should have a minimum of 25 mm (1 in.) of water above their surface. As soon as possible after placement in the water bath, remove the plastic bag and film from each specimen.

10.3.9. After 24 ± 1 h in the 60 ± 1°C (140 ± 2°F) water bath, remove the specimens and place them in a water bath at 25 ± 0.5°C (77 ± 1°F) for 2 h ± 10 min. The specimens should have a minimum of 25 mm (1 in.) of water above their surface. It may be necessary to add ice to the water bath to prevent the water temperature from rising above 25°C (77°F). Not more than 15 minutes should be required for the water bath to reach 25 ± 0.5°C (77 ± 1°F). Remove the specimens from the water bath, and test them as described in Section 11.

11. TESTING

11.1. Determine the indirect-tensile strength of dry and conditioned specimens at 25 ± 0.5°C (77 ± 1°F).

11.2. Remove the specimen from 25 ± 0.5°C (77 ± 1°F) water bath, and determine the thickness (t') by ASTM D 3549. Place it between the steel loading strips and then place the specimen and loading strips between the two bearing plates in the testing machine. Care must be taken so that the load will be applied along the diameter of the specimen. Apply the load to the specimen, by means of the constant rate of movement of the testing machine head, at 50 mm/min (2 in./min).

11.3. Record the maximum compressive strength noted on the testing machine, and continue loading until a vertical crack appears. Remove the specimen from the machine, and pull it apart at the crack. Inspect the interior surface for evidence of cracked or broken aggregate; visually estimate the approximate degree of moisture damage on a scale from “0” to “5” (with “5” being the most stripped), and record the observations in Table 1.

12. CALCULATIONS

12.1. Calculate the tensile strength as follows:

SI Units:

$$S_t = \frac{2000\,P}{\pi\,t\,D} \tag{4}$$

where:

S_t = tensile strength, kPa

P = maximum load, N

t = specimen thickness, mm

D = specimen diameter, mm

U.S. Customary units:

$$S_t = \frac{2\,P}{\pi\,t\,D} \tag{5}$$

where:

S_t = tensile strength, psi;

P = maximum load, lbf;

t = specimen thickness, in.; and

D = specimen diameter, in.

12.2. Express the numerical index of resistance of HMA to the detrimental effect of water as the ratio of the original strength that is retained after the moisture and freeze-thaw conditioning. Calculate the tensile strength ratio to two decimal places as follows:

$$\text{Tensile Strength Ratio (TSR)} = \frac{S_2}{S_1} \qquad (6)$$

where:

S_1 = average tensile strength of the dry subset, kPa (psi); and

S_2 = average tensile strength of the conditioned subset, kPa (psi).

13. REPORT

13.1. Report the following information:

13.1.1. Number of specimens in each subset;

13.1.2. Average air voids of each subset;

13.1.3. Tensile strength of each specimen in each subset;

13.1.4. Tensile strength ratio;

13.1.5. Results of visually estimated moisture damage observed when the specimen fractures; and

13.1.6. Results of observations of cracked or broken aggregate.

Standard Method of Test for

Asphalt Binder Content of Asphalt Mixtures by the Nuclear Method

---

AASHTO Designation: T 287-06

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Asphalt Binder Content of Asphalt Mixtures by the Nuclear Method

AASHTO Designation: T 287-06

1. SCOPE

1.1. This procedure covers the quantitative determination of the asphalt binder content of asphalt mixtures by testing a sample with a nuclear gauge that utilizes neutron-thermalization techniques.

1.2. The values expressed in SI units are to be regarded as the standard. The inch-pound equivalents of the SI units may be approximate.

1.3. Nuclear gauge operations and maintenance are not covered in detail. See the manufacturer's manual for details.

1.4. *This test method involves potentially hazardous materials, operations, and equipment. This method does not purport to address all of the safety concerns associated with its use. All operators will be trained in radiation safety prior to operating nuclear gauges. Some agencies require the use of personal monitoring devices such as a thermoluminescent dosimeter or film badge.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 40, Sampling Bituminous Materials
- T 110, Moisture or Volatile Distillates in Hot Mix Asphalt (HMA)
- T 168, Sampling Bituminous Paving Mixtures
- T 248, Reducing Samples of Aggregate to Testing Size
- T 255, Total Evaporable Moisture Content of Aggregate by Drying
- T 329, Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

3. SUMMARY OF METHOD

3.1. This procedure can be used for rapid determination of the asphalt binder content of asphalt mixtures. It is suitable for quality control and acceptance testing for construction and for research and development applications. This procedure is useful in the determination of asphalt binder content only and does not provide for gradation analysis.

3.2. This procedure determines the asphalt binder content of a test sample by comparing the measured asphalt binder content with previously established calibration data. The asphalt binder content is expressed as a percentage of the mass of the asphalt mixture.

3.3. Accurate results are dependent upon proper calibration of the nuclear gauge to the material being tested as covered in Annex A. This procedure is sensitive to the type and gradation of the aggregate, liquid anti-stripping additive or hydrated lime, and the percentage and source of the asphalt binder.

3.4. This procedure measures the total amount of hydrogen in a sample including the hydrogen present in the form of water. Unless the test sample is totally free of water, the moisture content must be determined according to T 110 or T 329 and the percentage subtracted from the asphalt binder content measured by the nuclear gauge. Alternatively, prior to testing, the sample may be dried to a constant mass in an oven at 110 ± 5°C (230 ± 9°F), thereby nullifying the need for a moisture correction.

3.5. This procedure can be used with recycled asphalt pavement (RAP) incorporated into the asphalt mixture, provided that the RAP is of uniform gradation, asphalt binder content, and asphalt binder type. When RAP is used, the RAP should be mixed in the calibration samples in the same proportion that will be used on the construction project.

4. APPARATUS

4.1. *Nuclear asphalt binder content gauge system consisting of*:

4.1.1. *Neutron Source*—an encapsulated and sealed radioactive source;

4.1.2. Thermal neutron detectors;

4.1.3. Read-out instrument displaying, at a minimum, the percent of asphalt binder to the nearest 0.1 percent; and

4.1.4. Three or more stainless-steel sample pans conforming to the gauge requirements.

4.2. Mechanical mixer with a 10-kg (22-lb) capacity, capable of producing a completely mixed, well-coated, homogenous asphalt mixture.

4.3. Sample containers such as paint cans or unwaxed, nonabsorbent cardboard boxes that can be closed to prevent contamination of the sample and are capable of withstanding the heating of the asphalt mixture to the mixing temperature.

4.4. Sample-quartering apparatus conforming to the requirements of T 248, Method B.

4.5. General-purpose balance or scale conforming to M 231, 20-kg (44-lb) capacity, readable to 0.1 g.

4.6. *Drying Oven*—capable of handling the required number of samples and sample sizes, of either of the following types:

4.6.1. Forced-air convection oven capable of maintaining a temperature of 177 ± 3ºC (350 ± 5ºF).

4.6.2. Microwave oven, determined not to be detrimental to the aggregate, capable of maintaining a temperature of 177 ± 3°C (350 ± 5°F).

4.7. *Leveling Plate*—flat, rigid plate of metal [minimum thickness of 10 mm (0.4 in.)], Plexiglas [minimum thickness of 12.5 mm (0.5 in.)], or non-absorptive plywood [minimum thickness of 19 mm (0.75 in.)], slightly larger than the sample pans.

4.8. Thermometer with a temperature range of 10 to 260°C (50 to 500°F).

4.9. Assorted pans, spoons, spatulas, and mixing bowls.

4.10. *Radioactive materials information/calibration packet containing*:

4.10.1. Daily standard count log;

4.10.2. Factory/laboratory calibration data sheet;

4.10.3. Leak test certificate;

4.10.4. Shipper's declaration for dangerous goods;

4.10.5. Procedure memo for storing, transporting, and handling nuclear testing equipment; and

4.10.6. Other radioactive materials documentation conforming to local regulatory requirements.

5. PRECAUTIONS

5.1. *The nuclear asphalt binder content gauge may be sensitive to outside influences and therefore*:

5.1.1. Any other source of neutron radiation shall be kept at least 10 m (33 ft) from the apparatus during use;

5.1.2. The space within 1 m (3.3 ft) of the apparatus shall be kept free of hydrogenous material such as water, plastics, asphalt binder, or asphalt mixtures during use;

5.1.3. All personnel shall be kept at least 1 m (3.3 ft) away from the gauge during testing; and

5.1.4. The gauge shall not be located within 10 m (33 ft) of any water supply tanks, fuel tanks, or other liquid containers subject to fluctuating liquid levels.

5.2. Moving the apparatus to a different location, even within the same laboratory, may cause a change in the background radiation measurements. New background measurements, and possibly recalibration, will be necessary prior to use whenever background conditions have changed. See Sections 6 and 7 for instructions concerning calibration and background measurements.

6. CALIBRATION

6.1. Perform calibrations and cross-calibrations on asphalt mixtures tested in gauges, and transfer calibrations between gauges according to Annex A.

7. STANDARDIZATION

7.1. Obtain and record a background count in accordance with the manufacturer's procedure each day prior to taking test measurements or whenever the gauge has been moved or the conditions within 1 m (3.3 ft) of the gauge have changed. The measurement time for the background count should be the same as that used for the test measurements.

7.2. If the background count has not changed by more than 1 percent from the previous background count, then the apparatus shall be considered stable and acceptable for use. If the gauge has been moved or if the surrounding conditions have changed, additional background counts must be obtained until the 1-percent standard is satisfied.

8. PROCEDURE

8.1. Obtain a representative sample of asphalt mixture in accordance with T 168. If required, reduce the sample to the approximate test size by splitting or quartering according to T 248, Method B. It is recommended that testing be performed while the asphalt mixture is still hot, and not reheated, if possible. If the asphalt mixture cools and reheating is necessary, heat it to the mid-point of the compaction temperature range for the asphalt binder used in the asphalt mixture.

8.2. Determine the mass of a clean gauge-sample pan, and tare the pan on the scale.

8.3. Place the asphalt mixture into the pan until it is about half full. Lightly tamp the asphalt mixture in the pan with a preheated spoon or spatula.

8.4. Place additional asphalt mixture into the pan until the required mass, as determined in Annex A, is reached within ±5 g.

8.5. Place the leveling plate on top of the asphalt mixture immediately after filling the pan. Compact the sample into the pan until it is level with the top of the pan by pressing down on the plate. Sight across the top of the pan to ensure that the asphalt mixture does not protrude above the pan.

8.6. Record the mass of the asphalt mixture compacted into the pan. The mass shall be within ±5 g of the target mass.

Note 1—If the gauge does not have temperature-compensation capability, measure and record the temperature of the compacted specimen. This temperature must be within ±5°C (9°F) of the calibration-test-specimen temperature.

8.7. If the gauge has the ability to store multiple calibrations, activate the calibration for the particular asphalt mixture. Place the pan into the gauge, and perform a 4-minute count.

8.8. Determine the uncorrected asphalt binder content by direct read-out from the gauge, calibration graph, or formula supplied by the manufacturer. Record the uncorrected asphalt binder content from the 4-minute reading to the nearest 0.1 percent.

8.9. Using a representative portion of the original sample or a portion of the material removed from the gauge pan, determine the moisture in the asphalt mixture according to T 110 or T 329, and record it to the nearest 0.1 percent. Alternatively, prior to testing, the sample may be dried to a constant mass in an oven at 110 ± 5°C (230 ± 9°F), thereby nullifying the need for a moisture correction.

9. CALCULATION

9.1. When determined, subtract the moisture content from the uncorrected asphalt binder content. Record this value as the corrected asphalt binder content.

10. REPORT

10.1. *Report the following information*:

10.1.1. Make, model, and serial number of the nuclear asphalt binder content gauge;

10.1.2. Date and source of the calibration;

10.1.3. Date of the test;

10.1.4. Name and signature of the operator;

10.1.5. Background count for the day of the test;

10.1.6. Asphalt mixture identification;

10.1.7. Aggregate type and sources;

10.1.8. Asphalt binder grade and source;

10.1.9. When used, source and amount of liquid anti-stripping additive or hydrated lime;

10.1.10. Calibration sample mass and temperature;

10.1.11. Test-sample mass and temperature if the gauge does not have temperature-compensation capability;

10.1.12. Gauge reading; and

10.1.13. Corrected asphalt binder content value to the nearest 0.1 percent.

ANNEXES

(Mandatory Information)

A1. SCOPE

A1.1. This annex covers the preparation of samples for, and the calibration of, nuclear asphalt binder content gauges. Job-mix formula (JMF) calibration and cross-calibration of master and field gauges are included.

A2. SAMPLING

A2.1. Obtain samples of aggregate according to T 2. Approximately 50 kg (110 lb) will be required for the calibration specimens.

A2.2. Obtain samples of asphalt binder according to T 40. Approximately 4 L (1 gal) will be required.

Note A1—The more accurately the ingredient materials (including liquid anti-stripping additive or hydrated lime) are prepared to match the JMF, the closer the calibration points will be to the production asphalt mixture. Therefore, the more accurate the results will be.

A3. AGGREGATE PREPARATION

A3.1. When used, hydrate the appropriate amount of lime on the aggregate.

A3.2. Dry the aggregate to a constant mass using the apparatus and temperatures from T 255.

A3.3. Separate the aggregate blend by dry-sieving on the specified sieves, including the minus 75-µm (No. 200) material.

A3.4. Calculate the required cumulative mass for each specified sieve using the following formula:

$$X = \frac{T(100 - P)}{100} \tag{A3.1}$$

where:

X = the required, cumulative batch mass for each specified sieve (g);

T = the initial, total aggregate mass (g); and

P = the percent passing for each specified sieve according to the JMF.

A3.5. *Perform an aggregate dust correction as follows*:

A3.5.1. Prepare a washed-gradation sample from the masses calculated in Section A3.4.

A3.5.2. Perform a washed gradation according to T 27 and T 11.

A3.5.3. Calculate the corrected batch mass for each specified sieve for the calibration points using the following formula:

$$Z_n = \frac{X^2}{Y} \tag{A3.2}$$

where:

Z_n = the adjusted, cumulative batch mass for any sieve size, n (g);

X = the pre-wash, cumulative batch mass for each specified sieve (g); and

Y = the post-wash, cumulative batch mass for each specified sieve (g).

A3.6. Blend the aggregate together at the proper proportion to match the JMF using the masses calculated in Section A3.5.3.

A4. ASPHALT BINDER PREPARATION

A4.1. Heat a minimum of 2 L (0.5 gal) of asphalt binder to the mid-point of the mixing temperature range in a covered container(s). When used, add the appropriate amount of liquid anti-stripping additive to the asphalt binder. Use the asphalt binder as soon as it reaches the mid-point of the mixing temperature range. If this operation is not possible, maintain the asphalt binder at this temperature for no more than 4 hours. Do not cool and reheat the asphalt binder.

A4.2. *Method A*—Asphalt binder percent by mass of the asphalt mixture.

A4.2.1. Calculate the mass of asphalt binder for each calibration point as follows:

$$B = (E)(P_{bm}) \qquad (A4.1)$$

where:

B = the mass of the asphalt binder to the nearest 0.1 g;
E = the mass of the asphalt mixture (g); and
P_{bm} = the percent of asphalt binder by total mass of the asphalt mixture, expressed as a decimal.

Asphalt binder contents will be chosen at the optimum asphalt binder content and at increments of ±0.8 percent from the optimum asphalt binder content. The minimum four samples are at 0.8 below, optimum, 0.8 above, and 1.6 percent above the optimum.

A4.2.2. Calculate the mass of aggregate required for each calibration point as follows:

$$A = E - B \qquad (A4.2)$$

where:

A = the mass of the aggregate to the nearest 0.1 g.

A4.3. *Method B*—Asphalt binder percent by mass of the aggregate.

A4.3.1. Calculate the mass of aggregate for each calibration point as follows:

$$A = \frac{E}{1 + P_{ba}} \qquad (A4.3)$$

where:

P_{ba} = the percent of asphalt binder by mass of the aggregate, expressed as a decimal.

Asphalt binder contents will be chosen at the optimum asphalt binder content and at increments of ±0.8 percent from the optimum asphalt binder content. The minimum four samples are at 0.8 below, optimum, 0.8 above, and 1.6 percent above the optimum.

A4.3.2. Calculate the mass of asphalt binder required for each calibration point as follows:

$$B = (A)(P_{ba}) \qquad (A4.4)$$

A5. PREPARATION FOR SPECIMENS

A5.1. The aggregate and asphalt binder materials must be heated to the mid-point of the mixing temperature range for that asphalt binder. Once these materials have stabilized at that temperature, proceed with the following steps:

A5.2. Determine the mass of the heated mixing bowl to the nearest 0.1 g.

A5.3. Place a heated aggregate specimen, of the required mass to the nearest 0.1 g, in the mixing bowl.

A5.4. Form a crater in the aggregate large enough to hold the required mass of asphalt binder.

A5.5. Place the mixing bowl on the scale. Add the required, preheated asphalt binder mass, to the nearest 0.1 g, into the aggregate crater.

A5.6. Mechanically mix the aggregate and asphalt binder rapidly for a minimum of two minutes until they are thoroughly blended. Check the bottom and sides of the bowl for unmixed aggregate and asphalt binder. If necessary, remix the sample by hand until it is thoroughly mixed.

Note A2—Hand-mixing is not recommended. However, mixing may be performed by hand in a large bowl. In this case, the mixing time shall be a minimum of five minutes, but it may be longer to ensure thorough mixing.

A5.7. Remove the asphalt mixture from the bowl, and determine the mass of the empty bowl to ensure that all material has been removed. The mass of the bowl shall be within ±5 g of the mass determined in Section A5.2. If it is not, scrape the bowl with a spatula, and deposit the excess into the sample, until the mass of the bowl is within the tolerance.

A6. TARGET MASS DETERMINATION

A6.1. An initial, or “butter,” batch is prepared to determine the mass to be used for the calibration samples using an asphalt binder/aggregate blend approximating the real batches. Based on experience with aggregate specific gravity and gradation, the target mass will be from 6000 to 9000 g.

Note A3—To find an approximate starting mass, place the dry aggregate in a gauge-sample pan. Fill the pan half full; then drop it from a height of 25 mm (1 in.). Fill the pan just over full, and strike it off even with the top. Determine this mass, and add 10 percent to obtain an approximate starting mass.

A6.2. Mix the preheated aggregate and asphalt binder according to Section A5.

A6.3. Determine the mass of a clean gauge-sample pan, and tare the pan on the scale.

A6.4. Place the asphalt mixture into the pan until it is about half full. Lightly tamp the asphalt mixture in the pan with a preheated spoon or spatula.

A6.5. Place the remaining asphalt mixture into the pan so that the asphalt mixture is mounded about 13 mm (0.5 in.) above the top of the pan.

A6.6. Place the leveling plate on top of the asphalt mixture immediately after filling the pan. Compact the sample into the pan until it is level with the top of the pan by pressing down on the plate. Sight across the top of the pan to ensure that the asphalt mixture does not protrude above the pan.

A6.7. Determine and record the mass of the asphalt mixture compacted into the pan. This value is the target mass. The subsequent calibration and sample specimens must be within ±5 g of this mass.

A7. CALIBRATION (GENERAL)

A7.1. The type of aggregate, source and grade of asphalt binder, liquid anti-stripping additive or hydrated lime, and asphalt mixture gradation will influence the test results obtained using this procedure. Accordingly, a calibration curve must be developed for each combination of these factors.

A7.2. The calibration curve must cover the range of expected values found in field samples. The limits for the calibration curve must consider the allowable range of asphalt binder content plus the allowable aggregate moisture (which reads as asphalt binder in the gauge). At a minimum, use 0.8 below, optimum, 0.8 above, and 1.6 percent above the optimum asphalt binder content when making the calibration-curve pans.

A8. JMF CALIBRATION

A8.1. Prepare four aggregate samples using the target mass determined in Section A6.7. Place them in separate pans designed for, and capable of, transferring the dry aggregate into a mixing bowl with a minimum loss of aggregate. Place them in an oven set at the mid-point of the mixing temperature range for the asphalt binder to be used.

A8.2. Determine the mass of the aggregate and asphalt binder for each calibration sample according to Sections A3 and A4, respectively.

A8.3. Mix the preheated aggregate and asphalt binder according to Section A5.

A8.4. Determine the mass of a clean gauge-sample pan, and tare the pan on the scale.

A8.5. Place the asphalt mixture into the pan until it is about half full. Lightly tamp the asphalt mixture in the pan with a preheated spoon or spatula.

A8.6. Place the remaining asphalt mixture into the pan so that the asphalt mixture is mounded about 13 mm (0.5 in.) above the top of the pan.

A8.7. Place the leveling plate on top of the asphalt mixture immediately after filling the pan. Compact the sample into the pan until it is level with the top of the pan by pressing down on the plate. Sight across the top of the pan to ensure that the asphalt mixture does not protrude above the pan.

A8.8. Determine and record the mass of the asphalt mixture compacted into the pan. The mass shall be within ±5 g of the target mass determined in Section A6.7.

A8.9. Place the pan into the gauge, and proceed in accordance with the manufacturer's instructions for the operation of the equipment and the sequence of operations.

Note A4—Do not forget to perform a background count according to the manufacturer's instructions.

A8.10. Repeat Sections A8.2 through A8.9 for the other calibration samples.

A9. PRESENTATION OF CALIBRATION DATA

A9.1. *For gauges that generate the calibration internally to the gauge*:

A9.1.1. Print or otherwise record the formula coefficients, the coefficient of fit, and the calculated percent difference for each calibration point. If the coefficient of fit is less than 0.998 for a dense-graded asphalt mixture or 0.995 for an open-graded asphalt mixture, or any calibration point has a calculated percent difference greater than 0.09 percent, the calibration is not acceptable and must be performed again.

A9.1.2. Store the acceptable calibration in the gauge's memory, using the JMF and an easily recognizable calibration number, according to the manufacturer's instructions.

A9.2. *For gauges that do not generate the calibration internally to the gauge*:

A9.2.1. Prepare a calibration curve by plotting the gauge readings for the calibration samples versus asphalt binder content on linear graph paper, choosing convenient scale factors for the gauge readings and asphalt binder content.

A10. CROSS-CALIBRATION (WHEN APPLICABLE)

A10.1. The formula coefficients are entered into the field gauge in the transfer mode during the cross-calibration process. The new formula coefficients, when printed, will not resemble the values entered because they will change based on this relationship. For more detailed information on the formula coefficients, refer to the manufacturer's instructions. If required, a "straight" calibration may be performed and used instead of the transfer program. This option requires that the sample pans used for the calibration be tested in another gauge if the testing must be verified by the agency.

Note A5—Some agencies cross-calibrate gauges. This process creates a relationship between the field gauge and the gauge used in the JMF calibration, allowing the testing of production asphalt mixture without the need to perform calibrations in the field. When several gauges are cross-calibrated, the asphalt mixture calibrations may be transferred to each gauge.

A10.2. Prepare six calibration samples, using a locally available, agency-approved aggregate, with asphalt binder contents between 3 and 8 percent at 1-percent increments. Mix the samples so that each pan of asphalt mixture equals the target mass ±5 g as determined for the aggregate. Test each sample in the master gauge using 16-minute counts in the normal calibration mode. After all samples are tested, the gauge will automatically calculate a coefficient of fit. The coefficient of fit must be at least 0.999. Seal each pan to prevent a change in hydrogen content, and repeat the procedure. Sealed pans must meet the same criteria as above.

Note A6—To seal the pan, cut a piece of tin the size of the top of the sample pan. Seal the edges of the pan and tin lid with an epoxy. This process will seal any moisture out.

A10.3. Test each of the six sealed calibration samples in the field gauge while it is in the cross-calibration mode. For each calibration sample, input the data obtained from the master gauge into the field gauge. The master and field gauges are now cross-calibrated.

Note A7—Annually, or whenever a field gauge differs from the master gauge, a new cross-calibration must be performed using the sealed pans originally produced for the gauge standardization. These six pans must be checked monthly in the master gauge to verify that the counts have not changed substantially.

Standard Method of Test for

Specific Gravity or API Gravity of Liquid Asphalts by Hydrometer Method

AASHTO Designation: T 295-08
ASTM Designation: D 3142-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity or API Gravity of Liquid Asphalts by Hydrometer Method

AASHTO Designation: T 295-08
ASTM Designation: D 3142-05

1. SCOPE

1.1. This test method covers the determination of the density of cutback asphalts using a glass hydrometer. It is applicable to cutback asphalts which are liquid at room temperature (Note 1). It provides more explicit testing procedures than those in AASHTO T 227.

Note 1—For materials that are solid or semi-solid at room temperature, use AASHTO T 228 or ASTM D 3289.

1.2. The values in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. Specific precautionary statements are given in Section 7.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 40, Sampling Bituminous Materials
- T 227, Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method
- T 228, Specific Gravity of Semi-Solid Asphalt Materials

2.2. *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- D 1250, Standard Guide for Use of the Petroleum Measurement Tables
- D 3289, Standard Test Method for Density of Semi-Solid and Solid Bituminous Materials (Nickel Crucible Method)
- D 4311, Standard Practice for Determining Asphalt Volume Correction to a Base Temperature
- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers
- E 100, Standard Specification for ASTM Hydrometers

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *API gravity*—a function of specific gravity (SG) 15.6/15.6ºC, represented by the following equation: ºAPI = (141.5/SG 15.6/15.6ºC) – 131.5

3.1.2. *density*—the mass per unit volume of a material.

3.1.3. *observed values*—values observed at temperatures other than the standard reference temperature. Values observed at other temperatures are only hydrometer readings and not density, relative density (specific gravity), or API gravity.

3.1.4. *relative density*—the ratio of the mass of a given volume of a material to the mass of the same volume of water at the same temperature.

3.1.5. *specific gravity*—relative density.

4. SUMMARY OF TEST METHOD

4.1. The sample is brought to the testing temperature and transferred to a cylinder at approximately the same temperature. The cylinder and its contents are placed in a constant-temperature bath to avoid excessive temperature variation during the test. The appropriate hydrometer is lowered into the sample and allowed to settle. After temperature equilibrium is achieved, the hydrometer is read, and the temperature of the sample is noted. The hydrometer reading is converted to the density at 15ºC (60°F) using standard tables.

5. SIGNIFICANCE AND USE

5.1. Values of density are used for converting volumes to units of mass, and for correcting measured volumes from the temperature of measurement to a standard temperature using ASTM D 4311.

6. APPARATUS

6.1. *Hydrometers*—glass, graduated in units of specific gravity and accurate to 0.001, API gravity and accurate to 0.1° API, or density and accurate to 0.5 kg/m^3 (0.03 lb/ft^3), conforming to Table 1.

Table 1—Recommended Hydrometers

Hydrometer Designation	Measurement	Range	Total Length, mm	Body Diameter, mm
1H to 4H	API Gravity	–1 to 41ºAPI	325 to 335	23 to 27
21H to 28H	API Gravity	0 to 41ºAPI	158 to 168	12 to 15
85H to 90H	Relative Density (SG) 15.6/15.6ºC (60°F)	0.8 to 1.1	325 to 335	23 to 27
105H to 108H	Relative Density (SG) 15.6/15.6ºC (60°F)	0.8 to 1.0	250 to 270	20 to 24
315H to 320H	Density at 15ºC (60°F)	800 to 1100 kg/m^3 (50–69 lb/ft^3)	325 to 335	21 to 27

6.2. Other hydrometers conforming to the performance and accuracy requirements of ASTM E 100 may be used.

6.3. *Thermometric Device*—accurate to 0.1ºC (0.2°F). An ASTM 12C thermometer as defined in ASTM E 1 is suitable. Any other thermometric device of equal accuracy may be used.

6.4. *Hydrometer Cylinder*—clear glass, plastic (Note 2), or metal. For convenience in pouring, the cylinder may have a lip on the rim. The inside diameter of the cylinder shall be at least 20 mm ($^3/_4$ in.) greater than the outside diameter of the hydrometer used in it. The height of the cylinder shall be such that the hydrometer floats in the sample with at least 25 mm (1 in.) clearance between the bottom of the hydrometer and the bottom of the cylinder.

Note 2—Hydrometer cylinders constructed of plastic materials shall be resistant to discoloration by oil samples and must not become opaque by prolonged exposure to sunlight or oil samples.

6.5. *Constant-Temperature Bath*—capable of maintaining the testing temperature within ±0.5ºC (1.0°F) and of such dimensions that the level of the liquid is approximately the same as that of the sample in the hydrometer cylinder.

6.5.1. *Thermometric Device*—a thermometer or electronic temperature-measuring device accurate to 0.25°C (0.5°F) shall be used to measure the temperature of the constant-temperature bath

6.6. *Oven*—for preheating the sample, and capable of maintaining the selected testing temperature within ±3ºC (5°F).

6.6.1. *Thermometric Device*—a thermometer or electronic temperature measuring device accurate to 1°C (2°F) shall be used to measure the temperature of the oven.

7. HAZARDS

7.1. Materials tested using this procedure may contain volatile and flammable hydrocarbons. Heat the sample in a covered container to minimize the loss of volatile components. Perform the test in a well-ventilated area, and avoid breathing any vapors that may be generated. Keep sources of ignition away from materials being tested.

8. SAMPLING

8.1. Take samples in accordance with AASHTO T 40. The sample shall be free of foreign substances.

8.2. Thoroughly mix the sample before removing a representative portion for testing.

9. TEMPERATURE OF TEST

9.1. Because of differences in viscosity between various grades of liquid asphalts, the temperature of the test must be adjusted so that it will provide sufficient fluidity to conduct the test over a reasonable period of time. The recommended testing temperatures for the various grades shown in Table 2 are based on a viscosity of approximately 200 to 500 cSt.

Table 2—Recommended Testing Temperatures for Various Grades of Liquid Asphalts

Grade	Testing Temperature, ºC (°F)
MC-30	Room
SC-70, MC-70, RC-70	40 (104)
SC-250, MC-250, RC-250	60 (140)
SC-800, MC-800, RC-800	80 (176)
SC-3000, MC-3000, RC-3000	100 (212)

9.2. When the hydrometer value is used to select multipliers for correcting volumes to standard temperatures, the hydrometer reading should be made preferably at a temperature within ±3ºC (5°F) of the temperature at which the bulk volume of the oil was measured (Note 3). However, in cases when appreciable amounts of light fractions may be lost during determination at the bulk asphalt temperature, the temperatures given in Table 2 should not be exceeded.

Note 3—Volume and density correction tables are based on an average coefficient of expansion for a number of typical materials. Since the same coefficients were used in computing both sets of tables, corrections made over the same temperature interval minimize errors arising from possible differences between the coefficients of the material under test and the standard coefficients. This effect becomes more important as temperatures diverge significantly from 15ºC (60°F).

10. PROCEDURE

10.1. Select the test temperature in accordance with Section 9. Heat the sample in an oven to ±3ºC (5°F) of the test temperature. The container shall be covered with a loose-fitting cover to prevent solvent evaporation. Bring the hydrometer cylinder and thermometer to approximately the same temperature as the sample to be tested.

10.2. Transfer the sample to a clean hydrometer cylinder (Note 4) without splashing to avoid the formation of air bubbles and reduce to a minimum the evaporation of the lower boiling constituents of the more volatile samples. Remove any air bubbles formed, after they have collected on the surface of the sample, by touching them with a piece of clean filter paper before inserting the hydrometer.

Note 4—When metal cylinders are used, accurate reading of the hydrometer can only be ensured if the level of the sample is within 5 mm (0.2 in.) of the top of the cylinder.

10.3. Place the cylinder containing the sample in the constant-temperature bath previously heated to the test temperature ±0.5ºC (1.0°F). Allow sufficient time for the sample to reach the bath temperature, and verify its temperature with the thermometer, ensuring that the mercury thread is fully immersed. If a thermohydrometer is used, it may be lowered into the sample at this point instead of the thermometer. As soon as a steady thermometer reading is obtained, record the temperature of the sample to the nearest 0.2ºC (0.5°F).

10.4. Lower the hydrometer gently into the sample. Avoid wetting the stem above the level to which it will be immersed in the liquid. Allow sufficient time for the hydrometer to become completely stationary and for all air bubbles to come to the surface. This step is particularly necessary in the case of more viscous samples.

10.5. When the hydrometer has come to rest, floating freely away from the walls of the cylinder, read the hydrometer to the nearest scale division. Take the reading by observing, with the eye slightly above the plane of the surface of the liquid, the point on the hydrometer scale to which the sample rises. This reading, at the top of the meniscus, requires correction, since hydrometers are standardized to be read at the principal surface of the liquid. The corrections for the particular hydrometer in use may be determined by observing the maximum height above the principal surface of the liquid to which oil rises on the hydrometer scale when the hydrometer in question is immersed in a transparent oil having a surface tension similar to that of the sample under test. For routine work, determine the height of the meniscus by sighting across the principal surface of the liquid and estimating the rise of the meniscus on the hydrometer scale.

10.6. Immediately after observing the hydrometer scale value, cautiously stir the sample with the thermometer, keeping the mercury thread fully immersed. Record the temperature of the sample to the nearest 0.2ºC (0.5°F) (Note 5). Should this temperature differ from the previous reading by more than 0.5ºC (1.0°F), repeat the hydrometer and thermometer observations until the temperature becomes stable within 0.5ºC (1.0°F).

Note 5—After use at a temperature higher than 37.8ºC (100ºF), allow all hydrometers of the "lead shot-in-wax" type to drain and cool in a vertical position.

11. CALCULATION

11.1. Apply any relevant corrections to the observed thermometer reading (for the scale and bulb) and to the hydrometer reading (for the scale). Make the appropriate correction to the observed hydrometer reading. Record the corrected hydrometer reading to the nearest 0.1ºAPI, 0.001 relative density (specific gravity), or 1 kg/m^3 (0.1 lb/ft^3). After application of any relevant corrections, record the mean temperature values observed immediately before and after the final hydrometer reading to the nearest 0.5ºC (1.0°F).

11.2. To convert the observed hydrometer reading to density at 15ºC (60°F), use the following tables from ASTM D 1250, Guide for Use of the Petroleum Measurement Tables:

11.2.1. When an API gravity hydrometer has been used, use Table 5A to convert the hydrometer reading to the API gravity. Then use Table 3 to obtain the density at 15ºC (60°F).

11.2.2. When a relative density (specific gravity) hydrometer has been used, use Table 23A to convert the hydrometer reading to the relative density 15.6/15.6ºC (60°F). Then use Table 21 to obtain the density at 15ºC (60°F).

11.2.3. When a density-scaled hydrometer has been used, use Table 53A to obtain the density at 15ºC (60°F).

12. REPORT

12.1. Report the density at 15ºC (60°F) to the nearest 1 kg/m^3 (0.1 lb/ft^3).

13. PRECISION AND BIAS

13.1. *Single-Operator Precision*—The single-operator standard deviation for the relative density of cutback asphalts has been found to be 0.00195. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 5.5 kg/m^3 (0.3 lb/ft^3).

13.2. *Multilaboratory Precision*—The multilaboratory standard deviation for the relative density of cutback asphalts has been found to be 0.00276. Therefore, results of two properly conducted tests by two laboratories on samples of the same material should not differ by more than 7.8 kg/m^3 (0.5 lb/ft^3).

Note 6—These numbers represent the 1s and d2s limits as described in ASTM C 670.

13.3. *Bias*—The bias of this test method has not been determined.

14. KEYWORDS

14.1. API Gravity; cutback asphalt; density; hydrometer; liquid asphalt; relative density; specific gravity.

Standard Method of Test for

Force Ductility Test of Asphalt Materials

AASHTO Designation: T 300-00 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Force Ductility Test of Asphalt Materials

AASHTO Designation: T 300-00 (2008)

1. SCOPE

1.1. The force ductility of an asphalt material is determined by measuring the tensile stress induced on a specimen when two ends of a briquet specimen of the material are pulled apart at 5 cm/min (2 in./min) and at a specified temperature. Unless otherwise specified, the test shall be performed at a temperature of 4.0 ± 0.5°C (39.2 ± 1.0°F) and a speed of 5 cm/min (2 in./min) ± 5.0 percent. The test is designed primarily for polymer-modified emulsions.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This test may involve hazardous materials, operations, and equipment. This test does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 316, Polymer-Modified Cationic Emulsified Asphalt

2.2. *ASTM Standards*:

- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers
- E 77, Standard Test Method for Inspection and Verification of Thermometers
- E 220, Standard Test Method for Calibration of Thermocouples by Comparison Techniques
- E 644, Standard Test Methods for Testing Industrial Resistance Thermometers

3. SIGNIFICANCE AND USE

3.1. The force ductility test is an indicator of the presence of polymer in an asphalt material.

3.2. When testing CRS-2P, a polymer-modified cationic emulsified asphalt specified in AASHTO M 316, perform the test at a temperature of 4°C (39°F) and a speed of 5 cm/min (2 in./min). The test is performed on the residue from evaporation.

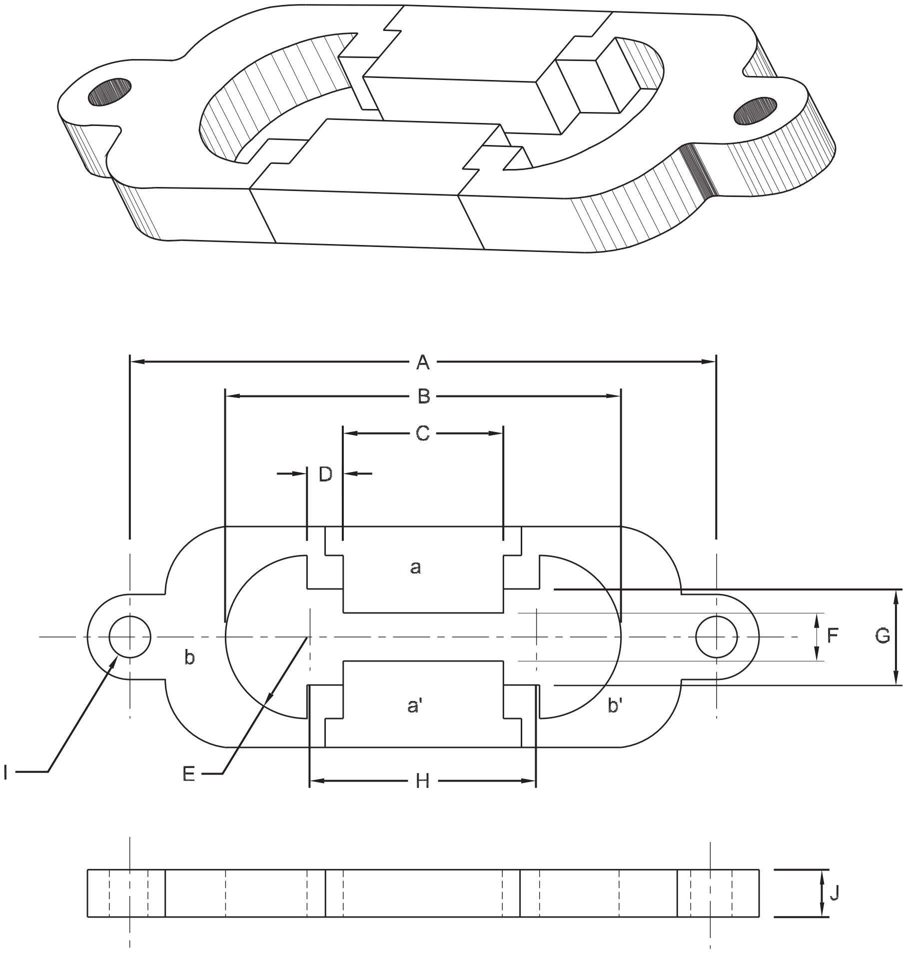
4. APPARATUS

4.1. *Molds*—The mold shall be similar in design to that shown in Figure 1 and made of brass. The dimensions of the assembled mold shall be as shown in Figure 1 with the permissible variations indicated.

4.2. *Base Plate*—The base plate shall be made of nonabsorbent material, of sufficient thickness to prevent deformation, and of a sufficient size to hold from one to three molds. The plate shall be uniformly flat to insure that the bottom surfaces of each mold will touch it throughout.

4.3. *Water Bath*—The water bath shall be maintained at the specified test temperature, varying not more than ±0.5ºC (±1.0ºF) from this temperature. The volume of water shall not be less than 10 L (10.5 qt). The depth of water shall not be less than 50 mm (2 in.) and such that the mold can be immersed to a depth of not less than 25 mm (1 in.). The water in the bath shall be free from oil and slime or other organic growth.

4.4. *Thermometers*—For tests at 4.0°C (39.2°F), use an ASTM Thermometer No. 63C (63F) as specified in ASTM E 1 to measure the temperature of the water bath and the temperature of the water in the testing machine. For tests at other temperatures, use ASTM thermometers of an appropriate range and accuracy equal to that of the No. 63. Since the accuracy of the test results is dependent upon closely controlled conditions of temperature, the thermometers should be standardized in accordance with ASTM E 77. An equivalent thermometric device that has been standardized in accordance with ASTM E 220 or E 644 may be used.



A - Distance between centers, 111.5 to 113.5 mm
B - Total length of briquet, 74.5 to 75.5 mm
C - Distance between clips, 29.7 to 30.3 mm
D - Shoulder, 6.8 to 7.2 mm
E - Radius, 15.75 to 16.25 mm
F - Width at minimum cross section, 9.9 to 10.1 mm
G - Width at mouth of clip, 19.8 to 20.2 mm
H - Distance between centers of radii, 42.9 to 43.1 mm
I - Hole diameter, 6.5 to 6.7 mm
J - Thickness, 9.9 to 10.1 mm

Figure 1—Mold Assembly

4.5. *Testing Machine*—For pulling the briquet of asphalt material apart, any apparatus may be used which is so constructed that the specimen will be continuously immersed in water, as specified in Section 4.3, while the two clips are pulled apart at a uniform speed, as specified, without undue vibration.

4.6. *Heater*—An oven or hot plate, heated by electricity or gas, may be used to melt the asphalt material.

4.7. *Container*—Any suitable container may be used to hold the asphalt material while it is being melted.

4.8. *Trimmer*—Any convenient implement, such as a putty knife or spatula, may be used provided that the cutting edge is straight and at least 38 mm ($1^1/_2$ in.) wide.

4.9. *Calibrated Force Adapter*—A stainless steel platform that incorporates an LVDT sensor for measuring tensile force [accurate to 0.04 N (0.01 lb)]. The unit is designed to utilize the existing pins on a ductility machine.

4.10. *Digital Indicator*—A power supply and digital display in Newtons (pounds) that serves the LVDT sensor on the force adapter. Includes a standard 0–5 VDC analog output for interfacing with a chart recorder, computer, or other readout.

4.11. *Chart Recorder (Optional)*—Records output of the digital indicator through the 0–5 VDC analog output.

5. PROCEDURE

5.1. *Preparation of Apparatus*—Assemble the mold on the base plate. To prevent the material from sticking, coat the surface of the plate and the interior surfaces of Sides a and a' (as indicated in Figure 1) with a suitable release agent.

Note 1—Mixtures of glycerin and dextrin or talc (3 g glycerin to about 5 g dextrin or talc has been used satisfactorily), Dow-Corning Silicone Stop-Cock Grease, or castor oil and Versamid 900 [100:1 mixture by mass heated to 204 to 232°C (400 to 450°F) and stirred until it is homogeneous] have proven suitable. Other release agents may be used provided the results obtained are comparable to those obtained when using one of the above.

5.2. *Molding Test Specimens*—Heat the sample with care to prevent local overheating until it has become sufficiently fluid to pour. After thorough stirring, pour the asphalt material into the mold, taking care not to entrain any air bubbles. Pour the material in a thin stream back-and-forth from end to end until the mold is more than “level full.” In filling the mold, take care not to disarrange the parts of the mold and distort the briquet. Let the mold and contents cool to room temperature for a period of 30 to 40 minutes, and then place the base plate and filled mold in the water bath maintained at the specified test temperature for 30 minutes. Remove the base plate and filled mold from the water bath, and with a hot trimmer, cut off the excess asphalt material so that the mold is just “level full.” Take care during the trimming operation that the specimen is not pulled away from the base plate or from the side pieces of the mold.

5.3. *Keeping Specimen at Standard Temperature*—Place the base plate and filled mold in the water bath or testing machine, and keep them at the specified temperature for a period of 85 to 95 minutes. Remove the briquet from the plate, detach the side pieces, and immediately test the briquet.

5.4. *Testing*—At the start of the test, the water in the tank of the testing machine shall cover the specimen both above and below by not less than 25 mm (1 in.). Attach the clips to the pins or hooks of the force adapter and the testing machine, and pull the clips apart at the specified rate of speed until the specified minimum ductility is met, the briquet ruptures, or the limit of travel of the machine is reached. If necessary, adjust the specific gravity of the liquid in the testing machine so that the asphalt material neither comes to the surface nor touches the bottom of the bath at any time during the test by adding a solute which does not interfere with the test (Note 2). Measure and record the distance through which the clips have been pulled.

Note 2—Solutes such as sodium chloride, methyl alcohol, or ethylene glycol have been used successfully.

6. REPORT

6.1. A normal test is one in which the material between the two clips is pulled out to a point where minimum ductility is met, rupture occurs at the point where the thread has practically no cross-sectional area, or until the capacity of the machine is reached. If the material comes in contact with the surface of the water or the bottom of the bath, the test shall not be considered normal.

6.2. A normal test will produce data which, when plotted, will result in a graph showing two peaks (f_1, f_2). Locate the two peaks on the graph of the data. The second peak will be less than the initial peak. If a readily definable second peak is not apparent, use the force at the minimum ductility (if specified), at the point of rupture, or at 30 cm (11.8 in.) as the second peak (f_2). The force ratio is defined as the force at the second peak (f_2) divided by the force at the initial peak (f_1).

6.3. Report the force ratio to the nearest 0.1.

7. PRECISION AND BIAS

7.1. *Precision*—The research required to develop precision estimates has not been conducted.

7.2. *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

8. KEYWORDS

8.1. Force ductility; ductility; force ratio; asphalt.

Standard Method of Test for

Elastic Recovery Test of Asphalt Materials by Means of a Ductilometer

AASHTO Designation: T 301-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Elastic Recovery Test of Asphalt Materials by Means of a Ductilometer

AASHTO Designation: T 301-08

1. SCOPE

1.1. This method is used to determine the elastic recovery of asphalt material through the use of a ductilometer and briquet specimens. The specimens are pulled apart at a rate of 5 cm/min (2 in./min) and held after a specified elongation. The specimens are then severed at the center and allowed to recover undisturbed for 1 hour.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This test may involve hazardous materials, operations, and equipment. This test does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standard*:

- E 77, Standard Test Method for Inspection and Verification of Thermometers

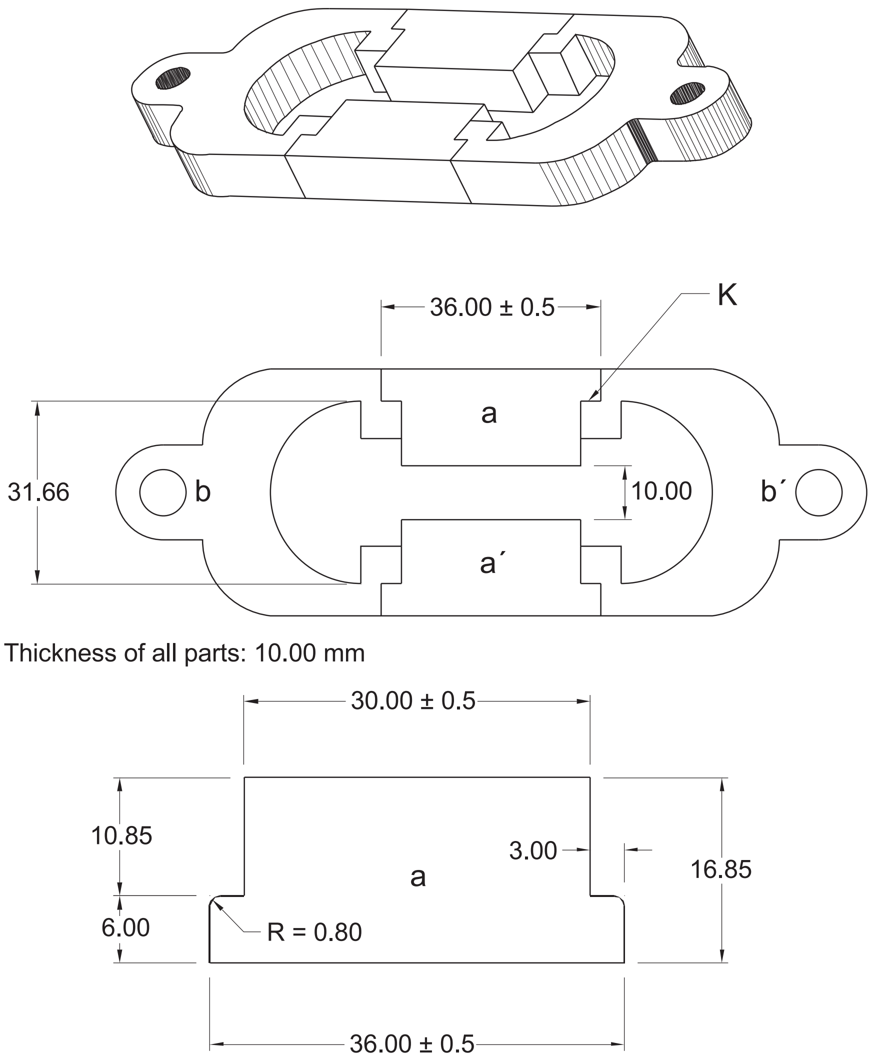
3. APPARATUS

3.1. *Molds*—The mold shall be similar in design to that shown in Figure 1. The mold shall be made of brass. The dimensions of the assembled mold shall be as shown with the permissible variations indicated.

3.2. *Base Plate*—The base plate shall be made of nonabsorbent material of sufficient thickness to prevent deformation and of a sufficient size to hold from one to three molds. The plate shall be uniformly flat to insure that the bottom surfaces of each mold will touch it throughout.

3.3. *Water Bath*—The water bath shall be maintained at the specified test temperature, varying not more than ±0.5ºC (±1.0ºF) from this temperature. The volume of water shall not be less than 10 L (2.6 gal). The depth of water shall not be less than 50 mm (2 in.) and such that the mold can be immersed to a depth of 25 mm (1 in.). The water in the bath shall be free from oil and slime or other organic growth.

3.4. *Thermometers*—For tests at 25ºC (77ºF), use ASTM Saybolt Viscosity Thermometer No. 17C (17F) to measure the temperature of the water bath and the temperature of the water in the testing machine. For tests at other temperatures, use ASTM thermometers of an appropriate range and accuracy equal to that of the No. 17. Since the accuracy of the test results is dependent upon closely controlled conditions of temperature, the thermometers should be calibrated in accordance with ASTM E 77.



Notes:
1. All dimensions in mm
2. Radius for clearance only
3. Thickness: 10.00 mm
4. Tolerances: ±0.1 mm unless otherwise specified
5. Material: 360 brass
6. Finish: None

Figure 1—Mold for Elastic Recovery Test Specimen

3.5. *Testing Machine*—For pulling the briquet of asphalt material apart, any apparatus may be used which is constructed so that the specimen will be continuously immersed in water as specified in Section 4.5 while the two clips are pulled apart at a uniform speed, without undue vibration.

3.6. *Heater*—An oven or hot plate, heated by electricity or gas, may be used to melt the asphalt material.

3.7. *Container*—Any suitable container may be used to hold the asphalt material while it is being melted.

3.8. *Trimmer*—Any convenient implement, such as a putty knife or spatula, may be used provided that the cutting edge is straight and at least 38 mm ($1^1/_2$ in.) wide.

3.9. *Scissors*.

4. PROCEDURE

4.1. *Preparation of Apparatus*—Assemble the mold on the base plate. To prevent the asphalt material from sticking, coat the surface of the plate and the interior surfaces of the sides with a suitable release agent (Note 1).

Note 1—Mixtures of glycerin and dextrine or talc (3 g of glycerin to about 5 g of dextrine or talc has been used satisfactorily), Dow-Corning Silicone Stop-Cock Grease, or castor oil-Versamid 900 (100:1 mixture by weight heated to 204 to 232ºC (400 to 450ºF) and stirred until it is homogeneous) has proven suitable. Other release agents may be used provided the results obtained are comparable to those obtained when using one of the above.

4.2. If the residue of a polymer-modified emulsion is being tested, the asphalt material obtained for the test should be the residue from oven evaporation of the emulsion sample at 162.8 ± 2.5ºC (325 ± 5ºF), not from distillation.

4.3. *Molding Test Specimens*—Heat the sample with care to prevent local overheating until it has become sufficiently fluid to pour. After thorough stirring, pour the asphalt material into the mold, taking care not to entrain any air bubbles. Pour the material in a thin stream back and forth from end to end until the mold is more than level full. In filling the mold, take care not to disarrange the parts of the mold and distort the briquet. Let the mold and contents cool to room temperature for 30 to 40 minutes. Then place the base plate and filled mold in the water bath maintained at the specified test temperature for 30 to 35 minutes. Remove the base plate and filled mold from the water bath and, with a hot trimmer, cut off the excess asphalt material so that the mold is just level full. Take care during the trimming operation that the specimen is not pulled away from the base plate or from the side pieces of the mold.

4.4. *Keeping Specimen at Standard Temperature*—Place the base plate and filled mold in the water bath or testing machine, and keep them at the specified temperature for 85 to 95 minutes. The test will be conducted at the specified temperature. Remove the briquet from the plate, detach the side pieces, and immediately test the briquet.

4.5. *Testing*—At the start of the test, the water in the tank of the testing machine shall cover the specimen both above and below. Also, the specimen shall be immersed to a depth of at least 25 mm (1 in.). Attach the clips to the pins of the testing machine, and pull the clips apart at 5 cm/min (2 in./min) ±5.0 percent until the briquet has been elongated to 20 cm (8 in.). After 20 cm (8 in.) has been reached, stop the ductilometer, and hold the specimen in its elongated position for 5 minutes. After 5 minutes, sever the specimen at its center with a pair of scissors, and allow the specimen to remain in the ductilometer, undisturbed, for 1 hour. At the end of 1 hour, release the ductilometer from the drive mechanism, and retract the half sample until the ends of the severed sample just touch. Read the ductilometer pointer, and record the value.

5. REPORT

5.1. Report the percent elongation recovery to the nearest whole number. The percent elongation recovery is given by the following equation:

$$\% \text{ Elongation Recovery} = \frac{20 - X}{20} \times 100 \qquad (1)$$

where:

X = final reading from the testing machine in centimeters after bringing the two severed ends of the specimen back together.

6. PRECISION AND BIAS

6.1. Information is not available to develop a precision and bias statement.

Standard Method of Test for

Polymer Content of Polymer-Modified Emulsified Asphalt Residue and Asphalt Binders

AASHTO Designation: T 302-05 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Polymer Content of Polymer-Modified Emulsified Asphalt Residue and Asphalt Binders

AASHTO Designation: T 302-05 (2009)

1. SCOPE

1.1. This test method is used to determine the percent concentration of a Styrene-Butadiene-Rubber (SBR), Styrene-Butadiene (SB), or Styrene-Butadiene-Styrene (SBS) polymer in a polymer-modified asphalt binder or emulsified asphalt residue. By using the infrared spectrum and the principles of Beer's Law, the polymer content of the asphalt material can be determined.

1.2. This test method implies that the equipment used for the analysis is operated by experienced personnel according to the manufacturer's directions for optimum performance. A thorough understanding of infrared spectral analysis is recommended.

1.3. *This standard involves hazardous materials, operations, or equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 59, Emulsified Asphalts

2.2. *Other Document*:

- Infrared Spectrophotometer Operator's Manual

3. APPARATUS

3.1. *Balance*—conforming to the requirements of M 231, Class G 1.

3.2. *Containers*—for blending the asphalt material with polymer–metal 1-Pt (0.47-L) cans with lids are suitable.

3.3. Variable-speed shearing mixer.

3.4. Heating coil with variable rheostat.

3.5. Thermometer for determining temperatures between 4 and 305ºC (40 and 580ºF).

3.6. High-temperature vacuum oven (if necessary for removal of residual moisture).

3.7. *Infrared Spectrophotometer or Fourier Transform Infrared Spectrometer*—capable of recording spectrum in the 1800 to 600 cm^{-1} region.

3.8. *Infrared Windows*—polished sodium chloride or potassium chloride windows, or other suitable medium for casting of infrared specimens. If testing by use of the attenuated total reflectance (ATR) method, an ATR accessory and the appropriate crystal are necessary.

3.9. *Testing by Solvent-Diluted Method*:

3.9.1. Glass vial with leak-resistant top.

3.9.2. Eyedroppers.

3.9.3. Infrared heat lamp.

3.9.4. Solvent.

Note 1—Trichloroethane, technical grade, or Tetrahydrofuran (THF) have been shown to be suitable solvents that do not interfere with the infrared spectrum. Other appropriate solvents may be used.

3.10. *Testing by ATR Method*:

3.10.1. Release paper (wax paper or other suitable medium).

3.10.2. *Spatula*—appropriate for spreading hot asphalt binder or emulsified asphalt residue.

3.10.3. *Solvent*—appropriate for removal of the test material from the infrared window.

4. PREPARATION OF CONTROL SAMPLES

4.1. Prepare a series of standards to cover the range from 0 to 5 percent weight-to-weight (w/w) polymer (rubber solids) according to Equation 1.

Note 2—The standards are prepared on a w/w percentage. This percentage is based on the solids weight of the polymer and the weight of the base asphalt binder or the emulsified asphalt residue. If the polymer is in an emulsified form or the standards are being made with an asphalt emulsion, an accurate determination of the rubber solids or percent asphalt residue must be made in order to prepare accurate standards.

4.1.1. This equation makes the assumption that there is no polymer contained in the base asphalt binder or emulsified asphalt (A) and that all solids in the polymer modifier are polymer (D):

$$E = \frac{(B)(A)(C)}{(100 - B)(D)} \qquad (1)$$

where:

E = mass of polymer modifier (g);

B = percent polymer in the standard (e.g., 1, 2, 3, etc.);

A = mass of the base asphalt binder or emulsified asphalt (g);

C = percent asphalt residue (determined by T 59 for emulsified asphalt, otherwise 100); and

D = percent rubber solids in polymer modifier (determined for emulsified polymers, otherwise 100).

4.2. For each standard, add the calculated amount of asphalt binder or emulsified asphalt needed into a container suitable for mixing. Allow sufficient material to be able to thoroughly blend each standard.

4.3. Heat the asphalt binder until it is fluid at a temperature not to exceed 163ºC (325ºF). An emulsion should be heated to 82 ± 1ºC (180 ± 2ºF).

4.4. While maintaining heat and with the mixer in operation, slowly add the calculated amount of polymer modifier for each standard to the container of base asphalt binder or emulsified asphalt. Allow the materials to mix thoroughly.

Note 3—The addition of solid polymers may require extensive heating and shearing. A gradual addition of the material may be necessary. Addition of emulsified polymers in heated asphalt binders should be performed slowly to prevent "boil-over."

5. PREPARATION OF POLYMER SAMPLES AND TESTING BY SOLVENT-DILUTED METHOD

5.1. Heat the asphalt binder until it is fluid, at a temperature not to exceed 163ºC (325ºF). An emulsion should be heated to 82 ± 1ºC (180 ± 2ºF) while stirring it to achieve a homogeneous state.

5.2. After the sample is thoroughly mixed, place approximately 1 g of the sample in a glass vial.

5.3. If there is any residual moisture in the sample, place the vial in a vacuum oven set at approximately 20 mm Hg and 104 ± 2ºC (220 ± 4ºF) until constant mass is achieved.

5.4. After drying, remove the vials from the oven, and cool them to room temperature.

5.5. Dilute the contents of each glass vial with approximately 10 mL (0.3 oz) of the solvent.

5.6. Shake the vial until the sample is completely dissolved in the solvent.

5.7. Place drops of each solvent-diluted material on a prepared infrared window using an eyedropper. Insure that an even layer is placed on the window.

Note 4—Five to nine drops of an asphalt material diluted 1 g to 10 mL (0.3 oz) on a 38 mm by 19 mm (1.5 in. by 0.75 in.) window has been shown to produce an adequate film thickness. Use of the ratio of the specified peak for the polymer to the peak for the asphalt negates any deviations due to film thickness.

5.8. Allow the solvent to evaporate at room temperature, or place the window under a heat lamp for approximately 10 min to drive off any residual solvent. Complete evaporation of any residual solvent will prevent the analysis of misleading spectra.

6. PROCEDURE—TESTING BY ATR METHOD

6.1. Heat the asphalt binder, or, heat the asphalt residue from evaporation (T 59) when testing emulsified asphalt, until it is fluid at a temperature not to exceed 163°C (325°F) while stirring it to achieve a homogenous state.

6.2. Pour the heated material, spreading it with a spatula, on a piece of release paper cut slightly larger than the face of an ATR crystal. Use enough material to result in a layer that will cover the face of the crystal. A thin film will make cleanup of the crystal easier. An asphalt thickness on the paper of about 1 mm (0.04 in.) is sufficient.

6.3. Prepare an ATR crystal following the manufacturer's guidelines.

6.4. Allow the material to cool for several minutes prior to affixing the asphalt surface in direct contact with the top of the face of the prepared ATR crystal. Apply finger pressure to the top of the asphalt material to push out any air bubbles. The material must make complete contact with the crystal without any bubbles. Examination of the underside of the crystal may expose any bubbles or points of non-contact.

Note 5—Follow the manufacturer's guidelines for treatment of the crystal. Placement of hot material or too much pressure on the face of the crystal may cause it to crack.

7. DATA COLLECTION AND ANALYSIS

7.1. *Analysis of the Standards*:

7.1.1. Using either the solvent-diluted or ATR method, acquire spectra on the prepared windows or crystal for each standard. Collection of a background spectrum is recommended prior to sample analysis.

7.1.2. Integrate the proper peak.

Note 6—The infrared spectrometer may be equipped with software that will quantify a specific peak or multiple peaks by using peak height or peak area. It may be necessary to correct the spectral baselines for offset or tilt.

7.1.2.1. For the solvent-diluted method, determine the absorbance at 965 cm^{-1} for the polymer modifier (SBR, SB, or SBS) and at 1375 cm^{-1} for the base asphalt binder or emulsified asphalt residue on each standard. Divide the value of the peak at 965 cm^{-1} (A_1) by the peak at 1375 cm^{-1} (A_2) to obtain the absorbance ratio of the relative peak values (A_1/A_2) of each standard. See the example in Figure 1.

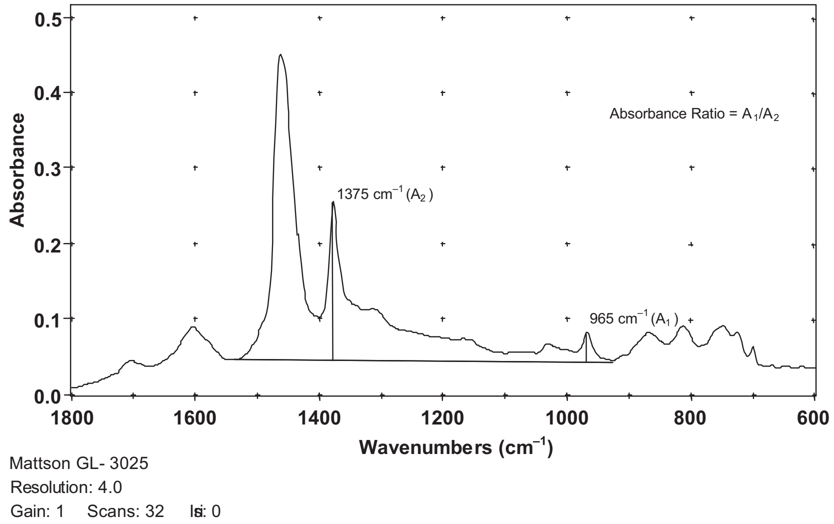


Figure 1—Infrared Scan of a Polymer-Modified Asphalt Material

7.1.2.2. For the ATR method, evaluate the peak area at 965 cm^{-1} for the polymer modifier (SBR, SB, or SBS). In the ATR method, the spectrum obtained is independent of the sample thickness, so it will not be necessary to integrate the peak at 1375 cm^{-1}.

7.1.3. Plot the absorbance ratio of the relative peak values (A_1/A_2) determined in the solvent-diluted method versus the corresponding polymer content or plot the peak area determined in the ATR method versus the corresponding polymer content, of each standard. Perform a first-order curve fit on the data to generate a standard curve. See the example for the solvent-diluted method in Table 1 and Figure 2.

Table 1—Typical Data for Standard Curve Development for Solvent-Diluted Method

Standard, % Polymer	Absorbance Ratio (A_1/A_2)
0	0.02
1	0.065
2	0.11
3	0.155
4	0.20
5	0.245

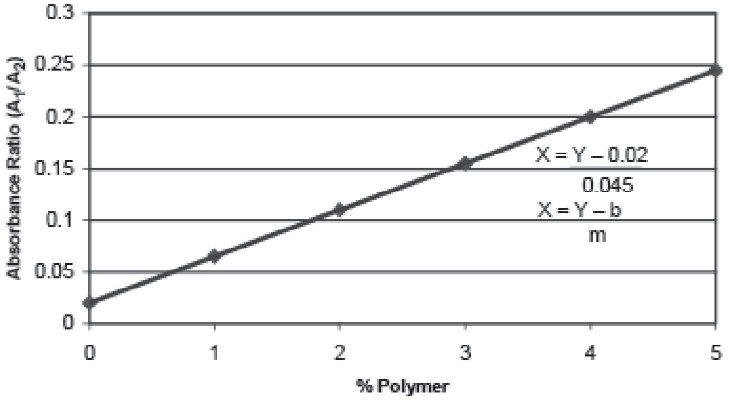

Figure 2—Polymer Content vs. Absorbance Ratio (A_1/A_2)—Solvent-Diluted Method

7.2. *Analysis of Sample*:

7.2.1. Analyze each sample using the applicable sections for the selected method (i.e., solvent-diluted or ATR) in Sections 7.1.1 through 7.1.2.2, and obtain the relative absorbance ratio (A_1/A_2) or peak area of the sample as appropriate.

7.2.2. Using the standard curve information, calculate the polymer content of the sample.

8. REPORT

8.1. The values determined for the polymer content shall be reported to the nearest 0.1 percent.

9. PRECISION AND BIAS

9.1. Information is currently not available to develop a precision and bias statement.

Standard Method of Test for

Determination of Draindown Characteristics in Uncompacted Asphalt Mixtures

---

AASHTO Designation: T 305-09

Washington, D.C. 20001

Standard Method of Test for

Determination of Draindown Characteristics in Uncompacted Asphalt Mixtures

AASHTO Designation: T 305-09

1. SCOPE

1.1. This test method covers the determination of the amount of draindown material in an uncompacted asphalt mixture sample when the sample is held at elevated temperatures comparable to those encountered during the production, storage, transport, and placement of the mixture. The test is particularly applicable to mixtures such as porous asphalt (open-graded friction course) and Stone Matrix Asphalt (SMA).

1.2. The values stated in the gram-millimeter units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- R 47, Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size
- T 245, Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus

3. DEFINITIONS

3.1. *Draindown material*—for the purpose of this test method, draindown material is considered to be that portion of material that separates itself from the sample as a whole and is deposited outside the wire basket during the test. The draindown material may be composed of either asphalt binder or a combination of asphalt binder and fine aggregate.

3.2. *Draindown*—the process by which draindown material separates itself from the sample as a whole.

4. SUMMARY OF METHOD

4.1. A sample of the asphalt mixture to be tested is prepared in the laboratory or obtained from field production. The sample is placed in a wire basket, which is positioned on a plate or other suitable container of known mass. The sample, basket, and plate or container are placed in a forced-draft oven for 1 hour at a pre-selected temperature. At the end of 1 hour, the basket containing the sample is removed from the oven, along with the plate or container and the mass of the plate or container is determined. The amount of draindown material is then calculated.

5. SIGNIFICANCE AND USE

5.1. This test method can be used to determine whether the amount of draindown material measured for a given asphalt mixture is within acceptable levels. The test provides an evaluation of the draindown potential of an asphalt mixture during mixture design or during field production. This test is primarily used for mixtures with high coarse aggregate content such as porous asphalt (open-graded friction course) and SMA.

6. APPARATUS

6.1. *Forced-draft oven*—capable of maintaining the temperature in a range from 120 to175ºC (250 to 350ºF). The oven should maintain the set temperature to within ±2ºC (±3.6ºF).

6.2. *Plates*—or other suitable containers of appropriate size. The plates or containers used should be of appropriate durability to withstand the oven temperatures. Cake pans or pie tins are examples of suitable types of containers.

6.3. *Standard Basket*—meeting the dimensions shown in Figure 1. The basket shall be constructed using standard 6.3-mm (0.25-in.) sieve cloth as specified in M 92.

6.4. *Balance*—accurate to 0.1 g.

6.5. *Other apparatus*—spatulas, trowels, bowls, and mixer as needed.

7. SAMPLE PREPARATION

7.1. *Laboratory-Prepared Samples*:

7.1.1. *Number of Samples*—For each mixture tested, the draindown characteristics should be determined at two different temperatures. The two temperatures should be the anticipated plant production temperature as well as 15ºC (27ºF) above that temperature (Note 1). For each temperature, duplicate samples should be tested. Thus for one asphalt mixture, a minimum of four samples will be tested.

Note 1—When using the test as part of the mixture design procedure, the test should be performed at two temperatures in order to determine the potential effect that plant temperature variation may have on the mixture during production. When the test is used in the field during production, it should be necessary to perform the test at the plant production temperature only.

7.1.2. Dry the aggregate to a constant mass and sieve it into the appropriate size fractions as indicated in T 245.

7.1.3. Determine the anticipated plant production temperature or select a mixing temperature in accordance with T 245.

7.1.4. Place into separate pans for each test sample the amount of each size fraction required to produce completed mixture samples having a mass of 1200 ± 200 g. The aggregate fractions shall be combined such that the resulting aggregate blend has the same gradation as the job mix formula. Place the aggregate samples in an oven and heat them to a temperature not to exceed the mixing temperature established in Section 7.1.3 by more than approximately 28ºC (50ºF).

7.1.5. Heat the asphalt binder to the temperature established in Section 7.1.3.

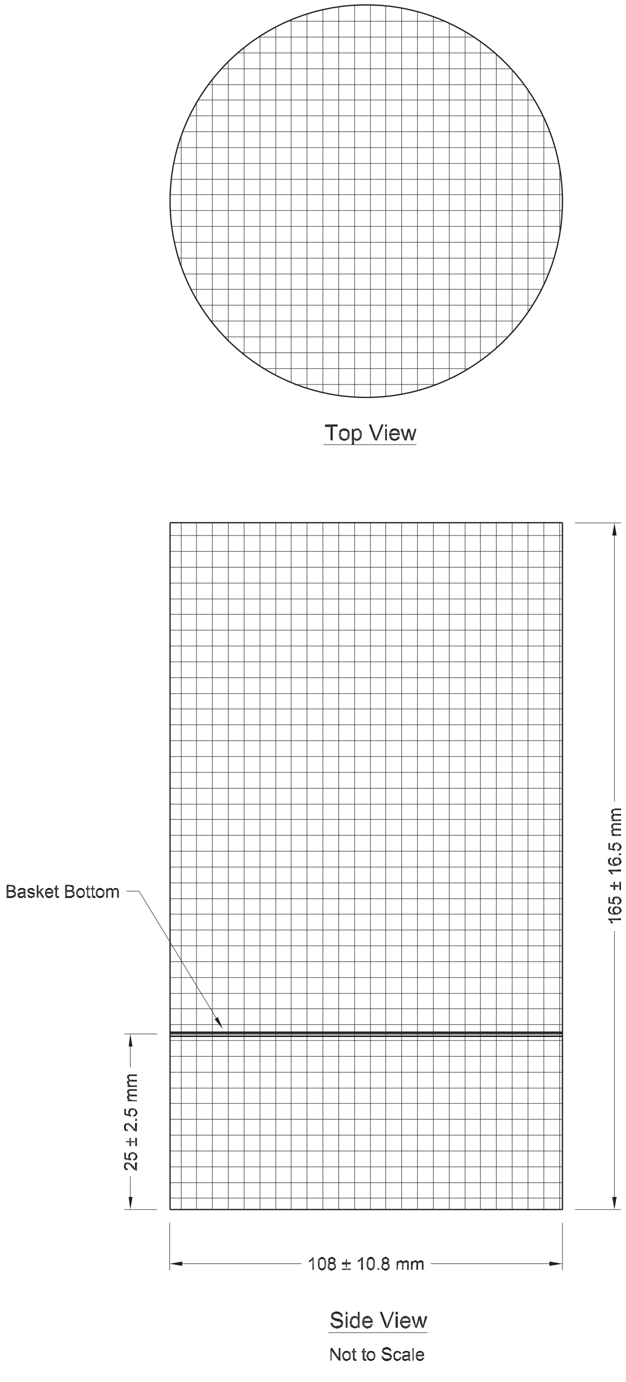

Figure 1—Wire Basket Assembly

7.1.6. Place the heated aggregate in the mixing bowl. Add any stabilizers (Note 2) and thoroughly mix the dry components. Form a crater in the aggregate blend and add the required amount of asphalt binder. The amount of asphalt binder shall be such that the final sample has the same asphalt content as the job mix formula. At this point, the temperature of the aggregate and asphalt binder shall be within the limits of the mixing temperature established in Section 7.1.3. Using a spatula (if mixing by hand) or a mixer, mix the aggregate (and stabilizer if any) and asphalt binder quickly until the aggregate is thoroughly coated.

Note 2—Some types of stabilizers such as fibers or some polymers must be added directly to the aggregate prior to mixing with the asphalt binder. Other types of stabilizers must be added directly to the asphalt binder prior to blending with the aggregate.

7.2. *Plant-Produced Samples*:

7.2.1. *Number of Samples*—For plant-produced samples, duplicate samples should be tested at the plant production temperature.

7.2.2. Samples may be obtained during plant production by sampling the mixture at any appropriate location such as the trucks prior to the mixture leaving the plant. Samples obtained during actual production should be reduced to the proper test sample size by R 47.

Note 3—Caution should be exercised when sampling from surge or storage bins because draindown may already have taken place.

8. PROCEDURE

8.1. Transfer the hot laboratory-produced or plant-produced uncompacted mixture sample to a tared wire basket as described in Section 6.3. Place the entire sample in the wire basket. Do not consolidate or otherwise disturb the sample after transferring it to the basket. Determine the mass of the sample to the nearest 0.1 g. Care should be exercised to ensure that the sample does not cool more than 25ºC (77°F) below the test temperature. (See Section 8.2.)

8.2. Determine and record the mass of a plate or other suitable container to the nearest 0.1 g. Place the basket on the plate or container and place the assembly into the oven at the temperature as determined in Section 7.1.1 or 7.2.1 for 60 ± 5 minutes. If the sample has cooled more than 25ºC (77°F) below the test temperature, the test should be conducted for 70 ± 5 min.

8.3. After the sample has been in the oven for the time specified in Section 8.2, remove the basket and plate or container from the oven. Determine and record the mass of the plate or container plus draindown material to the nearest 0.1 g.

9. CALCULATIONS

9.1. Calculate the percent of mixture that drained by subtracting the initial plate or container mass from the final plate or container mass and dividing this value by the initial total sample mass. Multiply the result by 100 to obtain a percentage.

$$\frac{M_f - M_i}{M_t} \times 100\% = \text{percent of mixture that drained or percent draindown}$$

where:

M_f = final plate or container mass,

M_i = initial plate or container mass, and

M_t = initial total sample mass.

10. REPORT

10.1. Report the average percent draindown (average percent of mixture that drained) at each of the test temperatures.

Standard Method of Test for

Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method

AASHTO Designation: T 308-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method

AASHTO Designation: T 308-10

1. SCOPE

1.1 This test method covers the determination of asphalt binder content of hot mix asphalt (HMA) by ignition at temperatures that reach the flashpoint of the binder in a furnace. The means of specimen heating may be the convection method or the direct infrared (IR) irradiation method. The aggregate remaining after burning can be used for sieve analysis using T 30.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 47, Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size
- T 2, Sampling of Aggregates
- T 30, Mechanical Analysis of Extracted
- T 40, Sampling Bituminous Materials
- T 168, Sampling Bituminous Paving Mixtures
- T 248, Reducing Samples of Aggregate to Testing Size
- T 329, Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

2.2 *Other Document*:

- Manufacturer's Instruction Manual

3. SUMMARY OF TEST METHOD

3.1 The asphalt binder in the HMA is ignited using the furnace equipment applicable to the particular method. This procedure covers two methods. Method A requires an ignition furnace with an internal balance. Method B requires an ignition furnace with an external balance.

3.2 The asphalt binder content is calculated as the difference between the initial mass of the HMA and the mass of the residual aggregate, with adjustments for an asphalt binder correction factor and the moisture content. The asphalt binder content is expressed as a mass percent of the moisture-free mixture. This method may be affected by the type of aggregate in the mixture. Accordingly, to optimize accuracy, correction factors for asphalt binder and aggregate will be established by testing a set of correction factor specimens for each type of HMA. Correction factors must be determined before any acceptance testing is performed.

4. SIGNIFICANCE AND USE

4.1 This method can be used for quantitative determinations of asphalt binder content and gradation in HMA and pavement specimens for quality control, specification acceptance, and mixture evaluation studies. This method does not require the use of solvents. Aggregate obtained by this test method may be used for gradation analysis according to T 30.

5. APPARATUS

5.1 *Ignition Furnace*—A forced-air ignition furnace that heats the specimens by either the convection or direct IR irradiation method. The convection-type furnace must be capable of maintaining the temperature at 578°C (1072°F). The furnace chamber dimensions shall be adequate to accommodate a specimen size of 3500 g. The furnace door shall be equipped so that the door cannot be opened during the ignition test. A method for reducing furnace emissions shall be provided. The furnace shall be vented into a hood or to the outside and, when set up properly, shall have no noticeable odors escaping into the laboratory. The furnace shall have a fan with the capability to pull air through the furnace to expedite the test and reduce the escape of smoke into the laboratory.

5.1.1 For Method A, the furnace shall also have an internal balance thermally isolated from the furnace chamber and accurate to 0.1 g. The balance shall be capable of weighing a 3500-g specimen in addition to the specimen baskets. A data collection system will be included so that the mass can be automatically determined and displayed during the test. The furnace shall have a built-in computer program to calculate the change in mass of the specimen baskets and provide for the input of a correction factor for aggregate loss. The furnace shall provide a printed ticket with the initial specimen mass, specimen mass loss, temperature compensation, correction factor, corrected asphalt binder content (percent), test time, and test temperature. The furnace shall provide an audible alarm and indicator light when the specimen mass loss does not exceed 0.01 percent of the total specimen mass for 3 consecutive minutes. The furnace shall also allow the operator to change the ending mass loss percentage to 0.02 percent.

5.2 *Specimen Basket Assembly*—consisting of specimen basket(s), catch pan, and an assembly guard to secure the specimen basket(s) to the catch pan.

5.2.1 *Specimen Basket(s)*—of appropriate size that allows the specimens to be thinly spread and allows air to flow through and around the specimen particles. Sets with two or more baskets shall be nested. The specimen shall be completely enclosed with screen mesh, perforated stainless steel plate, or other suitable material.

Note 1—Screen mesh or other suitable material with maximum and minimum openings of 2.36 mm (No. 8) and 0.600 mm (No. 30), respectively, has been found to perform well.

5.2.2 *Catch Pan*—of sufficient size to hold the specimen basket(s) so that aggregate particles and melting asphalt binder falling through the screen are caught.

5.3 *Oven*—Capable of maintaining 110 ± 5°C (230 ± 9°F).

5.4 *Balance*—of sufficient capacity and conforming to the requirements of M 231, Class G 2.

5.5 *Safety Equipment*—safety glasses or face shield, dust mask, high temperature gloves, long-sleeved jacket, a heat-resistant surface capable of withstanding 650°C (1202°F), and a protective cage capable of surrounding the specimen baskets during the cooling period.

5.6 *Miscellaneous Equipment*—a pan larger than the specimen basket(s) for transferring the specimen after ignition, spatulas, bowls, and wire brushes.

6. SAMPLING

6.1 Obtain samples of freshly produced HMA in accordance with T 168.

6.2 The specimen shall be the end result of reducing a larger sample in accordance with R 47.

6.3 If the mixture is not sufficiently soft to separate with a spatula or trowel, place it in a large, flat pan in an oven at 110 ± 5°C (230 ± 9°F) until it is workable. Do not leave the specimen in the oven for an extended period of time. Excessive heating may cause detrimental effects such as asphalt drain-down or oxidation.

6.4 The size of the test specimen shall be governed by the nominal-maximum aggregate size of the HMA and shall conform to the mass requirement shown in Table 1. When the mass of the specimen exceeds the capacity of the equipment used, the specimen may be divided into suitable increments, tested, and the results appropriately combined for calculation of the asphalt binder content (using a weighted average). Specimen sizes shall not be more than 500 g greater than the minimum recommended specimen mass.

Note 2—Large specimens of fine mixes tend to result in incomplete ignition of asphalt binder.

Table 1—Mass Requirements

Nominal-Maximum Aggregate Size,[a] mm	Sieve Size	Min Mass of Specimen, g
4.75	No. 4	1200
9.5	$^3/_8$ in.	1200
12.5	$^1/_2$ in.	1500
19.0	$^3/_4$ in.	2000
25.0	1 in.	3000
37.5	$1^1/_2$ in.	4000

[a] Nominal-maximum aggregate size—one size larger than the first sieve to retain more than 10 percent.

TEST METHOD A—INTERNAL BALANCE

7. TEST PROCEDURES

7.1 *Test Initiation*:

7.1.1 For the convection-type furnace, preheat the ignition furnace to 538°C (1000°F) or to the temperature determined by the correction factor process in the Annex. Manually record the furnace temperature (set point) prior to the initiation of the test if the furnace does not record automatically.

7.1.2 For the direct IR irradiation-type furnace, use the same burn profile as used during the correction factor determination.

7.2 Oven dry the HMA specimen to a constant mass at a temperature of 110 ± 5°C (230 ± 9°F), or determine the moisture content of a companion specimen according to T 329.

7.3 Enter into the ignition furnace, or manually record, the asphalt binder correction factor for the specific mix to be tested, as determined in the Annex.

7.4 Determine and record the mass of the specimen basket assembly to the nearest 0.1 g.

7.5 Prepare the specimen as described in Section 6. Place the specimen basket(s) in the catch pan. Evenly distribute the specimen in the basket(s), taking care to keep the material away from the edges of the basket. Use a spatula or trowel to level the specimen.

7.6 Determine and record the total mass of the specimen and specimen basket assembly at room temperature to the nearest 0.1 g. Calculate and record the initial mass of the specimen M_i (total mass minus the mass of the specimen basket assembly).

7.7 Input the initial mass of the specimen, M_i, in whole grams into the ignition furnace controller. Verify that the correct mass has been entered.

7.8 Open the chamber door, and place the specimen basket assembly in the furnace, carefully positioning the specimen basket assembly so it is not in contact with the furnace walls. Close the chamber door, and verify that the specimen mass (including the basket assembly) displayed on the furnace scale equals the total mass recorded in Section 7.6 within ±5 g. Differences greater than 5 g or failure of the furnace scale to stabilize may indicate that the specimen basket assembly is contacting the furnace wall.

Note 3—Due to the extreme heat of the furnace, the operator should wear safety equipment—high temperature gloves, face shield, fire-retardant shop coat—when opening the door to load or unload the specimen.

7.9 Initiate the test by pressing the start/stop button. This operation will lock the specimen chamber and start the combustion blower.

Note 4—The furnace temperature will drop below the set point when the door is opened but will recover with the door closed and when ignition occurs. Specimen ignition typically increases the temperature well above the set point, depending on the specimen size and asphalt binder content.

7.10 Allow the test to continue until the stable light and audible stable indicator indicate the test is complete (the change in mass does not exceed 0.01 percent for 3 consecutive minutes). Press the start/stop button. This operation will unlock the specimen chamber and cause the printer to print out the test results.

Note 5—An ending mass loss percentage of 0.02 may be substituted when aggregate exhibits an excessive amount of loss during ignition testing. The precision and bias statement was developed using 0.01 percent. Both precision and accuracy may be adversely affected by using 0.02 percent.

7.11 Open the chamber door; remove the specimen basket assembly, and place it on a cooling plate or block. Place the protective cage over the specimen basket assembly, and allow it to cool to room temperature (approximately 30 min).

7.12 Determine and record the total mass of the specimen and specimen basket assembly after ignition to the nearest 0.1 g. Calculate and record the final mass of the specimen, M_f (total mass minus the mass of the specimen basket assembly).

7.13 Use the corrected asphalt binder content (percent) from the printed ticket. If this value is not corrected, subtract the asphalt binder correction factor. If a moisture content has been determined per T 329, subtract the percent moisture from the asphalt binder content on the printed ticket, and report the resultant value as the corrected asphalt binder content (P_b).

Note 6—Asphalt binder content can also be calculated using Equation 1 from Method B (Section 8.16).

TEST METHOD B—EXTERNAL BALANCE

8. TEST PROCEDURES

8.1 Preheat the ignition furnace to 538°C (1000°F) or the temperature determined by the correction factor process in the Annex.

8.2 Oven dry the HMA specimen to a constant mass at a temperature of 110 ± 5°C (230 ± 9°F), or determine the moisture content of a companion specimen according to T 329.

8.3 Record the asphalt binder correction factor for the specific mix to be tested, as determined by the correction factor process in the Annex.

8.4 Determine and record the mass of the specimen basket assembly to the nearest 0.1 g.

8.5 Prepare the specimen as described in Section 5. Place the specimen baskets in the catch pan. Evenly distribute the specimen in the basket(s), taking care to keep the material away from the edges of the basket. Use a spatula or trowel to level the specimen.

8.6 Determine and record the total mass of the specimen basket assembly at room temperature to the nearest 0.1 g. Calculate and record the initial mass of the specimen, M_i (total mass minus the mass of the specimen basket assembly).

8.7 Open the chamber door and place the specimen basket assembly in the furnace. Burn the HMA specimen in the furnace for at least 45 min.

Note 7—The appropriate time for the initial burn of an HMA specimen is dependent on the specimen size. For large specimens, the time could be significantly longer than 45 min. See the manufacturer's manual for guidelines.

8.8 Open the chamber door; remove the specimen and specimen basket assembly and place it on a cooling plate or block. Place the protective cage over the specimen basket assembly, and allow it to cool to room temperature (approximately 30 min).

8.9 Determine and record the total mass of the specimen and specimen basket assembly after cooling to the nearest 0.1 g.

8.10 Place the specimen and specimen basket assembly back into the furnace.

8.11 Burn the specimen for at least 15 min after the furnace reaches the set point temperature.

8.12 Open the chamber door, remove the specimen and specimen basket assembly, and place it on a cooling plate or block. Place the protective cage over the specimen basket assembly, and allow it to cool to approximately room temperature (approximately 30 min).

8.13 Weigh and record the total mass of the specimen and specimen basket assembly after cooling to the nearest 0.1 g.

8.14 Repeat Sections 8.10 through 8.13 until the change in measured mass of the specimen after ignition does not exceed 0.01 percent of the initial specimen mass, M_i.

Note 8—An ending mass loss percentage of 0.02 may be substituted when aggregate exhibits an excessive amount of loss during ignition testing. The precision and bias statement was developed using 0.01 percent. Both precision and accuracy may be adversely affected by using 0.02 percent. After the time required to obtain the specified mass loss has been established for each mixture, repeated mass determinations may not be necessary.

8.15 Calculate and record the final mass of the specimen, M (total mass minus the mass of the specimen basket assembly).

8.16 Calculate the asphalt binder content of the specimen as follows:

$$P_b, \% = \left[\frac{\left(M_i - M_f\right)}{M_i} \times 100 \right] - C_F - MC \qquad (1)$$

where:

P_b = the measured (corrected) asphalt binder content, percent;

M_i = the total mass of the HMA specimen prior to ignition, g;

M_f = the total mass of aggregate remaining after the ignition, g;

C_F = the correction factor, percent by mass of HMA specimen; and

MC = the moisture content of companion HMA specimen, percent, as determined by T 329. (If the specimen was oven dried prior to initiating the procedure, $MC = 0$.)

9. GRADATION

9.1 Allow the contents of the specimen baskets to cool to room temperature prior to performing the gradation analysis. Empty the contents of the baskets into a flat pan, being careful to capture all material. Use a small wire sieve brush to ensure that any residual fines are removed from the baskets and catch pan.

9.2 Perform the gradation analysis according to T 30.

10. REPORT

10.1 *The report shall include the following*:

10.1.1 Test method (A or B);

10.1.2 Corrected asphalt binder content;

10.1.3 Correction factor;

10.1.4 Temperature compensation factor (if applicable);

10.1.5 Total percent loss;

10.1.6 Specimen mass;

10.1.7 Moisture content (if determined, per T 329); and

10.1.8 Test temperature.

Note 9—If Method A is performed, attach the original printed ticket to the report.

11. PRECISION AND BIAS

11.1 *Precision*—Criteria for judging the acceptability of ignition burn results for asphalt content obtained by Method A or Method B are given in Table 2.

11.1.1 *Single-Operator Precision*—The figures in Column 2 of Table 2 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results exceeds the values given in Table 2, Column 3.

11.1.2 *Multilaboratory Precision*—The figures in Column 2 of Table 2 are the standard deviations that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results exceeds the values given in Table 2, Column 3.

Table 2—Precision Estimates

Condition	Standard Deviation, (1s)[a]	Acceptable Range of Two Test Results, (d2s)[a]
Single-Operator Precision		
Asphalt content (%)	0.069	0.196
Multilaboratory Precision		
Asphalt content (%)	0.117	0.330

[a] These values represent the 1s and d2s limits described in ASTM C 670

Note 10—The precision estimates given in Table 2 are based on the analysis of test results from three pairs of AMRL proficiency samples. The data analyzed consisted of results from 353 to 461 laboratories for each of the three pairs of samples. The analysis included two binder grades: PG 52-34 and PG 64-22. Average results for asphalt content ranged from 4.049 to 5.098 percent. The details of this analysis are in NCHRP Final Report, NCHRP Project No. 9-26, Phase 3.

Note 11—The precision estimates are based on four aggregate types, four replicates, and 12 laboratories participating with no laboratory results deleted as outlying observations. All four aggregates were tested in surface mixes and had relatively low absorption values.

11.2 *Bias*—Any biases inherent to the ignition oven process used for Test Methods A and B, when testing for asphalt content and aggregate gradation, are accounted for by the determination and application of appropriate correction factors.

ANNEX

(Mandatory Information)

CORRECTION FACTORS

A1. ASPHALT BINDER AND AGGREGATE

A1.1. Asphalt binder content results may be affected by the type of aggregate in the mixture and the ignition furnace. Therefore, asphalt binder and aggregate correction factors must be established by testing a set of correction specimens for each job mix formula (JMF) mix design. Correction factor(s) must be determined before any acceptance testing is completed and repeated each time a change in the mix ingredients or design occurs. Any changes greater than 5 percent in stockpiled aggregate proportions should require a new correction factor. Historical data or scientific studies may be used to determine the correction factor(s) in lieu of using this testing procedure if the testing agency provides reference to the studies/data.

A1.1.1. *Asphalt binder correction factor*—Certain aggregate types may result in unusually high correction factors (greater than 1.0 percent). Such mixes should be corrected and tested at a lower temperature, as described below. Each ignition furnace will have its own unique asphalt binder correction factor determined in the location where testing will be performed.

A1.1.2. *Aggregate correction factor*—Due to potential aggregate breakdown during the ignition process, an aggregate correction factor will be determined for each ignition furnace in the location where testing will be performed when the following conditions occur: aggregates that have a proven history of excessive breakdown or aggregates from an unknown source.

A2. CORRECTION FACTOR PROCEDURE

A2.1. Obtain samples of aggregate in accordance with T 2.

A2.2. Obtain samples of asphalt binder in accordance with T 40.

Note A1—Include other additives that may be required by the JMF.

A2.3. Prepare an initial, or "butter mix" at the design asphalt binder content. Mix and discard the butter mix prior to preparing any of the correction specimens to ensure an accurate asphalt binder content.

A2.4. Prepare two correction specimens at the JMF design asphalt binder content and gradation. Aggregate used for correction specimens shall be sampled from the material designated for use in production. An additional "blank" (aggregate only) specimen shall be batched at the JMF gradation. Determine an aggregate gradation in accordance with T 30 on the "blank" specimen.

A2.5. Place the freshly mixed specimens directly into the specimen basket assembly. If specimens are allowed to cool prior to placement in the specimen basket assembly, the specimens must be dried to constant mass at a temperature of 110 ± 5°C (230 ± 9°F). Do not preheat the specimen basket assembly.

A2.6. Test the specimens in accordance with Method A or Method B of the procedure.

A2.7. Once both of the correction specimens have been burned, determine the asphalt binder content for each specimen by calculation or from the printed oven tickets, if available.

A2.8. If the difference between the asphalt binder contents of the two specimens exceeds 0.15 percent, repeat Section A2.3 through A2.7 with two more specimens and, from the four results, discard the high and low result. Determine the correction factor from the two original or remaining results as appropriate. Calculate the difference between the actual and measured asphalt binder contents for each specimen. The asphalt binder correction factor, C_F, is the average of the differences expressed as a percentage by mass of the HMA.

A2.8.1. If the asphalt binder correction factor exceeds 1.0 percent, the test temperature should be lowered to 482 ± 5°C (900 ± 8°F) for convection type furnace. If there is no improvement in the correction factor, it is permissible to use the higher temperature.

Note A2—The temperature for determining the asphalt binder content of HMA specimens by this procedure shall be the same temperature determined for the correction specimens.

A2.8.2. For the direct IR irradiation-type furnaces, the DEFAULT burn profile should be used for most materials. The operator may select burn-profile OPTION 1 or OPTION 2 to optimize the burn cycle. Option 1 is designed for aggregate that require a large aggregate correction factor (greater than 1 percent)—typically very soft aggregate (such as dolomite). Option 2 is designed for samples that may not burn completely using the DEFAULT burn profile. The burn profile for testing HMA samples shall be the same burn profile selected for correction samples.

A2.9. Perform a gradation analysis on the residual aggregate in accordance with T 30, if required. The results will be utilized in developing an aggregate correction factor and should be calculated and reported to the nearest 0.1 percent.

A2.9.1. From the gradation results, subtract the percent passing for each sieve for each specimen from the percent passing each sieve of the "blank" specimen gradation results from Section A2.4.

A2.9.2. Determine the average difference for the two values. If the difference for any single sieve exceeds the allowable difference for that sieve as listed in Table A1, then aggregate gradation correction factors (equal to the resultant average differences) for all sieves shall be applied to all acceptance gradation test results determined by T 30, prior to final rounding and reporting. If the 0.075-mm (No. 200) sieve is the only sieve outside the limits in Table A1, apply the aggregate correction factor to only the 0.075-mm (No. 200) sieve.

Table A1—Permitted Sieving Difference

Sieve	Allowable Difference
Sizes larger than or equal to 2.36 mm (No. 8)	±5.0 percent
Sizes larger than 0.075 mm (No. 200) and smaller than 2.36 mm (No. 8)	±3.0 percent
Sizes 0.075 mm (No. 200) and smaller	±0.5 percent

Standard Method of Test for

Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

AASHTO Designation: T 312-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

AASHTO Designation: T 312-09

1. SCOPE

1.1. This standard covers the compaction of cylindrical specimens of hot mix asphalt (HMA) using the Superpave gyratory compactor.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 30, Mixture Conditioning of Hot Mix Asphalt (HMA)
- R 35, Superpave Volumetric Design for Hot Mix Asphalt (HMA)
- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt Using Saturated Surface-Dry Specimens
- T 168, Sampling Bituminous Paving Mixtures
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 275, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Paraffin-Coated Specimens
- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer
- TP 71, Evaluation of Superpave Gyratory Compactor (SGC) Internal Angle of Gyration Using Simulated Loading

2.2. *Other Standard*:

- ASME B46.1, Surface Texture, Surface Roughness, Waviness and Lay

3. SIGNIFICANCE AND USE

3.1. This standard is used to prepare specimens for determining the mechanical and volumetric properties of HMA. The specimens simulate the density, aggregate orientation, and structural characteristics obtained in the actual roadway when proper construction procedure is used in the placement of the paving mix.

3.2. This test method may be used to monitor the density of test specimens during their preparation. It may also be used for field control of an HMA production process.

4. APPARATUS

4.1. *Superpave Gyratory Compactor*—An electrohydraulic or electromechanical compactor with a ram and ram heads as described in Section 4.3. The axis of the ram shall be perpendicular to the platen of the compactor. The ram shall apply and maintain a pressure of 600 ± 18 kPa perpendicular to the cylindrical axis of the specimen during compaction (Note 1). The compactor shall tilt the specimen molds at an average internal angle of 20.2 ± 0.35 mrad (1.16 ± 0.02 degrees), determined in accordance with TP 71. The compactor shall gyrate the specimen molds at a rate of 30.0 ± 0.5 gyrations per minute throughout compaction.

Note 1—This stress calculates to 10 600 ± 310 N total force for 150-mm specimens.

4.1.1. *Specimen Height Measurement and Recording Device*—When specimen density is to be monitored during compaction, a means shall be provided to continuously measure and record the height of the specimen to the nearest 0.1 mm during compaction once per gyration.

4.1.2. The system may include a connected printer capable of printing test information, such as specimen height per gyration. In addition to a printer, the system may include a computer and suitable software for data acquisition and reporting.

4.2. *Specimen Molds*—Specimen molds shall have steel walls that are at least 7.5 mm thick and are hardened to at least a Rockwell hardness of C48. The initial inside finish of the molds shall have a root mean square (rms) of 1.60 μm or smoother when measured in accordance with ASME B46.1 (Note 2). Molds shall have an inside diameter of 149.90 to 150.00 mm and be at least 250 mm high at room temperature.

Note 2—One source of supply for a surface comparator, which is used to verify the rms value of 1.60 μm, is GAR Electroforming, Danbury, Connecticut.

4.3. *Ram Heads and Mold Bottoms*—Ram heads and mold bottoms shall be fabricated from steel with a minimum Rockwell hardness of C48. The ram heads shall stay perpendicular to their axis. The platen side of each mold bottom shall be flat and parallel to its face. All ram and base plate faces (the sides presented to the specimen) shall be flat to meet the smoothness requirement in Section 4.2 and shall have a diameter of 149.50 to 149.75 mm.

4.4. *Thermometers*—Armored, glass, or dial-type thermometers with metal stems for determining the temperature of aggregates, binder, and HMA between 10 and 232°C.

4.5. *Balance*—A balance meeting the requirements of M 231, Class G 5, for determining the mass of aggregates, binder, and HMA.

4.6. *Oven*—An oven, thermostatically controlled to ±3°C, for heating aggregates, binder, HMA, and equipment as required. The oven shall be capable of maintaining the temperature required for mixture conditioning in accordance with R 30.

4.7. *Miscellaneous*—Flat-bottom metal pans for heating aggregates, scoop for batching aggregates, containers (grill-type tins, beakers, containers for heating asphalt), large mixing spoon or small trowel, large spatula, gloves for handling hot equipment, paper disks, mechanical mixer (optional), lubricating materials recommended by the compactor manufacturer.

4.8. *Maintenance*—In addition to routine maintenance recommended by the manufacturer, check the Superpave gyratory compactor's mechanical components for wear, and perform repair, as recommended by the manufacturer.

5. HAZARDS

5.1. Use standard safety precautions and protective clothing when handling hot materials and preparing test specimens.

6. STANDARDIZATION

6.1. Items requiring periodic verification of calibration include the ram pressure, angle of gyration, gyration frequency, LVDT (or other means used to continuously record the specimen height), and oven temperature. Verification of the mold and platen dimensions and the inside finish of the mold are also required. When the computer and software options are used, periodically verify the data-processing system output using a procedure designed for such purposes. Verification of calibration, system standardization, and quality checks may be performed by the manufacturer, other agencies providing such services, or in-house personnel. Frequency of verification shall follow the manufacturer's recommendations.

6.2. The angle of gyration refers to the internal angle (tilt of mold with respect to end plate surface within the gyratory mold). The calibration of the internal angle of gyration should be verified in accordance with TP 71.

7. PREPARATION OF APPARATUS

7.1. Immediately prior to the time when the HMA is ready for placement in the mold, turn on the main power for the compactor for the manufacturer's required warm-up period.

7.2. Verify the machine settings are correct for angle, pressure, and number of gyrations.

7.3. Lubricate any bearing surfaces as needed per the manufacturer's instructions.

7.4. When specimen height is to be monitored, the following additional item of preparation is required. Immediately prior to the time when the HMA is ready for placement in the mold, turn on the device for measuring and recording the height of the specimen, and verify the readout is in the proper units, mm, and the recording device is ready. Prepare the computer, if used, to record the height data, and enter the header information for the specimen.

8. HMA MIXTURE PREPARATION

8.1. Weigh the appropriate aggregate fractions into a separate pan, and combine them to the desired batch weight. The batch weight will vary based on the ultimate disposition of the test specimens. If a target air void level is desired, as would be the case for Superpave mix analysis and performance specimens, batch weights will be adjusted to create a given density in a known volume. If the specimens are to be used for the determination of volumetric properties, the batch weights will be adjusted to result in a compacted specimen having dimensions of 150 mm in diameter and 115 ± 5 mm in height at the desired number of gyrations.

Note 3—It may be necessary to produce a trial specimen to achieve this height requirement. Generally, 4500 to 4700 g of aggregate are required to achieve this height for aggregates with combined bulk specific gravities of 2.55 to 2.70, respectively.

8.2. Place the aggregate and binder container in the oven, and heat them to the required mixing temperature.

8.2.1. The mixing temperature range is defined as the range of temperatures where the unaged binder has a viscosity of 0.17 ± 0.02 Pa·s when measured in accordance with T 316.

Note 4—Modified asphalts may not adhere to the equiviscosity requirements noted, and the manufacturer's recommendations should be used to determine mixing and compaction temperatures.

8.3. Charge the mixing bowl with the heated aggregate from one pan and dry-mix thoroughly. Form a crater in the dry-blended aggregate, and weigh the required amount of binder into the mix. Immediately initiate mixing.

8.4. Mix the aggregate and binder as quickly and thoroughly as possible to yield HMA having a uniform distribution of binder. As an option, mechanical mixing may be used.

8.5. After completing the mixture preparation, perform the required mixture conditioning in accordance with R 30.

8.6. Place a compaction mold and base plate in an oven at the required compaction temperature for a minimum of 30 minutes prior to the estimated beginning of compaction (during the time the mixture is being conditioned in accordance with R 30).

8.7. Following the mixture conditioning period specified in R 30, if the mixture is at the compaction temperature, proceed immediately with the compaction procedure as outlined in Section 9. If the compaction temperature is different from the mixture conditioning temperature used in accordance with R 30, place the mix in another oven at the compaction temperature for a brief time (maximum of 30 minutes) to achieve the required temperature.

8.7.1. The compaction temperature is the midpoint of the range of temperatures where the unaged binder has a viscosity of 0.28 ± 0.03 Pa·s when measured in accordance with T 316 (Note 4).

8.8. If loose HMA plant mix is used, the sample should be obtained in accordance with T 168. The mixture shall be brought to the compaction temperature range by careful, uniform heating in an oven immediately prior to molding.

9. COMPACTION PROCEDURE

9.1. When the compaction temperature is achieved, remove the heated mold, base plate, and upper plate (if required) from the oven. Place the base plate and a paper disk in the bottom of the mold.

9.2. Place the mixture into the mold in one lift. Care should be taken to avoid segregation in the mold. After all the mix is in the mold, level the mix, and place another paper disk and upper plate (if required) on top of the leveled material.

9.3. Load the charged mold into the compactor, and center the loading ram.

9.4. Apply a pressure of 600 ± 18 kPa on the specimen.

9.5. Apply a 20.2 ± 0.35 mrad (1.16 ± 0.02 degrees) average internal angle to the mold assembly, and begin the gyratory compaction.

9.6. Allow the compaction to proceed until the desired number of gyrations specified in R 35 is reached and the gyratory mechanism shuts off.

9.7. Remove the angle from the mold assembly, remove the ram pressure, and retract the loading ram in the order specified by the SGC manufacturer (the preceding steps may be done automatically by the compactor on some models of SGCs). Remove the mold from the compactor (if required), and extrude the specimen from the mold.

Note 5—No additional gyrations with the angle removed are required unless specifically called for in another standard referencing T 312. The extruded specimen may not be a right angle cylinder. Specimen ends may need to be sawed to conform to the requirements of specific performance tests.

Note 6—The specimens can be extruded from the mold immediately after compaction for most HMA. However, a cooling period of 5 to 10 minutes in front of a fan may be necessary before extruding some specimens to ensure the specimens are not damaged.

9.8. Remove the paper disks from the top and bottom of the specimens.

Note 7—Before reusing the mold, place it in an oven for at least 5 minutes. The use of multiple molds will speed up the compaction process.

10. DENSITY PROCEDURE

10.1. Determine the maximum specific gravity (G_{mm}) of the loose mix in accordance with T 209 using a companion sample. The companion sample shall be conditioned to the same extent as the compaction sample.

10.2. Determine the bulk specific gravity (G_{mb}) of the specimen in accordance with T 166 or T 275 as appropriate.

10.3. When the specimen height is to be monitored, record the specimen height to the nearest 0.1 mm after each revolution.

11. DENSITY CALCULATIONS

11.1. Calculate the uncorrected relative density ($\%G_{mmux}$) at any point in the compaction process using the following equation:

$$\%G_{mmux} = \frac{W_m}{V_{mx} G_{mm} G_m} \times 100 \tag{1}$$

where:

$\%G_{mmux}$ = uncorrected relative density at any point during compaction expressed as a percent of the maximum theoretical specific gravity;

W_m = mass of the specimen in g;

G_{mm} = theoretical maximum specific gravity of the mix;

G_m = unit weight of water, 1 g/cm^3;

x = number of gyrations; and

V_{mx} = volume of the specimen, in cm^3, at any point based on the diameter (d) and height (h_x) of the specimen at that point (use "mm" for height and diameter measurements).

It can be expressed as:

$$V_{mx} = \frac{\pi d^2 h_x}{4 \times 1000} \tag{2}$$

Note 8—This formula gives the volume in cm^3 to allow a direct comparison with the specific gravity.

11.2. At the completion of the bulk specific gravity test (G_{mb}), determine the relative density ($\%G_{mmx}$) at any point in the compaction process as follows:

$$\%G_{mmx} = \frac{G_{mb} h_m}{G_{mm} h_x} \times 100 \tag{3}$$

where:

$\%G_{mmx}$ = corrected relative density expressed as a percent of the maximum theoretical specific gravity;

G_{mb} = bulk specific gravity of the extruded specimen;

h_m = height in millimeters of the extruded specimen; and

h_x = height in millimeters of the specimen after x gyrations.

12. REPORT

12.1. Report the following information in the compaction report, if applicable:

12.1.1. Project name;

12.1.2. Date of the test;

12.1.3. Start time of the test;

12.1.4. Specimen identification;

12.1.5. Percent binder in specimen, nearest 0.1 percent;

12.1.6. Average diameter of the mold used (d), nearest 1.0 mm;

12.1.7. Mass of the specimen (W_m), nearest 0.1 g;

12.1.8. Maximum specific gravity (G_{mm}) of the specimen by T 209, nearest 0.001;

12.1.9. Bulk specific gravity (G_{mb}) of the specimen by T 166 or T 275, nearest 0.001;

12.1.10. Height of the specimen after each gyration (h_x), nearest 0.1 mm;

12.1.11. Relative density ($\%G_{mm}$) expressed as a percent of the theoretical maximum specific gravity (G_{mm}), nearest 0.1 percent; and

12.1.12. Gyration angle, nearest 0.2 mrad (0.01 degrees), and the method used to determine or verify the gyration angle.

13. PRECISION AND BIAS

13.1. *Precision*:

13.2. *Single Operator Precision*—The single operator standard deviations (1s limits) for relative densities at N_{ini} and N_{des} for mixtures containing aggregate with an absorption of less than 1.5 percent are shown in Table 1. The results of two properly conducted tests on the same material, by the same operator, using the same equipment, should be considered suspect if they differ by more than the d2s single operator limits shown in Table 1.

13.3. *Multilaboratory Precision*—The multilaboratory standard deviations (1s limits) for relative densities at N_{ini} and N_{des} for mixtures containing aggregate with an absorption of less than 1.5 percent are shown in Table 1. The results of two properly conducted tests on the same material, by different operators, using different equipment, should be considered suspect if they differ by more than the d2s multilaboratory limits shown in Table 1.

Table 1—Precision Estimates[a]

	1s limit Relative Density (%)	d2s limit Relative Density (%)
Single Operator Precision:		
12.5-mm nominal max agg.	0.3	0.9
19.0-mm nominal max agg.	0.5	1.4
Multilaboratory Precision:		
12.5-mm nominal max agg.	0.6	1.7
19.0-mm nominal max agg.	0.6	1.7

[a] Based on an interlaboratory study described in NCHRP Research Report 9-26 involving 150-mm diameter specimens with 4 to 5 percent air voids, 26 laboratories, two materials (a 12.5-mm mixture and a 19.0-mm mixture), and three replicates. Specimens were prepared in accordance with T 312-04. The angle of gyration was verified using Method A, external angle.

13.4. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

14. KEYWORDS

14.1. Compaction; density; gyratory.

Standard Method of Test for

Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)

AASHTO Designation: T 313-10

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)

AASHTO Designation: T 313-10

1. SCOPE

1.1. This test method covers the determination of the flexural creep stiffness or compliance of asphalt binders by means of a bending beam rheometer. It is applicable to material having a flexural stiffness value from 20 MPa to 1 GPa (creep compliance values in the range of 50 nPa–1 to 1 nPa–1) and can be used with unaged material or with material aged using T 240 (RTFOT) and/or R 28 (PAV). The test apparatus is designed for testing within the temperature range from –36 to 0°C.

1.2. Test results are not valid for beams of asphalt binder that deflect more than 4 mm, or less than 0.08 mm, when tested in accordance with this method.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

3.1.2. *physical hardening*—a time-dependent stiffening of asphalt binder that results from the time-delayed increase in stiffness when the asphalt binder is stored at low temperatures. The increase in stiffness due to physical hardening is reversible when the temperature is raised.

3.2. *Descriptions of Terms Specific to This Standard*:

3.2.1. *flexural creep*—a test in which a simply supported asphalt binder prismatic beam is loaded with a constant load at its midpoint and the deflection of the beam is measured with respect to loading time.

3.2.2. *measured flexural creep stiffness,* $S_m(t)$—ratio obtained by dividing the maximum bending stress in the beam by the maximum bending strain.

3.2.3. *estimated creep stiffness,* $S(t)$—the creep stiffness obtained by fitting a second order polynomial to the logarithm of the measured stiffness at 8.0, 15.0, 30.0, 60.0, 120.0, and 240.0 seconds and the logarithm of time.

3.2.4. *flexural creep compliance,* $D(t)$—ratio obtained by dividing the maximum bending strain in the beam by maximum bending stress. $D(t)$ is the inverse of $S(t)$. $S(t)$ has been used historically in asphalt technology, while $D(t)$ is commonly used in studies of viscoelasticity.

3.2.5. *m-value*—absolute value of the slope of the logarithm of the stiffness curves versus the logarithm of the time.

3.2.6. *contact load*—load required to maintain positive contact between the beam and the loading shaft; 35 ± 10 mN.

3.2.7. *seating load*—load of 1-second duration required to seat the beam; 980 ± 50 mN.

3.2.8. *test load*—load of 240-second duration required to determine the stiffness of material being tested; 980 ± 50 mN.

3.2.9. *testing zero time, s*—time at which the signal is sent to the solenoid valve to switch from zero load regulator (contact load) to the testing load regulator (test load).

4. SUMMARY OF TEST METHOD

4.1. The bending beam rheometer measures the midpoint deflection of a simply supported beam of asphalt binder subjected to a constant load applied to the midpoint of the beam. The device operates only in the loading mode; recovery measurements are not obtained.

4.2. A test beam is placed in the controlled temperature fluid bath and loaded with a constant load for 240 seconds. The test load (980 ± 50 mN) and the midpoint of deflection of the beam are monitored versus time using a computerized data acquisition system.

4.3. The maximum bending stress at the midpoint of the beam is calculated from the dimensions of the beam, the span length, and the load applied to the beam for loading times of 8, 15, 30, 60, 120, and 240 seconds. The maximum bending strain in the beam is calculated for the same loading times from the dimensions of the beam and the deflection of the beam. The stiffness of the beam for the loading times specified above is calculated by dividing the maximum stress by the maximum strain.

4.4. The load and deflection at 0.0 and 0.5 seconds are reported to verify that the full-testing load (980 ± 50 mN) during the test is applied within the first 0.5 second. They are not used in the calculation of stiffness and *m*-value and should not be considered to represent material properties. The rise time of the load (time to apply full load) can be affected by improper operation of the pressure regulators, improper air bearing pressure, malfunctioning air bearing (friction), and other factors. By reporting the 0.0- and the 0.5-second signals, the user of the test results can determine the conditions of the loading.

5. SIGNIFICANCE AND USE

5.1. The test temperature for this test is related to the temperature experienced by the pavement in the geographical area for which the asphalt binder is intended.

5.2. The flexural creep stiffness or flexural creep compliance, determined from this test, describes the low-temperature, stress-strain-time response of asphalt binder at the test temperature within the linear viscoelastic response range.

5.3. The low-temperature thermal cracking performance of paving mixtures is related to the creep stiffness and the slope of the logarithm of the creep stiffness versus the logarithm of the time curve of the asphalt binder contained in the mix.

5.4. The creep stiffness and the slope of the logarithm of the stiffness versus the logarithm of the time curve are used as performance-based specification criteria for asphalt binders in accordance with M 320.

6. APPARATUS

6.1. *Bending Beam Rheometer (BBR) Test System*—A bending beam rheometer (BBR) test system consisting of (1) a loading frame which permits the test beam, supports, and the lower part of the test frame to be submerged in a constant temperature fluid bath; (2) a controlled temperature liquid bath which maintains the test beam at the test temperature and provides a buoyant force to counterbalance the force resulting from the mass of the beam; (3) a computer-controlled automated data acquisition component; (4) specimen molds; and (5) items needed to calibrate and/or verify the BBR.

6.1.1. *Loading Frame*—A frame consisting of a set of sample supports, a blunt-nosed shaft that applies the load to the midpoint of the test specimen, a load cell mounted on the loading shaft, a means for zeroing the load on the test specimen, a means for applying a constant load to the loading shaft, and a deflection measuring transducer attached to the loading shaft. A schematic of the device is shown in Figure 1.

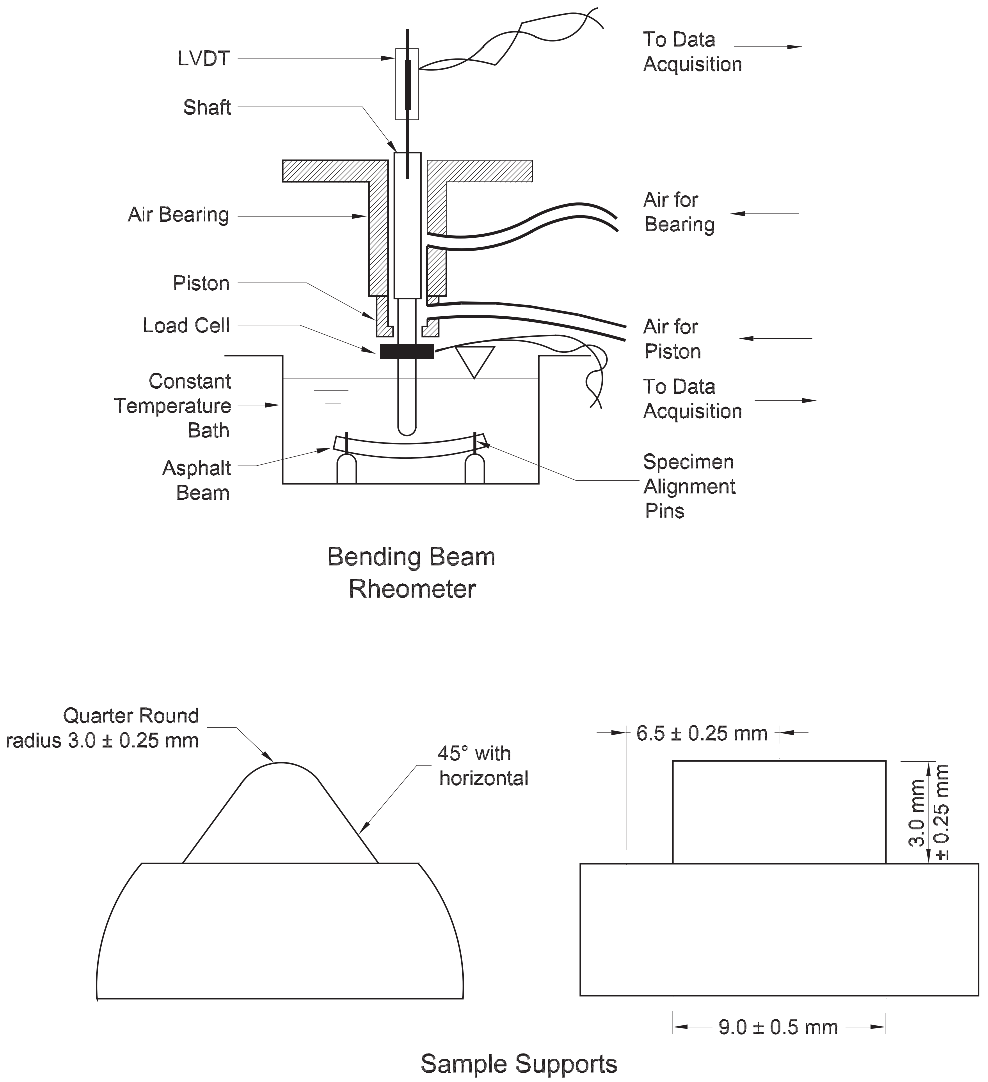

Figure 1—Schematic of the Bending Beam Rheometer

6.1.1.1. *Loading System*—A loading system that is capable of applying a contact load of 35 ± 10 mN to the test specimen and maintaining a test load of 980 ± 50 mN.

6.1.1.2. *Loading System Requirements*—The rise time for the test load shall be less than 0.5 second. The rise time is the time required for the load to rise from the 35 ± 10 mN contact load to the 980 ± 50 mN test load. During the rise time, the system shall dampen the test load to 980 ± 50 mN. Between 0.5 and 5.0 seconds, the test load shall be within ±50 mN of the average test load, and thereafter shall be within ±10 mN of the average test load.

6.1.1.3. *Sample Supports*—Sample supports with specimen support strips 3.0 ± 0.30 mm in top radius and inclined at an angle of 45 degrees with the horizontal (see Figure 1). The supports, made of stainless steel (or other corrosion-resistant metal), are spaced 102.0 ± 1.0 mm apart. The width of the supporting area of the supporting strips shall be 9.5 ± 0.25 mm. This is required to ensure that the edges of the specimen, resulting from the molding procedure, do not interfere with the mid-span deflection of the specimen measured during testing. The supports shall also include vertical alignment pins 2 to 4 mm in diameter placed at the back of each sample supports at 6.75 ± 0.25

mm from the center of the supports. These pins should be placed on the back side of the support to align the specimen on the center of the supports. See Figure 1 for details.

6.1.1.4. *Loading Shaft*—A blunt-nosed loading shaft (with a spherical contact point 6.25 (±0.30) mm in radius) continuous with a load cell and a deflection measuring transducer which is capable of applying a contact load of 35 ± 10 mN and maintaining a test load of 980 ± 50 mN. The rise time for the test load shall be less than 0.5 second where the rise time is the time required for the load to rise from the 35 ± 10 mN preload to the 980 ± 50 mN test load. During the rise time, the system shall dampen the test load after the first 5 seconds to a constant ±10-mN value.

6.1.1.5. *Load Cell*—A load cell with a minimum capacity of 2,000 mN, having a minimum resolution of 2.5 mN mounted in-line with the loading shaft and above the fluid to measure the contact load and the test load.

6.1.1.6. *Linear Variable Differential Transducer (LVDT)*—A linear variable differential transducer or other suitable mounted device mounted axially above the loading shaft capable of resolving a linear movement ≤ 2.5 μm with a range of at least 6 mm to measure the deflection of the test beam.

6.1.2. *Controlled-Temperature Fluid Bath*—A controlled-temperature liquid bath capable of maintaining the temperature at all points within the bath between –36 and 0°C within ±0.1°C. Placing a cold specimen in the bath may cause the bath temperature to fluctuate ±0.2°C from the target test temperature; consequently, bath fluctuations of ±0.2°C during isothermal conditioning shall be allowed.

6.1.2.1. *Bath Agitator*—A bath agitator for maintaining the required temperature homogeneity with agitator intensity such that the fluid current does not disturb the testing process, and mechanical noise caused by vibrations is less than the resolution specified in Sections 6.1.3 and 6.1.3.1.

6.1.2.2. *Circulating Bath (Optional)*—A circulating bath unit separate from the test frame which pumps the bath fluid through the test bath. If used, vibrations from the circulating system shall be isolated from the bath test chamber so that mechanical noise is less than the resolution specified in Sections 6.1.3 and 6.1.3.1.

6.1.3. *Data Acquisition System*—A data acquisition system that resolves loads to the nearest 2.5 mN, beam deflection to the nearest 2.5 μm, and bath fluid temperature to the nearest 0.1°C. The system shall sense the point in time when the signal is sent to the solenoid valve(s) to switch from zero load regulator (contact load) to the testing load regulator (test load). This is zero time. Using this time as a reference, the system shall provide a record of load and deflection measurements relative to this time. The system shall record the load and deflection at the loading times of 0.0, 0.5, 8.0, 15.0, 30.0, 60.0, 120.0, and 240.0 seconds. All readings shall be an average of three or more points within ±0.2 seconds from the loading time, e.g., for a loading time of 7.8, 7.9, 8.0, 8.1, and 8.2 seconds.

6.1.3.1. *Signal Filtering*—Digital or analog smoothing of the load and the deflection data may be required to eliminate electronic noise that could otherwise affect the ability of the second order polynomial to fit the data with sufficient accuracy to provide a reliable estimate of *m*-value. The load and deflection signals may be filtered with a low pass analog or digital filter that removes signals of greater than 4 Hz frequency. The averaging shall be over a time period less than or equal to ±0.2 seconds of the reporting time.

6.2. *Temperature Measuring Equipment*—A calibrated temperature transducer capable of measuring the temperature to 0.1°C over the range of –36 to 0°C mounted within 50 mm of the midpoint of the test specimen supports.

Note 1—Required temperature measurement can be accomplished with an appropriately calibrated platinum resistance thermometer (RTD) or a thermistor. Calibrations of an RTD or thermistor can be verified as per Section 6.6. An RTD meeting DIN Standard 43760 (Class A) is recommended for this purpose. The required precision and accuracy cannot be obtained unless each RTD is calibrated as a system with its respective meter or electronic circuitry.

6.3. *Test Beam Molds*—Test beam molds of suitable dimensions to yield demolded test beam 6.35 ± 0.05-mm thick by 12.70 ± 0.05-mm wide by 127 ± 2.0-mm long fabricated from aluminum flat stock as shown in Figure 2.

6.3.1. The thickness of the two spacers used for each mold (small end pieces used in the metal molds) shall be measured with a micrometer and shall not vary from each other in thickness by more than 0.05 mm.

Note 2—Small errors in the thickness of the test specimen can have a large effect on the calculated modulus because the calculated modulus is a function of the thickness, h, raised to the third power.

6.4. *Items for Calibration or Verification*—The following items are required to verify and calibrate the BBR.

6.4.1. *Stainless Steel (Thick) Beam for Compliance Measurement and Load Cell Calibration*—One stainless steel beam, 6.4 ± 0.1-mm thick by 12.7 ± 0.25-mm wide by 127 ± 5-mm long, for measuring system compliance and calibrating the load cell.

6.4.2. *Stainless Steel (Thin) Beam for Overall System Check*—One stainless steel beam, 1.3 ± 0.3-mm thick by 12.7 ± 0.1-mm wide by 127 ± 5-mm long, with an elastic modulus reported to three significant figures by the manufacturer. The manufacturer shall measure and report the thickness of this beam to the nearest 0.01 mm and the width to the nearest 0.05 mm. The dimensions of the beam shall be used to calculate the modulus of the beam during the overall system check. See Section 10.1.2.1.

6.5. *Standard Masses*—One or more standard masses are required as follows:

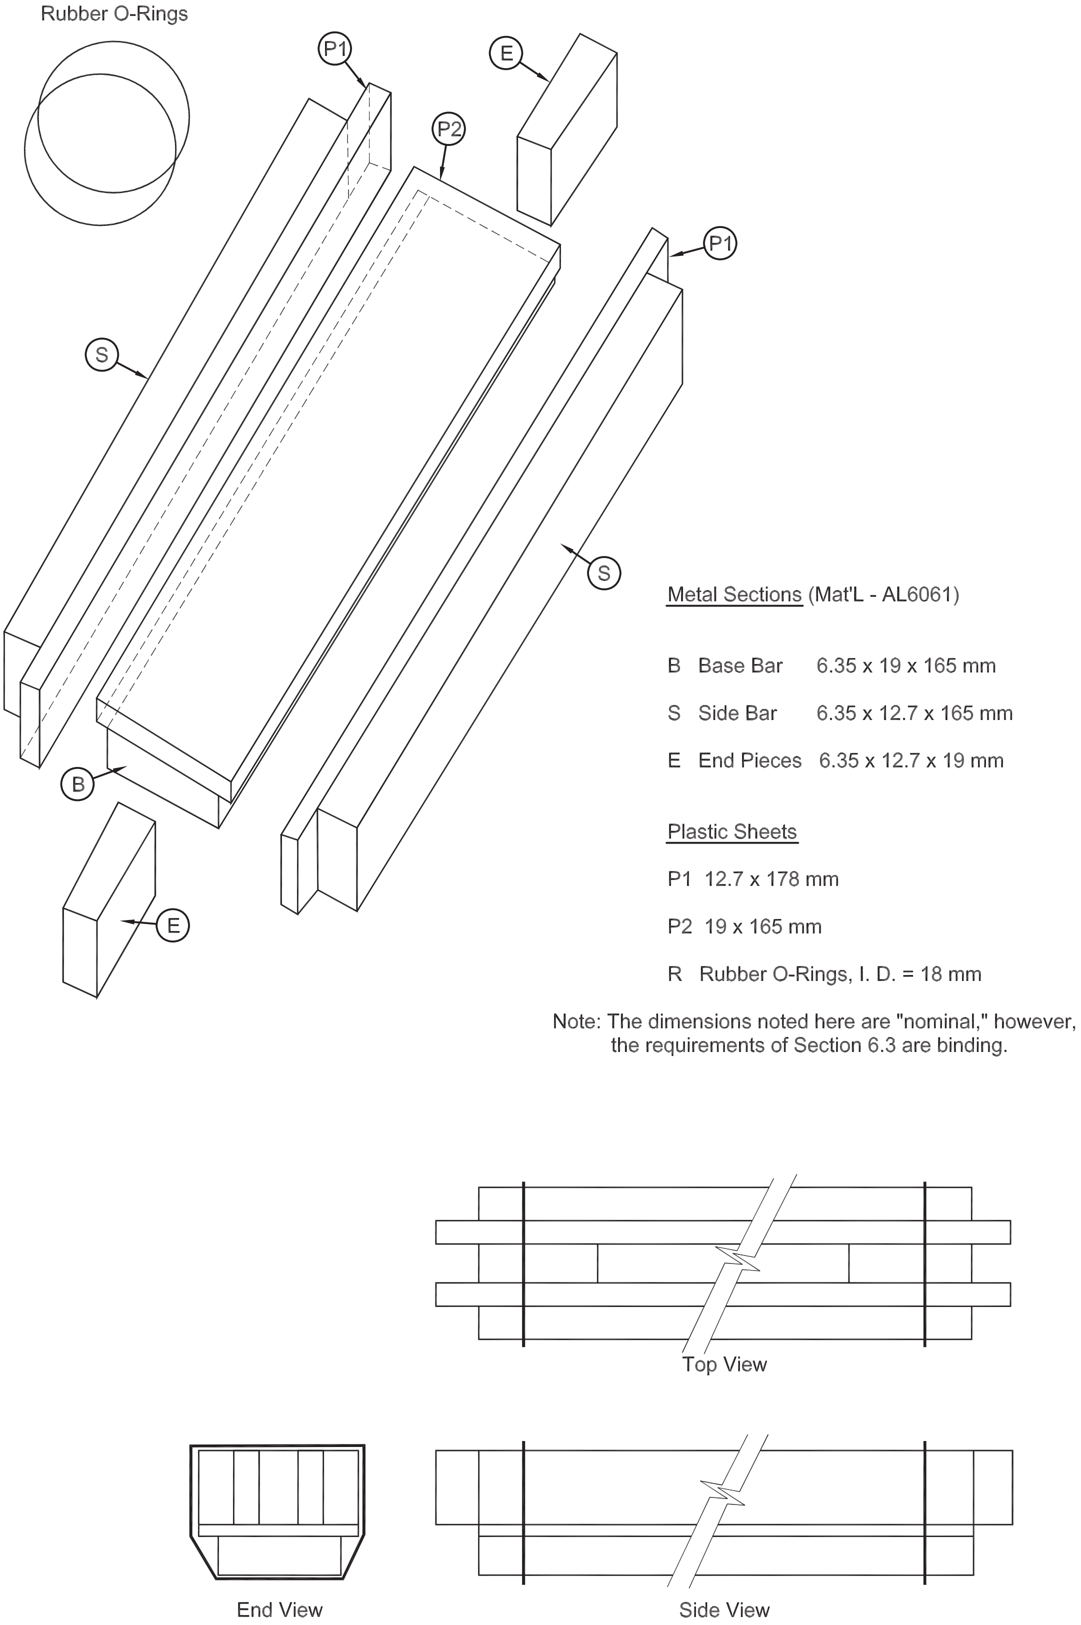
6.5.1. *Verification of Load Cell Calibration*—One or more masses totaling 100 ± 0.2 g and two masses of 2 ± 0.2 g each (see Note 3) for verifying the calibration of the load cell.

Note 3—Any suitable object may be used if the mass is confirmed to be 2 ± 0.2 g.

6.5.2. *Calibration of Load Cell*—Four masses, each of known mass ±0.2 g, and equally spaced in mass over the range of the load cell.

6.5.3. *Daily Overall System Check*—Two or more masses, each of known mass to 0.2 g, for conducting overall system check as specified by the manufacturer.

6.5.4. *Accuracy of Masses*—Accuracy of the masses in Section 6.5 shall be verified at least once each every 3 years.



Metal Sections (Mat'L - AL6061)

B Base Bar 6.35 x 19 x 165 mm

S Side Bar 6.35 x 12.7 x 165 mm

E End Pieces 6.35 x 12.7 x 19 mm

Plastic Sheets

P1 12.7 x 178 mm

P2 19 x 165 mm

R Rubber O-Rings, I. D. = 18 mm

Note: The dimensions noted here are "nominal," however, the requirements of Section 6.3 are binding.

Figure 2—Dimensions and Specifications for Aluminum Molds

6.6. *Calibrated Thermometers*—Calibrated liquid-in-glass thermometers for verification of the temperature transducer of suitable range with subdivisions of 0.1°C. These thermometers shall be partial immersion thermometers with an ice point and shall be calibrated in accordance with Test Method E 77 at least once per year. A suitable thermometer is designated 133C. An electronic thermometer of equal accuracy and resolution may be used.

6.7. *Thickness Gauge*—A stepped thickness gauge for verifying the calibrations of displacement transducer as described in Figure 3.

7. MATERIALS

7.1. *Plastic Sheeting*—Clear plastic sheeting, 0.12 ± 0.04-mm thick, for lining the interior faces of the three long aluminum mold sections. Sheeting should not be distorted by hot asphalt binder.

Note 4—Transparency film sold for use with laser printers has been found suitable.

7.2. *Petroleum-Based Grease*—A petroleum-based grease used to hold the plastic strips to the interior faces of the three long aluminum mold sections.

Note 5—Warning: Do not use any silicone-based products.

7.3. *Glycerol-Talc Mixture*—Used to coat the end pieces of aluminum molds.

Note 6—A mixture of 50 percent by weight USP grade glycerin and 50 percent USP grade talc or kaolin (china clay) is suitable for this purpose.

7.4. *Bath Fluid*—A bath fluid that is not absorbed by or does not affect the properties of the asphalt binder tested. The mass density of the bath fluid shall not exceed 1.05 g/cm^3 at testing temperatures. The bath fluid shall be optically clear at all testing temperatures. Silicone fluids or mixtures containing silicones shall not be used.

Note 7—Suitable bath fluids include ethanol, methanol, and glycol-methanol mixtures (e.g., 60 percent glycol, 15 percent methanol, 25 percent water).

8. HAZARDS

8.1. Observe standard laboratory safety procedures when handling hot asphalt binder and preparing test specimens.

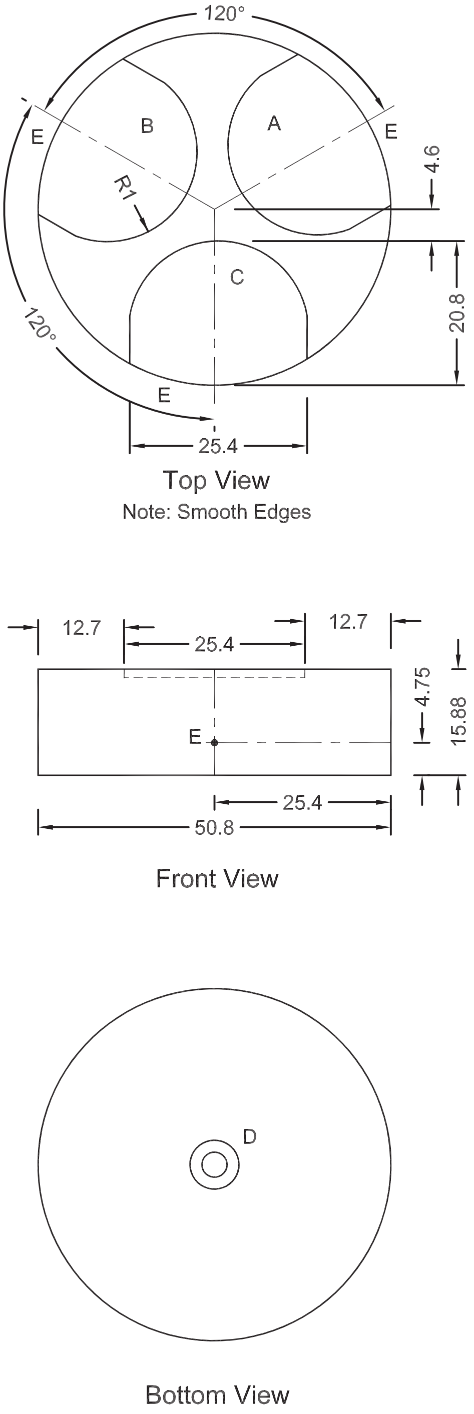
8.2. Alcohol baths are flammable and toxic. Locate the controlled temperature bath in a well-ventilated area away from sources of ignition. Avoid breathing alcohol vapors and contact of the bath fluid with the skin.

8.3. Contact between the bath fluid and skin at the lower temperatures used in this test method can cause frostbite.

9. PREPARATION OF APPARATUS

9.1. Clean the supports, loading head, and bath fluid of any particulates and coatings as necessary.

Note 8—Because of the brittleness of asphalt binder at the specified test temperatures, small fragments of asphalt binder can be introduced into the bath fluid. If these fragments are present on the supports or the loading head, the measured deflection will be affected. The small fragments, because of their small size, will deform under load and add an apparent deflection of the beam. Filtration of the bath fluid will aid in preserving the required cleanliness.



Note: Sections A, B, and C are depressions with depths from the top surface as follows:

A 1.00 mm (0.0394") ± 0.01 mm

B 3.00 mm (0.1181")

C 6.00 mm (0.2362")

Hole Sizes:

D 4 mm dia x 7.0 mm deep, Counterbore 6 mm dia x 0.8 mm deep

E Depression, 2.4 mm Ball End Mill, 1.52 mm deep. Three places in-line with corresponding top surface depressions.

Note: 1. Bottom surface is flat and parallel with top surface.
2. All dimensions are in millimeters unless otherwise indicated.

Figure 3—Typical Thickness Gauge Used to Calibrate Deflection Detector

9.2. Select the test temperature and adjust the bath fluid to the selected temperature. Wait until the temperature stabilizes and then allow the bath to equilibrate to the test temperature ±0.1°C prior to conducting a test.

9.3. Activate the data acquisition system and load the software as explained in the manufacturer's manual for the test system.

10. STANDARDIZATION

10.1. Verify the calibration of the displacement transducer, load cell, and temperature transducer as described in Sections 10.1.1 through 10.1.6. As a minimum, each of the verification steps and their frequency of performance shall be performed as described in this section. Additional verification steps may be performed at the recommendation of the manufacturer. Calibration procedures are described in the Annex. At the option of the manufacturer, the verification and calibration steps may be combined.

10.1.1. *Verification of Temperature Transducer*—On each day, before conducting tests, and whenever the test temperature is changed, verify calibration of the temperature detector by using a calibrated thermometer as described in Section 6.6. With the loading frame placed in the liquid bath, immerse the thermometer in the liquid bath close to the temperature transducer, and compare the temperature indicated by the thermometer to the temperature displayed by the data acquisition system. If the temperature indicated by the data acquisition system does not agree with the thermometer within ±0.1°C, calibration is required.

10.1.2. *Verification of Freely Operating Air Bearing*—On each day, before conducting tests, verify that the air bearing is operating freely and is free of friction. Sections 10.1.2.1 and 10.1.2.2 shall be used to verify that the shaft is free of friction. If the requirements of Sections 10.1.2.1 and 10.1.2.2 are not satisfied, friction is present in the air bearing. Clean the shaft, and adjust the clearance of the displacement transducer as per the manufacturer's instructions. If this does not eliminate the friction, discontinue use of the BBR, and consult the manufacturer.

Note 9—Friction may be caused by a poorly adjusted displacement transducer core that rubs against its housing, an accumulation of asphalt binder on the loading shaft, by oil or other particulates in the air supply, and other causes.

10.1.2.1. Place the thin steel beam (Section 6.4.2) on the sample supports, and apply a 35 ± 10-mN load to the beam using the zero load regulator. Observe the reading of the LVDT as indicated by the data acquisition system. Gently grasp the shaft, and lift it upwards approximately 5 mm by observing the reading of the LVDT. When the shaft is released, it shall immediately float downward and make contact with the beam.

10.1.2.2. Remove any beams from the supports. Use the zero load regulator to adjust the loading shaft so that it is free-floating at the approximate midpoint of its vertical travel. Gently add a 2-g mass to the loading shelf. The shaft shall slowly drop downward under the mass.

10.1.3. *Verification of Displacement Transducer*—On each day, before conducting tests, verify the calibration of the displacement transducer using a stepped gauge block of known dimensions similar to the one shown in Figure 3. With the loading frame mounted in the bath at the test temperature, remove all beams from the supports, and place the gauge block on a reference platform underneath the loading shaft according to the instructions supplied by the instrument manufacturer. Apply a 100 g ± 0.2-g mass to the loading shaft, and measure the rise of the steps with the displacement transducer. Compare the measured values as indicated by the data acquisition system with the known dimensions of the gauge. If the known dimensions as determined from the gauge block and the dimensions indicated by the data acquisition system differ by more than ±5 µm, calibration is required. Perform the calibration, and repeat Section 10.1.1. If the requirements of Section 10.1.1 cannot be met after calibration, discontinue use of the device, and consult the manufacturer.

10.1.4. *Daily Overall System Check*—On each day, before conducting tests and with the loading frame mounted in the bath, perform a check on the overall operation of the system. Place the 1.3 ± 0.3-mm-thick stainless steel (thin) beam of known modulus as described in Section 6.4.2 on the sample supports. Following the instructions supplied by the manufacturer, place the beam on the supports and apply a 50.0 or 100.0 ± 0.2-g initial mass (491 or 981 mN ± 2 mN) to the beam to ensure that the beam is seated and in full contact with the supports. Following the manufacturer's instructions, apply a second additional load of 100.0 to 300.0 ± 0.2 g to the beam. The software provided by the manufacturer shall use the change in load and associated change in deflection to calculate the modulus of the beam to three significant figures. The modulus reported by the software shall be within 10 percent of the modulus reported by the manufacturer of the beam; otherwise, the overall operation of the BBR shall be considered suspect and the manufacturer shall be consulted

10.1.5. *Verification of Load Cell*—Verify the calibration of the load cell as follows:

10.1.5.1. *Contact Load*—On each day, verify the calibration of the load cell in the range of the contact load. Place the 6.4-mm-thick stainless steel compliance beam (Section 6.4.1) on the supports. Apply a 20 ± 10-mN load to the beam using the zero load pressure regulator. Add the 2.0 ± 0.2-g mass as specified in Section 6.5.1 to the loading platform. The increase in the load displayed by the data acquisition system shall be 20 ± 5 mN. Add a second 2.0 ± 0.2-g mass to the loading platform. The increase in the load displayed by the data acquisition system shall be 20 ± 5 mN. If the increases in displayed load are not 20 ± 5 mN, calibration is required. Perform the calibration. If the requirements of Section 10.1.3.1 cannot be met after calibration, discontinue use of the device and consult the manufacturer.

10.1.5.2. *Test Load*—On each day, before conducting tests, verify the calibration of the load cell in the range of the test load. Place the 6.4-mm-thick stainless steel compliance beam (Section 6.4.1) on the supports. Use the zero load regulator (contact load) to apply a 20 ± 10-mN load to the beam. Add the 100-g mass to the loading platform. The increase in the load displayed by the data acquisition system shall be 981 ± 5 mN. Otherwise, calibrate the load cell. If the requirements of Section 10.1.3.2 cannot be met after calibration, discontinue use of the device and consult the manufacturer.

10.1.6. *Verification of Front-to-Back Alignment of Loading Shaft*—Every 6 months, check the alignment of the loading shaft with the center of the sample supports with an alignment gauge supplied by the manufacturer or by measurement as follows: Cut a strip of white paper about 25 mm in length and slightly narrower than the width of the compliance beam. Stick the paper strip to the center of the compliance beam with tape. Move the frame out of the bath, place the compliance beam on the supports, and place a small section of carbon paper over the paper. With the air pressure applied to the air bearing, push the shaft downward, causing the carbon paper to make an imprint on the white paper. Remove the beam, and measure the distance from the center of the imprint to each edge of the beam with a pair of vernier calipers. The difference between the two measurements shall be 1.0 mm or less. If this requirement is not met, contact the manufacturer of the device.

11. PREPARATION OF MOLDS AND TEST SPECIMENS

11.1. To prepare molds, spread a very thin layer of petroleum-based grease, only sufficient to hold the plastic to the aluminum, on the interior faces of the three long aluminum mold sections. Place the plastic strips over the aluminum faces and rub the plastic with firm finger pressure. Assemble the mold as shown in Figure 2 using the rubber O-rings to hold the pieces of the mold together. Inspect the mold and press the plastic film against the aluminum to force out any air bubbles. If air bubbles remain, disassemble the mold and recoat the aluminum faces with grease. Cover the inside faces of the two end pieces with a thin film of glycerol and talc to prevent the asphalt binder from sticking to the aluminum end pieces. After assembly, keep the mold at room temperature until pouring the asphalt binder.

Note 10—Thickness of the specimen is controlled by the end pieces. The thickness of the end pieces should be measured periodically to make sure that it meets the requirements of Section 6.3. The stiffness is proportional to the third power of the thickness.

11.2. If unaged binder is to be tested, obtain test sample according to T 40.

11.3. Heat the material in an oven set at the minimum temperature and for the minimum time necessary for it to be sufficiently fluid to pour.

Note 11—Minimum pouring temperatures that produce a consistency equivalent to that of SAE 10W30 motor oil (readily pours but not overly fluid) at room temperature are recommended. In all cases, heating time should be minimized. These precautions will help avoid oxidative hardening and volatile loss that will further harden the sample. During the heating process, the sample should be covered and stirred occasionally to ensure homogeneity.

11.4. *Molding*—Pour the binder from the one end of the mold and move toward the other end, slightly overfilling the mold. When pouring, hold the sample container 20 to 100 mm from the top of the mold and pour continuously toward the other end in a single pass. Allow the mold to cool 45 to 60 minutes to room temperature after pouring, and trim the exposed face of the cooled specimens flush with the top of the mold using a hot knife or heated spatula.

11.5. Store all test specimens in their molds at room temperature prior to testing. Schedule testing so that it is completed within 4 hours after specimens are poured.

Note 12—Time-dependent increases in stiffness can occur when asphalt binders are stored at room temperature for even short periods of time. This increase in stiffness is the result of molecular associations and is referred to as steric hardening in the literature.

11.6. Just prior to testing, cool the aluminum mold containing the test specimen in a freezer or ice bath at –5°C ± 7°C for 5 to 10 minutes, only long enough to stiffen the asphalt binder beam so that it can be readily demolded without distortion (Note 8). Some softer grades may require lower temperatures. Do not cool the molds containing the specimens in the test bath because it may cause temperature fluctuations in the bath to exceed ±0.2°C.

Note 13—Excessive cooling may cause unwanted hardening of the beam, thereby causing increased variability in the test data.

11.7. Immediately demold the specimen when it is sufficiently stiff to demold without distortion by disassembling the aluminum mold. Discard the plastic sheeting (lining the mold sections) if they become distorted.

Note 14—Minimize distortion of the specimen during demolding. If the plastic sheeting does not fully separate from the testing beam, you may remove the final portion of the sheeting as the beam is being immersed in the test bath to avoid distortion. Full contact at specimen supports is assumed in the analysis. A warped test beam yields a measured stiffness less than the actual stiffness.

12. PROCEDURE

12.1. When testing a specimen for compliance with M 320, select the appropriate test temperature from Table 1 of M 320. After demolding, immediately place the test specimen in the testing bath and condition it at the testing temperature for 60 ± 5 minutes.

Note 15—Asphalt binders may harden rapidly when held at low temperatures. This effect, which is called physical hardening, is reversible when the asphalt binder is heated to room temperature or slightly above. Because of physical hardening, conditioning time must be carefully controlled if repeatable results are to be obtained.

12.2. *Checking Contact Load and Test Load*—Check the adjustment of the contact load and test load prior to testing each set of test specimens. The 6.35-mm-thick stainless steel beam shall be used for checking the contact load and test load.

Note 16—Do not perform these checks with the thin steel beam or an asphalt test specimen.

12.2.1. Place the thick steel beam in position on the beam supports. Using the test load regulator valve, gently increase the force on the beam to 980 ± 50 mN.

12.2.2. Switch from the test load to the contact load, and adjust the force on the beam to 35 ± 10 mN. Switch between the test load and contact load four times.

12.2.3. When switching between the test load and contact load, watch the loading shaft and platform for visible vertical movement. The loading shaft shall maintain contact with the steel beam when switching between the contact load and test load while maintaining these loads at 35 ± 10 mN and 980 ± 50 mN, respectively.

12.2.4. *Corrective Action*—If the requirements of Sections 12.2.1 to 12.2.3 are not met, the device may require calibration as per the manufacturer's instructions or the loading shaft may be dirty or require alignment (see Section 10.1.2). If the requirements of Sections 12.2.1 to 12.2.3 cannot be met after calibration, cleaning, or other corrective action, discontinue use of the device and consult the equipment manufacturer.

12.3. Enter the specimen identification information, test load, test temperature, time the specimen is placed in the bath at the test temperature, and other information as appropriate into the computer which controls the test system.

12.4. After conditioning, place the test beam on the test supports, and initiate the loading sequence of the test. Maintain the bath at the test temperature ±0.1°C during testing; otherwise, the test shall be rejected.

12.5. Manually apply a 35 ± 10-mN contact load to the beam to ensure contact between the beam and the loading head for no more than 10 seconds. The specified contact load is required to ensure continuous contact between the loading shaft and support, and the specimen. Failure to establish continuous contact within the required load range gives misleading results. The contact load shall be applied by gently increasing the load to 35 ± 10 mN. While applying the contact load, the load on the beam shall not exceed 45 mN, and the time to apply and adjust the contact load shall be no greater than 10 seconds.

12.6. *Activate the automatic test system that is programmed to proceed as follows*:

12.6.1. Immediately after the application of the 35-mN contact load, increase the load from 35 ± 10 mN to the 980 ± 50-mN seating load for 1.0 ± 0.1 seconds.

Note 17—The seating loads described in Sections 12.6.1 and 12.6.2 are applied and removed automatically by the computer-controlled loading system and are transparent to the operator. Data are not recorded during the initial loading.

12.6.2. Reduce the load to 35 ± 10 mN and allow the beam to recover for 20.0 ± 0.1 seconds.

12.6.3. Apply a test load ranging as specified in Section 6.1.1.2.

Note 18—The actual load on the beam as measured by the load cell is used in calculating the stress in the beam. The 980 ± 50-mN initial seating and test load includes the 35 ± 10-mN preload.

12.6.4. Remove the test load and terminate the test.

12.6.5. At the end of the initial seating load, and at the end of the test, monitor the computer screen to verify that the load on the beam returns to 35 ± 10 mN in each case. If the beam does not return to 35 ± 10 mN, the test is invalid and the rheometer should be calibrated.

12.7. Remove the specimen from the supports and proceed to the next test.

13. CALCULATION AND INTERPRETATION OF RESULTS

13.1. See Annex.

14. REPORT

14.1. *Report data as shown in Figure 4 that describes individual test, including*:

14.1.1. Maximum and minimum temperature of the test bath measured during the 240 seconds of testing measured at 1.0-second intervals to the nearest 0.1°C;

14.1.2. Date and time when test load is applied;

14.1.3. File name of test data;

14.1.4. Name of operator;

14.1.5. Sample identification number;

Figure 4—Typical Test Report

14.1.6. Time beam in bath;

14.1.7. Time test started;

14.1.8. Any flags issued by software during test;

14.1.9. Correlation coefficient, R^2, for log stiffness versus log time, expressed to nearest 0.000001;

14.1.10. Anecdotal comments (maximum 256 characters);

14.1.11. Report constants A, B, and C to three significant figures; and

14.1.12. Difference between measured and estimated stiffness calculated as:
(Estimated – Measured) × 100 percent/Measured.

14.2. Report load and deflection as for times 0.0 and 0.5 seconds.

14.3. Report data as shown in Figure 4 for time intervals of 8.0, 15.0, 30.0, 60.0, 120.0, and 240.0 seconds, including:

14.3.1. Loading time, nearest 0.1 second;

14.3.2. Load, nearest 1.0 mN;

14.3.3. Beam deflection, nearest 1 µm;

14.3.4. Measured Stiffness modulus, MPa, expressed to three significant figures;

14.3.5. Estimated Stiffness Modulus, MPa, expressed to three significant figures;

14.3.6. Difference between measured and estimated Stiffness Modulus in percent;

14.3.7. Estimated *m*-value, nearest 0.001; and

14.3.8. Regression Coefficients and least square fit R^2 value.

15. PRECISION AND BIAS

15.1. *Precision*—Criteria for judging the acceptability of creep stiffness and slope results obtained by this method are given in Table 1.

15.1.1. *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

15.1.2. *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

Table 1—Precision Estimates

Condition	Coefficient of Variation (1s%)[a]	Acceptable Range of Two Test Results (d2s%)[a]
Single-Operator Precision:		
Creep Stiffness (MPa)	2.5	7.2
Slope (*m*-value)	1.0	2.9
Multilaboratory Precision:		
Creep Stiffness (MPa)	6.3	17.8
Slope (*m*-value)	2.4	6.8

[a] These values represent the 1s% and d2s% limits described in ASTM Practice C 670.

Note 19—The precision estimates given in Table 1 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 174 to 196 laboratories for each of the eight pairs of samples. The analysis included five binder grades: PG 52-34, PG 64-16, PG 64-22, PG 70-22, and PG 76-22 (SBS modified). Average creep stiffness results ranged from 125.4 MPa to 236.8 MPa. Average slope results ranged from an *m*-value of 0.308 to 0.374. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Note 20—As an example, two tests conducted on the same material yield creep stiffness results of 190.3 MPa and 200.7 MPa, respectively. The average of these two measurements is 195.5 MPa. The acceptable range of results is then 7.2 percent of 195.5 MPa or 14.1 MPa. As the difference between 190.3 MPa and 200.7 MPa is less than 14.1 MPa, the results are within the acceptable range.

15.2. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

16. KEYWORDS

16.1. Flexural; creep stiffness; flexural creep compliance; bending beam rheometer.

ANNEX

(Mandatory Information)

A1.1 *Calibration of Displacement Transducer*—Calibrate the displacement transducer using a stepped gauge block of known dimensions similar to the one shown in Figure 3. With the loading frame mounted in the bath at the test temperature, remove all beams from the supports, and place the stepped gauge block on a reference platform underneath the loading shaft according to the instructions supplied by the instrument manufacturer. Apply a 100-g mass on the loading shaft, and follow the manufacturer's instructions to obtain a displacement transducer reading on each step. The software provided by the manufacturer shall convert the measurements to a calibration constant in terms of µm/bit to three significant figures and shall automatically enter the new constant into the software. The calibration constant should be repeatable within 10 percent from one calibration to another; otherwise, the operation of the system may be suspect.

A1.2 *Calibration of Load Cell*—Calibrate the load cell in accordance with the manufacturer's instructions using a minimum of four masses evenly distributed over the range of the load cell. The software provided by the manufacturer shall convert the measurements to a calibration constant in terms of mN/bit to three significant figures and shall automatically enter the new constant into the software. The calibration constants should be repeatable within 10 percent from one calibration to another; otherwise, the operation of the system may be suspect. Repeat the process for each test temperature.

A1.3 *Calibration of Temperature Transducer*—Calibrate the temperature detector by using a calibrated thermometer of suitable range meeting the requirements of Section 10.1.5. Immerse the thermometer in the liquid bath close to the thermal detector, and compare the temperature indicated by the calibrated thermometer to the detector signal being displayed. If the temperature indicated by the thermal detector does not agree with the thermometer within ±0.1°C, follow the manufacturer's instructions for correcting the displayed temperature to agree with the thermometer temperature.

A1.4 *Determine the System Compliance*—Determine the system compliance in accordance with the manufacturer's instructions using a minimum of four masses evenly distributed over the range of the load cell. The data acquisition software shall measure the position of the displacement transducer at each load. The compliance shall be calculated as the measured deflection per unit load. The software provided by the manufacturer shall convert the measurements to a compliance in terms of µm/N to three significant figures and shall automatically enter the compliance into the software. The compliance measurement may be performed as part of the load cell calibration or as a separate operation. The compliance measurement shall be performed each time the load cell is calibrated. The compliance value should be repeatable within 10 percent from one determination to another; otherwise, the operation of the system may be suspect. Repeat the process for each test temperature.

A1.5 *Typical Test Result*—A typical test result is shown in Figure 4. Disregard measurements obtained and the curves projected on the computer screen during the initial 8 seconds of the application of the test load. Data from a creep test obtained immediately after the application of the test load may not be valid because of dynamic loading effects and the finite rise time. Use only the data obtained between the 8- and 240-second loading time for calculating $S(t)$ and m.

A1.6 *Deflection of an Elastic Beam*—Using the elementary bending theory, the midspan deflection of an elastic prismatic beam of constant cross-section loaded in three-point loading can be obtained by applying Equations A1.1 and A1.2 as follows:

$$\delta = PL^3/48EI \qquad (A1.1)$$

where:

δ = deflection of beam at midspan, mm;
P = load applied, N;
L = span length, mm;
E = modulus of elasticity, MPa; and
I = moment of inertia, mm^4.

and:

$$I = bh^3/12 \qquad (A1.2)$$

where:

I = moment of inertia of cross-section of test beam, mm^4;
b = width of beam, mm; and
h = thickness of beam, mm.

Note A1—The test specimen has a span to depth ratio of 16:1 and the contribution of shear to deflection of the beam can be neglected.

A1.7 *Elastic Flexural Modulus*—According to elastic theory, calculate the flexural modulus of a prismatic beam of constant cross-section loaded at its midspan using the following equation:

$$E = PL^3/4bh^3\delta \qquad (A1.3)$$

where:

E = time-dependent flexural creep stiffness, MPa;
P = constant load, N;
L = span length, mm;
b = width of beam, mm;
h = thickness of beam, mm; and
δ = deflection of beam, mm.

A1.8 *Maximum Bending Stress*—The maximum bending stress in the beam occurs at the midspan at the top and bottom of the beam. Calculate σ thus:

$$\sigma = 3PL/2bh^2 \qquad (A1.4)$$

where:

σ = maximum bending stress in beam, MPa;
P = constant load, N;
L = span length, mm;

b = width of beam, mm; and
h = thickness of beam, mm.

A1.9 *Maximum Bending Strain*—The maximum bending strain in the beam occurs at the midspan at the top and bottom of the beam. Calculate ϵ using the following equation:

$$\epsilon = 6\delta h/L^2 \text{ mm/mm} \qquad (A1.5)$$

where:
ϵ = maximum bending strain in beam, mm/mm;
δ = deflection of beam, mm;
h = thickness of beam, mm; and
L = span length, mm.

A1.10 *Linear Viscoelastic Stiffness Modulus*—According to the elastic-viscoelastic correspondence principle, it can be assumed that if a linear viscoelastic beam is subjected to a constant load applied at $t = 0$ and held constant, the stress distribution is the same as that in a linear elastic beam under the same load. Further, the strains and displacements depend on time and are derived from those of the elastic case by replacing E with $1/D(t)$. Since $1/D(t)$ is equivalent to $S(t)$, rearranging the elastic solution results in the following relationship for the stiffness:

$$S(t) = PL^3/4bh^3\delta(t) \qquad (A1.6)$$

where:
$S(t)$ = time-dependent flexural creep stiffness, MPa;
P = constant load, N;
L = span length, mm;
b = width of beam, mm;
h = thickness of beam, mm;
$\delta(t)$ = deflection of beam, mm; and
$\delta(t)$ and $S(t)$ indicate that the deflection and stiffness, respectively, are functions of time.

A1.11 *Presentation of Data*:

A1.11.1 Plot the response of the test beam to the creep loading as the logarithm of stiffness with respect to the logarithm of loading time. A typical representation of test data is shown in Figure 4. Over the limited testing time from 8 to 240 seconds, the plotted data shown in Figure A1.1 can be represented by a second order polynomial as follows:

$$\log S'(t) = A + B[\log(t)] + C[\log(t)]^2 \qquad (A1.7)$$

and, the slope, m, of the logarithm of stiffness versus logarithm time curve is equal to (absolute value):

$$|m(t)| = d[\log S'(t)]/d[\log(t)] = B + 2C[\log(t)] \qquad (A1.8)$$

where:
$S'(t)$ = time-dependent flexural creep stiffness estimated using Equation A1.7, MPa;
T = time in seconds; and
A, B, and C = regression coefficients.

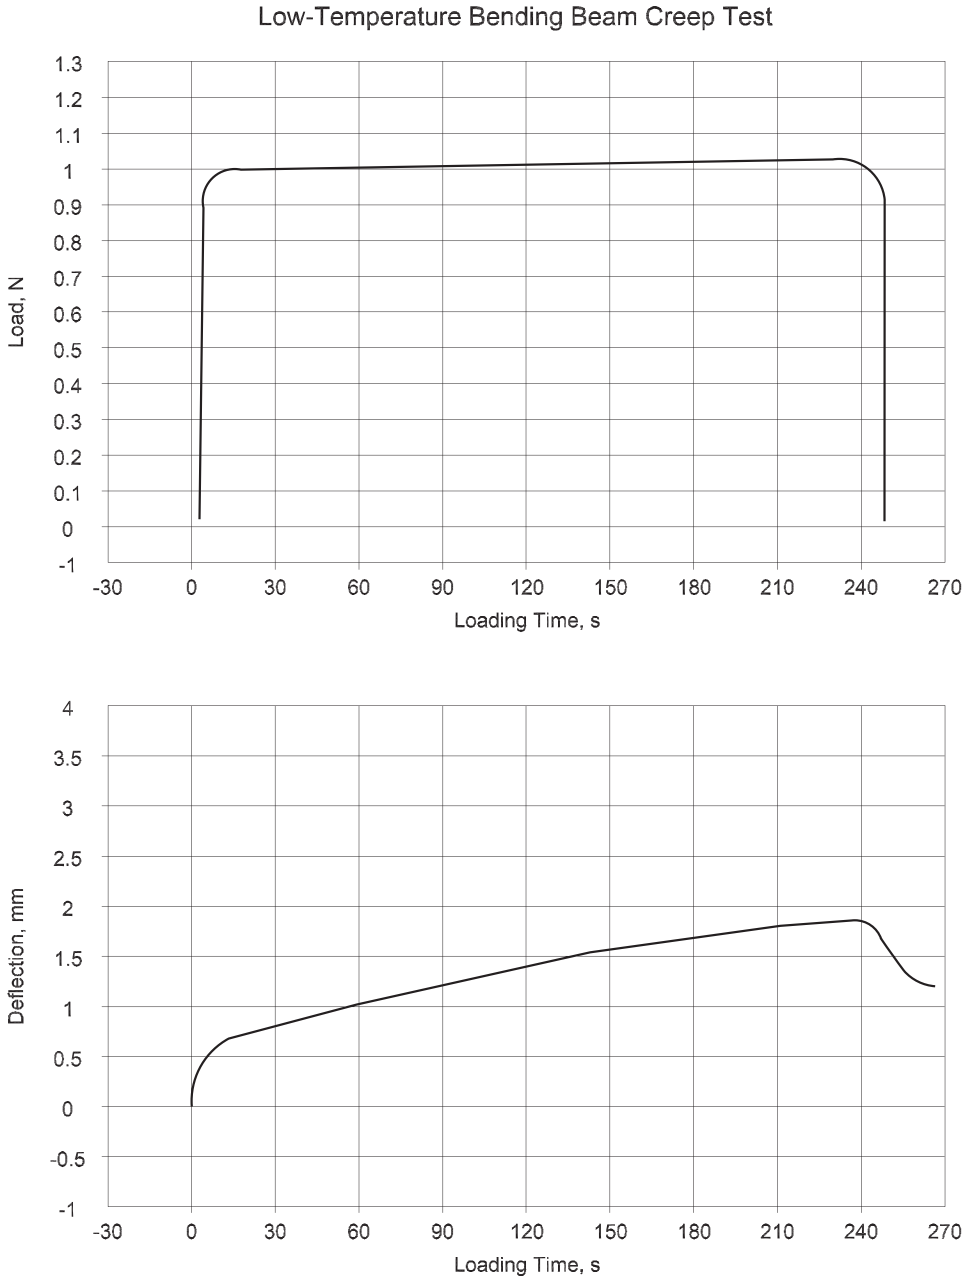

Figure A1.1—Typical Load and Deflection Plots

A1.11.2 Smoothing the data may be required to obtain smooth curves for the regression analysis as required to determine an *m*-value. This procedure can be performed by averaging five readings taken at the reported time ±0.1 and ±0.2 seconds.

A1.11.3 Obtain the constants *A*, *B*, and *C* from the least squares fit of Equation A1.7. Use data equally spaced with respect to the logarithm of time to determine the regression coefficients in Equations A1.7 and A1.8. Determine experimentally the stiffness values used for the regression to derive the coefficients *A*, *B*, and *C* and to, in turn, calculate values of *m* after loading times of 8, 15, 30, 60, 120, and 240 seconds.

A1.12 Calculation of regression coefficients, estimated stiffness values, and *m*:

A1.12.1 Calculate the regression coefficients *A*, *B*, and *C* in Equations A1.7 and A1.8 and the denominator *D* as follows:

$$A = S_y(S_{x2}S_{x4} - S_{x3}{}^2) - S_{xy}(S_{x1}S_{x4} - S_{x2}S_{x3}) + S_{xxy}(S_{x1}S_{x3} - S_{x2}{}^2)]/D \tag{A1.9}$$

$$B = [6(S_{xy}S_{x4} - S_{xxy}S_{x3}) - S_{x1}(S_yS_{x4} - S_{xxy}S_{x2}) + S_{x2}(S_yS_{x3} - S_{xy}S_{x2})]/D \tag{A1.10}$$

$$C = [6(S_{x2}S_{xxy} - S_{x3}S_{xy}) - S_{x1}(S_{x1}S_{xxy} - S_{x3}S_y) + S_{x2}(S_{x1}S_{xy} - S_{x2}S_y)]/D \tag{A1.11}$$

$$D = 6(S_{x2}S_{x4} - S_{x3}{}^2) - S_{x1}(S_{x1}S_{x4} - S_{x2}S_{x3}) + S_{x2}(S_{x1}S_{x3} - S_{x2}{}^2) \tag{A1.12}$$

where, for loading times of 8, 15, 30, 60, 120, and 240 seconds:
S_{x1} = log 8 + log 15 + ... log 240;
S_{x2} = $(\log 8)^2 + (\log 15)^2 + ...\ (\log 240)^2$;
S_{x3} = $(\log 8)^3 + (\log 15)^3 + ...\ (\log 240)^3$;
S_{x4} = $(\log 8)^4 + (\log 15)^4 + ...\ (\log 240)^4$;
S_y = log *S*(8) + log *S*(15) + ... log *S* (240);
S_{xy} = log *S*(8)(log (8)) + log *S*(15) log (15) + ... log *S*(240) log (240); and
S_{xxy} = $[\log (8)]^2 \log S(8) + [\log (15)]^2 \log S(15) + ...\ [\log (240)]^2 \log S(240)$.

A1.12.2 Calculate the estimated stiffness *S*′(*t*) at 8, 15, 30, 60, 120, and 240 seconds as follows:

$$\log S'(t) = A + B[\log(t)] + C\,[\log(t)]^2 \tag{A1.13}$$

A1.12.3 Calculate the estimated *m*-value at 8, 15, 30, 60, 120, and 240 seconds as the absolute value of

$$|m| = B + 2C\,[\log(t)] \tag{A1.14}$$

A1.12.4 Calculate $\overline{S}$ the average of the stiffness values at 8, 15, 30, 60, 120, and 240 seconds as:

$$\log \overline{S} = [\log S(8) + \ldots \log S(240)]/6 \tag{A1.15}$$

A1.12.5 Calculate the fraction of the variation in the stiffness explained by the quadratic model as:

$$R^2 = 1.00 - \left[\frac{[\log S(8) - \log S'(8)] + ...[\log S(240) - \log S'(240)]}{\left[\log S(8) - \log\left(\overline{S}\right)\right]^2 + ...\left[\log S(240) - \log\left(\overline{S}\right)\right]^2} \right] \tag{A1.16}$$

A1.12.6 Use the estimated values of the stiffness and *m* at 60 seconds for specification purposes. Measured and estimated stiffness values should agree to within 2 percent. Otherwise, the test is considered suspect.

Standard Method of Test for

Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)

AASHTO Designation: T 314-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)

AASHTO Designation: T 314-07

1. SCOPE

1.1. This test method covers the determination of the failure strain and failure stress of asphalt binders by means of a direct tension test. It can be used with unaged or aged material using T 240 (RTFOT), R 28 (PAV). The test apparatus is designed for testing within the temperature range from +6 to –36°C.

1.2. This test method is limited to asphalt binders containing particulate material having dimensions less than 250 μm.

1.3. This test method is not valid for specimens exhibiting a failure strain of greater than 10 percent considered outside the brittle-ductile range.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of particulate organic modifiers of size less than 250 µm.

3.2. *Description of Terms Specific to This Standard*:

3.2.1. *brittle*—type of failure in a direct tension test where the stress-strain curve is essentially linear up to the point of failure and the failure is by sudden rupture of the test specimen without appreciable reduction in cross-section of the specimen.

3.2.2. *brittle-ductile*—type of failure in a direct tension test where the stress-strain curve is curvilinear and the failure is by sudden rupture of the test specimen. Limited reduction in cross-section of the specimen occurs before rupture.

3.2.3. *ductile*—type of failure in a direct tension test where the specimen does not rupture but fails by flow at large strains.

3.2.4. *tensile strain*—axial strain resulting from the application of a tensile load and calculated as the change in length of the effective gauge length caused by the application of the tensile load divided by the original unloaded effective gauge length.

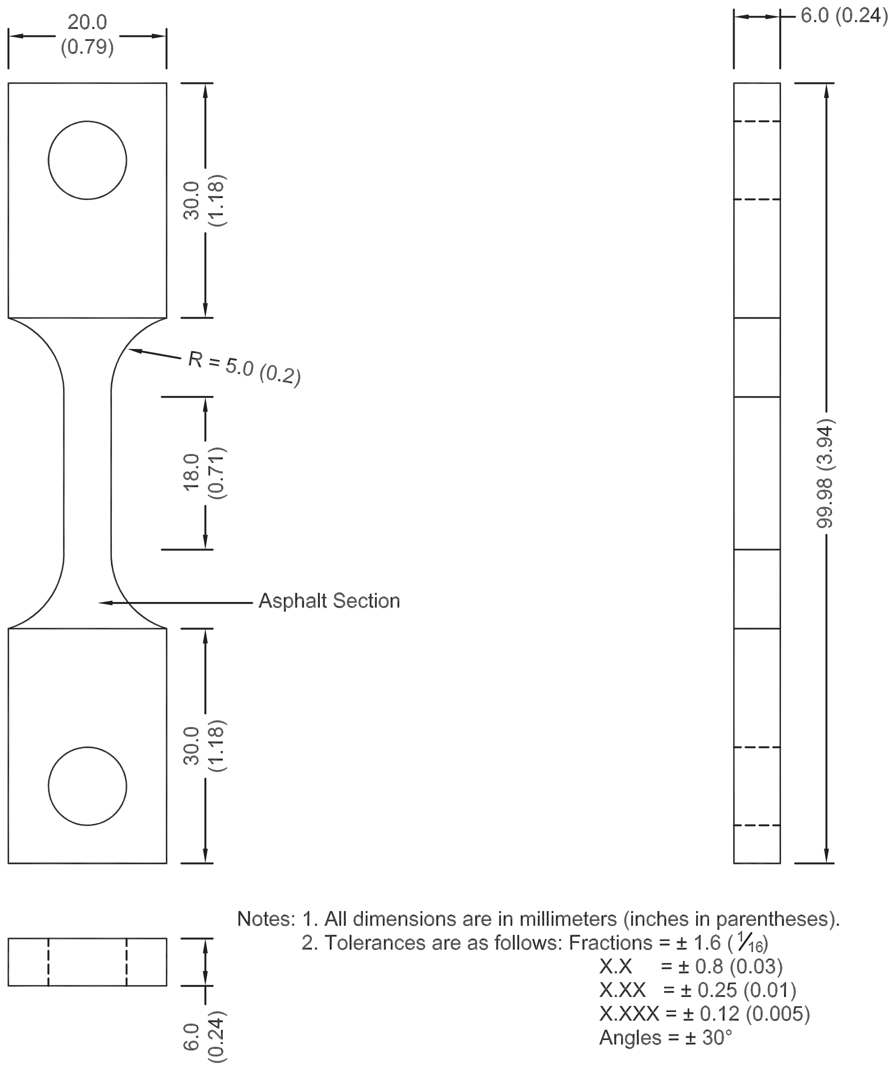
3.2.5. *tensile stress*—axial stress resulting from the application of a tensile load and calculated as the tensile load divided by the original area of cross-section of the specimen.

3.2.6. *failure*—point at which the tensile load reaches a maximum value as the test specimen is pulled at a constant rate of elongation.

3.2.7. *failure stress*—the tensile stress on the test specimen when the load reaches a maximum value during the test method specified in this standard.

3.2.8. *failure strain*—the tensile strain corresponding to the failure stress.

3.2.9. *gauge section*—the central portion of the specimen where the cross-section does not change with length. For this geometry the gauge section is 18 mm in length (see Figure 1).



Notes: 1. All dimensions are in millimeters (inches in parentheses).
2. Tolerances are as follows: Fractions = ± 1.6 ($^1\!/_{16}$)
X.X = ± 0.8 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°

3. Remove all sharp edges.
4. Surface finish for machined surfaces: $\sqrt[125]{}$ unless otherwise specified.

Figure 1—Superpave Direct Tension Specimen Geometry

3.2.10. *effective gauge length*—for specimens used in this test, the effective gauge length, L_e, has been determined to be 33.8 mm. This is an effective gauge length that represents the portion of the specimen that contributes to the majority of the strain.

4. SUMMARY OF TEST METHOD

4.1. This method describes the procedure used to measure the stress at failure and strain at failure in an asphalt binder test specimen pulled at a constant rate of elongation. Test specimens are prepared by pouring hot asphalt binder into a suitable mold. Two G10 phenolic end tabs are used to bond the asphalt binder during the test and to transfer the tensile load from the test machine to the asphalt binder.

4.2. This test method was developed for asphalt binders at temperatures where they exhibit brittle or brittle-ductile failure. A brittle or brittle-ductile failure will result in a fracture of the test specimen as opposed to a ductile failure in which the specimen simply stretches without fracturing. The test is not applicable at temperatures where failure is by ductile flow.

4.3. A displacement transducer is used to measure the elongation of the test specimen as it is pulled in tension at a constant rate of 1 mm/min. The load developed during the test is monitored and the tensile strain and stress in the test specimen when the load reaches a maximum are reported as the failure strain and failure stress, respectively.

5. SIGNIFICANCE AND USE

5.1. Stress at failure is used in a mechanistic pavement cracking model to compute critical cracking temperature. The procedure to compute critical cracking temperature is described in AASHTO R 49. The critical cracking temperature is then used in specifying the low temperature grade of asphalt binder in accordance with M 320.

5.2. The test is designed to measure the strength of the asphalt binder at the critical cracking temperature. The asphalt binder has limited ability to resist stress without cracking. In the asphalt binder specification failure, stress is used to determine the critical cracking temperature.

5.3. For evaluating an asphalt binder for conformance to M 320, the elongation rate of the gauge section is 1.0 mm/min and the test temperature is selected from Table 1 of M 320 according to the grade of asphalt binder. Other rates of elongation and test temperatures may be used to test asphalt binders.

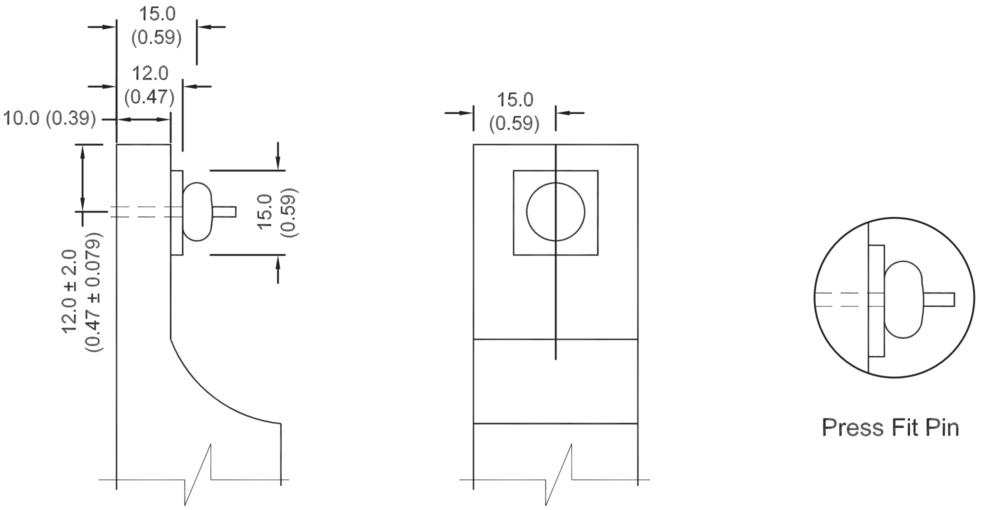
6. APPARATUS

6.1. *Direct Tension Test System*—A direct tension test system consisting of (1) a closed feedback loop displacement-controlled tensile loading machine; (2) a specimen gripping system; (3) either a fluid bath or an insulated chamber for reliable, accurate, and uniform temperature control during testing and conditioning of specimen; (4) real-time load measuring and recording devices; (5) real-time elongation measuring and recording devices; (6) a real-time temperature detection and recording device; and (7) real-time data acquisition and display devices.

The system shall have an electro-mechanical or a servo-hydraulic loading unit capable of applying and measuring tension and compression forces of at least 500 N and actuator travel of 20 mm (0.78 in.). The system stiffness shall be at least 3 mN/m including the load cell and the loading pins. The unit shall have a transducer to measure and control grip separation and provide a feedback for strain control with a displacement resolution of 1.0 μm. The system shall be capable of closed loop elongation rate control accurate to at least 1 percent of the commanded specimen elongation rate using feedback from a displacement transducer mounted between the loading pins or a non-contact extensometer measuring the elongation of the specimen.

6.1.1. *Tensile Loading Machine Equipped with Temperature Control*—A tensile loading machine with a controlled-displacement loading frame capable of producing at least a 500-N load is required. The loading frame shall be table mounted. The gripping system (loading pins and platens) shall be completely submerged under the cooling fluid if a fluid-based system is used. The gripping system shall be a minimum of 25 mm (1 in.) under the cooling fluid surface. Loading shall be accomplished by pulling directly in tension in the plane of the specimen. The distance between the load frame's loading points (between loading pins) shall accommodate specimens with total length (including the end tabs) of at least 100 mm (see Figure 1). If an air-cooled system is used, the testing frame shall be equipped with two standards (columns) with sufficient clear space between the standards so that an insulated temperature control chamber can be placed between the standards.

6.1.2. *Specimen Gripping System*—The gripping system must produce a self-aligning uniaxial test load and accept the end tabs described in Section 6.1.2.1 and be designed so that test specimens can be easily mounted in the machine. The system shall include two grips. Each grip shall include a specially shaped pin that is mounted rigidly to the loading platens of the testing machine. Figure 2 shows a typical grip and loading pin assembly. One grip shall be fixed and remain stationary during the test while the other grip is displaced at the desired elongation rate.



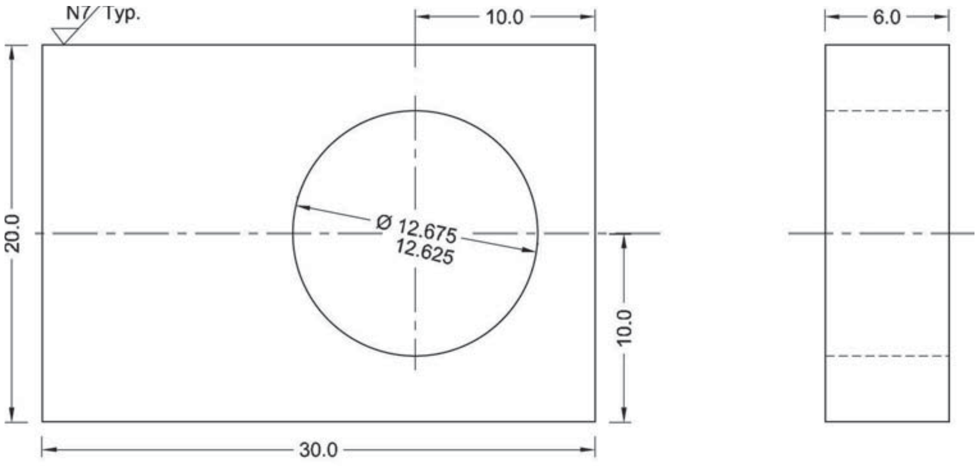
Typical Grip Showing the Pin Press-Fitted.
Two Grips Are Needed.

Notes: 1) All dimensions are in millimeters (inches in parentheses).
2) Tolerances are as follows: Fractions = ± 1.6 ($\frac{1}{16}$)
X.X = ± 0.8 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°

3) Remove all sharp edges.
4) Surface finish for machined surfaces: $\overset{125}{\surd}$ unless otherwise specified.

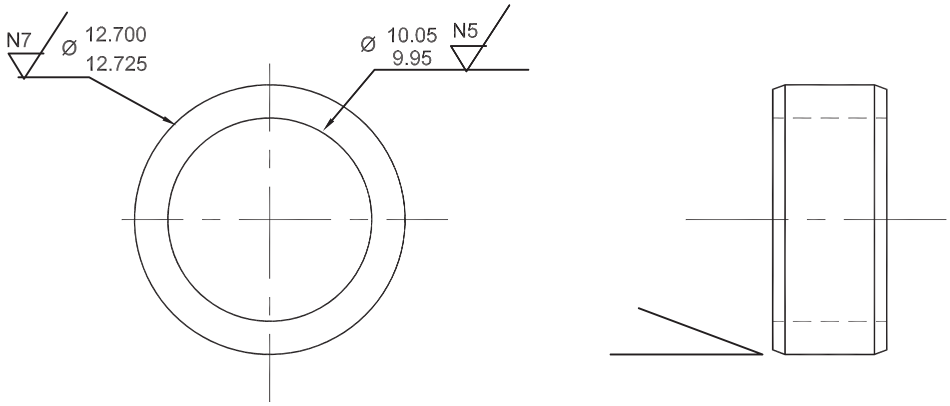
Figure 2—Loading Pin and Grip Assembly for the Superpave Direct Tension Test

6.1.2.1. *Specimen End Tabs*—End tabs made from G10 phenolic sheets having the dimensions specified in Figures 3, 4, and 5 shall be bonded to both ends of the test specimen to transfer the tensile load to the asphalt binder. The end tabs shall be machined from a standard G10 phenolic sheet. Each end tab shall contain a precisely machined hole lined with a 304 stainless steel ring. The diameter of the lined hole shall be 10 ± 0.05 mm. Gripping of the specimen is accomplished through the bond (adhesion) between the asphalt binder test specimen and the end tab. Each end tab shall be mounted on a specially shaped pin that is part of the gripping system. The specimen shall be mounted on the grips by positioning the end tabs in the test machine such that the end tabs fit onto the pins and are indexed against the face of the grips. Matching the coefficient of thermal expansion of the asphalt binder and the end tabs is necessary to reduce thermal shrinkage stresses at the interface that otherwise cause bond failures.



Notes: 1. All dimensions are in millimeters (inches in parentheses).
2. Tolerances are as follows: Fractions = ± 1.6 ($^1/_{16}$)
X.X = ± 0.6 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°
3. Remove all sharp edges.
4. Surface finish for machined surfaces: $\overset{125}{\surd}$ unless otherwise specified.
5. Material: G10 phenolic.
6. Also see Metal Ring and Assembly Drawings.

Figure 3—Superpave End Insert for Direct Tension Test (See Figure 4 for the Metal Ring Dimensions to Be Press Fitted into This End Insert.)



Notes: 1. All dimensions are in millimeters (inches in parentheses).

2. Tolerances are as follows: Fractions = ± 1.6 (1⁄16)
X.X = ± 0.8 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°

3. Remove all sharp edges.

4. Surface finish for machined surfaces: 125√ unless otherwise specified.

5. Material: Stainless Steel Type 316 or 304.
May be made from 1⁄4" schedule 40 seamless pipe.

Press Fit Ring into hole such that ring is
flush or slightly below surface on either side.

Notes: 1. All dimensions are in millimeters (inches in parentheses).
2. Tolerances are as follows: Fractions = ± 1.6 (1/16)
X.X = ± 0.8 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°

3. Remove all sharp edges.
4. Surface finish for machined surfaces: 125√ unless otherwise specified.

Figure 5—Superpave End Insert for Direct Tension Test (See Figures 3 and 4.)

6.1.3. *Test Chamber for Temperature Control and Testing*—The temperature control chamber shall have sufficient space for storing at least 12 specimens. The temperature control range for the cooling chamber, without asphalt binder specimens, at all points within the bath, shall be from +6 to –36°C with temperature stability as a minimum of ± 0.1°C. Placing a room temperature specimen in the cold chamber is allowed to cause the chamber temperature between the grips to fluctuate ± 0.2°C from the target test temperature during testing and isothermal conditioning of the specimen. However, during testing the temperature gradient between the grips shall not exceed ± 0.1°C. The temperature measurement shall be accomplished with a calibrated Platinum Resistance Temperature Detector (PRTD) located in the chamber in proximity of test area (NIST Traceable, calibrated at eight temperatures in the range of +6 to –36°C). If an air-based cooling system is used, mechanical cooling or liquid nitrogen may be used to cool the chamber. It shall have a dehumidifying system with a capacity such that the formation of frost on the interior of the chamber, the test specimen, or any of the test fixtures is eliminated. The chamber shall be capable of storing a minimum of 12 test specimens on a rack which is thermally isolated from the walls and floors of the chamber such that heat conducted from the walls and floors of the chamber does not affect the temperature of the stored specimens. If an air-based cooling system is used, the chamber shall be fitted with a front-opening door for maintenance and standardization purposes and an access port that allows for insertion of the operator's hand and forearm to position test specimens on the storage shelf for conditioning and to position test specimens on the grips for testing. The access port shall be designed so that changes in chamber temperature are ± 0.2°C during an operation in which the operator's hand or forearm is inserted into or removed from the chamber. Visual access to the interior of the test chamber shall be provided to permit proper mounting of test specimens and test monitoring. The test specimen elongation is measured with an optical laser. Use of the laser requires optical glass windows on two sides of the temperature chamber so that a beam of laser light can be passed through the chamber without distorting the laser beam.

6.1.4. If fluid is used as a cooling medium, a suitable fluid for temperature control and testing has been found to be an aqueous mixture of 42 percent potassium acetate powder and 58 percent deionized water by weight. Alcohols have been found to embrittle asphalt binders (i.e., affect failure properties in presence of stress) and, therefore, shall not be used as a medium for temperature control and failure testing of asphalt binder specimen.

Note 1—Potassium acetate is commercially available in the form of a deicing fluid mixture composed of approximately 50 percent potassium acetate and 50 percent deionized water. If this commercial fluid mixture is purchased, the required 42 percent to 58 percent potassium acetate to deionized water combination may be obtained by mixing the commercially available 50:50 deicing fluid with deionized or distilled water until a specific gravity of 1.2375 ± 0.0025 is obtained. The specific gravity may be measured using a suitable hydrometer.

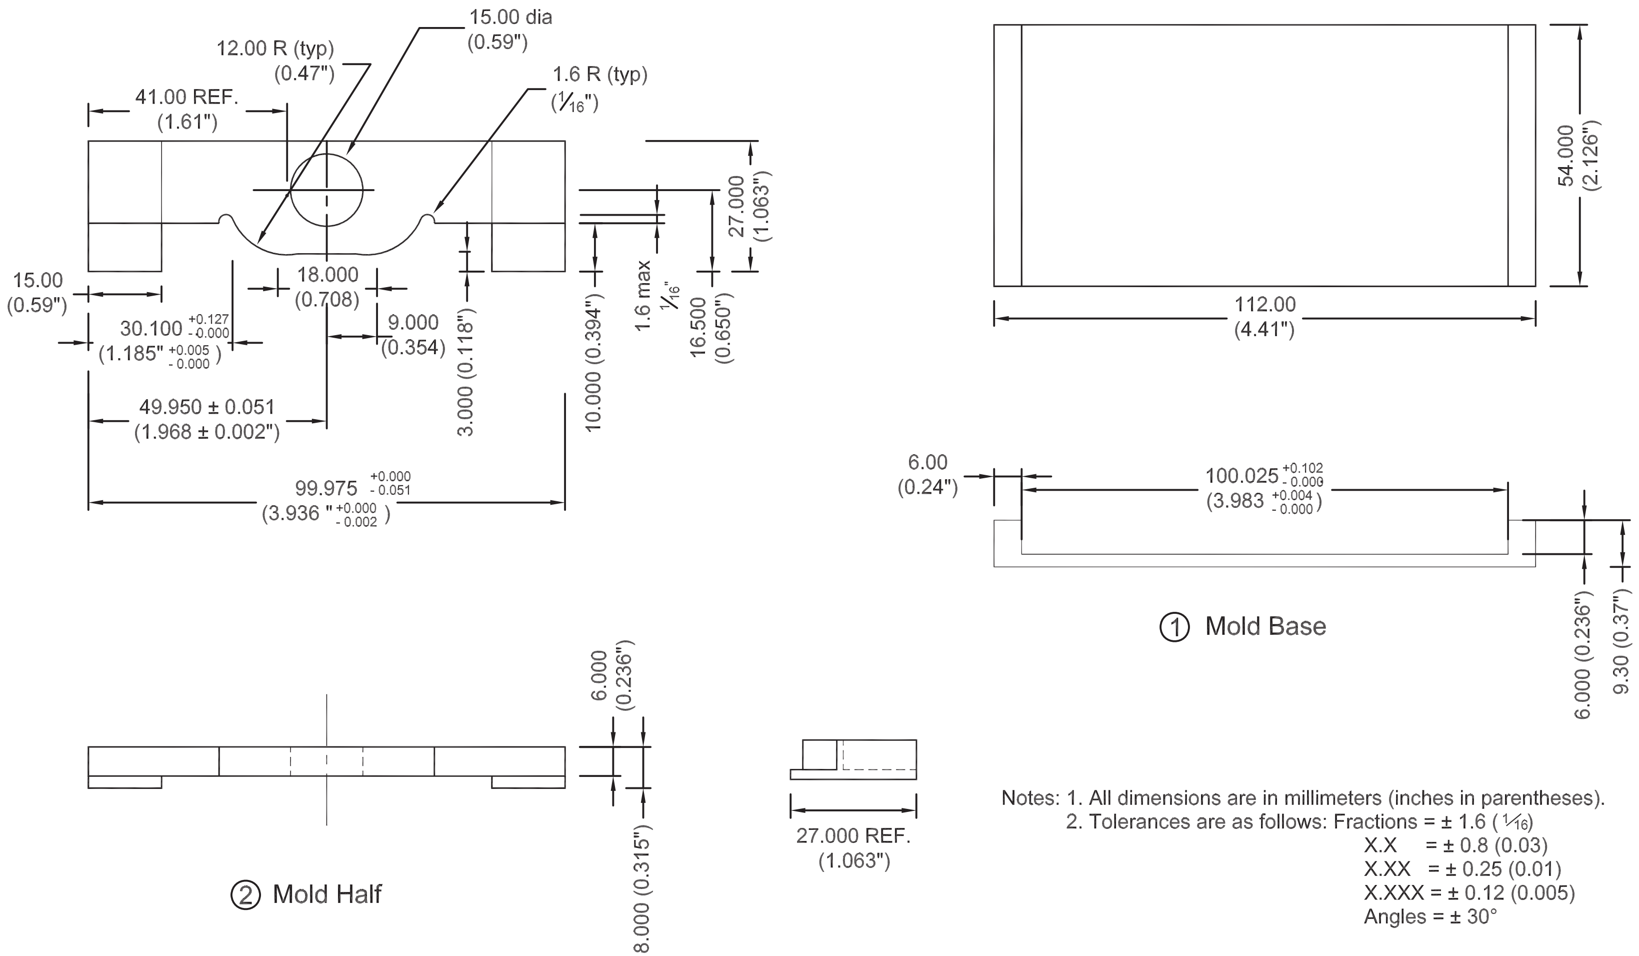
6.1.5. *Load Measuring and Recording Devices*—Load shall be measured with a load cell having a minimum capacity of 500 N and a sensitivity of 0.1 N. The load cell shall be calibrated at least annually in accordance with ASTM E 4. The load and elongation shall be monitored with the data acquisition system such that they can be resolved to 1 percent of the failure load and elongation, respectively. Once the test has started, the data acquisition system shall be able to detect the point in time when the load starts to change as a result of elongation in the sample. This shall be accomplished by monitoring the load cell signal with time. A change in the load signal equivalent to 2 ± 0.3N (threshold load) shall be used to mark the point in time where zero reading of the displacement transducer is obtained. The point in time where the peak load is obtained will be captured by the data acquisition system and the accumulated elongation from the zero reading to the elongation corresponding to the peak load shall be used to calculate the failure strain. Once the test is complete the device shall display the strain at failure. Peak loads typically range from 10 to 250 N depending on the test temperature, grade, aging, and source of the binder. Stress and strain shall be displayed to the nearest 0.1.

6.1.6. *Elongation Measuring and Recording Devices*—Specimen elongation shall be measured between the grips with a displacement transducer. The displacement transducer shall be capable of measuring and controlling grip separation and provide a feedback for elongation rate control with a displacement resolution of 1.0 µm.

6.1.6.1. If the data acquisition component consists of an IBM-compatible computer, it shall have three A/D channels, one for load, one for elongation, and one for temperature. Data shall be stored in ASCII format.

6.1.6.2. *Display of Stress-Strain Curve*—The data acquisition and display system shall be capable of displaying a stress-strain curve in units of stress (MPa) versus percent strain. This may be accomplished using the video screen of the data acquisition computer or with an x-y recorder. If a recorder is used, the units may be in volts, but in this case the test file shall contain the calibration factor in MPa/volt and percent strain/volt for both the x and y axes.

6.2. *Specimen Molds*—The specimen molds shall be manufactured from aluminum. Molds shall have the dimensions specified in Figure 6. A release agent along with a Teflon®-coated release paper, described later in Sections 7.2 and 7.3, shall be used to prevent asphalt binder from adhering to the aluminum mold sides and back plate when making the specimen. The release paper is required to prevent asphalt binder from adhering to the bottom plate of the mold.



Notes: 1. All dimensions are in millimeters (inches in parentheses).
2. Tolerances are as follows: Fractions = ± 1.6 (1⁄16)
X.X = ± 0.8 (0.03)
X.XX = ± 0.25 (0.01)
X.XXX = ± 0.12 (0.005)
Angles = ± 30°

3. Remove all sharp edges.
4. Surface finish for machined surfaces: $\sqrt[125]{}$ unless otherwise specified.

Figure 6—Superpave Direct Tension Specimen Mold

6.3. *Specimen Storage Plates*—Plexiglas™, Teflon®, or other plastic plates for transferring and storing test specimens in the air-cooled environmental chamber. These plates are not required if a fluid cooling bath is used.

6.4. *Calibrated Thermometer*—A calibrated liquid-in-glass thermometer of suitable range with subdivisions of 0.1°C is required for verification of the temperature transducer. This thermometer shall be calibrated in accordance with ASTM E 77. An ASTM 62C thermometer is suitable.

6.5. Freezer capable of maintaining a temperature of –15 ± 5°C. The freezer is only required when using the air-cooled chamber for testing.

6.6. A forced-air convection oven capable of reaching and maintaining a temperature of 160 ± 5°C for heating asphalt.

7. MATERIALS

7.1. *Fluid for temperature control in systems equipped with cooling baths*—An aqueous mixture of 42 percent potassium acetate powder and 58 percent deionized water by weight shall be used as a fluid for temperature control. Alcohols are not allowed because they have been found to lower the failure properties of all asphalts.

7.2. *Release Agent*—A mixture of 20 g of glycerin and 20 g of talc (USP) shall be used as a release agent for the aluminum molds.

7.3. *Release Paper*—A Teflon®-coated paper coated on both sides with a minimum of 0.3 micrometer of Teflon® has been found to be suitable for use as a release paper.

7.4. Solvent (Varsol™ or mineral spirits) or a degreasing spray cleaner formulated for use on asphalt for cleaning molds, end tabs, and plates.

7.5. Cleaning cloths (cotton) for wiping molds, end tabs, and plates.

8. HAZARDS

8.1. Use standard laboratory safety procedures required for handling the hot asphalt binder when preparing test specimens and required safety procedures when cleaning with solvents or degreasers.

9. CALIBRATION AND STANDARDIZATION

9.1. Verify calibration of the displacement transducer, load cell, and temperature transducer.

Note 2—Calibration is usually performed by a calibration service agency. Calibration verification, system standardization, and quality checks may be performed by the manufacturer, other agencies providing such services, or in-house personnel using the procedures described below.

9.1.1. *Load Cell and Displacement Transducer Verification*—A specially designed standard shall be used to verify the operation of both the load cell and the displacement transducer. The verification standard shall have a spring rate of approximately 135 N/mm and shall be capable of withstanding a 500-N load without damage. The verification standard shall be supplied by the manufacturer of the direct tension test system along with the stress-strain characteristics. The manufacturer shall provide a certificate with each verification standard that guarantees the NIST traceability of the equipment used to determine the stress-strain characteristics of the standard. Verify calibration of the load cell and displacement transducer at least every 6 months and when measurements are suspect.

9.1.2. *Verification of Elongation Rate*—The elongation rate shall be verified using the verification standard discussed in Section 9.1.1 To verify the elongation rate, elongation shall be plotted as a function of elapsed time. The resulting plot shall be a straight line with a slope 1.00 mm/min.

Note 3—Measurements shall be made at –18°C. Allow 10 minutes for the verification standard to achieve thermal equilibrium.

9.1.3. *Temperature Detector*—The temperature detector shall be calibrated at a minimum of once each year or sooner if it is believed the equipment may be out of calibration. The temperature shall be calibrated by a NIST-traceable device with measurement uncertainty less than one-third of the required tolerance of the measurement per ISO 10012, Section 4.3. For temperature control of ±0.1°C, the calibration device uncertainty shall be ± 0.033°C. The temperature shall be calibrated at each of the test temperatures used. Place the temperature calibration device in the environmentally controlled chamber and hold the RTD in intimate contact with the device. When the device and the temperature detection device have reached equilibrium, compare the temperature indicated on the readout for the RTD to the temperature observed by reading the calibration device. If the temperature indicated by the thermal detector does not agree with the calibration device within ± 0.1°C, apply an appropriate temperature correction to the temperature measurement indicated by the temperature detector or further calibration or maintenance is required.

10. PREPARATION OF SAMPLES AND TEST SPECIMENS

10.1. *Preparing Test Samples*—If unaged binder is to be tested, obtain test samples according to T 40.

10.1.1. Anneal the asphalt binder from which the test specimen is obtained by heating until sufficiently fluid to pour. Annealing prior to testing removes reversible molecular associations (steric hardening) that occur during normal storage at ambient temperature.

Note 4—Minimum pouring temperatures that produce a consistency equivalent to that of SAE 10W30 motor oil (readily pours but not overly fluid) at room temperature are recommended. The specific temperature will depend on the grade of binder and its prior aging history if any. Temperatures less than 135°C are desirable; however, temperatures above 135°C may be required for some modified asphalt binders or heavily aged binders.

10.2. Coat the specimen-forming surfaces of the two mold side plates of the aluminum mold with the release agent. The coating shall be applied so as to produce a thin uniform film on the metal surface such that no part of the metal surface is exposed. Place a single precut sheet of release paper on the bottom plate of the mold. Slide one side plate on to the bottom plate over the release paper. Place the end tabs into both ends of the mold. Slide the other side plate onto the bottom plate to complete the assembly of the mold. Place the molds and end tab assembly in the same oven that is used to heat the asphalt binder, i.e., at the same temperature for no more than 3 minutes. If molds are left in the oven for longer than 3 minutes, it will affect the release properties of the glycerin and talc coating.

10.3. Remove the mold from the oven and place it on a flat surface. Pour hot asphalt binder into the mold starting from one end of the cavity and moving across the cavity in a single pass. Pour the specimen in a continuous stream to avoid entraining air bubbles or gaps. Complete the pouring operation as quickly as possible to avoid any excessive drop in the temperature of the asphalt binder. Stop pouring when the asphalt is slightly above the top surface of the mold.

10.4. After pouring the test specimen, allow the entire assembly to cool on the bench top at ambient temperature for 30 to 60 minutes. Do not quench (quick or instantaneous cooling) the specimen to achieve ambient temperature (25°C or lower).

10.5. As soon as the specimen has cooled to room temperature, trim off the excess asphalt binder with an approximately 165°C straightedge (e.g., a flat, stiff, heavy-gauge putty knife) so that the asphalt binder is flush with the top of the mold. Use care during the trimming operation so that the asphalt binder is not pulled away from the mold and the bond between the end tabs and the asphalt binder is not damaged. Trim off the specimen in a consistent manner. Pull the hot knife along the long axis of the sample flush with the surface of the mold to remove the excess asphalt binder. After trimming, remove all debris or extraneous asphalt binder from the holes or slots in the end tab. Let the specimen sit at ambient temperature for 10 to 15 minutes after trimming.

10.6. Prior to demolding, place two side plates of an unused aluminum mold (Figure 4) into the cooling bath or air chamber and allow them to cool to the test temperature. These side plates will be used as holders for transferring the specimen to the test bath or chamber. Also prepare a specimen transfer plate as follows: Place an unused aluminum bottom plate of the mold (Figure 4) upside down on the work bench so as to form a transfer plate. Place two release papers so that they overlap lengthwise and cover the surface of the transfer plate.

10.7. Carefully demold the trimmed specimen.

10.7.1. Now demold the trimmed specimen by gently sliding the specimen and the two mold side plates towards one edge of the bottom plate until the side plate nearest to the edge is halfway across the edge. Pivot the overhanging side plate downwards using gentle pressure and demold that side. Replace the just released plate and now slide the specimen and the two side plates (one side demolded but reassembled) towards the other edge and repeat the procedure given above.

10.7.2. Next, repeat the above demolding procedure, except this time remove one side plate completely and gently mount one of the cold side plates from the cooling bath or chamber onto that side of the specimen. Now demold the other mold side plate and mount the other cold side plate from the cooling bath or chamber. At this point the specimen and mold assembly should look exactly like the trimmed specimen before demolding except the two side plates are now replaced with cold side plates that were placed in the cooling chamber or bath before the demolding process began.

10.7.3. Now turn the cold specimen mold assembly upside down by holding the mold assemble in the center between the thumb and the forefinger of each hand. Place the upside-down mold assembly on the transfer plate so as to form a cross, i.e., the mold assembly must be perpendicular to the transfer plate covered with release papers. Gently remove the bottom plate from the upside-down specimen assembly resting on the transfer plate by gently sliding it off. The release paper at the bottom of the specimen is now exposed. Hold the two side plates so as to secure the specimen while gently removing the release paper.

10.7.4. Carry the transfer plate with the upside-down but exposed specimen to the test chamber or bath. Immediately place the specimen (along with the two cold side plates) into the cooling bath or chamber onto one of the trays. Remove the two side plates after a 2-minute cool-down period. Some softer grades may require more than 2 minutes before removing the side plates.

10.7.5. Now flip the just-released specimen in the test bath or chamber so that the trimmed side is up. The specimen must always be tested with the trimmed side facing up. The transfer plate covered with the release papers should never be placed into the bath. Measurement of specimen dimensions after demolding is not necessary since dimensional tolerances are closely controlled in the molding process.

Note 5—Minimize distortion of the specimen during demolding. The variability in failure properties is increased if distorted (bent along or perpendicular to the loading axis) specimens are tested. A distorted specimen yields lower failure values.

11. SPECIMEN CONDITIONING

11.1. Set the cooling bath at the desired testing temperature and wait until it stabilizes to within ±0.1°C of the desired test temperature.

11.1.1. When testing for compliance with M 320, Table 1, use the test temperatures specified in Table 1 of M 320.

11.1.2. When testing for compliance with M 320, Table 2, use test temperatures specified in R 49.

11.2. Condition the specimens in the cooling bath or chamber at the test temperature for 60 ± 10 minutes. Adhere carefully to the time schedule to avoid testing variability due to physical hardening.

12. TEST PROCEDURE FOR SYSTEMS WITH FLUID BATH-BASED COOLING

12.1. Using rubber-tipped tongs, mount the specimen on the load frame by matching the holes on the end tabs at each end of the specimen to the loading pins on the load frame. If the holes do not match with the pins, mount one of the pins with a specimen end and adjust the load frame by moving the thumbwheel on the control box until the other end of the specimen falls into place as shown. Check the seating of the specimen by running the tongs lightly on the end tabs at each end of the specimen.

12.2. Once the specimen is on the loading pins, remove the slack between the specimen and the loading pins. Ideally the slack should be removed by setting up the test software to automatically monitor the load, zero the strain, and start the test when the load reaches a value of 2 ± 0.3 N. If such software control is not available or if the vertical test setup of an air-cooled test chamber is used, then remove the slack manually by manipulating the thumbwheel on the control box for fine adjustment. The thumbwheel is moved in the direction so as to produce tension (stretch the specimen). The thumbwheel is moved until a load of 2 ± 0.3 N is shown on the monitor screen. Once this has been accomplished, recheck the seating of the specimen with the tongs to avoid any erroneous load readings. Repeat the above manual loading procedure until a load of 2 ± 0.3 N is again obtained. Now zero the strain quickly and press the start key to start the test. If the slack is removed by setting up the software to automatically perform the slack removal, then the test is also automatically started by the software after zeroing the strain. No manual pressing of the start key is required in that case.

12.3. Set the strain rate to 3 percent/min (to allow an elongation rate of 1 mm/min) if it is not preset in the software.

13. TEST PROCEDURE FOR SYSTEMS WITH FORCED AIR BASED COOLING

13.1. After 60 ± 10 minutes, mount the specimen on the pins using the environmental chamber hand access port so that the back face of the end tab is centered on the mounting pin. Do not open the chamber door to handle or mount the specimen because that will produce excessive temperature fluctuations, which will take time to stabilize and lead to variable thermal histories. Handle the specimens with rubber surgeons' gloves to protect the operator's fingers and to minimize heating of the specimen. Handle the specimen by touching only the end tabs—do not touch the asphalt binder.

Note 6—Air currents for the circulation fan may cause the end tabs to move after being placed on the mounting pins. A silicone rubber or foam washer that remains flexible at the test temperature will help hold the end tab against the face of the grip. It is important that the end tab be centered on the pin (flush against the face of the grip) in order for the load to be applied axially through the center of the test specimen. A suitable washer may be cut from silicone rubber or foam sheeting with a cork borer. The washer may be 5- to 10-mm thick with an outer diameter of approximately 10 mm. The inside diameter of the washer should be sufficient to provide a friction fit on the 5-mm portion of the pin. The washer should slide easily on the pin providing only sufficient force to hold the end tab in place during the test.

13.2. *Loading Procedure*—Apply a preload to the test specimen by mounting the specimen as previously described and applying an elongation sufficient to develop a 1- to 2-N load; this may reduce testing variability. As soon as the 1- to 2-N load is reached, stop the movement of the platen and allow the load to relax until it is no longer detectable. The time required to relax the load will depend on the stiffness of the test specimen. Once the load has relaxed, continue the test as described in the following sections.

13.3. Select the desired strain rate and load the specimen to failure. Select a strain rate that gives an effective gauge section elongation rate of 1.00 ± 0.01 mm/min when testing for compliance with M 320. If a test specimen fails outside the gauge area of the specimen (from throat to throat), discard the test.

14. NUMBER OF REPLICATES

14.1. A total of six specimens shall be tested as described above. Fracture stress and strain are inherently variable for asphalt binders. Testing of multiple specimens may produce obvious outliers. Of six specimens tested, discard the two lowest values of failure stress, strain, and energy and recalculate the mean and standard deviation values for the four remaining failure values.

15. FAILURE IDENTIFICATION

15.1. The strain at failure is easily identified as the strain at peak load (maximum stress) when the failure is by fracture (i.e., breaks into two pieces on failure). However, when the specimen does not fracture but reaches a maximum stress and then flows without fracture the strain at failure is recorded as the strain corresponding to the maximum stress. Do not continue the test beyond 10 percent strain, and simply record the failure strain as "greater than 10 percent." If the asphalt binder can be stretched to 10 percent without fracture, it meets the requirements of M 320 at the test temperature.

15.2. If the specimen fails at the throat section, the data for failure should be recorded but it should also be noted that it failed in the throat. While the acceptable failure is in the gauge section (18-mm-long constant cross-section portion), ideally, failure should occur in the center of each specimen. The location of failure and the consistency or repeatability of failure data is directly related to straightness, how carefully the specimens are prepared, and how well they are mounted prior to testing.

16. CLEANING OF END TABS

16.1. If the end tabs are to be reused, after testing discard the asphalt portion of the spent specimen and clean the end tabs by soaking them in solvent and wiping with a soft cloth. After wiping the end tabs, use a detergent soap solution to remove any oil film residue left by the mineral spirit cleaner. Alternatively, use a degreasing spray cleaner. Clean the end tabs thoroughly. Grease-film on the asphalt bonding area can create a weak bond causing bond failures.

17. CALCULATIONS

17.1. Compute the failure stress by dividing the failure load by the original area of the test specimen cross-section (6 × 6 mm) as shown in Equation 1:

$$\sigma_f = P_f / A \tag{1}$$

where:

σ_f = failure stress, MPa;

P_f = failure load, N; and

A = original area of cross-section, m^2.

Note 7—For specimens used in this test, $A = 36 \bullet 10^{-6}$ m^2

17.2. Compute the failure strain by dividing the elongation at failure by the original gauge length, as shown in Equation 2:

$$\in_f = \delta_f / L_e \tag{2}$$

where:

$\in_f$ = failure strain, mm/mm;

δ_f = elongation at failure, mm; and

L_e = effective gauge length, mm.

Note 8—For specimens used in this test, the effective gauge length, L_e, has been determined to be 33.8 mm.

18. REPORT

18.1. Report the following information:

18.1.1. Sample identification;

18.1.2. Date and time of test;

18.1.3. Test temperature, nearest 0.1°C;

18.1.4. Rate of elongation, nearest 0.01 mm/min;

18.1.5. Failure strain, nearest 0.01 percent;

18.1.6. Failure stress, nearest 0.01 MPa;

18.1.7. Peak load, nearest N; and

18.1.8. Type of fracture observed (fracture or no fracture).

---

19. PRECISION AND BIAS

19.1. *Precision*—Criteria for judging the acceptability of failure stress and strain results obtained by this method are given in Table 1.

19.2. *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

19.3. *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

Table 1—Precision Estimates

Condition	Coefficient of Variation (1s%)[a]	Acceptable Range of Two Test Results (d2s%)[a]
Single-Operator Precision:		
Stress (MPa)	7.4	20.8
Strain (%)	11.4	32.2
Multilaboratory Precision:		
Stress (MPa)	18.6	52.5
Strain (%)	31.5	89.1

[a] These values represent the 1s% and d2s% limits described in ASTM Practice C 670.

Note 9—The precision estimates given in Table 1 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 34 to 61 laboratories for each of the eight pairs of samples. The analysis included five binder grades: PG 52-34, PG 64-16, PG 64-22, PG 70-22, and PG 76-22 (SBS modified). Average stress results ranged from 2.79 MPa to 4.22 MPa. Average strain results ranged from 0.91 to 3.00 percent. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Note 10—As an example, two tests conducted on the same material yield stress results of 2.95 MPa and 3.15 MPa, respectively. The average of these two measurements is 3.05 MPa. The acceptable range of results is then 20.8 percent of 3.05 MPa or 0.63 MPa. As the difference between 2.95 MPa and 3.15 MPa is less than 0.63 MPa, the results are within the acceptable range.

19.4. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

Standard Method of Test for

Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)

AASHTO Designation: T 315-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)

AASHTO Designation: T 315-10

1. SCOPE

1.1. This test method covers the determination of the dynamic shear modulus and phase angle of asphalt binder when tested in dynamic (oscillatory) shear using parallel plate test geometry. It is applicable to asphalt binders having dynamic shear modulus values in the range from 100 Pa to 10 MPa. This range in modulus is typically obtained between 6 and 88°C at an angular frequency of 10 rad/s. This test method is intended for determining the linear viscoelastic properties of asphalt binders as required for specification testing and is not intended as a comprehensive procedure for the full characterization of the viscoelastic properties of asphalt binder.

1.2. This standard is appropriate for unaged material or material aged in accordance with T 240 and R 28.

1.3. Particulate material in the asphalt binder is limited to particles with longest dimensions less than 250 μm.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

3.2. *Descriptions of Terms Specific to This Standard*:

3.2.1. *annealing*—heating the binder until it is sufficiently fluid to remove the effects of steric hardening.

3.2.2. *complex shear modulus (G^*)*—ratio calculated by dividing the absolute value of the peak-to-peak shear stress, τ, by the absolute value of the peak-to-peak shear strain, γ.

3.2.3. *calibration*—process of checking the accuracy and precision of a device using NIST-traceable standards and making adjustments to the device where necessary to correct its operation or precision and accuracy.

3.2.4. *dummy test specimen*—a specimen formed between the dynamic shear rheometer (DSR) test plates from asphalt binder or other polymer to measure the temperature of the asphalt binder held between the plates. The dummy test specimen is used solely to determine temperature corrections.

3.2.5. *loading cycle*—a unit cycle of time for which the test sample is loaded at a selected frequency and stress or strain level.

3.2.6. *phase angle (δ)*—the angle in radians between a sinusoidally applied strain and the resultant sinusoidal stress in a controlled-strain testing mode, or between the applied stress and the resultant strain in a controlled-stress testing mode.

3.2.7. *loss shear modulus (G'')*—the complex shear modulus multiplied by the sine of the phase angle expressed in degrees. It represents the component of the complex modulus that is a measure of the energy lost (dissipated during a loading cycle).

3.2.8. *storage shear modulus (G')*—the complex shear modulus multiplied by the cosine of the phase angle expressed in degrees. It represents the in-phase component of the complex modulus that is a measure of the energy stored during a loading cycle.

3.2.9. *parallel plate geometry*—refers to a testing geometry in which the test sample is sandwiched between two relatively rigid parallel plates and subjected to oscillatory shear.

3.2.10. *oscillatory shear*—refers to a type of loading in which a shear stress or shear strain is applied to a test sample in an oscillatory manner such that the shear stress or strain varies in amplitude by about zero in a sinusoidal manner.

3.2.11. *linear viscoelastic*—within the context of this specification refers to a region of behavior in which the dynamic shear modulus is independent of shear stress or strain.

3.2.12. *portable thermometer*—is an electronic device that consists of a temperature detector (probe containing a thermocouple or resistive element), required electronic circuitry, and readout system.

3.2.13. *reference thermometer*—a NIST–traceable liquid-in-glass or electronic thermometer that is used as a laboratory standard.

3.2.14. *temperature correction*—difference in temperature between the temperature indicated by the DSR and the test specimen as measured by the portable thermometer inserted between the test plates.

3.2.15. *thermal equilibrium*—is reached when the temperature of the test specimen mounted between the test plates is constant with time.

3.2.16. *verification*—process of checking the accuracy of a device or its components against an internal laboratory standard. It is usually performed within the operating laboratory.

3.2.17. *steric hardening*—see molecular association.

3.2.18. *molecular association*—a process where associations occur between asphalt binder molecules during storage at ambient temperature. Often called steric hardening in the asphalt literature, molecular associations can increase the dynamic shear modulus of asphalt binders. The amount of molecular association is asphalt specific and may be significant even after a few hours of storage.

4. SUMMARY OF TEST METHOD

4.1. This standard contains the procedure used to measure the complex shear modulus (G^*) and phase angle (δ) of asphalt binders using a dynamic shear rheometer and parallel plate test geometry.

4.2. The standard is suitable for use when the dynamic shear modulus varies between 100 Pa and 10 MPa. This range in modulus is typically obtained between 6 and 88°C at an angular frequency of 10 rad/s, dependent upon the grade, test temperature, and conditioning (aging) of the asphalt binder.

4.3. Test specimens 1 mm thick by 25 mm in diameter or 2 mm thick by 8 mm in diameter are formed between parallel metal plates. During testing, one of the parallel plates is oscillated with respect to the other at pre-selected frequencies and rotational deformation amplitudes (strain control) (or torque amplitudes (stress control)). The required stress or strain amplitude depends upon the value of the complex shear modulus of the asphalt binder being tested. The required amplitudes have been selected to ensure that the measurements are within the region of linear behavior.

4.4. The test specimen is maintained at the test temperature to within ±0.1°C by positive heating and cooling of the upper and lower plates or by enclosing the upper and lower plates in a thermally controlled environment or test chamber.

4.5. Oscillatory loading frequencies using this standard can range from 1 to 100 rad/s using a sinusoidal waveform. Specification testing is performed at a test frequency of 10 rad/s. The complex modulus (G^*) and phase angle (δ) are calculated automatically as part of the operation of the rheometer using proprietary computer software supplied by the equipment manufacturer.

5. SIGNIFICANCE AND USE

5.1. The test temperature for this test is related to the temperature experienced by the pavement in the geographical area for which the asphalt binder is intended to be used.

5.2. The complex shear modulus is an indicator of the stiffness or resistance of asphalt binder to deformation under load. The complex shear modulus and the phase angle define the resistance to shear deformation of the asphalt binder in the linear viscoelastic region.

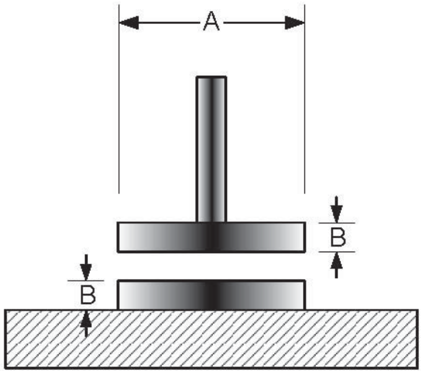
5.3. The complex modulus and the phase angle are used to calculate performance-related criteria in accordance with M 320.

6. APPARATUS

6.1. *Dynamic Shear Rheometer (DSR) Test System*—Consisting of parallel metal plates, an environmental chamber, a loading device, and a control and data acquisition system.

6.1.1. *Test Plates*—Stainless steel or aluminum plates with smooth ground surfaces. One 8.00 ± 0.02 mm in diameter and one 25.00 ± 0.05 mm in diameter (Figure 1). The base plate in some rheometers is a flat plate. A raised portion, a minimum of 1.50 mm high, with the same radius as the upper plate is required. The raised portion makes it easier to trim the specimen and may improve test repeatability.

Note 1—To obtain correct data, the upper and lower plates should be concentric with each other. At present there is no suitable procedure for the user to check the concentricity except to visually observe whether or not the upper and lower plates are centered with respect to each other. The moveable plate should rotate without any observable horizontal or vertical wobble. This operation may be checked visually or with a dial gauge held in contact with the edge of the moveable plate while it is being rotated. There are two values that determine the operating behavior of a measuring system: centricity (horizontal wobble) and runout (vertical wobble). Typically, wobble can be detected if it is greater than ±0.02 mm. For a new system, a wobble of ±0.01 mm is typical. If the wobble grows to more than ±0.02 mm with use, it is recommended that the instrument be serviced by the manufacturer.



Dimension	8-mm Nominal	25-mm Nominal
A	8 ± 0.02 mm	25 ± 0.05 mm
B	≥1.50 mm	≥1.50 mm

Figure 1—Plate Dimensions

6.1.2. *Environmental Chamber*—For controlling the test temperature, by heating or cooling (in steps or ramps), to maintain a constant specimen environment. The medium for heating and cooling the specimen in the environmental chamber shall not affect asphalt binder properties. The temperature in the chamber may be controlled by the circulation of fluid such as water, conditioned gas such as nitrogen, or by a suitable arrangement of solid state Peltier elements surrounding the sample. When forced air is used, a suitable drier must be included to prevent condensation of moisture on the plates and fixtures and, if operating below freezing temperatures, the formation of ice. The environmental chamber and the temperature controller shall control the temperature of the specimen, including thermal gradients within the sample, to an accuracy of ±0.1°C. The chamber shall completely enclose the top and the bottom plates to minimize thermal gradients.

Note 2—A circulating bath unit separate from the DSR which pumps the bath fluid through the test chamber may be required if a fluid medium is used. The flow rate of the bath media should not be modified once the temperature settings have been adjusted to the desired value. Media lines should be periodically inspected and cleaned or replaced if necessary to remove obstructions

6.1.2.1. *Temperature Controller*—Capable of maintaining specimen temperatures within ±0.1°C for test temperatures ranging from 3 to 88°C.

6.1.2.2. *Internal Temperature Detector for the DSR*—A platinum resistance thermometer (PRT) mounted within the environmental chamber as an integral part of the DSR and in close proximity to the fixed plate, with a range of 3 to 88°C, and with a resolution of 0.1°C (see Note 3). This thermometer shall be used to control the temperature of the test specimen between the plates and shall provide a continuous readout of temperature during the mounting, conditioning, and testing of the specimen. The PRT shall be calibrated as an integral unit with its respective meter or electronic circuitry.

Note 3—PTRs meeting DIN Standard 43760 (Class A) or equal are recommended for this purpose.

6.1.3. *Loading Device*—Capable of applying a sinusoidal oscillatory load to the specimen at a frequency of 10.0 ± 0.1 rad/s. If frequencies other than 10 rad/s are used, the frequency shall be accurate to one percent. The loading device shall be capable of providing either a stress controlled or strain controlled load. If the load is strain controlled, the loading device shall apply a cyclic torque sufficient to cause an angular rotational strain accurate to within 100 μ rad of the strain specified. If the load is stress controlled, the loading device shall apply a cyclic torque accurate to within 10 mN·m of the torque specified. Total system compliance at 100 N·m of torque shall be less than 2 mrad/N·m. The manufacturer of the device shall certify that the frequency, stress, and strain are controlled and measured with an accuracy of one percent or less in the range of this measurement.

6.1.4. *Control and Data Acquisition System*—Capable of providing a record of temperature, frequency, deflection angle, and torque. Devices used to measure these quantities shall meet the accuracy requirements specified in Table 1. In addition, the system shall calculate and record the shear stress, shear strain, complex shear modulus (G^*) and phase angle (δ). The system shall measure and record G^*, in the range of 100 Pa to 10 MPa, to an accuracy of 1.0 percent or less, and the phase angle, in the range of 0 to 90 degrees, to an accuracy of 0.1 degrees.

Table 1—Control and Data Acquisition System Requirements

Property	Accuracy
Temperature	0.1°C
Frequency	1%
Torque	10 mN·m
Deflection angle	100 μrad

6.2. *Specimen Mold (Optional)*—The overall dimensions of the silicone rubber mold for forming asphalt binder test specimens may vary but the thickness shall be greater than 5 mm. If the mold is a single sample mold, the following dimensions have been found suitable: For a 25-mm test plate with a 1-mm gap, a mold cavity approximately 18 mm in diameter and 2.0 mm deep. For an 8-mm test plate with a 2-mm gap, a mold cavity approximately 8 mm in diameter and 2.5 mm deep.

6.3. *Specimen Trimmer*—With a straightedge at least 4 mm wide.

6.4. *Wiping Material*—Clean cloth, paper towels, cotton swabs, or other suitable material as required for wiping the plates.

6.5. *Cleaning Solvents*—Mineral oil, citrus-based solvents, mineral spirits, toluene, or similar solvent as required for cleaning the plates. Acetone for removing the solvent residue from the surfaces of the plates is also necessary.

6.6. *Reference Thermometer*—Either NIST-traceable liquid-in-glass thermometer(s) or NIST–traceable electronic thermometric device(s). This temperature standard shall be used to standardize the portable thermometer (Section 9.3).

6.6.1. *Liquid-in-Glass Thermometer*—NIST-traceable thermometer(s) with a suitable range and subdivisions of 0.1°C. The thermometer(s) shall be a partial immersion thermometer(s) within an ice point and standardized in accordance with ASTM E 563.

6.6.1.1. *Optical Viewing Device (Optional)*—For use with liquid-in-glass thermometers that enhances readability and minimizes parallax when reading the liquid-in-glass reference thermometer.

6.6.2. *Electronic Thermometer*—Incorporating a resistive detector (Note 3) with an accuracy of ±0.05°C and a resolution of 0.01°C. The electronic thermometer shall be standardized at least once per year using a NIST–traceable reference standard in accordance with ASTM E 77.

6.7. *Portable Thermometer*—A standardized portable thermometer consisting of a resistive detector, associated electronic circuitry, and digital readout. The thickness of the detector shall be no greater than 2.0 mm such that it can be inserted between the test plates. The reference thermometer (see Section 6.6) may be used for this purpose if its detector fits within the dummy specimen as required by Section 9.4.1 or 9.4.2.

7. HAZARDS

7.1. Standard laboratory caution should be used in handling the hot asphalt binder when preparing test specimens.

8. PREPARATION OF APPARATUS

8.1. Prepare the apparatus for testing in accordance with the manufacturer's recommendations. Specific requirements will vary for different DSR models and manufacturers.

8.2. Inspect the surfaces of the test plates and discard any plates with jagged or rounded edges or deep scratches. Clean any asphalt binder residue from the plates with an organic solvent such as mineral oil, mineral spirits, a citrus-based solvent, or toluene. Remove any remaining solvent residue by wiping the surface of the plates with a cotton swab or a soft cloth dampened with acetone. If necessary, use a dry cotton swab or soft cloth to ensure that no moisture condenses on the plates.

8.3. Mount the cleaned and inspected test plates on the test fixtures and tighten firmly.

8.4. Select the testing temperature according to the grade of the asphalt binder or according to the preselected testing schedule (see Note 4). Allow the DSR to reach a stabilized temperature within ±0.1°C of the test temperature.

Note 4—M 320 and R 29 provide guidance on the selection of test temperatures.

8.5. With the test plates at the test temperature or the middle of the expected testing range, establish the zero gap level (1) by manually spinning the moveable plate, and while the moveable plate is spinning, close the gap until the removable plate touches the fixed plate (the zero gap is reached when the plate stops spinning completely), or, (2) for rheometers with normal force transducers, by closing the gap and observing the normal force and after establishing contact between the plates, setting the zero gap at approximately zero normal force.

Note 5—The frame, detectors, and fixtures in the DSR change dimension with temperature causing the zero gap to change with changes in temperature. Adjustments in the gap are not necessary when measurements are made over a limited range of temperatures. The gap should be set at the test temperature or, when tests are to be conducted over a range of temperatures, the gap should be set at the middle of the expected range of test temperatures. For most instruments, no gap adjustment is needed as long as the test temperature is within ±12°C of the temperature at which the gap is set. If the instrument has thermal gap compensation, the gap may be set at the first test temperature instead of the middle of the range of test temperatures.

8.6. Once the zero gap is established as per Section 8.5, move the plates apart to approximately the test gap and preheat the plates. Preheating the plates promotes adhesion between the asphalt binder and the plates, especially at the intermediate grading temperatures.

8.7. To preheat 25-mm plates, bring the test plates to the test temperature or the lowest test temperature if testing is to be conducted at more than one temperature. To preheat 8-mm plates, bring the plates to between 34 and 46°C. Move the plates apart and establish a gap setting of 1.05 mm (for 25-mm diameter test specimens) or 2.10 mm (for 8-mm diameter test specimens).

Note 6—In order to obtain adequate adhesion between the asphalt binder and the test plates, the plates must be preheated. Preheating is especially critical when the silicone mold is used to prepare the asphalt binder for transfer to the test plates and when the testing is conducted with the 8-mm plates. When the direct placement method is used, as long as the test plates are immediately brought in contact with the asphalt binder, the heat carried with the asphalt binder improves adhesion. The preheating temperature needed for proper adhesion will depend on the grade and nature of the asphalt binder and the test temperature (8-mm or 25-mm plates). For some of the stiffer binder grades, especially those with high levels of modification, heating the plates to 46°C may not be sufficient to ensure proper adhesion of the asphalt binder to the test plates, especially if the silicone mold is used and the testing is conducted with 8-mm plates. For highly modified asphalt binders only, higher preheat temperatures may be used.

9. VERIFICATION AND CALIBRATION

9.1. Verify the DSR and its components at least every six months and when the DSR or plates are newly installed, when the DSR is moved to a new location, or when the accuracy of the DSR or any of its components is suspect. Four items require verification—the test plate diameter, DSR torque transducer, portable thermometer, and DSR test specimen temperature. Verify the DSR temperature transducer before verifying the torque transducer.

9.2. *Verification of Plate Diameter*—Measure the diameters to the nearest 0.01 mm. Maintain a log of the measured diameters as part of the laboratory quality control program so that the measurements are clearly identified with the specific plates. Enter the actual measured dimensions into the DSR software for use in calculations. If the top and bottom plates differ in diameter, enter the smaller of the two measured diameters.

Note 7—An error of ± 0.05 mm in the diameter of the plate results in a 0.8 percent error in the complex modulus for the 25-mm plate. For the 8-mm plate, errors in diameter of ±0.01, ±0.02, and ±0.05 mm give respective errors in complex modulus of 0.5, 1.0, and 2.5 percent.

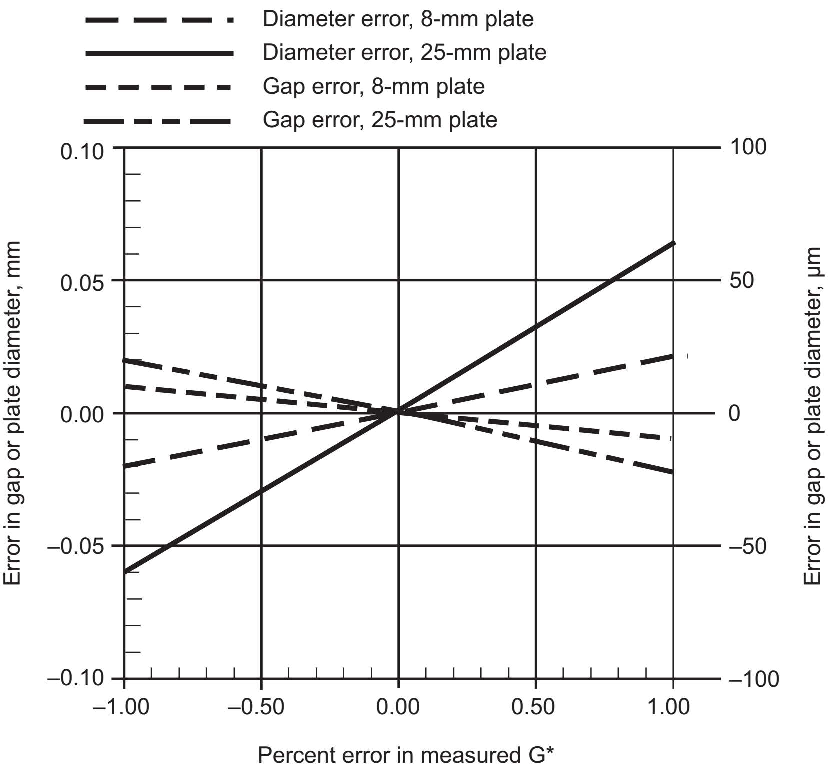


Figure 2—Effect of Error in Gap or Plate Diameter

9.3. *Verification of Portable Thermometer*—Verify the portable thermometer (used to measure the temperature between the test plates), using the laboratory reference thermometer. A portable thermometer shall be considered the combination of the meter (readout device) and the thermistor (temperature probe) as a single unit, and must be verified as such. If the reference thermometer (Section 6.6) is also used as a portable thermometer to measure the temperature between the test plates, it shall meet the requirements of Section 6.7.

9.3.1. *Recommended Verification Procedure*—Bring the reference thermometer into intimate contact with the detector from the portable thermometer and place them in a thermostatically controlled and stirred water bath (Note 8). Ensure that de-ionized water is used to prevent electrical conduction from occurring between the electrodes of the resistive temperature sensitive element. If de-ionized water is not available, encase the reference thermometer and detector of the portable thermometer in a waterproof plastic bag prior to placement in the bath. Obtain measurements at intervals of approximately 6°C over the range of test temperatures allowing the bath to reach thermal equilibrium at each temperature. If the readings of the portable thermometer and the reference thermometer differ by 0.1°C or more, record the difference at each temperature as a temperature correction, and maintain the corrections in a log as part of the laboratory quality control program.

Note 8—A recommended procedure for the high temperature range is to use a stirred water bath that is controlled within ±0.1°C such as the viscosity bath used for ASTM D 2170 or D 2171. For a low temperature bath, an ice bath or controlled temperature bath may be used. Bring the probe from the portable thermometer into contact with the reference thermometer, and hold the assembly in intimate contact. A rubber band works well for this purpose. Immerse the assembly in the water bath, and bring the water bath to thermal equilibrium. Record the temperature on each device when thermal equilibrium is reached.

Note 9—If the readings from the two devices differ by 0.5°C or more, the calibration or operation of the portable thermometer may be suspect, and it may need to be recalibrated or replaced. A continuing change in the temperature corrections with time may also make the portable thermometer suspect.

9.4. *Test Specimen Temperature Correction*—Thermal gradients within the rheometer can cause differences between the temperature of the test specimen and the temperature indicated by the DSR thermometer (also used to control the temperature of the DSR). The DSR thermometer shall be checked at an interval no greater than six months. When these differences are 0.1°C or greater, determine a temperature correction by using a thermal detector mounted in a silicone rubber wafer (Section 9.4.1) or by placing asphalt binder (dummy sample) between the plates and inserting the detector of the portable thermometer into the asphalt binder (Section 9.4.2).

9.4.1. *Method Using Silicone Rubber Wafer*—For the entire range of test temperatures, place the wafer between the 25-mm test plates, and close the gap to bring the wafer into contact with the upper and lower plate so that the silicone rubber makes complete contact with the surfaces of the upper and lower plates. If needed, apply a thin layer of petroleum grease or anti-seize compound (see Note 10) to completely fill any void space between the silicone rubber and the plates. Complete contact is needed to ensure proper heat transfer across the plates and silicone rubber wafer. Determine any needed temperature correction as per Section 9.4.3.

Note 10—Anti-seize compound available by that name at hardware and auto supply stores is much less apt to contaminate the circulating water than petroleum grease.

Note 11—The thickness of the silicone wafer should be measured with calipers to identify the actual thickness. The thickness can be used to set the gap for temperature.

9.4.2. *Method Using Dummy Test Specimen*—The dummy test specimen shall be formed from asphalt binder or other polymer that can be readily formed between the plates. Mount the dummy test specimen between the test plates, and insert the detector (probe) of the portable thermometer into the dummy test specimen. Close the gap to the test gap (1 mm for 25-mm plates and 2 mm for 8-mm plates) keeping the detector centered vertically and radially in the dummy test specimen. Heat the plates as needed to allow the dummy test specimen to completely fill the gap between the test plates. It is not necessary to trim the dummy test specimen but avoid excessive material around the edges of the plates. Determine any needed temperature correction as per Section 9.4.3.

Note 12—Silly putty can leave a residue of silicone oil on the surfaces of the plates, and for this reason, its use as a dummy specimen is not recommended.

9.4.3. *Determination of Temperature Correction*—Obtain simultaneous temperature measurements with the DSR thermometer and the portable thermometer at 6°C increments to cover the range of test temperatures. At each temperature increment, after thermal equilibrium has been reached, record the temperature indicated by the portable thermometer and the DSR thermometer to the nearest 0.1°C. Temperature equilibrium is reached when the temperature indicated by both the DSR thermometer and the portable thermometer do not vary by more than 0.1°C over a 5 min period. Obtain additional measurements to include the entire temperature range that will be used for measuring the dynamic shear modulus.

9.4.4. *Plot Correction versus Specimen Temperature*—Using the data obtained in Section 9.4, prepare a plot of the difference between the two temperature measurements versus the temperature measured with the portable thermometer (Figure 3). This difference is the temperature correction that must be applied to the DSR temperature controller to obtain the desired temperature in the test specimen between the test plates. Report the temperature correction at the respective test temperature from the plot and report the test temperature between the plates as the test temperature. Alternatively, the instrument software may be written to incorporate these temperature corrections.

Note 13—The difference between the two temperature measurements may not be a constant for a given rheometer but may vary with differences between the test temperature and the ambient laboratory temperature as well as with fluctuations in ambient temperature. The difference between the two temperature measurements is caused in part by thermal gradients in the test specimen and fixtures.

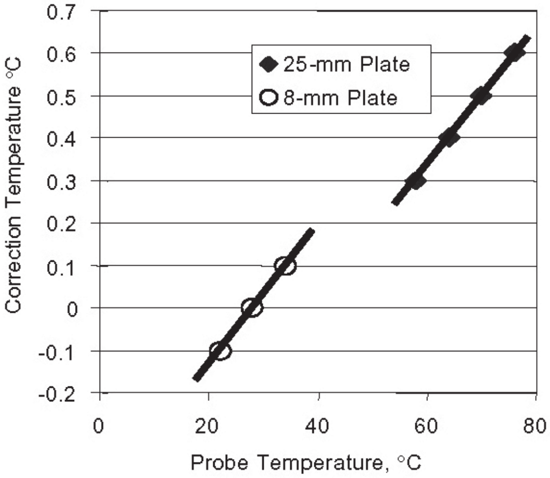

Figure 3—Determination of Temperature Correction

9.5. *Verification of DSR*—Verify the accuracy of the torque transducer and angular displacement transducer.

Note 14—A newly installed or reconditioned instrument should be verified on a weekly basis using the procedures in Section 9.5 until acceptable verification has been demonstrated. Maintaining the data in the form of a control chart where the verification measurements are plotted versus calendar date is recommended (see Appendix X2).

9.5.1. *Verification of Torque Transducer*—Verify the calibration of the torque transducer a minimum of once every six months using a reference fluid or manufacturer-supplied fixtures when the calibration of the torque transducer is suspect or when the dynamic viscosity, as measured for the reference fluid, indicates that the torque transducer is not in calibration.

9.5.1.1. *Verification of Torque Transducer with Reference Fluid*—The complex viscosity measured with the DSR shall be within three percent of the capillary viscosity as reported by the manufacturer of the reference fluid; otherwise, the calibration of the torque transducer shall be considered suspect. Calculate the complex viscosity as the complex modulus, *G**, divided by the angular frequency in rad/s. Recommended practice for using the reference fluid is given in Appendix X3.

$$\textit{Percent Variance} = [(\eta a - \eta b)/\eta a] * 100 \qquad (1)$$

where:

ηa = the standard capillary viscosity as reported by the supplier of the reference fluid; and

ηb = the measured viscosity as calculated from the complex modulus, *G**, divided by the angular frequency in rad/s.

Note 15—A suitable reference fluid is available from Cannon Instrument Company as Viscosity Standard Number N2700000SP. The viscosity of the standard is reported in mPa•s. Convert the viscosity measurements to mPa•s before calculating the percent variance.

9.5.1.2. *Verification of Torque Transducer with Fixtures*—Verify the calibration of the torque transducer using the manufacturer-supplied fixtures in accordance with the instructions supplied by the manufacturer. Suitable manufacturer-supplied fixtures are not widely available. If suitable fixtures are not available, this requirement shall be waived.

9.5.2. *Verification of Angular Displacement Transducer*—If manufacturer-supplied fixtures are available, verify the calibration every six months or when the calibration of the DSR is suspect. If suitable fixtures are not available, this requirement shall be waived.

9.5.3. If the DSR cannot be successfully verified according to Section 9.5, it shall not be used for testing in accordance with this standard until it has been successfully calibrated by the manufacturer or other qualified service personnel.

10. PREPARING SAMPLES AND TEST SPECIMENS

10.1. *Preparing Test Samples*—If unaged binder is to be tested, obtain test samples according to T 40.

10.1.1. Anneal the asphalt binder from which the test specimen is obtained by heating until sufficiently fluid to pour the required specimens. Annealing prior to testing removes reversible molecular associations (steric hardening) that occur during normal storage at ambient temperature. Avoid heating the binder samples above a temperature of 163°C; however, with some modified or heavily aged asphalt binders, pouring temperatures above 163°C may be required. Loosely cover the sample, and stir it occasionally during the heating process to ensure homogeneity and to remove air bubbles. Minimize the heating temperature and time to avoid hardening the sample.

Note 16—For neat asphalt binders, minimum pouring temperatures that produce a consistency equivalent to that of SAE 10W30 motor oil (readily pours but not overly fluid) at room temperature are recommended.

Note 17—For PAV aged samples, asphalt binder may be placed in a vacuum oven set at a maximum of 175°C for 40 minutes. Due to the poor heat transfer in the vacuum oven, the asphalt binder will not be overheated.

10.1.2. Cold material from storage containers must be annealed prior to usage. Structure developed during storage can result in overestimating the modulus by as much as 50 percent.

10.2. *Preparing Test Specimens*—Zero the gap as specified in Section 8. Carefully clean and dry the surfaces of the test plates so that the specimen will adhere to both plates uniformly and strongly. Heat the chamber to 34 to 46°C when using the 8-mm specimens. Heat the chamber to the test temperature or the beginning of the range (Note 6) when using 25-mm specimens. This requirement is to preheat the upper and lower plates to allow specimen adhesion to both plates. Prepare a test specimen using one of the methods specified in Section 10.3.1, 10.3.2, or 10.3.3.

10.3. Transfer asphalt binder to one of the test plates through pouring (Section 10.3.1), direct transfer (Section 10.3.2), or by use of a silicone mold (Section 10.3.3). Use a sufficient amount of asphalt binder so that trimming is required.

Note 18—Direct transfer and pouring are the preferred methods because the test results are less likely to be influenced by steric hardening than with the silicone mold method. Direct transfer and direct pouring result in higher asphalt binder temperatures when the plates and asphalt binder are brought into contact, thereby improving adhesion. For this reason, it is also important to bring the asphalt binder and plates into contact promptly after pouring or direct transfer.

10.3.1. *Pouring*—Only when using rheometers that are designed for removal of the plates without affecting the zero setting, remove the removable plate and, while holding the sample container approximately 15 mm above the test plate surface, pour the asphalt binder in the center of the upper test plate continuously until it covers the entire plate except for an approximate 2-mm wide strip at the perimeter (Note 19). Wait only long enough for the specimen to stiffen, to prevent movement, and then mount the test plate in the rheometer for testing.

Note 19—An eye dropper or syringe may be used to transfer the hot asphalt binder to the plate.

10.3.2. *Direct Transfer*—Transfer the hot asphalt binder to one of the plates using a glass or metal rod, spatula, or similar tool. Immediately after transferring the hot asphalt binder to one of the plates, proceed to Section 10.4 to trim the specimen and form the bulge.

Note 20—A small, narrow stainless steel spatula of the type used to weigh powders on an analytical balance has been found suitable for transferring the asphalt hot binder. When using a rod, form the test specimen with a twisting motion, using a mass of sufficient size. The twisting motion seems to keep the mass on the rod in control. A 4- to 5-mm diameter rod is suitable. The glass rod technique is especially useful for the 8-mm plate.

10.3.3. *Silicone Mold*—Pour the hot asphalt binder into a silicone rubber mold that will form a pellet having dimensions as required in Section 6.2. Allow the silicone rubber mold to cool to room temperature. Testing shall be initiated within 2 hours of pouring the specimen into the silicone rubber mold. The molds shall be covered while cooling to eliminate contamination. The specimen may be mounted to either the upper or lower plate. To mount the specimen to the lower plate, remove the specimen from the mold and center the pellet on the lower plate of the DSR. To mount the specimen to the upper plate, center the specimen on the upper plate while it is still in the silicone rubber mold,. Gently press the specimen to the upper plate and then carefully remove the silicone rubber mold leaving the specimen adhered to the upper plate.

10.3.3.1. The filled mold should be cooled at room temperature by placing the mold on a flat laboratory bench surface without chilling. Cooling to temperatures below room temperature results in an unknown thermal history that may affect the measured values of modulus and phase angle. Cooling may also result in the formation of moisture on the surface of the specimen that will interfere with adhesion of the specimen to the plates.

Note 21—Solvents should not be used to clean the silicone rubber molds. Wipe the molds with a clean cloth to remove any asphalt binder residue. With use, the molds will become stained from the asphalt binder, making it difficult to remove the binder from the mold. If sticking becomes a problem, discard the mold.

Note 22—Some binder grades cannot be removed from the silicone mold without cooling. Materials such as PG 52-34, PG 46-34, and some PG 58-34 grades do not lend themselves to being removed from the mold at ambient temperatures. If the binder specimen cannot be removed from the mold without cooling, the direct transfer or pouring method may be used, or the filled mold may be chilled in a freezer or refrigerator for a maximum of 10 min to facilitate demolding the specimen.

10.4. *Trimming Test Specimen*—Immediately after the specimen has been placed on one of the test plates as described above, move the test plates together until the gap between the plates equals the testing gap plus the gap closure required to create the bulge. (See Section 10.5 for gap closure required to create the bulge.) Trim excess binder by moving a heated trimming tool around the edges of the plates so that the asphalt binder is flush with the outer diameter of the plates.

Note 23—The trimming tool should be at a temperature that is sufficiently hot as to allow trimming but not excessively hot as to burn the edge of the specimen. The trimming tool should also not be excessively cool as to snag or damage the edge of the test specimen.

Note 24—The gap should be set at the starting test temperature (Section 11.1.1) or at the middle of the expected range of test temperatures (Section 11.1.2). See Note 5 for guidance on setting the gap. Typically, reliable test results may be obtained with a single sample using temperatures within 12°C of the temperature at which the gap is set.

10.5. *Creating Bulge*—Immediately after the trimming is complete, decrease the gap by the amount required to form a slight bulge at the outside face of the test specimen. The gap required to create a bulge is rheometer specific and depends upon factors such as the design of the rheometer and the difference between the trimming temperature and test temperature. Recommended closure values for creating the gap are 0.05 mm for the 25-mm plate and 0.10 mm for the 8-mm plate. A recommended practice for verifying the gap closure required to produce an appropriate bulge is given in Appendixes X8, X9, and X10.

Note 25—The complex modulus is calculated with the assumption that the specimen diameter is equal to the plate diameter. If the asphalt binder forms a concave surface at its outer edges this assumption will not be valid and the modulus will be underestimated. The calculated modulus is based upon the radius of the plate raised to the fourth power. A slight bulge equal to approximately one-quarter of the gap is recommended. A procedure for determining the closure required to form an acceptable gap is given in Appendixes X8, X9, and X10.

11. PROCEDURE

11.1. Bring the specimen to the test temperature ±0.1°C. See Note 4.

Note 26—The gap should be set at the starting test temperature (Section 11.1.1) or at the middle of the expected range of test temperatures (Section 11.1.2). See Note 5 for guidance on setting the gap. Typically, reliable test results may be obtained with a single sample, in an 8-mm to 25-mm plate, using temperatures within 12°C of the temperature at which the gap is set.

11.1.1. When testing a binder for compliance with M 320, select the test temperature from the appropriate table in M 320.

11.1.2. When conducting a temperature sweep, start at a midrange test temperature and increase or decrease the test temperature to cover the desired range of test temperatures. (See Sections 6 and 7 in R 29.)

11.2. Set the temperature controller to the desired test temperature, including any offset as required by Section 9.4.4. Allow the temperature indicated by the RTD to come to the desired temperature. The test shall be started only after the temperature has remained at the desired temperature ±0.1°C for at least 10 minutes.

Note 27—It is impossible to specify a single equilibration time that is valid for DSRs produced by different manufacturers. The design (fluid bath or air oven) of the environmental control system and the starting temperature will dictate the time required to reach the test temperature. The method for determining the correct thermal equilibration time is described in Appendix X12.

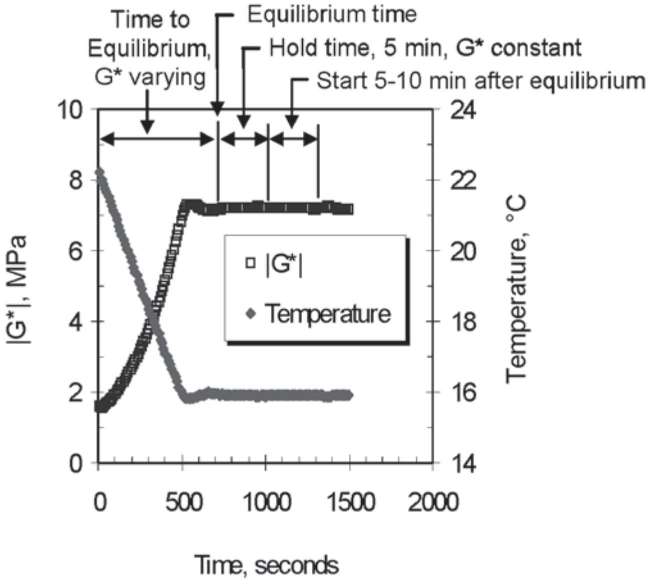

Figure 4—Determining Thermal Equilibrium Time

11.3. *Strain Control Mode*—When operating in a strain controlled mode, determine the strain value according to the value of the complex modulus. Control the strain within 20 percent of the target value calculated by Equation 2.

$$\gamma,\ \text{percent} = 12.0/(G^*)^{0.29} \tag{2}$$

where:

γ = shear strain in percent, and

G^* = complex modulus in kPa.

11.3.1. When testing specimens for compliance with M 320, select an appropriate strain value from Table 2. Software is available with the dynamic shear rheometers that will control the strain automatically without control by the operator.

Table 2—Target Strain Values

		Strain, percent	
Material	kPa	Target Value	Range
Original binder	1.0 $G^*/\sin\delta$	12	9 to 15
RTFO residue	2.2 $G^*/\sin\delta$	10	8 to 12
PAV residue	5000 $G^*\sin\delta$	1	0.8 to 1.2

11.4. *Stress Control Mode*—When operating in a stress controlled mode, determine the stress level according to the value of the complex modulus. Control the stress within 20 percent of the target value calculated by Equation 3.

$$\tau = 12.0\left(G^*\right)^{0.71} \tag{3}$$

where:

τ = shear stress in kPa, and

G^* = complex modulus in kPa.

11.4.1. When testing specimens for compliance with M 320 select an appropriate stress level from Table 3. Software is available with the dynamic shear rheometers that will control the stress level automatically without control by the operator.

Table 3—Target Stress Levels

Material	kPa	Stress, kPa Target Level	Range
Original binder	1.0 *G**/sin δ	0.12	0.09 to 0.15
RTFO residue	2.2 *G**/sin δ	0.22	0.18 to 0.26
PAV residue	5000 *G**sin δ	50.0	40.0 to 60.0

11.5. When the temperature has equilibrated, condition the specimen by applying the required strain for a recommended 10 cycles or a required range of 8 to 16 cycles at a frequency of 10 rad/s (see Note 28). Obtain a test measurement by recording data for an additional recommended 10 cycles or a range of 8 to 16 cycles. Reduce the data obtained for the second set of cycles to produce a value for the complex modulus and phase angle. Typically a Fast Fourier Transform (FFT) is used to reduce the data. Multiple measurements may be obtained to verify that the sample is properly prepared. Disbonding between the plates and the binder or fracture in the sample can result in a decrease in the modulus with repeat measurements. Some asphalt binders may exhibit a reduced modulus with continued application of shear stresses (multiple measurements). The data acquisition system automatically acquires and reduces the data when properly activated. When conducting tests at more than one frequency, start testing at the lowest frequency and increase to the highest frequency.

Note 28—The standard frequency of 10 rad/s is used when testing binder for compliance with M 320.

11.6. The data acquisition system specified in Section 6.1.4 automatically calculates *G** and δ from test data acquired when properly activated.

11.7. Initiate the testing immediately after preparing and trimming the specimen. The testing at subsequent temperatures should be done as quickly as possible to minimize the effect of molecular associations (steric hardening) that can cause an increase in modulus if the specimen is held in the rheometer for a prolonged period of time. When testing at multiple temperatures all testing should be completed within four hours.

12. INTERPRETATION OF RESULTS

12.1. The dynamic modulus and phase angle depend upon the magnitude of the shear strain; the modulus and phase angle for both unmodified and modified asphalt binder decrease with increasing shear strain as shown in Figure 5. A plot such as that shown in Figure 5 can be generated by gradually increasing the load or strain amplitude, thereby producing a strain sweep. It is not necessary to generate such sweeps during normal specification testing; however, such plots are useful for verifying the limits of the linear region.

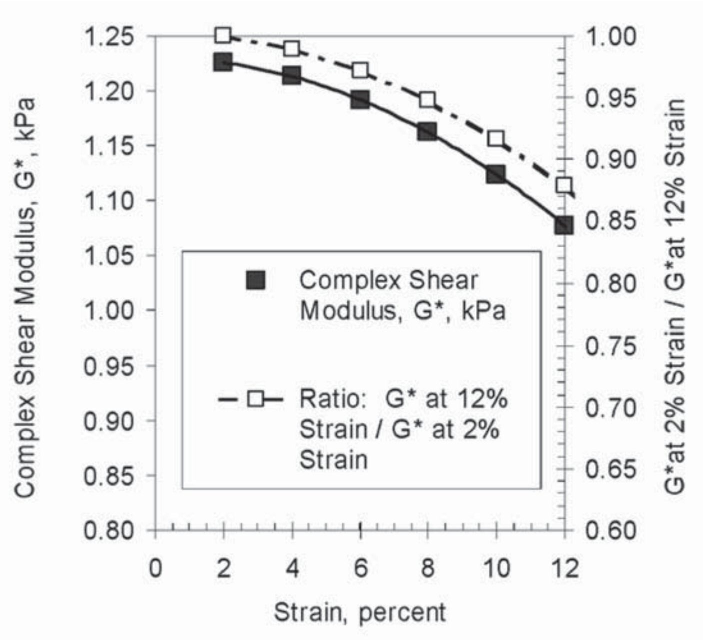

Figure 5—Example of Strain Sweep

12.2. A linear region may be defined at small strains where the modulus is relatively independent of shear strain. This region will vary with the magnitude of the complex modulus. The linear region is defined as the range in strains where the complex modulus is 95 percent or more of the zero-strain value.

12.3. The shear stress varies linearly from zero at the center of the plates to a maximum at the extremities of the plate perimeter. The shear stress is calculated from the applied or measured torque, measured or applied strain, and the geometry of the test specimen.

13. REPORT

13.1. A sample report format is given in Appendix X13. Provide a complete identification and description of the material tested including name, grade, and source.

13.2. Describe the instrument used for the test including the model number.

13.3. The strain and stress levels specified in Tables 2 and 3 have been selected to ensure a common reference point that has been shown to be within the linear region for neat and modified asphalt binders. Some systems may not be linear within this region. When this situation is observed, report the modulus at the recommended stress or strain levels but also report that the test conditions were outside the linear region.

13.4. *For each test, report the following*:

13.4.1. Test plate diameter, nearest 0.1 mm, and test gap, nearest 1 µm;

13.4.2. Test temperature, nearest 0.1°C;

13.4.3. Test frequency, nearest 0.1 rad/s;

13.4.4. Strain amplitude, nearest 0.01 percent, or torque, nearest mN·m;

13.4.5. Complex modulus (G^*) for the 10 measurements, kPa to three significant figures;

13.4.6. Phase angle (δ) for the second 10 cycles, nearest 0.1 degrees; and

13.4.7. $G^*/\sin\delta$, nearest 0.01 kPa, or $G^*\sin\delta$, nearest whole number.

14. PRECISION AND BIAS

14.1. *Precision*—Criteria for judging the acceptability of dynamic shear results obtained by this method are given in Table 4.

14.1.1. *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 4 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 4, Column 3.

14.1.2. *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 4 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 4, Column 3.

Table 4—Precision Estimates

Condition	Coefficient of Variation (1s%)[a]	Acceptable Range of Two Test Results (d2s%)[a]
Single-Operator Precision:		
Original Binder: $G^*/\sin\delta$ (kPa)	2.3	6.4
RTFO Residue: $G^*/\sin\delta$ (kPa)	3.2	9.0
PAV Residue: $G^*\cdot\sin\delta$ (kPa)	4.9	13.8
Multilaboratory Precision:		
Original Binder: $G^*/\sin\delta$ (kPa)	6.0	17.0
RTFO Residue: $G^*/\sin\delta$ (kPa)	7.8	22.2
PAV Residue: $G^*\cdot\sin\delta$ (kPa)	14.2	40.2

[a] These values represent the 1s% and d2s% limits described in ASTM Practice C 670.

Note 29—The precision estimates given in Table 4 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 185 to 208 laboratories for each of the eight pairs of samples. The analysis included five binder grades: PG 52-34, PG 64-16, PG 64-22, PG 70-22, and PG 76-22 (SBS modified). Average original binder results for $G^*/\sin\delta$ ranged from 1.067 kPa to 2.342 kPa. Average RTFO residue results for $G^*/\sin\delta$ ranged from 2.274 kPa to 7.733 kPa. Average PAV residue results for $G^*\cdot\sin\delta$ averaged from 1100 kPa to 4557 kPa. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Note 30—As an example, two tests conducted on the same PAV residue yield results of 1200 kPa and 1300 kPa, respectively. The average of these two measurements is 1250 kPa. The acceptable range of results is then 13.8 percent of 1250 kPa or 173 kPa. As the difference between 1200 kPa and 1300 kPa is less than 173 kPa, the results are within the acceptable range.

14.2. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

15. KEYWORDS

15.1. Dynamic shear rheometer; DSR; complex modulus; asphalt binder.

APPENDIXES

(Nonmandatory Information)

X1. TESTING FOR LINEARITY

X1.1. *Scope*:

X1.1.1. This procedure is used to determine whether an unaged asphalt binder exhibits linear or non-linear behavior at the upper grading temperature, e.g., 52, 58, 64, 70, 76, or 82°C. The determination is based on the change in complex shear modulus at 10 rad/s when the strain is increased from 2 to 12 percent.

X1.2. *Procedure*:

X1.2.1. Verify the DSR and its components in accordance with Section 9 of this standard.

X1.2.2. Prepare the DSR in accordance with Section 10 of this standard.

X1.2.3. Prepare a test specimen for testing with 25-mm plates as per Section 11 of this standard. Select the test temperature as the upper grading temperature for the binder in question.

X1.2.4. Determine the complex shear modulus at 2 and 12 percent strain following the test procedure described in Section 12 except as noted below. Always start with the lowest strain and proceed to the next larger strain.

X1.3. *Strain Controlled Rheometers*—If the software provided with the DSR will automatically conduct tests at multiple strains, program the DSR to obtain the complex shear modulus at strains of 2, 4, 6, 8, 10, and 12 percent. If this automatic feature is not available, test by manually selecting strains of 2, 4, 6, 8, 10, and 12 percent strain.

X1.4. For stress controlled rheometers, compute the starting stress based on the complex shear modulus, G^*, and shear stress, τ, as determined at the upper grading temperature during the grading of the binder. At this temperature the complex modulus, G^*, will be greater than or equal to 1.00 kPa and the shear stress, τ, will be between 0.090 and 0.150 kPa (see Table 2). Calculate the starting stress as τ /6.00 kPa. Increase the stress in five increments of τ /6.00 kPa.

Note X1—*Sample calculation*: Assume a PG 64-22 asphalt binder with G^* = 1.29 kPa at 64°C and τ = 0.135 kPa. The starting stress will be 1.35kPa/6 = 0.225 kPa. Test at 0.225, 0.450, 0.675, 0.900, 1.13, and 1.35 kPa, starting with 0.225 kPa.

X1.5. *Plot of Complex Modulus Versus Strain*—Prepare a plot of complex shear modulus versus percent strain as shown in Figure 5. From the plot, determine the complex shear modulus at 2 and 12 percent strain.

X1.6. *Calculations*:

X1.6.1. Calculate the modulus ratio as the complex shear modulus at 12 percent strain divided by the complex shear modulus at 2 percent strain.

X1.7. *Report*:

X1.7.1. *Report the following*:

X1.7.1.1. Complex shear modulus (*G**) to three significant figures,

X1.7.1.2. Strain, nearest 0.1 percent,

X1.7.1.3. Frequency, nearest 0.1 rad/s, and

X1.7.1.4. The ratio calculated by dividing the modulus at 12 percent strain by the modulus at 2 percent strain.

X1.8. *Data Interpretation*:

X1.8.1. The measurement was performed in the non-linear range of the material if the modulus ratio as calculated in Section X1.11 is <0.900 and linear if ≥0.900. If the measurement was performed in the non-linear range of the material, the results obtained under this standard will be considered as invalid for grading a binder according M 320.

X2. CONTROL CHART

X2.1. *Control Charts*:

X2.1.1. Control charts are commonly used by various industries, including the highway construction industry, to control the quality of products. Control charts provide a means for organizing, maintaining and interpreting test data. As such, control charts are an excellent means for organizing, maintaining, and interpreting DSR verification test data. Formal procedures based on statistical principles are used to develop control charts and the decision processes that are part of statistical quality control.

A quality control chart is simply a graphical representation of test data versus time. By plotting laboratory measured values for the reference fluid in a control chart format, it is easy to see when:

- The measurements are well controlled and both the device and the operator are performing properly.
- The measurements are becoming more variable with time, possibly indicating a problem with the test equipment or the operator.
- The laboratory measurements for the fluid are, on the average above or below the target (reference fluid) value.

Many excellent software programs are available for generating and maintaining control charts. Some computer-based statistical analysis packages contain procedures that can be used to generate control charts. Spreadsheets such as Microsoft's Excel can also be used to generate control charts and, of course, control charts can be generated manually. (See Table X3.1 as an example print-out.)

X2.2. *Care in Selecting Data*:

X2.2.1. Data used to generate control charts should be obtained with care. The idea of randomness is important but need not become unnecessarily complicated. An example will show why a random sample is needed—a laboratory always measures the reference fluid at the start of the shift or workday. These measurements could be biased by start-up errors such as a lack of temperature stability when the device is first turned on. The random sample ensures that the measurement is representative of the process or the material being tested. Said another way, a random sample has an equal chance of being drawn as any other sample. A measurement or sample always taken at the start or end of the day, or just before coffee break, does not have this chance.

X3. EXAMPLE

X3.1. The power of the control chart is illustrated in Table X3.1 using the verification data obtained for the DSR. Other DSR verification data suitable for a quality control chart presentation includes measurements for determining the temperature correction, calibrating the electronic thermometer, and maintaining data from internally generated asphalt binder reference samples. For this example, the reported viscosity for the reference fluid is 271 Pa·s; hence, the calculated value for G^* is 2.71 kPa. This value for G^* is labeled as "G^* from Reference Fluid" in Figure X3.1. The laboratory should obtain this value on average if there is no laboratory bias.

Table X3.1—Sample Test Data

Week	Measured G^*, kPa
1	2.83
2	2.82
3	2.77
4	2.72
5	2.69
6	2.72
7	2.77
8	2.75
9	2.71
10	2.82
11	2.66
12	2.69
13	2.75
14	2.69
15	2.73
16	2.77
17	2.72
18	2.67
19	2.66
20	2.78
21	2.74
22	2.69
Average	2.73
Std. Dev.	0.051
CV %	1.86

X3.2. *Comparison of 22-Week Laboratory Average for G* with Value Calculated from Reference Fluid*:

X3.2.1. The 22-Week average of the laboratory measurements is labeled as "22-Week Laboratory Average" in Figure X3.1. Over the 22 weeks, for which measurements were made, the average was 2.73 kPa. This value compares favorably with the calculated reference value, 2.71 kPa, differing on the average by only 0.7 percent. There appears to be little laboratory bias in this data.

Comparison of CV of Laboratory Measurements with Round Robin CV:

X3.2.2. From a previous round robin study, the within laboratory standard deviation (d1s) for the fluid was reported as 0.045 (CV = 1.67 percent). The 22-week standard deviation for the measured values of *G** is 0.051 CV = 1.86 percent), as compared to 0.045 (CV =1.67 percent) reported from the round robin. However, it should be pointed out that the 22-week CV, 1.86 percent, also includes day-to-day variability, a component of variability not included in the round-robin d1s value. Based on this information the variability of the laboratory measurements are acceptable.

X3.3. *Variability of Measured Values*:

X3.3.1. In Figure X3.1, the value of *G** calculated from the reference fluid is shown as a solid line. Also shown are two dotted lines that represent the *G** calculated from the reference fluid ±2 d1s where d1s is the value from the round robin. The calculated reference value for the fluid is 2.71 kPa, and the standard deviation is 0.045. Thus, a deviation of 2 d1s gives values of:

$$2.71\text{kPa} \pm (2)\,(0.045) = 2.80\text{ kPa}, 2.62\text{ kPa} \qquad (X3.1)$$

If the laboratory procedures are under control, the equipment is properly calibrated, and there is no laboratory bias, 95 percent of the measurements should fall within the limits 2.62 kPa and 2.80 kPa. Laboratory measurements outside this range are suspect, and the cause of the outlier should be investigated. The outlier may be the result of either testing variability or laboratory bias. The measurement from Week 10 in Figure X3.1 falls outside the ±2 d1s limits and is cause for concern such that testing procedures and verification should be investigated.

If a measurement deviates from the target, in this case *G** from the reference fluid, by more than ±3 d1s, corrective action should be initiated. The ±3 d1s limits 99.7 percent of the measured values if the laboratory procedures are under control and the equipment is properly calibrated.

X3.4. *Trends in Measured Value*:

X3.4.1. The control chart can also be used to identify unwanted trends in the data. For example, from weeks one to five, a steady decrease in the measured value is observed. This is cause for concern and the reason for the trend should be investigated. More sophisticated rules for analyzing trends in control charts can be found elsewhere.

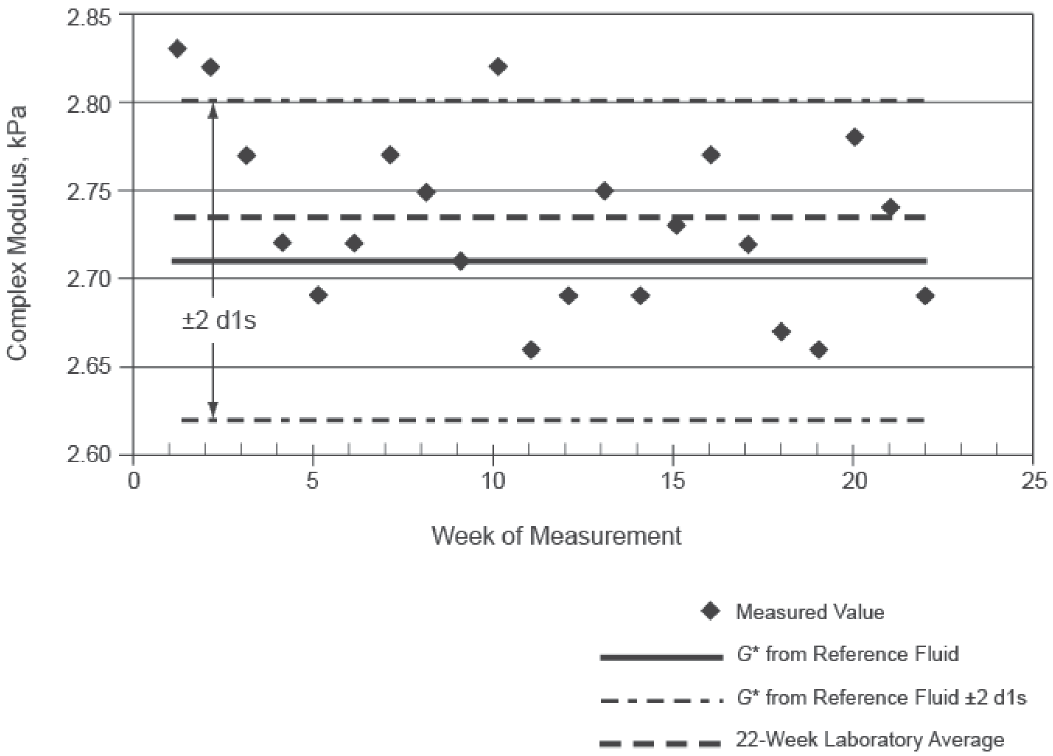

Figure X3.1—Control Chart

X4. USE OF REFERENCE FLUID

X4.1. *Source of Reference Fluid*:

X4.2. An organic polymer produced by Cannon Instrument Company as Viscosity Standard N2700000SP has been found suitable as reference fluid for verifying the calibration of the DSR. The viscosity of the fluid, as determined from NIST–traceable capillary viscosity measurements, is approximately 270 Pa·s at 64°C. However, the viscosity of the fluid varies from one lot to the next. The lot-specific viscosity is printed on the label of the bottle.

X5. CAUTIONS IN USING REFERENCE FLUID

X5.1. Some items of caution when using the reference fluid are:

- The fluid cannot be used to verify the accuracy of the phase angle measurement.
- The fluid must not be heated as heating can degrade the fluid causing a change in its viscosity.
- The fluid should be used for verification only after the DSR temperature measurements are verified.
- The fluid cannot be used to calibrate the torque transducer. The manufacturer or other qualified service personnel using a calibration device designed specifically for the rheometer should perform the calibration. These calibration devices are typically not available in operating laboratories.
- When tested at 10 rad/s, the reference fluid should only be used at 64°C and above. At lower temperatures, the fluid is viscoelastic; hence, the viscosity, η, reported on the certificate by Cannon will not match the complex viscosity $\eta^* = G^*/10$ rad/s determined from the measurement.

- Bubbles in the fluid will have a dramatic effect on the measured value of G^*. The fluid in the bottle should be free of bubbles and care must be taken not to introduce bubbles when preparing test specimens. Recommended procedures for preparing test specimens are given in Appendix X6.

X6. CALCULATION OF *G** FROM STEADY-STATE VISCOSITY MEASUREMENTS

X6.1. Among the different methods for converting between dynamic and steady-state viscosity of polymers, the most popular and most successful is the so-called Cox-Merz empirical rule. The rule leads, in simplified terms, to the following approximation.

$$G^*/\omega \sim \eta \qquad (X6.1)$$

where:

G^* = the complex modulus,

ω = the angular frequency in radians/s, and

η = the shear rate independent capillary viscosity as reported by the supplier of the reference fluid.

For this rule to apply the measurements must be in the viscous region where the phase angle approaches 90 degrees. The value of the complex modulus is then simply 10 times the value of the capillary viscosity. For example, if the capillary viscosity is 270,000 mPa·s the complex modulus is:

$$G^*\text{, kPa} \approx (270{,}000\ \text{mPa·s})(1\ \text{kPa}/1{,}000{,}000\ \text{mPa})(10\ \text{rad/s}) = 2.70\ \text{kPa·rad} \qquad (X6.2)$$

The reference fluid behaves as a viscous fluid at 64°C and above and provides very accurate estimates of G^* above 64°C. At temperatures below 58°C the fluid gives incorrect values for G^* with the error increasing as the temperature departs from 64°C. At 64°C and above G^* divided by the frequency in radians per second should be no more than three percent different than the viscosity printed on the bottle label. If this is the case, then the torque calibration should be considered suspect.

X7. METHODS FOR TRANSFERRING THE FLUID TO THE TEST PLATES

X7.1. Three different methods are recommended for transferring the fluid to the test plates:

X7.2. The glass rod method (Section X7.1), the spatula method (Section C4.3), and a direct method where a removable test plate is held in direct contact with the fluid in the bottle (Section C4.4).

X7.3. *Glass Rod Method (Figure X7.1)*:

X7.3.1. In this method, a glass rod is inserted into the fluid and rotated (Step 1) while in the fluid. Continue rotating the rod, and pull it slowly from the fluid (Step 2) carrying a small mass of the fluid with the rod. Touch the mass to the plate (Step 3) to transfer the fluid to the plate. See Figure X7.1.

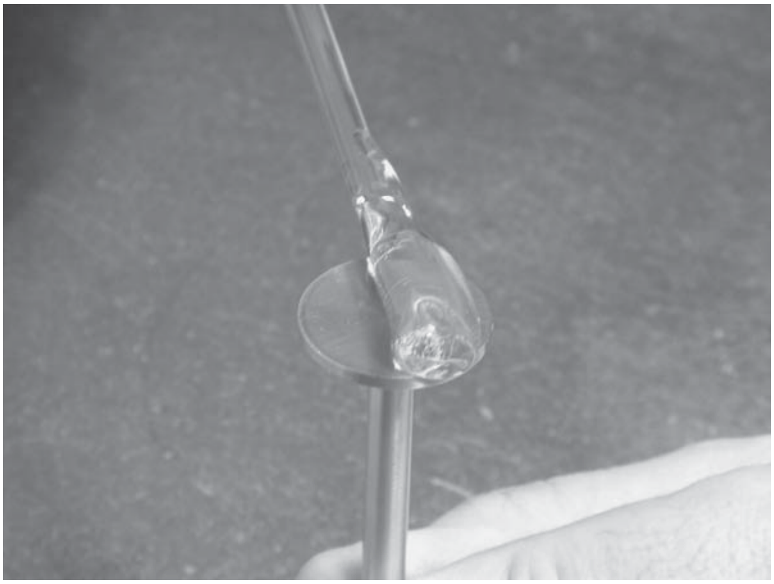

Figure X7.1—Using a Glass Rod to Place the Reference Fluid on the Plate

X7.4. *Spatula Method (Figure X7.2)*:

X7.5. When carefully used a spatula may be used to transfer the fluid. Special care must be taken not to trap air as the material is scooped from the bottle, Step 1. Smear the mass on the spatula onto the plate (Step 2) and cut the mass from the spatula by drawing the spatula across the edge of the plate (Step 3). This method appears to be the most difficult to implement and is the least recommended of the three methods.

Figure X7.2—Using a Spatula to Place the Reference Fluid on the Plate

X7.6. *Direct Touch Method (Figure X7.3)*—If the rheometer is equipped with plates that may be removed and reinstalled without affecting the gap reference, remove one of the plates and touch the surface of the plate to the surface of the fluid in the bottle (Step 1). Pull the plate from the bottle, bringing a mass of the fluid along with the plate (Step 2). Invert the plate and allow the fluid to flow out into a mushroom shape (Step 3).

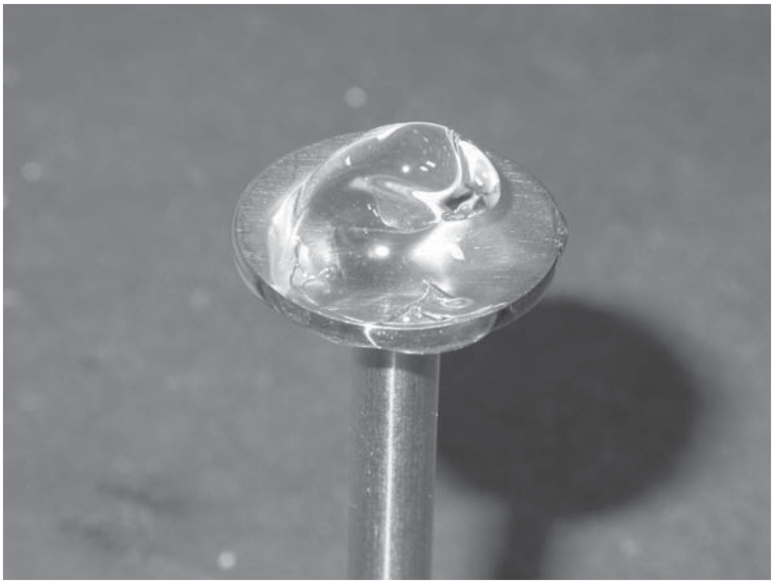

Figure X7.3—Direct Touch Method to Place the Reference Fluid on the Plate

Proceed immediately to Section 10.5 to trim the reference fluid specimen and form the bulge.

Proceed with testing the reference fluid specimen as described in Section 11.

X8. SELECTION OF GAP CLOSURE TO OBTAIN BULGE

X8.1. *Need for Accurate Measurement of Specimen Diameter*:

X8.2. The accuracy of the DSR measurements depends upon an accurate measurement of the diameter of the test specimen. The diameter of the test specimen is assumed equal to the diameter of the test plates. For this reason, the trimming of excess binder and the final closure of the gap to produce a slight bulge in the test specimen are critical steps in the DSR test procedure. When the gap is closed to its final dimension, the bulge must be of sufficient size to compensate for any shrinkage in the binder and consequently avoiding a concave surface as shown in Figure X8.1. The diameter of the test specimen in Figure X8.1 approaches d, rather than d', the diameter of the plate. The modulus, G^*, is calculated according to the following equation:

$$|G^*| = (2h/\pi r^4)\bullet(\tau/\Theta) \qquad (X8.1)$$

where:

G^* = Complex modulus

τ = Torque applied to test specimen

h = Thickness of test specimen

Θ = Angular rotation, radians

r = radius of test plate

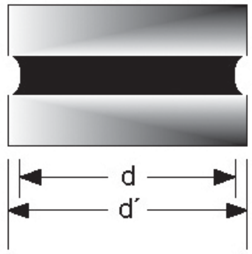

Figure X8.1—Concave Surface Resulting from Insufficient Closure after Trimming

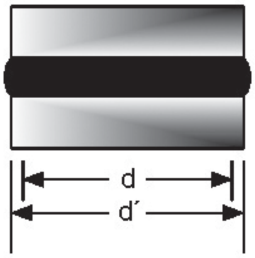

Figure X8.2—Proper Bulge

X8.3. According to Equation X8.1, the modulus depends upon the radius (or diameter) raised to the fourth power. Therefore, a small concavity in the outer surface of the test specimen, as shown in Figure X8.1, will have a large effect on the measured modulus because the actual specimen diameter will be less than the plate diameter. For a given amount of concavity, the effect on the measured modulus is greater for the 8-mm plate than the 25-mm plate. A more desirable result is a slight bulge as illustrated in Figure X8.2. Shear stresses are not transferred directly from the plate to the overhanging binder; therefore, the effect of a slight bulge on the measured modulus is much less than a slight concavity. It should be noted that errors in the diameter of the test specimen do not affect the measured values of the phase angle.

X9. RECOMMENDED GAP CLOSURE VALUES

X9.1. Recommended values for the gap closure required to form a bulge at the test temperature similar to the bulge illustrated in Figure X8.2 are given in Section 10.5 as 50 µm and 100 µm for the 25-mm and 8-mm plates, respectively. Although these values may be appropriate for many rheometers, they may not be appropriate for all rheometers. The applicability of these values to a specific rheometer may be determined by preparing a test specimen using the recommended closure and observing the shape of the bulge after the final closure of the gap and after the test specimen is at the test temperature. If the recommended closure values do not give an appropriate bulge, the recommended closure values should be adjusted as appropriate.

Proper and improper bulges are shown in Figures X10.1 through X10.3. A magnifying glass is useful for examining the shape of the bulge. Regardless of the closure required to produce a desirable bulge, the actual gap should be used in the calculations.

X10. FACTORS AFFECTING BULGE DEVELOPMENT

X10.1. A number of factors can affect the bulge formed at the test temperature. These include:

- The amount of closure used to create the bulge.
- The difference in temperature between the trimming temperature, the temperature at which the bulge is created, and the test temperature.
- Thermal expansion-contraction characteristics of the rheometer.
- Thermal contraction and expansion of the asphalt binder.

A concave surface is more likely to form at the intermediate temperatures, than at the upper test temperatures (8-mm plate rather than the 25-mm plate). In fact, at the higher test temperatures excessive material can be squeezed from the plates as shown in Figure X10.3. This situation should also be avoided and may require gap closures somewhat less than the recommended values.

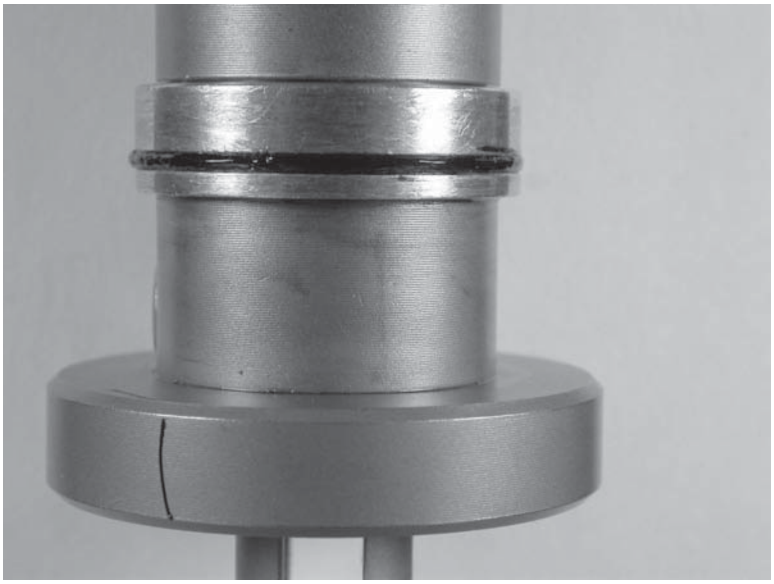

Figure X10.1—Good Bulge Size

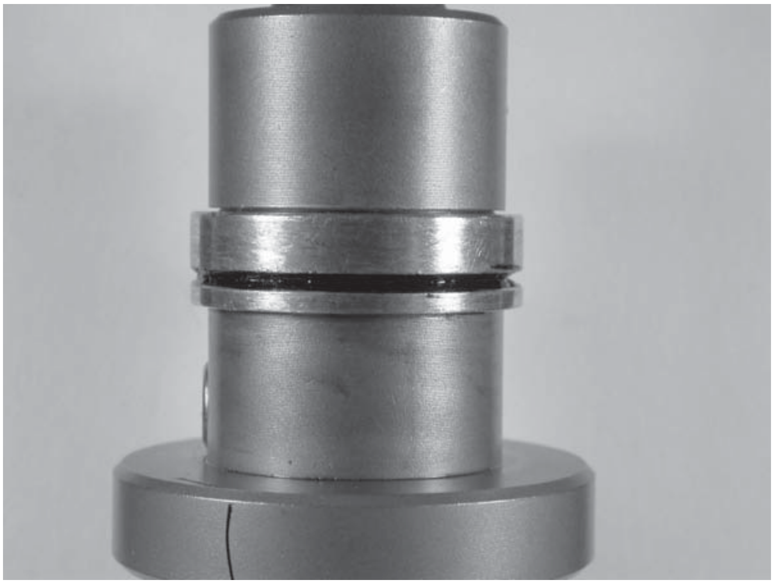

Figure X10.2—Concave Bulge

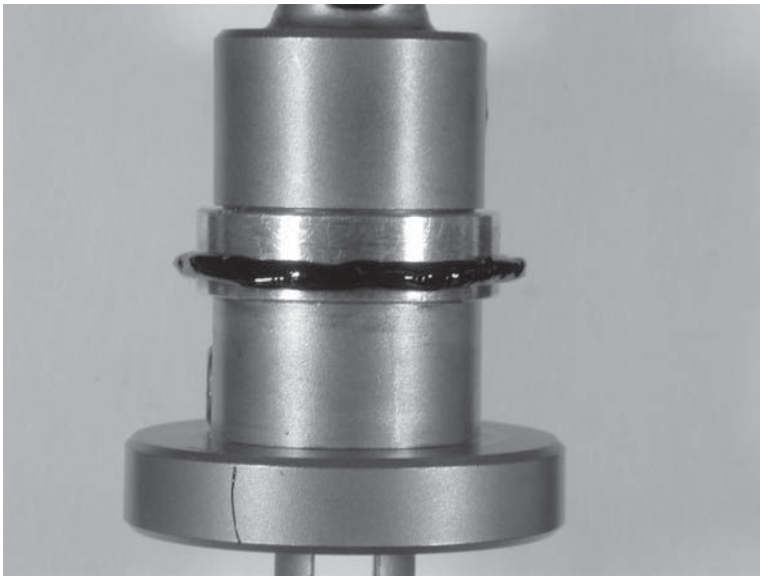

Figure X10.3—Oversized Bulge

X11. DETERMINATION OF TIME TO THERMAL EQUILIBRIUM

X11.1. *Reason for Determining Time Required to Obtain Thermal Equilibrium*:

X11.1.1. After the test specimen has been mounted in the DSR, it takes some time for the asphalt binder between the test plates to reach thermal equilibrium. Because of thermal gradients within the test plates and test specimen, it may take longer for the test specimen to come to thermal equilibrium than the time indicated by the DSR thermometer. Therefore, it is necessary to experimentally determine the time required for the test specimen to reach thermal equilibrium.

X11.1.2. The time required to obtain thermal equilibrium varies for different rheometers. Factors that affect the time required for thermal equilibrium include:

X11.1.3. Design of the rheometer and whether air or liquid is used as a heating-cooling medium;

X11.1.4. Difference between ambient temperature and the test temperature, different when testing below room temperature, and above room temperature;

X11.1.5. Difference in temperature between the trimming and test temperature; and

X11.1.6. Plate size, different for the 8-mm and 25-mm plate.

X11.2. It is not possible to specify a single time as the time required to obtain thermal equilibrium. For example, thermal equilibrium is reached much quicker with liquid-controlled rheometers than with air-cooled rheometer. This requires that the time to thermal equilibrium be established for individual rheometers, typical trimming and testing temperatures, and testing conditions.

X12. METHOD TO DETERMINE THE TIME REQUIRED TO OBTAIN THERMAL EQUILIBRIUM

X12.1. A reliable estimate of the time required for thermal equilibrium can be obtained by monitoring the DSR temperature and the complex modulus of a sample mounted between the test plates. Because the modulus is highly sensitive to temperature, it is an excellent indicator of thermal equilibrium. The following procedure is recommended for establishing the time to thermal equilibrium:

X12.2. Mount a binder sample in the DSR and trim in the usual manner. Create a bulge and bring the test chamber or fluid to the test temperature.

X12.3. Operate the rheometer in a continuous mode at 10 rad/s using an unmodified asphalt binder—one that does not change modulus with repeated shearing. Use the smallest strain value that gives good measurement resolution.

X12.4. Record the modulus at 30 s time intervals, and plot the modulus versus time (Figure 4).

X12.5. The time to reach thermal equilibrium is the time required to reach a constant modulus. Typically, this time will be greater than the time required to reach a constant reading on the DSR thermometer.

X12.6. Because the time required to reach thermal equilibrium will vary with the test temperature and testing conditions, the time to thermal equilibrium should be established separately for both intermediate and high-temperature measurements. Once the time to thermal equilibrium has been established, it does not have to be repeated unless the test conditions change.

Standard Method of Test for

Viscosity Determination of Asphalt Binder Using Rotational Viscometer

AASHTO Designation: T 316-10

1. SCOPE

1.1. This test method outlines the procedure for measuring the viscosity of asphalt binders at elevated temperature from 60 to over 200°C using a Rotational Viscometer apparatus as specified by M 320 and R 29.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the application of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 320, Performance-Graded Asphalt Binder
- R 29, Grading or Verifying the Performance Grade (PG) of an Asphalt Binder
- T 40, Sampling Bituminous Materials

2.2. *ASTM Standards*:
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. TERMINOLOGY

3.1. *viscosity*—the ratio between the applied shear stress and the rate of shear is called the coefficient of viscosity. This coefficient is a measure of the resistance to flow of the liquid. It is commonly called the viscosity. The SI unit of viscosity is the Pascal second (Pa·s).

4. SUMMARY OF METHOD

4.1. This test method can be used to measure the viscosity of asphalt at application temperatures. The torque required to maintain a constant rotational speed of a cylindrical spindle while submerged in an asphalt sample at a constant temperature is used to measure the relative resistance to rotation. The torque and speed are used to determine the viscosity of the binder in Pascal seconds.

5. SIGNIFICANCE AND USE

5.1. This test method can be used to measure the apparent viscosity of asphalt at application temperatures.

5.2. The measured viscosity at elevated temperatures can be used to determine whether the asphalt binder can be handled and pumped at the refinery, terminal, or hot mix plant facility. Measured viscosity from this procedure can be used to develop temperature viscosity charts for estimating mixing and compaction temperatures for use in hot mix asphalt mix design.

6. APPARATUS

6.1. *Oven*—An oven capable of maintaining any desired temperature setting from room temperature to 260°C to within ±3°C.

6.2. *Thermometers*—Thermometers having a range from 60 to over 200°C and readable to 0.2°C.

6.3. *Balance*—A balance with a capacity of 2000 g readable to 0.1 g for determining the mass of asphalt binder.

6.4. *Cylindrical Spindles* of various sizes for measurement of asphalt binders of different viscosities.

6.5. *Rotational Viscometer* capable of measuring the torque required to rotate the selected spindle at a selected constant speed while submerged in asphalt at constant desired test temperature and should display the viscosity in Pascal seconds automatically.

6.6. *Temperature Controller*—A proportional temperature controller capable of maintaining the specimen temperatures ±1.0°C for test temperatures ranging from 60 to 165°C or greater.

7. MATERIALS

7.1. Solvent (such as Mineral Spirits or Varsol) or a degreasing spray cleaner formulated for cleaning the sample holder, spindles and accessories.

8. HAZARDS

8.1. Use standard laboratory safety procedures required for handling the hot asphalt binder and required safety procedures when cleaning with solvents or degreasers.

9. PREPARATION OF APPARATUS

9.1. The rotational viscometer must be leveled to function properly. A bubble-type level is normally located on top of the viscometer and is adjusted by using leveling screws located on the base. If the torque controller and thermal chamber are separate units, both should be leveled.

10. CALIBRATION AND STANDARDIZATION

10.1. The accuracy of the rotary transducer is checked using a reference fluid (Newtonian fluid) of known viscosity at various temperatures. The reference fluid shall be certified to be Newtonian in behavior over the full range of expected test temperatures and shear rates. The viscosity measured should be within ±2 percent or the rotary transducer requires recalibration.

10.2. The accuracy of the temperature reading of the temperature controller is checked by placing an asphalt sample in the testing chamber and equilibrating to a given temperature. The indicated temperature shall be verified by using a NIST traceable measuring device as defined by ASTM E 1.

11. PREPARATION OF SAMPLES AND TEST SPECIMENS

11.1. *Preparing Test Samples*—Unaged asphalt and modified asphalt binders are obtained according to T 40.

11.1.1. Anneal the asphalt binder from which the specimen is obtained by heating until sufficiently fluid to pour. Annealing prior to testing removes reversible molecular associations (steric hardening) that may occur during normal storage at ambient temperature.

Note 1—Minimum pouring temperature that produces a consistency equivalent to that of SAE 10W30 motor oil (readily pours but not overly fluid) at room temperature are recommended. The specific temperature will depend on the grade of binder and its prior aging history, if any. Temperatures less than 135°C are desirable; however, temperatures above 135°C may be required for some modified asphalt binders or heavily aged binders.

12. PROCEDURE

12.1. Read and understand the information in the rotational viscometer manufacturer’s operating manual before proceeding.

12.2. Turn on the rotational viscometer and proportional temperature controller unit.

12.3. Preheat the sample holder with the sample chamber and the selected cylindrical spindle according to the manufacturer’s recommendation.

12.4. Set the proportional temperature controller to desired test temperature.

12.5. Heat the required amount of asphalt binder as recommended by the manufacturer for testing according to Section 11.1.1.

12.6. When the proportional temperature controller reads the desired test temperature, remove the sample holder, and add the required amount of asphalt into the sample chamber.

12.7. Insert the sample chamber into the proportional temperature controller unit.

12.8. Insert a preheated spindle and attach it to the viscometer using the necessary coupling. Gently lower the spindle into the asphalt so that asphalt covers the upper conical portion of the spindle. This procedure may vary based on the manufacturer’s recommendations.

12.9. Bring the asphalt sample to the desired temperature within approximately 30 minutes. Set the viscometer speed at 20 rpm and set the display to read the viscosity in Pascal seconds (Pa·s). This operation may be done manually or by using a software program.

12.10. Allow the asphalt sample to equilibrate at the desired test temperature for a minimum of 10 minutes. Begin the spindle rotation during the 10 minute temperature equilibration period. Allow the readings to stabilize before recording any viscosity measurements. If the observed torque is out of range for the selected spindle and speed, change the spindle and or speed based on the manufacturer's recommendations for the anticipated viscosity. Restart the test with a new sample.

12.11. Start the test after the asphalt sample has reached the specified temperature and equilibrated and the viscosity readings have stabilized, as required in Sections 12.9 and 12.10.

12.12. Measure the viscosity at one-minute intervals for a total of three minutes.

12.13. Follow the procedure in Sections 12.1 to 12.12 for other temperatures.

13. CALCULATION OF RESULTS

13.1. The viscosity is reported as the average of three readings. If the digital output of the rotational viscometer viscosity is in units of centipoise (cP), the following factor is used to convert to Pascal-seconds:

$$10\ \mathrm{P} = 1\ \mathrm{Pa{\cdot}s} \qquad (1)$$

$$1\ \mathrm{cP} = 1\ \mathrm{mPa{\cdot}s} \qquad (2)$$

Multiply viscosity in centipoise by 0.001 to obtain the viscosity in Pa·s.

14. REPORT

14.1. *Report the following information*:

14.1.1. Report the date and time of the test;

14.1.2. Report the test temperature to the nearest 1°C;

14.1.3. Report the speed in rpm;

14.1.4. Report the size of the spindle used;

14.1.5. Report the torque in percent; and

14.1.6. Report the average viscosity in Pa·s.

15. PRECISION AND BIAS

15.1. *Precision*—Criteria for judging the acceptability of viscosity results obtained by this method are given in Table 1.

15.1.1. *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

15.1.2. *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 1 are the coefficients of variation that have been found to be appropriate for the conditions of test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the values given in Table 1, Column 3.

Table 1—Precision Estimates

Condition	Coefficient of Variation (1s%)[a]	Acceptable Range of Two Test Results (d2s%)[a]
Single-Operator Precision:		
Average Viscosity (Pa·s)	1.2	3.5
Multilaboratory Precision:		
Average Viscosity (Pa·s)	4.3	12.1

[a] These values represent the 1s% and d2s% limits described in ASTM Practice C 670.

Note 2—The precision estimates given in Table 1 are based on the analysis of test results from eight pairs of AMRL proficiency samples. The data analyzed consisted of results from 142 to 202 laboratories for each of the eight pairs of samples. The analysis included five binder grades: PG 52-34, PG 64-16, PG 64-22, PG 70-22, and PG 76-22 (SBS modified). Unmodified binder average viscosity results ranged from 0.272 Pa·s to 0.719 Pa·s. The modified binder average viscosity results ranged from 1.621 Pa·s to 1.638 Pa·s. The details of this analysis are in the final report for NCHRP Project No. 9-26, Phase 3.

Note 3—As an example, two tests conducted on the same material yield viscosity results of 0.500 Pa·s and 0.510 Pa·s, respectively. The average of these two measurements is 0.505 Pa·s. The acceptable range of results is then 3.5 percent of 0.505 Pa·s or 0.018 Pa·s. As the difference between 0.500 Pa·s and 0.510 Pa·s is less than 0.018 Pa·s, the results are within the acceptable range.

15.2. *Bias*—No information can be presented on the bias of the procedure because no material having an accepted reference value is available.

16. KEYWORDS

16.1. Asphalt binder; viscosity.

Standard Method of Test for

Quantitative Extraction and Recovery of Asphalt Binder from Asphalt Mixtures

AASHTO Designation: T 319-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Quantitative Extraction and Recovery of Asphalt Binder from Asphalt Mixtures

AASHTO Designation: T 319-08

1. SCOPE

1.1. This standard describes a procedure for the extraction and recovery of asphalt binder from asphalt mixtures [both hot mix asphalt (HMA) and reclaimed asphalt pavement (RAP)] that have a minimal effect on the physical and chemical properties of the asphalt binder recovered. This standard is intended for use when the physical or chemical properties, or both, of the recovered asphalt binder are to be determined. It can also be used to determine the quantity of asphalt binder in the HMA or RAP. Recovered aggregate may be used for sieve analysis or other aggregate testing.

1.2. This method is applicable to HMA sampled from the pavement, RAP sampled from the pavement or stockpile, HMA plant production, or laboratory fabricated HMA.

1.3. *This procedure may involve hazardous materials, operations, and equipment. This procedure does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 110, Moisture or Volatile Distillates in Hot Mix Asphalt (HMA)
- T 168, Sampling Bituminous Paving Mixtures
- T 329, Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

2.2. *ASTM Standards*:

- D 96, Standard Test Methods for Water and Sediment in Crude Oil by Centrifuge Method (Field Procedure) (Withdrawn 2000)
- D 5361, Standard Practice for Sampling Compacted Bituminous Mixtures for Laboratory Testing

3. TERMINOLOGY

3.1. *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

4. SUMMARY OF METHOD

4.1. The asphalt mixture is repeatedly washed and filtered with solvent in an extraction/filtration apparatus. Each filtrate is distilled under vacuum in a rotary evaporator with the asphalt remaining in the flask. After recovery of the final filtrate, the solution is concentrated to about 300 mL and centrifuged to remove the aggregate fines. The decanted solution is distilled under vacuum to remove the extraction solvents. Nitrogen gas is introduced during the final phase of distillation to drive off any remaining traces of solvents. The quantity of asphalt binder in the asphalt mixture is calculated (optional) and the recovered asphalt (distillation residue) sample is subjected to further physical and chemical testing as required. The recovered aggregate can then be used for sieve analysis or other aggregate testing, if desired.

5. SIGNIFICANCE AND USE

5.1. This method is used for obtaining recovered asphalt binder residue samples from asphalt mixture samples for further physical and chemical analyses, and for the optional calculation of asphalt binder content.

6. APPARATUS

6.1. *Extraction Vessel*[1]—The extraction vessel shall be a device as shown in Figure 1, and shall have a 130-mm long piece of 150-mm I.D. Schedule 80 aluminum pipe or Schedule 80, Grade 304 stainless steel pipe (Figure 2) with removable top and bottom 13-mm thick aluminum or stainless steel plates. The top plate (Figure 3) shall have a mixing motor mount and 19-mm port for adding solvent. The bottom plate (Figure 4) shall be equipped with a quick-connect fitting. Four 100-mm by 25-mm baffles (Figure 5) shall be mounted in the extraction vessel followed by a 3-mm aluminum ring, 2-mm (No. 10) mesh screen, spacer (Figure 6), 0.3-mm (No. 50) mesh screen, another spacer, 0.075-mm (No. 200) mesh screen, then another 2-mm (No. 10) mesh screen, as shown in Figure 1.

Note 1—A vessel available from Pass Industries (133 MacArthur Court, Nicholasville, KY 40356, Telephone Number 859-881-0205) has proven acceptable for these requirements.

6.2. *In-Line Filter*—The in-line fine filter apparatus shall be a cartridge type with 20-μm retention and at least 820 cm^3 of effective filter area. The filter apparatus shall be able to be removed from the system to accommodate weighing before and after the procedure. The filter shall be capable of withstanding heat up to 135°C without degradation in order to accommodate oven drying of the filter apparatus.

Note 2—Whatman Polycap™ 75 HD (Catalog Number 6703-7521) or equivalent is a suitable filter. (Whatman Inc., 9 Bridewell Place, Clifton, NJ 07014)

6.3. *Filtrate Flasks with Tubulation*, 1000 mL (two required).

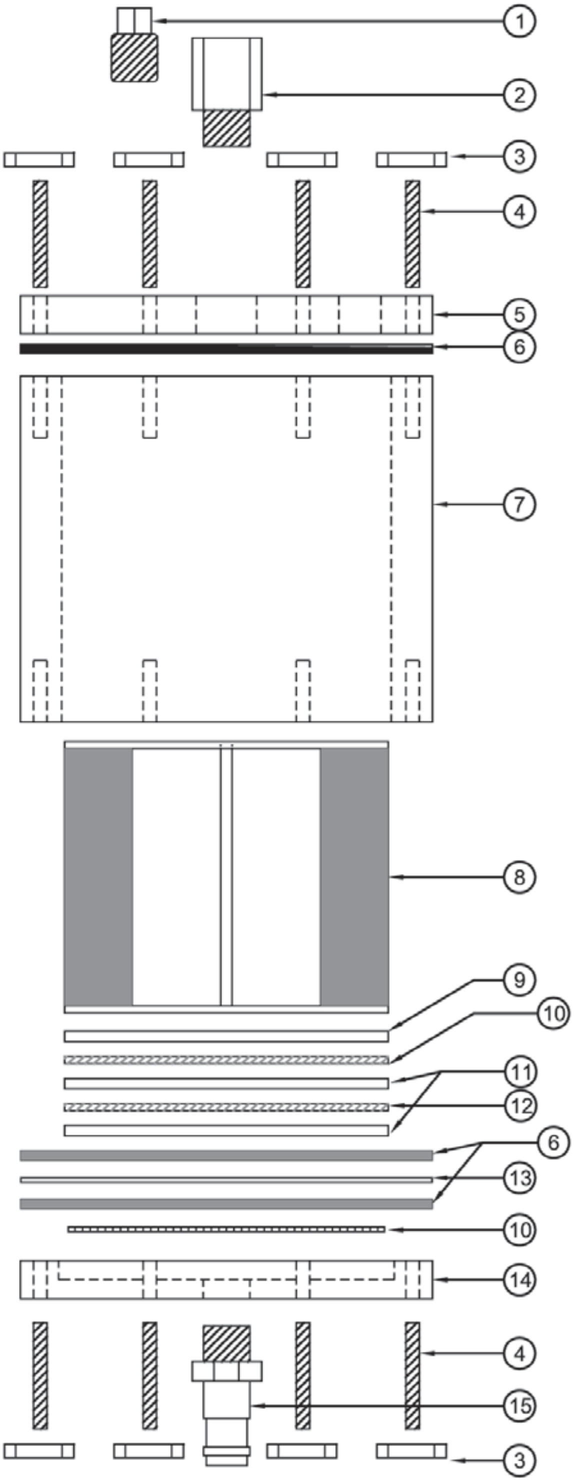
6.4. *Round-Bottom Flasks*, 1000 mL, with cork stands.

6.5. *Gas Flowmeter*, capable of indicating a gas flow up to 1000 mL/minute.

6.6. *Rotary Evaporator Device*, with transfer and purge tubes, capable of holding a recovery flask in oil at a 15° angle and rotating at 40 r/min.

Note 3—The Buchi Rotavapor RE-120 has proven acceptable for these requirements (Buchi, Labortechnik AG, Postfach, 9230 Flach 1, Switzerland).

6.7. *Hot Oil Bath*, capable of heating oil to 180°C.



(1) 2-ISO 12 RT (¾-in. NPT) plug.
(2) ISO 8 RT (½ in.-NPT) fitting with 16-mm I.D. hole for motor shaft.
(3) 12 M5 × 0.5 wing nuts.
(4) 12 M5 × 0.5 × 50 mm studs.
(5) Extraction vessel top.
(6) 3 vision gaskets 3 mm thick, 16 mm width with holes to fit over studs.
(7) Extraction vessel housing.
(8) Aluminum baffle.
(9) Aluminum ring, 3 mm thick, 148 mm O.D. ,10 mm width.
(10) Stainless steel screens, 10 mesh.
(11) Metal spacers.
(12) #50 Screen.
(13) #200 Screen.
(14) Extraction vessel bottom.
(15) ISO 4 RT (¾ -in. NPT) quick-connect fitting.

Figure 1—Extraction Vessel

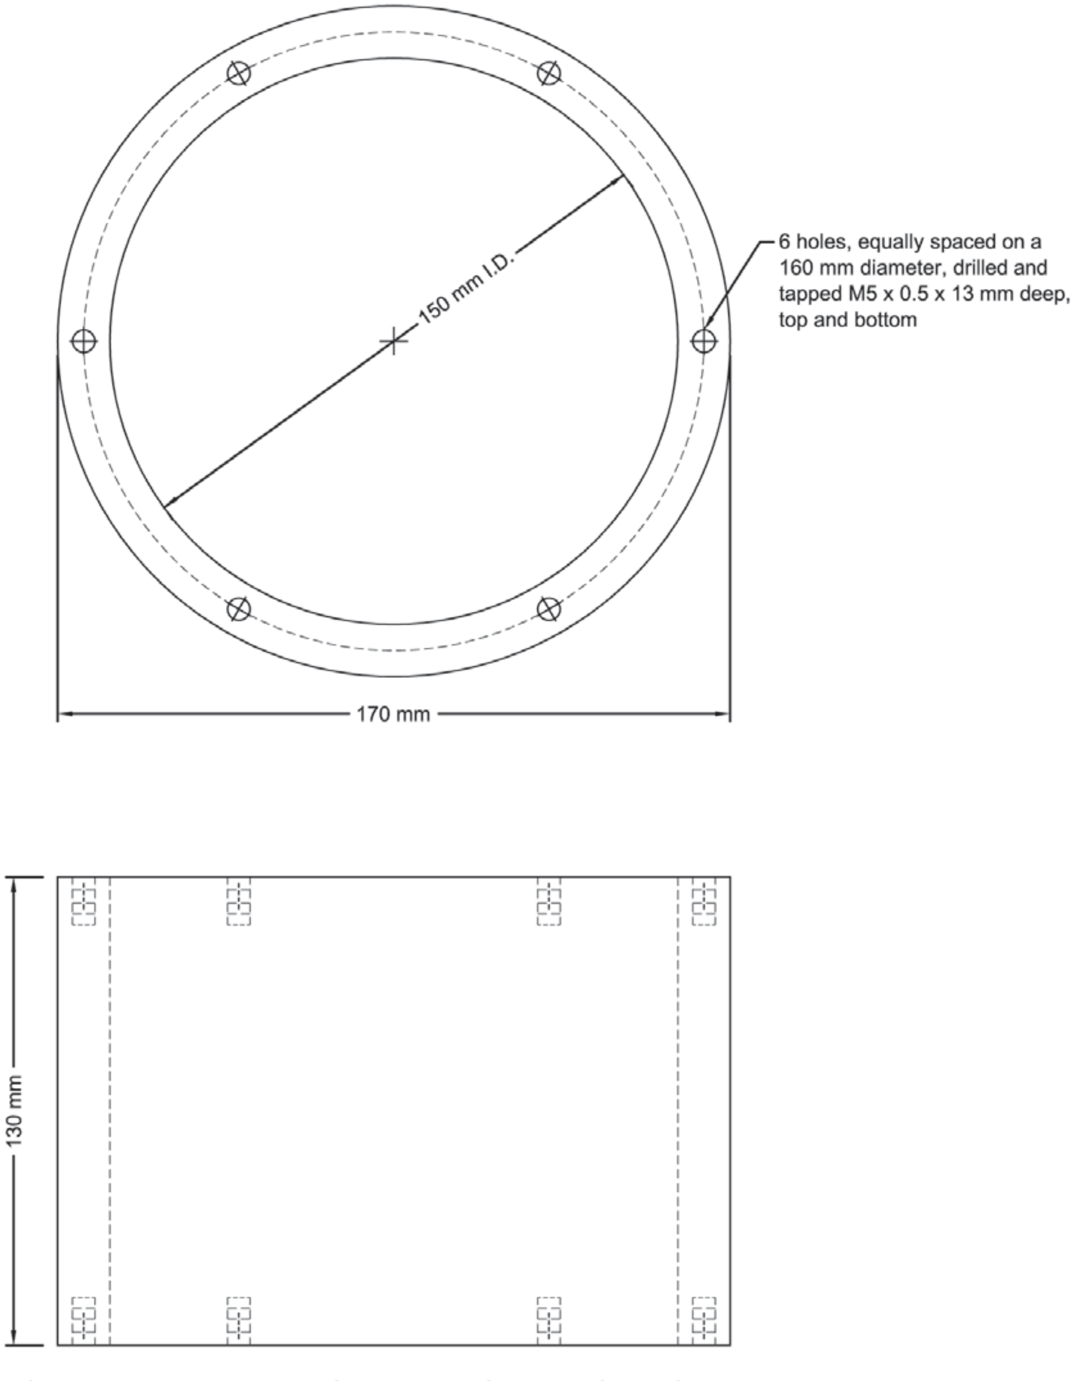


Figure 2—Extraction Vessel Housing

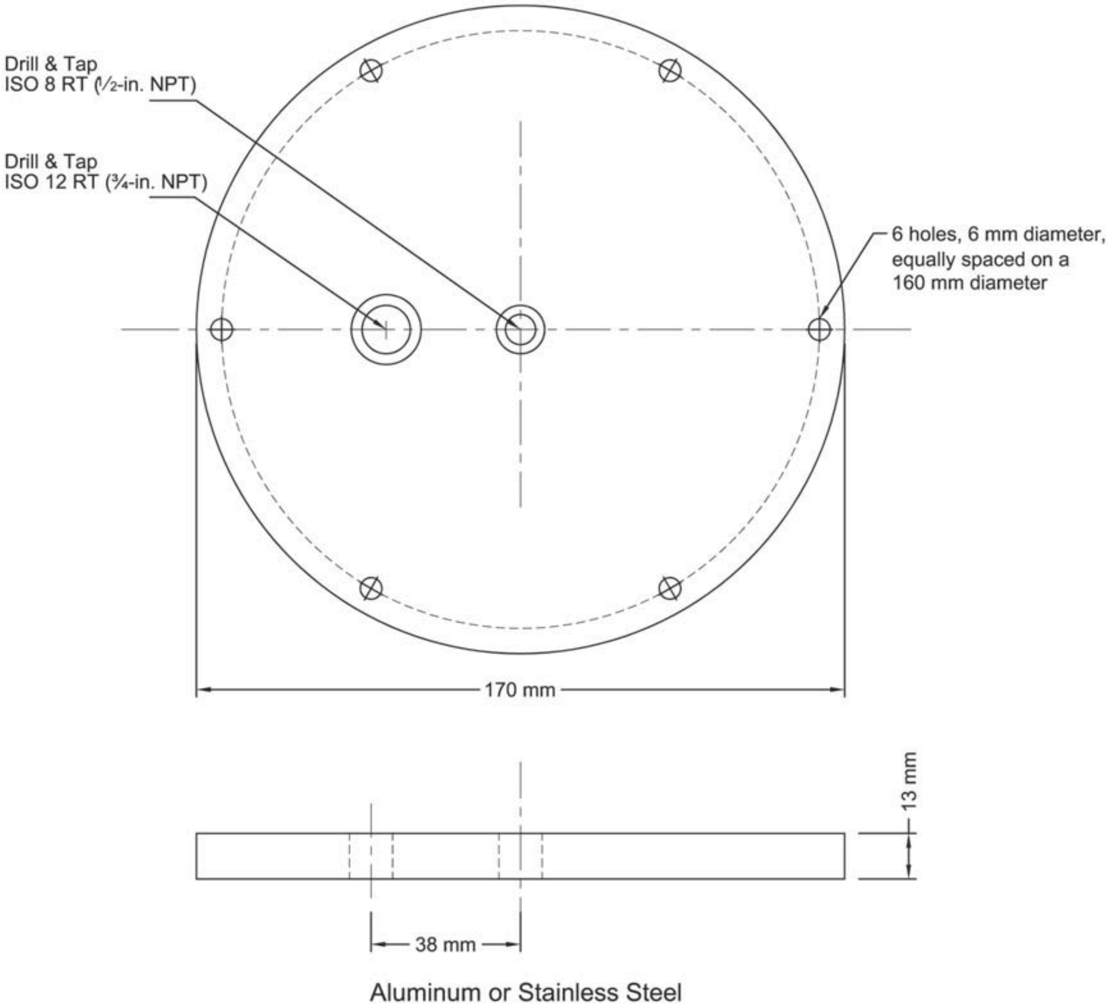
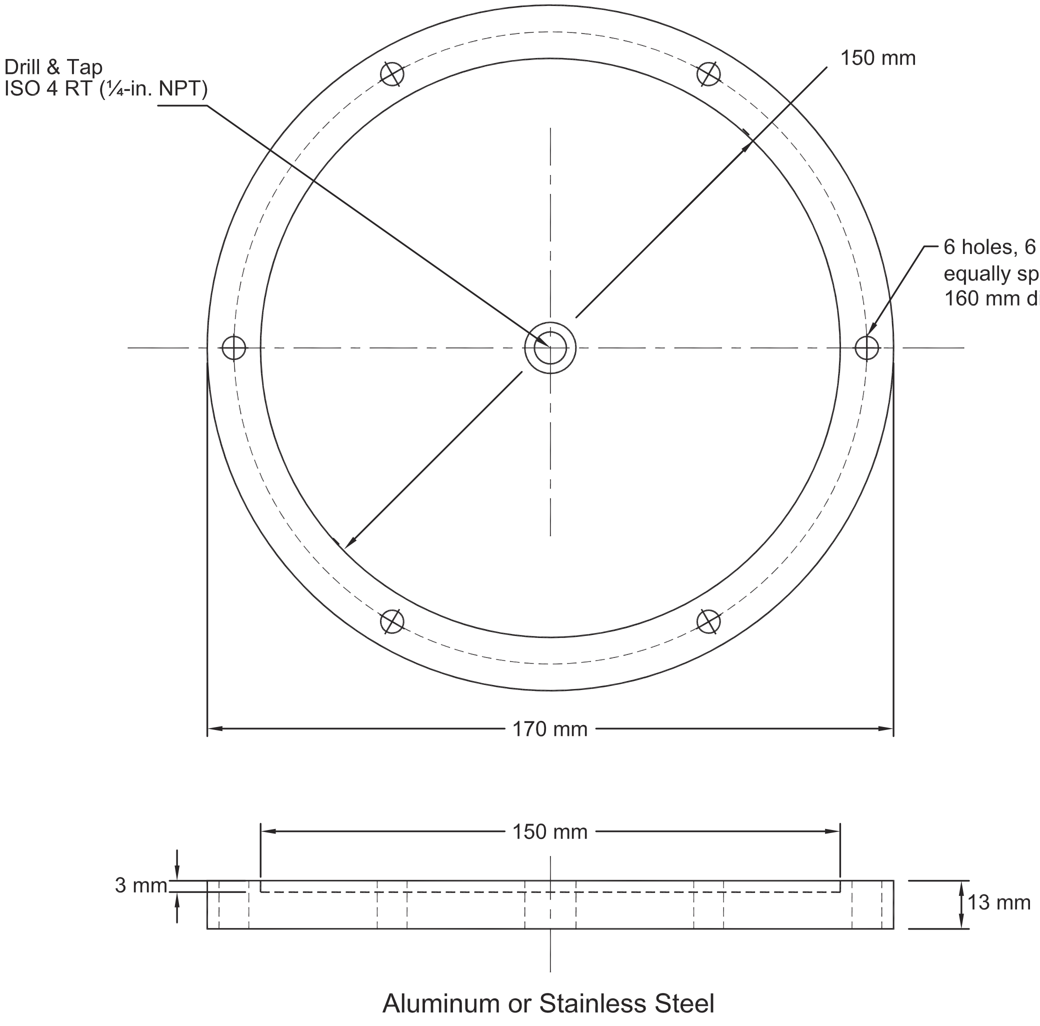


Notes: 1. Not to scale.
2. Assume a tolerance of 0.2 mm unless otherwise noted.

Figure 3—Extraction Vessel Top Plate



Notes: 1. Not to scale.
2. Assume a tolerance of 0.2 mm unless otherwise noted.

Figure 4—Extraction Vessel Bottom Plate

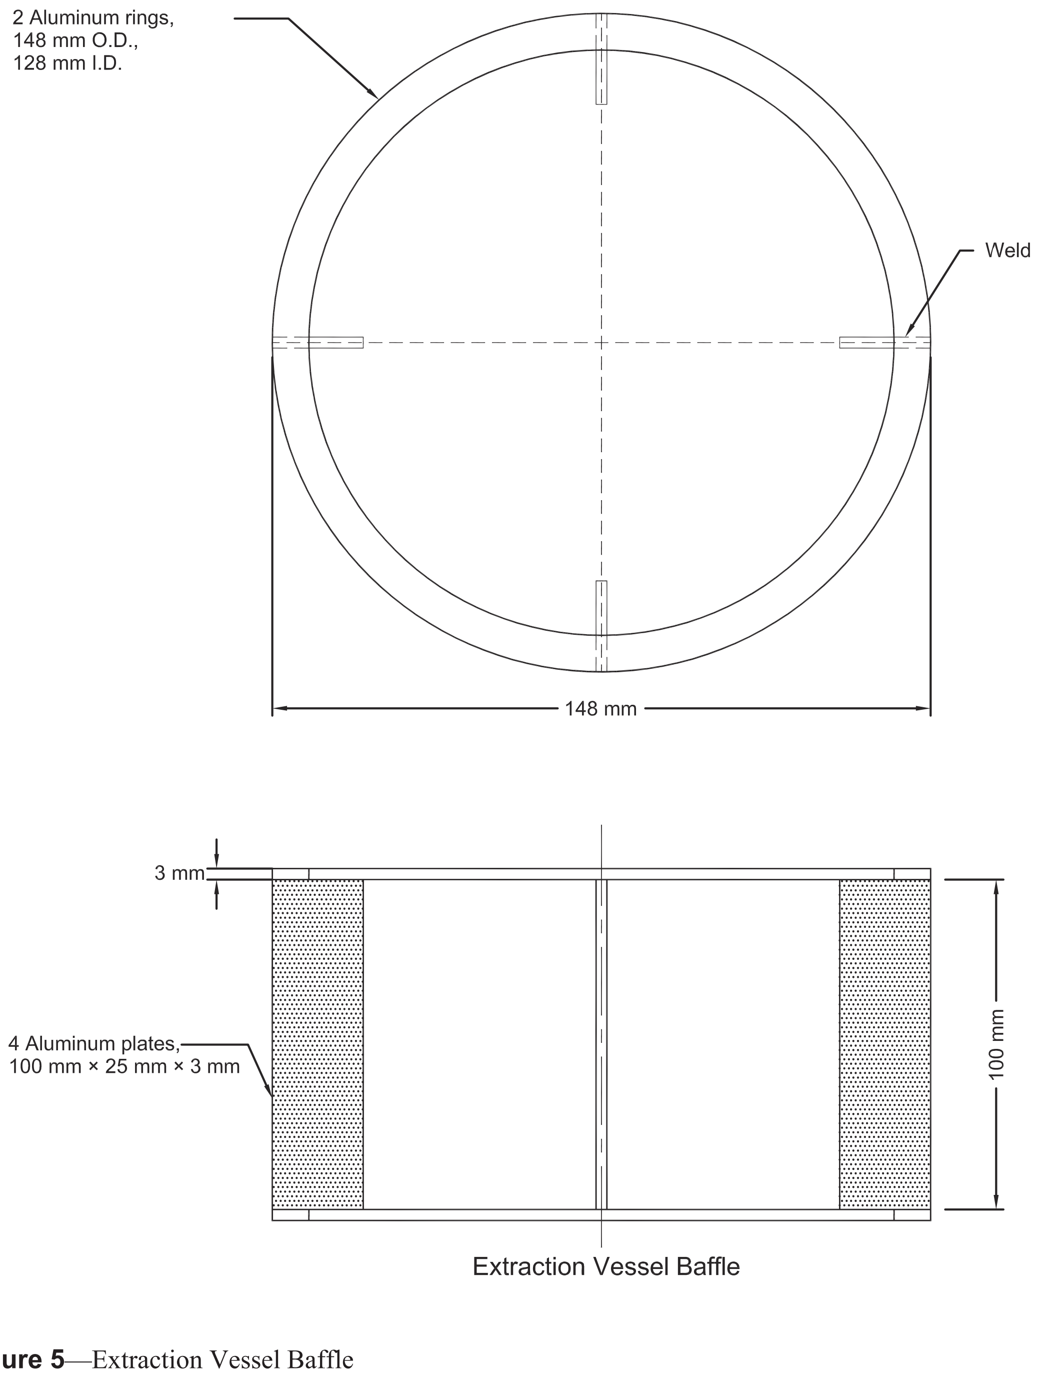


Figure 5—Extraction Vessel Baffle

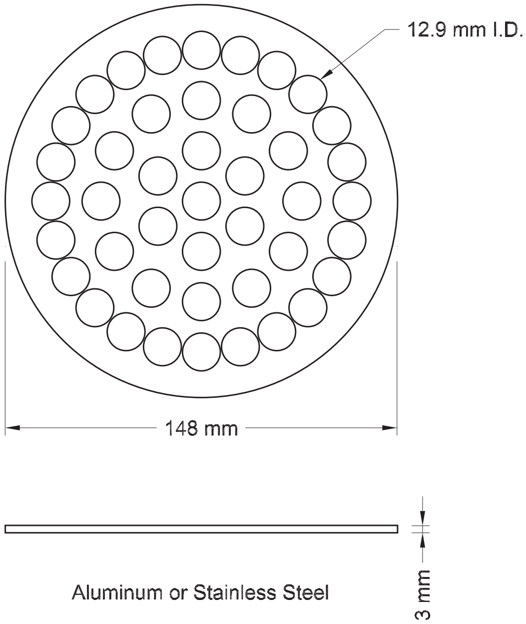

Figure 6—Extraction Vessel Spacer

6.8. *Single-Speed Mixing Motor*, 150 W ($^1/_5$ hp), 30 r/min.

6.9. *Centrifuge*, batch unit capable of exerting a minimum centrifugal force of 770 times gravity.

6.10. *Wide-Mouth Centrifuge Bottles*, 250 mL.

6.11. *Oven*, capable of maintaining a temperature of 110 ± 5°C.

6.12. *Balance*, of suitable capacity, meeting the requirements of M 231 for Class G 2 balances.

6.13. *Thermometer*, having a range of 30°C to 300°C.

6.14. *Utilities*—Vacuum source and cooling water source.

6.15. *Scale (optional)*—Having a capacity of 12 kg or more, sensitive to 0.1 g or less, and accurate within 0.1 percent of the test load at any point within the range of use for this test. Within any 100-g range of test load, a difference between readings shall be accurate within 0.1 g.

6.16. *6-mm Diameter Polypropylene Tubing*—varying length, for transferring solution throughout the procedure.

Note 4—To avoid contamination of the sample due to solvent degradation of the tubing, do not substitute Nalgene or rubber tubing for the polypropylene tubing specified.

6.17. *Copper Tubing*, of an amount and size adequate to connect the apparatus as shown in Figure 7.

7. MATERIALS AND REAGENTS

7.1. *Solvent* (n-Propyl Bromide or Trichloroethylene, reagent grade; or Toluene, reagent grade)—If using Toluene, combine with Ethanol, absolute, in proportions of 85 percent Toluene and 15 percent Ethanol after the third wash (Section 12.2).

7.2. *Nitrogen Gas*, at least 99.95 percent pure, in a pressurized tank with a pressure-reducing regulator valve.

8. HAZARDS

8.1. Use solvents only under a fume hood or with an effective surface exhaust system in a well-ventilated area. Observe the manufacturer's recommended safety precautions when using compressed nitrogen.

9. SAMPLING

9.1. Obtain asphalt mixture samples in accordance with T 168. When sampling from a compacted roadway, remove specimens from the roadway in accordance with ASTM D 5361. When sampling RAP, refer to T 2 for aggregate sampling.

10. PREPARATION OF APPARATUS

10.1. *Preparing the Extraction Vessel*—Install the baffle piece and other internal parts in the order shown in Figure 1. Tightly and evenly fasten the bottom end piece (with the quick connect fitting) of the vessel with wing nuts or hexagonal nuts.

10.2. *Preparing the Rotary Evaporator*—Turn on the cooling water. Turn on the oil bath, and set the temperature to 100 ± 2.5°C. Place six 3-mm glass boiling beads in a 1000-mL round-bottom flask. Attach this recovery flask to the rotary evaporator, and immerse approximately 38 mm of the flask into the oil bath. Set the angle of the recovery flask, from the horizontal to the bath, at 15°. Set the flask rotation at 40 r/min. Clamp the empty condensate flask onto the condenser. Attach the transfer tube inside the neck of the rotary evaporator. Attach the filtrate transfer line to the external fitting on the neck of the rotary evaporator.

11. STANDARDIZATION

11.1. At least every six months, verify the calibration of the oil bath temperature detector by using a certified mercury-in-glass thermometer of suitable range that is accurate to ±0.2°C. Immerse the thermometer in the oil bath close to the thermal detector, and compare the temperature indicated by the certified thermometer to the temperature setting for the oil bath. If the temperature indicated by the thermal detector does not agree with the certified thermometer within ±0.5°C, perform additional calibration or maintenance.

11.2. At least every six months, use a mercury manometer or other certified pressure measurement device to verify calibration of the vacuum indicator. If the vacuum indicator and the certified pressure measurement device do not agree within ±0.1 kPa, perform additional calibration or maintenance.

11.3. At least every six months, verify the rotational velocity of the rotary evaporator.

11.4. At least every six months, verify the flow rate of the nitrogen flowmeter.

12. PROCEDURE

12.1. *Sample Preparation*:

12.1.1. If a sample of asphalt mixture is not sufficiently soft to separate with a spatula or trowel, place the sample in a large, flat pan, and warm it in an oven at 110 ± 5°C only until it can be handled or mixed.

12.1.2. Split or quarter the loose asphalt mixture sample until an amount of the sample that will yield approximately 50 to 60 g of extracted asphalt binder is obtained. Typically 1000 g of asphalt mixture is sufficient.

Note 5—This procedure works best when recovering less than 60 g of asphalt binder. Therefore, if the asphalt binder content of the mix is already known, then the mass of the original sample required is that which yields about 50 to 60 g of asphalt binder.

Note 6—The maximum aggregate size in the test specimen will affect the calculated asphalt content. If the calculated results from this standard are used to represent the asphalt content of the asphalt mixture from which the sample was obtained, use a minimum mass of test specimens for calculations that will ensure that inclusion or removal of one maximum size particle will not change the calculated asphalt content by more than 0.05 percent. This restriction may require testing multiple test specimens.

12.1.3. If the asphalt binder content is to be determined, obtain a separate test specimen from the asphalt mixture sample. Determine the moisture content in accordance with T 110 or T 329 and record the mass percent of water in the test specimen.

12.2. *Extraction and Filtration*:

12.2.1. Place the asphalt mixture sample in the extraction vessel. Put the gasket and the upstream end piece on the vessel, and fasten the wing nuts tightly and evenly, creating a secure seal.

12.2.2. Charge 600 mL of solvent through the 19-mm port on the upstream end of the extractor. Blanket the interior of the extraction vessel by injecting nitrogen through the upstream port at a rate of 1000 mL/min for 1 min. Close the port with the threaded plug. Attach the extractor to the motor. Start the motor, and mix for 5 ± 1 minutes at 30 r/min. Turn off the motor.

12.2.3. Remove the extractor; place it on a stand, and attach the quick-connect fitting to the first filtrate-receiving flask. Ensure the filtrate transfer line is closed. Remove the upstream port, and blanket the extractor with nitrogen at a rate of 400 mL/min while drawing the asphalt/solvent solution into the first flask. Apply a vacuum of 93.3 ± 0.7 kPa (700 ± 5 mm Hg) to the first filtrate-receiving flask in order to draw the material from the vessel. Continue drawing the solution into the first flask until there is no noticeable amount of solution exiting the vessel. Turn off the vacuum.

12.2.4. Filtering through the in-line cartridge filter, switch the vacuum to the second filtrate-receiving flask, and apply a vacuum of 93.3 ± 0.7 kPa Filter until there is no noticeable amount of solution remaining in the first flask or the filter. Turn off the vacuum.

12.2.5. After filtration, open the filtrate transfer valve on the second receiving flask and allow the solution to flow from the filtrate-receiving flask to the recovery flask. Continue the transfer until the filtrate-receiving flask is empty or the recovery flask is about two-thirds full; then, begin the primary distillation.

12.2.6. After the distillation is started, disconnect the extractor from the quick-connect fitting. Repeat the extraction procedure. For the second wash, use 400 ± 10 mL of solvent, and mix/rotate for

10 ± 1 minutes. For subsequent washes (Note 7), use 400 ± 10 mL of solvent, and mix for 30 to 35 min.

Note 7—After the third wash, the condensate from the primary distillation step may be used for extraction solvent. Recycling solvent in this manner allows the entire procedure to use approximately 1500 mL of solvent.

12.2.7. Proceed to the final recovery step (Section 12.4) if the filtrate flowing through the transfer tube, after a 30-min wash, is a light brown color. A minimum of three washes is required.

12.3. *Primary Distillation*:

12.3.1. Close the filtrate transfer valve line, distill solvent at 100 ± 2.5°C (oil bath temperature), and at a vacuum of 93.3 ± 0.7 kPa.

12.3.2. If after the primary distillation step the condensate flask is over half full, empty the flask. Save this solvent for use in subsequent washes (Note 7). After primary distillation of each filtrate, maintain vacuum, temperature, flask rotation, and cooling water. Repeat the primary distillation after each filtration (Note 8).

Note 8—It is important to concentrate the asphalt in the recovery flask after each wash and at a low temperature. This procedure minimizes the temperature and the time spent in the dilute solution and, therefore, minimizes asphalt hardening in the solvent.

12.4. *Final Extraction and Recovery*:

12.4.1. Distill the contents of the recovery flask until it is about one-third full.

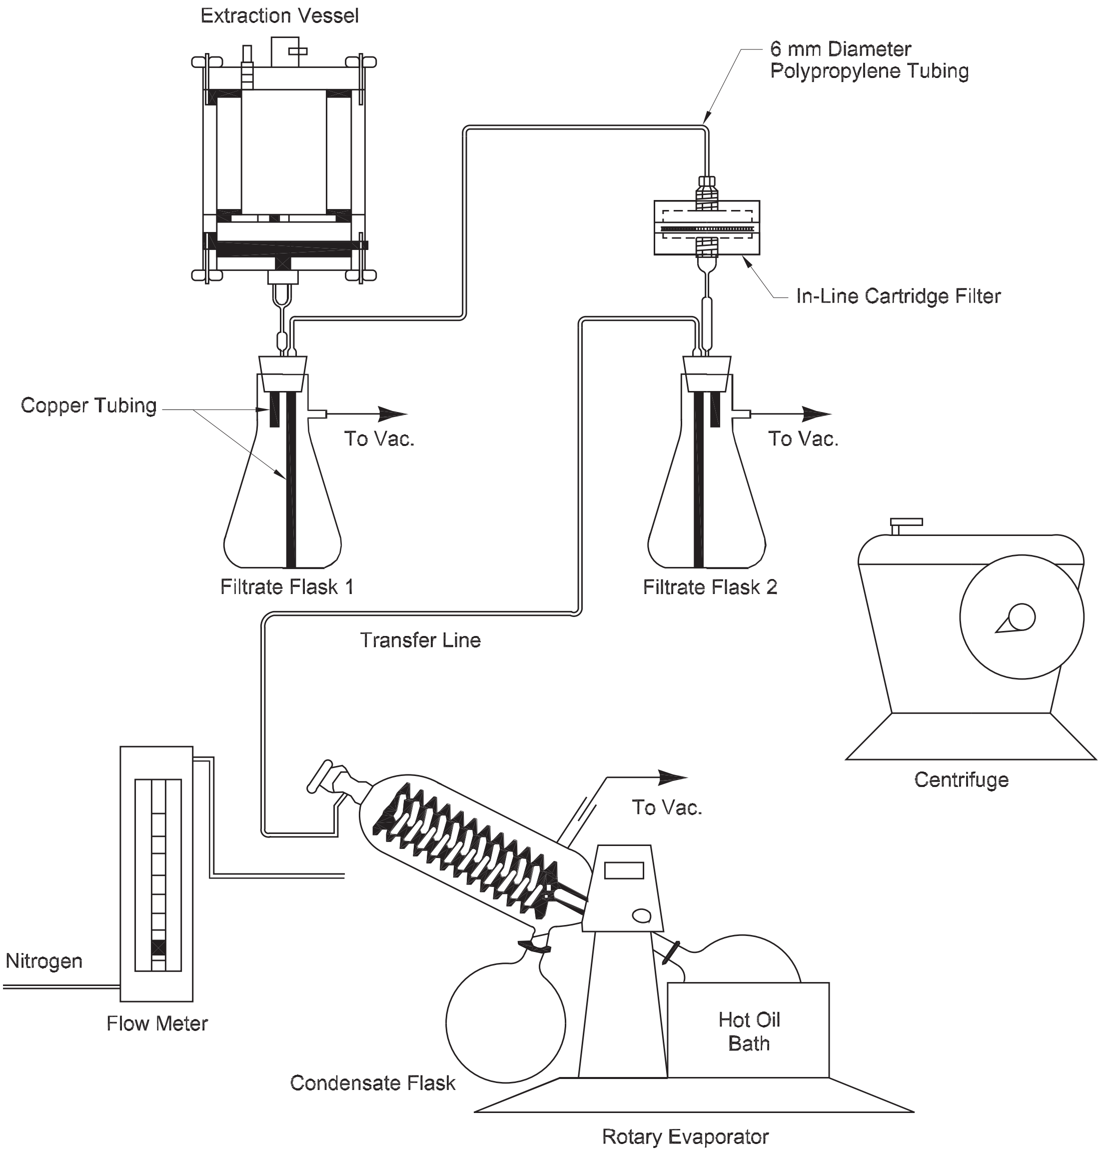

Figure 7—Extraction and Recovery Apparatus

12.4.2. Turn off the vacuum then clean and disconnect the recovery flask, and pour the contents into the centrifuge bottles using a funnel and screen to prevent the boiling beads from entering the bottles. Fill the bottles so that their masses are equal. Wash any remaining residue from the recovery flask into the centrifuge bottles. Increase the oil bath temperature to 174 ± 2.5°C. Centrifuge the bottles at 3600 r/min for 25 minutes.

12.4.3. Empty the centrifuge bottles back into the recovery flask, and add six 3-mm diameter glass boiling beads. Reattach the flask to the rotary evaporator. Disconnect the transfer tube from the rotary evaporator, and replace it with the gas purge tube. Disconnect the filtrate transfer line from the external rotary evaporator neck fitting, and replace it with the nitrogen gas line. Apply a vacuum of 93.3 ± 0.7 kPa. Lower the flask approximately 38 mm into the oil bath.

12.4.4. Distill the solvent.

12.4.5. When the condensation rate falls below one drop every 30 seconds, introduce nitrogen gas at a rate of 1000 mL/minute. Maintain the gas flow, vacuum, and bath temperature for 30 ± 1 minutes to reduce the residual solvent concentration to near zero. Complete removal of residual solvent is very important for obtaining accurate asphalt properties.

12.4.6. Shut down the oil bath, flask rotation, vacuum, gas flow, and cooling water. Remove the evaporating flask. If the asphalt binder content is to be determined, determine and record the mass of the recovered asphalt binder to the nearest 0.1 g. Pour the asphalt into a sample tin using a screen to prevent the boiling beads from entering the tin.

13. DETERMINATION OF ASPHALT BINDER CONTENT (OPTIONAL)

13.1. When a determination of asphalt binder content is desired, use the following procedure:

13.1.1. *Before Section 12.2.1, do the following*:

13.1.1.1. Determine the mass of the mixture sample;

13.1.1.2. Determine the mass of the cartridge filter; and

13.1.1.3. Determine the mass of the centrifuge bottles.

13.1.2. *Before Section 12.4.3, do the following*:

13.1.2.1. Dry the centrifuge bottles, in-line filter, and opened vessel (including inserts) to constant mass;

13.1.2.2. Determine the mass of fine material in the centrifuge bottles (dry original);

13.1.2.3. Determine the mass of fine material in the filter (dry original); and

13.1.2.4. Determine the mass of all aggregate material in the vessel (scrape/brush all screens, etc.);

13.1.2.5. Determine the asphalt content using the following equation:

$$\frac{\text{Asphalt content \%} = \text{Original sample} - (\text{Recovered aggregate} + \Delta\text{Bottles} + \Delta\text{Filter}}{\text{Original Sample}} \times 100$$

14. REPORT

14.1. *Report the following information*:

14.1.1. Source of the test sample.

14.2. *Report the following information if the asphalt binder content is to be determined*:

14.2.1. Mass of the test specimen to the nearest gram;

14.2.2. Mass percent of water in the companion test specimen to the nearest 0.01 percent;

14.2.3. Mass of asphalt binder in the test specimen to the nearest gram; and

14.2.4. Percent of asphalt binder in the test sample to the nearest 0.01 percent.

15. PRECISION AND BIAS

15.1. *Precision*—The research required to develop precision values has not been conducted.

15.2. *Bias*—The research required to establish the bias of this method has not been conducted.

16. KEY WORDS

16.1. Asphalt binder; extraction; recovery; rotary evaporator.

---

[1] An "International" No. 2 Centrifuge operating at 1900 r/min or an "SMM Continuous Centrifuge" exerting a force of 3000 times gravity at 9000 r/min has been found satisfactory for this purpose.

Standard Method of Test for

Determining the Permanent Shear Strain and Stiffness of Asphalt Mixtures Using the Superpave Shear Tester (SST)

AASHTO Designation: T 320-07

1. SCOPE

1.1. This standard provides performance-related test procedures for the determination of stiffness and permanent shear strain of asphalt mixtures using the Superpave Shear Tester (SST). Modified and unmodified asphalt mixtures can be tested and analyzed using this standard.

1.2. This standard is applicable to specimens prepared in a laboratory or cored from a pavement for post-construction analysis. It is intended for use with specimens having the following minimum dimensions:

Nominal Maximum Aggregate Size in Asphalt Mixture, mm	Specimen Diameter	Specimen Height
19	150	50
12.5, 9.5, 4.75	150	38

Note 1—*Nominal maximum aggregate size* is defined in R 35 as the sieve greater than the first sieve to retain more than 10 percent of the total aggregate. Asphalt mixtures with a nominal maximum aggregate size greater than 19 mm can be tested using this procedure, but it is not recommended. The larger aggregate sizes may significantly interfere with the material response, thereby affecting the repeatability of the test.

Note 2—The SST is only capable of testing specimens with a maximum diameter of 150 mm. The specimen height of 50 mm is preferred, but may not be available in roadway cores where layer thickness may only be 38 mm. Specimen heights less than 38 mm usually cannot be tested because of equipment constraints.

Note 3—The diameter-to-height ratio for shear test specimens should be 3:1 or greater. This effectively eliminates the use of 100-mm diameter specimens (because of minimum height requirement for testing discussed in Note 2).

1.3. *This practice may involve hazardous materials, operations, and equipment. It does not purport to address all the safety concerns associated with its use. It is the responsibility of the user of this practice to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to its use.*

3. SIGNIFICANCE AND USE

3.1. The test procedures and associated analysis techniques described in this method can be used to determine shear stiffness and permanent shear strain of asphalt mixtures. The shear frequency sweep test at constant height can be used to determine mixture stiffness. The simple shear test at constant height can be used to determine shear deformation from the application of a static shear load. The repeated shear test at constant height can be used with corresponding analysis procedures to estimate the rutting susceptibility of an asphalt mixture.

4. EQUIPMENT AND MATERIALS

4.1. *Shear Test System*—The shear test system shall consist of a loading device, specimen deformation measurement equipment, an environmental chamber, and a control and data acquisition system. It shall accommodate test specimens 150 mm in diameter and 50 mm in height.

4.1.1. *Loading Device*—The loading device shall be capable of simultaneously applying both vertical and horizontal loads to a specimen. It shall also be capable of applying static, ramped (increasing or decreasing), and repetitive loads of various waveforms. As a minimum, the loading device shall be capable of applying horizontal shear load pulses in a haversine waveform with a load duration of 0.1 s with 0.6 s between load pulses. Loading shall be provided by two hydraulic actuators (one each horizontal and vertical) and shall be controlled by closed-loop feedback using either stress or strain control throughout the entire range of frequencies and temperatures. The loading device shall be capable of meeting the minimum requirements specified in Table 1.

Table 1—Minimum Test System Requirements

Measurement and Control Parameters	Range	Resolution	Accuracy
Load (N)	0 to 31,000	2	5
Axial LVDT (mm)	0 to 5	0.0025	0.005
Shear LVDT (mm)	0 to 0.05	0.001	0.002
Temperature (˚C)	0 to 80	0.25	0.5

4.1.2. *Environmental Chamber*—The environmental chamber shall be capable of maintaining the temperature of the test specimen as specified in Table 1 during the testing sequence.

4.1.3. *Data Acquisition and Control System*—The data acquisition and control system shall automatically control user-selected measurement parameters, within the accuracy specified in Table 1, during the testing sequence. The system shall record load cycles, applied horizontal and vertical loads, specimen deformation in two directions (vertical and horizontal), environmental conditions, and the required frequency of data sampling. At the conclusion of the test, the data acquisition and control system shall provide all applicable test data.

4.2. *Conditioning Chamber*—The conditioning chamber shall be capable of maintaining the specimen conditioning temperatures as specified in Table 1.

4.3. *Platen-Specimen Assembly Device (optional)*—The platen-specimen assembly device is used to facilitate bonding the specimen to the loading platens with adhesive. The device shall maintain the platens in a parallel position (relative to each other) during the gluing operation. The platens must remain parallel so that stresses do not develop in the specimen when the specimen-platen assembly is clamped in the test system. The device shall be capable of testing specimens with a maximum diameter of 150 mm and maximum height of 50 mm.

4.4. *Aluminum Loading Platens*—Top and bottom aluminum loading platens at least 6.35 mm greater in diameter than the diameter of the specimen to be tested and at least 20 mm thick. The bearing face of each platen shall be plane to 0.025 mm.

4.5. *Adhesive*—Quickset adhesive with a minimum hardened stiffness modulus of 2000 MPa for bonding the platens to the specimen ends.

Note 4—Devcon™ 5-Minute Plastic Steel Epoxy Cement[3] is satisfactory for tests conducted at 20°C or higher.

4.6. *Solvent* —Acetone, kerosene, or other equivalent solvent for cleaning the platens after testing.

Note 5—Most of the epoxy and samples can be removed by heating and scraping the platens. The solvent is used only for a final cleaning.

5. STANDARDIZATION

5.1. The testing system shall be standardized prior to initial use and at least once every 12 months thereafter.

5.1.1. Verify the capability of the environmental control chamber to maintain the required temperature within the accuracy specified in Table 1.

5.1.2. Verify the calibration of all measurement components [such as load cells and linear variable differential transducers (LVDTs)] of the testing system.

5.1.3. If any of the verifications yield data that do not comply with the accuracy requirements specified in Table 1, correct the problem prior to proceeding with testing. Appropriate action may involve correction of menu entries, maintenance of system components, calibration of system components (using an independent calibration service, manufacturer service, or in-house resources), or replacement of system components.

6. SAMPLING AND SPECIMEN PREPARATION

6.1. Five test specimens are preferred, and a minimum of three specimens are required, for performing the repeated shear test at constant height. Three test specimens are preferred for performing the shear frequency sweep test at constant height and the simple shear test at constant height.

6.2. *Laboratory-Mixed, Laboratory-Compacted (LMLC) Specimens*—Sample asphalt binder and aggregates in accordance with T 40 and T 2, respectively. Use the appropriate proportions of asphalt binder and aggregates according to the final asphalt mix design.

6.2.1. Prepare aggregate batches of the appropriate size to produce a compacted specimen that will be 150 mm in diameter and 75 mm in height. Heat the aggregate batches to the appropriate mixing temperature.

Note 6—The Appendix contains information on the calculation of the appropriate aggregate batch weight to achieve the correct specimen dimension at the proper percentage of air voids.

6.2.2. Heat the asphalt binder to the appropriate mixing temperature. Mix the correct proportions of asphalt binder and combined aggregates to match the asphalt mix design.

6.2.3. After mixing, condition the asphalt mixture for 4.0 ± 0.1 h at 135 ± 5°C in accordance with "Short-Term Conditioning for Mixture Mechanical Property Testing," R 30.

6.2.4. Compact the HMA mixture in accordance with T 312 to obtain a specimen with the appropriate percentage of air voids as follows:

Test	Air Voids, %
Repeated Shear Test	3.0 ± 0.5
Simple Shear Test	7.0 ± 0.5
Shear Frequency Sweep Test	7.0 ± 0.5

Note 7—Other compaction procedures than the Superpave™ gyratory compactor (T 312) and other target air void percentages may be used. However, caution is needed to prevent comparisons between asphalt mixtures with different target air voids or compaction. The test procedures and analyses are sensitive to both the percentage of air voids and the compaction procedure.

Note 8—Specimens are often compacted to a target air void percentage that is higher than the anticipated percentage of air voids in the cut test specimen. This is done because cutting the top and bottom of a compacted specimen removes lower density material, thereby raising the density (lowering the air voids) of the test specimen. The magnitude of the difference between the target percentage of air voids for the compacted specimen and the target percentage of air voids for the test specimen is dependent upon the nominal maximum aggregate size of the mixture and the mixture gradation. Coarse mixes, and/or mixes with a larger nominal maximum aggregate size, tend to have greater differences between the compacted specimen air voids and the test specimen air voids. In general, a 1.0 percent offset (compact to a target of 4.0 percent air voids or 8.0 percent air voids) should be sufficient to achieve the appropriate percentage of air voids in the test specimen.

6.2.5. Cool the compacted specimen to room temperature. Cut the compacted specimen to a height of 50 mm with two parallel faces. Determine and record the height of the cut specimen at the least and greatest heights. If the difference in the least and the greatest height is more than 2 mm, then discard the specimen and prepare another.

6.2.6. Determine the percentage of air voids in the test specimens in accordance with T 269. Determine the height and diameter of the test specimens in accordance with ASTM D 3549.

6.3. *Field-Mixed, Laboratory-Compacted (FMLC) Specimens*—Obtain HMA samples in accordance with T 168. Compact specimens in accordance with T 312 to the appropriate percentage of air voids. (See Section 6.2.4 and Notes 7 and 8.)

6.3.1. Cool the compacted specimen to room temperature. Cut the compacted specimen to a height of 50 mm with two parallel faces. Determine and record the height of the cut specimen at the least and greatest heights. If the difference in the least and the greatest height is more than 2 mm, then discard the specimen and prepare another.

6.3.2. Determine the percentage of air voids in the test specimens in accordance with T 269. Determine the height and diameter of the test specimens in accordance with ASTM D 3549.

6.4. *Field-Mixed, Field-Compacted (FMFC), or Pavement Core Specimens*—Obtain asphalt pavement specimens having a diameter of 150 mm and a minimum thickness of 38 mm in accordance with ASTM D 5361.

6.4.1. Cut the specimens to the proper test dimensions. Cool the compacted specimen to room temperature. Cut the compacted specimen to a height of 50 mm with two parallel faces. Determine and record the height of the cut specimen at the least and greatest heights. If the difference in the least and the greatest height is more than 2 mm, then discard the specimen and prepare another.

6.4.2. Determine the percentage of air voids in the test specimens in accordance with T 269. Determine the height and diameter of the test specimens in accordance with ASTM D 3549.

6.5. *Preparing the Specimens for Testing*—The following steps discuss the bonding of the test specimen to the platens for testing in the shear tester.

6.5.1. Ensure that the platens are clean, aligned, and clamped in place in the platen-specimen assembly device (optional) or shear test device.

6.5.2. Prepare the adhesive. If using an epoxy, proportion and mix the resin and hardener together in accordance with the manufacturer's instructions (Note 4).

6.5.3. Apply a thin coating of the adhesive to the top of the test specimen and to the bottom platen. Center the test specimen on the bottom platen and lower the top platen onto the specimen. Rotate the specimen slightly to ensure good bonding.

Note 9—Approximately 135 g of epoxy cement has been found suitable to provide bonding without excess waste. Half of the epoxy cement should be used on the bottom platen and the other half on the top of the specimen.

6.5.4. Bond the specimen to the platens using a light pressure (approximately 35 kPa) for 5 minutes. Begin removing excess adhesive from the sides of the test specimen by trimming as soon as the light pressure is applied.

6.5.5. After the adhesive has stabilized, remove the test assembly (specimen with attached platens) from the platen-specimen assembly device (optional) or shear test device and allow the adhesive to cure for the minimum time recommended by the manufacturer.

7. PROCEDURE A—SHEAR FREQUENCY SWEEP TEST AT CONSTANT HEIGHT (STIFFNESS)

7.1. Turn on the hydraulic system at least 1 hour before starting the test to allow sufficient warm-up time. Warm up the actuators and hydraulic oil by using a sinusoidal waveform in stroke control.

7.2. Determine the lowest temperature at which the specimen will be tested and precondition the test specimens from 2 to 4 hours (Note 11) at the required test temperature ±0.5°C. Set the temperature for the environmental chamber of the shear test device at the required test temperature.

Note 10—Many specimens are tested at multiple temperatures depending on the desired data. For example, stiffness at an intermediate temperature (such as 20°C) may be desired to provide inputs to a fatigue analysis procedure. Stiffness at a higher temperature (such as 40°C) may be desired to provide an indication of the expected high temperature stiffness of an asphalt mixture. Because of equipment constraints, testing can only be conducted at temperatures where the mixture stiffness is less than approximately 3000 MPa (435 ksi). Because of nonlinear responses, testing should also be confined to temperatures no higher than 12°C below the high-temperature grade of the asphalt binder (i.e., 52°C for a PG 64-22 asphalt binder).

Note 11—A conditioning chamber is preferred since it allows the shear test device to be free to perform tests rather than be occupied for temperature conditioning.

7.3. After the conditioning period, remove the specimen (attached to platens) from the conditioning chamber. Quickly attach the shear and vertical linear variable differential transducers (LVDTs) to the specimen platens. Open the environmental chamber of the shear tester and place the sample with the attached LVDTs on the shear table.

7.4. Ensure that the LVDTs are plugged into the proper data acquisition ports within the shear tester's environmental chamber. Zero the shear and vertical LVDTs.

7.5. Confirm that the vertical test system heads are positioned to allow the platen-specimen assembly to slide between the bottom horizontal and top vertical heads. Confirm that the horizontal test head is positioned such that the top and bottom test heads are aligned vertically. Center the specimen between the heads and secure the platens. Close the environmental chamber.

7.6. Confirm that the environmental chamber temperature control is activated and on the proper setting to maintain the required test temperature with a tolerance of ±0.5°C. Allow the specimen temperature to stabilize for a minimum of 20 minutes and a maximum of 60 minutes. This stabilization time allows the specimen to reacquire the proper test temperature (lost during LVDT instrumentation) and for the LVDTs to stabilize after the temperature change.

7.7. Execute the shear frequency sweep test at constant height.

7.7.1. Precondition the specimen by applying a sinusoidal shear strain consisting of a peak-to-peak amplitude of 0.0001 mm/mm (0.01 percent) at 10 Hz for 100 cycles. During the loading cycle, maintain the specimen height constant, within ±0.013 mm, by applying sufficient axial stress during the loading cycle. This is accomplished by controlling the vertical actuator using closed-loop feedback from the axial LVDT.

7.7.2. Perform the shear frequency sweep test by applying a sinusoidal shear strain of 0.0001 mm/mm (0.01 percent) at each of the following frequencies –10, 5, 2, 1, 0.5, 0.2, 0.1, 0.05, 0.02, and 0.01 Hz. Use 50 cycles each for the 10 Hz and 5 Hz frequencies. Use 20 cycles each for the 2 Hz and 1 Hz frequencies. Use 7 cycles each for the 0.5, 0.2, and 0.1 Hz frequencies. Use 4 cycles each for the 0.05, 0.02, and 0.01 Hz frequencies.

7.7.3. Record the axial and shear deformations (from the LVDTs) and axial and shear loads. Record at a minimum rate of 50 data points per second for the number of cycles specified for each frequency in Section 8.7.2.

7.7.4. At the conclusion of the test, release the loads and return the actuators to the pretest position. Switch the control back to the actuators (from the axial LVDT) and disconnect the LVDTs.

Note 12—Since the shear frequency sweep test is executed in the (theoretically) linear viscoelastic region, the same specimen can be tested using either the simple shear test at constant height (Procedure B) or repeated shear test at constant height (Procedure C). At high temperatures (40°C and higher), the simple shear test at constant height will induce sufficient permanent shear strain to affect further mixture properties. The repeated shear test at constant height should always induce sufficient permanent shear strain to affect mixture properties. Both tests should be considered "destructive" tests. Therefore, it is recommended that shear frequency sweep testing not be conducted on specimens that have been subjected to "destructive" testing.

7.8. Remove the specimen from the test chamber.

Note 13—The shear frequency sweep test at constant height takes approximately 45 minutes to execute from the time the specimen is removed from the conditioning chamber until the test is completed and the specimen is removed from the shear tester.

7.9. If stiffness will be determined at other test temperatures, either: (a) return the specimen to the conditioning chamber and change the temperature of the SST and conditioning chamber to the next desired temperature; or (b) set the specimen aside without cleaning and wait until the temperature of the SST chamber can be adjusted.

7.10. Once stiffness has been determined at all desired temperatures, clean the specimen from the platens by placing the specimen-platen assembly in an oven at approximately 135°C for 60 minutes to debond the specimen and adhesive from the platens. Scrape the platens clean with a scraper. Use acetone or other suitable solvent to remove any remaining adhesive.

8. PROCEDURE B—SIMPLE SHEAR TEST AT CONSTANT HEIGHT

8.1. Turn on the hydraulic system at least 1 hour before starting the test to allow sufficient warm-up time. Warm up the actuators and hydraulic oil by using a sinusoidal waveform in stroke control.

8.2. Determine the lowest temperature at which the specimen will be tested (Note 14) and precondition the test specimens from 2 to 4 hours (Note 11) at the required test temperature ±0.5°C. Set the temperature for the environmental chamber of the shear test device at the required test temperature.

Note 14—Specimens may be tested at multiple temperatures. However, since this test does induce some permanent shear strain, the same specimen should not be tested at temperatures of 40°C or higher. At temperatures less than 40°C, the permanent shear strain should be sufficiently small to allow the specimen to be tested at other temperatures.

8.3. After the conditioning period, remove the specimen (attached to platens) from the conditioning chamber. Quickly attach the shear and vertical linear variable differential transducers (LVDTs) to the specimen platens. Open the environmental chamber of the shear tester and place specimen on the shear table.

8.4. Ensure that the LVDTs are plugged into the proper data acquisition ports within the shear tester's environmental chamber. Zero the shear and vertical LVDTs.

8.5. Confirm that the vertical test system heads are positioned to allow the platen-specimen assembly to slide between the bottom horizontal and top vertical heads. Confirm that the horizontal test head is positioned such that the top and bottom test heads are aligned vertically. Center the specimen between the heads and secure the platens to the heads. Close the environmental chamber.

8.6. Confirm that the environmental chamber temperature control is activated and on the proper setting to maintain the required test temperature with a tolerance of ±0.5°C. Allow the specimen temperature to stabilize for a minimum of 20 minutes and a maximum of 60 minutes. This stabilization time allows the specimen to reacquire the proper test temperature (lost during LVDT instrumentation) and for the LVDTs to stabilize after the temperature change.

8.7. Execute the simple shear test at constant height.

8.7.1. Determine the specified shear stress level for the test. Perform the test by increasing the shear stress at a rate of 70 kPa/s to: 345 ± 5 kPa (4°C); 105 ± 5 kPa (20°C); or 35 ± 1 kPa (40°C). Maintain the stress at the specified level for 10 ± 1 s. Reduce the shear stress to 0 kPa at a rate of 25 ± 1 kPa/s. Continue the test at a stress level of 0 kPa for an additional 10 ± 1 s. During the test, maintain the specimen height constant, within ±0.013 mm, by applying sufficient axial stress during the loading cycle. This is accomplished by controlling the vertical actuator using closed-loop feedback from the axial LVDT.

8.7.2. Record the axial and shear deformations (from the LVDTs) and axial and shear loads. Record at a minimum rate of 50 data points per second.

8.7.3. At the conclusion of the test, release the loads and return the actuators to the pretest position. Switch the control back to the actuators (from the axial LVDT) and disconnect the LVDTs.

8.8. Remove the specimen from the test chamber.

Note 15—The simple shear test at constant height takes approximately 30 minutes to execute from the time the specimen is removed from the conditioning chamber until the test is completed and the specimen is removed from the shear tester.

8.9. If the simple shear test will be executed at other test temperatures, either: (a) return the specimen to the conditioning chamber and change the temperature of the SST and conditioning chamber to the next desired temperature; or (b) set the specimen aside without cleaning and wait until the temperature of the SST chamber can be adjusted.

8.10. Once the simple shear test has been executed at all desired temperatures, clean the specimen from the platens by placing the specimen-platen assembly in an oven at approximately 135°C for 60 minutes to debond the specimen and adhesive from the platens. Scrape the platens clean with a scraper. Use acetone or other suitable solvent to remove any remaining adhesive.

9. PROCEDURE C—REPEATED SHEAR TEST AT CONSTANT HEIGHT

9.1. Turn on the hydraulic system at least one hour before starting the test to allow sufficient warm-up time. Warm up the actuators and hydraulic oil by using a sinusoidal waveform in stroke control.

9.2. Determine the test temperature (Note 15) and precondition the test specimens from 2 to 4 hours at the required test temperature ±0.5°C (Note 11). Set the temperature for the environmental chamber of the shear test device at the required test temperature.

Note 16—The test temperature can be determined in many ways, but is most commonly calculated as the 7-day maximum pavement temperature (at a depth of 50 mm) for the project location. If the mixture in question is the wearing (surface) course, and the thickness of the layer is less than 50 mm, then the actual layer thickness (e.g., 38 mm) may be used as the depth for calculating the test temperature. Information on calculating pavement temperatures is available in SHRP A-648A and LTPP's LTPPBind software.

9.3. After the conditioning period, remove the specimen (attached to platens) from the conditioning chamber. Quickly attach the shear and vertical linear variable differential transformers to the specimen platens. Open the environmental chamber of the shear tester and place the specimen on the shear table.

9.4. Ensure that the LVDTs are plugged into the proper data acquisition ports within the shear tester's environmental chamber. Zero the shear and vertical LVDTs.

9.5. Confirm that the vertical test system heads are positioned to allow the platen-specimen assembly to slide between the bottom horizontal and top vertical heads. Confirm that the horizontal test head is positioned such that the top and bottom test heads are aligned vertically. Center the specimen between the heads and secure the platens to the heads. Close the environmental chamber.

9.6. Confirm that the environmental chamber temperature control is activated and on the proper setting to maintain the required test temperature with a tolerance of ±0.5°C. Allow the specimen temperature to stabilize for a minimum of 20 minutes and a maximum of 60 minutes. This stabilization time allows the specimen to reacquire the proper test temperature (lost during LVDT instrumentation) and for the LVDTs to stabilize after the temperature change.

9.7. Execute the repeated shear test at constant height.

9.7.1. Apply a repeated haversine shear stress to the test specimen consisting of 69 ± 5 kPa (approximately 1220 N shear load for a 150-mm diameter test specimen) for 0.1 s followed by a 0.6-s rest period. During the loading cycle, maintain the specimen height constant, within ±0.013 mm, by applying sufficient axial stress during the loading cycle. This is accomplished by controlling the vertical actuator using closed-loop feedback from the axial LVDT.

9.7.2. Continue the test sequence for 5000 cycles or until the shear LVDT exceeds its range (usually at 2.5-mm or 5 percent shear strain), whichever comes first.

9.7.3. Record the axial and shear deformations (from the LVDTs) and axial and shear loads. Record at a minimum rate of 50 data points per second during the intervals specified in Table 2.

Table 2—Required Interval Ranges for Recording Data for Procedure B and C

Data	Cycles
1 through 10	1599 through 1601
19 through 21	1799 through 1801
29 through 31	1999 through 2001
49 through 51	2249 through 2251
79 through 81	2499 through 2501
99 through 101	2749 through 2751
199 through 201	2999 through 3001
299 through 301	3249 through 3251
399 through 401	3499 through 3501
499 through 501	3749 through 3751
599 through 601	3999 through 4001
799 through 801	4249 through 4251
999 through 1001	4499 through 4501
1199 through 1201	4749 through 4751
1399 through 1401	4999 through 5000

9.7.4. At the conclusion of the test, release the loads and return the actuators to the pretest position. Switch the control back to the actuators (from the axial LVDT) and disconnect the LVDTs.

9.8. Remove the specimen from the test chamber.

Note 17—The repeated shear test at constant height takes approximately 90 minutes to execute from the time the specimen is removed from the conditioning chamber until the test is completed and the specimen is removed from the shear tester.

9.9. Clean the specimen from the platens by placing the specimen-platen assembly in an oven at approximately 135°C for 60 minutes to debond the specimen and adhesive from the platens. Scrape the platens clean with a scraper. Use acetone or other suitable solvent to remove any remaining adhesive.

10. DATA ANALYSIS

10.1. *Procedure A (Shear Frequency Sweep Test at Constant Height)*—For each specimen, determine the complex shear modulus (G^*) and phase angle (δ) at each frequency. These values are usually calculated by software programs from the measured values of shear load, axial load, shear displacement, and axial displacement.

10.2. *Procedure B (Simple Shear Test at Constant Height)*—For each specimen, calculate the maximum shear strain achieved in Equations 1 and 2:

$$\gamma_{\text{max}} = \frac{\delta_{\text{shear, maximum}} - \delta_{\text{shear, initial}}}{h} \qquad (1)$$

where:

γ_{max} = maximum shear strain;

$\delta_{\text{shear, maximum}}$ = maximum recorded deformation by the shear LVDT;

$\delta_{\text{shear, initial}}$ = initial shear deformation at the start of the test (nominally zero); and

H = specimen height (platen-to-platen measurement only).

10.2.1. The recovery can also be calculated as follows:

$$\text{Recovery} = \frac{\delta_{\text{shear, maximum}} - \delta_{\text{shear, final}}}{\delta_{\text{shear, maximum}}} \qquad (2)$$

where:

Recovery = calculated recovery of the specimen;

$\delta_{\text{shear, maximum}}$ = maximum recorded deformation by the shear LVDT; and

$\delta_{\text{shear, final}}$ = final recorded shear deformation at the end of the test.

10.3. *Procedure C (Repeated Shear Test at Constant Height)*—For each specimen, determine the permanent shear strain at the end of the test (nominally 5000 cycles). The permanent shear strain (γ_p) is calculated as the change in shear deformation from the start of the test to the end of the test divided by the gauge length (nominally 50 mm when using platen-to-platen measurement) in Equation 3:

$$\gamma_p = \frac{\delta_{\text{shear, final}} - \delta_{\text{shear, initial}}}{h} \qquad (3)$$

where:

γ_p = permanent shear strain;

$\delta_{\text{shear, final}}$ = final recorded deformation by the shear LVDT at the end of the test;

$\delta_{\text{shear, initial}}$ = initial shear deformation at the start of the test (nominally zero); and

H = specimen height (platen-to-platen measurement only).

10.3.1. The permanent shear strain can also be expressed as a percentage by multiplying by 100.

11. REPORT

11.1. *Report the following information for each test specimen*:

11.1.1. Mixture identification and specimen identification;

11.1.2. Percentage of air voids in the test specimen, or bulk specific gravity;

11.1.3. Conditioning time and temperature (within 0.1°C);

11.1.4. Equilibration or stabilization time, minutes;

11.1.5. Measured temperature during the test (within 0.1°C);

11.1.6. Note any deviations from the test procedures for each specimen (i.e., shear loads out of tolerance, etc.).

11.2. *Report the following information for Procedure A (Shear Frequency Sweep Test at Constant Height)*:

11.2.1. For each specimen, report the complex shear modulus (G^*) and phase angle (δ) at each frequency.

11.3. *Report the following information for Procedure B (Simple Shear Test at Constant Height)*:

11.3.1. For each specimen, report the maximum shear strain obtained (usually expressed in terms of microns, or 10^{-6} mm/mm) and recovery (expressed as a percentage).

11.4. *Report the following information for Procedure C (Repeated Shear Test at Constant Height)*:

11.4.1. For each specimen, report the permanent shear strain obtained at 5000 cycles. If the test stops before 5000 cycles, report the permanent shear strain and the number of cycles.

12. PRECISION AND BIAS

12.1. *Precision*—The research required to develop precision estimates for the shear frequency sweep, simple shear, and repeated shear test procedures has not been formally conducted.

12.2. *Bias*—The research required to determine the bias of the procedures has not been conducted.

13. KEYWORDS

13.1. Frequency sweep; permanent strain; repeated shear; shear testing; simple shear; stiffness.

APPENDIX

(Nonmandatory Information)

X1. CALCULATING AGGREGATE BATCH WEIGHT FOR LABORATORY-MIXED, LABORATORY-COMPACTED SPECIMENS

X1.1. Calculate the aggregate batch weight required for laboratory-mixed, laboratory-compacted (LMLC) specimens, using Equation X1.1 (valid for 150-mm diameter specimens):

$$\text{Mass} = \frac{17.671 \times \text{Height} \times G_{mm} \times \left(1 - AV\right)}{\left(1 - AC\right)} \quad (X1.1)$$

where:

Mass = aggregate batch weight, g;

Height = target compacted height of the specimen, mm;

G_{mm} = maximum theoretical specific gravity (T 209) of the mixture;

AV = percentage of air voids desired, expressed as a decimal (i.e., 0.04 rather than 4.0 percent); and

AC = asphalt binder content of the mix, expressed as a decimal (i.e., 0.045 rather than 4.5 percent).

Example: A mixture with a 5.2 percent asphalt binder content and a G_{mm} of 2.533 is intended to be evaluated in the repeated shear test to estimate rutting susceptibility. The technician desires the test specimen to have 4.0 ± 0.5 percent air voids. Therefore, anticipate compacting a specimen to a height of 75 mm and allowing a 1 percent offset in air voids between the compacted specimen and the cut test specimen (Note 8). Using Equation X1.1, the aggregate batch weight is determined:

$$\text{Mass} = \frac{17.671 \times 75 \times 2.533 \times \left(1 - 0.05\right)}{\left(1 - 0.052\right)} = 3364 \text{ g} \quad (X1.2)$$

X2. CALCULATING MIXTURE SAMPLE WEIGHT FOR FIELD-MIXED, LABORATORY-COMPACTED SPECIMENS

X2.1. Calculate the mixture sample weight required for field-mixed, laboratory-compacted (FMLC) specimens, using Equation X2.1 (valid for 150-mm diameter specimens):

$$\text{Mass} = 17.671 \times \text{Height} \times G_{mm} \times \left(1 - AV\right) \qquad (X2.1)$$

where:

Mass = aggregate batch weight, g;

Height = target compacted height of the specimen, mm;

G_{mm} = maximum theoretical specific gravity (T 209) of the mixture; and

AV = percentage of air voids desired, expressed as a decimal (i.e., 0.04 rather than 4.0 percent).

X2.2. Alternatively, determine the compacted specimen height if the sample mass is known:

$$\text{Height} = \frac{\text{Mass}}{17.671 \times G_{mm} \times \left(1 - AV\right)} \qquad (X2.2)$$

Example: A mixture sample of 4220 g is obtained. The G_{mm} of the mixture is determined to be 2.471. To produce a test specimen having approximately 4.0 ± 0.5 percent air voids, the target compacted height should be calculated as follows:

$$\text{Height} = \frac{4220}{17.671 \times 2.47 \times \left(1 - 0.05\right)} = 101.7 \text{ mm} \qquad (X2.3)$$

Standard Method of Test for

Determining the Fatigue Life of Compacted Hot Mix Asphalt (HMA) Subjected to Repeated Flexural Bending

AASHTO Designation: T 321-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Fatigue Life of Compacted Hot Mix Asphalt (HMA) Subjected to Repeated Flexural Bending

AASHTO Designation: T 321-07

1. SCOPE

1.1. This standard provides procedures for determining the fatigue life and fatigue energy of 380 mm long by 50 mm thick by 63 mm wide hot mix asphalt (HMA) beam specimens sawed from laboratory or field compacted HMA and subjected to repeated flexural bending until failure.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. TERMINOLOGY

3.1. *Definitions:*

3.1.1. *failure point*—the load cycle at which the specimen exhibits a 50 percent reduction in stiffness relative to the initial stiffness.

4. SIGNIFICANCE AND USE

4.1. The fatigue life and failure energy determined by this standard can be used to estimate the fatigue life of HMA pavement layers under repeated traffic loading. The performance of HMA can be more accurately predicted when these properties are known.

5. APPARATUS

5.1. *Test System*—The test system shall consist of a loading device, an environmental chamber (optional), and a control and data acquisition system. The test system shall meet the minimum requirements specified in Table 1.

Table 1—Test System Minimum Requirements

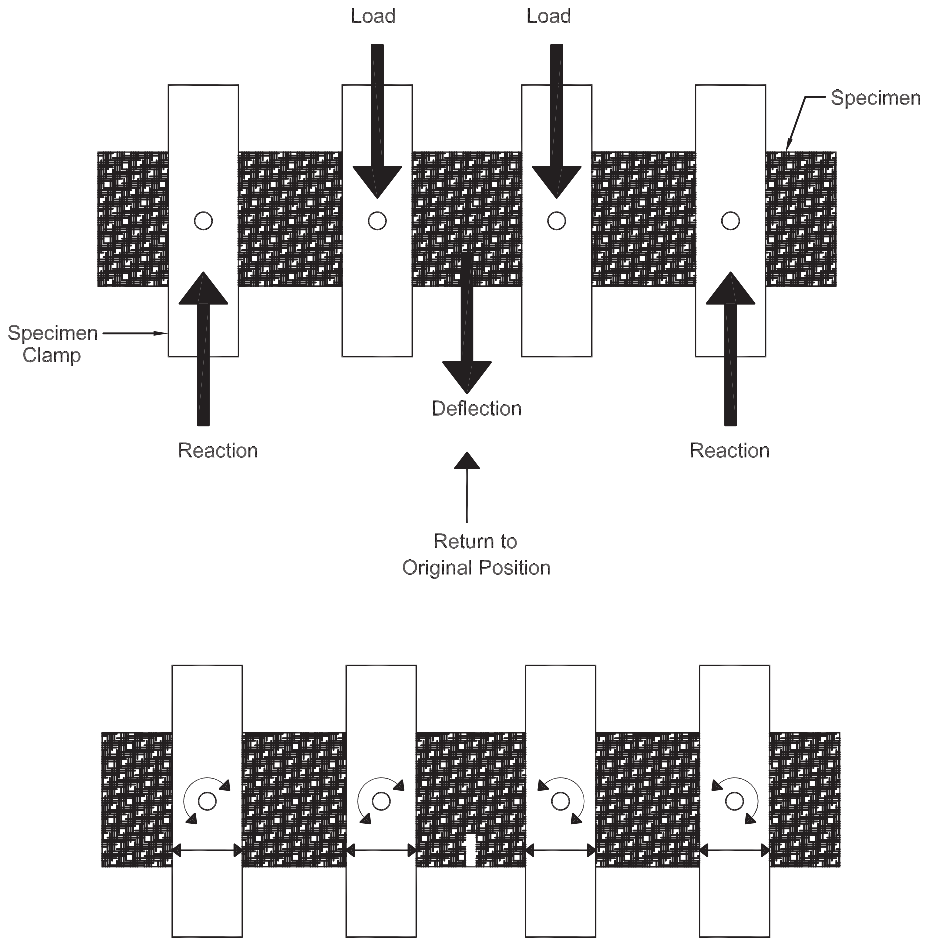
Load Measurement and Control	Range:	0 to 5 kN
	Resolution:	2 N
	Accuracy:	5 N
Displacement Measurement and Control	Range:	0 to 5 mm
	Resolution:	2 µm
	Accuracy:	5 µm
Frequency Measurement and Control	Range:	5 to 10 Hz
	Resolution:	0.005 Hz
	Accuracy:	0.01 Hz
Temperature Measurement and Control	Range:	–10 to 25˚C
	Resolution:	0.25˚C
	Accuracy:	±0.5˚C

5.1.1. *Loading Device*—The test system shall include a closed-loop, computer controlled loading component which, during each load cycle in response to commands from the data processing and control component, adjusts and applies a load such that the specimen experiences a constant level of strain during each load cycle. The loading device shall be capable of (1) providing repeated sinusoidal loading at a frequency range of 5 to 10 Hz; (2) subjecting specimens to four-point bending with free rotation and horizontal translation at all load and reaction points; and (3) forcing the specimen back to its original position (i.e., zero deflection) at the end of each load pulse. (Figure 1 illustrates the loading conditions.)

5.1.2. *Environmental Chamber (Optional)*—The environmental chamber shall enclose the entire specimen and maintain the specimen at 20.0 ± 0.5°C during testing. An environmental chamber is not required if the temperature of the surrounding environment can be maintained within the specified limits.

5.1.3. *Control and Data Acquisition System*—During each load cycle, the control and data acquisition system shall be capable of measuring the deflection of the beam specimen, computing the strain in the specimen, and adjusting the load applied by the loading device such that the specimen experiences a constant level of strain on each load cycle. In addition, it shall be capable of recording load cycles, applied loads, and beam deflections and computing and recording the maximum tensile stress, maximum tensile strain, phase angle, stiffness, dissipated energy, and cumulative dissipated energy at load cycle intervals specified by the user.

5.2. *Miscellaneous Apparatus and Materials*—A suitable saw for cutting the beams and a mechanism for setting proper clamp spacing. For loading devices that require a glued nut for deformation measurement, a screw, nut (suggested size M 8 by 1) and block assembly for referencing the linear variable differential transducer (LVDT) to the neutral axis of the specimen, and epoxy for attaching the nut to the specimen are also needed.



Free Translation and Rotation

Figure 1—Load and Freedom Characteristics of Fatigue Test Apparatus

6. HAZARDS

6.1. Observe standard laboratory safety precautions when preparing and testing HMA specimens.

7. SAMPLING AND SPECIMEN PREPARATION

7.1. *Laboratory-Mixed and Compacted Specimens*—Sample asphalt binder in accordance with T 40 and sample aggregate in accordance with T 2. Prepare three replicate hot mix asphalt beam specimens, from slab(s) or beam(s) compacted in accordance with PP 33 or ASTM D 3202.

Note 1—The type of compaction device may influence the test results. It is recommended to cut beams from a large slab compacted by a vibratory roller.

Note 2—Normally, test specimens are compacted using a standard compactive effort. However, the standard compactive effort may not reproduce the air voids of roadway specimens measured according to T 269. If specimens are to be compacted to a target air void content, the compactive effort to be used should be determined experimentally.

7.2. *Plant-Mixed, Laboratory-Compacted Specimens*—Obtain HMA samples in accordance with T 168. Prepare three replicate hot mix asphalt beam specimens, from slab(s) or beam(s) compacted in accordance with PP 3 or ASTM D 3202. (See Notes 1 and 2.)

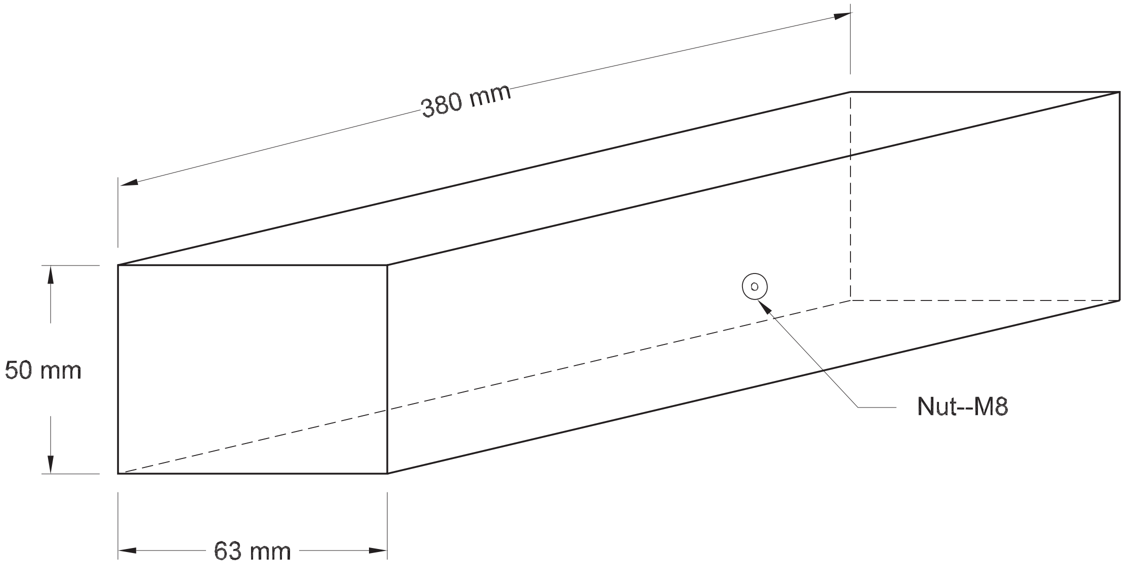
7.3. *Roadway Specimens*—Obtain compacted HMA samples from the roadway in accordance with ASTM D 5361.

7.4. Saw at least 6 mm from both sides of each test specimen to provide parallel (saw-cut) surfaces to eliminate high air void sections on the specimen surface. For loading devices that require gluing a nut for deformation measurement, these cut surfaces provide smooth surfaces for mounting the measurement gauges. The final required dimensions, after sawing, of the specimens are 380 ± 6 mm in length, 50 ± 6 mm in height, and 63 ± 6 mm in width.

8. PROCEDURE

8.1. *Specimen Measurement*—Measure the height and width of the specimen to the nearest 0.01 mm at three different points along the middle 100 mm of the specimen length in accordance with applicable sections of ASTM D 3549. Determine the average of the three measurements for each dimension and record the averages to the nearest 0.1 mm.

8.2. *Epoxying Nut to Neutral Axis of Specimen*—Locate the center of a specimen side. Apply epoxy in a circle around this center point and place the nut on the epoxy such that the center of the nut is over the center point. Avoid applying epoxy such that it fills the center of the nut. Allow the epoxy to cure before moving the specimen. (Figure 2 illustrates a nut epoxied to the neutral axis of the specimen.)



Note: Not to scale.

Figure 2—Nut Epoxied to the Neutral Axis

8.3. Place the specimen in an environment which is at 20.0 ± 0.5°C for 2 hours to ensure the specimen is at the test temperature prior to beginning the test.

8.4. Open the clamps and slide the specimen into position (Figures 3, 4, and 5). Use the jig to ensure proper horizontal spacing of the clamps, 119 mm center-to-center. When the specimen and clamps are in the proper positions, close the outside clamps by applying sufficient pressure to hold the specimen in place. Next, close the inside clamps by applying sufficient pressure to hold the specimen in place.

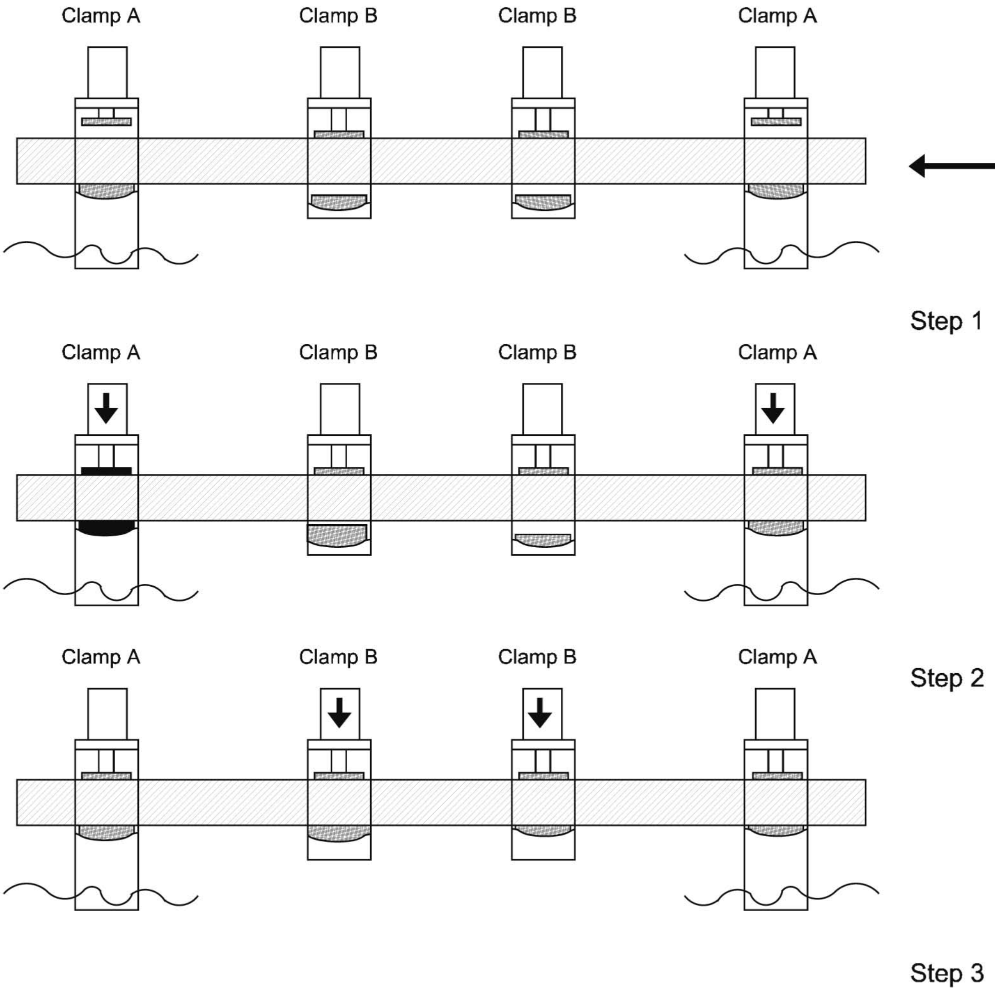


Figure 3—Specimen Clamping Procedure

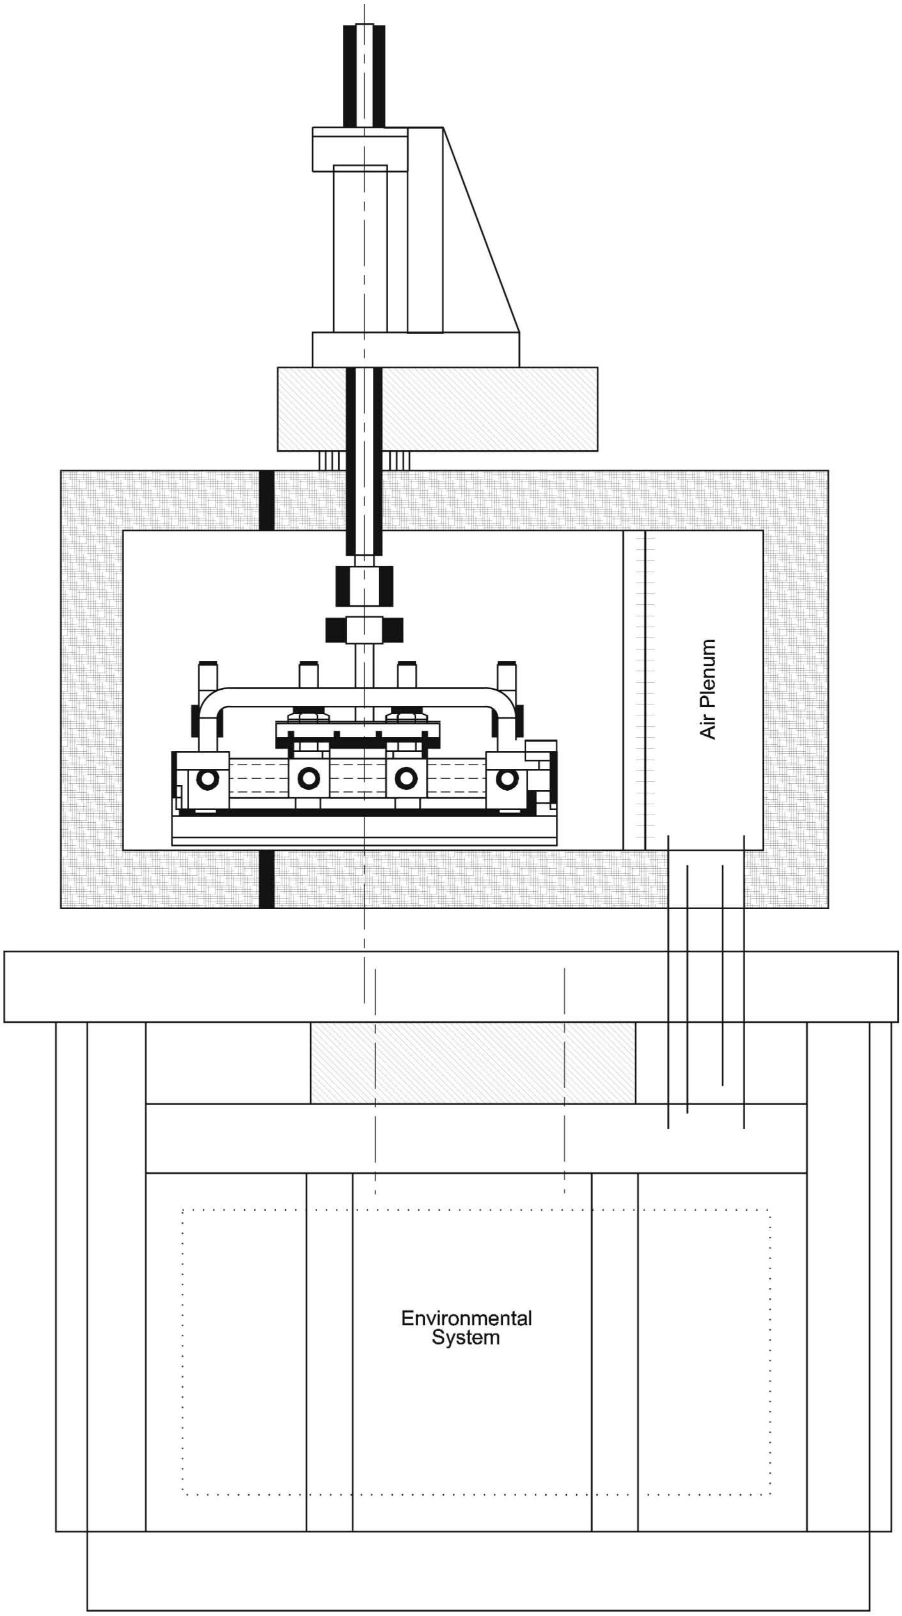

Figure 4—Schematic of Flexural Beam Fatigue Test Apparatus, Side View

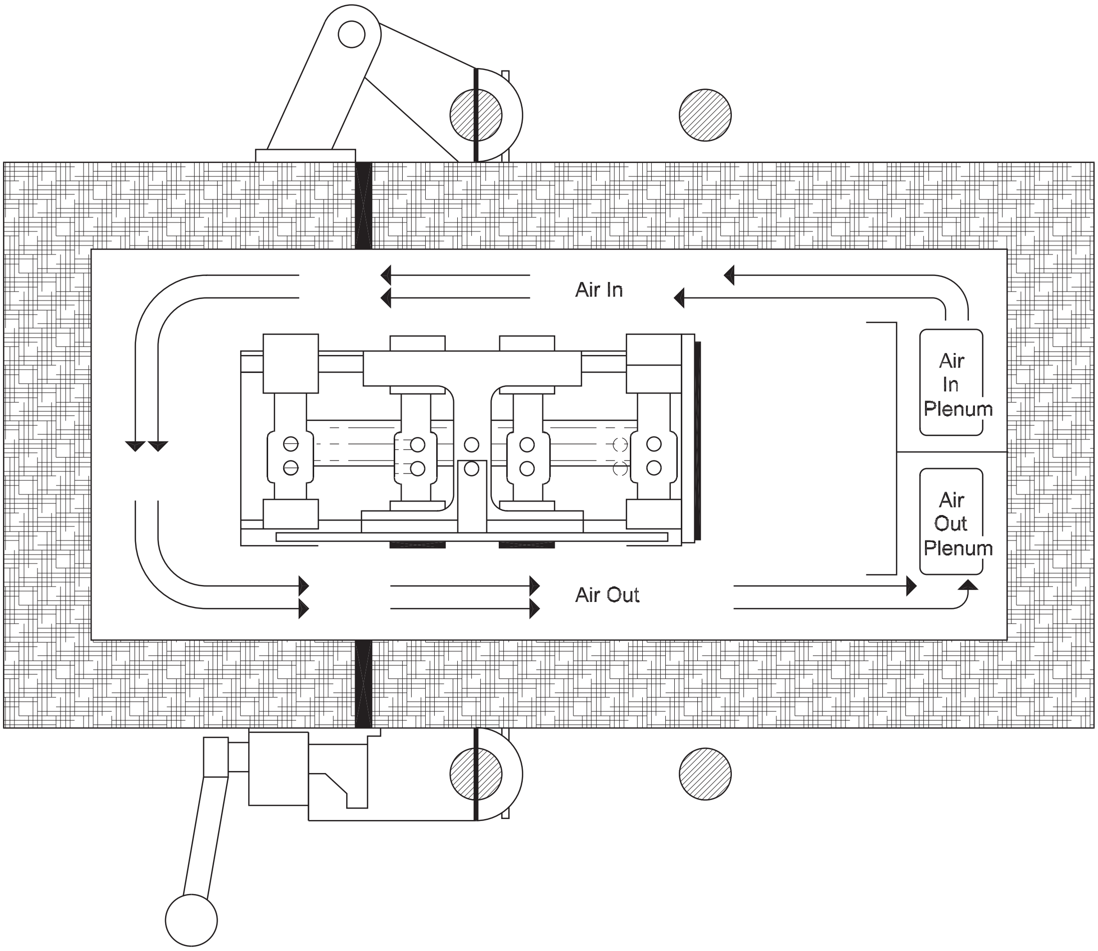

Figure 5—Schematic of Flexural Beam Fatigue Test Apparatus, Top View

8.5. Attach the LVDT block to the specimen by screwing the screw into the nut epoxied on the specimen. (Figure 4 illustrates the connection of the screw/nut/block assembly and the LVDT such that beam deflections at the neutral axis will be measured.) Clamp the LVDT into position such that the LVDT probe rests on top of the block and the LVDT is reading close to zero.

8.6. Select the desired initial strain (250 to 750 microstrain) and loading frequency, and the load cycle intervals at which test results are recorded and computed and enter them into the recording and control component's test program. Set the loading frequency within a range of 5 to 10 Hz.

Note 3—Selection of load cycle intervals at which test results are computed and recorded may be limited by the amount of memory available for storing data.

8.7. Apply 50 load cycles at a constant strain of 250 to 750 microstrain. Determine the specimen stiffness at the 50th load cycle. This stiffness is an estimate of the initial stiffness, which is used as a reference for determining specimen failure.

8.8. Select a deflection level (strain level) such that the specimen will undergo a minimum of 10,000 load cycles before its stiffness is reduced to 50 percent or less of the initial stiffness. A stiffness reduction of 50 percent or more represents specimen failure. A minimum of 10,000 load cycles ensures that the specimen does not decrease in stiffness too rapidly.

8.9. After selecting the appropriate test parameters, begin the test. Activate the recording and control components so that the test results at the selected load cycle intervals are monitored and recorded, ensuring that the test system is operating properly. When the specimen has experienced greater than 50 percent reduction in stiffness, terminate the test.

9. CALCULATIONS

9.1. Perform the following calculations at the operator-specified load cycle intervals:

9.1.1. *Maximum Tensile Stress (Pa)*:

$$\sigma_t = (0.357P)/(bh^2) \tag{1}$$

where:
P = load applied by actuator, in newtons;
b = average specimen width, in meters; and
h = average specimen height, in meters.

9.1.2. *Maximum Tensile Strain (m/m)*:

$$\in_t = (12\delta\, h)/(3L^2 - 4a^2) \tag{2}$$

where:
δ = maximum deflection at center of beam, in m;
a = space between inside clamps, 0.357/3 m, (0.119 m); and
L = length of beam between outside clamps, 0.357 m.

9.1.3. *Flexural Stiffness (Pa)*:

$$S = \sigma_t / \in_t \tag{3}$$

9.1.4. *Phase Angle* (deg):

$$\varphi = 360 fs \tag{4}$$

where:
f = load frequency, in Hz; and
s = time lag between $P_{\max}$ and $\delta_{\max}$, in seconds.

Note 4—When automated testing software is used in the recording and control component of the test system, φ is approximated by an algorithm contained in the automated testing software.

9.1.5. *Dissipated Energy (J/m^3) per cycle*:

$$D = \pi\sigma_t \in_t \sin(\varphi) \tag{5}$$

9.1.6. *Cumulative Dissipated Energy*, *J/m^3*:

$$\sum_{i=1}^{i=n} D_i \tag{6}$$

where:

D_i = D for the i^{th} load cycle.

Note 5—It may not be possible to calculate dissipated energy D for every load cycle due to memory limitations of the recording and control component. Therefore, dissipated energy may be plotted against load cycles for the particular load cycles at which data was collected (i.e., the load cycles selected by the operator) up to the load cycle of interest. The area under the curve represents the cumulative dissipated energy. See Figure 6 for a typical dissipated energy versus load cycle plot.

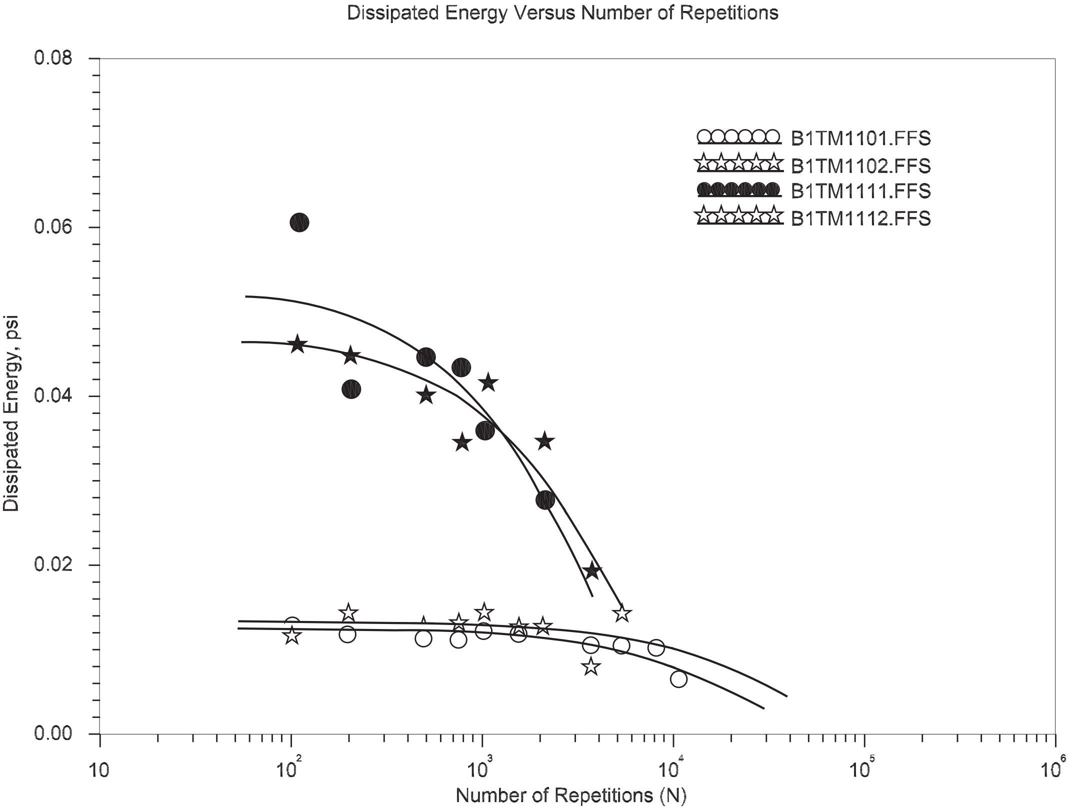

Figure 6—Dissipated Energy Versus Load Cycles (Repetitions)

9.1.7. *Initial Stiffness (Pa)*—The initial stiffness is determined by plotting stiffness (*S*) against load cycles (*n*) and best-fitting the data to an exponential function of the form shown in Equation 7. Figure 7 presents a typical plot of stiffness versus load cycles. The constant *A* represents the initial stiffness.

$$S = Ae^{bn} \quad (7)$$

where:

e = natural logarithm to the base e;
A = constant; and
b = constant.

9.1.8. *Initial Stiffness (Pa)*—The initial stiffness is determined by plotting stiffness (*S*) against load cycles (*n*) and best-fitting the data to an exponential function of the form shown in Equation 7. Figure 7 presents a typical plot of stiffness versus load cycles. The constant *A* represents the initial stiffness.

$$S = Ae^{bn} \quad (8)$$

where:

e = natural logarithm to the base e;
A = constant; and
b = constant.

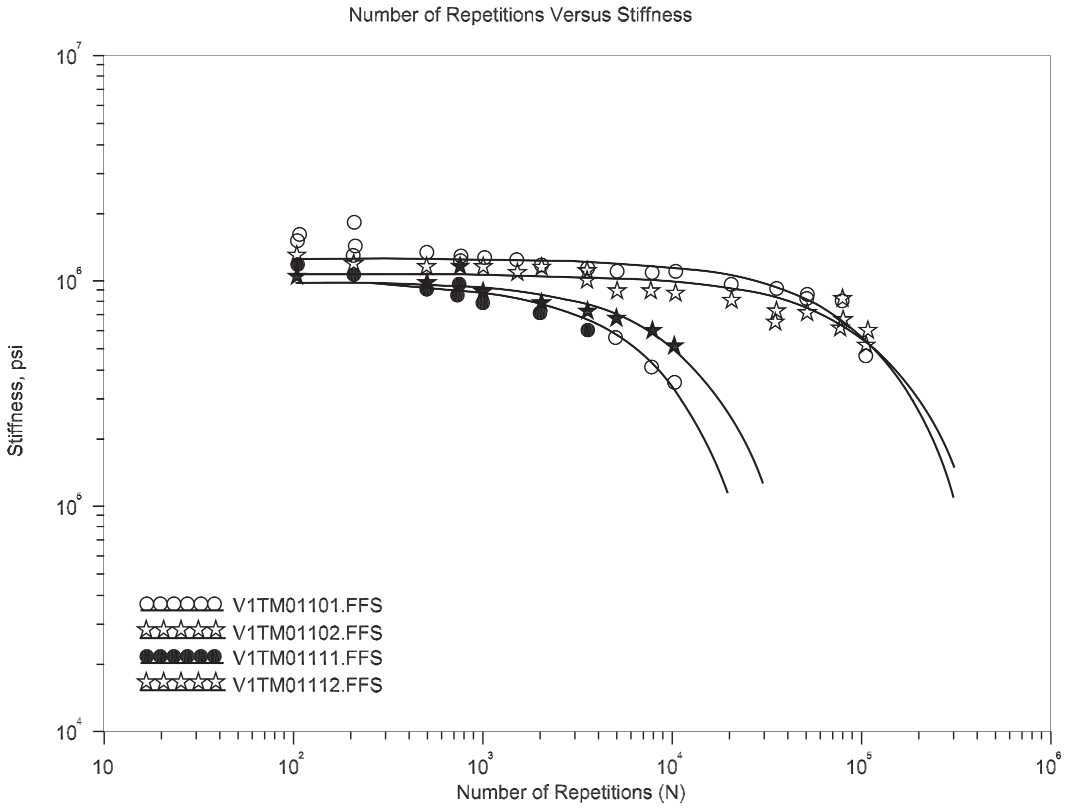

Figure 7—Stiffness Versus Load Cycles (Repetitions)

9.1.9. *Cycles to Failure*—Failure is defined as the point at which the specimen stiffness is reduced to 50 percent of the initial stiffness. The load cycle at which failure occurs is computed by solving for *n* from Equation 7, or simply:

$$n_{f,50} = \left[\ln\left(S_{f,50} / A\right)\right] / b \qquad (9)$$

where:

$S_{f,50}$ = stiffness, 50 percent of initial stiffness, in Pa; and
$S_{f,50}/A$ = 0.5, by definition.

9.1.10. *Cumulative Dissipated Energy to Failure (J/m^3)*:

$$\sum_{i=1}^{i=n_{f,50}} D_i \qquad (10)$$

Note 6—It is not necessary to measure the dissipated energy for every load cycle; however, the automated testing software used to control the fatigue test systematically determines the dissipated energy at specified load cycles during the test. The total dissipated energy to failure is summarized as part of the output.

10. REPORT

10.1. *Hot Mix Asphalt Description*—Report the binder type, binder content, aggregate gradation, and air void percentage.

10.2. *Specimen Dimensions*—Report the specimen length, average specimen height, and average specimen width in meters, to four significant figures.

Note 7—See E 29 for information on determination of significant figures in calculations.

10.3. Report the average test temperature to the nearest 0.2°C.

10.4. Report the test results listed in Table 2 for each load cycle interval selected by the operator to three significant figures.

Table 2—Test Results

Load Cycle	Applied Load	Beam Deflection	Tensile Stress	Tensile Strain	Flexural Stiffness	Phase Angle	Dissipated Energy	Cumulative Dissipated Energy
	N	m	Pa	m/m	Pa	degree	J/m^3	J/m^3

10.5. Report the initial flexural stiffness in pascals.

10.6. Report the cycles to failure.

10.7. Prepare a plot of stiffness versus load cycles as shown in Figure 7.

10.8. Prepare a plot of dissipated energy versus load cycles as shown in Figure 6.

11. PRECISION AND BIAS

11.1. *Precision*—The research required to develop precision values has not been conducted.

11.2. *Bias*—The research required to establish the bias of this method has not been conducted.

12. KEYWORDS

11.1.

12.1. Fatigue life; flexural bending; hot mix asphalt fatigue; hot mix asphalt flexural testing; hot mix asphalt tensile testing; hot mix asphalt stiffness; hot mix asphalt energy dissipation.

Standard Method of Test for

Determining the Creep Compliance and Strength of Hot Mix Asphalt (HMA) Using the Indirect Tensile Test Device

AASHTO Designation: T 322-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Creep Compliance and Strength of Hot Mix Asphalt (HMA) Using the Indirect Tensile Test Device

AASHTO Designation: T 322-07

1. SCOPE

1.1. This standard provides procedures for determining the tensile creep compliance at different loading times, tensile strength and Poisson's ratio of hot mix asphalt (HMA) using indirect loading techniques.

1.2. The procedures described in this standard provide the data required to conduct the thermal cracking analysis. These procedures apply to test specimens having a maximum aggregate size of 38 mm or less. Specimens shall be 38 to 50 mm high and 150 ± 9 mm in diameter.

1.3. *This test may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.3. *Other Document*:

- *The Superpave™ Mix Design Manual for New Construction and Overlays*

3. TERMINOLOGY

3.1. *Definitions*:

3.2. *creep*—the time-dependent part of strain resulting from stress.

3.3. *creep compliance*—the time-dependent strain divided by the applied stress.

3.4. *tensile strength*—the strength shown by a specimen subjected to tension, as distinct from torsion, compression, or shear.

3.5. *Poisson's ratio (ν)*—the absolute value of the ratio of transverse strain to the corresponding axial strain resulting from uniformly distributed axial stress below the proportional limit of the material.

4. SUMMARY OF METHOD

4.1. This standard describes the procedure for determining the tensile creep and tensile strength to be determined on the same specimen for thermal cracking analyses.

4.2. The tensile creep is determined by applying a static load of fixed magnitude along the diametral axis of a specimen. The horizontal and vertical deformations measured near the center of the specimen are used to calculate a tensile creep compliance as a function of time. Loads are selected to keep horizontal strains in the linear viscoelastic range (typically below a horizontal strain of 500×10^{-6} mm/mm) during the creep test. By measuring both horizontal and vertical deformations in regions where the stresses are relatively constant and away from the localized nonlinear effects induced by the steel loading strips, Poisson's ratio can be more accurately determined. Creep compliance is sensitive to Poisson's ratio measurements.

4.3. The tensile strength is determined immediately after determining the tensile creep or separately by applying a constant rate of vertical deformation (or ram movement) to failure.

5. SIGNIFICANCE AND USE

5.1. Tensile creep and tensile strength test data are required for Superpave mixtures to determine the master relaxation modulus curve and fracture parameters. This information is used to calculate the thermal cracking of HMA. The master relaxation modulus curve controls thermal crack development while the fracture parameter defines a mixture's resistance to fracture.

5.2. The values of creep compliance, tensile strength, and Poisson's ratio determined with this method can be used in linear viscoelastic analysis to calculate the low temperature thermal cracking potential of asphalt concrete.

5.3. Tensile creep data may be used to evaluate the relative quality of materials.

5.4. This procedure is applicable to newly prepared mixtures, reheated, and recompacted mixtures. Reheated and recompacted mixtures will have lower creep compliance values than newly prepared mixtures when measured under these specific loading conditions and temperatures.

5.5. This procedure is applicable for mixtures with a maximum aggregate size of 38 mm or less.

6. APPARATUS

6.1. *Indirect Tensile Test System*—The indirect tensile test system shall consist of an axial loading device, a load measuring device, specimen deformation measurement devices, an environmental chamber, and a control and data acquisition system.

6.1.1. *Axial Loading Device*—The loading device shall be capable of providing a fixed or constant load of 100 kN with a resolution of at least 20 N and constant rate of ram displacement of at least 12 mm/minute.

6.1.2. *Load Measuring Device*—The load measuring device shall consist of an electronic load cell, designed for placement between the loading platen and piston, with a sensitivity of 20 N, and a minimum capacity of 100 kN.

6.1.3. *Specimen Deformation Measurement Devices*—The specimen deformation measurement devices shall consist of four displacement transducers with a range of at least 25 mm, reducible to 0.25 mm through software, and a minimum resolution throughout the range of 0.10 μm.

6.1.4. *Environmental Chamber*—The environmental chamber shall be equipped with temperature conditioners and controls capable of generating test temperatures between –30 and +10°C inside the chamber and maintaining the desired test temperature to within ±0.5°C. The internal dimensions of the environmental chamber shall be sufficient to hold a minimum of three test specimens for a period of 12 hours prior to testing.

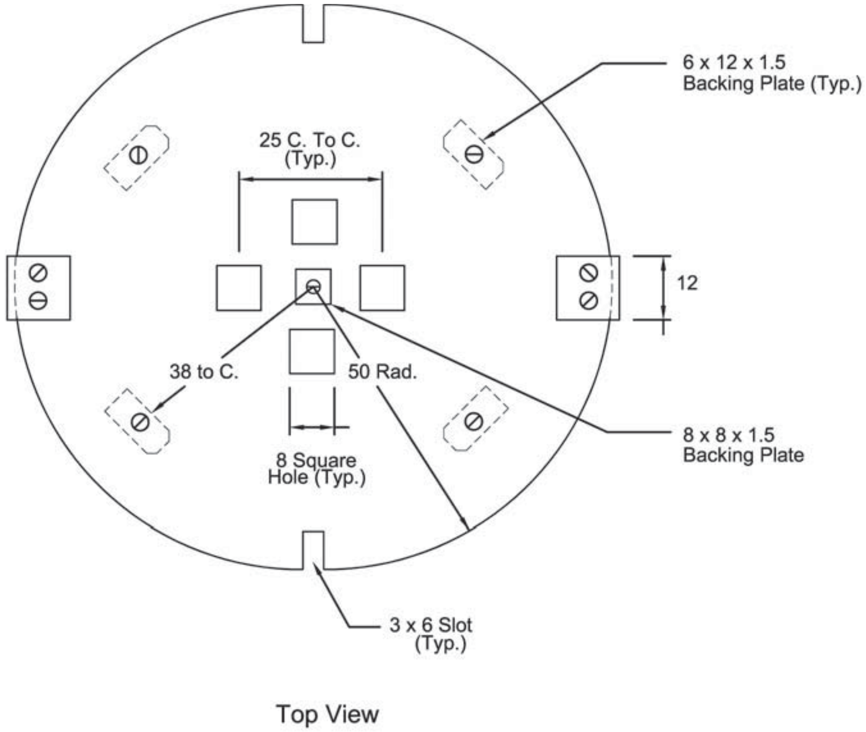
6.1.5. *Control and Data Acquisition System*—Specimen behavior in the creep compliance test is evaluated from time records of applied load and specimen deformation. These parameters shall be recorded on an analog to digital data acquisition device.

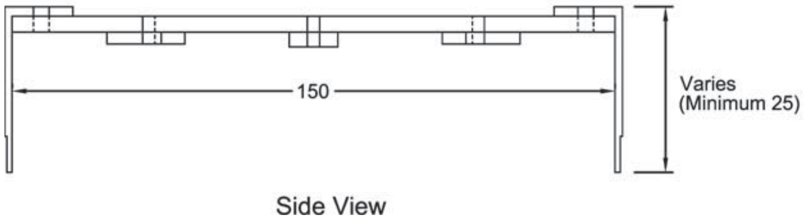
6.1.5.1. When determining the 100-second tensile creep for Superpave, digital data acquisition devices shall provide a sampling frequency of 10 Hz for the first 10 seconds and 1 Hz for the next 90 seconds. When determining the 1000-second tensile creep, digital data acquisition devices shall provide a sampling frequency of 10 Hz for the first 10 seconds, 1 Hz for the next 90 seconds, and 0.1 Hz for the rest of 900 seconds. When determining the tensile strength test, digital data acquisition devices shall provide a sampling frequency of 20 Hz through the entire test. A 16-bit A/D board is normally required to obtain the resolution needed when determining the tensile creep and the range needed when determining the tensile strength.

6.1.6. *Gauge Points*—Eight brass gauge points having a diameter of 8 mm and a height of 3.2 mm are required per specimen.

6.1.7. *Mounting Template*—A mounting template for placing and mounting the brass gauge points to each side of the test specimen (four per side) which have been used successfully are shown in Figures 1 and 2. An example of a template for use with 150-mm diameter specimens is shown in Figure 1. Other similar and comparable systems such as those used in T 320 can be used.

6.1.8. *Test Specimen Loading Frame*—The specimen load frame shall be as described in ASTM D 4123-82(95) and capable of delivering test loads coincident with the vertical diametral plane of the test specimen and with less than 20 N frictional resistance in guides and/or bearings. Often a smaller guide frame with special alignment capabilities is used in conjunction with the larger loading frame to accomplish this. The frame may be configured with two support columns or four support columns (Figure 2).





Notes:
1. All dimensions shown in millimeters unless otherwise noted.
2. Tolerances ±0.2 mm unless otherwise noted.
3. Not to scale.

Figure 1—150-mm Gauge Point Template

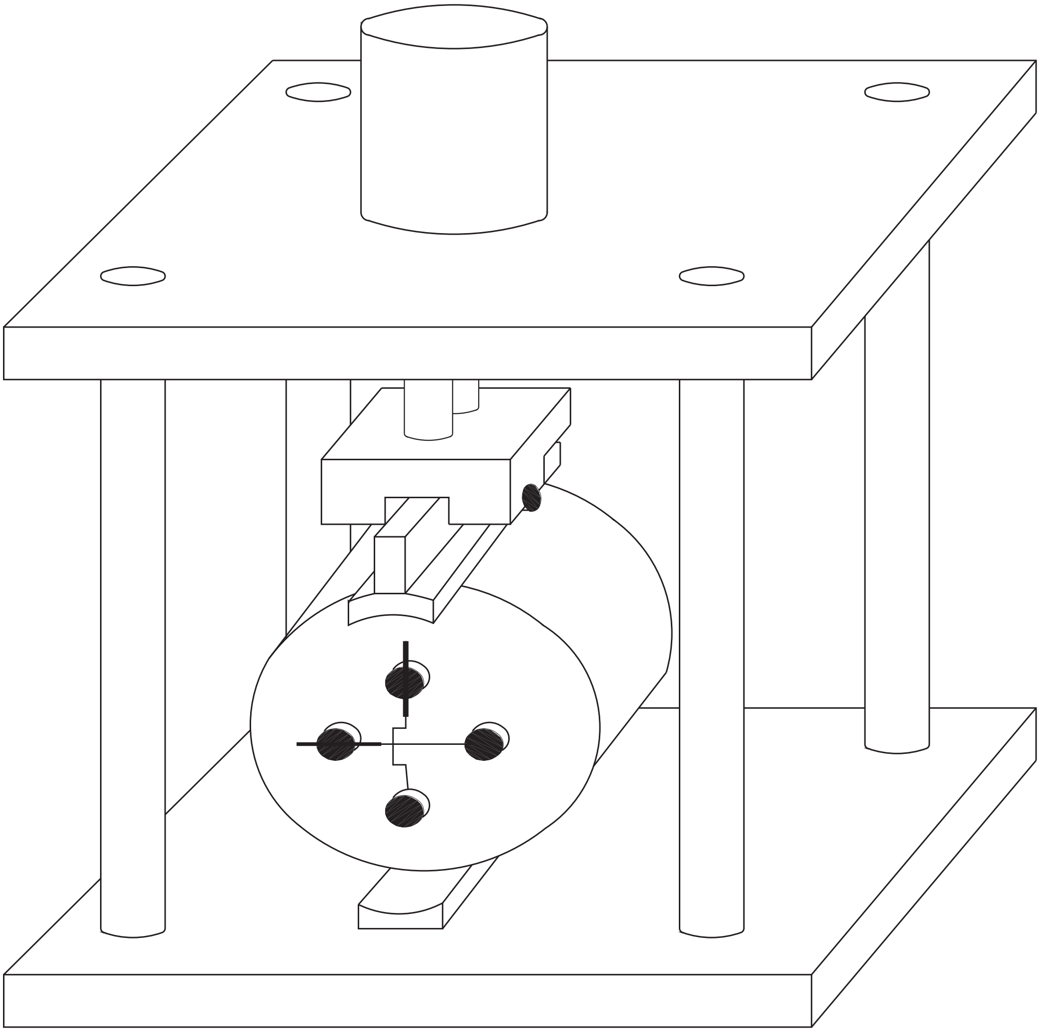


Figure 2—Specimen Loading Frame

7. HAZARDS

7.1. Observe standard laboratory safety precautions when preparing and testing HMA specimens.

8. STANDARDIZATION

8.1. Calibrate the testing system prior to initial use and at least once a year thereafter.

8.1.1. Calibrate the environmental control component to maintain the required temperature within the accuracy specified.

8.1.2. Calibrate all measurement components (such as load cells and displacement transducers) of the testing system.

8.1.3. If any of the verifications yield data that do not comply with the accuracy specified, correct the problem prior to proceeding with testing. Appropriate action may include correction of menu entries, maintenance on system components, calibration of system components (using an independent calibration agency, or service by the manufacturer, or in-house resources), or replacement of system components.

---

9. SAMPLING

9.1. *Laboratory Molded Specimens*—Prepare a minimum of three replicate laboratory molded specimens, in accordance with T 312 or PP 3. If PP 3 is used, use a suitable core drill to cut specimens from the sample after compaction.

9.2. *Roadway Specimens*—Obtain roadway specimens from the pavement in accordance with ASTM D 5361. Prepare cores with smooth and parallel surfaces that conform to the height and diameter requirements specified in Section 10.2. Prepare a minimum of three replicate cores.

---

10. SPECIMEN PREPARATION AND PRELIMINARY DETERMINATIONS

10.1. Saw at least 6 mm from both sides of each test specimen to provide smooth, parallel (saw-cut) surfaces for mounting the measurement gauges.

Note 1—Measurements taken on cut faces yield more consistent results, and gauge points can be attached with much greater bonding strength.

10.2. *Specimen Size*—Prepare specimens with a height of 38 to 50 mm and a diameter of 150 ± 9 mm.

10.3. *Determining Specimen Height and Diameter*—Determine and record the diameter and height (thickness) of each specimen in accordance with ASTM D 3549, to the nearest 1 mm.

10.4. *Determining the Bulk Specific Gravity*—Determine the specific gravity of each specimen in accordance with T 166, except that if the water absorbed by the specimen exceeds 2 percent, substitute a thin, adherent plastic wrap membrane that is water-resistant instead of the paraffin coating.

10.5. *Specimen Drying*—If specimens were immersed directly into the water, after determining the bulk specific gravity, allow each specimen to dry at room temperature to a constant mass.

10.6. *Mounting Displacement Tranducers*—Attach four brass gauge points with epoxy to each flat face of the specimen (four per face). On each flat face of the specimen, two gauge points shall be placed along the vertical and two along the horizontal axes with a center to center spacing of 38.0 ± 0.2 mm for a specimen diameter of 150 ± 9 mm. The placement and location of the gauge points on each face shall produce a mirror image of each other. Mount the displacement tranducers on the gauge points such that the transducer's center line is 6.4 mm above the specimen's surface. Figure 3 shows a system for mounting linear variable transducers that has been successfully used for IDT creep measurements at low temperature.

Notes: 1. All dimensions shown in millimeters unless otherwise noted.
2. Tolerances ±0.2 mm unless otherwise noted.
3. Not to scale.

Figure 3—Cross Section of LVDT Mounting System for 150-mm Specimen

11. TENSILE CREEP/STRENGTH TESTING (THERMAL CRACKING ANALYSIS)

11.1. Determine the tensile creep compliance of each of the three specimens at three measurements at 10°C intervals. The following test temperatures are recommended:

- For mixtures made using binder grades PG XX-34 or softer: −30, −20, and −10°C
- For mixtures made using binder grades PG XX-28 and PG XX-22, or mixtures for which binder grade is unknown: −20, −10, and 0°C

- For mixtures made using binder grades PG XX-16 or harder: −10, 0, and +10°C
- For mixtures subjected to severe age hardening, the test temperatures should be increased by 10°C

Note 2—The original Superpave mixture analysis procedures specified test temperatures of 0, –10, and –20°C.

11.2. Lower the temperature of the environmental chamber to the test temperature and, once the test temperature ±0.5°C is achieved, allow each specimen to remain at the test temperature from 3 ± 1 hours prior to testing. Under no circumstances shall the specimen be kept at 0°C or less for more than 24 hours.

11.3. Zero or rebalance the electronic measuring system and apply a static load of fixed magnitude (±2 percent) without impact to the specimen for 100 ± 2 seconds. If a complete analysis is required, a period of 1000 ± 20.5 seconds has been found suitable. Use a fixed load that produces a horizontal deformation of 0.00125 mm to 0.0190 mm for 150-mm diameter specimens. If either limit is violated, stop the test and allow a recovery time of 5 minutes before restarting with an adjusted load. Comply strictly with these limits to prevent both nonlinear response, characterized by exceeding the upper limit, and significant problems associated with noise and drift inherent in sensors, when violating the lower deformation limit.

11.4. After the creep tests have been completed at each temperature, determine the tensile strength by applying a load to the specimen at a rate of 12.5 mm of ram (vertical) movement per minute. Record the vertical and horizontal deformations on both ends of the specimen and the load until the load starts to decrease. The tensile strength should normally be determined at the middle temperature used for the creep tests.

Note 3—In some cases, it is acceptable to unload the specimen between the creep compliance and strength tests. This will facilitate control on certain testing machines.

12. CALCULATIONS

12.1. Calculate the air voids for each test specimen in accordance with T 269.

12.2. *Creep Compliance—Mathematical Model*:

12.2.1. The three reference specimens are analyzed simultaneously to reduce variability in determining Poisson's ratio and, therefore, creep compliance.

12.2.2. Obtain average thickness and diameter in mm and creep load in kN for the three replicates:

$$D_{avg} = \frac{\sum_{n=1}^{3} b_n}{3} \tag{1}$$

$$D_{avg} = \frac{\sum_{n=1}^{3} D_n}{3} \tag{2}$$

$$P_{avg} = \frac{\sum_{n=1}^{3} P_n}{3} \tag{3}$$

where:

Σ = sum of the three specimens, values for thickness, diameter, creep load, in kN;

b_{avg}, D_{avg}, P_{avg} = average thickness, diameter, and creep load of three replicate specimens; and

b_n, D_n, P_n = thickness, diameter, and creep load of specimen n (n = 1 to 3).

12.2.3. Compute normalized horizontal and vertical deformation arrays for each of the six specimen faces (three specimens, two faces per specimen).

$$\Delta X_{n,i,t} = \Delta X_{i,t} \times \frac{b_n}{b_{avg}} \times \frac{D_n}{D_{avg}} \times \frac{P_{avg}}{P_n} \tag{4}$$

$$\Delta Y_{n,i,t} = \Delta Y_{i,t} \times \frac{b_n}{b_{avg}} \times \frac{D_n}{D_{avg}} \times \frac{P_{avg}}{P_n} \tag{5}$$

where:

$\Delta X_{n,i,t}$ = normalized horizontal deformation for face i (i = 1 to 6) at time t (t = 0 to t_{final}, where t_{final} is the total creep time);

$\Delta Y_{n,i,t}$ = normalized vertical deformation for face i at time t;

$\Delta X_{i,t}$ = measured horizontal deformation for face i at time t; and

$\Delta Y_{i,t}$ = measured vertical deformation for face i at time t.

12.2.4. Obtain the average horizontal and vertical deformations $\Delta X_{a,i}$ and $\Delta Y_{a,i}$ at a time corresponding to one half the total creep test time for each of the six specimen faces. Thus, for a 100-second creep test, obtain the deformations corresponding to t = 50 seconds.

$$\Delta X_{a,i} = \Delta X_{n,i,t_{mid}} \tag{6}$$

$$\Delta Y_{a,i} = \Delta Y_{n,i,t_{mid}} \tag{7}$$

where:

$\Delta X_{a,i} + \Delta Y_{a,i}$ = average horizontal and vertical deformations for face i;

$\Delta X_{n,i,t_{mid}}$ = normalized horizontal deformation at a time corresponding to half the total creep test time for face i; and

$\Delta Y_{n,i,t_{mid}}$ = normalized vertical deformation at a time corresponding to half the total creep test time for face i.

12.2.5. Obtain the trimmed mean of the deflections ΔX_t and ΔY_t. This is accomplished by numerically ranking the six $\Delta X_{a,i}$ and $\Delta Y_{a,i}$ values and averaging the four middle values. Thus, the highest and lowest values of horizontal and vertical deformation are not included in the trimmed mean. Compute:

$$\Delta X_t = \frac{\sum_{j=2}^{5} \Delta X_{r,j}}{4} \tag{8}$$

$$\Delta Y_t = \frac{\sum_{j=2}^{5} \Delta Y_{r,j}}{4} \tag{9}$$

where:

$\Delta X_{r,j}$ = $\Delta X_{a,i}$ values sorted in ascending order;

$\Delta Y_{r,j}$ = $\Delta Y_{a,i}$ values sorted in ascending order;

ΔX_t = trimmed mean of horizontal deformations; and

ΔY_t = trimmed mean of vertical deformations.

12.2.6. Obtain the ratio of the horizontal to vertical deformations, X/Y, as follows:

$$\frac{X}{Y} = \frac{\Delta X_t}{\Delta Y_t} \tag{10}$$

12.2.7. Compute the trimmed mean, $\Delta X_{tm,t}$, of the six horizontal deformation arrays.

$$\Delta X_{tm,t} = \frac{\sum_{j=2}^{5} \Delta X_{r,j,t}}{4} \tag{11}$$

where:

$\Delta X_{r,j,t}$ = $\Delta X_{i,t}$ arrays sorted, where the $i = 6$ arrays are sorted according to the sorting order already established in Section 13.3.5 for $\Delta X_{r,j}$; and

$\Delta X_{tm,t}$ = Trimmed mean of the $\Delta X_{i,t}$ arrays.

12.2.8. Compute creep compliance, $D(t)$:

$$D(t) = \frac{\Delta X_{tm,t} \times D_{avg} \times b_{avg}}{P_{avg} \times GL} \times C_{cmpl} \tag{12}$$

where:

$D(t)$ = creep compliance at time t (kPa); and

GL = gauge length in meters (38×10^{-3} for 150-mm diameter specimens); and

$$C_{cmpl} = 0.6354 \times \left(\frac{X}{Y}\right)^{-1} - 0.332 \tag{13}$$

$$\left[0.704 - 0.213\left(\frac{b_{avg}}{D_{avg}}\right)\right] \le C_{cmpl} \le \left[1.566 - 0.195\left(\frac{b_{avg}}{D_{avg}}\right)\right]$$

12.2.9. Poisson's ratio, ν, may be computed as:

$$\nu = -0.10 + 1.480\left(\frac{X}{Y}\right)^2 - 0.778\left(\frac{b_{avg}}{D_{avg}}\right)^2\left(\frac{X}{Y}\right)^2 \tag{14}$$

where:

$0.05 \le \nu \le 0.50$

12.3. *Tensile Strength—Mathematical Model*:

12.3.1. Calculate tensile strength for each specimen, $S_{t,n}$, as:

$$S_{t,n} = \frac{2 \times P_{f,n}}{\pi \times b_n \times D_n} \tag{15}$$

where:

$P_{f,n}$ = maximum load observed for specimen, n;

$S_{t,n}$ = tensile strength of specimen, n.

12.3.2. Compute the average tensile strength:

$$S_t = \frac{\sum_{n=1}^{3} S_{t,n}}{3} \qquad (16)$$

where:

S_t = average tensile strength of mixture.

---

13. REPORT

13.1. *Report the following information*:

13.1.1. Bulk specific gravity of each specimen tested to the nearest 0.001;

13.1.2. Maximum specific gravity of the asphalt concrete mixture to the nearest 0.001;

13.1.3. Air voids of each specimen to the nearest 0.1 percent;

13.1.4. Height and diameter of all test specimens to the nearest millimeter;

13.1.5. Test temperature to the nearest 0.5°C, and for creep testing the load levels used during the test to the nearest 5 N;

13.1.6. Tensile creep compliance values $D(t)$; and

13.1.7. Tensile strength (σ_t) of the mixture to the nearest pascal as computed.

14. PRECISION AND BIAS

14.1. *Precision*—The research required to develop precision estimates has not been conducted.

14.2. *Bias*—The research required to establish the bias of this method has not been conducted.

15. KEYWORDS

15.1. Creep compliance; diametral creep compliance; linear variable differential transducer; tensile creep test; tensile failure test; tensile strength.

Standard Method of Test for

Hamburg Wheel-Track Testing of Compacted Hot Mix Asphalt (HMA)

AASHTO Designation: T 324-04 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Hamburg Wheel-Track Testing of Compacted Hot Mix Asphalt (HMA)

AASHTO Designation: T 324-04 (2008)

1. SCOPE

1.1. This test method describes a procedure for testing the rutting and moisture-susceptibility of hot mix asphalt (HMA) pavement samples in the Hamburg Wheel-Tracking Device.

1.2. The method describes the testing of submerged, compacted HMA in a reciprocating rolling-wheel device. This test provides information about the rate of permanent deformation from a moving, concentrated load. A laboratory compactor has been designed to prepare slab specimens. Also, the Superpave™ Gyratory Compactor (SGC) has been designed to compact specimens in the laboratory. Alternatively, field cores of large diameter, 255 mm (10 in.) or 300 mm (12 in.), or saw-cut slab specimens may be tested.

1.3. The test method is used to determine the premature failure susceptibility of HMA due to weakness in the aggregate structure, inadequate binder stiffness, or moisture damage. This test method measures the rut depth and number of passes to failure.

1.4. The potential for moisture damage effects are evaluated since the specimens are submerged in temperature-controlled water during loading.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 30, Mixture Conditioning of Hot Mix Asphalt (HMA)
- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens
- T 168, Sampling Bituminous Paving Mixtures
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 269, Percent Air Voids in Compacted Dense and Open Asphalt Mixtures
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

3. SIGNIFICANCE AND USE

3.1. This test measures the rutting and moisture susceptibility of an HMA specimen.

4. SUMMARY OF METHOD

4.1. A laboratory-compacted specimen of HMA, a saw-cut slab specimen, or a core taken from a compacted pavement is repetitively loaded using a reciprocating steel wheel. The specimen is submerged in a temperature-controlled water bath of 40 to 50ºC (104 to 122ºF) or a temperature specified for the binder being used. The deformation of the specimen, caused by the wheel loading, is measured.

4.2. The impression is plotted as a function of the number of wheel passes. An abrupt increase in the rate of deformation coincides with stripping of the asphalt binder from the aggregate in the HMA specimen.

5. APPARATUS

5.1. *Hamburg Wheel-Tracking Machine*—An electrically powered machine capable of moving a 203.2-mm (8-in.) diameter, 47-mm (1.85-in.) wide steel wheel over a test specimen. The load on the wheel is 705 ± 4.5 N (158 lb ± 1.0 lb). The wheel shall reciprocate over the specimen, with the position varying sinusoidally over time. The wheel shall make approximately 50 passes across the specimen per minute. The maximum speed of the wheel shall be approximately 0.305 m/s (1 ft/s) and will be reached at the midpoint of the specimen.

5.2. *Temperature Control System*—A water bath capable of controlling the temperature within ±1.0ºC (1.8ºF) over a range of 25 to 70ºC (77 to 158ºF). This bath shall have a mechanical circulating system to stabilize the temperature within the specimen tank.

5.3. *Impression Measurement System*—An LVDT device capable of measuring the depth of the impression of the wheel within 0.01 mm (0.0004 in.), over a minimum range of 0 to 20 mm (0.8 in.). The system shall be mounted to measure the depth of the impression at the midpoint of the wheel's path on the slab specimen. The impression shall be measured at least every 400 passes of the wheel. This system must be capable of measuring rut depth without stopping the wheel. This measurement must be referenced to the number of wheel passes.

5.4. *Wheel Pass Counter*—A non-contacting solenoid that counts each wheel pass over the specimen. The signal from this counter shall be coupled to the wheel impression measurement, allowing for the rut depth to be expressed as a function of the wheel passes.

5.5. *Specimen Mounting System*—A stainless steel tray that can be mounted rigidly to the machine. This mounting must restrict shifting of the specimen to within 0.5 mm (0.02 in.) during testing. The system shall suspend the specimen, allowing for free circulation of the water bath on all sides. The mounting system shall be designed to provide a minimum of 20 mm (0.8 in.) of free circulating water on all sides of the specimen.

5.6. *Balance*—Balance of 12,000 g capacity, accurate to 0.1 g.

5.7. *Ovens*—Ovens for heating aggregate and asphalt binders.

5.8. *Superpave Gyratory Compactor*—Superpave Gyratory Compactor (SGC) and molds conforming to T 312.

5.9. Bowls, spoon, spatula, etc.

6. SPECIMEN PREPARATION

6.1. *Number of Test Specimens*—There shall be two test specimens prepared for each test. Specimens may either be slab specimens or cylinders.

6.2. *Laboratory-Produced HMA*:

6.2.1. Mixture proportions are batched in accordance with the desired job mix formula.

6.2.2. The temperature to which the asphalt binder must be heated to achieve a viscosity of 170 ± 20 cSt shall be the mixing temperature. For modified asphalt binders, use the mixing temperature recommended by the binder manufacturer.

6.2.3. Dry-mix the aggregates and mineral admixture (if used) first; then add the correct percentage of asphalt binder. Mix the materials until all aggregates are thoroughly coated. (Wet-mix the aggregates if a lime slurry or other wet materials are used.)

6.2.4. Test samples shall be conditioned at the appropriate compaction temperature in accordance with the short-term conditioning procedure in R 30.

6.2.5. The temperature to which the asphalt binder must be heated to achieve a viscosity of 280 ± 30 cSt shall be the compaction temperature. For modified asphalt binders, use the compaction temperature recommended by the binder manufacturer.

6.2.6. *Laboratory Compaction of Specimens*—Specimens compacted in the laboratory shall be either compacted slab specimens or SGC specimens.

6.2.6.1. *Compacting Slab Specimens*—Material shall be compacted into slab specimens using a Linear Kneading Compactor (or equivalent) and shall be 320 mm (12.5 in.) long and 260 mm (10.25 in.) wide. A slab specimen thickness of 38 mm (1.5 in.) to 100 mm (4 in.) can be used. The slab specimen thickness shall be at least twice the nominal maximum aggregate size. Compacted slab specimen shall be cooled at normal room temperature on a clean, flat surface until the specimen is cool to the touch.

6.2.6.2. *Compacting SGC Specimens*—Material shall be compacted into specimens using an SGC according to T 312. A specimen thickness of 38 mm (1.5 in.) to 100 mm (4 in.) can be used. The specimen thickness shall be at least twice the nominal maximum aggregate size. Two 150-mm (6-in.) diameter specimens are needed. Compacted specimens shall be cooled at normal room temperature on a clean, flat surface until the specimen is cool to the touch.

6.3. *Field-Produced HMA—Loose Mix*:

6.3.1. Obtain a sample of HMA according to T 168.

6.3.2. *Laboratory Compaction of Specimens*—Specimens compacted in the laboratory shall be either compacted slab specimens or SGC specimens.

6.3.2.1. *Compacting Slab Specimens*—Material shall be compacted into slab specimens using a Linear Kneading Compactor (or equivalent) and shall be 320 mm (12.5 in.) long and 260 mm (10.25 in.) wide. A slab specimen thickness of 38 mm (1.5 in.) to 100 mm (4 in.) can be used. The slab specimen thickness shall be at least twice the nominal maximum aggregate size. Compacted slab specimens shall be cooled at normal room temperature on a clean, flat surface until the specimen is cool to the touch.

6.3.2.2. *Compacting SGC Specimens*—Material shall be compacted into specimens using an SGC according to T 312. A specimen thickness of 38 mm (1.5 in.) to 100 mm (4 in.) can be used. The specimen thickness shall be at least twice the nominal maximum aggregate size. Compacted specimens shall be cooled at normal room temperature on a clean, flat surface until the specimen is cool to the touch.

6.4. *Field-Produced HMA*—Field Compacted (Core/Slab Specimen):

6.4.1. *Cutting*—Field cores or field slab specimens shall consist of wet saw-cut compacted specimens taken from HMA pavements. Field cores shall be 250 mm (10 in.) in diameter. Field slab specimens shall be wet saw-cut to approximately 260 mm (10.25 in.) wide and 320 mm (12.5 in.) long. A slab specimen thickness of 38 mm (1.5 in.) to 100 mm (4 in.) may be used. The height of a field core or field slab specimen is typically 38 mm (1.5 in.), but may be adjusted to fit the specimen mounting system by wet saw-cutting.

Note 1—Care should be taken to load the sample so it is level to the surface of the mold. The sample must be trimmed if it is too tall or shimmed up if it is too short (support with plaster if needed). The down pressure from the wheel is calibrated to be 705 N (158 lb) at the center, level to the top of the mold position. Even a small change in elevation will change the down pressure significantly.

7. DETERMINING AIR VOID CONTENT

7.1. Determine the bulk specific gravity of the specimens in accordance with T 166.

7.2. Determine the maximum specific gravity of the mixture in accordance with T 209.

7.3. Determine the air void content of the specimens in accordance with T 269. It is recommended, for laboratory-compacted specimens, that the target air void content be 7.0 ± 2.0 percent. Field specimens may be tested at the air void content at which they are obtained.

8. PROCEDURE

8.1. *Specimen Mounting*—Use plaster of paris to rigidly mount the specimen in the mounting trays. The plaster shall be mixed at approximately a 1:1 ratio of plaster to water. Pour the plaster to a height equal to that of the specimen so that the air space between the specimen and the tray is filled. The plaster layer underneath the specimen shall not exceed 2 mm (0.08 in.). Allow the plaster at least 1 hour to set. If other mounting material is used, it should be able to withstand 890 N (200 lb) of load without cracking.

8.2. *Selecting the Test Temperature*—The test temperature shall be selected based upon the applicable specifications.

8.3. Be sure the drain valve(s) is closed. Fill the wheel-tracking device with hot water until the float device floats to a horizontal position. The water temperature may vary and should be adjusted if necessary.

8.4. When the water has reached the test temperature for 30 minutes, lower the wheels onto the specimens. Ensure that the micro-control unit's LVDT readout reads between 10 mm (0.4 in.) and 18 mm (0.7 in.). To adjust the LVDT height, loosen the two screws on the LVDT mount, and slide the LVDT up or down to the desired height. Tighten the screws.

8.5. Start the test.

8.6. The wheel-tracking device shall shut off when 20 000 passes have occurred. The device will also shut off if the average LVDT displacement (read from the micro-control unit, not the screen) is 40.90 mm (1.6 in.) or greater for an individual specimen. Note that the screen readout subtracts the initial LVDT reading from the total displacement.

8.7. Turn off the machine and the main power supply. To drain the baths, open the valve(s) beneath the tanks. Raise the wheels and remove the rutted specimens and the spacers.

8.8. Clean the water baths, heating coils, wheels, and temperature probe with water and scouring pads or as per the manufacturer's recommendations. Use a wet-dry vacuum to remove particles that have settled to the bottom of the baths. Clean the filter element and spacers after every test.

8.9. Turn the steel wheels after each test so the same section of the steel wheel surface is not in contact with the test specimen from test to test. This rotation will provide for even wear over the entire wheel. The test should run with a smooth movement across the test specimen.

9. CALCULATIONS

9.1. Plot the rut depth versus number of passes for each test. A typical plot of the output produced by the Hamburg Wheel-Tracking Device is shown in Figure 1. From this plot, obtain the following values:

Slope and intercept of the first steady-state portion of the curve.

Slope and intercept of the second steady-state portion of the curve.

9.2. Calculate the following test parameters:

All of the test parameters below are expressed in "Passes."

$$\text{Stripping Inflection Point (SIP)} = \frac{\text{Intercept (second portion)} - \text{Intercept (first portion)}}{\text{Slope (first portion)} - \text{Slope (second portion)}} \qquad (1)$$

where:

Failure Rut Depth is the specified maximum allowable rut depth for the test.

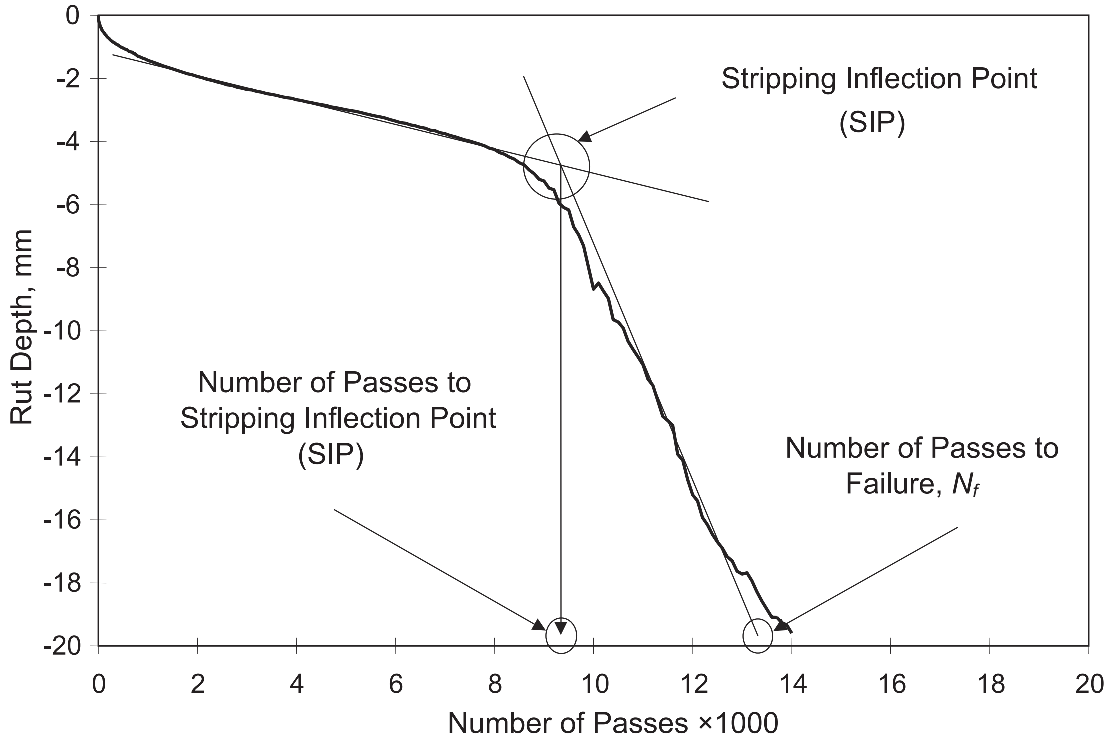

Figure 1—Hamburg Curve with Test Parameters

10. REPORT

10.1. *The report shall include the following parameters*:

10.2. HMA Production (Field or Lab);

10.3. Compaction method (slab or SGC specimen);

10.4. Number of passes at maximum impression;

10.5. Maximum impression;

10.6. Test temperature;

10.7. Specimen(s) air voids;

10.8. Type and amount of anti-stripping additive used;

10.9. Creep slope;

10.10. Strip slope; and

10.11. Stripping inflection point.

11. PRECISION AND BIAS

11.1. Work is under way to develop precision and bias statements for this standard.

12. KEYWORDS

12.1. Compacted hot mix asphalt; moisture-susceptibility; rutting; wheel-track testing.

APPENDIXES

(Nonmandatory Information)

X1. MAINTENANCE

X1.1. All eight of the grease fittings shall be greased with fresh grease every 20 tests (not to exceed 2 months) per the manufacturer's recommendations.

X2. CALIBRATION/EQUIPMENT VERIFICATION

X2.1. Verify that the water bath temperature is within ±1.0ºC (1.8ºF) of the temperature readout on the micro-control unit every 6 months.

X2.2. Verify that the LVDT height is within ±0.05 mm (0.002 in.) between the three (10, 20, and 30 mm) (0.4. 0.8, and 1.2 in.) calibration blocks.

X2.3. Verify that the load on the wheel, in the middle of the stroke on the sample, at the correct level elevation, to be 705 ± 4.5 N (158 ±1.0 lb). A calibrated load cell, accurate to 0.4 N (0.1 lb) is sufficient for this check.

X2.4. Verify that the steel wheel is reciprocating back and forth on the test sample at 50 ± 5 passes per minute.

Standard Method of Test for

Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

AASHTO Designation: T 329-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Moisture Content of Hot Mix Asphalt (HMA) by Oven Method

AASHTO Designation: T 329-08

1. SCOPE

1.1. This method is intended for the determination of moisture content of hot mix asphalt (HMA) by drying in an oven.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- R 47, Reducing Samples of Hot Mix Asphalt (HMA) to Testing Size
- T 168, Sampling Bituminous Paving Mixtures

3. TERMINOLOGY

3.1. *constant mass*—shall be defined as the mass at which further drying does not alter the mass by more than 0.05 percent.

4. SUMMARY OF TEST METHOD

4.1. A test specimen of HMA is dried in a forced-air, ventilated, or convection oven to constant mass.

5. APPARATUS

5.1. *Balance or Scale*—2-kg (4.4-lb) capacity, readable to at least 0.1 g and conforming to the requirements of M 231.

5.2. *Forced-Air, Ventilated, or Convection Oven*—capable of maintaining the temperature surrounding the sample at 163 ± 14°C (325 ± 25°F).

5.3. *Sample Container*—the container in which the sample is dried shall be of sufficient size to contain the sample without danger of spilling and to allow the sample to be evenly distributed in a manner that will allow completion of the test in an expeditious manner.

6. SAMPLE

6.1. A sample of HMA shall be obtained in accordance with T 168.

6.2. The sample shall be reduced in size in accordance with R 47. The size of the test sample shall be a minimum of 1000 g.

7. PROCEDURE

7.1. Determine and record the mass of the sample container to the nearest 0.1 g.

7.2. Place the test sample in the sample container. Determine and record the temperature of the test sample. To facilitate drying, evenly distribute the test sample in the sample container.

7.3. Determine and record the total mass of the sample container and moist test sample to the nearest 0.1 g.

7.4. Preheat the oven to drying temperature. The drying temperature shall fall within the Job Mix Formula mixing temperature range. If a mixing temperature range is not supplied, a temperature of 163 ± 14 °C (325 ± 25°F) will be used.

Note 1—For repeatability between operators and or laboratories the difference between drying temperatures for samples should not exceed 9°C (15°F).

7.5. Calculate the mass of the initial, moist test sample by subtracting the mass of the sample container determined in Section 7.1 from the total mass of the sample container and moist test sample determined in Section 7.3.

7.6. The sample shall initially be dried for 90 ± 5 minutes and its mass determined. Then dry the sample at 30 ± 5-minute intervals until a constant mass is reached.

Note 2—The moisture content of test samples and the number of test samples in the oven will affect the rate of drying at any given time. Placing wet test samples in the oven with nearly dry test samples could affect the drying process.

7.7. Cool the sample container and test sample to approximately the same temperature as determined in Section 7.2.

7.8. Determine and record the total mass of the sample container and dry test sample to the nearest 0.1 g.

Note 3—Do not attempt to remove the test sample from the sample container for the purposes of determining the dry mass of the test sample.

7.9. Calculate the mass of the final, dry test sample by subtracting the mass of the sample container determined in Section 7.1 from the total mass of the sample container, and dry test sample determined in Section 7.7.

8. CALCULATIONS

8.1. *Calculate moisture content as follows*:

$$\text{Moisture Content,\%} = \frac{M_i - M_f}{M_f} \times 100 \qquad (1)$$

where:

M_i = mass of the initial, moist test sample, g; and

M_f = mass of the final, dry test sample, g.

Example: M_i = 1134.9 g

M_f = 1127.3 g

$$\text{Moisture Content,\%} = \frac{1134.9\text{ g} - 1127.3\text{ g}}{1134.9\text{ g}} \times 100 = 0.67\%$$

9. REPORT

9.1. Report the moisture content to the nearest 0.01 percent.

10. KEYWORDS

10.1. Hot mix asphalt; moisture content; oven-drying.

Standard Method of Test for

Bulk Specific Gravity and Density of Compacted Hot Mix Asphalt (HMA) Using Automatic Vacuum Sealing Method

AASHTO Designation: T 331-10[1]
ASTM Designation: D 6752-03$^{\epsilon 1}$

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bulk Specific Gravity and Density of Compacted Hot Mix Asphalt (HMA) Using Automatic Vacuum Sealing Method

AASHTO Designation: T 331-10[1]

ASTM Designation: D 6752-03$^{\epsilon 1}$

1. SCOPE

1.1 This method covers the determination of bulk specific gravity of specimens of compacted hot mix asphalt (HMA) mixtures.

1.2 This method should be used with samples that contain open or interconnecting voids and/or absorb more than 2.0 percent of water by volume, as determined by T 166. An agency may specify this method as an alternative to T 275.

1.3 The bulk specific gravity of the compacted HMA may be used in calculating the unit mass of the mixture.

1.4 The values stated in SI units are to be regarded as the standard.

1.5 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

---

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 *bulk specific gravity (of solids)*—the ratio of the mass in air of a unit volume of a permeable material (including both permeable and impermeable voids normal to the material) at a stated temperature to the mass in air of equal density of an equal volume of gas-free distilled water at a stated temperature.

The form of the expression shall be:

$$\text{Bulk specific at gravity } x/y\,^{\circ}\text{C} \qquad (1)$$

where:

x = temperature of the material; and

y = temperature of the water.

3.1.2 *constant mass*—shall be defined as the mass at which further drying does not alter the mass by more than 0.05 percent when the mass is determined at 2-h intervals.

---

4. TEST SPECIMENS

4.1 Test specimens may be either laboratory-compacted HMA mixtures or sampled from HMA pavements. The mixtures may be surface or wearing course, binder or leveling course, or hot mix base.

4.2 *Size of Specimens*—Specimens shall conform to the requirements of T 166.

4.3 Specimens shall be taken from pavements with a core drill, diamond or carborundum saw, or by other suitable means.

4.4 Care shall be taken to avoid distortion, bending, or cracking of specimens during and after the removal from the pavement or mold. Specimens shall be stored in a safe, cool place.

4.5 Specimens shall be free from foreign materials such as seal coat, tack coat, foundation material, soil, paper, or foil.

4.6 If desired, specimens may be separated from other pavement layers by sawing or other suitable means. Care should be exercised to ensure sawing does not damage specimens. Jagged edges or sharp aggregates may puncture the plastic bag. Specimen ends or planar edges may require sawing if the bag does not conform to the specimen in a uniform manner.

---

5. APPARATUS

5.1 *Bag Cutter*—A knife, scissors, or other types of clipping devices may be used to quickly open bags.

5.2 *Oven*—The oven shall be capable of maintaining the appropriate temperature for drying specimens to a constant mass.

5.3 *Weighing Device*—The weighing device shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231. The weighing device shall be equipped with a suitable suspension apparatus and holder to determine the mass of the specimen while suspended from the center of the scale pan of the weighing device.

5.4 *Plastic Bags*—The two most commonly used sizes of bags are designated as small and large size bags. The small bags shall have a minimum opening of 235 mm (9.25 in.) and a maximum opening of 260 mm (10.25 in.) with a mass of less than 35 g. The large bags shall have a minimum opening of 375 mm (14.75 in.) and a maximum opening of 394 mm (15.5 in.) with a mass of 35 g or more. The bags shall be made of a plastic material that will not adhere to asphalt film, puncture resistant, capable of withstanding sample temperatures of up to 70ºC (158ºF), impermeable to water, and contain no air channels for evacuation of air from the bag. The bags shall have a minimum thickness of 0.100 mm (0.004 in.) and a maximum thickness of 0.152 mm (0.006 in.). The manufacturer shall provide the apparent specific gravity of the bags (usually located in the operator's manual). See the manufacturer's recommendations to ensure proper handling of bags.

5.5 *Specimen Sliding Plates*—Level and smooth-sided planar filler plates shall be inserted into the chamber to keep the samples of various heights level with the seal bar while being sealed. The plates shall be removable and of the appropriate dimensions to easily fit into the vacuum chamber. A smooth-sided specimen supporting plate shall easily slide on top of the smooth-sided plates. The opposite side of the smooth-sided specimen supporting plate shall have a cushioning membrane to help prevent tears in the plastic bag. The plate shall be large enough to fully support the specimen but small enough to allow movement during the sealing process.

5.6 *Suspension Apparatus*—The wire suspending the container shall be of the smallest practical size to minimize any possible effects of a variable immersed length. The suspension apparatus shall be constructed to enable the container to be immersed to a depth sufficient to cover it and the test sample during weighing.

5.7 *Thermometer*—ASTM 17°C (17°F), having a range of 19 to 27°C (66 to 80°F), graduated and conforming to ASTM E 1. An electronic temperature measuring device, such as a resistance thermometer or thermocouple, may be used.

5.8 *Vacuum Chamber*—The pump shall be capable of evacuating the sealed and enclosed chamber to 5 mm Hg in 60 s at sea level. The chamber shall be large enough to seal samples of 150 mm by 350 mm by 150 mm (6 in. by 14 in. by 6 in.) thick. A sealing bar of sufficient length to fully seal small and large size bags shall be located inside the chamber. The heat setting shall be set according to the manufacturer's recommendations and bag composition. The device shall automatically seal the plastic bag and exhaust air back into the chamber in a controlled manner to ensure proper conformance of the plastic bag to the specimen. The air exhaust and vacuum operation time should be calibrated to bring the chamber to atmospheric pressure in 80 to 120 s after completion of the vacuum operation. The vacuum system should be provided with a latch to control chamber door opening.

5.9 *Vacuum Gauge (Calibrated)*—The calibrated vacuum gauge shall be capable of being placed inside the automatic vacuum sealing device to verify vacuum performance and seal integrity. The gauge shall have a minimum range of 10 to 0 mm Hg (10 to 0 torr) and readable to 1 mm Hg (1 torr) increments as a minimum.

5.10 *Water Bath*—For immersing the specimen in water while suspended under the weighing device, equipped with an overflow outlet for maintaining a constant water level and thermostatically controlled so as to maintain the bath at 25 ± 1°C (77 ± 1.8°F). A heater and circulator may be attached. The circulator shall not be in use while recording sample masses. It is important that the water bath be of sufficient size to ensure sufficient space for the sample and the plastic bag suspension. A water bath with suggested minimum dimensions (length by width by depth) of 610 mm by 460 mm by 460 mm (24 in. by 18 in. by 18 in.) or a large cylindrical container has been found to work well for this test method.

Note 1—A cushioned holder located inside water bath for water displacement of the sample; should not have sharp edges. Holders without sufficient cushioning have been found to puncture the bags. A clip may be attached to the container to hold the bag underwater and to keep bag edges from touching water bath edges. Water baths at eye level may help prevent tears in bags and assist in ease of use.

6. PROCEDURE

6.1 *Initial Mass of Specimen in Air*—Dry the specimen to a constant mass at a temperature of 52 ± 3°C (125 ± 5°F), or vacuum-dry the specimen according to ASTM D 7227. Samples saturated with water shall initially be dried overnight and then the mass determined at 2-h drying intervals. Recently compacted laboratory samples, which have not been exposed to moisture, do not require drying. Cool the specimen to room temperature at 25 ± 5°C (77 ± 9°F), and record the initial dry mass as A. It is important that the sample contain less than 5 g of water before it is exposed to vacuum. At high vacuum, water will evaporate, potentially causing the bag around the sample to loosen due to trapped gas, thus resulting in a higher volume determination and a lower bulk specific gravity result.

Note 2—Bulk specific gravity determined by this method may be lower, and air voids higher, than the results obtained by T 166. The differences may be more pronounced for coarse and absorptive mixtures. Users of this test method are cautioned to evaluate any alteration in asphalt content or aggregate gradation for mix designs with a positive performance history. If this procedure will be used for control or assurance testing, users are cautioned to follow this procedure during the laboratory mix design.

Note 3—Laboratory-compacted specimens of 3000 to 6000 g may be considered at room temperature equilibrium after 2 h of cooling under a fan. The cooling time may be reduced for smaller specimens or if verified to have no significant differences in properties from those cooled to room temperature equilibrium.

Note 4—Some steps may be performed in conjunction with T 166.

6.2 *Sealing the Specimen*—Select an appropriately sized bag for the specimen. Specimens of 100 mm (4 in.) and 150 mm (6 in.) up to 50 mm (2 in.) in thickness are usually tested with the small bag. Specimens of 150 mm (6 in.) in diameter by 50 mm (2 in.) or greater in thickness will usually be tested with a large bag.

6.2.1 Set the heat sealing bar temperature according to the bag manufacturer’s recommendations.

6.2.2 Inspect the bag for holes and irregularities, record the bag mass. Place the bag inside the vacuum chamber on top of the specimen sliding plate.

6.2.3 Insert the specimen into the bag with the smoothest plane of the specimen on the bottom. This operation may be done inside the chamber while holding the bag open with one hand over the sliding plate and gently inserting the specimen with the other hand. There should be about 25 mm (1 in.) of slack between the presealed bag end and the specimen.

6.2.4 If needed, filler plates should be added or removed prior to inserting the specimen. Grab the unsealed end of the bag on each side, and gently pull and center it over the seal bar, overlapping the bag at least 25 mm (1 in.).

6.2.5 Ensure that there are no wrinkles in the bag along the seal bar just prior to closing the lid.

6.2.6 Close the lid, and engage the lid-retaining latch. The vacuum pump light will illuminate “red,” and the vacuum gauge on the exterior of the chamber will become active, or a digital reading will show the vacuum state. It is normal for the bag to expand or “puff up” during this process.

6.2.7 Once sealed, the “de-vac” valve will open, and air will enter the chamber, causing atmospheric pressure to collapse the bag around the specimen.

6.2.8 Disengage the lid-retaining latch, and carefully remove the sealed specimen from the chamber. Gently pull on the bag at any areas that appear loose. Loose areas indicate a poor seal and the process must then be restarted at Section 6.1 with a new bag and a new initial mass.

6.3 *Sealed Specimen Mass*—Calculate the mass of the sealed specimen in air by summing the masses recorded in Sections 6.1 and 6.2.2. Designate this mass as *B*.

6.4 *Mass of Sealed Specimen in Water*—Quickly weigh the sealed specimen in a water bath at 25 ± 1ºC (77 ± 1.8ºF). Fully submerge the specimen and bag to ensure no trapped air bubbles exist under the specimen. Ensure that the bag is completely underwater and that it is not touching the edges of the water bath. Designate this mass as *E*.

Note 5—The time between the lid opening after sealing and the time to placement of the specimen into the water bath should not exceed 1 min to reduce the potential for bag leaks.

6.5 *Check*—To ensure a tight seal in the bag, remove the sample from the water, and cut the bag open. Remove the sample from the bag, and determine its mass. Designate this mass as *C*. Compare this mass with initial dry mass determined in Section 6.1 as *A*. If *A* is more than 5 g from the mass of dry specimen *C*, the results from this method may not be accurate. The check passes if less than 0.08 percent is lost or no more than 0.04 percent is gained. A loss indicates sample material loss, and a gain indicates a possible bag leakage problem. Remove the bag, and restart the process at Section 6.1 if this check fails.

6.6 If the specimen may be needed for referee testing, oven-dry the specimen as described in Method C of T 166 or vacuum-dry it according to ASTM D 7227.

6.7 If the specimen will not be needed for referee testing, oven-dry the specimen as described in Method A of T 166, or vacuum-dry it according to ASTM D 7227.

7. CALCULATION

7.1 Calculate the bulk specific gravity of the specimen as follows. Round and report the value to the nearest 0.001.

$$G_{mb} = \frac{A}{\left[C + (B - A)\right] - E - \left[\frac{B - A}{F}\right]}$$

where:

G_{mb} = specimen bulk specific gravity;

A = initial mass of the dried specimen in air, g;

B = calculated mass of the dry, sealed specimen, g;

C = final mass of the specimen after removal from the sealed bag, g;

E = mass of the sealed specimen underwater, g; and

F = apparent specific gravity of the plastic sealing material at 25° C (77°F), provided by the manufacturer.

7.2 Calculate the density of the specimen as follows. Round and report the value to the nearest 1 kg/m³ (lb/ft³).

$\tilde{n} = G_{mb} (\tilde{a})$

where:

G_{mb} = bulk specific gravity of the specimen;
ñ = density of the specimen, kg/m^3 or lb/ft^3 (pcf); and
ã = density of water at 25ºC (77ºF), (997.0 kg/m^3, 0.997 g/cm^3, or 62.2 lb/ft^3, pcf).

8. VERIFICATION

8.1 *Vacuum System Verification*:

8.1.1 The vacuum settings of the device shall be verified once every 3 months, after repairs, and after shipment or relocation as a minimum.

8.1.2 Verification shall be performed with an absolute vacuum gauge capable of being placed inside the chamber and reading the vacuum setting of the sealing device.

8.1.3 Place the gauge inside the chamber and record the setting. The gauge should indicate a reading of 10 mm Hg (10 torr) or less. The unit should not be used if the gauge reading is above 10 mm Hg (10 torr).

8.2 *Plastic Bag Verification*:

8.2.1 The apparent specific gravity of the plastic bag provided by the manufacturer shall be verified periodically.

8.2.2 Compact a specimen of 4.75-mm (No. 4) nominal-maximum aggregate size HMA with a Marshall compactor or gyratory compactor (according to T 245 or T 312, respectively) to minimum dimensions of 100 mm (4 in.) in diameter by 60 mm (2.4 in.) thick. The sample should be compacted to produce air voids of 4.0 ± 1.0 percent.

8.2.3 Using three bags from the same size set of plastic bags and the compacted specimen from Section 8.2.2 follow Section 6, as appropriate; determine the bulk specific gravity of the compacted specimen for each individual bag.

8.2.4 Average the three bulk specific gravities (or densities) obtained with each bag.

8.2.5 Determine the bulk specific gravity of the same compacted specimen, by T 166.

8.2.6 The average bulk specific gravity (or density) calculated for the HMA specimen using the plastic bags shall be within ±0.020 g/cm^3 (20 kg/m^3) of the bulk specific gravity (or density) as determined by T 166 for the same HMA specimen. If the difference between T 166 and T 331 bulk specific gravities is outside of the required tolerance, dry the sample per the procedures in Section 6.1, and repeat the above verification test. Average the values for the first and second verification tests, and ensure that the difference is less than or equal to 0.02 g/cm^3. Contact the manufacturer if this verification test fails.

8.2.7 This section shall be repeated for each bag size.

9. PRECISION

9.1 Criteria for judging the acceptability of bulk specific gravity results obtained by this test method are given in Table 1:

Table 1—Acceptability of Bulk Specific Gravity[a]

Test and Type Index	Standard Deviation	Acceptable Range of Two Results
Single-Operator Precision	0.0124	0.035
Multilaboratory Precision	0.0135	0.038

[a] The precision estimates were obtained from *Bulk Specific Gravity Round-Robin Using the CoreLok*^{TM} *Vacuum Sealing Device* report. The FHWA pooled-fund study report number was FHWA-IF-02-044, NCAT Report No. 02-11.

9.2 The figures given in Column 2 are the standard deviations that have been found to be appropriate for the conditions of the test described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between results of two properly conducted tests.

---

[1] Similar, but not identical, to ASTM D 6752-03$^{\in 1}$.

Standard Method of Test for

Determining Rutting Susceptibility of Hot Mix Asphalt (HMA) Using the Asphalt Pavement Analyzer (APA)

AASHTO Designation: T 340-10

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Determining Rutting Susceptibility of Hot Mix Asphalt (HMA) Using the Asphalt Pavement Analyzer (APA)

AASHTO Designation: T 340-10

1. SCOPE

1.1. This method describes a procedure for testing the rutting susceptibility of hot mix asphalt (HMA) using the Asphalt Pavement Analyzer (APA).

1.2. Annex A1 contains procedures for calibration checks for several APA components and related equipment.

1.3. Appendix X1 presents specifications for, and discussion concerning, several options for APA testing parameters often employed by APA users.

1.4. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.5. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens
- T 168, Sampling Bituminous Paving Mixtures
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 269, Percent Air Voids in Compacted Dense and Open Asphalt Mixtures
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

2.2. *ASTM Standard*:

- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. APPARATUS

3.1. *APA*—A thermostatically controlled device designed to test the rutting susceptibility of HMA by applying repetitive linear loads to compacted test specimens through pressurized hoses via wheels.

3.1.1. The APA shall be thermostatically controlled to maintain the test temperature and conditioning chamber at any set point between 4 and 72°C (40 and 160°F) within 1°C (2°F).

3.1.2. The APA shall be capable of independently applying loads up to 578 N (130 lbf) to the wheels. The loads shall be calibrated to the specified test load by an external-force transducer.

3.1.3. The APA shall be capable of adjusting the pressure in the test hoses and maintaining up to 862 kPa (125 psi) in the test hoses.

3.1.4. The APA shall be capable of testing six cylindrical specimens.

3.1.5. The test molds shall be rectangular in shape, be composed of ultra-high molecular weight (UHMW) polyethylene, fit snugly within the testing position in the APA testing chamber, and contain two holes in which to insert the specimens. The dimensions of each hole shall be 150 ± 2.0 mm (5.91 ± 0.08 in.) in diameter by 75.0 ± 2.0 mm (2.95 ± 0.08 in.) tall.

3.1.6. The APA shall have a programmable master cycle counter that can be preset to the desired number of cycles for a test. The APA shall be capable of automatically stopping the test at the completion of the programmed number of cycles.

3.1.7. The test hoses shall be composed of a nylon tube with high-tensile textile cord reinforcement and a synthetic rubber cover. The nominal inside diameter of the hoses shall be 19.0 mm (0.75 in.); the nominal outside diameter of the hoses shall be 29.5 mm (1.16 in.). The maximum working pressure (WP) of the hoses shall be 5.17 MPa (750 psi). The hoses should be replaced when any of the outer rubber casing exhibits significant wear. Follow the APA manufacturer's instructions for the technique on replacing hoses.

Note 1—A Gates 77B Paint Spray and Chemical hose has been found to be satisfactory. This hose is available from the Gates Corporation (Product No. 3207-0296).

3.1.8. When electing to manually measure rut depths, a rut depth measurement template is required. This template shall be machined aluminum plate [approximately 31.7 to 38.1 mm (1.25 to 1.50 in.) thick] and have the following dimensions: 400.0 mm (15.75 in.) long by 152.4 mm (6 in.) wide. The rut depth measurement template shall contain five openings, spaced along the length of the template, in which the ruts are measured. The locations of the openings on the template will coincide with the locations utilized by the automatic measurement system. Each of the five openings shall be approximately 11 mm (0.43 in.) wide.

Note 2—Manual rut depth measurements on specimens that are rutted significantly may result in erroneous data. The rut depth measurement template may rest on the displaced material rather than on the test mold. In these cases, the rut depth measurement template should be modified with a channel removed from the bottom side of the template in order to span the displaced material and ensure that the template rests on the test mold.

3.1.9. The APA shall be calibrated in accordance with Annex A1.

3.2. *Ovens for maintaining temperature of plant-produced HMA and preheating specimens.*

3.3. *Compaction device and molds*:

3.3.1. Superpave gyratory compactor (SGC) and compaction molds conforming to T 312, or

3.3.2. Vibratory compactor and compaction molds.

3.3.2.1. *Vibratory compactor*—A steel-frame device mounted on noise-absorbing isolators and supports that utilizes adjustable vibratory compression forces to consolidate and compact HMA to produce cylindrical specimens for further testing. The device shall be timer-controlled and capable of compacting the specimens to a specified height and extracting the specimens after compaction. The vibratory compactor shall have a control panel separate from the compaction unit. The panel shall contain a mode switch to control specimen compaction and extraction and a timer to control the compaction-time cycle.

3.3.2.2. The compaction molds used for specimens produced in the vibratory compactor shall be composed of steel with the following dimensions:

- inside diameter of 149.9 ± 0.5 mm (5.90 ± 0.02 in.);
- inside height of 133.4 ± 0.5 mm (5.25 ± 0.02 in.);
- overall height of 152.7 ± 0.5 mm (6.01 ± 0.02 in.);
- wall thickness of 7.81 ± 0.5 mm (0.31 ± 0.02 in.); and
- bottom plate diameter of 149.0 ± 0.5 mm (5.87 ± 0.02 in.).

4. PREPARATION OF TEST SPECIMENS

4.1. *Number and dimensions of test specimens*—Six cylindrical specimens, 150 mm (5.91 in.) in diameter by 75 ± 2 mm (3.0 ± 0.1 in.) tall.

4.2. *Roadway Core Specimens*:

4.2.1. Roadway core specimens shall be 140 to 152 mm (5.5 to 6.0 in.) in diameter and a minimum of 50 mm (2 in.) tall with all surfaces of the perimeter perpendicular to the surface of the core within 5 mm (0.2 in.). Cores taller than the desired height shall be trimmed with a saw to a height of 75 ± 2 mm (3.0 ± 0.1 in.). For cores with diameters between 140 and 152 mm (5.5 and 6.0 in.) or heights between 50 and 73 mm (2.0 and 2.9 in.), plaster of paris or comparable material may be used to achieve the proper testing height of 75 ± 2 mm (3.0 ± 0.1 in.) and to ensure that specimens with small diameters fit snugly within the testing mold. Testing shall be conducted on the uncut face of the core.

4.3. *Plant-Produced (HMA)*:

4.3.1. Samples of plant-produced HMA shall be obtained in accordance with T 168. HMA samples shall be reduced to the appropriate test size and compacted while the HMA is within the compaction temperature range as determined by the specifying agency. Reheating of loose plant HMA should be avoided.

4.3.2. When using an SGC, compact specimens conforming to the dimensional requirements of Section 4.1 to 7.0 ± 0.5 percent air voids in accordance with T 312.

4.3.3. When using a vibratory compactor, compact specimens conforming to the dimensional requirements of Section 4.1 to 7.0 ± 0.5 percent air voids in accordance with the following procedure:

4.3.3.1. Attach and level the appropriate compaction head to the vibrating assembly in accordance with the manufacturer's instructions. Verify that the compaction head is correctly attached and arranged to produce a specimen of the desired height. Check the position of the compaction head against the specimen mold in accordance with the manufacturer's instructions.

4.3.3.2. Adjust the compaction force and vibration time settings in accordance with the manufacturer's instructions.

4.3.3.3. Heat and charge the specimen mold in accordance with the manufacturer's instructions.

4.3.3.4. Operate the vibratory compactor in order to compact and extrude the specimen in accordance with the manufacturer's instructions.

4.3.4. Compacted specimens should remain at room temperature, approximately 25°C (77°F), to allow the entire specimen to cool, for a minimum of 3 hours.

4.4. *Laboratory-Prepared (HMA)*:

4.4.1. Prepare the ingredient materials and mix the HMA specimens in accordance with T 312.

4.4.2. When using an SGC, compact specimens conforming to the dimensional requirements of Section 4.1 to 7.0 ± 0.5 percent air voids in accordance with T 312.

4.4.3. When using a vibratory compactor, compact specimens conforming to the dimensional requirements of Section 4.1 to 7.0 ± 0.5 percent air voids in accordance with the procedure given in Sections 4.3.3.1 through 4.3.3.4.

4.4.4. Compacted specimens should remain at room temperature, approximately 25°C (77°F), to allow the entire specimen to cool, for a minimum of 3 hours.

5. DETERMINING THE AIR VOID CONTENT

5.1. Determine the bulk specific gravity of the HMA specimens in accordance with T 166. In the case of sawn specimens as described in Section 4.2.1, determine the bulk specific gravity of the specimens after sawing.

5.2. Determine the maximum specific gravity of the loose HMA in accordance with T 209.

5.3. Determine the air void content of the HMA specimens in accordance with T 269.

6. SELECTING THE TEST TEMPERATURE

6.1. The test temperature shall be set to the high temperature of the standard Superpave performance-graded (PG) binder identified by the specifying agency for the project that the HMA is intended. For circumstances where the high-temperature binder grade has been increased, the APA test temperature will remain at the standard PG binder high temperature.

7. SPECIMEN PREHEATING

7.1. Place the specimens in the test molds.

7.2. Specimens shall be preheated at the test temperature in the temperature-calibrated APA test chamber or a separate calibrated oven for a minimum of 6 hours. Specimens should not be held at the test temperature for more than 24 hours prior to testing.

8. PROCEDURE

8.1. Set the hose pressure gap reading to 690 ± 35 kPa (100 ± 5 psi). Set the load cylinder pressure reading for each wheel to achieve a load of 445 ± 22 N (100 ± 5 lbf).

8.2. Stabilize the testing chamber temperature at the temperature selected in Section 6.

8.3. Secure the preheated, molded specimens in the APA. The preheated APA chamber should not be open for more than 6 minutes when securing the test specimens into the machine. Close the chamber doors and allow a minimum of 10 minutes for the temperature to stabilize prior to starting the test.

8.4. *Manual Rut-Depth Measurement*:

8.4.1. Apply 25 cycles to seat the specimens before taking the initial measurements. Make adjustments to the hose pressure as needed during these 25 cycles.

8.4.2. Open the chamber doors; unlock and pull out the sample holding tray.

8.4.3. Place the rut-depth-measurement template conforming to Section 3.1.8 over the specimen. Ensure that the rut-depth-measurement template is properly seated and firmly rests on top of the testing mold.

8.4.4. Zero the measuring gauge. Take initial readings at each of the four outside locations on the template; the center measurement is not used. Measurements shall be determined by placing the measuring gauge in the template slots and sliding the gauge slowly across each slot. Record the smallest measurement for each location to the nearest 0.01 mm (0.0004 in.).

8.4.5. Repeat Sections 8.4.3 and 8.4.4 for each set of cylinders in the testing position. All measurements shall be completed within 6.0 ± 0.5 minutes.

8.4.6. Push the sample holding tray in and secure it. Close the chamber doors and allow a minimum of 10 minutes for the temperature to stabilize.

8.4.7. Set the preset counter to 8000 cycles.

8.4.8. Start the test. When the test reaches 8000 cycles, the APA will stop and the load wheels will automatically retract.

8.4.9. Repeat Sections 8.4.2 through 8.4.5 to obtain the final measurements.

8.5. *Automatic Rut-Depth Measurement*:

Note 3—Some APA users have reported significant differences in rut depths between automatic measurements and manual measurements.

8.5.1. Initialize the APA computer software. Using the APA computer software or on the APA as appropriate, enter the applicable test parameters and project information prior to starting the test.

8.5.2. Ensure that the cycle-countdown mechanism is set to a value that will permit the specimens to be seated, a complete test of 8000 cycles to be performed, and the computer program to be disengaged at the end of the test. Normally, this value is between 8050 and 8100 cycles.

8.5.3. Using the APA computer software or on the APA as appropriate, start the test.

8.5.4. The APA will stop when the test is complete, and the wheels will automatically retract. Save the rut-depth data file to the computer. Print the data if desired.

9. CALCULATIONS

9.1. Determine the average rut depth for each of the three test positions.

9.1.1. When utilizing manual rut-depth measurement, determine the rut depth at each location by subtracting the final measurement from the initial measurement. Use the rut depth for all four locations to calculate the average rut depth for each of the three test positions.

9.1.2. When utilizing automatic rut-depth measurement, obtain the rut depths from the three test positions as displayed on the APA computer software.

9.2. *Outlier Evaluation*—Calculate the sample standard deviation for the three test positions. If the sample standard deviation of the three test positions is greater than or equal to 2.0 mm (0.08 in.), then the position with the rut depth farthest from the average may be discarded. The testing procedure, device calibration, and test specimens should be investigated to determine possible causes for the excessive variation.

9.3. The APA rut depth for the HMA is the overall average rut depth for the three test positions, less any outliers, from the six cylindrical specimens.

10. REPORT

10.1. *The test report shall include the following information*:

10.1.1. The laboratory name, technician name, and date of the test;

10.1.2. The HMA type and description;

10.1.3. The type of test specimens (cylinders or cores);

10.1.4. For cylinders, the type of compaction device (SGC or vibratory compactor);

10.1.5. The average air void content of the test specimens;

10.1.6. The test temperature;

10.1.7. The method utilized to measure rut depth (manual or automatic); and

10.1.8. The average rut depth for each of the three test positions, and the overall average rut depth for the HMA, to the nearest 0.1 mm (0.0004 in.).

11. PRECISION AND BIAS

11.1. Work is underway to develop precision and bias statements for this standard.

ANNEX

(Mandatory Information)

A1. CALIBRATION

A1.1. The following items should be checked for calibration no less than once per year: (1) preheating oven; (2) APA temperature; (3) APA wheel load; and (4) APA hose pressure. Instructions for each of these calibration checks are included in this section. For APAs equipped with the automatic rut-depth measurement system, calibrate the horizontal and vertical components of the data-acquisition system according to the manufacturer's schedule and instructions.

A1.2. *Temperature calibration of the preheating oven*:

A1.2.1. The preheating oven must be calibrated with a NIST-traceable thermometer [an ASTM No. 65C (65F) calibrated thermometer conforming to ASTM E 1 is recommended] and a metal thermometer well to avoid rapid heat loss when checking the temperature.

A1.2.2. *Temperature Stability*:

A1.2.2.1. Set the oven to the chosen temperature [e.g., 64°C (147°F)]. Place the thermometer in the well, and place the thermometer and well on the center of the shelf where the samples and molds will be preheated. It usually takes an hour or so for the oven chamber, well, and thermometer to stabilize. After 1 hour, open the oven door and read the thermometer without removing it from the well. Record this temperature. Close the oven door.

A1.2.2.2. Thirty minutes after obtaining the first reading, obtain another reading of the thermometer. Record this temperature.

A1.2.2.3. If the readings from Sections A1.2.2.1 and A1.2.2.2 are within 0.4°C (0.8°F), average the readings. If the readings differ by more than 0.4°C (0.8°F), continue to take readings every 30 minutes until the temperature stabilizes within 0.4°C (0.8°F) on two consecutive readings.

A1.2.3. *Temperature Uniformity*:

A1.2.3.1. To check the uniformity of the temperature in the oven chamber, move the thermometer and well to another location in the oven so that they are on a shelf where the samples and molds will be preheated, but as far as possible from the first location. Take and record readings of the thermometer at the second location every 30 minutes until two consecutive readings at the second location are within 0.4°C (0.8°F).

A1.2.3.2. Compare the average of the two readings at the first location from Section A1.2.2.3 with the average of the stabilized temperature at the second location. If the average temperatures from the two locations are within 0.4°C (0.8°F), the oven temperature is relatively uniform, and it is suitable for use in preheating APA samples. If the average of the readings at the two locations differs by more than 0.4°C (0.8°F), another oven that will maintain this level of uniformity and meet calibration must be utilized.

A1.2.4. *Temperature Accuracy*:

A1.2.4.1. Average the temperatures from the two locations (Section A1.2.2.3 and A1.2.3.2.). If that average temperature is within 0.4°C (0.8°F) of the set-point temperature on the oven, the oven is reasonably accurate and calibration is complete.

A1.2.4.2. If the set point differs from the average temperature by more than 0.4°C (0.8°F), adjust the oven set point appropriately to raise or lower the temperature inside the oven chamber so that the thermometer and well will be at the desired temperature [e.g., 64°C (147°F)].

A1.2.4.3. Place the thermometer and well on the center of the shelf. At 30-minute intervals, take readings of the thermometer. When two consecutive readings are within 0.4°C (0.8°F), and the average of the two consecutive readings is within 0.4°C (0.8°F) of the desired test temperature [e.g., 64°C (147°F)], the oven has been properly adjusted and calibration is complete. If these two conditions are not satisfied, repeat Sections A1.2.4.2 and A1.2.4.3.

A1.3. *APA Temperature Calibration*:

A1.3.1. The APA must be calibrated with a NIST-traceable thermometer [an ASTM No. 65C (65F) calibrated thermometer conforming to ASTM E 1 is recommended] and a metal thermometer well to avoid rapid heat loss when checking the temperature.

A1.3.2. *Temperature Stability*:

A1.3.2.1. Turn on the APA main power, and set the chamber temperature controller so that the inside of the testing chamber is at the anticipated testing temperature [e.g., 64°C (147°F)]. Also, if applicable, set the water temperature controller to achieve the anticipated testing temperature.

Note A1—Due to possible variability in the APA temperature controller, the thermometer reading should always be considered as the chamber temperature.

A1.3.2.2. Place the thermometer in the well, and place the thermometer and well on the left side of the APA where the samples are tested.

Note A2—It may be helpful to remove the hose rack from the APA during the temperature calibration to avoid breaking the thermometer.

A1.3.2.3. It usually takes about 5 hours for the APA temperature to stabilize. After the temperature display on the controller has stabilized, open the chamber doors and read the thermometer without removing it from the well. Record this temperature. Close the chamber doors.

A1.3.2.4. Thirty minutes after obtaining the first reading, obtain another reading of the thermometer. Record this temperature.

A1.3.2.5. If the readings from Sections A1.3.2.3 and A1.3.2.4 are within 0.4°C (0.8°F), average the readings. If the readings differ by more than 0.4°C (0.8°F), continue to take readings every 30 minutes until the temperature stabilizes within 0.4°C (0.8°F) on two consecutive readings.

A1.3.3. *Temperature Uniformity*:

A1.3.3.1. To check the uniformity of the temperature in the APA chamber, move the thermometer and well to the right side of the APA where the samples are tested. Take and record readings of the thermometer at the second location every 30 minutes until two consecutive readings at the second location are within 0.4°C (0.8°F).

A1.3.3.2. Compare the average of the two consecutive readings obtained in Sections A1.3.2.5 and A1.3.3.1. If the average temperatures from the two locations are within 0.4°C (0.8°F), the APA temperature is relatively uniform, and it is suitable for use. If the average of the readings at the two locations differs by more than 0.4°C (0.8°F), consult the manufacturer on improving the temperature uniformity.

A1.3.4. *Temperature Accuracy*:

A1.3.4.1. Average the temperatures from the two locations (Sections A1.3.2.5 and A1.3.3.2.). If that average temperature is within 0.4°C (0.8°F) of the desired test temperature [e.g., 64°C (147°F)], the APA temperature is reasonably accurate and calibration is complete.

A1.3.4.2. If the average temperature differs from the desired test temperature [e.g., 64°C (147°F)] by more than 0.4°C (0.8°F), adjust the APA temperature controller so that the thermometer and well will be at the desired test temperature.

Note A3—It is advisable to keep the water bath set at the same temperature as the test chamber.

A1.3.4.3. Place the thermometer and well on the center of the shelf. At 30-minute intervals, take readings of the thermometer. When two consecutive readings are within 0.4°C (0.8°F), and the average of the two consecutive readings is within 0.4°C (0.8°F) of the desired test temperature [e.g., 64°C (147°F)], the APA temperature has been properly adjusted and calibration at that temperature is complete. Record the current set points on the temperature controllers for later reference. If these two conditions are not satisfied, repeat Sections A1.3.4.2 and A1.3.4.3.

A1.4. APA wheel load calibration of the air cylinders at the three test positions.

A1.4.1. Check the APA wheel loads with the calibrated load cell provided with the APA. Check and adjust the loads one at a time while the other wheels are in the "down" position and bearing on a dummy sample or wooden block of approximately the same height as a test sample. Calibration of the wheel loads should be accomplished with the APA at room temperature.

A1.4.1.1. Remove the hose rack from the APA.

A1.4.1.2. "Jog" the wheel carriage until the wheels are over the center of the sample tray when the wheels are in the "down" position.

A1.4.1.3. Raise and lower the wheels 20 times to heat up the cylinders.

A1.4.1.4. Adjust the bar on top of the load cell until the total height of the load cell/load bar assembly is 105 ± 5 mm (4.1 ± 0.2 in.).

A1.4.1.5. Position the load cell under one of the wheels. Place wooden blocks or dummy samples under the other two wheels.

A1.4.1.6. Zero the load cell.

A1.4.1.7. Lower all wheels by turning the cylinder switch to "CAL."

A1.4.1.8. If the load cell is not centered left-to-right beneath the wheel, then raise the wheel and adjust the position of the load cell. To determine if the load cell is centered front-to-back beneath the wheel, unlock the sample tray and move it SLOWLY until the wheel rests in the indentation on the load-cell bar (where the screw is located).

A1.4.1.9. After the load cell has been properly centered, adjust the pressure in the cylinder to obtain 445 ± 5 N (100 ± 1 lbf). Allow 3 minutes for the load-cell reading to stabilize between adjustments. Record the pressure and load.

A1.4.1.10. With the wheel on the load cell remaining in the "down" position, raise and lower the other wheels one time. Allow 3 minutes for the load-cell reading to stabilize. Record the pressure and load.

A1.4.1.11. With the other wheels remaining in the "down" position, raise and lower the wheel over the load cell. Allow 3 minutes for the load-cell reading to stabilize. Record the pressure and load.

A1.4.1.12. Repeat Sections A1.4.1.5 through A1.4.1.11 for each wheel/cylinder.

A1.4.1.13. Return the load cell to the first wheel and repeat Sections A1.4.1.5 through A1.4.1.11.

A1.4.1.14. Place the load cell under the second wheel and repeat Sections A1.4.1.5 through A1.4.1.11.

A1.4.1.15. Place the load cell under the third wheel and repeat Sections A1.4.1.5 through A1.4.1.11. The current cylinder pressures will be used to set the wheel loads to 445 N (100 lbf).

A1.5. *Replacement of the APA hoses*:

A1.5.1. New hoses shall be placed in service in accordance with Section 3.1.7.

A1.5.1.1. Remove the hose rack from the APA.

A1.5.1.2. Remove the used hoses from the hose rack. For each position, place the new hose on the barbed nipples and secure it with the hose clamps.

A1.5.1.3. Position each new hose in the rack, ensuring that any curvature in the hose is aligned vertically (concave down toward the specimen) without any curvature in the horizontal direction. Tighten the nuts at the ends of the hoses only until the hoses are secure. Over-tightening will affect the contact pressure and hose life.

A1.5.1.4. Place the hose rack back into the APA and ensure that the hoses are aligned beneath the wheels.

A1.5.1.5. Prior to formal testing, "break in" the new hoses by running 8000 cycles on a set of previously tested samples at a temperature of 55°C (131°F) or higher.

A1.6. *APA hose pressure check*:

A1.6.1. The air pressure in the APA test hoses shall be checked with a NIST-traceable test gauge or transducer with a suitable range while the APA is operating. Since the hoses are connected in series, it is satisfactory to connect the test gauge to the end of the right-most hose. The pressure should not fluctuate outside of the range of 690 ± 35 kPa (100 ± 5 psi) during normal operation. Adjust the pressure as necessary with the hose-pressure regulator.

Note A4—The Ashcroft test gauge, Model 450182As02L200#, has been found to be satisfactory for this purpose. This gauge is available through Grainger (Stock No. 2F008).

APPENDIX

(Nonmandatory Information)

X1. OPTIONAL APA TESTING PARAMETERS

X1.1. The numerous testing parameters involved when utilizing the APA (e.g., hose pressure/wheel load, specimen air-void content, specimen height, etc.) present a great opportunity for multiple combinations. Accordingly, very few APA users employ the same set of testing parameters. One reason for this diversity is that the use of the APA predated the development of a standard for the APA. Most users developed their own method based on the manufacturer's instructions, accumulated substantial data with that method, and in some cases, implemented a specification based on those data. Understandably, many APA users are hesitant to modify their testing parameters at this point.

X1.2. This standard establishes a set of APA testing parameters for the sake of consistency and development of precision and bias statements. The parameters specified are based on the general experience of numerous APA users and are widely accepted within the industry. In fact, the specified test conditions represent the majority of APA users. However, the parameters established in this standard do not agree with the recommendations from NCHRP 9-17 (*NCHRP Report 508*) in every case. The NCHRP 9-17 study attempted to identify the APA test parameters that best correlate with field rutting performance.

X1.3. Due to the diversity involved with the APA testing parameters throughout the community of users, this appendix presents specifications for, and discussion concerning, other test-condition options often employed by APA users.

X1.4. *Beam Specimens*:

X1.4.1. Some APA users test HMA beam specimens, rather than cylindrical specimens, for rut depth. Beam specimens can only be prepared by using the vibratory compactor. NCHRP 9-17 (*NCHRP Report 508*) included beam specimens as part of the research effort. When utilizing beam specimens in the APA, the following additional specifications are recommended:

X1.4.1.1. The APA shall be capable of testing cylindrical or beam specimens.

X1.4.1.2. The test molds for beam specimens shall be rectangular in shape, be composed of UHMW polyethylene, fit snugly within the testing position in the APA testing chamber, and contain one hole in which to insert the specimen. The dimensions of the hole shall be 75.0 ± 2.0 mm (2.95 ± 0.08 in.) tall by 125.0 ± 2.0 mm (4.92 ± 0.08 in.) wide by 300.0 ± 2.0 mm (11.81 ± 0.08 in.) long.

X1.4.1.3. The compaction molds used for beam specimens shall be composed of steel and reinforced with 25.4 mm (1.00 in.) by 28.6 mm (1.13 in.) angle mounted 25.4 mm (1.00 in.) from the top of the mold. The molds shall conform to the following dimensions:

- inside length of 299.9 ± 0.5 mm (11.81 ± 0.02 in.);
- inside width of 124.5 ± 0.5 mm (4.90 ± 0.02 in.);
- inside height of 133.5 ± 0.5 mm (5.26 ± 0.02 in.);
- overall height of 152.5 ± 0.5 mm (6.00 ± 0.02 in.);
- wall thickness of 6.25 ± 0.5 mm (0.25 ± 0.02 in.);
- bottom plate length of 297.4 ± 0.5 mm (11.71 ± 0.02 in.); and
- bottom plate width of 122.2 ± 0.5 mm (4.81 ± 0.02 in.).

X1.4.1.4. For either laboratory-prepared or plant-produced HMA, compact three beam specimens per test in accordance with the procedure given in Sections 4.3.3.1 through 4.3.3.4. Ensure the beam specimens conform to the following dimensions: 75 ± 2 mm (3.0 ± 0.1 in.) tall by 125 mm (4.92 in.) wide by 300 mm (11.81 in.) long.

X1.4.1.5. When performing manual rut-depth measurement for beam specimens, take initial readings at each of the five locations on the rut-depth-measurement template conforming to Section 3.1.8. Otherwise, obtain manual rut-depth measurements in accordance with Section 8.4.

X1.4.1.6. When calculating the rut depth from manual rut-depth measurements for beam specimens, use the rut depth for all five locations to calculate the average rut depth for each of the three test positions. The APA rut depth for the HMA is the overall average rut depth for the three test positions, less any outliers as described in Section 9.2, from the three beam specimens.

X1.4.1.7. Report that beam specimens were the type of test specimens utilized to evaluate the HMA rut depth.

X1.5. *115-mm Cylindrical Specimens*:

X1.5.1. Some APA users test cylindrical specimens with a specimen height of 115 mm, rather than a specimen height of 75 mm, for rut depth. NCHRP 9-17 (*NCHRP Report 508*) did not include cylindrical specimens with a specimen height of 115 mm as part of the research effort. Additional research is needed to compare rut depths between the two sample heights (75 mm and 115 mm) for cylindrical specimens. When utilizing cylindrical specimens with a specimen height of 115 mm in the APA, the following additional specifications are recommended:

X1.5.1.1. The dimensions of each of the two holes in the test molds for cylindrical specimens shall be 150.0 ± 2.0 mm (5.91 ± 0.08 in.) in diameter by 115.0 ± 2.0 mm (4.53 ± 0.08 in.) tall.

X1.5.1.2. The number and dimensions of test specimens shall be as follows: six cylindrical specimens, 150 mm (5.91 in.) in diameter by 115 ± 2 mm (4.5 ± 0.1 in.) tall.

X1.5.1.3. Report that cylindrical specimens with a specimen height of 115 mm were the type of test specimens utilized to evaluate the HMA rut depth.

X1.6. *Lower Target Air Void Content*:

X1.6.1. Some APA users test cylindrical specimens compacted to 4.0 percent air voids or beam specimens compacted to 5.0 percent air voids rather than using a target air void content of 7.0 percent. When desiring a lower target air void content, beam specimens are normally compacted to 5.0 percent air voids rather than 4.0 percent due to a frequent inability to compact beam specimens to 4.0 percent.

X1.6.2. NCHRP 9-17 (*NCHRP Report 508*) evaluated these lower air void targets during the course of the research and found that the lower targets more closely related to field rutting performance than cylindrical and beam specimens compacted to 7.0 percent air voids. However, the vast majority of APA users utilize a target air void content of 7.0 percent.

X1.6.3. When utilizing cylindrical specimens compacted to 4.0 percent air voids or beam specimens compacted to 5.0 percent air voids, the following additional specifications are recommended:

X1.6.3.1. When producing either laboratory-prepared or plant-produced HMA specimens using an SGC, compact cylindrical specimens conforming to the dimensional requirements of Section 4.1 or Section X1.5.1.2 to 4.0 ± 0.5 percent air voids in accordance with T 312.

X1.6.3.2. When producing either laboratory-prepared or plant-produced HMA specimens using a vibratory compactor, compact cylindrical specimens conforming to the dimensional requirements of Section 4.1 or Section X1.5.1.2 to 4.0 ± 0.5 percent air voids. Alternatively, compact beam specimens conforming to the dimensional requirements of Section X1.4.1.4 to 5.0 ± 0.5 percent air voids. In both cases, compact the specimens in accordance with the procedure given in Sections 4.3.3.1 through 4.3.3.4.

X1.7. *Higher Wheel Load and Hose Pressure*:

X1.7.1. Some APA users test specimens using a wheel load of 534 N (120 lbf) and a hose pressure of 830 kPa (120 psi) rather than 445 N (100 lbf) and 690 kPa (100 psi), respectively. NCHRP 9-17 (*NCHRP Report 508*) evaluated the higher load and pressure during the course of the research. However, the vast majority of APA users utilize a wheel load of 445 N (100 lbf) and a hose pressure of 690 kPa (100 psi) when testing APA specimens. Additional research is needed to compare rut depths between the two loading conditions. When utilizing a wheel load of 534 N (120 lbf) and a hose pressure of 830 kPa (120 psi), the following additional specifications are recommended:

X1.7.1.1. Set the hose pressure gap reading to 830 ± 35 kPa (120 ± 5 psi). Set the load cylinder pressure reading for each wheel to achieve a load of 534 ± 22 N (120 ± 5 lbf).

X1.7.1.2. Report that a wheel load of 534 N (120 lbf) and a hose pressure of 830 kPa (120 psi) were utilized to evaluate the HMA rut depth.

X1.7.1.3. When calibrating the APA wheel load, after the load cell has been properly centered, adjust the pressure in the cylinder to obtain 534 ± 5 N (120 ± 1 lbf). Otherwise, calibrate the APA wheel load for each test position in accordance with Section A1.4. Use the current cylinder pressures to set the wheel loads to 534 N (120 lbf) as described in Section A1.4.1.15.

X1.7.1.4. When checking the APA hose pressure, ensure that the pressure does not fluctuate outside the range of 830 ± 35 kPa (120 ± 5 psi) during normal operation. If necessary, adjust the pressure with the hose-pressure regulator.

Standard Method of Test for

Helical Continuously Welded Seam Corrugated Steel Pipe

AASHTO Designation: T 241-95 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Helical Continuously Welded Seam Corrugated Steel Pipe

AASHTO Designation: T 241-95 (2008)

1. SCOPE

1.1. This method describes the procedure to be used in determining the quality of the seam or helical, continuously welded seam, corrugated steel pipe. The procedure to be used involves distorting a short length of welded seam by using a 25-mm diameter, hemispherical punch and a 38-mm inside diameter contoured die. The resulting distorted weld area will hereafter be called the "cup."

1.2. At the option of the engineer, or in the event of a disagreement between the engineer and fabricator, the referee test described in Section 4 will be performed.

2. APPARATUS

2.1. *Die*—A die having an inside diameter of 38 mm and machined to conform to the corrugation of the sample. (See Figure 1.)

2.2. *Punch*—A punch consisting of a 25-mm steel ball attached to a section of 19-mm diameter steel rod. (See Figure 1.)

2.3. *Bending Test Device*—Bending jig with roller bending edges, adjustable supports, and 13-mm diameter mandrel. (See Figure 2.)

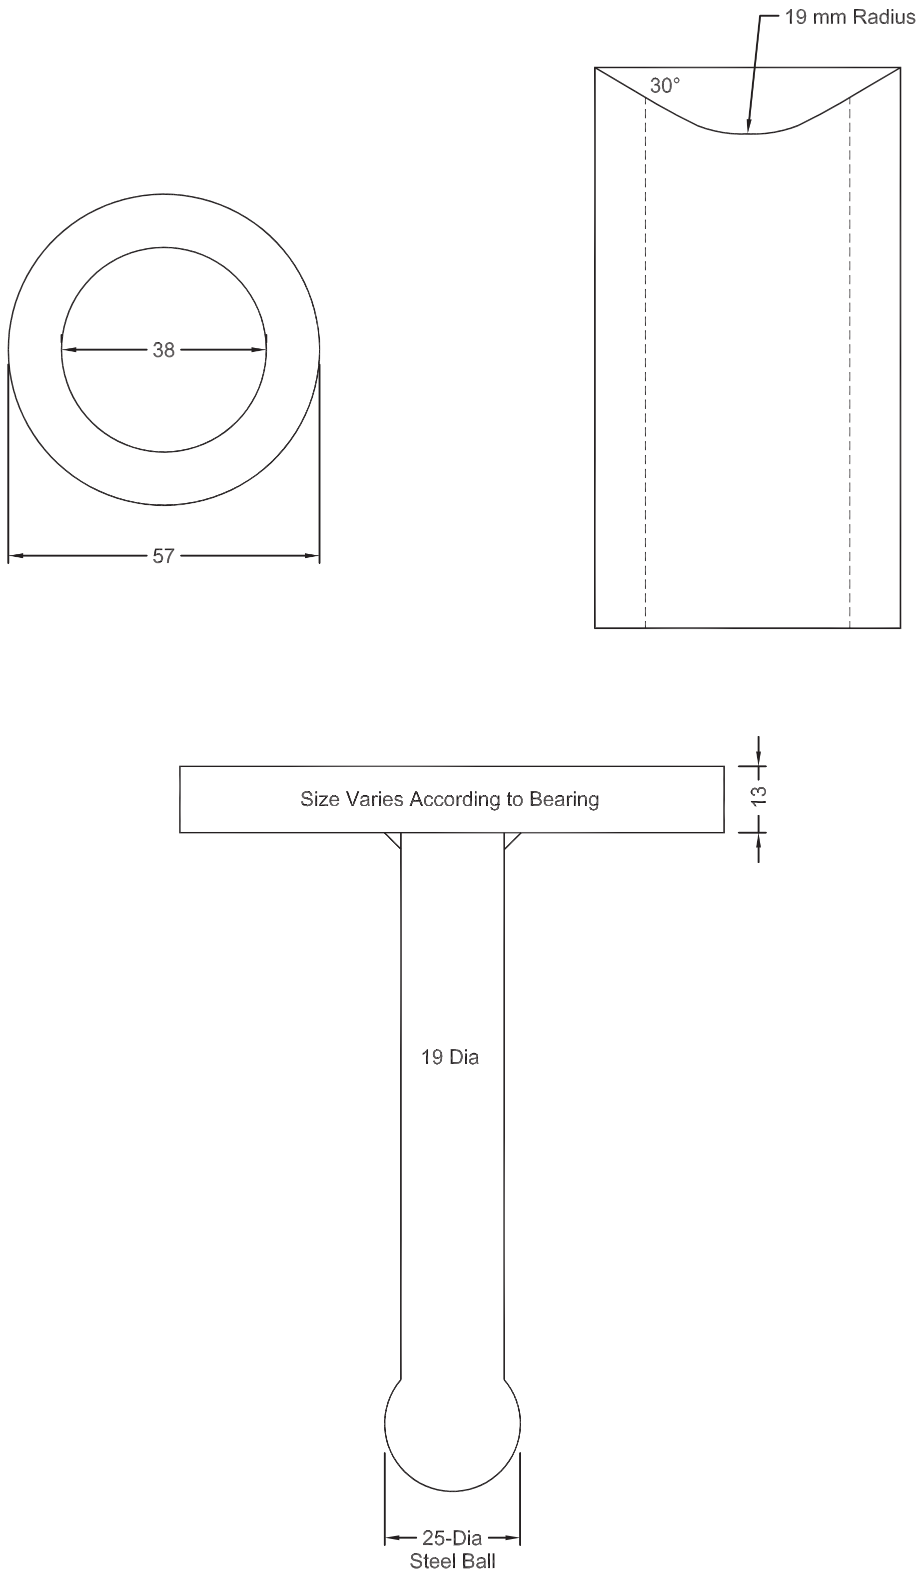
2.4. *Gauge*—Figure 3 shows a gauge recommended for use in measuring various dimensions in connection with the cup test, and also for checking acceptable width of the area burned by welding. It is used in the following manner:

2.4.1. The projections at the top of the gauge are dimensioned horizontally in accordance with the widths of burned area (three times thickness of metal) acceptable under the specification for each indicated gauge of metal.

2.4.2. The 76.2-mm overall length dimension is used to check the positioning of the test.

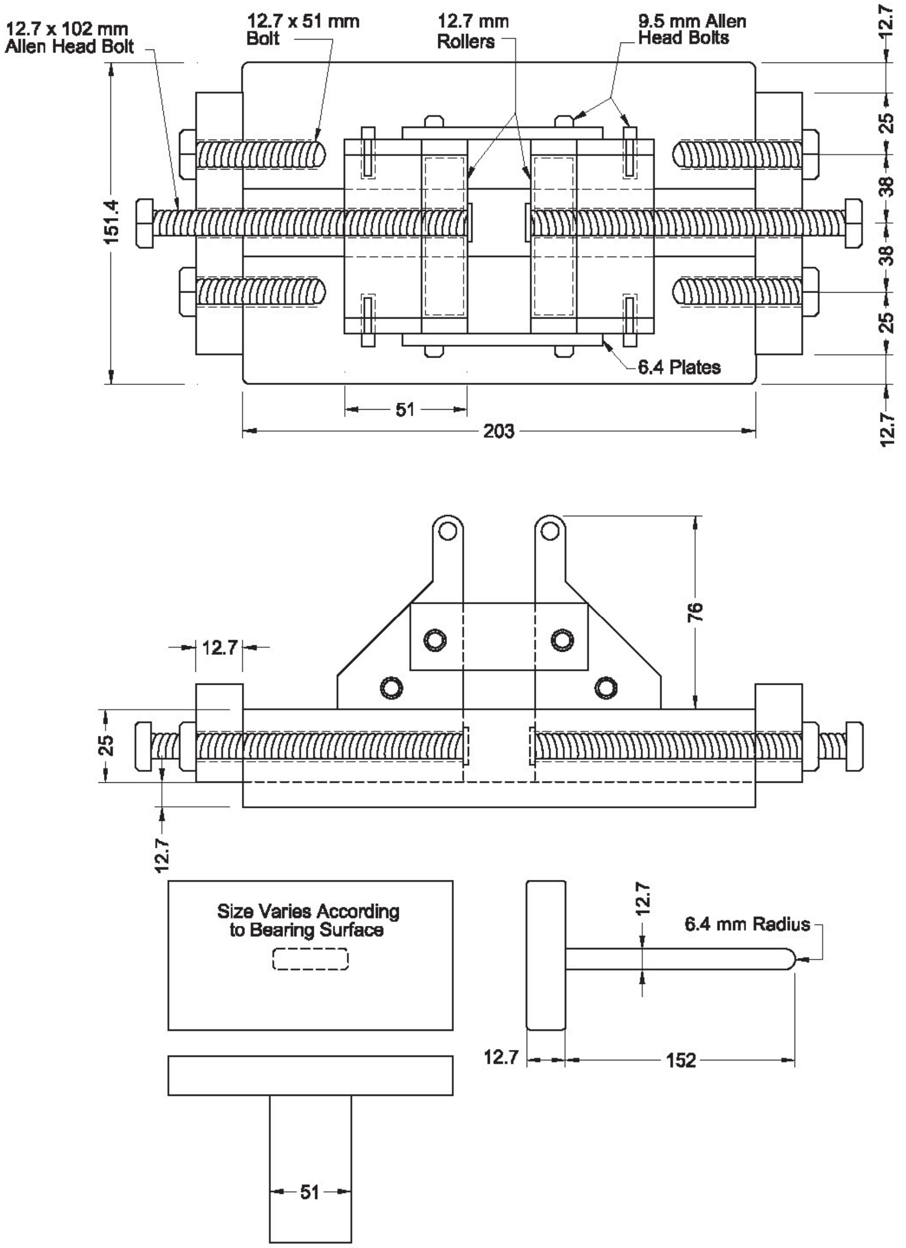
2.4.3. When the gauge is positioned on the pipe so that the bottom legs straddle the convex side of the cup, the 10.31-mm projection should always touch the cup. The interval corresponds to the minimum allowable depth of the cup after relaxation.

2.4.4. The 6.35-mm side projection can be used to check conformance to the limits set forth in Section 3.3.



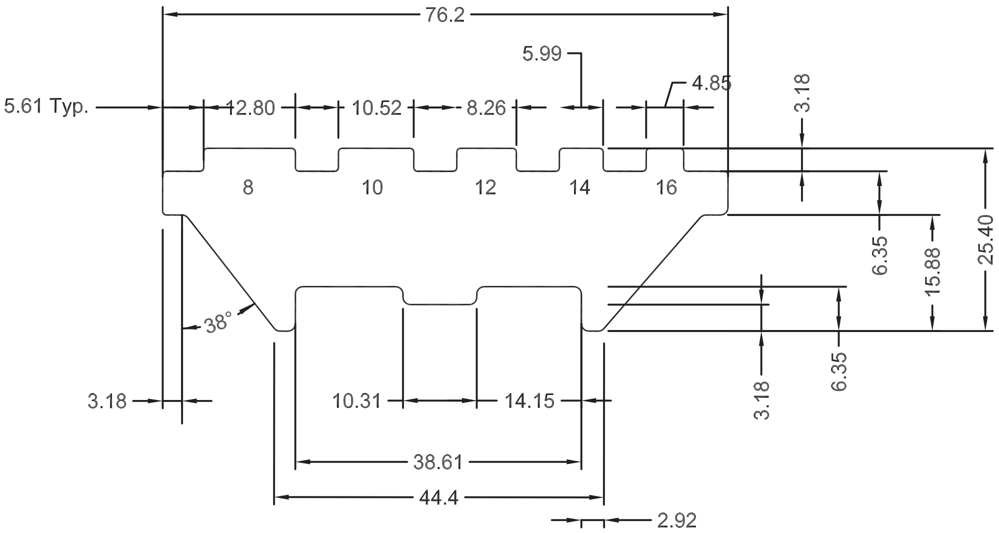
Note: All dimensions shown in millimeters unless otherwise noted.

Figure 1—Die and Punch for Cup Test



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Bend Test Apparatus



Material—2.38 mm Stainless Steel

Note: All dimensions shown in millimeters unless otherwise noted.

Figure 3—Cup Gauge

2.5. *Loading Device*—The loading device may be either a hydraulic or a screw-type testing machine with sufficient opening between the upper bearing surface and the lower bearing surface of the machine to permit the introduction of the specimen to be tested, or any suitable device that is capable of applying sufficient load to cause the die to penetrate the weld to the depth specified.

3. CUP TEST PROCEDURE

3.1. Position the punch on one side and center over the welded seam at the desired testing location. The direction of the cup shall be with the concavity of the corrugation. Tests shall be made not less than 75 mm from the end of the pipe and the minimum distance between tests shall be 75 mm.

3.2. Center the punch opposite the die, on the other side of the pipe wall, and, using the loading device described in Section 2.5, force the punch into the weld to a nominal depth under load of 5 mm. The resulting cup after relaxation must be at least 3 mm in depth.

3.3. For a length of a pipe to be acceptable, the sum of the lengths of cracks or other defects on either side of the cup shall be not more than 6 mm.

3.3.1. If the first cup indicates a failure, punch a second cup at another location on the weld not less than 76 mm or more than 300 mm from the first cup and in the direction of the center of the pipe. If this second cup test indicates a failure, the pipe shall be rejected.

3.4. *Report*—No formal test report is necessary for the cup test. This test will be part of the routine quality control and inspection procedure for acceptance of the pipe.

4. REFEREE TEST METHOD

4.1. The referee test consists of destructive tests requiring two 600- by 600-mm samples of pipe containing approximately 600-mm length of weld running through the center. No reformed corrugations will be allowed in the samples.

4.2. Each sample shall be cut into test specimens of the number and type shown in Table 1.

Table 1—Number and Type of Specimens

Number of Test Specimens Required	Type
3	Tensile test across the weld
3	Tensile test of the base metal above the weld
3	Tensile test of the base metal below the weld
3	Face bends
3	Root bends
3	Cup test of the weld
3	Cup test of base metal

4.3. *Tensile Test Specimens*—The tensile test specimens will be prepared in accordance with T 244, Figure 3. The grip of each specimen area will be flattened with care to prevent damage to the welds. The ultimate strength of the across-the-weld test specimens shall be equal to 90 percent of the ultimate strength of the lowest base metal test specimen.

4.4. In determining the mechanical properties, the base metal thickness of the specimen shall be measured after stripping the coating from the ends of the specimen contacting the grips of the testing machine, before testing.

4.5. *Bend Test*—All face and root bend specimens shall have a 5.0-mm gauge length on their appropriate sides across the weld area. The face bend specimen corrugations shall be flattened before testing. The test shall be performed by centering the weld on a 13-mm mandrel and bending the specimen 180 degrees. The root bend test shall be performed by forcing the corrugated specimen to a flat position. Any visible cracks in the weld resulting from the bend tests will be cause for rejection. The data resulting from the bend tests shall be the percent elongation of the gauge length.

4.5.1. *Bend Test Specimen*—The bend specimens shall be 150 mm long and 25 mm wide cut across the welded seam.

4.6. *Report*—The following elements are essential in reporting results of referee tests:

4.6.1. Ultimate strength of base metal and weld specimens,

4.6.2. Percentage of ultimate strength of weld metal compared with lowest ultimate strength of base metal,

4.6.3. Results of bend tests,

4.6.4. Results of cup tests of both the weld and base metal, and

4.6.5. Evaluation of test data.

Standard Method of Test for

Helical Lock Seam Corrugated Pipe

AASHTO Designation: T 249-03 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Helical Lock Seam Corrugated Pipe

AASHTO Designation: T 249-03 (2007)

1. SCOPE

1.1. This method of test is to be followed in ascertaining the quality of the seam of a helical lock seam corrugated pipe.

VISUAL METHOD

2. PROCEDURE

2.1. Determine lock seam quality by examining samples of the lock seam cross section sawed from the pipe. See Figure 1 for location of sample. See Figure 2 for the cross section of the sample.

2.2. The manufacturer will saw a triangular sample from the seam at one end of a length of pipe so as to show the cross section normal to the seam. The base of the triangular sample shall be of sufficient width to show complete lock seam profile. (See Figure 1.)

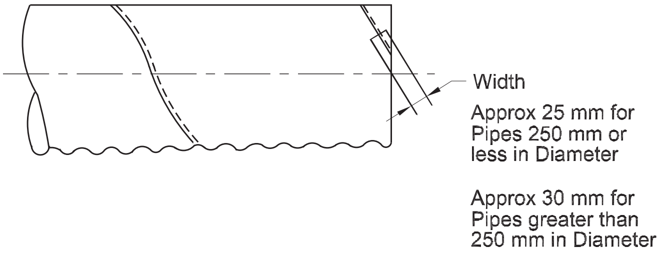


Figure 1—Location of Sample

2.3. The edges of the sheets within the cross section of the lock seam shall lap at least 4.0 mm for pipe 250 mm or less in diameter and at least 7.9 mm for pipe greater than 250 mm in diameter, with an occasional tolerance of –10 percent of lap width allowable. The lapped surfaces shall be in tight contact. There shall be no visible cracks in the metal, loss of metal-to-metal contact, or excessive angularity on the interior of the 180-degree fold of metal at the completion of forming the lock seam. Measure the seam lap and retaining offset distances (Figure 2) for conformance with specified maximum or minimum dimensions. See Figure 3 for examples of unacceptable seam cross sections.

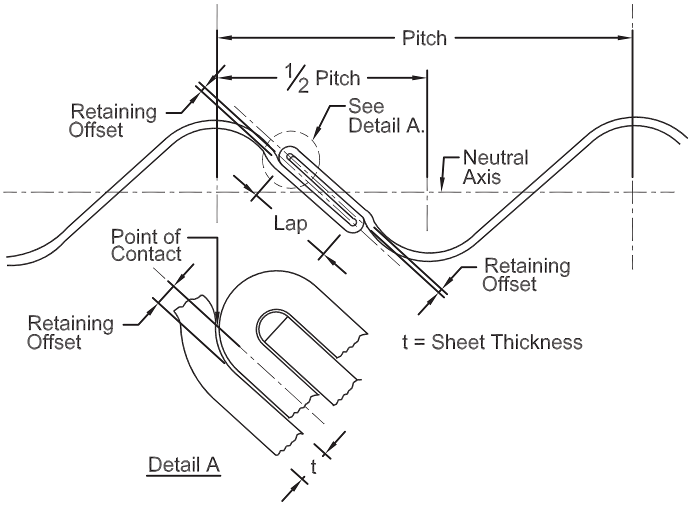

Figure 2A—Type I Lock Seam Cross Section

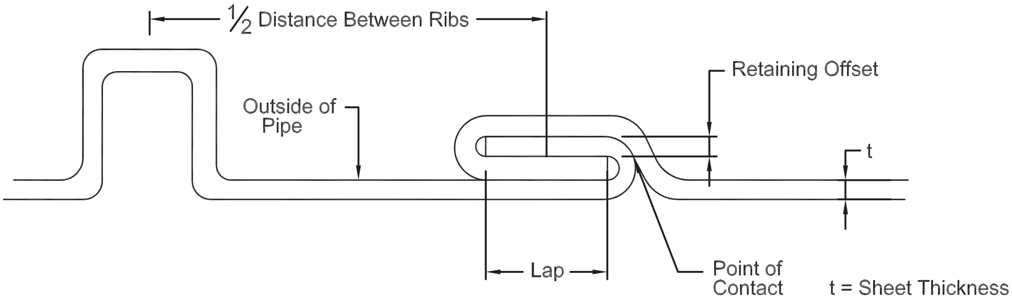

Figure 2B—Type IR Lock Seam Cross Section

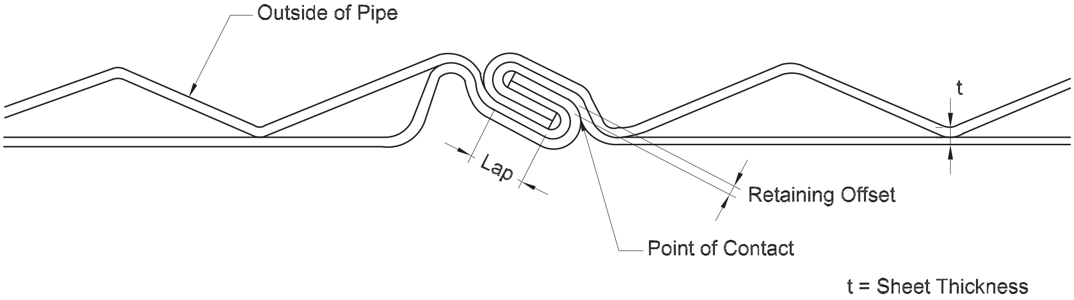

Figure 2C—Type IA Lock Seam Cross Section

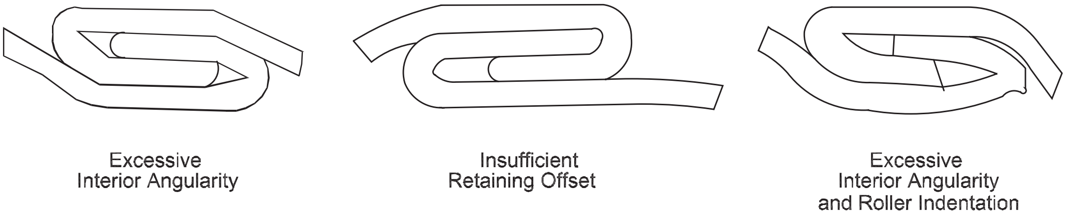

Figure 3—Examples of Unacceptable Seams

TENSION TEST METHOD

3. APPARATUS

3.1. A standard calibrated tensile testing machine.

4. TEST SPECIMEN

4.1. Cut a sample from the end of a fabricated pipe by sawing or burning, with dimensions at least 100 mm parallel to the lock seam and 150 mm perpendicular to the lock seam. If the ends of the pipe have been rerolled to form annular corrugations, take the sample from an area that has not been rerolled unless it is specifically intended to test for the seam strength after rerolling.

4.2. Trim the edges of the sample by sawing to provide a test specimen 25 mm wide (measured parallel to the lock seam), with the edges parallel. (See Figure 4.)

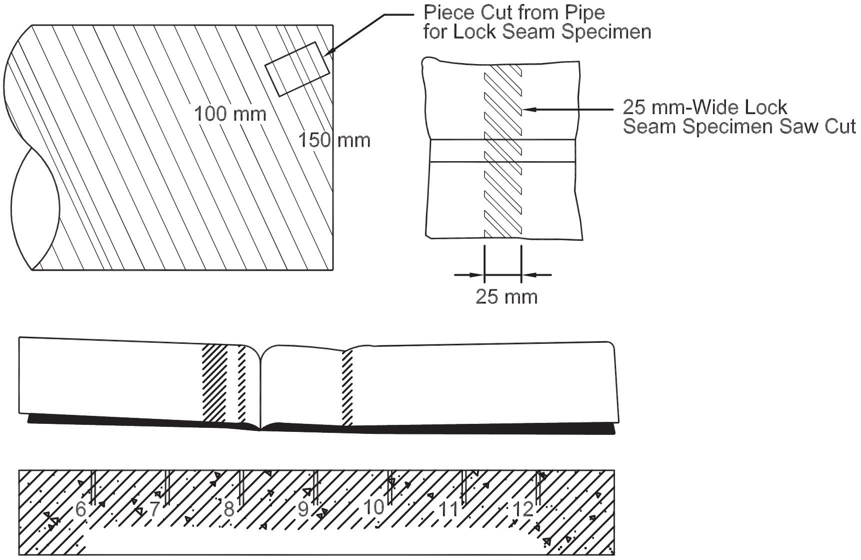

Figure 4—Type of Lock Seam Coupon Tension Specimen

4.3. Flatten the ends of the specimen for gripping in the testing machine, using a vise or similar tool. Insert one end at a time into the vise to 13 mm from the lock seam. As the vise flattens the corrugations, the unrestrained end will rotate. Realign the lock seam with the flattened ends by use of a crescent wrench (or similar) tightened over the lock seam to prevent distortion of the seam itself while bending the strip back into line.

5. PROCEDURE

5.1. Measure the width of the specimen at the lock seam to the nearest 0.2 mm. Measure the thickness of the sheet to the nearest 0.02 mm to determine the nominal sheet thickness.

5.2. Insert the specimen in the testing machine and apply a tensile load until the specimen separates at the lock seam. Record the maximum load.

6. CALCULATION AND REPORT

6.1. Determine the lock seam tensile strength by dividing the maximum load by the width of the specimen. Report the results as kilonewtons per meter (kN/m), and indicate whether the specimen is from an area where the corrugations have been rerolled.

Standard Method of Test for

Concrete Pipe, Manhole Sections, or Tile

AASHTO Designation: T 280-06[1]
ASTM Designation: C 497-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Concrete Pipe, Manhole Sections, or Tile

AASHTO Designation: T 280-06[1]
ASTM Designation: C 497-05

1. SCOPE

1.1. These test methods cover testing of concrete pipe, manhole sections, and tile. The test methods described are used in production testing and acceptance testing to evaluate the properties provided for in the specifications.

1.2. The test methods appear in the following order:

	Section
External load crushing strength	4
Flat slab tops	5
Core strength	6
Absorption	7
Hydrostatic	8
Permeability	9
Manhole step	10
Cylinder strength	11
Gasket lubricant	12
Joint shear	13
Alkalinity	14
Gasket measurement	15
Off-center hydrostatic joint test	16

1.3. The test specimens shall not have been exposed to a temperature below 4ºC [40ºF] for the 24 hours immediately preceding the test.

1.4. If any test specimen fails because of mechanical reasons such as failure of testing equipment or improper specimen preparation, it shall be discarded and another specimen taken.

1.5. Specimens shall be selected in accordance with the specifications for the type of pipe or tile being tested.

1.6. The values stated in SI units are to be regarded as the standard.

1.7. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. For definitions of terms relating to concrete pipe, see M 262.

4. EXTERNAL LOAD CRUSHING STRENGTH TEST BY THE THREE-EDGE-BEARING TEST METHOD

4.1. *Summary of Test Method*—The test specimen is tested in a machine designed to apply a crushing force upon the specimen in a plane through the vertical axis extending along the length of the specimen.

4.2. *Significance and Use*—The crushing test shall be either a quality-control test performed to establish that the finished, shippable pipe has sufficient strength to withstand the crushing loads stated in the specifications or a proof of design test performed to prove the adequacy of design.

4.3. *Apparatus*:

4.3.1. The testing machine shall be of any type of sufficient capacity and shall be capable of providing the rate of loading prescribed in Section 4.5.3.

4.3.2. The testing machine shall be substantial and rigid throughout, so that the distribution of the load will not be affected appreciably by the deformation or yielding of any part.

4.3.3. The three-edge-bearing method of loading shall be used. The test specimen shall be supported on a lower bearing of two parallel longitudinal strips and the load applied through an upper bearing (Figures 1, 2, 3, and 4). At the option of the manufacturer, either or both the lower bearing and the upper bearing beam shall extend the full length or any portion of the length of the specimen (Figure 5).

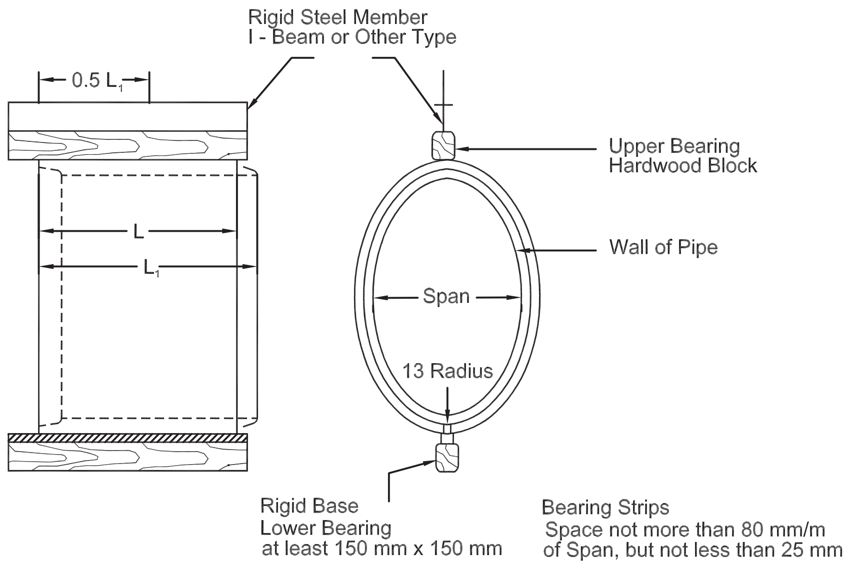
Figure 3—Three-Edge-Bearing Test, Horizontal Elliptical Pipe



Note: The figure illustrates a method of applying the load to the pipe.

Figure 4—Three-Edge-Bearing Test, Vertical Elliptical Pipe

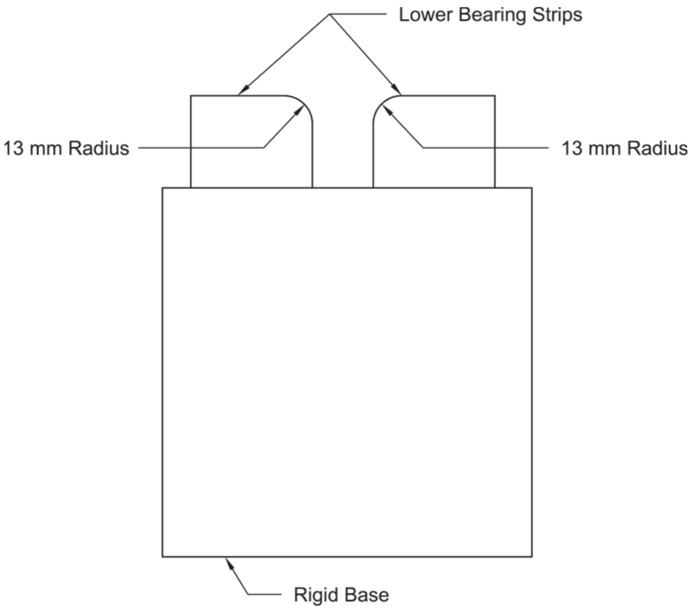


Figure 5—Lower Bearing Strip Detail

4.3.4. The lower bearings shall consist of wood or hard rubber strips. Wooden strips shall be straight, have a cross section of not less than 50 mm [2 in.] in width and not less than 25 mm [1 in.] nor more than 38 mm [1$^1/_2$ in.] in height and shall have the top inside corners rounded to a radius of 13 mm [$^1/_2$ in.]. Hard rubber strips shall have a durometer hardness of not less than 45, nor more than 60. They shall be rectangular in cross section, having a width of not less than 50 mm [2 in.], a thickness of not less than 25 mm [1 in.] nor more than 38 mm [1$^1/_2$ in.], and shall have the top inside corner rounded to a radius of 13 mm [$^1/_2$ in.].

4.3.5. The lower bearing strips shall be fastened to a wooden or steel beam or directly to a concrete base, any of which shall provide sufficient rigidity so that deflection is not greater than $^1/_{720}$ of the specimen length when the maximum load is applied. The rigid base shall be at least 150 mm [6 in.] wide. The interior vertical sides of the strips shall be parallel and spaced a distance apart of not more than 90 mm/m [1 in./ft] of specimen diameter, but in no case less than 25 mm [1 in.]. The bearing faces of the lower strips shall not vary from a straight line vertically or horizontally by more than 2.5 mm/m [$^1/_{32}$ in./ft] of length under no load.

4.3.6. The upper bearing shall be a rigid wood beam with or without an attached hard rubber strip. The wood block shall be sound, free of knots, and straight and true from end to end. It shall be fastened to a steel or wood-faced steel beam of such dimensions that deflections under maximum load will not be greater than $^1/_{720}$ of the specimen length. The bearing face of the upper bearing block shall not deviate from a straight line by more than 2.5 mm/m [$^1/_{32}$ in./ft] of length. When a hard rubber strip is used on the bearing face it shall have a durometer hardness of not less than 45 nor more than 60, and shall have a width of not less than 50 mm [2 in.] and a thickness of not less than 25 mm [1 in.] nor more than 38 mm [$1^1/_2$ in.] and shall be secured to a wood beam meeting the above requirements.

4.3.7. If mutually agreed upon by the manufacturer and the owner prior to the test, before the specimen is placed, a fillet of plaster of paris not exceeding 25 mm [1 in.] in thickness shall be cast on the surface of the upper and lower bearings. The width of the fillet cap, upper or lower, shall not be more than 80 mm/m [1 in./ft] of the specimen diameter, but in no case less than 25 mm [1 in.].

4.3.8. The equipment shall be so designed that the load will be distributed about the center of the overall length (L_1) of the specimen (Figures 1, 2, 3, and 4). At the option of the manufacturer, the center of the load shall be applied at any point of the overall length (L_1) of the specimen. The load shall be applied either at a single point or at multiple points dependent on the length of the specimen being tested and the rigidity of the test frame.

Note 1—The user of these test methods is advised that multiple points of load applications to the upper bearing will permit use of lighter beams without excess deflection.

4.4. *Calibration*—The loading device shall be one that shall provide an accuracy of ±2 percent at the specified test loads. A calibration curve shall be used. The machines used for performing the three-edge-bearing tests shall be verified in accordance with ASTM E 4.

4.5. *Procedure*:

4.5.1. Place the specimen on the two lower bearing strips in such a manner that the pipe or tile rests firmly and with uniform bearing on each strip.

4.5.2. Mark the two ends of the specimen at a point midway between the lower bearing strips and then establish the diametrically opposite point on each end. Place the upper bearing so that it is aligned with these marks.

4.5.3. For reinforced concrete pipe any rate of load application up to a maximum of 110 kN/linear meter [7500 lbf/linear foot] of pipe per minute shall be used up to 75 percent of the specified design strength, at which time the rate of loading shall be reduced to a maximum uniform rate of one-third of the specified design strength of the pipe per minute. This rate of loading shall be continuous until the specified acceptance design strength is reached. If both the design strength and the ultimate strength are being determined, a specified rate of loading need not be maintained after the acceptance design strength has been reached. For non-reinforced concrete pipe any rate of load application up to a maximum of 110 kN/linear meter [7500 lbf/linear foot] of pipe per minute may be used up to 75 percent of the specified ultimate strength at which time the rate of loading shall be reduced to the maximum uniform rate of 44 kN/linear meter [3000 lbf/linear foot] of pipe per minute. At the manufacturer's option, the rates of loading in this paragraph shall be any rates that do not exceed the specified maximums.

4.5.4. As defined in M 262, the design strength is the maximum load, expressed as a D-load, supported by the pipe before a crack having a width of 0.3 mm [0.01 in.] occurs throughout a continuous length of 300 mm [1 ft] or more measured parallel to the longitudinal axis of the pipe barrel. The crack is 0.3 mm [0.01 in.] in width when the point of the measuring gauge will, without forcing, penetrate 1.5 mm [$^1/_{16}$ in.] at close intervals throughout the specified distance of 300 mm [1 ft]. Measure the width of the crack by means of a gauge made from a leaf 0.3 mm [0.01 in.] in thickness (as in a set of standard machinist gauges), ground to a point of 1.5 mm [$^1/_{16}$ in.] in width with corners rounded and with a taper of 0.25 mm/mm [$^1/_4$ in./in.] as shown in Figure 6.

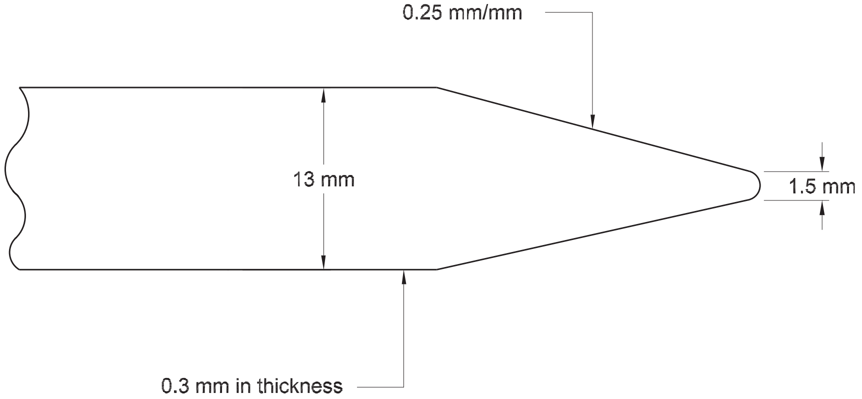

Figure 6—Gauge Leaf for Measuring Cracks

Note 2—As used in this specification, the 0.3-mm [0.01-in.] crack is a test criterion for pipe under load in three-edge-bearing test and is not intended as an indication of overstressed or failed pipe under installed conditions.

4.5.5. As defined in M 262, the ultimate strength is the maximum load supported by the pipe.

Note 3—Ultimate strength of concrete pipe in the buried condition is dependent on varying soil bedding factors and varying failure modes and shall have no relationship to the ultimate strength as defined under three-edge-bearing conditions.

4.6. *Conditioning*—The moisture requirements of Section 1.3 are not required, at the option of the manufacturer.

4.7. *Calculations*:

4.7.1. Strength test results shall be calculated in terms of newtons per linear meter [pounds per linear foot]. The laying length used in calculating the strength values shall be that indicated by *L* in Figures 1, 2, 3, and 4. For plain end pipe, no bell or spigot, the length *L* shall be the overall length. For pipe having a bell or spigot on one end with the opposite end being plain, *L* shall be the distance from the plain end to the center of the joint, where *L* equals the overall length minus one-half of the depth of the bell, or the overall length minus one-half the length of the spigot.

4.7.2. The ultimate strength in kilonewtons per linear meter [pounds per linear foot] shall be calculated by dividing the maximum test load applied to the pipe by the laying length *L*.

4.7.3. The D-load strength in kilonewtons per linear meter per meter [pounds per linear foot per foot] of inside diameter or horizontal span shall be either the 0.3-mm [0.01-in.] crack D-load strength or the ultimate D-load strength. The 0.3-mm [0.01-in.] crack D-load shall be calculated by dividing the test load required to produce the 0.3-mm [0.01-in.] crack by the laying length *L* and by the pipe inside diameter or horizontal span.

4.8. *Precision and Bias*—The user of this test method is advised that the true value for the strength of a concrete pipe cannot be determined because the specimen is tested to destruction and an exact duplicate specimen cannot be obtained. Therefore, no calculations of precision and bias are presently possible. Specifications that include this test method for the various types of concrete pipe should include a provision for additional tests of one or more specimens.

5. TEST METHOD FOR FLAT SLAB TOPS

5.1. *Summary of Test Method*—A load is applied to the flat slab top and the supporting capacity of the flat slab top is measured.

5.2. *Significance and Use*—The test method is a proof of design test performed to prove the adequacy of the design.

5.3. *Conditioning*—The moisture requirements of Section 1.3 are not required, at the option of the manufacturer.

5.4. *Procedure*—Place the section that has been designated to receive the flat slab top on a firm, even surface. Assemble the flat slab top to this section. If a frame or riser has been designed to be fitted to the access portion of the flat slab top, assemble it to the slab top. Apply the test load to the riser or frame as assembled to the flat slab top. If no access opening has been provided to the flat slab top, apply the test load to the center of the flat slab top by means of a 300 by 300 by 100 mm [12 by 12 by 4 in.] wood bearing block. (See Figure 7.) Calculate the test load as follows:

$$P_u = 1.3D + 2.17L + (1 + I) \tag{1}$$

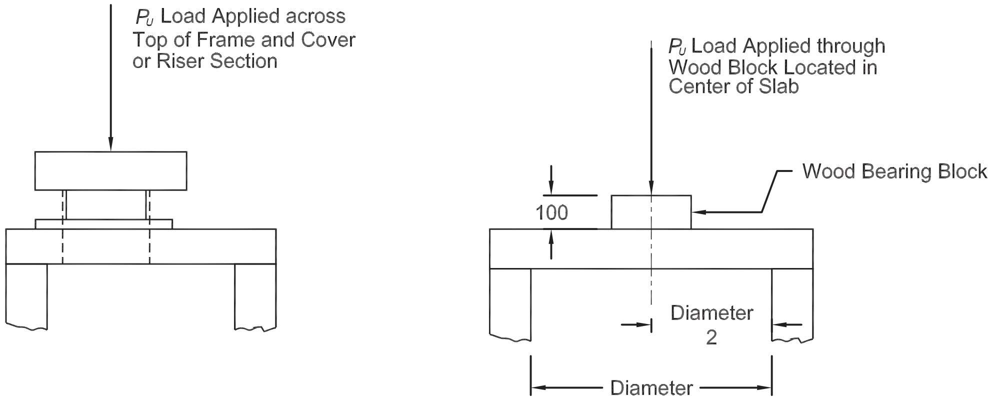
where:

P_u = applied minimum ultimate proof-of-design test load, N [lb];

D = total calculated field dead load on the slab, N [lb];

L = calculated live load on the flat slab top; and

I = impact factor, 30-percent minimum.



Flat Slab Top with Access Opening   Flat Slab Top without Access Opening

Figure 7—Flat Slab Top Test

6. CORE STRENGTH TEST METHOD

6.1. *Summary of Test Method*—The compressive strength of the concrete in the pipe is determined by making crushing tests of cores from the pipe.

6.2. *Significance and Use*—The core strength test is a quality-control test performed to establish the fact that the finished, shippable precast concrete product had sufficient concrete strength to meet the strengths stated in the specifications.

6.3. *Apparatus*—A core drill shall be used for securing cylindrical core specimens from the wall of the pipe; a shot drill or a diamond drill shall be used.

6.4. *Test Specimens*:

6.4.1. A core specimen for the determination of compressive strength shall have a diameter at least three times the maximum size of the coarse aggregate used in the concrete. If cores are cut from the wall of the pipe and tested, the length to diameter ratio shall lie between one and two after the curved surfaces have been removed from the cut core.

6.4.2. *Moisture Conditioning*—Unless the agency for which the testing is being done directs otherwise, the core test specimens shall be submerged in lime-saturated water in accordance with the provisions of T 24.

6.5. *Procedure*:

6.5.1. *End Preparation and Capping*—Core specimens to be tested in compression shall have ends that are essentially smooth and perpendicular to the axis and of the same diameter as the body of the specimen. Before making the compression test, cap the ends of the specimen in order to meet the requirements of T 231.

6.5.2. *Measurement*—Prior to testing, measure the length of the capped specimen to the nearest 2.5 mm [0.1 in.] and determine its average diameter to the nearest 2.5 mm [0.1 in.] from two measurements taken at right angles near the center of the length.

6.5.3. Test specimens as prescribed in the applicable sections of T 22.

6.6. *Calculation and Report*—Calculate the compressive strength of each specimen in pascals [pounds-force per square inch] based on the average diameter of the specimen. If the ratio of length to diameter is less than two, make allowance for the ratio of length to diameter by multiplying the compressive strength by the applicable correction factor given in the following table (determine values not given in the table by interpolation):

Ratio Length of Cylinder to Diameter, *l/d*	Strength Correction Factor
1.75	0.98
1.50	0.96
1.25	0.94
1.10	0.90
1.00	0.85

6.7. *Precision and Bias*—The user of this test method is advised that this method for testing concrete pipe for strength is considered satisfactory for acceptance testing of commercial shipments since the test method has been used extensively for acceptance testing. In cases of disagreement arising from differences in values reported by the owner and the manufacturer when using this test method for acceptance testing, the statistical bias, if any, between the laboratory of the owner and the laboratory of the manufacturer should be determined with each comparison being based on testing specimens randomly drawn from one pipe of the type being evaluated.

7. ABSORPTION TEST METHOD

7.1. *Summary of Test Method*—This test method covers the testing of a specimen that is a sample or core from the wall of the pipe. The test specimen is first subjected to drying, then to immersion to determine the specimen's absorption of water when tested by the described procedures.

7.2. *Significance and Use*—The test method is a quality-control test performed to establish the fact that the finished, shippable pipe meets the absorption limits stated in the specifications.

7.3. *Test Specimens*—Absorption test specimens shall be in accordance with the requirements of the applicable pipe specification.

7.4. *Procedure for Boiling Absorption Test*:

7.4.1. *Drying Specimens*—Dry specimens in a ventilated mechanical convection oven at a temperature of 105 to 115ºC [221 to 239ºF], until two successive weighings at intervals of not less than 6 hours show an increment of loss not greater than 0.10 percent of the last oven-dry mass of the specimen. Dry specimens with a wall thickness of 38 mm [1.5 in.] or less for a minimum of 24 hours; dry specimens with a wall thickness of 38 to 75 mm [1.5 to 3 in.] for a minimum of 48 hours; dry specimens with a wall thickness exceeding 75 mm [3 in.] for a minimum of 72 hours. Use the last 6 hours of the minimum drying time to determine whether or not the sample has obtained the proper dried mass.

7.4.2. *Weighing Dried Specimens*—Determine the mass of the oven-dried specimens immediately upon removal from the oven.

7.4.3. *Immersion and Boiling*—Within 24 hours, carefully place the dried specimen whose mass has been determined in a suitable receptacle that contains clean water at a temperature of 10 to 24ºC

[50 to 75ºF]. Use distilled water, rain water, or tap water that is known to have no effect on test results. Heat the water to boiling in not less than 1 hour and not more than 2 hours. Do not apply live steam to the water to shorten the pre-boil period until 1 hour of heating by gas or electricity has been completed. Continue the boiling for 5 hours. At the end of the 5-hour boiling period, turn off the heat, and allow the specimen to cool in water to room temperature by natural loss of heat for not less than 14 hours nor more than 24 hours.

7.4.4. *Reweighing Wet Specimens*—Remove the water-cooled specimens from the water, place on an open drain rack, and allow to drain for 60 seconds. Remove the remaining superficial water by quickly blotting the specimen with a dry absorbent cloth or paper. Determine the mass of the specimen immediately following blotting.

7.4.5. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

7.5. *Calculation and Report*—Take the increase in mass of the boiled specimen over its dry mass as the absorption of the specimen, and express it as a percentage of the dry mass. Report the results separately for each specimen.

7.6. *Precision and Bias*—The user of this test method is advised of the following:

7.6.1. *Single-Operator Precision*—The single operator standard deviation has been found to be 0.143 percent. Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 0.40 percent.

Note 4—The numbers in Section 7.6.1 represent, respectively, the (1s) and (d2s) limits described in ASTM C 670.

7.6.2. *Multilaboratory Precision*—Multilaboratory Precision has not been determined, but is being investigated. Statements will be included when the proper data have been obtained and analyzed.

7.6.3. *Bias*—Bias cannot be determined since the true value of absorption is not known and cannot be determined except by application of tests for which the bias is not known.

8. HYDROSTATIC TEST METHOD

8.1. *Summary of Test Method*—The section of pipe or manhole is subjected to hydrostatic pressure and observed for leakage at the joint or on the surface of the wall. The joint is defined as a connection between the concrete section of the pipe or manhole that provides alignment and the flexible watertight seal using either rubber gaskets, sealing bands, or preformed flexible joint sealant.

8.2. *Significance and Use*—The test method is a quality-control test performed to establish the fact that the finished, shippable pipe or manhole meets the hydrostatic requirements stated in the specifications for the installed wall or joint, or both.

8.3. *Procedure*:

8.3.1. The equipment for making the test shall be such that, when the specimen under test is filled with water to the exclusion of air and subjected to the required hydrostatic pressure, there shall not be enough leakage of water from the ends of the pipe to interfere with the test. The specimen under test shall be free of all visible moisture prior to the initiation of the test.

8.3.2. Do not test when the temperature of the specimen, the air around the specimen, or the water within the specimen is below 1ºC [33ºF].

8.3.3. If the joint seal or flexible connector is being tested, it shall be the sole element providing joint watertightness. No mortar for concrete coatings, fillings, or packing shall be used prior to the test.

8.3.4. Connect a standardized pressure gauge to the specimen. If being tested in a vertical position, the gauge shall be placed at or as close to as is practical above the joint or section being tested. If being tested in a horizontal position, the gauge shall be placed to measure pressure at or as close to as practical above the horizontal axis. Raise the pressure of the water in approximately 1 minute to the required level and hold for the specified time. There shall be no visible leakage. Moisture appearing in the form of patches or beads adhering to the surface shall not be considered leakage. If leakage occurs, the manufacturer is not prohibited from extending the soak time to 24 hours.

8.4. *Precision and Bias*—No justifiable statement is presently possible either on precision or on the bias of this method of testing for leakage under hydrostatic pressure since the test result merely states whether there is conformance to the criteria for success specified.

9. PERMEABILITY TEST METHOD

9.1. *Summary of Test Method*—A section of pipe is kept filled with water for a specified time and the outer surface is tested for moisture.

9.2. *Significance and Use*—The test method is a quality-control test performed to establish the fact that the finished, shippable pipe meets the leakage limits stated in the specifications.

9.3. *Procedure*—The pipe specimen under test shall be free of all visible moisture prior to the initiation of the test. Perform tests by placing the specimen to be tested with the spigot end down on a soft rubber mat or its equivalent, weighted if necessary, and kept filled with water to a level of the base of the socket during the test period. Make the initial inspection approximately 15 minutes after the test has begun. If the pipe shows moist or damp spots on the outer surface of the pipe at that time, continue the tests for a period not to exceed 24 hours at the option of the manufacturer. Examine the pipe during the extended period for existence of moist or damp spots.

9.4. *Precision and Bias*—No justifiable statement is presently possible either on precision or on the bias of this method of testing for leakage since the test result merely states whether there is conformance to the criteria for success specified.

10. MANHOLE STEP TEST METHODS

10.1. *Summary of Test Method*—This test method determines the ability of an installed step to withstand a specified horizontal pull at right angles to the wall of a manhole riser or cone section, and then a vertical load parallel to the wall of the section.

10.2. *Significance and Use*—The manhole step tests are intended to be used for production control, lot acceptance, or adequacy of design. These tests are performed to establish whether or not the installed step has sufficient strength to withstand the specified loads.

10.3. *Apparatus*—In making the tests, any mechanical or hand-powered devices that have calibrated load indicators attached shall be used. The attachments from the heads of each testing device to the rung of the step are to be sufficiently sturdy to preclude any bending of the attachment and rung over the length of the attachment. The attachments to the rung are to be 90 mm [$3^1/_2$ in.] in length.

10.4. *Conditioning*—The moisture requirements of Section 1.3 are not required, at the option of the manufacturer.

10.5. *Procedure*—It is not prohibited that the tests be made with the section to be tested placed on its side for easier access to the step to be tested. The first load shall be applied to the plane of the step by means of a pullout device centered on the step rung and shall be applied at a uniform rate until the specified load is reached. The pullout device is then removed and the test attachment is centered at the same location on the rung, and a second load is applied perpendicular to the plane of the first load application. The second load is applied at a uniform rate until the specified load is reached.

10.5.1. *Maximum Loads*—The first load as defined in Section 10.4 shall be 1800 N [400 lb]. The second load as defined in Section 10.5 shall be 3600 N [800 lb].

10.6. *Precision and Bias*—No justifiable statement is presently possible either on precision or bias of these methods of testing for pull-out strength since the test results merely state whether there is conformance to the criteria for success specified.

---

11. CYLINDER STRENGTH TEST METHOD

11.1. *Summary of Test Method*—The concrete compressive strength of a concrete pipe, box section, or manhole is determined by making crushing tests of concrete cylinders.

11.2. *Significance and Use*—The concrete cylinder strength test is a quality-control test performed to establish the fact that the finished, shippable precast concrete product had sufficient concrete compressive strength to meet the strengths stated in the specifications.

11.3. *Test Specimens*:

11.3.1. Cylinders shall be made, cured, and tested in accordance with T 23 and T 22 or by methods comparable to those used to consolidate and cure the concrete in the manufactured concrete product. Cylinder specimens of sizes other than 150 by 300 mm [6 by 12 in.] are not prohibited provided all other requirements of T 23 are met.

11.3.2. If the concrete consistency is too stiff for compaction by rodding or internal vibrations, the following alternative method shall be used:

11.3.2.1. Attach a cylinder mold to the top of a vibrating table or to the actual concrete pipe form being used to produce the concrete product.

11.3.2.2. Place concrete in the cylinder mold in three equal lifts.

11.3.2.3. Place a cylindrical hammer on the surface of each lift with the hammer to be 6 mm [$^1/_4$ in.] less in diameter than the inside diameter of the mold and of a weight to create a pressure of 2.4 kPa [0.353 psi] on the surface of the concrete.

11.3.2.4. External vibration shall be applied on each lift with a frequency of at least 800 vibrations per minute, and continue the vibration until cement paste begins to ooze up around the bottom edge of the hammer.

11.4. *Procedure*:

11.4.1. *End Preparation and Capping*—Cylinder specimens to be tested in compression shall have ends that are essentially smooth and perpendicular to the axis and of the same diameter as the body of the specimen. Before making the compression test, cap the ends of the specimen to meet the requirements of T 231 or ASTM C 1231.

11.4.2. *Testing*—Test specimens as prescribed in T 22.

11.5. *Calculation and Report*—Calculate the compressive strength of each specimen in kilopascal [pounds force per square inch] based on the average diameter of the specimen.

11.6. *Precision and Bias*—The user of this specification is advised that this method of testing concrete products for concrete compressive strength is considered satisfactory for acceptance testing of commercial shipments since the test method has been used extensively for acceptance testing. In cases of disagreement arising from differences in values reported by the owner and the manufacturer when using this method for acceptance testing, the statistical bias, if any, between the laboratory of the owner and the laboratory of the manufacturer should be determined with each comparison being based on testing specimens randomly selected from the specimens available for the type of concrete product being evaluated.

12. GASKET LUBRICANT TESTS

12.1. The lubricant manufacturer shall be responsible for all testing.

12.2. *Durometer and Volume Change Tests*:

12.2.1. The concrete pipe manufacturer or the gasket manufacturer shall supply the lubricant manufacturer with a minimum of three samples of each gasket material used by the pipe manufacturer.

12.2.2. Measure 50-mm [2-in.] samples from each gasket type for volume. The durometer shall be checked in accordance with ASTM D 2240. The samples shall be immersed in lubricant in a closed container.

12.2.3. The immersed samples shall be held at 21ºC [7ºF] for a period of 3 days.

12.2.4. At the end of the 3-day period, the volume of the samples shall be remeasured and the durometer of the samples rechecked in accordance with ASTM D 2440.

12.3. *Wash Test for Subaqueous Lubricants*:

12.3.1. A clean piece of concrete from the pipe shall be thoroughly wetted and then coated with a 3-mm [$^1/_8$-in.] layer of lubricant covering an area of 100 mm by 100 mm [4 by 4 in.].

12.3.2. The prepared specimen shall then be washed for 5 minutes with a soft stream 250 mL/min [0.07 gal/min] of tap water 21ºC [70ºF] from a height of 600 mm [2 ft] using equipment as shown in Figure 8.

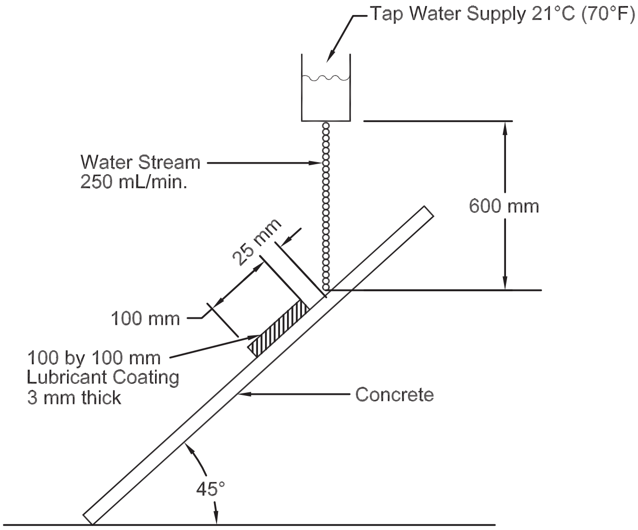


Figure 8—Lubricant Wash Test

12.3.3. After air drying, the washed-off area shall be divided by the original coated area and multiplied by one hundred; the result is the percentage washed away.

12.4. *Certification*:

12.4.1. The lubricant manufacturer shall supply the purchaser written certification that the gasket lubricant has met all test requirements specified for the gasket samples supplied.

12.4.2. Tests shall be performed each year on a gasket lubricant for certification, which shall be valid for one year, provided there are no changes in the materials or process used in the manufacture of either the gaskets or the lubricant.

12.4.3. No gasket lubricant shall be used on concrete pipe joints meeting this specification without valid certification provided to the concrete pipe manufacturer.

12.5. *Marking*:

12.5.1. The following information shall be clearly marked on each container of lubricant supplied to the pipe manufacturer.

12.5.1.1. Name of lubricant manufacturer.

12.5.1.2. Usable temperature range.

12.5.1.3. Shelf life.

12.5.1.4. Lot or batch number.

13. JOINT SHEAR TEST

13.1. *Summary of Test Method*—A shear force, normal to the longitudinal axis of the pipes, is applied across the assembled joint between two concrete pipes.

13.2. *Significance and Use*—This is a proof-of-design test that evaluates the structural capability of the pipe joint when subjected to a differential load.

13.3. *Apparatus*:

13.3.1. The testing machine shall be of any type that has sufficient capacity to apply the required test load or a suitable dead load shall be applied. The applied force shall not be less than the required force by more than two percent.

13.3.2. Supporting timber cradle blocks, with one face curved to match the outer diameter of the pipe barrel, shall be used to transmit the shear force from the test apparatus to the test pipe joint. The curved face shall be lined with a 25-mm [1-in.] thick hard rubber strip. Additional timber blocks or similar supports are necessary to elevate the test pipes. At the manufacturer's option, it is permissible to use flat timbers in lieu of cradle blocks.

13.4. *Procedure*:

13.4.1. To perform the test, two test pipes shall be assembled with one pipe fully supported and the spigot or tongue end of the second pipe installed in the bell or groove end of the first pipe as illustrated in Figure 9. Both pipes shall be supported so a uniform invert elevation is maintained. The user of this specification is advised that for safety reasons the pipe supports shall be constructed as shown in Figure 9. (**Warning**—Block or restrain the test pipe assembly horizontally to prevent any inadvertent pipe movements. The blocking or restraints shall be designed to avoid beneficial effects on the test.)

13.4.2. The joint shear test shall be run without water in the pipe or bulkheads installed on the pipe. A vertical test load (*F*) shall be applied to the suspended portion of the test joint until the total differential load, including the weight of a pipe, is 58.33 kN/m [4000 lb/ft] of pipe diameter.

Note 5—The manufacturer shall have the option to conduct concurrently a hydrostatic test and this structural test. If proven watertight under these combined conditions, hairline cracks that do not leak shall not be cause for rejection.

13.4.3. The test load shall be applied to the unsupported spigot of the test joint until the force reaches 58.33 kN/m [4000 lb/ft] for no less than 1 minute or the joint reaches the limit of its shear strength. The shear strength limit shall be noted by a sudden reduction in the applied load or shearing of the concrete.

Note 6—This is also a quality control test result for the lowest concrete strength and lowest class of pipe produced.

13.4.4. Cracks that occur during the test load are not considered failure, provided those cracks close to a width of less than 0.3 mm [0.01 in.] on release of the load.

13.4.5. *Calculations*:

13.4.6. The shear force resisted by the test joint shall be calculated by the resolution of applied and gravity forces on the pipe section. The total shear force on the joint is the sum of the resultants of the pipe weight and the applied force. (See Figures 9 and 10.)

13.5. *Precision and Bias*—The differential shear test provides an objective value of the structural strength of a concrete pipe joint. There is no widely accepted method of analysis for differential shear through the joints in buried concrete pipes. All current methods of concrete pipe design assume that the installed pipes are uniformly bedded along the length of the pipeline. Stronger joints will resist greater flaws in subgrade design or installation.

14. ALKALINITY OF CONCRETE MIXTURE

14.1. *Summary of Test Method*—This test method compares the ability of a sample of powdered, hardened concrete and pure calcium carbonate to neutralize acid. The concrete alkalinity is the ratio of the mass of acid neutralized by powdered concrete divided by the mass of acid neutralized by a similar sample of pure calcium carbonate.

14.2. *Significance and Use*—The user of this specification is advised that this is a proof-of-design test that evaluates the ability of the concrete mixture used in concrete pipes to resist the attack of acids that at times can form in sanitary sewers. The alkalinity rating of the concrete mixture is one of the design criteria used to predict the service life of concrete pipelines where hydrogen sulfide may be generated.

14.3. *Apparatus*:

14.3.1. One method of extracting powdered concrete samples is by use of a rotary drill with a twist bit.

14.3.2. A buret is required to complete the titration process on the concrete and calcium carbonate samples.

14.4. *Procedure*:

14.4.1. Samples of concrete from a pipe are obtained by drilling two 25-mm [1-in.] diameter cores from the interior pipe wall to the depth of the reinforcement. Each core sample is then placed in a separate container and dried in an oven for 1 to 2 hours at a temperature between 100 and 110°C [212 and 230°F]. The samples are then pulverized to obtain 100 percent passing a 150-µm [100-mesh] sieve.

14.4.2. Place approximately one gram of a sample into a beaker and add 10 milliliters of water. Next, slowly add 40 milliliters of standard 1-Normal hydrochloric acid, HCl, to the sample and water. When the effervescence has subsided, heat the mixture to boiling. Continue to boil for 30 seconds, and then cool.

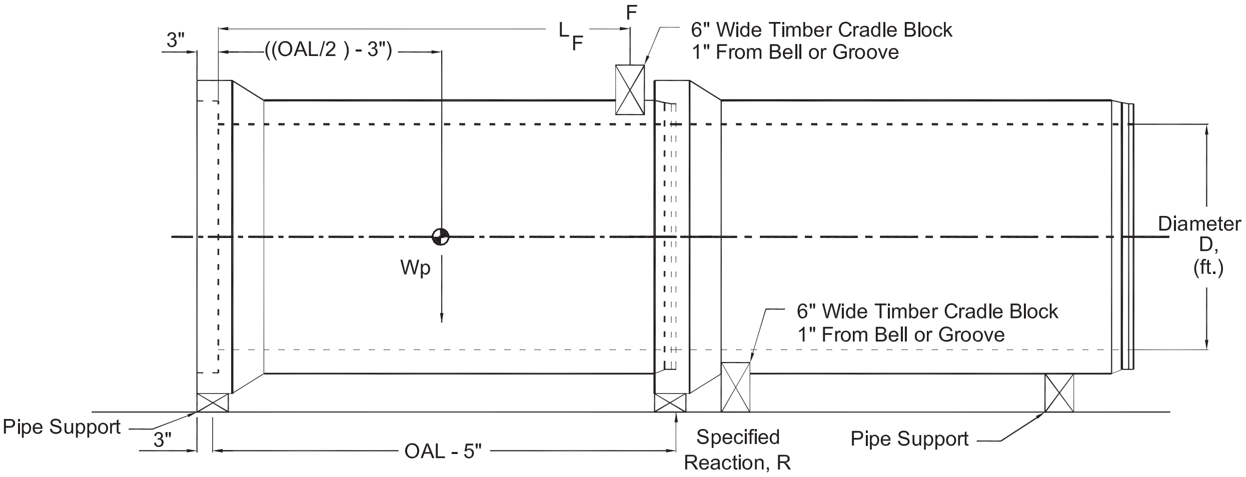
14.4.3. Add 50 to 100 milliliters of water to the cooled mixture and titrate with a carbonate free standard 1-Normal sodium hydroxide, NaOH, solution. Titrate the mixture until the pH stays above 6.8 for 2 minutes. The final pH shall be between 6.8 and 7.8. Run two tests on each core sample.

14.5. *Calculations*:

14.5.1. The alkalinity of the material is the average of all samples.

14.5.2. The net calcium carbonate equivalent of the sample is:

$$\text{CaCO}_3\ \text{Equivalent} = \frac{5[(\text{ml of HCl}) - (\text{ml of NaOH})]}{(\text{sample mass in grams})} \qquad (2)$$



R = Test Requirement
Wp = Nominal Weight of Test Pipe
F = Additional Test Force

R = 4000 lbs x Internal Diameter in Feet

$$F = \frac{((OAL) - 5^*)\,R - ((OAL/2) - 3")\,Wp}{L_F}\ (\text{lbs})$$

Figure 11—Dial Indicator

15. MEASUREMENT OF RUBBER GASKET VOLUME AND DIMENSIONS

Note 7—These are measurements performed by the pipe manufacturer for quality control checks.

15.1. *Volume*—This method is used to determine the volume of a solid, circular cross section pipe gasket. Measure the mass of the gasket to the nearest gram. Next, immerse the gasket completely in water and measure the mass of the gasket while totally submerged. A surfactant shall be added to the water to minimize air bubbles from clinging to the gasket material. The difference in the dry mass and the immersed mass of the gasket, measured in grams, is the volume of the gasket in cubic centimeters.

15.1.1. As an alternate to the above, the gasket shall be placed in a water tank and the displaced water shall be collected. The volume of water is then measured directly in cubic centimeters or by pouring into a calibrated tube or the water displaced shall be weighed. One gram of water equals 1 cm^3.

15.2. *Unstretched Length*—This method is used to determine the unstretched length of a pipe gasket. Construct a flat, straight calibrated measuring scale such as a measuring tape attached to a table or the floor. Make an index mark on the gasket cross-section with the flat side down (or out). Place the gasket index mark at the zero point on the measuring scale and carefully roll the uncut gasket loop without sliding or stretching. The gasket length is the distance measured at the point where the index mark retouches the scale.

15.3. *Height of Profile Gasket*—These methods are used to determine the profile gasket height, while stretched to the design strain of the proposed joint geometry for which the gasket is to be utilized.

15.3.1. *Method 1*—This method requires a precise measuring device mounted on a rigid fixture attached to the pipe joint (see Figure 11).

15.3.1.1. Install the test gasket at the location on the joint that is designated by the joint data sheet. Equalize the gasket stretch according to the gasket manufacturer's recommendations.

15.3.1.2. Carefully measure the distance to the highest sealing surface of the gasket. For self-lubricating gaskets, the tube containing the lubricant must be rolled over the gasket body and held under slight pressure as the measurement is taken. Without disturbing the measuring device, slide the gasket out of the joint recess. Measure the point on the joint gasket bearing surface immediately under the point where the gasket measurement was taken. The difference in measurements is the stretched gasket height.

15.3.2. *Method 2*—Position the gasket or a segment of a gasket in the same orientation that the cross-section is to be installed on the pipe joint. Make two index marks 300 mm [12 in.] apart on a straightened, but nonstretched segment of gasket. With an axial force, elongate the gasket until the distance between the marks is equal 300[(100% + % design stretch)/100] [12[(100% + % design stretch)/100]]. Hold or clamp the gasket segment in the stretched position. Measure the distance between the two sealing surfaces of the gasket with a vernier, micrometer, or dial gauge.

16. OFF-CENTER HYDROSTATIC JOINT TEST

16.1. *Summary of Test Method*—An assembled concrete pipe joint sealed with a gasket shall be hydrostatically tested while the bell and spigot of the test joint assembly are placed in the maximum off-center position.

16.2. *Significance and Use*—This is a proof-of-design test that evaluates the performance of a gasketed joint between concrete pipes to remain sealed under hydrostatic pressure with both minimum and maximum gasket compression.

16.3. *Apparatus*:

16.3.1. Hydrostatic pressure tests on joints shall be made on an assembly of two sections of pipe, properly connected in accordance with the joint design. The hydrostatic pressure shall be measured with a gauge or manometer accurate to 65 percent of the test pressure.

16.3.2. The testing machine shall be of any type that has sufficient capacity to apply the required test load that is in addition to the weight of the pipe filled with water, or a suitable dead load shall be applied. The applied force shall not be less than the required force by more than 5 percent.

16.3.3. Timber blocks shall be used to support the pipes. An additional block shall be used to transmit the force from the test machine to the test pipe joint.

16.3.4. It is not prohibited to fill the assembled pipes with water under a pressure of 90 kPa [13 psi] or less for a maximum of 24 hours prior to the test.

16.4. *Procedure*:

16.4.1. Two test pipes shall be assembled with one pipe fully supported and the spigot or tongue end of the second pipe installed in the bell or groove end of the first pipe as illustrated in Figure 11. The bell or groove end of the second pipe shall be supported by a block. The supports for the pipes shall maintain a uniform invert elevation for both pipes.

16.4.2. A vertical test load (F) shall be applied to the suspended portion of the test pipe section until the total differential load on the joint, including the weight of the pipe filled with water, shall be either a minimum of 26.25 kN/m [1800 lb/ft] of pipe diameter or until there is concrete-to-concrete contact within the joint.

Note 8—26.25 kN/m (26.25 N/mm) [1800 lb/ft (150 lb/in.)] is approximately the load required to compress to 50 percent an unconfined 40 durometer rubber gasket with a 17 mm [$^{21}/_{32}$ in.] diameter circular cross-section.

16.4.3. The joint assembly shall be subjected to the required hydrostatic pressure of 90 kPa [13 lb/in.^{2}] for 20 minutes without leakage. Moisture or beads of water appearing on the surface of the joint shall not be considered as leakage. If leakage of the joint initially occurs, the manufacturer is not prohibited from extending the test period up to a maximum of 24 hours.

16.5. *Calculations*:

16.5.1. The additional force required to cause the maximum off-center position in the test joint shall be calculated by the resolution of applied and gravity forces on the joint. The total force on the joint is the sum of the resultants of the pipe weight, the water weight, and the force applied by the test machine (see Figures 12 and 13).

16.5.2. *Precision and Bias*—This test provides a subjective evaluation of the seal formed between the bell and spigot of a concrete pipe joint under conditions causing minimum and maximum gasket compression. The performance of a gasketed pipe joint is affected by its geometric design, manufacturing tolerances, and variability in subgrade support of an installed pipe. Tighter joints will resist greater flaws in subgrade design or installation.

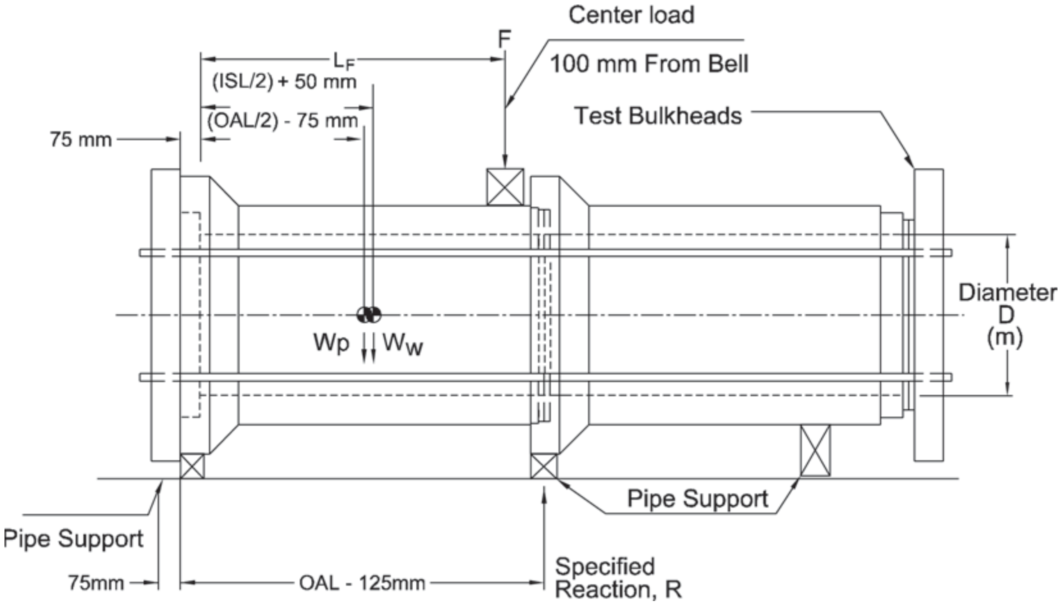

Figure 12—Off-Center Hydrostatic Joint Test

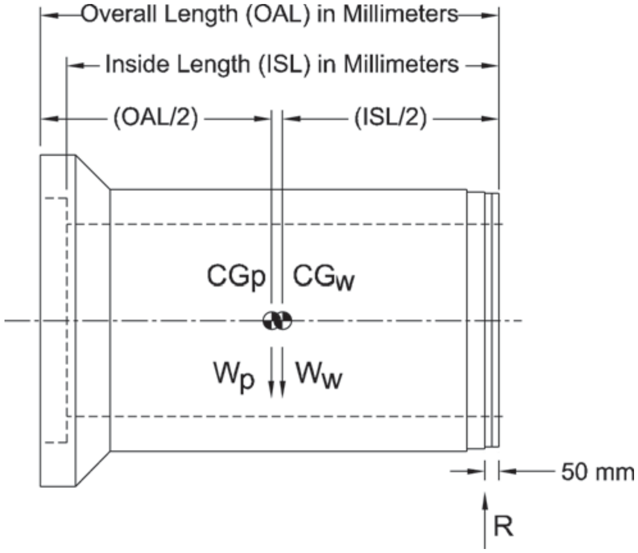

Figure 13—Center of Gravity of Pipe Filled with Water

---

[1] This method agrees with ASTM C 497-05 except that the 5-hour boil absorption is the only absorption method, and for reference to weighing apparatus.

Standard Method of Test for

Vitrified Clay Pipe

AASHTO Designation: T 281-06[1]
ASTM Designation: C 301-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Vitrified Clay Pipe

AASHTO Designation: T 281-06[1]

ASTM Designation: C 301-04

1. SCOPE

1.1. These test methods cover the equipment for, and the techniques of, testing vitrified clay pipe prior to installation. Tests using whole pipe determine the resistance to crushing and hydrostatic forces. Tests using pipe fragments measure the amount of water absorption of the pipe body and the quantity of acid-soluble material that may be extracted from it.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Note 1—The following standards also apply to clay pipe and can be referenced for further information: ASTM C 12, C 425, C 700, and C 828.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 231, Weighing Devices Used in the Testing of Materials

2.2. *ASTM Standards*:

- C 12, Standard Practice for Installing Vitrified Clay Pipe Lines
- C 425, Standard Specification for Compression Joints for Vitrified Clay Pipe and Fittings
- C 700, Standard Specification for Vitrified Clay Pipe, Extra Strength, Standard Strength, and Perforated
- C 828, Standard Test Method for Low-Pressure Air Test of Vitrified Clay Pipe Lines
- C 896, Standard Terminology Relating to Clay Products
- E 6, Standard Terminology Relating to Methods of Mechanical Testing

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. For definitions of terms used in these test methods, refer to ASTM E 6 and C 896.

4. SIGNIFICANCE AND USE

4.1. *Meaning and Suitability*—The tests called for herein, from their results, indicate the suitability and acceptability of vitrified clay pipe for specifications acceptance, design purposes, regulatory statutes, manufacturing control, and research.

5. BEARING STRENGTH

5.1. *Test Specimens*:

5.1.1. The test specimens shall be sound, full-size pipe and shall be selected by the purchaser, or purchaser's representative, at points designated by the purchaser when placing the order.

5.1.2. The number of specimens to be tested shall not exceed 0.5 percent of the number of pipe of each size furnished, except that no less than two specimens shall be tested.

5.2. *Measurement and Inspection of Specimens*:

5.2.1. The specimens shall be free of all visible moisture and frost. These specimens shall be inspected and measured for conformance with the applicable specifications. The results of these observations shall be recorded.

5.2.2. Specimens that are observed to have defects in excess of the limits permitted in the applicable specifications shall be discarded and replaced with additional specimens from the lot to be tested.

5.3. *Loading Apparatus*—See Figure 1.

5.3.1. *Testing Machine*:

5.3.1.1. The loading apparatus shall consist of a testing machine capable of applying loads, with upper and lower bearings capable of transmitting these loads to the pipe. The bearings shall be bearing beams and contact edges.

5.3.1.2. Any motor-driven testing machine, capable of applying a load at a uniform rate of 29.2 ± 7.3 kilonewtons per minute per linear meter [2000 ± 500 pounds-force per minute per linear foot] of pipe length, may be used for making the test.

5.3.1.3. The load may be applied at a rapid rate until 50 percent of the required bearing strength is reached. Subsequently, the load shall be applied to the pipe at the rate of 29.2 ± 7.3 kilonewtons per minute per linear meter [2000 ± 500 pounds-force per minute per linear foot] of pipe length without vibration or shock.

5.3.1.4. The testing machine shall be sufficiently rigid so that the load distribution will not be appreciably affected by the deformation or yielding of any part. The machine and bearings shall be constructed to transmit the load in a vertical plane through the longitudinal axes of the bearings and pipe. The bearings shall be attached to the machine so as to receive and uniformly transmit the loads required in the tests, without vibration or shock. The upper bearing shall be free to rotate in a vertical plane through the longitudinal axis of the bearing and the pipe.

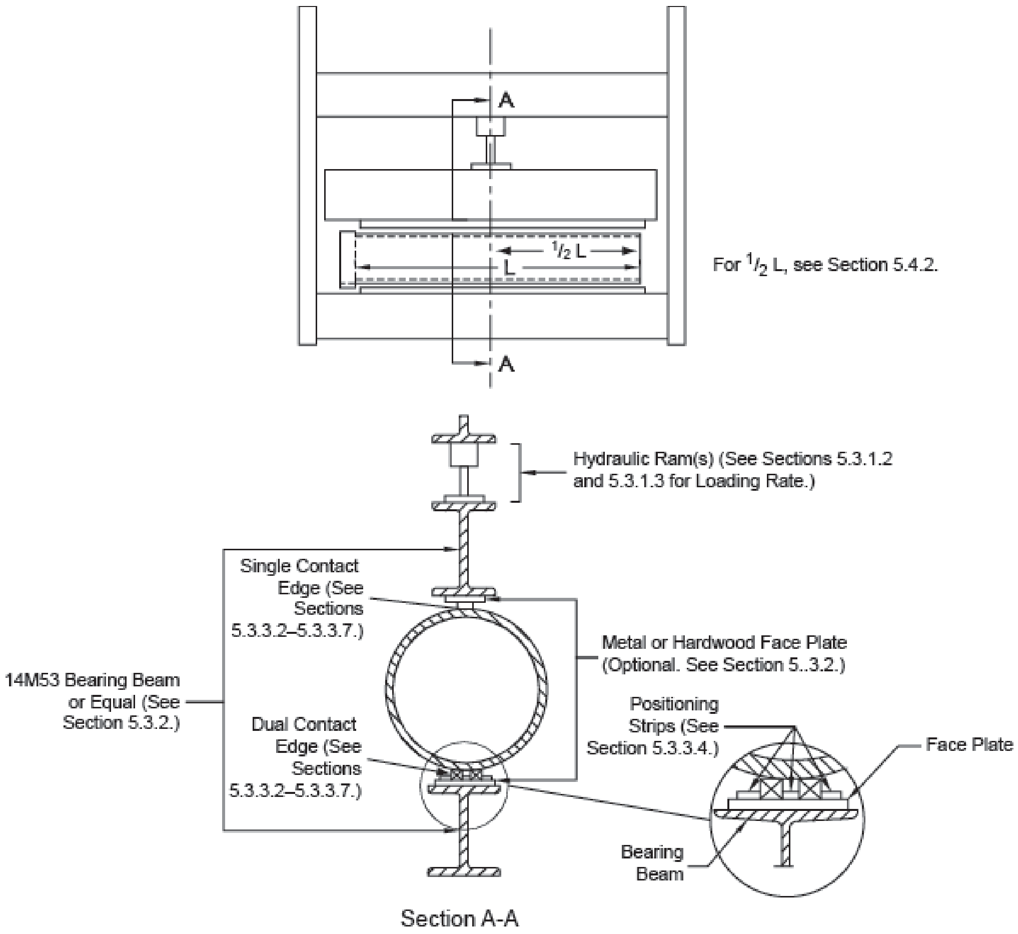

Figure 1—Three-Edge-Bearing Testing (Section 5.3.4 Segmented Testing)

5.3.2. *Bearing Beams*—Bearing beams shall not deflect more than a 355 by 205 mm [14 by 8 in.], 73 kg/linear m [53 lb/linear ft], wide flange beam as specified by the American Institute of Steel Construction. Under no circumstances shall the deflection in millimeters [inches] under maximum load exceed that given by the ratio $^{L}/_{720}$ in which L is the beam length in millimeters [inches]. The length of the bearing beams shall be no less than the full length of the outside barrel of the pipe. Built-up bearing beams may be used, provided their deflection does not exceed that specified. In order for the bell or socket of the pipe to clear the bearing beams, it is recommended that the bearing beams be faced with a metal or hardwood member for affixing the contact edges.

5.3.3. *Three-Edge-Bearings*:

5.3.3.1. Three-edge-bearings shall consist of an upper member, comprised of a bearing beam on which one contact edge is located so that it lies in the vertical plane passing through the longitudinal axis of the pipe, and a lower member comprised of a bearing beam on which two contact edges are symmetrically located parallel to that vertical plane.

5.3.3.2. The contact edges shall consist of rubber strips alone, or hardwood strips with plaster of paris fillets. Contact edges shall uniformly contact the outside barrel of the pipe.

5.3.3.3. The two contact edges on the lower member shall be spaced apart approximately 83 mm/m [1 in./ft] of pipe diameter, but in no case less than 25 mm [1 in.].

5.3.3.4. Positioning strips may be used to align the upper contact edge and to align and space the lower contact edges. In the case of rubber contact edges, positioning strips shall not exceed one-half of the thickness of the contact edge and may remain in place.

5.3.3.5. If rubber strips are used as contact edges, they shall be cut or formed from material having a Shore A, instantaneous, durometer hardness between 45 and 60. The strips shall be of rectangular cross section, having a 51-mm [2-in.] width, and a thickness not less than 25 mm [1 in.] nor more than 38 mm [$1^1/_2$ in.]. The contact edges shall be used with the 51-mm [2-in.] dimension in contact with the bearing beam. Rubber contact edges may be attached to the bearing beam by an adhesive, provided the contact edge remains firmly fixed in position.

5.3.3.6. If hardwood strips with plaster of paris fillets are used as contact edges, the strips shall be straight, and have a cross section not less than 25 mm [1 in.] in either direction. The bottom contact edges shall have vertical sides, with the interior top corners having a radius of approximately 13 mm [$^1/_2$ in.]. The contact edges shall be securely fastened to the beams.

5.3.3.7. Plaster of paris fillets shall be cast on hardwood contact edges to provide uniform bearing contact on the pipe barrel. Fillets shall be cast on the two lower contact edges and on the upper contact edge, along the pipe crown. Sufficient excess plaster shall be removed from between the two lower contact edges to eliminate the possibility of a single continuous lower contact. The pipe and contact edges shall be joined while the plaster of paris is still workable. Testing shall be performed only after the fillets have set.

5.3.4. *Segmented Bearings (Alternative to Three-Edge-Bearing)*—This apparatus shall consist of segmented upper and lower bearing members with the segments of each member connected to a common hydraulic manifold to provide uniform load along the length of the barrel. The segmented bearings shall be of uniform length with the number of segments equal to the nominal length of the test pipe measured in meters [feet]. They shall be adjustable to accommodate the length variation allowed in the pipe specification. In no instance shall the length of the segmented bearing be greater than the external length of the barrel of the pipe. Rubber contact edges conforming to Section 5.3.3.5 shall be attached to the bearing segments.

5.4. *Bearing Tests*—See Figure 1.

5.4.1. Test pipe for bearing strength in accordance with the three-edge-bearing or segmented method. Use either of the specified bearing methods on retests as provided in the applicable specifications.

5.4.2. For tests using rigid bearing beams, multiple loading rams may be used. Each ram must be the same load range, connected by a common hydraulic system, and spaced above the top bearing beam to deliver a uniformly distributed load. In testing pipe that is not straight, place it between the bearings in the position that most nearly gives uniform loading on the pipe.

5.4.3. The loading of the pipe shall be a continuous operation. Do not allow the pipe to stand under load longer than is required to apply the load and record the observations.

5.4.4. The loading shall be stopped after the required strength has been met.

5.4.5. For further evaluation or quality assurance, the loading may be continued to the point of pipe failure.

5.4.6. Record the maximum load sustained by the specimen.

5.5. *Calculation and Report*:

5.5.1. Calculate the crushing strength by dividing the applied load by the inside length of the barrel. The length shall be the average of two measurements taken at points 180 degrees [3.1 rad] apart. Report the individual results of the tests of pipe of each size or lot.

6. ABSORPTION

6.1. *Test Specimens*:

6.1.1. Absorption specimens shall be sound pieces of the full thickness of the barrel of the pipe, with all edges broken. Each specimen shall be as nearly square as possible, with the area on one barrel surface not less than 12 times the wall thickness, expressed as square units. They shall be free of observable cracks or shattered edges and shall not contain laminations and fissures more than is typical of the pipe from which the specimens were taken.

6.1.2. Each specimen shall be marked so that it may be identified with the lot of pipe from which it was taken. The markings shall be applied so that the pigment used shall cover not more than 1 percent of the area of the specimen.

6.1.3. Test at least one specimen from each size of pipe.

6.2. *Balance*—The balance shall have sufficient capacity, be readable to 0.1 percent of the sample mass, or better, and conform to the requirements of M 231.

6.3. *Procedure*:

6.3.1. Dry the specimen at least 8 hours in a ventilated oven at a temperature between 110 and 120ºC [230 and 248ºF], and make successive mass determinations at intervals of not less than 3 hours until the loss at any mass determination is not greater than 0.1 percent of the original mass of the specimen.

6.3.2. Suspend the dried specimens in distilled, rain, or tap water that is known to have no effect on test results; heat to boiling; boil for 5 hours, and then cool in the water to ambient temperature. Take care that no fragments are broken from the specimens by physical disturbance during the test. When cool, remove the specimens from the water, and drain for not more than 60 seconds. Then remove the superficial moisture with a damp cloth and determine the mass of the specimens immediately.

6.4. *Calculation and Report*:

6.4.1. Calculate the absorption of each specimen as a percentage of the initial dry mass as follows:

$$\text{Absorption, } \% = \left[\left(SW - DW\right)/DW\right] \times 100 \qquad (1)$$

where:

SW = mass of specimen after boiling 5 hours, and

DW = initial dry mass of specimen.

6.4.2. Report the result for each specimen, together with the averages for the pipe of each size and shipment.

7. HYDROSTATIC PRESSURE TEST

7.1. When the pipe is subjected to an internal hydrostatic pressure of 69 kPa [10 psi] for the elapsed time shown in the following table, there shall be no leakage on the exterior of the pipe. At the option of the manufacturer, water within approximately 3ºC [5ºF] of the ambient air temperature may be introduced into the pipe for control of condensation. Moisture appearing on the surface of the pipe in the form of beads adhering to the surface shall not be considered leakage. However, moisture that starts to run on the pipe shall be construed as leakage regardless of quantity.

Testing Time for Pipes

Thickness of Barrel, mm [in.]	Test Time, min
Up to and including 25 [1]	7
Over 25 [1] and including 38 [$1^1/_2$]	9
Over 38 [$1^1/_2$] and including 51 [2]	12
Over 51 [2] and including 64 [$2^1/_2$]	15
Over 64 [$2^1/_2$] and including 76 [3]	18
Over 76 [3]	21

8. ACID RESISTANCE

8.1. Determine the acid resistance of clay pipe by the extraction of acid-soluble matter.

8.2. *Reagent*—When testing with sulfuric (H_2SO_4), hydrochloric (HCl), nitric (HNO_3), or acetic acid (CH_3COOH), as specified by the purchaser, a 1-normal acid solution shall be used.

Note 2—These 1-normal solutions should contain 40, 36.5, 63, and 60 g of the acid per liter of solution, respectively. For the purpose of these tests the solutions can be prepared by taking the following volumes of acid and diluting to 1 liter: H_2SO_4 (sp gr 1.84), 28.5 mL; HCl (sp gr 1.19), 88.9 mL; HNO_3 (sp gr 1.42), 65 mL; and glacial acetic acid (sp gr 1.05), 57.7 mL.

8.3. *Test Specimens*:

8.3.1. The specimens for acid resistance tests shall be about 51 mm [2 in.] square, and weigh not more than 200 g. They shall be sound pieces with all edges freshly broken, free of cracks or shattered edges, and shall be thoroughly cleaned.

8.3.2. Test at least one specimen from each size of pipe.

8.4. *Balances*—The balance for determining the mass of the specimens shall conform to the requirements for Class C balances in M 231.

8.5. *Procedure*:

8.5.1. Dry the specimens to constant mass at a temperature not less than 110ºC [230ºF].

8.5.2. Suspend the dried specimens in the acid at a temperature between 21 and 32ºC [70 and 90ºF] for a period of 48 hours, then remove them from the solution and thoroughly wash with hot water, allowing the washings to run into the solution in which the specimen was immersed. Filter the solution and wash the filter with hot water, adding the washings to the filtrate. Add 5 mL of H_2SO_4 (sp gr 1.84) to the filtrate. Then evaporate the solution (avoid loss by spattering) to about 5 mL, transfer to a porcelain crucible (previously ignited to constant mass), and heat cautiously to dryness. Then ignite the residue to constant weight.

8.6. *Calculation and Report*:

8.6.1. Calculate the percentage of acid-soluble matter as follows:

$$\text{Acid-soluble matter, \%} = (R/W) \times 100 \qquad (2)$$

where:

R = mass of residue, and

W = initial mass of the specimen.

8.6.2. Report the results for each specimen.

9. VISUAL INSPECTION

9.1. The specification for vitrified clay pipe requires visual inspection; reference should be made to ASTM C 700.

10. PRECISION AND BIAS

10.1. No statements are made on the precision or bias of these test methods for measuring (1) bearing strength, (2) absorption, (3) acid resistance, or (4) moisture transmitted through the pipe wall in the hydrostatic pressure test, since conformance to specific criteria is the only measure for success specified in these test methods.

11. KEYWORDS

11.1. Absorption; acid resistance; bearing strength; clay pipe; corrosion; corrosion resistance; hydrostatic; inspection; loading; pipe; segmented bearing; testing procedure; tests; three-edge-bearing; vitrified clay pipe.

[1] This method agrees with ASTM C 301-04 except for reference to weighing apparatus.

Standard Method of Test for

Determination of Compression Capacity for Profile Wall Plastic Pipe by Stub Compression Loading

AASHTO Designation: T 341-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determination of Compression Capacity for Profile Wall Plastic Pipe by Stub Compression Loading

AASHTO Designation: T 341-10

1. SCOPE

1.1 This test method covers determination of compression capacity of profile wall plastic pipe in the stub compression test.

1.2 This test method covers thermoplastic resin pipe.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *ASTM Standards*:

- D 695, Standard Test Method for Compressive Properties of Rigid Plastics
- D 1600, Standard Terminology for Abbreviated Terms Relating to Plastics
- E 177, Standard Practice for Use of the Terms Precision and Bias in ASTM Test Methods
- F 412, Standard Terminology Relating to Plastic Piping Systems

3. TERMINOLOGY

3.1 Definitions are in accordance with ASTM F 412, and abbreviations are in accordance with ASTM D 1600, unless otherwise specified.

3.2 *Definitions of Terms Specific to This Standard*:

3.2.1 *local buckling*—local wrinkling resulting from compressive load in one or more elements of the wall section visible to the eye. When advanced, it may result in failure of the entire profile.

3.2.2 *period*—the length of a single repetition of the corrugation or rib pattern, defined as the distance from the centerline of a valley or liner element to the centerline of the adjacent valley or liner element (see Figure 1).

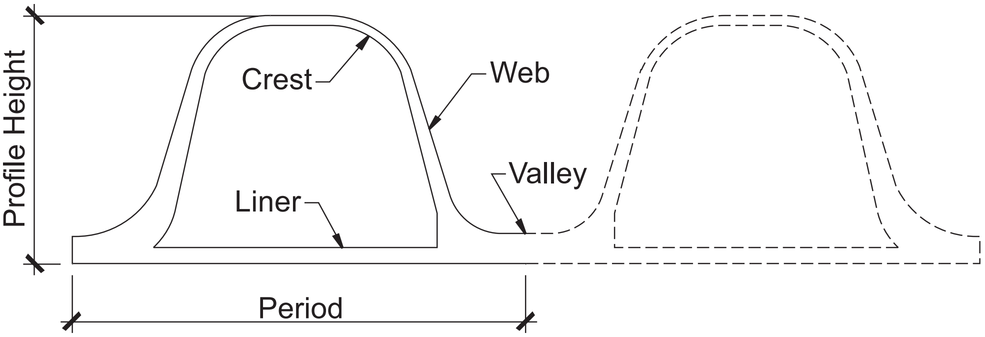

Figure 1—Typical Lined Profile Wall

3.2.3 *profile height*—the distance from the surface of the inside wall of the pipe (inner surface of the valley or liner element) to the surface of the outside wall of the pipe (outer surface of the crest or rib element in Figure 1). May also be determined as (OD – ID)/2.

3.2.4 *profile wall*—thin-walled pipe with corrugated or ribbed geometry.

4. SUMMARY OF TEST METHOD

4.1 A small sample of pipe wall is compressed between two rigid plates at a controlled rate. Both plates are fixed with respect to rotation. The sample has a longitudinal length of three periods and a chord (circumferential) length of 1.5 times the profile height. Load, displacement (of the load plates), and time data are obtained. The test ends when the ultimate load is exceeded and the level of load begins to decrease. The ultimate load, crosshead displacement at ultimate load, and test time at ultimate load are recorded.

5. SIGNIFICANCE AND USE

5.1 *The maximum load achieved in this test may be used for the following*:

5.1.1 To evaluate compression load capacity of profile wall thermoplastic pipe.

5.1.2 To evaluate the manufactured consistency of pipe wall cross-section thickness distribution.

6. APPARATUS

6.1 *Testing Machine*—A properly calibrated compression testing machine of the constant-rate-of-crosshead-movement type meeting the requirements of ASTM D 695 shall be used to conduct the test. The rate of head approach shall be 0.05 ± 0.01 in./min (1.27 ± 0.25 mm/min). The testing machine shall be capable of compressing the sample to its capacity. The testing machine shall monitor the applied load to accuracy of ±25 lb (110 N).

6.2 *Loading Plates*—The load shall be applied to the specimen through two parallel steel bearing plates. The plates shall be flat, smooth, and clean. The thickness of the plates shall be sufficient so that no bending or deformation occurs during the test, but shall not be less than 0.25 in. (6.0 mm). The plate length shall equal or exceed the specimen longitudinal length, and the plate width shall not be less than the profile height plus 6.0 in. (150 mm).

6.3 *Deflection Indicator*—The crosshead displacement shall be measured with a suitable instrument meeting the requirements of ASTM D 695, except that the instrument shall be accurate to 0.001 in. (0.025 mm).

Note 1—Monitoring crosshead motion of the test machine is an acceptable method of recording deflection; however, the test machine flexibility may result in apparent deflection in addition to the specimen deflection. This must be accounted for if the deflection data are used to evaluate strain at maximum load.

7. SAMPLING, TEST SPECIMENS, AND TEST UNITS

7.1 The test specimen shall be a wall section cut from a finished pipe product.

7.2 The specimen longitudinal length shall be three periods.

7.3 The specimen chord (circumferential) length shall be 1.5 times the profile height with tolerance of $^1/_4$ in.

7.4 Specimen ends shall be cut flat and parallel to each other and to the radial line through the center of the sample. The cut ends are not radial.

Note 2—The most important aspect of specimen preparation is cutting the ends to planar parallel surfaces. This is complicated by the thin flexible elements of many profile wall pipe. Guidance for specimen preparation is provided in Annex A.

8. CONDITIONING

8.1 Condition pipe for at least 4 hours in air, at a temperature of 73.4 ± 3.6ºF (23 ± 2ºC), and conduct the test in a room maintained at the same temperature.

9. PROCEDURE

9.1 Record the pipe nominal diameter, pipe model/classification, profile type, manufacturer, conditioning temperature, and date of test.

9.2 *Make and record the following measurements for each specimen*:

9.2.1 Determine the longitudinal length of each specimen to the nearest $^1/_{16}$ in. (1.5 mm) by making and averaging three measurements equally spaced over the chord length.

9.2.2 Determine the chord length of each specimen to the nearest $^1/_{16}$ in. (1.5 mm) by making and averaging three measurements equally spaced along the longitudinal length.

9.2.3 Determine the profile height of each specimen to the nearest $^1/_{16}$ in. (1.5 mm) by making and averaging three measurements equally spaced along the longitudinal length.

9.3 Place the specimen on the lower plate, centering the specimen under the testing machine crosshead vertical axis, as illustrated in Figure 2.

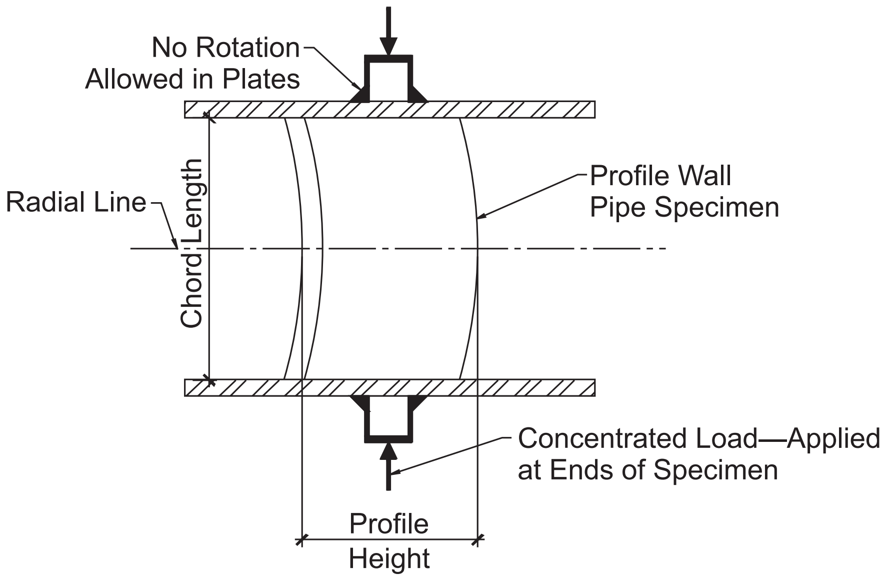

Figure 2—Stub Compression Test Setup

9.4 With the displacement indicator in place, bring the upper plate into contact with the specimen with no more than 50-lb (220-N) seating force.

9.5 Compress the sample at a constant rate of 0.05 ± 0.01 in./min (1.27 ± 0.25 mm/min).

9.6 Record the load, displacement, and time measurements continuously or intermittently with reference to the relative movement of the bearing plates. If measurements are made intermittently, make and record such measurements at increments of not more than 1 percent of the original specimen chord length.

9.7 Note the ultimate load carried by the sample.

9.8 Discontinue the test when the load on the specimen fails to increase with increasing deflection.

10. CALCULATION OR INTERPRETATION OF RESULTS

10.1 Calculate the ultimate compressive load capacity per unit length of pipe wall as the ultimate load (lb) divided by the average longitudinal length (in.).

11. REPORT

11.1 *Report the following information*:

11.1.1 Agency conducting test.

11.1.2 Date of test.

11.1.3 Complete identification of the material tested, including type, source, manufacturer's code, previous history (if any), product identification by standard number, and pipe nominal diameter.

11.1.4 Specimen dimensions, including longitudinal length, chord length, and profile height.

11.1.5 Conditioning temperature, time, and environment.

11.1.6 The ultimate load carried by the specimen.

11.1.7 The ultimate compressive load capacity of the pipe wall.

11.1.8 The average load rate throughout the test duration.

12. PRECISION AND BIAS

12.1 *Precision*—An interlaboratory study of stub-compression-test ultimate loads was conducted with six laboratories participating. The pipe samples were 24A = 24-in. high density polyethylene (HDPE) corrugated pipe, 24C = 24-in. HDPE corrugated pipe, 24D = 24-in. polyvinylchloride (PVC) ribbed pipe, 42B = 42-in. HDPE corrugated pipe, and 42C = 42-in. HDPE corrugated pipe. Information regarding the precision is found in Table 1.

Table 1—Stub Compression Test—Precision Statistics[a]

Material	Sample	Average	s_{mean}	s_r[b]	s_R[c]	r	R	Standard Deviation of Averages[d]	Repeat-ability Standard Deviation[d]	Reproduci-bility Standard Deviation[d]	Repeat-ability Limit (95%)[d]	Reproduci-bility Limit (95%)[d]
HDPE	24A	726	59.1	56.6	49.1	111	96	8.1	7.8	6.8	15.3	13.3
HDPE	24C	891	76.1	70.8	60.9	139	119	8.5	7.9	6.8	15.6	13.4
PVC	24D	1991	118.6	84.9	122.5	166	240	6.0	4.3	6.2	8.4	12.1
HDPE	42B	952	68.8	55.5	59.4	109	116	7.2	5.8	6.2	11.4	12.2
HDPE	42C	998	80.5	65.1	60.9	128	119	8.1	6.5	6.1	12.8	12.0

[a] Terms are as specified in ASTM E 177.

[b] s_r = standard deviation of repeatability (variation of replicate samples by the same laboratory).

[c] s_R = standard deviation of reproducibility (variation between laboratories).

[d] Precision statistics as percent of average.

13. KEYWORDS

13.1 Compression; local buckle; stub compression; thermoplastic pipe.

ANNEX

(Mandatory Information)

A1. SPECIMEN PREPARATION

A1.1. This annex provides a detailed procedure for preparing specimens for the stub compression test. Test specimens must be carefully prepared and have square, parallel faces equidistant from the radial line at the center of the specimen. Specimens are composed of thin elements and are very flexible; therefore, clamping and care are required to produce parallel ends for loading between the parallel plates. Suggested tools are those found to work best during the research to develop this standard. Other labs may use different procedures or equipment. Precise specimen preparation is critical to obtaining repeatable and reproducible test results.

A1.2. *A suggested specimen cutting procedure follows*:

A1.2.1. Rough cut specimens from the pipe to a chord length approximately 2 in. longer than the final chord length of 1.5 times the corrugation depth using a reciprocating saw or circular saw (Figure A1.1).

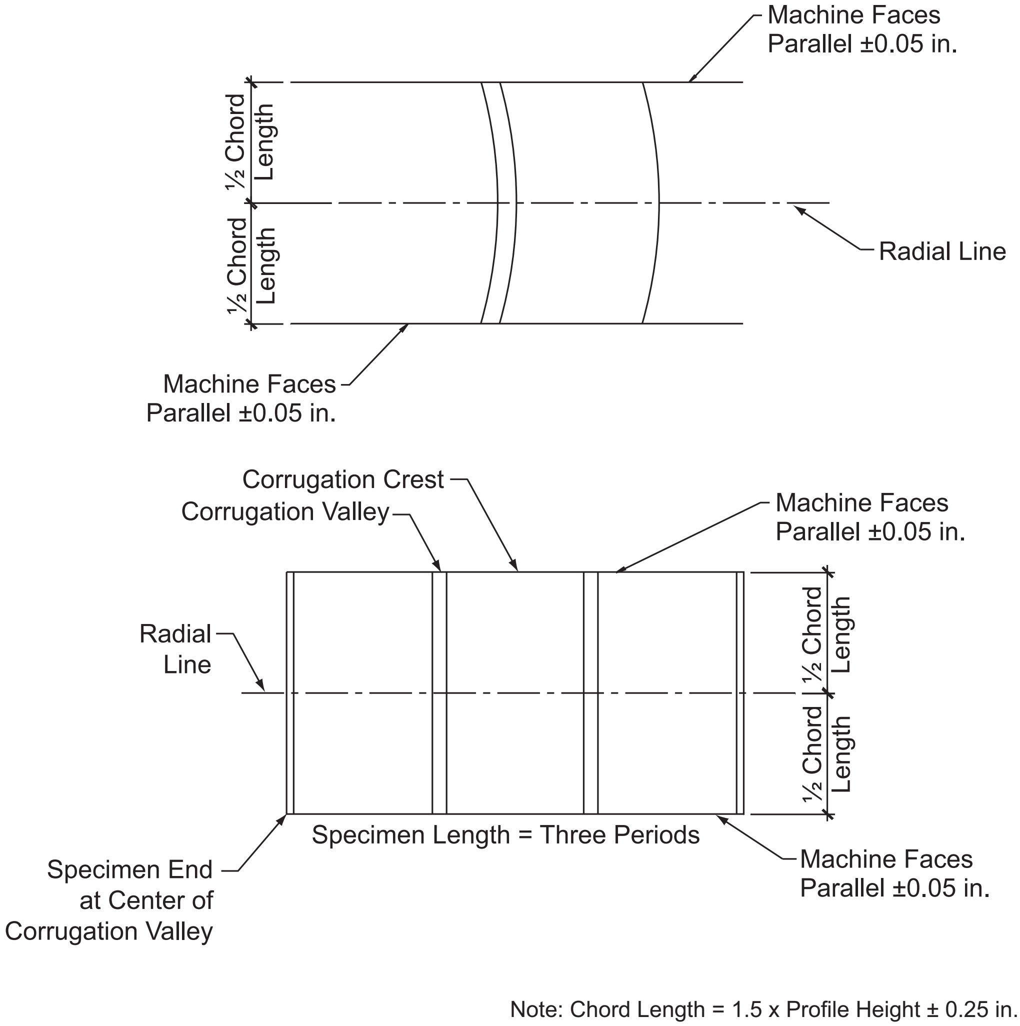

Figure A1.1—Specimen Dimensions

A1.2.2. Square the longitudinal ends to be parallel to the circumference of the pipe. Use a milling machine or belt sander to ensure the ends are square, and evaluate with a carpenter's square (Figure A1.2).

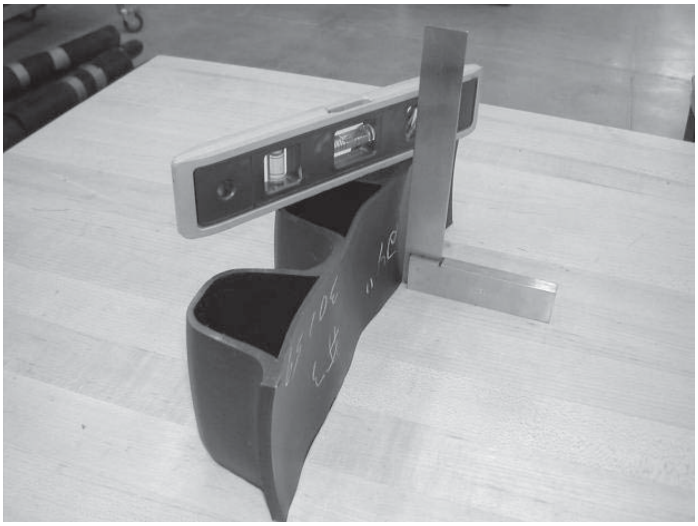

Figure A1.2—Evaluate the Ends of Milled Specimen with a Carpenter's Square

A1.2.3. Cut the circumferential ends of each specimen square and parallel with a milling machine. Clamp the test specimen to the table of the milling machine, supporting it at the center of the entire chord length. The sample must be clamped down firmly enough that it does not move during the milling process, but not so firmly that its shape is warped from the clamping pressure.

A1.2.4. To ensure a square cut, alternate milling each side of the specimen until the chord length is within the specified tolerance of 1.5 times the profile height, and the longitudinal faces are parallel to and equidistant from a radial passing through the center of the pipe and the midheight of the specimen.

A1.2.5. Place the specimen on a flat, level surface to check that the ends are plane, parallel, and square. Place a 6-in. level on the specimen in several locations to check that ends are plane along the specimen length and across the corrugation depth. Use a carpenter's square to check that the specimen center is parallel with a radial line from the center of the pipe from which the specimen was removed. Flip the specimen so that the opposing end is flat against the table, and repeat these checks.

A1.2.6. If necessary, make small adjustments to the ends of the sample using a belt sander. Following any adjustments, repeat checks for plane, parallel, and square ends described in the previous step.

Standard Method of Test for

Sampling and Testing Brick

AASHTO Designation: T 32-10
ASTM Designation: C 67-09

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling and Testing Brick

AASHTO Designation: T 32-10
ASTM Designation: C 67-09

AASHTO T 32-10 is based on ASTM C 67-09, but contains only such portions of C 67 as are required for testing brick for conformance to AASHTO M 91 and M 114. Sections of C 67 that do not pertain to testing brick have not been adopted by AASHTO. All references to ASTM C 150 shall be replaced with AASHTO M 85.

Standard Method of Test for

Compressive Strength of Cylindrical Concrete Specimens

AASHTO Designation: T 22-10[1]
ASTM Designation: C 39/C 39M-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Compressive Strength of Cylindrical Concrete Specimens

AASHTO Designation: T 22-10[1]
ASTM Designation: C 39/C 39M-05

1. SCOPE

1.1 This test method covers determination of compressive strength of cylindrical concrete specimens such as molded cylinders and drilled cores. It is limited to concrete having a unit weight in excess of 800 kg/m^3 (50 lb/ft^3).

1.2 The values stated in SI units are the preferred standard.

1.3 *This standard may involve hazardous materials, operations, or equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Means should be provided to contain concrete fragments during sudden rupture of specimens. Tendency for sudden rupture increases with increasing concrete strength (Note 1).

Note 1—The safety precautions given in the *Manual of Aggregate and Concrete Testing*, located in the Related Materials section of Volume 04.02 of the *Annual Book of ASTM Standards*, are recommended.

1.4 The text of this standard references notes that provide explanatory material. These notes shall not be considered as requirements of the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field

3. SUMMARY OF TEST METHOD

3.1 This test method consists of applying a compressive axial load to molded cylinders or cores at a rate that is within a prescribed range until failure occurs. The compressive strength of the specimen is calculated by dividing the maximum load attained during the test by the cross-sectional area of the specimen.

4. SIGNIFICANCE AND USE

4.1 Care must be exercised in the interpretation of the significance of compressive strength determinations by this test method because strength is not a fundamental or intrinsic property of concrete made from given materials. Values obtained will depend on the size and shape of the specimen, batching, mixing procedures, the methods of sampling, molding, and fabrication, and the age, temperature, and moisture conditions during curing.

4.2 This test method may be used to determine compressive strength of cylindrical specimens prepared and cured in accordance with R 39, T 23, T 24M/T 24, T 231, and ASTM C 873.

4.3 The results of this test method may be used as a basis for quality control of concrete proportioning, mixing, and placing operations; determination of compliance with specification; and control for evaluating effectiveness of admixtures and similar uses.

5. APPARATUS

5.1 *Testing Machine*—The testing machine shall be of a type having sufficient capacity and capable of providing the rates of loading prescribed in Section 7.5.

5.1.1 Verify calibration of the testing machines in accordance with ASTM E 4, except that the verified loading range shall be as required in Section 5.3. Verification is required under the following conditions:

5.1.1.1 At least annually, but not to exceed 13 months;

5.1.1.2 On original installation or immediately after relocation;

5.1.1.3 Immediately after making repairs or adjustments that affect the operation of the force applying system or the values displayed on the load indicating system, except for zero adjustments that compensate for the mass (weight) of tooling, or specimen, or both; or

5.1.1.4 Whenever there is reason to suspect the accuracy of the indicated loads.

5.1.2 *Design*—The design of the machine must include the following features:

5.1.2.1 The machine must be power-operated and must apply the load continuously rather than intermittently, and without shock. If it has only one loading rate (meeting the requirements of Section 7.5), it must be provided with a supplemental means for loading at a rate suitable for verification. This supplemental means of loading may be power or hand-operated.

5.1.2.2 The space provided for test specimens shall be large enough to accommodate, in a readable position, an elastic calibration device that is of sufficient capacity to cover the potential loading range of the testing machine and that complies with the requirement of ASTM E 74.

Note 2—The types of elastic calibration devices most generally available and most commonly used for this purpose are the circular proving rings or load cells.

5.1.3 *Accuracy*—The accuracy of the testing machine shall be in accordance with the following provisions:

5.1.3.1 The percentage of error for the loads within the proposed range of use of the testing machine shall not exceed ±1.0 percent of the indicated load.

5.1.3.2 The accuracy of the testing machine shall be verified by applying five test loads in four approximately equal increments in ascending order. The difference between any two successive test loads shall not exceed one-third of the difference between the maximum and minimum test loads.

5.1.3.3 The test load as indicated by the testing machine and the applied load computed from the readings of the verification device shall be recorded at each test point. Calculate the error, E, and the percentage of error, E_p, for each point from these data as follows:

$$E = A - B \tag{1}$$

$$E_p = 100\,(A - B)/B \tag{2}$$

where:

A = load, kN (or lbf) indicated by the machine being verified; and

B = applied load, kN (or lbf) as determined by the calibrating device.

5.1.3.4 The report on the verification of a testing machine shall state within what loading range it was found to conform to specification requirements rather than reporting a blanket acceptance or rejection. In no case shall the loading range be stated as including loads below the value that is 100 times the smallest change of load that can be estimated on the load-indicating mechanism of the testing machine or loads within that portion of the range below 10 percent of the maximum range capacity.

5.1.3.5 In no case shall the loading range be stated as including loads outside the range of loads applied during the verification test.

5.1.3.6 The indicated load of a testing machine shall not be corrected either by calculation or by the use of a calibration diagram to obtain values within the required permissible variation.

5.2 The testing machine shall be equipped with two steel bearing blocks with hardened faces (Note 3), one of which is a spherically-seated block that will bear on the upper surface of the specimen, and the other a solid block on which the specimen shall rest. Bearing faces of the blocks shall have a minimum dimension at least 3 percent greater than the diameter of the specimen to be tested. Except for the concentric circles described below, the bearing faces shall not depart from a plane by more than 0.02 mm (0.001 in.) in any 150 mm (6 in.) of blocks 150 mm (6 in.) in diameter or larger, or by more than 0.02 mm (0.001 in.) in the diameter of any smaller block; and new blocks shall be manufactured within one-half of this tolerance. When the diameter of the bearing face of the spherically seated block exceeds the diameter of the specimen by more than 13 mm (0.5 in.), concentric circles not more than 0.8 mm (0.03 in.) deep and not more than 1 mm (0.04 in.) wide shall be inscribed to facilitate proper centering.

Note 3—It is desirable that the bearing faces of blocks used for compression testing of concrete have a Rockwell hardness of not less than 55 HRC.

5.2.1 Bottom bearing blocks shall conform to the following requirements:

5.2.1.1 The bottom bearing block is specified for the purpose of providing a readily machinable surface for maintenance of the specified surface conditions (Note 4). The top and bottom surfaces shall be parallel to each other. Its least horizontal dimension shall be at least 3 percent greater than the diameter of the specimen to be tested. Concentric circles as described in Section 5.2 are optional on the bottom block.

Note 4—The block may be fastened to the platen of the testing machine.

5.2.1.2 Final centering must be made with reference to the upper spherical block when the lower bearing block is used to assist in centering the specimen. The center of the concentric rings, when provided, or the center of the block itself must be directly below the center of the spherical head. Provision shall be made on the platen of the machine to assure such a position.

5.2.1.3 The bottom bearing block shall be at least 25 mm (1 in.) thick when new and at least 22.5 mm (0.9 in.) thick after resurfacing operations.

Note 5—If the testing machine is so designed that the platen itself can be readily maintained in the specified surface condition, a bottom block is not required.

5.2.2 The spherically seated bearing block shall conform to the following requirements:

5.2.2.1 The maximum diameter of the bearing face of the suspended spherically seated block shall not exceed the values given below:

Table 1—Maximum Diameter of Bearing Face

Diameter of Test Specimens, mm (in.)	Max Diameter of Bearing Face, mm (in.)
50 (2)	105 (4)
75 (3)	130 (5)
100 (4)	165 (6.5)
150 (6)	255 (10)
200 (8)	280 (11)

Note 6—Square bearing faces are permissible, provided the diameter of the largest possible inscribed circle does not exceed the above diameter.

5.2.2.2 The center of the sphere shall coincide with the surface of the bearing face within a tolerance of ±5 percent of the radius of the sphere. The diameter of the sphere shall be at least 75 percent of the diameter of the specimen to be tested.

5.2.2.3 The ball and the socket shall be designed so that the steel in the contact area does not permanently deform when loaded to the capacity of the test machine.

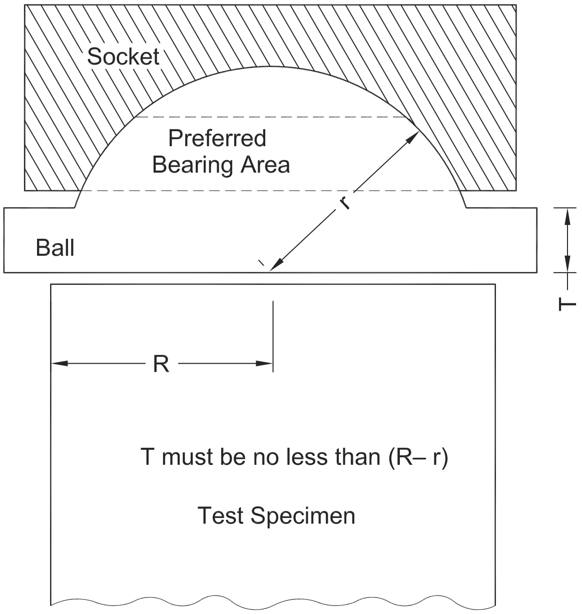
Note 7—The preferred contact area is in the form of a ring (described as "preferred bearing area") as shown in Figure 1.

5.2.2.4 The curved surfaces of the socket and the spherical portion shall be kept clean and shall be lubricated with a petroleum-type oil such as conventional motor oil, not with a pressure-type grease. After contacting the specimen and application of a small initial load, further tilting of the spherically seated block is not intended and is undesirable.

5.2.2.5 If the radius of the sphere is smaller than the radius of the largest specimen to be tested, the portion of the bearing face extending beyond the sphere shall have a thickness not less than the difference between the radius of the sphere and radius of the specimen. The least dimension of the bearing face shall be at least as great as the diameter of the sphere. (See Figure 1.)

5.2.2.6 The movable portion of the bearing block shall be held closely in the spherical seal, but the design shall be such that the bearing face can be rotated freely and tilted at least 4 degrees in any direction.

5.2.2.7 If the ball portion of the upper bearing block is a two-piece design composed of a spherical portion and a bearing plate, a mechanical means shall be provided to ensure that the spherical portion is fixed and centered on the bearing plate.



Note: Provision shall be made for holding the ball in the socket and for holding the entire unit in the testing machine.

Figure 1—Schematic Sketch of a Typical Spherical Bearing Block

5.3 *Load Indication*:

5.3.1 If the load of a compression machine used in concrete tests is registered on a dial, the dial shall be provided with a graduated scale that can be read to at least the nearest 0.1 percent of the full scale load (Note 8). The dial shall be readable within 1 percent of the indicated load at any given load level within the loading range. In no case shall the loading range of a dial be considered to include loads below the value that is 100 times the smallest change of load that can be read on the scale. The scale shall be provided with a graduation line equal to zero and so numbered. The dial pointer shall be of sufficient length to reach the graduation marks; the width of the end of the pointer shall not exceed the clear distance between the smallest graduations. Each dial shall be equipped with a zero adjustment located outside the dial case and easily accessible from the front of the machine while observing the zero mark and dial pointer. Each dial shall be equipped with a suitable device that at all times, until reset, will indicate to within 1 percent accuracy the maximum load applied to the specimen.

Note 8—As close as can reasonably be read is considered to be 0.5 mm (0.02 in.) along the arc described by the end of the pointer. Also, one-half of the scale interval is about as close as can reasonably be read when the spacing on the load-indicating mechanism is between 1 mm (0.04 in.) and 2 mm (0.06 in.). When the spacing is between 2 mm and 3 mm (0.06 in. and 0.12 in.), one-third of a scale interval can be read with reasonable certainty. When the spacing is 3 mm (0.12 in.) or more, one-fourth of a scale interval can be read with reasonable certainty.

5.3.2 If the testing machine load is indicated in digital form, the numerical display must be large enough to be easily read. The numerical increment must be equal to or less than 0.10 percent of the full-scale load of a given loading range. In no case shall the verified loading range include loads less than the minimum numerical increment multiplied by 100. The accuracy of the indicated load must be within 1.0 percent for any value displayed within the verified loading range. Provision must be made for adjusting to indicate true zero at zero load. There shall be provided a maximum load indicator that at all times until reset will indicate within 1.0 percent system accuracy the maximum load applied to the specimen.

5.4 Provide a means for containing fragments in the event of explosive rupture of the cylinders during testing.

6. SPECIMENS

6.1 Specimens shall not be tested if any individual diameter of a cylinder differs from any other diameter of the same cylinder by more than 2 percent (Note 9).

Note 9—This may occur when single-use molds are damaged or deformed during shipment, when flexible single-use molds are deformed during molding, or when a core drill deflects or shifts during drilling.

6.2 Neither end of compressive test specimens when tested shall depart from perpendicularity to the axis by more than 0.5 degrees (approximately equivalent to 3 mm in 300 mm (0.12 in. in 12 in.)). The ends of compression test specimens that are not plane within 0.050 mm (0.002 in.) shall be sawed or ground to meet that tolerance or capped in accordance with either T 231 or, when permitted, ASTM C 1231. The diameter used for calculating the cross-sectional area of the test specimen shall be determined to the nearest 0.25 mm (0.01 in.) by averaging two diameters measured at right angles to each other at about mid-height of the specimen.

6.3 The number of individual cylinders measured for determination of average diameter may be reduced to one for each ten specimens or three specimens per day, whichever is greater, if all cylinders are known to have been made from a single lot of reusable or single-use molds which consistently produce specimens with average diameters within a range of 0.5 mm (0.02 in.). When the average diameters do not fall within the range 0.5 mm (0.02 in.) or when the cylinders are not made from a single lot of molds, each cylinder tested must be measured and the value used in calculation of the unit compressive strength of that specimen. When the diameters are measured at the reduced frequency, the cross-sectional areas of all cylinders tested on that day shall be computed from the average of the diameters of the three or more cylinders representing the group tested that day.

6.4 If the purchaser of the testing services requests measurement of density of the test specimen, determine the mass of the specimen before capping. Remove any surface moisture with a towel and measure the mass of the specimen using a balance or scale that is accurate to within 0.3 percent of the mass being measured. Measure the length of the specimen to the nearest 1 mm (0.05 in.) at three locations spaced evenly around the circumference. Compute the average length and record to the nearest 1 mm (0.05 in.). Alternatively, determine the cylinder density by weighing the cylinder in air and then submerged under water at 23.0 ± 2.0°C (73.5 ± 3.5°F), and computing the volume according to Section 8.3.1.

6.5 When density determination is not required and the length to diameter ratio is less than 1.8 or more than 2.2, measure the length of the specimen to the nearest 0.05 *D*.

7. PROCEDURE

7.1 Compression tests of moist-cured specimens shall be made as soon as practicable after removal from moist storage.

7.2 Test specimens shall be kept moist by any convenient method during the period between removal from moist storage and testing. They shall be tested in the moist condition.

7.3 All test specimens for a given test age shall be broken within the permissible time tolerances prescribed as follows:

Table 2—Permissible Time Tolerances

Test Age	Permissible Tolerance
12 h	±0.25 h or 2.1 percent
24 h	±0.5 h or 2.1 percent
3 days	2 h or 2.8 percent
7 days	6 h or 3.6 percent
28 days	20 h or 3.0 percent
56 days	40 h or 3.0 percent
90 days	2 days or 2.2 percent

7.4 *Placing the Specimen*—Place the plain (lower) bearing block, with its hardened face up, on the table or platen of the testing machine directly under the spherically-seated (upper) bearing block. Wipe clean the bearing faces of the upper- and lower-bearing blocks and of the test specimen and place the test specimen on the lower bearing block.

7.4.1 *Zero Verification and Block Seating*—Prior to testing the specimen, verify that the load indicator is set to zero. In cases where the indicator is not properly set to zero, adjust the indicator (Note 10). As the spherically-seated block is brought to bear on the specimen, rotate its movable portion gently by hand so that uniform seating is obtained.

Note 10—The technique used to verify and adjust the load indicator to zero will vary depending on the machine manufacturer. Consult your owner's manual or compression machine calibrator for the proper technique.

7.5 *Rate of Loading*—Apply the load continuously and without shock, except as permitted by ASTM C 1231/C 1231M.

7.5.1 The load shall be applied at a rate of movement (platen to crosshead measurement) corresponding to a stress rate on the specimen of 0.25 ± 0.05 MPa/s (35 ± 7 psi/s) (Note 11). The designated rate of movement shall be maintained at least during the latter half of the anticipated loading phase.

Note 11—For a screw driven or displacement-controlled testing machine, preliminary testing will be necessary to establish the required rate of movement to achieve the specified stress rate. The required rate of movement will depend on the size of the test specimen, the elastic modulus of the concrete, and the stiffness of the testing machine.

7.5.2 During application of the first half of the anticipated loading phase, a higher rate of loading shall be permitted. Apply the higher loading rate in a controlled manner so the specimen is not subjected to shock loading.

7.5.3 Do not adjust the rate of movement (platen to crosshead) as the ultimate load is being approached and the stress rate decreases due to cracking in the specimen.

7.6 Apply the compressive load until the load indicator shows that the load is decreasing steadily and the specimen displays a well-defined fracture pattern (Figure 2). For a testing machine equipped with a specimen break detector, automatic shut-off of the testing machine is prohibited until the load has dropped to a value that is less than 95 percent of the peak load. When testing with unbonded caps, a corner fracture may occur before the ultimate capacity of the specimen has been attained. Continue compressing the specimen until the user is certain that the ultimate capacity has been attained. Record the maximum load carried by the specimen during the test, and note the type of fracture pattern according to Figure 2. If the fracture pattern is not one of the typical patterns shown in Figure 2, sketch and describe briefly the fracture pattern. If the measured strength is lower than expected, examine the fractured concrete and note the presence of large air voids, evidence of segregation, whether fractures pass predominantly around or through the coarse aggregate particles, and verify end preparations were in accordance with T 231 or ASTM C 1231/C 1231M.

8. CALCULATION

8.1 Calculate the compressive strength of the specimen by dividing the maximum load carried by the specimen during the test by the average cross-sectional area determined as described in Section 6 and express the result to the nearest 0.1 MPa (10 psi).

8.2 If the specimen length-to-diameter (*L*/*D*) ratio is 1.75 or less, correct the result obtained in Section 8.1 by multiplying the appropriate correction factor shown in the following table (Note 12):

L/*D* ratio:	1.75	1.50	1.25	1.00
Factor:	0.98	0.96	0.93	0.87

Use interpolation to determine correction factors for *L*/*D* values between those given in the table.

Note 12—Correction factors depend on various conditions such as moisture condition, strength level, and elastic modulus. Average values are given in the table. These correction factors apply to lightweight concrete weighing between 1,600 and 1,920 kg/m^3 (100 and 120 lb/ft^3) and to normal weight concrete. They are applicable to concrete dry or soaked at the time of loading and for nominal concrete strengths from 15 to 45 MPa (2000 to 6000 psi). For strengths higher than 45 MPa (6000 psi) correction factors may be larger than the values listed above.[2]

8.3 When required, calculate the density of the specimen to the nearest 10 kg/m^3 (1 lb/ft^3) as follows:

$$Density = \frac{W}{V} \qquad (3)$$

where:

W = mass of specimen, kg (lb); and

V = volume of specimen computed from the average diameter and average length or from weighing the cylinder in air and submerged, m^3 (ft^3)

8.3.1 When the volume is determined from submerged weighing, calculate the volume as follows:

$$V = \frac{W - W_s}{\gamma_w} \qquad (4)$$

where:

W_s = apparent mass of submerged specimen, kg (lb); and

γ_w = density of water at 23°C (73.5°F) = 997.5 kg/m^3 (62.27 lb/ft^3).

9. REPORT

9.1 *The report shall include the following*:

9.1.1 Identification number;

9.1.2 Diameter (and length, if outside the range of 1.8D to 2.2D), in inches or millimeters;

9.1.3 Cross-sectional area, in square inches or square centimeters;

9.1.4 Maximum load, in pounds-force or kilonewtons;

9.1.5 Compressive strength calculated to the nearest 0.1 MPa (10 psi);

9.1.6 Type of fracture, if other than the usual cone (see Figure 2);

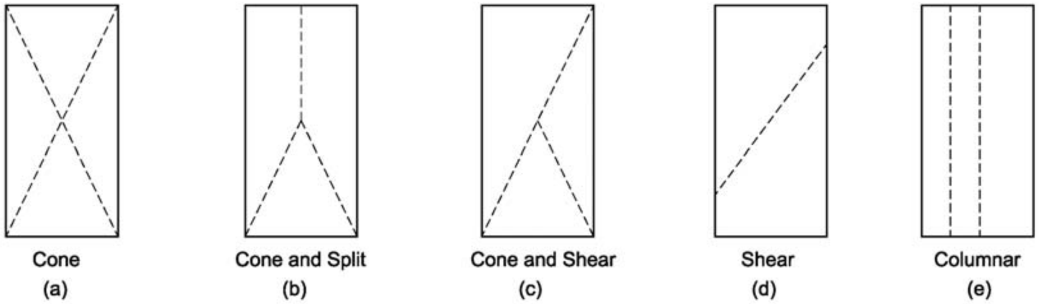


Figure 2—Sketches of Types of Fracture

9.1.7 Defects in either specimen or caps; and

9.1.8 Age of specimen.

9.1.9 When determined, record the density to the nearest 10 kg/m^3 (1 lb/ft^3).

10. PRECISION AND BIAS

10.1 *Precision*:

10.1.1 *Within-Test Precision*—The following table provides the within-test precision of tests of 150 by 300 mm (6 by 12 in.) and 100 by 200 mm (4 by 8 in.) cylinders made from a well-mixed sample of concrete under laboratory conditions and under field conditions (see Section 10.1.2):

	Coefficient of Variation[a]	Acceptable Range[a] of Individual Cylinder Strengths	
150 × 300 mm (6 × 12 in.)		2 cylinders	3 cylinders
Laboratory conditions	2.4 %	6.6 %	7.8 %
Field conditions	2.9 %	8.0 %	9.5 %
100 × 200 mm (4 × 8 in.)			
Laboratory conditions	3.2%	9.0%	10.6%

[a] These numbers represent respectively the (1s) and (d2s) limits as described in ASTM C 670.

10.1.2 The within-test coefficient of variation represents the expected variation of measured strength of companion cylinders prepared from the same sample of concrete and tested by one laboratory at the same age. The values given for the within-test coefficient of variation of 150 by 300 mm (6 by 12 in.) cylinders are applicable for compressive strengths between 15 to 55 MPa (2000 and 8000 psi) and those for 100 by 200 mm (4 by 8 in.) cylinders are applicable for compressive strengths between 17 to 32 MPa (2500 and 4700 psi.) The within-test coefficients of variation for 150 by 300 mm (6 by 12 in.) cylinders are derived from CCRL concrete proficiency sample data for laboratory conditions and a collection of 1265 test reports from 225 commercial testing laboratories in 1978 (ASTM Research Report RR: C09-1006).[3] The within-test coefficient of variation of 100 by 200 mm (4 by 8 in.) cylinders are derived from CCRL concrete proficiency sample data for laboratory conditions (ASTM Research Report RR C09-1027).[4]

10.1.3 *Multilaboratory Precision*—The multilaboratory coefficient of variation for compressive strength test results of 150 by 300 mm (6 by 12 in.) cylinders has been found to be 5.0 percent; therefore, the results of properly conducted tests by two laboratories on specimens prepared from the same sample of concrete are not expected to differ by more than 14 percent of the average (see Note 13). A strength test result is the average of two cylinders tested at the same age.

Note 13—The multilaboratory precision does not include variations associated with different operators preparing test specimens from split or independent samples of concrete. These variations are expected to increase the multilaboratory coefficient of variation.

10.1.4 The multilaboratory data were obtained from six separate organized strength testing round-robin programs where 150 by 300 mm (6 by 12 in.) cylindrical specimens were prepared at a single location and tested by different laboratories. The range of average strength from these programs was 17.0 to 90 MPa (2500 to 13000 psi).

Note 14—ASTM Subcommittee C09.61 will continue to examine recent concrete proficiency sample data and field test data and make revisions to precision statements when data indicate that they can be extended to cover a wider range of strengths and specimen sizes.

10.2 *Bias*—Since there is no accepted reference material, no statement on bias is being made.

---

[1] This method agrees technically with C 39/C 39M-05 except for the use of SI units, and C 39 provides qualification restrictions for concrete laboratory technicians performing acceptance tests.

Standard Method of Test for

Making and Curing Concrete Test Specimens in the Field

AASHTO Designation: T 23-08[1]
ASTM Designation: C 31-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Making and Curing Concrete Test Specimens in the Field

AASHTO Designation: T 23-08[1]
ASTM Designation: C 31-06

1. SCOPE

1.1. This method covers procedures for making and curing cylinder and beam specimens from representative samples of fresh concrete for a construction project.

1.2. The concrete used to make the molded specimens shall be sampled after all on-site adjustments have been made to the mixture proportions, including the addition of mix water and admixtures. This practice is not satisfactory for making specimens from concrete not having measurable slump or requiring other sizes or shapes of specimens.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to exposed skin and tissue upon prolonged exposure.

3. TERMINOLOGY

3.1. For definitions of terms used in this practice, refer to ASTM C 125.

4. SIGNIFICANCE AND USE

4.1. This method provides standardized requirements for making, curing, protecting, and transporting concrete test specimens under field conditions.

4.2. If the specimens are made and standard cured, as stipulated herein, the resulting strength test data where the specimens are tested are able to be used for the following purposes:

4.2.1. Acceptance testing for specified strength,

4.2.2. Checking the adequacy of mixture proportions for strength,

4.2.3. Quality control.

4.3. If the specimens are made and field cured, as stipulated herein, the resulting strength test data when the specimens are tested are able to be used for the following purposes:

4.3.1. Determination of whether a structure is capable of being put in service,

4.3.2. Comparison with test results of standard cured specimens or with test results from various in-place test methods,

4.3.3. Adequacy of curing and protection of concrete in the structure, or,

4.3.4. Form or shoring removal time requirements.

5. APPARATUS

5.1. *Molds, General*—Molds for specimens or fastenings thereto in contact with the concrete shall be made of steel, cast iron, or other nonabsorbent material, nonreactive with concrete containing portland or other hydraulic cements. Molds shall hold their dimensions and shape under conditions of use. Molds shall be watertight during use as judged by their ability to hold water poured into them. Provisions for tests of watertightness are given in M 205M/M 205. A suitable sealant, such as heavy grease, modeling clay, or microcrystalline wax shall be used where necessary to prevent leakage through the joints. Positive means shall be provided to hold base plates firmly to the molds. Reusable molds shall be lightly coated with mineral oil or a suitable nonreactive form release material before use.

5.2. *Cylinder*—Molds for casting concrete test specimens shall conform to the requirements of M 205M/M 205.

5.3. *Beam Molds*—Beam molds shall be of the shape and dimensions required to produce the specimens stipulated in Section 6.2. The inside surfaces of the molds shall be smooth. The sides, bottom, and ends shall be at right angles to each other and shall be straight and true and free of warpage. Maximum variation from the nominal cross section shall not exceed 3.2 mm ($^1/_8$ in.) for molds with depth or breadth of 152 mm (6 in.) or more. Molds shall produce specimens not more than 1.6 mm ($^1/_{16}$ in.) shorter than the required length in accordance with Section 5.2, but may exceed it by more than that amount.

5.4. *Tamping Rods*—Two sizes are specified as indicated in Table 1. Each shall be a round, straight steel rod with at least the tamping end rounded to a hemispherical tip of the same diameter as the rod. Both ends may be rounded if preferred.

Table 1—Tamping Rod Requirements

	Rod Dimensions[a]	
Diameter of Cylinder or Width of Beam, mm (in.)	Diameter, mm (in.)	Length of Rod, mm (in.)
<150 (6)	10 ($^3/_8$)	300 (12)
150 (6)	16 ($^5/_8$)	500 (20)
225 (9)	16 ($^5/_8$)	650 (26)

[a] Rod tolerances length ±100 mm (4 in.) and diameter ±2 mm ($^1/_{16}$ in.).

5.5. *Vibrators*—Internal vibrators shall be used. The vibrator frequency shall be at least 7000 vibrations per minute (150 Hz) while the vibrator is operating in the concrete. The diameter of a round vibrator shall be no more than one-fourth the diameter of the cylinder mold or one-fourth the width of the beam mold. Other shaped vibrators shall have a perimeter equivalent to the circumference of an appropriate round vibrator. The combined length of the vibrator shaft and vibrating element shall exceed the depth of the section being vibrated by at least 75 mm (3 in.). The vibrator frequency shall be checked periodically.

Note 1—For information on size and frequency of various vibrators and a method to periodically check vibrator frequency, see ACI 309R.

5.6. *Mallet*—A mallet with a rubber or rawhide head weighing 0.57 ± 0.23 kg (1.25 ± 0.50 lb) shall be used.

5.7. *Small Tools*—Tools and items that may be required are shovels, pails, trowels, wood float, metal float, blunted trowels, straightedge, feeler gauge, scoops, and rules.

5.8. *Slump Apparatus*—The apparatus for measurement of slump shall conform to the requirements of T 119M/T 119.

5.9. *Sampling and Mixing Receptacle*—The receptacle shall be a suitable heavy gauge metal pan, wheelbarrow, or flat, clean, nonabsorbent mixing board of sufficient capacity to allow easy remixing of the entire sample with a shovel or trowel.

5.10. *Air Content Apparatus*—The apparatus for measuring air content shall conform to the requirements of T 196M/T 196 or T 152.

5.11. *Temperature Measuring Devices*—The temperature measuring devices shall conform to the applicable requirements of T 309M/T 309.

6. TEST SPECIMENS

6.1. *Compressive Strength Specimens*—Compressive strength specimens shall be cylinders cast and allowed to set in an upright position. The length shall be twice the diameter. The cylinder diameter shall be at least three times the nominal maximum size of the coarse aggregate. When the nominal maximum size of the coarse aggregate exceeds 50 mm (2 in.), the concrete sample shall be treated by wet sieving through a 50-mm (2-in.) sieve as described in T 141. When the nominal maximum size of the coarse aggregate does not exceed 25.0 mm (1 in.), the specimens may be 100 by 200 mm (4 by 8 in.) cylinders.

Note 2—When molds in SI units are required and not available, equivalent inch–pound unit size molds should be permitted.

6.2. *Flexural Strength Specimens*—Flexural strength specimens shall be beams of concrete cast and hardened with long axes horizontal. The length shall be at least 50 mm (2 in.) greater than three times the depth as tested. The ratio of width to depth as molded shall not exceed 1.5. The standard beam shall be 152 by 152 mm (6 by 6 in.) in cross section, and shall be used for concrete with maximum size coarse aggregate up to 50 mm (2 in.) When the nominal maximum size of the coarse aggregate exceeds (50 mm) 2 in., the smaller cross-sectional dimension of the beam shall be at least three times the nominal maximum size of the coarse aggregate. Unless required by project specifications, beams made in the field shall not have a width or depth of less than 6 in.

7. SAMPLING CONCRETE

7.1. The samples used to fabricate test specimens under this standard shall be obtained in accordance with T 141 unless an alternative procedure has been approved.

7.2. Record the identification of the sample with respect to the location of the concrete represented and the time of casting.

8. SLUMP, AIR CONTENT, AND TEMPERATURE

8.1. *Slump*—Measure and record the slump of each batch of concrete, from which specimens are made, immediately after remixing in the receptacle as required in T 119.

8.2. *Air Content*—Determine and record the air content in accordance with either T 152 or T 196M/T 196. The concrete used in performing the air content test shall not be used in fabricating test specimens.

8.3. *Temperature*—Determine and record the temperature in accordance with T 309M/T 309.

Note 3—Some specifications may require the measurement of the unit weight of concrete. The volume of concrete produced per batch may be desired on some projects. Also, additional information on the air content measurements may be desired. Test Method T 121M/T 121 is used to measure the unit weight, yield, and gravimetric air content of freshly mixed concrete.

9. MOLDING SPECIMENS

9.1. *Place of Molding*—Mold specimens promptly on a level, rigid, horizontal surface, free from vibration and other disturbances, at a place as near as practicable to the location where they are to be stored.

9.2. *Casting the Concrete*—Place the concrete in the molds using a scoop, blunted trowel, or shovel. Select each scoopful, trowelful, or shovelful of concrete from the mixing pan to ensure that it is representative of the batch. Remix the concrete in the mixing pan with a shovel or trowel to prevent segregation during the molding of specimens. Move the scoop, trowel, or shovel around the perimeter of the mold opening when adding concrete so the concrete is uniformly distributed within each layer with a minimum of segregation. In placing the final layer, the operator shall attempt to add an amount of concrete that will exactly fill the mold after compaction. Underfilled molds shall be adjusted with representative concrete during consolidation of the top layer. Overfilled molds shall have excess concrete removed.

9.2.1. *Number of Layers*—Make specimens in layers as indicated in Tables 2 or 3.

Table 2—Molding Requirements by Rodding

Specimen Type and Size	Number of Layers of Approximately Equal Depth	Number of Roddings per Layer
Cylinders:		
Diameter, mm (in.)		
100 (4)	2	25
150 (6)	3	25
225 (9)	4	50
Beams:		
Width, mm (in.)		
150 (6) to 200 (8)	2	See Section 9.3.2
Over 200 (8)	3 or more equal depths, each not to exceed 150 mm (6 in.)	See Section 9.3.2

Table 3—Molding Requirements by Vibration

Specimen Type and Size	Number of Layers	Number of Vibrator Insertions per Layer	Approximate Depth of Layer, mm (in.)
Cylinders:			
Diameter, mm (in.)			
100 (4)	2	1	one-half depth of specimen
150 (6)	2	2	one-half depth of specimen
225 (9)	2	4	one-half depth of specimen
Beams:			
Width, mm (in.)			
150 (6) to 200 (8)	1	See Section 9.3.3.2	depth of specimen 200 (8) as near as practicable
over 200 (8)	2 or more	See Section 9.3.3.2	depth of specimen 200 (8) as near as practicable

9.2.2. Select the proper tamping rod from Section 5.4 and Table 1 or the proper vibrator from Section 5.5. If the method of consolidation is rodding, determine molding requirements from Table 2. If the method of consolidation is vibration, determine molding requirements from Table 3.

9.3. *Consolidation*:

9.3.1. *Methods of Consolidation*—Preparation of satisfactory specimens requires different methods of consolidation. The methods of consolidation are rodding and vibration. Base the selection of the method of consolidation on the slump, unless the method is stated in the specifications under which the work is being performed. Rod or vibrate concretes with slump greater than 25 mm (1 in.). Vibrate concretes with slump of less than or equal to 25 mm (1 in.). Concretes of such low water content that they cannot be properly consolidated by the methods described herein, or requiring other sizes and shapes of specimens to represent the product or structure, are not covered by this method. Specimens for such concretes shall be made in accordance with the requirements of R 39 with regard to specimen size and shape and method of consolidation.

9.3.2. *Rodding*—Place the concrete in the mold, in the required number of layers of approximately equal volume. Rod each layer with the rounded end of the rod using the number of roddings specified in Table 2. The number of roddings per layer required for beams is one for each 13 cm^2 (2 in.^2) top surface area of the specimen. Rod the bottom layer throughout its depth. Distribute the strokes uniformly over the cross section of the mold. For each layer, allow the rod to penetrate through the layer being rodded and into the layer below approximately 25 mm (1 in.). After each layer is rodded, tap the outsides of the mold lightly 10 to 15 times with the mallet, to close any holes left by rodding and to release any large air bubbles that may have been trapped. Use an open hand to tap light-gauge single-use molds that are susceptible to damage if tapped with a mallet. After tapping, spade each layer of the concrete along the sides and ends of beam molds with a trowel or other suitable tool.

9.3.3. *Vibration*—Maintain a uniform time period for duration of vibration for the particular kind of concrete, vibrator, and specimen mold involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Usually, sufficient vibration has been applied as soon as the surface of the concrete has become relatively smooth and large air bubbles cease to break through the top surface. Continue vibration only long enough to achieve proper consolidation of the concrete. (See Note 4.) Fill the molds and vibrate in the required number of approximately equal layers. Place all the concrete for each layer in the mold before starting vibration of that layer. Compacting the specimen, insert the vibrator slowly and do not allow it to rest on the bottom or sides of the mold. Slowly withdraw the vibrator so that no large air pockets are left in the specimen. When placing the final layer, avoid overfilling by more than 6 mm ($^1/_4$ in.).

Note 4—Generally, no more than 5 s of vibration should be required for each insertion to adequately consolidate concrete with a slump greater than 75 mm (3 in.). Longer times may be required for lower slump concrete, but the vibration time should rarely have to exceed 10 s per insertion.

9.3.3.1. *Cylinders*—The number of insertions of a vibrator per layer is given in Table 3. When more than one insertion per layer is required, distribute the insertion uniformly within each layer. Allow the vibration to penetrate through the layer being vibrated, and into the layer below, approximately 25 mm (1 in.). After each layer is vibrated, tap the outsides of the mold at least 10 times with the mallet, to close holes left by vibrating and to release entrapped air voids. Use an open hand to tap cardboard and single-use metal molds that are susceptible to damage if tapped with a mallet.

9.3.3.2. *Beam*—Insert the vibrator at intervals not exceeding 150 mm (6 in.) along the center line of the long dimension of the specimen. For specimens wider than 6 in., use alternating insertions along two lines. Allow the shaft of the vibrator to penetrate into the bottom layer approximately 25 mm (1 in.). After each layer is vibrated, tap the outsides of the mold sharply at least 10 times with the mallet, to close any holes left by vibrating and to release entrapped air voids.

9.4. *Finishing*—After consolidation, strike off excess concrete from the surface and float or trowel it as required. Perform all finishing with the minimum manipulation necessary to produce a flat even surface that is level with the rim or edge of the mold and that has no depressions or projections larger than 3.2 mm ($^1/_8$ in.).

9.4.1. *Cylinders*—After consolidation, finish the top surfaces by striking them off with the tamping rod where the consistency of the concrete permits or with a wood float or trowel. If desired, cap the top surface of freshly made cylinders with a thin layer of stiff portland cement paste that is permitted to harden and cure with the specimen. See section on Capping Materials of T 231.

9.4.2. *Beams*—After consolidation of the concrete, strike off the top surface to the required tolerance to produce a flat even surface. A wood float may be used.

9.5. *Initial Storage*—Immediately after being struck off, the specimens shall be moved to the storage place where they will remain undisturbed for the initial curing period. If specimens made in single-use mold are moved, lift and support the specimens from the bottom of the molds with a large trowel or similar device.

10. CURING

10.1. *Standard Curing*—Standard curing is the curing method used when the specimens are made and cured for the purposes stated in Section 4.2.

10.1.1. *Storage*—If specimens cannot be molded at the place where they will receive initial curing, immediately after finishing, move the specimens to an initial curing place for storage. The supporting surface on which specimens are stored shall be level to within 20 mm/m ($^1/_4$ in./ft). If cylinders in the single-use molds are moved, lift and support the cylinders from the bottom of the molds with a large trowel or similar device. If the top surface is marred during movement to place of initial storage, immediately refinish.

10.1.2. *Initial Curing*—Immediately after molding and finishing, the specimens shall be stored for a period up to 48 h in a temperature range from 16 to 27ºC (60 to 80ºF), and in an environment preventing moisture loss from the specimens. For concrete mixtures with a specified strength of 40 MPa (6000 psi) or greater, the initial curing temperature shall be between 20 and 26ºC (68 and 78ºF). Various procedures are capable of being used during the initial curing period to maintain the specified moisture and temperature conditions. An appropriate procedure or combination of procedures shall be used (Note 5). Shield all specimens from direct sunlight and, if used, radiant heating devices. The storage temperature shall be controlled by the use of heating and cooling devices, as necessary. Record the temperature using a maximum-minimum thermometer. If cardboard molds are used, protect the outside surface of the molds from contact with wet burlap or other sources of water.

Note 5—A satisfactory moisture environment can be created during the initial curing of the specimens by one or more of the following procedures: (1) immediately immerse molded specimens with plastic lids in water saturated with calcium hydroxide, (2) store in properly constructed wood boxes or structures, (3) place in damp sand pits, (4) cover with removable plastic lids, (5) place inside plastic bags, or (6) cover with plastic sheets or nonabsorbent plates if provisions are made to avoid drying and damp burlap is used inside the enclosure, but the burlap is prevented from contacting the concrete surfaces. A satisfactory temperature environment can be controlled during the initial curing of the specimens by one or more of the following procedures: (1) use of ventilation, (2) use of ice, (3) use of thermostatically controlled heating or cooling devices, or (4) use of heating methods such as stoves or light bulbs. Other suitable methods may be used if the requirements limiting specimen storage temperature and moisture loss are met. For concrete mixtures with a specified strength of 40 MPa (6000 psi) or greater, heat generated during the early ages may raise the temperature above the required storage temperature. When specimens are to be immersed in water saturated with calcium hydroxide, specimens in cardboard molds or other molds that expand when immersed in water should not be used. Early-age strength test results may be lower when stored at 16ºC (60ºF) and higher when stored at 27ºC (80ºF). On the other hand, at later ages, test results may be lower for higher initial storage temperatures.

10.1.3. *Final Curing*:

10.1.3.1. *Cylinders*—Upon completion of initial curing and within 30 minutes after removing the molds, cure specimens with free water maintained on their surfaces at all times at a temperature of 23 ± 2ºC (73 ± 3ºF) using water storage tanks or moist rooms complying with the requirements of Specification M 201, except when capping with sulfur mortar capping compound and immediately before testing. When capping with sulfur mortar capping compounds, the ends of the cylinder shall be dry enough to preclude the formation of steam or foam pockets under or in cap larger than 6 mm ($^1/_4$ in.) as described in T 231. For a period not to exceed 3 h immediately prior to test, standard curing temperature is not required provided free moisture is maintained on the cylinders and ambient temperature is between 20 to 30°C (68 to 80°F).

10.1.3.2. *Beams*—Beams are to be cured the same as cylinders (see Section 10.1.3.1), except that they shall be stored in water saturated with calcium hydroxide at 23 ± 2ºC (73 ± 3ºF) at least 20 hours prior to testing. Drying of the surfaces of the beam shall be prevented between removal from water storage and completion of testing (Note 6).

Note 6—Relatively small amounts of surface drying of flexural specimens can induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

10.2. *Field Curing*—Field curing is the curing method used for the specimens made for the purposes stated in Section 4.3.

10.2.1. *Cylinders*—Store cylinders in or on the structure as near to the point of deposit of the concrete represented as possible. Protect all surfaces of the cylinders from the elements in as near as possible the same way as the formed work. Provide the cylinders with the same temperature and moisture environment as the structural work. Test the specimens in the moisture condition resulting from the specified curing treatment. To meet these conditions, specimens made for the purpose of determining when a structure is capable of being put in service shall be removed from the molds at the time of removal of form work.

10.2.2. *Beams*—As nearly as practicable, cure beams in the same manner as the concrete in the structure. At the end of 48 ± 4 h after molding, take the molded specimens to the storage location and remove from the molds. Store specimens representing pavements of slabs on grade by placing them on the ground as molded, with their top surfaces up. Bank the sides and ends of the specimens with earth or sand that shall be kept damp, leaving the top surfaces exposed to the specified curing treatment. Store specimens representing structure concrete as near the point in the structure they represent as possible, and afford them the same temperature protection and moisture environment as the structure. At the end of the curing period, leave the specimens in place exposed to the weather in the same manner as the structure. Remove all beam specimens from field storage and store in water saturated with calcium hydroxide at 23 ± 2ºC (73 ± 3ºF) for 24 ± 4 h immediately before time of testing to ensure uniform moisture condition from specimen to specimen. Observe the precautions given in Section 10.1.3.2 to guard against drying between time of removal from curing to testing.

10.3. *Structural Lightweight Concrete Curing*—Cure structural lightweight concrete cylinders in accordance with M 195.

11. TRANSPORTATION OF SPECIMENS TO LABORATORY

11.1. Prior to transporting, cure and protect specimens as required in Section 10. Specimens shall not be transported until at least 8 hours after final set. (See Note 7.) During transporting, protect the specimen with suitable cushioning material to prevent damage from jarring. During cold weather, protect the specimens from freezing with suitable insulation material. Prevent moisture loss during transportation by wrapping the specimens in plastic, wet burlap, by surrounding them with wet sand or tight-fitting plastic caps on plastic molds. Transportation time shall not exceed 4 hours.

Note 7—Setting time may be measured by T 197M/T 197.

12. REPORT

12.1. *Report the following information to the laboratory that will test the specimens*:

12.1.1. Identification number;

12.1.2. Location of concrete represented by the samples;

12.1.3. Date, time, and name of individual molding specimens;

12.1.4. Slump, air content, and concrete temperature, test results and results of any other tests on the fresh concrete and any deviations from referenced standard test methods; and

12.1.5. *Curing Method*—For standard curing method, report the initial curing method with maximum and minimum temperatures and final curing method. For field curing method, report the location where stored, manner of protection from the elements, temperature, and moisture environment, and time of removal from molds.

---

[1] T 23 conforms to ASTM C 31-06 except C 31 includes requirements for certification of field technicians.

Standard Method of Test for

Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

AASHTO Designation: T 24M/T 24-07
ASTM Designation: C 42/C 42M-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

AASHTO Designation: T 24M/T 24-07
ASTM Designation: C 42/C 42M-04

1. SCOPE

1.1. This method covers obtaining, preparing, and testing (1) cores drilled from concrete for length or compressive or splitting tensile strength determinations; and (2) beams sawed from concrete for flexural strength determinations.

1.2. The values stated in SI units or inch-pound units are to be regarded separately as the standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3. *This standard does not purport to address safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.3. *ACI Standard*:
- ACI 318, Building Code Requirements for Structural Concrete

3. SIGNIFICANCE AND USE

3.1. This test method provides standardized procedures for obtaining and testing specimens to determine the compressive, tensile, and flexural strength of in-place concrete. Sampling and sample preparation requirements are given to ensure that dimensional requirements are met and that the specimens are made of intact, sound concrete, and are as free of flaws as the particular structure will allow.

3.2. Generally, test specimens are obtained when doubt exists about the in-place concrete quality due to either too low strength test results during construction or signs of distress in the structure. Additionally, this method is used to provide strength information on older structures.

3.3. Concrete strength is affected by the location of the concrete in a structural element, with the concrete at the bottom tending to be stronger than the concrete at the top. Core strength is also affected by core orientation relative to the horizontal plane of the concrete as placed, with strength tending to be lower when measured parallel to the horizontal plane.[1] These factors shall be considered in planning the locations for obtaining concrete samples and in comparing strength test results.

3.4. The strength of concrete measured by tests of cores and beams is affected by the amount and distribution of moisture in the specimen at the time of test. There is no standard procedure to condition a specimen that will ensure that, at the time of test, it will be in the identical moisture condition as concrete in the structure. The moisture conditioning procedures in this test method are intended to provide reproducible moisture conditions that minimize within-laboratory and between-laboratory variations and to reduce the effects of moisture introduced during specimen preparation.

3.5. There is no universal relationship between the compressive strength of a core and the corresponding compressive strength of standard-cured molded cylinders. The relationship is affected by many factors, such as the strength level of the concrete, the in-place temperature and moisture history, and the strength gain characteristics of the concrete. Historically, it has been assumed that core strengths are generally 85 percent of the corresponding standard-cured cylinder strengths, but this is not applicable to all situations. The acceptance criteria for core strength is to be established by the specifying authority.

4. APPARATUS

4.1. *Core Drill*—For obtaining cylindrical core specimens, a diamond drill shall be used.

4.2. *Saw*—For cutting beam specimens to size for flexural strength tests and to trim ends of cores. The saw shall have a diamond or silicon-carbide cutting edge and shall be capable of cutting specimens, which conform to the prescribed dimensions, without excessive heating or shock.

5. SAMPLING

5.1. *General*:

5.1.1. Samples of hardened concrete for use in the preparation of strength test specimens shall not be taken until the concrete has become hard enough to permit sample removal without disturbing the bond between the mortar and the coarse aggregate (see Note 1 and Note 2). When preparing strength test specimens from samples of hardened concrete, samples that show abnormal defects or samples that have been damaged in the process of removal shall not be used unless the area with defects or damaged portions are removed and resulting test specimen is of suitable length.

Note 1—ASTM C 823 provides guidance on the development of a sampling plan for concrete in constructions.

Note 2—It is not possible to specify a minimum age when concrete is strong enough to withstand damage during removal, because the strength at any age depends on the curing history and strength grade of the concrete. If time permits, the concrete should not be removed before it is 14 days old. If this is not practical, removal of concrete can proceed if the cut surfaces do not display erosion of the mortar and the exposed coarse aggregate particles are embedded firmly in the mortar. In-place test methods may be used to estimate the level of strength development prior to attempting removal of concrete samples.

5.1.2. Specimens containing embedded reinforcement shall not be used for determining compressive, splitting tensile strength or flexural strength.

5.2. *Core Drilling*—A core specimen taken perpendicular to a horizontal surface shall be located, when possible, so that its axis is perpendicular to the bed of the concrete as originally placed and not near formed joints or obvious edges of a unit of deposit. A specimen taken perpendicular to a vertical surface, or perpendicular to a surface with a batter, shall be taken from near the middle of a unit of deposit when possible and not near formed joints or obvious edges of a unit of deposit.

5.3. *Slab Removal*—Remove a slab sufficiently large to secure the desired test specimens without the inclusion of any concrete that has been cracked, spalled, undercut, or otherwise damaged.

DRILLED CORES

6. LENGTH OF DRILLED CORE SPECIMENS

6.1. *Minimum Diameter*—A core specimen for the determination of length shall have a diameter of at least 95 mm [3.75 in.] or as specified by the specifying authority.

6.2. Measure the length of cores for determining the thickness of pavements, slabs, walls, or other structural elements in accordance with the provisions of T 148.

6.3. For cores that are not intended for determining structural dimensions, measure the longest and shortest lengths on the cut surface along lines parallel to the core axis. Record the average length to the nearest 5 mm [$^1/_4$ in.].

7. CORES FOR COMPRESSIVE STRENGTH

7.1. *Test Specimens*—The nominal diameter of core specimens for the determination of compressive strength shall be at least 95 mm [3.75 in.]. Core diameters less than 95 mm [3.75 in.] are permitted when it is impossible to obtain cores with length-to-diameter (L/D) ratio ≥ 1 for compressive strength evaluations in cases other than load bearing situations. For concrete with nominal maximum aggregate size greater than 37.5 mm [$1^1/_2$ in.], the nominal diameter should preferably be at least three times the nominal maximum size of the coarse aggregate and must be at least twice the nominal maximum size of the coarse aggregate. The preferred length of the capped or ground specimen is between 1.9 and 2.1 times the diameter. If the ratio of the length to the diameter of the core exceeds 2.1, reduce the length of the specimen so that the ratio is between 2.1 and 1.9. Core specimens with length-to-diameter ratios less than 1.75 require corrections to the measured compressive strength (see Section 7.7.1). A core having a maximum length of less than 95 percent of its diameter before capping or a length less than its diameter after capping shall not be tested.

Note 3—The compressive strengths of nominal 50 mm [2-in.] diameter cores are known to be somewhat lower and more variable than those of nominal 100 mm [4-in.] diameter cores. In addition, small diameter cores appear to be more sensitive to the effect of the length-to-diameter ratio.[2]

7.2. *End Preparation*—The ends of core specimens to be tested in compression shall be essentially smooth, perpendicular to the longitudinal axis, and of the same diameter as the body of the specimen in accordance with T 22. If necessary, saw or tool the ends of the specimens prior to capping until the following requirements are met:

7.2.1. Projections, if any, shall not extend more than 5 mm [0.2 in.] above the end surfaces.

7.2.2. The end surfaces shall not depart from perpendicularity to the longitudinal axis by a slope of more than 1: 0.3d or [1: 8d] where d is the average core diameter in mm or [inches].

7.2.3. The diameter of the ends shall not depart more than 2 mm [0.1 in.] from the mean diameter of the specimen.

7.3. *Moisture Conditioning*—Test cores after moisture conditioning as specified in this test method or as directed by the specifying authority. The moisture conditioning procedures specified in this test method are intended to preserve the moisture of the drilled core and to provide a reproducible moisture condition that minimizes the effects of moisture gradients introduced by wetting during drilling and specimen preparation.

7.3.1. After cores have been drilled, wipe off surface drill water and allow remaining surface moisture to evaporate. When surfaces appear dry, but not later than 1 h after drilling, place cores in separate plastic bags or nonabsorbent containers and seal to prevent moisture loss. Maintain cores at ambient temperature, and protect cores from exposure to direct sunlight. Transport the cores to the testing laboratory as soon as practicable. Keep cores in the sealed plastic bags or nonabsorbent containers at all times except during end preparation and for a maximum time of 2 hours to permit capping before testing.

7.3.2. If water is used during sawing or grinding of core ends, complete these operations as soon as practicable, but no later than 2 days after drilling of cores unless stipulated otherwise by the specifier of tests. After completing end preparation, wipe off surface moisture, allow the surfaces to dry, and place the cores in sealed plastic bags or nonabsorbent containers. Minimize the duration of exposure to water during end preparation.

7.3.3. Allow the cores to remain in the sealed plastic bags or nonabsorbent containers for at least 5 days after last being wetted before testing, unless stipulated otherwise by the specifier of tests.

Note 4—The waiting period of at least 5 days is intended to reduce moisture gradients introduced when the core is drilled or wetted during sawing or grinding.

7.3.4. When direction is given to test cores in a moisture condition other than achieved by conditioning according to Sections 7.3.1, 7.3.2, and 7.3.3, report the alternative procedure.

7.4. *Capping*—Before making the compression test, saw or grind the ends of the specimens in accordance with the tolerance requirements of T 22 or cap the ends of the specimens in conformance with the procedure prescribed in the applicable section of T 231. The capped surfaces of the specimens shall conform to the planeness requirements of T 231.

Note 5—Prior to capping, the density of a core may be determined by weighing it and dividing it by the volume calculated from the average diameter and length, or by any other standard method for determining density.

7.5. *Measurement*—Prior to testing, measure the length of the capped or ground specimen to the nearest 2 mm [0.1 in.] and use this length to compute the length-diameter ratio. Determine the average diameter by averaging two measurements taken at right angles to each other about the mid-height of the specimen. Measure core diameters to the nearest 0.2 mm [0.01 in.] when the difference in core diameters does not exceed 2 percent of their average, otherwise measure to the nearest 2 mm [0.1 in.]. Do not test cores if differences between the largest and smallest diameter exceed 5 percent of their average.

7.6. *Testing*—Test the specimens in accordance with the applicable provision of T 22. Test the specimens within 7 days after coring, unless specified otherwise.

7.7. *Calculations*—Calculate the compressive strength of each specimen using the computed cross-sectional area based on the average diameter of the specimen.

7.7.1. If the ratio of the length to diameter of the specimen is 1.75 or less, correct the result obtained in Section 7.7 by multiplying by the appropriate correction factor shown in the following table (see Note 6):

Ratio of Length of Cylinder to Diameter, 1/*D*	Strength Correction Factor
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.87

Use interpolation to determine correction factors for *L*/*D* values not given in the table.

Note 6—Correction factors depend on various conditions, such as moisture condition, strength level, and elastic modulus. Average values are given in Table 1. These correction factors apply to lightweight concrete weighing between 1600 and 1920 kg/m^3 [100 and 120 lb/ft^3] and normal weight concrete. They are applicable to both dry and wet concrete for strengths between 14 to 42 MPa [2000 and 6000 psi]. For strengths above 70 MPa [10000 psi], test data on cores show that the correction factors may be larger than the values listed above. Thus, these factors should be applied to high-strength concrete with caution.

7.8. *Report the results as required by T 22 with the addition of the following information*:

7.8.1. Length of core as drilled to the nearest 5 mm [0.2 in.];

7.8.2. Length of test specimen before and after capping or end grinding to the nearest 2 mm [0.1 in.], and average diameter of core to the nearest 0.2 mm [0. 01 in.] or 2 mm [0.1 in];

7.8.3. Compressive strength to the nearest 0.1MPa [10 psi] when the diameter is measured to the nearest 0.2 mm [0.01 in.], and to the nearest 0.5 MPa [50 psi] when the diameter is measured to the nearest 2 mm [0.1 in.], after correction for length-diameter ratio when required;

7.8.4. Direction of application of the load on the specimen with respect to the horizontal plane of the concrete as placed;

7.8.5. The moisture conditioning history:

7.8.5.1. The date and the time core was obtained and first placed in sealed bag or nonabsorbent container;

7.8.5.2. If water was used during end preparation, the date and time end preparation was completed and the core placed in sealed bag or nonabsorbent container;

7.8.6. The date and time when tested;

7.8.7. If determined, the density;

7.8.8. If applicable, description of defects in cores that could not be tested; and

7.8.9. If any deviation from this test method was required, describe the deviation and explain why it was necessary.

7.9. *Precision*:

7.9.1. The single-operator coefficient of variation on cores has been found to be 3.2 percent[3] for a range of compressive strength between 32.0 MPa [4500 psi] and 48.3 MPa [7000 psi]. Therefore, results of two properly conducted tests of single cores by the same operator on the same sample of material should not differ from each other by more than 9 percent[3] of their average.

7.9.2. The multilaboratory coefficient of variation on cores has been found to be 4.7 percent[3] for range of compressive strength between 32.0 MPa [4500 psi] and 48.3 MPa [7000 psi]. Therefore results on two properly conducted tests on cores sampled from the same hardened concrete (where a single test is defined as the average of two observations (cores), each made on separate adjacent drilled 100-mm [4-in.] diameter cores), and tested by two different laboratories should not differ from each other by more than 13 percent[3] of their average.

7.10. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

8. SPLITTING TENSILE STRENGTH

8.1. *Test Specimens*—The specimens shall conform to the dimensional requirements in Sections 7.1, 7.2.1, and 7.2.2. Ends are not to be capped.

8.2. *Moisture Conditioning*—Prior to testing, the specimens shall be conditioned as described in Section 7.3.

8.3. *Bearing Surfaces*—The line of contact between the specimen and each bearing strip shall be straight and free of any projections or depressions higher or deeper than 0.2 mm [0.01 in.]. When the line of contact is not straight or contains projections or depressions having heights or depths greater than 0.2 mm [0.01 in.], grind or cap the specimen so as to produce bearing lines meeting these requirements. Do not use specimens with projections or depressions greater than 2 mm [0.1 in.]. When capping is employed, the caps shall be as thin as practicable and shall be formed of high-strength gypsum plaster.

Note 7—Figure 1 illustrates a device suitable for applying caps to the bearing surfaces of core specimens.

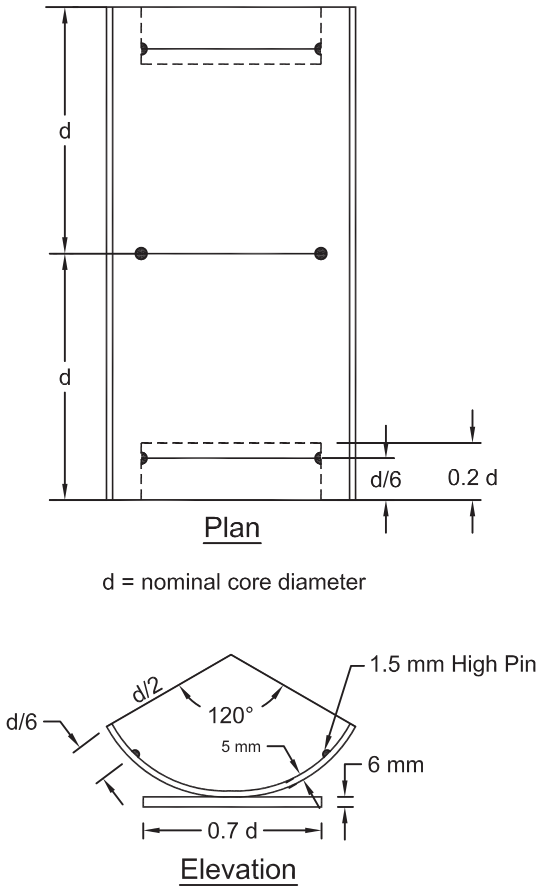

Figure 1—Suitable Capping Device for Splitting Tensile Strength Test

8.4. *Testing*—Test specimens in accordance with the applicable provisions of T 198.

8.5. *Calculation and Report*—Calculate the splitting tensile strength and report the results as required in T 198. When grinding or capping of the bearing surfaces is required, the diameter shall be measured between the finished surfaces. Indicate that the specimen was a core and state its moisture condition at the time of testing.

8.6. *Precision*:

8.6.1. The within laboratory single operator coefficient of variation for splitting tensile strength between 3.6 MPa [520 psi] and 4.1 MPa [590 psi] of cores has been found to be 5.3 percent. Therefore, results of two properly conducted tests by the same operator in the same laboratory on the same sample of material should not differ by more than 14.9 percent of their average.

8.6.2. The multilaboratory coefficient of variation for splitting tensile strength between 3.6 MPa [520 psi] and 4.1 MPa [590 psi] of cores has been found to be 15 percent. Therefore, results of two properly conducted tests on the same sample of material of hardened concrete and tested by two different laboratories should not differ from each other by more than 42.3 percent of their average.

8.7. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

SAWED BEAMS

9. FLEXURAL STRENGTH

9.1. *Test Specimens*—A beam specimen for the determination of flexural strength shall in general have a cross section of 150 × 150 mm [6 × 6 in.] (see Note 8). The specimen shall be at least 530 mm [21 in.] in length, but when two tests for flexural strength are to be made on one beam specimen, it shall be at least 840 mm [33 in.] in length. Perform the sawing operation so that the concrete will not be weakened by shock or by heating. The sawed surfaces shall be smooth, plane, parallel, and free from steps, ridges, and grooves. Take care in handling sawed beam specimens to avoid chipping or cracking.

Note 8—In many cases, particularly with prisms cut from pavement slabs, the width will be governed by the size of the coarse aggregate and the depth by the thickness of the slab.

9.2. *Moisture Conditioning*—Protect the surfaces of sawed specimens from evaporation by covering them with wet burlap and plastic sheeting during transportation and storage. Test the specimens within 7 days of sawing. Submerge the test specimens in lime-saturated water at 23.0 ± 2.0ºC [73.5 ± 3.5ºF] for at least 40 hours immediately prior to the flexure test. Test the specimens promptly after removal from water storage. During the period between removal from water storage and testing, keep the specimens moist by covering with a wet blanket of burlap or other suitable absorbent fabric.

9.2.1. When the specifying authority for the project so directs, beams shall be tested in a moisture condition other than that achieved by conditioning in accordance with Section 9.2. Relatively small amounts of drying of the surface of flexural specimens induce tensile stresses in the extreme fibers that will markedly reduce the indicated flexural strength.

9.3. *Testing*—Test the specimens in accordance with the applicable provisions of T 97.

Note 9—The compressive strengths of portions of beams broken in flexure may be determined by testing such portions as modified cubes in accordance with T 140 (Modified Cube Method).

Note 10—Sawing may greatly reduce the indicated flexural strength; beams shall, therefore, be tested with a molded surface in tension whenever possible. The location of the tension face with respect to the position of the concrete as placed and the position of the sawed surfaces should be reported.

9.4. *Report*—Report the results in accordance with the applicable provisions of T 97 and the requirements of this method, including the moisture condition at the time of testing. Identify orientation of the specimen's finished, sawed, and tension faces with respect to their positions in the test apparatus.

10. PRECISION AND BIAS

10.1. *Precision*—Data are not available for preparing a statement on the precision of flexural strength measured on sawed beams.

Note 11—Users of this method who have replicate test data that may be appropriate for a statement on repeatability are encouraged to contact the chairman of the technical section.

10.2. *Bias*—Since there is no accepted reference material suitable for determining the bias for the procedure in this test method, no statement on bias is being made.

11. KEYWORDS

11.1. Compressive strength; concrete; concrete coring; concrete sawing; flexural strength; splitting tensile strength.

Standard Method of Test for

Quality of Water to Be Used in Concrete

AASHTO Designation: T 26-79 (2008)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Quality of Water to Be Used in Concrete

AASHTO Designation: T 26-79 (2008)

1. SCOPE

1.1 This specification covers determination of the acidity or alkalinity in water to be used in concrete.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)
- T 107, Autoclave Expansion of Hydraulic Cement
- T 131, Time of Setting of Hydraulic Cement by Vicat Needle
- T 154, Time of Setting of Hydraulic Cement by Gillmore Needles

2.2 *ASTM Standards*:

- D 512, Chloride Ion in Water
- D 516, Sulfate Ion in Water

2.3 *Other Documents*:

- *Industrial and Engineering Chemistry*, Vol. V, No. 5, p. 336
- *Scott's Standard Methods of Chemical Analysis, Sixth Edition* (1963), Vol. II, p. 2388

3. ACIDITY AND ALKALINITY

3.1 The acidity or alkalinity shall be determined by one of the following methods, A or B. If extreme accuracy is desired, the method under "B" should be used.

3.1.1 *Method A*: The acidity or alkalinity shall be determined with standard solutions of one-tenth normal alkali or acid, respectively, using not less than 200 mL of the water under examination. Phenolphthalein or methyl orange should be used as an indicator. Excessive acidity or alkalinity indicates the necessity for further tests.

3.1.2 *Method B*:

3.1.2.1 The hydrogen ion concentration shall be determined either by electrometric or colorimetric method in conjunction with the necessary indicator, and shall be expressed in pH units ($\text{pH} = \log {}^{1}/_{H}+$). When the pH of the water is less than pH 4.5 or more than pH 8.5, further tests should be made. (The pH value of the solution is the logarithm of the reciprocal of the hydrogen ion concentration (H^+) in moles per liter. For example, a solution of 4.5 pH has a hydrogen ion concentration of $10^{-4.5}$).

3.1.2.2 The procedure for securing pH values shall be regulated entirely by the method used; that is, either by electrometric or colorimetric methods. The procedure to be followed in making the determinations shall be based on the type of apparatus used and in accordance with the methods and instruction furnished by the manufacturer for the particular type of apparatus in use. The apparatus used, either colorimetric or electrometric, shall have a working range suitable for the test being performed.

3.2 *Chloride Ion Concentration*—The chloride ion concentration shall be determined by ASTM D 512.

4. REFEREE METHOD B

4.1 *Sulfate Ion Concentration*—The sulfate ion concentration shall be determined by ASTM D 516, Referee method (gravimetric).

5. TOTAL SOLIDS AND INORGANIC MATTER

5.1 Evaporate 500 mL of the water to dryness in a dish. For this purpose a platinum dish of 100 to 200 mL capacity is found most convenient. The dish shall be nearly filled with water and placed on a water bath, additional portions of the sample of water being added from time-to-time until 500 mL have been used. The contents of the dish shall be evaporated to dryness, then placed in an oven at 132ºC (270ºF) and baked for one hour. The dish and contents shall then be cooled in a desiccator and the mass determined. The mass of the residue in grams divided by five is the percentage of total solids in the water.

5.2 The total solids obtained as described may consist of organic matter, or inorganic matter, or of combinations of organic and inorganic matter. The platinum dish shall be ignited at low red heat, and the darkening of the residue during the early stage of the ignition usually indicates the presence of organic matter. The percentage loss on ignition at low red heat will usually be an indicator of the amount of organic matter, but it should be noted that some mineral salts tend to volatilize or partly decompose on heating.

5.3 The determination of the composition of the mineral matter in the water requires a complete chemical analysis and is not generally undertaken except when the percentage of total solids is large, or the water appears to give abnormal tests in other respects. When the mineral analysis is desired, the procedure starting on page 2388 of *Scott's Standard Methods of Chemical Analysis* should be used. The results should be reported as the separate constituents in parts per million. If the hypothetical combination into salts is desired, the method given by Scott, or the method given on page 336 of *Industrial and Engineering Chemistry* should be used.

5.4 A comparison of the given water with distilled water can be obtained in accordance with T 107, T 131, or T 154 and T 106M/T 106 tests, using the same cement of standard quality with each water. (Suggested limits for the last named tests are as follows: Any indication of unsoundness, marked change in time-of-setting, or a reduction of more than 10 percent in strength from results obtained with mixtures containing the water of satisfactory quality shall be sufficient cause for rejection of the water under test).

Standard Method of Test for

Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)

AASHTO Designation: T 97-10
ASTM Designation: C 78-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)

AASHTO Designation: T 97-10
ASTM Designation: C 78-08

1. SCOPE

1.1 This test method covers determination of the flexural strength of concrete by the use of a simple beam with third-point loading.

1.2 The values stated in SI units are to be regarded as the standard.

Note 1—For methods of molding concrete specimens, see T 23 and R 39.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 231, Capping Cylindrical Concrete Specimens

2.2 *ASTM Standards*:

- C 31/C 31M, Standard Practice for Making and Curing Concrete Test Specimens in the Field
- C 42/C 42M, Standard Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- C 192/C 192M, Standard Practice for Making and Curing Concrete Test Specimens in the Laboratory
- C 617, Standard Practice for Capping Cylindrical Concrete Specimens
- C 1077, Standard Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation
- E 4, Standard Practices for Force Verification of Testing Machines

3. SIGNIFICANCE AND USE

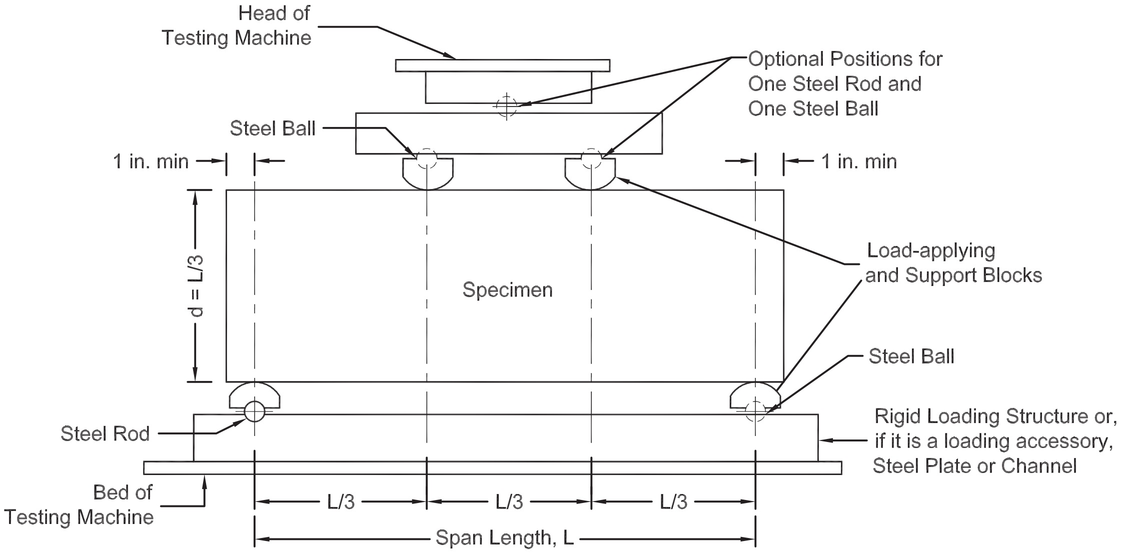
3.1 This test method is used to determine the flexural strength of specimens prepared and cured in accordance with T 23, T 24M/T 24, or R 39. Results are calculated and reported as the modulus of rupture. The strength determined will vary where there are differences in specimen size, preparation, moisture condition, curing, or where the beam has been molded or sawed to size.

3.2 The result of this test method may be used to determine compliance with specifications or as a basis for proportioning, mixing, and placement operations. It is used in testing concrete for construction of slabs and pavements.

4. APPARATUS

4.1 The testing machine shall conform to the requirements of sections on Basis of Verifications, Corrections, and Time Interval Between Verification of ASTM E 4. Hand-operated testing machines having pumps that do not provide a continuous loading in one stroke are not permitted. Motorized pumps or hand-operated positive displacement pumps having sufficient volume in one continuous stroke to complete a test without requiring replenishment are permitted and shall be capable of applying loads at a uniform rate without shock or interruption.

4.2 *Loading Apparatus*—The third-point loading method shall be used in making flexure tests of concrete employing bearing blocks, which will ensure that forces applied to the beam will be perpendicular to the face of the specimen and applied without eccentricity. A diagram of an apparatus that accomplishes this purpose is shown in Figure 1.



Notes: 1. in. = 25.4 mm

2. This apparatus may be used inverted. If the Testing Machine applies force through a spherically seated head, the center pivot may be omitted, provided one-load applying block pivots on a rod and the other on a ball.

Figure 1—Diagrammatic View of a Suitable Apparatus for Flexure Test of Concrete by Third-Point Loading Method

4.2.1 All apparatus for making flexure tests of concrete should be capable of maintaining the specified span length and distances between load-applying blocks and support blocks constant within ±1.3 mm (±0.05 in.).

4.2.2 The ratio of the horizontal distance between the point of application of the load and the point of application of the nearest reaction to the depth of the beam shall be 1.0 ±0.03.

4.2.3 If an apparatus similar to that illustrated in Figure 1 is used:

(a) The load-applying and support blocks should not be more than 64 mm ($2^1/_2$ in.) high, measured from the center or the axis of pivot, and should extend entirely across or beyond the full width of the specimen. Each case-hardened bearing surface in contact with the specimen shall not depart from a plane by more than 0.05 mm (0.002 in.) and should be a portion of a cylinder, the axis of which is coincidental with either the axis of the rod or center of the ball, whichever the block is pivoted upon. The angle subtended by the curved surface of each block should be at least 45 degrees (0.79 rad).

(b) The load-applying and support blocks should be maintained in a vertical position and in contact with the rod or ball by means of spring-loaded screws that hold them in contact with the pivot rod or ball.

(c) The uppermost bearing plate and centerpoint ball in Figure 1 may be omitted when a spherically seated bearing block is used, provided one rod and one ball are used as pivots for the upper load-applying blocks.

5. TESTING

5.1 The test specimen shall conform to all requirements of T 23, T 24M/T 24, and R 39. The specimen shall have a test span within 2 percent of being three times its depth as tested. The sides of the specimen shall be at right angles with the top and bottom. All surfaces shall be smooth and free of scars, indentations, holes, or inscribed identification marks.

6. PROCEDURE

6.1 Flexural tests of moist-cured specimens shall be made as soon as practical after removal from moist storage. Surface drying of the specimen results in a reduction in the measured flexural strength.

6.2 When using molded specimens, turn the test specimen on its side with respect to its position as molded and center it on the support blocks. When using sawed specimens, position the specimen so the tension face corresponds to the top or bottom of the specimen as cut from the parent material. Center the loading system in relation to the applied force. Bring the load-applying blocks in contact with the surface of the specimen at the third points and apply a load of between 3 and 6 percent of the estimated ultimate load. Using 0.10-mm (0.004-in.) and 0.38-mm (0.015-in.) leaf-type feeler gauges, determine whether any gap between the specimen and the load-applying or support blocks is greater or lesser than each of the gauges over a length of 25 mm (1 in.) or more. Grind, cap, or use leather shims on the specimen contact surface to eliminate any gap in excess of 0.10 mm (0.004 in.) in width. Leather shims shall be of uniform 6.4 mm (0.25 in.) thickness, 25 to 50 mm (1 to 2 in.) width, and shall extend across the full width of the specimen. Gaps in excess of 0.38 mm (0.015 in.) shall be eliminated only by capping or grinding. Grinding of lateral surfaces should be minimized in as much as grinding may change the physical characteristics of the specimens. Capping shall be in accordance with T 231.

6.3 Load the specimen continuously and without shock. The load shall be applied at a constant rate to the breaking point. Apply a load at a rate that constantly increases the maximum stress on the tension face between 0.9 and 1.2 MPa/min (125 and 175 psi), until rupture occurs. The loading rate is calculated using the following equation:

$$r = Sbd^2/L \qquad (1)$$

where:

r = loading rate, MN/min (lb/min);

S = rate of increase in extreme fiber stress, MPa/min (psi/min);

b = average width of specimen mm (in.);

d = average depth of specimen mm (in.); and

L = span length, mm (in.).

7. MEASUREMENT OF SPECIMENS AFTER TEST

7.1 To determine the dimensions of the specimen cross section for use in calculating modulus of rupture, take measurements across one of the fractured faces after testing. The width and depth are measured with the specimen as oriented for testing. For each dimension, take one measurement at each edge and one at the center of the cross section. Use the three measurements for each direction to determine the average width and the average depth. Take all measurements to the nearest 1.3 mm (0.05 in.). If the fracture occurs at a capped section, include the cap thickness in the measurement.

8. CALCULATIONS

8.1 If the fracture initiates in the tension surface within the middle third of the span length, calculate the modulus of rupture as follows:

$$R = Pl/bd^2 \tag{2}$$

where:

R = modulus of rupture, kPa (psi);

P = maximum applied load indicated by the testing machine, N (lbf);

l = span length, mm (in.);

b = average width of specimen mm (in.); and

d = average depth of specimen mm (in.).

Note 2—The weight of the beam is not included in the above calculation.

8.2 If the fracture occurs in the tension surface outside of the middle third of the span length by not more than 5 percent of the span length, calculate the modulus of rupture as follows:

$$R = 3Pa/bd^2 \tag{3}$$

where:

a = average distance between line of fracture and the nearest support measured on the tension surface of the beam, mm (in.).

See Note 2.

8.3 If the fracture occurs in the tension surface outside of the middle third of the span length by more than 5 percent of the span length, discard the results of the test.

9. REPORT

9.1 *The report shall include the following*:

9.1.1 Identification number;

9.1.2 Average width to the nearest 1 mm (0.05 in.);

9.1.3 Average depth to the nearest 1 mm (0.05 in.);

9.1.4 Span length in millimeters (inches);

9.1.5 Maximum applied load in newtons (pounds-force);

9.1.6 Modulus of rupture calculated to the nearest 0.05 MPa (5 psi);

9.1.7 Curing history and apparent moisture condition of the specimens at the time of test;

9.1.8 If specimens were capped, ground, or if leather shims were used;

9.1.9 If specimens were sawed or molded and any defects in the specimens; and

9.1.10 Age of specimens.

10. PRECISION AND BIAS

10.1 *Precision*—The coefficient of variation of test results has been observed to be dependent on the strength level of the beams. The single operator coefficient of variation has been found to be 5.7 percent. Therefore, results of two properly conducted tests by the same operator on beams made from the same batch sample should not differ from each other by more than 16 percent. The multilaboratory coefficient of variation has been found to be 7.0 percent. Therefore, results of two different laboratories on beams made from the same batch sample should not differ from each other by more than 19 percent.

10.2 *Bias*—Since there is no accepted standard for determining bias in this test method, no statement on bias is made.

Standard Method of Test for

Slump of Hydraulic Cement Concrete

AASHTO Designation: T 119M/T 119-10
ASTM Designation: C 143/C 143M-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Slump of Hydraulic Cement Concrete

AASHTO Designation: T 119M/T 119-10
ASTM Designation: C 143-03/C 143M-08

1. SCOPE

1.1. This test method covers determination of slump of concrete, both in the laboratory and in the field.

1.2. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3. The text of the standard reference notes and footnotes provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.4. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*
Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 141, Sampling Freshly Mixed Concrete

3. SUMMARY OF TEST METHOD

3.1. A sample of freshly mixed concrete is placed and compacted by rodding in a mold shaped as the frustum of a cone. The mold is raised and the concrete allowed to subside. The vertical distance between the original and displaced position of the center of the top surface of the concrete is measured and reported as the slump of the concrete.

4. SIGNIFICANCE AND USE

4.1. This test method is intended to provide the user with a procedure to determine the slump of plastic hydraulic cement concretes.

Note 1—This test method was originally developed to provide a technique to monitor the consistency of unhardened concrete. Under laboratory conditions, with strict control of all concrete materials, the slump is generally found to increase proportionally with the water content of a given concrete mixture, and thus to be inversely related to concrete strength. Under field conditions, however, such a strength relationship is not clearly and consistently shown. Care should therefore be taken in relating slump results obtained under field conditions to strength.

4.2. This test method is considered applicable to plastic concrete having coarse aggregate up to 37.5 mm [1.5 in.]. If the coarse aggregate is larger than 37.5 mm [1.5 in.] in size, the test method is applicable when it is performed on the fraction of concrete passing a 37.5-mm [1.5-in.] sieve, with the larger aggregate being removed in accordance with the section titled "Additional Procedures for Large Maximum Size Aggregate Concrete" in T 141.

4.3. This test method is not considered applicable to non-plastic and non-cohesive concrete.

Note 2—Concretes having slumps less than 15 mm [0.5 in.], may not be adequately plastic and concretes having slumps greater than about 230 mm [9 in.] may not be adequately cohesive for this test to have significance. Caution should be exercised in interpreting such results.

5. APPARATUS

5.1. *Mold*—The test specimen shall be formed in a mold made of metal not readily attacked by the cement paste. The metal shall not be thinner than 1.5 mm [0.060 in.] and if formed by the spinning process, there shall be no point on the mold at which the thickness is less than 1.15 mm [0.045 in.]. The mold shall be in the form of the lateral surface of the frustum of a cone with the base 203 mm [8 in.] in diameter, the top 102 mm [4 in.] in diameter, and the height 305 mm [12 in.]. Individual diameters and heights shall be within ±3.2 mm [0.125 in.] of the prescribed dimensions. The base and the top shall be open and parallel to each other and at right angles to the axis of the cone. The mold shall be provided with foot pieces and handles similar to those shown in Figure 1. The mold shall be constructed without a seam. The interior of the mold shall be relatively smooth and free from projections. The mold shall be free from projections. A mold that clamps to a nonabsorbent base plate is acceptable instead of the one illustrated, provided the clamping arrangement is such that it can be fully released without movement of the mold and the base is large enough to contain all of the slumped concrete in an acceptable test.

5.1.1. Check and record conformance to the mold's specified dimensions when it is purchased or first placed in service and at least annually thereafter.

5.1.2. *Mold with Alternative Materials*:

5.1.2.1. Molds other than metal are permitted if the following requirements are met: The mold shall meet the shape, height, and internal dimensional requirements of Section 5.1. The mold shall be sufficiently rigid to maintain the specified dimensions and tolerances during use, resistant to impact forces, and shall be nonabsorbent. The mold shall be demonstrated to provide test results comparable to those obtained when using a metal mold meeting the requirements of Section 5.1. Comparability shall be demonstrated on behalf of the manufacturer by an independent testing laboratory. Test for comparability shall consist of not less than 10 consecutive pairs of comparisons performed at each of three different slumps ranging from 50 to 200 mm [2 to 8 in.]. No individual test results shall vary by more than 15 mm [0.50 in.] from that obtained using the metal mold. The average test results of each slump range obtained using the mold constructed of alternative material shall not vary by more than 6 mm [0.25 in.] from the average of test results obtained using the metal mold. Manufacturer comparability test data shall be available to users and laboratory inspection authorities (see Note 4). If any changes in material or method of manufacture are made, tests for comparability shall be repeated.

Note 3—The phrase "consecutive pairs of comparisons" does not mean without interruption or all in 1 day. At a schedule selected by the testing entity, the pairs of tests leading to 10 consecutive pairs may be accomplished in small groups. The word consecutive prevents ignoring pairs of tests that may not meet criteria.

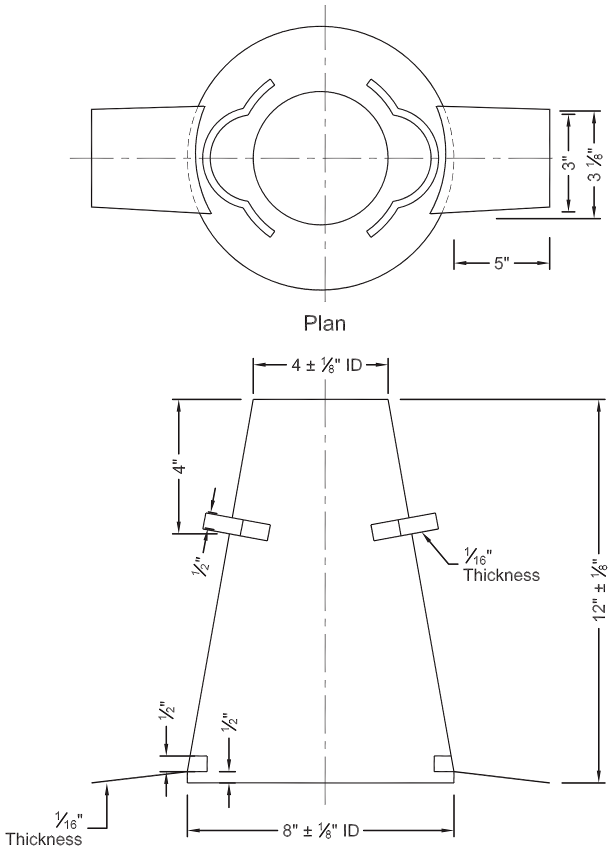
Note 4—Because the slump of concrete decreases with time and higher temperatures, it will be advantageous for the comparability tests to be performed by alternating the use of metal cones and alternative material cones, to utilize several technicians, and to minimize the time between test procedures.

5.1.2.2. If the condition of any individual mold is suspected of being out of tolerance from the as manufactured condition, a single comparative test shall be performed. If the test results differ by more than 15 mm [0.50 in.] from that obtained using the metal mold, the mold shall be removed from service.

5.2. *Tamping Rod*—The tamping rod shall be a round, straight steel rod 16 mm [0.625 in.] in diameter and approximately 600 mm [24 in.] in length, having the tamping end or both ends rounded to a hemispherical tip the diameter of which is 16 mm [0.625 in.].

5.3. *Measuring Device*—A ruler, metal roll-up measuring tape, or similar rigid or semi-rigid length measuring instrument marked in increments of 5 mm [0.25 in.] or smaller. The instrument length shall be at least 300 mm [12 in.].

5.4. *Scoop*—A scoop of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the mold.



Dimensional Units

mm	2	3	15	25	75	80	100	200	300
in.	[0.0625]	[0.125]	[0.5]	[1]	[3]	[3.128]	[4]	[8]	[12]

Figure 1—Mold for Slump Test

6. SAMPLE

6.1. The sample of concrete from which test specimens are made shall be representative of the entire batch. It shall be obtained in accordance with T 141.

7. PROCEDURE

7.1. Dampen the mold and place it on a flat, level, moist, nonabsorbent (rigid) surface such as a premoistened concrete floor or a base plate. It shall be held firmly in place during filling and perimeter cleaning by the operator standing on the two foot pieces, or by clamping arrangements to a base plate as described in Section 5.1. From the sample of concrete obtained in accordance with Section 6, immediately fill the mold in three layers, each approximately one-third the volume of the mold. Place the concrete in the mold using the scoop described in Section 5.4. Move the scoop around the perimeter of the mold opening to ensure an even distribution of the concrete with minimal segregation.

Note 5—One-third of the volume of the slump mold fills it to a depth of 67 mm [2.625 in.]; two-thirds of the volume fills it to a depth of 155 mm [6.125 in.].

7.2. Rod each layer with 25 strokes of the tamping rod. Uniformly distribute the strokes over the cross section of each layer. For the bottom layer this will necessitate inclining the rod slightly and making approximately half of the strokes near the perimeter, and then progressing with vertical strokes spirally toward the center. Rod the bottom layer throughout its depth. Rod the second layer and the top layer each throughout its depth, so that the strokes just penetrate into the underlying layer.

7.3. In filling and rodding the top layer, heap the concrete above the mold before rodding is started. If the rodding operation results in subsidence of the concrete below the top edge of the mold, add additional concrete to keep an excess of concrete above the top of the mold at all times. After the top layer has been rodded, strike off the surface of the concrete by means of a screeding and rolling motion of the tamping rod. Continue to hold the mold down firmly and remove concrete from the area surrounding the base of the mold to preclude interface with the movement of slumping concrete. Remove the mold immediately from the concrete by raising it carefully in a vertical direction. Raise the mold a distance of 300 mm [12 in.] in 5 ± 2 seconds by a steady upward lift with no lateral or torsional motion. Complete the entire test from the start of the filling through removal of the mold without interruption and complete it within an elapsed time of 2.5 minutes.

7.4. Immediately measure the slump by determining the vertical difference between the top of the mold and the displaced original center of the top surface of the specimen. If a decided falling away or shearing off of concrete from one side or portion of the mass occurs (Note 6), disregard the test and make a new test on another portion of the sample.

Note 6—If two consecutive tests on a sample of concrete show a falling away or shearing off of a portion of the concrete from the mass of the specimen, the concrete probably lacks necessary plasticity and cohesiveness for the slump test to be applicable.

8. REPORT

8.1. Record the slump in terms of inches [millimeters] to the nearest 5 mm [0.25 in.] of subsidence of the specimen during the test.

9. PRECISION AND BIAS

9.1. *Precision*—The estimates of precision for this test method are based upon results from tests conducted in Fayetteville, Arkansas by 15 technicians from 14 laboratories representing three states. All tests at three different slump ranges, from 25 mm [1.0 in.] to 160 mm [6.5 in.], were performed using one load of truck-mixed concrete. The concrete was delivered and tested at a low slump, with water then being added and mixed into the remaining concrete to independently produce moderate and finally high-slump concrete. The concrete mixture that used a No. 67 crushed limestone aggregate and a washed river sand, contained 297 kg of cementitious material per cubic meter [500 lb of cementitious materials per cubic yard]. The 227 kg [500 lb] were equally divided between a C 150, Type I/II cement and a Class C fly ash. A double dosage of a chemical retarder was used in an attempt to minimize slump losses and maintain workability of the concrete. Concrete temperatures ranged from 30 to 34°C [86 to 93°F]. Slump losses averaged 17 mm [0.68 in.] during the 20 minutes required to perform a series of six tests at one slump range. Testing was performed alternately using metal and plastic molds, which were determined to produce comparable results. Precision data thus applies to both metal and plastic molds. A total of 270 slump tests were performed.

9.1.1. *SI [Inch-Pound]*—The data used to develop the precision statement were obtained using metric units (millimeters). The precision values shown in inch-pound units are conversions from the millimeter measurements, which were recorded to the nearest 1 mm.

9.1.2. *Measure of Variability*—The standard deviation was determined to be the most consistent measure of variability and was found to vary with the slump value.

9.1.3. *Single-Operator Precision*—The single-operator standard deviation represented by (1s) is shown in Table 1 by average slump values. The reported results for the replicate readings apply to tests conducted by the same operator performing successive tests, one immediately following the other. Acceptable results of two properly conducted tests by the same operator on the same material (Note 7) will not differ from each other by more than the (d2s) value of the last column of Table 1 for the appropriate slump value and single-operator precision.

Table 1—Precison

Slump and Type Index	Standard Deviation (1s)[a]		Acceptable Range of Two Results (d2s)[a]	
	mm	[in.]	mm	[in.]
Single-Operator Precision:				
Slump 30 mm [1.2 in.]	6	[0.23]	17	[0.65]
Slump 85 mm [3.4 in.]	9	[0.38]	25	[1.07]
Slump 160 mm [6.5 in.]	10	[0.39]	28	[1.10]
Multilaboratory Precision:				
Slump 30 mm [1.2 in.]	7	[0.29]	20	[0.82]
Slump 85 mm [3.4 in.]	10	[0.39]	28	[1.10]
Slump 160 mm [6.5 in.]	13	[0.53]	37	[1.50]

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in Practice C 670.

9.1.4. *Multilaboratory Precision*—The multilaboratory standard deviation represented by (1s) is shown in Table 1 by average slump values. The reported results for the replicate readings apply to tests conducted by different operators from different laboratories performing tests less than 4 minutes apart. Therefore, acceptable results of two properly conducted slump tests on the same material (Note 7) by two different laboratories will not differ from each other by more than the (d2s) value of the last column of Table 1 for the appropriate slump value and multilaboratory precision.

Note 7—"Same materials" is used to mean freshly mixed concrete from one batch.

9.2. *Bias*—This test method has no bias because slump is defined in terms of this test method.

10. KEYWORDS

10.1. Concrete; cone; consistency; plasticity; slump; workability.

Standard Method of Test for

Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

AASHTO Designation: T 121M/T 121-09
ASTM Designation: C 138/C 138M-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

AASHTO Designation: T 121M/T 121-09
ASTM Designation: C 138/C 138M-08

1. SCOPE

1.1 This method covers determination of the density (see Note 1) of freshly mixed concrete and gives formulas for calculating the yield, cement content, and the air content of the concrete. Yield is defined as the volume of concrete produced from a mixture of known quantities of the component materials.

1.2 The values stated in either SI or inch-pound units shall be regarded separately as standard. The inch-pound units are shown in brackets. The values stated might not be exact equivalents; therefore, each system must be used independently of the other.

Note 1—Unit weight was the previous terminology used to describe the property determined by this test method, which is mass per unit volume.

1.3 The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this test method.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:
- M 85, Portland Cement
- T 19M/T 19, Bulk Density ("Unit Weight") and Voids in Aggregate
- T 133, Density of Hydraulic Cement
- T 141, Sampling Freshly Mixed Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method

2.2 *ASTM Standard*:
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. DEFINITIONS

3.1 *Symbols*:

A = air content (percentage of voids) in the concrete;

C = Actual cement content, kg/m^3 [lb/yd^3];

C_b = mass of cement in the batch, kg [lb];

D = density (unit weight) of concrete, kg/m^3 [lb/ft^3];

M = total mass of all materials batched, kg [lb] (see Note 3);

M_c = mass of the measure filled with concrete, kg [lb];
M_m = mass of the measure, kg [lb];
R_y = relative yield;
T = theoretical mass of the concrete computed on an airfree basis, or kg/m^3 [lb/ft^3] (see Note 2);
V = total absolute volume of the component ingredients in the batch, m^3 [ft^3];
V_m = volume of the measure;
Y_d = volume of concrete which the batch was designed to produce, m^3 [yd^3];
Y = yield, volume of concrete produced per batch, m^3 or [yd^3].

Note 2—The theoretical density, customarily, a laboratory determination, the value for which is assumed to remain constant for all batches made using identical component ingredients and proportions. It is calculated from the equation:

$$T = M/V \qquad (1)$$

The absolute volume of each ingredient in cubic meters is equal to the quotient of the mass of the ingredient divided by the product of its specific gravity times 62.4. The absolute volume of each ingredient in cubic meters is equal to the mass of the ingredient in kilograms divided by 1000 times its specific gravity. For the aggregate components, the bulk specific gravity and mass should be based on the saturated, surface-dry condition. For cement, the actual specific gravity should be determined by T 133. A value of 3.15 may be used for cements manufactured to meet the requirements of M 85.

Note 3—The total mass of all materials batched is the sum of the masses of the cement, the fine aggregate in the condition used, the coarse aggregate in the condition used, the mixing water added to the batch and any other solid or liquid materials used.

4. APPARATUS

4.1 *Balance*—A balance or scale accurate to within 45 g [0.1 lb] or 0.3 percent of the test load, whichever is greater, at any point within the range of use. The range of use shall be considered to extend from the mass of the measure empty to the mass of the measure plus its contents at 2600 kg/m^3 [160 lb/ft^3].

4.2 *Tamping Rod*—A round, straight steel rod, 16 mm [$^5/_8$ in.] in diameter and approximately 60 mm [24 in.] in length, having the tamping end rounded to a hemispherical tip the diameter of which is 16 mm [$^5/_8$ in.].

4.3 *Internal Vibrator*—Internal vibrators may have rigid or flexible shafts, preferably powered by electric motors. The frequency of vibration shall be 117 Hz [7000 vibrations per minute] or greater while in use. The outside diameter or the side dimension of the vibrating element shall be at least 19 mm [0.75 in.] and not greater than 38 mm [1.50 in.]. The length of the shaft shall be at least 610 mm [24 in.].

4.4 *Measure*—A cylindrical container made of steel or other suitable metal (Note 3). The minimum capacity of the measure shall conform to the requirements of Table 1 based on the nominal size of aggregate in the concrete to be tested. All measures, except for measuring bowls of air meters, which are also used for T 121 tests, shall conform to the requirements of T 19M/T 19. When measuring bowls of air meters are used, they shall conform to the requirements of T 152 and shall be calibrated for volume as described in T 19M/T 19. The top rim of the air meter bowls shall be smooth and plane within 0.25 mm [0.01 in.].

Note 4—The metal should not be readily subject to attack by cement paste. However, reactive materials such as aluminum alloys may be used in instances where as a consequence of an initial reaction, a surface film is rapidly formed which protects the metal against further corrosion.

Note 5—The top rim is satisfactorily plane if a 0.25-mm [0.01-in.] feeler gauge cannot be inserted between the rim and a piece of 6 mm [1/4 in.] or thicker plate glass laid over the top of the measure.

4.5 *Strike-Off Plate*—A flat rectangular metal plate at least 6 mm [1/4 in.] thick or a glass or acrylic plate at least 13 mm [1/2 in.] thick with a length and width at least 50 mm [2 in.] greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within a tolerance of 1.6 mm [1/16 in.].

4.6 *Mallet*—A mallet (with a rubber or rawhide head) having a mass of 600 ± 200 g [1.25 ± 0.50 lb] for use with measures 14 L [0.5 ft^3] or smaller, and a mallet having a mass of 1000 ± 200 g [2.25 ± 0.50 lb] for use with measures larger than 0.014 m^3 [0.5 ft^3].

Table 1—Capacity of Measures

Nominal Maximum Size of Coarse Aggregate[a]		Capacity of Measure[a]	
mm	in.	L	ft^3
25.0	1	6	0.2
37.5	1 1/2	11	0.4
50	2	14	0.5
75	3	28	1.0
112	4 1/2	70	2.5
150	6	100	3.5

[a] The indicated size of measure shall be used to test concrete containing aggregates of a nominal maximum size equal to or smaller than that listed. The actual volume of the measure shall be at least 95 percent of the nominal volume listed.

4.7 *Scoop*—A scoop of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the measure.

5. SAMPLE

5.1 Obtain the sample of freshly mixed concrete in accordance with T 141.

6. PROCEDURE

6.1 The methods of consolidation are rodding and internal vibration. Rod concretes with a slump greater than 75 mm [3 in.]. Rod or vibrate concrete with a slump of 25 to 75 mm [1 to 3 in.]. Consolidate concretes with a slump less than 25 mm [1 in.] by vibration.

Note 6—The nonplastic concrete, such as is commonly used in the manufacture of pipe and unit masonry, is not covered by this test method.

6.2 *Rodding*—Place the concrete in the measure in three layers of approximately equal volume using scoop described in 4.7. Rod each layer with 25 strokes of the tamping rod when the 0.014 m^3 [0.5 ft^3] or smaller measures are used and 50 strokes when the 0.028 m^3 [1 ft^3] measure is used. Rod the bottom layer throughout its depth but the rod shall not forcibly strike the bottom of the measure. Distribute the strokes uniformly over the cross section of the measure and for the top two layers, penetrate about 25 mm [1 in.] into the underlying layer. After each layer is rodded, tap the sides of the measure smartly 10 to 15 times with the appropriate mallet (Section 4.6) using such force so as to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. Add the final layer so as to avoid overfilling.

6.3 *Internal Vibration*—Fill and vibrate the measure in two approximately equal layers. Place all of the concrete for each layer in the measure before starting vibration of that layer. Insert the vibrator at three different points of each layer. In compacting the bottom layer, do not allow the vibrator to rest on or touch the bottom or sides of the measure. In compacting the final layer, the vibrator shall penetrate into the underlying layer approximately 25 mm [1 in.]. Take care that the vibrator is withdrawn in such a manner that no air pockets are left in the specimen. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator (Note 7). Continue vibration only long enough to achieve proper consolidation of the concrete (Note 8). Observe a constant duration of vibration for the particular kind of concrete, vibrator, and measure involved.

Note 7—Usually, sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth.

Note 8—Overvibration may cause segregation and loss of appreciable quantities of intentionally entrained air.

6.4 On completion of consolidation, the measure must not contain a substantial excess or deficiency of concrete. An excess of concrete protruding approximately 3 mm [$^1/_8$ in.] above the top of the mold is optimum. A small quantity of concrete may be added to correct a deficiency. If the measure contains a great excess of concrete at completion of consolidation, remove a representative portion of the excess concrete with a trowel or scoop immediately following completion of consolidation and before the measure is struck-off.

6.5 *Strike-Off*—After consolidation, strike-off the top surface of the concrete and finish it smoothly with the flat strike-off plate using great care to leave the measure just level full. The strike-off is best accomplished by pressing the strike-off plate on the top surface of the measure to cover about two-thirds of the surface and withdrawing the plate with a sawing motion to finish only the area originally covered. Then place the plate on the top of the measure to cover the original two-thirds of the surface and advance it with a vertical pressure and a sawing motion to cover the whole surface of the measure. Several final strokes with the inclined edge of the plate will produce a smooth finished surface.

6.6 *Mass Determination*—After strike-off, clean all excess concrete from the exterior of the measure and determine the net mass of the concrete in the measure to an accuracy consistent with the requirements of Section 4.1.

7. CALCULATIONS

7.1 *Density (Unit Mass)*—Calculate the net mass of the concrete in kilograms (pounds) by subtracting the mass of the measure from the gross mass. Calculate the unit mass, M_m, from the mass of the measure filled with concrete M_c. Calculate the density, D, by dividing the net mass of the concrete by the volume of the measure V_m as follows:

$$D = (M_c - M_m)/V_m \qquad (2)$$

7.2 *Yield*—Calculate the yield as follows:

$$Y(\mathrm{yd}^3) = M / (D \times 27) \qquad (3)$$

or,

$$Y(m^3 \text{ or } ft^3) = M/D \qquad (4)$$

7.3 *Relative Yield*—Relative yield is the ratio of the actual volume of concrete obtained to the volume as designed for the batch (see Note 9) calculated as follows:

$$R_y = Y/Y_d \qquad (5)$$

Note 9—A value for R_y greater than 1.00 indicates an excess of concrete being produced whereas a value less than this indicates the batch to be "short" of its designed volume. In practice, a ratio of yield in cubic feet per cubic yard of design concrete mixture is frequently used, for example, 27.3 ft^3/yd^3.

7.4 *Cement Content*—Calculate the actual cement content as follows:

$$C = C_b / Y \tag{6}$$

7.5 *Air Content*—Calculate the air content as follows:

$$A = \left[\left(T - D \right) / T \right] \times 100 \tag{7}$$

or,

$$A = \left[\left(Y - V \right) / Y \right] \times 100 \left(\text{SI units} \right) \tag{8}$$

or,

$$A = \left[(Y_f - V) / Y_f \right] \times 100 \left(\text{Inch-pound unit} \right) \tag{9}$$

8. REPORT

8.1 Report on the following information:

8.1.1 Identification of concrete represented by the sample.

8.1.2 Date of Test.

8.1.3 Volume of Density measure to the nearest .001 ft^3 (0.01 L).

8.1.4 Density (Unit Weight) to the nearest 0.1 lb/ft^3 (1.0 kg/m^3).

8.1.5 Yield, when requested, to the nearest 0.1 yd^3 (0.1m^3).

8.1.6 Relative Yield, when requested, to the nearest 0.01.

8.1.7 Cement Content, when requested, to the nearest 1.0 lb (0.5 kg).

8.1.8 Air Content, when requested, to the nearest 0.1 percent.

9. PRECISION AND BIAS

9.1 The following estimates of precision for this test method are based on a collection of data from various locations by the National Ready Mixed Concrete Association. The data represent concrete mixtures with slump ranging from 75 to 150 mm [3 to 6 in.] and density ranging from 1842 to 2483 kg/m^3 [115 to 155 lb/ft^3] and included air-entrained and non air-entrained concrete. The study was conducted using 7-L [0.25 ft^3] and 14-L [0.5 ft^3] measures.

9.1.1 *Single-Operator Precision*—The single operator standard deviation of density of freshly mixed concrete has been found to be 10.4 kg/m^3 [0.65 lb/ft^3] (1s). Therefore, results of two properly conducted by the same operator on the same sample of concrete should not differ by more than 29.6 kg/m^3 [1.85 lb/ft^3] (d2s).

9.1.2 *Multi-Operator Precision*—The multi-operator standard deviation of density of freshly mixed concrete has been found to be 13.1 kg/m^3 [0.82 lb/ft^3] (1s). Therefore, results of two properly conducted tests by the two operators on the same sample of concrete should not differ by more than 37.0 kg/m^3 [2.31 lb/ft^3] (d2s).

9.2 *Bias*—This test method has no bias since the density is defined only in terms of this test method.

10. KEYWORDS

10.1 Air content; cement content; concrete; relative yield; unit weight; yield.

Standard Method of Test for

Compressive Strength of Concrete Using Portions of Beams Broken in Flexure

AASHTO Designation: T 140-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Compressive Strength of Concrete Using Portions of Beams Broken in Flexure

AASHTO Designation: T 140-97 (2009)

1. SCOPE

1.1. This method covers the determination of compressive strength of concrete, using portions of beams broken in flexure for test specimens.

Note 1—This method was originally developed to cover testing portions of beams having a square cross section as "modified cubes" and former versions of this procedure were subtitled "Modified Cube Method." This terminology no longer applies because beams of rectangular cross section may be tested as provided under Section 6.1.

Note 2—For methods of making flexural test specimens from which the specimens for this test method may be obtained, refer to R 39, T 23, and T 24M/T 24.

Note 3—For methods of making the flexural strength test, refer to T 97 and T 177.

1.2. The values stated in inch-pound units are to be regarded as the standard.

1.3. *This standard does not purport to address the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 97, Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)
- T 177, Flexural Strength of Concrete (Using Simple Beam with Center-Point Loading)
- T 231, Capping Cylindrical Concrete Specimens

2.2. *ASTM Standard*:

- E 4, Standard Practices for Force Verification of Testing Machines

3. SIGNIFICANCE AND USE

3.1. This test method is intended for use in the laboratory and as a research tool for determining relative compressive strength values for various concrete mixtures. It is not intended as an alternative for T 22, and the test values obtained by these two test methods are not interchangeable and not necessarily comparable.

4. APPARATUS

4.1. The testing machine may be of any type of sufficient capacity that will provide the rate of loading prescribed in Section 6.3. It shall conform to the requirements of the sections on Basis of Verification, Corrections, and Time Interval between Verifications of ASTM E 4. The testing machine shall be equipped with two steel bearing blocks with hardened faces (Note 4), one of which is a spherically seated block that will bear on the top bearing plate described in Section 4.2, and the other a plain rigid block that will support the bottom bearing plate described in Section 4.2. The diameter of the spherical bearing block shall be at least 75 percent of the width (B in Figure 1) of the specimen. The bearing faces shall not depart from a plane by more than 0.001 in. (0.025 mm) in any 6 in. (152 mm) for a block 6 in. (152 mm) in diameter or larger, or by more than 0.001 in. (0.025 mm) in the diameter of any smaller block; new blocks shall be manufactured within one-half of this tolerance.

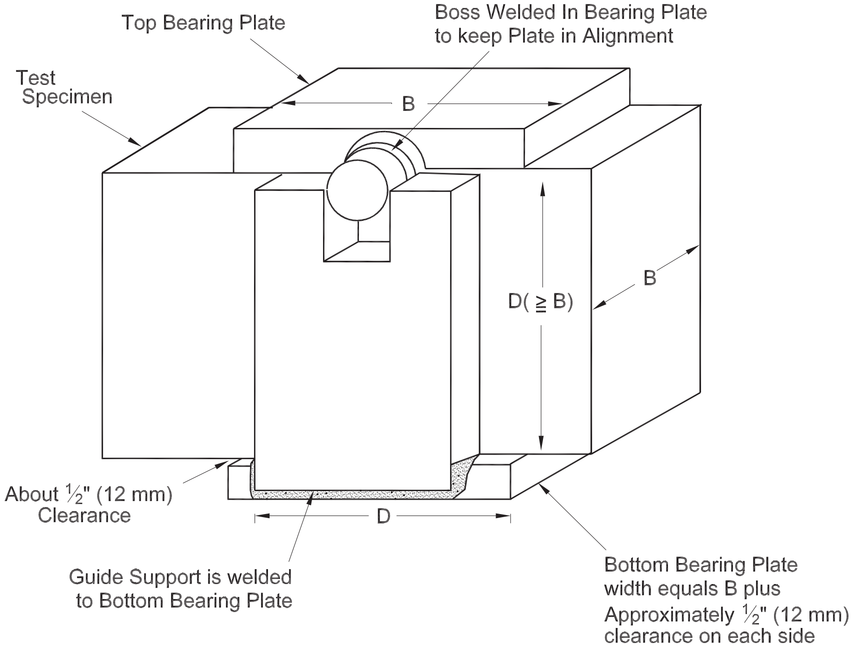


Figure 1—Device Suitable for Aligning Bearing Plates

Note 4—It is desirable that the bearing faces of blocks used for compression testing of concrete have a Rockwell hardness of not less than HRC 60.

4.2. Machined or ground metal bearing plates not less than $^3/_4$ in. (19 mm) in thickness, that meet the planeness requirements for the bearing faces of specimens specified in Section 5.2.1 and the hardness requirements for bearing blocks specified in Section 4.1, shall be mounted on the bearing surfaces of the specimen. The bearing plates shall be of such dimensions that the contact faces shall be substantially square and shall have the same dimensions as the nominal width of the beam tested. The upper bearing plate shall be placed directly over the lower plate. A drawing of a satisfactory device designed to ensure the proper location of the upper plate with reference to the lower plate is shown in Figure 1. The bearing faces shall not depart from a plane by more than 0.001 in. (0.025 mm) in 6 in. (152 mm), and new bearing plates shall be manufactured within one-half of this tolerance.

5. TEST SPECIMENS

5.1. The length of broken portions of beams selected for the compression test shall be at least 2 in. (50 mm) greater than the width. The selected compression test section shall be free from cracks, chipped surfaces and other obvious defects.

5.2. *Preparation of Test Specimens*:

5.2.1. The bearing faces of the specimen shall not depart from a plane by more than 0.002 in. (0.05 mm); bearing faces that are not plane shall be ground or capped to meet the 0.002 in. (0.05 mm) tolerance. Capping procedures shall follow the applicable provisions of T 231. Caps shall cover the full width of the beam and shall be of such length as to permit the adjustment of the bearing plates for the test so that the upper bearing plate may be aligned directly above the lower plate (Figure 1).

5.2.2. During the interval between testing of specimens in flexure, or after capping and testing the broken portions in compression, the specimens shall be kept in the same condition as prescribed under the method for making and curing flexural test specimens from which the specimens for this test were obtained.

6. PROCEDURE

6.1. Orientation of the specimen shall be such that the width (B in Figure 1) shall be equal to or less than the height (D in Figure 1). If the beam has a square cross section the bearing surfaces may be the sides of the beam as originally cast.

6.2. Center the bearing plates in the testing machine so that the thrust of the spherically seated block of the test machine is aligned with the center of the bearing plates. Apply the load to the bearing plates by means of an adjustable head.

6.3. *Rate of Loading*—Apply the load continuously and without shock. The moving head of the screw type of testing machine shall travel at the rate of approximately 0.05 in./minute (1.3 mm/min) when the machine is running idle. In hydraulic machines, adjust the loading to a constant rate within the limits of 35 ± 15 psi/second (241 ± 103 kPa/second).

6.4. Test specimens to failure. Record the total load indicated by the testing machine at failure of the test specimen.

7. CALCULATION

7.1. Calculate the unit compressive strength calculated to the nearest 10 psi (69 kPa). The cross-sectional area of the specimen shall be taken as the average of at least two measurements of the "B" dimensions (Figure 1) of both the top and bottom bearing plates multiplied by the average of at least two measurements of the "B" dimension of both the top and bottom bearing surfaces of the specimen determined to the nearest 0.01 in. (0.25 mm).

8. REPORT

8.1. *Report the following information*:

8.1.1. That the determination was made using this test method,

8.1.2. Specimen identification number,

8.1.3. "B" and "D" dimensions in inches (or millimeters),

8.1.4. Cross-sectional area, in square inches (or square millimeters),

8.1.5. Maximum load, in pound-force (newtons),

8.1.6. Compressive strength calculated to the nearest 10 psi (69 kPa),

8.1.7. Method of obtaining specimen,

8.1.8. Age of specimen and details of curing,

8.1.9. Orientation of specimen with respect to the top of the beam as cast,

8.1.10. Type of failure and appearance of concrete, and

8.1.11. Conditions of curing the specimens and moisture condition at time of test.

9. PRECISION AND BIAS

9.1. The precision of this test has not been determined, but data are being collected and a precision statement will be included when it is developed.

9.2. No statement concerning bias is being made at this time.

10. KEYWORDS

10.1. Compressive strength; concrete; flexural beams; strength testing.

Standard Method of Test for

Sampling Freshly Mixed Concrete

AASHTO Designation: T 141-05 (2009)
ASTM Designation: C 172-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling Freshly Mixed Concrete

AASHTO Designation: T 141-05 (2009)

ASTM Designation: C 172-04

1. SCOPE

1.1. This method covers the procedures for obtaining representative samples of fresh concrete as delivered to the project site and on which tests are to be performed to determine compliance with quality requirements of the specifications under which the concrete is furnished (Note 1). The method includes sampling from stationary, paving, and truck mixers, and from agitating and nonagitating equipment used to transport central mixed concrete.

1.2. The values stated in SI units are to be regarded as the standard. The inch-pound equivalents of metric units may be approximate.

Note 1—Composite samples are required by this method, unless specifically excepted by procedures governing the tests to be performed, such as tests to determine uniformity of consistency and mixer efficiency. Procedures used to select the specific test batches are not described in this method, but it is recommended that random sampling be used to determine overall specification compliance.

1.3. This practice also covers the procedures to be used for preparing a sample of concrete for further testing where it is desirable or necessary to remove the aggregate larger than a designated size. This removal of larger aggregate particles is preferably accomplished by wet-sieving.

1.4. The text of this standard references notes and footnotes that provide explanatory material and shall not be considered as requirements of the practice.

1.5. *This standard does not purport to address of all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- M 92, Wire-Cloth Sieves for Testing Purposes

3. SIGNIFICANCE AND USE

3.1. This practice is intended to provide standard requirements and procedures for sampling freshly mixed concrete from different containers used in the production or transportation of concrete. The detailed requirements as to materials, mixtures, air content, temperature, number of specimens, slump, interpretation of results, and precision and bias are in specific test methods.

4. SAMPLING

4.1. The elapsed time shall not exceed 15 minutes between obtaining the first and final portions of the composite sample.

4.1.1. Transport the individual samples to the place where fresh concrete tests are to be performed or where test specimens are to be molded. They shall then be combined and remixed with a shovel the minimum amount necessary to ensure uniformity and compliance with the minimum time limits specified in Section 4.1.2.

4.1.2. Start tests for slump, temperatures, and air content, within 5 minutes after obtaining the final portion of the composite sample. Complete these tests quickly. Start molding specimens for strength tests within 15 minutes after fabricating the composite sample. Quickly obtain and use the sample and protect the sample from the sun, wind, and other sources of rapid evaporation, and from contamination.

5. PROCEDURE

5.1. *Size of Sample*—Make the samples to be used for strength tests a minimum of 28 L (1 ft^3). Smaller samples are not prohibited for routine air content and slump tests and the size shall be dictated by the maximum aggregate size.

5.2. The procedures used in sampling shall include the use of every precaution that will assist in obtaining samples that are truly representative of the nature and condition of concrete sampled as follows:

Note 2—Sampling should normally be performed as the concrete is delivered from the mixer to the conveying vehicle used to transport the concrete to the forms; however, specifications may require other points of sampling, such as at the discharge of a concrete pump.

Note 3—As routine air content and slump tests are not readily adaptable to sampling the concrete at two or more regularly spaced intervals during discharge of the middle portion of the batch as specified in this method, the sample for air content, slump, and temperature may be taken after at least one-quarter cubic yard of concrete has been discharged.

5.2.1. *Sampling from Stationary Mixers, Except Paving Mixers*—Sample the concrete by collecting two or more portions taken at regularly spaced intervals during discharge of the middle of the batch. Obtain these portions within the time limit specified in Section 4. Composite the portions into one sample for testing purposes. Do not obtain portions of the composite sample from the very first or last part of the batch discharge (Note 4).

Perform sampling by passing a receptacle completely through the discharge stream, or by completely diverting the discharge into a sample container. If discharge of the concrete is too rapid to divert the complete discharge stream, discharge the concrete into a container or transportation unit sufficiently large to accommodate the entire batch and then accomplish the sampling in the same manner as given above. Take care not to restrict the flow of concrete from the mixer, container, or transportation unit so as to cause segregation. These requirements apply to both tilting and nontilting mixers.

Note 4—No sample should be taken before 10 percent or after 90 percent of the batch has been discharged. Due to the difficulty of determining the actual quantity of concrete discharged, the intent is to provide samples that are representative of widely separated portions, but not the beginning and end of the load.

5.2.2. *Sampling from Paving Mixers*—Sample the concrete after the contents of the paving mixer have been discharged. Obtain samples from at least five different portions of the pile and then composite into one sample for test purposes. Avoid contamination with subgrade material or prolonged contact with an absorptive subgrade. To preclude contamination or absorption by the subgrade, sample the concrete by placing three shallow containers on the subgrade and discharging the concrete across the containers. Composite the samples so obtained into one sample for test purposes. The containers shall be of a size sufficient to provide a composite sample size that is in agreement with the maximum aggregate size.

Note 5—In some instances, the containers may have to be supported above the subgrade to prevent displacement during discharge.

5.2.3. *Sampling from Revolving Drum Truck Mixers or Agitators*—Sample the concrete by collecting two or more portions taken at regularly spaced intervals during discharge of the middle portion of the batch. Take the samples so obtained within the time limit specified in Section 4 and composite them into one sample for test purposes. In any case do not obtain samples until after all of the water has been added to the mixer; also do not obtain samples from the very first or last portions of the batch discharge (Note 4). Sample by repeatedly passing a receptacle through the entire discharge stream or by completely diverting the discharge into a sample container. Regulate the rate of discharge of the batch by the rate of revolution of the drum and not by the size of the gate opening.

5.2.4. *Sampling from Open-Top Truck Mixers, Agitators, Nonagitating Equipment, or Other Types of Top Containers*—Take samples by whichever of the procedures described in Sections 5.2.1, 5.2.2, or 5.2.3 is most applicable under the given conditions.

6. ADDITIONAL PROCEDURE FOR LARGE, MAXIMUM SIZE AGGREGATE CONCRETE

6.1. When the concrete contains aggregate larger than that appropriate for the size of the molds or equipment to be used, wet-sieve the sample as described below except perform density (unit weight) tests for use in yield computations on the full mix.

Note 6—The effect of wet-sieving on the test results should be considered. For example, wet-sieving concrete causes the loss of a small amount of air due to additional handling. The air content of the wet-sieved fraction of concrete is greater than that of the total concrete because the larger size aggregate that is removed does not contain air. The apparent strength of wet-sieved concrete in smaller specimens is usually greater than that of the total concrete in larger appropriate size specimens. The effect of these differences may need to be considered or determined by supplementary testing for quality control or test result evaluation purposes.

6.2. *Definition*:

6.2.1. *Wet-Sieving Concrete*—the process of removing aggregate larger than a designated size from the fresh concrete by sieving it on a sieve of the designated size.

6.3. *Apparatus*:

6.3.1. Sieves, as designated, conforming to M 92.

6.3.2. *Wet-Sieving Equipment*—Equipment for wet-sieving concrete shall be a sieve as noted in Section 6.3.1 of suitable size and conveniently arranged and supported so that one can shake it rapidly by either hand or mechanical means. Generally, a horizontal back and forth motion is preferred. The equipment shall be capable of rapidly and effectively removing the designated size of aggregate.

6.3.3. *Hand Tools*—Shovels, hand scoops, plastering trowels, and rubber gloves as required.

6.4. *Procedure*:

6.4.1. *Wet-Sieving*—After sampling the concrete, pass the concrete over the designated sieve and remove and discard the aggregate retained. This shall be done before remixing. Shake or vibrate the sieve by hand or mechanical means until no undersize material remains on the sieve. Mortar adhering to the aggregate retained on the sieve shall not be wiped from it before it is discarded. Place only enough concrete on the sieve at any one time so that after sieving, the thickness of the layer of retained aggregate is not more than one particle thick. The concrete that passes the sieve shall fall into a batch pan of suitable size that has been dampened before use or onto a clean, moist, nonabsorbent surface. Scrape any mortar adhering to the sides of the wet-sieving equipment into the batch. After removing the larger aggregate particles by wet-sieving, remix the batch with a shovel the minimum amount necessary to ensure uniformity and proceed testing immediately.

7. KEYWORDS

7.1. Air content; batch; composite sample; concrete; slump; temperature; wet-sieving.

Standard Method of Test for

Measuring Length of Drilled Concrete Cores

AASHTO Designation: T 148-07[1]
ASTM Designation: C 174/C 174M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Measuring Length of Drilled Concrete Cores

AASHTO Designation: T 148-07[1]
ASTM Designation: C 174/C 174M-06

1. SCOPE

1.1. This test method covers determination of the length of a core drilled from a concrete pavement or structural element by measuring the length of a core drilled from a concrete structure.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. SIGNIFICANCE AND USE

2.1. This method is used to determine the compliance of concrete construction with design specifications. It is especially important in determining the thickness of pavements and other slab construction.

3. APPARATUS

3.1. The apparatus shall consist of a 3-point calipering device that will measure the length of axial elements of the core. While the details of the mechanical design are not prescribed, the apparatus shall conform to the requirements of Sections 3.2 to 3.6.

3.2. The apparatus shall be so designed that the specimen will be held with its axis in a vertical position by three symmetrically placed supports bearing against the lower end. These supports shall be short posts or studs of hardened steel, and the ends that bear against the surface of the specimen shall be rounded to a radius of not less than 6 mm ($^1/_4$ in.) and not more than 13 mm ($^1/_2$ in.).

3.3. The apparatus shall provide for the accommodation of specimens of different nominal lengths over a range of at least 100 to 250 mm (4 to 10 in.).

3.4. The calipering device shall be so designed that it will be possible to make a length measurement at the center of the upper end of the specimen, and at eight additional points spaced at equal intervals along the circumference of a circle whose center points coincides with that of the end area of the specimen and whose radius is not less than one-half nor more than three-fourths of the radius of the specimen.

3.5. The measuring rod or other device that makes contact with the end surface of the specimen for measurement shall be rounded to a radius of 3 mm ($^1/_8$ in.). The scale on which the length readings are made shall be marked with clear, definite, accurately spaced graduations. The spacing of the graduations shall be 1.0 mm (0.10 in.) during all normal measuring operations.

3.6. The apparatus shall be stable and sufficiently rigid to maintain its shape and alignment without a distortion or deflection of more than 0.25 mm (0.01 in.) during all normal measuring operations.

4. TEST SPECIMENS

4.1. Cores used as specimens for length measurement shall be in every way representative of the concrete in the structure from which they are removed. The specimen shall be drilled with the axis normal to the surface of the structure, and the ends shall be free from all conditions not typical of the surfaces of the structure. Cores that show abnormal defects or that have been damaged appreciably in the drilling operation shall not be used. If a core drilled from a pavement or structure placed on dense-graded base course aggregates includes particles of the aggregate bonded to the bottom surface of the concrete, the bonded particles shall be removed by wedging or by chisel and hammer applied so as to expose the lower surface of the concrete. If the concrete is placed on an open-graded aggregate base course, the mortar in the concrete may penetrate into the base and surround some particles. Use sufficient force with a wedge or chisel and hammer to remove bonded particles, but not such force as to fracture particles substantially surrounded by mortar. If during the removal of bonded aggregate the concrete is broken so that the instructions of Section 5.4 cannot be followed, the core shall not be used for length measurement.

5. PROCEDURE

5.1. Before any measurements of the core length are made, calibrate the apparatus with suitable gages so that errors caused by mechanical imperfections in the apparatus are known. When these errors exceed 0.25 mm (0.01 in.), apply suitable corrections to the core length measurements.

5.2. Place the specimen in the measuring apparatus with the smooth end of the core, that is, the end that represents the upper surface of the pavement slab or a formed surface in the case of other structures, placed down so as to bear against the three hardened-steel supports. So place the specimen on the supports that the central measuring position of the measuring apparatus is directly over the midpoint of the upper end of the specimen.

5.3. Make nine measurements of the length on each specimen, one at the central position and one each at eight additional positions spaced at equal intervals along the circumference of the circle of measurement. Read each of these nine measurements directly to the nearest 1.0 mm (0.05 in.).

5.4. If, in the course of the measuring operation, it is discovered that at one or more of the measuring points the surface of the specimen is not representative of the general plane of the core end because of a small projection or depression, the specimen shall be rotated slightly about its axis and a complete set of nine measurements made with the specimen in the new position. With cores from pavements placed over open-graded aggregate bases, the foregoing provisions frequently cannot be met because of the great number of projections or voids on the bottom surface.

6. REPORT

6.1. The individual observations shall be recorded to the nearest 1.0 mm (0.05 in.), and the average of the nine measurements expressed to the nearest 1.0 mm (0.1 in.) shall be reported as the length of the concrete core.

7. PRECISION AND BIAS

7.1. *Precision*:

7.1.1. *3-Point Caliper*—No statement is made about the precision of this Test Method, however, a precision statement may be drafted in the future.

7.2. *Bias*—Because there are not acceptable reference cores suitable for determining the bias of these procedures, no statement on bias is being made.

8. KEYWORDS

8.1. 3-point caliper; concrete; cores; length measurement; thickness measurement.

---

[1] This method is the same as ASTM C 174/C 174M-06 except for the following: Section 1.2 of C 174 allows either the SI units or inch-pound units to be regarded as standard. Figure 1 of C 174 is not included.

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Pressure Method

AASHTO Designation: T 152-10
ASTM Designation: C 231-08c

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Pressure Method

AASHTO Designation: T 152-10
ASTM Designation: C 231-08c

1. SCOPE

1.1 This method covers determination of the air content of freshly mixed concrete from observation of the change in volume of concrete with a change in pressure.

1.2 This method is intended for use with concretes and mortars made with relatively dense aggregates for which the aggregate correction factor can be satisfactorily determined by the technique described in Section 5. It is not applicable to concretes made with light-weight aggregates, air-cooled blast-furnace slag, or aggregates of high porosity. In these cases, T 196M/T 196 should be used. This test method is also not applicable to nonplastic concrete such as is commonly used in the manufacture of pipe and concrete masonry units.

1.3 The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements for this standard.

1.4 The values stated in inch-pound units are to be regarded as the standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. See Note A1.7 for a specific caution statement.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

---

3. SIGNIFICANCE AND USE

3.1 This test method covers the determination of the air content of freshly mixed concrete. The test determines the air content of freshly mixed concrete exclusive of any air that exists inside voids within aggregate particles. For this reason, it is applicable to concrete made with relatively dense aggregate particles and requires determination of the aggregate correction factor. (See Sections 6.1 and 9.1.)

3.2 This test method and T 121M/T 121 and T 196M/T 196 provide pressure, gravimetric, and volumetric procedures, respectively, for determining the air content of freshly mixed concrete. The pressure procedure of this test method gives substantially the same air content as the other two test methods for concrete made with dense aggregates.

3.3 The air content of hardened concrete may be either higher or lower than that determined by this test method. This depends upon the methods and amount of consolidation effort applied to the concrete from which the hardened concrete specimen is taken; uniformity and stability of the air bubbles in the fresh and hardened concrete; accuracy of the microscopic examination, if used; time of comparison; environmental exposure; stage in the delivery, placement, and consolidation processes at which the air determined, that is, before or after the concrete goes through a pump; and other factors.

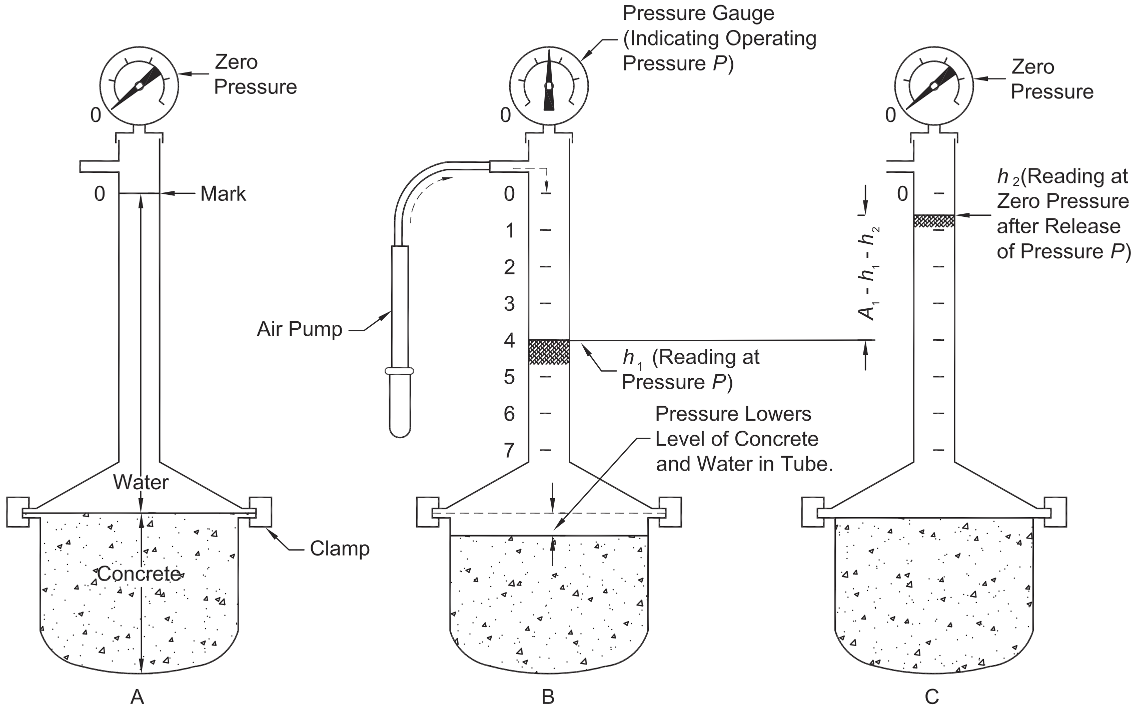
4. APPARATUS

4.1 *Air Meters*—There are available satisfactory apparatus of two basic operational designs employing the principle of Boyle's Law. For purposes of reference herein these are designated Meter Type A and Meter Type B.

4.1.1 *Meter Type A*—An air meter consisting of a measuring bowl and cover assembly (Figure 1) conforming to the requirements of Sections 4.2 and 4.3. The operational principle of this meter consists of introducing water to a predetermined height above a sample of concrete of known volume, and the application of a predetermined air pressure over the water. The determination consists of the reduction in volume of the air in the concrete sample by observing the amount the water level is lowered under the applied pressure, the latter amount being calibrated in terms of percent of air in the concrete sample.

4.1.2 *Meter Type B*—An air meter consisting of a measuring bowl and cover assembly (Figure 2) conforming to the requirements of Sections 4.2 and 4.3. The operational principle of this meter consists of equalizing a known volume of air at a known pressure in a sealed air chamber with the unknown volume of air in the concrete sample, the dial on the pressure gauge being calibrated in terms of percent air for the observed pressure at which equalization takes place. Working pressures of 7.5 to 30.0 psi (51 to 207 kPa) have been used satisfactorily.

4.2 *Measuring Bowl*—The measuring bowl shall be essentially cylindrical in shape, made of steel, hard metal, or other hard material not readily attacked by the cement paste, having a minimum diameter equal to 0.75 to 1.25 times the height, and a capacity of at least 0.20 ft^3 (5.7 L). It shall be flanged or otherwise constructed to provide for a pressure-tight fit between bowl and cover assembly. The interior surfaces of the bowl and surfaces of rims, flanges, and other component fitted parts shall be machined smooth. The measuring bowl and cover assembly shall be sufficiently rigid to limit the expansion factor, *D*, of the apparatus assembly (Annex A1.5) to not more than 0.1 percent of air content on the indicator scale when under normal operating pressure.



Note: $A_1 = h_1 - h_2$ when bowl contains concrete as shown in this figure; when bowl contains only aggregate and water, $h_1 - h_2 = G$ (aggregate correction factor). $A_1 - G = A$ (entrained air content of concrete).

Figure 1—Illustration of the Pressure Method for Air Content: Type A Meter

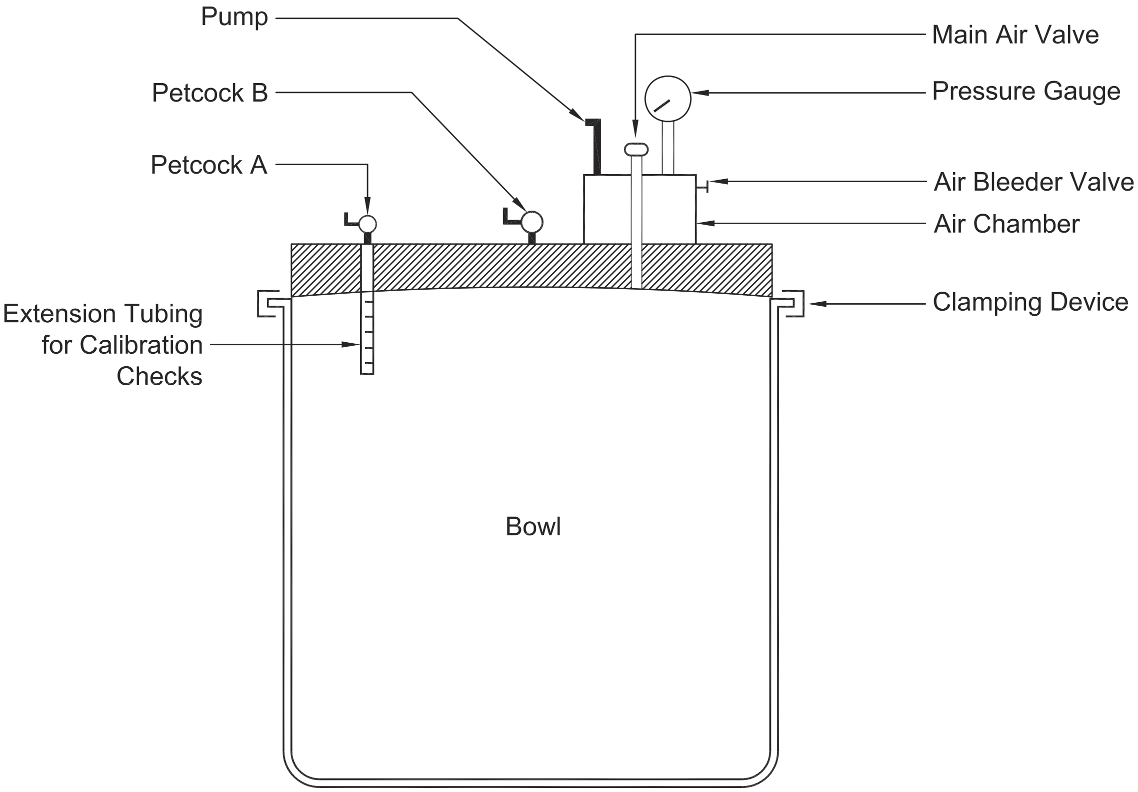


Figure 2—Schematic Diagram: Type B Meter

4.3 *Cover Assembly*:

4.3.1 The cover assembly shall be made of steel, hard metal, or other hard material not readily attacked by the cement paste. It shall be flanged or otherwise constructed to provide for a pressure-tight fit between bowl and cover assembly and shall have machined-smooth interior surfaces contoured to provide an air space above the level of the top of the measuring bowl. The cover shall be sufficiently rigid to limit the expansion factor of the apparatus assembly as prescribed in Section 4.2.

4.3.2 The cover assembly shall be fitted with a means of direct reading of the air content. The cover for the Type A meter shall be fitted with a standpipe, which may be a transparent graduated tube or may be a metal tube of uniform bore with a glass water gauge attached. In the Type B meter, the dial of the pressure gauge shall be calibrated to indicate the percent of air. Graduations shall be provided for a range in air content of at least 8 percent easily readable to 0.1 percent as determined by the proper air pressure calibration test.

4.3.3 The cover assembly shall be fitted with air valves, air bleeder valves, and petcocks for bleeding off or through which water may be introduced as necessary for the particular meter design. Suitable means for clamping the cover to the bowl shall be provided to make a pressure-tight seal without entrapping air at the joint between the flanges of the cover and bowl. A suitable hand pump shall be provided with the cover either as an attachment or as an accessory.

4.4 *Calibration Vessel*—A measure having an internal volume equal to a percent of the volume of the measuring bowl corresponding to the approximate percent of air in the concrete to be tested; or, if smaller, it shall be possible to check calibration of the meter indicator at the approximate percent of air in the concrete to be tested by repeated filling of the measure. When the design of the meter requires placing the calibration vessel within the measuring bowl to check calibration, the measure shall be cylindrical in shape and of an inside depth $^1/_2$ in. (13 mm) less than that of the bowl.

Note 1—A satisfactory calibration vessel to place within the measure bowl may be machined for No. 16 gauge brass tubing, of a diameter to provide the volume desired, to which a brass disk $^1/_2$ in. thick is soldered to form an end. When design of the meter requires withdrawing of water from the water-filled bowl and cover assembly to check calibration, the measure may be an integral part of the cover assembly or may be a separate cylindrical measure similar to the above described cylinder.

4.5 The designs of various available types of airmeters are such that they differ in operating techniques and therefore, all of the items described in Sections 4.6 through 4.16 may not be required. The items required shall be those necessary for use with the particular design of apparatus used to satisfactorily determine air content in accordance with the procedures prescribed herein.

4.6 *Coil Spring or Other Device for Holding Calibration Cylinder in Place*:

4.7 *Spray Tube*—A brass tube of appropriate diameter, which may be an integral part of the cover assembly or which may be provided separately. It shall be so constructed that when water is added to the container, it is sprayed to the walls of the cover in such a manner as to flow down the sides causing a minimum of disturbance to the concrete.

4.8 *Trowel*—A standard brick mason's trowel.

4.9 *Tamping Rod*—The tamping rod shall be a round straight steel rod $^5/_8$ in. (16 mm) in diameter and not less than approximately 16 in. (400 mm) in length, having the tamping end rounded to hemispherical tip the diameter of which is $^5/_8$ in. (16 mm).

4.10 *Mallet*—A mallet (with a rubber or rawhide head) weighing approximately 1.25 ± 0.50 lb (0.57 ± 0.23 kg) for use with measures of 0.5 ft^3 (14 L) or smaller, and a mallet weighing approximately 2.25 ± 0.50 lb (1.02 ± 0.23 kg) for use with measures larger than 0.5 ft^3 (14 L).

4.11 *Strike-Off Bar*—A flat straight bar of steel or other suitable metal at least $^1/_8$ in. (3 mm) thick and $^3/_4$ in. (20 mm) wide by 12 in. (300 mm) long.

4.12 *Strike-Off Plate*—A flat rectangular metal plate at least $^1/_4$ in. (6 mm) thick or a glass or acrylic plate at least $^1/_2$ in. (12 mm) thick with a length and width at least 2 in. (50 mm) greater than the diameter of the measure with which it is to be used. The edges of the plate shall be straight and smooth within a tolerance of $^1/_{16}$ in. (1.5 mm).

4.13 *Funnel*—with the spout fitting into spray tube.

4.14 *Measure for Water*—having the necessary capacity to fill the indicator with water from the top of the concrete to the zero mark.

4.15 *Vibrator*—as described in R 39.

4.16 *Sieves*—$1^1/_2$ in. (37.5 mm) with not less than 2 ft^2 (0.19 m^2) of sieving area.

4.17 *Scoop*—of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the measuring bowl.

5. CALIBRATION OF APPARATUS

5.1 Make calibration tests in accordance with procedures prescribed in the annex. Rough handling will affect the calibration of both Types A and B meters. Changes in barometric pressure will affect the calibration of the Type A meter but not the Type B meter. The steps described in Sections A1.2 to A1.6, as applicable to the meter type under consideration, are prerequisites for the final calibration test to determine the operating pressure, *P*, on the pressure gauge of the Type A meter as described in Section A1.7, or to determine the accuracy of the graduations indicating air content on the dial face of the pressure gauge of the Type B meter. Normally, the steps in Sections A1.2 to A1.6 need be made only once (at the time of initial calibration), or only occasionally to check volume constancy of the calibration cylinder and measuring bowl. On the other hand, the calibration test described in Sections A1.7 and A1.9, as applicable to the meter type being checked, must be made as frequently as necessary to ensure that the proper gauge pressure, *P*, is being used for the Type A meter or that the correct air contents are being indicated on the pressure gauge air content scale for the Type B meter. A change in elevation of more than 600 ft (183 m) from the location at which a Type A meter was last calibrated will require recalibration in accordance with Section A1.7.

5.2 *Calibration Records*—Information to be maintained in the records shall include determination of expansion factor, size of the calibration vessel used, and the reading of the meter at the calibration test point(s).

6. DETERMINATION OF AGGREGATE CORRECTION FACTOR

6.1 *Procedure*—Determine the aggregate correction factor on a combined sample of fine and coarse aggregate as directed in Sections 6.2 to 6.4. It is determined independently by applying the calibrated pressure to a sample of inundated fine and coarse aggregate in approximately the same moisture condition, amount, and proportions occurring in the concrete sample under test.

6.2 *Aggregate Sample Size*—Calculate the weights of fine and coarse aggregate present in the sample of fresh concrete whose air content is to be determined, as follows:

$$F_s = (S/B) \times F_b \tag{1}$$

$$C_s = (S/B) \times C_b \tag{2}$$

where:

F_s = weight of fine aggregate in concrete sample under test, lb (kg);
S = volume of concrete sample (same as volume of measuring bowl), ft^3 (m^3);
B = volume of concrete produced per batch (Note 2), ft^3 (m^3);
F_b = total weight of fine aggregate in the moisture condition used in batch, lb (kg);
C_s = weight of coarse aggregate in concrete sample under test, lb (kg); and
C_b = total weight of coarse aggregate in the moisture condition used in batch, lb (kg).

Note 2—The volume of concrete produced per batch can be determined in accordance with applicable provisions of T 121M/T 121.

Note 3—The term “weight” is temporarily used in this standard because of established trade usage. The word is used to mean both “force” and “mass” and care must be taken to determine which is meant in each case (SI unit for force = newton and for mass = kilogram).

6.3 *Placement of Aggregate in Measuring Bowl*—Mix representative samples of fine aggregate F_s, and coarse aggregate C_s, and place in the measuring bowl filled one-third full with water. Place the mixed aggregate, a small amount at a time, into the measuring bowl; if necessary, add additional water so as to inundate all of the aggregate. Add each scoopful in a manner that will entrap as little air as possible and remove accumulations of foam promptly. Tap the sides of the bowl and lightly rod the upper 1 in. (25 mm) of the aggregate about 8-12 times. Stir after each addition of aggregate to eliminate entrapped air.

6.4 *Aggregate Correction Factor Determination*:

6.4.1 *Initial Procedure for Types A and B Meters*—When all of the aggregate has been placed in the measuring bowl, remove excess foam and keep the aggregate inundated for a period of time approximately equal to the time between introduction of the water into the mixer and the time of performing the test for air content before proceeding with the determination as directed in Section 6.4.2 or 6.4.3.

6.4.2 *Type A Meter*—Complete the test as described in Sections 8.2.1-8.2.3. The aggregate correction factor, G, is equal to $h_1 - h_2$. (See Figure 1, Note 4.)

6.4.3 *Type B Meter*—Perform the procedures as described in Section 8.3.1. Remove a volume of water from the assembled and filled apparatus approximately equivalent to the volume of air that would be contained in a typical concrete sample of a size equal to the volume of the bowl. Remove the water in the manner described in Section A1.9 of the Annex for the calibration tests. Complete the test as described in Section 8.3.2. The aggregate correction factor, G, is equal to the reading on the air-content scale minus the volume of water removed from the bowl expressed as a percent of the volume of the bowl. (See Figure 1.)

Note 4—The aggregate correction factor will vary with different aggregates. It can be determined only by test, because apparently it is not directly related to absorption of the particles. The test can be easily made and must not be ignored. Ordinarily the factor will remain reasonably constant for given aggregates, but an occasional check test is recommended.

7. PREPARATION OF CONCRETE TEST SAMPLE

7.1 Obtain the sample of freshly mixed concrete in accordance with applicable procedures of T 141. If the concrete contains coarse aggregate particles that would be retained on a 2-in. (50-mm) sieve, wet-sieve a sufficient amount of the representative sample over a $1^1/_2$-in. (37.5-mm) sieve, as described in T 141 to yield somewhat more than enough material to fill the measuring bowl of the size selected for use. Carry out the wet-sieving operation with the minimum practical disturbance of the mortar. Make no attempt to wipe adhering mortar from coarse aggregate particles retained on the sieve.

8. PROCEDURE FOR DETERMINING AIR CONTENT OF CONCRETE

8.1 *Placement and Consolidation of Sample*:

8.1.1 Dampen the interior of the measuring bowl and place it on a flat, level, firm surface. Using the scoop described in 4.17 place a representative sample of the concrete, prepared as described in Section 7, in the measuring bowl in equal layers. Consolidate each layer by the rodding procedure (Section 8.1.2) or by vibration (Section 8.1.3). Strike off the finally consolidated layer (Section 8.1.4). Rod concretes with a slump greater than 3 in. (75 mm). Rod or vibrate concrete with a slump of 1 to 3 in. (25 to 75 mm). Consolidate concretes with a slump of less than 1 in. (25 mm) by vibration.

8.1.2 *Rodding*—Place the concrete in the measuring bowl in three layers of approximately equal volume. Consolidate each layer of concrete by 25 strokes of the tamping rod evenly distributed over the cross section. After each layer is rodded, tap the sides of the measure smartly 10 to 15 times with the mallet to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. Rod the bottom layer throughout its depth, but the rod shall not forcibly strike the bottom of the measure. In rodding the second and final layers, use only enough force to cause the rod to penetrate the surface of the previous layer about 1 in. (25 mm). Add the final layer of concrete in a manner to avoid excessive overfilling (Section 8.1.4).

8.1.3 *Vibration*—Place the concrete in the measuring bowl in two layers of approximately equal volume. Place all of the concrete for each layer before starting vibration of that layer. Consolidate each layer by three insertions of the vibrator evenly distributed over the cross section. Add the final layer in a manner to avoid excessive overfilling (Section 8.1.4). In consolidating each layer, do not allow the vibrator to rest on or touch the measuring bowl. Take care in withdrawing the vibrator to ensure that no air pockets are left in the specimen. Observe a standard duration of vibration for the particular kind of concrete, vibrator, and measuring bowl involved. The duration of vibration required will depend upon the workability of the concrete and the effectiveness of the vibrator. Continue vibration only long enough to achieve proper consolidation of the concrete. Overvibration may cause segregation and loss of intentionally entrained air. Usually, sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth and has a glazed appearance. Never continue vibration long enough to cause escape of froth from the sample.

Note 5—Overvibration may cause segregation and loss of intentionally entrained air. Usually, sufficient vibration has been applied as soon as the surface of the concrete becomes relatively smooth and has a glazed appearance.

8.1.4 *Strike Off*—After consolidation of the concrete, strike off the top surface by sliding the strike-off bar across the top flange or rim of the measuring bowl with a sawing motion until the bowl is just level full. On completion of consolidation, the bowl must not contain an excess or deficiency of concrete. Removal of approximately $^1/_8$ in. (3 mm) during strike off is optimum. A small quantity of representative concrete may be added to correct a deficiency. If the measure contains a great excess, remove a representative portion of concrete with a trowel or scoop before the measure is struck off. When a strike-off plate is used, strike off concrete as prescribed in T 121M/T 121.

Note 6—A small quantity of representative concrete may be added to correct a deficiency. If the measure contains great excess, remove a representative portion of the concrete with a trowel or scoop before the measure is struck off.

Note 7—The use of the strike-off plate on cast aluminum or other relatively soft metal air meter bases may cause rapid wear of the rim and require frequent maintenance, calibration, and ultimately, replacement.

8.1.5 *Application of Test Method*—Any portion of the test method not specifically designated as pertaining to Type A or Type B meter shall apply to both types.

8.2 *Procedure—Type A Meter*:

8.2.1 *Preparation for Test*—Thoroughly clean the flanges or rims of the bowl and of the cover assembly so that when the cover is clamped in place a pressure-tight seal will be obtained. Assemble the apparatus and add water over the concrete by means of the tube until it rises to about the halfway mark in the standpipe. Incline the apparatus assembly about 30 degrees from vertical and, using the bottom of the bowl as a pivot, describe several complete circles with the upper end of the column, simultaneously tapping the cover lightly to remove any entrapped air bubbles above the concrete sample. Return the apparatus assembly to a vertical position and fill the water column slightly above the zero mark, while lightly tapping the sides of the bowl. Bring the water level to the zero mark of the graduated tube before closing the vent at the top of the water column. (See Figure 1A.)

Note 8—Some Type A meters have a calibrated starting fill mark above the zero mark. Generally, this starting mark should not be used since, as noted in Section 8.2.3, the apparent air content is the difference between the water level reading H, at pressure P and the water level h_2 at zero pressure after release of pressure P.

8.2.2 The internal surface of the cover assembly shall be kept clean and free from oil or grease; the surface shall be wet to prevent adherence of air bubbles that might be difficult to dislodge after assembly of the apparatus.

8.2.3 *Test Procedure*—Apply slightly more than the desired test pressure, P, (about 0.2 psi (1380 kPa) more) to the concrete by means of the small hand pump. To relieve local restraints, tap the sides of the measure sharply and, when the pressure gauge indicates the exact test pressure, P, as determined in accordance with Section A1.7, read the water level, h_1, and record to the nearest division or half-division on the graduated precision-bore tube or gauge glass of the standpipe. (See Figure 1B.) For extremely harsh mixes it may be necessary to tap the bowl vigorously until further tapping produces no change in the indicated air content. Gradually release the air pressure through the vent at the top of the water column and tap the sides of the bowl lightly for about one minute. Record the water level, h_2, to the nearest division or half-division. (See Figure 1C.) Calculate the apparent air content as follows:

$$A_1 = h_1 - h_2 \tag{3}$$

where:

A_1 = apparent air content;
h_1 = water level reading at pressure, P (Note 9); and
h_2 = water level reading at zero pressure after release of pressure, P.

8.2.4 *Check Test*—Repeat the steps described in Section 8.2.3 without adding water to reestablish the water level at the zero mark. The two consecutive determinations of apparent air content should check within 0.2 percent of air and shall be averaged to give the value A_1 to be used in calculating the air content, A_s, in accordance with Section 9.

8.2.5 In the event the air content exceeds the range of the meter when it is operated at the normal test pressure P, reduce the test pressure to the alternative test pressure P_1 and repeat the steps outlined in Sections 8.2.2 and 8.2.3.

Note 9—See Section A1.7 for exact calibration procedures. An approximate value of the alternative pressure, P_1, such that the apparent air content will equal twice the meter reading can be computed from the following relationship:

$$P_1 = P_a P / (2P_a + P) \tag{4}$$

where:

P_1 = alternative test pressure, psi (kPa);
P_a = atmospheric pressure, psi (kPa) (approximately 14.7 psi (101 kPa) but will vary with altitude and weather conditions); and
P = normal test or operating gauge pressure, psi (kPa).

8.3 *Procedure—Type B Meter.*

8.3.1 *Preparation for Test*—Thoroughly clean the flanges or rims, of the bowl and the cover assembly so that when the cover is clamped in place a pressure-tight seal will be obtained. Assemble the apparatus. Close the air valve between the air chamber and the measuring bowl and open both petcocks on the holes through the cover. Using a rubber syringe, inject water through one petcock until water emerges from the opposite petcock. Jar the meter gently until all air is expelled from this same petcock.

8.3.2 *Test Procedure*—Close the airbleeder valve on the air chamber and pump air into the air chamber until the gauge hand is on the initial pressure line. Allow a few seconds for the compressed air to cool to normal temperature. Stabilize the gauge hand at the initial pressure line by pumping or bleeding off air as necessary, tapping the gauge lightly by hand. Close both petcocks on the holes through the cover. Open the air valve between the air chamber and the measuring bowl. Tap the sides of the measuring bowl smartly with the mallet to relieve local restraints. Lightly tap the pressure gauge by hand to stabilize the gauge hand and read the percentage of air on the dial of the pressure gauge. Failure to close the main air valve before releasing the pressure from either the container or the air chamber will result in water being drawn into the air chamber, thus introducing error in subsequent measurements. In the event water enters the air chamber, it must be bled from the air chamber through the bleeder valve followed by several strokes of the pump to blow out the last traces of water. Release the pressure by opening both petcocks (Figure 2) before removing the cover.

9. CALCULATION

9.1 *Air Content of Sample Tested*—Calculate the air content of the concrete in the measuring bowl as follows:

$$A_s = A_1 - G \qquad (5)$$

where:

A_s = air content of sample tested, percent;

A_1 = apparent air content of the sample tested, percent (Sections 8.2.3 and 8.3.2); and

G = aggregate correction factor, percent (Section 6).

9.2 *Air Content of Full Mixture*—When the sample tested represents that portion of the mixture that is obtained by wet-sieving to remove aggregate particles larger than a $1^1/_2$-in. (37.5-mm) sieve, the air content of the full mixture may be calculated as follows:

$$A_t = 100 A_s V_c / (100\, V_t - A_s V_a) \qquad (6)$$

where (see Note 10):

A_t = air content of the full mixture, percent;

V_c = absolute volume of the ingredients of the mixture passing a $1^1/_2$-in. (37.5-mm) sieve, airfree, as determined from the original batch weights, ft^3 (m^3);

V_t = absolute volume of all ingredients of the mixture, airfree, ft^3 (m^3); and

V_a = absolute volume of the aggregate in the mixture coarser than a $1^1/_2$-in. (37.5-mm) sieve, as determined from original batch weights, ft^3 (m^3).

9.3 *Air Content of the Mortar Fraction*—When it is desired to know the air content of the mortar fraction of the mixture, calculate it as follows:

$$A_m = 100 A_s V_c \Big/ \left[100 V_m + A_s \left(V_c - V_m \right) \right] \qquad (7)$$

where (see Note 10):

A_m = air content of the mortar fraction, percent; and

V_m = absolute volume of the ingredients of the mortar fraction of the mixture, airfree, ft^3 (m^3).

Note 10—The values for use in Equations 6 and 7 are most conveniently obtained from data on the concrete mixture tabulated as follows for a batch of any size:

	Absolute Volume, ft^3 (m^3)	
Cement		
Water	____	
Fine aggregate	____	$V_m \} V_c$
Coarse aggregate No. 4 (4.75-mm) to $1^1/_2$ in. (37.5-mm)	____ ____	
Coarse aggregate $1^1/_2$-in. (37.5-mm)	____	V_a
Total	____	V_t

10. REPORT

10.1 *Report the following information*:

10.1.1 The air content of the concrete sample to the nearest 0.1 percent after subtracting the aggregate correction factor, unless the gauge reading of the meter exceeds 8 percent, in which case the corrected reading shall be reported to the nearest 1⁄2 scale division on the dial.

10.1.2 The date and time of the test.

10.1.3 When requested, and when the absolute volume of the ingredients of the mortar fraction of the mixture can be determined, the air content of the mortar fraction of the mixture to the nearest 0.25 percent.

11. PRECISION AND BIAS

11.1 *Precision*:

11.1.1 *Single-Operator Precision*—The single operator standard deviation cannot be established because the sample requirements for this test, as established in T 141, do not allow a single operator time to conduct more than one test on a sample.

11.1.2 *Multilaboratory Precision*—The multilaboratory standard deviation has not been established.

11.1.3 *Multi-Operator Precision*—The multi-operator standard deviation of a single test has been found to be 0.28 percent air by volume of concrete for Type A air meter as long as the air content does not exceed 7 percent. Therefore, results of the two tests properly conducted by different operators but on the same materials should not differ by more than 0.8 percent air by volume of concrete. (See ASTM E 177, Notes 11 and 12).

Note 11—These numbers represent, respectively the (1s) and (d2s) limits as described in ASTM C 670. The precision statements are based on the variation in tests on three different concretes, each tested by eleven different operators.

Note 12—The precision of this test method using Type B air meters has not been determined.

11.2 *Bias*—This test method has no bias because the air content of freshly mixed concrete can only be defined in terms of the test methods.

12. KEYWORDS

12.1 Air content; calibration; concrete; correction factor; measuring bowl; meter; pressure; pump; unit weight.

ANNEX

(Mandatory Information)

A1. CALIBRATION OF APPARATUS

A1.1. Calibration tests shall be performed in accordance with the following procedures as applicable to the meter type being employed.

A1.2. *Calibration of the Calibration Vessel*—Determine accurately the weight of water required to fill the calibration vessel, w, using a scale accurate to 0.1 percent of the weight of the vessel filled with water. This step shall be performed for Type A and B Meters.

A1.3. *Calibration of the Measuring Bowl*—Determine the weight of water required to fill the measuring bowl, W, using a scale accurate to 0.1 percent of the weight of the bowl filled with water. Slide a glass plate carefully over the flange of the bowl in a manner to ensure that the bowl is completely filled with water. A thin film of cup grease smeared on the flange of the bowl will make a watertight joint between the glass plate and the top of the bowl. This step shall be performed for Types A and B meters.

A1.4. *Effective Volume of the Calibration Vessel, R*—The constant R represents the effective volume of the calibration vessel expressed as a percentage of the volume of the measuring bowl.

A1.4.1. For Type A meters, calculate R as follows (Note A1):

$$R = 0.98\, w/W \tag{A1.1}$$

where:

w = weight of water required to fill the calibration vessel, and

W = weight of water required to fill the measuring bowl.

Note A1—The factor 0.98 is used to correct for the reduction in the volume of air in the calibration vessel when it is compressed by a depth of water equal to the depth of the measuring bowl. This factor is approximately 0.98 for an 8-in. (203-mm) deep measuring bowl at sea level. Its value decreases to approximately 0.975 at 5000 ft (1524 m) above sea level and 0.970 at 13000 ft (3962 m) above sea level. The value of this constant will decrease by about 0.01 for each 4 in. (102 mm) increase in bowl depth. The depth of the measuring bowl and atmospheric pressure do not affect the effective volume of the calibration vessel for Type B meters.

A1.4.2. For Type B meters, calculate R as follows (Note A1):

$$R = w/W \tag{A1.2}$$

A1.5. *Determination of, or Check of, Allowance for Expansion Factor, D*:

A1.5.1. For meter assemblies of Type A, determine the expansion factor, *D* (Note A2) by filling the apparatus with water only (making certain that all entrapped air has been removed and the water level is exactly on the zero mark (Note A3) and applying an air pressure approximately equal to the operating pressure, *P*, determined by the calibration test described in Section A1.7. The amount the water column lowers will be the equivalent expansion factor, *D*, for that particular apparatus and pressure (Note A5).

Note A2—Although the bowl, cover, and clamping mechanism of the apparatus must of necessity be sturdily constructed so that it will be pressure-tight, the application of internal pressure will result in a small increase in volume. This expansion will not affect the test results because, with the procedure described in Sections 6 and 8, the amount of expansion is the same for the test for air in concrete as for the test for aggregate correction factor on combined fine and coarse aggregates, and is thereby automatically cancelled. However, it does enter into the calibration test to determine the air pressure to be used in testing fresh concrete.

Note A3—The water columns on some meters of Type A design are marked with an initial water level and a zero mark, the difference between the two marks being the allowance for the expansion factor. This allowance should be checked in the same manner as for meters not so marked and in such a case, the expansion factor should be omitted in computing the calibration readings in Section A1.7.

Note A4—It will be sufficiently accurate for this purpose to use an approximate value for *P* determined by making a preliminary calibration test as described in Section A1.7 except that an approximate value for the calibration factor, *K*, should be used. For this test $K = 0.98R$ which is the same as Equation A1.2 except that the expansion reading, *D*, as yet unknown, is assumed to be zero.

A1.5.2. For meters of Type B design, the allowance for the expansion factor, *D*, is included in the difference between the initial pressure indicated on the pressure gauge and the zero percent mark on the air-content scale on the pressure gauge. This allowance shall be checked by filling the apparatus with water (making certain that all entrapped air has been removed), pumping air into the air chamber until the gauge hand is stabilized at the indicated initial pressure line, and then releasing the air to the measuring bowl (Note A5). If the initial pressure line is correctly positioned, the gauge should read zero percent. The initial pressure line shall be adjusted if two or more determinations show the same variation from zero percent and the test repeated to check the adjusted initial pressure line.

Note A5—This procedure may be accomplished in connection with the calibration test described in Section A1.9.

A1.6. *Calibration Reading, K*—The calibration reading, *K*, is the final meter reading to be obtained when the meter is operated at the correct calibration pressure.

A1.6.1. For Type A meters, the calibration reading, K, is as follows:

$$K = R + D \tag{A1.3}$$

where:

R = effective volume of the calibration vessel (Section A1.4.1), and

D = expansion factor (Section A1.5.1, Note A6).

A1.6.2. For Type B meters, the calibration reading, *K*, equals the effective volume of the calibration vessel (Section A1.4.2) as follows:

$$K = R \tag{A1.4}$$

Note A6—If the water column indicator is graduated to include an initial water level and a zero mark, the difference between the two marks being equivalent to the expansion factor, the term *D* shall be omitted from Equation A1.4.

A1.7. *Calibration Test to Determine Operating Pressure, P, on Pressure Gauge, Type A Meter*—If the rim of the calibration cylinder contains no recesses or projections, fit it with three or more spacers equally spaced around the circumference. Invert the cylinder and place it at the center of the dry bottom of the measuring bowl. The spacers will provide an opening for flow of water into the calibration cylinder when pressure is applied. Secure the inverted cylinder against displacement and carefully lower the cover assembly. After the cover is clamped in place, carefully adjust the apparatus assembly to a vertical position and add water at air temperature, by means of the tube and funnel, until it rises above the zero mark on the standpipe. Close the vent and pump air into the apparatus to the approximate operating pressure. Incline the assembly about 30 degrees from vertical and, using the bottom of the bowl as a pivot, describe several complete circles with the upper end of the standpipe, simultaneously tapping the cover and sides of the bowl lightly to remove any entrapped air adhering to the inner surfaces of the apparatus. Return the apparatus to a vertical position, gradually release the pressure (to avoid loss of air from the calibration vessel) and open the vent. Bring the water level exactly to the zero mark by bleeding water through the petcock in the top of the conical cover. After closing the vent, apply pressure until the water level has dropped an amount equivalent to about 0.1 to 0.2 percent of air more than the value of the calibration reading, *K*, determined as described in Section A1.6. To relieve local restraints, lightly tap the sides of the bowl and when the water level is exactly at the value of the calibration reading, *K*, read the pressure, *P*, indicated by the gauge and record to the nearest 0.1 psi (690 kPa). Gradually release the pressure and open the vent to determine whether the water level returns to the zero mark when the sides of the bowl are tapped lightly (failure to do so indicates loss of air from the calibration vessel or loss of water due to a leak in the assembly). If the water level fails to return to within 0.05 percent air of the zero mark and no leakage beyond a few drops of water is found, some air probably was lost from the calibration cylinder. In this case, repeat the calibration procedure step-by-step from the beginning of this paragraph. If the leakage is more than a few drops of water, tighten the leaking joint before repeating the calibration procedure. Check the indicated pressure reading promptly by bringing the water level exactly to the zero mark, closing the vent, and applying pressure, *P*, just determined. Tap the gauge lightly with a finger. When the gauge indicates the exact pressure, *P*, the water column should read the value of the calibration factor, *K*, used in the first pressure application within about 0.05 percent of air.

Note A7—**Caution**: The apparatus assembly must not be moved from the vertical position until pressure has been applied which will force water about one-third of the way up into the calibration cylinder. Any loss of air from this cylinder will nullify the calibration.

A1.8. *Calibration Test to Determine Alternative Operating Pressure P_1—Type A Meter*—The range of air contents which can be measured with a given meter can be doubled by determining an alternative operating pressure P_1 such that the meter reads half of the calibration reading, *K*, (Equation A1.3). Exact calibration will require determination of the expansion factor at the reduced pressure in Section A1.5. For most purposes the change in expansion factor can be disregarded and the alternative operating pressure determined during the determination of the regular operating pressure in Section A1.7.

A1.9. *Calibration Test to Check the Air Content Graduations on the Pressure Gauge, Type B Meter*—Fill the measuring bowl with water as described in Section A1.3. Screw the short piece of tubing or pipe furnished with the apparatus into the threaded petcock hole on the underside of the cover assembly. Assemble the apparatus. Close the air valve between the air chamber and the measuring bowl and open the two petcocks on holes through the cover assembly. Add water through the petcock on the cover assembly having the extension below until all air is expelled from the second petcock. Pump air into the air chamber until the pressure reaches the indicated initial pressure line. Allow a few seconds for the compressed air to cool to normal temperature. Stabilize the gauge hand at the initial pressure line by pumping or bleeding off air as necessary, tapping the gauge lightly. Close the petcock not provided with the tube or pipe extension on the under side of the cover. Remove water from the assembly to the calibrating vessel controlling the flow, depending on the particular meter design, by opening the petcock provided with the tube or pipe extension and cracking the air valve between the air chamber and the measuring bowl, or by opening the air valve and using the petcock to control flow. Perform the calibration at an air content that is within the normal range of use. If the calibration vessel (Section A1.2) has a capacity within the normal range of use, remove exactly that amount of water. With some meters the calibrating vessel is quite small and it will be necessary to remove several times that volume to obtain an air content within the normal range of use. In this instance, carefully collect the water in an auxiliary container and determine the amount removed by weighing to the nearest 0.1 percent. Calculate the correct air content, R, by using Equation A1.2. Release the air from the apparatus at the petcock not used for filling the calibration vessel and if the apparatus employs an auxiliary tube for filling the calibration container, open the petcock to which the tube is connected to drain the tube back into the measuring bowl (Note A7). At this point of procedure the measuring bowl contains the percentage of air determined by the calibration test of the calibrating vessel. Pump air into the air chamber until the pressure reaches the initial pressure line marked on the pressure gauge, close both petcocks in the cover assembly, and then open the valve between the air chamber and the measuring bowl. The indicated air content on the pressure gauge dial should correspond to the percentage of air determined to be in the measuring bowl. If two or more determinations show the same variation from the correct air content, the dial hand shall be reset to the correct air content and the test repeated until the gauge reading corresponds to the calibrated air content within 0.1 percent. If the dial hand was reset to obtain the correct air content, recheck the initial pressure mark as in Section A1.5.2. If a new initial pressure reading is required, repeat the calibration to check the accuracy of the graduation on the pressure gauge described earlier in this section. If difficulty is encountered in obtaining consistent readings, check for leaks, for the presence of water inside the air chamber (Figure 2), or the presence of air bubbles clinging to the inside surfaces of the meter from the use of cool, aerated water. In this latter instance, use deaerated water, which can be obtained by cooling hot water to room temperature.

Note A8—If the calibrating vessel is an integral part of the cover assembly, the petcock used in filling the vessel should be closed immediately after filling the calibration vessel and not opened until the test is complete.

Standard Method of Test for

Water Retention by Liquid Membrane-Forming Curing Compounds for Concrete

AASHTO Designation: T 155-08
ASTM Designation: C 156-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Water Retention by Liquid Membrane-Forming Curing Compounds for Concrete

AASHTO Designation: T 155-08
ASTM Designation: C 156-05

1. SCOPE

1.1. This test method covers laboratory determination of the efficiency of liquid membrane-forming compounds for curing concrete, as measured by their ability to reduce moisture loss during the early hardening period.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 85, Portland Cement
- T 71, Effect of Organic Impurities in Fine Aggregate on Strength of Mortar

2.2. *ASTM Standards*:
- C 230/C 230M, Standard Specification for Flow Table for Use in Tests of Hydraulic Cement
- C 305, Standard Practice for Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency
- C 778, Standard Specification for Standard Sand
- D 1475, Standard Test Method For Density of Liquid Coatings, Inks, and Related Products
- D 1644, Standard Test Methods for Nonvolatile Content of Varnishes
- D 1653, Standard Test Methods for Water Vapor Transmission of Organic Coating Films
- D 2369, Standard Test Method for Volatile Content of Coatings
- E 178, Standard Practice for Dealing With Outlying Observations

3. SIGNIFICANCE AND USE

3.1. The moisture retaining ability of a product as determined by this test method is used to assess the suitability of materials for contributing to an appropriate curing environment for concrete. The laboratory test method is used both in formulating and in specifying or qualifying curing products. This test method gives the user a measure of the ability of tested curing materials to impede the escape of moisture from a hydraulic cement mortar. Since it is desirable to retain moisture in fresh concrete to promote the hydration process, failure of the product to minimize the escape of moisture may lead to loss of strength, cracking, shrinkage, or low abrasion resistance of the hardened concrete, or a combination thereof.

3.2. Many factors affect the laboratory test results. Test results obtained may be highly variable as indicated by the precision statement. Critical factors include the precision of the control of the temperature, humidity, and air circulation in the curing cabinet; preparation and sealing of the mortar specimens, the age and surface condition of the mortar specimen when the curing product is applied; and the uniformity and quantity of application of the curing membrane.

4. APPARATUS

4.1. *Mechanical Mortar Mixer*—as described in ASTM C 305, or a larger size mixer operating on the same principle.

4.2. *Molds*—Molds shall be made of metal, glass, hard rubber, or plastic, and shall be watertight and rigidly constructed to prevent distortion during molding of the specimens or handling the mold containing fresh mortar. They shall have a minimum surface area of 12000 mm^2 (18.6 in.), and a minimum depth of 19 mm ($^3/_4$ in.). The top surface shall be round, square, or rectangular with length not more than twice the width. The top of the mold shall have a rim to provide a firm level surface to support the wood float and to facilitate the grooving and sealing steps of the procedure. The rim shall be parallel with the bottom surface of the mold.

Note 1—Take care to avoid use of an excessive amount of oil, grease, or mold release compound on molds, particularly along the top rim where sealing compound will be applied. Use of masking tape on the top rim during application of release compound to prevent contamination has been found to be expedient.

4.3. *Gloves*—of rubber or plastic to be worn while molding the specimens.

4.4. *Tamper*—of a nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak rendered non-absorptive by immersion for 15 minutes in paraffin at approximately 200ºC. The tamper shall be rectangular with a 25- by 50-mm (1- by 2-in.) cross section and it shall be a convenient length (150 to 300 mm (6 to 12 in.)).

4.5. *Wood Float*—approximately 75 by 280 by 20 mm thick (3 by 11 by $^3/_4$ in.).

Note 2—A commercial wood float equipped with a substantial handle can be readily reduced to these dimensions. The float shall be resurfaced or replaced when there is noticeable wear to the floating surface.

4.6. *Brush*—medium-soft bristle 50-mm (2-in.) paintbrush to brush the surface of the specimens prior to sealing.

4.7. *Curing Cabinet*—maintained at a temperature of 37.8 ± 1.1ºC (100 ± 2ºF) and a relative humidity of 32 ± 2 percent. The curing cabinet shall be of a design that allows movement of conditioned air such that the solvent from the curing compound will be readily evaporated and eliminated from the system. Air circulation shall be equivalent for all specimens.

4.8. *Balance*—having a capacity to determine the mass of a filled specimen mold to the nearest 0.1 g or less.

4.9. *Applicator*—For spray application, any apparatus that can be used to apply the curing compound uniformly and with minimum overspray is acceptable. For brush or roller application, use the equipment recommended by the curing compound manufacturer.

4.10. *Spoon*—A stainless steel serving spoon having a bowl 75 to 100 mm (3 to 4 in.) long and 50 to 75 mm (2 to 3 in.) wide for transferring the mortar from the mixing bowl to the mold.

5. MATERIALS

5.1. Portland cement conforming to the requirements for Type 1 of M 85.

5.2. Graded standard sand conforming to the requirements of ASTM C 778.

5.3. Sealing compound that will not be affected by the curing material and that effectively seals against moisture loss between the boundary of the specimen and the edge of the mold.

Note 3—Issue embedding wax, readily available from scientific supply houses, is a convenient and reliable sealant.

6. CONDITIONING

6.1. The temperature of the room and of all materials when used in this test shall be 23 ± 2ºC (73 ± 4ºF) unless otherwise specified, and the room humidity shall be 50 ± 10 percent.

7. NUMBER OF SPECIMENS

7.1. A set of three or more test specimens shall be made in order to constitute a test of a given curing material.

Note 4—When more than one set of specimens is to be prepared, each set should be handled as a group throughout the preparation to make the elapsed time between molding and application of the curing product as uniform as possible. This may require mixing the mortar for each set separately.

7.2. For determining the quantity of curing compound to be applied (MA), calculate the total top surface area of the specimen, including the seal and the rim of the mold, in square millimeters using appropriate geometric formulae.

Note 5—The area (A) used in calculating the mass loss per unit area (L) is calculated in Section 4.2 from the surface dimensions measured inside the seal of the specimen.

8. PROPORTIONING AND MIXING MORTAR

8.1. *Proportioning*—Determine the sand content of the mortar by adding dry sand to a cement paste having a water-cement ratio of 0.40 by weight, to produce a flow of 35 ± 5 in 10 drops. Determine the flow in accordance with T 71. Discard the mix used to determine the proportion of sand to cement.

Note 6—This mix is discarded because it is thought that the age and the mixing history of the mortar where the curing compound is applied, measured from the first addition of water, affects the final results and must be controlled.

8.2. *Mixing*—Combine the components of the mortar in a mortar-mixing machine to produce a homogeneous mortar not more than 6 minutes from the time the water and the cement are combined.

Note 7—A generally effective sequence is to add the cement to all of the water in the mixing bowl and allow it to stand for 30 seconds. Then, mix at low speed for 30 seconds and, without stopping the mixer, add the sand within 30 seconds and continue mixing for 1 minute. Stop the mixer for 1 minute. During the first 15 seconds, scrape down the sides of the bowl. Finish by mixing for an additional 1 minute, and promptly begin molding the specimens.

---

9. PREPARING SPECIMENS

9.1. Thoroughly clean the molds before each use. Use of a mold release is acceptable provided that care is taken to avoid its application to the top rim of the mold to prevent interference with sealing of the edge.

9.2. Half fill the mold and spread the mortar with the back of the spoon to create a layer of approximately uniform thickness. Tamp over the entire surface with one stroke of the 25 by 50 mm (1 by 2 in.) face of the tamper per 1000 mm^2 of surface area rounded to the nearest integer. Place a second layer of mortar, sufficient in amount to slightly overfill the mold, and tamp in a similar manner. Using the 25-mm (1-in.) wide by 150- to 300-mm (6- to 12-in.) long edge of the tamper, fill the indentations made by the tamping and level the surface by pressing down firmly with a series of contacts across the entire surface. Strike off the specimen level with the top of the mold using a wood float with one pass only, in the direction of the long axis of the specimen for rectangular molds, using a sawing motion of the float. Keep the 75-mm (3-in.) face of the float firmly in contact with the mortar and edges of the mold so the float creates a uniformly dense surface free of voids and cracks.

9.3. Immediately after molding, wipe the outside surfaces of the molds clean and then place the specimens in the curing cabinet maintained at the conditions specified in Section 4.9. The specimens shall be level and not subject to vibration. The spacing between the individual specimens and between the specimens and the side walls of the cabinet shall be between 50 and 175 mm (2 to 7 in.). Within these limits, the spacing shall be the same for all specimens. Use dummy specimens to fill any empty spaces in the cabinet.

---

10. SURFACE PREPARATION AND EDGE SEALING

10.1. Remove the specimens from the cabinet immediately upon disappearance of the surface water and lightly brush the surface using sufficient force to remove the laitance and glaze but not so as to scarify the mortar surface. If surface water appears upon brushing, return the specimen to the cabinet. When the water brought to the surface by the brushing operation disappears, immediately remove the specimen and then brush again. The mortar shall be free of surface water but shall not be dry below the surface. The proper surface condition will be attained when brushing does not bring free water to the surface or does not produce smearing when rubbing an area with the fingertip.

Note 8—The exposure time in the cabinet and the initial moisture loss that will result in the proper surface condition is characteristic of the curing cabinet used and other testing conditions related to the laboratory performing the test. Uniformity of test surface conditions may be maintained by setting an expected exposure time or initial moisture loss. When any test condition is changed (sand, cement, or the like), a new exposure time or initial moisture loss, or both, shall be determined.

10.2. Form a V-shaped groove approximately 3 mm ($^1/_8$ in.) deep and not more than 3 mm ($^1/_8$ in.) wide between the edge of the mortar specimen and the mold. Fill the groove with the sealing compound. The sealing compound shall not extend more than 6 mm ($^1/_4$ in.) from the edge of the mold onto the surface of the specimen.

Note 9—To cut out the groove for sealing, the tip of a pointed trowel, a pointed spatula, a pointed triangular can opener, or a "hawksbill point" ground on the end of a spatula or knife blade have all been reported to be effective.

11. APPLICATION OF CURING MATERIAL

11.1. *Liquid Membrane-Forming Compounds*:

11.1.1. Calculate the mass of the curing compound to be applied (*MA*) to the nearest 0.1 g based on the specified application rate, the total surface area calculated per Section 7.2, and the density of the curing compound determined in accordance with ASTM D 1475. If no rate is specified, apply the curing compound at the rate of 0.2 L/m^2 (gal/200 ft^2). The method of application shall be in accordance with the manufacturer's recommendations.

11.1.2. Immediately after sealing, weigh the specimen to the nearest 0.1 g (M_1), then uniformly apply the curing compound at the specified rate of application. Application shall be made expeditiously to only one specimen at a time.

Note 10—It is desirable to use a spray booth or a laboratory hood to control overspray and solvent fumes especially for curing compounds that are sprayed. However, the velocity of air movement in the vicinity of the specimen must be kept at a minimum so as to prevent, as much as possible, significant loss of volatiles during spraying and before the final weighing. Spraying shall be accomplished with the minimum pressure and flow rate of air with which an acceptable spray pattern can be attained.

11.1.3. Determine the proper coverage by comparing the initial mass of the specimen (M_1), before applying the curing compound to the mass after coating. The final mass shall equal the initial mass of the specimen plus the predetermined mass of the curing compound to be applied. This will necessitate frequent weighing of the specimen during application as full coverage is approached. In the case of brush application, proper coverage may be determined by weighing the container, brush, and curing compound before and after application of the compound to the specimen. Total time for application shall not exceed 2 minutes. Weigh to the nearest 0.1 g (M_2). If the final amount of curing compound applied differs from the calculated amount for the specified coverage by more than 10 percent, the sample shall be discarded.

Note 11—In previous versions of this test method, coverage was determined by weighing the application equipment and the curing compound before and after application to the specimen. Which method is more precise has not been established.

11.2. Return the specimens to the cabinet without delay.

Note 12—Unusual loss caused by a leaking mold or a faulty seal may be detected by weighing the specimens 3 to 4 hours after application of the curing material. If one specimen has lost considerably more than the others, this specimen is probably faulty. If only three specimens are being tested, consider the test invalid. (See Section 14.4.)

12. DETERMINATION OF NON-VOLATILE CONTENT OF CURING COMPOUNDS

12.1. Determine the proportion of non-volatile matter in the curing compound (*NV*) in accordance with ASTM D 1644.

Note 13—Previous versions of this test method required that non-volatile content be determined by coating a metal pan, or plate, of known mass having an area equal to that of the top of the test specimen with the same mass of curing compound as used on the specimen, placing the sample in the curing cabinet with the test specimens, and weighing at the conclusion of the test.

13. DURATION OF TEST

13.1. Specimens shall be stored in the test cabinet for 72 hours, then removed, and immediately weighed (M_3). Other test times may be specified by the purchaser.

14. CALCULATIONS

14.1. *Loss of Mass*:

14.1.1. Calculate the loss of mass from each specimen in grams as follows:

$$ML = M_1 + \left(NV \times MA\right) - M_3 \qquad (1)$$

where:

ML = mass loss of the sample, g;

M_1 = mass of the sealed sample, g;

NV = proportion of non-volatile matter in the curing compound, g;

MA = mass of the curing compound applied, $g = M_2 - M_1$;

M_2 = mass of the sample immediately after applying curing compound, g; and

M_3 = mass of sample at the conclusion of the test, g.

14.2. *Specimen Area*:

14.2.1. Calculate the area of the specimen (A) in square millimeters by measuring the dimensions of the surface from the inner edges of the seal to the nearest millimeter and applying the appropriate geometric formula.

14.3. For each specimen, calculate the mass loss per unit area (L) in kg/m^2 as:

$$L = 1000 \times ML/A \qquad (2)$$

14.4. *Rejection of Results*:

14.4.1. In a set of three or more specimens, if the difference in moisture loss between the specimen having the greatest loss and that with the least loss exceeds 0.15 kg/m^2, the test shall be repeated and the average taken as that of all specimens in the original and repeat tests. If, after the repeat test, it is determined that the result on a single specimen, whether from the original or repeat test, meets the criteria for rejection as an outlier as given in ASTM E 178, such value shall be disregarded and a new average calculated that does not include such outlying value.

15. REPORT

15.1. The report shall include the following information for the materials tested:

15.1.1. Manufacturer's name, address, and brand designation;

15.1.2. Type of curing material;

15.1.3. Manufacturer's batch number;

15.1.4. Quantity of material represented by the sample;

15.1.5. Date sampled; and

15.1.6. Source of the sample.

15.2. The report shall include the following information regarding the test:

15.2.1. Laboratory sample identification,

15.2.2. Brand of cement used,

15.2.3. Proportions of mortar by weight,

15.2.4. Method of application,

15.2.5. Duration of the test,

15.2.6. Rate of application (membrane-forming compounds), and

15.2.7. Average loss of water per unit area.

16. PRECISION AND BIAS

16.1. *Precision*—Efforts to establish a more meaningful measure of the precision of this test method continue. The previous version of this test method, containing some differences in testing technique, contained a precision statement.[1] The single-operator standard deviation was reported as 0.13 kg/m^2 and the multilaboratory standard deviation as 0.30 kg/m^2.

16.2. *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is being made.

17. KEYWORDS

17.1. Concrete curing materials; liquid membrane-forming curing compounds; moisture retention by concrete curing materials.

ANNEX

(Mandatory Information)

A1. STANDARDIZATION OF EVAPORATION RATE IN TEST CABINETS

A1.1. This procedure provides a means for measuring the rate of evaporation of water from a standard surface in order to characterize a controlled set of environmental conditions (temperature, humidity, air circulation) by providing a system that will lose water at a nearly constant rate for a period of time long enough to establish a characteristic rate. Comparison of results from different positions in the same cabinet can establish whether or not conditions are uniform throughout the cabinet. Comparisons between labs may help to rationalize differing results.

A1.2. *Apparatus:*

A1.2.1. *Cup*—A permeability cup, conforming to the specifications of ASTM D 1653.

A1.2.2. *Filter Paper*—7-cm disks.

A1.2.3. *Absorbent Filler*—Absorbent cotton balls.

A1.2.4. *Mold Cover*—Stiff cardboard or sheet metal plate having the same dimensions as the top of the specimen mold and having a 63-mm ($2^1/_2$-in.) diameter hole in its center.

A1.2.5. *Balance*—Any balance having a capacity of 200 g or more and a sensitivity and accuracy of 0.01 g or less.

A1.3. *Procedure*:

A1.3.1. Fill the permeability cup with the absorbent filler using three cotton balls pulled together to make a uniform sponge. Fill the cup with distilled water, lay a disk of filter paper over the cup, and complete assembly of the cup. Place the mold cover on top of an empty specimen mold and fasten it in place with masking tape. Put the cup in the hole in the center of the mold. Place the mold and cup in the test cabinet in the position to be tested and allow 1 hour for it to reach temperature equilibrium. Determine the mass of the cup to the nearest 0.01 g and immediately return it to the cabinet. Reweigh at approximately 1 hour intervals for 5 to 7 hours. Record the mass and the total elapsed time to the nearest 2 minutes for each interval.

A1.4. *Calculation*:

A1.4.1. Calculate the total mass loss at each time interval as follows:

$$L = m_i - m_t \qquad (3)$$

where:

L = cumulative mass loss,

m_i = initial mass, and

m_t = mass at time t.

A1.4.2. Plot the cumulative mass loss (L) versus elapsed time (t) and determine the slope for the test period. Report calculated by a "least squares" method. (The rate of loss should be nearly constant throughout the test period.)

A1.5. *Precision and Bias*:

A1.5.1. *Precision*—Data for a precision statement are being collected.

A1.5.2. *Bias*—This test method has no bias because the evaporation rate is defined only in terms of this test method.

---

Standard Method of Test for

Air-Entraining Admixtures for Concrete

AASHTO Designation: T 157-06
ASTM Designation: C 233-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Air-Entraining Admixtures for Concrete

AASHTO Designation: T 157-06
ASTM Designation: C 233-04

1. SCOPE

1.1. This method covers the testing of materials proposed for use as air-entraining admixtures in the field.

1.2. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information purposes only.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4. The text of this standard references notes and footnotes that provide explanatory materials. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 6, Fine Aggregate for Hydraulic Cement Concrete
- M 80, Coarse Aggregate for Hydraulic Cement Concrete
- M 85, Portland Cement
- M 154, Air-Entraining Admixtures for Concrete
- M 240, Blended Hydraulic Cement
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 2, Sampling of Aggregates

3. SIGNIFICANCE AND USE

3.1. This test method is used to develop data for comparison with the requirements of M 154. These tests are based on arbitrary stipulations permitting highly standardized testing in the laboratory,and are not intended to simulate actual job conditions.

4. MATERIALS

4.1. *Cementitious Material*—The cementitious material used in any series of tests shall meet any of the following:

- The cementitious material proposed for specific work in accordance with Section 4.4, portland cement conforming to the specifications for either Type I, Type II, or Type III M 85 hydraulic cement, conforming to the specification of ASTM C 1157;
- Blended hydraulic cement conforming to the specification of M 240. If a blend of cements is used, it shall be a combination that produces an air content of less than 10 percent when tested in accordance with T 137 (Note 3).

4.2. *Aggregates*—Except when tests are made in accordance with Section 4.4, using the aggregates proposed for specific work, the fine and coarse aggregates used in any series of tests shall come from single lots of well-graded, sound materials that conform to the requirements of M 6 and M 80, except that the grading of the aggregates shall conform to the following requirements:

4.2.1. *Fine Aggregate Grading*—The fine aggregate shall meet the requirements for the fine aggregate in ASTM C 33.

Sieve	Percentage Passing
4.75 mm (No. 4)	100
1.18 mm (No. 16)	65 to 75
0.300 mm (No. 50)	15 to 20
0.150 mm (No. 100)	2 to 5

4.2.2. *Coarse Aggregate Grading*—The coarse aggregate shall meet the requirements for Size 57 of ASTM C 33.

Note 1—Take care in loading and delivery to avoid segregation.

4.2.3. The coarse aggregate used for each set of reference concrete and comparable test admixture-treated concrete shall be essentially the same. Therefore, a set of test concrete consists of one reference concrete and as many test admixture-containing concretes as are intended to be compared to that one reference. Thus, coarse aggregate for one set shall consist of enough material for one reference concrete, the test admixture-containing concrete to be compared with that reference, and the sample for grading analysis testing.

4.2.3.1 Prepare coarse aggregate for a set, comprising a sample large enough for concrete trials, as follows: fill tared containers, one each for a sample, a batch of reference concrete, and one or more test concretes to the required mass from the aggregate stockpile. Accomplish this by starting with a scoopful into the first container and repeat this procedure until all containers have the required mass. Repeat the process for each of the three or more sets needed. One or more spare sets may be needed. See the Appendix of ASTM D 75, Practice for Sampling Aggregates, and the *Manual of Aggregate and Concrete Testing* (See *Annual Book of ASTM Standards*, Vol. D 4.02.) for guidance for conditions and procedures.

4.2.4. Test coarse aggregate samples representing each set by ASTM C 136 requirements for the sieves shown below. Discard any set for which the sample does not comply with Size 57. Average test results for samples that comply with Size 57 for each sieve size. Discard any set for which the sample deviates from this average by more than the amount shown in Column 3. Continue the process of preparation, testing, and averaging until sufficient sets of aggregate within tolerance are obtained.

Sieve	Specification C 33, No. 57 Percent Passing	Maximum Variation from Average/Passing
37.5 mm	100	00
25.0 mm	95 to 100	1.0
12.5 mm	25 to 60	4.0
4.75 mm	0 to 10	4.0
2.36 mm	0 to 5	1.0

Note 2—All of the results required for demonstrating compliance under this specification are dependent on the uniformity of the aggregate samples prepared and used. Careful, skilled, and well-supervised work is essential.

4.3. *Reference Admixture*—For this method, unless otherwise requested by the purchaser, the reference admixture used in the concrete mixture specified in Section 5 shall be "neutralized Vinsol resin."[1]

4.4. *Materials for Tests for Specific Uses*—When it is desired to test an air-entraining admixture for use in specific work, the cementitious material and aggregates used should be representative of those proposed for use in the work, and the concrete mixtures should be designed to have the cementitious material content specified for use in the work (Note 3). If the maximum size of coarse aggregate is greater than 25.0 mm (1 in.), the freshly mixed concrete shall be screened over a 25.0-mm (1-in.) sieve prior to fabricating the test specimens in accordance with the wet sieving procedure described in T 141. When other admixtures are intended to be used in the production of concrete, they should be included in the trial batch.

4.5. *Preparation and Mass Determination*—All materials shall be prepared and all mass determinations shall be made as prescribed in R 39.

Note 3—It is recommended that whenever practicable, tests be made in accordance with Section 4.4 using the cementitious materials and chemical admixtures, if any, proposed for specific work.

5. CONCRETE MIXTURES

5.1. *Proportions*—Using ACI 211.1-91, all concrete shall be proportioned to conform to the following requirements:

5.1.1. The cement content shall be 307 ± 3 kg/m^3 (517 ± 5 lb/yd^3) except when tests are being made for specific uses (Section 4.4).

5.1.2. The first trial mixture shall contain the amount of coarse aggregate shown in Table 6.3.6 of ACI 211.1-91 for the maximum size of aggregate and for the fineness modulus of the sand being used.

Note 4—The volumes of coarse aggregate in Table 6.3.6 of ACI 211.1-91 are intended to assure workable mixtures with the least favorable combinations of aggregate likely to be used. It is suggested, therefore, that for a closer approximation of the proportions required for this test, the recommended values selected from Table 6.3.6 be increased by about 7 percent for the first trial mixture.

5.1.3. The air content used in the computation of proportions for all concrete shall be 5.5 percent except where the admixture under test is for use in specific work (Section 4.4). In this case the air content used in selecting proportions shall be the median of the range to be permitted in the work. If lightweight aggregates are to be used in specific work, the unit mass of concrete used in selecting proportions shall be the median of the range permitted in the work.

5.1.4. The water content and sand content shall be adjusted to obtain a slump of 89 ± 13 mm (3.5 ± 0.5 in.). The workability of the concrete mixture shall be suitable for consolidation by hand rodding and the concrete mixture shall have the minimum water content possible. These conditions shall be achieved by final adjustments in the proportion of fine aggregate to total aggregate, in the amount of total aggregate, or both, while maintaining the yield and slump in the required ranges.

5.2. *Conditions*—Concrete mixtures shall be prepared both with the air-entraining admixture under test and with the reference admixture. The admixtures shall be added in the amounts necessary to produce the air content selected in accordance with Section 5.1.3 within a tolerance of ±0.5 percent of the volume of concrete.

6. MIXING

6.1. Machine mix the concrete as prescribed in R 39.

7. TESTS AND PROPERTIES OF FRESHLY MIXED CONCRETE

7.1. Test samples of freshly mixed concrete from at least three separate batches for each condition of concrete in accordance with the following methods. The minimum number of tests shall be as prescribed in Table 1.

7.1.1. *Slump*—Refer to T 119M/T 119.

7.1.2. *Air Content*—Refer to T 152. When lightweight aggregates, air-cooled blast furnace slag, or aggregates are used under the provisions of Section 4.4, use T 196M/T 196.

7.1.3. *Bleeding*—Refer to T 158.

7.1.4. *Time of Setting*—Refer to T 197M/T 197, except that the temperature of each of the ingredients of the concrete mixtures, just prior to mixing, and the temperature at which the time of setting specimens are stored during the test period shall be 23.0 ± 1.7ºC (73.4 ± 3ºF).

Table 1—Types and Minimum Number of Specimens and Tests

Test	Number of Types of Specimens[a]	Number of Test Ages	Number of Conditions of Concrete[b]	Minimum Number of Specimens
Slump	1	1	2	[c]
Air content	1	1	2	[c]
Bleeding	1	1	2	6
Time of setting	1	[d]	2	6
Compressive strength	1	3	2	18
Flexural strength	1	3	2	18
Freezing and thawing	1	1	2	12[e]
Length change	1	1	2	6

[a] See Sections 7 and 9.2.

[b] See Section 4.2.

[c] Determined on each batch of concrete mixed.

[d] See Section 7.1.4.

[e] Specimens for duplicate tests from each batch.

8. PREPARATION OF TEST SPECIMENS

8.1. Specimens for tests of hardened concrete, representing each test and age of test and each condition of concrete being compared, shall be made from at least three separate batches, and the minimum number of specimens shall be as prescribed in Table 1. On a given day, at least one specimen shall be made for each test and age of test from each condition of concrete except that at least two specimens for the freezing and thawing test shall be made from each condition of concrete. The preparation of all specimens shall be completed in 3 days of mixing.

8.2. *Manifestly Faulty Specimens*—Each group of specimens representing a given test or a given age of test, including tests of freshly mixed concrete, shall be examined visually before or during the test, or both, whichever is appropriate. Discard any specimens found to be manifestly faulty by such examination without testing. Visually examine all specimens representing a given test at a given age after testing and should any specimen be found to be manifestly faulty, the test results thereof shall be disregarded. Should more than one specimen representing a given test at a given age be found manifestly faulty, either before or after testing, the entire test shall be disregarded and repeated. The test result reported shall be the average of the individual test results of the specimens tested or, in the event that one specimen or one result has been discarded, it shall be the average of the test results of the remaining specimens.

9. TEST SPECIMENS OF HARDENED CONCRETE

9.1. *Number of Specimens*—Make six or more test specimens for the freezing and thawing test and three or more test specimens for each other type of test and age of test specified in Table 1 for each condition of concrete to be compared.

9.2. *Types of Specimens*—Prepare specimens made from concrete with and without the air-entraining admixture under test in accordance with the following:

9.2.1. *Compressive Strength*—Make and cure test specimens in accordance with R 39.

9.2.2. *Flexural Strength*—Make and cure test specimens in accordance with R 39.

9.2.3. *Resistance to Freezing and Thawing*—Test specimens shall consist of prisms made and cured in accordance with the applicable requirement of R 39. Test specimen dimensions shall be as required by T 161. Make one set of specimens from the concrete mixture containing the air-entraining admixture under test and from the reference concrete mixture, the air content of each mixture being as specified in Section 5.2.

9.2.4. *Length Change*—Make and cure test specimens in accordance with T 160. The moist-curing period, including the period in the molds, shall be 14 days.

10. TESTS ON HARDENED CONCRETE

10.1. Test specimens of hardened concrete in accordance with the following methods:

10.1.1. *Compressive Strength*—Refer to T 22. Test specimens at ages 3, 7, 28, 56, and 180 days, and 1 year. Calculate the compressive strength of the concrete containing the admixture under test as a percentage of the compressive strength of the reference concrete as follows:

10.1.1.1 Divide the average compressive strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average compressive strength of the specimens made from the reference concrete at the same age of test and then multiply the quotient by 100.

10.1.2. *Flexural Strength*—Refer to T 97. Test specimens at ages 3, 7, 28, 56, and 180 days, and 1 year. Calculate the flexural strength of the concrete containing the admixture under test as a percentage of the flexural strength of the reference concrete as follows:

10.1.2.1 Divide the average flexural strength of the specimens made from the concrete containing the admixture under test at a given age of test by the average flexural strength of the specimens made from the reference concrete at the same age of test and then multiply the quotient by 100.

10.1.3. *Resistance to Freezing and Thawing*—Procedure A of T 161. Place specimens under test at the age of 14 days.

10.1.4. *Length Change*—Refer to T 160. The drying period shall be 14 days.

10.1.5. The flexural strength and length change tests are applicable only when specifically required by the purchaser.

11. CHECK TESTS FOR UNIFORMITY

11.1. The check tests enumerated in M 154 in the section on Optional Uniformity Requirements shall be determined as follows:

11.1.1. *pH*—The pH of liquid air-entraining admixtures shall be determined in accordance with ASTM E 70. Non-liquid admixtures should be prepared in solution to determine pH. Unless there is reason to do otherwise, dissolve the material in water in the proportions specified for job use as shown on the package or in the manufacturer's instructions. The temperature of the check test sample shall be within ±1ºC (±2ºF) of that for the acceptance sample and preferably in the range of 21 to 27ºC (70 to 80ºF).

11.1.2. *Air Content of Mortar*—Using the same amounts of successive lots of air-entraining admixtures with the same cement, determine the air contents of mortars in accordance with T 137. The air-entraining admixture shall be combined with the mixing water prior to the start of the mixing procedure. The determinations for both the check test sample and acceptance sample should be made on the same day. Any changes in the air-entraining capacity of the acceptance sample as successive check tests are made should be noted.

12. PROCEDURE FOR RESIDUE BY OVEN DRYING

12.1. Determine the mass of an aluminum dish (about 57-mm diameter, 15-mm height, and about 1 g in mass) to the nearest 0.0001 g. Using a pipet, evenly distribute 1 mL of the liquid air-entraining admixture in the dish and determine the mass to the nearest 0.0001 g. Place the aluminum dish in a drying oven (Section 11.1.4.2); dry for 25 ± 2 minutes at 125 ± 1ºC (257 ± 2ºF). At the end of the drying period, transfer the aluminum dish to a desiccator, cool to room temperature, and determine its mass to the nearest 0.0001 g.

12.2. The drying oven shall be either a forced circulation type or one with provision for free access of air. There shall be precise control of temperature and time of drying so that the degree of volatilization of the material other than water from sample to sample will not vary.

12.3. *Calculation*:

12.3.1. Record the following masses:

M_1 = mass of aluminum dish and admixture prior to heating,

M_2 = mass of empty aluminum dish,

M_3 = $M_1 - M_2$ = mass of sample,

M_4 = mass of aluminum dish and dried residue, and

M_5 = $M_4 - M_2$ = mass of dried residue.

12.3.2. Calculate the residue by using the following equation:

$$\text{Residue by Oven Drying } (\%\text{ of mass}) = \left(M_5 \times 100\right) \Big/ M_3 \qquad (1)$$

13. REPORT

13.1. *Report the following information*:

13.1.1. Results of the tests specified in this method as compared with the requirements of M 154.

13.1.2. Brand name, manufacturer's name and lot number, character of the material, and quantity represented by the sample of the admixture under test.

13.1.3. Brand name, manufacturer's name, and other data on the reference admixture.

13.1.4. Brand name, manufacturer's name, type, and test data on the portland cement or cements used.

13.1.5. Description of and test data on the fine and coarse aggregate used.

13.1.6. Detailed data on the concrete mixtures used, including amounts and proportions of admixtures used, actual amounts of cementitious materials, water-cementitious material ratios, ratios of fine to total aggregate, consistency, and air content.

13.1.7. In reporting on check tests for uniformity, report both the initial and current air contents of mortar for the acceptance sample and the air content of the check test sample, all as determined by ASTM C 185.

14. PRECISION AND BIAS[2]

14.1. *Precision*:

14.1.1. The single-laboratory coefficient of variation of residue by oven drying has been found to be 0.79 percent. Therefore, the results of two properly conducted tests on the same material in the same laboratory should not differ by more than 2.24 percent of their average.[3]

Note 5—As an example, two tests conducted on the same material yield residues by oven drying of 6.14 percent and 6.04 percent, respectively. The average of these two measurements is 6.09 percent. The acceptable range of results is then 2.24 percent of 6.09 percent or ±0.136 percent. As the difference between 6.14 percent and 6.04 percent is 0.10 percent, the results are within the acceptable range.

14.1.2. The multilaboratory coefficient of variation of residue by oven drying has been found to be 2.35 percent. Therefore, the results of two properly conducted tests on the same material in different laboratories should not differ by more than 6.65 percent of their average.[3]

14.1.3. Other procedures referenced in this test method use results obtained from other AASHTO and ASTM test methods listed in the Referenced Documents section. Refer to these documents for their respective precision statements.

14.2. *Bias*—Since there is no accepted reference material suitable for determining the bias of this test method, no statement on bias is made.

15. KEYWORDS

15.1. Air content; air-entraining admixture; cement; concrete; pH; residue; specific gravity.

---

[1] Vinsol resin is manufactured by Hercules, Inc., Wilmington, Delaware. Neutralization may be accomplished by treating 100 parts of the Vinsol with 9 to 15 parts of NaOH by mass. In an aqueous solution, the ratio of water to the resinate shall not exceed 12:1 by mass.

[2] A copy of the research report used to develop the precision statement is available by requesting Research Report RR: C09-1005 from the American Society for Testing and Materials, 100 Barr Harbor Drive, West Conshohocken, PA 19428-2959.

[3] These numbers represent, respectively, the (1s percent) and (d2s percent) limits as described in ASTM C 670.

Standard Method of Test for

Bleeding of Concrete

AASHTO Designation: T 158-09
ASTM Designation: C 232-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bleeding of Concrete

AASHTO Designation: T 158-09
ASTM Designation: C 232-07

1. SCOPE

1.1. These test methods cover the determination of the relative quantity of mixing water that will bleed from a sample of freshly mixed concrete. Two test methods that differ primarily in the degree of vibration to which the concrete sample is subjected are included.

1.2. The two test methods are not expected to yield the same test results when samples of concrete from the same batch are tested by each method. When various concretes are to be compared, all the tests should be conducted using the same method, and the sample masses, if the batches are of similar unit weight, should not differ by more than 1 kg (2 lb).

1.3. The values stated in SI units are to be regarded as standard. The values in parentheses are provided for information purposes only.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 141, Sampling Freshly Mixed Concrete

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SIGNIFICANCE AND USE

3.1. This test method provides procedures to be used for determining the effect of variables of composition, treatment, environment, or other factors in the bleeding of concrete. It may also be used to determine the conformance of a product or treatment with a requirement relating to its effect on bleeding of concrete.

3.2. *Method A*—For a sample consolidated by rodding only and tested without further disturbance, thus simulating conditions in which concrete, after placement, is not subjected to intermittent vibration.

3.3. *Method B*—For a sample consolidated by vibration and tested with further intermittent periods of vibration, thus simulating conditions in which concrete, after being placed is subjected to intermittent vibration.

METHOD A—SAMPLE CONSOLIDATED BY TAMPING

4. APPARATUS

4.1. *Container*—A cylindrical container of approximately 14 L (approximately $^1/_2$-ft^3) capacity, having an inside diameter of 255 ± 5 mm (10 ± $^1/_4$ in.) and an inside height of 280 ± 5 mm (11 ± $^1/_4$ in.). The container shall be made of metal having a thickness of 2.67 to 3.40 mm (0.105 to 0.134 in.) and shall be externally reinforced around the top with a 2.67 to 3.40 mm (0.105 to 0.134 in.) metal band, 40 mm (1$^1/_2$ in.) wide. The inside shall be smooth and free from corrosion, coatings, or lubricants.

4.2. *Scale*, of sufficient capacity to determine the mass of the load required with an accuracy of 0.5 percent. Balances or scales shall be calibrated at least annually or whenever there is a reason to question the accuracy of the equipment. Equipment not in operating condition or out of tolerance shall be marked as such and taken out of service until corrected.

4.3. *Pipet* or similar instrument, for drawing off free water from the surface of the test specimen.

4.4. *Glass Graduate*, of 100-mL capacity for collecting and measuring the quantity of water withdrawn.

4.5. *Tamping Rod*—A round, straight steel rod, 16 mm ($^5/_8$ in.) in diameter and approximately 610 mm (approximately 24 in.) in length, having the tamping end rounded to a hemispherical tip, the diameter of which is 16 mm ($^5/_8$ in.).

4.6. *Metal Beaker (Optional)*—A 1000-mL metal beaker for collecting the decanted supernatant water and sludge (Note 1).

4.7. *Balance (Optional)*—A balance sensitive to one gram for determining the mass of the decanted water and sludge (Note 1).

4.8. *Hot Plate (Optional)*—A small electric hot plate or other source of heat for evaporating decanted water (Note 1).

Note 1—The apparatus listed in Sections 4.6, 4.7, and 4.8 will be required if the procedure of measuring the amount of bleeding water recovered is one involving weighing, evaporation, and reweighing.

5. TEST SPECIMEN

5.1. For concrete made in the laboratory, prepare the concrete as described in R 39. For concrete made in the field, sample the concrete as described in T 141. The apparatus described in this method may be used with samples of concrete containing any size of aggregate graded up to and including a nominal maximum size of 50 mm (2 in.). Concrete containing aggregate larger than 50 mm (2 in.) in nominal maximum size shall be wet-sieved over a 37.5-mm ($1^1/_2$-in.) sieve and the test performed on a portion of the sample that passes through the sieve.

5.2. Fill the container with the concrete in accordance with T 121M/T 121, except that the container shall be filled to a height of 254 ± 3 mm (10 ± $^1/_8$ in.). Level the top surface of the concrete to a reasonably smooth surface by a minimum amount of troweling.

6. PROCEDURE

6.1. During the test, maintain the ambient temperature between 18 to 24ºC (65 and 75ºF). Immediately after troweling the surface of the specimen, record the time and determine the mass of the container and contents. Place the specimen and container on a level platform or floor free from noticeable vibration and cover the container to prevent evaporation of the bleed water. Keep the cover in place throughout the test, except when drawing off the water. Draw off (with pipet or similar instrument) the water that has accumulated on the surface, at 10-minute intervals during the first 40 minutes and at 30-minute intervals thereafter, until cessation of bleeding. To facilitate the collection of bleeding water, tilt the specimen carefully by placing a block approximately 50-mm (2-in.) thick under the one side of the container 2 minutes prior to each time the water is withdrawn. After the water is removed, return the container to a level position without jarring. After each withdrawal, transfer the water to a 100-mL graduate. Record the accumulated quantity of water after each transfer. When only the total volume of bleeding is desired to be determined, the periodic removal procedure may be omitted and the entire amount removed in a single operation. If it is desired to determine the mass of the bleeding water and to exclude the material present other than the water, carefully decant the contents of the cylinder into a metal beaker. Determine the mass and record the mass of the beaker and its contents. Dry the beaker and its contents to constant mass and record the final mass. The difference between the two masses, D, is equal to the mass of the bleeding water. The mass of the sludge may also be obtained, if desired, by initially determining the tare mass of the beaker.

7. CALCULATIONS

7.1. Calculate the volume of bleeding water per unit area of surface, V, as follows:

$$V = V_1/A \tag{1}$$

where:

V_1 = volume of bleeding water during the selected time interval, mL; and

A = area of exposed concrete, cm^2.

The comparative rate of bleeding can be determined as the test progresses by comparing the volume of bleeding water for each equal time interval.

7.2. Calculate the accumulated bleeding water, expressed as a percentage of the net mixing water contained within the test specimen, as follows:

$$C = (w/M) \times S \qquad (2)$$

$$\text{Bleeding, percent} = D/C \times 100 \qquad (3)$$

where:

C = mass of water in the test specimen, g;

M = total mass of batch, kg;

w = net mixing water (the total amount of water minus the water absorbed by the aggregates), kg;

S = mass of sample, g; and

D = mass of bleeding water, g, or total volume withdrawn from the test specimen in cubic centimeters multiplied by 1 g/mL^3.

METHOD B—SAMPLE CONSOLIDATED BY VIBRATION

8. APPARATUS

8.1. *Vibrating Platform*—A platform shall be provided upon which the filled container shall be mounted. The platform shall be equipped with a suitable device so that intermittent periods of vibration of reproducible duration, frequency, and amplitudes will be imparted to the specimen container as prescribed by Section 8. (See Figure 1.) Suitable vibration will be provided if there is bolted to the platform a 93-W ($^1/_8$-hp) electric motor, to the shaft of which a small eccentric whose mass is approximately 110 g is attached by means of a setscrew. The eccentric should be fabricated from cold-rolled stock in accordance with the details and dimensions shown in Figure 2. The hole through the eccentric is 13.5 mm ($^{17}/_{32}$ in.) or an appropriate size to accommodate the motor shaft. The platform should be supported on rubber supports resting on a concrete slab. The concrete slab should be separated from the floor by a layer of cork as shown in Figure 2.

8.2. *Timer*—A timing device, by means of which the periods of vibration provided to the platform and specimen in accordance with the provisions of Section 8 may be regulated.

8.3. *Container*—A steel container 290 mm (11$^1/_2$ in.) in diameter at the top, 279 mm (11 in.) in diameter at the bottom, and 280 mm (11$^1/_8$ in.) high shall be provided. A steel container cover shall also be provided. The container and cover shall conform with the details given in Figure 3.

8.3.1. The remainder of the apparatus is identical with that given for Method A.

9. VIBRATING CYCLE

9.1. The vibrating cycle shall be as follows: Power on for 3 seconds, power off 30 seconds. However, due to the coasting of the motor after the power is turned off, the period of perceptible vibration is approximately 7 seconds (Figure 1).

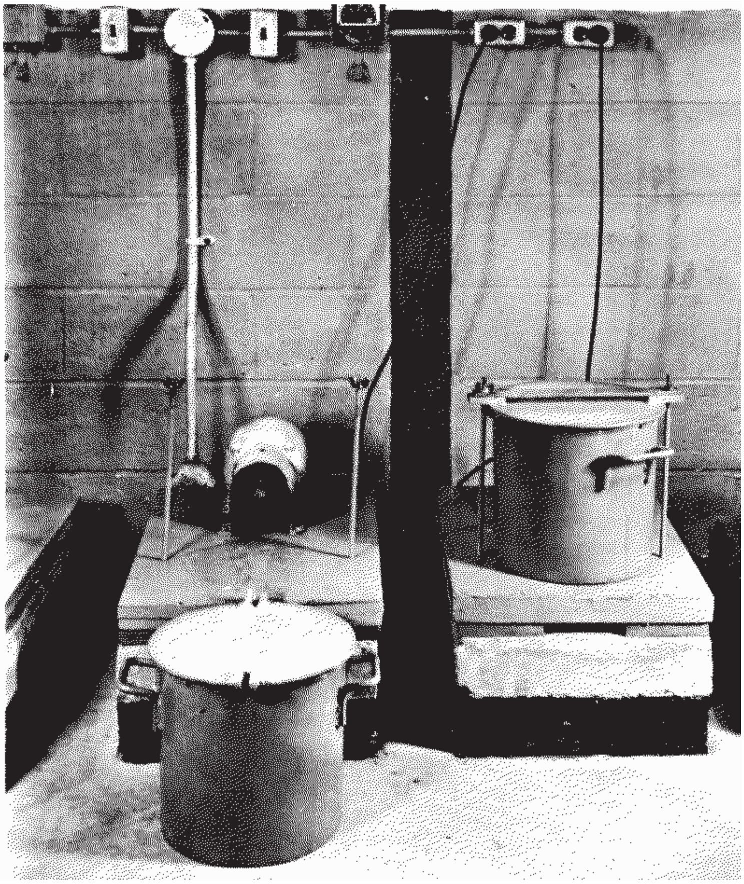

Figure 1—Vibrating Platform and Timer

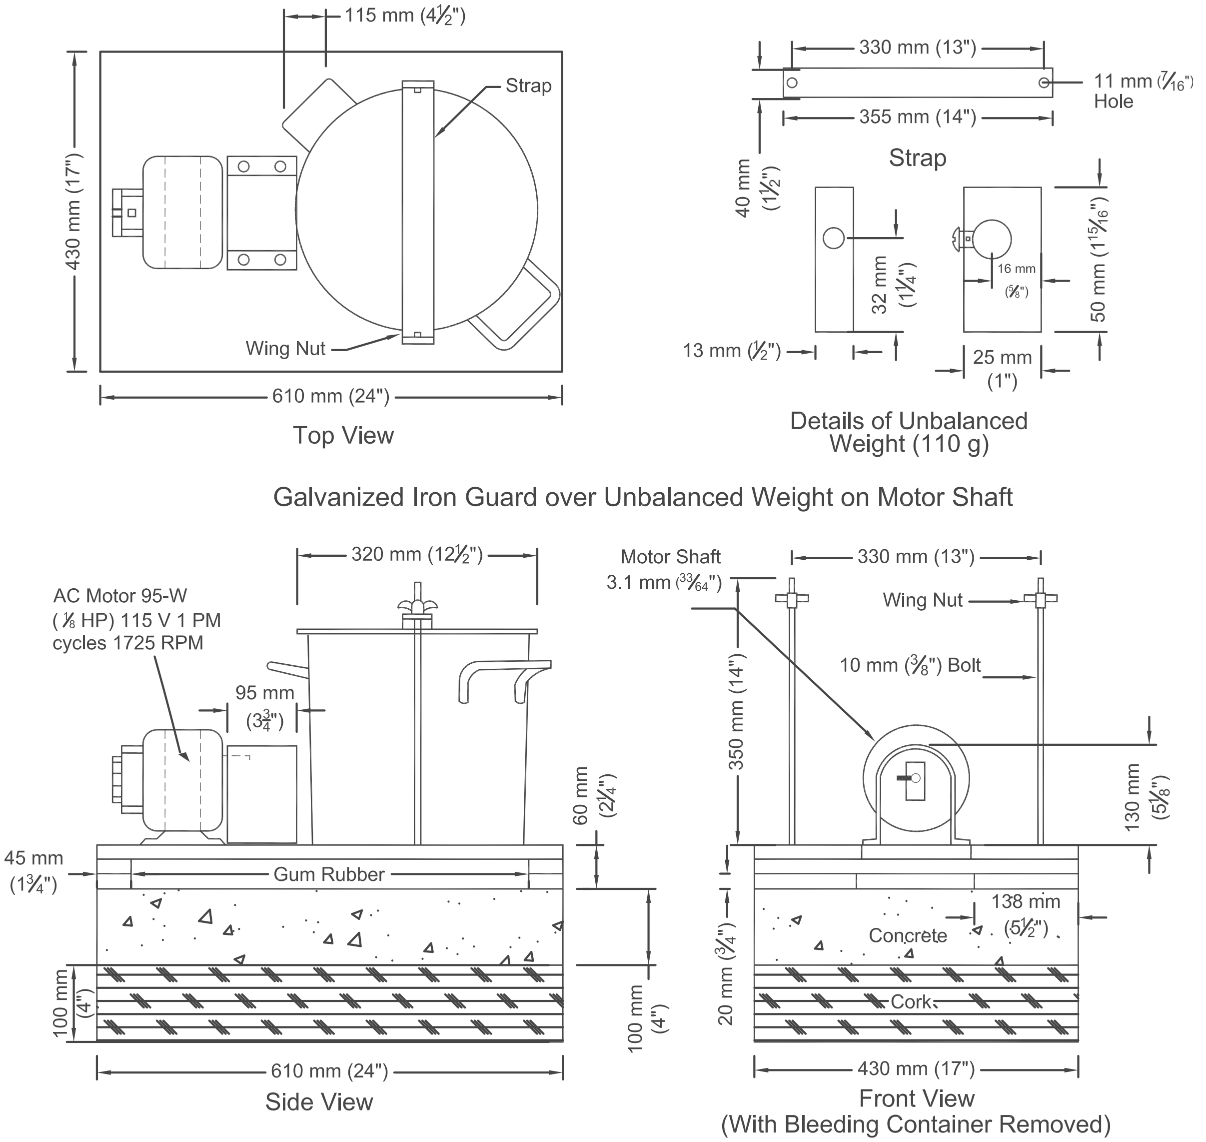

Figure 2—Detail of Vibrating Platform Apparatus

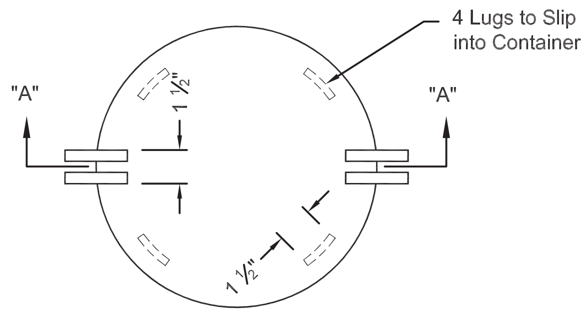
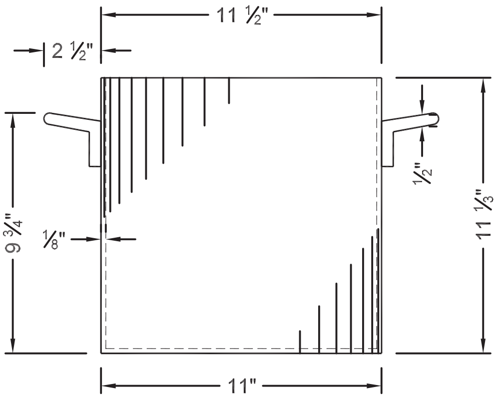
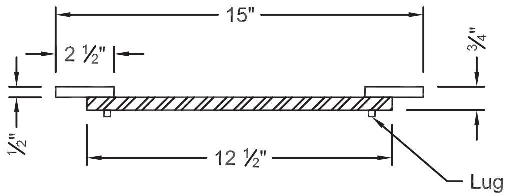


Top View of Cover



Bleeding Container



Section "A-A"

Figure 3—Container and Cover

---

10. TEST SPECIMEN

10.1. The sample shall be prepared as described for Method A.

10.2. The sample shall be placed in the container to a depth equal to approximately one-half the average diameter of the container. The size of the test sample can best be regulated by mass; a sample weighing with a mass of 20 ± 0.5 kg (45 ± 1 lb) usually meets the requirements for the apparatus described herein (Figure 2).

11. PROCEDURE

11.1. *Consolidation of Test Specimen*—Consolidate the sample in the container by means of vibration of only that duration required to affect the desired degree of compaction. Sufficient vibration has been applied as soon as the surface of the concrete has become relatively smooth. Stop the consolidating procedure immediately upon the first appearance of free water segregating from the concrete, as indicated by the development of a water sheen on its surface. For some unusually wet or plastic mixtures, no consolidating effort will be needed beyond that supplied by placing the sample in the container and handling the container during the operations of determining the mass and placing it on the platform for test.

11.2. *Intermittent Vibration*—Place the cover on the container and the container on the vibrating platform. Clamp the container and cover down tightly. Note and record the time, and start the motor. Continue intermittent vibration for 1 hour.

11.3. *Determination of Bleeding Water*—The intermittent periods of vibrations do not permit the determination of bleeding water at a number of different time intervals. Determine the total volume of bleeding water as described for Method A.

12. CALCULATIONS

12.1. Calculate the percentage bleeding water as described for Method A.

13. PRECISION AND BIAS

13.1. *Precision*:

13.1.1. *Method A*—Data are not available to evaluate the precision of Method A directly. However, there is reason to believe that the precision for Method A is at least as good as that for Method B. The values given for Method B shall be used as maximum precision limits for Method A.

13.1.2. *Method B*—The single operator-day-multibatch standard deviation (1s) has been found to be 0.71 percent for a bleeding range from 200 to 10 percent, 1.06 percent for a bleeding range from 10 to 20 percent, and 1.77 percent for more than 20 percent. Therefore, results of two properly conducted tests by the same operator on the same day on different batches of the same mixture should not deviate by more than 2.0 percent (d2s) for a bleeding range from 200 to 10 percent, 3.0 percent for a range from 10 to 20 percent, and 5.0 percent for more than 20 percent. (See Note 2.)

Note 2—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670 for preparing Precision and Bias Statements for Test Methods for Construction Materials.

13.2. *Bias*—The test methods have no bias because the values determined can be defined only in terms of the test methods.

14. KEYWORDS

Standard Method of Test for

Length Change of Hardened Hydraulic Cement Mortar and Concrete

AASHTO Designation: T 160-09
ASTM Designation: C 157/C 157M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Length Change of Hardened Hydraulic Cement Mortar and Concrete

AASHTO Designation: T 160-09
ASTM Designation: C 157/C 157M-06

1. SCOPE

1.1. This test method covers determination of the length changes that are produced by causes other than externally applied forces and temperature changes in hardened hydraulic-cement mortar and concrete specimens made in the laboratory and exposed to controlled conditions of temperature and moisture.

1.2. The values stated in either inch-pound or SI units are to be regarded separately as standard. An exception is with regard to sieve sizes and nominal size of aggregate, in which the SI values are the standard, as stated in specification E 11. Within the text, the SI units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system must be used independently of the other, without combining values in any way.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- E 337, Standard Test Method for Measuring Humidity with a Psychrometer (the Measurement of Wet- and Dry-Bulb Temperatures)

3. TERMINOLOGY

3.1. *Definitions*—The terms used in this test method are defined in terminology C 125.

3.2. *Definition of Terms Specific to This Standard*:

3.2.1. *length change*—an increase or decrease in the length of a test specimen that has been caused to change by any factor other than externally applied forces and temperature changes.

4. SIGNIFICANCE AND USE

4.1. Measurement of length change permits assessment of the potential for volumetric expansion or contraction of mortar or concrete due to various causes other than applied force or temperature change. The method is particularly useful for comparative evaluation of this potential in different hydraulic-cement mortar or concrete mixtures.

4.2. This test method provides useful information for experimental purposes or for products that require testing under nonstandard mixing, placing, handling, or curing conditions, such as high product workability or different demolding times. Standard Conditions are described in Section 5.4.1.

4.3. If conditions for mixing, curing, sampling, and storage other than those specified in this method are required, they shall be reported but are not to be considered as standard conditions of this test method. Nonstandard conditions and the reasons for departure from standard conditions shall be reported clearly and prominently with comparator values.

5. APPARATUS

5.1. *Molds and Length Comparator*—The molds for casting test specimens and the length comparator for measuring length change shall conform to the requirements of M 210.

5.2. *Tamper*—The tamper shall be made of a nonabsorptive, nonabrasive material such as medium-hard rubber or seasoned oak wood rendered nonabsorptive by immersion for 15 minutes in paraffin at approximately 200ºC (392ºF), and shall have a cross section of 13 by 25 mm or $^1/_2$ by

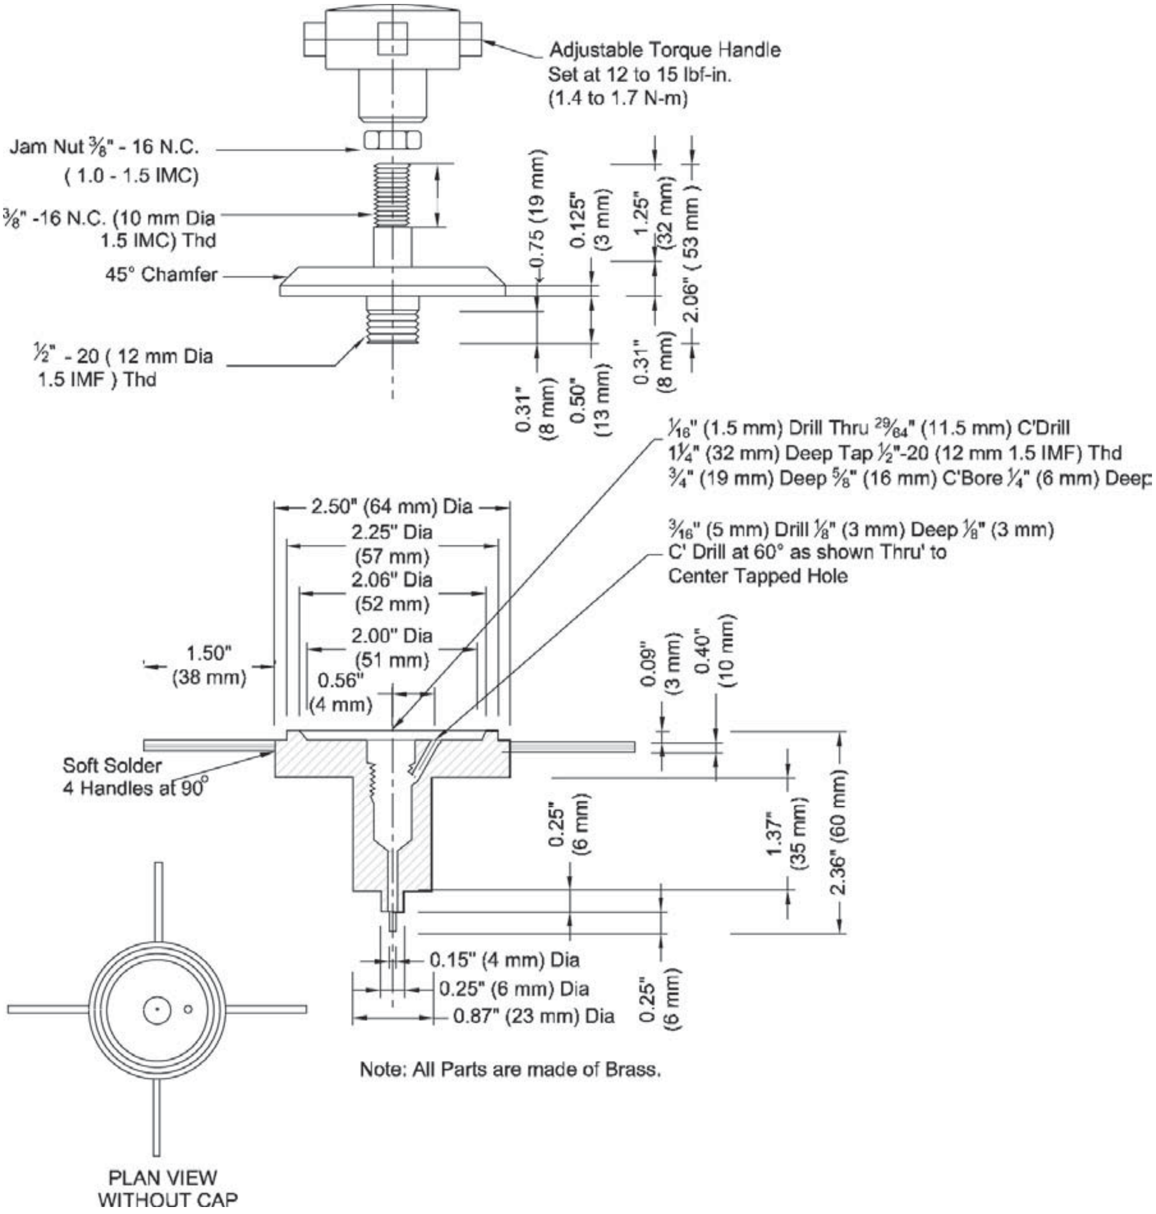
1 in. and a convenient length of about 150 mm or 6 in. The tamping face of the tamper shall be flat and at right angles to the length of the tamper.

5.3. *Tamping Rod*—The tamping rod shall be a straight steel rod 10 mm or $^3/_8$ in. in diameter and not less than 250 mm or 10 in. in length, having at least the tamping end rounded to a hemispherical tip of the same diameter.

5.4. *Drying Room and Controls*—A drying room with suitable racks shall be provided when storing specimens in air. The racks shall be designed for free circulation of air around specimens, except for necessary supports, and shall be so situated with respect to the nearest wall or other obstruction that air circulation is not restricted in the intervening space. The supports shall be horizontal and shall consist of two nonabsorptive members not deeper than 25 mm or 1 in. and having a bearing area of not more than 6 mm or $^1/_4$ in. in width. Conditioned air shall be circulated into and out of the room in a uniform manner so that the specified rate of evaporation is attained adjacent to all specimens.

5.4.1. The air in the room shall be maintained at a temperature of 23.0 ± 1.7ºC (73.4 ± 3.0ºF) and a relative humidity of 50 ± 4 percent. The air movement past all specimens shall be such that the rate of evaporation is 77 ± 30 mL/24 hours from an atmometer or 13 ± 15 mL/24 hours from a 400-mL Griffin low-form beaker filled to $^3/_4$ in. or 20 mm from the top. The temperature and relative humidity of the air in the room shall be measured with either a sling or Assmann psychrometer at least twice each working day. The psychrometer shall comply with ASTM E 337, except that thermometers having an overall length of 250 mm or 10 in. and marked in subdivisions of 0.25ºC (0.5ºF) are permitted. The room shall be equipped with a means of measuring and recording wet- and dry-bulb temperatures continuously. Correction factors as indicated by the sling or Assmann psychrometer shall be applied to the recorded data. The rate of evaporation within the room shall be determined daily by the use of the atmometer or by the loss of mass of water from a 400-mL Griffin low-form beaker filled initially to 20 mm or $^3/_4$ in. from the top.

5.5. *Atmometer*—The atmometer shall be constructed as shown in Figure 1.



Note: All parts are made of brass.

Figure 1—Atmometer

5.5.1. *Mounting*—Figure 2 shows a suggested arrangement for operating the atmometer. Punch a central hole 13 mm or $^1/_2$ in. in diameter in a filter paper, place it on the atmometer, and secure it in place while dry, by turning the torque handle only, until it just starts to slip. Mount the atmometer on a stand with the filter paper in a horizontal position. Mount a 100-mL glass graduate so that the 100-mL mark is from 25 to 75 mm or 1 to 3 in. below the level of the filter paper. Stopper the graduate so that entrance is provided for two short glass tubes not extending to the water level and one long tube extending to the bottom of the graduate. Connect the glass tubing leading from the bottom of the graduate to the inlet of the atmometer by means of clear plastic tubing.

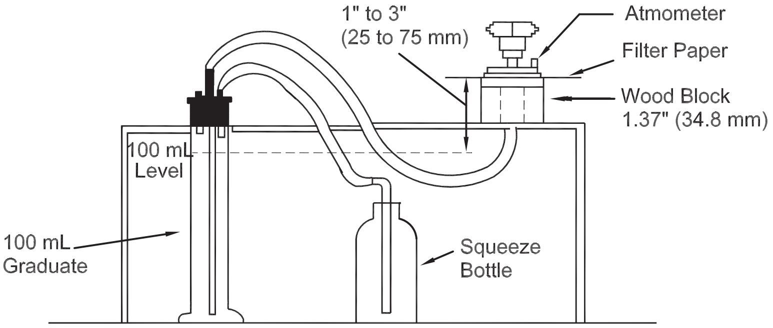


Figure 2—Suggested Arrangement for Operating the Atmometer

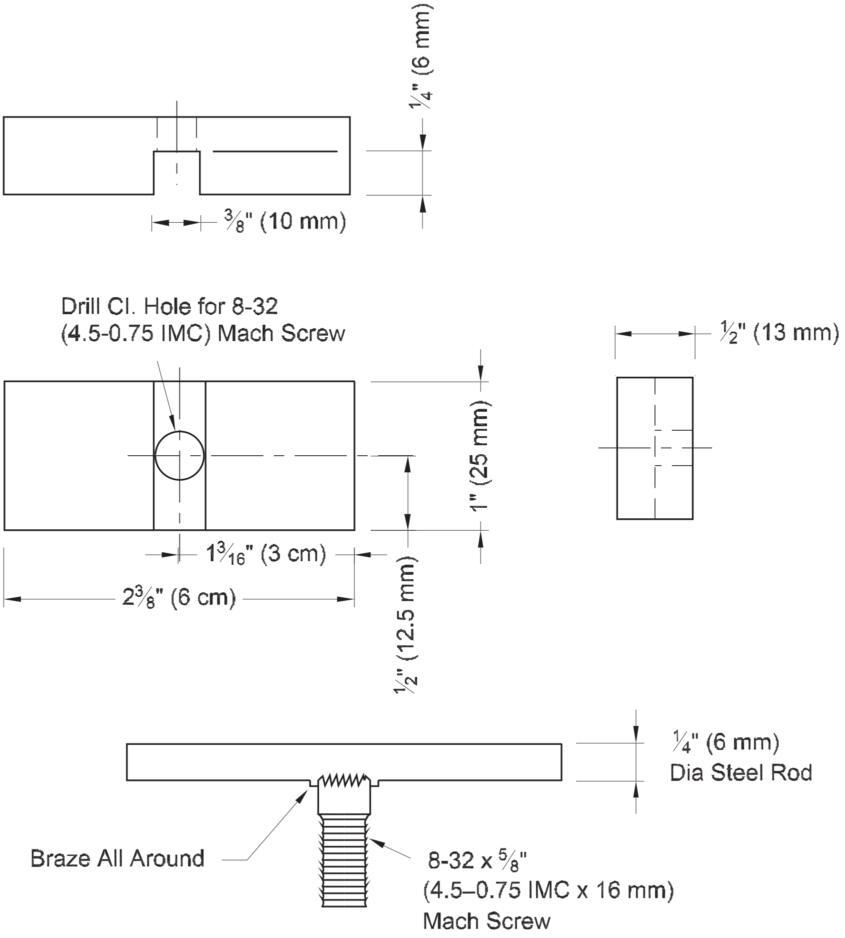
5.5.2. *Operation*—Use clear plastic tubing to connect a squeeze bottle containing distilled or deionized water to one of the short glass tubes into the graduate. Force water into the graduate until it is about half full and then close the remaining glass tube into the graduate. Continue to force water through the graduate into the atmometer until the filter paper is saturated and there are no air bubbles in the system. Open the glass tube into the graduate and release pressure on the squeeze bottle gradually to avoid trapping air in the tube leading to the atmometer. Adjust the level of water in the graduate to approximately the 100-mL mark. If the atmometer is to be used under variable temperature conditions, disconnect the squeeze bottle after filling the graduate to avoid the possibility of additional water being forced into the graduate. Permit evaporation of water from the filter paper for one hour before recording the time and initial reading of the graduate. It is not permitted to omit the waiting period during subsequent use of the atmometer provided the filter paper does not become dry. Change the filter paper whenever it shows signs of contamination but not less frequently than once every two weeks.

5.6. *Filter Paper*—The filter paper to be used with the atmometer shall be white with a smooth surface texture. It shall be 152 mm (6 in.) in diameter and 1.27 ± 0.08 mm (0.050 ± 0.003 in.) thick and shall have a cotton fiber content of not less than 75 weight. The density shall be between 0.400 and 0.425 g/cm^3. The Mullen bursting strength shall not be less than 345 kPa (50 psi).

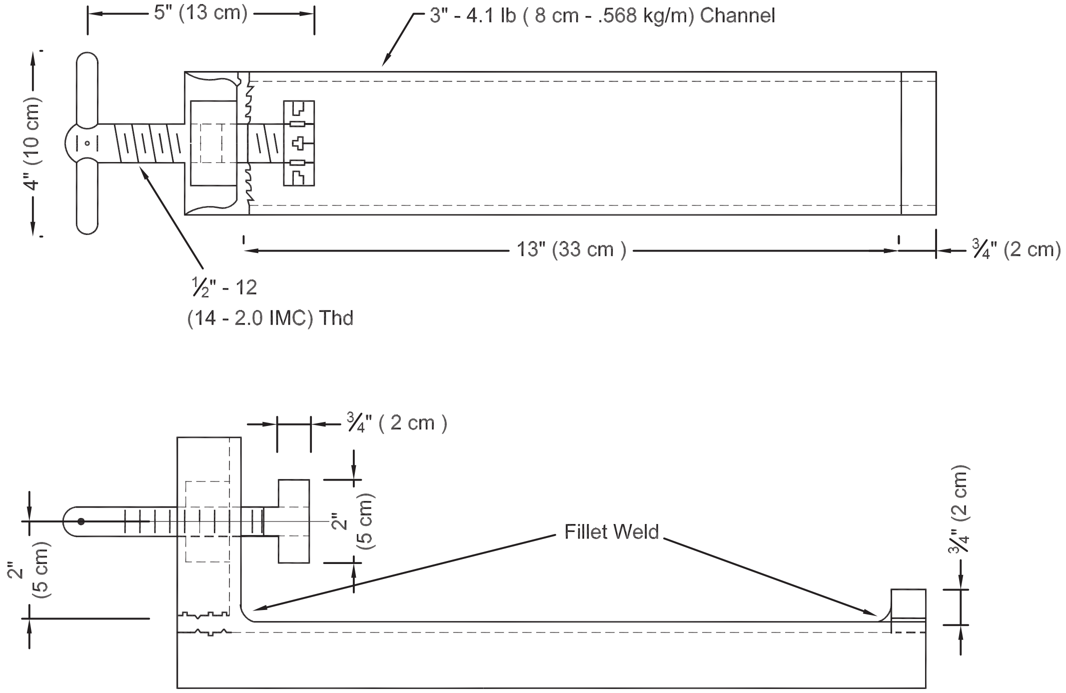
Note 1—E and D filter paper No. 625 has been found suitable.[1]

5.7. *Apparatus for Demolding Specimens*—It is useful to construct an apparatus for demolding specimens molded in double molds as detailed in Fig. 3 or to a different design that serves the same purpose. When this device is to be used, the center side plate of the double mold must be appropriately drilled and tapped to receive the 8-32 (4.5-0.75 IMC) machine screw of the demolding thumb screw. Figure 4 shows the details of a suitable apparatus for demolding specimens molded in single molds.



Instructions for Use: Remove end and outer side plates leaving base, center side plate, and gauge stud holders in place. Engage machine screw in drilled and tapped end of center side plate. Turn thumb screw to loose bars.

Figure 3—Device for Detaching 25-mm (1-in.) Square by 285-mm ($11^{1}/_{4}$- in.) Bars from Center Side Plate of Double Molds



Note: Dimensions shown are appropriate for one design of mold for 3 in. (8 cm) square specimens. Change dimensions are required for other molds.

Figure 4—Device for Demolding Specimens from Single Molds

6. SAMPLING

6.1. Take samples according to the applicable provisions of R 39 from batches of hydraulic-cement mortar or concrete made in the laboratory (Note 2).

Note 2—When collecting samples in nonstandard conditions, such as field concrete, it is suggested that T 141 be followed. Field cast specimens can show up to twice as much drying shrinkage as laboratory cast specimens from the same materials and proportions.

7. TEST SPECIMENS

7.1. *Mortar*—The test specimen for mortar shall be a prism of 25-mm or 1-in. square cross section and approximately 285 mm or $11^{1}/_{4}$ in. in length. Three specimens shall be prepared for each test condition.

7.2. *Concrete*—The test specimen for concrete, in which all of the aggregate passes a 50-mm (2-in.) sieve, shall be a prism of 100-mm or 4-in. square cross section and approximately 285 mm or $11^{1}/_{4}$ in. long. However, a prism of 75-mm or 3-in. square cross section may be used if all of the aggregate passes a 25.0-mm (1-in.) sieve. Three specimens shall be prepared for each test condition. Since length change is capable of being influenced by the size of the specimen, specimens to be compared shall have the same dimensions, and any specification limit based upon this method shall be applied to a specified size of specimen.

8. PROCEDURE FOR MIXING MORTARS AND CONCRETE

8.1. If the mortar or concrete to be tested is made in accordance with requirements other than those given in one of the following paragraphs, samples shall be taken and specimens molded as described in the sections on sampling and on molding specimens.

8.2. Bring all materials to a temperature between 18 and 24ºC (65 and 75ºF) before using to make mortar or concrete. Proportion solid materials by mass (that is, not by volume). It is permitted to batch water and liquid admixtures either by mass or by volume. For calculation of batch quantities, assume aggregates to be saturated and surface-dry; if they are not in this condition at the time of use, apply appropriate corrections, as necessary, to batch quantities to compensate for absorption or free moisture.

8.3. *Mortar*—Mix mortar in a mechanical mixer as described in T 162. The clearances between paddle and bowl specified in T 162 are suitable only for mortars made with fine aggregates that are finer than the 2.36 mm (No. 8) sieve. Mortars made with aggregates containing particles coarser than this sieve require special clearances or a different type of paddle to permit the mixer to operate freely and to avoid damage to the paddle and bowl. The sequence of mixing shall be in accordance with the applicable provisions of T 162. Determine the flow of the mortar in accordance with the applicable provisions of T 106, and use sufficient mixing water to produce a flow of 110 ± 5 percent.

8.4. *Concrete*—Mix concrete in a suitable laboratory mixer in accordance with the applicable provisions of R 39. Determine the slump of the concrete using T 119M/T 119 and use sufficient mixing water to produce a slump of 90 ± 15 mm or $3^1/_2 \pm {}^1/_2$ in.

9. PROCEDURE FOR MOLDING SPECIMENS

9.1. *Mortar Specimens*—Place the mortar in the mold in two approximately equal layers. Compact each layer with the tamper. Work the mortar into the corners, around the gauge studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, strike off the mortar flush with the top of the mold, and smooth the surface with a few strokes of a trowel. Immediately after completion of molding, loosen the device by holding the gauge studs in position at each end of the mold in order to prevent any restraint of the gauge studs during initial shrinkage of the specimen.

9.2. *Concrete Specimens*—Place the concrete in the mold in two approximately equal layers in accordance with the general instructions for placing concrete in specimens given in R 39. Consolidate each layer by rodding, except use external vibration if the slump is less than 75 mm or 3 in. in accordance with the instructions for consolidation of flexure test specimens given in R 39. The same method of consolidation is to be used for all specimens to be compared. In addition, as the top layer is being placed, work the concrete thoroughly around each gauge stud with the fingers. The top layer shall slightly overfill the mold. After consolidation is complete, strike off the excess material with a straightedge. Immediately after completion of molding, loosen the device by holding the gauge studs in position at each end of the mold in order to prevent any restraint of the gauge studs before the test specimens are demolded.

10. PROCEDURE FOR CURING OF SPECIMENS

10.1. Cure the test specimens in the molds in a moist cabinet or room in accordance with M 201. Protect specimens from dripping water.

10.2. Remove specimens from the molds at an age of 23$^1/_2$ hours ± $^1/_2$ hour after the addition of water to the cement during the mixing operation. In order to avoid damage during removal from the molds, it is not permitted, especially in the case of certain slow-hardening cements, to allow specimens to remain in the molds for more than 24 hours. When this is found necessary, the moist curing schedule shall be extended, but all specimens that are to be directly compared with each other shall be subjected to the same conditions of moist-curing and shall have their initial comparator reading made within ±$^1/_2$ hour of the same age. It is permitted to use the demolding device to remove specimens without striking or jarring and with particular care not to exert pressure directly against the gauge studs. The gauge stud holder shall remain attached to the stud during this operation. Marks placed on the specimens for identification or positioning are only to be made by graphite applied either by a soft pencil or as a liquid that deposits essentially graphite without binder, or made with waterproof indelible ink. Upon removal of the specimens from the molds, place them in lime-saturated water maintained at 23.0 ± 0.5ºC (73. ± 1ºF) for a minimum of 15 minutes in the case of 25-mm or 1-in. square cross-section specimens and for a minimum of 30 minutes in the case of 75-mm or 3-in. or 100-mm or 4-in. square cross-section specimens before being measured for length. This is to minimize variation in length due to variation in temperature. At an age of 24 hours ± $^1/_2$ hour after the addition of water to the cement during the mixing operation, remove the specimens from water storage one at a time, wipe with a damp cloth, and immediately take the initial comparator reading.

10.3. After the initial comparator reading, store the specimens in lime-saturated water at 23.0 ± 2ºC (73.4 ± 3.0ºF) until they have reached an age of 28 days, including the period in the molds At the end of the curing period, make a second comparator reading after the specimens have been brought to a more closely controlled temperature as was done prior to the earlier reading and in the manner described above.

11. PROCEDURE FOR STORAGE OF SPECIMENS

11.1. After measurement at the end of the curing period, store the specimens as described in either of the following:

11.1.1. *Water Storage*—Immerse the specimens in lime-saturated water storage in accordance with M 201. Take comparator readings of each specimen when it has reached an age, including the curing period of 8, 16, 32, and 64 weeks. Make these readings immediately after the specimens have been subjected to storage in water at 23.0 ± 0.5ºC (73. ± 1.0ºF) for at least 15 minutes in the case of 25-mm (or 1-in.) specimens or 30 minutes in the case of 75-mm (or 3-in.) or 100-mm (or 4-in.) specimens.

11.1.2. *Air Storage*—Store the specimens in the drying room, so that the specimens have a clearance of at least 1 in. or 25 mm on all sides. Take comparator readings of each specimen after periods of air storage after curing of 4, 7, 14, and 28 days, and after 8, 16, 32, and 64 weeks. Preferably, take these readings in a room maintained at a relative humidity of 50 ± 4 percent while the specimens are at a temperature of 23.0 ± 2ºC (73. ± 3.0ºF).

12. PROCEDURE FOR CALCULATING LENGTH CHANGE

12.1. *Comparator Reading*—Read the comparator dial with the test specimen in the comparator; then read the comparator dial with the reference bar in the comparator. Calculate the difference between the two readings as described in M 210.

12.2. *Length Change*—Calculate the length change of any specimen at any age after the initial comparator reading as follows:

$$\triangle L_x = \frac{CRD - \text{ initial } CRD}{G} \times 100 \qquad (1)$$

where:

ΔL_x = length change of specimen at any age, percent;

CRD = difference between the comparator reading of the specimen and the reference bar at any age; and

G = the gauge length (250 mm or 10 in.). (See Note 3.)

Note 3—In M 210, the comparator dial gauge specified for use with 10-gauge length specimens shall be graduated in fractions of an inch; the comparator dial gauge specified for use with 250-mm gauge length specimens shall be graduated in fractions of a millimeter.

13. REPORT

13.1. *Report the following information*:

13.1.1. Identification as mortar or concrete specimens, number of specimens for each condition, and date molded;

13.1.2. Source and identification of each material employed;

13.1.3. Type, maximum size, moisture condition, and grading of the aggregate;

13.1.4. Size of specimens;

13.1.5. Mortar or concrete mixture data at time of mixing, including flow or slump and temperature of mixture;

13.1.6. Description of consolidation of concrete, specifying whether rodding or external vibration was used;

13.1.7. Conditions and periods of moist-curing prior and subsequent to removal of molds, if different from those specified;

13.1.8. Description of storage condition, including temperature and humidity, either by indicating whether water or air storage was followed or by giving the details of any procedure not conforming to either of these conditions;

13.1.9. Total elapsed time of storage and total age of specimen, or total elapsed time of curing and storage if the same condition was used for both;

13.1.10. Length change data, reported as percent increase or decrease in linear dimension to the nearest 0.001 percent, of the gauge length based on the initial measurement made at the time of removal from the molds; and

13.1.11. Any other pertinent information.

14. PRECISION AND BIAS

14.1. *Precision*:

14.1.1. When this test method was used for the purpose of determining drying shrinkage of mortar as affected by the choice of portland cement used in making it, the precision was found to be as reported in ASTM C 596.

14.1.1.1. The following single-laboratory, multiple-operator precision applies to concrete specimens measured at 180 days.

14.1.1.2. For specimens stored in water, the standard deviation (1s) among specimens is 0.0045 percent. When three replicate specimens are tested, the maximum range among them is not expected to exceed 0.0266 percent in 95 percent of the sets tested. When a test result represents the mean of three specimens, the 1s is 0.0026 percent. The difference between two such means is not expected to exceed 0.0074 percent in 95 percent of such duplicate tests performed.

14.1.1.3. For specimens stored in air, the standard deviation (1s) among specimens is 0.0084 percent. When three replicate specimens are tested, the maximum range among them is not expected to exceed 0.0496 percent in 95 percent of the sets tested. When a test result represents the mean of three specimens, the 1s is 0.0048 percent. The difference between two such means is not expected to exceed 0.0137 percent in 95 percent of such duplicate tests performed.

Note 4—These precision values were calculated from data taken on specimens described on page 47 of STP 205,[2] representing 193 concrete mixtures; two specimens made from each of three batches made on separate days, one of each two specimens stored in water, the other stored at nominal 50 percent relative humidity.

14.2. *Bias*—No statement on bias is being made since there is no accepted reference material suitable for determining the bias of these procedures.

Standard Method of Test for

Resistance of Concrete to Rapid Freezing and Thawing

AASHTO Designation: T 161-08
ASTM Designation: C 666/C 666M-03

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance of Concrete to Rapid Freezing and Thawing

AASHTO Designation: T 161-08
ASTM Designation: C 666/C 666M-03

1. SCOPE

1.1. This method covers the determination of the resistance of concrete specimens to rapidly repeated cycles of freezing and thawing in the laboratory by two different procedures: Procedure A, Rapid Freezing and Thawing in Water, and Procedure B, Rapid Freezing in Air and Thawing in Water. Both procedures are intended for use in determining the effects of variations in the properties of concrete on the resistance of the concrete to the freezing and thawing cycles specified in the particular procedure. Neither procedure is intended to provide a quantitative measure of the length of service that may be expected from a specific type of concrete.

1.2. The values stated in SI units are the preferred standard.

1.3. All material in this test method not specifically designated as belonging to Procedure A or Procedure B applies to either procedure.

1.4. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- C 823, Standard Practice for Examination and Sampling of Hardened Concrete in Constructions

3. SIGNIFICANCE AND USE

3.1. As noted in the scope, the two procedures described in this method are intended to determine the effects of variations in both properties and conditioning of concrete in the resistance to freezing and thawing cycles specified in the particular procedure. Specific applications include specified use in M 194, T 157, and ranking of coarse aggregates as to their effect on concrete freeze–thaw durability, especially where soundness of the aggregate is questionable.

3.2. It is assumed that the procedures will have no significantly damaging effects on frost-resistant concrete that may be defined as (1) any concrete not critically saturated with water (that is, not sufficiently saturated to be damaged by freezing) and (2) concrete made with frost-resistant aggregates and having an adequate air-void system that has achieved appropriate maturity and thus will prevent critical saturation by water under common conditions.

3.3. If, as a result of performance tests as described in this method, concrete is found to be relatively unaffected, it can be assumed that it was either not critically saturated, or was made with “sound” aggregates, a proper air-void system, and allowed to mature properly.

3.4. No relationship has been established between the resistance to cycles of freezing and thawing of specimens cut from hardened concrete and specimens prepared in the laboratory.

4. APPARATUS

4.1. *Freezing and Thawing Apparatus*:

4.1.1. The freezing and thawing apparatus shall consist of a suitable chamber or chambers in which the specimens may be subjected to the specified freezing and thawing cycle, together with the necessary refrigerating and heating equipment and controls to produce continuously and automatically, reproducible cycles within the specified temperature requirements. In the event that the equipment does not operate automatically, provision shall be made for either its continuous manual operation on a 24-hour a day basis or for the storage of all specimens in a frozen condition when the equipment is not in operation.

4.1.2. The apparatus shall be so arranged that, except for necessary supports, each specimen is: (1) for Procedure A, completely surrounded by not less than 1 mm ($^1/_{32}$ in.) nor more than 3 mm ($^1/_8$ in.) of water at all times while it is being subjected to freezing and thawing cycles, or (2) for Procedure B, completely surrounded by air during the freezing phase of the cycle and by water during the thawing phase. Rigid containers, which have the potential to damage specimens, are not permitted. Length change specimens in vertical containers shall be supported in a manner to avoid damage to the gauge studs.

Note 1—Experience has indicated that ice or water pressure, during freezing tests, particularly in equipment that uses air rather than a liquid as the heat transfer medium, can cause excessive damage to rigid metal containers, and possibly to the specimens therein. Results of tests during which bulging or other distortion of containers occurs should be interpreted with caution.

4.1.3. The temperature of the heat-exchanging medium shall be uniform within 3°C (6°F) throughout the specimen cabinet when measured at any given time, at any point on the surface of any specimen container for Procedure A or on the surface of any specimen for Procedure B, except during the transition between freezing and thawing and vice versa.

4.1.3.1. Support each specimen at the bottom of its container in such a way that the temperature of the heat-exchanging medium will not be transmitted directly through the bottom of the container to the full area of the bottom of the specimen, thereby subjecting it to conditions substantially different from the remainder of the specimen.

Note 2—A flat spiral of 3-mm ($^1/_8$-in.) wire placed in the bottom of the container has been found adequate for supporting specimens.

4.1.4. For Procedure B, it is not contemplated that the specimens will be kept in containers. The supports on which the specimens rest shall be such that they are not in contact with the full area of the supported side or end of the specimen, thereby subjecting this area to conditions substantially different from those imposed on the remainder of the specimen.

Note 3—The use of relatively open gratings, metal rods, or the edges of metal angles has been found adequate for supporting specimens, provided the heat-exchanging medium can circulate in the direction of the long axis of the rods or angles.

4.2. *Temperature-Measuring Equipment*—consisting of thermometers, resistance thermometers, or thermocouples, capable of measuring the temperature at various points within the specimen chamber and at the centers of control specimens to within 1°C (2°F).

4.3. *Dynamic Testing Apparatus*—conforming to the requirements of ASTM C 215.

4.4. *Optional Length Change Test Length, Change Comparator*—conforming to the requirements of M 210. When specimens are longer than the nominal 285-mm ($11^1/_4$-in.) length provided for in M 210 are used for freeze-thaw tests, use an appropriate length reference bar, which otherwise meets the M 210 requirements. Dial gauge micrometers for use on these longer length change comparators shall meet the gradation interval and accuracy requirements for M 210 for the millimeter (inch) calibration requirements. Prior to the start of measurements on any specimens, fix the comparator at an appropriate length to accommodate all of the specimens to be monitored for length change.

4.5. *Scales*—with a capacity approximately 50 percent greater than the weight of the specimens and accurate to at least 5 g (0.01 lb) within the range of ±10 percent of the specimen weight will be satisfactory.

4.6. *Tempering Tank*—with suitable provisions for maintaining the temperature of the test specimens in water, such that when removed from the tank and tested for fundamental transverse frequency and length change, the specimens will be maintained within –1° and +2°C (–2° and +4°F) of the target thaw temperature for specimens in the actual freezing and thawing cycle and equipment being used. The use of the specimen chamber in the freezing and thawing apparatus by stopping the apparatus at the end of the thawing cycle and holding the specimens in it shall be considered as meeting this requirement, provided the specimens are tested for fundamental transverse frequency within the above temperature range. It is required that the same target specimen thaw temperature be used throughout the testing of an individual specimen because a change in specimen temperature at the time of length measurement can affect the length of the specimen significantly.

5. FREEZING AND THAWING CYCLE

5.1. Base conformity with the requirements for the freezing and thawing cycle on temperature measurements of control specimens of similar concrete to the specimens under test in which suitable temperature-measuring devices have been imbedded. Change the position of these control specimens frequently in such a way as to indicate the extremes of temperature variation at different locations in the specimen cabinet.

5.2. The nominal freezing and thawing cycle for both procedures of this method shall consist of alternately lowering the temperature of the specimens from 4 to –18°C (40 to 0°F) and raising it from –18 to 4°C (0 to 40°F) in not less than 2 nor more than 5 hours. For Procedure A, not less than 25 percent of the time shall be used for thawing, and for Procedure B, not less than 20 percent of the time shall be used for thawing (Note 4). At the end of the cooling period the temperature at the centers of the specimens shall be –18 ± 2°C (0 ± 3°F), and at the end of the heating period the temperature shall be 4 ± 2°C (40 ± 3°F), with no specimen at any time reaching a temperature lower than –20°C (–3°F) nor higher than 6°C (43°F). The time required for the temperature at the center of any single specimen to be reduced from 3 to –16°C (37 to 3°F) shall be no less than one-half of the length of the cooling period, and the time required for the temperature at the center of any single specimen to be raised from –16 to 3°C (3 to 37°F) shall be not less than one-half of the length of the heating period. For specimens to be compared with each other, the time required to change the temperature at the centers of any specimens from 2 to –12°C (35 to 10°F) shall not differ by more than one-sixth of the length of the cooling period from the time required for any specimen and the time required to change the temperature at the centers of any specimens from –12 to 2°C (10 to 35°F) shall not differ by more than one-third of the length of the heating period from the time required for any specimen.

Note 4—In most cases, uniform temperature and time conditions can be controlled most conveniently by maintaining a capacity load of specimens in the equipment at all times. In the event that a capacity load of test specimens is not available, dummy specimens can be used to fill empty spaces. This procedure also assists greatly in maintaining uniform fluid level conditions in the specimen and solution tanks.

The testing of concrete specimens composed of widely varying materials or with widely varying thermal properties, in the same equipment at the same time, may not permit adherence to the time-temperature requirements for all specimens. It is advisable that such specimens be tested at different times and that appropriate adjustments be made to the equipment.

5.3. The difference between the temperature at the center of a specimen and the temperature at its surface shall at no time exceed 28°C (50°F).

5.4. The period of transition between the freezing and thawing phases of the cycle shall not exceed 10 minutes, except when specimens are being tested in accordance with Section 8.3.

6. SAMPLING

6.1. Constituent materials for concrete specimens made in the laboratory shall be sampled using applicable standard methods.

6.2. Samples cut from hardened concrete are to be obtained in accordance with ASTM C 823.

7. TEST SPECIMENS

7.1. The specimens for use in this test shall be prisms or cylinders made and cured in accordance with the applicable requirements of M 210 and R 39.

7.2. Specimens used shall not be less than 75 mm (3 in.) nor more than 125 mm (5 in.) in width, depth, or diameter, and not less than 275 mm (11 in.) nor more than 405 mm (16 in.) in length.

7.3. Test specimens may also be cores or prisms cut from hardened concrete. If so, the specimens should not be allowed to dry to a moisture condition below that of the structure from which they were taken. This may be accomplished by wrapping in plastic or by other suitable means. The specimens so obtained shall be furnished with gauge studs in accordance with ASTM C 341.

7.4. For this test the specimens shall be stored in saturated lime water from the time of their removal from the molds until the time freezing and thawing tests are started. All specimens to be compared with each other initially shall be of the same nominal dimensions.

8. PROCEDURE

8.1. Molded beam specimens shall be cured for 14 days prior to testing unless otherwise specified. Beam specimens sawed from hardened concrete shall be moisture-conditioned by immersing in saturated lime water at 23 ± 2°C (73 ± 3°F) for 48 hours prior to testing unless otherwise specified.

8.2. Immediately after the specified curing or conditioning period, bring the specimen to a temperature within –1° and +2°C (–2° and +4°F) of the target thaw temperature that will be used in the freeze-thaw cycle and test for fundamental transverse frequency, determine the mass, determine the average length and cross-section dimensions of the concrete specimen within the tolerance required in ASTM C 215, and determine the initial length comparator reading (optional) for the specimen with the length change comparator. Protect the specimens against loss of moisture between the time of removal from curing and the start of the freezing and thawing cycles.

8.3. Start freezing and thawing tests by placing the specimens in the thawing water at the beginning of the thawing phase of the cycle. Remove the specimens from the apparatus, in a thawed condition, at intervals not exceeding 36 cycles of exposure to the freezing and thawing cycles, test for fundamental transverse frequency and measure length change (optional) with the specimens within the temperature range specified for the tempering tank in Section 4.6, determine the mass of each specimen, and return them to the apparatus. To ensure that the specimens are completely thawed and at the specified temperature, place them in the tempering tank or hold them at the end of the thaw cycle in the freezing and thawing apparatus for a sufficient time for this condition to be attained throughout each specimen to be tested. Protect the specimens against loss of moisture while out of the apparatus and turn them end-for-end when returned. For Procedure A, rinse out the container and add clean water. Return the specimens either to random positions in the apparatus or to positions according to some predetermined rotation scheme that will ensure that each specimen that continues under test for any length of time is subjected to conditions in all parts of the freezing apparatus. Continue each specimen in the test until it has been subjected to 300 cycles or until its relative dynamic modulus of elasticity reaches 60 percent of the initial modulus, whichever occurs first, unless other limits are specified (Note 5). For the optional length change test, 0.10 percent expansion may be used as the end of test. Whenever a specimen is removed because of failure, replace it for the remainder of the test by a dummy specimen. Each time a specimen is tested for fundamental frequency (Note 6) and length change, make a note of its visual appearance and make special comment on any defects that develop (Note 7). When it is anticipated that specimens may deteriorate rapidly, they should be tested for fundamental transverse frequency and length change (optional) at intervals not exceeding 10 cycles when initially subjected to freezing and thawing.

Note 5—It is not recommended that specimens be continued in the test after their relative dynamic modulus of elasticity has fallen below 50 percent.

Note 6—It is recommended that the fundamental longitudinal frequency be determined initially and as a check whenever a question exists concerning the accuracy of determination of fundamental transverse frequency, and that the fundamental torsional frequency be determined initially and periodically as a check on the value of Poisson's ratio.

Note 7—In some applications, such as airfield pavements and other slabs, popouts may be defects that are a concern. A popout is characterized by the breaking away of a small portion of the concrete surface due to internal pressure, thereby leaving a shallow and typically conical spall in the surface of the concrete through the aggregate particle. Popouts may be observed as defects in the test specimens. Where popouts are a concern, the number and general description should be reported as a special comment. The aggregates causing the popout may be identified by petrographic examination as in ASTM C 295.

8.4. When the sequence of freezing and thawing cycles must be interrupted, store the specimens in a frozen condition.

Note 8—If, due to equipment breakdown or for other reasons, it becomes necessary to interrupt the cycles for a protracted period, store the specimens in a frozen condition in such a way as to prevent loss of moisture. For Procedure A, maintain the specimens in the containers and surround them by ice, if possible. If it is not possible to store the specimens in their containers, wrap and seal them, in as wet a condition as possible, in moisture-proof material to prevent dehydration and store in a refrigerator or cold room maintained at –18 ± 2°C (0 ± 3°F). Follow the latter procedure when Procedure B is being used. In general, for specimens to remain in a thawed condition for more than two cycles is undesirable, but a longer period may be permissible if this occurs only once or twice during a complete test.

9. CALCULATIONS

9.1. *Relative Dynamic Modulus of Elasticity*—Calculate the numerical values of relative dynamic modulus of elasticity as follows:

$$P_c = (n_1^2/n^2) \times 100 \qquad (1)$$

where:

P_c = relative dynamic modulus of elasticity, after c cycles of freezing and thawing, percent;

n = fundamental transverse frequency at 0 cycles of freezing and thawing; and

n_1 = fundamental transverse frequency after c cycles of freezing and thawing.

Note 9—This calculation of relative dynamic modulus of elasticity is based on the assumption that the mass and dimensions of the specimen remain constant throughout the test. This assumption is not true in many cases due to disintegration of the specimen. However, if the test is to be used to make comparisons between the relative dynamic moduli of different specimens or of different concrete formulations, P_c as defined is adequate for the purpose.

9.2. *Durability Factor*—Calculate the durability factor as follows:

$$DF = PN/M \qquad (2)$$

where:

DF = durability factor of the test specimen;

P = relative dynamic modulus of elasticity at N cycles, percent;

N = number of cycles at which P reaches the specified minimum value for discontinuing the test or the specified number of cycles at which the exposure is to be terminated, whichever is less; and

M = specified number of cycles at which the exposure is to be terminated.

9.3. *Length Change in Percent (Optional)*—Calculate the length change as follows:

$$L_c = \frac{(l_2 - l_1)}{L_s} \times 100 \qquad (3)$$

where:

L_c = length change of the test specimen after c cycles of freezing and thawing, percent;

I_1 = length comparator reading at 0 cycles;

I_2 = length comparator reading after c cycles; and

L_s = the effective gauge length between the innermost ends of the gauge studs as shown in the mold diagram in M 210.

10. REPORT

10.1. Report the following data such as are pertinent to the variables or combination of variables studied in the tests:

10.2. *Properties of Concrete Mixture*:

10.2.1. Type and proportions of cement, fine aggregate, and coarse aggregate, including maximum size and grading (or designated grading indices), and ratio of net water content to cement.

10.2.2. Kind and proportion of any addition or admixture used.

10.2.3. Air content of fresh concrete.

10.2.4. Unit mass of fresh concrete.

10.2.5. Consistency of fresh concrete.

10.2.6. Air content of the hardened concrete when available.

10.2.7. Indicate if the test specimens are cut from hardened concrete, and if so, state the size, shape, orientation of the specimens in the structure, and any other pertinent information available.

10.2.8. Curing period.

10.3. *Mixing, Molding, and Curing Procedures*—Report any departures from the standard procedures for mixing, molding, and curing as prescribed in Section 7.

10.4. *Procedure*—Report which of the two procedures was used.

10.5. *Characteristics of Test Specimens*:

10.5.1. Dimensions of specimens at zero cycles of freezing and thawing,

10.5.2. Mass of specimens at zero cycles of freezing and thawing,

10.5.3. Nominal gauge length between embedded ends of gauge studs, and

10.5.4. Any defects in each specimen present at zero cycles of freezing and thawing.

10.6. *Results*:

10.6.1. Values for the durability factor of each specimen, calculated to the nearest whole number, and for the average durability factor for each group of similar specimens, also calculated to the nearest whole number, and the specified values for minimum relative dynamic modulus and maximum number of cycles (Note 10);

10.6.2. Values for the percent length change of each specimen and for the average percent length change for each group of similar specimens (Note 10);

10.6.3. Values of loss or gain of mass for each specimen and average values for each group of similar specimens; and

10.6.4. Any defects in each specimen that develop during testing, and the number of cycles at which such defects were noted.

Note 10—It is recommended that the results of the test on each specimen, and the average of the results on each group of similar specimens, be plotted as curves showing the value of relative modulus of elasticity or percent length change against time expressed as the number of cycles of freezing and thawing.

11. PRECISION

11.1. *Dynamic Modulus*:

11.1.1. *Within-Laboratory Precision (Single Beams)*—Criteria for judging the acceptability of durability factor results obtained by the two procedures in the same laboratory on concrete specimens made from the same batch of concrete or from two batches made with the same materials are given in Table 1. Precision data for length change (optional) are not available at this time.

Table 1—Within-Laboratory Durability Factor Precision for Single Beams

Range of Average Durability Factor	Procedure A		Procedure B	
	Standard Deviation[a]	Acceptable Range of Two Results[a]	Standard Deviation[a]	Acceptable Range of Two Results[a]
0 to 5	0.8	2.2	1.1	3.0
5 to 10	1.5	4.4	4.0	11.4
10 to 20	5.9	16.7	8.1	22.9
20 to 30	8.4	23.6	10.5	29.8
30 to 50	12.7	35.9	15.4	43.5
50 to 70	15.3	43.2	20.1	56.9
70 to 80	11.6	32.7	17.1	48.3
80 to 90	5.7	16.0	8.8	24.9
90 to 95	2.1	6.0	3.9	11.0
Over 95	1.1	3.1	2.0	5.7

[a] These numbers represent the (1s) and (d2s) limits as described in ASTM C 670.

Note: The values given in Columns 2 and 4 are the standard deviations that have been found to be appropriate for Procedures A and B, respectively, for tests for which the average durability factor is in the corresponding range given in Column 1. The values given in Columns 3 and 5 are the corresponding limits that should not be exceeded by the difference between the results of two single test beams.

Note 11—The between-batch precision of durability factors has been found to be the same as the within-batch precision. Thus, the limits given in this precision statement apply to specimens from different batches made with the same materials and mix design and having the same air content as well as to specimens from the same batch.

Note 12—The precision of this method for both procedures has been found to depend primarily on the average durability factor and not on the maximum N or minimum P specified for terminating the test nor on the size of the beams within limits. The data on which these precision statements are based cover maximum N_s from 100 to 300 cycles, and minimum P_s from 50 to 70 percent of E_o. The indexes of precision are thus valid at least over these ranges.

11.1.1.1. The different specimen sizes represented by the data include the following: 75 by 75 by 405 mm; 75 by 75 by 420 mm; 75 by 100 by 405 mm; 90 by 115 by 405 mm; 75 by 75 by 280 mm; 90 by 100 by 405 mm; and 100 by 75 by 405 mm (3 by 3 by 16 in.; 3 by 3 by $16^1/_4$ in.; 3 by 4 by 16 in.; $3^1/_2$ by $4^1/_2$ by 16 in.; 3 by 3 by 11 in.; $3^1/_2$ by 4 by 16 in.; and 4 by 3 by 16 in.). The first dimension given represents the direction in which the specimens were vibrated in the test for fundamental transverse frequency. The most commonly used size was 75 by 100 by 405 mm (3 by 4 by 16 in.).

11.1.2. *Within-Laboratory Precision (Averages of Two or More Beams)*—Specifications sometimes call for comparisons between averages of two or more beams. Tables 2 and 3 give appropriate standard deviations and acceptable ranges for the two procedures for two averages of the number of test beams shown.

Table 2—Within-Laboratory Durability Factor Precision for Averages of Two or More Beams—Procedure A

Range of Average Durability Factor	Number of Beams Averaged									
	2		3		4		5		6	
	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]
0 to 5	0.6	1.6	0.5	1.3	0.4	1.1	0.4	1.0	0.3	0.9
5 to 10	1.1	3.1	0.9	2.5	0.8	2.2	0.7	2.0	0.6	1.8
10 to 20	4.2	11.8	3.4	9.7	3.0	8.4	2.7	7.5	2.4	6.8
20 to 30	5.9	16.7	4.8	13.7	4.2	11.8	3.7	10.6	3.4	9.7
30 to 50	9.0	25.4	7.4	20.8	6.4	18.0	5.7	16.1	5.2	14.7
50 to 70	10.8	30.6	8.8	25.0	7.6	21.6	6.8	19.3	6.2	17.6
70 to 80	8.2	23.1	6.7	18.9	5.8	16.4	5.2	14.6	4.7	13.4
80 to 90	4.0	11.3	3.3	9.2	2.8	8.0	2.5	7.2	2.3	6.5
90 to 95	1.5	4.2	1.2	3.5	1.1	3.0	0.9	2.7	0.9	2.4
Above 95	0.8	2.2	0.6	1.8	0.5	1.5	0.5	1.4	0.4	1.3

[a] These numbers represent the (1s) and (d2s) limits as described in ASTM C 670.

Table 3—Within-Laboratory Durability Factor Precision for Averages of Two or More Beams—Procedure B

Range of Average Durability Factor	Number of Beams Averaged									
	2		3		4		5		6	
	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]	Standard Deviation[a]	Acceptable Range[a]
0 to 5	0.8	2.1	0.6	1.8	0.5	1.5	0.5	1.4	0.4	1.2
5 to 10	2.9	8.1	2.3	6.6	2.0	5.7	1.8	5.1	1.7	4.7

90 to 95	2.8	7.8	2.3	6.4	2.0	5.5	1.7	4.9	1.6	4.5
Above 95	1.4	4.1	1.2	3.3	1.0	2.9	0.9	2.6	0.8	2.3

[a] These numbers represent the (1s) and (d2s) limits as described in ASTM C 670.

11.1.3. *Multilaboratory Precision*—No data are available for evaluation of multilaboratory precision. It is believed that a multilaboratory statement of precision is not appropriate because of the limited possibility that two or more laboratories will be performing freezing and thawing tests on the same concretes.

11.2. *Length Change*:

11.2.1. *Within-Laboratory Precision*—The single operator coefficient of variation has been determined to be 29.9 percent. Therefore results of two properly conducted tests by the same operator on samples from the same batch of concrete, using the same freeze-thaw apparatus and the same length comparator, should not differ from each other by more than 84.6 percent of the average.

11.2.2. *Multilaboratory Precision*—No data are available for multilaboratory precision. It is believed that a multilaboratory statement of precision is not appropriate because of the limited possibility that two or more laboratories will be performing freeze-and-thawing tests on the same concretes.

11.3. *Bias*—This test method has no bias because the values determined can be defined only in terms of this test method.

12. KEYWORDS

12.1. Accelerated testing; concrete-weathering tests; conditioning; freezing and thawing; resistance-frost.

Standard Method of Test for

Flexural Strength of Concrete (Using Simple Beam with Center-Point Loading)

AASHTO Designation: T 177-10
ASTM Designation: C 293-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Flexural Strength of Concrete (Using Simple Beam with Center-Point Loading)

AASHTO Designation: T 177-10
ASTM Designation: C 293-08

1. SCOPE

1.1. This method covers the determination of the flexural strength of concrete specimens by the use of a simple beam with center-point loading. It is not an alternative to T 97.

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 97, Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)
- T 231, Capping Cylindrical Concrete Specimens

2.2. *ASTM Standards*:
- C 31/C 31M, Standard Practice for Making and Curing Concrete Test Specimens in the Field
- C 78, Standard Test Method for Flexural Strength of Concrete (Using Simple Beam with Third-Point Loading)
- C 192/C 192M, Standard Practice for Making and Curing Concrete Test Specimens in the Laboratory
- C 617, Standard Practice for Capping Cylindrical Concrete Specimens
- C 1077, Standard Practice for Laboratories Testing Concrete and Concrete Aggregates for Use in Construction and Criteria for Laboratory Evaluation
- E 4, Standard Practices for Force Verification of Testing Machines

3. SIGNIFICANCE AND USE

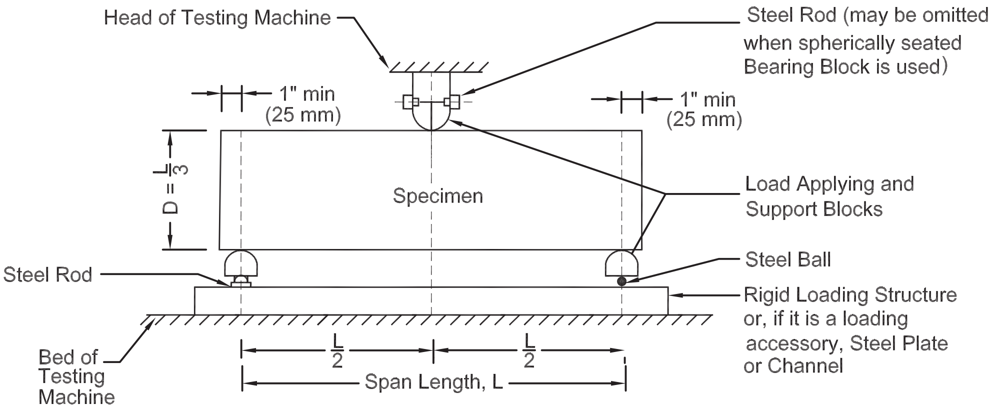
3.1. This test method is used to determine the modulus of rupture of specimens prepared and cured in accordance with R 39 or T 23. The strength determined will vary where there are differences in specimen size, preparation, moisture, condition, or curing.

3.2. The results of this test method may be used to determine compliance with specifications or as a basis for proportioning mixing and placement operations. This test method produces values of flexural strength significantly higher than T 97.

4. APPARATUS

4.1. *Testing Machine*—The testing machine shall conform to the requirements of the sections on Basis of Verification, Corrections, and Time Interval Between Verifications of ASTM E 4. Hand-operated testing machines having pumps that do not provide a continuous loading to failure in one stroke are not permitted. Motorized pumps or hand-operated positive displacement pumps having sufficient volume in one continuous stroke to complete a test without requiring replenishment are permitted and shall be capable of applying loads at a uniform rate without shock or interruption.

4.2. *Loading Apparatus*—The mechanism by which forces are applied to the specimen shall employ a load-applying block and two specimen support blocks. It shall ensure that all forces are applied perpendicular to the face of the specimen without eccentricity. A diagram of an apparatus that accomplishes this purpose is shown in Figure 1.



Note: Apparatus may be used inverted.

Figure 1—Diagrammatic View of a Suitable Apparatus for Flexure Test of Concrete by Center-Point Loading Method

4.2.1. All apparatus for making center-point loading flexural tests shall be similar to Figure 1 and maintain the span length and central position of the load-applying block with respect to the support blocks constant within ±1.3 mm (±0.05 in.).

4.2.2. Reactions shall be parallel to the direction of the applied load at all times during the test and the ratio of the horizontal distance between the point of load application and nearest reaction to the depth of the beam shall be 1.5 ± 2 percent.

4.2.3. The load-applying and support blocks shall not be more than 64 mm ($2^{1}/_{2}$ in.) high, measured from the center or the axis of pivot, and shall extend at least across the full width of the specimen. Each hardened bearing surface in contact with the specimen shall not depart from a plane by more than 0.051 mm (0.002 in.) and shall be a portion of a cylinder, the axis of which is coincidental with either the axis of the rod or center of the ball, whichever the block is pivoted upon. The angle subtended by the curved surface of each block shall be at least 0.79 rad (45 degrees). The load-applying and support blocks should be maintained in a vertical position and in contact with the rod or ball by means of spring-loaded screws that hold them in contact with the pivot rod or ball. The rod in the center load-applying block in Figure 1 may be omitted when a spherically seated bearing block is used.

5. TESTING

5.1. The test specimen shall conform to all requirements of R 39 or T 23 applicable to beam specimens and shall have a test span within 2 percent of being three times its depth as tested. The sides of the specimen shall be at right angles with the top and bottom. All surfaces shall be smooth and free of scars, indentations, holes, or inscribed identification marks.

5.2. The individual who tests concrete beams for acceptance testing shall meet the concrete laboratory requirements of ASTM C 1077 including Test T 177 as a relevant test.

6. PROCEDURE

6.1. Flexural tests of moist-cured specimens shall be made as soon as practical after removal from moist storage. Surface drying of the specimen results in a reduction in the measured modulus of rupture.

6.2. Turn the test specimen on its side with respect to its position as molded and center it on the support blocks. Center the loading system in relation to the applied force. Bring the load-applying block in contact with the surface of the specimen at the center and apply a load of between 3 and 6 percent of the estimated ultimate load. Using 0.10 mm (0.004 in.) and 0.38 mm (0.015 in.) leaf-type feeler gauges, determine whether any gap between the specimen and the load-applying or support blocks is greater or less than each of the gauges over a length of 25 mm (1 in.) or more. Grind, cap, or use leather shims on the specimen contact surface to eliminate any gap in excess of 0.10 mm (0.004 in.). Leather shims shall be of uniform 6.4 mm (0.25 in.) thickness, 25 to 50 mm (1 to 2 in.) in width, and shall extend across the full width of the specimen. Gaps in excess of 0.38 mm (0.015 in.) shall be eliminated only by capping or grinding. Grinding of lateral surfaces shall be minimized in as much as grinding may change the physical characteristics of the specimens. Capping shall be in accordance with T 231.

6.3. Load the specimen continuously and without shock. The load shall be applied at a constant rate for the duration of the test. Apply the load so the maximum stress on the tension face increases at a rate between 0.9 and 1.2 MPa/min (125 and 175 psi). The loading rate is computed using:

$$r = 2Sbd^2/3L \qquad (1)$$

where:

r = loading rate, mN/min (lb/min);

S = rate of increase in extreme fiber stress, MPa/min (psi/min);

b = average width of the specimen, mm (in.);

d = average depth of the specimen, mm (in.); and

L = span length, mm (in.).

7. MEASUREMENT OF SPECIMENS AFTER TEST

7.1. To determine the dimensions of the specimen section for use in calculating modulus of rupture, take measurements across one of the fractured faces after testing. The width and depth are measured with the specimen as oriented for testing. For each dimension, take one measurement at each end of the specimen and one at the center of the cross section. Use the three measurements for each direction to determine the average width and the average depth. Take all measurements to the nearest 1.3 mm (0.05 in.). If the fracture occurs at a capped section, include the cap thickness in the measurement.

8. CALCULATIONS

8.1. Calculate the modulus of rupture as follows:

$$R = \frac{3Pl}{2bd^2} \qquad (2)$$

where:

R = modulus of rupture, MPa (psi);

P = maximum applied load indicated by the testing machine, (N or lbf);

l = span length, mm (in.);

b = average width of specimen, at the point of fracture, mm (in.); and

d = average depth of specimen, at the point of fracture, mm (in.).

Note 1—The weight of the beam is not included in the above calculation.

9. REPORT

9.1. *Report the following information*:

9.1.1. Identification number;

9.1.2. Average width to the nearest 1.3 mm (0.05 in.), at the fracture;

9.1.3. Average depth to the nearest 1.3 mm (0.05 in.), at the fracture;

9.1.4. Span length in millimeters (or inches);

9.1.5. Maximum applied load in newtons (or pounds-force);

9.1.6. Modulus of rupture calculated to the nearest 0.05 MPa (5 psi);

9.1.7. Record of curing and apparent moisture condition of the specimens at the time of test;

9.1.8. If specimens were capped, ground, or if leather shims were used;

9.1.9. Defects in specimens; and

9.1.10. Age of specimens.

10. PRECISION AND BIAS

10.1. *Precision*—The coefficient of variation of test results has been observed to be dependent on the strength level of the beams. The single operator coefficient of variation has been found to be 4.4 percent. Therefore, results of two properly conducted tests by the same operator on beams made from the same batch sample should not differ from each other by more than 12 percent. The multilaboratory coefficient of variation has been found to be 5.3 percent. Therefore, results of two different laboratories on beams made from the same batch sample should not differ from each other by more than 15 percent.

10.2. *Bias*—Because there is no accepted standard for determining bias in this test method, no statement on bias is made.

Standard Test Method for

Portland-Cement Content of Hardened Hydraulic-Cement Concrete

AASHTO Designation: T 178-10
ASTM Designation: C 1084-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Portland-Cement Content of Hardened Hydraulic-Cement Concrete

AASHTO Designation: T 178-10
ASTM Designation: C 1084-02

1. SCOPE

1.1 This test method covers the determination of portland cement content of a sample of hardened hydraulic-cement concrete.

1.2 The values in SI units are to be regarded as the standard. The values given in parentheses are provided for information purposes only.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Disposal of some or all of the chemicals used in this method may require adherence to EPA or other regulatory guidelines.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 105, Chemical Analysis of Hydraulic Cement
- T 248, Reducing Samples of Aggregate to Testing Size

2.2 *ASTM Standards*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 823, Standard Practice for Examination and Sampling of Hardened Concrete in Constructions
- C 856, Standard Practice for Petrographic Examination of Hardened Concrete
- D 1193, Standard Specification for Reagent Water
- E 832, Standard Specification for Laboratory Filter Papers

3. SIGNIFICANCE AND USE

3.1 This test method consists of two independent procedures: an oxide-analysis procedure that consists of two sub-procedures and an extraction procedure. Each procedure requires a substantial degree of chemical skill and relatively elaborate chemical instrumentation. Except for the influence of known interference, determined cement contents are normally equal to, or slightly greater than, actual values except for the Maleic Acid procedure, where results can also be significantly lower when the paste is carbonated (Note 1).

Note 1—With certain limitations, the procedure is also applicable for eliminating the combined content of portland cement and pozzolan or slag in concretes made with blended hydraulic cement and blends of portland cement with pozzolans and slags. The results of this test method when applied to concrete made with blended cement or pozzolans depend on the composition of the pozzolan, the age of the concrete, the extent of the reaction of the pozzolan, and the fact that this test method may determine only the portland cement component of a blended cement. The test method should be applied to determine the blended cement content or the pozzolanic content only by use of calibration concrete samples or other information. Earlier versions of this test method can provide useful information as detailed by Hime[1] and Minnick.[2]

4. INTERFERENCES

4.1 Many constituents of concrete may interfere with the analysis of the concrete for portland cement content. The following limited lists of materials have been provided as a guide. The rocks, minerals, or mineral admixtures listed will interfere with the cement content determination to the extent of their solubility during the dissolution procedure used. The solubility of rocks, minerals, or mineral admixtures may depend on the fineness of the test sample, the water-cement ratio of the concrete, the extent of hydration, and the age of the concrete (extended exposure of the high pH of the concrete may affect the solubility of some minerals).

4.2 *Substances Affecting Calcium Oxide Sub-Procedure*:

4.2.1 The following are soluble in even the cold dilute hydrochloric acid of this procedure and will contribute a high bias to the cement content calculated from the soluble calcium oxide: limestone, marble, dolomitic limestone, calcareous sandstone, calcareous chert, and caliche-encrusted and calcite- or dolomite-coated rocks.

4.2.2 The following may be soluble depending on the age and pH of the concrete; whether the mineral present is glassy or crystalline, or weathered or strained; and the fineness of the minerals present, and, if soluble, will bias the cement content calculated from the soluble calcium oxide high depending on the calcium content of the minerals: weathered or altered plagioclase feldspar, caliche-encrusted rocks, altered volcanic rocks (with calcareous inclusions), and many other calcium containing rocks.

4.2.3 Every percent of soluble calcium oxide that is contributed by soluble aggregate or mineral admixtures will bias the cement content high by approximately 1.6 percent.

4.2.4 Silica fume may lower the acid solubility of the sample and hence bias the result low.

4.3 *Substances Affecting the Soluble Silica Sub-Procedure*:

4.3.1 The following may be soluble depending on the age and pH of the concrete; whether the aggregate is glassy or crystalline, or weathered or strained; and the fineness of the minerals: chert, opal, chalcedony, glassy volcanic rock, strained quartz (highly strained), quartzite, cataclastic rocks (mylonite, phyllonite), gneiss, schist, metagraywacke, and many other soluble silicon-containing rocks and minerals.

4.3.2 Every percent of soluble SiO_2 contributed by aggregate or mineral admixtures will bias the reported cement content high by approximately 4.7 percent.

4.3.3 Silica fume may lower the acid solubility of the sample and hence bias the result low. If the digestion time or temperature are sufficient to digest all of the portland cement, the silica fume will also be solubilized and bias the calculated cement content high.

4.4 *Substances Affecting the Maleic Acid Procedure*:

4.4.1 The same substances that are soluble in the soluble calcium or the soluble silica sub-procedures may be soluble in the maleic acid procedure. (See Sections 4.2.1, 4.2.2, and 4.3.1.)

4.4.2 Every 1 percent of the sample that is aggregate or mineral admixture dissolved by the maleic acid will bias the cement content high by 1 percent.

4.4.3 Carbonated cement paste may not be soluble in the maleic acid-methanol dissolution and thus may bias the cement content results low.

4.4.4 The unhydrated iron and aluminum phases of the portland cement may not be soluble in the maleic acid and, if not soluble, will bias the cement content low. This may be significant at early ages and less significant at later ages.

5. APPARATUS

5.1 Choose the apparatus from applicable items given in T 105 and from the following:

5.1.1 Chipmunk (jaw ore crusher).

5.1.2 Disk Pulverizer.

5.1.3 Rotary Mill (rotating puck).

5.1.4 Sieve, 300 um (No. 50), 1.18-mm (No.16), and 4.75-mm (No. 4).

5.1.5 Ice Bath or electric cooling apparatus.

5.1.6 Steam Bath.

5.1.7 Funnel, Buchner-type porcelain funnel.

5.1.8 Filter paper, Type II, Class F and Class G as described in ASTM Specification E 832.

5.1.9 Beakers, 1000 and 250 mL.

5.1.10 Magnetic Stirrer, variable speed, with a TFE-fluorocarbon-coated magnetic stirring rod, or an overhead stirrer with a propeller.

5.1.11 Volumetric flask, 1000 mL and 500 mL.

5.1.12 Filtering flask, 2000 mL.

5.1.13 Vacuum pump.

5.1.14 Watch glass, 125 mm.

6. REAGENT AND MATERIALS

6.1 *Soluble Silica Sub-Procedure*:

6.1.1 *Hydrochloric Acid,* reagent grade, density 1.19 Mg/m^3.

6.1.2 *Hydrochloric Acid (1:3)*—Mix 300 mL of hydrochloric acid into 900 mL of water.

6.1.3 *Hydrochloric Acid (1:9)*—Mix 100 mL of hydrochloric acid into 900 mL of water.

6.1.4 *Sodium Hydroxide (10 g/L)*—Dissolve 5 g of reagent grade sodium hydroxide in 200 mL of water and dilute to 500 mL.

6.1.5 *Hydrofluoric Acid,* 48 percent, reagent grade.

6.1.6 *Sulfuric Acid,* density 1.84 Mg/m^3, reagents grade.

6.2 *Calcium Oxide Sub-Procedure*—Use reagent as required in T 105.

6.3 *Maleic Acid Procedure*:

6.3.1 *Maleic Acid*, technical grade.

6.3.2 *Methanol,* technical grade, anhydrous.

6.3.3 *Maleic acid solution*—prepare a fresh solution of 15 percent maleic acid in methanol by dissolving and diluting 180 + 1 g of maleic acid with methanol to a final solution volume of 1200 mL. Prepare this solution fresh daily. Care must be taken to use methanol only in well ventilated areas, preferably under a hood, to avoid skin contact and breathing vapors. Disposal of the maleic acid/methanol solution shall be according to applicable regulations.

6.3.4 *Fuller's earth*—a clay-like material consisting of a porous colloidal aluminum silicate. Its high absorptivity has been found very beneficial for decolorizing and purifying materials.

6.4 *Water*—All references to water shall be understood to mean reagent water Type I through IV of ASTM D 1193.

7. SAMPLING

7.1 Choose the concrete sample in accordance with the purposes of the investigation (Note 2).

Note 2—A standard procedure for sampling hardened concrete is given in ASTM C 823 and a standard procedure for obtaining cores is given in T 24.

7.2 Both the sample for cement content and for density shall have a minimum length and diameter of four times the nominal maximum size of the aggregate (Note 3).

Note 3—A single concrete core taken through the entire depth of the concrete is ordinarily an appropriate sample. This sample may be sawed or split lengthwise to provide samples for cement content, density, and petrographic examination, provided that the length and thickness of the split samples for cement content and density meet the minimum size specified in Section 7.2. If the split sample would not meet the minimum size requirements, perform the density measurement first, and then crush the entire dry sample for cement content determination. The recommended mass of concrete for cement content determination is 4.5 kg (10 lb). This mass should be obtained from more than one core when the concrete depth is small and one core will not supply a mass of 4.5 kg (10 lb). If the concrete sample did not have a mass of 4.5 kg (10 lb), it should be so stated in the final report for the cement content result.

7.3 For cement content determination, crush the sample to pass a 4.75-mm (No. 4) sieve, mix thoroughly, and obtain a representative subsample for analysis by coning and quartering or by riffle splitting as described in T 248. The subsample should have a mass of 0.45 kg (1 lb).

8. CEMENT CONTENT PROCEDURE

8.1 *Oxide Analysis Procedure*:

8.1.1 Crush or grind the subsample prepared as described in Section 7.3 using a chipmunk (jaw ore crusher), a disk pulverizer, or a rotary mill (rotating-puck) device, so that all of the material passes a 300-μm (No. 50) sieve. To minimize production of very fine material, use several passes of the sample through the equipment, removing the portion passing the device before regrinding the remainder of the sample. Thoroughly mix by coning ten times from one paper to another.

8.1.2 Dry the crushed and ground materials in an oven at 105 to 115°C (220 to 240°F) for 3 h and retain the sample in a sealed container.

8.1.3 Sub-procedure to be used:

8.1.3.1 The soluble silica sub-procedure shall be performed in all cases except where a petrographic examination has indicated there are siliceous aggregates or mineral admixtures that will be soluble in cold hydrochloric acid.

8.1.3.2 The calcium oxide sub-procedure shall also be employed unless the aggregate contains a significant amount of calcareous components.

8.1.3.3 All analysis shall be done in triplicate and the average of the three values shall be used in calculating cement content.

8.1.4 *Soluble Silica Sub-Procedure*:

8.1.4.1 Introduce 100 mL of dilute hydrochloric acid (1:3) into each of three 250-mL beakers. Cool until within the range of 3 to 5°C (38 to 41°F) using an ice bath or electric cooling apparatus.

8.1.4.2 Weigh a 2-g sample to 0.001 g and slowly, over a 1-minute period, add it to the cold hydrochloric acid. Maintain the 3 to 5°C (38 to 41°F) temperature for a 5-minute period, and stir the mixture either continuously or at least several times during this period (Note 4).

Note 4—Observation of the solution during the introduction of the sample may provide useful information. Considerable effervescence indicates a substantial amount of calcite or carbonated paste. Delayed effervescence suggests a dolomitic aggregate. Lack of effervescence suggests the applicability of the calcium oxide sub-procedure.

8.1.4.3 Decant through a Buchner-type porcelain funnel fitted snugly with two disks of a quantitative filter paper for fine precipitate, Type II, Class G filter paper. Once the filtration has begun, take care so that the mat and accumulated residue do not dry completely until the filtration process is complete. Regulate the suction so as to maintain a rapid rate of dripping during the greater part of the filtration. Retain as much of the residue in the beaker as possible. Wash twice by decantation with hot water. Save the filtrate. Transfer the filter paper from the funnel to the beaker containing the balance of the residue, being careful that no residue is lost. Add 75 mL of hot sodium hydroxide solution (10 g/L) to the residue while stirring, macerate the filter paper, and digest, covered, on a steam bath for 15 minutes. During the digestion, occasionally stir the mixture. Filter all solids, and wash twice with hot water until the filtrate is neutral to litmus. Combine the filtrates.

8.1.4.4 The filtrate now contains the silica in the form of silicic acid, either in true solution or in suspension in the hydrochloric acid medium. To ensure analysis of only the soluble silicon, refilter any filtrate that is cloudy. (Allowing the filtrate to stand overnight will usually permit suspended silica to settle.) The soluble silica may be analyzed by either Section 8.1.4.4.1 or 8.1.4.4.2.

8.1.4.5 Analysis of soluble silica by conversion to silicon tetrafluoride with hydrofluoric acid—In the case where the aggregate of the original sample contains a substantial amount of material that yields calcium oxide (CaO) on acid treatment, add 10 mL of hydrochloric acid (density 1.19 Mg/m^3) to the solution from Section 8.1.4.4. Transfer to a suitable beaker, with several rinsings of the filter flask. Evaporate to dryness with great care to minimize spattering, bake at not over 120^{o}C (248^{o}F) for 1 h, moisten with hydrochloric acid (density 1.19 Mg/m^3), evaporate and bake again, and take up for filtration in 75 mL of hydrochloric acid (1:3). Heat to boiling, filter through an ashless filter paper, and wash the residue with 50 mL of hot hydrochloric acid (1:9) and hot water until the washings are free of chlorides. Determine the silica present in the sample by treatment with hydrofluoric acid and sulfuric acid in accordance T 105.

8.1.4.6 *Instrumental analysis of soluble silica*—Transfer the filtrate from Section 8.1.4.4 to a 500-mL volumetric flask with several rinsings of the filtration flask and bring the volume in the volumetric flask to 500 mL with water. Analyze the soluble silica by any instrumental method found acceptable for cement analysis in accordance with the performance requirement for rapid method of T 105, provided it can be applied to the filtrate. Suitable instrumental techniques may include atomic absorption or inductively coupled plasma spectroscopy.

8.1.4.7 *Calculation*—Calculate the cement percentage, C_s, by dividing the percentage of silica (SiO_2) in the concrete by the percentage of silica (SiO_2) in the cement and multiplying by 100. If the cement silica value is unknown, assume 21.0 percent.

8.1.5 *Calcium Oxide Sub-Procedure*—Calcium oxide may be determined by either of the following procedures. Omit the determination if it is known that the aggregate contains a substantial amount of calcareous components.

8.1.5.1 *Oxalate Precipitation of Calcium*—Using the filtrate from the removal of the silica (Section 8.1.4.4), separate the ammonium hydroxide group and then determine the calcium oxide, both in accordance with T 105 or proceed as described in Section 8.1.5.2.

8.1.5.2 *Instrumental analysis of calcium oxide*—Any calcium method found acceptable for cement analysis in accordance with the performance requirements for rapid methods of T 105 may be used, provided that the method may be applied to the filtrate. Further, the method must be acceptable for cement analysis in the same silica-present or silica-absent condition as is the case for the state of analysis of the concrete.

8.1.5.3 *Calculation*—Calculate the cement percentage, C_c, by dividing the percentage of calcium oxide in the concrete by the percentage of calcium oxide in the cement and multiplying by 100. If the cement calcium oxide value is unknown, assume 63.5 percent.

8.2 *Maleic Acid Extraction Procedure*:

8.2.1 Crush or grind and dry the sample as described in Sections 8.1.1 and 8.1.2, except that the materials shall pass a 1.18-mm (No. 16) sieve meeting M 92.

8.2.2 *Combined water*—Measure 10 g of the dried crushed sample to the nearest 0.001g into a tared pre-heated crucible and dry at 520 ± 5°C (970 ± 40°F) for 3 hours or to constant mass (Note 5). Cool in a desiccator and determine the mass.

Note 5—The temperature of 540°C (1005°F) should not be exceeded to avoid the decomposition of the calcite or dolomitic carbonates in certain aggregates.

8.2.2.1 Calculate the percentage of combined water as follows:

$$L_c, \% = \frac{(C - D) \times 100}{C} \qquad (1)$$

where:

L_c = percentage of combined water, dry basis,

C = mass of dried sample, g, and

D = mass after heating at 520°C (1005°F), g.

8.2.3 *Extraction—Determine* the mass of a 20-g sample of the ground dried concrete and a 2.5-g sample of Fuller's earth, dried at 105 to 115°C (220 to 240°F), to 0.001 g, and transfer both to a 1000-mL beaker or flask. Add 800-mL of maleic acid solution, and stir with a magnetic stirrer (or overhead stirrer equipped with a propeller) for 60 minutes. Allow the mixture to settle for 60 minutes. Filter the solution by carefully decanting through a Whatman 41 filter paper or equivalent of known mass fitted into a 100-mm Buchner funnel, using suction, and collect the filtrate in a 2000-mL vacuum filtering flask. Allow the residue to remain in the beaker.

8.2.3.1 Add 400-mL of maleic acid solution to the residue in the beaker and stir for 10 minutes. Allow the mixture to settle for 30 minutes and filter the entire contents of the beaker through the original filter paper. Rinse the beaker thoroughly with methanol to ensure complete transfer. Wash the residue contained on the filter paper 4 to 5 times with approximately 50 mL portions of methanol to remove any residual maleic acid. Also wash any iron filling that may be attached to the magnetic stir bar into the Buchner funnel. The filtrate should be clear.

8.2.3.2 Transfer the filter paper and residue onto a 125-mm watch glass and place in an oven at 105°C (220°F). Dry to a constant mass and determine the mass of the residue and filter paper to the nearest 0.001 g.

8.2.4 *Calculation*—Calculate the percentage of insoluble residue as follows:

$$R, \% = \frac{(F - G) \times 100}{E} \qquad (2)$$

where:

R = percentage of insoluble residue;

E = mass of sample used, g;

F = combined mass of residue, filter paper, and Fuller's earth, g; and

G = combined mass of filter paper and Fuller's earth, g.

8.2.5 *Calculation*—Calculate the percentage of cement content, C_m, by subtracting R and L_c from 100.

---

9. UNIT WEIGHT AND LOSS OF FREE WATER

9.1 Determine the density of a separate sample of the concrete, of a minimum dimension four times the maximum size of the aggregate and a sample mass of at least 0.45 kg (1 lb), as follows:

9.1.1 *Saturated surface dry density*—For saturated surface-dry density, which will usually correlate well with the density of the concrete as placed, immerse the concrete in water and soak it for a minimum of 24 hours or to constant weight. (Constant weight may take 48 hours for $^1/_2$ of a 100-mm (4-in.) diameter core.) Determine the mass of the sample while immersed in the water to the nearest 0.1 g (0.001 lb). Remove from the water, surface dry, and determine the mass to the nearest 0.1 g (0.001 lb). Calculate the density, D_{SSD}, in kilograms per cubic meter (or alternately in pounds per cubic foot), as:

$$D_{SSD} = \frac{W_1 \times \rho}{W_1 - W_2} \qquad (3)$$

where:

D_{SSD} = saturated surface- dry unit weight, kg/m^3 (or, alternatively, lb/ft^3);

W_1 = saturated surface-dry (SSD) mass in air after the 48 hour soak, kg;

W_2 = SSD mass suspended and immersed in water, kg; and

ρ = density of water, 997 kg/m^3 (62.3 lb/ft^3)

9.1.2 *Dry unit weight and free water*—Dry the sample from Section 9.1.1 for a minimum of 24 hours or to constant weight at 105 to 115°C (220 to 240°F). Cool. Determine the mass to the nearest 0.1 g (0.001 lb). Calculate the density, D_{SSD}, in kilograms per cubic meter (pounds per cubic foot), and the free water, L_f, as:

$$D_{\mathrm{dry}} = \frac{D_{SSD} \times W_3}{W_1} \qquad (4)$$

$$L_f = \frac{(W_1 - W_3) \times \rho}{W_1 - W_2}$$

where:

D_{SSD} = saturated surface-dry unit weight, kg/m^3 (or, alternatively, lb/ft^3);

W_1 = saturated surface-dry (SSD) mass in air after the 48 hour soak, kg;

W_3 = dry mass, kg; and

L_f = free water, kg/m^3 (or, alternatively, lb/ft^3).

10. ADDITIONAL CALCULATIONS

10.1 *Cement content*—Calculate the cement content of the concrete from the data for each procedure used as follows:

$$\text{Cement content, kg/m}^3 = \frac{C \times D_1}{100} \quad (5)$$

$$\text{Cement content, lb/yd}^3 = \frac{C \times D_2 \times 27}{100} \quad (6)$$

where:

C = determine cement percentage, percentage by mass, either as C_s, C_c, or C_m;

D_1 = D_{dry}, kg/m^3; and

D_2 = D_{dry}, lb/ft^3.

11. REPORT

11.1 Report the cement percentage, and, if required, the cement content, to the nearest kg/m^3 (lb/yd^3) as follows:

11.1.1 If two or more procedures or sub-procedures have been performed, report the lowest result and report the procedure used.

12. PRECISION AND BIAS

12.1 *Precision*—The precision of the cement content test procedures is dependent upon the composition of the concrete.

12.1.1 The use of the soluble silica procedure may lead to erroneously high results for concrete that contains siliceous aggregates, pozzolans, or other cementitious components.

12.1.2 The use of the calcium oxide procedure will lead to erroneously high results if calcareous aggregates or other cementitious materials are present, and may do so with many pozzolanic materials.

12.1.3 The use of the maleic acid procedure may lead to erroneously low or high results, depending upon the solubility of the aggregates in the maleic acid solution, the amount of unhydrated aluminate and ferrite phases in the cement that are insoluble, and the carbonation of the paste.

12.1.4 For these reasons, precision data obtained on one concrete may not be useful in estimating that obtainable for another concrete.

12.1.5 The following sections on the soluble silica and calcium oxide procedures are based on results of cooperative analyses of a suite of three samples (Note 6), one having an aggregate providing a calcium interference, one an aggregate providing a silica interference, and one providing both interferences.

Note 6—These precision statements are based on tests of samples that were ground to pass a 600-µm (No. 30) sieve by a single laboratory. For this reason, interlaboratory tests did not include any variation in results that will occur because of sampling and sample preparation.

12.1.6 The section on maleic acid extraction is based on results of cooperative analyses from eleven laboratories on a suite of four concrete samples (Note 7), one with a limestone coarse aggregate, one with dolomite, and two with siliceous aggregates. One specimen contained fly ash. Total cementitious material contents ranged from 250 to 355 kg/m^3 (400 to 600 lb/yd^3).

Note 7—This precision statement is based on tests of samples that were ground to pass a 1.18 mm (No. 16) sieve by a single laboratory. For this reason, interlaboratory tests did not include any variation in results that will occur because of sampling and sampling preparation.

12.1.7 *Soluble silica procedure*—The single laboratory standard deviation has been found to be 15.6 kg/m^3 (26.3 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 71.4 kg/m^3 (120.3 lb/yd^3) (Note 8).

12.1.8 *Calcium oxide procedure*—Where applicable, the single laboratory standard deviation has been found to be 2.8 kg/m^3 (4.7 lb/yd^3). Therefore, results of two properly conducted tests in the same laboratory on the same material should not differ by more than 7.8 kg/m^3 (13.2 lb/yd^3) (Note 8).

12.1.8.1 The multilaboratory standard deviation has been found to be 10.0 kg/m^3 (16.9 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 28.4 kg/m^3 (47.9 lb/yd^3) (Note 8).

Note 8—These numbers represent, respectively, the 1s and d2s limits as described in ASTM C 670.

12.1.9 *Maleic Acid Procedure*—The single laboratory standard deviation has been found to be 14 kg/m^3 (24 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests in the same laboratory on the same materials should not differ by more than 40 kg/m^3 (67 lb/yd^3) (Note 8).

12.1.9.1 The multilaboratory standard deviation has been found to be 22 kg/m^3 (37 lb/yd^3) (Note 8). Therefore, results of two properly conducted tests from two different laboratories on samples of the same material should not differ by more than 62 kg/m^3 (104 lb/yd^3) (Note 8).

12.2 *Bias*—The bias of the test procedure is dependent upon the composition of the concrete for reasons described in Sections 12.1.1–12.1.3. For these reasons, bias data obtained on one concrete may be useless in estimating that obtainable for another concrete. Refer to Section 12.1.5 for a description of the test program on which the following is based.

12.2.1 *Soluble Silica Sub-Procedure*—For the soluble silica procedure, determined values may be expected to be from about 20 kg/m^3 (50 lb/yd^3) below the true value to 10 kg/m^3 (25 lb/yd^3) above for no silica interference, to 45 kg/m^3 (100 lb/yd^3) or more above for severe silica interferences (for example, for samples containing slag or volcanic aggregate, or a fly ash addition).

12.2.2 *Calcium Oxide Sub-Procedure*—Where the calcium procedure is applicable, determined values should be within 10 kg/m^3 (25 lb/yd^3) of the true value.

12.2.3 The use of either of the oxide determination procedures may lead to error to the extent that the oxide content used for calculations differs from the true value for the cement. Errors greater than 4 percent relative are unusual for this parameter.

12.2.4 Bias may be reduced by analysis of separate samples of calcareous aggregates representing those used in the concrete, employing the same procedures and applying corrections based on mix design data or estimates of aggregate proportion as based on petrographic studies. Where corrected values are 45 kg/m^3 (100 lb/yd^3) or more below uncorrected values, the method is probably inapplicable.

12.2.5 *Maleic Acid Procedure*—The bias of the maleic acid procedure is dependent upon the composition of the concrete for reasons stated in Section 12.1.3. Based on the mean values from the interlaboratory test program described under the precision, the values determined should be within –10 to +4 kg/m^3 (–17 to +6 lb/yd^3) of the actual values.

12.2.5.1 Approximately 40 percent of the fly ash in the interlaboratory test program was consumed in the extraction and contributed to the determined cement content of the concrete. Other sources have found that variable amounts of fly ash can be consumed in some cases. This demonstrates the need for caution and compensation for induced bias when testing concrete containing fly ash, slag, silica fumes, or natural pozzolan. Various sources of these materials will have highly variable effects on the results from this test.

12.2.5.2 Concrete samples that have deeply carbonated should be tested with caution as the maleic acid test results can be significantly affected, producing erroneously low cement content values.

12.2.6 Particular aggregate sources have been found to significantly affect the bias of this test method. Therefore, the separate testing of aggregate materials may be useful to indicate the solubility of the materials and possible significant contribution from the aggregates to the cement content results.

12.2.7 Petrographic studies such as those performed according to ASTM C 856 can be used in indicating potential interferences to each of the cement content procedures.

13. KEYWORDS

13.1 Cement content; concrete; hardened.

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Volumetric Method

---

AASHTO Designation: T 196M/T 196-09
ASTM Designation: C 173/C 173M-08

American Association of State Highway and Transportation Officials

Washington, D.C. 20001

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Volumetric Method

AASHTO Designation: T 196M/T 196-09
ASTM Designation: C 173/C 173M-08

1. SCOPE

1.1. This test method covers determination of the air content of freshly mixed concrete containing any type of aggregate, whether it be dense, cellular, or lightweight.

1.2. The values stated in either inch-pound or SI units shall be regarded separately as standard. The inch-pound units are shown in brackets. The values stated are not exact equivalents; therefore each system must be used independently of the other. Combining values from the two units may result in nonconformance.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 141, Sampling Freshly Mixed Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SIGNIFICANCE AND USE

3.1. This test covers the determination of the air content of freshly mixed concrete. It measures the air contained in the mortar fraction of the concrete, but is not affected by air that may be present inside porous aggregate particles. Therefore, this is the appropriate test to determine the air content of concretes containing lightweight aggregates, air-cooled slag, and highly porous or vesicular natural aggregates.

3.2. This test method requires the addition of sufficient isopropyl alcohol, when the meter is initially being filled with water, so that after the first or subsequent rolling little or no foam collects in the neck of the top section of the meter. If more foam is present than that equivalent to 2 percent air above the water level, the test is declared invalid and must be repeated using a larger quantity of alcohol. Addition of alcohol to dispel foam any time after the initial filling of the meter to the zero mark is not permitted.

3.3. The air content of hardened concrete may be either higher or lower than that determined by this test method. This depends upon the methods and amounts of consolidation effort applied to the concrete from which the hardened concrete specimen is taken; uniformity and stability of the air bubbles in the fresh and hardened concrete; accuracy of the microscopic examination, if used; time of comparison; environmental exposure; stage in the delivery, placement, and consolidation processes at which the air content of the unhardened concrete is determined, that is, before or after the concrete goes through a pump; and other factors.

4. APPARATUS

4.1. *Air Meter*—An air meter consisting of a bowl and a top section (Figure 1) conforming to the following requirements:

4.1.1. The bowl and top sections shall be of sufficient thickness and rigidity to withstand rough field use. The material shall not be attacked by high pH cement paste, deform when stored at high temperatures in closed spaces, or become brittle or crack at low temperatures. A watertight seal must be obtained when the top section is attached to the bowl.

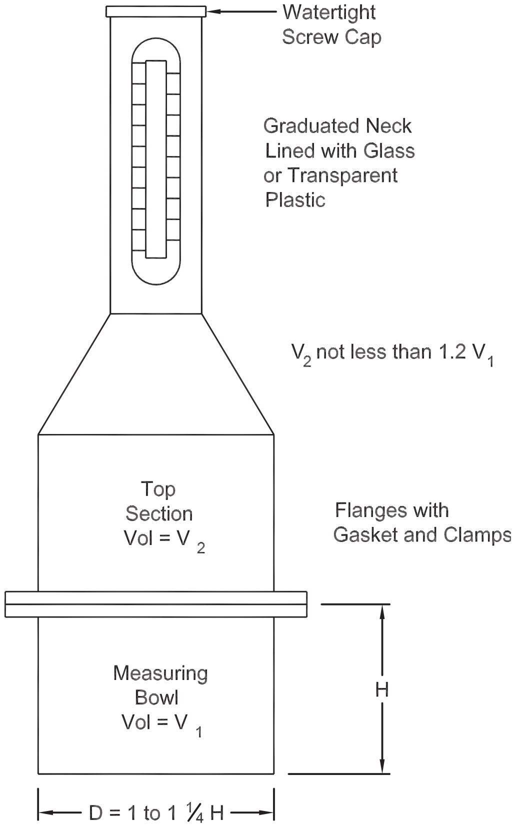

Figure 1—Apparatus for Measuring Air Content of Fresh Concrete by Volumetric Method

4.1.2. *Bowl*—The bowl shall have a diameter equal to 1 to 1.25 times the height and be constructed with a flange at or near the top surface. Bowls shall not have a capacity of less than 2.0 L [0.075 ft^3].

4.1.3. *Top Section*—The top section shall have a capacity at least 20 percent larger than the bowl and shall be equipped with a flexible gasket and a device to attach the top section to the bowl and make a watertight connection. The top section shall be equipped with a transparent scale, graduated in increments not greater than 0.5 percent from zero at the top, to 9 percent or more of the volume of the bowl. Graduations shall be accurate to ± 0.1 percent by volume of the bowl. The upper end of the neck shall have a watertight cap that will maintain a seal when the meter is inverted and rolled.

4.2. *Funnel*—A funnel with a spout of a size permitting it to be inserted through the neck of the top section and long enough to extend to a point just above the bottom of the top section. The discharge end of the spout shall be so constructed that when water is added to the container there will be a minimum disturbance of the concrete.

4.3. *Tamping Rod*—A round, smooth, straight 16 ± 2-mm [$^5/_8$ ± $^1/_{16}$-in.] diameter rod at least 300 mm [12 in.] long with both ends rounded to a hemispherical tip of the same diameter. The rod shall be made of steel, high-density polyethylene, or other plastic of equal or greater abrasion resistance.

4.4. *Strike-Off Bar*—A flat, straight steel bar at least 3 by 20 by 300 mm [0.125 by 0.75 by 12 in.], or a flat, straight, high-density polyurethane bar, or other plastic of equal or greater abrasion resistance, at least 6 by 20 by 300 mm [$^1/_4$ by $^3/_4$ by 12 in.].

4.5. *Calibrated Cup*—A metal or plastic cup either having a capacity of or being graduated in increments equal to 1.0 ± 0.04 percent of the volume of the bowl of the air meter. The calibrated cup is only to be used to add water when the concrete air content exceeds 9 percent or the calibrated range of the meter.

4.6. *Measuring Vessel for Isopropyl Alcohol*—A vessel with a minimum capacity of at least 500 mL [1 pt] with graduations not larger than 100 mL [4 oz] for measuring a quantity of isopropyl alcohol.

4.7. *Syringe*—A rubber syringe having a capacity of at least 50 mL [2 oz].

4.8. *Pouring Vessel for Water*—A container of approximately 1 L [1 qt] capacity.

4.9. *Scoop*—Of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the bowl.

4.10. *Isopropyl Alcohol*—Use 70 percent by volume isopropyl alcohol (approximately 65 percent by mass) (Note 1). Other foam-dispersing agents are permitted if tests demonstrate that the use of the agent does not change the indicated air content, in the amounts being used, by more than 0.1 percent or if correction factors are developed similar to those in Table 1. When other dispersing agents are used, a copy of the records documenting the testing or calculations shall be available in the laboratory.

Note 1—Seventy percent isopropyl alcohol is commonly available as rubbing alcohol. More concentrated grades can be diluted with water to the required concentration.

Table 1—Correction for the Effect of Isopropyl Alcohol on ASTM C 173/C 173M Air Meter Reading

70% Isopropyl Alcohol Used			Correction
pt	oz	L	(Subtract)[a]
0.5	8	0.2	0.0[b]
1.0	16	0.5	0.0[b]
1.5	24	0.7	0.0[b]
2.0	32	0.9	0.0[b]
3.0	48	1.4	0.3
4.0	64	1.9	0.6
5.0	80	2.4	0.9

[a] Subtract from final meter reading.

[b] Corrections less than 0.125 are not significant and are to be applied only when 1.2 L [2.5 pt] or more alcohol is used. The effect occurs when the meter is inverted after being filled with an alcohol-water solution which then becomes further diluted when it's mixed with the water in the concrete. The values given are for air meters that have a bowl volume of 2.1 L [0.075 ft^3] and a top section that is 1.2 times the volume of the bowl.

4.11. *Mallet*—A mallet (with a rubber or rawhide head) with a mass of approximately 600 ± 200 g [1.25 ± 0.5 lb].

5. CALIBRATION

5.1. Calibrate the meter and calibrated cup initially and at 3-year intervals or whenever there is reason to suspect damage or deformation of the meter or calibrated cup.

5.2. Determine the volume of the bowl, with an accuracy of at least 0.1 percent, by determining the mass of water required to fill it at room temperature and dividing this weight by the density of water at the same temperature. Follow the calibration procedure outlined in T 19M/T 19.

5.3. Determine the accuracy of the graduations on the neck of the top section of the air meter by filling the assembled measuring bowl and top section with water to a preselected air content graduation and then determining the quantity of 21.1ºC (70ºF) water required to fill the meter to the zero mark. The quantity of water added shall equal the preselected air content graduation within ± 0.1 volume percent of the measuring bowl. Repeat the procedure to check a minimum of three gradations within the expected range of use.

5.3.1. Add water in increments of 1.0 percent of the volume of the bowl to check accuracy throughout the graduated range of air content. The error at any point throughout the graduated range shall not exceed 0.1 percent of air.

5.4. Determine the volume of the calibrated cup using water at 21.1ºC (70ºF) by the method outlined in Section 5.2. A quick check can be made by adding one or more calibrated cups of water to the assembled apparatus and observing the increase in the height of the water column after filling to a given level.

6. SAMPLING

6.1. Obtain the sample of freshly mixed concrete in accordance with T 141. If the concrete contains coarse aggregate particles that would be retained on a 37.5-mm [$1^1/_2$-in.] sieve, wet-sieve a representative sample over a 25-mm [1-in.] sieve to yield somewhat more than enough material to fill the measuring bowl. The wet-sieving procedure is described in T 141. Carry out the wet-sieving operation with the minimum practicable disturbance of the mortar. Make no attempt to wipe adhering mortar from coarse aggregate particles retained on the sieve.

7. PROCEDURE

7.1. *Rodding and Tapping*—Wet the inside of the bowl and dry it to a damp, not shiny appearance. Using the scoop described in Section 4.9, fill the bowl with freshly mixed concrete in two layers of equal depth. Rod each layer 25 times with the tamping rod. Do not forcibly strike the bottom of the bowl when rodding the first layer. When rodding the second layer, penetrate the prior layer approximately 25 mm [1 in.]. After each layer is rodded, tap the sides of the measure 10 to 15 times with the mallet to close any voids left by the tamping rod and to release any large bubbles of air that may have been trapped. After tapping the final layer, a slight excess of concrete, 3 mm [$^1/_8$ in.] or less, above the rim is acceptable. Add or remove a representative sample of concrete if necessary to obtain the required amount of concrete.

7.2. *Striking Off*—After rodding and tapping of the second layer, strike off the excess concrete with the strike-off bar until the surface is flush with the top of the bowl. Wipe the flange of the bowl clean.

7.3. *Adding Water*—Wet the inside of the top section of the meter, including the gasket. Attach the top section into position on the bowl, and then insert the funnel. Add at least 0.5 L [1 pt] of water followed by the selected amount (Note 2) of isopropyl alcohol. Record the amount of isopropyl alcohol added. Continue adding water until it appears in the graduated neck of the top section (Note 3). Remove the funnel. Adjust the liquid level until the bottom of the meniscus is level with the zero mark. A rubber syringe is useful for this purpose. Attach and tighten the watertight cap.

Note 2—The amount of isopropyl alcohol necessary to obtain a stable reading and a minimum of foam at the top of the water column will depend upon a number of factors. Many concretes made with less than 300 kg/m^3 [500 lb/yd^3] of cement and air contents less than 4 percent may require less than 200 mL [0.5 pt] of alcohol. Some high-cement mixes made with silica fume that have air contents of 6 percent or more may require more than 1400 mL [3 pt] of alcohol. The amount required will vary with the concrete air content, the amount and type of air-entraining admixture, the cement content and cement alkali content, and perhaps other factors. Generally, the amount of alcohol necessary can be established for given mixture proportions and should not change greatly during the course of a job.

Note 3—When, if ever, it is necessary to use more than 2.0 L [4 or 4.5 pt] of isopropyl alcohol, it may be necessary to restrict the amount of water added initially to avoid overfilling the meter. However, it is desirable to add at least some water initially to aid in mixing the alcohol and limit the contact of the concentrated alcohol with the top surface of the concrete.

7.4. Displace the volume of air in the concrete specimen using these procedures:

7.4.1. *Free the Concrete from the Base*—Quickly invert the meter, shake the base horizontally, and return the meter to the upright position. To prevent the aggregate from lodging in the neck of the unit, do not keep it inverted for more than 5 seconds at a time. Repeat the inversion and shaking process for a minimum of 45 seconds and until the concrete has broken free and the aggregate can be heard moving in the meter as it is inverted.

7.4.2. *Rolling*—Place one hand on the neck of the meter and the other on the flange. Using the hand on the neck, tilt the top of the meter approximately 45 degrees from the vertical position with the bottom edge of the base of the meter resting on the floor or on the work surface. Maintain this position through the procedures described in this section. Using the hand on the flange to rotate the meter, vigorously roll the meter $^1/_4$ to $^1/_2$ turn forward and back several times, quickly starting and stopping the roll. Turn the base of the meter about $^1/_3$ turn and repeat the rolling procedure as stated previously. Continue the turning and rolling procedures for approximately 1 minute. The aggregate must be heard sliding in the meter during this process.

7.4.2.1. If, at any time, during the inversion and rolling procedures liquid is found to be leaking from the meter, the test is invalid and a new test shall be started as in Section 6.1.

7.4.2.2. Set the unit upright and loosen the top to allow any pressure to stabilize. Allow the meter to stand while the air rises to the top and until the liquid level stabilizes. The liquid level is considered stable when it does not change more than 0.25 percent air within a 2-minute period.

7.4.2.3. If it takes more than 6 minutes for the liquid level to stabilize or if there is more foam than that equivalent to 2 full percent air content divisions on the meter scale over the liquid level, discard the trial and start a new test as in Section 6.1. Use a larger addition of alcohol than was used in the initial trial.

7.4.2.4. If the level is stable without excessive foam, read the bottom of the meniscus to the nearest 0.25 percent and record the *initial meter reading*.

7.4.2.5. If the air content is greater than the 9 percent range of the meter, add a sufficient number of calibrated cups of water to bring the liquid level within the graduate range. Read the bottom of the meniscus to the nearest 0.25 percent. Record the number of calibrated cups of water to be added to the final meter reading in Section 8.1.3.

7.5. *Confirmation of the Initial Meter Reading*:

7.5.1. When an initial meter reading is obtained as in Section 7.4.2.4, retighten the top and repeat the 1-minute rolling as in Sections 7.4.2, 7.4.2.2, and 7.4.2.3.

7.5.2. When the liquid level is stable as in Section 7.4.2.2 and the requirements of Section 7.4.2.3 are met, make a direct reading to the bottom of the meniscus and estimate to 0.25 percent air. If this reading has not changed more than 0.25 percent from the initial meter reading in Section 7.4.2.4, record it as the *final meter reading* of the sample tested.

7.5.2.1. If the reading has changed from the *initial meter reading* by more than 0.25 percent air, record this reading as a new "*initial reading*" and repeat the 1-minute rolling as in Section 7.4.2. Read the indicated air content. If this reading has not changed by more than 0.25 percent air from the "*newest initial reading*" record it as the *final meter reading*.

7.5.2.2. If the reading has changed by more than 0.25 percent, discard the test and start a new test on a new sample of concrete as in Section 6.1 using more alcohol.

7.6. Disassemble the apparatus and examine the contents to be sure that there are no portions of undisturbed, tightly packed concrete in the base. If portions of undisturbed concrete are found, the test is invalid.

8. CALCULATION

8.1. The final meter reading tends to be slightly higher than the actual air content of the sample when 1.2 L [2.5 pt] or more of isopropyl alcohol is used. (See Note 5.)

8.1.1. When less than 1.2 L [2.5 pt] of isopropyl alcohol is used, the final meter reading is the air content of the sample of concrete tested except as modified in Sections 8.1.3 or 8.2.

8.1.2. When 1.2 L [2.5 pt] or more isopropyl alcohol is used, subtract the correction from Table 1 from the final meter reading to obtain the air content of the concrete sample tested, except as modified in Sections 8.1.3 or 8.2.

Note 4—Use linear interpolation to obtain a correction factor if the quantity of isopropyl used falls between amounts listed in Table 1.

8.1.3. If it was necessary to add calibrated cups of water to obtain a reading as in Section 7.4.2.5, add the number of cups recorded to the air content found in Sections 8.1.1 or 8.1.2.

8.1.4. Report the air content to the nearest 0.25 percent air.

Note 5—When the top section is initially filled to the zero mark with water and isopropyl alcohol, that mixture has a defined volume; however, when that solution is further mixed with the water present in the concrete, the concentration of alcohol changes, and the new solution occupies a volume slightly smaller than it did when the meter was initially filled to the zero mark. For this reason, the meter tends to indicate a higher than actual air content when more than about 1.2 L [2.5 pt] of alcohol is used. Therefore, when large amounts of alcohol are used, the correction factors in Table 1 reduce the air content indicated by the meter.

8.2. When the sample tested represents that portion of the mixture obtained by wet-sieving over a 25-mm [1-in.] sieve, calculate the air content of the mortar or of the full mixture using the formulas given in T 152. Use appropriate quantities coarser or finer than the 25-mm [1-in.] sieve instead of the 37.5-mm [$1^1/_2$-in.] sieve specified in T 152.

9. PRECISION AND BIAS

9.1. The standard deviation is essentially proportional to the average for different levels of air content. The following precision statement is based on 979 tests made in six field experiments by the West Virginia DOT. The multi-operator coefficient of variation has been found to be 11 percent of the measured air content. Therefore, results of tests by two different operators on specimens taken from a single concrete sample should not differ from each other by more than 32 percent of their average air content (Note 6).

Note 6—These numbers represent, respectively, the 1s percent and d2s percent limits described in ASTM C 670. The data collected for the precision statement were obtained using procedures standard prior to the use of large amounts of isopropyl alcohol in ASTM C 173/C 173M.

9.2. This test method provides volumetric procedures for determining the air content of freshly mixed concrete. When conducted properly, this test method has no bias because the value of the air content can only be defined in terms of the test method.

10. KEYWORDS

10.1. Air content; calibration; concrete; correction factor; freshly mixed concrete; measuring bowl; meter; volumetric method.

APPENDIX

(Nonmandatory Information)

X1. CHECK LIST FOR PERFORMING THE VOLUMETRIC AIR CONTENT TEST METHOD

X1.1. The following outline (Figures X1.1a–X1.1c) does not include all steps and precautions required to perform this test method properly. It is provided to help new users follow the sequence of the procedures.

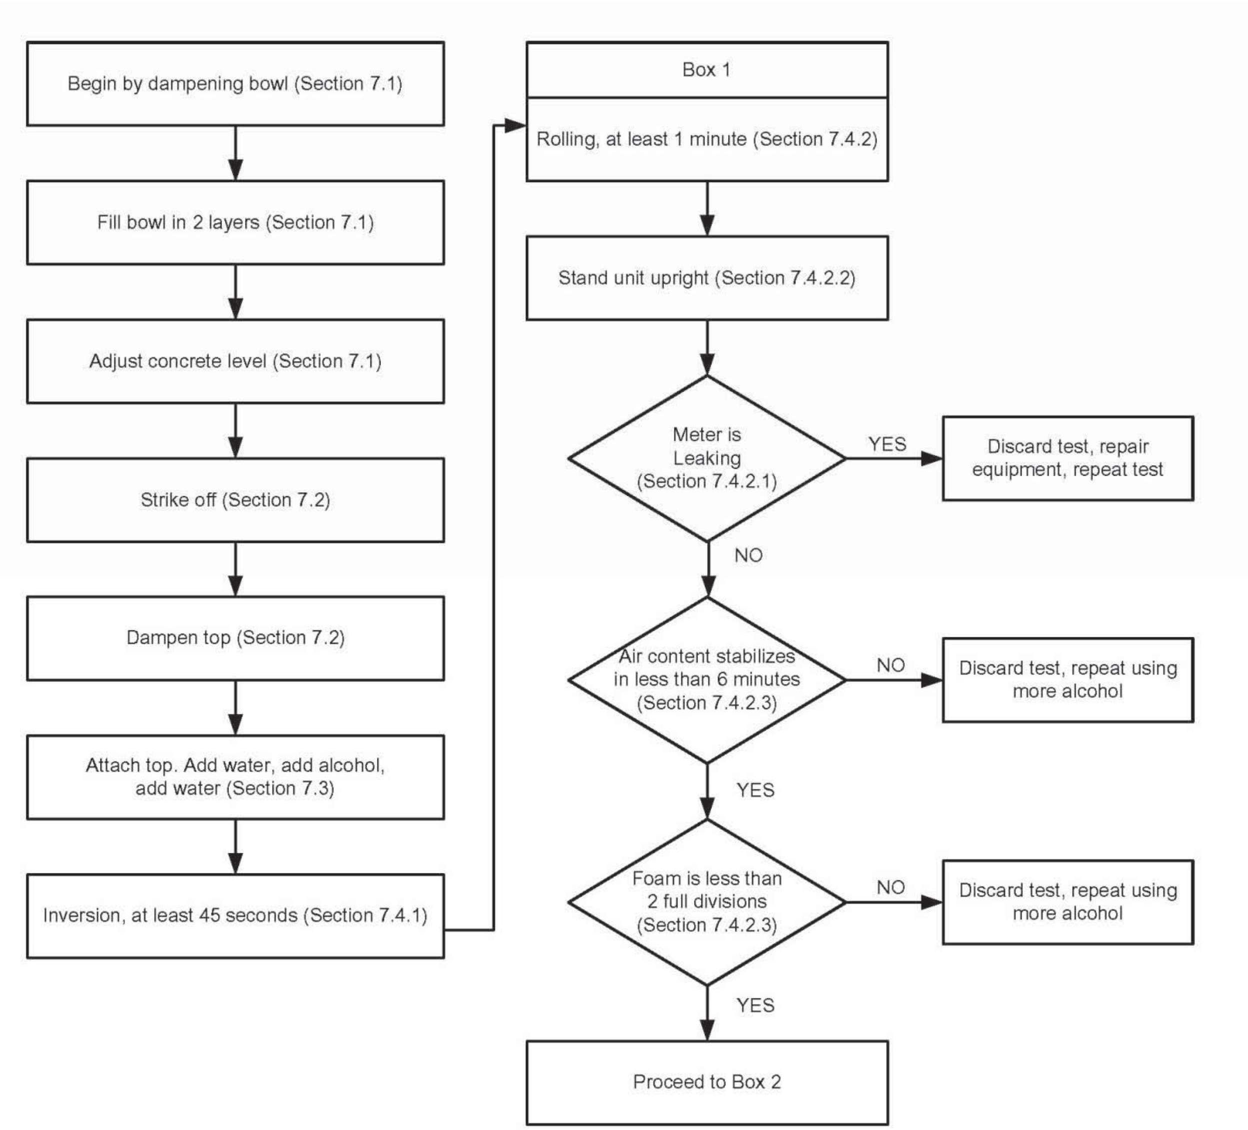

Figure X1.1a—Outline of Checklist for Performing the Volumetric Air Content Test Method

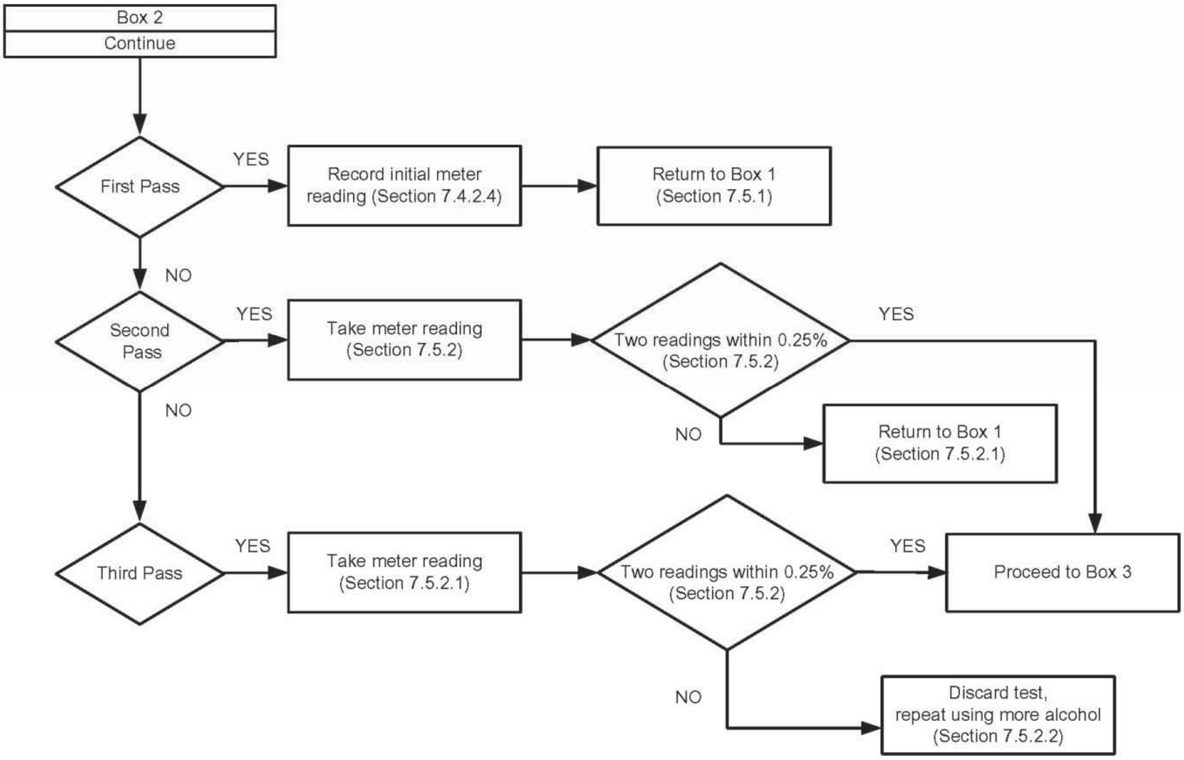

Figure X1.1b—Outline of Checklist for Performing the Volumetric Air Content Test Method (*Continued*)

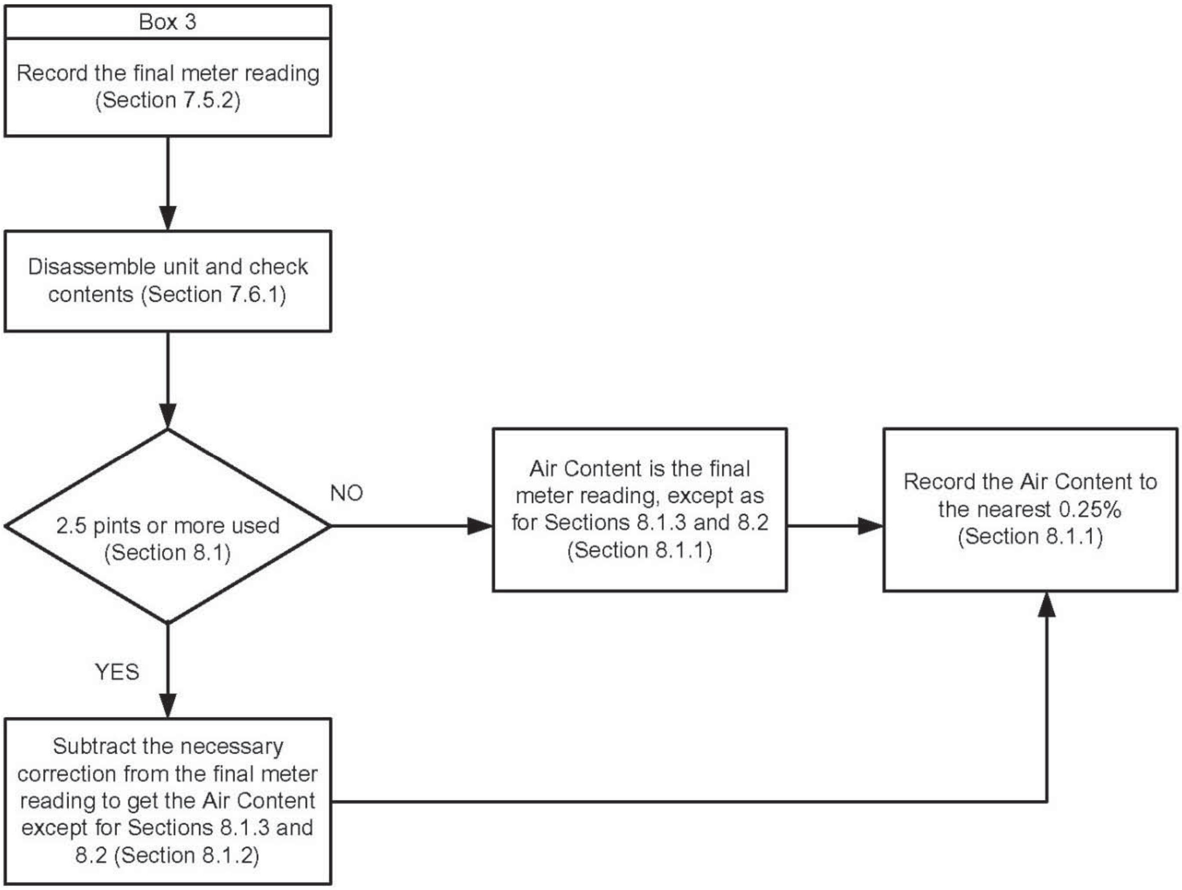

Figure X1.1c—Outline of Checklist for Performing the Volumetric Air Content Test Method (*Continued*)

Standard Method of Test for

Time of Setting of Concrete Mixtures by Penetration Resistance

AASHTO Designation: T 197M/T 197-08
ASTM Designation: C 403/C 403M-06

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Time of Setting of Concrete Mixtures by Penetration Resistance

AASHTO Designation: T 197M/T 197-08
ASTM Designation: C 403/C 403M-06

1. SCOPE

1.1. This test method covers the determination of the time of setting of concrete, with slump greater than zero, by means of penetration resistance measurements on mortar sieved from the concrete mixture.

1.2. This test method is suitable for use only when tests of the mortar fraction will provide the information required.

1.3. This test method may also be applied to prepared mortars and grouts.

1.4. This test method is applicable under controlled laboratory conditions, as well as under field conditions.

1.5. The values stated in SI units are to be regarded as the standard.

1.6. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *time of initial setting*—the elapsed time, after initial contact of cement and water, required for the mortar sieved from the concrete to reach a penetration resistance of 3.5 MPa (500 psi).

3.1.2. *time of final setting*—the elapsed time, after initial contact of cement and water, required for the mortar sieved from the concrete to reach a penetration resistance of 27.6 MPa (4000 psi).

4. SUMMARY OF TEST METHOD

4.1. A mortar sample is obtained by sieving a representative sample of fresh concrete. The mortar is placed in a container and stored at a specified ambient temperature. At regular time intervals, the resistance of the mortar to penetration by standard needles is measured. From a plot of penetration resistance versus elapsed time, the times of initial and final setting are determined.

5. SIGNIFICANCE AND USE

5.1. Since the setting of concrete is a gradual process, any definition of time of setting must necessarily be arbitrary. In this test method, the times required for the mortar to reach specified values of resistance to penetration are used to define times of setting.

5.2. This test method can be used to determine the effects of variables, such as brand, type and content of cementitious material, water content, and admixtures, upon the time of setting of concrete. This test method may also be used to determine compliance with specified time of setting requirements.

5.3. This test method may also be applied to prepared mortars and grouts. However, when the setting time of concrete is desired, the test shall be performed on mortar sieved from the concrete mixture and not on a prepared mortar intended to simulate the mortar fraction of the concrete; it has been shown that the initial and final setting times may be increased when using the prepared mortar.

6. APPARATUS

6.1. *Containers for Mortar Specimens*—The containers shall be rigid, watertight, nonabsorptive, nonoiled, and either cylindrical or rectangular in cross section. Mortar surface area shall be provided for 10 undisturbed readings of penetration resistance in accordance with Section 9.2 for clear distance requirements. The minimum lateral dimension shall be 150 mm (6 in.) and the height at least 150 mm (6 in.).

6.2. *Penetration Needles*—Needles shall be provided which can be attached to the loading apparatus and which have the following bearing areas: 645, 323, 161, 65, 32, and 16 mm^2 (1, $^1/_2$, $^1/_4$, $^1/_{10}$, $^1/_{20}$, and $^1/_{40}$ in.^{2}). Each needle shank shall be scribed circumferentially at a distance 25 mm (1 in.) from the bearing area. The length of the 16-mm^2 ($^1/_{40}$-in.^{2}) needle shall not be more than 90 mm (3$^1/_2$ in.).

6.3. *Loading Apparatus*—A device shall be provided to measure the force required to cause penetration of the needles. The device shall be capable of measuring the penetration force with an accuracy of ±10 N (2 lbf) and shall have a capacity of at least 600 N (130 lbf).

Note 1—Suitable loading apparatus can be of the spring-reaction type as described in ASTM D 1558, or of other types with a calibrated force measuring device, such as an electronic load cell or a hydraulic pressure gauge.

6.4. *Tamping Rod*—The tamping rod shall be a round, straight, steel rod 16 mm ($^5/_8$ in.) in diameter and approximately 600 mm (24 in.) in length, having the tamping end or both ends rounded to a hemispherical tip, the diameter of which is 16 mm ($^5/_8$ in.).

6.5. *Pipet*—A pipet or other suitable instrument shall be used for drawing off bleeding water from the surface of the test specimen.

6.6. *Thermometer*—The thermometer shall be capable of measuring the temperature of the fresh mortar to ±0.5ºC (±1ºF). ASTM liquid-in-glass thermometers having a temperature range from –18 to 49ºC (0 to 120ºF), and conforming to the requirements of Thermometer 97ºC (97ºF), as prescribed in ASTM E 1 are satisfactory. Other thermometers of the required accuracy, including the metal immersion type, are acceptable.

7. SAMPLING, TEST SPECIMENS, AND TEST UNITS

7.1. For tests under field conditions, three specimens shall be prepared from each sample of concrete.

7.2. For tests under laboratory conditions, the requirements depend upon the purpose of the tests.

7.2.1. For testing to prove compliance of a material with performance requirements, make at least three separate concrete batches for each variable under investigation. One time of setting test shall be made on each batch. An equal number of batches for each condition shall be made on any given day. When it is impossible to make at least one test for each variable on a given day, the mixing of the entire series of batches shall be completed in as few days as possible and one of the mixtures shall be repeated each day as a standard of comparison.

7.2.2. For other tests, three test specimens shall be prepared from one batch of concrete for each test condition.

7.3. Record the time at which initial contact was made between cement and mixing water.

7.4. For tests under field conditions, obtain a representative sample of the fresh concrete in accordance with T 141. Determine and record the slump (T 119M/T 119) and air content (T 196M/T 196 or T 152) of the fresh concrete.

7.5. From the concrete mixture not used in the slump and air content tests, select a representative portion of concrete of sufficient volume to provide enough mortar to fill the test container, or containers, to a depth of at least 140 mm (5$^1/_2$ in.).

7.6. Using the procedure in Section 6.4.1 of T 141, obtain a mortar sample by wet-sieving the selected portion of concrete through a 4.75-mm (No. 4) sieve[1] onto a nonabsorptive surface.

7.7. Thoroughly remix the mortar by hand methods on the nonabsorptive surface. Measure and record the temperature of the mortar. Place the mortar in the container, or containers, using a single layer. Consolidate the mortar to eliminate air pockets in the specimen and level the top surface. This may be accomplished by rocking the container back and forth on a solid surface, by tapping the sides of the container with the tamping rod, by rodding the mortar or by placing the container on a vibrating table. (See Note 2.) If rodding is used, rod the mortar with the round end of the tamping rod. Rod the mortar once for each 645 mm2 (1 in.^{2}) of top surface area of the specimen and distribute the strokes uniformly over the cross section of the specimen. After completion of the rodding, tap the sides of the containers lightly with the tamping rod to close voids left by the tamping rod and to further level the surface of the specimen. Upon completion of specimen preparation, the mortar surface shall be at least 13 mm (0.5 in.) below the top edge of the container to provide space for the collection and removal of bleeding water and to avoid contact between the mortar surface and the protective covering specified in Section 8.

Note 2—Sieved mortar is generally of fluid consistency and air pockets are readily removed by the listed consolidation methods. The user is called upon to exercise judgment in the selection of the consolidation method. Rocking the container or tapping of the sides should be sufficient for fluid mortars. Rodding or using a vibrating table may be desirable for stiffer mortars. When using a vibrating table, use low-amplitude vibration so that portions of the sample are not ejected from the container.

8. CONDITIONING

8.1. For tests under laboratory conditions, the storage temperature for specimens shall be within the range 20 to 25ºC (68 to 77ºF), or as specified by the user.

8.2. For tests under field conditions, store the specimens under ambient conditions, or as specified by the user. Shield the specimens from direct sunlight.

8.3. Measure and record the ambient temperature at the start and finish of the test. To prevent excessive evaporation of moisture, keep the specimens covered with a suitable material such as damp burlap or a tight-fitting, water-impermeable cover for the duration of the test, except when bleeding water is being removed or penetration tests are being made.

9. PROCEDURE

9.1. Just prior to making a penetration test, remove bleeding water from the surface of the mortar specimens by means of a pipet or suitable instrument. To facilitate collection of bleeding water, tilt the specimen carefully to an angle of about 10 degrees from the horizontal by placing a block under one side 2 minutes prior to removal of the bleeding water.

9.2. Insert a needle of appropriate size, depending upon the degree of setting of the mortar, in the penetration resistance apparatus and bring the bearing surface of the needle into contact with the mortar surface. Gradually and uniformly apply a vertical force downward on the apparatus until the needle penetrates the mortar to a depth of 25 ± 1.5 mm (1 ± 0.0625 in.), as indicated by the scribe mark (Note 4). The time required to penetrate to the 25 mm (1 in.) depth shall be 10 ± 2 seconds. Record the force required to produce the 25 mm (1 in.) penetration and the time of application, measured as elapsed time after initial contact of cement and water. Calculate the penetration resistance by dividing the recorded force by the bearing area of the needle, and record the penetration resistance. In subsequent penetration tests take care to avoid areas where the mortar has been disturbed by previous tests. The clear distance between needle impressions shall be at least two diameters of the needle being used, but not less than 13 mm (0.5 in.). The clear distance between any needle impression and the side of the container shall be at least 25 mm (1 in.), but no more than 2 in. [50 mm] as depicted in Figure 1.

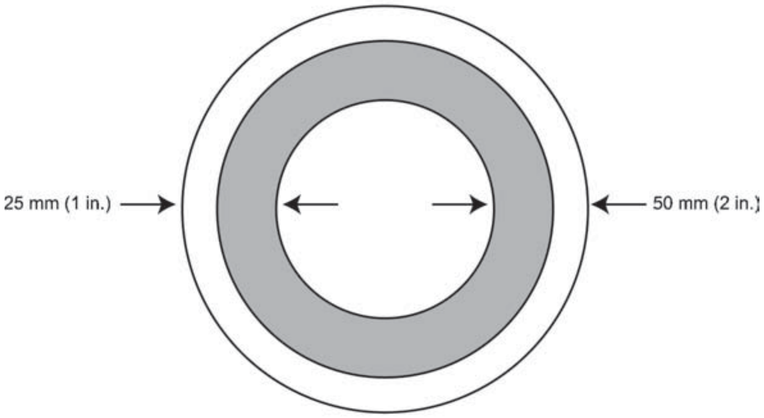
Note 3—For a cylindrical container with the smallest allowable outer diameter of 6 in., the operator can reasonably expect to achieve approximately eight penetrations before impinging upon previous penetrations. This is based on using needles of the following surface areas: 1 at $^1/_2$ (13), 2 at $^1/_4$ (6), 2 at $^1/_{10}$ (2.5), 2 at $^1/_{20}$ (1.3), and 1 at $^1/_{40}$ (0.6) mm^2 (in.^{2}).

Note 4—To facilitate determination of when the required penetration has been attained, a sliding marker may be attached to the needle shaft. For example, a paper clip or masking tape may be placed on the shaft so that it coincides with the scribe mark. The marker should not interfere with the penetration of the needle into the mortar. The position of the marker should be checked prior to making a penetration.

9.3. For conventional concrete mixtures at laboratory temperatures 20 to 25ºC (68 to 77ºF), make the initial test after an elapsed time of 3 to 4 hours after initial contact between cement and water. Subsequent tests should be made at $^1/_2$ to 1-hour intervals. For concrete mixtures containing accelerators, or at temperatures higher than laboratory, it is advisable to make the initial test after an elapsed time of 1 to 2 hours and subsequent tests at $^1/_2$-hour intervals. For concrete mixtures containing retarders, or at temperatures lower than laboratory, the initial test may be deferred until an elapsed time of 4 to 6 hours. In all cases, time intervals between subsequent tests may be adjusted as necessary, depending upon the rate of setting, to obtain the required number of penetrations.

9.4. Make at least six penetrations for each time-of-setting test, with the time intervals of such duration to provide a satisfactory curve of penetration resistance versus elapsed time (Note 5). Continue the tests until at least one penetration resistance reading equals or exceeds of 27.6 MPa [4000 psi].

Note 5—A satisfactory curve is one that represents the overall development of penetration resistance and includes points before and after the times of initial and final setting to improve the accuracy of the required interpolation. For normal setting mixtures, test points are usually at equally spaced time intervals. This may decrease the accuracy of the estimated setting time by biasing the best fit line when regression analysis is used to analyze the penetration resistance data.



Note: Gray shaded areas define where needle penetrations are permitted.

Figure 1—Top View of Mortar Test Specimen

9.5. *Plotting Test Results*—One of two alternative procedures may be used to plot the test results and obtain times of setting (Note 6). Appendix X1 illustrates the application of these procedures.

Note 6—The plot of penetration resistance versus elapsed time provides information on the rate of setting. The plot may be used to select the time for subsequent penetration tests and it can assist in identifying spurious test results. Therefore, it is recommended that the data be plotted as they are being accumulated.

9.5.1. The following procedure is used to determine the times of setting by hand-fitting a smooth curve through the data. Prepare a graph of penetration resistance, as the ordinate, versus elapsed time, as the abscissa, using a scale such that 3.5 MPa (500 psi) and 1 hour are each represented by a distance of at least 13 mm (0.5 in.). Plot the values of penetration resistance as a function of elapsed time.

9.5.2. The following procedure is used to determine the times of setting by linear regression analysis of the logarithms of the data. Using log-log graph paper, prepare a graph of penetration resistance, as the ordinate, versus elapsed time in minutes, as the abscissa. The limits of penetration resistance on the ordinate should extend from 0.1 MPa (10 psi) to 100 MPa (10000 psi), and the limits of elapsed time on the abscissa should extend from 10 to 1,000 minutes. If slow setting mixtures are used, the time limits may have to be 100 to 10,000 minutes. Plot the values of penetration resistance as a function of elapsed time (Note 5).

9.5.3. Use the following procedure if a computer and suitable software are used to plot test results and obtain the times of setting by regression analysis of the data. As the test results are obtained, enter the time and penetration resistance into the computer and plot the penetration resistance as the ordinate and the elapsed time as the abscissa. For software that permits only linear regression analysis, convert the data by taking their logarithms. The converted data will be fitted by a straight line (see Equation 1):

$$\mathrm{Log}(PR) = a + b\,\mathrm{Log}(t) \tag{1}$$

where:

PR = penetration resistance,

t = elapsed time, and

a and b = regression constants.

The data do not have to be converted if the software permits direct fitting of a power function:

$$PR = ct^{d} \tag{2}$$

where:

c and d = regression constants.

9.5.4. The procedures in Sections 9.5.2 and 9.5.3 assume that the data obey Equation 1 or Equation 2. Verify that the data obey one of these relationships. If the correlation coefficient for the regression analysis, after removal of outliers (see Note 7), is less than 0.98, use the procedure in Section 9.5.1.

10. CALCULATION

10.1. For each test variable under investigation, separately plot the results of three or more time-of-setting tests. For each plot prepared according to Section 9.5.1, hand fit a smooth curve to the data points. For each plot prepared according to Section 9.5.2 or 9.5.3, use the method of least squares to obtain the constants of the best-fit relationship given by Equation (1) or Equation (2), whichever is applicable. Disregard data points that are obvious outliers from the trend defined by the rest of the point (Note 7).

Note 7—Outliers may occur because of factors such as: interferences due to the larger particles in the mortar; presence of large voids within the penetration zone; interferences from the impressions created by adjacent penetrations; failure to maintain the instrument perpendicular to the test surface during penetration; errors in reading the load; variations in the penetration depths; or variation in rate of loading. Judgment of the operator is required to identify those points that should not be included in the data analysis.

10.2. For each plot, determine the times of initial and final setting as the times when the penetration resistance equals 3.5 MPa (500 psi) and 27.6 MPa (4000 psi), respectively. For plots made according to Section 9.5.1, determine times of setting by visual inspection of the drawn curves. For plots made according to Section 9.5.2 or 9.5.3, determine the times of setting by interpolation using the best-fit regression. Record the setting times in hours and minutes to the nearest 5 minutes.

10.3. For each variable under investigation, calculate the times of initial and final setting as the average values of the individual test results. Record the average times in hours and minutes to the nearest 5 minutes.

11. REPORT

11.1. *Data on Concrete Mixture*—The report shall include the following information on the concrete mixture:

11.1.1. Brand and type of cementitious materials, mass of cementitious materials, fine aggregate and coarse aggregate per cubic meter (cubic yard) of concrete, nominal maximum aggregate size, and water-cement ratio;

11.1.2. The name, type, and amount of admixture(s) used;

11.1.3. Air content of fresh concrete and method of determination;

11.1.4. Consistency of concrete as determined by the slump test;

11.1.5. Temperature of mortar after sieving;

11.1.6. Record of ambient temperature during the test period; and

11.1.7. Date of test.

11.2. *Time of Setting Results*—The report shall include the following information on the time of setting tests:

11.2.1. A plot of penetration resistance versus elapsed time for each time of setting test;

11.2.2. The times of initial and final setting for each test, reported in hours and minutes to the nearest minute; and

11.2.3. The average times of initial and final setting for each test condition, reported in hours and minutes to the nearest 5 minutes.

---

12. PRECISION AND BIAS

12.1. The data used to develop the precisions statement were obtained using the inch-pound version of this test method. Estimates of time of setting were determined by both graphical methods and regression analysis. The temperature of the laboratory, where the concrete mixtures were sieved and the resulting mortar fraction measured for penetration resistance, was maintained at 73 ± 2°F (23 ± 1°C) for the duration of the test.

12.2. The following precisions values were obtained from an interlaboratory study involving five operators and three concrete mixtures.[2] The average time of initial setting varied between 169 and 252 min, and the average time of final setting varied between 240 and 341 min. Three replicate determinations were made by each operator on specimens made from a single batch of each mixture.

12.3. *Single-Operator Precision*—The single-operator standard deviations of a single test result are shown in Table 1. The results of two properly conducted tests by the same operator are not expected to differ by more than the values shown in the third column of Table 1. The test method calls for reporting three test results. The range (difference between highest and lowest) of the tree test results obtained by the same operator on specimens from the same batch of concrete are not expected to exceed the values shown in the fourth column of Table 1.

Table 1—Single-Operator Precision

Time of Setting	Single-Operator Standard Deviation, min[a]	Acceptable Difference between Two Results, min[a]	Acceptable Range of Three Results, min[b]
Initial	3.5	9.8	11.4
Final	4.4	12.5	14.6

[a] These numbers represent, respectively, the 1s and d2s limits as described in ASTM C 670.

[b] Calculated as described in the section “acceptable range of more than two results” of ASTM C 670.

12.4. *Multi-Operator Precision*—The multi-operator standard deviations of a single test result are shown in Table 2. The results of two properly conducted tests by different operators on the same material are not expected to differ by more than the values shown in the third column of Table 2. The averages of three test results by two different operators obtained on specimens from a single batch of the same concrete are not expected to differ by more than the values in the fourth column of Table 2.

Table 2—Multi-Operator Precision

Time of Setting	Multi-Operator Standard Deviation, min[a]	Acceptable Difference between Two Results, min[a]	Acceptable Difference between Average of Three Results, min[b]
Initial	6.9	19.4	11.1
Final	10.1	28.7	16.4

[a] These numbers represent, respectively, the 1s and d2s limits as described in ASTM C 670.

[b] Calculated as described in the section “multilaboratory precision expressed as a maximum allowable difference between two averages” of ASTM C 670.

12.5. The bias of this test method cannot be determined because times of setting can be defined only in terms of the test method.

APPENDIX

(Nonmandatory Information)

X1. ILLUSTRATIVE EXAMPLES

X1.1. The penetration resistance *PR* and the elapsed time *t* data in Table X1.1 will be used to illustrate the two procedures for determining times of setting.

Table X1.3—Penetration Resistance Data

Penetration Resistance *(PR)*		Elapsed Time (*t*) (min)	Log *(PR)*		Log (*t*)
MPa	(psi)				
0.30	(44)	200	–0.518	(1.643)	2.301
0.76	(110)	230	–0.120	(2.041)	2.362

X1.2. *Hand Fit*—Figure X1.1 is a plot of the penetration resistance versus elapsed time values in Table X1.1. The smooth curve was drawn by hand using a flexible drawing curve. The curve was drawn so as to achieve the visual best-fit to the data. Horizontal lines are drawn at penetration resistance values of 3.5 MPa (500 psi) and 27.6 MPa (4000 psi). The intersections of the horizontal lines with the curve define the times of initial and final setting, which in this case are 289 minutes and 389 minutes, respectively.

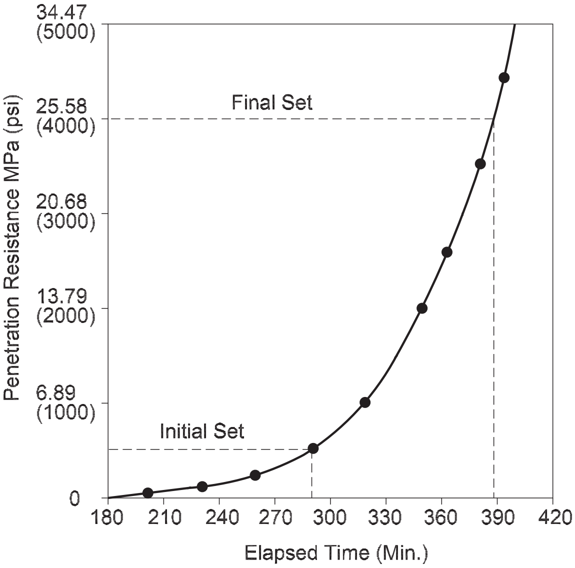

Figure X1.1—Plot of Penetration Resistance versus Elapsed Time and Hand Fit Curve Used to Determine Times of Setting

X1.3. *Regression Analysis*:

X1.3.1. Figure X1.2 is a log-log plot of the penetration resistance versus elapsed time values. The plot shows that for this particular data there is approximately a straight line relationship between the logarithms of penetration resistance and elapsed time. The straight line is obtained by linear regression analysis using the logarithms shown in the third and fourth columns of Table X1.1. The equation for this line is:

$$\mathrm{Log}\left(PR\right) = -16.356 + 6.871\,\mathrm{Log}\left(t\right) \qquad (X1.1)$$

where:

PR = penetration resistance; and

t = elapsed time, and the correlation coefficient is 0.999.

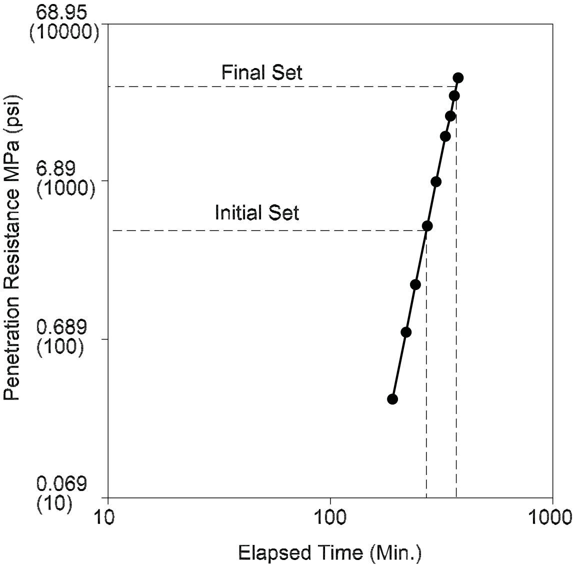

Figure X1.2—Log-Log Plot Showing Straight Line to Determine Times of Setting by Using Regression Analysis

X1.3.2. To obtain the times of setting, the equation is rewritten as:

$$\mathrm{Log}\left(t\right) = \frac{\mathrm{Log}\left(PR\right)\ +\ 6.356}{6.871} \qquad (X1.2)$$

For time of initial setting, substitute the value 3.45 for PR:

$$\mathrm{Log}\left(t\right) = \frac{\mathrm{Log}\left(3.45\right)\ +\ 16.356}{6.871}$$

$$= \frac{0.538\ +\ 16.356}{6.871}$$

$$= 2.459$$

therefore:

$t = (10)2.459 = 288$ minutes

For time of final setting, substitute the value 27.58 for *PR*:

$$\mathrm{Log}\left(t\right) = \frac{\mathrm{Log}\left(27.58\right) \ + \ 16.356}{6.871}$$

$$= \frac{1.441 \ + \ 16.356}{6.871}$$

$$= 2.590$$

therefore:

$t = (10)2.590 = 389$ minutes

---

[1] Detailed requirements for this sieve are given in M 92.

Standard Method of Test for

Splitting Tensile Strength of Cylindrical Concrete Specimens

AASHTO Designation: T 198-09
ASTM Designation: C 496/C 496M-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Splitting Tensile Strength of Cylindrical Concrete Specimens

AASHTO Designation: T 198-09
ASTM Designation: C 496/C 496M-04

1. SCOPE

1.1. This test method covers the determination of the splitting tensile strength of cylindrical concrete specimens, such as molded cylinders and drilled cores.

Note 1—For methods of molding cylindrical specimens, see R 39 and T 23. For methods of obtaining drilled cores, see T 24M/T 24.

1.2. The values stated in either inch-pound or SI units are to be regarded separately as standard. The SI units are shown in parentheses. The values stated in each system may not be exactly equivalent; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.4. The text of this standard references notes that provide explanatory material. These notes shall not be considered as requirements of the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

2.2. ASTM Standards:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SUMMARY OF TEST METHOD

3.1. This test method consists of applying a diametral compressive force along the length of a cylindrical concrete specimen at a rate that is within a prescribed range until failure occurs. This loading induces tensile stresses on the plane containing the applied load and relatively high compressive stresses in the area immediately around the applied load. Tensile failure occurs rather than compressive failure because the areas of load application are in a state of triaxial compression, thereby allowing them to withstand much higher compressive stresses than would be indicated by a uniaxial compressive strength test result.

3.2. Thin plywood bearing strips are used to distribute the load applied along the length of the cylinder.

3.3. The maximum load sustained by the specimen is divided by appropriate geometrical factors to obtain the splitting tensile strength.

4. SIGNIFICANCE AND USE

4.1. Splitting tensile strength is generally greater than direct tensile strength and lower than flexural strength (modulus of rupture).

4.2. Splitting tensile strength is used in the design of structural lightweight concrete members to evaluate the shear resistance provided by concrete and to determine the development length of reinforcement.

5. APPARATUS

5.1. *Testing Machine*—The testing machine shall conform to the requirements of T 22, and be of a type with sufficient capacity that will provide the rate of loading prescribed in Section 7.5.

5.2. *Supplementary Bearing Bar or Plate*—If the diameter or the largest dimension of the upper bearing face or the lower bearing block is less than the length of the cylinder to be tested, a supplementary bearing bar or plate of machined steel shall be used. The surfaces of the bar or plate shall be machined to within ±0.001 in. (0.025 mm) of planeness, as measured on any line of contact of the bearing area. It shall have a width of at least 2 in. (50 mm), and a thickness not less than the distance from the edge of the spherical or rectangular bearing block to the end of the cylinder. The bar or plate shall be used in such manner that the load will be applied over the entire length of the specimen.

5.3. *Bearing Strips*—Two bearing strips of nominal $^1/_8$-in. (3.2-mm) thick plywood, free of imperfections, approximately 1 in. (25 mm) wide, and of a length equal to, or slightly longer than that of the specimen shall be provided for each specimen. The bearing strips shall be placed between the specimen and both the upper and lower bearing blocks of the testing machine or between the specimen and supplemental bars or plates, when used. (See Section 5.2.) Bearing strips shall not be reused.

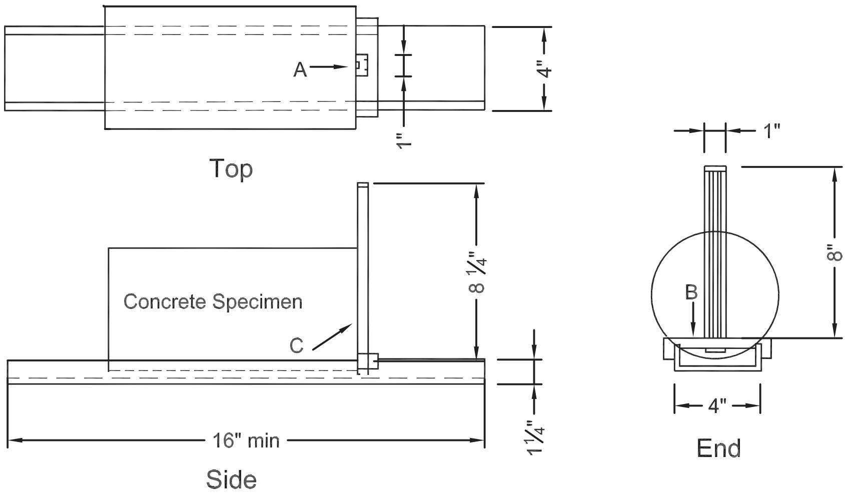
6. TEST SPECIMENS

6.1. The test specimens shall conform to the size, molding, and curing requirements set forth in either T 23 (field specimens) or R 39 (laboratory specimens). Drilled cores shall conform to the size and moisture-conditioning requirements set forth in T 24M/T 24. Moist-cured specimens, during the period between their removal from the curing environment and testing, shall be kept moist by a wet burlap or blanket covering, and shall be tested in a moist condition as soon as practicable.

6.2. The following curing procedure shall be used for evaluations of light-weight concrete: specimens tested at 28 days shall be in an air-dry condition after 7 days moist curing followed by 21 days drying at 73.5 ± 3.5ºF (23.0 ± 2ºC) and 50 ± 5 percent relative humidity.

7. PROCEDURE

7.1. *Marking*—Draw diametral lines on each end of the specimen using a suitable device that will ensure that they are in the same axial plane (Figure 1, Fig. 2 and Note 2), or as an alternative, use the aligning jig shown in Figure 2 (Note 3).



Metric Equivalents

in.	$^{1}/_{16}$	$^{1}/_{8}$	$^{3}/_{16}$	$^{1}/_{4}$	$^{1}/_{2}$	$^{3}/_{4}$	1	$1^{1}/_{4}$	2	$2^{1}/_{2}$	4	$7^{1}/_{2}$	8	$8^{1}/_{4}$	15	16
mm	1.6	3.2	4.8	6.4	13	19	25	32	50	65	100	190	200	205	375	400

Figure 1—Detailed Plans for a Suitable Apparatus for Marking End Diameters Used for Aligning the Specimen

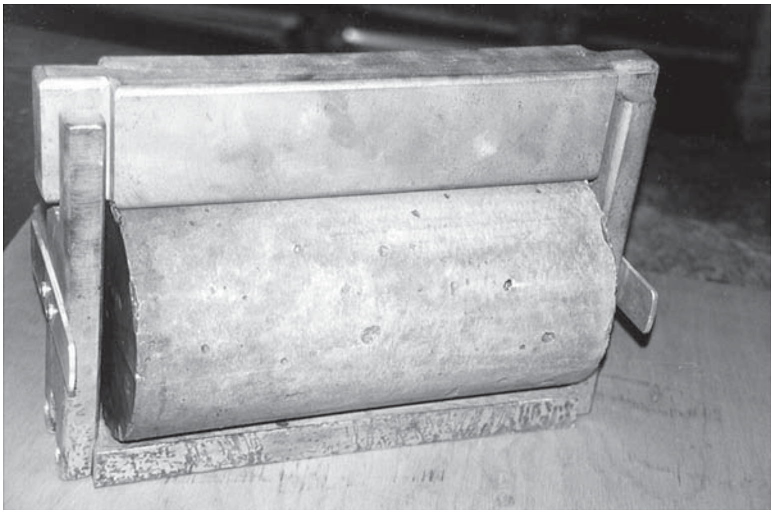


Figure 2—Jig for Aligning Concrete Cylinder and Bearing Strips

Note 2—Figure 1 shows a suitable device for drawing diametral lines on each end of a 6 by 12 in. (152 by 305 mm) cylinder in the same axial plane. The device consists of three parts as follows:

1. A length of 4-in. (100-mm) steel channel, the flanges of which have been machined flat.
2. A section, part *B*, that is grooved to fit smoothly over the flanges of the channel and that includes cap screws for positioning the vertical member of the assembly, and
3. A vertical bar, *C*, for guiding a pencil or marker.

The assembly (part B and part C) is not fastened to the channel and is positioned at either end of the cylinder without disturbing the position of the specimen when marking the diametral lines.

Note 3—Figure 3 is a detailed drawing of the aligning jig shown in Figure 2 for achieving the same purpose as marking the diametral lines. The device consists of:

1. A base for holding the lower bearing strip and cylinder.
2. A supplementary bearing bar conforming to the requirements in Section 4 as to critical dimensions and planeness, and
3. Two uprights to serve for positioning the test cylinder, bearing strips, and supplementary bearing bar.

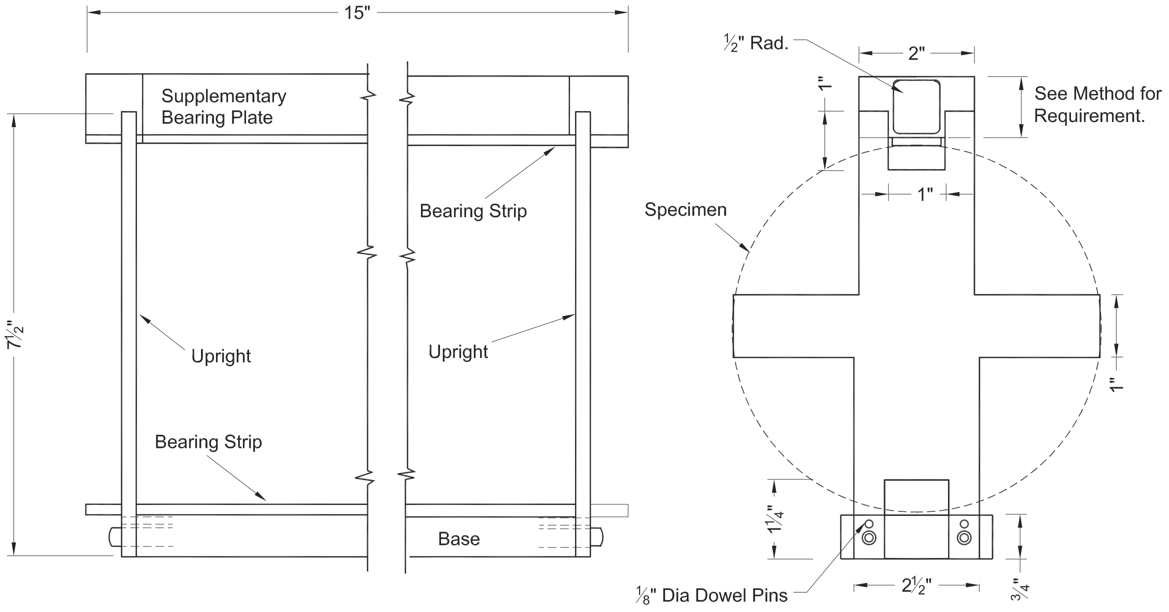

Figure 3—Detailed Plans for a Suitable Aligning Jig for 6 by 12 in. (152 by 305 mm) Specimen

7.2. *Measurements*—Determine the diameter of the test specimen to the nearest 0.01 in. (0.25 mm) by averaging three diameters measured near the ends and the middle of the specimen and lying in the plane containing the lines marked on the two ends. Determine the length of the specimen to the nearest 0.1 in. (2.5 mm) by averaging at least two length measurements taken in the plane containing the lines marked on the two ends.

7.3. *Positioning Using Marked Diametral Lines*—Center one of the plywood strips along the center of the lower bearing block. Place the specimen on the plywood strip and align so that the lines marked on the ends of the specimen are vertical and centered over the plywood strip. Place a second plywood strip lengthwise on the cylinder, centered on the lines marked on the ends of the cylinder. Position the assembly to ensure the following conditions:

7.3.1. The projection of the plane of the two lines marked on the ends of the specimen intersects the center of the upper bearing plate, and

7.3.2. The supplementary bearing bar or plate, when used, and the center of the specimen are directly beneath the center of thrust of the spherical bearing block. (See Figure 4.)

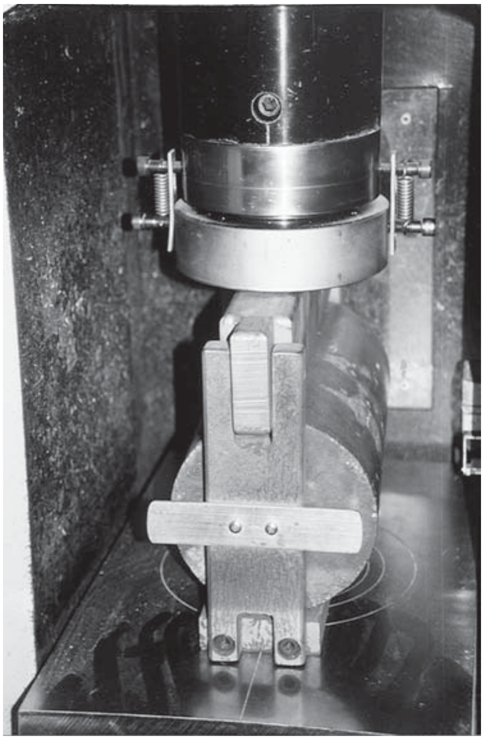

Figure 4—Specimen Positioned in a Testing Machine for Determination of Splitting Tensile Strength

7.4. *Positioning by Use of Aligning Jig*—Position the bearing strips, test cylinder, and supplementary bearing bar by means of the aligning jig as illustrated in Figure 2 and center the jig so that the supplementary bearing bar and the center of the specimen are directly beneath the center of thrust of the spherical bearing block.

7.5. *Rate of Loading*—Apply the load continuously and without shock, at a constant rate within the range 100 to 200 psi (689 to 1380 kPa)/min splitting tensile stress until failure of the specimen (Note 4). Record the maximum applied load indicated by the testing machine at failure. Note the type of failure and the appearance of the concrete.

Note 4—The relationship between splitting tensile stress and applied load is shown in Section 8. The required loading range in splitting tensile stress corresponds to applied total load in the range of 11.300 to 22.600 lbf (50 to 100 kN)/min for 6 by 12 in. (152 by 305 mm) cylinders.

8. CALCULATION

8.1. Calculate the splitting tensile strength of the specimen as follows:

$$T = 2P/\pi\, ld \qquad (1)$$

where:

T = splitting tensile strength, psi (kPa);

P = maximum applied load indicated by the testing machine, lbf (kN);

l = length, in in. (m); and

d = diameter, in in. (m).

9. REPORT

9.1. *Report the following information*:

9.1.1. Identification number;

9.1.2. Diameter and length, in inches (in.) (m);

9.1.3. Maximum load, in lbf (kN);

9.1.4. Splitting tensile strength calculated to the nearest 5 psi (35 kPA);

9.1.5. Estimated proportion of coarse aggregate fractured during the test;

9.1.6. Age of specimen;

9.1.7. Curing history;

9.1.8. Defects in specimen;

9.1.9. Types of fracture; and

9.1.10. Type of specimen.

10. PRECISION AND BIAS

10.1. *Precision*—An interlaboratory study of this test method has not been performed. Available research data, however, suggests that the within batch coefficient of variation is 5 percent (Note 5) for 6 by 12 in. (152 by 305 mm) cylindrical specimens with an average splitting tensile strength of 405 psi (2.8 MPa). Results of two properly conducted tests on the same material, therefore, should not differ by more than 14 percent (Note 5) of their average for splitting tensile strengths of 400 psi (2.8 MPa).

Note 5—These numbers represent, respectively, the (1s percent) and (d2s percent) limits as defined in ASTM C 670.

10.2. *Bias*—The test method has no bias because the splitting tensile strength can be defined only in terms of this test method.

11. KEYWORDS

11.1. Cylindrical concrete specimens; splitting tension; tensile strength.

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Chace Indicator

AASHTO Designation: T 199-00 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Air Content of Freshly Mixed Concrete by the Chace Indicator

AASHTO Designation: T 199-00 (2009)

1. SCOPE

1.1 This method of test covers the determination of the air content of freshly mixed concrete by displacing the air with alcohol and observing the change in level of the liquid in a tube. The apparatus is light and small, and the test procedure requires only a few minutes.

1.2 This method has been found satisfactory for determining the approximate air content of freshly mixed concrete. It shall not, however, be considered suitable for replacing T 121M/T 121 (gravimetric method), T 152 (pressure method), or T 196M/T 196 (volumetric method). In no case should the value obtained through the use of this method be accepted as determining the compliance of the air content of concrete with the requirements of specifications. The method is most useful for determining whether the concrete has a low, medium, or high air content, and whether the air content is reasonably constant from batch to batch of concrete.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method
- T 196M/T 196, Air Content of Freshly Mixed Concrete by the Volumetric Method

3. APPARATUS

3.1 *Indicator*—The indicator as shown in Figure 1 consists of three pieces: a glass tube about 75 mm (3 in.) long and 25 mm (1 in.) in diameter with a stem 75 mm (3 in.) long and 6.4 mm (0.25 in.) in diameter at one end resembling a filter tube for Gooch crucibles, a rubber stopper to fit the larger end of the glass tube, and a metal cup mounted on the smaller end of the stopper. The stem of the glass tube is scribed with 11 lines, each pair indicating an approximate volume of 0.08 mL. A reference line is also scribed on the large portion of the tube. The exact stem factor should be determined in accordance with Section 3.2. The brass cup is 19 mm (0.75 in.) in inside diameter, 13 mm (0.5 in.) in depth, and contains a volume of 3.6 mL. When the stopper and cup are inserted into the glass tube, the volume of the latter and stem is about 27 mL.

3.2 *Indicator Stem Factor*—Experience has shown that it is difficult to fabricate indicators to a close tolerance at a reasonable price. Therefore, indicators should be calibrated and inscribed with a calibration factor that represents the percent of the volume of the bowl contained in one graduation on the stem. An indicator can be calibrated in a few minutes by filling the bowl and stem with a liquid, such as alcohol, and noting the quantity of liquid contained in the bowl and in 10 graduations on the stem.

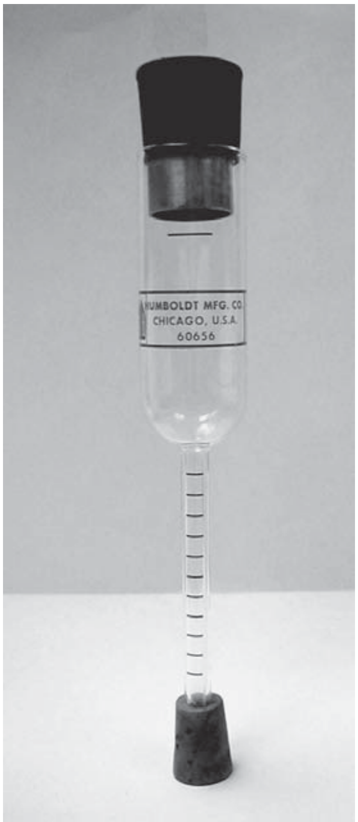

Figure 1—Chace Indicator

3.3 *Alcohol*—70 percent isopropyl alcohol.

3.4 *Dropper*—A medicine dropper having a tip small enough to enter into the graduated stem of the indicator.

4. PROCEDURE

4.1 Fill the brass cup with cement mortar from the concrete to be tested, excluding particles of sand that would be retained on a 2.00-mm (No. 10) sieve. A narrow knife blade is most suitable to pick up the mortar. Rod the mortar in the cup using a thin stiff wire[1] and strike off the mortar flush with the top of the cup. Clean the sides of the cup and stopper of mortar if necessary. Close the smaller end of the indicator with a finger and fill the tube with alcohol to the reference line. Insert the stopper into the tube, invert the indicator, and bring the level of the alcohol to the upper mark of the stem by pushing the stopper in further or by adding alcohol with the medicine dropper. Be certain that no air bubbles are in the stem of the indicator.

4.1.1 Close the opening in the stem with a finger and gently roll the indicator from a vertical to a horizontal position while tapping the side of the indicator with a finger of the other hand. Care shall be taken not to change the setting of the stopper. Continue the rolling and tapping until all of the mortar is dispersed in the alcohol and no more bubbles of air appear. With the indicator held in a vertical position, remove the finger from the end of the stem and read the level of the alcohol in the stem to the nearest half graduation.

5. COMPUTATION OF AIR CONTENT

5.1 The air content can be determined from Table 1 or Figure 2. By noting the mortar content of the concrete and the Chace factor, the stem reading can be multiplied by the appropriate mortar correction factor shown in Table 1 to provide the mortar-corrected air content. The mortar-corrected air content should be increased or decreased by the curve corrections shown in Table 2 to provide the actual air content. For example, if the mortar content is 0.556 (m^3/m^3), the Chace factor is 2.3, and the stem reading is 6.0 percent; multiply the stem reading by 1.26 (1.28), as indicated by Table 1 (based on average of values for Chace factors of 2.2 and 2.4), to give a mortar-corrected air content of 7.6 (7.7) percent. The 7.6 (7.7) percent is increased by 0.9 percent, as indicated by Table 2, to give an air content of 8.5 (8.6) percent.

As an alternative, the air content can be determined from the Chace conversion nomograph shown in Figure 2. For example, enter the nomograph at the lower left side at the Chace factor, which is 2.3, move horizontally to the right to intersect the mortar content, which is 0.556 m^3/m^3, move vertically to intersect the stem reading, which is 6.0 percent, and move horizontally to the left edge of the nomograph to read the air content, which is 8.5 (8.6) percent.

Table 1—Mortar Correction Factors

Mortar Content, m^3/m^3 (ft^3/yd^3)	Chace Factor[a]				
	1.6	1.8	2.0	2.2	2.4
1.00 (27)	1.60	1.80	2.00	2.20	2.40
0.75 (20)	1.20 (1.19)	1.35 (1.33)	1.50 (1.48)	1.65 (1.63)	1.80 (1.78)
0.70 (19)	1.12 (1.13)	1.26 (1.27)	1.40 (1.41)	1.54 (1.55)	1.68 (1.69)
0.65 (18)	1.04 (1.07)	1.17 (1.20)	1.30 (1.33)	1.43 (1.47)	1.56 (1.60)
0.60 (17)	0.96 (1.01)	1.08 (1.13)	1.20 (1.26)	1.32 (1.39)	1.44 (1.51)
0.55 (16)	0.88 (0.95)	0.99 (1.07)	1.10 (1.19)	1.21 (1.30)	1.32 (1.42)
0.50 (15)	0.80 (0.89)	0.90 (1.00)	1.00 (1.11)	1.10 (1.22)	1.20 (1.33)
0.45 (14)	0.72 (0.83)	0.81 (0.93)	0.90 (1.04)	0.99 (1.14)	1.08 (1.24)
0.40 (13)	0.64 (0.77)	0.72 (0.87)	0.80 (0.96)	0.88 (1.06)	0.96 (1.16)
0.35 (12)	0.56 (0.71)	0.63 (0.80)	0.70 (0.89)	0.77 (0.98)	0.84 (1.07)
0.30 (11)	0.48 (0.65)	0.54 (0.73)	0.60 (0.81)	0.66 (0.90)	0.72 (0.98)
0.25 (10)	0.40 (0.59)	0.45 (0.67)	0.50 (0.74)	0.50 (0.81)	0.68 (0.89)

[a] Volume of one graduation on stem as a percentage of the volume of the bowl.

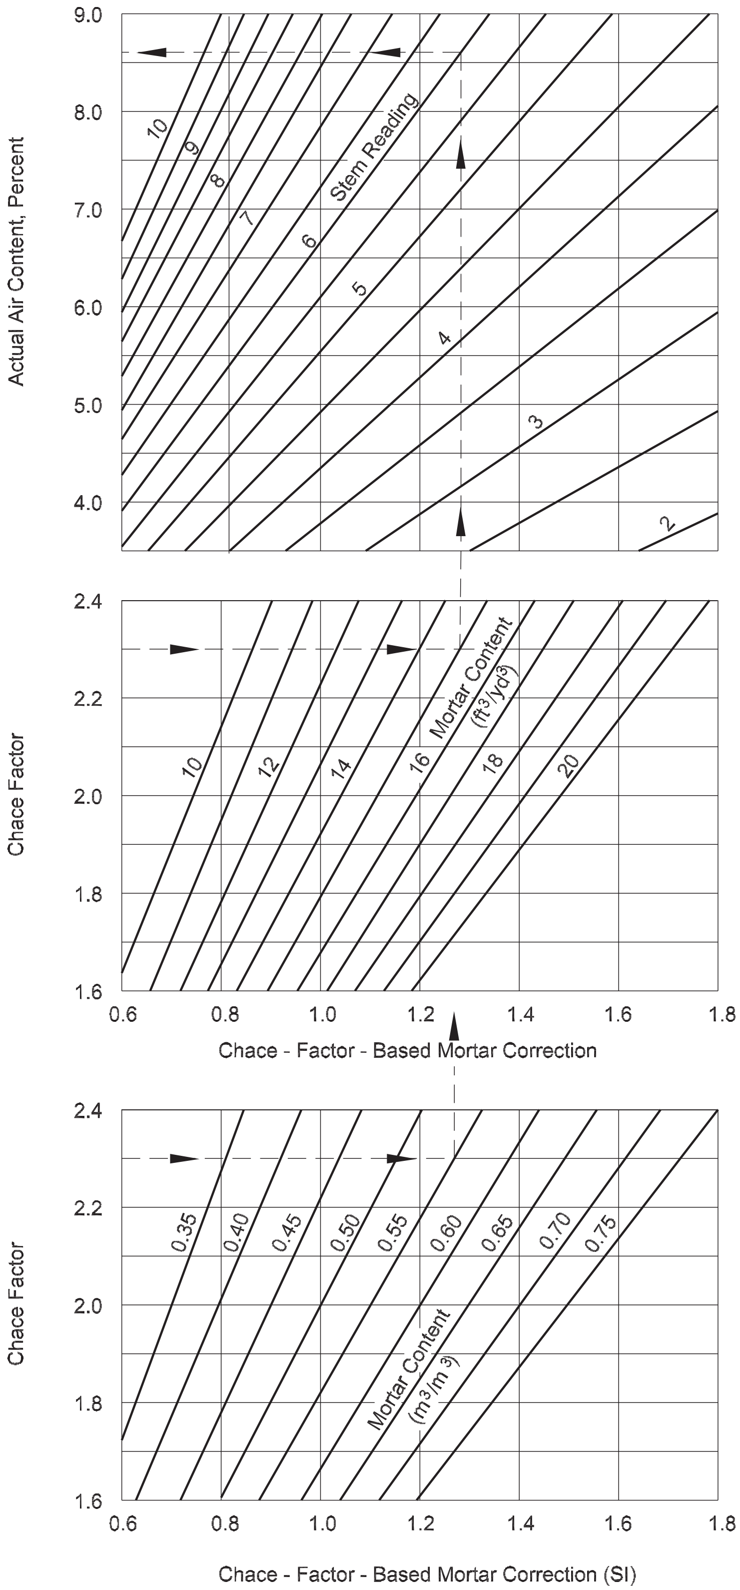

Figure 2—Chase Conversion Nomograph

Table 2—Curve Corrections

Mortar-Corrected Air Content, (%)	Curve Correction, (%)	Mortar-Corrected Air Content, (%)	Curve Correction, (%)
1.0	–0.1	7.0	0.8
2.0	0.0	7.5	0.9
3.0	0.2	8.0	1.0
3.5	0.3	8.5	1.1
4.0	0.3	9.0	1.2
4.5	0.4	9.5	1.3
5.0	0.5	10.0	1.3
5.5	0.6	11.0	1.5
6.0	0.7	12.0	1.7
6.5	0.8	13.0	1.8

6. LIMITATIONS

6.1 Because of the small amount of mortar used in a test, the Chace indicator will not give the air content of concrete as accurately as will the other methods mentioned in Section 1.2. However, a reasonably accurate indication of the air content can be obtained by taking the average of the results of tests on two samples. The average of tests on five samples provides the same statistical level of confidence as one test by T 152 (pressure method).

Standard Practice for

Capping Cylindrical Concrete Specimens

AASHTO Designation: T 231-05 (2009)
ASTM Designation: C 617-98 (2003)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Capping Cylindrical Concrete Specimens

AASHTO Designation: T 231-05 (2009)
ASTM Designation: C 617-98 (2003)

1. SCOPE

1.1 This method covers apparatus, materials, and procedures for capping freshly molded concrete cylinders with neat cement and hardened cylinders and drilled concrete cores with high-strength gypsum plaster or sulfur mortar.

1.2 The values stated in SI units are the preferred standard.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*. For specific precaution statements, see Sections 4.3 and 6.2.4.1.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 85, Portland Cement
- M 240, Blended Hydraulic Cement
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm 2-in. Cube Specimens)

2.2 *ASTM Standards*:

- C 287, Standard Specification for Chemical-Resistant Sulfur Mortar
- C 472, Standard Test Methods for Physical Testing of Gypsum, Gypsum Plasters and Gypsum Concrete
- ASTM *Manual of Aggregate and Concrete Testing*

2.3 *ANSI Standard*:

- B 46.1, Standard for Surface Texture, Surface Roughness, Waviness and Lay

3. SIGNIFICANCE AND USE

3.1 This practice describes procedures for providing plane surfaces on the end surfaces of freshly molded concrete cylinders, hardened cylinders, or drilled concrete cores when the end surfaces do not conform with the planeness and perpendicularity requirements of applicable standards.

4. CAPPING EQUIPMENT

4.1 *Capping Plates*—Neat cement caps and high-strength gypsum plaster caps shall be formed against a glass plate of at least 6 mm (0.25 in.) thick, a machined metal plate at least 11 mm (0.45 in.) thick (Note 1), on a polished plate of granite or diabase at least 75 mm (3 in.) thick. Sulfur mortar caps shall be formed against similar metal or stone plates. In all cases, plates shall be at least 25 mm (1 in.) greater in diameter than the test specimen and the working surfaces shall not depart from a plane by more than 0.05 mm (0.002 in.) in 150 mm (6 in.). The surface roughness of newly finished metal plates shall not exceed that set forth in Table 4 of the American National Standard for Surface Texture (ANSI B46.1) or 0.003 mm (125 μ in.) for any type of surface and direction of lay. The surface when new shall be free of gouges, grooves, or indentations beyond those caused by the finishing operation. Metal plates that have been in use shall be free of gouges, grooves, or indentations greater than 0.25 mm (0.010 in.) deep or greater than 32 mm^2 (0.05 $in.^2$) in surface area. If a recess is machined into the metal plate, the thickness of the plate beneath the recessed area shall be at least 13 mm (0.5 in.). In no case shall the recess in the plate be deeper than 13 mm (0.5 in.).

Note 1—In vertical capping devices, use of two-piece metal capping plates is advantageous as this facilitates refinishing of the capping surface should it become necessary to do so. In such devices, the lower section is a solid plate and the upper section has a circular hole that forms the recess. The two sections are customarily fastened together with machine screws. It is advantageous to have the upper surface of the lower plate case hardened. A Rockwell hardness of HRC 48 is suggested.

4.2 *Alignment Devices*—Suitable alignment devices such as guide bars or bull's-eye levels shall be used in conjunction with capping plates to ensure that no single cap will depart from perpendicularity of cylindrical specimen by more than 0.5 degrees [approximately equivalent to 3.2 mm in 305 mm (0.125 in. in 12 in.)]. The same requirement is applicable to the relationship between the axis of the alignment device and the surface of a capping plate when guide bars are used. In addition, the location of each bar with respect to its plate must be such that no cap will be off-centered on a test specimen by more than 1.6 mm (0.06 in.).

4.3 *Melting Pots for Sulfur Mortars*—Pots used for melting sulfur mortars shall be equipped with automatic temperature controls and shall be made of metal or lined with a material that is non-reactive with molten sulfur.

Caution—Melting pots equipped with peripheral heating will ensure against accidents during reheating of cooled sulfur mixtures that have a crusted-over surface. When using melting pots not so equipped, a buildup of pressure under the hardened surface crust on subsequent reheating may be avoided by use of a metal rod that contacts the bottom of the pot and projects above the surface of the fluid sulfur mix as it cools. The rod should be of sufficient size to conduct enough heat to the top of reheating to melt a ring around the rod first and thus avoid the development of pressure. A large metal ladle can be substituted for the rod.

Sulfur melting pots should be used under a hood to exhaust the fumes to outdoors. Heating over an open flame is dangerous because the flash point of sulfur is approximately 227ºC (440ºF) and the mixture can ignite due to overheating. Should the mixture start to burn, covering will snuff out the flame. The pot should be recharged with fresh material after the flame has been extinguished.

5. CAPPING MATERIALS

5.1 The strength of the capping material and the thickness of the caps shall conform to the requirements of Table 1.

Table 1—Compressive Strength and Maximum Thickness of Capping Materials

Cylinder Compressive Strength, MPa (psi)	Minimum Strength of Capping Material	Maximum Average Thickness of Cap	Maximum Thickness Any Part of Cap
3.5 to 50 MPa (500 to 7000 psi)	35 MPa (5000 psi) or cylinder strength, whichever is greater	6 mm (0.25 in.)	8 mm (0.31 in.)
greater than 50 MPa (7000 psi)	Compressive strength not less than cylinder strength, except as provided in Section 5.1.1.	3 mm (0.125 in.)	5 mm (0.20 in.)

5.1.1 If sulfur mortar, high strength gypsum plaster and other materials except neat cement paste are to be used to test concrete with a strength greater than 50 MPa (7000 psi), the manufacturer or the user of the material must provide documentation:

- that the average strength of 15 cylinders capped with the materials is not less than 98 percent of the average strength of 15 companion cylinders capped with neat cement paste or 15 cylinders ground plane to within 0.05 mm (0.002 in.),
- that the standard deviation of the strengths of the capped cylinders is not greater than 1.57 times that of the standard deviation of the reference cylinders,
- that the cap thickness requirements were met in the qualification tests, and
- of the hardening time of the caps used in the qualification tests.

5.1.2 Additionally, the qualification test report must include the compressive strength of 50-mm (2-in.) cubes of the material qualified and of neat cement paste cubes, if used. Capping materials conforming to these requirements are permitted to be used for cylinders with strengths up to 20 percent greater than the concrete tested in these qualification tests. The manufacturer must requalify lots of material manufactured on an annual basis or whenever there is a change in the formulation of the raw materials. The user of the material must retain a copy of the qualification results, and the dates of manufacture of material qualified and of the material currently being used. (See Table 2.)

Table 2—Sample Report of Qualifications of a Capping Material

Note-Manufacturer: Testing Supplies Co.
Capping Material: Super Strong AAA-Sulfur mortar
Lot: 12a45 Date Tested: 11/3/98
Signed by:____(Testing Agency and Responsible Official)

Item	Capping Material	Control Cylinders	Ratio	Criteria	Pass/Fail
Concrete Cylinder Test Data					
Type of Capping Material	Sulfur	Ground			
Average Concrete Strength, MPa (psi)	76.2 (11,061)	75.9 (11,008)	1.005	>0.98 Xc	Pass
Standard Deviation MPa (psi)	2.59 (376)	1.72 (250)	1.504	≤1.57 C	Pass
Number of cylinders tested	15	15			
Cap age when cylinders tested	7 days	n/a			
Capping Material Test Data					
Average cap thickness mm (in.)	2.8 (0.11)	n/a			
Compressive strength of 50-mm (2-in.) cubes, MPa (psi)	91 (12,195)				
Cube age when tested	7 days				
Maximum concrete strength qualified, MPa (psi)				1.2 Av. Str = 91.5 (13,273)[a]	

[a] Nominally a specified strength of 75 MPa (11,000 psi) and perhaps somewhat higher.

5.1.3 The compressive strength of capping materials shall be determined by testing 50-mm (2-in.) cubes following the procedure described in Test Method T 106M/T 106. Except for sulfur mortars, molding procedures shall be as in Test Method T 106M/T 106 unless other procedures are required to eliminate large entrapped air voids. See test methods for alternative compaction procedures. Cure cubes in the same environment for the same length of time as the materials used to cap specimens.

5.1.4 The strength of the capping material shall be determined on receipt of a new lot and at intervals not exceeding three months. If a given lot of the capping material fails to conform to the strength requirements, it shall not be used, and strength tests of the replacement material shall be made weekly until four consecutive determinations conform to specification requirements.

5.2 *Neat Hydraulic Cement Paste*:

5.2.1 Make qualification test of the neat hydraulic cement paste prior to use for capping to establish the effects of water-cement ratio and age on compressive strength of 50-mm (2-in.) cubes (Note 2).

Note 2—The cements used generally conform to Specification M 85 Types I, II, or III; however, Specification M 240 blended cements, calcium aluminate or other hydraulic cements producing acceptable strength may be used.

5.2.2 Mix the neat cement paste to the desired consistency at a water-cement ratio equal to or less than that required to produce the required strength, generally 2 to 4 hours before the paste is to be used (Note 3). Remix as necessary to maintain acceptable consistency (Note 4). Some re-tempering of the paste is acceptable if the required water-cement ratio is not exceeded. Optimum consistency is generally produced at water-cement ratios of 0.32 to 0.36 by mass for Type I and Type II cements and 0.35 to 0.39 by mass for Type III cements.

Note 3—Freshly mixed pastes tend to bleed, shrink, and make unacceptable caps. The 2 to 4 hour period is generally appropriate for portland cements.

Note 4—The required consistency of the paste is determined by the appearance of the cap when it is stripped. Fluid paste results in streaks in the cap. Stiff paste results in thick caps.

5.3 *High-Strength Gypsum Cement Paste*:

5.3.1 No fillers or extenders may be added to neat high-strength gypsum cement paste subsequent to the manufacture of the cement (Note 5). Qualification tests shall be made to determine the effects of water-cement ratio and age on the compressive strength 50-mm (2-in.) cubes. Retarders may be used to extend working time, but their effects on required water-cement ratio and strength must be determined (Note 6.)

Note 5—Low-strength molding plaster, plaster of paris, or mixtures of plaster of paris and portland cement are unsuitable for capping.

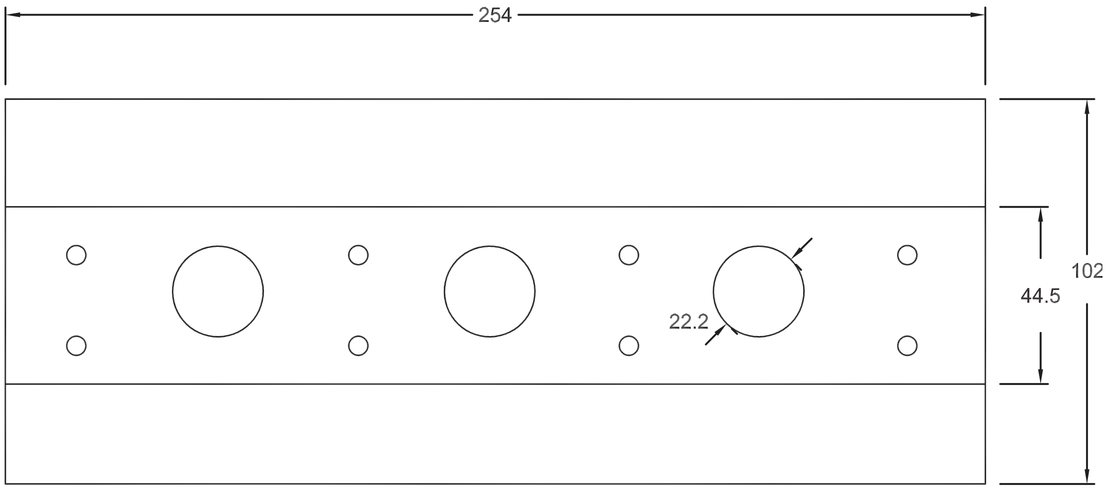
Note 6—The water-gypsum cement ratio should be between 0.26 and 0.30. Use of low water-cement ratios and vigorous mixing will usually permit development of 35 MPa (5000 psi) at ages of 1 to 2 hours. Higher water-gypsum cement ratios extend working time, but reduce strength.

5.3.2 Mix the neat gypsum cement paste at the desired water-cement ratio and use it promptly since it sets rapidly.

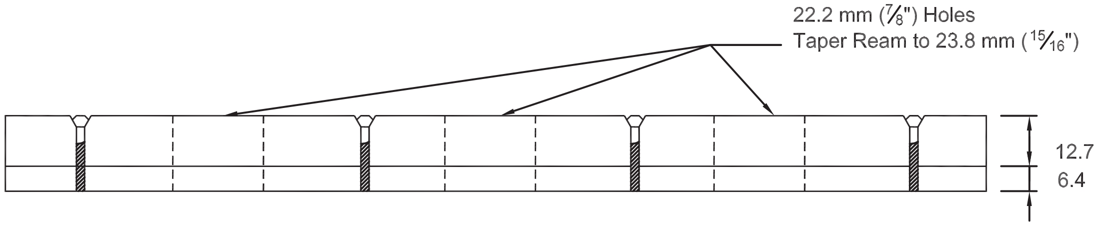
5.4 *Sulfur Mortar*:

5.4.1 Proprietary or laboratory prepared sulfur mortars are permitted if allowed to harden a minimum of 2 hours before testing concrete with strength less than 35 MPa (5000 psi). For concrete strengths of 35 MPa (5000 psi) or greater, sulfur mortar caps must be allowed to harden at least 16 hours before testing, unless a shorter time has been shown to be suitable as specified in Section 5.1.1.

5.4.2 *Determination of Compressive Strength*—Prepare test specimens using a cube mold and base plate conforming to the requirements of T 106M/T106 and a metal cover plate conforming in principle to the design shown in Figure 1 (Note 7). Bring the various parts of the apparatus to a temperature of 20 to 30ºC (68 to 86ºF), lightly coat the surfaces that will be in contact with the sulfur mortar with mineral oil and assemble near the melting pot. Bring the temperature of the molten sulfur mortar in the pot within a range of 129 to 143ºC (265 to 290ºF), stir thoroughly, and begin casting cubes. Using a ladle or other suitable pouring device, quickly fill each of the three compartments until the molten material reaches the top of the filling hole. Allow sufficient time for maximum shrinkage, due to cooling, and solidification to occur (approximately 15 minutes) and refill each hole with molten material (Note 8). After solidification is complete, remove the cubes from the mold without breaking off the knob formed by the filling hole in the cover plate. Remove oil, sharp edges, and fins from the cubes and check the planeness of the bearing surfaces in the manner described in T 106M/T 106. After storage at room temperature to the desired age, but not less than 2 hours, test cubes in compression following the procedure described in T 106M/T 106 and calculate the compressive strength in MPa (psi).



Cover Plate - Plan View



Cover Plate - Front View

Dimensional Equivalents

mm	6.4	12.7	22.2	44.5	100	250
in.	$^{1}/_{4}$	$^{1}/_{2}$	$^{7}/_{8}$	$1^{3}/_{4}$	4	10

Notes: All dimensions shown in millimeters unless otherwise noted.

Figure 1—Sketch of Cover for 50-mm (2-in.) Cube Mold

Note 7—If desired, a plane phenol formaldehyde (bakelite) plate of 3 mm (0.125 in.) thickness, provided with three appropriately spaced filling holes, may be inserted between the cover plate and the mold to slow the rate of cooling of test specimens.

Note 8—The second filling helps to prevent the formation of a large void or shrinkage pipe in the body of a cube. However, such defects may occur no matter how much care is exercised, and it therefore is advisable to inspect the interior of tested sulfur mortar cubes for homogeneity whenever the strength values obtained are significantly lower than anticipated.

6. CAPPING PROCEDURES

6.1 *Freshly Molded Cylinders*—Use only neat portland cement pastes (Note 9) to cap freshly molded cylinders. Make caps as thin as practical. Do not apply the neat paste to the exposed end until the concrete has ceased settling in the molds, generally from 2 to 4 hours after molding. During the molding of the cylinder, strike off the upper end even with or slightly below the plane of the rim of the mold. Mix the neat paste to a stiff consistency 2 to 4 hours before it is to be used in order to allow the paste to go through its period of initial shrinkage. The strength of the paste will depend on the consistency, water-cement ratio, curing, brand, and type of cement. For Type I and Type II cement pastes, the optimum consistency is generally produced at a water-cement ratio of 0.32 to 0.36 by mass. For Type III cement, the water ratio should generally be between 0.35 to 0.39 by mass. The paste will stiffen during the 2 to 4 hours waiting period and the use of re-tempering water is not recommended. However, if retempering water is used, the amount should not increase the water-cement ratio by more than 0.05 by mass. Remove free water and laitance from the top of the specimen immediately before capping. Form the cap by placing a conical mound of paste on the specimen and then gently pressing a freshly oiled capping plate on the conical mound until the plate contacts the rim of the mold. A very slight twisting motion may be required to extrude excess paste and minimize air voids in the paste. The capping plate must not rock during this operation. Carefully cover the capping plate and mold with a double layer of damp burlap and a polyethylene sheet to prevent drying. Removal of the capping plate after hardening may be accomplished by tapping the edge with a rawhide hammer in a direction parallel to the plane of the cap.

Note 9—Type I neat cement caps generally require at least 6 days to develop acceptable strength and Type III neat cement caps at least 2 days. Dry concrete specimens will absorb water from freshly mixed neat cement paste and produce unsatisfactory caps. Neat cement paste caps will shrink and crack on drying and, therefore, should be used only for specimens that are to be moist-cured continuously until time of testing.

6.2 *Hardened Concrete Specimens*:

6.2.1 *General*—Caps should be about 3 mm (0.125 in.) thick, and in no instance shall any part of a cap be more than 8 mm (0.31 in.) thick. If either or both ends of a specimen have coatings or deposits of oily or waxy materials that would interfere with the bond of the cap, remove such coatings or deposits. If necessary, the ends of a specimen may be slightly roughened with a steel file or wire brush to produce proper adhesion of the cap. If desired, capping plates may be coated with a thin layer of mineral oil or grease to prevent the capping material from adhering to the surface of the plate.

Form the caps as described in Section 6.1 using capping plates described in Section 4.1 to achieve the alignment required in Section 4.2 (Note 10). Generally capping plates may be removed within 45 minutes with gypsum cement pastes and after 12 hours with neat cement paste, without visibly damaging the cap.

Note 10—A number of methods have been used to obtain the desired perpendicularity of the cap to the axis of the cylinder. A mound of paste can be placed on a capping plate and the specimen lowered into it. A bull's-eye level on the top of the cylinder helps obtain alignment. A mound of paste can be placed on top of the cylinder and a capping plate pressed into it, again using the bull's-eye level. A better system is to make a half-height mold with a vertical split so that it can be slipped over the hardened cylinder. A clamp is used to position the mold and to ensure the required cap thickness. The mound of paste can then be placed either on a capping plate or on top of the cylinder and pressed until the plate contacts the mold. As noted earlier, very stiff paste may require excessive force and produce thick or defective caps.

6.2.2 *End Condition*—The distance of any point on an uncapped end from a plane that passes through the highest point of the end surface and is perpendicular to the axis of the cylinder shall not exceed 3 mm (0.125 in.) (Note 11). If the end exceeds this limit, the end of the cylinder shall be cut, lapped or ground prior to capping.

Note 11—This provision is to control the difference between the thickest and thinnest parts of a cap. The distance may be checked using a square with one blade touching the cylinder parallel to the cylinder axis and the other blade touching the highest point on the end of the cylinder. The distance between the blade of the square and the lowest point on the end of the cylinder is measured.

6.2.3 *Capping with High-Strength Gypsum Plaster*—Mix high-strength plaster for capping, using the same percent of mixing water as was used in making the qualification test described in Section 5.2.1 (Note 12).

Note 12—High-strength gypsum caps soften and deteriorate on contact with water and cannot be used on freshly mixed concrete or stored in a moist room for more than very brief periods up to 4 hours.

6.2.4 *Capping with Sulfur Mortar*—Prepare sulfur mortar for use by heating to about 130ºC (265ºF), as periodically determined by an all-metal thermometer inserted near the center of the mass. Empty the pot and recharge with fresh material at frequent enough intervals to ensure that the oldest material in the pot has not been used more than five times (Note 13). Fresh sulfur mortar must be dry at the time it is placed in the pot as dampness may cause foaming. Keep water away from molten sulfur mortar for the same reason. The capping plate or device should be warmed slightly before use to slow the rate of hardening and permit the production of thin caps. Oil the capping plate lightly and stir the molten sulfur mortar immediately prior to pouring each cap. The ends of moist-cured specimens shall be dry enough at the time of capping to preclude the formation of steam or foam pockets under or in the cap larger than 6 mm (0.25 in.) in diameter. To ensure that the cap shall be bonded to the surface of the specimen, the end of the specimen shall not be oiled prior to application of the cap. When using a vertical device, pour the mortar onto the surface of the capping plate, lift the cylinder above the plate and contact the cylinder sides with the guides; slide the cylinder down the guides onto the capping plate while keeping constant contact with the alignment guides. The cylinder end should continue to rest on the capping plate with cylinder sides in positive contact with the alignment guides until the mortar has hardened. Use sufficient material to cover the cylinder end after the sulfur mortar solidifies. The sulfur mortar cap may be tapped or rubbed with a light metal implement. If a hollow sound is produced, an unsatisfactory mortar cap is indicated. See Section 25.16 of the ASTM *Manual of Aggregate and Concrete Testing*.

Note 13—Reuse of material must be restricted in order to minimize loss of strength and pourability occasioned by contamination of the mortar with oil, miscellaneous debris, and loss of sulfur through volatilization.

6.2.4.1 **Caution**—Hydrogen sulfide gas may be produced during capping when sulfur mortar is contaminated with organic materials such as paraffin or oil. The gas is colorless and has a notoriously bad odor of rotten eggs; however, the odor should not be relied upon as a warning sign, since the sensitivity to the odor disappears rapidly on exposure. High concentrations are lethal and less concentrated dosages may produce nausea, stomach ache, distress, dizziness, headache, or irritation of the eyes. For this and other reasons, it is desirable that the melting pot be located under a hood or near an exhaust fan and that the capping area be well ventilated.

6.2.5 *Daily Check*—During each day's capping operation, planeness of the caps on at least three specimens representing the start, middle, and end of the run, shall be checked by means of a straightedge and feeler gauge, making a minimum of three measurements on different diameters to ensure that the surfaces of the caps do not depart from a plane by more than 0.05 mm (0.002 in.).

7. PROTECTION OF SPECIMENS AFTER CAPPING

7.1 Moist-cured specimens shall be maintained in a moist condition between the completion of capping and the time of testing by returning them to moist storage or wrapping them with a double layer of wet burlap. Specimens with gypsum plaster caps shall not be immersed in water and shall not be stored in a moist room for more than 4 hours. If stored in a moist room, the plaster caps shall be protected against water dripping on their surfaces.

APPENDIX

(Nonmandatory Information)

X1. COMPOSITION AND DETERMINATION OF LOSS ON IGNITION OF SULFUR MORTAR CAPPING MATERIALS

X1.1. *Composition*:

X1.1.1. Loss on ignition, percent 48 to 70 Residue after ignition, percent 30 to 52.

X1.2. *Determination of Loss on Ignition*—Obtain samples from caps on concrete cylinders or from cast specimens similar to caps in size and thickness. Divide each cap-size specimen into eight approximately equal triangular sections, and secure test samples by breaking either two or four of the triangular sections into small pieces with the fingers. Using a balance capable of determining mass to an accuracy of 0.01 g, measure out 20 to 25 g of fragmented material in a previously ignited, cooled, and tared Coors No. 3, high-form porcelain crucible. Place the crucible on a ring approximately 50 mm (2 in.) above a Terrel-type bunsen burner and adjust the flame so that the sulfur burns slowly without spattering (Note X1). (See Section 4.) When the sulfur has been completely consumed, adjust the burner for high heat and ignite the residue for 30 minutes. Cool the crucible and residue in a desiccator and determine the mass. Continue to ignite, cool, and determine the mass of the crucible until a constant mass is obtained. Calculate the percentage of loss on ignition, C, as follows (Note X2):

$$C = \frac{A}{B} \times 100 \tag{X1.1}$$

where:

A = original mass of sample less mass of the residue after ignition, and

B = original mass of sample.

Note X1—Where the filler is known or found to be composed of carbonate minerals, the ignition test shall be made at a carefully controlled temperature in the range from 600 to 650ºC (1110 to 1200°F), to prevent calcination of the mineral. Small amounts of plasticizer and carbon filler will be included in the reported value for loss on ignition using the simple test herein described.

Note X2—A referee procedure for the determination of the percent of sulfur contained in sulfur mortar may be found in ASTM C 287.

Standard Method of Test for

Coated Dowel Bars

AASHTO Designation: T 253-02 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Coated Dowel Bars

AASHTO Designation: T 253-02 (2007)

1. SCOPE

1.1. These methods are designed to test the qualifications of the organic coating of corrosion-resistant dowel bars to withstand the effects of weathering, deicing chemicals, and the abrading and loading stresses experienced in field joints.

1.2. The units of measure to be used shall be either SI units or inch-pound units (shown in parentheses in this standard) depending on the units used in the applicable material specification.

1.3. The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortar (Using 50-mm or 2-in. Cube Specimens)

2.2. *ASTM Standards*:

- D 1474, Standard Test Methods for Indention Hardness of Organic Coatings
- G 8, Standard Test Methods for Cathodic Disbonding of Pipeline Coatings
- G 12, Standard Test Method for Nondestructive Measurement of Film Thickness of Pipeline Coatings on Steel
- G 14, Standard Test Method for Impact Resistance of Pipeline Coatings (Falling Mass Test)
- G 20, Standard Test Method for Chemical Resistance of Pipeline Coatings

3. MATERIALS AND APPARATUS

3.1. The concrete design and constituents shall comply with the procedure and specification stated by the purchasing or specifying agency.

3.2. Suitable containers, molds, and miscellaneous concrete mixing equipment necessary for mixing and casting the simulated doweled joints for load, pullout, and corrosion tests to meet condition stated in R 39.

3.3. An abradometer capable of operating at 60 to 70 double strokes per minute using 100-mm (4-in.) long strokes.

3.4. Universal test machine capable of operating accurately in the 0 to 45 kN (10000 lbf) ranges and capable of controlled stress and strain rate loading.

3.5. Suitable hold-down devices for positioning and holding the casting in place without rotation during the flexure tests.

3.6. Freeze–thaw equipment of sufficient capacity to handle the pullout and corrosion–abrasion test specimens.

3.7. Sufficient quantities of chemical to maintain solution for corrosion tests.

4. PREPARATION OF SAMPLES

4.1. The coated dowels for deflection tests may be in support baskets or loose. The coated dowels for the remainder of tests shall be loose.

4.2. Type A-coated dowels shall be cast without additional coating of any kind. Type B-coated dowels shall be covered before casting with the debonding agent specified by the coating manufacturer.

4.3. The prepared dowels shall be cast in the appropriate molds specified for the various tests.

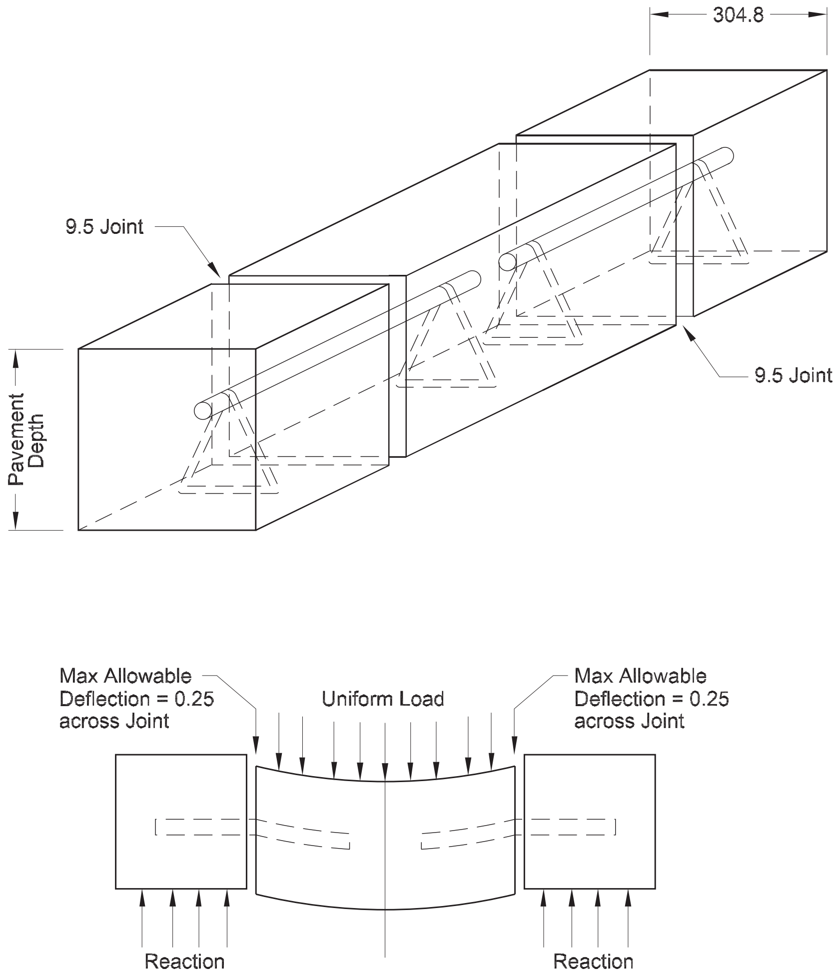
5. LOAD-DEFLECTION TEST PROCEDURE

5.1. Six dowels with basket assemblies, if any, will be utilized in three load-deflection tests. The test will be conducted in accordance with the following procedures:

5.2. Two dowels with basket assemblies, or without basket assemblies in case of loose dowels, shall be cast into each concrete test specimen in a manner to simulate two 305-mm (12-in.) long highway contraction joints. (See Figure 1.) The contraction joints are formed by dividing the mold into three sections with two-piece plates 9.5 mm ($^3/_8$ in.) thick. After the mold has been filled, the concrete shall be consolidated by vibration.

5.3. The concrete test specimens shall be made and cured in accordance with R 39. The specimens shall be removed from the molds after a 24-hour curing period, and shall be further moist-cured for a total of 14 days.

5.4. Upon completion of curing, the simulated joint shall be placed in a testing machine and loaded as illustrated in Figure 1. The end sections will be provided with suitable hold-down devices to prevent rotation. The load shall be applied at the rate of 8.9 kN/min (2000 lbf/min) until a load of 17.8 kN (4000 lbf) is obtained. The relative deflection between the loaded center section and the supported stationary ends will be measured under the 17.8 kN (4000 lbf) maximum load. Record maximum relative deflection under load.



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 1—Load-Deflection Test Specimen and Diagram

6. PULLOUT TEST PROCEDURE

6.1. Three dowels shall be tested in accordance with the following procedures:

6.2. For one-half of its length, each dowel shall be cast into a 152.4-mm (6-in.) diameter concrete cylinder. Care shall be taken to assure that the dowels are on the centerline axis of the concrete cylinder. The concrete shall be consolidated by vibration.

6.3. Cure the molded specimens in accordance with R 39. Remove the molds from the specimens after the first 24 hours of a 48-hour moist-curing period.

6.4. After 48-hour curing ±2 hours, place the concrete cylinder in the testing machine and apply a tensile load parallel to the axis of the dowel. Record the maximum pullout tensile load for the first 12.7 mm (0.5 in.) of movement for each of the three test specimens. The testing machine shall be adjusted to a free-running speed of 0.76 mm/min (0.030 in./min) prior to performing this test and this setting shall be maintained during the test.

6.5. After the first 12.7 mm (0.5 in.) of movement of the dowels, the test specimens will be further cured as before for an additional 12 days. Then the test specimens will be placed in a 10 mass percent sodium chloride solution in such a manner as to inundate half of the cross-section perimeter of the dowels. The sodium chloride solution will be maintained at this level and once a week it will be replaced by a fresh solution. The partially submerged specimens will be subjected to 50 cycles of freezing and thawing consisting of freezing in air for 16 hours at a temperature of –28.9 ± 1.7ºC (–20 ± 3ºF) and thawing in air for 8 hours at a temperature of 22.8 ± 1.7ºC (73 ± 3ºF).

6.6. Upon completion of the freeze–thaw cycling, the test specimens will again be placed in the testing machine and the pullout load redetermined by pulling out the dowels an additional 12.7 mm (0.5 in.) at the rate specified in Section 6.4. Again record the maximum tensile load for each of the specimens.

6.7. After the total 25.4-mm (1-in.) movement of the dowel, remove the concrete by breaking it away from the dowel. The dowel and the concrete–dowel interface will be examined for corrosion, tearing, and perforation.

7. CORROSION–ABRASION TEST PROCEDURE

7.1. Three dowel bars shall be subjected to corrosion–abrasion testing in accordance with the following procedures:

7.2. Abrasion resistance of the dowels will be determined by the use of an abradometer. The abradometer is operated at 60 to 70 double strokes per minute using a 100-mm (4-in.) long stroke. The abrading block is a 4-in. long mortar block made of portland cement and Ottawa sand (T 106) cast to fit over about $^1/_3$ of the perimeter of the test dowel. The test load is the 2500-g mass of the abrading assembly and block. Each dowel will be tested for a total of 10000 double strokes (from the starting point to the far end and returning to the starting point is considered one double stroke).

7.3. Upon completion of the abrading, the dowels will be examined for wear, perforation, and wrinkling.

7.4. After completion of testing in Section 7.3, determine loss of thickness due to abrasion by ASTM G 12. A minimum of five readings shall be taken in both the abraded and unabraded portions of the dowel. The average of the five readings shall determine the respective thickness.

7.5. The abraded dowels will be placed in a 10 mass percent sodium chloride solution so as to inundate half of the cross-section perimeter of the abraded area and expose the upper half to the atmosphere. The sodium chloride solution will be maintained at this level and once a week it will be replaced by a fresh solution. A sufficient length of the coated dowel will be subjected to the test so that not less than 50 mm (2 in.) of unabraded coating is tested at each end of the abraded area. The partially submerged specimens will be subjected to 50 cycles of freezing and thawing as specified in Section 6.5.

7.6. After the 50 cycles of freezing and thawing, the dowel will be removed and thoroughly examined for corrosion under five-power magnification.

8. CHEMICAL RESISTANCE TEST PROCEDURE

8.1. Three dowel bars will be subjected to chemical resistance testing in accordance with the following procedure:

8.2. Sample bars will be tested in the manner described in ASTM G 20, by immersion for 45 days in each of the following: distilled water, an aqueous solution of 3 molar $CaCl_2$, an aqueous solution of 3 molar NaOH, and a solution saturated with $Ca(OH)_2$ at a temperature of 23.9 ± 1.7ºC (75 ± 3ºF).

9. CATHODIC DISBONDING TEST PROCEDURE

9.1. Two dowel bars shall be tested to determine their resistance to cathodic disbonding in the following manner:

9.2. The test procedure shall be Method A of ASTM G 8, except: (1) the cathode and anode shall be dowel bars coated with the same material, (2) the electrolyte shall be an aqueous solution of 7 percent mass NaCl, (3) a potential of two volts shall be applied, and (4) no intentional holes shall be cut except for a single 6.4-mm ($^1/_4$-in.) diameter hole made in the middle of the immersed length in both the anode and the cathode. The test period duration shall be 30 days.

10. COATING HARDNESS TEST PROCEDURE

10.1. Three dowel bars shall be tested in the following manner to determine the hardness of the plastic coating:

10.2. The hardness of the coating shall be determined using the method of ASTM D 1474, using a 100-g (0.22-lb) mass.

11. COATING IMPACT RESISTANCE TEST PROCEDURE

11.1. Three dowel bars shall be tested in the following manner to determine the resistance of the coating to impact:

11.2. The coating shall be subjected to an impact force of 9 J (80 in.-lb) with a 1.8-kg (4-lb) tup at 23.9 ± 1.7ºC (75 ± 3ºF) according to the procedure of ASTM G 14.

12. REPORT

12.1. The report shall show all temperature, load, and miscellaneous data pertinent to the test conditions, including the following:

12.1.1. Maximum relative deflection under a 17.8-kN (4000-lbf) load for each specimen, procedure in Section 5, Load-Deflection Test Procedure.

12.1.2. Maximum kilonewton (lbf) load for pullout of each specimen after 48-hour curing period and after the subsequent 50 cycle freeze–thaw procedure in Section 6, Pullout Test.

12.1.3. Original thickness of coating and abraded thickness, procedure in Section 7, Corrosion–Abrasion Test.

12.1.4. Observation of the condition of each specimen after completion of the freeze–thaw cycling of procedure in Section 6, Pullout Test and procedure in Section 7, Corrosion–Abrasion Test.

12.1.5. Coating condition after completion of procedure in Section 8, Chemical Resistance Test.

12.1.6. Evidence, if any, of hydrogen evolution, corrosion products, undercutting or other film failure resulting from procedure in Section 9, Cathodic Disbonding Test.

12.1.7. Coating hardness as determined by procedure in Section 10, Coating Hardness Test.

12.1.8. Nature of the coating failure, if any, when subjected to procedure in Section 11, Coating Impact Resistance Test.

Standard Method of Test for

Resistance of Concrete to Chloride Ion Penetration

AASHTO Designation: T 259-02 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Resistance of Concrete to Chloride Ion Penetration

AASHTO Designation: T 259-02 (2006)

1. SCOPE

1.1. This method covers the determination of the resistance of concrete specimens to the penetration of chloride ion. It is intended for use in determining the effects of variations in the properties of concrete on the resistance of the concrete to chloride ion penetration. Variations in the concrete may include, but are not limited to, changes in the cement type and content, water–cement ratio, aggregate type and proportions, admixtures, treatments, curing, and consolidation. This test method is not intended to provide a quantitative measure of the length of service that may be expected from a specific type of concrete.

1.2. The values stated in SI units are to be regarded as the preferred standard.

2. TEST SPECIMENS

2.1. The specimens for use in this test shall be slabs made and cured in accordance with the applicable requirements of R 39, Making and Curing Concrete Test Specimens in the Laboratory.

Note 1—This method contemplates the use of a minimum of four specimens for each evaluation with each slab not less than 75 mm (3 in.) thick and a minimum surface area of 17,500 mm^2 (28 $in.^2$).

2.2. For this test the specimens shall be removed from moist curing at 14 days of age unless earlier removal is recommended by the manufacturer of a special concrete. The specimens shall then be stored until 28 days of age in a drying room of the type specified by T 160, Length Change of Hardened Hydraulic Cement Mortar and Concrete.

2.3. When the test method is used to evaluate concrete treatments, the slabs shall be fabricated from concrete having a cement factor of 390 kg/m^3 (658 lb/yd^3), a water–cement ratio mass of 0.5, and an air content of 6 ± 1 percent.

The concrete treatment shall be applied at 21 days of age and in accordance with the manufacturer's recommendations for field usage.

Note 2—If field application of a sealer by spraying is recommended, the sealer should be applied to the specimens by spraying rather than brushing.

2.4. When a special overlay material is to be evaluated, the concrete slab shall be cast 50 mm (2 in.) thick using the mix design specified under Section 2.3 and then the special overlay material shall be placed 25 mm (1 in.) thick, unless specified otherwise, according to the manufacturer's recommendations.

3. PROCEDURE

3.1. Immediately after the specified drying period stipulated in Section 2.2 (i.e., 29th day of specimen age), 3.2 ± 1.6 mm (0.125 ± 0.062 in.) of the slab surface shall be abraded using grinding or sandblasting techniques if the concrete or treatment are to be subjected to the wearing effect of vehicular traffic. No water shall be used in the abrading process. If the concrete or treatment is to be used on surfaces not subject to wear from vehicular traffic then the abrading step shall be omitted.

3.2. Place approximately 19 mm (0.75 in.) high by 13 mm (0.5 in.) wide dams around the top edge of all slabs except one, which will then become the control slab. In lieu of this, a dam meeting these dimension requirements may be cast as an integral part of the slab. However, such previously cast dams shall not interfere with the abrasion of the surface as specified under Section 3.1.

3.3. All slabs shall then be returned to the drying room as specified under Section 2.2 for an additional 13 days (i.e., until 42 days of age).

Note 3—The degree of saturation of the specimens at the time of ponding will affect chloride ingress. In general, water saturated concrete will absorb significantly less chloride during the 90 days of ponding than a drier but similar material. Thus, for proper definition of chloride ingress by this method, the requirements in Sections 2.2 and 3.1 through 3.3 (for a total of 28 days of air drying prior to ponding) must be followed.

3.4. The slabs with dams shall be subjected to continuous ponding with 3-percent sodium chloride solution to a depth of approximately 13 mm (0.5 in.) for 90 days. Glass plates shall be placed over the ponded solutions to retard evaporation of the solution. Placement of the glass plates shall not be done in such a manner that the surface of the slab is sealed from the surrounding atmosphere. Additional solution shall be added if necessary to maintain the 13 mm (0.5 in.) depth. All slabs shall then be returned to the drying room as specified under Section 2.2.

3.5. After 90 days of exposure the solution shall be removed from the slabs. The slabs shall be allowed to dry and then the surfaces shall be wire brushed until all salt crystal buildup is completely removed.

3.6. Samples for chloride ion analysis shall then be taken from all slabs in accordance with the procedure described in T 260. These samples shall be obtained from each slab at each of the following depths unless otherwise directed by the specifying agency:

- 1.6 mm (0.0625 in.) to 13 mm (0.5 in.), and
- 13 mm (0.5 in.) to 25 mm (1.0 in.).

The chloride content of each sample shall be determined in accordance with the instructions in T 260.

Note 4—Many starter bits for use inside hollow rotary hammer pulverizing bits are significantly longer than the pulverizing bit. This results in a sampling depth that is greater in the center of the “core hole” than at the edges. To minimize this effect, the chuck end of the starter bit should be cut off such that its overall length does not exceed that of the outside bit by more than 1.6 mm ($^1/_{16}$ in.) (i.e., such that the variation in sampling depth is not greater than 1.6 mm ($^1/_{16}$ in.)). When it is desired to remove only 1.6 mm ($^1/_{16}$ in.) of material from the surface of a test specimen or a bridge deck, it may be more convenient to complete that operation by use of a grinder. The sample can then be taken with the rotary hammer without fear of contamination from the salt on the surface of the item being sampled.

4. CALCULATIONS

4.1. The baseline chloride ion content for the test specimens shall be determined as the average chloride ion content of samples obtained from the 1.6-mm (0.0625 in.) to 13-mm (0.5-in.) and 13-mm (0.5-in.) to 25-mm (1-in.) depths within the slab that was not ponded with 3-percent sodium chloride solution.

4.2. The absorbed chloride ion content of each sample from the ponded slabs shall be determined as the difference between the total chloride ion content of that sample and the baseline value calculated in Section 4.1. If the result is less than zero, the result shall be reported as zero. The average chloride ion absorbed at each sampling depth shall be calculated.

5. REPORT

5.1. Reporting shall include (1) each total chloride ion value determined in Section 3.6, (2) the average and maximum baseline chloride ion (Section 4.1), (3) each calculated absorbed chloride ion value determined in Section 4.2, (4) the average and maximum absorbed chloride ion values calculated in Section 4.2 for each depth, (5) a statement detailing whether or not the surface abrasion described in Section 3.1 was performed.

Standard Method of Test for

Sampling and Testing for Chloride Ion in Concrete and Concrete Raw Materials

AASHTO Designation: T 260-97 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling and Testing for Chloride Ion in Concrete and Concrete Raw Materials

AASHTO Designation: T 260-97 (2009)

1. SCOPE

1.1. This method covers procedures for the determination of the acid-soluble chloride ion content or the water-soluble chloride ion content of aggregates, portland cement, mortar or concrete.

1.2. The total amount of chloride is usually equal to the acid-soluble chloride. However, organic additives or minerals that contain acid-insoluble chloride may be present in concrete and concrete raw materials. These constituents may become acid soluble during long-term exposure to the alkaline environment in concrete or mortar.

1.3. The age of concrete mortar, or hydrated portland cement at the time of sampling will have an affect on the water-soluble chloride ion content. Therefore, unless early age studies are desired, it is recommended that the material be well cured and at least 28 days of age before sampling.

1.4. This standard provides for the determination of chloride ion content by two procedures: Procedure A, Determination of Acid-Soluble Chloride Ion Content and Water-Soluble Chloride Ion Content by Potentiometric Titration or Ion-Selective Electrode (Laboratory Test Method); and Procedure B, Acid-Soluble Chloride Ion by Atomic Absorption (Laboratory Test Method).

1.5. Sulfides are known to interfere with the determination of chloride content. Blast-furnace slag aggregates and cements contain sulfide sulfur in concentrations that can cause such interference, which can be eliminated by treatment as noted in the test procedures. Other materials that produce a strong odor of H_2S when acid is added to them should be similarly treated.

1.6. The values stated in SI units are to be regarded as the preferred standard.

PROCEDURE A—ACID-SOLUBLE CHLORIDE ION AND WATER-SOLUBLE CHLORIDE ION BY POTENTIOMETRIC TITRATION OR ION SELECTIVE ELECTRODE (LABORATORY TEST METHOD)

2. APPARATUS

2.1. Sampling equipment for Procedures A and B are listed in Sections 2.1.1 or 2.1.2.

2.1.1. Core drill.

2.1.2. Rotary impact-type drill with a depth indicator and drill or pulverizing bits of sufficient diameter to provide a representative sample of sufficient size for testing.

2.1.2.1. Sample containers capable of maintaining the sample in an uncontaminated state.

2.1.2.2. Spoons of adequate size to collect the sample from the drilled holes.

2.1.2.3. A "blow out" bulb or other suitable means of removing excess pulverized material from the hole prior to re-drilling operations.

2.1.2.4. A device capable of determining the location and depth of steel reinforcement to ±3 mm ($\pm^1/_8$ in.).

2.2. *Equipment for Chemical Testing*:

2.2.1. Chloride ion or silver/sulfide ion selective electrode and manufacturer-recommended filling solutions.

Note 1—Suggested electrodes are the Orion 96-17 Combination Chloride Electrode or the Orion 94-6 Silver/Sulfide Electrode or equivalents. The Silver/Sulfide Electrode requires use of an appropriate reference electrode (Orion 90-02 or equivalent).

2.2.2. A millivoltmeter compatible with the ion electrode.

Note 2—Suggested millivoltmeter is the Orion Model 701 A Digital ph/mV meter or equivalent.

2.2.3. Magnetic stirrer and Teflon stirring bars.

2.2.4. Burette with 0.1-mL graduations.

2.2.5. Balance complying with M 231, Class A.

2.2.6. Balance complying with M 231, Class G 2.

2.2.7. Hot plate, 250 to 400ºC heating surface temperature.

2.2.8. Glassware, 100 and 250-mL beakers, filter funnels, stirring rods, watch glasses, dropper, wash bottles.

2.2.9. Sieve, U.S. Standard 300 μm (No. 50).

2.2.10. Whatman No. 40 and No. 41 filter papers (or equivalent).

Note 3—If equivalent filter papers are used, they should be checked to confirm they do not contain chloride, which will contaminate the sample.

3. REAGENTS

3.1. Concentrated HNO_3 (sp gr 1.42).

3.2. Sodium chloride, NaCl, reagent grade (primary standard).

3.3. Standard 0.01 normality NaCl solution. Dry reagent grade NaCl in an oven at 105ºC. Cool, in a desiccator, determine the mass of approximately 0.5844 g to the nearest 0.0001 g, dissolve in distilled H_2O, and transfer to a 1-L volumetric flask. Make up to the mark with distilled H_2O and mix. Calculate the exact normality as follows:

$$N_{\text{NaCl}} = (0.0100)\frac{(W_{\text{actual}})}{0.5844} \tag{1}$$

where:

W_{actual} = actual mass of NaCl, and

N_{NaCl} = normality of NaCl solution.

3.4. Standard 0.01 normality $AgNO_3$. Determine the mass of 1.7 grams of reagent $AgNO_3$, dissolve in distilled H_2O, filter into a 1-L brown glass bottle, fill, and mix thoroughly. Standardize against 25.00 mL of the NaCl solution by the titration method given in Section 5.4. Calculate the exact normality as follows:

$$N_{\text{AgNO}_3} = \frac{(V_{\text{NaCl}})(N_{\text{NaCl}})}{V_{\text{AgNO}_3}} \tag{2}$$

where:

N_{AgNO_3} = normality of $AgNO_3$ solution,

V_{NaCl} = volume (mL) of NaCl solution,

N_{NaCl} = normality of NaCl solution, and

V_{AgNO_3} = volume (mL) of $AgNO_3$ solution.

3.5. Distilled Water.

Note 4—Deionized water may be used in place of distilled water for samples where extreme precision and accuracy are not demanded.

3.6. Methyl orange indicator.

3.7. Ethanol, denatured, or methanol, technical.

3.8. Hydrogen Peroxide (30 percent).

4. METHOD OF SAMPLING

4.1. *Concrete Sample*:

4.1.1. Determine the depth within the concrete for which the chloride content is desired.

Note 5—A convenient method of determining the location and depth of reinforcement bars is a pachometer capable of determining the location and depth of steel reinforcement to ±3 mm (0.125 in.).

4.1.2. *Core Method*—Drill the core to chosen depth and retrieve.

4.1.2.1. When samples are received in the laboratory in other than pulverized condition, the sample shall be crushed and ground to a powder. All sawing or crushing shall be done dry (i.e., without water). All material shall pass a 0.300-mm (No. 50) sieve. All pulverizing tools and sieves shall be washed with alcohol or distilled water and shall be dry before use with each separate sample. (See note following Section 4.1.3.7.)

4.1.3. *Pulverizing Method*:

4.1.3.1. Set the rotary hammer depth indicator so that it will drill to 13 mm (0.5 in.) above the desired depth.

4.1.3.2. Using a drill or pulverizing bit, drill until the depth indicator seats itself on the concrete surface.

4.1.3.3. Thoroughly clean the drilled hole and surrounding area utilizing the “blow out” bulb or other suitable means.

4.1.3.4. Reset the depth indicator to permit 13 mm (0.5 in.) additional drilling.

4.1.3.5. Pulverize the concrete until the depth indicator again seats itself on the concrete.

Note 6—Care must be exercised during this pulverizing operation to prevent the drill bit from abrading concrete from the sides of the hole above the sampling depth. To insure against this, some users utilize a 6-mm (0.25-in.) smaller diameter bit in this step than that used in Section 4.1.3.2.

4.1.3.6. Collect at least 10 g of the material remaining in the hole using a spoon and place in the sample container.

4.1.3.7. If the sample, as collected, does not completely pass a 0.300-mm (No. 50) sieve, additional pulverizing shall be performed in the laboratory until the entire sample is finer than 0.300-mm (No. 50).

Note 7—During sample collection and pulverizing, personnel shall use caution to prevent contact of the sample with hands, or other sources of body perspiration or contamination. Further, all sampling tools (drill bits, spoons, bottles, sieves, etc.) shall be washed with alcohol or distilled water and shall be dry prior to use on each separate sample. Alcohol is normally preferred for washing because of the rapid drying, which naturally occurs.

4.2. *Raw Material Sample*:

4.2.1. Cement samples shall be taken and prepared as prescribed in T 127, Sampling and Amount of Testing Hydraulic Cement.

4.2.2. Coarse and fine aggregate samples shall be taken as prescribed in T 2, Sampling of Aggregates. Samples shall be reduced in accordance with T 248, Reducing Samples of Aggregates to Testing Size.

4.2.3. Test samples shall contain the following minimum sizes:

- cement—100 g,
- sand—300 g,
- coarse aggregate—3000 g.

4.2.4. Coarse aggregate samples shall be crushed to pass a 4.75-mm (No. 4) sieve and then reduced down to about 300 g. The final 300 g of coarse or fine aggregate shall be ground to a minus 0.300-mm (No. 50) sieve.

5. PROCEDURE

Two distinct procedures are presented here for determination of acid-soluble chloride ion or water-soluble chloride ion content. For acid-soluble chloride ion content follow Sections 5.1 and 5.2, then continue with Section 5.4. For water-soluble chloride ion content follow Sections 5.1 and 5.3, then continue with Section 5.4.

5.1. Determine the mass to the nearest milligram of a 3-g powdered sample representative of the material under tests.

Note 8—Some users dry the sample to constant mass in a 105ºC oven and determine the dry sample prior to analysis. This optional procedure provides a constant base for comparison of all results by eliminating moisture content as a variable. It is generally believed that drying is only necessary when very high accuracy is desired. (See Reference 1 for data in this area.)

5.2. *Procedure for Acid-Soluble Chloride Ion Content*:

5.2.1. Transfer the sample quantitatively to a beaker; add 10 mL of distilled H_2O, swirling to bring the powder into suspension. Add 3 mL of concentrated HNO_3 with continued swirling until the material is completely decomposed. Break up any lumps with a stirring rod and dilute with hot H_2O to 50 mL. Stir thoroughly to ensure complete sample digestion.

If the sample contains blast-furnace slag or other sulfide-bearing material, add 3 mL of hydrogen peroxide (30 percent solution).

Add five drops of methyl orange indicator and stir. If yellow to yellow-orange color appears, solution is not sufficiently acidic. Add additional concentrated HNO_3 dropwise with continuous stirring until a faint pink or red color persists in the solution. Cover with a watch glass, retaining the stirring rod in the beaker. Heat the acid solution or slurry to boiling on a hot plate at medium heat (250 to 400ºC) and boil for about 1 minute. Remove from the hot plate, filter through double filter paper (Whatman No. 41 over No. 40 filter paper or equivalent).

5.2.2. Wash the filter paper 10 times with hot distilled H_2O, being careful not to lift the paper away from the funnel surface. Finally, lift the filter paper carefully from the funnel and wash the outside surface of the paper with hot distilled H_2O; then wash the tip of the funnel. The final volume of the filtered solution should be 125 to 150 mL. Cover with a watch glass and allow to cool to room temperature in an HCl fume-free atmosphere.

Note 9—Due to the presence of relatively insoluble materials in the sample, the solution generally will have a strong gray color, making the detection of indicator color difficult at times. Running of several trial samples is suggested to give the analyst practice in detecting the indicator color.

Note 10—A sample prepared to 100 percent passing 0.300-mm (No. 50) sieve should generally allow determination of any expected chloride level with adequate precision and accuracy. Samples containing highly siliceous aggregates may require finer grinding to minimize bumping during the procedure in Section 5.2. This may also be the case when the concrete contains modifiers such as latex or polymer.

5.3. *Procedure for Water-Soluble Chloride Ion Content*:

5.3.1. Transfer the sample quantitatively to a beaker, add 60–70 mL distilled H_2O. Cover the beaker with a watch glass and bring to a boil on a hot plate-magnetic stirrer using a small magnet. Boil for 5 minutes, then let stand for 24 hours in an HCl fume-free atmosphere.

5.3.2. Filter the clear supernatant liquid in the beaker through double filter paper (Whatman No. 41 over No. 40 or equivalent) into a 250-mL beaker; take care to quantitatively transfer any adhering drops on the watch glass, and use a stirring rod to aid transfer. Add sufficient hot distilled H_2O to cover any residue left in the original beaker, stir 1 minute on a magnetic stirrer, and filter into the 250-mL beaker with a swirling action. Wash the beaker and the stirring rod once into the filter with hot distilled H_2O. Wash the filter paper once with hot distilled H_2O. Lift the filter paper carefully from the funnel and wash the outside surface of the paper with hot distilled H_2O. Set aside the paper and wash the interior of the funnel and its tip with hot distilled H_2O. Finally, add 1–2 drops of methyl orange indicator to the 150-mL beaker; then add concentrated HNO_3 dropwise with continuous stirring until a permanent pink to red color is obtained. If the sample contains blast-furnace slag or other sulfide-bearing material, add 3 mL of hydrogen peroxide (30-percent solution). Make up the volume to 125 to 150 mL with distilled H_2O.

5.4. Three alternate methods are available to determine the Cl^- content of the solution. All methods utilize an ion selective electrode (Cl^- or Ag^+) and all methods for the purpose of this analysis give results of essentially equal accuracy and precision.

5.4.1. *Method 1: Potentiometric Titration*—Fill the Cl^- or the Ag^+ electrode with the solution(s) recommended by the manufacturer, plug it into the millivoltmeter (preferably the type with a digital rather than a dial readout), and determine the approximate equivalence point by immersing the electrode in a beaker of distilled H_2O. Note the approximate millivoltmeter reading (which may be unsteady in H_2O). Take the cooled sample beaker from Section 5.3 and carefully add 4.00 mL of 0.0100 normality NaCl, swirling constantly. Remove the beaker of distilled H_2O from the electrode, wipe the electrode with absorbent paper, and immerse the electrode in the sample solution. Place the entire beaker-electrode assembly on a magnetic stirrer and begin gentle stirring. Using a calibrated buret, add gradually and record the amount of standard 0.01 normality $AgNO_3$ solution necessary to bring the millivoltmeter reading to –40 mV of the equivalence point determined in distilled H_2O. Then add standard 0.01 normality $AgNO_3$ solution in 0.10 mL increments recording the millivoltmeter reading after each addition.

As the equivalence point is approached, the equal additions of $AgNO_3$ solution will cause larger and larger changes in the millivoltmeter reading. Past the equivalence point, the changes per unit volume will again decrease. Continue the titration until the millivoltmeter reading is at least 40 mV past the approximate equivalence point.

The endpoint of the titration usually is near the approximate equivalence point in distilled water and may be determined by (1) plotting the volume of $AgNO_3$ solution added versus the millivoltmeter readings. The endpoint will correspond to the point of inflection of the resultant smooth curve, or (2) calculating the differences in millivoltmeter readings between successive $AgNO_3$ additions and calculating the total volume of $AgNO_3$ that corresponds with each difference (i.e., the midpoints between successive additions).

Raw Data		Differences	
Titrant Volume	Millivolt Reading	Titrant Midpoints	Millivolt Difference
4.2 mL	130.0	4.25 mL	5.0
4.3 mL	135.0	4.35 mL	7.0
4.4 mL	142.0	4.45 mL	10.0
4.5 mL	152.0	etc.	
etc.			

The endpoint will be near the midpoint, which produced the largest change in millivoltmeter reading. It may be determined by plotting midpoints versus differences and defining the $AgNO_3$ volume, which corresponds to the maximum difference on a smooth, symmetrical curve drawn through the points. However, it can usually be estimated accurately without plotting the curve by choosing the midpoint, which corresponds to the maximum difference and adjusting for asymmetry, if any. In other words, if the differences on each side of the largest difference are not symmetrical, adjust the endpoint mathematically in the direction of the largest differences. Detailed examples of this adjustment are contained in Reference 1.

5.4.1.1. *Calculations*:

Determine the endpoint of the titration as described in Section 5.4.1 by either plotting a curve or estimating from the numerical data. Calculate the percent Cl^- ion from the equation:

$$Cl^- \text{ percent} = \frac{\left(3.5453\left(V_1N_1 - V_2N_2\right)\right)}{W} \qquad (3)$$

where:

V_1 = endpoint in mL of $AgNO_3$;

N_1 = normality of $AgNO_3$;

W = mass of original concrete sample in grams;

V_2 = volume of NaCl solution added, in mL; and

N_2 = normality of NaCl solution.

5.4.2. *Method II: Gran Plot Method*—This method is compatible with either a Cl^- or Ag^+ ion selective electrode. Attach the electrode of choice to a compatible digital millivoltmeter after filling the required solutions as per the electrode manufacturer's instructions. Clean the electrode with distilled H_2O and pat dry with absorbent paper.

Determine the mass of the solution and beaker from Section 5.3 without the watch glass and record the mass. Using a calibrated buret, titrate the sample to 225 ± 5 mV (Cl^- electrode) or 310 ± 5 mV (Ag^+ electrode) with standard 0.01 normality $AgNO_3$ solution. Record the volume added and the millivoltmeter reading.

Continue to titrate in 0.50-mL increments recording the volume added and the millivoltmeter reading for each increment. Add and record the data for at least five increments. Empty, clean, dry, and determine the mass of the beaker. Subtract beaker mass from beaker + solution mass determined above to define solution mass.

Example shown in Figure 1. Additional information on the Gran Method is given in Reference 2.

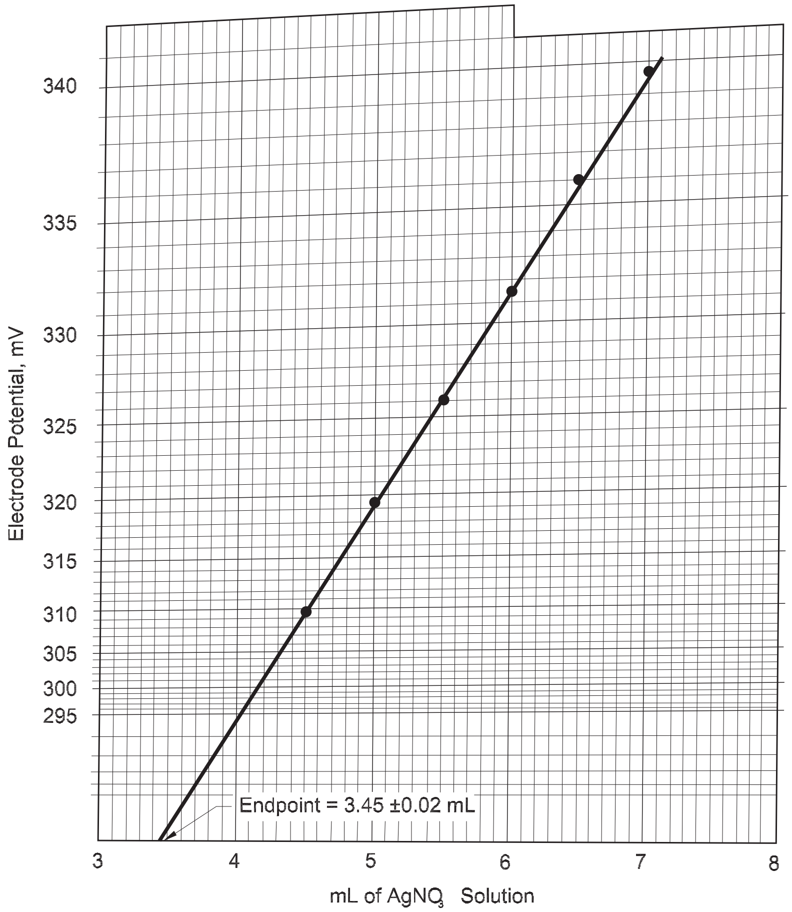


Figure 1—Use of Gran Method to Determine Endpoint in the Potentiometric Titration of an Acid Extract of Concrete

5.4.2.1. *Gran Method Calculations*:

Calculate corrected values for each of the volumes recorded in Section 5.4.2 by the equation:

$$V_{\text{correct}} = \frac{V_{\text{record}}}{W/100} \qquad (4)$$

W = original solution mass in g, and

V_{record} = volumes recorded in mL.

If any of the V correct values are greater than 10, see Section 5.4.2.2. If less than 10, plot these corrected values versus the corresponding millivolt readings on Orion Gran Plot Paper (10 percent volume corrected type with each major vertical scale division equal to five millivolts) or equivalent. Draw the best straight line through the points and read the endpoint at the intersection of the line with the horizontal axis of the graph. Calculate the actual endpoint by the equation:

$$E_a \text{ Actual Endpoint} = E_g\left(\frac{W}{100}\right) \qquad (5)$$

where:

E_g = endpoint determined from graph in mL, and

W = mass of solution in g.

then:

$$\text{Percent Cl} = \frac{3.5453\, E_a N}{W_c} \tag{6}$$

where:

E_a = actual endpoint in mL,

N = normality of $AgNO_3$ solution, and

W_c = concrete sample mass in g.

5.4.2.2. *Supplementary Gran Method Calculations*:

When the V correct volumes determined in Section 5.4.2.1 are greater than 10, discard the values and follow the following procedure.

Choose a constant which, when subtracted from all V record volumes, yields values less than 10 mL.

Note 11—This constant, designated as X in the formulas below, is normally assigned an even value such as 5, 10, 15, 20, etc.

Calculate a revised solution mass (W_r) as:

$$W_r = W + X \tag{7}$$

where:

W = original solution in g, and

X = the constant.

Then calculate corrected volumes for each recorded volume as:

$$V_{\text{correct}} = \frac{V_{\text{record}} - X}{W_r/100} \tag{8}$$

Plot these values and determine the graph endpoint E_g as described in Section 5.4.2.1. The actual endpoint (E_a) is then:

$$E_a = E_g\left(\frac{W_r}{100}\right) + X \tag{9}$$

where:

E_a = actual endpoint in mL,

E_g = endpoint from graph in mL,

W_r = revised solution mass in g, and

X = the constant chosen above.

Calculate the chloride content using the formula given in Section 5.4.2.1.

5.4.3. *Method III: Automatic Titrator*—This method is compatible with either a Cl^- or Ag^+ ion-selective electrode. The millivolt endpoint determination and testing procedure shall be in accordance with the instrument manufacturer's recommendation.

5.4.3.1. *Automatic Titrator Calculations*:

Having determined the endpoint with the automatic titrator, calculations will be identical with Section 5.4.1.1.

5.5. The percent chloride may be converted to kg of Cl/m^3 (lb/yd^3) of concrete as follows:

$$\text{kg Cl}/\text{m}^3 = \text{Percent Cl}\left(\frac{UW}{100}\right) \tag{10}$$

$$\left(\text{lb Cl}^{-}/\text{yd}^{3} = \text{Percent Cl}\left(\frac{UW}{100}\right)\right) \qquad (11)$$

where:

UW = unit mass of concrete per cubic meter (cubic yard).

Note 12—A unit mass of 2323 kg/m^3 (3915 lb/yd^3) is often assumed for normal structural mass concrete when the actual unit mass is unknown.

6. PRECISION

6.1. The precision statements presented below are based on guidelines presented in ASTM C 670, Preparing Precision Statements for Test Methods for Construction Materials. They are, of necessity slightly different since the within-laboratory standard deviation was essentially constant over the chloride levels examined while the between-laboratory precision varied with chloride level. Both statements, however, are based on the difference two-sigma limit, (d2s). The (d2s) index is the difference between two individual test results that would be equaled or exceeded in the long run in only 1 case in 20 in the normal and correct operation of the chemical analysis.

6.2. *Single-Operator*—The single-operator standard deviation has been found to be 0.0024 percent chloride.[1] Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 0.0068-percent chloride.[1]

6.3. *Multilaboratory Precision*—Criteria for judging the acceptability of chloride ion concentration test results obtained by different laboratories by this test method are given in Table 1.

Table 1—Multilaboratory Precision

Percent Chloride Concentration Multilaboratory Precision	Standard Deviation[a]	Acceptable Range of Two Results[a]
0.0176	0.0030	0.0085
0.0268	0.0031	0.0088
0.0313	0.0032	0.0091
0.0592	0.0037	0.0105
0.1339	0.0048	0.0136
0.2618	0.0069	0.0195

[a] These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM 670, Recommended Practice for Preparing Precision Statements for Test Methods for Construction Materials.

Note: The figures given in Column 2 are the standard deviations that have been found to be appropriate for the chloride ion concentrations described in Column 1. The figures given in Column 3 are the limits that should not be exceeded by the difference between the results of two properly conducted tests.

PROCEDURE B—ACID-SOLUBLE CHLORIDE ION BY ATOMIC ABSORPTION (LABORATORY TEST METHOD)

7. APPARATUS

7.1. See Section 2.1 for sampling equipment.

7.2. *Equipment for Chemical Testing*:

7.2.1. Atomic Absorption Spectrophotometer.

Note 13—The text of this method is most applicable to the use of a Perkin Elmer Model 503 A.A., with a 50-mm (2-in.) path length burner and digital readout. Laboratories using instruments other than Perkin Elmer should utilize the method to the fullest extent possible.

7.2.2. Millipore filter assembly No. XX1104710 (47 mm in diameter), or equivalent. Millipore filter membrane No. HAWPO4700 (0.45-μm membrane), or equivalent.

Note 14—If equivalent filter membranes are used, they should be checked to confirm they do not contain chloride, which will contaminate the sample.

7.2.3. 100-mL volumetric flasks with glass stoppers (clear glass).

7.2.4. 100-mL volumetric flasks (low actinic with glass stoppers).

7.2.5. Pipettes of suitable sizes, which meet or exceed the tolerances specified in NBS circular 602 for Class A Volumetricware.

7.2.6. Analytical balance sensitive to 0.0001 g complying with M 231, Class A.

7.2.7. Fisher filtrator (vacuum) with either a glass or plastic bell jar, tall enough to place a 100-mL volumetric flask underneath.

7.2.8. Hot plates (electric).

7.2.9. Vacuum source.

7.2.10. Vinyl tubing.

8. REAGENTS

8.1. Calcium carbonate, reagent grade.

8.2. Hydrogen peroxide (30 percent).

8.3. Methyl orange.

8.4. Nitric acid, concentrated (sp gr 1.42).

8.5. Silver nitrate, reagent grade (primary standard).

8.6. Sodium chloride, reagent grade (primary standard).

8.7. Sodium nitrate, reagent grade.

8.8. Water, distilled.

9. METHOD OF SAMPLING

9.1. See Section 4 for method of sampling.

10. STANDARDIZATION

10.1. Dry a sufficient quantity of standard materials ($AgNO_3$, NaCl, $CaCO_3$, and $NaNO_3$) at 105ºC to constant mass. Cool and retain in a desiccator.

10.1.1. Determine the mass of a sufficient sample of each of the above standards to effect the following solutions:

- Ag^+, 100 mg/L,
- Cl^-, 100 mg/L,
- Na^+, 100 mg/L, and
- Ca^{++}, 500 mg/L.

10.2. Add 10 mL of 1 + 9 HNO_3 to each of eight 100-mL low actinic volumetric flasks. Aliquot sufficient chloride solution so that each flask will contain a chloride ion concentration of 0.0, 0.1, 0.25, 0.50, 0.75, 1.0, 2.0, and 3.0 mg/L, respectively. The 0.0 concentration will be the 10-mg/L silver standard.

10.3. Proceed with the eight volumetric flasks following Sections 11.7.1 through 11.7.3.

10.4. Set the operating parameters for A.A. in accordance with the manufacturer's procedures when using a silver lamp.

10.5. Aspirate the 10 mg/L Ag^+ standard with a zero chloride ion concentration, and set 10 mg/L in the readout window.

10.6. Aspirate the remaining seven volumetrics containing 0.1 through 3.0 mg/L chloride ion concentrations, and note the readings. Repeat this procedure at least three times on 3 different days to obtain an average reading. Develop the standardization data by aspirating randomly.

10.7. Prepare a curve on linear graph paper, plotting remaining Ag^+ ions determined by A.A. against the seven chloride standards. (See Figure 2a.)

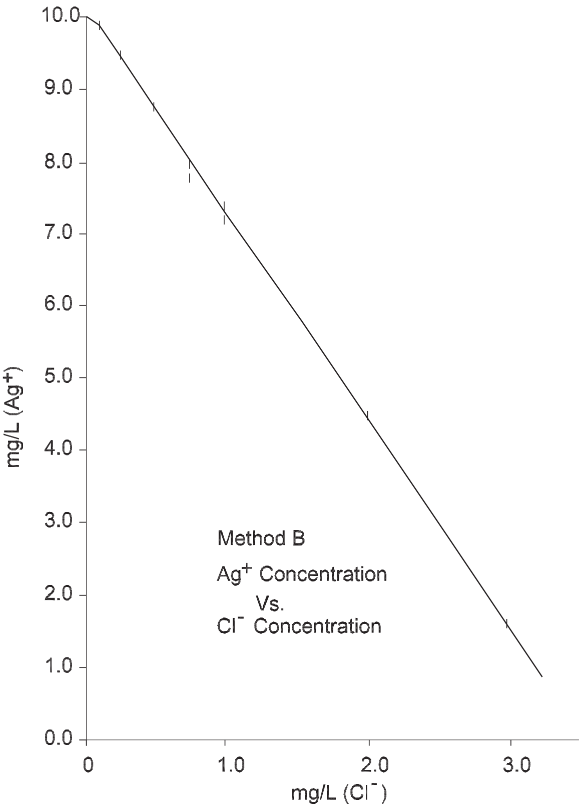

Figure 2a—Method B

11. PROCEDURE

11.1. The sample as received shall be made to pass a 300-µm (No. 50) sieve, after removing any free iron that may have been introduced in sample preparation. If received sample is excessively large, quartering may be necessary before grinding.

11.2. Dry sample at 105ºC to constant mass and cool in desiccator.

11.3. Determine the mass to the nearest mg of a one (1) g powdered sample representative of the material under test. Transfer to a 150-mL beaker, and add 10 mL of dilute nitric acid (1 + 9) to dissolve as much of the sample as possible. Break up any lumps with a stirring rod.

11.4. If carbonates are present, let sample stand until all effervescence is completed.

11.5. If the solution is not acid at this point, add only enough nitric acid to produce a red color with methyl orange.

11.6. Heat the slurry on a hot plate to just under boiling, and digest for 5 minutes or until all reaction ceases. Remove from hot plate and cool. Vacuum filter (Fisher filtrator or equivalent through a 0.45-µm membrane (Millipore filter assembly No. XX1104710, Millipore filter membrane No. HAWP04700, or equivalents) into a 100-mL volumetric flask. (See Figure 2b.) Wash the precipitate with three or four small portions of distilled water. Dilute to volume.

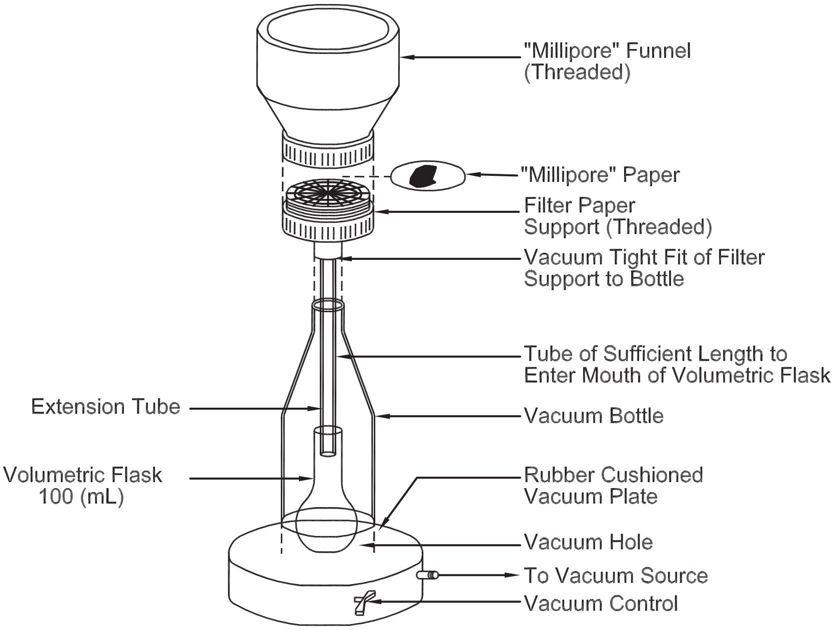

Figure 2b—Schematic Sketch of Filtration Apparatus, Method B

11.7. Aliquot 10 mL of the filtered sample solution into a 100-mL volumetric flask (low actinic). Save balance of the sample; other dilutions may be needed if concentration is relatively high.

11.7.1. Add 1.5-mL hydrogen peroxide and agitate for 1 minute.

11.7.2. Add 10 mL of the 100 mg/L silver nitrate solution. Agitate the flask once again and let stand for 1 hour.

11.7.3. Vacuum filter, using above Millipore or equivalent equipment, into a 100-mL volumetric flask (low actinic) containing 5 mL of the sodium solution and 1 mL of the calcium solution. Wash the precipitate with three or four small portions of distilled water. Dilute to volume. This filtrate contains the unreacted silver ions from the silver chloride precipitation that are found by standard atomic absorption procedures for silver, including measurements of suitable standards during the determinations.

11.7.4. Enter the curve (Figure 1) with Ag^+ remaining, and determine the chloride concentration (mg/L).

12. CALCULATION

Calculate the percentage of chloride in the concrete or concrete raw material, as indicated below:

$$\text{Percent Cl}^- = \left(\frac{1}{V}\right)\left(\frac{\text{mg/L Cl}^-}{W}\right) \qquad (12)$$

where:

V = volume of aliquot used in Section 11.7, in mL; and

W = mass of original concrete sample, in g.

This equation assumes that the aliquot is diluted to 100 mL.

13. PRECISION

Data are being compiled that will be suitable for use in developing precision statements for this method.

Standard Method of Test for

Density of Plastic and Hardened Portland Cement Concrete In-Place by Nuclear Methods

AASHTO Designation: T 271-83 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density of Plastic and Hardened Portland Cement Concrete In-Place by Nuclear Methods

AASHTO Designation: T 271-83 (2009)

1. SCOPE

1.1. These methods cover the determination of the density of plastic and hardened concrete in-place by gamma radiation.

1.2. Two methods are described as follows:

	Section
Method A—Direct Transmission	7
Method B—Backscatter	8

1.3. The values stated in SI units are to be regarded as the preferred standard.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 19M/T 19, Bulk Density ("Unit Weight") and Voids in Aggregate
- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete

3. SIGNIFICANCE AND USE

3.1. The methods described are useful as rapid, nondestructive techniques for the in-place determination of the density of plastic concrete. The backscatter method is also useful for the same purpose on hardened concrete. The fundamental assumptions inherent in the methods are that Compton scattering is the dominant interaction and that the material under test is homogeneous.

3.2. The methods are suitable for control and acceptance testing during construction, for evaluation subsequent to construction, and for research and development.

3.3. Test results may be affected by reinforcing steel, by chemical composition, and by sample heterogeneity. Results of tests by the backscatter method may also be affected by the density of underlying material. The backscatter method exhibits spatial bias in that the apparatus's sensitivity to the material under it decreases with distance from the surface of the concrete.

4. APPARATUS

4.1. The system shall consist of the following items. The exact details of construction of the apparatus may vary, but the apparatus as a whole shall satisfy the requirements for system precision stated in Section 10.1.

4.1.1. *Gamma Source*—An encapsulated and sealed radioisotopic source such as cesium-137.

4.1.2. *Detector*—Any type of gamma detector such as a Geiger-Muller tube, scintillation crystal, or proportional counter.

4.1.3. *Probe*—For direct transmission measurements, either the gamma source or the detector shall be housed in a probe for inserting in a preformed hole in the material to be tested. The probe shall be marked in increments of 50 mm (2 in.) for tests with probe depths from 50 to 300 mm (2 to 12 in.). The probe shall be so made mechanically that when moved manually to the marked depth desired it would be held securely in position at that depth.

4.1.4. *Readout Instrument*—a suitable scaler or direct readout meter.

4.1.5. *Gauge Housing*—The source, detector, readout instrument and appropriate power supplies shall be in housings of rugged construction that are moisture and dust proof.

4.1.6. *Reference Standard*—A block of uniform, unchanging density provided for checking equipment operation, background count, and count rate reproducibility.

4.1.7. *Guide Plate and Hole-Forming-Device*—For direct transmission measurements, a guide plate and a device, such as a pin or drill rod, having a nominal diameter equal to slightly larger than the probe, for forming a hole normal to the concrete surface.

4.1.8. *Calibration Adjustment Container*—A rigid, watertight container, whose minimum inside dimensions are large enough to allow the calibration curve adjustment procedure (Section 5.2) to be followed with no effect of the finite size of the container on the instrument's response. The volume of the container shall be established following the procedure outlined in T 19M /T 19.

Note 1—For backscatter measurements, a container 450 by 450 by 150 mm (18 by 18 by 6 in.) will meet this requirement for most equipment currently available commercially. For 50 mm (2 in.) depth direct transmission measurements, a container 600 by 600 by 100 mm (24 by 24 by 4 in.) will meet this requirement.

4.1.9. *Scale*—A scale accurate to within 0.2 kg (0.5 lb) of the test load at any point within the range of use. The range of use shall be considered to extend from the mass of the calibration adjustment container empty to the mass of the measure plus the contents at 2600 kg/m^3 (160 lb/ft^3).

4.1.10. *Strike-Off Bar*—A straight steel bar or angle 900 mm (36 in.) long.

5. CALIBRATION

5.1. Calibration curves are established by determining the nuclear count rate of each of several materials at different and known densities, plotting the count rate (or count ratio) versus each known density, and placing a curve through the resulting points. The method used in establishing the curve must be the same as will be used in determining the density. The materials used for calibration must be of uniform density.

5.1.1. Calibration curves are supplied by gauge manufacturers or can be established using blocks of known density or prepared containers of uniform, unchanging material compacted to known densities. Materials considered satisfactory for use in blocks include granite, aluminum, chalk, limestone, and magnesium.

5.2. *Adjusting Calibration Curves*—Prior to use, the instrument's calibration curve may require an adjustment to compensate for the chemical composition effect. This is recommended whenever a change is made either in the chemical composition of the concrete to be tested or in the testing equipment and is recommended particularly for backscatter method measurements. Determine the necessary adjustments using the same mode of operation and at the same depth (if using direct transmission) as that intended for testing. A recommended procedure for making this adjustment is as follows:

5.2.1. Prepare a concrete mix similar in composition to the material to be tested subsequently.

5.2.2. Fill the calibration adjustment container with concrete and consolidate to produce a uniform, homogeneous material with approximately the density that will be achieved in the subsequent construction. Strike off the container with a ground glass plate or metal strike-off bar.

Note 2—Consolidation may be achieved by the procedure used for unit mass testing (T 121M/T 121) or by other methods such as spading the concrete and then dropping the ends of the container alternately on a rigid surface.

5.2.3. Determine the mass of the concrete in the container to the nearest 225 g (0.5 lb) and determine the mass density as follows:

$$W = \frac{W_c}{V} \qquad (1)$$

where:

W = determined mass density of concrete, kg/m^3 (lb/ft^3);

W_c = mass of the concrete in kg (lb); and

V = volume of the container, m^3 (ft^3).

Note 3—Care must be taken to make the concrete surface flat and flush with the container edges. A 1.6-mm ($^1/_{16}$-in.) average difference between the concrete surface and the container edges will produce a 1.0 percent error in *W*.

5.2.4. Take three automatically timed direct transmission or backscatter readings with the instrument centered on the surface of the concrete in the container. Rotate the base of the instrument 90 degrees around the vertical axis, with subsequent rotations of 180 and 270 degrees from the original position, and obtain three additional automatically timed counts at each position. The instrument must be centered over the surface of the concrete in each rotated position to prevent edge effects on the instrument reading.

5.2.5. Using the applicable calibration curve, determine the density from the average of the 12 counts obtained in Section 5.2.4.

5.2.6. Determine the difference between the two density readings obtained in Sections 5.2.3 and 5.2.5.

5.2.7. Repeat Sections 5.2.2 through 5.2.6 on two additional concrete mixes of the same proportions. Determine the adjustment factor by averaging the three values obtained in Sections 5.2.6 and 5.2.7. If one of the three values differs from the average by more than 24 kg/m^3 (1.5 lb/ft^3), discard it as a statistical outlier and recalculate the adjustment factor as the average of the remaining two values.

5.2.8. Use the adjustment factor determined in Section 5.2.7 to plot a corrected count-rate calibration curve that shall be parallel to the original calibration curve and offset by the amount indicated in Section 5.2.7. Alternatively, the value of the adjustment factor shall be attached to the instrument and applied subsequently to all density determinations arrived at from an original (unadjusted) calibration curve.

Note 4—In some circumstances, e.g., where chemical composition changes are minimal, calibration curve adjustments may be established on permanent, uniform, hardened concrete blocks.

6. STANDARDIZATION

6.1. Standardization of equipment on the reference standard is required at the start of each day and whenever test measurements are suspect.

Note 5—In some older instrument models, count rates are strongly influenced by the ambient temperature and frequent standardization may be necessary.

6.2. Warm-up time shall be in accordance with the manufacturer's recommendation.

6.3. Take at least five readings on the reference standard, or more if recommended by the manufacturer, or take one, 4-minute or longer count if the instrument is equipped with automatic standard count storage.

6.4. If more than one of the individual readings is outside the limit set by Equation 2, repeat the standardization. If the second attempt does not satisfy Equation 2, check the system for a malfunction. If no malfunction is found, establish a new N_o, by taking the average of a minimum of 10 counts on the reference standard.

$$\left| N_s - N_o \right| < 1.96 \sqrt{N_o} \qquad (2)$$

where:

N_s = count currently measured in checking the instrument operation, and

N_o = average count previously established on the reference standard.

Note 6—In instruments where the count has been prescaled, that is, divided by a constant factor k before it is displayed, Equation 2 shall be replaced by

$$\left| N_s - N_o \right|^5 1.96 \sqrt{N_o / k} \qquad (3)$$

6.4.1. If automatic standard count storage is used and the newly established count is outside the limit set by Equation 2, repeat the standardization.

6.4.2. If the second attempt does not satisfy Equation 2, check the system for a malfunction.

6.4.3. If no malfunction is found, establish a new N_o, equal to the average count found in Section 6.4.2.

6.5. If a new N_o, differs by more than 10 percent from the standard count at which the calibration curve (Section 5.1) was established, recalibrate the instrument.

METHOD A—DIRECT TRANSMISSION

7. PROCEDURE

7.1. Select a test location such that, when the gauge is placed in test position:

7.1.1. Any point on the source-detector axis shall be at least 230 mm (9 in.) from any pavement edge or object.

7.1.2. Reinforcing steel shall not be present in the volume bounded by the extended probe and the detector tubes.

7.1.3. The test location shall contain concrete to a depth 25 mm (1 in.) greater than that to which the probe will be inserted. In concrete overlay projects, this may require removal of the underlying (original) concrete 25 to 50 mm (1 to 2 in.) down over a small area before placement of the overlay.

7.2. Smooth the surface with a wood float. If necessary, use the guide plate and hole-forming device (Section 4.1.7) to make a hole slightly larger than the probe and perpendicular to the surface. In some concretes, the probe may be inserted directly into the concrete without use of the guide plate and hole-forming device.

7.3. Insert the probe so that the side of the probe facing the center of the gauge is in intimate contact with the side of the hole. Keep all other radioactive sources at such a distance from the gauge that the readings will not be affected. The recommended minimum distance from other nuclear density gauges is 10 m (30 ft).

7.4. Use the same warm-up time as in standardization. Take automatically timed readings, for a minimum of 1 minute, and determine the in-place density from the adjusted calibration curve, or, alternatively, determine the in-place density from the unadjusted calibration curve and then apply the calibration adjustment factor (Section 5.2.8). If the instrument has a direct reading display that is not programmed to apply the calibration adjustment factor (Section 5.2.7), correct the displayed density by applying that factor.

METHOD B—BACKSCATTER

8. PROCEDURE

8.1. Select a test location such that, when the gauge is placed in test position:

8.1.1. Any point on the source-detector axis shall be at least 230 mm (9 in.) from any pavement edge or object.

8.1.2. No reinforcing steel with less than 75 mm (3 in.) of concrete cover shall lie directly under the source-detector axis.

Note 7—The user may find that certain instrument models and operating modes allow gauges to operate over steel with 38 to 75 mm (1.5 to 3 in.) of concrete cover.

8.2. *Prepare the test site in the following manner*:

8.2.1. On plastic concrete, smooth the surface with a wood float.

8.2.2. On hardened concrete, for best results find as smooth a surface as possible. Remove all loose material. The maximum void beneath the gauge shall not exceed 3 mm ($^1/_8$ in.). Use fine sand or other fine material to fill these voids and smooth the surface with a rigid plate or other suitable tool.

8.3. Seat the gauge firmly. Keep all other radioactive sources at such a distance from the gauge that the readings will not be affected.

8.4. Use the same warm-up time as in standardization. Take automatically timed readings, for a minimum of 1 minute, and determine the in-place density from the adjusted calibration curve (Section 5.2.8) or, alternatively, determine the in-place density from the unadjusted calibration curve and then apply the calibration adjustment factor. If the instrument has a direct reading display that is not programmed to apply the calibration adjustment factor (Section 5.2.7), correct the displayed density by applying that factor.

8.5. On lifts less than 75 mm (3 in.) thick, readings may be erroneous if the density of the underlying material differs significantly from that of the concrete being placed. Correction procedures are available for some gauge models.

9. REPORT

9.1. *The report shall include the following*:

9.1.1. Method (direct transmission or backscatter).

9.1.2. Depth of probe, if using direct transmission.

9.1.3. Thickness of layer tested.

9.1.4. Identification of raw materials.

9.1.5. Mix design.

9.1.6. Count rate for standardization.

9.1.7. Count rate for each test reading and the converted mean density value, or the corrected direct reading density value in kg/m^3 (lb/ft^3).

10. PRECISION

10.1. The precision of the instrument is determined from the slope of the calibration curve and the statistical standard deviation of the count rate, as follows:

$$P = \sigma / S \tag{4}$$

where:

P = precision, kg/m^3 (lb/ft^3);
σ = standard deviation, cpm; and
S = slope, cpm/kg/m^3 (cpm/lb/ft^3).

The slope of the calibration curve is determined at the 2240 kg/m^3 (140 lb/ft^3) point and the standard deviation is calculated from 10 individual automatically timed readings taken on 2240 ± 80 kg/m^3 (140 ± 5 lb/ft^3) material. The gauge is not moved after seating for the first count. For a direct reading gauge, the precision, kg/m^3 (lb/ft^3), is the standard deviation of 10 individual automatically timed density readings. The value of P shall be less than 16 kg/m^3 (1.0 lb/ft^3) for backscatter and 8 kg/m^3 (0.5 lb/ft^3) for direct transmission measurements.

APPENDIX

(Nonmandatory Information)

X1. NOTES ON THE NUCLEAR TEST

X1.1. It should be noted that the volume of concrete represented in the measurements is indeterminate and will vary with the source-detector geometry of the equipment used and with the characteristics of the material tested. In general and with all other conditions constant, the denser the material, the smaller the volume involved in a backscatter measurement. The density so determined is not necessarily the average density within the volume involved in the measurement. Typically, backscatter gauge readings are influenced by 75 to 125 mm (3 to 5 in.) of material; the top 25 mm (1 in.) of the material determines 50 to 70 percent of the measured count rate, and the top 50 mm (2 in.) determine 80 to 95 percent. Where these materials are of uniform density, this characteristic of this method is of no effect. However, reinforcing steel and underlying concrete are both often within the volume in which they may influence gauge readings. Also the extent of the influence of vertical density variations, such as those caused by reinforcing steel, depends on the depth at which the steel is located.

X1.2. The use of cesium-137 and other radioisotope sources in density gauges is regulated by the U.S. Nuclear Regulatory Commission or, in agreement states, by state regulatory agencies. The primary objective of these regulations is the use of these materials in a manner safe to the operator, to other workers, and to the general public. While detailed safety procedures are beyond the scope of this method, the originating committee emphasizes its support of these objectives. It strongly recommends that users of this equipment become completely familiar with possible safety hazards and that they establish effective operator instruction and use procedures together with routine safety procedures such as source leak tests, recording and evaluation of film badge data, the use of survey meters, etc., in connection with the operation of this type of equipment.

X1.3. The determination of density by the nuclear means of this method is indirect. The relationship between nuclear gauge count rate and density necessarily is determined by correlation tests on materials at known average densities. Calibration curves established in this manner do not necessarily hold for all concretes because of differences in chemical composition.

This effect is particularly significant for backscatter method measurements. Because of these considerations, provisions are included in this method for adjusting calibration curves on a project-by-project basis.

Standard Method of Test for

Measuring Early-Age Compression Strength and Projecting Later-Age Strength

AASHTO Designation: T 276-10
ASTM Designation: C 918-02

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Measuring Early-Age Compression Strength and Projecting Later-Age Strength

AASHTO Designation: T 276-10

ASTM Designation: C 918-02

1. SCOPE

1.1. This test method covers a procedure for making and curing concrete specimens and for testing them at an early age. The specimens are stored under standard curing conditions and the measured temperature history is used to compute a maturity index that is related to strength gain.

1.2. This test method also covers a procedure for using the results of early-age compressive-strength tests to project the potential strength of concrete at later ages.

1.3. The values stated in SI units are to be regarded as the standard. The values given in parentheses are for information only.

1.4. The text of this standard references notes and footnotes that provide explanatory material. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements of the standard.

1.5. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 205M/M 205, Molds for Forming Concrete Test Cylinders Vertically
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 141, Sampling Freshly Mixed Concrete
- T 231, Capping Cylindrical Concrete Specimens

2.2. *ASTM Standards*:

- C 617, Standard Practice for Capping Cylindrical Concrete Specimens
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 1074, Standard Practice for Estimating Concrete Strength by the Maturity Method

- C 1231, Standard Practice for Use of Unbonded Caps in Determination of Compressive Strength of Hardened Concrete Cylinders

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. Refer to ASTM C 1074 for the definition of the following terms: datum temperature, equivalent age, maturity, maturity function, maturity index, and temperature-time factor.

3.2. *Definition of Terms Specific to This Standard*:

3.2.1. *potential strength*—the strength of a test specimen that would be obtained at a specified age under standard curing conditions.

3.2.2. *prediction equation*—the equation representing the straight-line relationship between compressive strength and the logarithm of the maturity index.

3.2.2.1. *Discussion*—The prediction equation is used to project the strength of a test specimen based upon its measured early-age strength. The general form of the prediction equation used in this test method is:

$$S_M = S_m + b\left(\log M - \log m\right) \qquad (1)$$

where:

S_M = predicted strength at maturity index, M;

S_m = measured compressive strength at maturity index, m;

b = slope of the line;

M = maturity index under standard curing conditions; and

m = maturity index of the specimen tested at early age.

The prediction equation is developed by performing compressive strength tests at various ages, computing the corresponding maturity indices at the test ages, and plotting the compressive strength as a function of the logarithm of the maturity index. A best-fit line is drawn through the data and the slope of this line is used in the prediction equation.

3.2.3. *projected strength*—the potential strength estimated by using the measured early-age strength and the previously established prediction equation.

4. SUMMARY OF TEST METHOD

4.1. Cylindrical test specimens are prepared and cured in accordance with the appropriate section of T 23 or in accordance with R 39. The temperature of a representative specimen is monitored during the curing period. Specimens are tested for compressive strength at an early age beyond 24 hours, and the concrete temperature history is used to compute the maturity index at the time of test.

4.2. A procedure is presented for acquiring a series of compressive strength values and the corresponding maturity indices at different ages. These data are used to develop a prediction equation that is used subsequently to project the strengths at later ages based upon measured early-age strengths.

5. SIGNIFICANCE AND USE

5.1. This test method provides a procedure to estimate the potential strength of a particular test specimen based upon its measured strength at an age as early as 24 hours. The early-age test results provide information on the variability of the concrete production process for use in process control.

5.2. The relationship between early-age strength of a test specimen and strength achieved at some later age under standard curing depends upon the materials comprising the concrete. In this test method, it is assumed that there is a linear relationship between strength and the logarithm of the maturity index. Experience has shown that this is an acceptable approximation for test ages between 24 hours and 28 days under standard curing conditions. The user of this method shall verify that the test data used to develop the prediction equation are represented correctly by the linear relationship. If the underlying relationship between strength and the logarithm of the maturity index cannot be approximated by a straight line, the principle of this test method is applicable provided an approximate equation is used to represent the non-linear relationship.

5.3. Strength projections are limited to concretes using the same materials and proportions as the concrete used to establish the prediction equation.

Note 1—Confidence intervals developed in accordance with the appendix are helpful in evaluating predictions.

5.4. This test method is not intended for estimating the in-place strength of concrete. ASTM C 1074 provides procedures for using the measured in-place maturity index to estimate in-place strength.

6. APPARATUS

6.1. *Equipment and Small Tools*—for fabricating specimens and measuring the characteristics of fresh concrete; shall conform to the applicable requirements of R 39 or T 23.

6.2. *Molds*—shall conform to the requirements for cylinder molds in Specification M 205M/M 205.

6.3. *Temperature Recorder*:

6.3.1. A device is required to monitor and record the temperature of a test specimen as a function of time. Acceptable devices include thermocouples or thermistors connected to a continuous chart recorder or digital data-loggers. For digital instruments, the recording time interval shall be $^1/_2$ hour or less for the first 48 hours and 1 hour or less thereafter. The temperature recording device shall be accurate to within ±1°C (±2°F).

6.3.2. Alternative devices include commercial maturity instruments that automatically compute and display the temperature-time factor or the equivalent age as described in ASTM C 1074.

Note 2—Commercial maturity instruments use specific values of the datum temperature to evaluate the temperature-time factor or of the Q-value to evaluate equivalent age. Refer to the appendix of ASTM C 1074 for additional explanation and recommendations.

7. SAMPLING

7.1. Sample and measure the properties of the fresh concrete in accordance with R 39, T 23, or T 141.

8. PROCEDURE FOR EARLY-AGE AND PROJECTED STRENGTHS

8.1. Mold and cure the specimens in accordance with R 39 or T 23, whichever is applicable. Record the time when molding of the specimens is completed.

8.2. Embed a temperature sensor into the center of one of the specimens of the sampled concrete. Activate the temperature recording device. Continue curing for at least 24 hours. Maintain a record of the concrete temperature during the entire curing period.

8.3. *Capping and Testing*— Remove the specimens from the molds as soon as practical after 24 hours. Cap the specimens in accordance with T 231.

8.3.1. The capping materials after, if used, shall develop, at the age of 30 minutes, a strength equal to or greater than the strength of the cylinder to be tested.

8.3.2. Do not test specimens sooner than 30 minutes after capping.

8.4. Determine the cylinder compressive strength in accordance with T 22 at the age of 24 hours or later. Record the strength and the age at the time of the test. The age of the cylinder is measured to the nearest 15 minutes from the time of molding. Strength at each test age shall be the average strength of at least two cylinders.

8.5. Determine the maturity index at the time of the test by using the manual procedure described in the section titled Maturity Functions in ASTM C 1074 or by using a maturity instrument. Record the maturity index, m, of the early-age test specimens.

8.6. When the data representing the compressive strength and the maturity index, m, are to be used to project the strength of the concrete at some later age, determine the projected strength by using the prediction equation determined in Section 9.

9. PROCEDURE FOR DEVELOPING PREDICTION EQUATION

9.1. Develop a prediction equation for each concrete to be used on the job. Prepare specimens in accordance with R 39. Use the procedure in Section 8 to obtain compressive strength values and the corresponding maturity indices at the time of testing. These data shall include tests at ages of 24 hours and 3,7,14, and 28 days. If the age for which the projected strength is to be determined exceeds 28 days, the data shall include tests at the desired later age (see Section 5.2). Strength at each age shall be the average strength of at least two cylinders.

9.1.1. Field data are acceptable, provided they furnish all of the information in Section 9.1 and provided the specimens are cured in accordance with T 23.

9.2. The constant b for use in the prediction equation (see Equation 1) is established using one of two alternative methods: (1) by regression analysis, or (2) by manual plotting.

9.2.1. *Regression Analysis*—Convert the values of the maturity indices by taking their logarithms. Plot the average cylinder strength versus the logarithm of the maturity index. Compute the best-fit straight line to the point using an appropriate calculator or computer program. The straight line has the following equation:

$$S_m = a + b \log m \qquad (2)$$

where:

S_m = compressive strength at m;

a = intercept of line;

b = slope of line; and

m = maturity index.

9.2.1.1. Plot the best-fit straight line on the same graph as the data to verify that the correct equation has been determined.

9.2.2. *Manual plotting*—Prepare a sheet of semi-log graph paper with the y-axis representing compressive strength and the logarithmic scale (x-axis) representing the maturity index (see Note 3). Plot the strength values from Section 9.1 versus the corresponding maturity index. Determine the best-fitting straight line by drawing a line that visually minimizes the distance between the point and the line. The slope of the line is the vertical distance, in units of stress, between the intersection of the line with the beginning and the end of one cycle on the x-axis (see Figure X1.1) This slope is the value of b for use in the prediction equation (see Equation 1).

Note 3—The scale for the y-axis and the number of cycles in the semi-log graph paper should be chosen so that the data fill up as much of the paper as possible. When the maturity index is expressed as the temperature-time factor in degree-hours, three cycles are generally appropriate. If the maturity index is expressed as the equivalent age in hours, two cycles are appropriate.

9.3. Use the constant, b, and Equation 1 to determine the projected strength based on early-age test results.

Note 4—If it is desired to check the accuracy of the first estimate of the value of b, fabricate companion specimens to those for testing at an early age, cure them in accordance with T 23, record their temperature histories, and test them at 28 days. The value of b is re-estimated by use of the equation:

$$b = \left[\sum \left(S - S_m \middle/ \sum \left(\log M - \log m \right) \right) \right] \qquad (3)$$

where:

Σ = indicating that the values are to be added;

S = measured compression strength at M;

M = maturity index corresponding to test at 28 days;

S_m = measured compressive strength at, m; and

m = maturity index corresponding to early-age test.

10. INTERPRETATION OF RESULTS

10.1. As stated in Section 12, the variability of early-age compressive strength obtained by this test method is the same or less than that obtained from traditional test methods. Thus, results are applicable for rapid assessment of variability for process control and signaling the need for adjustments. Use of the results from this test method to predict specification compliance of strength at later ages must be applied with caution because strength requirements in existing specifications and codes are not based upon early-age testing.

10.2. Develop a one-sided confidence interval for the projected strength for use in the acceptance decision. The confidence interval is based on the measured difference between projected and measured strengths at a designated age. Usually, such an interval is developed at a 95 percent confidence level, and the decision is to accept the concrete as conforming to specification requirements if the following condition is satisfied:

$$S_M > (S_L + K) \qquad (4)$$

where:
S_M = projected strength at designated age; and
S_L = specified lower limit, specifically, the specified strength at the designated age.

$$K = \bar{d} + t_{0.95,\, n-1} \frac{S_d}{\sqrt{n}} \qquad (5)$$

$\bar{d}$ = average difference between the measured and projected strength.

$$\bar{d} = \frac{\sum_{i-1}^{n} \left(S_M - S\right)_i}{n} = \frac{\sum_{i-1}^{n} d_i}{n} \qquad (6)$$

where:
S = measured strength after standard curing up to designated age,
d_i = the difference between the ith pair of strength values,
n = number of paired (S_m and S) values used in the analysis,
$t_{0.95,n-1}$ = value from the t-distribution at the 95 percent level for n–1 degrees of freedom, and
S_d = standard deviation for the difference between the measured and projected strengths.

$$S_d = \sqrt{\frac{\sum_{i=1}^{n} (d_i - \bar{d})^2}{(n-1)}} \qquad (7)$$

11. REPORT

11.1. *The report of the early-age results shall include the following*:

11.1.1. Identification number of test cylinder;

11.1.2. Diameter (and length, if not standard) of test cylinder, in inches or millimeters;

11.1.3. Cross-sectional area of test cylinder, in square inches or square millimeters;

11.1.4. Maximum test load on cylinder in pounds-force or newtons;

11.1.5. Compressive strength of cylinder calculated to the nearest 10 psi (0.1 MPa);

11.1.6. Type of fracture of cylinder, if other than the usual cone;

11.1.7. Age of cylinder at the time of test;

11.1.8. Initial mix temperature to the nearest 2ºF or 1ºC;

11.1.9. Temperature records; and

11.1.10. Method of transportation used for shipping the specimens to the laboratory.

11.2. If the early-age strength data are used to project later-age strength, the report shall include the following:

11.2.1. The maturity index, *m*, of the early-age specimens at time of test;

11.2.2. The age of the projected strength; and

11.2.3. The projected strength calculated to the nearest 10 psi (0.1 MPa).

12. PRECISION AND BIAS

12.1. *Precision*:

12.1.1. The data used to prepare the following precision statements were obtained using measurements in the inch-pound system.

12.1.2. The single laboratory coefficient of variation has been determined as 3.6 percent for a pair of cylinders (152 by 305 mm (6 by 12 in.)) cast from the same batch. Therefore, results of two properly conducted strength tests by the same laboratory on two individual cylinders made with the same materials should not differ by more than 10 percent of their average.

12.1.3. The single-laboratory, multi-day coefficient of variation has been determined as 8.7 percent for the average of pairs of cylinders (152 by 305 mm (6 by 12 in.)) cast from single batches mixed on 2 days. Therefore, results of two properly conducted strength tests, each consisting of the average of two cylinders from the same batch made in the same laboratory on different days with the same materials and proportions, should not differ by more than 25 percent of their average.

12.2. *Bias*—This test method has no determinable bias, as the values obtained can only be defined in terms of this test method.

13. KEYWORDS

13.1. Compressive strength; early-age strength; maturity; potential strength; projected strength.

APPENDIX

(Nonmandatory Information)

X1. EXAMPLE OF USE

X1.1. *Development of Prediction Equation*:

X1.1.1. To establish a reliable relationship between strength and the maturity index, concrete must be made from the actual materials, including admixtures, to be used in the work. While field data are acceptable, the initial data will normally originate in the laboratory before field production begins. Compressive strength specimens will, therefore, normally be made and cured in the laboratory and tested at ages of 24 hours, 3 days, 7 days, 14 days, and 28 days. It is suggested that a minimum of 14 cylinders be made and cured in accordance with R 39.

X1.1.1.1. *Example Data*—An example of age-strength data obtained from these test cylinders (two at each age) is as follows:

Age (No. of Cylinders)	Average Strength, psi
24 h (2)	1370
3 days (2)	2484
7 days (2)	3157
14 days (2)	3714
28 days (6)	4247

X1.1.1.2. In this example, the temperature-time factor, with a datum temperature of 0°C (32°F), is used as the maturity index. Refer to ASTM C 1074 for additional information. The temperature-time factor is calculated from the measured temperature history of the concrete by dividing the age into suitable time intervals and summing the products of the time intervals and the corresponding average temperatures for each interval. For this example, it is assumed that the concrete temperature is 21°C (70°F) prior to stripping the molds and is 23°C (73°F) thereafter. The cumulative temperature-time factor at the various test ages is calculated as shown in Table X1.1.

X1.1.2. The strength data shown in X1.1.1.1 and the temperature-time factor values in Table X1.1 can be plotted using semi-log axes as shown in Figure X1.1, which is a computer-generated plot.

X1.1.3. Determine the best-fit straight line through the plotted points. In this example, the straight line was obtained by regression analysis using a computer program. This line represents the prediction equation that is the assumed relationship between strength and the temperature-time factor for the particular concrete. The equation for this straight line is expressed in the following form:

$$S_M = S_m + b\,(\log M - \log m) \qquad (X1.1)$$

where:

S_M and S_m are strengths at values of the temperature-time factor equal to M and m, respectively.

Table X1.1—Temperature-Time Factor at Test Ages

Age, days	Age Increment, (Δt), h	Temperature T, °C	Temperature-Time Factor Increment, ($T - 0$) $X\,\Delta t$, °C·h	Cumulative Temperature-Time Factor, °C·h (°F·h)
1	24	21	504	504 (1675)
3	48	23	1104	1608 (5198)
7	96	23	2208	3816 (12244)
14	168	23	3868	7680 (24575)
28	336	23	7728	15408 (49237)

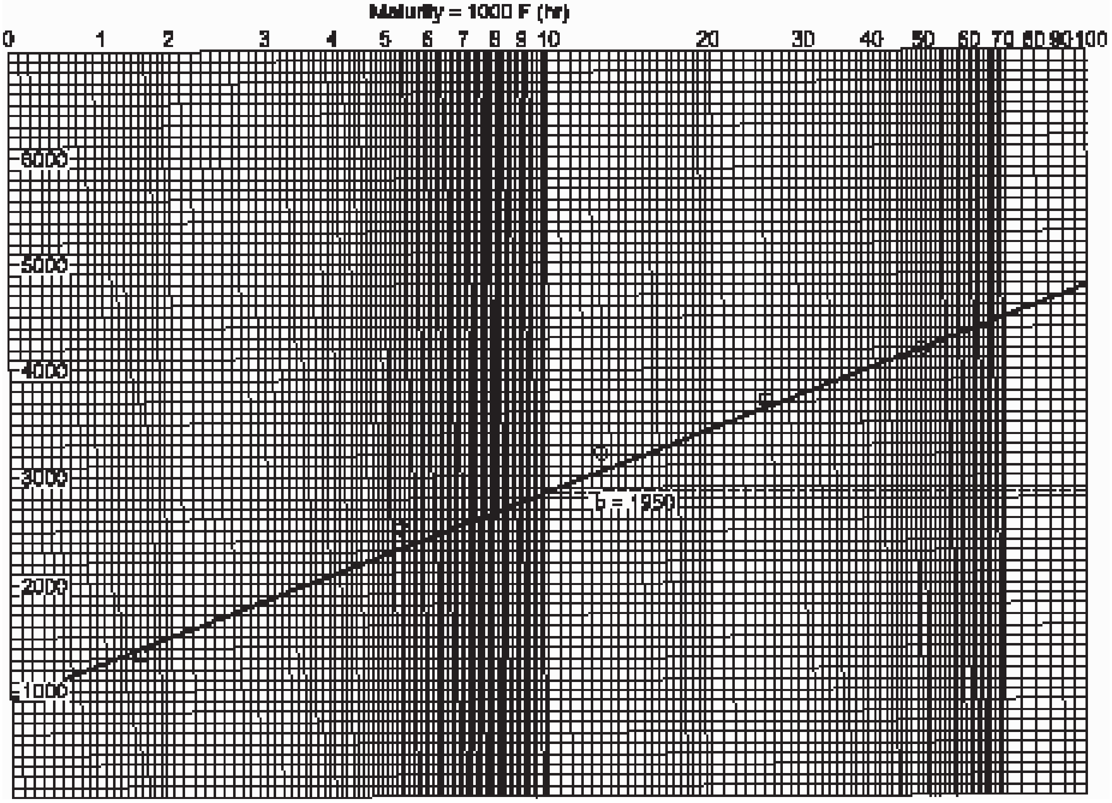

Figure X1.1—Strength Versus Maturity Relationship

X1.1.4. The value *b* is the slope of the prediction equation and the vertical distance, in units of stress, between the intersects of the line with the beginning and the end of the cycle on the *x*-axis (see Figure X1.1). For this particular example, *b* = 13.3 MPa (1930 psi), which represents the strength increase for a tenfold increase in the temperature-time factor.

X1.1.5. Any concrete produced from the same materials and proportions that were used to develop the prediction equation would have the same strength versus temperature-time factor relationship.

X1.2. *Projected Strength*:

X1.2.1. To use the prediction equation to project the strength of field concrete based upon early-age strength, sample and test the fresh concrete in accordance with T 23. Install a temperature recording device into a cylinder to monitor the concrete temperature. Continue for at least 24 hours.

X1.2.2. As soon as practical after the minimum 24-hour curing period, remove the specimens from the molds and prepare for testing in accordance with T 22. Record the age at the time of test. Use this age, together with the recorded temperature history, to determine the maturity index, *m*, at time of test. Report the early-age compressive strength, S_m, as the average of the cylinders tested. The prediction equation is then used to project the strength of the concrete represented by the test specimens.

X1.2.3. As an example:

X1.2.3.1. Compressive strength specimens fabricated in the field were cured for 24 hours under standard conditions at the job site. At the age of 24 hours, the specimens were removed from their molds, capped, and the caps were allowed to harden. The cylinders were tested at an age of 26 hours. The average strength at this age was 9.8 MPa (1420 psi).

X1.2.3.2. Columns 1 and 2 in Table X1.2 show the recorded temperature history obtained from the instrumented specimen. The sixth column shows the increment of temperature-time factor during each age interval. The last column shows the cumulative temperature-time factor. At an age of 26 hours, the cumulative temperature-time factor, *m*, is 616°C·h (1109°F·h).

X1.2.3.3. The temperature-time factor after 28 days of curing at the standard temperature of 23°C (73°F) is:

$$M = (23 - 0)^{\circ}\text{C} \times 28 \text{ days} \times 24 \text{ hours} = 15\,456^{\circ}\text{C·h } (27\,829^{\circ}\text{F·h}) \qquad (X1.2)$$

X1.2.3.4. The projected 28-day strength is calculated as:

$$S_M = S_m + b\,(\log M - \log m) \qquad S_M = 1427 + 1950\,(\log 50000 - \log 1950.5)$$

$$S_M = 1427 + 1950\,(4.699 - 3.290)$$

$$S_M = 1427 + 2747$$

$$S_M = 4174 \text{ psi}$$

Therefore, had the specimens been cured at 23°C (73°F) for the full 28 days, their expected average compressive strength would be 4174 psi, if tested at 28 days.

Table X1.2—Example Temperature Record and Calculations to Determine the Temperature-Time Factor at Test Age

Standard Method of Test for

Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration

AASHTO Designation: T 277-07
ASTM Designation: C 1202-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration

AASHTO Designation: T 277-07
ASTM Designation: C 1202-05

1. SCOPE

1.1. This test method covers the determination of the electrical conductance of concrete to provide a rapid indication of its resistance to the penetration of chloride ions. This test method is applicable to types of concrete where correlations have been established between this test procedure and long-term chloride ponding procedures such as those described in T 259. Examples of such correlations are discussed in References (1–5).[1]

1.2. The values stated in SI units are to be regarded as the standard.

1.3. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 259, Resistance of Concrete to Chloride Ion Penetration

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SUMMARY OF TEST METHOD

3.1. This test method consists of monitoring the amount of electrical current passing through 50-mm (2-in.) thick slices of 100-mm (4-in.) nominal diameter cores or cylinders during a 6-hour period. A potential difference of 60 V dc is maintained across the ends of the specimen, one of which is immersed in a sodium chloride solution, the other in a sodium hydroxide solution. The total charge passed, in coulombs, has been found to be related to the resistance of the specimen to chloride ion penetration.

4. SIGNIFICANCE AND USE

4.1. This test method covers the laboratory evaluation of the electrical conductance of concrete samples to provide a rapid indication of their resistance to chloride ion penetration. In most cases the electrical conductance results have shown good correlation with chloride ponding tests, such as T 259, on companion slabs cast from the same concrete mixtures (References 1–5).

4.2. This test method is suitable for evaluation of materials and material proportions for design purposes and research and development.

4.3. The numerical results (total charge passed, in coulombs) from this test method must be used with caution, especially in applications such as quality control and acceptance testing. The qualitative terms in the right-hand column of Table 1 should be used in most cases unless otherwise noted by the specifying agency.

Table 1—Chloride Ion Penetrability Based on Charge Passed

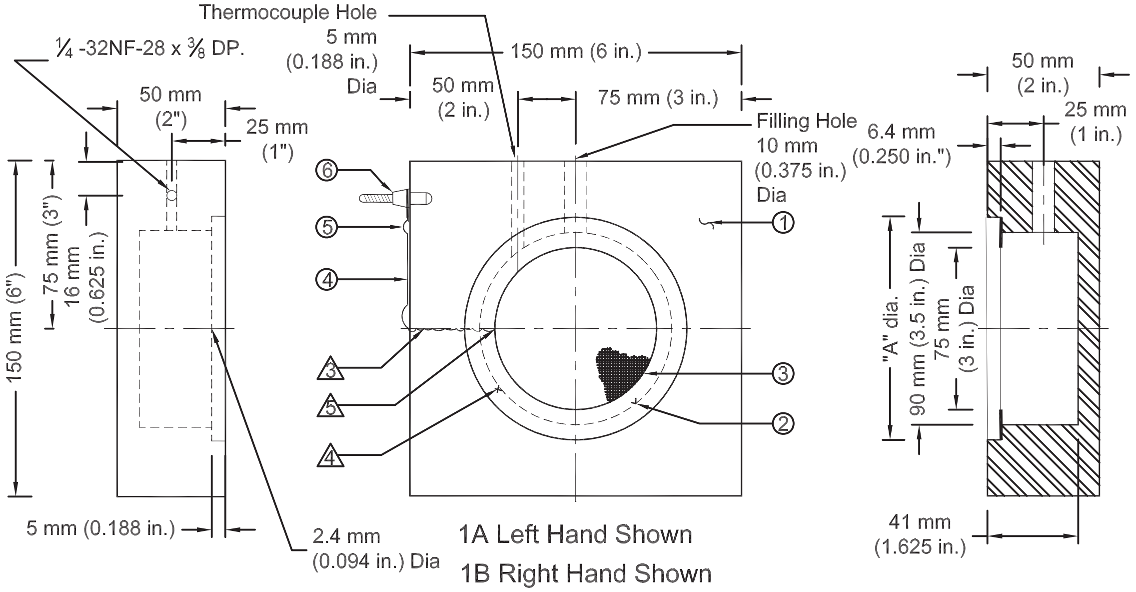
Charge Passed (Coulombs)	Chloride Ion Penetrability
>4000	High
>2000–4000	Moderate
>1000–2000	Low
100–1000	Very low
<100	Negligible

4.4. Care should be taken in interpreting results of this test when it is used on surface-treated concretes, for example, concretes treated with penetrating sealers. The results from this test on some such concretes indicate low resistance to chloride ion penetration, while 90-day chloride ponding tests on companion slabs show a higher resistance.

4.5. The details of the test method apply to 100-mm (4 in.) nominal diameter specimens. This includes specimens with actual diameters ranging from 95 mm (3.75 in.) to 100 mm (4 in.). Other specimen diameters may be tested with appropriate changes in the applied voltage cell design. (See Section 7.5 and Figure 1.)

4.5.1. For specimen diameters other than 95 mm (3.75 in.), the test result value for total charge passed must be adjusted following the procedure in Section 11.2. For specimens with diameters less than 95 mm (3.75 in.), particular care must be taken in coating and mounting the specimens to ensure that the conductive solutions are able to contact the entire end areas during the test.

4.6. Sample age may have significant effects on the test results, depending on the type of concrete and the curing procedure. Most concretes, if properly cured, become progressively and significantly less permeable with time.



△ Notes:
1. Diameter "A" should be 3.2 mm (0.125 in.) larger than outside diameter of specimen.
2. Not to scale
3. Seal Wire in hole with Silicone Rubber Caulk.
4. Screen soldered between Shims.
5. Solder Wire to Brass Shim.
6. Polymethylmethacrylate, e.g., Plexiglas

Equivalents

Item	Qty.	Nomenclature	Specification
1.A 1.B	1 1	Cell Block End	DMMA Sheet
2	4	Shim, Brass	0.5 mm (0.02 in.) THK
3	2	Screen, Brass	0.85 mm (No. 20) mesh. “A” diameter
4	2	Wire, Copper	14, Solid Nylclad
5	2	Terminal	12-10-$^{1}/_{4}$
6	2	Banana Plug	6.4 mm (0.25 in.) male insulated

Figure 1—Applied Voltage Cell (Construction Drawing)

5. INTERFERENCES

5.1. This test method can produce misleading results when calcium nitrite has been admixed into a concrete. The results from this test on some such concretes indicate higher coulomb values, that is, lower resistance to chloride ion penetration, than from tests on identical concrete mixtures (controls) without calcium nitrite. However, long-term chloride ponding tests indicate the concretes with calcium nitrite were at least as resistant to chloride ion penetration as the control mixtures.

Note 1—Other admixtures might affect results of this test similarly. Long-term ponding tests are recommended if an admixture effect is suspected.

5.2. Because the test results are a function of the electrical resistance of the specimen, the presence of reinforcing steel or other embedded electrically conductive materials may have a significant effect. The test is not valid for specimens containing reinforcing steel positioned longitudinally; that is, providing a continuous electrical path between the two ends of the specimen.

6. APPARATUS

6.1. *Vacuum Saturation Apparatus*: (See Figure 2 for example.)

Figure 2—Vacuum Saturation Apparatus

6.1.1. *Separatory Funnel*—or other sealable, bottom-draining container with a minimum capacity of 500 mL.

6.1.2. *Beaker* (1000 mL or larger) or other container—Capable of holding concrete specimen(s) and water and of fitting into vacuum desiccator. (See Section 6.1.3.)

6.1.3. *Vacuum Desiccator*—250-mm (9.8-in.) inside diameter or larger. Desiccator must allow two hose connections, through rubber stopper and sleeve or through rubber stopper only. Each connection must be equipped with a stopcock.

6.1.4. *Vacuum Pump*—Capable of maintaining a pressure of less than 6650 Pa (50 mm Hg) in a desiccator.

Note 2—Because the vacuum will be drawn over water, the pump should be protected with a water trap or pump oil should be changed after each operation.

6.1.5. *Vacuum Gauge or Manometer*—Accurate to ±665 Pa (±5 mm Hg) over range 0 to 13300 Pa (0 to 100 mm Hg) pressure.

6.2. *Coating Apparatus and Materials*:

6.2.1. *Coating*—Rapid setting, electrically nonconductive, capable of sealing side surface of concrete cores.

6.2.2. *Balance or Scale, Paper Cups, Wooden Spatulas, and Disposable Brushes*—For mixing and applying coating.

6.3. *Specimen-Sizing Equipment* (not required if samples are cast to final specimen size).

6.3.1. *Movable Bed Water-Cooled Diamond Saw or Silicon Carbide Saw*.

---

7. REAGENTS, MATERIALS, AND TEST CELL

7.1. *Specimen-Cell Sealant*—Capable of sealing concrete to polymethylmethacrylate, for example, Plexiglas, against water and dilute sodium hydroxide and sodium chloride solutions at temperatures up to 90ºC (200ºF); examples include RTV silicone rubbers, silicone rubber caulkings, other synthetic rubber sealants, silicone greases, and rubber gaskets.

7.2. *Sodium Chloride Solution*—3.0 percent by mass (reagent grade) in distilled water.

7.3. *Sodium Hydroxide Solution*—0.3 Normal (reagent grade) in distilled water.

7.3.1. **Warning**—Before using NaOH, review: (1) the safety precautions for using NaOH; (2) first aid for burns; and (3) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. NaOH can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment should always be used. These should include full-face shields, rubber aprons, and gloves impervious to NaOH. Gloves should be checked periodically for pin holes.

7.4. *Filter Papers*—90 mm (No. 2) diameter (not required if rubber gasket is used for sealant (Section 7.1) or if sealant can be applied without overflowing from shim onto mesh).

7.5. *Applied Voltage Cell (Figures 1 and 3)*—Two symmetric polymethylmethacrylate chambers, each containing electrically conductive mesh and external connectors. One design in common use is shown in Figures 1 and 3. However, other designs are acceptable, provided that overall dimensions (including dimensions of the fluid reservoir) are the same as shown in Figure 1 and width of the screen and shims are as shown.

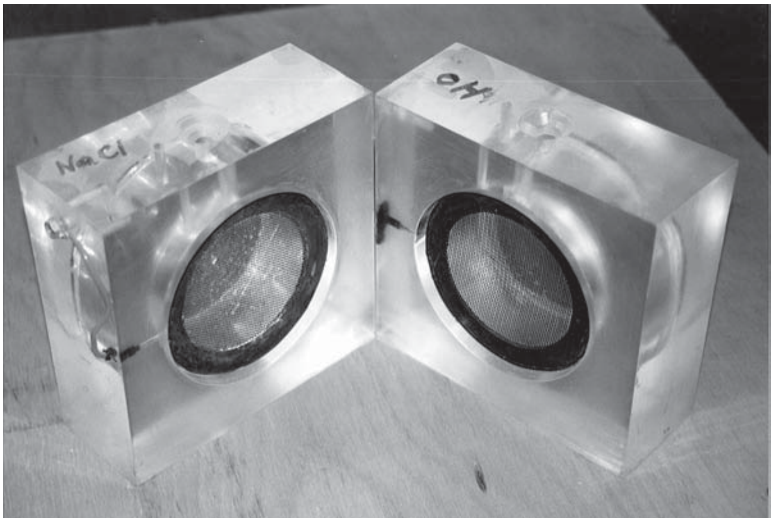


Figure 3—Applied Voltage Cell-Face View

7.6. *Temperature Measuring Device (optional)*—0 to 120ºC (30 to 250ºF) range.

7.7. *Voltage Application and Data Readout Apparatus*—Capable of holding 60 ± 0.1 V dc across applied voltage cell over entire range of currents and of displaying voltage accurate to ±0.1 V and current to ±1 mA. Apparatus listed in Sections 7.7.1 through 7.7.5 is a possible system meeting this requirement.

7.7.1. *Voltmeter*—Digital (DVM), 3 digit, minimum 0-99.9 V range, rated accuracy ±0.1 percent.

7.7.2. *Voltmeter*—Digital (DVM), $4^1/_2$ digit, 0-200 mV range, rated accuracy ±0.1 percent.

7.7.3. *Shunt Resistor*—100 mV, 10A rating, tolerance ±0.1 percent. Alternatively, a 0.01 Ω resistor, tolerance ±0.1 percent, may be used, but care must be taken to establish very low resistance connections.

7.7.4. *Constant Voltage Power Supply*—0-80 V dc, 0-2 A, capable of holding voltage constant at 60 ± 0.1 V over entire range of currents.

7.7.5. *Cable*—Two conductor, 1.6 mm (No. 14), insulated, 600 V.

8. TEST SPECIMENS

8.1. Sample preparation and selection depends on the purpose of the test. For evaluation of materials or their proportions, samples may be (a) cores from test slabs or from large diameter cylinders or (b) 100-mm (4-in.) diameter cast cylinders. For evaluation of structures, samples may be (a) cores from the structure or (b) 100-mm (4-in.) diameter cylinders cast and cured at the field site. Coring shall be done with a drilling rig equipped with a 100-mm (4-in.) diameter diamond-dressed core bit. Select and core samples following procedures in T 24M/T 24. Cylinders cast in the laboratory shall be prepared following procedures in R 39. Unless specified otherwise, moist cure test specimens for 56 days prior to the start of specimen preparation (Note 3). When cylinders are cast in the field to evaluate a structure, care must be taken that the cylinders receive the same treatment as the structure, for example, similar degree of consolidation, curing, and temperature history during curing.

Note 3—This test method has been used with various test durations and curing regimens to meet agency guidelines or specifications. Care should be exercised when comparing results obtained from specimens subjected to differing conditions.

Note 4—The maximum allowable aggregate size has not been established for this test. Users have indicated that test repeatability is satisfactory on specimens from the same concrete batch for aggregates up to 25.0-mm (1-in.) nominal maximum size.

8.2. Transport the cores or field-cured cylinders to the laboratory in sealed (tied) plastic bags. If specimens must be shipped, they should be packed to be properly protected from freezing and damage in transit or storage.

8.3. Using the water-cooled diamond saw or silicon carbide saw, cut a 50 ± 3 mm (2 ± 0.125 in.) slice from the top of the core or cylinder, with the cut parallel to the top of the core. This slice will be the test specimen. Use a belt sander to remove any burrs on the end of the specimen.

8.4. Special processing is necessary for core samples where the surface has been modified, for example, by texturing or by applying curing compounds, sealers, or other surface treatments, and where the intent of the test is not to include the effect of the modifications. In those cases, the modified portion of the core shall be removed and the subsequent 50 ± 3 mm (2 ± 0.125 in.) slice shall be used for the test.

9. CONDITIONING

9.1. Vigorously boil a liter or more of tap water in a large sealable container. Remove container from heat, cap tightly, and allow water to cool to ambient temperature.

9.2. Allow specimen prepared in Section 8 to surface dry in air for at least 1 hour. Prepare approximately 10 g (0.5 oz) of rapid setting coating and brush onto the side surface of specimen. Place the sample on a suitable support while coating to ensure complete coating of sides. Allow coating to cure according to the manufacturer's instructions.

9.3. The coating should be allowed to cure until it is no longer sticky to the touch. Fill any apparent holes in the coating and allow additional curing time, as necessary. Place specimen in beaker or other container (Section 6.1.2), then place container in vacuum desiccator. Alternatively, place specimen directly in vacuum desiccator. Both end faces of specimen must be exposed. Seal desiccator and start vacuum pump. Pressure should decrease to less than 6650 Pa (50 mm Hg) within a few minutes. Maintain vacuum for 3 hours.

9.4. Fill separatory funnel or other container (Section 6.1.1) with the de-aerated water prepared in Section 9.1. With vacuum pump still running, open water stopcock and drain sufficient water into beaker or container to cover specimen. (Do not allow air to enter desiccator through this stopcock.)

9.5. Close water stopcock and allow vacuum pump to run for 1 additional hour.

9.6. Close vacuum line stopcock, then turn off pump. (Change pump oil if a water trap is not being used.) Turn vacuum line stopcock to allow air to re-enter desiccator.

9.7. Soak specimen under water (the water used in Sections 9.4 through 9.6) in the beaker for 18 ± 2 hours.

10. PROCEDURE

10.1. Remove specimen from water, blot off excess water, and transfer specimen to a sealed can or other container, which will maintain the specimen in 95 percent or higher relative humidity.

10.2. Specimen mounting (all sealants other than rubber gaskets: use Section 10.2.2 or Section 10.2.3, as appropriate):

10.2.1. If using two-part specimen-cell sealant, prepare approximately 20 to 40 g (0.7 to 1.4 oz).

10.2.2. *Low-Viscosity, Specimen-Cell Sealant*—If filter paper is necessary, center filter paper over one screen of the applied voltage cell. Trowel sealant over brass shims adjacent to applied voltage cell body. Carefully remove filter paper. Press specimen onto screen; remove or smooth excess sealant that has flowed out of specimen-cell boundary.

10.2.3. *High-Viscosity, Specimen-Cell Sealant*—Set specimen onto screen. Apply sealant around specimen-cell boundary.

10.2.4. Cover exposed face of specimen with an impermeable material such as rubber or plastic sheeting. Place rubber stopper in cell filling hole to restrict moisture movement. Allow sealant to cure per manufacturer's instructions.

10.2.5. Repeat steps in Sections 10.2.2 (or 10.2.3) and 10.2.4 on second half of cell. (Specimen in applied voltage cell now appears as shown in Figure 4.)

10.3. *Specimen Mounting (Rubber Gasket Alternative)*—Place a 100-mm (4-in.) outside diameter by 75-mm (3-in.) inside diameter by 6-mm (0.25-in.) circular vulcanized rubber gasket in each half of the test cell. Insert sample and clamp the two halves of the test cell together to seal.

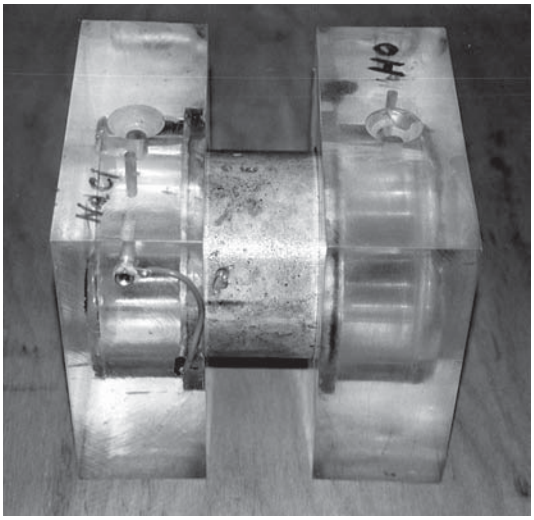

Figure 4—Specimen Ready for Test

10.4. Fill the side of the cell containing the top surface of the specimen with 3.0 percent NaCl solution. (That side of the cell will be connected to the negative terminal of the power supply in Section 10.5.) Fill the other side of the cell (which will be connected to the positive terminal of the power supply) with 0.3 Normal NaOH solution.

10.5. Attach lead wires to cell banana posts. Make electrical connections to voltage application and data readout apparatus as appropriate: for example, for systems listed in Sections 7.7.1 through 7.7.5, connect as shown in Figure 5. Turn power supply on, set to 60.0 ± 0.1 V, and record initial current reading. Temperatures of the specimen, applied voltage cell, and solutions shall be 20 to 25ºC (68 to 77ºF) at the time the test is initiated, that is, when the power supply is turned on.

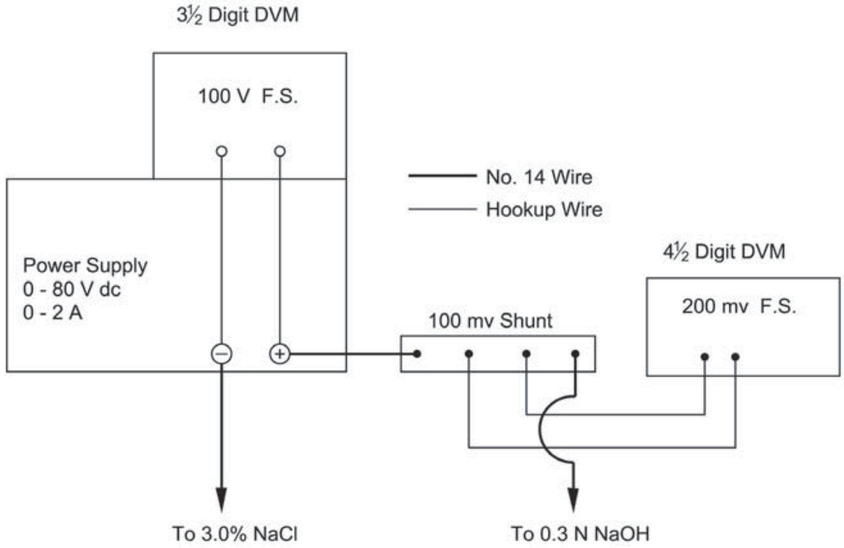

Figure 5—Electrical Block Diagram (example)

10.6. During the test, the air temperature around the specimens shall be maintained in the range of 20 to 25ºC (68 to 77ºF).

10.7. Read and record current at least every 30 minutes. If a voltmeter is being used in combination with a shunt resistor for the current reading (Figure 5), use appropriate scale factors to convert voltage reading to amperes. Each half of the test cell must remain filled with the appropriate solution for the entire period of the test.

Note 5—During the test, the temperature of the solutions should not be allowed to exceed 90ºC (190ºF) in order to avoid damage to the cell and to avoid boiling off the solutions. Although it is not a requirement of the method, the temperature of the solutions can be monitored with thermocouples installed through the 3-mm (0.125-in.) venthole in the top of the cell. High temperatures occur only for highly penetrable concretes. If a test of a 50-mm (2-in.) thick specimen is terminated because of high temperatures, this should be noted in the report, along with the time of termination, and the concrete rated as having very high chloride ion penetrability. (See Section 12.1.9.)

10.8. Terminate test after 6 hours, except as discussed in Note 5.

10.9. Remove specimen. Rinse cell thoroughly in tap water; strip out and discard residual sealant.

11. CALCULATION AND INTERPRETATION OF RESULTS

11.1. Plot current (in amperes) versus time (in seconds). Draw a smooth curve through the data, and integrate the area underneath the curve in order to obtain the ampere-seconds, or coulombs, of charge passed during the 6-hour test period. (See Note 6.) Alternatively, use automatic data processing equipment to perform the integration during or after the test and to display the coulomb value. The total charge passed is a measure of the electrical conductance of the concrete during the period of the test.

Note 6—*Sample Calculation*—If the current is recorded at 30-minute intervals, the following formula, based on the trapezoidal rule, can be used with an electronic calculator to perform the integration:

$$Q = 900\left(I_0 + 2I_{30} + 2I_{60} \cdots + 2I_{300} + 2I_{330} + I_{360}\right) \tag{1}$$

where:

Q = charge passed (coulombs),

I_0 = current (amperes) immediately after voltage is applied, and

I_t = current (amperes) at t min after voltage is applied.

11.2. If the specimen diameter is other than 95 mm (3.75 in.), the value for total charge passed established in Section 11.1 must be adjusted. The adjustment is made by multiplying the value established in Section 11.1 by the ratio of the cross-sectional areas of the standard and the actual specimens. That is:

$$Q_s = Q_x \times \left(\frac{3.75}{x}\right)^2 \tag{2}$$

where:

Q_s = charge passed (coulombs) through a 95-mm (3.75-in.) diameter specimen,

Q_x = charge passed (coulombs) through x mm (in.) diameter specimen, and

x = diameter mm (in.) of the nonstandard specimen.

11.3. Use Table 1 to evaluate the test results. These values were developed from data on slices of cores taken from laboratory slabs prepared from various types of concretes.

11.3.1. Factors that are known to affect chloride ion penetration include: water-cement ratio, the presence of polymeric admixtures, sample age, air-void system, aggregate type, degree of consolidation, and type of curing.

12. REPORT

12.1. *Report the following, if known*:

12.1.1. Source of core or cylinder, in terms of the particular location the core or cylinder represents.

12.1.2. Identification number of core or cylinder and specimen.

12.1.3. Location of specimen within core or cylinder.

12.1.4. Type of concrete, including binder type, water–cement ratio, and other relevant data supplied with samples.

12.1.5. Description of specimen, including presence and location of reinforcing steel, presence and thickness of overlay, and presence and thickness of surface treatment.

12.1.6. Curing history of specimen.

12.1.7. Unusual specimen preparation, for example, removal of surface treatment.

12.1.8. Test results, reported as the total charge passed over the test period (adjusted per Section 11.2), and

12.1.9. The qualitative chloride ion penetrability equivalent to the calculated charge passed (from Table 1).

13. PRECISION AND BIAS[2]

13.1. *Precision*:

13.1.1. *Single-Operator Precision*—The single operator coefficient of variation of a single test result has been found to be 12.3 percent (Note 7). Therefore, the results of two properly conducted tests by the same operator on concrete samples from the same batch and of the same diameter should not differ by more than 42 percent (Note 7).

13.1.2. *Multilaboratory Precision*—The multilaboratory coefficient of variation of a single test result has been found to be 18.0 percent (Note 7). Therefore results of two properly conducted tests in different laboratories on the same material should not differ by more than 51 percent (Note 7). The average of three test results in two different laboratories should not differ by more than 42 percent (Note 8).

Note 7—These numbers represent, respectively, the (1s percent) and (d2s percent) limits as described in ASTM C 670. The precision statements are based on the variations in tests on three different concretes, each tested in triplicate in 11 laboratories. All specimens had the same actual diameters, but lengths varied within the range 50 ± 3 mm (2 ± 0.125 in.).

Note 8—Although the test method does not require the reporting of more than one test result, testing of replicate specimens is usually desirable. The precision statement for the averages of three results is given because laboratories frequently will run this number of specimens. When averages of three results are established in each laboratory, the multilaboratory coefficient of variation S_{ML} is calculated as:

$$S_{ML} = \text{Square Root of } (S^2_{WL}/3) + S^2_{BL} \qquad (3)$$

where:

S^2_{WL} = within-laboratory variance and

S^2_{BL} = between-laboratory variance

The percentage cited represents the (d2s%) limit based on the value for the multilaboratory coefficient of variation.

13.2. *Bias*—The procedure of this test method for measuring the resistance of concrete to chloride ion penetration has no bias because the value of this resistance can be defined only in terms of a test method.

14. KEYWORDS

14.1. Chloride content; corrosion; deicing chemicals; resistance-chloride penetration.

Standard Method of Test for

Bend Test for Bars for Concrete Reinforcement

AASHTO Designation: T 285-89 (2005)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bend Test for Bars for Concrete Reinforcement

AASHTO Designation: T 285-89 (2005)

1. SCOPE

1.1 This method covers a bend test for evaluating the ductility of bars used for concrete reinforcement.

1.2 The units of measure to be used shall be either SI units or inch-pound units (shown in parentheses in this standard) depending on the units used in the applicable material specification.

1.3 The values stated in SI units are to be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 31M/M 31, Deformed and Plain Billet-Steel Bars for Concrete Reinforcement
- M 322M/M 322, Rail-Steel and Axle-Steel Deformed Bars for Concrete Reinforcement

3. SUMMARY OF THE METHOD

3.1 The test is made by bending test specimens around pins of appropriate diameters until the specified angle of bend has been achieved. Test specimens are expected to withstand bending without cracking. The speed of bending is ordinarily not an important factor. The severity of the test is primarily a function of the angle of bend and inside diameter to which the specimen is bent, and of the cross section of the specimen.

4. APPARATUS

4.1 The bend test apparatus shall provide for:

4.1.1 Continuous and uniform application of force throughout the duration of the bending operation (Note 1).

4.1.2 Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate, or bending about a central pin on a simple span with end supports free to rotate. The end support must be strong enough and sufficiently rigid to resist significant deformation.

4.1.3 Close wrapping of the specimen around the pin during the bending operation.

4.2 The diameter of the pin around which bending occurs shall not differ from the nominal value by more than ±2 percent or 3 mm (0.1 in.), whichever is greater. The pin shall be made of steel, and the surface in contact with the bar shall be uniformly curved around the axis of the pin, free of dents and flat spots.

4.2.1 The nominal diameter of pins shall be as specified in M 31M/M 31, M 322M/M 322, or other specification, as appropriate, based on the nominal diameter of bar.

Note 1—Application of force by hand usually does not satisfy this requirement of the method.

Note 2—Bars of size numbers 45 and 55 (14 and 18) are normally specified for use without bending. Consequently, some laboratories are not equipped to conduct bend tests of such bars.

5. SAMPLING

5.1 Sampling shall be performed in accordance with the requirements of relevant specifications.

5.2 Specimens shall be the full section of the bar as rolled and the length shall be sufficient to permit free bending to the angle specified.

6. CONDITIONING

6.1 The temperature of the room in which tests are performed shall be maintained above 15ºC (60ºF) at all times. Specimens that have been exposed to temperatures of less than 15ºC (60ºF) in the preceding 24 hours shall be brought to test temperature by storage in the laboratory air for at least 24 hours prior to test, or by immersion in water maintained at a temperature of 15 to 32ºC (60 to 90ºF) for at least 1 hour prior to test.

7. PROCEDURE

7.1 Place the specimen in the bend test apparatus in such position that the plane intersecting the longitudinal ribs is parallel to the axis of the pin.

7.2 Apply force to the test specimen continuously and uniformly throughout the bending operation.

7.3 Discontinue the application of force when the angle of bend specified in the material specification has been achieved before rebound.

7.4 Examine the tension surface of the specimen for cracking.

8. REPORT

8.1 *The report shall include the following*:

8.1.1 Specimen identification;

8.1.2 Steel specification designation, grade, and bar size of specimen;

8.1.3 Pin diameter and angle of bend; and

8.1.4 Whether specimen passed or failed to meet requirements.

9. PRECISION

9.1 A precision statement is not made for this method because the test result is a non-numerical report of success or failure.

Standard Method of Test for

Rapid Identification of Alkali-Silica Reaction Products in Concrete

AASHTO Designation: T 299-93 (2009)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Rapid Identification of Alkali-Silica Reaction Products in Concrete

AASHTO Designation: T 299-93 (2009)

1. SCOPE

1.1. This test covers the rapid visual detection of the products of alkali-silica reaction (ASR) in portland cement concrete.

1.2. The values stated in SI units are to be regarded as standard.

1.3. *This test involves hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns with its use. It is the responsibility of the user of this test to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to its use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 198, Splitting Tensile Strength of Cylindrical Concrete Specimens

3. SIGNIFICANCE AND USE

3.1. This test covers the identification of alkali-silica reaction products in concrete samples by means of visual observation. Test results have shown that the products formed by the reaction of alkalis and a wide variety of reactive aggregates can be identified by this method. The amount and location of the products are indicators of the development of alkali-silica reaction in the concrete sample tested. This test is not meant to be used to detect the products of alkali-carbonate reaction in concrete.

3.2. This test is intended to be used as one in a series of tests to diagnose alakali-silica reaction in a concrete structure. The results of this test will help to confirm or deny the presence of alakali-silica reaction products in the concrete structure under investigation.

3.3. Sodium present in concrete can react with the reagent in this test to form a product that fluoresces with a greenish-yellow color and that can interfere with the interpretation of the results. However, sodium is dispersed rather uniformly in the hydrated cement matrix in concrete whereas the alkali-silica reaction products are formed particularly in and around the aggregate particles. Interference by sodium from the de-icing salts or seawater can be minimized by rinsing the test surface.

3.4. Care should be taken in interpreting the results of this test when it is used on concrete surfaces subjected to wearing, erosion, and abrasion, because these processes may remove reaction products and, therefore, the absence of reaction products may not be indicative of the development of the reaction in the interior of the concrete. Care should also be taken in interpreting the results for concrete showing carbonation or containing fly ash or silica fume. Both fly ash and silica fume can react with alkalies in concrete to produce reaction products similar to those produced by ASR. The extremely fine nature and dispersion of fly ash and silica fume, however, result in a product that is well dispersed. The fluorescence of such products is generally faint and uniform, but may be influenced by the dispersion of fly ash and silica fume.

4. APPARATUS, REAGENTS, AND MATERIALS

4.1. *Specimen Conditioning Apparatus*:

4.1.1. Plastic beaker—500-mL capacity.

4.1.2. Plastic squeeze bottle (for water)—250-mL capacity.

4.1.3. Disposable polyethylene gloves.

4.1.4. Protective clothing (lab coat).

4.1.5. Absorbent paper towels.

4.1.6. Enclosed space for spraying reagent application.

Note 1—A fume hood, glove box, or disposable glove bags have been found to be suitable for this purpose.

4.2. *Specimen Treatment Apparatus*:

4.2.1. Medicine dropper for applying reagent.

4.2.2. Sprayer for water—A small, hand-held sprayer for spraying tap water.

4.3. *Reagent (Uranyl Acetate Solution)*:

4.3.1. Acetic acid solution (1N).

4.3.2. Glass boiling flask—250-mL capacity.

4.3.3. Two polyethylene storage bottles with tight-fitting cap—100-mL capacity.

4.3.4. Polyethylene volumetric flask—100-mL capacity.

4.3.5. Uranyl acetate powder (ACS reagent grade).

4.3.6. The balance shall have sufficient capacity and conform to M 231, Class G 1.

4.3.7. Uranyl acetate solution prepared as follows: Weigh out 5 g of powdered uranyl acetate. Measure 100 mL of acetic acid solution using the 100-mL volumetric flask. (**Caution**—Use proper lab safety precautions in handling the uranyl acetate and the acetic acid.) Transfer the measured acetic acid solution from the volumetric flask to the boiling flask. Add the 5 g of powdered uranyl acetate to the boiling flask. Warm the mixture over a low flame until the powder is dissolved. Do not bring the mixture to a boil. Remove the flask from the burner, cover, and let it cool to room temperature. Store the cooled solution at room temperature in the polyethylene storage bottle with tight-fitting cap. The reagent, when stored as described, will keep for at least one year.

4.4. *Shortwave (254 nm) Ultraviolet (UV) Lamp*—with peak intensity of at least 1200 $\mu W/cm^2$ at 15 cm (6 in.).

4.5. *Viewing Cabinet or a Dark Room*—The viewing cabinet can be a box, approximately 38 cm by 30 cm by 30 cm (15 in. by 12 in. by 12 in.) in size, made of steel, wood, or cardboard with an opening at the top for placing the UV lamp.

4.6. *Goggles* that shield shortwave ultraviolet light.

Note 2—Because of the toxic, carcinogenic, and radioactive nature of uranyl acetate, special caution should be taken in both preparation and application of the reagent. The use of the reagents should be kept to a minimum.

5. SPECIMENS

5.1. Obtain representative samples from the structure to be evaluated in the form of cores or slabs. The number of samples and the location of samples should be specified by the engineer responsible for the service evaluation of the structure. At any given location, however, samples shall be of such a size and shape that exposed interior surfaces for testing of at least 155 cm^2 (24 $in.^2$) can be obtained from the samples. The total area of 155 cm^2 (24 $in.^2$) can be obtained from more than one sample at the given location, if necessary.

5.2. Maintain the field moisture content of the test specimen. Place the samples in plastic bags for transport to the testing location.

5.3. Break or split the specimens to expose interior-fractured surfaces of the concrete. If the specimens are in the form of cores, use the splitting tensile arrangement described in T 198 to expose interior surfaces of the specimens. Conduct the test immediately on exposure of interior surfaces.

Note 3—The interpretation of the results of the test is simplified if the test is conducted immediately.

6. PROCEDURE

6.1. *Conditioning*:

6.1.1. Dampen specimen with a light spray of tap water. Proceed with the conduct of the test while the specimen is still wet.

6.1.2. Prescreening for natural fluorescence.

6.1.3. Wear protective clothing including polyethylene gloves, lab coat, and UV-filtering goggles.

Note 4—Shortwave ultraviolet light can be harmful to the eye. Normal eyeglasses or plastic goggles or face shield will absorb the harmful rays.

6.1.4. If a viewing cabinet is being used, place the ultraviolet lamp in the opening on the top to allow the light to shine directly on the specimen. Place the damp specimen inside the viewing cabinet. If a darkened room is being used, place the damp specimen on the table and turn off the lights in the room.

6.1.5. Turn on the shortwave ultraviolet light in the viewing cabinet or the darkened room and shine it on the damp specimen. Use UV-filtering goggles and observe and note for future comparison whether any of the aggregates fluoresce. *Note the location and nature of any fluorescence.*

Note 5—Nonfluorescent aggregates will appear dark while cement paste and naturally fluorescent aggregates such as opal and some slags will fluoresce mildly.

6.2. *Observation*:

6.2.1. Wear protective clothing, including polyethylene gloves, lab coat, and UV-filtering goggles.

6.2.2. Conduct the test only on interior fractured surfaces of concrete specimens. If the interior surface of the specimen is not damp, dampen it using the water sprayer filled with tap water.

6.2.3. Line the bottom of the glove box, glove bag, or fume hood with absorbent paper towels. Place the squeeze bottle, medicine dropper, 500-mL plastic beaker, and the dampened specimen inside the glove box, glove bag, or fume hood.

6.2.4. Place the specimen on a paper towel. Apply the uranyl acetate solution to the wet interior surface of the specimen with a medicine dropper. Do not apply uranyl acetate on any other surface except the interior surface of the concrete specimen. Attempt to apply a minimal amount of reagent in a controllable fashion to avoid excess.

6.2.5. Allow the uranyl acetate to absorb on the interior surface of the concrete for 60 seconds.

6.2.6. After 60 seconds, hold the specimen in a vertical position over the 500-mL plastic beaker and wash the interior surface with water three times to remove excess uranyl acetate. Use the squeeze bottle filled with water for washing. Collect the wash water from the specimen in the plastic beaker.

6.2.7. Remove the specimen from the glove box, glove bag, or fume hood and place it on a paper towel. Proceed with observation of the specimen immediately after the uranyl acetate treatment is completed.

6.2.8. If a viewing cabinet is being used, place the ultraviolet lamp in the opening on the top to allow the light to shine directly on the specimen. Line the bottom surface of the viewing cabinet with paper towels. If a dark room is being used, line an area of a table top with paper towels.

6.2.9. Dampen the specimen with tap water again using the water sprayer. Place the specimen inside the viewing cabinet on the paper towel. If a dark room is being used, place the wet specimen on the paper towel on the table top in the dark room and turn off the lights in the room.

6.2.10. Turn on the ultraviolet lamp and shine the light on the treated specimen. The specimen surface will fluoresce with a bright greenish-yellow color.

6.2.11. The presence of bright fluorescing areas in and around aggregates indicates the presence of alkali-silica reaction products in the sample. If the fluorescence is present around the coarse aggregates, count the number of aggregates with fluorescence associated with them. Also count the total number of exposed coarse aggregate particles in the test sample. This procedure is not practical if the fluorescence is associated with the fine aggregates.

Note 6—It may be helpful for comparison and confirmation purposes to develop a set of reference samples (and photos), both with and without alkali-silica reaction, for use when performing the test.

6.2.12. Note the presence of reaction products in voids and cracks, and in and around the aggregate.

Note 7—The presence of reaction product in cracks can be indicative of an advanced state of deterioration due to alkali-silica reaction.

Note 8—Sodium in concrete reacts with uranyl acetate to form a product, which fluoresces with greenish-yellow color. However, sodium is dispersed in the cement paste matrix in the concrete and only increases the generally uniform background fluorescence intensity. Evidence of alkali-silica reaction product should be searched in and around the aggregate particles where a distinct greenish-yellow fluorescence should be observed.

Note 9—Carbonated areas of concrete may also fluoresce in the test. The fluorescence due to carbonation products, however, is uniform and is normally only present at the edges of the test specimen. If the test is conducted on a freshly broken interior surface, as prescribed, the interference due to carbonation products is minimized in the interior of the specimen.

Note 10—Fly ash and silica fume can react with alkalis in cement and form reaction products, which fluoresce in the test. Well dispersed fly ash and silica fume, however, cause only an increase in the generally uniform background fluorescence intensity in the paste. If the fly ash and silica fume are not well dispersed or are clumped together, fluorescence will be observed as discrete “points” randomly distributed over the specimen. The size of these “points” is normally very small and can be distinguished from the bright fluorescence of alkali-silica reaction products derived from the coarse and fine aggregates.

7. REPORT

7.1. *The report shall include the following*:

7.1.1. Identification number of the specimen, its source (in terms of the structure, and the particular location in the structure from where it was obtained), its complete description (including presence and location of reinforcing steel, presence and thickness of overlay, and presence of visible cracks and other deterioration), any other relevant data provided (such as the age of concrete, composition, mix proportion, etc.), and the method used to break the specimen to obtain interior surfaces and the approximate area of interior surfaces tested.

7.1.2. Any variation in the test method from that given in this procedure.

7.1.3. Any occurrence of natural fluorescence before treatment with the reagent, and test results reported as the presence or absence of fluorescing reaction products in the test specimen. If fluorescing reaction products are present, detail the presence or absence of reaction products in cracks and voids in the concrete. If the products are associated with coarse aggregate, indicate the total number of coarse aggregate particles in the test surface and the number of particles with fluorescing reaction products. This is done for qualitative purposes only and it does not reflect a quantitative analysis. Also note the presence or absence of fluorescence that may be associated with carbonation products at the edges of the test specimen.

8. PRECISION AND BIAS

8.1. No statement is made about either precision or bias of this test method since the results merely indicate the presence or absence of alkali-silica reaction product in concrete.

9. KEYWORDS

9.1. Alkali-silica reaction; concrete.

Standard Method of Test for

Accelerated Detection of Potentially Deleterious Expansion of Mortar Bars Due to Alkali-Silica Reaction

AASHTO Designation: T 303-00 (2008)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Accelerated Detection of Potentially Deleterious Expansion of Mortar Bars Due to Alkali-Silica Reaction

AASHTO Designation: T 303-00 (2008)[1]

1. SCOPE

1.1. This test method allows detection within 16 days of the potential for deleterious expansion of mortar bars due to the alkali-silica reaction.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific precautionary statement is given in Note 3.

1.3. The values stated in SI units are to be regarded as standard. The values in inch–pound units are shown in parentheses, and are for informational purposes only.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 85, Portland Cement
- M 92, Wire-Cloth Sieves for Testing Purposes
- M 201, Mixing Rooms, Moist Cabinets, Moist Rooms, and Water Storage Tanks Used in the Testing of Hydraulic Cements and Concretes
- M 210, Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete

- T 162, Mechanical Mixing of Hydraulic Cement Pastes and Mortars of Plastic Consistency

2.2. *ASTM Standards*:

- C 295, Standard Guide for Petrographic Examination of Aggregates for Concrete
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- C 856, Standard Practice for Petrographic Examination of Hardened Concrete
- D 1193, Standard Specification for Reagent Water

3. SIGNIFICANCE AND USE

3.1. This test method provides a means of detecting the potential of an aggregate used in concrete for undergoing alkali-silica reaction and resulting in potentially deleterious internal expansion. It is based on the NBRI accelerated test method (Davis and Obserholster, 1987a; Davis and Obserholster, 1987b; Hooton and Rogers, 1989; and Obserholster and Davis, 1986).

3.2. When expansions greater than 0.10 percent are developed within 16 days from casting, it is recommended that supplementary information be developed to confirm that the expansion is actually due to alkali reactivity. Sources of such supplementary information include: (1) petrographic examination of the aggregate by ASTM C 295 to determine if known reactive constituents are present; and (2) examination of the specimens after tests by ASTM C 856 to identify the products of alkali reactivity.

3.3. When it has been concluded from the results of tests performed using this test method and supplementary information that a given aggregate should be considered potentially deleteriously reactive, additional studies, using alternative methods, may be appropriate to develop further information on the potential reactivity.

4. APPARATUS

4.1. The apparatus shall conform to M 210, except as follows:

4.2. *Sieve*—Square hole, woven-wire, cloth sieves, shall conform to the requirements of M 92.

4.3. *Mixer, Paddle, and Mixing Bowl*—Mixer, paddle, and mixing bowl shall conform to the requirements of T 162, except that the clearance between the lower end of the paddle and the bottom of the bowl shall be 5.1 ± 0.3 mm (0.20 ± 0.01 in.).

4.4. *Tamper and Trowel*—The tamper and trowel shall conform to T 106.

4.5. *Containers*—The containers shall permit the test specimens to be totally immersed in either water or 1.0 normal NaOH solution. The containers shall be made of material that can withstand prolonged exposure to 80ºC (176ºF) and shall be inert to a 1.0 normal NaOH solution. The containers shall be equipped with tight-fitting covers, seals, or both. The containers shall be constructed in a manner that permits test specimens to be supported, without using the gauge studs, so that the solution has access to the whole test specimen, and the specimens do not touch the sides of the container or each other.

Note 1—The NaOH solution will corrode glass or metal containers. Polypropylene containers are recommended.

4.6. *Oven*—A thermostatically controlled oven capable of maintaining a temperature of 80.0 ± 1.7ºC (176 ± 3ºF) or a thermostatically controlled water bath capable of maintaining the same temperature range.

4.7. *Moist Room or Closet*—The moist closet or room shall conform to M 201.

5. REAGENTS

5.1. *Sodium Hydroxide (NaOH)*—USP or technical grade may be used, provided the Na^+ and OH^- concentrations are shown by chemical analysis to lie between 0.99 and 1.01 normal.

5.2. *Purity of Water*—Unless otherwise indicated, water shall be reagent Type IV water conforming to ASTM D 1193.

5.3. *Sodium Hydroxide Solution*—Each liter of solution shall contain 40 g of NaOH dissolved in 900 mL of water, and shall be diluted with additional distilled or deionized water to obtain 1 L of solution. The volume proportion of sodium hydroxide solution to mortar bars in a storage container shall be 4.5 ± 1.0 volumes of solution to one volume of mortar bars.

Note 2—The volume of a mortar bar may be taken as 184 mL (11.25 $in.^3$).

Note 3—**Precaution**: Before using NaOH, review: (1) the safety precautions for using NaOH; (2) first aid for burns; and (3) the emergency response to spills, as described in the manufacturer's Material Safety Data Sheet or other reliable safety literature. NaOH can cause very severe burns and injury to unprotected skin and eyes. Suitable personal protective equipment should always be used. These should include full-face shields, rubber aprons, and gloves impervious to NaOH. Gloves should be checked periodically for pinholes.

6. CONDITIONING

6.1. Maintain the temperature of the molding room and dry materials at no less than 20ºC (68ºF) and no more than 27.5ºC (81.5ºF). Maintain the temperature of the mixing water, and of the moist closet or moist room, at 23.0 ± 1.7ºC (73.4 ± 3.0ºF).

6.2. The relative humidity of the molding room shall be not less than 50 percent.

6.3. Maintain the storage oven in which the specimens are stored in the containers at a temperature of 80.0º ± 1.7ºC (176 ± 3ºF).

7. SAMPLING AND PREPARATION OF TEST SPECIMENS

7.1. *Selection of Aggregate*—Process materials proposed for use as fine aggregate in concrete as described in Section 7.2 with a minimum of crushing. Process materials proposed for use as coarse aggregate in concrete by crushing to produce as nearly as practical a graded product from which a sample can be obtained. The sample shall have the grading as prescribed in Section 7.2 and be representative of the composition of the coarse aggregate as proposed for use.

7.1.1. When a given quarried material is proposed for use both as coarse and as fine aggregate, test the material only by selection of an appropriate sample crushed to the fine aggregate sizes, unless there is reason to expect that the coarser size fractions have a different composition than the finer sizes and that these differences might significantly affect expansion due to reaction with the alkalies in cement. In this case, the coarser size fractions shall be tested in a manner similar to that employed in testing the fine aggregate sizes.

7.2. *Preparation of Aggregate*—Grade all aggregates in accordance with the requirements prescribed in Table 1. Crush aggregates for which sufficient quantities of the sizes specified in Table 1 do not exist until the required material has been produced. In the case of aggregates containing insufficient amounts of one or more of the larger sizes listed in Table 1, and if no larger material is available for crushing, the first size in which sufficient material is available shall contain the cumulative percentage of material down to that size as determined from the grading specified in Table 1. Note in the test report when such procedures are required. After the aggregate has been separated into the various sieve sizes, wash each size with a water spray over the sieve to remove adhering dust and fine particles from the aggregate. Dry the portions retained on the various sieves and, unless used immediately, store each portion individually in a clean container. Seal the container to prevent moisture loss or gain.

Table 1—Grading Requirements

Passing Sieve Size	Retained on Sieve Size	Mass, Percent
4.75 mm (No. 4)	2.36 mm (No. 8)	10
2.36 mm (No. 8)	1.18 mm (No. 16)	25
1.18 mm (No. 16)	600 µm (No. 30)	25
600 µm (No. 30)	300 µm (No. 50)	25
300 µm (No. 50)	150 µm (No. 100)	15

7.3. *Selection and Preparation of Cement*—Select a reference cement that meets the requirements of M 85. Pass the reference cement through a 850-µm (No. 20) sieve to remove lumps before use.

7.4. *Preparation of Test Specimens*:

7.4.1. Prepare at least three test specimens for each cement–aggregate combination.

7.4.2. Prepare the specimen molds in accordance with the requirements of M 210, except cover the interior surfaces of the mold with a release agent.

Note 4—A release agent is acceptable if it serves as a parting agent without affecting the setting of the cement and without leaving any residue that will inhibit the penetration of water into the specimen. TFE-fluorocarbon tape complies with the requirements for a mold release agent.

7.4.3. Proportion the dry materials for the test mortar using 1 part of cement to 2.25 parts of graded aggregate by mass. Mix 440 g of cement and 990 g of dry aggregate (made up by recombining the portions retained on the various sieves in the grading prescribed in Table 1) at one time to prepare a batch of mortar sufficient for making three specimens. Use a water-to-cement ratio equal to 0.50 by mass.

7.4.4. Mix the mortar in accordance with the requirements of T 162 using water that meets the requirements of Section 5.2.

7.4.5. Mold test specimens with a total elapsed time of not more than 135 s after completion of the original mixing of the mortar batch. Fill the molds with two approximately equal layers, each layer being compacted with the tamper. Work the mortar into the corners, around the gauge studs, and along the surfaces of the mold with the tamper until a homogeneous specimen is obtained. After the top layer has been compacted, cut off the mortar flush with the top of the mold and smooth the surface with a few strokes of the trowel.

8. PROCEDURE

8.1. Place each mold in the moist cabinet or moist room immediately after it has been filled. Cure the specimens in the molds for 24 ± 2 h. Remove the specimens from the molds and, while they are being protected from loss of moisture, properly identify and determine the initial length of each specimen using the length comparator. Record all length measurements to the nearest 0.002 mm (0.0001 in.).

8.2. Place the specimens of each aggregate sample in a storage container with sufficient tap water to totally immerse them. Seal the containers and place them in an oven maintained at 80.0 ± 1.7ºC (176 ± 3ºF) for a period of 24 hours.

8.3. Measure the comparator bar prior to measuring each set of specimens since the heat from the mortar bars may cause the length of the comparator to change. If the length of the comparator bar has changed, wait until the comparator has returned to room temperature before remeasuring the comparator bar. Remove the containers from the oven one at a time. Remove other containers only after the specimens in the first container have been measured and returned to the oven. Remove the specimens one at a time from the water and dry their surface with a towel, paying particular attention to the two metal gauge measuring studs. Record the zero measurements of each specimen immediately after drying, as soon as the specimen is in position. Complete the process of drying and measuring within 15 ± 5 s of removing the specimen from the water. After measurement, leave the specimen on a towel until the remainder of the bars have been measured. Place each set of specimens in separate containers with the 1.0 normal NaOH solution, at 80.0 ± 1.7ºC (176 ± 3ºF) to totally immerse the samples. Seal the containers and return them to the oven.

8.4. Undertake subsequent measurement of the specimens periodically, with at least three intermediate readings, for 14 days after the zero reading, at approximately the same time each day. The measuring procedure is identical to that described in Section 8.3 except that the specimens are returned to their own container after measurement.

9. CALCULATION

9.1. Calculate the difference between the zero length of the specimen and the length at each period of measurement to the nearest 0.001 percent of the effective gauge length and record as the expansion of the specimen for that period. Report the average expansion of the three specimens of a given cement-aggregate combination to the nearest 0.01 percent as the expansion for the combination for a given period.

Note 5—When the mean expansion of the test specimens exceeds 0.10 percent at 16 days from casting (14 days from zero reading), it is indicative of potentially deleterious expansion. This value has been determined from tests of aggregate with known field performance in concrete. When the mean expansion of the test specimens is less than 0.10 percent at 16 days after casting, it is indicative of innocuous behavior (Hooton and Rogers, 1989).

10. REPORT

10.1. *The report shall include the following*:

10.1.1. The type and source of aggregate;

10.1.2. The type and source of portland cement;

10.1.3. The average length change in percent at each reading of the specimens;

10.1.4. Any relevant information concerning the preparation of aggregates, including the grading of the aggregate when it differs from that given in Section 7.2;

10.1.5. Any significant features revealed by examination of the specimens during and after test;

10.1.6. The amount of mixing water expressed as mass percent to cement;

10.1.7. The type, source, proportions and chemical analyses, including Na_2O and K_2O, of any pozzolans employed in the tests; and

10.1.8. A graph of the length change data from the time of the zero reading to the end of the 16-day period.

11. PRECISION AND BIAS

11.1. *Precision*:

11.1.1. *Within-Laboratory Precision*—It has been found that the average within-laboratory, single operator coefficient of variation for materials with an average expansion greater than 0.1 percent at 14 days is 2.94 percent (Note 6). Therefore, the results of two properly conducted tests within the same laboratory on specimens of a sample of aggregate should not differ by more than 8.3 percent (Note 6) of the mean expansion.

11.1.2. *Multilaboratory Precision*—It has been found that the average multilaboratory coefficient of variation for materials with an average expansion greater than 0.1 percent at 14 days is 15.2 percent (Note 6). Therefore, the results of two properly conducted tests in different laboratories on specimens of a sample of aggregate should not differ by more than 43 percent (Note 6) of the mean expansion.

Note 6—These four percentages represent, respectively, the (1s percent) and (d2s percent) limits as described in ASTM C 670.

11.2. *Bias*—Since there is no accepted reference material for determining the bias of this test method, no statement on bias is being made.

Standard Method of Test for

Temperature of Freshly Mixed Hydraulic Cement Concrete

AASHTO Designation: T 309M/T 309-10
ASTM Designation: C 1064/C 1064M-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Temperature of Freshly Mixed Hydraulic Cement Concrete

AASHTO Designation: T 309M/T 309-10
ASTM Designation: C 1064/C 1064M-05

1. The values stated in SI units are to be regarded as the standard.
2. All references to ASTM standards contained in ASTM C 1064/C 1064M-05, listed in the following table, shall be replaced with the corresponding AASHTO standard.

Referenced Standards	
ASTM	AASHTO
C 172	T 141

3. Replace Sections 4.2 and 4.4 of ASTM C 1064/C 1064M-05 with the following:

   4.2 *Temperature Measuring Device*—The temperature measuring device shall be capable of measuring the temperature of the freshly mixed concrete to ±0.5ºC (±1ºF) throughout the entire temperature range likely to be encountered in the fresh concrete. Liquid-in-glass thermometers having a range of –18 to 49ºC (0 to 120ºF) are satisfactory. Other thermometers of the required accuracy, including the metal immersion type, are acceptable.

   4.4 *Reference Temperature Measuring Device*—The reference temperature measuring device shall be a thermometric device readable to 0.2ºC (0.5ºF) that has been verified and calibrated. The calibration certificate or report indicating conformance to the requirements of ASTM E 77 shall be available for inspection.

4. Replace Section 5 of ASTM C 1064/C 1064M-05 with the following:

   5. *Calibration of Temperature Measuring Device*

   5.1 Each temperature measuring device used for determining temperature of freshly mixed concrete shall be calibrated annually, or whenever there is a question of accuracy. This calibration shall be performed by comparing the readings on the temperature measuring device at two temperatures at least 15ºC (27ºF) apart.

Standard Method of Test for

Water Content of Freshly Mixed Concrete Using Microwave Oven Drying

AASHTO Designation: T 318-02 (2007)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Water Content of Freshly Mixed Concrete Using Microwave Oven Drying

AASHTO Designation: T 318-02 (2007)

1. SCOPE

1.1. This method covers the measurement of total water content of fresh concrete. It consists of drying a test specimen of fresh concrete using a relatively high-power microwave oven within a short period of time. The difference in mass between the fresh and dry concrete test specimen will be the water content of that test specimen. Water content per unit volume of concrete can be determined by knowing the unit weight of that concrete.

1.2. This standard is applicable to both laboratory and field tests as long as a power source is available.

1.3. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 141, Sampling Freshly Mixed Concrete
- T 255, Total Evaporable Moisture Content of Aggregate by Drying

2.2. *ASTM Standard*:

- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials

3. SUMMARY OF TEST METHOD

3.1. A test specimen of freshly mixed concrete is wrapped in a fiberglass cloth and dried in a microwave oven using a minimum of three intervals. The test specimen is broken up, separating the coarse aggregate from the mortar, and the mortar is ground with a pestle after the first drying interval. The test specimen is stirred and its mass is determined after subsequent drying intervals. The water content of the test specimen is calculated based on loss in mass of the test specimen at completion of the test. Total drying time is usually less than 15 minutes.

4. SIGNIFICANCE AND USE

4.1. This test is for both laboratory and field measurements of water content in fresh concrete. The test results have been shown to correlate with the actual water content in freshly mixed concrete.

4.2. This test can be used as a quality control tool to check the water content of as-delivered concrete and to calculate the water/cement ratio if the cement content of the tested concrete is known.

Note 1—If it is desired to calculate the net water content of concrete from results of this test, the water absorption of coarse and fine aggregates used in the concrete must be determined.

5. APPARATUS

5.1. *Microwave Oven*—A microwave oven with a power setting of 900 watts, a turntable, and sufficient capacity to accept the specified tray and test specimen.

Note 2—A commercial microwave oven (such as the SHARP Model R-9H93) with a capacity of 0.042 m^3 (1.5 ft^3) and turntable system is suitable.

5.2. *Glass Tray*—A heat-resistant glass tray with dimensions of approximately 230 × 230 × 50 mm (9 × 9 × 2 in.).

5.3. *Balance*—A balance of sufficient capacity meeting the requirements of M 231.

5.4. *Metal Scraper*—A small metal scraper having a sharp edge and a blade approximately 25 mm (1 in.) wide.

5.5. *Grinding Pestle*—A pestle having a porcelain grinding head with a diameter of approximately 50 mm (2 in.).

6. MATERIALS

6.1. *Fiberglass Cloth*—Plain weave fiberglass cloth having a mass of 0.34 kg/m^2 (10 oz/yd^2) and a thickness of 0.35 mm (14 mils).

7. HAZARDS

7.1. Microwave radiation can be hazardous. Follow the safety precautions provided by the microwave oven manufacturer and OSHA at all times. Refer to the caution statements in T 255.

8. SAMPLING TEST SPECIMENS

8.1. Obtain 1500 ± 100 g test specimens from a sample of freshly mixed concrete as described in T 141.

9. PROCEDURE

9.1. Cut a piece of fiberglass cloth large enough to completely wrap a 1500 ± 100 g test specimen of freshly mixed concrete.

Note 3—The minimum size fiberglass cloth that has generally been found to be adequate is 0.5 m by 0.5 m (20 in. by 20 in.).

9.2. Place the fiberglass cloth on the heat-resistant glass tray with the cloth uniformly overhanging the outside edges of the tray.

9.3. Determine the mass of the tray and cloth together (WS). Make this mass determination and all subsequent mass determinations to the nearest 0.1 g.

9.4. Leave the tray and cloth on the balance. Record the tare weight. Place the 1500 ± 100 g test specimen on the fiberglass cloth and wrap the test specimen completely with the cloth.

9.5. Determine the mass of the tray, cloth, and freshly mixed concrete test specimen together (WF).

9.6. Place the tray with the completely wrapped test specimen on the turntable in the microwave oven. Dry the test specimen with the turntable rotating for a period of 5.0 ± 0.5 minutes at the 900-W-power setting.

9.7. At the end of the first drying period, remove the tray and test specimen from the microwave oven and quickly unwrap the test specimen. With the edge of the scraper, break the mass of concrete until the coarse aggregate is separated from the mortar. Carefully grind the mortar with the pestle for no more than 60 s to expose a greater surface area. Avoid losing any material.

9.8. Rewrap the test specimen. Place the tray with the completely wrapped test specimen on the turntable in the microwave oven and dry it with the turntable rotating for 5.0 ± 0.5 minutes at the 900-W-power setting.

9.9. Remove the tray and test specimen from the microwave oven and unwrap the test specimen. Stir the test specimen with the scraper and determine the mass of the tray, fiberglass cloth, and sample together.

9.10. Rewrap the test specimen. Place the tray with the completely wrapped test specimen on the turntable in the microwave oven and dry it with the turntable rotating for 2.0 ± 0.5 minutes at the 900-W-power setting.

9.11. Remove the tray containing the test specimen from the microwave oven and determine the mass. If the change in mass is 1 g or more, repeat the 2-minute drying period until the change in mass is less than 1 g. Record the mass of the tray, cloth, and dry test specimen together (WD).

10. CALCULATIONS

10.1. *Water Content Percentage*—Calculate the water content percentage as follows:

$$WC = 100\,(WF - WD) / (WF - WS) \qquad (1)$$

where:

WC = water content percentage;

WF = mass of the tray + cloth + fresh test specimen;

WD = mass of the tray + cloth + dry test specimen; and

WS = mass of the tray + cloth.

10.2. *Total Water Content*—Calculate the total water content as follows:

10.2.1. For kg/m^3 use:

$$WT = [(WC)(UW)]/100 \qquad (2)$$

10.2.2. For lb/yd^3 use:

$$WT = (27)(WC)(UW)/100 \qquad (3)$$

where:

WT = total water content, kg/m^3 (lb/yd^3);

UW = unit mass of the fresh concrete kg/m^3 (lb/ft^3); and

27 = ft^3/yd^3, a constant (not used for SI calculation).

11. REPORT

11.1. *Report the following information*:

11.1.1. Sample identification information;

11.1.2. Percent water content, nearest tenth of a percent; and

11.1.3. Total water content, nearest kg/m^3 (lb/yd^3).

12. PRECISION AND BIAS

12.1. *Single Operator Precision*—The single operator within-laboratory standard deviation has been found to be 1.6 kg/m^3 (2.7 lb/yd^3). Therefore, results of two properly conducted tests by the same operator on the same material should not differ by more than 4.5 kg/m^3 (7.6 lb/yd^3).

Note 4—These numbers represent, respectively, the (1s) and (d2s) limits as described in ASTM C 670.

12.2. *Multilaboratory Precision*—Multilaboratory estimates of precision have not been determined.

12.3. *Bias*—The bias of this method has not been determined.

Standard Method of Test for

Estimating the Strength of Concrete in Transportation Construction by Maturity Tests

AASHTO Designation: T 325-04 (2008)

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Estimating the Strength of Concrete in Transportation Construction by Maturity Tests

AASHTO Designation: T 325-04 (2008)

1. SCOPE

1.1. This standard provides procedures for estimating concrete strength in roads, bridges, and other transportation structures through the use of a maturity index.

1.2. This standard requires determination of the strength-maturity relationship of the approved concrete job mix in the laboratory, and determination of the temperature history subsequent to placement in the field.

1.3. *This standard may involve hazardous materials, operations, and equipment. It does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- R 9, Acceptance Sampling Plans for Highway Construction
- T 276, Measuring Early-Age Compression Strength and Projecting Later-Age Strength

2.2. *ASTM Standards*:

- C 1074, Standard Practice for Estimating Concrete Strength by the Maturity Method
- D 3665, Standard Practice for Random Sampling of Construction Materials
- E 105, Standard Practice for Probability Sampling Of Materials
- E 122, Standard Practice for Calculating Sample Size to Estimate, With Specified Precision, the Average for a Characteristic of a Lot or Process
- E 141, Standard Practice for Acceptance of Evidence Based on the Results of Probability Sampling

3. TERMINOLOGY

3.1. *equivalent age*—the number of days or hours at a specified temperature that would equal the maturity of a concrete at the actual age and temperature history that has been measured.

3.2. *maturity*—the extent of development of concrete properties that are dependent on cement hydration and pozzolanic reactions.

3.3. *maturity function*—a mathematical expression that converts the temperature history of concrete to an index, which indicates its maturity.

3.4. *maturity index*—an index, calculated by using a maturity function, that can be used as an indicator of strength development in concrete.

3.5. *strength-maturity relationship*—an empirical relationship between concrete strength and its maturity index, usually determined by comparing the strength of concrete cylinders, made from a specific concrete mix, to their maturity index at time of strength testing.

4. SIGNIFICANCE AND USE

4.1. This standard can be used to estimate the strength of concrete placed in pavements and structures. These estimates provide guidance useful in making decisions concerning opening to traffic, form removal, post tensioning, termination of curing procedures, and initiation of strength tests on the in-place concrete such as coring and pullout tests.

4.2. The most critical limitations of the procedures presented are (1) batching or placement errors that are not detected, (2) curing errors other than those that affect temperature that are not detected, and (3) the actual strength of the concrete that is not measured.

Note 1—Concrete must be cured in a condition that supports cement hydration/pozzolanic reactions.

4.3. This standard provides technical personnel with a coordinated procedure for (1) developing a strength-maturity relationship for the approved concrete job mix in the laboratory, (2) determining the temperature history of the in-place concrete, (3) determining the maturity index of the in-place concrete, and (4) using the strength-maturity relationship and the maturity index to estimate the strength of the in-place concrete.

5. APPARATUS

5.1. *Laboratory Requirements*:

5.1.1. Personal safety equipment required by the laboratory or OSHA, or both, for work in the laboratory concrete mixing and testing areas.

5.1.2. Temperature sensors suitable for embedment in the center of cylindrical concrete test specimens and a device suitable for monitoring and recording the temperature.

5.1.3. A computer terminal for input of laboratory test data or a supply of concrete test reports.

5.2. *Field Requirements*:

5.2.1. Personal safety equipment required by the laboratory/field organization or OSHA, or both, for work in the field concrete placement areas.

5.2.2. Temperature probes/sensors suitable for embedment in the concrete placement.

5.2.3. A device suitable for monitoring and recording the temperature of the concrete. The device may be a system with a computer remote from the job site that reads and logs the probes/sensors through a modem for necessary calculations; a system with a computer at the job site that automatically reads, logs, and makes the necessary calculations; or a system with a device that automatically reads the probe/sensor signals, calculates the maturity index, and digitally displays the data on demand.

Note 2—SHRP researchers identified eleven reusable maturity meters and three disposable maturity meters, all commercially available. Seven used the Arrhenius maturity function, six used the Nurse-Saul maturity function, and one used either that was chosen.

6. HAZARDS

6.1. Observe the safety procedures required by the laboratory/field agency or OSHA, or both, for each laboratory and field operation, as applicable.

7. FIELD SAMPLING

7.1. Select the temperature sampling sites for installing probes/sensors by determining the quantity of concrete that is to be evaluated and dividing the concrete placement into lots that approximate the quantities indicated in Table 1. For the purposes of this standard, the quantity of pavement shall be estimated in square meters and the quantity of structural concrete shall be estimated in cubic meters.

Table 1—Minimum Number of Probes/Sensors Required to Be Placed in Each Concrete Lot

Structure Component	Quantity of Concrete in Lot	Number of Probes/Sensors
Slabs, beams, and abutment walls	100 m^3	5
Columns	2–10 m^3	1
Columns	More than 10 m^3	2
Pavement, pavement overlays	1000 m^2	2
Pavement repairs	Per repair or per 750 m^2, whichever is smaller	2

7.2. Select temperature sampling alternates in the following manner:

7.2.1. When the maturity of all lots is to be determined, use a stratified random selection procedure in determining where to place the temperature probes/sensors in each concrete lot to be evaluated, as indicated in Table 1.

7.2.2. When the maturity of only a fraction of the total lots is to be measured, determine the number of lots in accordance with Equation 1:

$$L_1 = FT - L_L \qquad (1)$$

where:

L_1 = lots to be randomly chosen,

F = fraction of lots to be sampled for maturity testing,

T = total number of lots, and

L_L = last lot placed.

7.2.2.1. Round L_1 to the next higher whole number. Then randomly select the number of lots, L_1, from the available lots, excluding the last lot placed, L_L. Add L_L to the list of randomly chosen lots scheduled for maturity testing. Finally, use a stratified random selection procedure to determine where to place each of the temperature probes/sensors, as indicated in Table 1, in each concrete lot scheduled for evaluation.

Note 3—*Example*: if $T = 10$, and $F = {}^{1}/_{8}$, then $L_1 = 0.25$. Rounding to the next higher whole number, $L_1 = 1$. Then, excluding the last lot placed, there are $(10 - L_L) = 9$ lots from which L_1 is randomly selected. Assume that lot number 4 is the randomly selected lot, and that lot number 10 is L_L, the last lot placed. Then lots numbered 4 and 10 are scheduled for maturity testing. The purpose for excluding L_L from the random selection of lots scheduled for testing and then specifically including L_L in the list of lots scheduled for testing is to assure that the lot containing the last concrete placed is one of those evaluated in the maturity testing process. If all other factors are equal, L_L will be the weakest lot at the times likely to be of interest during the construction process. A similar approach should be followed with regard to a lot(s) that will be exposed to significantly more adverse curing conditions than other lots under evaluation.

Note 4—ASTM D 3665 contains a table of random numbers, including instructions for use. AASHTO R 9 and ASTM E 105, E 122, and E 141 contain additional information concerning sampling practices.

8. PREPARATIONS

8.1. *Laboratory Operations*—Prior to the initiation of the laboratory concrete placement operation, check to ensure that an adequate supply of temperature sensors is available for the scheduled work and prepare the concrete temperature monitoring and recording device for attachment to the temperature sensors immediately after they are embedded in the concrete cylinders.

8.2. *Field Operations*—Prior to the initiation of the field concrete placement operation (1) select which sampling alternate is to be used, (2) check to ensure that an adequate supply of temperature probes/sensors is available for the scheduled concrete placement, (3) determine the locations at which the temperature probes/sensors will be installed, and (4) prepare the concrete temperature monitoring and recording system for attachment to the temperature probes/sensors immediately after placement of the concrete lot.

9. STANDARDIZATION

9.1. Verify the calibration of systems used for monitoring the maturity of concrete on a periodic basis.

Note 5—System verification can be accomplished by placing the temperature probe/sensor in a controlled temperature water bath and recording whether the indicated result agrees with the known temperature of the water bath. Use at least three different temperature points (e.g., 5°C, 25°C, and 45°C).

10. PROCEDURE

10.1. Develop the strength-maturity relationship for the approved concrete job mix in accordance with the Strength Maturity Relationship section of ASTM C 1074.

Note 6—Other standards that use strength-maturity relationships include T 276.

10.2. Determine the temperature history of concrete after placement in the field as follows:

10.2.1. Insert the active end of the temperature probe/sensor in the fresh concrete at the predetermined location(s). If the probe/sensor is installed prior to placement of the concrete, tie the sensor wire for reinforcement to prevent displacement during the placement of the concrete. Probes/sensors can be inserted through an open surface of the concrete or through very small holes in forms.

10.2.2. Generally, probes/sensors should be placed 50 to 100 mm from any surface of the concrete placement. In a pavement overlay, place probes/sensors at mid-depth.

10.2.3. Protect wires connecting the probes/sensors to meter locations from construction operations. In critical locations, use duplicate probes/sensors with separated wiring runs.

Note 7—SHRP research indicated that if a concrete surface is protected from a high rate of heat loss, the difference in maturity indexes between the center and surface of pavements, bridge decks, and structures 300 mm or less thick is negligible.

10.2.4. Make final maturity system connections with the probes/sensors immediately after concrete placement and activate the system.

10.3. After placement of the concrete in the field, determine the maturity index at each probe/sensor location by reading the appropriate channel(s) of the maturity monitoring system.

Note 8—SHRP researchers recommend that all maturity meters used for highway pavement and structures should use the Arrhenius function, because the Arrhenius function is better able to represent the effects of temperature on strength development than the Nurse-Saul function. Meters using the Nurse-Saul function will increasingly produce less accurate estimates of strength gain as the temperature deviates from the standard temperature used to establish the strength-maturity relationship.

10.4. Estimate the in-place strength of concrete in the field using the strength-maturity relationship and the maturity index.

10.4.1. Compare the maturity index determined in Section 10.3 to the strength-maturity relationship determined in Section 10.1. The concrete strength value of the strength-maturity relationship that corresponds to the measured maturity index from a particular probe/sensor location is the estimated concrete strength at that location.

10.4.2. Determine the estimated strength of a concrete lot using Equation 2:

$$S_{L(est)} = \frac{\sum_{i=1}^{i=n} X_i}{n} \qquad (2)$$

where:

$S_{L(est)}$ = estimated strength of the concrete lot,

X_i = estimated strength of the concrete at a specific probe/sensor location,

i = individual probe/sensor, and

n = number of probes/sensors in the concrete lot.

11. REPORT

11.1. *Report the following laboratory information*:

11.1.1. Identification of the laboratory and date of testing;

11.1.2. Identification of the concrete job mix used for laboratory tests;

11.1.3. Strength of each test specimen and the average strength of test specimens at each test age;

11.1.4. Maturity index for each instrumented test specimen and the average maturity index for the instrumented specimens at each test age;

11.1.5. A graph of the average compressive strength versus the average value of the maturity index as described in the Strength-Maturity Relationship section of ASTM C 1074; and

11.1.6. Any other information required by the laboratory organization.

11.2. *Report the following field information*:

11.2.1. Project and route number; and

11.2.2. A list for each concrete lot evaluated, identifying the concrete job mix used and showing the following:

11.2.2.1. Station numbers;

11.2.2.2. Offset;

11.2.2.3. Item number;

11.2.2.4. Quantity of concrete;

11.2.2.5. Number (how many) and location of each probe/sensor installed;

11.2.2.6. Maturity index determined for each probe/sensor location;

11.2.2.7. Estimated strength determined for each probe/sensor location; and

11.2.2.8. Estimated average strength for each concrete lot.

11.3. *Optional*—Any additional data required by the laboratory/field organization responsible for estimating the concrete strength by means of the maturity method.

12. PRECISION AND BIAS

12.1. The research required to determine the precision and bias of this standard has not been performed.

13. KEYWORDS

13.1. Concrete; estimating concrete strength; maturity, maturity index; strength-maturity relationship.

Standard Method of Test for

Determining Chloride Ions in Concrete and Concrete Materials by Specific Ion Probe

AASHTO Designation: T 332-07[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Chloride Ions in Concrete and Concrete Materials by Specific Ion Probe

AASHTO Designation: T 332-07[1]

1. SCOPE

1.1 This method covers the procedures for determining acid-soluble chloride ions in concrete and concrete mix ingredients.

1.2 The age of concrete, mortar, or hydrated portland cement at the time of sampling will have an effect on the acid-soluble chloride ion content. Therefore, unless early age studies are desired, it is recommended that the material be well cured and at least 28 days of age before sampling.

1.3 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- M 231, Weighing Devices Used in the Testing of Materials
- T 260, Sampling and Testing for Chloride Ion in Concrete and Concrete Raw Materials

2.2 *ASTM Standards*:

- D 1193, Standard Specification for Reagent Water
- E 1, Standard Specification for ASTM Liquid-in-Glass Thermometers

3. SUMMARY OF TEST METHOD

3.1 A 3.0-g drilled concrete powder sample is digested in 20 mL of an acid digestion solution and stabilized by the addition of 80 mL of a stabilizing solution. Millivolt readings, taken for the sample solution using a specific chloride ion probe, are converted mathematically into equivalent total percent chloride content or chloride content in kg/m^3 (lb/yd^3) of concrete.

4. INTERFERENCES

4.1 The operational response of the specific ion electrode is subject to interference by the presence of OH^-, S^{2-}, Br^-, I^-, and CN^- in the measured solution and is based on the electrode manufacturer's allowable chloride interference ratio.

4.2 Sulfides are known to interfere with the determination of chloride in solution. This test procedure is, therefore, unsuitable for determining the chloride content of concrete containing mineral aggregates containing significant quantities of pyrite.

5. SIGNIFICANCE AND USE

5.1 This method provides a rapid means of sampling and testing for total chloride ions in concrete in the field.

6. APPARATUS

6.1 *Impact Hammer*—A heavy-duty rotary impact hammer with a drilling stop gauge is used. See Figures 1 through 3.

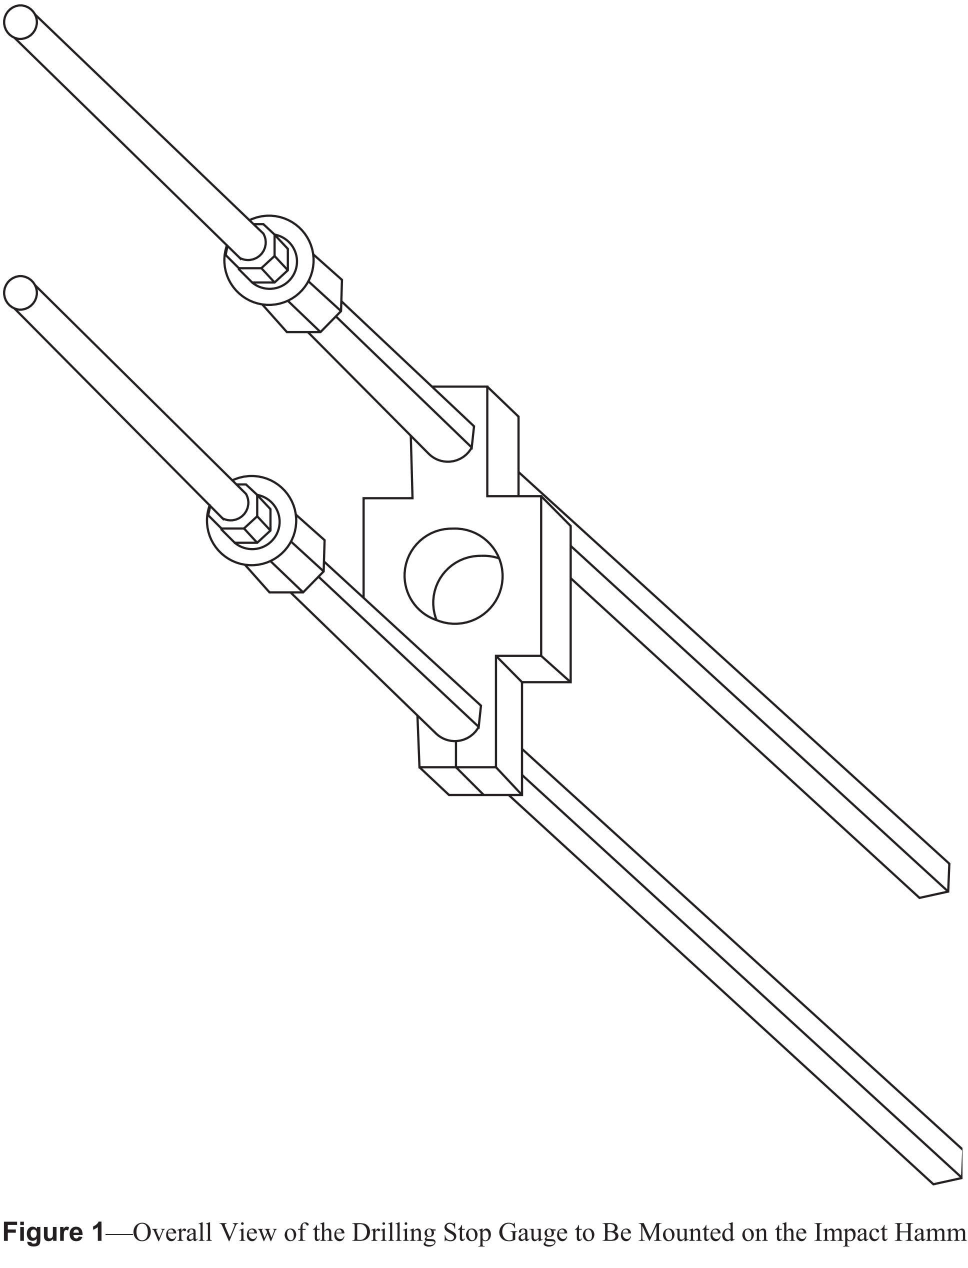

Figure 1—Overall View of the Drilling Stop Gauge to Be Mounted on the Impact Hammer

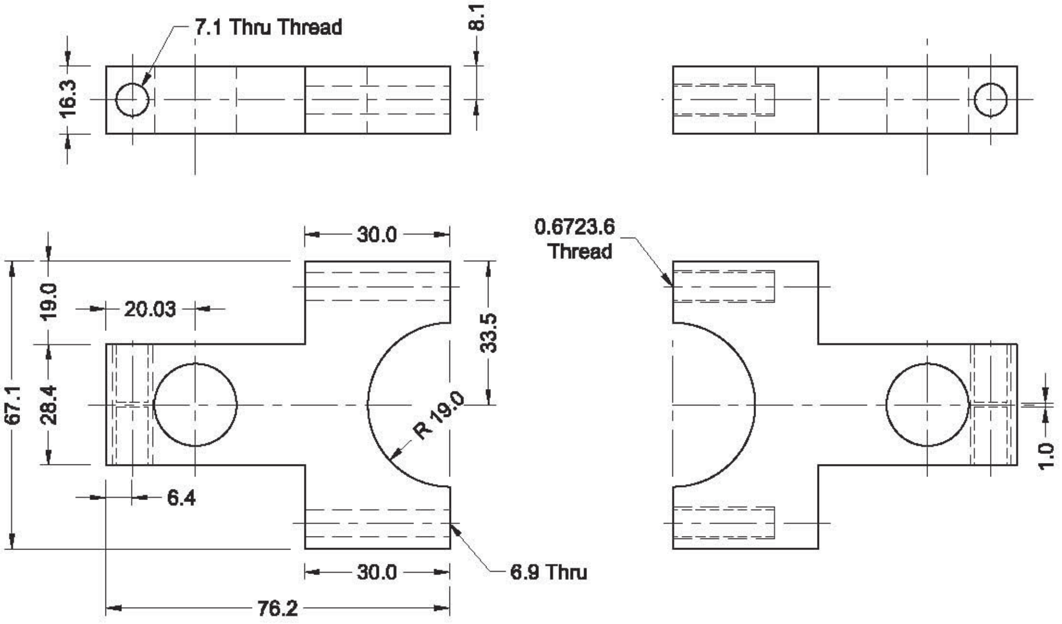
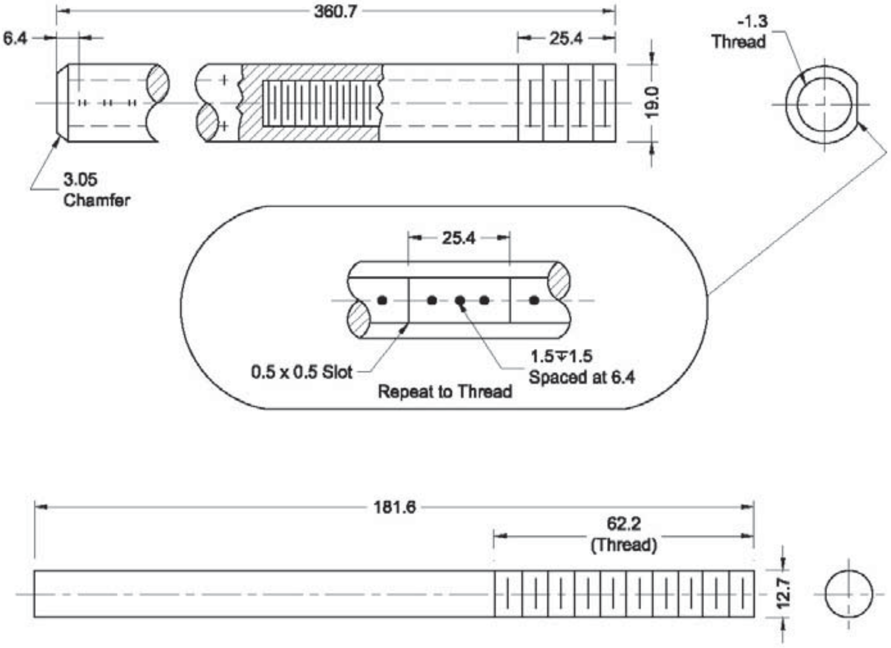


Note: All dimensions shown in millimeters unless otherwise noted.

Figure 2—Details of the Split Ring Collar for the Drilling Stop Gauge



Note: All dimensions shown in millimeters unless otherwise noted.

Figure 3—Details of the Depth Rods for the Drilling Stop Gauge

6.2 *Bit*—A vacuum bit with a diameter equivalent to 1.5 times the maximum aggregate size in the concrete is used. A 28-mm (1.25-in.) bit size is recommended for a maximum coarse aggregate size of 19 mm (0.75 in.). The bit grinds the concrete to a fineness of 99 percent passing the 850-μm (No. 20) sieve conforming to M 92. The finely ground powder is drawn into the collection unit through a coaxial hole in the bit.

6.3 *Sample Collection Unit*—A cylindrical polymethyl methacrylate vacuum chamber is connected to the carbide bit through a vacuum hose for sample collection. Vacuum is provided by a 2.25-HP wet/dry shop vacuum unit. Figures 4 through 8 present the details of the sample collection unit that is to be attached to the wet/dry shop vacuum unit.

6.4 *Filter*—An inexpensive coffee filter is adequate for collecting the powdered concrete samples in the polymethyl methacrylate chamber.

6.5 *Plastic Bottles/Containers*—Widemouth polypropylene bottles with screw caps in the following two sizes are needed:

6.5.1 For calibration solutions and for storing powdered concrete samples: 30 mL.

6.5.2 For digestion solution: 125 mL.

6.6 *Weighing Papers*—76 by 76 mm (3 by 3 in.) size weighing papers are needed for determining the mass of the powdered concrete samples.

6.7 *Spatula*—A stainless steel small spoon spatula is needed for transferring small quantities of the powdered concrete samples from the plastic container for mass determinations.

6.8 *Balances*—An electronic balance sensitive to 0.1 g is needed to determine the mass of the specimens. An electronic balance sensitive to 0.0001 g is needed to determine the mass of sodium chloride for the calibration and stabilizing solutions.

6.9 *Specific Chloride Ion Electrode*—The specific ion electrode for measuring the chloride ion concentration in solution must conform to the following specifications:

6.9.1 Concentration measuring range 5×10^{-5} to 1 mol, or 1.8 to 35 mg/L.

6.9.2 The electrode resistance shall be less than 1.0 megohm.

6.9.3 Reproducibility shall be ±2 percent.

6.9.4 Operating temperature range shall be 10 to 100°C by thermometers specified in ASTM E 1.

Note 1—A suitable specific chloride ion electrode is the Orion Combination Chloride Electrode Model 96-17B with chamber filling solution number 900017 (for use with chloride solution concentrations up to 355 mg/L).

6.10 *Multimeter*—The multimeter used in the procedure must conform to the following specifications:

6.10.1 Maximum common mode voltage shall be 1500 VDC or peak AC.

6.10.2 Resolution at minimal range shall be 100 μV.

6.10.3 Accuracy shall be ± (0.25 percent of the reading + 1 digit).

6.10.4 Operating temperature range shall be 0 to 50°C (32 to 122°F).

6.10.5 Input impedance shall be greater than 2 MΩ.

Note 2—The Orion Model 250A is a suitable meter.

---

7. MATERIALS AND REAGENTS

7.1 *Sodium Chloride*—Reagent grade.

7.2 *Ethyl Alcohol*—Reagent grade.

7.3 *Acetic Acid*—Glacial acetic acid having the following properties:

Note 3—In the use of acetic acid, the operator must use caution to avoid injuries to hands and eyes. Wear safety goggles and gloves.

7.3.1 Specific gravity at 25°C 1.05.

7.3.2 Chloride content: ≤0.4 mg/L.

7.3.3 Normality: 17.4.

7.4 *Isopropyl Alcohol*—Reagent grade having the following properties:

7.4.1 Specific Gravity at 25°C: 0.781 to 0.783.

7.4.2 Boiling Point: 82.3 ± 0.1°C.

7.5 *Distilled Water*—Distilled water conforming to ASTM D 1193, Type IV.

7.6 *Concrete Samples*—The concrete sample to be analyzed shall be in powdered form, 99 percent passing the 850-μm (No. 20) sieve, as taken from the rotary impact hammer extraction procedure.

7.7 *Digestion Solution*—The digestion solution is prepared by combining acetic acid, isopropyl alcohol, and distilled water. Take 800 mL of distilled water in a 1-L measuring flask, and add 60 mL of glacial acetic acid and 60 mL of isopropyl alcohol to the flask. Thoroughly stir the solution and make up the volume to 1 L by adding distilled water. Allow the solution to cool to room temperature. Dispense the solution in 20-mL volumes into the 125-mL polypropylene bottles.

7.8 *Calibration Solutions*—The calibration solutions are prepared by dissolving sodium chloride in distilled water. The concentration levels are 1.25, 0.6, 0.3, 0.03, and 0.01 percent chloride ions by mass of concrete, based on a 3.0-g concrete sample. To obtain the respective concentration levels, dissolve the following quantities of sodium chloride each in 1 L of distilled water: 0.6169 g, 0.2961 g, 0.1481 g, 0.0148 g, and 0.0049 g. (This will result in solutions with chloride ion concentrations of 374, 180, 90, 9, and 3 mg/L, respectively, which in turn correspond to the above-noted percentages by mass of concrete.) Dispense 20 mL of each of the calibration solutions into a separate 30-mL polypropylene bottle, and label each bottle accordingly.

7.9 *Stabilizing Solution*—The stabilizing solution is a diluted standard chloride solution. It is prepared as follows: Dissolve 0.1545 g of sodium chloride in distilled water in a 1-L flask and make up the volume to 1 L with distilled water. Take 40 mL of this solution and dilute it further to 1 L by adding distilled water.

7.10 *Solution Temperature*—The temperature of the solution during testing significantly affects the determined chloride concentration. To minimize errors caused by temperature variations, ensure that the calibration, digestion, and stabilizing solutions are maintained at 22.2 ± 1.1°C (72 ± 2°F).

8. FIELD SAMPLING

8.1 Obtain a sample from the concrete structure using the rotary impact hammer with depth gauge and the carbide vacuum bit.

8.2 Using the sample collection unit, collect at least 10.0 g of powdered concrete in the filter. A hole, drilled about 28.6 mm ($1^1/_8$ in.) in diameter and 12.7 mm ($^1/_2$ in.) deep, will yield approximately 25 g of powdered concrete sample.

8.3 Place the filter containing the sample in the 30-mL polypropylene bottle.

9. CALIBRATION PROCEDURE

9.1 The measurement of the calibration solutions determines the response characteristics of the specific ion electrode in combination with the multimeter. Mathematical regression of the responses produces a representative equation for the combination used to determine the chloride contents of powdered concrete samples. A minimum of five calibration solution concentrations is needed to adequately calibrate the equipment combination. Any alterations to equipment combinations shall require recalibration and the formulation of a new calibration equation.

9.2 Determine the electrode response to chloride ion concentration of the calibration solutions as described below. Start with the calibration solution with the lowest chloride ion concentration.

9.2.1 Place chloride ion electrode halfway into the calibration solution, and wait for 3 minutes to allow the millivolt reading to stabilize. The millivolt reading is stable when it oscillates by less than ±0.5 mV. Record at least five readings and calculate average value to be used for determining the calibration equation.

9.2.2 Repeat the above process (Step 9.2.1) for each of the remaining calibration solutions.

9.3 The calibration equation is determined as follows:

9.3.1 Calculate the $\log_{10}$ of the mg/L chloride concentrations of the calibration solutions, e.g., $\log_{10}$ (374 mg/L Cl) = 2.573.

9.3.2 Perform a linear regression of the millivolt responses (X) versus the $\log_{10}$ of the chloride concentrations of the respective calibration solutions (Y), producing Equation 1 in the following format:

$$\log_{10}(\text{mg/L Cl}) = \text{constant} + \text{coefficient} \times \text{mV} \qquad (1)$$

Note 4—The constant and coefficient will vary with varying equipment combinations. However, the constant is numerically characterized by x.xxx and the coefficient is characterized by -0.0^{xxx}, where *x* represents digits. The slope should be between 54 and 60 mV/decade at 25°C. If not, consult the troubleshooting section of the electrode operation manual or the manufacturer.

9.3.3 The percent chloride is determined from the logarithmic inverse of the regression equation (Equation 1) minus the chloride added by the stabilizing solution, converted to percent chloride by mass of concrete, as follows in Equation 2:

$$\%\text{Cl} = \left[10^{x\ xxx\ +\ 0.0xxx\text{mV}} - 3.0\ \text{mg/L}\right](0.00333) \qquad (2)$$

9.4 Although unnecessary for calibration, measurements of the calibration solutions, both at the beginning and the end of testing, are recommended as a check on the operational integrity of the instrument combination. A deviation in the calibration solution millivolt response indicates a problem involving one or more of the following:

9.4.1 Contamination of calibration solutions.

9.4.2 Contamination of the internal filling solution of the specific ion electrode.

9.4.3 Defective specific ion electrode.

9.4.4 Defective multimeter.

9.5 The percent chloride is based on a 3.0-g powdered concrete sample, and the mg/L chloride is the resulting concentration of a 100-mL solution. The allowable deviations of the specific ion electrode for various chloride ion concentrations are presented in Table 1:

Table 1—Allowable Deviations of Ion Electrodes

% Cl Concentration	Allowable Deviation (mV)
1.25 (374 mg/L)	1.5
0.60 (180 mg/L)	1.5
0.30 (90 mg/L)	1.5
0.03 (9 mg/L)	1.5
0.01 (3 mg/L)	4.5

10. TEST MEASUREMENTS

10.1 Place 20 mL of the digestion solution in a clean, dry 125-mL polypropylene bottle.

10.2 Transfer the powdered concrete sample from the filter to a 30-mL polypropylene storage container, and discard the filter. Stir the powdered sample with a spatula to provide a uniformly mixed sample. Measure a mass of 3.0 ± 0.1 g on a weighing paper.

10.3 Place the measured concrete sample in the bottle containing the 20-mL digestion solution. Place the cap on the bottle, and shake vigorously to suspend the powder in the solution. Let the powder digest for approximately 10 minutes. The bottle may be opened after shaking to relieve pressure for the effervescence due to the reaction, and should be closed immediately.

10.4 Carefully remove the bottle cap and add 80 mL of the stabilizing solution (a 3.75-mg/L chloride solution).

10.5 Replace the cap and shake vigorously for 1 minute.

10.6 Remove the bottle cap and place the electrode halfway into the digested sample suspension.

10.7 Wait for 3 minutes and record the stable millivolt reading. The millivolt reading is stable when it oscillates by less than ±0.5 mV.

10.8 After each sample measurement, the electrode shall be rinsed clean with distilled water.

11. CALCULATIONS

11.1 Calculate the percent chloride content in the sample as follows in Equations 3 and 4:

$$\%\mathrm{Cl} - (A + By) \qquad (3)$$

in which:

$$y = [10^{(C + D\,\mathrm{mV})} - 3.0](0.00333) \qquad (4)$$

and:

A and B = unique values for a combination of a probe and meter determined from the comparison between a standard titration method and this rapid specific ion electrode method; typical values of A and B are 0.0094 and 0.7645, respectively. The procedure for establishing factors A and B is given in Section 11.2.

C and D = the constant and the coefficient, respectively, in the calibration regression equation (Equation 1); typical values are 3.103 and –0.01957, respectively.

11.2 To establish factors A and B of Equation 3, determine the chloride content of a set of concrete samples by T 260, Method A (Standard Titration Method) and this specific ion electrode method (Equation 2). A minimum of 10 samples, with chloride contents covering the range of calibration solutions (Section 7), is recommended for this comparison. Perform a linear regression of the values obtained by the specific ion electrode method (X) versus those by the standard titration method (Y). A and B are the constant and the coefficient, respectively, in this regression equation. The values of A and B will remain valid as long as a particular probe and meter combination is not changed, but will need to be redetermined in case of any equipment replacement or change.

12. REPORT

12.1 Report the percent chloride content to the third decimal (thousandth of a percent). To convert percent chloride into kg/m^3, use a multiplying factor of 23.22. For conversion into lb/yd^3, multiply by 39.15.

13. PRECISION AND BIAS

13.1 *Precision*—The single-operator within-laboratory standard deviation was found to be 1.91 mV (1s). Therefore, the results of two properly conducted tests by the same operator on the same material should not differ by more than 5.40 mV (d2s).

13.2 *Bias*—The test method was found to have no bias in comparing experimental results with reference values determined in accordance to T 260, Method A.

14. SIGNIFICANCE OF RESULTS

14.1 This test method permits determination of the chloride contamination level of concrete structures as a function of depth. Using the values obtained, the chloride diffusion constant can be calculated and the time to corrosion of embedded steel reinforcement can be estimated.

Note 5—A statistical number of samples should be taken on a structure to provide a valid determination of the chloride content of the concrete in the structure. A minimum of 10 samples from a concrete structure is recommended.

15. KEYWORDS

15.1 Chloride content; chloride profile; concrete bridges; on-site testing; reinforcement corrosion; specific ion probe.

Standard Method of Test for

Estimating the Cracking Tendency of Concrete

AASHTO Designation: T 334-08[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Estimating the Cracking Tendency of Concrete

AASHTO Designation: T 334-08[1]

1. SCOPE

1.1. This method covers the determination of the cracking tendency of restrained concrete specimens. The procedure determines the effects of variations in the properties of concrete as related to the time-to-cracking of concrete when restrained. The procedure is comparative and not intended to determine the time of initial cracking of concrete cast in a specific type of structure.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and to determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 210, Use of Apparatus for the Determination of Length Change of Hardened Cement Paste, Mortar, and Concrete
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 160, Length Change of Hardened Hydraulic Cement Mortar and Concrete

2.2. *ASTM Standards*:

- A 53/A 53M, Standard Specification for Pipe, Steel, Black and Hot-Dipped, Zinc-Coated, Welded and Seamless
- A 501, Standard Specification for Hot-Formed Welded and Seamless Carbon Steel Structural Tubing

3. SIGNIFICANCE AND USE

3.1. This test can determine the effects of concrete variations on cracking tendency. These variations might include aggregate source, aggregate gradation, aggregate-paste bond, cement type, cement content, water content, mineral admixtures, silica fume admixtures, fiber reinforcement, or chemical admixtures.

3.2. Actual cracking in service depends on many variables including bridge type, degree of restraint, hydration effects, construction and curing methods, and environmental factors. The method is useful for determining the relative likelihood of early concrete cracking and for aiding in the selection of concrete mixtures that are less likely to crack. The test method may also be modified to evaluate other factors that may affect cracking such as curing time, curing method, evaporation rate, or temperatures.

3.3. The test method measures the strain in a steel ring as a surrounding concrete ring shrinks. The time-to-cracking of the concrete ring is measured as the time when an abrupt drop in strain is seen in the steel ring. Simple visual monitoring of the time-to-first-cracking may also be useful, but it is less accurate and more time-consuming than monitoring strains, and large errors may result with visual monitoring. The test can also evaluate environmental and construction factors by modifying the test environment or curing procedures.

3.4. Other concrete tests that may be related to cracking tendency are unrestrained free-shrinkage according to T 160, compressive strength, tensile strength, elastic modulus, Poisson's ratio, and creep.

4. APPARATUS

4.1. *Steel Ring*—The standard steel ring shall have a wall thickness of 12.7 mm ± 0.4 mm ($^1/_2$ in. ± $^1/_{64}$ in.), an outside diameter of 305 mm (12 in.), and a height of 152 mm (6 in.). As shown in Figure 1, the inner and outer faces shall be machined smooth, round and true, and polished.

Note 1—Theoretical elastic analysis indicates that decreasing the steel thickness increases stresses in the steel significantly but only slightly affects concrete stresses. Bond strain gauges at four equidistant midheight locations on the interior of the steel ring.

Note 2—Structural steel pipe conforming to ASTM A 501 or A 53M/A 53 12-in. extra-strong pipe with an outside diameter of 324 mm (12$^3/_4$ in.) and wall thickness of 13 mm ($^1/_2$ in.) may be substituted, if its inner and outer faces are machined to a smooth, polished surface.

4.2. *Data Acquisition*—The data acquisition unit shall be compatible with the strain instrumentation and automatically record each strain gauge independently.

Note 3—Often when cracking occurs, only one or two gauges indicate significant strain relief.

4.3. *Forms*—The forms shall be nonabsorbent. Fabricate the base forms of resin-coated or polyethylene-coated plywood to minimize friction restraint of the concrete. Thin 3-mm ($^1/_8$-in.) polyethylene sheeting works well as the outside radius form.

4.4. *Curing*—Wet cure the top surface, using prewetted burlap covered with plastic.

4.5. *Curing and Test Room*—After wet curing, store the samples in a controlled-environment room with a constant air temperature of 21 ± 1.7°C (73.4 ± 3°F) and a relative humidity of 50 ± 4 percent. Note and record the evaporation rate near the ring surfaces as described in T 160.

5. SPECIMEN FABRICATION

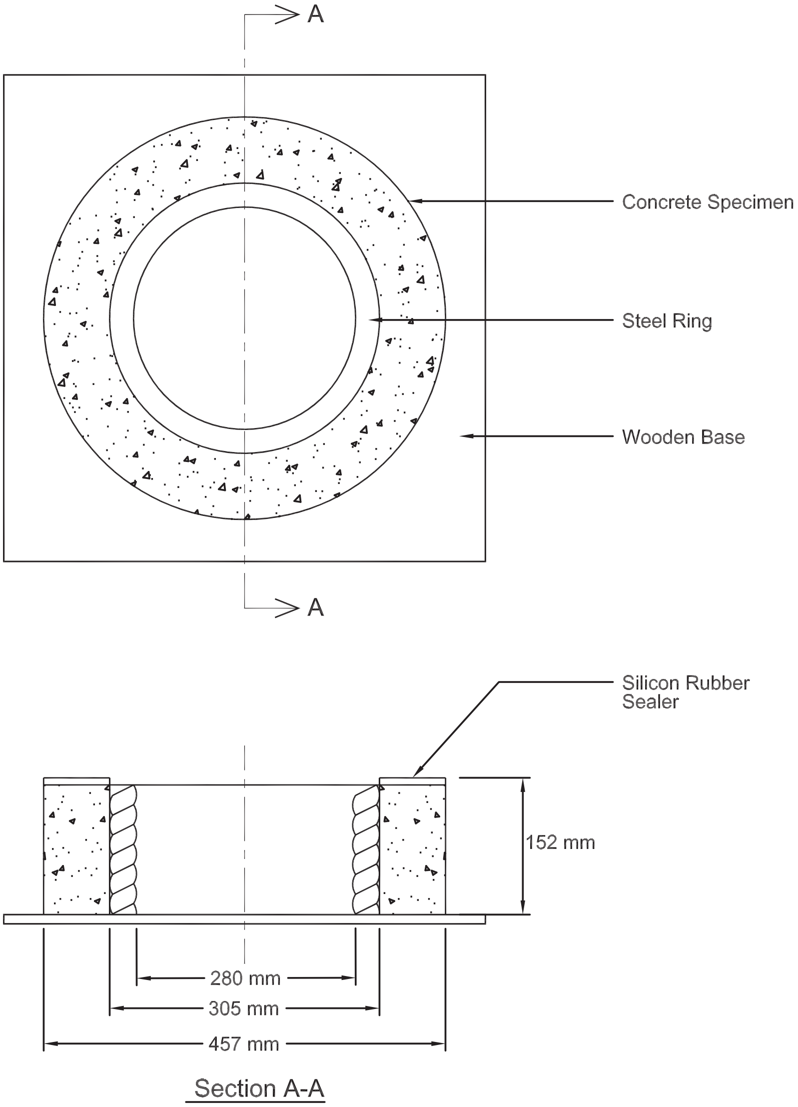
5.1. Secure the steel ring to the base with a central hold-down device during casting.

5.2. Coat the steel ring surface in contact with the concrete with a release agent such as paraffin wax dissolved in solvent or other suitable form-release agent. Do not use form-release agents on the outside radius form.

5.3. Make and cure the test ring specimens following the applicable requirements of M 210 and R 39.

5.4. Cast at least two concrete rings, using the apparatus shown in Figures 1a and 1b, for each batch. Rod the concrete into the molds in three equal lifts, using a 16-mm ($^5/_8$-in.) diameter round-nosed rod. Rod the concrete equidistantly 75 times per layer, ensuring that the rod slightly penetrates into the previous layer. Spade the inside and outside surfaces of the mold after each lift to eliminate large voids along the form faces. Lightly tap the base of the mold with a rubber mallet to close any holes left by rodding and to release any large air bubbles; do not tap on the exterior radius of the molds or on the steel ring.

Note 4—While not recommended, if external or internal vibration is used, vibrate the concrete following R 39 and record the vibration frequency and time.



Notes: 1. Not to scale.
2. Assume a tolerance of ±5 mm throughout.

Figure 1a—Cracking-Tendency Test Apparatus

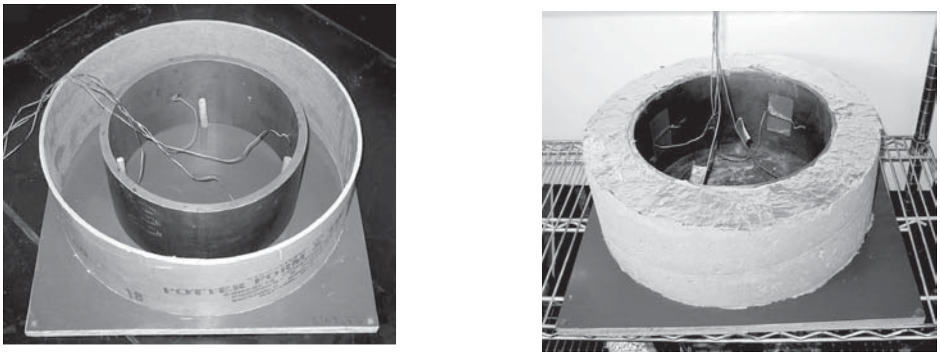


Figure 1b—Cracking-Tendency Test Apparatus (Left–Empty; Right–Full of Concrete)

5.5. After consolidation, strike off and wood-float the concrete surface. Clean any excess concrete from the top and sides of the forms to achieve a level surface. Finish with minimum manipulation necessary to achieve a finished, flat, and even surface. Immediately transfer the specimens to the cure room.

5.6. Loosen the tie-down holding the steel ring to the base form. Connect and begin monitoring the strain instrumentation immediately after placing the specimens in the cure room, cleaning the strain gauge, and connecting wires with an emery cloth before attachment. After the concrete hardens sufficiently to resist indentation of the burlap, cover the specimens with wet burlap followed by plastic. Leave undisturbed for 24 hours. Keep the burlap wet until the forms are removed.

5.7. Remove the forms from the concrete rings at an age of 24 ± 1 hours. Gently slide the ring or lift and tap the base to break the specimen free from the base form. Check that no debris is caught between the concrete and the base form. Keep the ring in contact with the base during testing or seal the bottom to prevent drying. Lightly dress the top outside edge of the concrete to remove sharp edges. Seal the top surface by running a bead of silicon caulk on the inside and outside edge of the top of the concrete ring and pressing a rubber mat or plastic into the caulk. Because some silicone caulks will corrode the steel ring, protect the top edge of the steel ring with a coat of varnish or do not allow the caulk to contact the steel.

6. TESTING

6.1. Record ambient temperatures.

6.2. Temperature compensation for the steel ring gauge readings shall be performed by monitoring a strain gauge mounted on an unstressed piece of steel.

6.3. Monitor the strains in the rings as soon after casting as practical, recording strains every 30 minutes. Measure each strain gauge separately. Every 2 to 3 days, review the strain measurements and visually inspect the ring for cracking.

Note 5—A strain decrease of more than 30 microstrain in one or more gauges usually indicates cracking.

6.4. After cracking, note the cracking pattern and crack widths on the exterior radial face. Monitor the specimens for two additional weeks after cracking, measuring crack widths so the strain decrease and crack pattern can be characterized.

6.5. Measure crack width at three equidistant locations 33, 76, and 114 mm (1.3, 3.0, and 4.5 in.) across the height of the ring and calculate the average width.

7. CALCULATION

7.1. Time-to-cracking is the age when strains measured by one or more of the strain gauges mounted on the steel ring suddenly decrease. Average the results from each specimen cast from the batch, and report the age at cracking to one-tenth of a day. If compressive strain increases in the steel ring are followed by gradual decreases and the concrete rings do not crack, report the results as "no cracking" and record the age when the test was terminated.

7.2. Plot the free-shrinkage strain of the unrestrained samples and determine the unrestrained shrinkage at the average time-to-cracking measured in accordance with T 160 (optional).

8. REPORT

8.1. *Report the following information as pertinent to the variables studied*:

8.1.1. *Properties of the Concrete Mixture*—batch materials and proportions, air content, consistency, and unit weight of fresh concrete;

8.1.2. Variations in ring dimensions, forming, casting, or curing;

8.1.3. Steel ring thickness and outside diameter;

8.1.4. Casting and curing temperatures;

8.1.5. Temperature, relative humidity, and evaporation rate of the test room;

8.1.6. Time-to-cracking in days for each specimen, and the average to one-tenth of a day;

8.1.7. Average strain of steel ring at cracking;

8.1.8. Plots of steel ring strain versus time; and

8.1.9. Average unrestrained free-shrinkage at the average time-to-cracking.

8.2. *Optional*—Pattern of the cracking and the measured crack widths on the exterior face.

[1] Formerly AASHTO Provisional Standard PP 34.

Standard Method of Test for

Coefficient of Thermal Expansion of Hydraulic Cement Concrete

AASHTO Designation: T 336-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Coefficient of Thermal Expansion of Hydraulic Cement Concrete

AASHTO Designation: T 336-10[1]

1. SCOPE

1.1 This test method covers determination of the coefficient of thermal expansion (CTE) of hydraulic cement concrete cores and cylinders. Since it is known that the degree of saturation of concrete influences its measured coefficient of thermal expansion, the moisture condition of the concrete specimens must be controlled. For this test procedure, the specimens must be in a saturated condition.

1.2 The values stated in SI units shall be regarded as the standard.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete

3. SUMMARY OF TEST METHOD

3.1 This method determines the CTE of a cylindrical concrete specimen, maintained in a saturated condition, by measuring the length change of the specimen due to a specified temperature change. The measured length change is corrected for any change in length of the measuring apparatus (previously determined), and the CTE is then calculated by dividing the corrected length change by the temperature change and then the specimen length, as described in the section on calculations.

4. SIGNIFICANCE AND USE

4.1 Measurement of the CTE permits assessment of the potential for length/volume change of concrete due to a uniform temperature change and of the potential deformation of a concrete structure due to a temperature gradient through the concrete. As an example, for pavement slabs on grade, uniform temperature change will affect the openings at joints and a temperature gradient through the thickness of these same slabs will produce curling of the slabs. Using the results of this test, better estimates of slab movement and stress development due to temperature change can be obtained.

Note 1—When using version 1.0 of the MEPDG software, AASHTO TP 60-00 (2007) should be used instead of T 336-09.

5. APPARATUS

5.1 *Concrete Saw*—Capable of sawing the ends of a cylindrical specimen perpendicular to the axis and parallel to each other.

5.2 *Balance*—A scale or balance having a capacity of 20 kg (44 lb) and an accurateness of 0.1 percent over its range.

5.3 *Caliper*—Comparator or other suitable device to measure the specimen length to the nearest 0.1 mm (0.004 in.).

5.4 *Water Bath*—A controlled-temperature water bath with a temperature range of 10 to 50°C (50 to 122°F), capable of controlling the temperature to 0.1°C (0.2°F).

5.5 *Support Frame*—A rigid support frame for the specimen to be used during length change measurement. The frame should be designed to have minimal influence on the length change measurements obtained during the test and should support the specimen such that the specimen is allowed to freely adjust to any change in temperature. A suitable support frame is described in detail in Appendix X1.

5.6 *Temperature Measuring Devices*—Four submersible temperature measuring devices with a resolution of 0.1°C (0.2°F) and an accurateness of 0.2°C (0.4°F).

5.7 *Gauge*—A submersible LVDT gauge head with excitation source and digital readout, with a minimum resolution of 0.00025 mm (0.00001 in.), and a range suitable for the test (for ease in setting up the apparatus, a range of ±3 mm (0.1 in.) has been found practical) (Note 1).

Note 2—Linear variable differential transformers (LVDTs) with the appropriate associated electronic actuating and indicating apparatus appear to give the best results with respect to stability, sensitivity, and reliability. Multichannel recording of outputs has been found to be practical and efficient. As an alternative, a data logger can be used to excite the LVDT and record the LVDT and both temperature and time outputs. The data can be stored directly in a personal computer for graphing of test results.

5.8 *Micrometer*—A micrometer or other suitable device for calibrating the LVDT over the range to be used in the test and with a minimum resolution of 0.00025 mm (0.00001 in.).

6. TEST SPECIMENS

6.1 Test specimens shall consist of drilled 100-mm (4-in.) nominal diameter cores sampled from the concrete structure being evaluated or 100-mm (4-in.) nominal diameter cylinders. Cores shall be obtained in accordance with T 24. Cylinders shall be cast in accordance with T 23 or R 39. The specimens shall be sawed perpendicular to the axis at a suitable length. A length of 180 ± 2 mm (7.0 ± 0.1 in.) has been found acceptable. The standard reference materials used for calibration and specification (see Appendix X2) shall be the same length and diameter as the test specimen so that the frame does not have to be adjusted between calibration/verification and testing. The length of the calibration specimen should be within 2.5 mm (0.1 in) of the concrete specimens intended to be tested. The sawed ends shall be flat and parallel, according to AASHTO T 22. At least two specimens should be tested per mixture.

7. PROCEDURE

7.1 *Specimen Conditioning*—The specimens shall be conditioned by submersion in saturated limewater at 23 ± 2°C (73 ± 4°F) for not less than 48 hours and until two successive weighings of the surface-dried sample at intervals of 24 hours show an increase in weight of less than 0.5 percent. A surface-dried sample is obtained by removing the surface moisture with a towel.

7.2 *LVDT Calibration*—The LVDTs should be calibrated according to the manufacturer's recommendations every 6 months or in circumstances where the CTE results are inconsistent.

7.3 *Equation Verification*—In order to verify the proper function of the LVDT and overall equipment operations, the CTE set up should be verified every month by testing a verification specimen of known CTE other than the calibration specimen. The reference specimen should have a CTE value at least 5×10^{-6} /°C less or greater than the certified value. The calibration factor should be determined again using the procedure outlined in Appendix X2.

7.4 *Testing Procedure*:

7.4.1 Place the measuring apparatus, with the LVDT attached, in the water bath and fill the bath with cold tap water. Place the four temperature sensors in the bath at locations that will provide an average temperature for the bath as a whole. The height of the water should remain constant throughout the test and be set to the same level as that used to calibrate the frame. To avoid any sticking at the points of contact with the specimen, put a very thin film of silicon grease on the end of the support buttons and the LVDT tip.

7.4.2 Remove the specimen from the saturation tank and measure its length at room temperature to the nearest 0.1 mm (0.004 in.). After measuring the length, place the specimen in the measuring apparatus located in the controlled-temperature bath, making sure that the lower end of the specimen is firmly seated against the support buttons and that the LVDT tip is seated against the upper end of the specimen (Note 2).

Note 3—The desired range of travel is the linear range of the LVDT over which it has been calibrated. The LVDT travel during the test should remain well within this range to ensure accurate results.

7.4.3 Set the temperature of the water bath to 10 ± 1°C (50 ± 2°F). When the bath reaches this temperature, allow the bath to remain at this temperature until thermal equilibrium of the specimen has been reached, as indicated by consistent readings of the LVDT to the nearest 0.00025 mm (0.00001 in.) taken every 10 minutes over a one-half hour period. Also at this time, check that the specimen is firmly seated against the support buttons, as confirmed by the LVDT reading.

7.4.4 Record the temperature readings from the four sensors to the nearest 0.1°C (0.2°F). Record the LVDT reading to the nearest 0.00025 mm (0.00001 in.). These are the initial readings.

7.4.5 Set the temperature of the water bath to 50 ± 1°C (122 ± 2°F). Once the bath has reached 50 ± 1°C (122 ± 2°F), allow the bath to remain at this temperature until thermal equilibrium of the specimen has been reached, as indicated by consistent readings of the LVDT to the nearest 0.00025 mm (0.00001 in.) taken every 10 minutes over a one-half hour period.

7.4.6 Record the temperature readings from the four sensors to the nearest 0.1°C (0.2°F). Record the LVDT reading to the nearest 0.00025 mm (0.00001 in.). These are the second readings.

7.4.7 Set the temperature of the water bath to 10 ± 1°C (50 ± 2°F). When the bath reaches this temperature, allow the bath to remain at this temperature until thermal equilibrium of the specimen has been reached, as indicated by consistent readings of the LVDT to the nearest 0.00025 mm (0.00001 in.) taken every 10 minutes over a one-half hour period.

7.4.8 Record the temperature readings from the four sensors to the nearest 0.1°C (0.2°F). Record the LVDT reading to the nearest 0.00025 mm (0.00001 in.). These are the final readings.

8. CALCULATIONS

8.1 *Coefficient of Thermal Expansion*—Calculate the CTE of one expansion or contraction test segment of a concrete specimen as follows (reported in micro strains/°C):

$$CTE = \left(\Delta L_a / L_o\right) / \Delta T \qquad (1)$$

where:

ΔL_a = actual length change of specimen during temperature change, mm, (see Equation 2);

L_o = measured length of specimen at room temperature, mm; and

ΔT = measured temperature change (average of the four sensors), °C (increase = positive, decrease = negative).

$$\Delta L_a = \Delta L_m + \Delta L_f \qquad (2)$$

where:

ΔL_m = measured length change of specimen during temperature change, mm (increase = positive, decrease = negative); and

ΔL_f = length change of the measuring apparatus during temperature change, mm. (See Equation 3.)

$$\Delta L_f = C_f \times L_o \times \Delta T \qquad (3)$$

where:

C_f = correction factor accounting for the change in length of the measurement apparatus with temperature, in.$^{-6}$/in./°C. (See Appendix X2.)

8.2 For the expansion test segment, the initial and second readings are used in the calculations. For the contraction test segment, the second and final readings are used in the calculations.

8.3 The test result is the average of the two CTE values obtained from the two test segments, provided the two values are within 0.3 micro strain/°C (0.2 micro strain/°F) of each other. If the two values are not within 0.3 micro strain/°C (0.2 micro strain/°F) of each other, one or more additional test segments are completed until two successive test segments yield CTE values within 0.3 micro strain/°C (0.2 micro strain/°F) of each other. The test result is the average of these two CTE values (Note 3).

$$CTE = \left(CTE_1 + CTE_2\right)/2 \qquad (4)$$

Note 4—Differences in successive CTEs greater than the required value sometimes occur during the first few cycles of temperature change due to minor misalignment or lack of proper initial seating of the specimen. This is usually self-correcting during the first few temperature cycles. However, it does point out the importance of carefully positioning the specimen at the start of the test.

9. REPORT

9.1 *The report shall include the following information*:

9.1.1 Identification number;

9.1.2 Specimen type, description, and source;

9.1.3 Specimen dimensions, including length and diameter;

9.1.4 Mixture proportions and aggregate type, if available;

9.1.5 All temperature and length measurements collected during the test;

9.1.6 All calculated values, including CTE data and the final CTE value;

9.1.7 The frame's correction factor, C_f, as well as the reference material used and its thermal coefficient;

9.1.8 Date of test;

9.1.9 Place of test;

9.1.10 Technician conducting the test; and

9.1.11 Any other pertinent information.

10. PRECISION AND BIAS

10.1 *Precision*—No precision has been established for this test method.

10.2 *Bias*—No bias can be established because no reference material is available for this test.

APPENDIXES

(Nonmandatory Information)

X1. SPECIMEN MEASURING APPARATUS

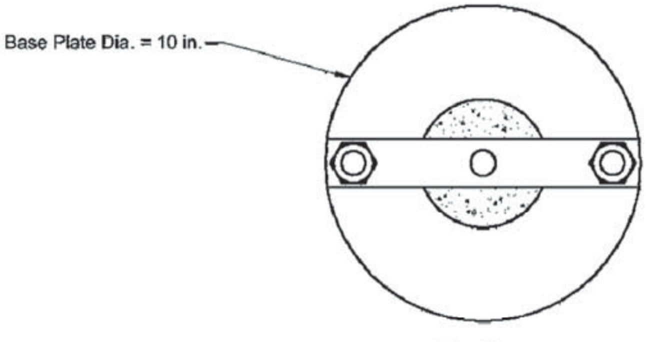
X1.1. The measuring apparatus consists of two primary components: a frame and a length change measuring device.

X1.2. *Frame*:

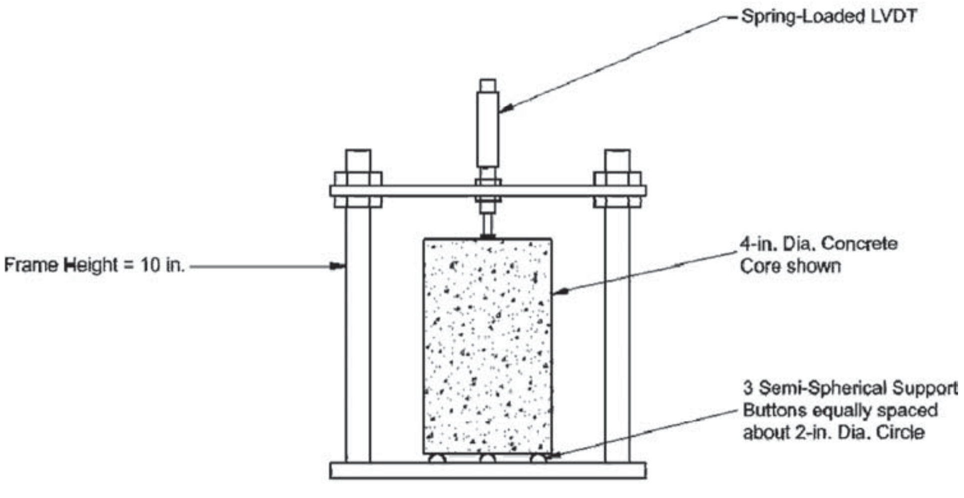
X1.2.1. Figure X1.1 shows a schematic of a suitable measuring frame. Any specimen measuring frame should be constructed with the following features in mind:

X1.2.2. Because the frame will be submerged in water throughout the test, components should be made of a noncorroding material such as stainless steel. Insofar as possible, the portions of the frame, that directly affect measurement over a change in temperature, should be constructed of Invar and protected from corrosion as necessary.

X1.2.3. The frame may be designed to be adjustable to accommodate different sample lengths; however, calibrations will be required after each adjustment.



Top View



Front View

Figure X1.1—Schematic of a Measuring Frame

X1.3. *Length Change Measurement Devices*:

X1.3.1. The sample length change may be measured using any suitable apparatus that can be submerged in water, has sufficient resolution, and gives reproducible results. Some apparatus use a submersible spring-loaded LVDT gauge head for length change measurement.

X1.3.2. Appropriate signal conditioning equipment will be required if an LVDT or other electronic transducer is used for length change measurements. A voltmeter or a computer and data acquisition software may also be required if the signal conditioning equipment does not have a digital readout. The LVDT will require calibration using a micrometer to relate the digital readout output (which may be in volts or arbitrary units) to actual length changes.

X1.3.3. The contact tip (at the point of contact between the measuring device and the specimen) must be attached to the length change measuring device with a suitable adhesive to prevent loosening during a test.

X2. REFERENCE TEST FOR DETERMINATION OF CORRECTION FACTOR

X2.1. The test procedure described in Section 7.2 is used to determine a correction factor to account for expansion of the measuring apparatus during the test. A calibration specimen with a known coefficient of thermal expansion should be used. The specimen should be composed of a material that is essentially linearly elastic, noncorroding, non-oxidizing, nonporous, and nonmagnetic, and it should have a known thermal coefficient as close as possible to that of concrete [e.g., a range of 9 to 18 × $10^{-6}/^{o}C$ within the temperature range of 10 to $50^{o}C$ (304 stainless steel is a suitable material)]. An ISO 9001 or equivalent laboratory should determine the CTE of the calibration specimen according to ASTM E 228-06 or ASTM E 289-04 within the temperature range of 10 to $50^{o}C$ and provide a certificate of the CTE value including the lot number of the sample tested. The CTE shall be marked permanently on the calibration specimen. The calibration sample should also be of the same nominal dimensions as the test samples so that no adjustment of the frame and/or the LVDT is necessary between calibration and testing.

X2.2. *Calculation of the Correction Factor*:

X2.3. Assuming that the length change of the apparatus varies linearly with temperature, the correction factor C_f is defined as:

$$C_f = \Delta L_f / L_{cs} / \Delta T \qquad (X2.1)$$

where:

ΔL_f = length change of the measuring apparatus during temperature change, mm (see Equation X2.2);

L_{cs} = measured length of calibration specimen at room temperature, mm; and

ΔT = measured temperature change, °C (increase = positive, decrease = negative).

$$\Delta L_f = \Delta L_a - \Delta L_m \qquad (X2.2)$$

where:

ΔL_a = actual length change of calibration specimen during temperature change, mm (see Equation X2.3); and

ΔL_m = measured length change of calibration specimen during temperature change, mm (increase = positive, decrease = negative).

$$\Delta L_a = L_{cs} \times \alpha_c \times \Delta T \qquad (X2.3)$$

where:

α_c = CTE of calibration specimen, °C (known).

Note X1—It is recommended that at least three calibration tests be performed and that the average of the correction factors calculated for each test be used for calculations on actual concrete tests.

Standard Method of Test for

Fineness of Portland Cement by the Turbidimeter

AASHTO Designation: T 98-99 (2008)[1]
ASTM Designation: C 115-96a

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Fineness of Portland Cement by the Turbidimeter

AASHTO Designation: T 98-99 (2008)[1]
ASTM Designation: C 115-96a

1. SCOPE

1.1. This test method covers determination of the fineness of portland cement as represented by a calculated measure of specific surface, expressed as square centimeters of total surface area per gram, or square meters of total surface area per kilogram, of cement, using the Wagner turbidimeter.[2]

1.2. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

1.3. The values stated in SI units are to be regarded as the standard. The inch-pound equivalents may be approximate.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- T 105, Chemical Analysis of Hydraulic Cement
- T 192, Fineness of Hydraulic Cement by the 45-μm (No. 325) Sieve

2.2. *ASTM Standard*:
- C 670, Standard Practice for Preparing Precision and Bias Statements for Test Methods for Construction Materials
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications

3. SIGNIFICANCE AND USE

3.1. The purpose of this test method is to determine whether or not the hydraulic cement under test meets the Wagner turbidimetric fineness requirements of the applicable hydraulic cement specification for which the test is being made. Fineness of the cement component is only one of the many characteristics that influence the strength capabilities of concrete.

4. APPARATUS

4.1. *Nature of Apparatus*—The Wagner turbidimeter consists essentially of a source of light maintained at constant intensity and adjusted so that approximately parallel rays of light pass through a suspension of the cement to be tested and impinge upon the sensitive plate of a photoelectric cell. The current generated in the cell is measured by means of a microammeter and the indicated reading is a measure of the turbidity of the suspension. General considerations indicate that turbidity is in turn a measure of the surface area of the suspended sample of cement. The apparatus shall consist specifically of the parts described in Sections 4.2 through 4.7 and shall be constructed in accordance with the detailed design and dimensional requirements shown in Figure 1 and Table 1, except that the case may be either of wood or of metal.

Table 1—Turbidimeter Apparatus Dimensions (see Figure 1)

Letter	mm	in.	Letter	mm	in.
A	445	$17^{1}/_{2}$	T	51	2

[a] These are pure numbers such as part of a thread designation and numbers of links per unit; consequently, they do not correspond with column titles.

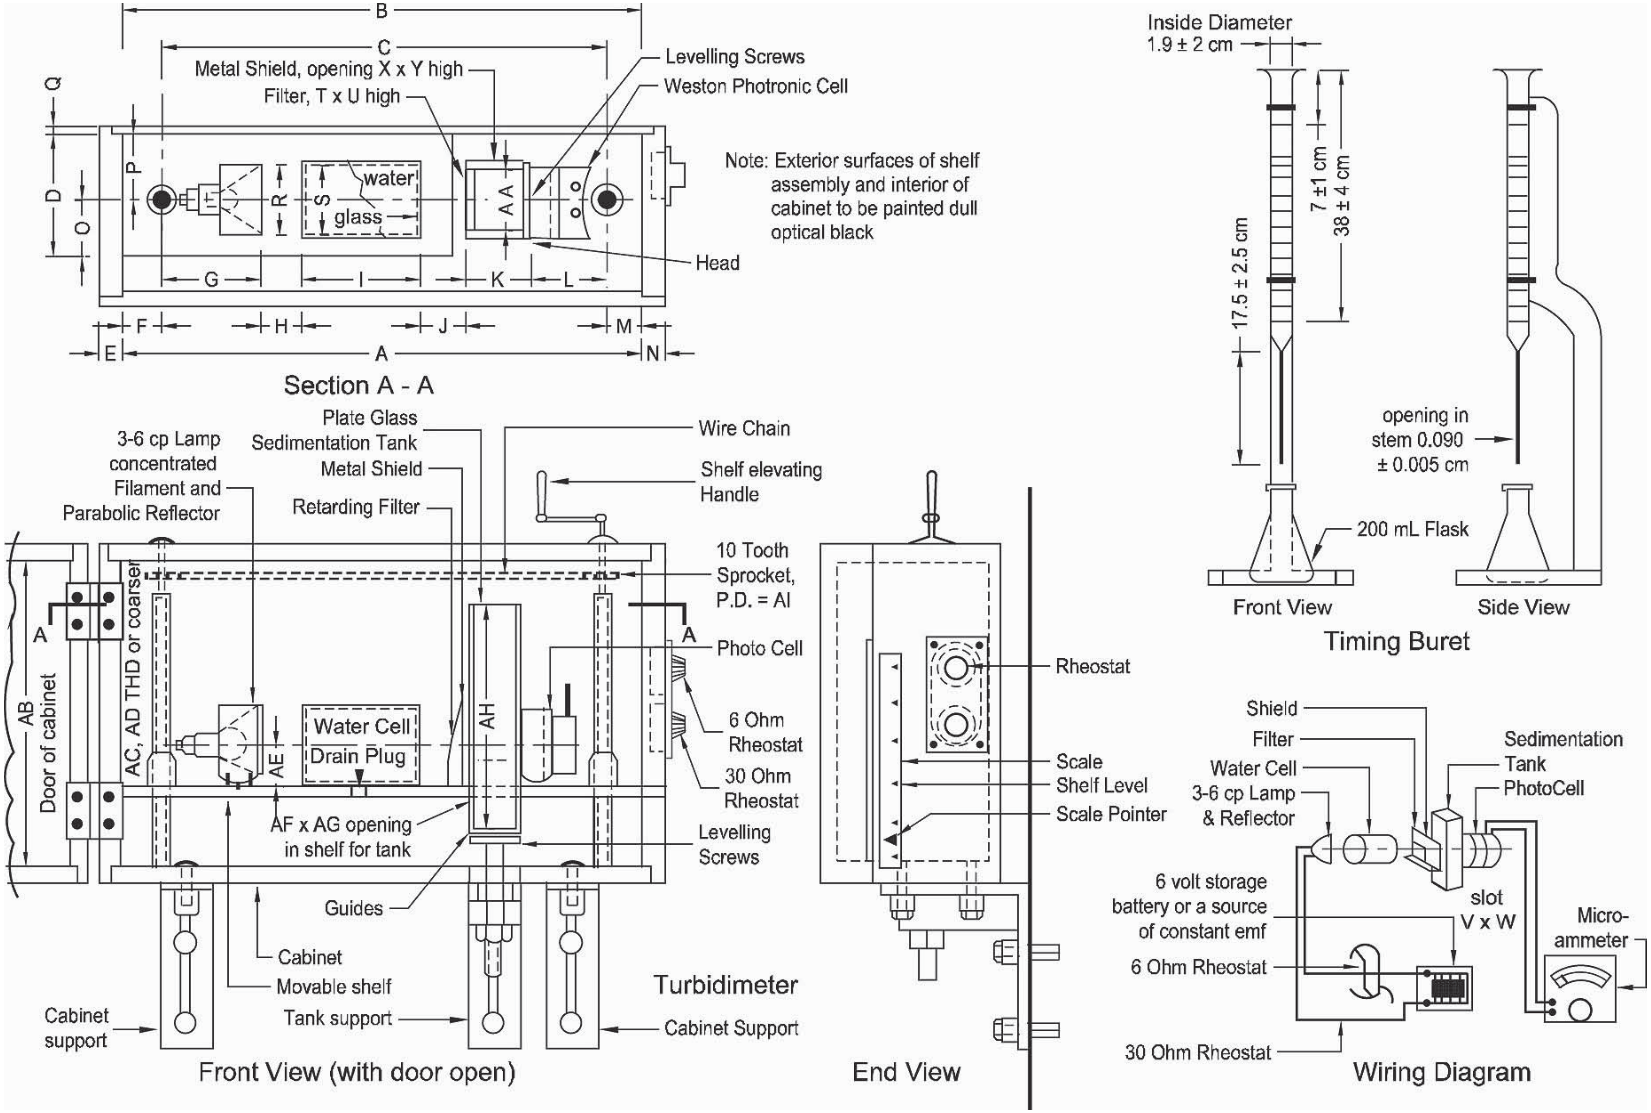

Figure 1—Dimensional Details of Turbidimeter Fineness Test Apparatus (see Table 1)

4.2. *Turbidimeter*—Mounted in a suitable wood or metal case including the following features:

4.2.1. *Source of Light*—The source of light (Figure 1) shall consist of a concentrated-filament electric lamp of between 3 and 6 cp operated by a source of constant emf. The lamp shall be mounted rigidly in the socket. A clean, bright parabolic metallic reflector shall be rigidly mounted behind the lamp, focused so that approximately parallel rays of light will pass through the sedimentation tank and impinge upon the photoelectric cell. The light intensity shall be regulated by two rheostats of approximately 6 and 30 Ω, respectively, and they shall possess such characteristics that uniform changes in light intensity may be obtained over the full range of resistance. The rheostats shall be mounted in parallel with each other and in series with the lamp.

4.2.2. *Heat-Absorbing Device*—The light shall pass through a suitable heat-absorbing device before entering the sedimentation tank in order that radiant heat from the beam shall be absorbed, the device being either (1) a water cell or (2) a special heat-absorbing glass filter. The water cell shall be made from 76-mm (3-in.) outside diameter seamless brass tubing, 3-mm ($^1/_8$-in.) thick wall, 102 mm (4 in.) in length with glass windows sealed in the ends. The cell shall contain a hole for filling with distilled water. The hole shall be sealed with a metal plug. The cell, when mounted on the movable shelf, may have the plug in either the top or bottom position. The heat-absorbing device shall be so arranged that essentially all rays of light entering the sedimentation tank shall first pass through the heat-absorbing device.

4.2.3. *Retarding Filter*—A light-retarding glass or other device shall be provided that will reduce the intensity of light from that corresponding to 100 μA to a reading of 20 to 30 μA. The light intensity shall be uniformly retarded over the entire area of that portion of the cell which is exposed to light during a test. The retarding filter shall be mounted in a carrier on the shield and shall be capable of being swung out of the light path by means of a handle.

4.2.4. *Sedimentation Tank*—The sedimentation tank shall be either (1) constructed of 5- to 6-mm ($^3/_{16}$- to $^1/_4$-in.) plate glass or borosilicate glass cemented or sealed together to form a rectangular tank, or (2) a molded glass tank having walls approximately 5 mm ($^3/_{16}$ in.) thick with plane surfaces. The inside dimensions of the rectangular tank shall be 51 by 38 mm (2 by $1^1/_2$ in.) by 203 mm (8 in.) in height. The permissible variation on the inside dimensions of the tank shall be ±2.5 mm (0.1 in.) in length and ±0.76 mm (0.03 in.) in width. The 51-mm faces of the tank shall be equidistant within 0.25 mm (0.01 in.) at all points. A mark shall be placed on the side of the tank to indicate a volumetric content of 335 mL, which is the level to which the tank will be filled in a test. A tank filled to the mark with clear kerosine and placed in the turbidimeter light beam shall yield uniform microammeter readings, within ±0.1 μA, for the entire usable portion of the tank.

4.2.5. *Photoelectric Cell*—The means of measuring the light intensity shall be a sensitive photoelectric cell[3] connected directly to a microammeter. A hood with a horizontal slot 13 mm ($^1/_2$ in.) in height by 35 mm ($1^3/_8$ in.) in width shall be mounted over the photoelectric cell. The front of the hood shall be 25 ± 1 mm (1 ± $^1/_{16}$ in.) in front of the face of the cell. The face of the photocell shall be parallel to the tank faces within 0.5 mm (0.02 in.)

4.2.6. *Shield*—A metallic shield having a slot 16 mm ($^5/_8$ in.) in height by 38.1 mm ($1^1/_2$ in.) in width, as indicated in Figure 1, shall be placed between the heat-absorbing device and the sedimentation tank.

4.2.7. *Elevating Device*—The source of the light, the heat-absorbing device, the photoelectric cell, the retarding filter, and the shield shall be mounted on a movable shelf which may be raised or lowered by two connected lead screws, and which may be readily and accurately adjusted so that the turbidity of the suspension may be determined at any desired depth. The center of the light source, the heat-absorbing device, the photocell, the center of the slots of the metal shield, and the hood shall be on a straight line, which is parallel to the shelf. The sedimentation tank shall be mounted on a base, which is independent of the rest of the apparatus so that the tank shall be free from vibration caused by moving the shelf. Care shall be taken that the shelf shall be level at all points of elevation and that the tank shall be normal to the shelf. The distance between the tank and the edges of the opening in the shelf shall vary not more than 0.4 mm ($^1/_{64}$ in.) between the "30–50" and "0" positions. The level of the light beam with reference to the surface of the suspension shall be indicated by a pointer, which will travel along a scale mounted on the cabinet. The zero of the scale shall indicate that position at which the center lines of the slots for the light beam are at the same elevation as the surface of the liquid in the tank when filled to the 335-mL level. The lines on the scale to be marked 7.5, 10, 15, 20, 25, and 30–50 shall be located at distances from the zero mark equal to suspension depth values, *h*, in Table 2.

The scale, when compared with a standard scale accurate to within 0.1 mm at all points, shall not show a deviation at any point greater than 0.25 mm and shall indicate the positions at which the pointer should be located when turbidity readings for these values of *h* are taken. The interior of the turbidimeter cabinet and the exterior surfaces of the shelf, the parabolic reflector, the heat-absorbing device, the shield, and the photoelectric cell hood shall be painted with a dull flat black paint.

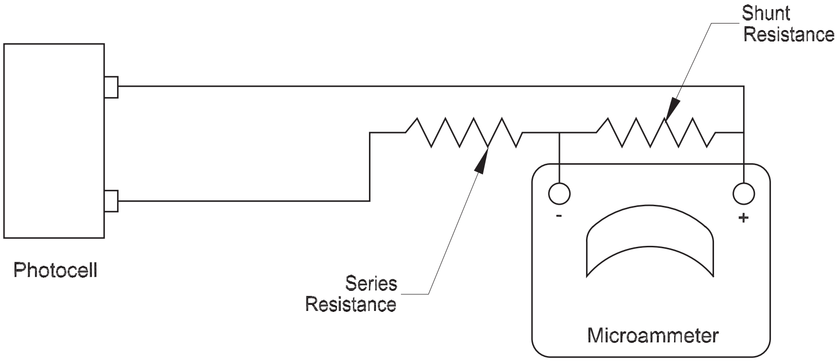
Note 1—The requirement of the 0 to 50 markings on the scale shall apply only to new Wagner Turbidimeters and not to equipment in use that meets the other requirements of this method.

Table 2—Values of *h*, *d*, and h/d^2 to Be Used in Calibration of the Turbidimeter Apparatus

Particle Diameter, *d*, μm	Depth of Suspension, *h*, cm	h/d^2
50	15	0.00600
45	15	0.00741
40	15	0.00938
35	15	0.01224
30	15	0.01667
25	13.1	0.0210
20	10	0.0250
15	6.6	0.0293
10	3.3	0.0330
7.5	2.1	0.0373

4.3. *Microammeters*:

4.3.1. D'Arsonval-Type Microammeters shall have a range from 0 to 50 μA and shall be readable to 0.1 μA. New microammeters shall be accurate to ±0.5 percent of full scale value at any part of the scale at 25ºC (77ºF). For microammeters, in use, the accuracy shall be the same as for new instruments except that the accuracy at 40 and 50 μA shall be ±1 percent of full scale. The internal resistance of the microammeter shall be between 50 and 150 Ω. The microammeter shall not be mounted upon a working surface containing or consisting of iron or steel, or near other magnetic influence.



Microammeter Internal Resistance = 90 Ω

Shunt Equivalent Resistance:

$$470\ \Omega \text{ in Parallel with } 100\Omega = \frac{470 \times 100}{470 + 100} = 82\Omega$$

Meter & Shunt Equivalent + Resistance:

$$90\ \Omega \text{ in Parallel with } 82\Omega = \frac{90 \times 82}{90 + 82} = 43\Omega$$

Series Resistance = 90 - 43 = 47Ω

Figure 2—Illustrated Example of D'Arsonval Meter Circuit for I_r Determination

4.3.2. *Digital Microammeter*:

Note 2—A meter with a range of 199.9 μA is satisfactory for use and enables the operator to read the theoretical *Io* directly without supplementary devices. The high internal resistance of the digital microammeter does not affect the linearity of readings at the light intensity levels encountered in a Wagner turbidimetric determination of fineness.

4.4. *Source of Current*—A 6-V automobile starting and lighting storage battery or a source of constant emf shall be used for supplying current to the lamp.

4.5. *Sieve*—The sieve shall conform to the requirements of T 192.

4.6. *Stirring Apparatus*—The stirring apparatus shall consist of either (1) a cylindrical brush, 19 mm ($^3/_4$ in.) in diameter and about 45 mm (1$^3/_4$ in.) in length, with an end approximately fitting the contour of the bottom of a 22-mm ($^7/_8$-in.) diameter test tube, or (2) any other stirring device that will be equally efficient in dispersion as measured by specific surface determinations on a standard sample. The stirring apparatus shall rotate at a speed of approximately 3500 r/min.

4.7. *Timing Buret*—The time of settling for the different-sized particles shall be obtained by use of a buret from which kerosine is allowed to flow. The buret shall consist of a glass tube having a capillary tube fused into the lower end. The upper end of the large tube shall be flared to serve as a funnel for introducing kerosine into the tube. The buret shall conform to the limiting dimensions given in Table 3. The graduation lines on the buret shall be complete circles. A filter made of 45-μm (No. 325) wire cloth shall be used with the timing buret and a cover shall be placed over the top of the buret when it is not in use.

4.8. *Standard Masses and Balances*—shall conform to the requirements of T 105.

Table 3—Buret Dimensions[a]

	Dimension, cm	Permissible Variation, cm
Length of large tube	38	±4
Inside diameter of large tube	1.9	±0.2
Length of capillary	17.5	±2.5
Diameter of capillary	0.09	±0.005
Top of buret to zero line	7	±1

[a] Since glass tubing of desired dimensions is not always obtainable, the wide permissible variations listed above allow selection of dimensions to produce a buret having a duration of flow which will permit calibration as described in Section 7.1.1.

5. MATERIALS

5.1. *Suspending Liquid*—Clear white kerosine shall be used with the turbidimeter apparatus. The kerosine shall not be reused.

6. TEST SPECIMEN OR SAMPLE

6.1. *Size of Test Sample*—Select the size of the sample of cement for test so that the initial microammeter reading is between 12 and 20 μA.

Note 3—The following approximations will be helpful in many instances in selecting the size of the sample: 0.25 g for normal fineness cements and 0.20 g for high fineness cements.

7. CALIBRATION

7.1. *Calibration of Turbidimeter*—Calibrate the turbidimeter apparatus in accordance with the following procedure:

7.1.1. *Calibration of Buret Scale*:

7.1.1.1. For calibration of the buret scale use a kerosine having a known viscosity and density for the temperature at which the calibration is to be made. Density and viscosity of the kerosine should be determined. Calculate the times of flow from the buret that correspond to the times of settling for the different sized particles, from the following equation:

$$t = [1{,}837{,}000\eta/(\rho_1 - \rho_2)] \times (h/d^2) \qquad (1)$$

where:

t = time of settling, or time of flow, s;
η = density of cement particles, Mg/m^3 (g/cm^3) = 3.15 for portland cement (Note 4);
ρ_1 = density of cement particles, Mg/m^3 (g/cm^3) = 3.15 for portland cement (Note 4);
ρ_2 = density of kerosine, Mg/m^3 at the temperature of calibration;
h = depth of the suspension to level of light, cm; and
d = diameter of particle, μm.

Values of h/d^2 are given in Table 2.

7.1.1.2. Fill the buret with kerosine at the calibrating temperature, start a timing clock at the instant the kerosine in the buret drains past the zero line, and mark on the buret the levels reached by the draining kerosine for each of the time intervals, t, calculated as described above. At these marks, etch permanent lines and numbers on the buret indicating the corresponding diameters (Note 5). The construction and the graduation of the buret shall be such that at the temperature of calibration the time required for the kerosine to pass the permanent lines of the buret agrees with the calculated time of settling within one percent, except that the permissible variation shall be not less than one second.

Note 4—The density of portland cement does not vary greatly and in this work it is considered constant at 3.15. A variation of 0.15 from this value when substituted in Stokes' law gives a variation of 2.5 percent in the diameter of the particle measured.

Note 5—By using the calibrated buret the apparatus may be used within the normal range of room temperatures without further correction, the change in rate of flow of the kerosine from the buret automatically compensating for change in viscosity of the suspension due to temperature. The temperature of the kerosine in the buret and that of the suspension should be kept the same within 0.5ºC (1ºF). This condition will ordinarily exist if the supply of kerosine is kept in the same room as the apparatus.

Care must be taken to ascertain that only clean kerosine is used in the buret, and, in addition, the capillary should be examined frequently to make sure that no small pieces of lint or other foreign material have become lodged in it.

7.1.2. *Calibration of 45-μm (No. 325) Sieve*—Calibration shall be made in accordance with T 192, basing the percentage sieve correction on the difference between the test residue obtained and the assigned residue value indicated by the electroformed sheet sieve fineness specified for the standard sample, expressed as a percentage of the test residue.

7.1.3. *Determination of the Proper Light Intensity, I_r:*

7.1.3.1. Fill the sedimentation tank to the mark with clear kerosine.

7.1.3.2. For a turbidimeter equipped with a digital-type microammeter with a range of 199.9 μA, place the sedimentation tank containing clear kerosine against the guides of the tank support in the turbidimeter. Set the light intensity so that the microammeter reads 100.0 μA. Readjust the light intensity until equilibrium is established at this reading. Place the light-retarding filter in the path of the light beam. When equilibrium is established, record this meter reading as I_r. This meter reading becomes the reference value for the intensity of the light. Meter readings are also taken at the beginning and end of each test through the light retarding filter alone to check the requirements of Section 8.3.8.

7.1.3.3. For a turbidimeter equipped with a D'Arsonval-type microammeter, place the sedimentation tank containing clear kerosine against the guides of the turbidimeter. Set the light intensity so that the microammeter reads 50.0 μA with the light-retarding filter removed from the light path. Readjust the light intensity until equilibrium is established at this reading. Connect resistors or resistor combinations as indicated in Figure 2 so that the meter reading is reduced to an equilibrium value between 23.0 and 25.0 μA. Increase the light intensity until the equilibrium light reading obtained between 23.0 and 25.0 μA is exactly doubled. Readjust the light intensity until the equilibrium is established at this doubled meter reading level. Place the light-retarding filter in the path of the light beam. Remove the resistors from the meter circuit. When equilibrium is established, record this meter reading as I_r. This becomes the reference value for the intensity of the light. Adjust the rheostats at the beginning of each test to give this meter reading through the filter plus the tank of clear kerosine. This meter reading corresponds to a meter reading of 100.0 μA through the tank containing clear kerosine with the light filter removed from the light path. Meter readings are also taken at the beginning and at the end of each test through the light retarding filter alone to check the requirements of Section 8.3.8.

Note 6—A half-watt carbon resistor preferably with 5 percent tolerance limits can be used to obtain the desired meter readings. The shunt resistor or resistor combination as shown in Figure 2 shall have a resistance value between 85 and 100 percent of the value of the internal resistance of the meter as printed on the card in the meter cover. The series resistor shall have a resistance value equal to the difference between the internal resistance of the meter and the calculated resistance of the meter and shunt combination.

Note 7—A less exact, but still acceptable procedure for determining a meter setting that corresponds to a current of 100.0 μA through the meter with the light filter removed from the light path can be achieved by eliminating the series resistor in the meter circuit. The internal resistance of the photocell is sufficiently large to cause only a minor error of approximately 0.5 percent in the desired setting when the series resistor is omitted from the circuit.

7.1.3.4. *Example*—If the internal resistance of the meter is 90 Ω, and the meter is shunted with a 470-Ω resistor in parallel with a 100-Ω resistor, the combined resistance of the meter and shunts would be reduced to 43 Ω. This would reduce the meter reading from 50.0 μA to a calculated value of 23.9 μA.

7.1.4. *Determination of the Value of K in the Specific Surface Equation*—Using the regular procedure in Sections 8.1, 8.2, and 8.3; and with the light adjusted in accordance with the appropriate procedure in Section 7.1.3, make a specific surface determination on the current lot of National Institute of Standards and Technology's Reference Material No. 114.[4] Determine the value of *K* in the specific surface equation in Section 10.1.1 by dividing the assigned specific surface of the standard sample by the value obtained for the expression in brackets [ ]. Repeat this calibration procedure twice more. Use the average of the three results (Note 8) obtained for the value of *K* during calibration in the specific surface equation in Section 10.1.1.

Note 8—The three individual values of *K* determined during calibration should not vary from the average value by more than 1.5 percent.

7.1.5. *Frequency of Calibration*—The turbidimeter apparatus shall be calibrated within six months prior to testing a cement sample.

8. PROCEDURE

8.1. *Sieve Determination*—Make a 45-μm (No. 325) sieve determination on a 1-g sample of cement in accordance with the procedure stated in T 192. Record the percentage (corrected) of cement passing the sieve as *r*.

8.2. *Preparation of the Suspension*:

8.2.1. *Dispersion of the Sample*—Place the cement sample in a test tube together with 10 to 15 mL of kerosine and five drops of dispersing agent—oleic acid or aged linseed oil (Note 9). Stir the mixture for 60 seconds, using the apparatus described in Section 4.6, and then transfer to the sedimentation tank. Wash the stirring apparatus and the tube with clear kerosine, which is then added together with additional clear kerosine until the total volume of the suspension in the tank is 335 mL (Note 10).

Note 9—The oleic acid, if used, shall be of USP grade. The aged linseed oil, if used, shall have a density in the range from 0.948 to 0.953 Mg/m^3 (g/cm^3). These dispersing agents have slight or no effect on the viscosity of the kerosine. Each of these dispersing agents changes with age or with exposure to heat and light—hence should be kept in well-stoppered, dark-glass bottles. Dropping bottles should be emptied, thoroughly cleaned, dried, and refilled periodically. Where conditions are such that poor dispersion is obtained with oleic acid or when foaming of the suspension occurs (possibly due to traces of water in the kerosine), aged linseed oil shall be used as the dispersing agent. The same dispersing agent shall be used for both the instrument calibration and the fineness determination.

Note 10—Since it is important that the level of the liquid in the tank coincide with the zero mark on the scale of the instrument (see Section 4.2.7), it is correspondingly important that the volume of the suspension be close to 335 mL, as specified. This may be accomplished by the use of a flask, calibrated to deliver 335 mL, from which all the kerosine used in making up a suspension is taken; or a point gage may be used, consisting essentially of a flat plate approximately 50 by 63 mm (2 by $2^1/_2$ in.), to the center of which is attached vertically a metal pin of such length that, when the plate is placed in position on top of the tank, the point of the pin is at the 335-mL level. Either of these methods should ensure the position of the liquid level within a few tenths of a millimeter.

8.2.2. *Agitation of the Suspension*—Just before placing the tank in the path of the light beam, agitate the contents to effect a uniformity of the suspension. Cover the tank with a ground-glass cover and oscillate 180º about a horizontal axis through the center of the tank, turning the tank upside down and back again to its original upright position approximately once each second for about 60 seconds (Note 11). Take care to prevent loss of kerosine (Note 12). The suspension is then ready to place in its proper position in the path of the light beam.

Note 11—The procedure described for oscillating the suspension shall be carefully followed. The procedure used in shaking a cocktail shall not be employed.

Note 12—The lid to the tank shall fit so that no kerosine drains down the outside faces of the tank. The faces of the glass tank shall be clean when the suspension is added, and care shall be taken to avoid the necessity of cleaning the faces until the determination is complete.

8.3. *Operation of Turbidimeter*—Operate the turbidimeter apparatus in accordance with the following procedure:

8.3.1. With retarding filter and sedimentation tank containing approximately 100 mL of clear kerosine in the light path, adjust the light to the intensity, I_r, as determined in Section 7.1.3, by taking repeated readings at 60-second intervals until an unchanging value indicates that the lamp and the photoelectric cell are in equilibrium. Remove the tank, check and record the intensity of the lamp.

Note 13—To protect the microammeter, the lamp shall be turned on only with a suspension or the retarding filter in position to reduce the light intensity to a value within the range of the microammeter. A freshly charged storage battery should be momentarily short-circuited to reduce the voltage to constant value. If the microammeter indication continues to fluctuate, look for loose connections in the lamp and photoelectric cell circuits, see that the rheostat contacts are clean, and make certain that the lamp, socket, and reflector are rigidly fixed in their mounting.

8.3.2. Determine the mass of the sample of cement in the appropriate amount and record the mass to the nearest 0.0002 g. Prepare a suspension in accordance with Section 8.2.

8.3.3. Place the shelf-level pointer at the 30–50 μm position.

8.3.4. Fill the buret to the predetermined height with kerosine from the same lot and at the same temperature as the kerosine used in the suspension, and start oscillation of the tank containing the suspension in accordance with Section 8.2.2. Continue the oscillation until the kerosine drains to the zero line on the buret; then stop the agitation. Immediately place the tank in position in the path of the light beam.

8.3.5. Immediately remove the retarding filter from the light path and close the cabinet door.

8.3.6. Read the microammeter to the nearest 0.1 µA at the instant the kerosine in the buret drains past marks 50, 45, 40, 35, and 30.

8.3.7. Raise the shelf successively to the marks 25, 20, 15, 10, and 7.5 on the pointer scale, reading the microammeter at each position as the kerosine drains past the corresponding mark on the buret.

8.3.8. Lower the shelf to the 30–50 µm position. Replace the filter in the path of the light beam, remove the tank, and check the intensity of the lamp. If the microammeter indication has shifted more than 0.3 µA from the initial setting through the filter alone, the test must be repeated.

9. DATA RECORDING

9.1. The form shown in Table 4 is suggested for the recording of turbidimeter data and for the calculation of specific surface.

Table 4— Illustrative Form for Recording Turbidimeter Test Data and Calculation of Specific Surface (See Note 14.)

Sample Identification	Sample
	X
Passing 45-µm (No. 325) sieve, *r*, corrected, *T*	90.4
Calibration factor, *K*	33.9
Meter reading through filter alone, µA:	
Before test	17.5
After test	17.5
Mass of sample tested, g	0.25

Particle Size, µm	*I*, µA	log *I*
50	17.3	1.238[a]
45	17.4	1.241
40	17.6	1.246
35	17.9	1.253
30	18.4	1.265
25	19.1	1.281
20	20.1	1.303
15	21.6	1.334
10	23.9	1.378
7.5	25.6	1.408[a]
	0.75 × 1.408	1.506
		1.500
	Sum =	12.857
	9.5 × 1.238	11.761
	Difference =	1.096

$S = (33.9 \times 90.4 \times 0.762)/1.096 = 2131\ \text{cm}^2/\text{g}$
(Round to 2130 cm2/g or 213 m2/kg)

[a] For convenience in calculation, log I_{50} and log $I_{7.5}$ are rounded in a separate column.

Note 14—Values shown in Table 4 are for purpose of illustration only.

10. CALCULATION

10.1. *Calculation of Specific Surface*:

10.1.1. Calculate the turbidimeter specific surface as follows:

$$S = K\left(\frac{r(2 - \log I_{50})}{1.5 + 0.75 \log I_{7.5} + \log I_{10} + \log I_{15} \ldots + \log I_{45} - 9.5 \log I_{50}}\right) \qquad (2)$$

where:

S = specific surface of the sample, m^2/kg;
K = calibration factor as determined in Section 7.1.4; and
r = corrected mass percent of sample passing the 45-μm (No. 325) sieve (Note 15), and $I_{7.5}$, I_{10}, $I_{15}\ldots$, I_{50} = microammeter readings, μA, that correspond to the particle diameters 7.5, 10, 15…, 50 μm.

Note 15—The value of K as determined in Section 7.1.3 applies only to a material having the density of portland cement (approximately 3.15 Mg/m^3 or g/cm^3). For any other material, the corresponding value must be calculated for this factor which, in the derivation of the formula, varies inversely as the density of the particles (g/cm^3).

10.1.2. To calculate the specific surface values in square meters per kilogram, multiply the surface area in cm^2/g by the factor of 0.1.

10.1.3. Round values in cm^2/g to the nearest 10 units (in m^2/kg to the nearest unit).

10.2. *Specific Surface from First Turbidity Reading* I_{50}—This test method may be used or successive determinations from the same plant, provided that the same size test samples are used and that there is no great change in fineness, color, or other properties of the cement. Under these conditions the specific surface of a sample may be calculated from the first turbidity reading, I_{50}, by using the following equation:

$$S = c(2 - \log I_{50}) \qquad (3)$$

where:

S = specific surface of the sample, m^2/kg;
I_{50} = microammeter reading corresponding to particle diameter of 50 μm; and
c = transmittancy constant for the particular plant.

Note 16—The transmittancy constant, c, may be evaluated by substituting in the above equation known values of S and $2 - \log I_{50}$ as determined from a complete turbidimeter test. The average of not less than five values of c, as determined from complete tests, should be used in the above equation.

10.3. If fineness of a sample as determined in accordance with Section 10.2 fails to conform with the specification requirements for fineness, a retest shall be made using the complete procedure in Sections 8.3, 9.1, and 10.1.

11. PRECISION AND BIAS

11.1. *Single-Operator Precision*—The single-operator coefficient of variation has been found to be 2.6 percent (Note 17). Therefore, results of two properly conducted tests by the same operator on the same sample should not differ by more than 7.3 percent (Note 13) of their average.

11.2. *Multilaboratory Precision*—The multilaboratory coefficient of variation has been found to be 3.8 percent (Note 17). Therefore, results of two different laboratories on identical samples of a material should not differ from each other by more than 10.6 percent (Note 17) of their average.

Note 17—These numbers represent, respectively, the (d1s percent) and (d2s percent) limits as described in Recommended Practice ASTM C 670.

11.3. Since there is no accepted reference material suitable for determining any bias that may be associated with this test method, no statement on bias is being made.

12. KEYWORDS

12.1. Fineness; portland cement; turbidimeter; Wagner.

APPENDIX

(Nonmandatory Information)

X1. CALCULATION OF PARTICLE-SIZE DISTRIBUTION

X1.1. For research or comparative purposes, particle-size distributions to a minimum of 7.5 µm may be of value.

X1.2. *Calculate the particle-size distribution as follows*:

The form shown in Table X1.1 is suggested for the calculation of particle-size distribution.

Table X1.1—Illustrative Form for Calculation of Particle-Size Distribution from Record Turbidimetric Test Data

Particle Size, µm	*I*, µA	$\log_1$	Difference	Average Particle Size, d_1	d_1 × Difference	Mass, Percent	
						Fractional	Cumulative
50	17.3	1.238	0.003	47.5	0.143	2.34	90.4
45	17.4	1.241	0.005	42.5	0.213	3.49	88.1
40	17.6	1.246	0.007	37.5	0.263	4.31	84.6
35	17.9	1.253	0.012	32.5	0.390	6.39	80.3
30	18.4	1.265	0.016	27.5	0.440	7.21	73.9
25	19.1	1.281	0.022	22.5	0.495	8.11	66.7
20	20.1	1.303	0.031	17.5	0.543	8.89	58.6
15	21.6	1.334	0.044	12.5	0.550	9.01	49.7
10	23.9	1.378	0.030	8.75	0.263	4.31	40.7
7.5	25.6	1.408	0.592	3.75	2.220	36.36	36.4
(0)	(100.0)	(2.000)			—		
					5.520		

$F = r/Sum\ (d_1 \times diff) = 90.4/5.520 = 16.377$

Percent fraction = $F\ (d_1 \times diff)$

---

[1] Except for the use of SI units, this method agrees with ASTM C 115-96a.

[2] This turbidimeter was developed by L. A. Wagner, Research Associate of the Cement Reference Laboratory, National Institute of Standards and Technology, Washington, DC. A description of the apparatus and the original mathematical derivations of formulas used are given in the paper: Wagner, L. A., "A Rapid Method for the Determination of the Specific Surface of Portland Cement," Proceedings, ASTM, ASTEA, Vol 33, Part II, 1933, *p*. 553.

[3] Weston Photronic type, Model 594YY, is acceptable.

[4] Obtainable at the National Institute of Standards and Technology, Gaithersburg, MD 20899.

Standard Method of Test for

Chemical Analysis of Hydraulic Cement

AASHTO Designation: T 105-09[1]
ASTM Designation: C 114-07

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Chemical Analysis of Hydraulic Cement

AASHTO Designation: T 105-09[1]
ASTM Designation: C 114-07

1. SCOPE

1.1. These test methods cover the chemical analyses of hydraulic cements. Any test methods of demonstrated acceptable precision and bias may be used for analysis of hydraulic cements, including analyses for referee and certification purposes, as explained in Section 3. Specific chemical test methods are provided for ease of reference for those desiring to use them. They are grouped as Reference Test Methods and Alternate Test Methods. The reference test methods are long accepted classical chemical test methods, which provide a reasonably well-integrated basic scheme of analysis for hydraulic cements. The alternative test methods generally provide individual determination of specific components and may be used alone or as alternates and determinations within the basic scheme at the option of the analyst and as indicated in the individual method. The individual analyst must demonstrate achievement of acceptable precision and bias, as explained in Section 3, when these methods are used.

1.2. *Contents*:

Section	Reference Test Methods (continued)
9	Phosphorus Pentoxide
10	Titanium Dioxide
11	Zinc Oxide
12	Aluminum Oxide
13	Calcium Oxide
14	Magnesium Oxide
15	Sulfur
15.1	Sulfur Trioxide
15.2	Sulfide
16	Loss on Ignition
16.1	Portland Cement
16.2	Portland Blast-Furnace Slag Cement and Slag Cement
17	Sodium and Potassium Oxides
17.1	Total Alkalies
17.2	Water-Soluble Alkalies
18	Manganic Oxide
19	Chloride
20	Chloroform-Soluble Organic Substances
	Alternative Test Methods
21	Calcium Oxide
22	Carbon Dioxide (Reference Test Method)
23	Magnesium Oxide
24	Loss on Ignition
24.1	Portland Blast Furnace Slag Cement and Slag Cement
25	Titanium Dioxide
26	Phosporus Pentoxide
27	Manganic Oxide
28	Free Calcium Oxide

Appendixes	Title
X1	Example of Determination of Equivalence Point for the Chloride Determination
X2	CO_2 Determinations in Hydraulic Cements

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* See Sections 6.3.2.1 and 14.4.1 for specific caution statements.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 85, Portland Cement
- M 240, Blended Hydraulic Cement

- T 98, Fineness of Portland Cement by the Turbidimeter
- T 127, Sampling and Amount of Testing of Hydraulic Cement

2.2. *ASTM Standards*:

- C 25, Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime
- D 1193, Standard Specification for Reagent Water
- E 29, Standard Practice for Using Significant Digits in Test Data to Determine Conformance with Specifications
- E 275, Standard Practice for Describing and Measuring Performance of Ultraviolet and Visible Spectrophotometers
- E 350, Standard Test Methods for Chemical Analysis of Carbon Steel, Low-Alloy Steel, Silicon Electrical Steel, Ingot Iron, and Wrought Iron
- E 617, Standard Specification for Laboratory Weights and Precision Mass Standards
- E 832, Standard Specification for Laboratory Filter Papers

3. NUMBER OF DETERMINATIONS AND PERMISSIBLE VARIATIONS

3.1. *Referee Analyses*—The referee methods that follow in Sections 5 through 20, or other test methods qualified according to Section 3.3, are required for referee analysis in those cases where conformance to chemical specification requirements are questioned. In these cases, a cement shall not be rejected for failure to conform to chemical requirements unless all determinations of constituents involved and all necessary separations prior to the determination of any one constituent are made entirely by referenced test methods prescribed in the appropriate sections of this test method or by other qualified test methods, except when specific test methods are prescribed in the standard specification for the cement in question. The test methods actually used for the analysis shall be designated.

3.1.1. Referee analyses, when there is a question regarding acceptance, shall be made in duplicate and the analyses shall be made on different days. If the two results do not agree within the permissible variation given in Table 1, the determination shall be repeated until two or three results agree within the permissible variation. When two or three results do agree within the permissible variation, their average shall be accepted as the correct value. When an average of either two or three results can be calculated, the calculation shall be based on the three results. For the purpose of comparing analyses and calculating the average of acceptable results, the percentages shall be calculated to the nearest 0.01 (or 0.001 in the case of chloroform-soluble organic substances), although some of the average values are reported to 0.1 as indicated in the methods. When a blank determination is specified, one shall be made with each individual analysis or with each group of two or more samples analyzed on the same day for a given component.

3.1.2. Referee analyses or analyses intended for use as a basis for acceptance or rejection of a cement or for manufacturer's certification shall be made only after demonstration of precise and accurate analyses by the methods in use by meeting the requirements of Section 3.1.3, except when demonstrated under Section 3.3.2.1. Such demonstration may be made concurrently with analysis of the cement being tested and must have been made within the preceding two years. The requirements for verification of equipment and personnel are summarized in Table 2. The demonstration is required only for those constituents being used as a basis for acceptance, rejection, or certification of a cement, but may be made for any constituent of cement for which a standard exists.

Table 1—Maximum Permissible Variation in Results[a]

(Column 1) Component	(Column 2) Maximum Difference between Duplicates[d]	(Column 3) Maximum Difference of the Average of Duplicates from CRM Certificate Values[b,c,d]
SiO_2 (silicon dioxide)	0.16	±0.20
Al_2O_3 (aluminum oxide)	0.20	±0.20
Fe_2O_3 (ferric oxide)	0.10	±0.10
CaO (calcium oxide)	0.20	±0.30
MgO (magnesium oxide)	0.16	±0.20
SO_3 (sulfur trioxide)	0.10	±0.10
LOI (loss on ignition)	0.10	±0.10
Na_2O (sodium oxide)	0.03	±0.05
K_2O (potassium oxide)	0.03	±0.05
TiO_2 (titanium dioxide)	0.02	±0.03
P_2O_5 (phosphorus pentoxide)	0.03	±0.03
ZnO (zinc oxide)	0.03	±0.03
Mn_2O_3 (manganic oxide)	0.03	±0.03
S (sulfide sulfur)	0.01	[f]
Cl (chloride)	0.02	[f]
IR (insoluble residue)	0.10	[f]
Cx (free calcium oxide)	0.20	[f]
Alk_{sol} (water-soluble alkali)[e]	$0.75/^{w}$	[f]
Chl_{sol} (chloroform-soluble organic substances)	0.004	[f]

[a] When all seven CRM cements are required, as for demonstrating performance of rapid test methods, at least six of the seven shall be within the prescribed limits and the seventh shall differ by no more than twice that value. When more than seven CRMs are used, as for demonstrating the performance of rapid test methods, at least 77 percent shall be within the prescribed limits, and the remainder no more than twice the value. When a lesser number of CRM cements are required, all of the values shall be within the prescribed limits.

[b] Interelement corrections may be used for any oxide standardization provided improved accuracy can be demonstrated when correction is applied to all seven CRM cements.

[c] Where an CRM certificate value includes a subscript number, that subscript number shall be treated as a valid significant figure.

[d] Where no value appears in Column 3, CRM certificate values do not exist. In such cases, only the requirement for differences between duplicates shall apply.

[e] w = mass, in grams, of samples used for the test.

[f] Not Applicable. No certificate value given.

3.1.3. Initial qualification of the operator/analyst shall be demonstrated by analysis of each constituent of concern in at least one CRM cement (Note 1) no matter what test method is used (for example, gravimetric, instrumental). Duplicate samples shall be run on different days. The same test methods to be used for analysis of cement being tested shall be used for analysis of the CRM cement. If the duplicate results do not agree within the permissible variation given in Table 1, the determinations shall be repeated, following identification and correction of problems or errors, until a set of duplicate results do agree within the permissible variation.

Note 1—The term CRM (Certified Reference Material) samples refers to National Institute of Standards and Technology (NIST) Hydraulic-Cement Chemical Standard Reference Materials, or other acceptable reference cement as defined in Section 3.1.6.

Table 2—Minimum Number of CRMs Required for Qualification of Chemical Testing

	Method Type	
	Reference[a]	Other[b]
Equipment Qualification	None	7
Operator Qualification[c]	1	1

[a] Reference Methods are those outlined in Sections 5 through 20.

[b] These may be any test method as described in Section 3.2 or any instrumental or rapid test method, which must be qualified in accordance with Section 3.3.

[c] Each operator performing acceptance or reference analyses must be qualified in accordance with Section 3.1.3 at a frequency of two years. If qualification of the instrument is completed by a single operator, the operator has demonstrated individual qualifications per Section 3.1.3.

3.1.4. The average of the results of acceptable duplicate determinations for each constituent may differ from the CRM value by no more than the value shown in Column 2 of Table 1 after correction for minor components when needed.

3.1.5. Data demonstrating that precise and accurate results were obtained with CRM cements by the same analyst making the acceptance determination shall be made available on request to all parties concerned when there is a question of acceptance of a cement. If the CRM used is not a NIST cement, the traceability documentation of the CRM used shall also be made available on request.

3.1.6. Acceptable reference cements are NIST CRMs (Note 1), or other reference cements traceable to the NIST CRMs. The reference cement must have an assigned value for the analyte being determined. Traceability consists of documentary evidence that the assigned values of the reference cement are compatible with the certified values of NIST CRMs. To demonstrate traceability for a given analyte, perform a referee analysis (as defined in Section 3.1) on the proposed reference cement, using a NIST CRM for demonstration of precision and accuracy. The reference cement is acceptable if its assigned value agrees with the average referee value within the limits given in Column 3 of Table 1. If the reference cement, as supplied, has no documented guarantee of homogeneity, establish its homogeneity by analyzing at least six randomly selected samples. No result shall deviate from the assigned value by more than the limits given in Column 2 of Table 1. Acceptable reference cement must be accompanied by a document showing the data produced in demonstrating traceability and homogeneity.

3.2. *Optional Analyses*—The alternative test methods provide, in some cases, procedures that are shorter or more convenient to use for routine determination of certain constituents than are the referenced test methods (Note 2). Longer, more complex procedures, in some instances, have been retained as alternative test methods to permit comparison of results by different procedures or for use when unusual materials are being examined, where unusual interferences may be suspected, or when unusual preparation for analysis is required. Test results from alternative test methods may be used as a basis for acceptance or rejection when it is clear that a cement does or does not meet the specification requirement. Any change in test method procedures from those procedures listed in Sections 5 through 28 requires method qualification in accordance with Section 3.3.

Note 2—It is not intended that the use of reference test methods be confined to referee analysis. A reference test method may be used in preference to an alternate test method when so desired. A reference test method must be used where an alternate method is not provided.

3.2.1. Duplicate analyses and blank determinations are not required when using the alternative test methods. If, however, a blank determination is desired for an alternative test method, one may be used and it need not have been obtained concurrently with the analysis. The final results, when corrected for blank values, should, in either case, be so designated.

3.3. *Performance Requirements for Rapid Test Methods*:[2]

3.3.1. *Definition and Scope*—Where analytical data obtained in accordance with this test method are required, any method may be used that meets the requirements of Section 3.3.2. A test method is considered to consist of the specific procedures, reagents, supplies, equipment, instrument, etc., selected and used in a consistent manner by a specific laboratory. See Note 3 for examples of procedures.

Note 3—Examples of methods used successfully by their authors for analysis of hydraulic cement are given in the list of references. Included are test methods using atomic absorption X-ray spectrometry, and spectrophotometry-EDTA.

3.3.1.1. If more than one instrument, even though substantially identical, is used in a specific laboratory for the same analyses, use of each instrument shall constitute a separate test method and each must be qualified separately.

3.3.2. *Qualification of a Test Method*—Prior to use for analysis of hydraulic cement, each test method (see Section 3.3.1) must be qualified individually for such analysis. Qualification data, or if applicable, requalification data, shall be made available pursuant to the Manufacturer's Certification Section of the appropriate hydraulic cement specification.

3.3.2.1. Using the test method chosen, make single determinations for each oxide under consideration on at least any seven of the CRM samples (Note 1). Complete two rounds of tests on nonconsecutive days repeating all steps of sample preparations. Calculate the differences between values and averages of the values from the two rounds of tests.

3.3.2.2. When seven CRMs are used in the qualification procedure, at least six of the seven differences between duplicates obtained of any single component shall not exceed the limits shown in Column 2 of Table 1 and the remaining differences by no more than twice that value. When more than seven CRMs are used, the values for at least 77 percent of the samples shall be within the prescribed limits, while the values for the remainder shall differ by no more than twice that value.

3.3.2.3. For each component and each CRM, the average obtained shall be compared to the certified concentrations. Where a certificate value includes a subscript number, that subscript shall be assumed to be a significant number. When seven CRMs are used in the qualification procedure, at least six of the seven averages for each component (oxide) shall not differ from the certified concentrations by more than the value shown in Column 3 of Table 1, and the remaining average by more than twice that value. When more than seven CRMs are used in the qualification procedure, at least 77 percent of the averages for each component (oxide) shall not differ from the certified concentrations by more than the value shown in Column 3 of Table 1, and the remaining average(s) by more than twice that value.

3.3.2.4. The standardization, if needed, used for qualification and for analysis of each constituent shall be determined by valid curve-fitting procedures. The qualification testing shall be conducted with newly prepared specimens. A point-to-point, saw-tooth curve that is artificially made to fit a set of data points does not constitute a valid curve-fitting procedure. A complex polynomial drawn through the points is similarly not valid. For the same reason, empirical inter-element corrections may be used only if $\leq (N - 3)/2$ are employed, where N is the number of different standards used. The qualification testing shall be conducted with specimens newly prepared from scratch, including all the preparation stages applicable for analysis of an unknown sample, and employing the reagents currently in use for unknown analyses.

3.3.3. *Partial Results*—Test methods that provide acceptable results for some components but not for others may be used only for those components for which acceptable results are obtained.

3.3.4. *Report of Results*—Chemical analyses obtained by qualified rapid test methods and reported pursuant to the Manufacturer's Certification Section of the appropriate hydraulic cement specification shall be indicated as having been obtained by rapid methods and the type of test method used shall be designated.

3.3.5. *Rejection of Material*—See Sections 3.1 and 3.2.

3.3.6. *Requalification of a Test Method*:

3.3.6.1. Requalification of a test method shall be required upon receipt of substantial evidence that the test method may not be providing data in accordance with Table 1 for one or more constituents. Such requalification may be limited to those constituents indicated to be in error and shall be carried out prior to further use of the test method for analysis of those constituents.

3.3.6.2. Substantial evidence that a test method may not be providing data in accordance with Table 1 shall be considered to have been received when a laboratory is informed that analysis of the same material by Reference Test Methods run in accordance with Section 3.1.1, the final average of a CCRL sample, a certificate value of an NIST CRM, the assigned value of an alternate CRM or an accepted value of a known secondary standard differs from the value obtained by the test method in question by more than twice the value shown in Column 2 of Table 1 for one or more constituents. When indirect test methods are involved, as when a value is obtained by difference, corrections shall be made for minor constituents in order to put analyses on a comparable basis prior to determining the differences. (See Note 4.) For any constituents affected, a test method also shall be requalified after any substantial repair or replacement of one or more critical components of an instrument essential to the test method.

Note 4—Instrumental analyses can usually detect only the element sought. Therefore, to avoid controversy, the actual procedure used for the elemental analyses should be noted when actual differences with reference procedures can exist. For example, P_2O_5 and TiO_2 are included with Al_2O_3 in the usual wet test method and sulfide sulfur is included in most instrumental procedures with SO_3.

3.3.6.3. If an instrument or piece of equipment is replaced, even if by one of identical make or model, or is significantly modified, a previously qualified test method using such new or modified instrument or equipment shall be considered a new test method and must be qualified in accordance with Section 3.3.2.

3.4. *Precision and Bias*—Different analytical test methods are subject to individual limits of precision and bias. It is the responsibility of the user to demonstrate that the test methods used at least meet the limits of precision and bias shown in Table 1.

4. GENERAL

4.1. *Interferences and Limitations*:

4.1.1. These test methods were developed primarily for the analysis of portland cements. However, except for limitations noted in the procedure for specific constituents, the reference test methods provide for accurate analyses of other hydraulic cements that are completely decomposed by hydrochloric acid or where a preliminary sodium carbonate fusion is made to ensure complete solubility. Some of the alternate test methods may not always provide accurate results because of interferences from elements that are not removed during the procedure.

4.1.2. When using a test method that determines total sulfur, such as most instrumental test methods, sulfide sulfur will be determined with sulfate and included as such. In most hydraulic cements, the difference resulting from such inclusion will be insignificant, less than 0.05 percent weight. In some cases, notably slags and slag-containing cements but sometimes other cements as well, significant levels of sulfide may be present. In such cases, especially if there is a question of meeting or not meeting a specification limit or when the most accurate results are desired, analytical test methods shall be chosen so that sulfate and sulfide can be reported separately.

4.2. *Apparatus and Materials*:

4.2.1. *Balance*—The analytical balance used in the chemical determinations shall conform to the following requirements:

4.2.1.1. The balance shall have a capacity of not more than 200 g. It may be of conventional design, either with or without "quick-mass determination" devices, or it may be a constant-load, direct-reading type. It shall be capable of reproducing results within 0.2 mg with an accuracy of ±0.2 mg. Direct-reading balances shall have a sensitivity not exceeding 0.1 mg (Note 5). Conventional two-pan balances shall have a maximum sensibility reciprocal of 0.3 mg. Any rapid mass determination device that may be provided, such as a chain, damped motion, or heavy riders, shall not increase the basic inaccuracy by more than 0.1 mg at any reading and with any load within the rated capacity of the balance.

Note 5—The sensitivity of a direct-reading balance is the mass required to change the reading one graduation. The sensibility reciprocal for a conventional balance is defined as the change in mass required on either pan to change the position of equilibrium one division on the pointer scale at capacity or at any lesser load.

4.2.2. *Standard Masses*—Standard masses used for analysis shall conform to Types I or II, Grades S or O, Classes 1, 2, or 3 as described in ASTM E 617. They shall be checked at least once a year, or when questioned, and adjusted at least to within allowable tolerances for Class 3 standard masses (Note 6). For this purpose each laboratory shall also maintain, or have available for use, a reference set of standard masses from 50 g to 10 mg, which shall conform at least to Class 3 requirements and be calibrated at intervals not exceeding five years by the National Institute of Standards and Technology (NIST). After initial calibration, recalibration by NIST may be waived provided it can be shown by documented data obtained within the time interval specified that a mass comparison between summations of smaller masses and a single larger mass nominally equal to that summation, establishes that the allowable tolerances have not been exceeded. All new sets of weights purchased shall have the masses of 1 g and larger made of stainless steel or other corrosion-resisting alloy not requiring protective coating, and shall meet the density requirements for Grades S or O.

Note 6—The scientific supply houses do not presently list masses as meeting ASTM E 617. They list masses as meeting NIST or International Organization of Legal Metrology (OIML) standards. The situation with regard to masses is in a state of flux because of the trend toward internationalization. Hopefully, this will soon be resolved. NIST Classes S and S-1 and OIML Class F_1 masses meet the requirements of this standard.

4.2.3. *Glassware and Laboratory Containers*—Standard volumetric flasks, burets, and pipets should be of precision grade or better. Standard-taper, interchangeable, ground-glass joints are recommended for all volumetric glassware and distilling apparatus, when available. Wherever applicable, the use of special types of glassware, such as colored glass, for the protection of solutions against light, alkali-resistant glass, and high-silica glass having exceptional resistance to thermal shock is recommended. Polyethylene containers are recommended for all aqueous solutions of alkalies and for standard solutions where the presence of dissolved silica or alkali from the glass would be objectionable. Such containers shall be made of high-density polyethylene having a wall thickness of at least 1 mm.

4.2.4. *Desiccators*—Desiccators shall be provided with a good desiccant, such as magnesium perchlorate, activated alumina, or sulfuric acid. Anhydrous calcium sulfate may also be used provided it has been treated with a color-change indicator to show when it has lost its effectiveness. Calcium chloride is not a satisfactory desiccant for this type of analysis.

4.2.5. *Filter Paper*—Filter paper shall conform to the requirements of ASTM E 832, Type II, Quantitative. When coarse-textured paper is required, Class E paper shall be used; when medium-textured paper is required, Class F paper shall be used; and when retentive paper is required, Class G shall be used.

4.2.6. *Crucibles*—Platinum crucibles for ordinary chemical analysis should preferably be made of pure unalloyed platinum and be of 15 to 30-mL capacity. Where alloyed platinum is used for greater stiffness or to obviate sticking of crucible and lid, the alloyed platinum should not decrease in mass by more than 0.2 mg when heated at 1200°C for one hour.

4.2.7. *Muffle Furnace*—The muffle furnace shall be capable of operation at the temperatures required and shall have an indicating pyrometer accurate within ±25°C, as corrected, if necessary, by calibration. More than one furnace may be used provided each is used within its proper operating temperature range.

4.3. *Reagents*:

4.3.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available.[3] Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

4.3.2. Unless otherwise indicated, references to water shall mean water conforming to the numerical limits for type II reagent water described in ASTM D 1193.

4.3.3. *Concentration of Reagents*:

4.3.3.1. *Prepackaged Reagents*—Commercial prepackaged standard solutions or diluted prepackaged concentrations of a reagent may be used whenever that reagent is called for in the procedures provided that the purity and concentrations are as specified. Verify purity and concentration of such reagents by suitable tests.

4.3.3.2. *Concentrated Acids and Ammonium Hydroxide*—When acids and ammonium hydroxide are specified by name or chemical formula only, it shall be understood that concentrated reagents of the following specific gravities or concentrations by mass are intended:

Acetic acid ($HC_2H_3O_2$)	99.5 percent
Hydrochloric acid (HCl)	sp gr 1.19
Hydrofluoric acid (HF)	48 percent
Nitric acid (HNO_3)	sp gr 1.42
Phosphoric acid (H_3PO_4)	85 percent
Sulfuric acid (H_2SO_4)	sp gr 1.84
Ammonium hydroxide (NH_4OH)	sp gr 0.90

4.3.3.3. The desired specific gravities or concentrations of all other concentrated acids shall be stated whenever they are specified.

4.3.4. *Diluted Acids and Ammonium Hydroxide*—Concentrations of diluted acids and ammonium hydroxide, except when standardized, are specified as a ratio stating the number of volumes of the concentrated reagent to be added to a given number of volumes of water, for example: HCl (1 + 99) means 1 volume of concentrated HCl (sp gr 1.19) added to 99 volumes of water.

4.3.5. *Standard Solutions*—Concentrations of standard solutions shall be expressed as normalities (*N*) or as equivalents in grams per milliliter of the component to be determined, for example: 0.1 (*N*) $Na_2S_2O_3$ solution or $K_2Cr_2O_7$ (1 mL = 4 mg Fe_2O_3). The average of at least three determinations shall be used for all standardizations. When a material is used as a primary standard, reference has generally been made to the standard furnished by NIST. However, when primary standard grade materials are otherwise available they may be used or the purity of a salt may be determined by suitable tests.

4.3.6. *Nonstandardized Solutions*—Concentrations of nonstandardized solutions prepared by dissolving a given mass of the solid reagent in a solvent shall be specified in grams of the reagent per liter of solution, and it shall be understood that water is the solvent unless otherwise specified, for example: NaOH solution (10 g/L) means 10 g of NaOH dissolved in water and diluted with water to 1 L. Other nonstandardized solutions may be specified by name only, and the concentration of such solutions will be governed by the instructions for their preparation.

4.3.7. *Indicator Solutions*:

4.3.7.1. *Methyl Red*—Prepare the solution on the basis of 2 g of methyl red/L of 95 percent ethyl alcohol.

4.3.7.2. *Phenolphthalein*—Prepare the solution on the basis of 1 g of phenolphthalein/L of 95 percent ethyl alcohol.

4.4. *Sample Preparation*:

4.4.1. Before testing, pass representative portions of each sample through an 850-µm (No. 20) sieve, or any other sieve having approximately eight openings per 10 mm (20 openings per l in.) in order to mix the sample, break up lumps, and remove foreign materials. Discard the foreign materials and hardened lumps that do not break up on sieving or brushing.

4.4.2. By means of a sample splitter or by quartering, the representative sample shall be reduced to a laboratory sample of at least 50 g. Where larger quantities are required for additional determinations such as water-soluble alkali, chloride, duplicate testing, etc., prepare a sample of at least 100 g.

4.4.3. Pass the laboratory sample through a 150-µm (No. 100) sieve. Further grind the sieve residue so that it also passes the 150-µm sieve determinations. Homogenize the entire sample by again passing it through the sieve.

4.4.4. Transfer the sample to a clean, dry glass container with an airtight lid and further mix the sample thoroughly.

4.4.5. Expedite the above procedure so that the sample is exposed to the atmosphere for a minimum time.

4.5. *General Procedures*:

4.5.1. *Mass Determinations*—The calculations included in the individual test methods assume that the exact mass specified has been used. Samples that are approximately but not exactly equal to the mass specified may be used provided appropriate corrections are made in the calculations. Unless otherwise stated, the mass of all samples and residues should be recorded to the nearest 0.1 mg.

4.5.2. *Tared or Weighed Crucibles*—The tare mass of crucibles shall be determined by preheating the empty crucible to constant mass at the same temperature and under the same conditions as shall be used for the final ignition of a residue and cooling in a desiccator for the same period of time used for the crucible containing the residue.

4.5.3. *Constancy of the Mass of Ignited Residues*—To definitely establish the constancy of mass of an ignited residue for referee purposes, the residue shall be ignited at the specified temperature and for the specified time, cooled to room temperature in a desiccator, and its mass determined. The residue shall then be reheated for at least 30 minutes, cooled to room temperature in a desiccator, and its mass determined. If the two masses do not differ by more than 0.2 mg, constant mass is considered to have been attained. If the difference in mass is greater than 0.2 mg, additional ignition periods are required until two consecutive mass determinations agree within the specified limits. For ignition loss, each reheating period shall be five minutes.

4.5.4. *Volatilization of Platinum*—The possibility of volatilization of platinum or alloying constituents from the crucibles must be considered. On reheating, if the crucible and residue lose the same mass (within 0.2 mg) as the crucible containing the blank, constant mass can be assumed. Crucibles of the same size, composition, and history shall be used for both the sample and the blank.

4.5.5. *Calculation*—In all operations on a set of observed values such as manual multiplication or division, retain the equivalent of at least two more places of figures than in the single observed values. For example, if observed values are read or determined to the nearest 0.1 mg, carry numbers to the nearest 0.001 mg in calculation. When using electronic calculators or computers for calculations, perform no rounding, except in final report value.

4.5.6. *Rounding Figures*—Rounding of figures to the number of significant places required in the report should be done after calculations are completed, in order to keep the final results substantially free of calculation errors. The rounding procedure should follow the principle outlined in ASTM E 29.[4] In assessing analyst-and method-qualification in accordance with Section 3, the individual duplicate results, the difference between them, the average of duplicates on CRMs, and the difference of this average from the certificate value shall be left un-rounded for comparison with the required limits. Round results for reporting as shown in Table 3 (Note 7).

Note 7—The rounding procedure referred to in Section 4.5.6, in effect, drops all digits beyond the number of places to be retained if the next figure is less than five. If it is more than five, or equal to five and subsequent places contain a digit other than zero, then the last retained digit is increased by one. When the next digit is equal to five and all other subsequent digits are zero, the last digit to be retained is unchanged when it is even and increased by one when it is odd. For example, 3.96 (50) remains 3.96, but 3.95 (50) becomes 3.96.

4.6. *Recommended Order for Reporting Analyses*—The following order is recommended for reporting the results of chemical analysis of portland cement:

4.6.1. *Major Components*:

- SiO_2 (silicon dioxide)
- Al_2O_3 (aluminum oxide)
- Fe_2O_3 (ferric oxide)
- CaO (calcium oxide)
- MgO (magnesium oxide)
- SO_3 (sulfur trioxide)
- LOI (loss on ignition)

4.6.2. *Minor Components*:

- Na_2O (sodium oxide)
- K_2O (potassium oxide)
- TiO_2 (titanium dioxide)
- P_2O_5 (phosphorus pentoxide)
- ZnO (zinc oxide)
- Mn_2O_3 (manganic oxide)
- S (sulfide sulfur)

4.6.3. *Separate Determinations*:

- IR (insoluble residue)
- Cx (free calcium oxide)
- CO_2 (carbon dioxide)
- Alk_{sol} (water soluble alkali)
- Chl_{sol} (chloroform-soluble organic substances)

REFERENCE TEST METHODS

5. INSOLUBLE RESIDUE (REFERENCE TEST METHOD)

5.1. *Summary of Test Method*:

5.1.1. In this test method, insoluble residue of a cement is determined by digestion of the sample in hydrochloric acid followed, after filtration, by further digestion in sodium hydroxide. The resulting residue is ignited and the mass is determined (Note 8).

Note 8—This test method or any other test method designed for the estimation of an acid-insoluble substance in any type of cement is empirical, because the amount obtained depends on the reagents and the time and temperature of digestion. If the amount is large, there may be a little variation in duplicate determination. The procedure should be followed closely in order to reduce the variation to a minimum.

5.1.2. When the test method is used on blended cement, the decomposition in acid is considered to be complete when the portland cement clinker is decomposed completely. An ammonium nitrate solution is used in the final washing to prevent finely ground insoluble material from passing through the filter paper.

5.2. *Reagents*:

5.2.1. *Ammonium Nitrate Solution* (20 g NH_4NO_3/L).

5.2.2. *Sodium Hydroxide Solution* (10 g NaOH/L).

Table 3—Rounding of Reported Results

Component	Decimal Places
SiO_2 (silicon dioxide)	1
Al_2O_3 (aluminum oxide)	1
Fe_2O_3 (ferric oxide)	2
CaO (calcium oxide)	1
MgO (magnesium oxide)	1
SO_3 (sulfur trioxide)	2
LOI (loss on ignition)	1
Na_2O (sodium oxide)	2
K_2O (potassium oxide)	2
SrO (strontium oxide)	2
TiO_2 (titanium dioxide)	2
P_2O_5 (phosphorous pentoxide)	2
ZnO (zinc oxide)	2
Mn_2O_3 (manganic oxide)	3
S (sulfide sulfur)	2
Cl (chloride)	3
IR (insoluble residue)	2
Cx (free calcium oxide)	1
CO_2 (carbon dioxide)	1
Alk_{sol} (water-soluble alkali)	2
Chl_{sol} (chloroform-soluble organic substances)	3

5.3. *Procedure*:
