6.3.2 If the composition falls in one of the two ranges identified as “Aggregates considered non-expansive” in Figure 2, the aggregate is not potentially alkali-carbonate reactive, and it should be tested to determine the potential for alkali-silica reaction using the accelerated mortar bar test (Section 6.4) or the concrete prism test (Section 6.5), or both.

6.3.3 If the composition falls in the range of “aggregates considered to be potentially expansive,” the aggregate is potentially alkali-carbonate reactive and must be evaluated further. There are two options for further testing. One option is to test the aggregate in the concrete prism test, ASTM C 1293 (see Section 6.5), to simultaneously determine the potential for alkali-carbonate and alkali-silica reactivity. After the test, the prisms are examined by petrography to determine the role played by the alkali-carbonate reaction (see Section 6.5.5). The second option is to test using the concrete prism test, ASTM C 1105, with a reduced alkali loading to determine the potential for alkali-carbonate reaction only (see Section 6.6). If the aggregate passes the expansion criteria in Section 6.6, it is considered not to be alkali-carbonate reactive and can be tested in the same manner as aggregates with a composition that falls in the two ranges identified as “Aggregate considered non-expansive” in Figure 2 (see Section 6.3.2).

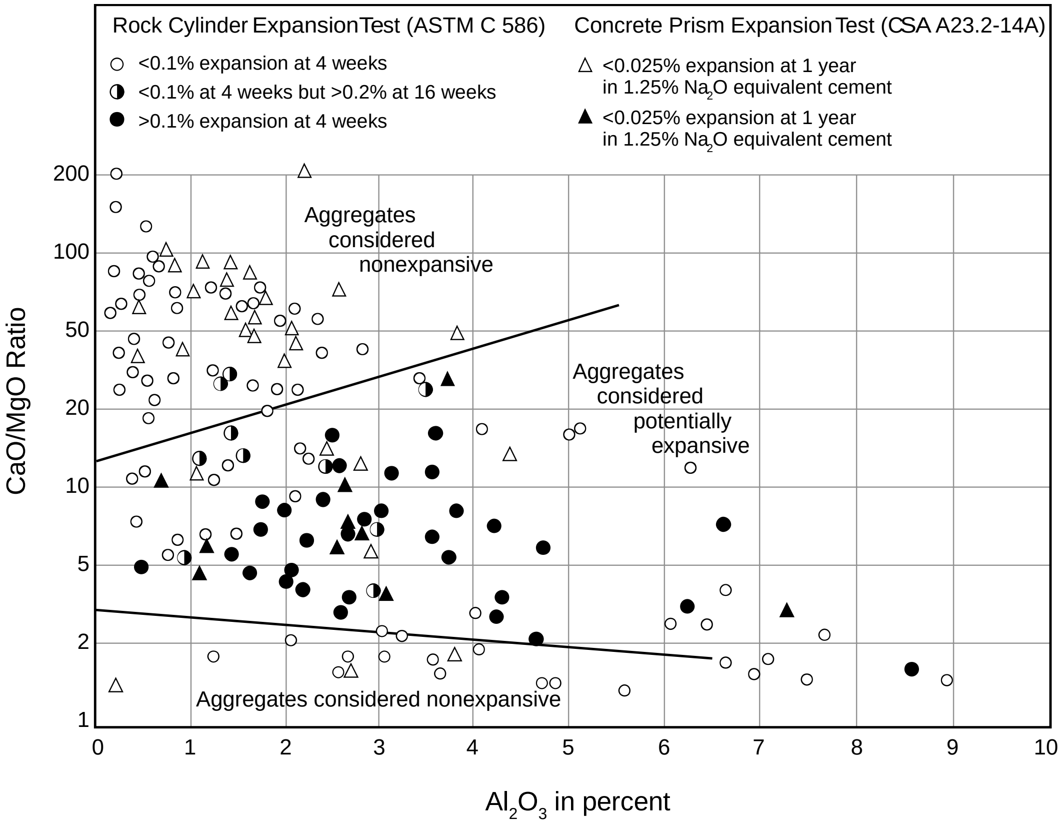

Figure 2—Using Chemical Composition as a Basis for Determining Potential Alkali-Carbonate Reactivity of Quarried Carbonates (from CSA A23.2-26A)

6.4 *Accelerated Mortar Bar Test (T 303)*:

6.4.1 The aggregate may be tested in accordance with T 303 if it meets one of the following three criteria: (1) the aggregate is not a quarried carbonate, (2) the aggregate is a quarried carbonate with a composition that falls outside of the region of “aggregates considered to be potentially expansive” in Figure 2 when tested in accordance with CSA A23.2-26A, or (3) the aggregate is a quarried carbonate that does not cause excessive expansion when tested in ASTM C 1105 in accordance with Section 6.6.

6.4.2 This test is intended to evaluate coarse and fine aggregates separately and should not be used to evaluate job combinations of coarse and fine aggregates.

6.4.3 If the expansion of mortar bars following 14 days immersion in sodium hydroxide solution is not greater than 0.10 percent, the aggregate is considered non-deleteriously reactive and can be accepted for use (see Note 4).

6.4.4 If the mortar bar expansion is greater than 0.10 percent at 14 days, the aggregate is considered to be potentially deleteriously reactive and its reactivity should be confirmed by testing in ASTM C 1293 (Section 6.5). If there is insufficient time or resources to run ASTM C 1293, the aggregate should be treated as potentially reactive and appropriate preventive measures must be selected.

Note 4—Many aggregates fail the accelerated mortar bar test (14-day expansion > 0.10 percent) but do not cause deleterious expansion in concrete. An aggregate should not be rejected solely on the basis of this test.

Note 5—A number of aggregates (e.g., some siliceous sandstones and granite/gneiss) that pass this test (14-day expansion ≤ 0.10 percent) have been found to cause deleterious expansion when used in concrete. There is a level of risk associated with relying solely on this test to identify reactive aggregates.

Note 6—Some agencies have used a lower expansion limit or an extended test duration, or both, (e.g., 0.08 percent and 28 days) or a higher expansion limit (e.g., 0.15 percent at 14 days).

6.5 *Concrete Prism Test (ASTM C 1293)*:

6.5.1 The concrete prism test is suitable for evaluating all aggregate types and is considered to be the most reliable laboratory test for predicting the field performance of aggregates. The test should be conducted in accordance with ASTM C 1293.

6.5.2 If the aggregate being tested is a coarse aggregate, it is blended with a non-deleteriously-reactive fine aggregate for testing. Similarly if the aggregate being tested is a fine aggregate, it is blended with a non-deleteriously-reactive coarse aggregate for testing. The coarse-fine aggregate combination is used to produce concrete prisms that have a specified high alkali loading.

6.5.3 If the expansion of concrete prisms is not greater than 0.04 percent after 1 year, the aggregate is considered non-deleteriously reactive and may be used in concrete with no further testing (for ASR or ACR).

6.5.4 If the expansion of concrete prisms is greater than 0.040 percent after 1 year, the aggregate is considered to be alkali-silica reactive provided it meets one of the following three criteria: (1) the aggregate is not a quarried carbonate, (2) the aggregate is a quarried carbonate with a composition that falls outside of the region of “aggregates considered to be potentially expansive” in Figure 2 when tested in accordance with CSA A23.2-26A, or (3) the aggregate is a quarried carbonate that does not cause excessive expansion when tested in ASTM C 1105 in accordance with Section 6.6. Preventive measures are required if the aggregate is to be used in concrete construction (see Sections 7 and 8).

6.5.5 If the expansion of concrete prisms is greater than 0.04 percent after 1 year and the aggregate tested was a quarried carbonate rock with a chemical composition that fell within the region of “aggregates considered to be potentially reactive,” the concrete prisms must be examined by an experienced petrographer to determine whether alkali-carbonate reaction contributed to the expansion. If damaging ACR is detected, either in isolation or in combination with ASR, the aggregate should not be used in concrete without selective quarrying or processing to limit the reactive components to acceptable levels. If ASR is determined to be the only cause of expansion of the concrete, preventive measures are required if the aggregate is to be used in concrete construction (see Sections 7 and 8). The use of ASTM C 1105 may be used as an option to ASTM C 1293 for determining the potential for alkali-carbonate reaction (see Section 6.6).

6.6 *Concrete Prism Test for Alkali-Carbonate Reaction (ASTM C 1105)*:

6.6.1 The aggregate shall be tested using ASTM C 1105, but the alkali content of the concrete shall be kept below 1.8 kg/m^3 (3.0 lb/yd^3) Na_2Oe to ensure that ASR does not occur. It is preferred that the test be run for a duration of 12 months, but expansion values at earlier ages may be used if necessary.

6.6.2 If the expansion of the cement-aggregate combination is equal to or greater than 0.025 percent at 6 months or 0.030 percent at 1 year, the aggregate shall be considered to be alkali-carbonate reactive and shall not be used in concrete.

6.6.3 If the expansion of the concrete prisms does not exceed the values set forth in Section 6.6.2, the aggregate shall be considered not to be alkali-carbonate reactive and should be tested to determine the potential for alkali-silica reactivity using the accelerated mortar bar test (T 303) or the concrete prism test (ASTM C 1293), or both, in accordance with Sections 6.4 and 6.5.

7. SELECTING PREVENTIVE MEASURES FOR ALKALI-SILICA REACTION (ASR)—PERFORMANCE APPROACH

7.1 *Using the Concrete Prism Test (ASTM C 1293) to Evaluate Preventive Measures*:

7.1.1 The concrete prism test may be used to evaluate the efficacy of supplementary cementitious materials (SCM), such as pozzolans and slag, blended cements (containing SCM), and lithium nitrate admixtures for preventing damaging alkali-silica reaction. It is prudent to conduct a number of tests using varying levels of SCM or lithium nitrate to determine the amount required to prevent deleterious expansion.

7.1.2 When testing blended cement or supplementary cementitious materials (SCM), the test should be conducted in accordance with ASTM C 1293 (see Note 7).

7.1.3 When testing lithium nitrate admixtures, the admixture should be added to the mix water and necessary corrections should be made to account for the water in the admixture. The test should otherwise be conducted in accordance with ASTM C 1293 (see Note 7). See Annex A2 on calculation of lithium nitrate additions.

7.1.4 If the expansion of concrete prisms is not greater than 0.04 percent after 2 years, the combination of SCM or lithium nitrate admixture and reactive aggregate is considered acceptable for use in concrete construction provided that the (equivalent) alkali content of the portland cement used in the job mixture does not exceed 1.00 percent Na_2Oe.

Note 7—If a reactive aggregate is to be used in a job mixture that contains a cement with an alkali content in excess of 1.00 percent Na_2Oe, the test procedure of ASTM C 1293 should be used with the following modifications. The job cement should be used in the test and the cement alkalis should be raised by 0.25 percent Na_2Oe above the alkali content of the job cement by the addition of NaOH to the mix water.

7.1.5 If the expansion of concrete prisms is greater than 0.04 percent after 2 years, the preventive measure is not deemed to be effective with the reactive aggregate. Consideration should be given to retesting the aggregate with an increased level of SCM or lithium nitrate.

7.2 *Using the Accelerated Mortar-Bar Test (T 303) to Evaluate Preventive Measures*:

7.2.1 Before the accelerated mortar bar test (AMBT) is used to determine the performance of a specific blended cement-aggregate, SCM-aggregate, or lithium nitrate-aggregate combinations, it is recommended that it first be demonstrated that the aggregate being evaluated responds well to the accelerated test. This requires a comparison of the results from the accelerated mortar bar test and the concrete prism test for the aggregate being used (without preventive measures). After subjecting the aggregate to both tests, the results are plotted on Figure 3. Provided the data fall within the region indicated in Figure 3, the accelerated mortar bar test (ASTM C 1567) is generally considered to be suitable for determining the efficacy of blended cements, SCMs, and lithium nitrate. The results from the accelerated mortar bar test and the concrete prism test should be compared every 2 years unless the results of petrography or other tests indicate a significant change in the composition of the material in the quarry, in which case new tests should be commenced immediately. If there is insufficient time to conduct a comparison between the two tests, then the accelerated mortar bar test can be used; however, there is an increased level of risk associated with making decisions based on this test alone.

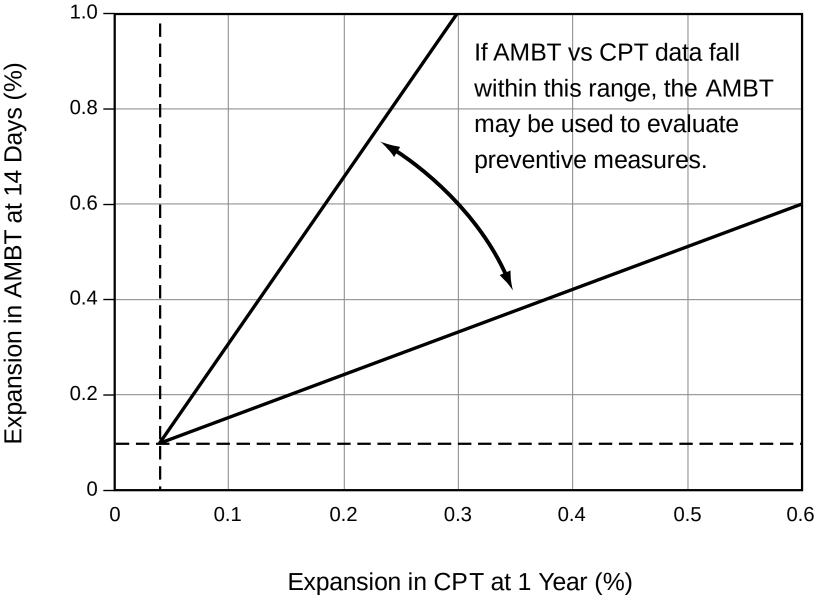

Figure 3—Comparison of AMBT and CPT Data for the Purpose of Determining Whether the AMBT is Suitable for Evaluating Preventive Measures with a Specific Aggregate

7.2.2 The effectiveness of blended cements or supplementary cementitious materials in controlling damaging expansion shall be determined in accordance with ASTM C 1567.

7.2.3 If the expansion of mortar bars containing blended cement or supplementary cementitious materials is not greater than 0.10 percent after 14 days in sodium hydroxide solution, the combination of blended cement or SCM and reactive aggregate shall be considered acceptable for use in concrete construction provided the alkali content of the portland cement used in the job does not exceed 1.0 percent Na_2Oe.

Note 8—If a reactive aggregate is to be used in a job mixture that contains a cement with an alkali content in excess of 1.00 percent Na_2Oe, the job cement should be used in the test.

7.2.4 If the expansion of mortar bars containing blended cement or supplementary cementitious materials is greater than 0.10 percent after 14 days in sodium hydroxide solution, the blended cement or level of SCM tested is not deemed to be effective with the reactive aggregate. Consideration should be given to retesting the aggregate with an increased level of SCM, a different blended cement, or a combination thereof.

7.2.5 When using the accelerated mortar bar test to determine the lithium nitrate dose required with a specific aggregate, the approach proposed by Tremblay et al. (2008) is recommended; the procedure is as follows:

7.2.5.1 Test the aggregate using the standard accelerated mortar bar test (T 303). Extend the duration of the test such that the mortar bars are exposed to sodium hydroxide for a period of 28 days. Let E_1 = expansion of bars without lithium nitrate at 28 days.

7.2.5.2 Test the aggregate in a modified version of the accelerated mortar bar test. In this test add sufficient lithium nitrate to the mortar bar mixture and the soak solution to achieve lithium-to-alkali molar ratios of [Li]/[Na + K] = 0.74 in the mortar and [Li]/[Na + K] = 0.148 in the soak solution. (See Annex A2 on calculation of lithium nitrate additions.) Conduct the rest of the test in accordance with T 303, extending the period in sodium hydroxide to 28 days. Let E_2 = expansion of bars with lithium nitrate at 28 days.

Note 9—To achieve [Li]/[Na+K] = 0.74 in the mortar add 4.6 L of 30 percent-$LiNO_3$ solution for every 1 kg of alkali (as Na_2Oe) in the mix (70.4 fl oz of 30 percent-$LiNO_3$ solution for every 1 lb of alkali).

7.2.5.3 If $(E_2 - E_1)/E_1 < 0.1$, then use the following lithium-to-alkali molar ratio in the job mix:

$$[Li]/[Na + K] = 1.0 + 0.7[(E_2 - E_1)/E_1]$$

7.2.5.4 If $(E_2 - E_1)/E_1 \geq 0.1$, then use the concrete prism test to determine the lithium nitrate content required (see Section 7.1).

8. SELECTING PREVENTIVE MEASURES FOR ALKALI-SILICA REACTION (ASR)—PRESCRIPTIVE APPROACH

8.1 The level of prevention is determined by considering the class, size, and exposure condition of the structure; the degree of aggregate reactivity and the level of alkalis from the portland cement (when SCMs are used as preventive measures). Worked examples using the prescriptive approach are given in Annex A3.

8.2 *Aggregate Reactivity*:

8.2.1 The degree of alkali-silica reactivity of an aggregate is determined by testing the aggregate in the concrete prism test (Section 6.5) and using the expansion value at 1 year. If data from the concrete prism test are not available, the degree of reactivity may be determined by testing the aggregate in the accelerated mortar bar test (Section 6.4). If data are not available from either test, the aggregate may be considered as very highly reactive (R3). Aggregate-reactivity classes are given in Table 1. Where the coarse and fine aggregates are of different reactivity, the level of prevention should be selected for the most reactive aggregate.

Table 1—Classification of Aggregate Reactivity

Aggregate-Reactivity Class	Description of Aggregate Reactivity	1-Year Expansion in CPT (percent)	14-Day Expansion in AMBT (percent)
R0	Non-reactive	≤ 0.04	≤ 0.10
R1	Moderately reactive	$> 0.04, \leq 0.12$	$> 0.10, \leq 0.30$
R2	Highly reactive	$> 0.12, \leq 0.24$	$> 0.30, \leq 0.45$
R3	Very highly reactive	> 0.24	> 0.45

8.3 *Risk of ASR*:

8.3.1 The risk of ASR occurring in a structure is determined by considering the aggregate reactivity and the exposure conditions using Table 2.

Table 2—Determining the Level of ASR Risk

Size and Exposure Conditions	Aggregate-Reactivity Class			
	R0	R1	R2	R3
Non-massive concrete[a] in a dry environment[b]	Level 1	Level 1	Level 2	Level 3
Massive elements[a] in a dry environment[b]	Level 1	Level 2	Level 3	Level 4
All concrete exposed to humid air, buried or immersed	Level 1	Level 3	Level 4	Level 5
All concrete exposed to alkalis in service[c]	Level 1	Level 4	Level 5	Level 6

[a] A massive element has a least dimension > 0.9 m (3 ft).

[b] A dry environment corresponds to an average ambient relative humidity lower than 60 percent, normally found only in buildings.

[c] Examples of structures exposed to alkalis (sodium and potassium) in service include marine structures exposed to seawater and highway structures exposed to deicing salts (e.g., NaCl) or anti-icing salts (e.g., potassium acetate, potassium formate, sodium acetate, sodium formate, etc.).

8.4 *Level of Prevention*:

8.4.1 The level of prevention required is determined from Table 3 by considering the risk of ASR from Table 2 together with the class of structure from Table 4.

Table 3—Determining the Level of Prevention

Level of ASR Risk (Table 4)	Classification of Structure (Table 4)			
	S1	S2	S3	S4
Risk Level 1	V	V	V	V
Risk Level 2	V	V	W	X
Risk Level 3	V	W	X	Y
Risk Level 4	W	X	Y	Z
Risk Level 5	X	Y	Z	ZZ
Risk Level 6	Y	Z	ZZ	[a]

[a] It is not permitted to construct a Class S4 structure (see Table 4) when the risk of ASR is Level 6. Measures must be taken to reduce the level of risk in these circumstances.

The level of prevention V, W, X, Y, Z, and ZZ are used in Tables 5 to 8.

Table 4—Structures Classified on the Basis of the Severity of the Consequences Should ASR Occur[a] (Modified for Highway Structures from RILEM TC 191-ARP)

Class	Consequences of ASR	Acceptability of ASR	Examples[b]
S1	Safety, economic, or environmental consequences small or negligible	Some deterioration from ASR may be tolerated.	• Non-load-bearing elements inside buildings • Temporary structures (e.g., < 5 years)
S2	Some safety, economic, or environmental consequences if major deterioration	Moderate risk of ASR is acceptable.	• Sidewalks, curbs, and gutters • Service-life < 40 years
S3	Significant safety, economic, or environmental consequences if minor damage	Minor risk of ASR acceptable.	• Pavements • Culverts • Highway barriers • Rural, low-volume bridges • Large numbers of precast elements where economic costs of replacement are severe • Service life normally 40 to 75 years
S4	Serious safety, economic, or environmental consequences if minor damage	ASR cannot be tolerated.	• Major bridges • Tunnels • Critical elements that are very difficult to inspect or repair • Service life normally > 75 years

[a] This table does not consider the consequences of damage due to ACR. This practice does not permit the use of alkali-carbonate aggregates.

[b] The types of structures listed under each class are meant to serve as examples. Some owners may decide to use their own classification system. For example, sidewalks or curbs and gutters may be placed in the Class S3.

Note 10—Structures are classified on the basis of the severity of the consequences should ASR occur. For example, the consequences of ASR are far more severe for a reinforced concrete bridge element than they are for a sidewalk. As such, more onerous measures are required to prevent damaging ASR in a bridge.

8.5 *Requirements for Prevention Level V*:

8.5.1 No special measures need to be taken for Prevention Level V.

8.6 *Requirements for Prevention Level W, X, or Y*:

8.6.1 If it is determined that Prevention Level W, X, or Y is required, there are two options for prevention as follows:

8.6.1.1 *Option 1—Limiting the Alkali Content of the Concrete*:

Table 5 prescribes maximum permissible concrete alkali contents. The alkali content of concrete is calculated on the basis of the alkali contributed by the portland cement alone. For blended cement, the alkali available from the portland cement component of the blend should be used.

Table 5—Maximum Alkali Contents in Portland Cement Concrete to Provide Various Levels of Prevention

Prevention Level	Maximum Alkali Content of Concrete (Na_2Oe)	
	kg/m^3	lb/yd^3
V	No limit	No limit
W	3.0	5.0
X	2.4	4.0
Y	1.8	3.0
Z[a]	Table 8	Table 8
ZZ[a]	Table 8	Table 8

[a] SCMs must be used in Prevention Levels Z and ZZ.

Note 11—The alkali content of the concrete is calculated by multiplying the portland cement content of the concrete by the alkali content of the portland cement. For example, for concrete containing 300 kg/m^3 of portland cement, which has an alkali content of 0.91 percent Na_2Oe, the alkali content of the concrete is 300 × 0.91/100 = 2.73 kg/m^3 Na_2Oe. The alkali content in pounds per cubic yard (lb/yd^3) is calculated by multiplying the cement content of the concrete in lb/yd^3 by the alkali content of the cement divided by 100. For example, for a concrete containing 550 lb/yd^3 of portland cement, which has an alkali content of 0.82 percent Na_2Oe, the alkali content of the concrete is 550 × 0.82/100 = 4.51 lb/yd^3 Na_2Oe.

Note 12—Other components of the mix, such as aggregates, wash water, and chemical admixtures, may contribute alkalis to the concrete and such alkalis should be considered when calculating the alkali content of the concrete. Supplementary cementing materials also contain alkalis; however, the use of SCM usually increases the amount of alkalis bound by the hydrates and thus reduces the available alkali content in the concrete. Thus, the alkalis present in SCMs need not be considered when calculating the alkali content of the concrete. However, the alkali content of the SCM should not exceed the limits given in Table 6.

Table 6—Minimum Levels of SCM to Provide Various Levels of Prevention

Type of SCM[a]	Alkali Level of SCM (% Na_2Oe)	Minimum Replacement Level[b] (% by Mass of Cementitious Material)				
		Level W	Level X	Level Y	Level Z	Level ZZ
Fly ash (CaO ≤ 18 percent)	≤ 3.0	15	20	25	35	Table 7
	> 3.0, ≤ 4.5	20	25	30	40	Table 7
Slag	≤ 1.0	25	35	50	65	Table 7
Silica Fume[c] (SiO_2 ≥ 85 percent)	≤ 1.0	2.0 × KGA or 1.2 × LBA	2.5 × KGA or 1.5 × LBA	3.0 × KGA or 1.8 × LBA	4.0 × KGA or 2.4 × LBA	Table 7

[a] The SCM may be added directly to the concrete mixer or it may be a component of a blended cement. SCMs should meet the requirements of M 295, M 302, or M 307. Blended cements should meet the requirements of M 240 or ASTM C 1157.

[b] The use of high levels of SCM in concrete may increase the risk of problems due to deicer salt scaling if the concrete is not properly proportioned, finished, and cured.

[c] The minimum level of silica fume (as a percentage of cementitious material) is calculated on the basis of the alkali (Na_2Oe) content of the concrete contributed by the portland cement and expressed in either units of kg/m^3 (KGA in Table 6) or lb/yd^3 (LBA in Table 6). KGA is calculated by multiplying the cement content of the concrete in kg/m^3 by the alkali content of the cement divided by 100. For example, for a concrete containing 300 kg/m^3 of cement with an alkali content of 0.91 percent Na_2Oe, the value of KGA = 300 × 0.91/100 = 2.73 kg/m^3. For this concrete, the minimum replacement level of silica fume for Level X is 2.5 × 2.73 = 6.8 percent. LBA is calculated by multiplying the cement content of the concrete in lb/yd^3 by the alkali content of the cement divided by 100. For example, for a concrete containing 500 lb/yd^3 of cement with an alkali content of 0.81 percent Na_2Oe the value of LBA = 500 × 0.81/100 = 4.05 lb/yd^3. For this concrete, the minimum replacement level of silica fume for Level Y is 1.8 × 4.05 = 8.1 percent. Regardless of the calculated value, the minimum level of silica fume shall not be less than 7 percent when it is the only method of prevention.

8.6.1.2 *Option 2—Using Supplementary Cementitious Materials or Blended Cements*:

Table 6 prescribes minimum replacement levels for fly ash with calcium content not greater than 18 percent CaO and alkali content not greater than 4.5 percent Na_2Oe, and for slag and silica fume with alkali content not greater than 1.0 percent Na_2Oe.

Fly ashes with greater than 18 percent CaO or greater than 4.5 percent Na_2Oe and slag and silica fume with greater than 1.0 percent Na_2Oe are not covered by these prescriptive measures; the ability of these materials to control ASR with a particular reactive aggregate should be determined by performance testing (see Section 7).

When natural pozzolans are to be used to control ASR, the efficacy of a particular aggregate-pozzolan combination should be determined by performance testing (see Section 7).

When two or more SCMs (including SCMs in blended cements) are used together to control ASR, the minimum replacement levels given in Table 6 for the individual SCMs may be reduced provided the sum of the parts of each SCM is greater than or equal to one.

Note 13—For example, when silica fume and slag are used together, the silica fume level may be reduced to one-third of the minimum silica fume level given in the table provided the slag level is at least two-thirds of the minimum slag level.

The minimum replacement levels in Table 6 are appropriate for use with portland cements of moderate to high alkali contents (0.7 to 1.0 percent Na_2Oe). Table 7 provides recommendations for adjusting the level of SCM when the alkali content of the portland cement is above or below this range. The replacement levels should not be below those given in Table 6 for prevention level W, regardless of the alkali content of the portland cement.

Table 7—Adjusting the Minimum Level of SCM Based on the Alkali Content of the Portland Cement

Cement Alkalis (% Na_2Oe)	Level of SCM
≤ 0.70	Reduce the minimum amount of SCM given in Table 6 by one prevention level.[a]
> 0.70, ≤ 1.00	Use the minimum levels of SCM given in Table 6.
> 1.00, ≤1.25	Increase the minimum amount of SCM given in Table 6 by one prevention level.
> 1.25	No guidance is given.

[a] The replacement levels should not be below those given in Table 6 for prevention level W, regardless of the alkali content of the portland cement.

No guidance is given for using preventive measures with reactive aggregates when the alkali content of the portland cement exceeds 1.25 percent Na_2Oe.

Note 14—If this approach is used for portland cements with alkali contents in excess of 1.25 percent Na_2Oe, there will be an increased risk of damaging ASR.

8.7 *Requirements for Prevention Level Z*:

8.7.1 If it is determined that Prevention Level Z is required, there are two options: (1) use the minimum level of supplementary cementitious material shown in Table 6, or (2) use the minimum level of supplementary cementitious material and the maximum concrete alkali content shown in Table 8.

Table 8—Using SCM and Limiting the Alkali Content of the Concrete to Provide Exceptional Levels of Prevention

Prevention Level	SCM as Sole Prevention	Limiting Concrete Alkali Content Plus SCM	
	Minimum SCM Level	Maximum Alkali Content, kg/m^3 (lb/yd^3)	Minimum SCM Level
Z	SCM level shown for Level Z in Table 6	1.8 (3.0)	SCM level shown for Level Y in Table 6
ZZ	Not permitted	1.8 (3.0)	SCM level shown for Level Z in Table 6

8.8 *Requirements for Prevention Level ZZ*:

8.8.1 If it is determined that Prevention Level ZZ is required, use the minimum level of supplementary cementitious material and the maximum concrete alkali content shown in Table 8.

9. REPORTING

9.1 The report shall list the tests conducted and the results of the tests.

9.2 If a study was conducted to determine the field performance history of the aggregate, details should be provided of the structures examined including type, age, visual and photographic observations, and details of laboratory testing of cores removed from the structure.

9.3 If a petrographic examination was conducted on the aggregate, the report should be produced in accordance with ASTM C 295.

9.4 If testing in accordance with CSA A23.2-26A was performed, the lime (CaO), magnesia (MgO) and alumina (Al_2O_3) content of the rock shall be reported.

9.5 If accelerated mortar bar or concrete prism tests were conducted, the results shall be reported in accordance with the relevant test method (T 303, ASTM C 1293, or ASTM C 1567).

9.6 The chemical composition of the cement, SCM, and lithium nitrate admixture used in expansion tests shall be reported.

10. KEYWORDS

10.1 Alkali-aggregate reaction; alkali-carbonate reaction; alkali-silica reaction; concrete; expansion; fly ash; lithium nitrate; pozzolan; preventive measures; reaction; reactive aggregate; silica fume; slag.

(Mandatory Information)

A1. CALCULATING LITHIUM NITRATE ADDITIONS

A1.1. These calculations assume that the admixture being used is a 30 percent $LiNO_3$ solution. This is the only solution commercially available at this time.

A1.2. Published research indicates that a lithium nitrate dose that results in a lithium-to-sodium-plus-potassium molar ratio of [Li]/[Na + K] = 0.74 will be effective with many, but not all, aggregates. It is recommended that concrete prism tests be conducted at this lithium nitrate dose and at lower and higher doses.

A1.3. To achieve a dose of [Li]/[Na + K] = 0.74 using a 30 percent $LiNO_3$ solution requires 4.6 liters of solution for every kilogram of alkali (as Na_2Oe) in the concrete (from the portland cement) or 0.55 gallons for every pound of alkali.

A1.4. A solution of 30 percent $LiNO_3$ contains 70 percent water by mass, and this amount should be included in the calculation of the batch water. One liter of 30 percent $LiNO_3$ solution weighs 1.2 kg and contains 0.84 kg of water. One gallon of 30 percent $LiNO_3$ solution weighs 10.02 lb and contains 7.01 lb of water.

A1.5. *Metric Example*—For a 16-liter batch of concrete (typical quantity for CPT) with 420 kg/m^3 of cement raised to 1.25 percent Na_2Oe, the quantity of alkali present is $16/1000 \times 420 \times 1.25/100 = 0.084$ kg Na_2Oe. To achieve [Li]/[Na + K] = 0.74 in the mix, $4.6 \times 0.084 = 0.3864$ liters of 30 percent $LiNO_3$ solution needs to be added to the mix. This quantity of solution contains $0.3864 \times 0.84 = 0.3246$ kg of water that should be subtracted from the mix water.

A1.6. *English Example*—For a 0.6 ft^3 batch of concrete (typical quantity for CPT) with 708 lb/yd^3 of cement raised to 1.25 percent Na_2Oe, the quantity of alkali present is $0.6/27 \times 708 \times 1.25/100 = 0.197$ lb Na_2Oe. To achieve [Li]/[Na + K] = 0.74 in the mix, $0.55 \times 0.197 = 0.1084$ gallons of 30 percent $LiNO_3$ solution needs to be added. This quantity of solution contains $0.1084 \times 7.01 = 0.7600$ lb of water that should be subtracted from the mix water.

A2. CALCULATING LITHIUM NITRATE ADDITIONS FOR THE MODIFIED ACCELERATED MORTAR BAR METHOD (FOR LITHIUM NITRATE SOLUTIONS)

A2.1. The calculations below assume that the admixture being used is a 30 percent $LiNO_3$ solution. This is the only solution commercially available at this time.

A2.2. In this modified version of the accelerated mortar bar test, sufficient lithium nitrate shall be added to the mortar bar mixture and to the soak solution to achieve: (1) lithium-to-alkali molar ratios of

[Li]/[Na + K] = 0.74 in the mortar, and (2) [Li]/[Na + K] = 0.148 in the soak solution (i.e., 20 percent of the «standard dosage» of 0.74).

A2.3. *Example of calculation of the lithium nitrate dose in the mortar*—The cement content in the modified AMBT is 440 g. For a cement with 1 percent Na_2Oe, the alkali content for $LiNO_3$ calculation is: 440 g × 1/100 = 4.4 g of Na_2Oe. To achieve a dose of [Li]/[Na + K] = 0.74 using a 30 percent $LiNO_3$ solution requires 4.6 liters of solution for every kilogram (or 4.6 mL for every gram) of alkali (as Na_2Oe) in the mortar (provided by the portland cement). So, 4.4 g of Na_2Oe × 4.6 mL (of $LiNO_3$ solution) = 20.2 mL of $LiNO_3$ solution (= [Li] / [Na + K] of 0.74).

A2.4. The water content in the $LiNO_3$ solution needs to be accounted for in the calculation of the mortar mix water. Since 1 mL of 30 percent $LiNO_3$ solution weighs 1.2 g and there is 70 percent water (by mass in the 30 percent $LiNO_3$ solution), the mass of water in 20.2 mL of $LiNO_3$ solution is: 20.2 × 1.2 × 0.7 = 17 g. Since the water-to-cement ratio to use in the AMBT is 0.47 and the cement content is 440 g, then the mixing water content is: 0.47 × 440 g = 206.8 g – 17 g (water provided by the $LiNO_3$ solution) = 189.8 g.

A3. WORKED EXAMPLES FOR SELECTING PREVENTIVE MEASURES FOR ALKALI-SILICA REACTION (ASR)—PRESCRIPTIVE APPROACH

A3.1. *Example 1—Major Bridge Crossing*:

A3.1.1. Preventive measures are required for a major bridge that is not exposed to deicing salts. When tested, according to ASTM C 1293, the coarse and fine aggregates intended for use produced 1-year expansion values of 0.093 percent and 0.032 percent, respectively. Portland cement with an alkali content of 0.86 percent Na_2Oe and fly ash with a calcium content of 14.1 percent CaO and an alkali content of 3.51 percent Na_2Oe are available.

A3.1.2. *Aggregate Reactivity*—Table 1 indicates the coarse aggregate reactivity to be R1 (moderately reactive) and the fine aggregate to be R0 (non-reactive). Design for worse case: R1.

A3.1.3. *Level of ASR Risk*—Table 2 indicates the risk of ASR to be Level 3 for a moderately reactive (R1) aggregate exposed to humid air, buried or immersed (no deicing salts).

A3.1.4. *Level of Prevention*—Table 3 indicates the level of prevention required to be Level Y for an S4 class of structure (Table 4) with an ASR risk of Level 3.

A3.1.5. *Prevention Required*—Either control alkali content of concrete or use SCM.

A3.1.5.1. *Option to Limit Alkali Content of Concrete*—Table 5 indicates that the maximum alkali content is 3.0 lb/yd^3 Na_2Oe for Prevention Level Y. This translates to a maximum cement content of 3/(0.86/100) = 349 lb/yd^3 for a cement with an alkali content of 0.86 percent Na_2Oe (this option is unlikely to be feasible).

A3.1.5.2. *Option to use SCM*—Table 6 indicates a minimum fly ash replacement of 30 percent for fly ash with 14.1 percent CaO and 3.51 percent Na_2Oe for Prevention Level Y.

A3.2. *Example 2—Sidewalk Exposed to Deicing Salts*:

A3.2.1. Preventive measures are required for a city sidewalk exposed to deicing salts. When tested in T 303, the coarse and fine aggregates produce 14-day expansions of 0.35 percent and 0.55 percent, respectively. Portland cement with an alkali content of 0.38 percent Na_2Oe and slag with an alkali content of 0.71 percent Na_2Oe are available.

A3.2.2. *Aggregate Reactivity*—Table 1 indicates the coarse aggregate reactivity to be R2 (highly reactive) and the fine aggregate to be R3 (very highly reactive). Design for worse case: R3.

A3.2.3. *Level of ASR Risk*—Table 3 indicates the risk of ASR to be Level 6 for a very highly reactive (R3) aggregate exposed to alkalis in service (deicing salts).

A3.2.4. *Level of Prevention*—Table 3 indicates the level of prevention to be Level Z for an S2 class of structure (Table 4) with an ASR risk of Level 6.

A3.2.5. *Prevention Required*—Use SCM. (Table 5 does not permit the control of the concrete alkali content as the only prevention measure for Prevention Level Z.)

A3.2.5.1. *Option to Use SCM*—Table 6 indicates a minimum slag replacement of 65 percent for slag for Prevention Level Z. Table 7 allows the minimum amount of SCM in Table 6 to be reduced by one prevention level if the cement alkalis are below 0.70 percent Na_2Oe. Therefore, the minimum slag replacement level is 50 percent (Prevention Level Y).

Standard Method of Test for

Specific Gravity and Absorption of Aggregate by Volumetric Immersion Method

AASHTO Designation: TP 77-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Specific Gravity and Absorption of Aggregate by Volumetric Immersion Method

AASHTO Designation: TP 77-09[1]

1. SCOPE

1.1 This method covers the determination of bulk and apparent specific gravity and absorption of fine and coarse aggregate at 20 ± 1°C (70 ± 2°F) for dry and saturated aggregates.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of whoever uses this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 2, Sampling of Aggregates
- T 19M/T 19, Bulk Density ("Unit Weight") and Voids in Aggregate
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 248, Reducing Samples of Aggregate to Testing Size
- T 255, Total Evaporable Moisture Content of Aggregate by Drying

3. SIGNIFICANCE AND USE

3.1 Bulk specific gravity is the characteristic generally used for calculations of the volume occupied by the aggregate in various mixtures containing aggregate including portland cement concrete (PCC), bituminous concrete, and other mixtures that are proportioned or analyzed on an absolute volume basis. Bulk specific gravity is also used in the computation of voids in aggregate in T 19M/T 19. Bulk specific gravity determined on the saturated surface-dry basis is used if the aggregate is wet, that is, if its absorption has been satisfied. Conversely, the bulk specific gravity determined on the oven-dry basis is used for computations when the aggregate is dry or assumed to be dry.

3.2 Apparent specific gravity pertains to the relative density of the solid material making up the constituent particles not including the pore space within the particles that is accessible to water. This value is not widely used in construction aggregate technology.

3.3 When it is deemed that the aggregate has been in contact with water long enough to satisfy most of the absorption potential, the absorption values are used to represent the change in the mass of an aggregate due to water absorbed into the pore spaces within the constituent particles, compared to the dry condition. The laboratory standard for absorption is that obtained after submerging dry aggregate for approximately 15 hours in water. Aggregates mined from below the water table may have a higher absorption when used, if not allowed to dry. Conversely, some aggregates when used may contain an amount of absorbed moisture less than the 15-hour soaked condition. For an aggregate that has been in contact with water and that has free moisture on the particle surfaces, the percentage of free moisture can be determined by deducting the absorption from the total moisture content determined by T 255 drying.

3.4 Users of this method are encouraged to be cautious in applying the results. Values achieved for specific gravity and absorption are significantly different from those achieved from T 84 and T 85. Results from this method will affect the calculated results for volumetrics in hot mix asphalt (HMA) and absorption in PCC. The user is cautioned to thoroughly evaluate these effects before implementing this test method. Correlation methods discussed in Appendix X2.1 or X2.2 should be utilized when the values from this method are to be directly substituted for those from T 84 or T 85.

4. APPARATUS

4.1 *Flask with Plug for Coarse Aggregate*—A glass flask with a bulb volume of 3000 to 4000 mL and a separate plug. The neck of the flask shall be marked with 5 mL graduated increments which correspond to a precision of at least 0.1 percent of the sample volume. Overall length of the flask is approximately 760 mm (30 in.). (See Note 1 and Figure 1.)

4.2 *Flask for Fine Aggregate*—A glass flask with a bulb volume of 2000 mL. The neck of the flask shall be marked with 1 mL graduated increments which correspond to a precision of at least 0.1 percent of the sample volume. Overall length of the flask is approximately 760 mm (30 in.). (See Note 1 and Figure 1.)

Note 1—The flask to be used for fine aggregate will have a neck approximately 25 mm (1 in.) in diameter. The flask used for coarse aggregate will have a neck approximately 51 mm (2 in.) in diameter. These flasks are available from Humboldt Manufacturing Company, 7300 W. Agatite Avenue, Norridge, IL 60706.

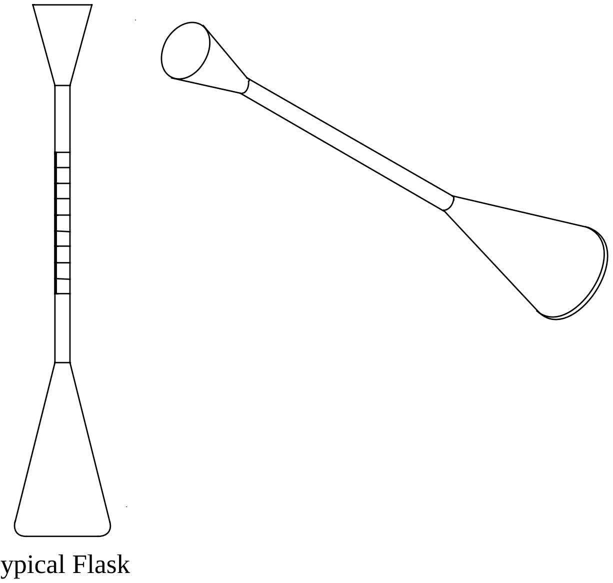

Figure 1—Typical Flask

4.3 *Scale with a capacity of at least 10,000 g*—The scale shall comply with the requirements in M 231.

4.4 Minimum 450-mm (18-in.) long rod with dry, absorbent swab.

4.5 Timer that can be read to the nearest second, and that can measure elapsed time up to 24 hours.

5. CALIBRATION OF FLASK

5.1 Determine and record the empty weight of the flask, to the nearest gram.

5.2 Fill flask with distilled water at 20 ± 1°C (70.0 ± 2°F) such that the bottom of the meniscus is exactly even with the zero mark.

Note 2—If a flask does not have a zero mark, add water to the first major graduation (10 mL mark on a fine aggregate flask); then subtract that amount from the calibrated flask volume in Equation 1.

5.3 Determine and record the weight of the filled flask to the nearest gram.

5.4 Determine the calibrated volume of the flask as follows:

$$V_{cal} = B - A \tag{1}$$

where:

V_{cal} = calibrated volume of the flask, mL;

A = weight of empty flask, g; and

B = weight of flask filled with water, g.

Note 3—Due to the definition of a milliliter and a gram (1 milliliter of water weighs 1 gram), these values can be interchanged without conversions.

6. SAMPLING

6.1 Sampling of aggregate shall be accomplished in accordance with T 2.

7. PREPARATION OF TEST SPECIMEN

7.1 Obtain approximately 2 kg of fine aggregate or 3 kg of coarse aggregate using the applicable procedures described in T 248.

7.2 Dry the sample in an oven or a suitable pan or vessel to constant mass at a temperature of 110 ± 5ºC (230 ± 9ºF). Allow it to cool to comfortable handling temperature, without allowing it to re-absorb any water from the surrounding environment. This can be accomplished by covering the container with a plate or cover that blocks direct access of the ambient humid air to the cooling sample.

8. TEST PROCEDURE

8.1 Weigh out 1200 ± 10 g of oven-dry fine aggregate or 2500 ± 50 g of oven-dry coarse aggregate to be tested. If testing lightweight aggregate, reduce the amount of material to 600 ± 10 g for fine aggregate, or 900 g ± 10 g for coarse aggregate.

8.2 The actual weight, W_d, of oven dry aggregate should be recorded to the nearest 0.01 grams.

8.3 Fill the bottom portion of the flask approximately one half full, by height, with 20 ± 1°C (70 ± 2°F) distilled water. (See Note 4.)

8.4 Measure out, but do not add, approximately 250 g of 20 ± 1°C (70 ± 2°F) distilled water.

Note 4—The volume of water in Sections 8.2 and 8.3 may need to be adjusted for the individual flask being used. It is important that during the filling process, the combined initial volume of water and the dry aggregate not plug the neck of the flask. Therefore, the following procedure is intended to allow sufficient water for the aggregate to become completely submerged, but to not rise into the narrow neck of the flask.

8.5 Dry the inside of the neck of the flask with a dry absorbent swab.

Note 5—If the inside of the neck is not completely dry, finer portions of the sample may adhere to the moisture, plugging the neck of the flask as the sample is added.

8.6 Pour the aggregate sample into the flask as quickly as possible, without plugging the neck.

Note 6—It is recommended that an outside funnel not be used. The sand has a tendency to plug the smaller hole of the funnel, where it typically pours through the built-in funnel without plugging.

8.7 Start the timer immediately when the aggregate first hits the water in the flask.

8.8 After all of the sample has been poured into the flask, immediately add enough of the holdback water measured out in Section 8.3 to raise the water level sufficiently up into the graduated portion of the neck of the flask, so that the water level does not drop below the graduated portion during the duration of the test.

8.9 Do not shake, agitate, or otherwise disturb the flask at this time.

8.10 Take the reading of the initial water level, R_i, in the neck of the flask 30 seconds after the first particle has entered the water.

8.11 Determine and record the weight of the flask filled with aggregate and water, W_T to 0.01 grams.

8.12 Aggressively shake, roll, and otherwise agitate the flask in order to remove all of the released air. Place a plug into the neck of the coarse aggregate flask to prevent loss of water during the shaking and agitation of the flask. Stop shaking and agitating the flask when the timer shows three minutes.

8.13 Allow the flask to remain undisturbed for two minutes.

8.14 Obtain and record the reading of the water level in the neck of the flask at five minutes elapsed time (from when the aggregate first hits the water).

8.15 It is recommended that water level readings be taken at 10 minutes, 30 minutes, 60 minutes, 2 hours, and 4 hours elapsed time (see Note 7). Make sure to agitate all of the air out of the sample, and allow the flask to settle for at least two minutes before taking each reading. See Appendix X1.

Note 7—It is not critical that the readings are taken at the exact times shown. Record the time the water level reading is actually made.

8.16 Take the final water level reading, R_{final}, at 25 ± 1 hour. It is extremely important that all air released during the soak period be completely eliminated from the flask before taking the final reading. Make sure that the flask has been thoroughly and completely shaken and agitated, and then left undisturbed to allow all of the air to escape from the flask until there is no air left in the system. Make sure that the air removal process is started early enough to completely eliminate all of the air within the designated time.

9. ABSORPTION

9.1 Calculate the absorption as follows:

$$\text{Absorption, (\%)} = [W_{abs}/W_d] \times 100 \qquad (2)$$

where:

W_{abs} = water absorbed into the sample, $(R_i - R_{\text{final}})$, mL, where
  R_i = initial water level reading, mL; and
  R_{final} = final water level reading, mL; and
W_d = original dry weight of sample, g

10. SATURATED BULK SPECIFIC GRAVITY (S_S)

10.1 Calculate the saturated bulk specific gravity as follows:

$$S_s = (W_d + W_{abs})/[V_i - V_w] \qquad (3)$$

where:

W_d = original dry weight of sample, g;
W_{abs} = water absorbed into the sample, mL;
V_i = initial volume, $(R_i + V_{cal})$, mL, where
  V_{cal} = calibrated flask volume, mL;
V_w = volume of test water $[W_T - (W_d + W_f)]$, mL, where
  W_T = total weight of flask, water and sample, g; and
  W_f = weight of flask, g.

11. DRY BULK SPECIFIC GRAVITY (S_d)

11.1 Calculate the dry bulk specific gravity as follows:

$$S_d = W_d/(V_i - V_w) \qquad (4)$$

12. APPARENT DRY SPECIFIC GRAVITY (S_a)

12.1 Calculate the apparent dry specific gravity as follows:

$$S_a = W_d/[(W_d + W_f + V_{cal}) - (WT - R_{final})] \qquad (5)$$

13. CONVENTIONAL ABSORPTION

13.1 Use the correlation equation shown in Appendix X2.3 to calculate the conventional absorption for fine aggregate (T 84) as follows:

$$\text{Conventional Absorption, (\%)} = [(\text{Absorption \{from Section 9.1\}} \times 1.8243) + 0.0038] \qquad (6)$$

13.2 Use the correlation procedure in Appendix X2.2 to determine the conventional absorption and specific gravities for fine or coarse aggregates, according to T 84 or T 85, respectively.

Note 8—The use of either of these methods is at the discretion of the user. The user is encouraged to use the method of preference.

14. REPORT

14.1 Report the specific gravity results to the nearest 0.001, and indicate the type of specific gravity, whether bulk, bulk (saturated-surface-dry), or apparent.

14.2 Report the absorption result to the nearest 0.1 percent. Unless otherwise specified, the end user shall use the absorption value that is appropriate to the specific application.

APPENDIXES

(Nonmandatory Information)

X1. INTERMEDIATE WATER LEVEL READINGS

X1.1. This test provides an internal quality process check. By plotting the intermediate readings against time on a logarithmic scale, an approximately straight line should be determined. If the line is not essentially straight, then something happened during the performance of the test.

X1.2. It also provides the ability to determine the time-rate of absorption relationship for a particular material. Once the time-rate of absorption plot has been established, it can then be used in the field. If intermediate levels of absorption are to be acknowledged during the delivery and construction procedures using this aggregate, the starting and anticipated ending points and their relative degree of saturation can be taken directly from the resulting plot.

X1.3. A typical plot is shown in Figure X1.1:

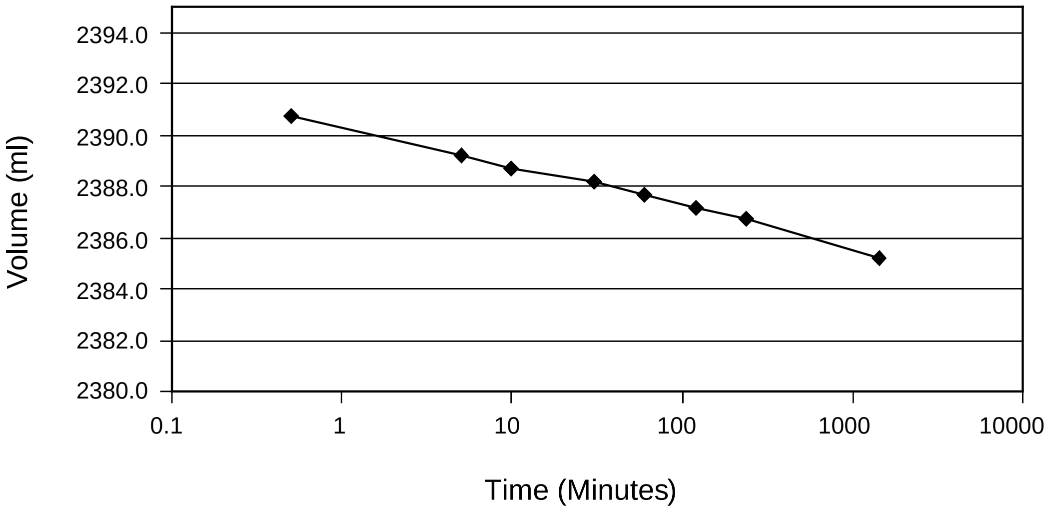

Figure X1.1—Phunque Absorption Test

X1.4. Plot the readings on semi-log paper with the *x*-axis being time on the logarithmic scale.

X1.5. *Example Data*:

X1.6. A typical datasheet that has been found to work well with this procedure is shown in Figure X1.2.

Source of Sample:	ABC Contractor—Concrete Sand		
Tare Weight of Flask, g:	887.90		
Calibrated Volume of the Flask, g:	2312.20		
Conventional Absorption (T 84/T 85):	0.8%		
Conventional Bulk Specific Gravity (SSD) (T 84/T 85):	2.623		
Dry Weight of Sample:	1200.00		
Total Initial Volume of Water Added:	1937.2		
Total Weight of Flask, Sample and Water, g:	4025.10		
Elapsed Time (in minutes):	Readings		Total Volume (mL)
R_i 0.5		78.5	2390.7
5		77.0	2389.2
10		76.5	2388.7
30		76.0	2388.2
60		75.5	2387.7
120	2 Hrs	75.0	2387.2

Bulk Specific Gravity (SSD)	2.658		2.623
Bulk Specific Gravity (apparent)	2.679		2.656

Figure X1.2—Sample of Phunque Absorption Test Datasheet

X2. STATISTICAL CORRELATION WITH T 84

X2.1. The absorption values for fine aggregates determined from this method vary significantly from those determined by T 84. In many applications the magnitude of effect from using Phunque values in lieu of the conventional values makes it extremely difficult to proceed with the intended application. At this time, it is not known which is more accurate. However, the Phunque method is much more consistent, repeatable, and easier to perform. Therefore, a statistical study was performed by comparing representative samples of fine aggregate sources throughout the country and determining the specific gravities and absorptions using both methods concurrently. The relationship for fine aggregate absorption shown in Figure X2.1 is the result of this effort.

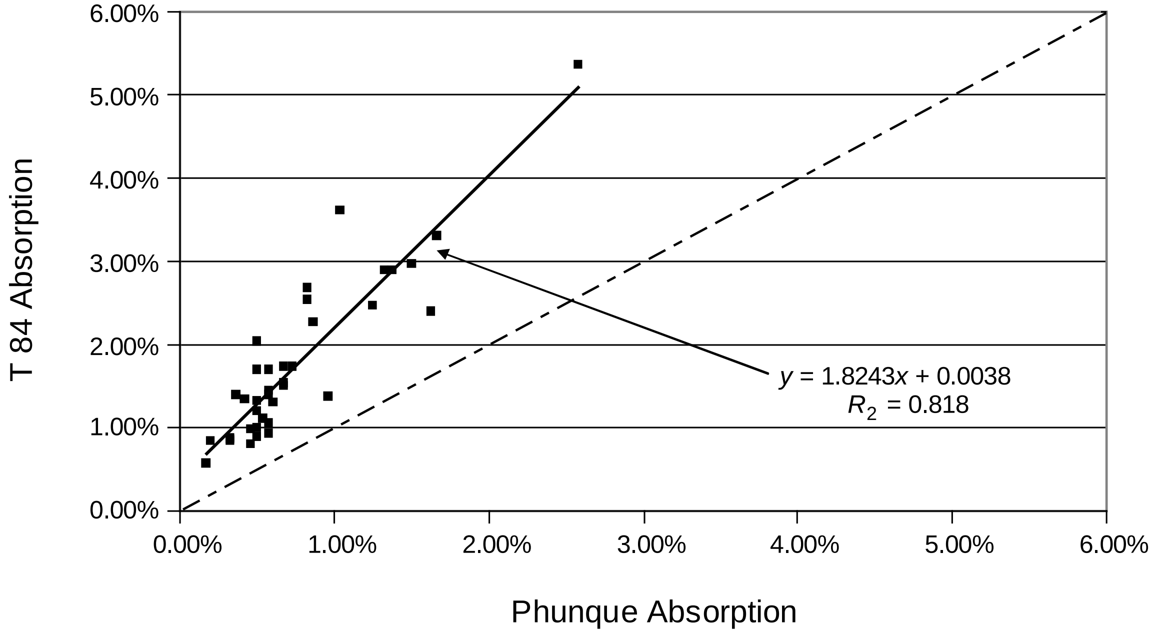

Figure X2.1—Absportion Comparison (Fine Aggregate Only)

X2.2. *Direct Correlation with T 84 or T 85*:

X2.3. In situations where these numbers will be used in significant applications, and where a preliminary evaluation has not been performed to assess the nature and magnitude of the differences using the Phunque values in lieu of T 84 or T 85 values, the user is encouraged to perform a source specific correlation for each material type from each source or stockpile. This correlation effort should be performed by using the Phunque method to determine the specific gravities and absorption on at least three samples split from a single master sample. The process should be repeated using T 84 or T 85 procedures on at least five samples split from the same master sample. Once completed, the correlation factor, *CF*, can be calculated as follows:

CF = (Average Conventional Measurements)/(Average Phunque Measurements)

Example: Determine the *CF* to use in the conventional applications:

(Values taken from Figure X1.2)

Average Phunque Absorption = 0.5	Average T 84 Absorption = 0.8
Average Phunque Dry Bulk Specific Gravity, S_d = 2.646	Average T 84 Dry Bulk Specific Gravity, S_d = 2.601
Average Phunque Saturated Bulk Specific Gravity, S_s = 2.658 Average	T 84 Saturated Bulk Specific Gravity, S_s = 2.623
Average Phunque Apparent Dry Specific Gravity, S_a =2.679	Average T 84 Apparent Dry Specific Gravity, S_a =2.656

Calculating the *CF* for each property:

$CF_{\text{absorption}}$ = 0.8/0.5 = 1.6

CF_{S_d} = 2.601/2.646 = 0.983

CF_{S_s} = 2.623/2.658 = 0.987

CF_{S_a} = 2.656/2.679 = 0.991

Standard Method of Test for

Determining Aggregate Shape Properties by Means of Digital Image Analysis

AASHTO Designation: TP 81-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Aggregate Shape Properties by Means of Digital Image Analysis

AASHTO Designation: TP 81-10

1. SCOPE

1.1. This standard covers the measurement of aggregate shape properties using the Digital Image Analysis techniques.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 92, Wire-Cloth Sieves for Testing Purposes
- T 2, Sampling of Aggregates
- T 11, Materials Finer Than 75-µm (No. 200) Sieve in Mineral Aggregates by Washing
- T 27, Sieve Analysis of Fine and Coarse Aggregates
- T 84, Specific Gravity and Absorption of Fine Aggregate
- T 85, Specific Gravity and Absorption of Coarse Aggregate
- T 248, Reducing Samples of Aggregate to Testing Size

3. TERMINOLOGY

3.1. *aggregate size*—sieve size in which material is retained after passing the next larger sieve.

3.1.1. *fine aggregate*—aggregate material passing 4.75-mm (No. 4) sieve. Sieve sizes are 2.36 mm (No. 8), 1.18 mm (No. 16), 0.60 mm (No. 30), 0.30 mm (No. 50), 0.15 mm (No. 100), and 0.075 mm (No. 200).

3.1.2. *coarse aggregate*—aggregate material retained on 4.75-mm (No. 4) sieve. Sieve sizes are 25.0 mm (1 in.), 19.0 mm ($^3/_4$ in.), 12.5 mm ($^1/_2$ in.), 9.5 mm ($^3/_8$ in.), and 4.75 mm (No. 4).

3.2. *Shape Properties for Each Retained sieve (x)*:

3.2.1. *gradient angularity (GA)*—applies to both fine and coarse aggregate sizes and is related to the sharpness of the corners of 2-dimensional images of aggregate particles. The gradient angularity quantifies changes along a particle boundary with higher gradient values indicating a more angular shape. Gradient angularity has a relative scale of 0 to 10000 with a perfect circle having a value of 0.

Gradient Angularity:

$$GA = \frac{1}{\frac{n}{3} - 1} \sum_{i=1}^{n-3} \left| \theta_i - \theta_{i+3} \right| \qquad (1)$$

where:

θ = angle of orientation of the edge points

n = the total number of points

i = denoting the *i*th point on the edge of the particle

3.2.2. *texture or micro-texture (TX)*—applies to coarse aggregate sizes only describing relative smoothness or roughness of surface features less than approximately 0.5 mm in size that are too small to affect the overall shape. Texture has a relative scale of 0 to 1000 with a smooth polished surface approaching a value of 0.

$$TX = \frac{1}{3N} \sum_{i=1}^{3} \sum_{j=1}^{N} \left(D_{i,j} \left(x, y \right) \right)^2 \qquad (2)$$

where:

D = decomposition function

n = decomposition level

N = total number of coefficients in an image

i = 1, 2, or 3 for detailed images

j = wavelet index

x, y = location of the coefficients in transformed domain

3.2.3. *sphericity (SP)*—applies to coarse aggregate sizes only and describes the overall three-dimensional shape of a particle. Sphericity has a relative scale of 0 to 1. A sphericity value of one indicates a particle has equal dimensions (cubical).

$$SP = \sqrt[3]{\frac{d_S * d_I}{d_L^2}} \qquad (3)$$

where:

d_S = particle shortest dimension

d_I = particle intermediate dimension

d_L = particle longest dimension

3.2.4. *Form 2D*—Applies to fine aggregate sizes only and is used to quantify the relative form from 2-dimensional images of aggregate particles. Form 2D has a relative scale of 0 to 20. A perfect circle has a Form 2D value of zero.

$$\text{Form 2D} = \sum_{\theta=0}^{\theta=360-\Delta\theta} \left[\frac{R_{\theta+\Delta\theta} - R_\theta}{R_\theta} \right] \qquad (4)$$

where:

R_θ = the radius of the particle at an angle of θ

$\Delta\theta$ = the incremental difference in the angle

3.2.5. *flat **and** elongated*—those particles having a ratio of longest dimension to shortest dimension greater than a specified value.

Aggregate particle dimensions in an *x, y, z* coordinate system:

d_S = particle shortest dimension
d_I = particle intermediate
d_L = particle longest dimension

Flatness Ratio (*S/L*): $Flatness = \frac{d_S}{d_I}$ (5)

Elongation Ratio (*I/L*): $Elongation = \frac{d_I}{d_L}$ (6)

Flat and Elongated Value (*F&E*): $L/S = \frac{d_L}{d_S}$ (7)

3.2.6. *flat **or** elongated*—those particles having a ratio of intermediate dimension to shortest dimension or longest dimension to intermediate dimension greater than a specified value.

Flat or Elongated Value (*F* or *E*): $\frac{d_I}{d_S}$ or $\frac{d_L}{d_I} >$ Ratio (i.e., 1, 2, 3…) (8)

4. SIGNIFICANCE AND USE

4.1. Shape, angularity, and surface texture of aggregates have been shown to directly affect the engineering properties of highway construction materials such as hot mix asphalt concrete, Portland cement concrete, and unbound aggregate layers. This standard provides direct measurement of aggregate shape, angularity, and texture. For coarse aggregates, the shape properties include: Gradient Angularity, Sphericity, Texture, and Flat and Elongated value. For fine aggregates the shape properties include: Gradient Angularity and Form 2D.

Note 1—The National Cooperative Highway Research Program Report 555 provides background information relevant to characterizing aggregate shape, texture, and angularity.

4.2. This test method may be used to characterize and monitor the shape properties of aggregate material sizes 0.075 mm (No. 200) through 25.0 mm (1 in.). This method may be used to characterize a single size within a material source or all sizes within the source.

5. APPARATUS

5.1. *Digital Image Acquisition and Analysis System*—A computer controlled electro-mechanical instrument for capturing digital images at variable magnification and software for image analysis. Instrumentation and analysis software shall include algorithms for Gradient Angularity, Form 2D, Flat and Elongated, Sphericity, and Texture.

5.1.1. A camera and optic system capable of providing the required resolutions over the range of particles being analyzed.

5.1.2. A system for positioning the particle for imaging. This can be a movable camera, a movable support tray, or a combination thereof.

5.1.3. A system for auto-focusing the image.

5.1.4. A system for determining particle three-dimensional measurements *x, y, z* in millimeters.

5.1.5. A system for detecting and removing touching particles from the analysis.

5.1.6. A system for presenting the particles for imaging consisting of trays or other support surface for aggregate sizes from 0.075 mm (No. 200) through 25.0 mm (1 in.). The particles shall be presented for imaging on a flat surface. A small recess for aligning particles is acceptable.

5.1.7. A variable lighting system for backlighting or top lighting, or both, the material sample.

Note 2—The Aggregate Image Measurement System and the associated AIMS Software algorithms for image analysis computations have proven to be an acceptable system for a Digital Image Acquisition and Analysis System.

5.2. *Balance*—A balance meeting the requirements of M 231, Class G 5, for determining the mass of aggregates.

5.3. *Oven*—An oven of appropriate size capable of maintaining a uniform temperature of 110 ± 5°C (290 ± 9°F).

5.4. *Miscellaneous*—Equipment to perform sample preparation methods according to one or more of the following: T 2, T 11, T 27, or T 248.

6. HAZARDS

6.1. Use standard safety precautions and protective clothing when handling materials and preparing material samples.

7. STANDARDIZATION

7.1. Confirm the digital image acquisition system has been standardized. Frequency and method of standardization shall follow manufacturer's instructions.

8. PREPARATION OF APPARATUS

8.1. Confirm the system has been standardized by verifying the standardization date.

8.2. Confirm the machine operation settings are correct for the analysis to be performed.

9. SAMPLE PREPARATION

9.1. Obtain sample of the aggregate according to procedures in T 2.

Note 3—Material samples obtained for T 84 and T 85 specific gravity determinations have proven to be acceptable.

9.2. Thoroughly mix the sample and reduce it to the approximate quantity needed using the applicable procedures in T 248.

9.3. Determine the amount of material finer than 0.075 mm (No. 200) by T 11.

9.4. Dry the sample to a constant mass at a temperature of 110 ± 5°C (230 ± 9°F).

9.5. Determine the sample grading on the washed, dry sample in accordance with T 27. Calculate the percentage of material in each size fraction. Maintain sample material as separate retained sieve sizes.

9.6. Obtain the required aggregate of each size from the sample using the procedures described in T 248.

9.7. Maintain the necessary size fractions obtained in a dry condition in separate containers for each size.

9.7.1. The following list provides approximate sample mass to achieve the required minimum particle count for each size fraction:

Size	Approx. Mass	Minimum Number of Particles
0.075 mm (No. 200)	200 g	150
0.15 mm (No. 100)	200 g	150
0.3 mm (No. 50)	200 g	150
0.6 mm (No. 30)	200 g	150
1.18 mm (No. 16)	200 g	150
2.36 mm (No. 8)	200 g	150
4.75 mm (No. 4)	2 kg	50
9.5 mm ($^3/_8$-in.)	2 kg	50
12.5 mm ($^1/_2$-in.)	2 kg	50
19.0 mm ($^3/_{©}$-in.)	2 kg	50
25.0 mm (1-in.)	5 kg	50

10. PROCEDURE FOR COARSE AGGREGATE

10.1. Position the coarse aggregate sample for digital image acquisition by size fraction. Each size fraction of retained material may be run separately.

10.2. Distribute the coarse aggregate sample over the support surface in a manner which provides separation of at least 1.0 mm between particles. Particle orientation shall be determined by permitting them to come to rest randomly.

10.3. Initiate the digital image acquisition sequence and analysis algorithms. This process is typically automated. The operator inputs the material size and the system automatically captures the required images and calculates the shape properties for each particle.

10.4. Each characterization requires the minimum number of particles for each size fraction listed in Section 9.7 to be analyzed. If the required particle count is not achieved in one sequence, repeat the sequence with additional particles until the required number of images is acquired.

10.4.1. For sizes that contain inadequate percent retained mass to achieve minimum particle count, use the shape value obtained from the next larger or the next smaller size, whichever is present.

11. PROCEDURE FOR FINE AGGREGATE

11.1. Position the fine aggregate sample for digital image acquisition by size fraction. Each size fraction of retained material may be run separately.

Note 4—Most fine aggregate materials are analyzed using backlighting. However, some translucent materials may require a dark background and top lighting to achieve the appropriate image contrast. If the system fails to capture usable images with backlighting, use a dark background and top lighting. A dark background is typically required for 0.30 mm (No. 50) and smaller sizes.

11.2. Distribute the fine aggregate sample over the support surface in a manner which provides separation between particles. Typically, only a very light coating is needed. Particles' orientation shall be determined by permitting them to come to rest randomly.

11.3. Initiate the digital image acquisition sequence and run the analysis routines. This process is typically automated. The operator selects the material size and the system automatically captures the required images and calculates the shape properties for each particle.

11.4. Each characterization requires the minimum number of particles for each size fraction listed in Section 9.7 to be analyzed. If the required particle count is not achieved in one sequence, repeat the sequence until the required number of images is acquired.

11.4.1. For sizes that contain inadequate percent retained mass to achieve minimum particle count, use the shape value obtained from the next larger or the next smaller size, whichever is present.

12. CALCULATIONS

12.1. Calculate gradient angularity value for each fine and coarse aggregate particle.

12.1.1. Calculate the gradient angularity mean and standard deviation for each size fraction.

12.2. Calculate the texture (TX) value for each coarse particle.

12.2.1. Calculate the texture mean and standard deviation for each coarse size fraction.

12.3. Calculate the sphericity (SP) for each coarse aggregate particle.

12.3.1. Calculate the sphericity mean and standard deviation for each coarse size fraction.

12.4. Calculate the Form 2D value for each fine particle.

12.4.1. Calculate the Form 2D mean and standard deviation for each fine size fraction.

12.5. Calculate the percent distribution of Flat ***and*** Elongated at the following ratios:
≥1:1, >2:1, >3:1, >4:1, >5:1

$\%L/S(\geq 1)_x$ = % of Particles with $d_L/d_S \geq 1$

$\%L/S(>2)_x$ = % of Particles with $d_L/d_S > 2$

$\%L/S(>3)_x$ = % of Particles with $d_L/d_S > 3$

$\%L/S(>4)_x$ = % of Particles with $d_L/d_S > 4$

$\%L/S(>5)_x$ = % of Particles with $d_L/d_S > 5$

where:

x designates the retained sieve size

12.6. Calculate the percent distribution of Flat ***or*** Elongated at the following ratios: ≥1:1, >2:1, >3:1, >4:1, >5:1

$\%F \text{ or } E(\geq 1)_x$ = % of Particles with d_I/d_S or $d_L/d_I \geq 1$

$\% F \text{ or } E\ (>2)_x$ = % of Particles with d_I/d_S or $d_L/d_I > 2$

$\% F \text{ or } E\ (>3)_x$ = % of Particles with d_I/d_S or $d_L/d_I \leq 3$

$\% F \text{ or } E\ (>4)_x$ = % of Particles with d_I/d_S or $d_L/d_I > 4$

$\% F \text{ or } E\ (>5)_x$ = % of Particles with d_I/d_S or $d_L/d_I > 5$

where:

x designates the retained sieve size

13. REPORT

13.1. *Report the following information*:

13.1.1. Procedure used;

13.1.2. Date of the analysis;

13.1.3. *Material Sample Identification*—type, source, and size;

13.1.4. Number of particles analyzed; and

13.1.5. Material shape property mean and standard deviation. Graphical representations of the property distributions may be included.

13.2. A sample report format is presented in Appendix X1.

14. PRECISION AND BIAS

14.1. *Precision*—The research required to determine the precision of this procedure has not been completed.

14.2. *Bias*—The research required to determine the bias of this procedure has not been conducted.

15. KEYWORDS

15.1. Aggregate; angularity; consensus property; elongated; form; shape; texture.

APPENDIX

(Nonmandatory Information)

Standard Specification for

Use of Reclaimed Asphalt Shingles as an Additive in Hot Mix Asphalt (HMA)

AASHTO Designation: MP 15-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Use of Reclaimed Asphalt Shingles as an Additive in Hot Mix Asphalt (HMA)

AASHTO Designation: MP 15-09[1]

1. SCOPE

1.1. This specification covers reclaimed asphalt shingle material used as an additive in hot mix asphalt (HMA). The use of reclaimed asphalt shingles in hot-in-place pavements, cold-in-place pavements, and cold recycled pavements is not included in this specification.

1.2. The values stated in SI units are to be regarded as the standard.

Note 1—Refer to PP 53 for information on mix design, determining shingle aggregate gradation, and binder considerations when designing HMA mixtures which incorporate reclaimed asphalt shingles as an additive.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 29, Fine Aggregate for Bituminous Paving Mixtures
- M 320, Performance-Graded Asphalt Binder
- M 323, Superpave Volumetric Mix Design
- PP 53, Design Considerations When Using Reclaimed Asphalt Shingles (RAS) in New Hot Mix Asphalt (HMA)
- T 2, Sampling of Aggregates
- T 30, Mechanical Analysis of Extracted Aggregate
- T 164, Quantitative Extraction of Asphalt Binder from Hot Mix Asphalt (HMA)
- T 170, Recovery of Asphalt Binder from Solution by Abson Method
- T 319, Quantitative Extraction and Recovery of Asphalt Binder from Asphalt Mixtures

2.2. *ASTM Standards*:

- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- D 692, Standard Specification for Coarse Aggregate for Bituminous Paving Mixtures

2.3. *Other Standard*:

- Code of Federal Regulations Title 40 Chapter 1 Subchapter C Part 61 Subpart M (40 CFR 61 Subpart M), National Emission Standard for Asbestos

3. TERMINOLOGY

3.1. The definition of coarse and fine aggregate in terms of bituminous paving mixtures is provided in M 29 and ASTM C 125 and D 692.

3.2. *manufactured shingle waste*—for the purpose of this specification, shall mean rejected asphalt shingles or shingle tabs that are discarded in the manufacturing process of new asphalt shingles.

3.3. *post-consumer asphalt shingles*—for the purpose of this specification, shall mean asphalt shingles that are removed from the roofs of residential dwellings, as defined by the U.S. Environmental Protection Agency's National Emission Standards for Hazardous Air Pollution (NESHAP), 40 CFR 61 Subpart M, when new roofs are being installed. Post-consumer asphalt shingles are often called "tear-off" shingles.

3.4. *reclaimed asphalt shingles*—for the purpose of this specification, shall mean either manufactured shingle waste or post-consumer asphalt shingles that have been processed into a product that meets the requirements of this standard.

3.5. *shingle asphalt binder*—for the purpose of this specification, shall mean the asphalt binder that is present in the reclaimed asphalt shingles.

3.6. *shingle aggregate*—for the purpose of this specification, shall mean mineral granules, sand, or other mineral matter present in the reclaimed asphalt shingles, excluding the shingle fiber content.

3.7. *shingle fiber*—for the purpose of this specification, shall mean glass felt, paper felt, foil, and fabrics or films used as the structural basis of asphalt shingles and other asphalt roofing products.

3.8. *virgin asphalt binder*—for the purpose of this specification, shall mean new performance-graded asphalt binder to be used in the new HMA.

3.9. *final blended binder*—for the purpose of this specification, shall mean the mixture of virgin asphalt binder and shingle asphalt binder.

3.10. *virgin aggregate*—for the purpose of this specification, shall mean coarse and fine aggregate introduced into new HMA that is exclusive of the shingle aggregate.

3.11. *new HMA*—for the purpose of this specification, shall mean HMA manufactured using aggregates, recycled asphalt pavement (if used), virgin asphalt binder, and reclaimed asphalt shingles.

4. ORDERING INFORMATION

4.1. The purchaser or specifier shall include the following information in the purchase order or contract documents:

4.1.1. Reference to this specification and year of issue;

4.1.2. Additional testing requirements; and

4.1.3. Any exceptions to this specification.

5. SOURCES AND SAMPLING

5.1. Reclaimed asphalt shingles may be derived from either manufactured shingle waste or from post-consumer asphalt shingles (see Note 2).

Note 2—Asphalt shingle material is construction debris, and various state and local regulations may be applicable to its use. The user of this specification is advised to contact state and local transportation departments and environmental agencies to determine what additional requirements may be necessary.

5.2. Post-consumer asphalt shingles shall be processed prior to use to meet the requirements of Section 8 of this specification and shall consist of asphalt roll roofing, cap sheets, and shingles, including underlayment, only. Roofing debris, including coal tar epoxy, rubber materials, or other undesirable components, shall not be used. Post-consumer asphalt shingles shall be certified as conforming to EPA's NESHAP and any other local requirements concerning asbestos.

5.3. Manufactured shingle waste and post-consumer asphalt shingles shall not be blended for the production of new HMA.

5.4. Reclaimed asphalt shingle samples collected and analyzed, for the purpose of identifying the properties of reclaimed asphalt shingles as defined in this specification, shall be representative of the reclaimed asphalt shingle material that will be used in the full production run of new HMA.

6. GRADATION OF RECLAIMED ASPHALT SHINGLES

6.1. Reclaimed asphalt shingles shall be processed so that 100 percent passes the 12.5-mm (0.5-in.) sieve, or as required by the specifying jurisdiction.

Note 3—The HMA supplier may wish to uniformly blend fine aggregate or reclaimed asphalt pavement (RAP) with the reclaimed asphalt shingles as a method of preventing the agglomeration of reclaimed asphalt shingle particles. The fine aggregate or RAP so added must be considered in the final gradation of the new HMA.

7. ADDITION RATES OF RECLAIMED ASPHALT SHINGLES

7.1. The addition rate of reclaimed asphalt shingles shall be such that the gradation of the new HMA shall comply with the gradation requirements of M 323 (see Note 4).

Note 4—The gradation of the new HMA shall account for the shingle aggregate as well as the virgin aggregate. The shingle aggregate gradation shall be determined in accordance with the procedures outlined in PP 53.

7.2. The addition rate of reclaimed asphalt shingles shall be such that the new HMA shall comply with the volumetric mix design requirements of M 323.

7.3. If the virgin asphalt binder content expressed as a percentage of the total binder content of the new HMA is less than 70 percent (see Note 5), the virgin asphalt binder and shingle binder combination shall be further evaluated to ensure that the performance grade of the final blended binder complies with the performance grade requirements of M 320 (see Note 6).

Note 5—The virgin asphalt binder content, expressed as a percentage of the total binder content of the new HMA, is the percentage of virgin asphalt binder introduced into the new HMA (P_{bv}) divided by the sum of the percentage of available shingle asphalt binder present in the reclaimed shingles (P_{br}) and the percentage of virgin asphalt introduced into the new HMA (P_{bv}).

Note 6—The performance grade and percentage of virgin asphalt binder introduced into the new HMA (P_{bv}) shall be determined in accordance with the procedures outlined in PP 53.

8. DELETERIOUS SUBSTANCES

8.1. Reclaimed asphalt shingles shall not contain extraneous waste materials and shall be essentially nail-free. Extraneous materials such as metals, glass, rubber, soil, brick, tars, paper, wood, and plastic shall not exceed 3.0 percent by mass as determined on material retained on the 4.57-mm (No. 4) sieve. Lightweight material such as paper, wood, and plastic shall not exceed 1.5 percent by mass as determined on material retained on the 4.75-mm (No. 4) sieve.

8.2. Reclaimed asphalt shingles shall contain less than the maximum percentage of asbestos fibers based on testing procedures and frequencies established in conjunction with the specifying jurisdiction and state or federal environmental regulatory agencies.

9. METHODS OF SAMPLING AND TESTING

9.1. Sample and test the reclaimed asphalt shingles using the following AASHTO standards, except as otherwise provided in this specification:

9.1.1. Sampling according to T 2;

9.1.2. Extraction and recovery of asphalt binder according to T 164, T 170, or T 319;

9.1.3. Mechanical analysis of extracted aggregate according to T 30. Additional guidance for handling fibers may be found in PP 53.

---

[1] Approved in December 2005, this standard was first published in July 2006. Revised in 2009.

Standard Specification for

Performance-Graded Asphalt Binder Using Multiple Stress Creep Recovery (MSCR) Test

AASHTO Designation: MP 19-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Performance-Graded Asphalt Binder Using Multiple Stress Creep Recovery (MSCR) Test

AASHTO Designation: MP 19-10

1. SCOPE

1.1 This specification covers asphalt binders graded by performance using the multiple stress creep recovery (MSCR) test. Grading designations are related to the average seven-day maximum pavement design temperature, minimum pavement design temperature, and traffic loading.

1.2 This specification incorporates TP 70 for determining non-recoverable creep compliance, J_{nr}. “S”, “H”, “V”, or “E” grades must be specified for standard, high, very high, or extremely high traffic loading, respectively.

Note 1—For asphalt cements graded by viscosity at 60ºC, see M 226.

Note 2—For Performance-Graded Asphalt Binder, see M 320.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 226, Viscosity-Graded Asphalt Cement
- M 320, Performance-Graded Asphalt Binder
- M 323, Superpave Volumetric Mix Design
- R 28, Accelerated Aging of Asphalt Binder Using a Pressurized Aging Vessel (PAV)
- R 29, Grading or Verifying the Performance Grade (PG) of an Asphalt Binder
- R 35, Superpave Volumetric Design for Hot-Mix Asphalt (HMA)
- T 40, Sampling Bituminous Materials
- T 44, Solubility of Bituminous Materials
- T 48, Flash and Fire Points by Cleveland Open Cup
- T 55, Water in Petroleum Products and Bituminous Materials by Distillation
- T 240, Effect of Heat and Air on a Moving Film of Asphalt Binder (Rolling Thin-Film Oven Test)
- T 313, Determining the Flexural Creep Stiffness of Asphalt Binder Using the Bending Beam Rheometer (BBR)
- T 314, Determining the Fracture Properties of Asphalt Binder in Direct Tension (DT)
- T 315, Determining the Rheological Properties of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)

- T 316, Viscosity Determination of Asphalt Binder Using Rotational Viscometer
- TP 70, Multiple Stress Creep Recovery (MSCR) Test of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)

2.2 *ASTM Standards*:

- D 8, Standard Terminology Relating to Materials for Roads and Pavements
- D 5546, Standard Test Method for Solubility of Asphalt Binders in Toluene by Centrifuge

3. TERMINOLOGY

3.1 *Definitions*:

3.1.1 Definitions for many terms common to asphalt binder are found in ASTM D 8.

3.1.2 *asphalt binder*—an asphalt-based cement that is produced from petroleum residue either with or without the addition of non-particulate organic modifiers.

4. ORDERING INFORMATION

4.1 When ordering under this specification, include in the purchase order the performance grade (PG) of asphalt binder required and the grade (e.g., MP 19, PG 64-22, Grade S).

4.2 The required environmental asphalt binder grades may be selected by following the procedures described in M 323 and R 35, except do not use the “grade bumping” procedure in M 323. Select the environmentally appropriate high and low temperature grades and the appropriate “S”, “H”, “V”, or “E” grade for the expected traffic level and traffic load rate.

4.2.1 Standard Grade “S” in most typical situations will be for traffic levels fewer than 10 million Equivalent Single Axle Loads (ESALs) and less than the standard traffic load rate (>70 km/h).

4.2.2 High Grade “H” in most situations will be for traffic levels of 10 to 30 million ESALs or slow-moving traffic (20 to 70 km/h).

4.2.3 Very High Grade “V” in most situations will be for traffic levels of greater than 30 million ESALs or standing traffic (< 20 km/h).

4.2.4 Extremely High Grade “E” in most situations will be for traffic levels of greater than 30 million ESALs and standing traffic (< 20 km/h) such as toll plazas or port facilities.

Note 3—“Grade bumping” is accomplished by using “H”, “V”, or “E” grades and not by increasing the PG high temperature grade as recommended in M 323.

5. MATERIALS AND MANUFACTURE

5.1 Asphalt binder shall be prepared by the refining of crude petroleum by suitable methods, with or without the addition of modifiers.

5.2 Modifiers may be any organic material of suitable manufacture that is used in virgin or recycled condition and that is dissolved, dispersed, or reacted in asphalt binder to enhance its performance.

5.3 The asphalt binder shall be homogeneous, free from water and deleterious materials, and shall not foam when heated to 175°C.

5.4 The asphalt binder shall be at least 99.0 percent soluble as determined by T 44 or ASTM D 5546.

5.5 This specification is not applicable for asphalt binders in which fibers or other discrete particles are larger than 250 μm in size.

5.6 The grades of asphalt binder shall conform to the requirements given in Table 1.

6. SAMPLING

6.1 The material shall be sampled in accordance with T 40.

7. TEST METHODS

7.1 The properties outlined in Sections 5.3, 5.4, and 5.6 shall be determined in accordance with R 28, T 44 or ASTM D 5546, T 48, T 55, T 240, T 313, T 314, T 315, T 316, and TP 70.

8. INSPECTION AND CERTIFICATION

8.1 Inspection and certification of the material shall be agreed upon between the purchaser and the seller. Specific requirements shall be part of the purchase contract. The seller shall provide material handling and storage procedures to the purchaser for each asphalt binder grade certified.

9. REJECTION AND RETESTING

9.1 If the results of any test do not conform to the requirements of this specification, retesting to determine conformity is performed as indicated in the purchase order or as otherwise agreed upon between the purchaser and the seller.

10. KEYWORDS

10.1 Asphalt binder; asphalt cement; direct tension; flash point; modifier; multiple stress creep recovery (MSCR), performance specifications; pressure aging; rheology.

Table 1—Performance-Graded Asphalt Binder Specification[a]

Performance Grade	PG 46			PG 52							PG 58				
	34	40	46	10	16	22	28	34	40	46	16	22	28	34	40
Average 7-day max pavement design temp, °C[b]	<46			<52							<58				
Min pavement design temp, °C[b]	>–34	>–40	>–6	>–10	>–6	>–22	>–28	>–34	>–40	>–46	>–16	>–22	>–28	>–34	>–40
Original Binder

Viscosity, T 316:[c] max 3 Pa·s, test temp, °C	135														
Dynamic shear, T 315:[d] G*/sinδ, min 1.00 kPa[e] test temp @ 10 rad/s, °C	46			52							58				
Rolling Thin-Film Oven Residue (T 240)															
Mass change, max, percent[f]	1.00														
MSCR, TP 70: Standard Traffic "S" Grade $J_{nr3.2}$, max 4.0 kPa^{-1} $J_{nr\mathrm{diff}}$, max 75% test temp, °C	46			52							58				
MSCR, TP 70: Heavy Traffic "H" Grade $J_{nr3.2}$, max 2.0 kPa^{-1} $J_{nr\mathrm{diff}}$, max 75% test temp, °C	46			52							58				
MSCR, TP 70: Very Heavy Traffic "V" Grade $J_{nr3.2}$, max 1.0 kPa^{-1} $J_{nr\mathrm{diff}}$, max 75% test temp, °C	46			52							58				
MSCR, TP 70: Extremely Heavy Traffic "E" Grade $J_{nr3.2}$, max 0.5 kPa^{-1} $J_{nr\mathrm{diff}}$, max 75% test temp, °C	46			52							58				
Pressurized Aging Vessel Residue (R 28)															
PAV aging temp, °C[g]	90			90							100				
Dynamic shear, T 315: "S" Grade G* sinδ, max 5000 kPa[e] test temp @ 10 rad/s, °C	10	7	4	25	22	19	16	13	10	7	25	22	19	16	13
Dynamic shear, T 315: "H", "V", "E" Grades G* sinδ, max 6000 kPa[e] test temp @ 10 rad/s, °C	10	7	4	25	22	19	16	13	10	7	25	22	19	16	13
Creep stiffness, T 313:[h] *S*, max 300 MPa *m*-value, min 0.300 test temp @ 60 s, °C	–24	–30	–36	0	–6	–12	–18	–24	–30	–36	–6	–12	–18	–24	–30
Direct tension, T 314:[h] Failure strain, min 1.0% test temp @ 1.0 mm/min, °C	–24	–30	–36	0	–6	–12	–18	–24	–30	–36	–6	–12	–18	–24	–30

[a] MSCR testing on RTFO residue should be performed at the PG grade based on the environmental high pavement temperature. Grade bumping is accomplished by requiring a lower J_{nr} value while testing at the environmental temperature.

[b] Pavement temperatures are estimated from air temperatures using an algorithm contained in the LTPP Bind program, may be provided by the specifying agency, or by following the procedures as outlined in M 323 and R 35, excluding the provisions for "grade bumping".

[c] This requirement may be waived at the discretion of the specifying agency if the supplier warrants that the asphalt binder can be adequately pumped and mixed at temperatures that meet all applicable safety standards.

[d] For quality control of unmodified asphalt binder production, measurement of the viscosity of the original asphalt binder may be used to supplement dynamic shear measurements of G*/sinδ at test temperatures where the asphalt is a Newtonian fluid.

[e] G*/sinδ = high temperature stiffness and G* sinδ = intermediate temperature stiffness.

[f] The mass change shall be less than 1.00 percent for either a positive (mass gain) or a negative (mass loss) change.

[g] The PAV aging temperature is based on simulated climatic conditions and is one of three temperatures, 90°C, 100°C, or 110°C. Normally the PAV aging temperature is 100°C for PG 58-xx and above. However, in desert climates, the PAV aging temperature for PG 70-xx and above may be specified as 110°C.

[h] If the creep stiffness is below 300 MPa, the direct tension test is not required. If the creep stiffness is between 300 and 600 MPa, the direct tension failure strain requirement can be used in lieu of the creep stiffness requirement. The *m*-value requirement must be satisfied in both cases.

AASHTO Designation: PP 53-09[1]

1. SCOPE

1.1. This recommended practice provides guidance for designing new hot mix asphalt (HMA) that incorporates reclaimed asphalt shingles (RAS). Specific guidance includes design considerations, how to determine the shingle aggregate gradation, how to determine the performance grade (PG) and percentage of the virgin asphalt binder, and how to estimate the contribution of the shingle asphalt binder to the final blended binder.

Note 1—Refer to MP 15 for information specifying the use of RAS in HMA. Additionally, refer to the *White Paper for Recycled Asphalt Shingle as an Additive in Hot-Mix Asphalt* for more details concerning the origins and development of this recommended practice.

3. INTRODUCTION

3.1. Although RAS has been used as an additive in HMA in the United States for more than 15 years, it remains a relatively new application. As a result, there are design considerations that are not generally known to the specification user. Four separate areas are addressed by this recommended practice, with each elaborating on and providing recommendations relative to the following:

- Design Considerations When Using RAS in HMA
- Determining the Shingle Aggregate Gradation and Specific Gravity
- Estimating the Contribution of the Shingle Asphalt Binder to the Final Blended Binder in New HMA (Values of *F*)
- Determining the Performance Grade (PG) and Percentage of the Virgin Asphalt Binder in New HMA

4. DESIGN CONSIDERATIONS WHEN USING RAS IN NEW HMA

4.1. The introduction of shingle aggregate from RAS will affect the gradation properties of the new HMA. The designer must determine the particle size and percentage of shingle aggregate present and adjust the virgin aggregate composition, if necessary, to ensure that the new HMA meets the appropriate gradation requirements.

4.2. The introduction of RAS will affect virgin asphalt binder content requirements. The designer must determine the virgin asphalt binder content of the new HMA as part of the volumetric design procedure.

4.3. During the production of the new HMA, shingle asphalt binder present in the RAS will mix with the virgin asphalt binder to produce a final blended binder. The properties of the shingle asphalt binder can be considerably different from those of virgin asphalt binder. If the quantity of virgin asphalt binder is less than 70 percent by mass of the total binder, the properties (PG) of the final blended binder may be measurably different from the design PG of the binder as specified by the local jurisdiction. In addition, the size of the RAS can be expected to affect the percentage of shingle asphalt binder that contributes to the final blended binder. For example, material that is ground to a size passing a 12.5-mm (0.5-in.) sieve can be expected to release lower levels of available shingle asphalt binder (20 to 40 percent) than RAS ground to a size passing a 4.75-mm (No. 4) sieve (as much as 95 percent available). The designer must be prepared to adjust the PG of the virgin asphalt binder to compensate for this effect.

4.4. The release of shingle asphalt binder into the virgin asphalt binder can result in reduced virgin asphalt binder requirements. It is unlikely, however, that all of the shingle asphalt binder will dissolve and blend with the virgin asphalt binder. Particles of undissolved shingle asphalt binder may act like aggregate particles that require more virgin asphalt binder to accomplish coating. Additionally, particles of shingle asphalt binder may absorb bituminous oils from the virgin asphalt binder. The location in an HMA plant where RAS is introduced into new HMA can also affect the binder blending process. This point of introduction must minimize damage to the RAS from excess heat and maximize the softening of shingle asphalt binder to facilitate the blending of the shingle asphalt binder with virgin asphalt binder.

5. DETERMINING THE SHINGLE AGGREGATE GRADATION AND SPECIFIC GRAVITY

5.1. Collect a representative sample of RAS and proceed in accordance with T 164, T 170, or T 319 to extract the shingle asphalt binder. The size of the sample should be such that the amount of aggregate material recovered will meet the size requirements of the gradation procedure. Alternate extraction methods, when it is not necessary to retain the shingle asphalt binder, are provided in T 308 and ASTM D 228.

5.2. To determine the shingle aggregate gradation, it is suggested that the shingle fiber present in the RAS be removed prior to testing the recovered aggregate in accordance with T 30. Since the major portion of the shingle fiber will be retained on a 4.75-mm (No. 4) sieve, the fiber fabric can be removed by tweezers or other appropriate method prior to grading the shingle aggregate during the T 30 test procedure.

Note 2—Sieving the aggregate may liberate fiberglass or other fibers present in the RAS. The amount of aggregate contributed by the RAS produces an almost negligible effect in the overall mixture gradation. The following gradation, which approximates the composition of most types of shingles, may be used as a standard gradation in lieu of determining the shingle aggregate gradation:

Shingle Aggregate Gradation	
Sieve Size	Percent Passing by Mass
9.5 mm ($^3/_8$ in.)	100
4.75 mm (No. 4)	95
2.36 mm (No. 8)	85
1.18 mm (No. 16)	70
600 µm (No. 30)	50
300 µm (No. 50)	45
150 µm (No. 100)	35
75 µm (No. 200)	25

5.3. Determine the shingle aggregate specific gravity by determining the theoretical maximum specific gravity (G_{mm}) of the RAS according to T 209 and calculating the effective specific gravity (G_{se}) of the aggregate according to Equation 1. A fine spray of alcohol may help reduce surface tension to allow fine particles to sink.

$$G_{se} = \frac{100 - P_{br}}{\left(\frac{100}{G_{mm}}\right) - \left(\frac{P_{br}}{1.03}\right)} \quad (1)$$

where:

G_{se} = the effective specific gravity of the shingle aggregate;

G_{mm} = the theoretical maximum specific gravity of the RAS; and

P_{br} = the percentage of shingle asphalt binder in the RAS by mass, percent.

Note 3—The absorption of most shingle aggregate is so low that little difference exists between the bulk and apparent specific gravities. Therefore, the effective specific gravity of the shingle aggregate may be substituted for the bulk specific gravity in subsequent calculations.

6. ESTIMATING THE CONTRIBUTION OF THE SHINGLE ASPHALT BINDER TO THE FINAL BLENDED BINDER IN NEW HMA (VALUES OF *F*)

6.1. When RAS is added to new HMA, there is uncertainty as to the exact amount of asphalt binder that is released from the shingle asphalt binder to blend with the virgin asphalt binder. There are many factors that control the blending of these two binders. Perhaps the most significant factor is the size to which the RAS is ground. The finer the grind, the greater the amount of the contribution of binder from the RAS is to the final blended binder. Other factors include the location in the manufacturing process where the RAS is added to the new HMA, the temperature of the aggregates, the temperature of the virgin asphalt binder, and the length of mixing time.

6.2. A calculated initial estimate of the percentage of asphalt binder (F_c) that is released from the RAS and blends with the virgin asphalt binder may be made by determining the difference between the design binder content of a mix without RAS (P_{bv}) and the design binder content of the new HMA with RAS (P_{vbr}), and dividing this value by the total available shingle asphalt binder in the new HMA. Expressed mathematically:

$$F_c = \frac{P_{bv} - P_{bvr}}{(P_{sr})(P_{br})} \tag{2}$$

where:

F_c = the estimated shingle asphalt binder availability factor, percent;

P_{bv} = the design asphalt binder content of a mix without RAS, percent;

P_{bvr} = the design asphalt binder content of the same mix (new HMA) with RAS, percent;

P_{sr} = the percentage of RAS in the new HMA expressed as a decimal; and

P_{br} = the percentage of shingle asphalt binder in the RAS expressed as a decimal.

Define the value of Δ as follows:

$$\Delta = P_{bv} - P_{bvr} \tag{3}$$

then:

$$F_c = \frac{\Delta}{(P_{sr})(P_{br})} \tag{4}$$

For example, assuming the following values for the variables involved, F_c is calculated as follows:

- P_{bv} = 5.3 percent;
- P_{bvr} = 5.0 percent;
- P_{sr} = 5.0 percent, or 0.05; and
- P_{br} = 40 percent, or 0.40.

$$F_c = \frac{5.3 - 5.0}{(0.05)(0.40)} = \frac{0.3}{0.02} = 15 \text{ percent}$$

This calculation will underestimate the value of F_c. A corrected value of F, used in Section 7.3, is defined as follows:

$$F = 100\left(\frac{1+F_c}{2}\right) \qquad (5)$$

where:

F = the shingle asphalt binder availability factor (determined using the procedure outlined in Section 6.2.6), percent; and

F_c = the estimated shingle asphalt binder availability factor (determined from Equation 4) expressed as a decimal.

For example, using the value for F_c determined above (expressed as a decimal), F is calculated as follows:

$$F = 100\left(\frac{1+0.15}{2}\right) = 100\left(\frac{1.15}{2}\right) = 57.5 \text{ percent}$$

A discussion of the corrected value of F is presented in Section 6.2.6. More detailed instructions, which outline the steps in this procedure, are as follows:

6.2.1 Perform a volumetric mix design on the new HMA that includes all of the components of the mixture except for the RAS in accordance with R 35. Select the design aggregate structure and prepare replicate mixtures in accordance with R 35. Condition the mixtures according to R 30. Determine the design binder content (P_{bv}).

6.2.2 Perform a second volumetric mix design procedure according to R 35 with the same combination of materials but including the RAS in the percentage desired for the new HMA. The RAS should be added at ambient temperature to the heated aggregates just prior to the addition of the heated virgin asphalt binder. Condition the mixtures according to R 30. Determine the design binder content (P_{br}).

6.2.3 If the value of Δ as calculated in Equation 3 is positive, then the shingle asphalt binder is contributing to the final blended binder. If the value of Δ as calculated in Equation 3 is negative, then coating undissolved shingle asphalt binder particles and absorption of virgin asphalt binder by RAS particles resulting from the introduction of the RAS is exceeding the amount of shingle asphalt binder contributing to the final blended binder. Additional virgin binder will then be required.

6.2.4 Multiply the percentage of shingle asphalt binder in the RAS (P_{br}) by the percentage of RAS added to the mixture (P_{sr}). This value represents the total available shingle asphalt binder expressed as a percentage of the new HMA.

6.2.5 Divide the value for Δ determined in Section 6.2.3 by the product of $(P_{sr})(P_{br})$ determined in Section 6.2.4. The quotient from this calculation is the initial estimate of the percentage of asphalt binder that is released from the RAS and blends with the virgin asphalt binder (F_c).

6.2.6 There are practical limitations, however, to this approach for estimating the value of F. These limitations are inherent in the assumption that Δ is the quantity of shingle asphalt binder that is contributing to the final blended binder. The value of Δ is dependent on at least three factors:

- The amount of shingle asphalt binder released into the mix,
- Minus the additional absorption due to the RAS present in the mix,
- Minus the additional coating requirements due to the RAS present in the mix.

As a result, the calculated value of F [$\Delta/(P_{sr})(P_{br})$] will always be less than the true value of F, and the critical design temperature of the virgin asphalt will always be overestimated. This relationship is illustrated more clearly in Figure 1.

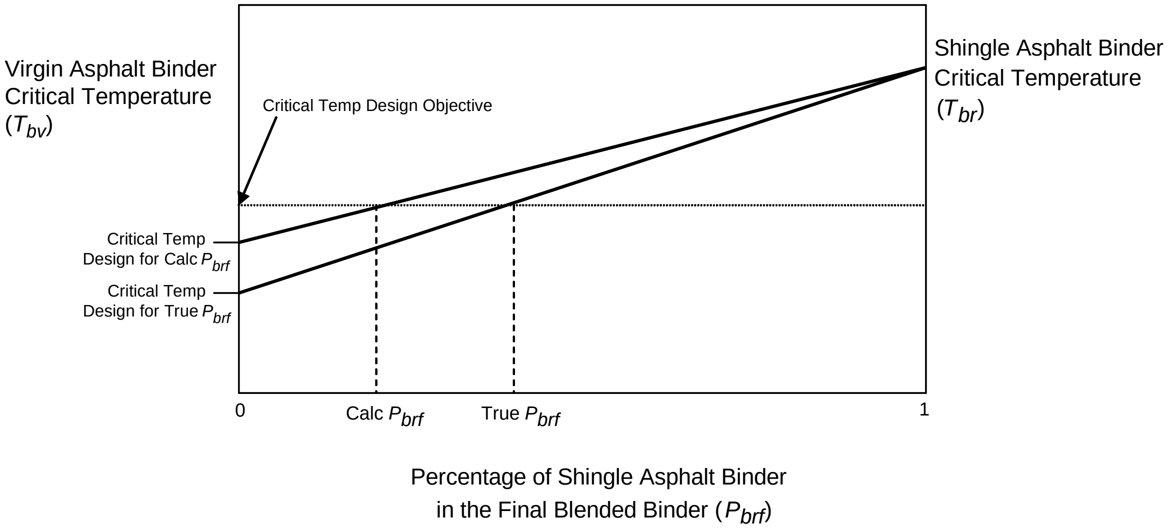

Figure 1—RAS Hypothetical Blending Chart

In the blending, it can be observed that since the calculated value of P_{brf} will always be less than the true value, the calculated critical temperature will always be higher than the true critical temperature. In the design (selection of critical temperature/PG of the virgin binder), this relationship must be considered in order to avoid selecting a harder asphalt binder.

Since the maximum value of F is theoretically equal to 1, the true value of F can be expected to lie between the value of F_c and 1, or expressed mathematically, $F_c < F < 1$. As a result, the best approximation of F can be expressed by Equation 5.

This value of F is used to calculate P_{brf} in Section 7.3.

7. DETERMINING THE PG AND PERCENTAGE OF THE VIRGIN ASPHALT BINDER IN NEW HMA

7.1. Select the percentage of RAS (P_{sr}) to be introduced into the new HMA.

7.2. Determine the percentage of shingle asphalt binder (P_{br}) present in the RAS in accordance with T 164, T 170, or T 319.

7.3. Determine the expected percentage of shingle asphalt binder present in the final blended binder (P_{brf}) using the following equation:

$$P_{brf} = \frac{F(P_{sr})(P_{br})}{P_{bbf}} \qquad (6)$$

where:

P_{brf} = the percentage of shingle asphalt binder in the final blended binder;

F = the shingle asphalt binder availability factor (determined using the procedure outlined in Section 6.2.6), percent;

P_{sr} = the percentage of RAS in the new HMA expressed as a decimal;

P_{br} = the percentage of shingle asphalt binder in the RAS (determined in Section 7.2) expressed as a decimal; and

P_{bbf} = the percentage of final blended binder in the new HMA expressed as a decimal.

For example, assuming the following values for the variables involved, P_{brf} is calculated as follows:

- F = 57.5 percent (as determined in the example for Equation 5);
- P_{sr} = 5.0 percent, or 0.05;
- P_{br} = 40 percent, or 0.40; and
- P_{bbf} = 5.0 percent, or 0.05.

$$P_{brf} = \frac{(57.5)(0.05)(0.40)}{0.05} = \frac{1.15}{0.05} = 23 \text{ percent of the final blended binder is contributed by RAS.}$$

7.4. Establish the required PG (or critical temperatures for the high, intermediate, and low properties) for the virgin asphalt binder in accordance with M 323. This procedure can be accomplished by constructing a blending chart and plotting the critical temperature of the shingle asphalt binder for 100 percent shingle asphalt binder and the value of P_{brf} on the chart abscissa to determine the critical temperatures of virgin asphalt binder that must be used in the new HMA. The blending chart approach in M 323 considers the effect of reclaimed asphalt pavement (RAP) on the virgin asphalt binder PG; in this practice, the effect of RAS is evaluated instead. Figure 1 of this practice provides a conceptual representation of this procedure. As an alternative to this procedure, utilize the following equation, which is a mathematical representation of the blending chart:

$$T_{bv} = T_{br} - \frac{\left(T_{br} - T_{bbf}\right)}{\left(1 - P_{brf}\right)} \qquad (7)$$

where:

T_{bv} = the critical temperature of the virgin asphalt binder (°C);

T_{br} = the critical temperature of the shingle asphalt binder (°C);

T_{bbf} = the critical temperature of the final blended binder (°C); and

P_{brf} = the percentage of shingle asphalt binder in the final blended binder expressed as a decimal.

For example, assuming the following values for the variables involved, T_{bv} is calculated as follows:

- T_{br} = 88°C (determined by laboratory analysis conforming to M 320);
- T_{bbf} = 64°C (the high-temperature PG specified for the project in question); and
- P_{brf} = 23 percent, or 0.23, as determined in the example for Equation 6.

$$T_{bv} = 88 - \frac{\left(88 - 64\right)}{\left(1 - 0.23\right)} = 88 - \frac{24}{0.77} = 56.8 \text{ degrees Celsius}$$

In this case (the high critical temperature analysis), the next highest available PG (T_{bv} = 58ºC) would be selected.

7.5. To make use of Equation 7, T_{br} values for high, intermediate, and low critical temperatures for each of the defined properties in M 320 must be determined by testing the extracted shingle asphalt binder from Section 7.2. The value for T_{bbf} is based on the climatic conditions where the new HMA will be used, while the value for P_{brf} is determined in Section 7.3. The equation may then be solved for T_{bv} (for the high, intermediate, and low critical temperatures).

7.6. If the PG for the virgin asphalt binder as determined in Sections 7.4 and 7.5 is different from the grade used in Section 6.2.2, then an additional volumetric design for the new HMA must be performed in accordance with R 35 and a revised design binder content (P_{bvr}) in the HMA determined.

---

[1] Approved in December 2005, this standard was first published in July 2006. Revised in 2009.

Standard Practice for

Preparation of Cylindrical Performance Test Specimens Using the Superpave Gyratory Compactor (SGC)

AASHTO Designation: PP 60-09[1,2]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Preparation of Cylindrical Performance Test Specimens Using the Superpave Gyratory Compactor (SGC)

AASHTO Designation: PP 60-09[1,2]

1. SCOPE

1.1 This practice covers the use of a Superpave gyratory compactor (SGC) to prepare 100-mm diameter by 150-mm tall cylindrical test specimens for use in a variety of axial compression and tension performance tests. This practice is intended for dense-, gap-, and open-graded hot mix asphalt (HMA) with nominal maximum aggregate sizes up to 37.5 mm.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- R 30, Mixture Conditioning of Hot Mix Asphalt (HMA)
- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens
- T 209, Theoretical Maximum Specific Gravity and Density of Hot Mix Asphalt (HMA)
- T 269, Percent Air Voids in Compacted Dense and Open Asphalt Mixtures
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor
- TP 62, Determining Dynamic Modulus of Hot Mix Asphalt (HMA)
- TP 79, Determining the Dynamic Modulus and Flow Number for Hot Mix Asphalt (HMA) Using the Asphalt Mixture Performance Tester (AMPT)

2.2 *ASTM Standard*:

- D 3549, Standard Test Method for Thickness or Height of Compacted Bituminous Paving Mixture Specimens

3. TERMINOLOGY

3.1 *SGC specimen*—a 150-mm diameter by 170-mm tall (minimum) cylindrical specimen prepared in an SGC meeting the requirements of T 312.

3.2 *test specimen*—a 100-mm diameter by 150-mm tall cylindrical specimen that is sawed and cored from the SGC specimen.

3.3 *end perpendicularity*—the degree to which an end surface departs from being perpendicular to the axis of the cylindrical test specimen. This configuration is measured using a combination square with the blade touching the cylinder parallel to its axis, and the head touching the highest point on the end of the cylinder. The distance between the head of the square and the lowest point on the end of the cylinder is measured with feeler gauges.

3.4 *end planeness*—maximum departure of the specimen end from a plane. This dimension is measured using a straightedge and feeler gauges.

4. SUMMARY OF PRACTICE

4.1 This practice presents methods for preparing 100-mm diameter by 150-mm tall cylindrical test specimens for use in a variety of axial compression and tension performance tests.

5. SIGNIFICANCE AND USE

5.1 This practice should be used to prepare specimens for TP 62 and TP 79.

5.2 This practice may also be used to prepare specimens for other tests requiring 100-mm diameter by 150-mm tall cylindrical test specimens.

6. APPARATUS

6.1 *Superpave Gyratory Compactor*—Meeting the requirements of T 312 and capable of preparing 150-mm diameter specimens that are a minimum of 170 mm tall.

6.2 *Mixture Preparation Equipment*—Balances, ovens, thermometers, mixer, pans, and other miscellaneous equipment needed to prepare SGC specimens in accordance with T 312 and perform bulk specific gravity (G_{mb}) measurements in accordance with T 166 and T 209.

6.3 *Core Drill*—An air- or water-cooled, diamond-bit core drill capable of cutting cores to a nominal diameter of 100 mm and meeting the dimensional requirements of Section 9.6.3. The core drill shall be equipped with a fixture for holding 150-mm diameter SGC specimens.

Note 1—Core drills with fixed and adjustable rotational speed have been used successfully to prepare specimens meeting the dimensional tolerances given in Section 9.6.3. Rotational speeds from 450 to 750 rpm have been used.

Note 2—Core drills with automatic and manual feed-rate control have been used successfully to prepare specimens meeting the dimensional tolerances given in Section 9.6.3.

6.4 *Masonry Saw*—An air- or water-cooled, diamond-bladed masonry saw capable of cutting specimens to a nominal length of 150 mm and meeting the tolerances for end perpendicularity and end flatness given in Section 9.6.3.

Note 3—Single- and double-bladed saws have been used successfully to prepare specimens meeting the dimensional tolerances given in Section 9.6.3. Both types of saws require a fixture to securely hold the specimen during sawing and to control the feed rate.

Note 4—In NCHRP Project 9-29, a machine that performs both the sawing and coring operation within the tolerances specified in Section 9.6.3 was developed. To obtain one of these devices, contact Shedworks, Inc., 2151 Harvey Mitchell Parkway S., Suite 320, College Station, TX 77840-5244, Phone (979) 695-8416, Fax 695-9629, e-mail wwc@shedworks.com.

6.5 *Square*—Combination square with a 300-mm blade and 100-mm head.

6.6 *Feeler Gauges*—Tapered-leaf feeler gauges in 0.05-mm increments.

6.7 *Metal Ruler*—Capable of measuring nominal 150-mm long (nominal) specimens to the nearest 1 mm.

6.8 *Calipers*—Capable of measuring nominal 100-mm diameter (nominal) specimens to the nearest 0.1 mm.

7. HAZARDS

7.1 This practice and associated standards involve handling of hot asphalt binder, aggregates, and asphalt mixtures, and the use of sawing and coring machinery. Use standard safety precautions, equipment, and clothing when handling hot materials and operating machinery.

8. STANDARDIZATION

8.1 Items associated with this practice that require calibration or verification are included in the AASHTO standards referenced in Section 2. Refer to the pertinent section of the referenced standards for information concerning calibration or verification.

9. PROCEDURE

9.1 *Select SGC Specimen Target Height*:

9.1.1 SGC specimens shall be prepared to a minimum height of 170 mm.

9.1.2 SGC specimen height shall be chosen based on the air void gradient produced by the specific SGC and effect of the sawing equipment.

Note 5—Test specimens with acceptable properties have been prepared from SGC specimens ranging in height from 165 mm to greater than 180 mm. Coarse-graded mixtures may require a taller height in order to ensure smooth, uniform ends with minimal or no surface irregularities after the sawing process. For tension performance testing, a taller height is required for all mixtures.

Note 6—Each laboratory should determine a target SGC specimen height based on the procedure for evaluating test specimen uniformity given in Appendix X2, and an evaluation of the ability of the sawing equipment to maintain the dimensional tolerances given in Table 1.

9.2 *HMA Preparation*:

9.2.1 Prepare HMA for each test specimen and a companion maximum specific gravity (G_{mm}) test in accordance with T 312.

9.2.2 The mass of HMA needed for each specimen will depend on the SGC specimen height, the G_{mm} of the aggregate, nominal maximum aggregate size, gradation (coarse or fine), and target air void content for the test specimens.

Note 7—Appendix X1 describes a trial-and-error procedure developed in NCHRP 9-19 for determining the mass of HMA required to reach a specified test specimen target air void content for SGC specimens prepared to a height of 170 mm.

9.2.3 Perform conditioning for the test specimens and companion G_{mm} sample test in accordance with R 30.

9.3 *SGC Specimen Compaction*:

9.3.1 Compact the SGC specimens to the target specimen height determined in Section 9.1 in accordance with T 312.

9.4 *Long-Term Conditioning (Optional)*:

9.4.1 If it is desired to simulate long-term aging, condition the SGC specimen in accordance with R 30.

9.4.2 To obtain accurate volumetric measurements on the long-term-conditioned specimens, also condition a companion sample of short-term-conditioned loose HMA meeting the sample size requirements of T 209 in accordance with R 30.

9.5 *SGC Specimen Density and Air Voids (Optional)*:

9.5.1 Determine the G_{mm} of the HMA in accordance with T 209. If long-term conditioning has been used, determine the G_{mm} on the long-term-conditioned loose HMA. Record the G_{mm} of the mixture.

9.5.2 For dense- and gap-graded mixtures, determine the G_{mb} of the SGC specimen in accordance with T 166. Record the G_{mb} of the SGC specimen.

9.5.3 For open-graded mixtures, determine the G_{mb} of the SGC specimen in accordance with T 269. Record the G_{mb} of the SGC specimen.

9.5.4 Compute the air void content of the SGC specimen in accordance with T 269. Record the air void content of the SGC specimen.

Note 8—Section 9.5 is optional because acceptance of the test specimen for mechanical property testing is based on the air void content of the test specimen, not the SGC specimen. However, monitoring SGC specimen density can identify improperly prepared specimens early in the specimen fabrication process. Information on SGC specimen air voids and test specimen air voids will also assist the laboratory in establishing potentially more precise methods than Appendix X1 for preparing test specimens to a target air void content.

9.6 *Test Specimen Preparation*:

9.6.1 Drill a core of nominal diameter of 100 mm from the center of the SGC specimen. Both the SGC specimen and the drill shall be adequately supported to ensure that the resulting core is cylindrical with sides that are smooth, parallel, and meet the tolerances on specimen diameter given in Table 1.

9.6.2 Saw the ends of the core to obtain a test specimen of a nominal height of 150 mm. Both the core and the saw shall be adequately supported to ensure that the resulting test specimen meets the tolerances given in Table 1 for height, end flatness, and end perpendicularity.

Note 9—With most equipment, it is better to perform the coring before the sawing. However, these operations may be performed in either order as long as the dimensional tolerances in Table 1 are satisfied.

9.6.3 Test specimens shall meet the dimensional tolerances given in Table 1.

Table 1—Test Specimen Dimensional Tolerances

Item	Specification	Method Reference
Average diameter	100 to 104 mm	9.6.3.1
Standard deviation of diameter	≤0.5 mm	9.6.3.1
Height	147.5 to 152.5 mm	9.6.3.2
End flatness	≤0.5 mm	9.6.3.3
End perpendicularity	≤1.0 mm	9.6.3.4

9.6.3.1 Using calipers, measure the diameter at the center and third points of the test specimen along axes that are 90 degrees apart. Record each of the six measurements to the nearest 0.1 mm. Calculate the average and the standard deviation of the six measurements. The standard deviation shall be less than 0.5 mm. Reject specimens not meeting the average and standard deviation requirements listed in Table 1. The average diameter, reported to the nearest 0.1 mm, shall be used in all material property calculations.

9.6.3.2 Measure the height of the test specimen in accordance with ASTM D 3549. Reject specimens with an average height outside the height tolerance listed in Table 1. Record the average height.

9.6.3.3 Using a straightedge and feeler gauges, measure the flatness of each end. Place a straightedge across the diameter at three locations approximately 120 degrees apart, and measure the maximum departure of the specimen end from the straightedge using tapered-end feeler gauges. For each end, record the maximum departure along the three locations as the end flatness. Reject specimens with end flatness exceeding 0.5 mm.

9.6.3.4 Using a combination square and feeler gauges, measure the perpendicularity of each end. At two locations approximately 90 degrees apart, place the blade of the combination square in contact with the specimen along the axis of the cylinder and the head in contact with the highest point on the end of the cylinder. Measure the distance between the head of the square and the lowest point on the end of the cylinder using tapered-end feeler gauges. For each end, record the maximum measurement from the two locations as the end perpendicularity. Reject specimens with end perpendicularity exceeding 1.0 mm.

9.7 *Test Specimen Density and Air Voids*:

9.7.1 Determine the G_{mm} of the HMA in accordance with T 209. If long-term conditioning has been used, determine the G_{mm} on the long-term-conditioned loose HMA. Record the G_{mm} of the HMA.

9.7.2 For dense- and gap-graded mixtures, determine the G_{mb} of the test specimen in accordance with T 166. Record the G_{mb} of the test specimen.

Note 10—When wet-coring and sawing methods are used, measure the immersed mass, followed by the surface-dry mass followed by the dry mass, to minimize drying time and expedite the specimen fabrication process.

9.7.3 For open-graded mixtures, determine the G_{mb} of the test specimen in accordance with T 269. Record the G_{mb} of the test specimen.

9.7.4 Compute the air void content of the test specimen in accordance with T 269. Record the air void content of the test specimen. Reject test specimens exceeding the air void tolerances specified in the applicable test.

9.8 *Test Specimen Storage*:

9.8.1 Mark the test specimen with a unique identification number.

9.8.2 Store the test specimen, until tested, on its end on a flat shelf in a room with the temperature controlled between 15 and 27°C.

Note 11—Definitive research concerning the effects of test specimen aging on various mechanical property tests has not been completed. Some users enclose specimens in plastic wrap and minimize specimen storage time to 2 weeks.

10. REPORTING

10.1 *Report the following information*:

10.1.1 Unique test specimen identification number.

10.1.2 Mixture design data including design compaction level and air void content, asphalt binder type and grade, binder content, binder specific gravities, aggregate types and bulk specific gravities, aggregate consensus properties, and G_{mm}.

10.1.3 Type of conditioning used.

10.1.4 G_{mm} for the conditioned specimens.

10.1.5 SGC specimen target height (optional).

10.1.6 SGC specimen G_{mb} (optional).

10.1.7 SGC specimen air void content (optional).

10.1.8 Test specimen average height.

10.1.9 Test specimen average diameter.

10.1.10 Test specimen G_{mb}.

10.1.11 Test specimen air void content.

10.1.12 Test specimen end flatness for each end.

10.1.13 Test specimen end perpendicularity for each end.

10.1.14 Remarks concerning deviations from this standard practice.

11. KEYWORDS

11.1 Gyratory compaction; performance test specimens.

APPENDIXES

(Nonmandatory Information)

X1. METHOD FOR ACHIEVING A TARGET AIR VOID CONTENT

X1.1. *Purpose*:

X1.1.1. This appendix presents a procedure for estimating the mass of HMA required to produce test specimens at a target air void content. It was developed to reduce the number of trial specimens needed to obtain a target air void content for a specific mixture.

X1.1.2. This procedure can be used with either plant-produced or laboratory-prepared HMA.

X1.2. *Summary*:

X1.2.1. Trial test specimens are prepared as described in this standard practice from SGC specimens produced with a standard mass of 6650 g and compacted to a standard height of 170 mm.

X1.2.2. Based on the air void content of the trial specimens, the mass of HMA required to produce test specimens at a target air void content is estimated using a regression equation. Background information regarding the regression equation is presented in Section X1.4.

X1.2.3. To use this method, it is critical that all SGC specimens are prepared to a standard height of 170 mm. The approach described in Section X1.4 can be used to develop a similar equation for other SGC specimen heights.

X1.3. *Procedure*:

X1.3.1. Prepare the first and second trial test specimens following this standard practice from SGC specimens produced with a standard mass of 6650 g and compacted to a standard height of 170 mm.

X1.3.2. Determine the air void content of the first and second trial test specimens.

X1.3.3. Calculate the average air void content of the two specimens, and designate this value as Va_s.

X1.3.4. Estimate the mass of HMA, W_t, required to produce test specimens with a target air void content of Va_t using Equation X1.1.

$$W_t = 7175 - (525)\frac{Va_t}{Va_s} \quad (X1.1)$$

where:

W_t = the estimated mass of HMA required to produce a SGC specimen for a test specimen with a target air void content of Va_t, g;

Va_t = the target air void content for the test specimen, % by volume; and

Va_s = the test specimen air void content produced with a gyratory mass of 6650 g, % by volume.

X1.3.5. Prepare the third trial test specimen following this standard practice from a SGC specimen produced with the target mass estimated in Section X1.3.4 and compacted to the standard height of 170 mm.

X1.3.6. Determine the air void content of the third trial test specimen.

X1.3.7. If the air void content of the third trial test specimen is within 0.5 percent of the target air void content, use the mass determined in Section X1.3.4 as the target mass for test specimen production.

X1.3.8. If the air void content of the third trial test specimen is not within 0.5 percent of the target air void content, prepare the fourth trial specimen using 50 g less than the mass calculated in Section X1.3.4 and the fifth trial test specimen using 50 g more than the mass calculated in Section X1.3.4.

X1.3.9. Determine the air void content of the fourth and fifth trial test specimens.

X1.3.10. Plot the air void content of the third, fourth, and fifth trial test specimens on the *y* axis versus the mass of HMA used to prepare the SGC specimen on the *x* axis, and draw the best-fit line through the three data points.

X1.3.11. From the best-fit line, determine the mass of HMA needed to produce a test specimen with the target air void content.

X1.3.12. Use the mass determined in Section X1.3.11 as the target mass for test specimen production.

X1.4. *Background*:

X1.4.1. The method described in this appendix was developed by the Arizona State University during NCHRP 9-19. It is based on analysis of 38 different mixtures, where test specimens were prepared to varying target air void contents representative of *in situ* conditions.

X1.4.2. For a given mixture, when SGC specimens are prepared to a specific height, the relationship between the HMA mass used to prepare the SGC specimen and the air void content of the test specimens was found to be linear as provided in Equation X1.2 as follows:

$$Va = I + S(W) \quad (X1.2)$$

where:

Va = the test specimen air void content, % by volume;

W = the mass of HMA used to produce the SGC specimen;

I = the intercept of the regression line; and

S = the slope of the regression line.

X1.5. When a wide range of mixtures is considered, the intercepts and slopes for individual mixtures were also found to be linearly related as provided in Equation X1.3 as follows:

$$I = -C(S) \tag{X1.3}$$

where:

I = the intercept of the individual mixture regression lines;

S = the slope of the individual mixture regression lines; and

C = a constant.

X1.6. In the NCHRP 9-19 research, the constant, *C*, was found to be 7175 for SGC specimens prepared to a standard height of 170 mm. Substituting this constant into Equation X1.3, then substituting Equation X1.3 into Equation X1.2 and simplifying, yields an equation relating the air void content of the test specimen to the mass of HMA used to prepare the SGC specimen to the standard height of 170 mm as provided in Equation X1.4 as follows:

$$Va = S(W - 7175) \tag{X1.4}$$

X1.7. If SGC specimens are compacted using a standard mass, W_s, and the air void contents for the resulting test specimens are determined to be Va_s, then Equation X1.4 can be solved for the slope as provided in Equation X1.5 as follows:

$$S = \frac{Va_s}{W_s - 7175} \tag{X1.5}$$

where:

Va_s = the test specimen air void content produced with an SGC mass of W_s, % by volume;

W_s = the mass of HMA used to produce the SGC specimen, g; and

S = the slope of the regression line.

X1.8. Using the slope from Equation X1.5, the target SGC specimen mass, W_t, required to produce a test specimen with a specific air void content, Va_t, can be estimated by substituting Equation X1.5 into Equation X1.4 and simplifying as provided in Equation X1.6 as follows:

$$W_t = 7175 + \frac{Va_t}{Va_s}(W_s - 7175) \tag{X1.6}$$

where:

W_t = the estimated mass of HMA required to produce an SGC specimen for a test specimen with a target air void content of Va_t, g;

Va_t = the target air void content for the test specimen;

Va_s = the test specimen air void content produced with an SGC mass of W_s, % by volume; and

W_s = the mass of HMA used to produce the SGC specimen.

X1.9. For a standard HMA mass of 6650 g, which was the average mass used in the NCHRP 9-19 study, Equation X1.6 reduces to the following:

$$W_t = 7175 - (525)\frac{Va_t}{Va_s} \qquad (X1.7)$$

where:

W_t = the estimated mass of HMA required to produce an SGC specimen for a test specimen with a target air void content of Va_t, g;

Va_t = the target air void content for the test specimen;

Va_s = the test specimen air void content produced with an SGC mass of W_s, % by volume; and

W_s = the mass of HMA used to produce the SGC specimen.

X2. METHOD FOR ASSESSING TEST SPECIMEN UNIFORMITY

X2.1. *Purpose*:

X2.1.1. This appendix presents a procedure for assessing the uniformity of the air void content in test specimens produced using this standard practice.

X2.1.2. The approach tests the significance of the difference in mean G_{mb} between the top and bottom third of the specimen relative to the middle third.

X2.1.3. The procedure can be used to determine the height for preparing SGC specimens with a specific SGC to minimize within-sample variations in air voids.

X2.2. *Summary*:

X2.2.1. Three test specimens are prepared as described in this standard practice from SGC specimens produced with the same mass and compacted to the same height.

X2.2.2. The test specimens are cut into three slices of equal thickness and the G_{mb} of each slice is determined.

X2.2.3. A statistical hypothesis test is conducted to determine the significance of the difference in the mean G_{mb} of the top and bottom slices relative to the middle third.

X2.3. *Procedure*:

X2.3.1. Prepare three test specimens following this standard practice to a target air void content of 5.5 percent. All three specimens shall have air void contents between 5.0 and 6.0 percent.

X2.3.2. Label the top, middle, and bottom third of each specimen; then saw the specimens into three slices of equal thickness.

X2.3.3. Determine the G_{mb} of each of the nine test section slices in accordance with T 166 for dense- and gap-graded HMA or T 269 for open-graded HMA.

X2.3.4. Assemble a summary table of the G_{mb} data where each column contains data for a specific slice and each row contains the data from a specific core.

X2.3.5. For each column, compute the mean and variance of the G_{mb} measurements using Equations X2.1 and X2.2 as follows:

$$\bar{y} = \frac{\sum_{i=1}^{3} y_i}{3} \qquad (X2.1)$$

$$s^2 = \frac{\sum_{i=1}^{3} \left(y_i - \bar{y}\right)^2}{2} \qquad (X2.2)$$

where:

$\bar{y}$ = the mean of the G_{mb} of the three slices;

s^2 = the variance of the G_{mb} of the slices; and

y_i = the measured G_{mb} of each slice.

X2.3.6. *Statistical Comparison of Means*—Compare the mean G_{mb} of the top and bottom slices to the middle slice using the hypothesis tests described below. In the descriptions below, the subscripts *t*, *m*, and *b* refer to the top, middle, and bottom slices, respectively.

X2.3.6.1. Check the top slice relative to the middle slice.

Null Hypothesis:

The mean G_{mb} of the top slice equals the mean G_{mb} of the middle slice, $\mu_t^2 = \mu_m^2$.

Alternative Hypothesis:

The mean G_{mb} of the top slice is not equal to the mean G_{mb} of the middle slice, $\mu_t^2 \neq \mu_m^2$.

Test Statistic:

$$t = \frac{\left(\bar{y}_t - \bar{y}_m\right)}{0.8165\left(s\right)} \qquad (X2.3)$$

where:

$$s = \sqrt{\frac{s_t^2 + s_m^2}{2}}$$

where:

$\bar{y}_t$ = the computed mean for the top slices;

$\bar{y}_m$ = the computed mean for the middle slices;

s_t^2 = the computed variance for the top slices; and

s_m^2 = the computed variance for the middle slices.

Region of Rejection:

For the sample sizes specified, the absolute value of the test statistic must be less than 2.78 to conclude that G_{mb} of the top and middle slices are equal.

X2.3.6.2. Check the bottom slice relative to the middle slice.

Null Hypothesis:

The mean G_{mb} of the bottom slice equals the mean G_{mb} of the middle slice, $\mu_b{}^2 = \mu_m{}^2$.

Alternative Hypothesis:

The mean G_{mb} of the bottom slice is not equal to the mean G_{mb} of the middle slice, $\mu_b{}^2 \neq \mu_m{}^2$.

Test Statistic:

$$t = \frac{\left(\bar{y}_b - \bar{y}_m\right)}{0.8165\left(s\right)} \qquad (X2.4)$$

where:

$$s = \sqrt{\frac{s_b{}^2 + s_m{}^2}{2}}$$

where:

$\bar{y}_b$ = the computed mean for the bottom slices;

$\bar{y}_m$ = the computed mean for the middle slices;

$s_b{}^2$ = the computed variance for the bottom slices; and

$s_m{}^2$ = the computed variance for the middle slices.

Region of Rejection:

For the sample sizes specified, the absolute value of the test statistic must be less than 2.78 to conclude that G_{mb} of the bottom and middle third slices are equal.

X2.4. *Analysis*:

X2.4.1. Significant differences in the G_{mb} of the top and bottom slices relative to the middle third indicate a systematic variation in density within the specimen.

X2.4.2. Specimens with differences for the top or bottom slices relative to the middle slices on the order of 0.025 have performed satisfactorily in the dynamic modulus, flow number, flow time, and continuum damage fatigue tests.

X2.4.3. Changing the height of the SGC specimen can improve the uniformity of the density in the test specimen.

---

[1] This provisional practice was adopted and first published in 2009.

[2] This provisional practice was developed from NCHRP Project 9-29, Simple Performance Tester for Superpave Mix Design. The name of the device has been changed to the “Asphalt Mixture Performance Tester.” To obtain research documents, refer to the Simple Performance Tester.

Standard Practice for

Developing Dynamic Modulus Master Curves for Hot Mix Asphalt (HMA) Using the Asphalt Mixture Performance Tester (AMPT)

AASHTO Designation: PP 61-10[1,2]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Developing Dynamic Modulus Master Curves for Hot Mix Asphalt (HMA) Using the Asphalt Mixture Performance Tester (AMPT)

AASHTO Designation: PP 61-10[1,2]

1. SCOPE

1.1 This practice describes testing and analysis for developing a dynamic modulus master curve for hot mix asphalt (HMA) using the Asphalt Mixture Performance Tester (AMPT). This practice is intended for dense- and gap-graded mixtures with nominal-maximum aggregate sizes up to 37.5 mm. This practice accounts for the temperature limitations of the AMPT and provides guidance to the user for the selection of appropriate test temperatures.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- PP 60, Preparation of Cylindrical Performance Test Specimens Using the Superpave Gyratory Compactor (SGC)
- *Mechanistic-Empirical Pavement Design Guide* (MEPDG)

2.2 *Other Publication*:

- Equipment Specification for the Simple Performance Test System, Version 3.0, Prepared for National Cooperative Highway Research Program (NCHRP), October 16, 2007.

3. TERMINOLOGY

3.1 *dynamic modulus master curve*—a composite curve constructed at a reference temperature by shifting dynamic modulus data from various temperatures along the “log frequency” axis.

3.2 *reduced frequency*—the computed frequency at the reference temperature, equivalent to the actual loading frequency at the test temperature.

3.3 *reference temperature*—the temperature at which the master curve is constructed.

3.4 *shift factor*—shift in frequency associated with a shift from a test temperature to the reference temperature.

4. SUMMARY OF PRACTICE

4.1 This practice describes the testing required using the AMPT and the analysis needed to develop a dynamic modulus master curve for HMA. It involves collecting dynamic modulus test data at specified temperatures and loading rates, then manipulating the test data to obtain a continuous function describing the dynamic modulus as a function of frequency and temperature.

5. SIGNIFICANCE AND USE

5.1 Dynamic modulus master curves can be used for mixture evaluation and for characterizing the modulus of HMA for mechanistic-empirical pavement design.

6. APPARATUS

6.1 *Specimen Fabrication Equipment*—For fabricating dynamic modulus test specimens as described in PP 60.

6.2 *Dynamic Modulus Test System*—Meeting the requirements of the equipment specification for the Simple Performance Test (SPT) System, Version 3.0.

6.3 *Analysis Software*—Capable of performing numerical optimization of non-linear equations.

Note 1—The “Solver” tool included in Microsoft Excel® is capable of performing the numerical optimization required by this practice.

7. HAZARDS

7.1 This practice and associated standards involve handling of hot asphalt binder, aggregates, and HMA. It also includes the use of sawing and coring machinery and servo-hydraulic testing equipment. Use standard safety precautions, equipment, and clothing when handling hot materials and operating machinery.

8. STANDARDIZATION

8.1 Items associated with this practice that require calibration or verification are included in the documents referenced in Section 2. Refer to the pertinent section of the referenced documents for information concerning calibration or verification.

9. DYNAMIC MODULUS TEST DATA

9.1 *Test Specimen Fabrication*:

9.1.1 Prepare at least two test specimens at the target air void content ±0.5 percent and with the aging condition in accordance with PP 60. Use Table 1 to select an appropriate number of specimens based on the uncertainty that can be tolerated in the analysis.

Note 2—The coefficient of variation for properly conducted dynamic modulus tests is approximately 13 percent. The coefficient of variation of the mean dynamic modulus for tests on multiple specimens is given in Table 1.

Table 1—Coefficient of Variation for the Mean of Dynamic Modulus Test on Replicate Specimens

Number of Specimens	Coefficient of Variation for Mean
2	9.2
3	7.5
4	6.5
5	5.8
6	5.3
7	4.9
8	4.6
9	4.3
10	4.1

9.1.2 Record the following volumetric properties for each test specimen:

- Voids in the mineral aggregate (VMA)
- Voids filled with asphalt (VFA)

9.2 *Testing Conditions*:

9.2.1 Measure the dynamic modulus and phase angle of each specimen using the dynamic modulus test system at each of the temperatures and loading frequencies given in Table 2. Begin testing at the lowest temperature and highest frequency. Test all frequencies in descending order before moving to the next highest temperature.

Table 2—Recommended Testing Temperatures and Loading Frequencies

PG 58-XX and softer		PG 64-XX and PG 70-XX		PG 76-XX and stiffer	
Temperature, °C	Loading Frequencies, Hz	Temperature, °C	Loading Frequencies, Hz	Temperature, °C	Loading Frequencies, Hz
4	10, 1, 0.1	4	10, 1, 0.1	4	10, 1, 0.1
20	10, 1, 0.1	20	10, 1, 0.1	20	10, 1, 0.1
35	10, 1, 0.1, and 0.01	40	10, 1, 0.1, and 0.01	45	10, 1, 0.1, and 0.01

Note 3—The dynamic modulus testing may be performed with or without confinement. The same confining stress conditions must be used at all temperatures and loading rates. An unconfined dynamic modulus master curve is typically used in mechanistic-empirical pavement analysis methods.

9.2.2 Accept only test data meeting the data quality statistics given in Table 3. Repeat tests as necessary to obtain test data meeting the data quality statistics requirements.

Table 3—Data Quality Statistics Requirements

Data Quality Statistic	Limit
Load standard error	10%
Deformation standard error	10%
Deformation uniformity	30%
Phase uniformity	3 degrees

Note 4—The data quality statistics in Table 3 are reported by the AMPT software. If a dynamic modulus test system other than the AMPT is used, refer to the equipment specification for the SPT

System, Version 3.0, for algorithms for the computation of dynamic modulus, phase angle, and data quality statistics.

9.3 *Dynamic Modulus Data Summary*:

9.3.1 Prepare a summary table of the dynamic modulus data. At each temperature and frequency, compute the following:

1. Average dynamic modulus;
2. Average phase angle;
3. Coefficient of variation of the dynamic modulus; and
4. Standard deviation of the phase angle.

Figure 1 presents an example summary data sheet.

Conditions		Specimen 1		Specimen 2		Specimen 3					
Temperature, °C	Frequency, Hz	Modulus, ksi	Phase Angle, degree	Modulus, ksi	Phase Angle, degree	Modulus, ksi	Phase Angle, degree	Average Modulus, ksi	Modulus CV, %	Average Phase Angle, degree	Std Dev Phase Angle, degree

Figure 1—Example Dynamic Modulus Summary Sheet

10. DATA ANALYSIS

10.1 *Dynamic Modulus Master Curve Equation*:

10.1.1 *General Form*—The general form of the dynamic modulus master curve is a modified version of the dynamic modulus master curve equation included in the *Mechanistic-Empirical Pavement Design Guide* (MEPDG).

$$\log\left|E^*\right| = \delta + \frac{\left(\text{Max} - \delta\right)}{1 + e^{\beta + \gamma \log f_r}} \qquad (1)$$

where:

$\left|E^*\right|$ = the dynamic modulus, psi;

δ, β, and γ = the fitting parameters;

Max = the limiting maximum modulus, psi; and

f_r = the reduced frequency, Hz.

10.1.2 *Reduced Frequency*—The reduced frequency in Equation 1 is computed using the Arrhenius equation.

$$\log f_r = \log f + \frac{\Delta E_a}{19.14714}\left(\frac{1}{T} - \frac{1}{T_r}\right) \qquad (2)$$

where:

f_r = the reduced frequency at the reference temperature, Hz;

f = the loading frequency at the test temperature, Hz;

ΔE_a = the activation energy (treated as a fitting parameter);

T = the test temperature, °K; and

T_r = the reference temperature, °K.

10.1.3 *Final Form*—The final form of the dynamic modulus master curve equation is obtained by substituting Equation 2 into Equation 1.

$$\log\left|E^*\right| = \delta + \frac{(\text{Max} - \delta)}{1 + e^{\beta + \gamma\left\{\log f + \frac{\Delta E_a}{19.14714}\left[\left(\frac{1}{T}\right) - \left(\frac{1}{T_r}\right)\right]\right\}}} \qquad (3)$$

10.2 *Shift Factors*—The shift factors at each temperature are given in Equation 4 as follows:

$$\log\left[a(T)\right] = \frac{\Delta E_a}{19.14714}\left(\frac{1}{T} - \frac{1}{T_r}\right) \qquad (4)$$

where:

$a(T)$ = the shift factor at temperature *T*;

ΔE_a = the activation energy (treated as a fitting parameter);

T = the test temperature, °K; and

T_r = the reference temperature, °K.

10.3 *Limiting Maximum Modulus*—The maximum limiting modulus is estimated from HMA volumetric properties using the Hirsch model (Christensen et al., 2003) and a limiting binder modulus of 1 GPa as provided in Equations 5 and 6.

$$\left|E^*\right|_{\max} = P_c\left[4,200,000\left(1 - \frac{VMA}{100}\right) + 435,000\left(\frac{VFA \times VMA}{10,000}\right) + \frac{1 - P_c}{\frac{\left(1 - \frac{VMA}{100}\right)}{4,200,000} + \frac{VMA}{435,000(VFA)}}\right] \qquad (5)$$

where:

$$P_c = \frac{\left(20 + \frac{435,000(VFA)}{VMA}\right)^{0.58}}{650 + \left(\frac{435,000(VFA)}{VMA}\right)^{0.58}} \qquad (6)$$

$\left|E^*\right|_{\max}$ = the limiting maximum HMA dynamic modulus, psi;

VMA = the voids in the mineral aggregate, %; and

VFA = the voids filled with asphalt, %.

10.4 *Fitting the Dynamic Modulus Master Curve*:

10.4.1 Estimate Limiting Maximum Modulus:

10.4.1.1 Using the average VMA and VFA of the specimens tested, compute the limiting maximum modulus using Equations 5 and 6.

10.4.1.2 Compute the logarithm of the limiting maximum modulus, and designate this value as “max.”

10.4.2 Select the Reference Temperature:

10.4.2.1 Select the reference temperature for the dynamic modulus master curve, and designate this value as T_r. Usually 20°C (293.15°K) is used as the reference temperature.

10.4.3 Perform Numerical Optimization:

10.4.3.1 Substitute “max,” computed in Section 10.4.1.2, and T_r, selected in Section 10.4.2.1, into Equation 3.

10.4.3.2 Determine the four fitting parameters of Equation 3 (δ, β, γ, and ΔE_a) using numerical optimization. The optimization can be performed using the “Solver” function in Microsoft Excel®. This calculation is performed by a spreadsheet to compute the sum of the squared errors between the logarithm of the average measured dynamic moduli at each temperature/frequency combination and the values predicted by Equation 3. The “Solver” function is used to minimize the sum of the squared errors by varying the fitting parameters in Equation 3. The following initial estimates are recommended: $\delta = 0.5$, $\beta = -1.0$, $\gamma = -0.5$, and $\Delta E_a = 200\,000$.

10.4.4 Compute “Goodness of Fit” Statistics:

10.4.4.1 Compute the standard deviation of the logarithm of the average measured dynamic modulus values for each temperature/frequency combination. Designate this value as S_y.

10.4.4.2 Compute the standard error of estimate using Equation 7.

$$S_e = \left[\frac{1}{6} \sum_{1}^{10} \left(\log \left| \hat{E}^* \right|_i - \log \left| E^* \right|_i \right)^2 \right]^{0.5} \qquad (7)$$

where:

S_e = the standard error of estimate;

$\log \left| \hat{E}^* \right|_i$ = the value predicted by Equation 3 after optimization for each temperature/frequency combination; and

$\log \left| E^* \right|_i$ = the logarithm of the average measured dynamic modulus for each temperature/frequency combination.

10.4.4.3 Compute the explained variance, R^2, using Equation 8.

$$R^2 = 1 - \frac{8{S_e}^2}{9{S_y}^2} \qquad (8)$$

where:

R^2 = the explained variance;

S_e = the standard error of estimate from Equation 7; and

S_y = the standard deviation of the logarithm of the average dynamic modulus values.

10.5 *Evaluate Fitted Master Curve*:

10.5.1 The ratio of S_e to S_y should be less than 0.05.

10.5.2 The explained variance should exceed 0.99.

10.6 *Determine AASHTO Mechanistic-Empirical Pavement Design Guide (MEPDG) Inputs*:

10.6.1 Substitute the logarithm of the limiting maximum modulus (max) determined in Section 10.4.1.2 and the fitting parameters (δ, β, γ, and ΔE_a) determined in Section 10.4.3.2 into Equation 3, and compute the dynamic modulus at the following temperatures and loading frequencies. A total of 30 dynamic modulus values will be calculated.

Temperatures, °C	Frequencies, Hz
–10, 4.4, 21.1, 37.8, and 54.4 (14, 40, 70, 100, and 130)	25, 10, 5, 1, 0.5, and 0.1

11. REPORT

11.1 *Report the following*:

11.1.1 Mixture identification.

11.1.2 Measured dynamic modulus and phase angle data for each specimen at each temperature/frequency combination.

11.1.3 Average measured dynamic modulus and phase angle at each temperature/frequency combination.

11.1.4 Coefficient of variation of the measured dynamic modulus data at each temperature/frequency combination.

11.1.5 Standard deviation of the measured phase angle data at each temperature/frequency combination.

11.1.6 VMA and VFA of each specimen tested.

11.1.7 Average VMA and VFA for the specimens tested.

11.1.8 Reference temperature.

11.1.9 Parameters of the fitted master curve (Max, δ, β, γ, and ΔE_a).

11.1.10 “Goodness of fit” statistics for the fitted master curve (S_e, S_y, S_e/S_y, R^2).

11.1.11 Plot of the fitted dynamic modulus master curve as a function of reduced frequency showing average measured dynamic modulus data.

11.1.12 Plot of shift factors as a function of temperature.

11.1.13 Plot of average phase angle as a function of reduced frequency.

11.1.14 Tabulated temperature, frequency, and dynamic modulus for input into MEPDG.

12. KEYWORDS

12.1 Dynamic modulus; master curve; phase angle.

Standard Practice for

Developing Dynamic Modulus Master Curves for Hot Mix Asphalt (HMA)

AASHTO Designation: PP 62-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Developing Dynamic Modulus Master Curves for Hot Mix Asphalt (HMA)

AASHTO Designation: PP 62-10[1]

1. SCOPE

1.1 This practice describes testing and analysis for developing a dynamic modulus master curve for hot mix asphalt (HMA). This practice is intended for dense- and gap-graded mixtures with nominal-maximum aggregate sizes up to 37.5 mm. This practice is intended for use with TP 62 and addresses the wide range of test temperatures and frequencies specified therein.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- PP 60, Preparation of Cylindrical Performance Test Specimens Using the Superpave Gyratory Compactor (SGC)
- R 35, Superpave Volumetric Design for Hot Mix Asphalt (HMA)
- TP 62, Determining Dynamic Modulus of Hot Mix Asphalt (HMA)
- *Mechanistic-Empirical Pavement Design Guide* (MEPDG)

3. TERMINOLOGY

3.1 *dynamic modulus master curve*—a composite curve constructed at a reference temperature by shifting dynamic modulus data from various temperatures along the “log frequency” axis.

3.2 *reduced frequency*—the computed frequency at the reference temperature, equivalent to the actual loading frequency at the test temperature.

3.3 *reference temperature*—the temperature at which the master curve is constructed.

3.4 *shift factor*—the shift in frequency associated with a shift from a test temperature to the reference temperature.

4. SUMMARY OF PRACTICE

4.1 This practice describes the testing and analysis needed to develop a dynamic modulus master curve for HMA. It involves collecting dynamic modulus test data at specified temperatures and loading rates, then manipulating the test data to obtain a continuous function describing the dynamic modulus as a function of frequency and temperature.

5. SIGNIFICANCE AND USE

5.1 Dynamic modulus master curves can be used for mixture evaluation and for characterizing the modulus of HMA for mechanistic-empirical pavement design.

6. APPARATUS

6.1 *Specimen Fabrication Equipment*—For fabricating dynamic modulus test specimens as described in PP 60.

6.2 *Dynamic Modulus Test System*—Meeting the requirements of TP 62.

6.3 *Analysis Software*—Capable of performing numerical optimization of non-linear equations.

Note 1—The “Solver” tool included in Microsoft Excel® is capable of performing the numerical optimization required by this practice.

7. HAZARDS

7.1 This practice and associated standards involve handling of hot asphalt binder, aggregates, and HMA. It also includes the use of sawing and coring machinery and servo-hydraulic testing equipment. Use standard safety precautions, equipment, and clothing when handling hot materials and operating machinery.

8. STANDARDIZATION

8.1 Items associated with this practice that require calibration or verification are included in the documents referenced in Section 2. Refer to the pertinent section of the referenced documents for information concerning calibration or verification.

9. DYNAMIC MODULUS TEST DATA

9.1 *Test Specimen Fabrication*:

9.1.1 Prepare at least two test specimens at the target air void content ±0.5 percent and with the aging condition in accordance with PP 60. Use Table 1 to select an appropriate number of specimens based on the uncertainty that can be tolerated in the analysis.

Note 2—The coefficient of variation for properly conducted dynamic modulus tests is approximately 13 percent. The coefficient of variation of the mean dynamic modulus for tests on multiple specimens is given in Table 1.

Table 1—Coefficient of Variation for the Mean of Dynamic Modulus Test on Replicate Specimens

Number of Specimens	Coefficient of Variation for Mean
2	9.2
3	7.5
4	6.5
5	5.8
6	5.3
7	4.9
8	4.6
9	4.3
10	4.1

9.1.2 Record the following volumetric properties for each test specimen:

- Air void content
- Binder content
- Voids in the mineral aggregate (VMA)
- Voids filled with asphalt (VFA)

9.1.2.1 Refer to R 35 for methods for computing volumetric properties.

9.2 *Testing Conditions*:

9.2.1 Determine the dynamic modulus and phase angle for each specimen as specified in TP 62.

9.2.2 Accept only test data meeting the data quality statistics given in Table 2. Repeat tests as necessary to obtain test data meeting the data quality statistics requirements.

Table 2—Data Quality Statistics Requirements

Data Quality Statistic	Limit
Load standard error	10%
Deformation standard error	10%
Deformation uniformity	30%
Phase uniformity	3 degrees

Note 3—Algorithms for computation of the data quality statistics are given in TP 62.

9.3 *Dynamic Modulus Data Summary*:

9.3.1 Prepare a summary table of the dynamic modulus data. At each temperature and frequency, compute the following:

1. Average dynamic modulus;
2. Average phase angle;
3. Coefficient of variation of the dynamic modulus; and
4. Standard deviation of the phase angle.

Figure 1 presents an example of a summary data sheet.

Conditions		Specimen 1		Specimen 2		Modulus		Phase Angle

Figure 1—Example Dynamic Modulus Summary Sheet

10. DATA ANALYSIS

10.1 *Dynamic Modulus Master Curve Equation*:

10.1.1 *General Form*—The general form of the dynamic modulus master curve is the sigmoid function included in the *Mechanistic-Empirical Pavement Design Guide* (MEPDG).

$$\log\left|E^*\right| = \delta + \frac{(\alpha)}{1+e^{\beta+\gamma\log f_r}} \qquad (1)$$

where:

$\left|E^*\right|$ = the dynamic modulus, psi;

α, β, δ, and γ = the fitting parameters; and

f_r = the reduced frequency, Hz.

10.1.2 *Reduced Frequency*—The reduced frequency in Equation 1 is computed using time-temperature shift factors. Several time temperature shift functions are available in the literature. This practice presents two shift factor equations: shift factors from the MEPDG and second-order polynomial.

10.1.2.1 MEPDG Shift Factors:

$$\log f_r = \log f + c\left(\log \eta - \log \eta_{T_R}\right) \qquad (2)$$

where:

f_r = the reduced frequency at the reference temperature;
f = the loading frequency at the test temperature;
c = a fitting coefficient;
η = the viscosity of the binder at the test temperature, cP;
T_R = the reference temperature, °R; and
η_{T_R} = the viscosity of the binder at the reference temperature, cP.

Viscosities in Equation 2 are determined using Equation 3 as follows:

$$\log \eta = 10^{\left[A + VTS \log(T)\right]} \qquad (3)$$

where:

η = the viscosity, cP;
A and *VTS* = the parameters of the binder viscosity-temperature susceptibility relationship; and
T = the test temperature, °R (°F + 459.67).

10.1.2.2 Second-Order Polynomial:

$$\log f_r = \log f + a_1\left(T_R - T\right) + a_2\left(T_R - T\right)^2 \qquad (4)$$

where:

f_r = the reduced frequency at the reference temperature;
f = the loading frequency at the test temperature;
a_1, a_2 = the fitting coefficients;
T_R = the reference temperature, °F; and
T = the test temperature, °F.

10.1.3 *Final Form*—The final form of the dynamic modulus master curve equation is obtained by substituting the selected shift factor relationship into Equation 1.

10.1.3.1 MEPDG Shift Factors:

$$\log\left|\hat{E}*\right| = \delta + \frac{(\alpha)}{1 + e^{\beta + \gamma\left\{\log f + c\left[10^{\left(A + VTS \log T\right)} - 10^{\left(A + VTS \log T_R\right)}\right]\right\}}} \qquad (5)$$

10.1.3.2 Second-Order Polynomial Shift Factors:

$$\log\left|\hat{E}^*\right| = \delta + \frac{(\alpha)}{1+e^{\beta+\gamma\left[\log f + a_1(T_R - T) + a_2(T_R - T)^2\right]}} \qquad (6)$$

10.1.4 Fitting the Dynamic Modulus Master Curve:

10.1.4.1 Select Reference Temperature:

Select the reference temperature for the dynamic modulus master curve, and designate this value as T_R. Usually 70°F is used as the reference temperature.

10.1.4.2 Perform Numerical Optimization:

Determine the fitting parameters of Equation 5 or 6 using numerical optimization. The optimization can be performed using the "Solver" function in Microsoft Excel®. This calculation is performed by a spreadsheet to compute the sum of the squared errors between the logarithm of the average measured dynamic moduli at each temperature/frequency combination and the values predicted by Equation 5 or 6. See Equation 7.

$$\sum \text{error}^2 = \sum_{1}^{n}\left(\log\left|\hat{E}^*\right|_i - \log\left|E^*\right|_i\right)^2 \qquad (7)$$

where:

$\sum \text{error}^2$ = the sum of squared errors;

n = the number of temperature/frequency combinations used in the testing;

$\log\left|\hat{E}^*\right|_i$ = the value predicted by Equation 5 or 6 for each temperature/frequency combination; and

$\log\left|E^*\right|_i$ = the logarithm of the average measured dynamic modulus for each temperature/frequency combination.

The "Solver" function is used to minimize the sum of the squared errors by varying the fitting parameters. Recommended initial estimates are listed in Table 3. Note that these estimates depend on the units used as shown in Table 3.

Table 3—Recommended Initial Estimates

MEPDG Shift Factors T_R = 529.67°R $\left\|E^*\right\|$ = ksi f = Hz		Polynomial Shift Factors T_R = 70°F $\left\|E^*\right\|$ = ksi f = Hz	
Fitting Parameter	Initial Estimate	Fitting Parameter	Initial Estimate
α	3.0	α	3.0
β	–1.0	β	–1.0
δ	0.5	δ	0.5
γ	–0.5	γ	–0.5
c	1.0	a_1	0.1
		a_2	0.0001

10.1.4.3 Compute “Goodness of Fit” Statistics:

Compute the standard deviation of the logarithm of the average measured dynamic modulus values for all temperature/frequency combinations. Designate this value as S_y.

$$S_y = \sqrt{\frac{\sum_{1}^{n}\left(\log\left|E^*\right|_i - \overline{\log\left|E^*\right|}\right)^2}{n-1}} \qquad (8)$$

where:

S_y = the standard deviation of the logarithm of the average measured data;

$\log\left|E^*\right|_i$ = the logarithm of the average measured dynamic modulus for each temperature/frequency combination;

$\log\left|E^*\right|_i$ = the logarithm of the average measured dynamic modulus for each temperature/frequency combination;

$\overline{\log\left|E^*\right|}$ = the average of the logarithm of the average measured dynamic moduli

= $\sum_{1}^{n}\frac{\log\left|E^*\right|_i}{n}$; and

n = the number of temperature/frequency combinations used in the testing.

Compute the standard error of estimate using Equation 7 as follows:

$$S_e = \left[\frac{1}{(n-p-1)}\sum_{1}^{n}\left(\log\left|\hat{E}^*\right|_i - \log\left|E^*\right|_i\right)^2\right]^{0.5} \qquad (9)$$

where:

S_e = the standard error of estimate;

n = the number of temperature/frequency combinations used in the testing;

p = the number of fitting parameters;

$\log\left|\hat{E}^*\right|_i$ = the value predicted by Equation 5 or 6 after optimization for each temperature/frequency combination; and

$\log\left|E^*\right|_i$ = the logarithm of the average measured dynamic modulus for each temperature/frequency combination.

Compute the explained variance, R^2, using Equation 10 as follows:

$$R^2 = 1 - \frac{(n-p-1)\,{S_e}^2}{(n-1)\,{S_y}^2} \qquad (10)$$

where:

R^2 = the explained variance;

n = the number of temperature/frequency combinations used in the testing;

p = the number of fitting parameters;

S_e = the standard error of estimate from Equation 9; and

S_y = the standard deviation of the logarithm of the average measured dynamic modulus values from Equation 8.

10.1.5 Evaluate Fitted Master Curve:

10.1.5.1 The ratio of S_e to S_y should be less than 0.05.

10.1.5.2 The explained variance should exceed 0.99.

11. REPORT

11.1 *Report the following*:

11.1.1 Mixture identification.

11.1.2 Measured dynamic modulus and phase angle data for each specimen at each temperature/frequency combination.

11.1.3 Average measured dynamic modulus and phase angle at each temperature/frequency combination.

11.1.4 Coefficient of variation of the measured dynamic modulus data at each temperature/frequency combination.

11.1.5 Standard deviation of the measured phase angle data at each temperature/frequency combination.

11.1.6 Air voids, binder content, VMA, and VFA of each specimen tested.

11.1.7 Average air voids, average binder content, average VMA, and average VFA for the specimens tested.

11.1.8 Reference temperature.

11.1.9 Parameters of the fitted master curve.

11.1.10 "Goodness of fit" statistics for the fitted master curve (S_e, S_y, S_e/S_y, R^2).

11.1.11 Plot of the fitted dynamic modulus master curve as a function of reduced frequency showing average measured dynamic modulus data.

11.1.12 Plot of shift factors as a function of temperature.

11.1.13 Plot of average phase angle as a function of reduced frequency.

12. KEYWORDS

12.1 Dynamic modulus; master curve; phase angle.

Standard Practice for

Determination of Long-Term Strength for Geosynthetic Reinforcement

AASHTO Designation: PP 66-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determination of Long-Term Strength for Geosynthetic Reinforcement

AASHTO Designation: PP 66-10

INTRODUCTION

Through this protocol, the long-term strength and stiffness of geosynthetic reinforcements can be determined. This protocol contains test and evaluation procedures to determine reduction factors for installation damage, creep, and chemical/biological durability, as well as the method to combine these factors to determine the long-term strength. The long-term strength and stiffness values determined from this protocol can be used as input values for geosynthetic structure designs conducted in accordance with the *AASHTO LRFD Bridge Design Specifications* and related FHWA design guidelines. The long-term strength and stiffness values determined from this protocol can also be compared to the required design strength and stiffness values provided in the contract for the geosynthetic structure(s) in question to determine whether the selected product meets the contract requirements. This protocol can be used for initial product qualification or acceptance (e.g., for inclusion in a Qualified Products List), or for quality assurance (QA) to facilitate periodic review of products for which the long-term strength has been previously determined using this standard practice.

1. SCOPE

1.1 This protocol has been developed to address polypropylene (PP), polyethylene (PE or HDPE), and polyester (PET) geosynthetics (i.e., geotextiles and geogrids). For other geosynthetic polymers [(e.g., polyamide (PA) or polyvinyl alcohol (PVA)], the installation damage and creep protocols provided herein are directly applicable. While the chemical and biological durability procedures and criteria provided herein may also be applicable to other polymers (for example, hydrolysis testing as described in Annex C is likely applicable to PA and PVA geosynthetics), additional investigation will be required to establish a detailed protocol and acceptance criteria for these other polymers. These other polymers may be considered for evaluation using this protocol once modifications to the chemical/biological durability aspects of this protocol have been developed and are agreed upon by the approval authority.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not propose to address all safety problems associated with its usage. It is the duty and responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Note 1—The values stated in SI units are to be regarded as the standard.

3. TERMINOLOGY

3.1 *apertures*—the open spaces formed between the interconnected network of longitudinal and transverse ribs of a geogrid.

3.2 d_{50}—the grain size at 50 percent passing by weight for the backfill.

3.3 *effective design temperature*—the temperature that is halfway between the average yearly air temperature and the normal daily air temperature for the warmest month at the geosynthetic structure site.

3.4 *HDPE*—high-density polyethylene.

3.5 *hydrolysis*—the reaction of water molecules with the polymer material, resulting in polymer chain scission, reduced molecular weight, and strength loss.

3.6 *in-isolation testing*—geosynthetic testing in which the specimen is surrounded by air or a fluid (not soil).

3.7 *installation damage*—damage to the geosynthetic, such as cuts, holes (geotextiles only), abrasion, fraying, etc., created during installation of the geosynthetic in the backfill soil.

3.8 *load level*—for creep or creep-rupture testing, the load applied to the test specimen divided by T_{lot}, the short-term ultimate strength of the lot or roll of material used form the creep testing.

3.9 *MARV*—the minimum average roll value for the geosynthetic, defined as two standard deviations below the mean for the product (i.e., 97.5 percent of all test results will meet or exceed the MARV). For practical purposes, from the user's viewpoint, the average for a sample taken from any roll in the lot shipped to the job site should meet or exceed the MARV.

3.10 *minimum value*—the lowest sample value from documented manufacturing quality control test results for a defined population from one test method associated with one specific property.

3.11 *MSE*—mechanically stabilized earth.

3.12 *nonaggressive environment*—for geosynthetic walls and slopes, soils that have a d_{50} of 4.75 mm or less, a maximum particle size of 31.5 mm or less, a pH of 4.5 to 9, and an effective design temperature of 30°C (85°F) or less.

3.13 *oxidation*—the reaction of oxygen with the polymer material, initiated by heat, UV radiation, and possibly other agents, resulting in chain scission and strength loss.

3.14 *PET*—polyester.

3.15 *post-consumer recycled material*—polymer products sold to consumers that have been returned by the consumer after use of the products for the purpose of recycling.

3.16 *PP*—polypropylene.

3.17 *product line*—a series of products manufactured using the same polymer (including stabilizers) in which the polymer for all products in the line comes from the same source, the manufacturing process is the same for all products in the line, and the only difference is in the product weight/unit area or number of fibers contained in each reinforcement element.

3.18 *QPL*—qualified products list.

3.19 *RF*—combined reduction factor to account for long-term degradation due to installation damage, creep, and chemical/biological aging.

3.20 RF_{CR}—strength reduction factor to prevent long-term creep rupture of the reinforcement.

3.21 RF_{D}—strength reduction factor to prevent rupture of the reinforcement due to long-term chemical and biological degradation.

3.22 RF_{ID}—strength reduction factor to account for installation damage to the reinforcement.

3.23 *sample*—a portion of material that is taken for testing or for record purposes, from which a group of specimens can be obtained to provide information that can be used for making statistical inferences about the population(s) from which the specimens are drawn.

3.24 *specimen*—a specific portion of a material or laboratory sample upon which a test is performed or that is taken for that purpose.

3.25 *survivability*—the ability of a geosynthetic to survive a given set of installation conditions with an acceptable level of damage.

3.26 T_{al}—the long-term tensile strength that will not result in rupture of the reinforcement during the required design life, calculated on a load per unit of reinforcement width basis.

3.27 T_{ult}—the ultimate tensile strength of the reinforcement determined from wide width tensile tests.

3.28 *UV*—Ultraviolet light.

4. SIGNIFICANCE AND USE

4.1 This recommended practice provides a protocol to assess the reduction in tensile strength and stiffness of geosynthetic (i.e., geotextiles and geogrids) reinforcement that occurs due to the installation of the material in or immediately beneath soil backfill and due to time exposure to the ambient environment (e.g., temperature, pH, oxygen, water, or other materials or chemicals in the surrounding environment) during the design life for the structure. This recommended practice is applicable to the assessment of these long-term properties for individual geosynthetic reinforcement products as well as for geosynthetic reinforcement products lines. This reduced strength can be used as a design value in the design of geosynthetic reinforced structures such as walls, reinforced slopes, or embankment base reinforcement, or at can be used for material acceptance and QA purposes for the construction of such structures.

4.2 Due to the length of time required to obtain the test data required by this recommended practice, this recommended practice is generally not practical to be carried out on a suite of products for a specific project. Its primary use is to establish values that can be used at a program level by an agency or the geosynthetic manufacturer, using data developed for a range of site conditions likely to be encountered that can be adapted to the site specific conditions encountered in specific construction projects as needed.

4.3 This practice has not been developed to establish strength and stiffness properties directly applicable to dynamic loading situations such as in pavement base course reinforcement. The strength and stiffness properties obtained using this practice have been shown to be applicable to seismic loading situations, though the values obtained are likely to be conservative in that case, at least with regard to creep.

5. EVALUATION OF SOIL ENVIRONMENT AGGRESSIVENESS EFFECTS ON LONG-TERM STRENGTH DETERMINATION

5.1 The aggressiveness of the environment with regards to geosynthetic long-term strength determination shall be based on soil gradation and particle characteristics of the backfill soil, chemical properties of the backfill soil and adjacent environment, and site temperature. The backfill pH should be considered the key chemical property that will affect the chemical aggressiveness of the geosynthetic environment. Soil gradation and particle characteristics primarily affect potential RF_{ID} values, chemical properties affect the potential for high RF_D values, and temperature affects potential for high RF_D and high RF_{CR} values. The aggressiveness of the soil gradation will depend on the distribution, the maximum size, the angularity, and the durability of the soil particles. In general, the more angular the soil, the more uniform its gradation, the greater the maximum particle size, and the more durable the particles, the more aggressive the soil is with regard to potential for installation damage. Installation damage for geosynthetic reinforcement has been approximately correlated to the d_{50} size of the soil, and the d_{50} size can be used as a basis to interpolate to a specific soil gradation using test results at other gradations (Elias, 2000). However, other gradation characteristics may need to be considered to more accurately interpolate to a specific soil gradation and angularity. While installation damage can be evaluated for the anticipated soil gradation and characteristics, it is generally undesirable to use soils and associated installation conditions that result in a RF_{ID} value that is greater than approximately 1.7 due to the likelihood of excessive variability in the results. The decision regarding what gradation characteristics are to be considered too aggressive shall be made by the approval authority.

5.2 Regarding chemical properties of the environment surrounding the geosynthetic in the wall or slope, the pH shall be between 4.5 and 9 to be considered nonaggressive. This applies both in the reinforced backfill and at the back of the face of walls or other surficial treatments.

5.3 Regarding temperature, the effective design temperature at the wall or slope site shall be less than 30°C (85°F) for the environment to be considered nonaggressive. In all but the most southerly tier of states in the United States, all geosynthetic structure sites are anticipated to have an effective design temperature that is below 30°C (85°F). Unless otherwise indicated in the contract specifications for a given project, the design temperature used to determine RF and T_{al} from product specific data shall be assumed to be 20°C (68°F).

5.4 The contract specifications for the geosynthetic structure should identify whether the environment is anticipated to be aggressive and the reason for the aggressive environment designation (i.e., backfill gradation, site chemistry, or site temperature). If aggressive conditions are not identified in the contract specifications, and the contract specifications provide soil chemical criteria that are consistent with nonaggressive conditions as described herein, the environment should be considered to be nonaggressive to determine the long-term strength. However, the backfill should be tested prior to use to verify that it is nonaggressive.

Note 2—For most soil conditions in the United States, the environment will likely be chemically nonaggressive. A possible exception to this is immediately behind a concrete wall face, where pH levels could possibly be elevated above a pH of 9. However, recent research has indicated that for well-drained backfills, the pH adjacent to a concrete face stays below 9 in the long-term (Koerner, et al., 2001, Koerner, et al., 2002). In any case, the long-term strength determination must account for the environment at the face. However, there are specific geological regions in the United States that are more likely to have chemically aggressive conditions, as described in Elias (2000). Examples include salt-affected soils in the arid western (especially southwest) regions of the United States, acid-sulphate soils that are commonly found in the Appalachian region of the United States, and calcareous soils commonly found in Florida, Texas, New Mexico, and many western states.

---

6. PRODUCT QUALIFICATION TESTING AND EVALUATION

6.1 *Product Qualification Testing Approach*:

6.1.1 As a first step, it shall be verified which geosynthetic products should be included as a single product line, unless only a single product is to be evaluated. The focus of the product qualification testing program shall be to characterize the long-term strength and stiffness properties for the entire product line, selecting samples from specific products within the product line to represent the entire product line. If a single product is to be evaluated, the product shall be subjected to the full suite of product qualification tests as described herein.

Note 3—The product line concept provides the ability to conduct performance testing to assess strength reduction factors and stiffness values on selected representative products in the product line. The test results from these representative products are then used to interpolate the reduction factors and stiffness values for the products in the product line not performance tested. This interpolation or, in some cases extrapolation, is performed using a parameter for which a clear relationship with the value of the strength reduction factor or stiffness for the product line exists (e.g., unit weight or tensile strength). Alternatively, a lower bound value could be applied to the rest of the product line based on the test results from the weakest or lightest weight product in the product line, provided the lower bound value can be selected with confidence. The ability to test only representative products from the product line can significantly reduce testing costs. However, it must be recognized that there is some risk associated with the use of this product line concept with regard to the determination of the properties of the intermediate products not specifically tested. The product line concept relies on the ability of the testing/evaluating organization to verify that the polymer source and fibers used to make the products in the line not tested are, in fact, the same as those used in the products that are specifically tested. In addition, for coated geogrids, the consistency of the coating type, process, and thickness/weight across all the products in the product line must also be verified. To reduce this risk to an acceptable level, a manufacturing plant auditing process should be used, and a limited testing program focused on evaluating the consistency among all products in the product line should be conducted on products in the product line not selected and subjected to performance tests as product line representatives. See Section 6.3 for details.

6.2 *Sampling*:

6.2.1 All materials or products, or both, to be tested will be furnished by the manufacturer/supplier at no cost to the review/approval authority. Samples will be selected for testing by agency or owner personnel or designated parties.

6.2.2 Sampling shall be conducted in accordance with the requirements in the specific AASHTO, ASTM, GRI, or ISO test standard for the specific tests conducted as part of this standard practice. For products selected as representative of the product line, an entire roll should be taken, but no less than the sum of the sample sizes required for all tests to be conducted on each product. For the remaining products in the product line, a sample with the dimensions of the product roll width by 20 ft should be taken. As a minimum, the following shall be obtained:

- a geosynthetic product sample of sufficient size to accommodate all of the specified testing;
- information showing the manufacturer’s name and description of product (style, brand name, etc.);
- product roll and lot number; and
- a sample of the polymer component(s) used to manufacture the product or product line in sufficient quantity to conduct the specified polymer tests.

6.2.3 All samples for the specified product qualification testing shall be from the same roll of material for each product tested. Regarding the polymer components, they should be obtained from the production line used to produce the geosynthetic products being evaluated.

6.2.4 A sampling report should be developed and, as a minimum, should include the following information:

- date of sampling;
- a brief description of the manufacturing facility/production line;
- the facility location;
- any prearrangements made with the manufacturer to sample, especially considering any advance warning of the sampling event provided to the manufacturer;
- the information for each sample required in Section 6.2.2;
- where the sample was taken within the facility; and
- how the sample was prepared for shipping and supervised by the sampler.

6.3 *Evaluation of Product Lines*:

6.3.1 *Assessment to Define Product Line*—If determining the long-term strength or stiffness values for a product line, data must be obtained for each product to facilitate the determination of which products should be considered as included in the product line. A product line is defined as a series of products manufactured using the same polymer (including stabilizers) in which the polymer for all products in the line comes from the same source, the manufacturing process is the same for all products in the line, and the only difference is in the product weight/unit area or number of fibers contained in each reinforcement element. The assessment of whether or not all products identified as a product line by the geosynthetic manufacturer qualify as such should be based, as a minimum, on the following information for each product in the product line:

- geosynthetic type, structure, and weaving process used to construct yarns or ribs;
- spacing and dimensions of geogrid elements, including photographs or small samples for visual examination. The receiving laboratory should verify these dimensions upon receipt of the sample(s) using hand measurement techniques. This is especially critical for strength determination based on a single or limited number of ribs in the specimens tested.

- polymer(s) used for fibers, ribs, etc.;
- polymer(s) used for coating, if present;
- polymer source(s) used for product;
- for HDPE and PP, primary resin ASTM type, class, grade, category (for HDPE use ASTM D 1248, and for PP use ASTM D 4101), and any other specifications used as manufacturing targets;
- for PET, minimum production number average molecular weight (ASTM D 4603 and GRI-GG8) and maximum carboxyl end group content (GRI-GG7), with supporting test data. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided, and any other specifications used as manufacturing targets;
- percent of post-consumer recycled material by weight;
- minimum weight per unit area for product (ASTM D 5261);
- Minimum average roll value (MARV) for ultimate wide width tensile strength (ASTM D 4595 or ASTM D 6637), with supporting test data. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided.

Additional guidance on assessing whether or not a product or series of products should be included within a product line is provided in Annex B, Section B1.7.

6.3.2 Once an initial assessment of the product line has been made based on the product description and index property data described above, performance and additional index property testing for installation damage, creep, and durability shall be conducted for the products identified as a product line. The full suite of performance tests for installation damage, creep, and durability shall be obtained for at least one product in the product line to qualify the product line. This product shall be designated as the “primary product” for product line characterization purposes. For certain tests, such as UV resistance and oven aging, it is permissible to only test the lightest weight product in the product line, provided it is obvious that doing so will be a conservative characterization of the entire product line for those specific properties. Additional product specific test results for installation damage, creep, and durability as described herein shall be obtained for other products in the product line to verify consistency of the other products in the line with the primary product and the ability to interpolate installation damage, creep, and durability behavior to estimate strength reduction factors for the entire product line. In addition, a limited manufacturing plant audit should be conducted at the time the samples for testing are obtained. See Sections 6.3.2.1 through 6.3.2.4 and Note 3 for additional guidance on the assessment of each product in the product line.

6.3.2.1 Product specific installation damage data obtained in accordance with Annex A should be obtained for each product in the line. However, it is permissible to obtain installation damage data for only some of the products in the product line if interpolation of the installation damage reduction factor between products is feasible, or if an upper bound value of RF_{ID} can be determined for the entire product line. Testing and interpretation requirements to determine RF_{ID} for each product in the product line provided in Annex A, Section A1.1.6.4 shall be followed. For the products in the product line not tested in accordance with Annex A as primary or secondary products for product line characterization, a limited testing program should be conducted that allows direct comparison to the installation damage test results obtained for the products (primary and secondary per Section 6.3.2) used to characterize the product line. One of the following two options should be used to accomplish this:

1. Conduct bench-scale installation damage tests (ISO 10722-1) on all products in the product line, or
2. Conduct a full-scale field installation damage test per Annex A and ASTM D5818, but only using the coarsest soil used in the testing for characterizing the product line with regard to installation damage.

This limited testing program should be used to verify that the installation damage test results for products not tested as primary or secondary products per Section 6.3.2 for product line characterization are consistent with the installation damage data for the primary and secondary products. Consistency between the primary and secondary product test results and the limited test results for the remaining products in the product line should be judged as follows:

- If there is no consistent trend or relationship between a product property such as strength or weight and strength retained after damage, and a lower bound approach must be used to estimate strength retained (and RF_{ID}) for all products in the product line, the measured retained strength after damage shall be greater than or equal to the retained strength measured for the primary and secondary products.
- If there is a consistent trend or relationship between a product property such as strength or weight and strength retained after damage, the installation damage test results for the remaining products in the product line shall be greater than or equal to the 95 percent prediction limit for the regression of the primary and secondary product installation damage data (see Section 7.5.3.2 for procedures to be used to conduct this analysis).

The comparison between the primary/secondary product installation damage test results and the test results for the remaining products shall be conducted for the same type of installation damage test (i.e., ISO tests for all products in the product line, or full-scale installation damage tests for the coarsest soil for all products in the product line).

6.3.2.2 For extension of the creep data obtained on the product identified as the primary product for the product line to the entire product line as defined herein, a limited creep testing program shall be conducted on at least two additional products (i.e., secondary products per Section 6.3.2) in the product line. If the results are not consistent with the primary product creep-rupture envelope in accordance with Section B1.7 in Annex B, all products in the product line shall be creep tested, or the product line should be divided into groups of products that are consistent and that meet the definition of a product line. The testing and analysis shall be conducted in accordance with Annex B, Section B1.7.

6.3.2.3 For determination of the durability reduction factor, RF_D, for the product line, the weakest or lightest product in the range of products in the product line should be tested. For molecular weight/viscosity and carboxyl end group testing of polyester geosynthetics, it is acceptable to perform the tests on the yarn sampled at the geosynthetic manufacturing facility provided that it can be demonstrated that the yarn sampled is used to manufacture the geosynthetic products that are included in the product line being evaluated, in accordance with Section 6.3.2.4. If this cannot be verified, then yarn/fibers obtained from each product in the product line shall be tested.

6.3.2.4 The focus of the geosynthetic reinforcement manufacturing plant limited audit is to verify traceability of materials used for each product in the product line, and to verify consistency in the manufacturing process used for all products in the product line. The audit of the geosynthetic reinforcement manufacturing facility, as a minimum, shall include the following:

- verification that the same base polymer and yarn is used in all products included in the product line;
- verification of polymer source(s) used and consistency of the polymer property standards for the sources used;
- verification in the consistency of the manufacturing process used with regard to the base polymeric yarn, filament, or rib, including heating/quenching history, weaving, rib junction construction, etc.; and
- for coated geogrids, verification of the coating material used and its consistency for all products in the line, including thickness and/or weight per unit area, temperature history, and other processing variables.

The audit should be conducted in conjunction with the sampling conducted. A report of the audit findings shall be developed by the auditor and included with the sampling report.

6.4 *Determination of Long-Term Geosynthetic Strength for Initial Product Qualification*:

The long-term geosynthetic strength shall be determined by applying strength reduction factors to the ultimate tensile strength of the geosynthetic, Tult. Tult shall be determined in accordance with ASTM D 4595 for geotextiles and ASTM D 6637 for geogrids.

$$T_{al} = \frac{T_{\mathrm{ult}}}{RF} \qquad (1)$$

where:

$$RF - RF_{ID} \times RF_{CR} \times RF_{D} \qquad (2)$$

where:

T_{al} = the long-term tensile strength that will not result in rupture of the reinforcement during the required design life, calculated on a load per unit of reinforcement width basis;

T_{ult} = the ultimate tensile strength (MARV) of the reinforcement determined from wide width tensile tests;

RF = a combined reduction factor to account for potential long-term degradation due to installation damage, creep, and chemical/biological aging;

RF_{ID} = a strength reduction factor to account for installation damage to the reinforcement;

RF_{CR} = a strength reduction factor to prevent long-term creep rupture of the reinforcement;

RF_{D} = a strength reduction factor to prevent rupture of the reinforcement due to chemical and biological degradation.

6.4.1 The value selected for T_{ult} is the MARV for the product to account for statistical variance in the material strength. For geogrids, a statistically based minimum value may be used in lieu of the MARV. Other sources of uncertainty and variability in the long-term strength include installation damage (Annex A), creep extrapolation (Annex B), and chemical degradation (Annex C). It is assumed that the observed variability in the creep-rupture envelope is 100 percent correlated with the short-term tensile strength, T_{ult}, as the creep strength is typically directly proportional to the short-term tensile strength within a product line (see Annex B and Note B7 in Annex B if this is not the case). Therefore, the MARV of T_{ult} adequately takes into account that source of variability. For additional discussion of this issue, see Note 4.

Note 4—The product strength variability is not taken into account by using the creep limited strength, T_l, directly or in normalizing T_l by T_{baseline} (see Annex B). T_l only accounts for extrapolation uncertainty. Furthermore, T_{lot} is specific to the lot of material used for the creep testing. Normalizing by T_{lot} makes the creep reduction factor RF_{CR} applicable to the rest of the product line, as creep strength is typically directly proportional to the ultimate tensile strength, within a product line. As shown below, it is not correct to normalize the creep strength T_l using T_{ult}, the MARV of the tensile strength for the product, nor is it correct to use T_l directly in the numerator to calculate T_{al}.

$$RF_{CR} = \frac{T_{\mathrm{baseline}}}{T_l} \neq \frac{T_{\mathrm{ult}}}{T_l} \qquad \text{and} \qquad T_{al} \neq \frac{T_l}{RF_{ID} \times RF_{D}}$$

In the former case, the creep strength is not indexed to the actual tensile strength of the material used in the creep testing, and since there is a 50 percent chance that T_{baseline} will be less than or equal to T_{baseline}, using T_{ult} in this case would result in an unconservative determination of RF_{CR}. In the latter case, where T_l is used directly as a creep-reduced strength, the product strength variability is not taken into account, since T_l is really a mean creep strength. Hence, RF_{CR} must be determined as shown in Equation B-9 (see Annex B), and the MARV or minimum value must be used for T_{ult} when determining T_{al}. Note that the use of the MARV for T_{ult} may not fully take into account the additional variability caused by installation damage. For the typical degree of installation damage observed in practice, this additional variability is minor and can be easily handled through the overall safety factor used in design of reinforced structures. For durability (RF_D), additional variability does not come into play if a default reduction factor is used. If a more refined durability analysis is performed, additional variability resulting from chemical degradation may need to be considered.

6.4.2 The RF_{ID} and RF_{CR} shall be determined from product specific data for all geosynthetic reinforcement products or product lines. The product specific data for these reduction factors shall be interpreted/extrapolated in accordance with Annexes A and B. RF_D shall be determined from long-term product specific data interpreted/extrapolated in accordance with Annex C, or a default value may be used as described below. A default reduction factor for RF_D may be used if the environment is nonaggressive and if the product meets the minimum polymer and physical property requirements provided in Table 1. In this case, a default value for RF_D of 1.3 may be used for PET, HDPE, and PP geosynthetics.

Note 5—The default value for RF_D of 1.3, which can be used for products that meet the minimum property requirements in Table 1, was determined for effective design temperatures that are less than or equal to 20°C (68°F). A higher default value of 1.5 for products that meet the property requirements in Table 1 may be desirable for more temperate climates that still meet the requirements for a nonaggressive environment, especially to address polyolefin oxidative degradation, as the potential for this type of degradation, even for products that meet the property requirements in Table 1, becomes more uncertain at higher temperatures due to the lack of protocols that can accurately identify the amount or effectiveness of end use antioxidants present.

6.4.3 If the environment is identified as aggressive due to the chemical regime or due to temperature, or if the geosynthetic product does not meet the requirements in Table 1, default reduction factors should **not** be used for RF_D. For chemically aggressive or elevated temperature environments, RF_D must be determined based on long-term product specific data for an environment that is as or more aggressive than the project specific environment in question. Aggressive environments need to be addressed in the product submittal only if specifically requested by the contracting agency or the geosynthetic supplier. Once the appropriate reduction factors are established, the long-term geosynthetic strength is determined using Equations 1 and 2, or as determined in Note B7 of Annex B.

6.4.4 If a default reduction factor for RF_D is to be used, geosynthetic products likely to have good resistance to installation stresses and to long-term chemical degradation are required to minimize the risk of significant long-term degradation. Polymer materials not meeting the requirements in Table 1 could be used if detailed product specific data are extrapolated to the design life intended for the geosynthetic structure (see Annex C) is provided.

6.4.5 Unless otherwise specified by the agency or owner, geosynthetic reinforcement elements in MSE walls and reinforced slopes should be designed to have a durability to ensure a minimum design life of 75 years for permanent structures in accordance with the *AASHTO LRFD Bridge Design Specifications*. This design life requirement should be reflected in the long-term strength test data and analysis.

Table 1—Minimum Requirements for Geosynthetic Products to Allow Use of Default Reduction Factor for Long-Term Degradation

Polymer Type	Property	Test Method	Criteria to Allow Use of Default *RF**
PP and HDPE	UV Oxidation Resistance	ASTM D 4355	Min. 70% strength retained after 500 hours in weatherometer
PET	UV Oxidation Resistance	ASTM D 4355	Min. 50% strength retained after 500 hours in weatherometer if geosynthetic will be buried within 1 week, 70% if left exposed for more than 1 week.
PP and HDPE	Thermo-Oxidation Resistance	ENV ISO 13438:1999, Method A (PP) or B (HDPE)	Min. 50% strength retained after 28 days (PP) or 56 days (HDPE)
PET	Hydrolysis Resistance	Inherent Viscosity Method (ASTM D 4603 and GRI-GG8), or Determine Directly Using Gel Permeation Chromatography	Min. Number Average Molecular Weight of 25 000
PET	Hydrolysis Resistance	GRI-GG7	Max. Carboxyl End Group Content of 30
All Polymers	% Post-Consumer Recycled Material by Weight	Certification of Materials Used	Maximum of 0%

Note 6—The requirements provided in Table 1 utilize currently available index tests and are consistent with current *AASHTO LRFD Bridge Design Specifications*, with the exception of the oven aging test (i.e., ENV ISO 13438:1999) to assess thermo-oxidation resistance for PP and HDPE, which is a new requirement. These index tests can provide an approximate measure of relative resistance to long-term chemical degradation of geosynthetics. Values selected as "minimum" criteria to allow use without additional long-term testing are based on values for such properties based on long-term research reported in the literature. These values are considered indicative of good long-term performance or represent a readily available current standard within the industry that signifies that a product has been enhanced for long-term environmental exposure. There is little long-term history or even laboratory data regarding the durability of geosynthetics containing a significant percentage of recycled material. Therefore, their potential long-term performance is unknown, and it is recommended that long-term data be obtained for products with significant recycled material to verify their performance before using them.

6.5 *Report—Initial Product Qualification Testing*:

For initial product qualification, the following information shall be included in the product or product line evaluation report:

6.5.1 Basis for Determination of Product Line Members:

6.5.1.1 Geosynthetic type, structure, and weaving process used to construct yarns or ribs.

6.5.1.2 Spacing and dimensions of geogrid elements, including photographs or small samples for visual examination. The receiving laboratory should verify these dimensions upon receipt of the sample(s) using hand measurement techniques. This is especially critical for strength determination based on a single or limited number of ribs in the specimens tested.

6.5.1.3 Polymer(s) used for fibers, ribs, etc.

6.5.1.4 Polymer(s) used for coating, if present.

6.5.1.5 Polymer source(s) used for product.

6.5.1.6 For HDPE and PP, primary resin ASTM type, class, grade, category (for HDPE use ASTM D 1248, and for PP use ASTM D 4101), and any other specification used as manufacturing targets.

6.5.1.7 For PET, minimum production number average molecular weight (ASTM D 4603 and GRI-GG8) and maximum carboxyl end group content (GRI-GG7), with supporting test data. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided, and any other specifications used as manufacturing targets.

6.5.1.8 Percent of post-consumer recycled material by weight.

6.5.1.9 Minimum weight per unit area for product (ASTM D 5261).

6.5.1.10 MARV for ultimate wide width tensile strength (ASTM D 4595 or D 6637), with supporting test data. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided.

6.5.2 Installation Damage Data Requirements (RF_{ID}):

Installation damage testing and interpretation shall be conducted in accordance with Annex A. As a minimum, for each product tested, the following information should be obtained:

6.5.2.1 Date tests were conducted.

6.5.2.2 Name(s), location(s), and telephone number(s) of laboratory(ies) conducting the testing and evaluation.

6.5.2.3 Identify whether installation damage testing was conducted as a site specific evaluation for an actual construction project or was conducted as a non-site specific evaluation.

6.5.2.4 Description of specific procedures used to conduct the installation damage testing, including installation procedures, sample size, method of specimen selection, sample removal procedures, etc. Identify any deviations in the installation procedures relative to typical installation practice in full-scale structures, if the testing was not site specific.

6.5.2.5 Photographs illustrating procedures used and the conditions at the time of the testing, if available.

6.5.2.6 Measured mass/unit area per ASTM D 5261 for the sample tested for installation damage and for the sample used to establish the undamaged strength. Also obtain product manufacturer Quality Control (QC) data on the uncoated product (i.e., “greige-good”) for the lot used for installation damage testing.

6.5.2.7 Tensile test results for the product before exposure to installation conditions (i.e., virgin material, T_{baseline}), and whether both virgin and damaged samples were taken from the same roll of material, or just from rolls within the same lot of material.

6.5.2.8 Tensile test results for specimens taken from the damaged material after installation.

6.5.2.9 Tensile test results for both virgin and damaged specimens should include individual test results for each specimen, typical individual load-strain curves that are representative of the specimens tested, including associated calibration data as necessary to interpret the curves (curves in which strain and load/unit width are already calculated are preferred), the average value for each sample, the coefficient of variation for each sample, and a description of any deviations from the standard tensile test procedures required by Annex A.

6.5.2.10 Gradation curves for backfill material located above and below the installation damage geosynthetic samples, including the d_{50} size, maximum particle size, and a description of the angularity of the soil particles per ASTM D 2488, including photographs illustrating the soil particle angularity, if available. Also include LA Abrasion (T 96) test results for the backfill material used.

6.5.2.11 Photographs or a description, or both, of the type and extent of damage visually evident in the exhumed samples and specimens.

6.5.2.12 The RF_{ID}, and a description of the data interpretation method used to determine RF_{ID} for each sample.

6.5.2.13 For geogrids, evaluation of geogrid flexibility per WSDOT Test Method T 925. Creep Data Requirements (RF_{CR} and Creep Stiffness J):

Creep testing and interpretation shall be conducted in accordance with Annex B. As a minimum, for each product tested, the following information should be obtained:

6.5.2.14 Date tests were conducted.

6.5.2.15 Name(s), location(s), and telephone number(s) of laboratory(ies) conducting the testing and evaluation.

6.5.2.16 Photographs illustrating the creep testing equipment and procedures used, as available.

6.5.2.17 Tensile test results for the product before creep testing (i.e., virgin material), and whether both virgin and creep tested samples were taken from the same roll of material or just from rolls within the same lot of material.

6.5.2.18 Tensile test results should include individual test results for each specimen, typical load-strain curves that are representative of the specimens tested, including associated calibration data as necessary to interpret the curves (curves in which strain and load/unit width are already calculated are preferred), the average value for each sample, the coefficient of variation for each sample, and a description of any deviations from the standard tensile test procedures required by Annex B.

6.5.2.19 Creep test procedures used, especially any deviations from the procedures required in Annex B.;

6.5.2.20 Iif RF_{CR} is determined using data obtained in accordance with Annex B, provide load and time to rupture for each specimen as a minimum; however, strain data as a function of time are desirable if available.

6.5.2.21 If elevated temperature testing is conducted, creep data before and after time/load shifting, including shift factors used and a description of how the shift factors were derived, shall be provided.

6.5.2.22 Data illustrating the variability of the creep test environment, including temperature and humidity, during the creep test time period, or some assurance that the creep test environment was maintained within the variation of temperature prescribed herein, shall be provided.

6.5.2.23 Description of statistical extrapolation procedures used in accordance with Annex B, if statistical extrapolation is performed.

6.5.2.24 RF_{CR}, and a description of how RF_{CR} was determined for each product.

6.5.2.25 In addition, regardless which approach is used to determine RF_{CR}, creep strain data at a load level that results in a strain of 2 percent at approximately 1000 hours shall be submitted to determine the low strain (i.e., 2 percent) creep stiffness at 1000 hours and at the specified design life (typically 75 years).

6.5.2.26 For both creep rupture and low strain creep stiffness testing, if single-rib, yarn, or narrow width specimens are used, 1000-hour creep data in accordance with Annex B that demonstrate the single-rib, yarn, or narrow width test results are consistent with the results from multi-rib/wide width testing.

6.5.3 Long-Term Durability Data Requirements to Establish Default Value of RF_D:

If a default value for RF_D is to be used, the following information and test results shall be provided in the report:

6.5.3.1 Ultraviolet resistance at 500 hours in weatherometer (ASTM D 4355). As a minimum, test data for the lightest weight product submitted in the product line should be included in the report. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided.

6.5.3.2 Oven aging tests conducted in accordance with ENV ISO 13438:1999, Method A (PP) or B (HDPE), for polyolefin geosynthetics. As a minimum, test data for the lightest weight product in the product line should be included in the report. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided.

6.5.3.3 Inherent viscosity/molecular weight (ASTM D 4603 and GRI-GG8) and carboxyl end group (CEG) content (GRI-GG7) for polyester geosynthetics conducted on the base yarn used for the manufacture of the geosynthetic. Information regarding the laboratory where the testing was conducted and date of testing shall also be provided.

6.5.4 Long-Term Durability Data Requirements if Default Value for RF_D is Not Used:

If it is desired to submit detailed durability performance test data to justify a lower RF_D, or to allow use in environments classified as chemically aggressive, durability testing and interpretation shall be conducted in accordance with Annex C and, as a minimum, for each product tested, the following information shall be obtained:

6.5.4.1 Date tests were conducted.

6.5.4.2 Name(s), location(s), and telephone number(s) of laboratory(ies) conducting the testing and evaluation.

6.5.4.3 Photographs and drawings illustrating the durability testing equipment and procedures used as well as a summary of the specific procedures used.

6.5.4.4 Tensile test results for the product before durability testing (i.e., virgin material), and whether both virgin and durability test samples were taken from the same roll of material, or just from rolls within the same lot of material.

6.5.4.5 Polymer characteristics for the lot or roll of material actually tested before long-term exposure in the laboratory, including, for example, molecular weight and carboxyl end group content for PET, melt flow index and OIT for polyolefins, percent crystallinity, SEM photographs of fiber surface, etc.

Note 7—Percent crystallinity can be determined using differential scanning calorimetry (DSC). An appropriate test method is ASTM D 3418. By definition, crystallinity (*X*) is calculated as follows:

$X = \Delta H / \Delta H^\circ$ (× 100 for %)

where:

ΔH = the latent heat under the DSC melt curve, and

ΔH° = the latent heat for a 100 percent crystalline polymer, °C.

Temperature scan should start 10°C below, continue through, and stop 10°C above the melt range. Recommended test parameters are as follows:

Homo-Polymer	Sample Size, (mg)	Melt Range, (°C)	Latent Heat, ΔH°, (cal/gm)	DSC Scan Speed, (°C/min)
HDPE	5	100–145	68.4	10
PP	7.5	100–165	45	10
PET	10	200–245	30	10

Other values of sample size, melt range, and DSC scan speed can be used with justification.

6.5.4.6 Tensile test results for specimens taken for each retrieval from the incubation chambers.

6.5.4.7 Tensile test results, including tensile strength, strain at peak load, and 5 percent secant or offset modulus, for both virgin material and degraded material, should include individual test results for each specimen, typical load-strain curves that are representative of the specimens tested, including associated calibration data as necessary to interpret the curves (curves in which strain and load/unit width are already calculated are preferred), the average value for each sample, the coefficient of variation for each sample, and a description of any deviations from the standard tensile test procedures required by Annex C.

6.5.4.8 A detailed description of the data characterization and extrapolation procedures used, including data plots illustrating these procedures and their theoretical basis.

6.5.4.9 Results of any chemical tests taken (e.g., OIT or HPOIT, molecular weight, product weight/unit area, etc.), and any scanning electron micrographs taken, to verify the significance of any degradation in strength observed.

6.5.4.10 Results of biological degradation testing, if performed.

6.5.4.11 The RF_D and a description of the method used to determine RF_D for the product.

7. QUALITY ASSURANCE REQUIREMENTS FOR GEOSYNTHETIC PRODUCTS THAT HAVE BEEN THROUGH INITIAL PRODUCT QUALIFICATION TESTING

7.1 *Quality Assurance (QA) Geosynthetic Product Verification and Testing Approach*:

As a first step, it shall be verified in accordance with the data verification requirements provided below that the current product or product line has not changed significantly relative to the product or product line that was tested and evaluated for initial product qualification. If the product or product line has not changed significantly based on this data verification step, results from index and performance tests on the product or product line shall be compared to baseline index or performance test results obtained for initial product qualification purposes. If the QA test results are within acceptable tolerances relative to the baseline results in accordance with Section 7.5, the baseline test data obtained for product qualification purposes shall be considered valid for the product line. Retesting shall be done if there is any change in the product. If it is determined that one or more products in the product line has changed since the last product qualification testing program was conducted, a complete assessment of the product or product line in accordance with this standard practice instead of just a QA evaluation may be required by the approval authority to maintain acceptance status, depending on the nature and magnitude of the change(s). Examples of changes that could necessitate a new product qualification testing program be conducted include changes in the processing technique or variables used for the product line, changes in the polymer properties or additives used that could affect the product's(s') mechanical/chemical durability or creep resistance, changes in the shape or surface area of the ribs or yarns, changes in the way ribs and cross-ribs are connected together, changes in the coating properties or thickness, changes in tensile strength, etc. The potential impact of such changes on the long-term strength of the reinforcement product(s) should be assessed by the approval authority. Some types of product changes may only affect certain aspects of the product's(s') long-term strength, necessitating that only a portion of the product qualification testing program be conducted (e.g., changes in yarn or rib geometry may only affect installation damage resistance). Therefore, the approval authority may need to make a determination of what portions of the product qualification testing program that should be conducted.

7.2 *Data Verification Requirements*:

The following information about each product shall be submitted for verification purposes:

7.2.1 Geosynthetic type and structure, and weaving process used to construct yarns or ribs.

7.2.2 Spacing and dimensions of geogrid elements. The receiving laboratory should verify these dimensions upon receipt of the sample(s) using hand measurement techniques. This is especially critical for strength determination based on a single or limited number of ribs in the specimens tested.

7.2.3 Polymer(s) used for fibers, ribs, etc.

7.2.4 Polymer(s) used for coating, if present.

7.2.5 Polymer source(s) used for product.

7.2.6 For HDPE and PP, primary resin ASTM type, class, grade, and category (for HDPE, use ASTM D 1248, and for PP use ASTM D 4101).

7.2.7 Percent post-consumer recycled material by weight.

7.2.8 Minimum weight per unit area for product (ASTM D 5261).

7.2.9 MARV for ultimate wide width tensile strength (ASTM D 4595 or D 6637).

7.3 *Quality Assurance (QA) Sampling*:

7.3.1 All materials and/or products to be tested will be furnished by the manufacturer/supplier at no cost to the review/approval authority. Samples will be selected for testing by agency or owner personnel or designated parties. Sampling shall be conducted in accordance with the requirements in the specific AASHTO, ASTM, GRI, or ISO test standard for the specific tests conducted as part of this standard practice. For products selected as representative of the product line, an entire roll should be taken, but no less than the sum of the sample sizes required for all tests to be conducted on each product. As a minimum, the following shall be obtained:

- a geosynthetic product sample of sufficient size to accommodate all of the specified testing;
- information showing the manufacturer's name and description of product (style, brand name, etc.);
- product roll and lot number; and
- a sample of the polymer component(s) used to manufacture the product or product line in sufficient quantity to conduct the specified polymer tests.

7.3.2 All samples for the specified QA testing shall be from the same roll of material for each product tested. Regarding the polymer components, they should be obtained from the production line used to product the geosynthetic products being evaluated.

7.4 *Quality Assurance (QA) Testing*:

Short-term ultimate tensile strength test results and other QA test results to verify that the values of RF_{ID}, RF_{CR}, and RF_D determined from initial product qualification testing are accurate for the product or product line, shall be obtained. Short-term tensile strength shall be determined in accordance with ASTM D 4595 for geotextiles and ASTM D 6637 for geogrids. Quality Assurance testing required to verify that the values of RF_{ID}, RF_{CR}, and RF_D determined from initial product qualification testing are applicable to the current product (i.e., the QA test results are statistically consistent with the initial product qualification test results) is as follows:

7.4.1 Installation Damage Testing:

For installation damage evaluation, a field-exposure trial conducted in accordance with Annex A shall be conducted for the product in the product line with the highest RF_{ID} from the initial product qualification testing using the soil with a d_{50} size that is equal to or larger than a d_{50} size of 4.75 mm, or other d_{50} size as determined by the approval authority, and the aggregate shall have a maximum LA Abrasion (T 96) percent loss of 35 percent. The d_{50} size, angularity, and durability of the selected backfill should be consistent with the d_{50} size used for initial product qualification testing (preferably, the same material should be used for both the product qualification testing and the QA testing, if possible). Alternatively, reduced scale laboratory installation damage tests conducted in accordance with ISO/DIS 10722-1 may be used. In this case, these laboratory installation damage tests must also be conducted during initial product qualification testing to establish a baseline value. The ultimate tensile strength of the lot or roll of material used in the installation damage testing obtained in accordance with ASTM D 4595 or ASTM D 6637 using the multi-rib procedure (or ISO 10319 if ISO/DIS 10722-1 is used) shall be obtained to normalize the installation damage test results in accordance with Annex A. If it was determined during the initial product qualification testing for coated geogrids that the installation damage factor was not a function of product weight or tensile strength, the coating weight shall also be evaluated. In this case, the mass/unit area of the sample tested shall be determined in accordance with ASTM

D 5261. The coating weight can then be established using the lot specific mass/unit area of the uncoated product from product manufacturer QC data.

7.4.2 Creep Testing:

7.4.2.1 For creep-rupture evaluation, a minimum of three creep-rupture points shall be obtained using the Stepped Isothermal Method (i.e., SIM) per ASTM D 6992 or conventional ASTM D 5262 tests (for which elevated test temperatures may be employed to accelerate creep—see Annex B) at a load level established at the time of initial product qualification testing that corresponds to a minimum rupture time of 100 000 hours at the reference temperature. If elevated temperature conventional creep testing using ASTM D 5262 is performed, the shift factors obtained from the conventional creep testing for the temperatures used in the QA testing conducted for initial product qualification testing shall be used to extrapolate the test data to the reference temperature. A fourth SIM test (or conventional ASTM D 5262 test conducted at the reference temperature) shall be performed at a load level established at the time of initial product qualification testing that corresponds to a minimum rupture time of 500 hours at the reference temperature.

7.4.2.2 For creep stiffness evaluation, if the product qualification testing conducted indicates that the creep is log linear at the low strain levels tested, short-term (1,000-second) ramp and hold (R+H) tests as described in ASTM D 6992 may be used and extrapolated to 1000 hours in lieu of 1000-hour creep tests. A minimum of two R+H tests shall be conducted for one product in the product line at the load level in which 2 percent strain at 1000 hours was achieved in the product qualification testing. If the product qualification testing indicates that the creep is not log linear at the low strain level tested, then a minimum of two full 1000-hour creep tests must be conducted at that load level. These tests shall be conducted on the same width specimens as used for the product qualification creep stiffness testing.

7.4.2.3 If SIM is used for this creep-rupture testing, it shall have been demonstrated for the initial qualification testing that the reduced specimen width typically used for SIM testing does not have a significant effect on the creep-rupture results, and have been provided that the validity of SIM for the product through comparison of SIM data with “conventional” creep-rupture data was established for the initial product qualification testing.

7.4.2.4 The ultimate tensile strength of the lot or roll of material used in the creep testing obtained in accordance with ASTM D 4595 or D 6637 shall be obtained to normalize the creep-rupture loads in accordance with Annex B.

Note 8—If “conventional” creep testing is performed for QA purposes, it is assumed that the product has not changed relative to what was tested for initial product qualification purposes, thereby allowing the assumption to be made that the shift factors obtained through the initial product qualification testing are valid to be applied to the QA testing. Requiring new “conventional” creep test shift factors to be re-established would result in the need to fully repeat the test program for the initial product qualification, which would not be practical for QA purposes. Regarding the fourth creep test data point, the requirement to use only data obtained at the reference temperature if “conventional” creep testing is performed provides a second check that eliminates the need for this shift factor assumption and any inaccuracies associated with that assumption.

7.4.3 Durability Testing:

7.4.3.1 If only index durability testing was conducted to allow use of a default value for RF_D for the initial product qualification testing, only index durability testing should be conducted for QA purposes. In this case, durability testing for QA purposes shall consist of the determination of molecular weight based on GRI-GG7 and carboxyl end group content based on GRI-GG8 for polyesters, UV resistance based on ASTM D 4355 for polyolefins and PETs), and an oven aging exposure test per ENV ISO 13438:1999 for polyolefin geosynthetics. Regarding the oven aging test, control and postexposure specimens shall be tested for tensile properties (ASTM D 4595 or D 6637). The results of this oven aging testing should be used only to compare a product with itself, and to meet the minimum requirements in Table 1.

7.4.3.2 If long-term performance durability testing was conducted to justify the use of a lower RF_D or to justify use in aggressive environments for initial product qualification, a minimum of five specimens shall be exposed to the most aggressive environment used in the initial product qualification testing, at the highest temperature tested, for a minimum of 2000 hours. These specimens, and unexposed specimens from the same roll of material, shall be tested for tensile properties (ASTM D 4595 or D 6637). In addition, for polyolefins, either oxidative induction time per ASTM D 3895 or high pressure oxidative induction time per ASTM D 5885 shall be conducted for each specimen tested (before and after exposure), and for PETs, molecular weight (ASTM D 4603 and GRI-GG8) and specimen weight per unit area (ASTM D 5261) shall be conducted for each specimen tested (before and after exposure).

7.5 *Quality Assurance (QA) Analysis and Reporting*:

The acceptability of the QA test results to allow a product or product line to maintain its prior qualification or acceptance status shall be established based on the statistical significance, or lack thereof, of the difference between the QA test results and the initial product qualification test results. The criteria and methods for determining the statistical significance between the QA and initial product qualification test results shall be as follows:

7.5.1 Short-Term Index Tensile Testing:

For wide width tensile strength, the mean of the test results for the sample for each product tested shall be greater than or equal to the MARV reported for the product. Report both the MARV, or minimum value, and the QA tensile test results.

7.5.2 Installation Damage Testing:

7.5.2.1 If the mean of the average strength of the sample after damage as a percent of the undamaged strength is less than the average value obtained for the same product and condition during the product qualification testing, the maximum difference between the two means shall be no greater that what is defined as statistically insignificant based on a one-sided Student's *t*-distribution at a level of significance of 0.05. In this case, *t* is determined as follows:

$$t_{\alpha/2,n_1+n_2-2} = \frac{\left(\bar{P}_1 - \bar{P}_2\right) - \delta}{\sqrt{\left(n_1 - 1\right)s_1^2 + \left(n_2 - 1\right)s_2^2}} \sqrt{\frac{n_1 n_2 \left(n_1 + n_2 - 2\right)}{\left(n_1 + n_2\right)}} \qquad (3)$$

where:

$t_{\alpha/2,n_1+n_2-2}$ = value of the *t*-distribution for the installation damage samples;

$\bar{P}_1$ = the mean of the strength retained after installation damage (i.e., T_{dam}/T_{lot}) obtained for initial product qualification;

$\bar{P}_2$ = the mean of the strength retained after installation damage (i.e., T_{dam}/T_{lot}) obtained for QA testing;

δ = the difference in the means for the populations corresponding to the sample means $\bar{P}_1$ and $\bar{P}_2$ (assumed equal to zero for this test);

s_1 = the standard deviation corresponding to $\bar{P}_1$;

s_2 = the standard deviation corresponding to $\bar{P}_2$;

n_1 = the number of data points corresponding to $\bar{P}_1$;

n_2 = the number of data points corresponding to $\bar{P}_2$.

7.5.2.2 The $t_{\alpha/2,n_1+n_2-2}$ calculated using Equation 3 shall be no greater than *t* determined from the applicable Student's *t*-table (or from the Microsoft EXCEL function TINV(α,*n*–2)) at $\alpha = 0.05$ and n_1+n_2-2 degrees of freedom. If this is not true, the difference between $\bar{P}_1$ and $\bar{P}_2$ is determined to be statistically significant and $\bar{P}_1 > \bar{P}_2$, two additional samples from the same installation condition shall be tested, and $\bar{P}_2$ recalculated and statistically compared to $\bar{P}_1$. If the QA test results are still too low, a full installation damage study for initial product qualification must be completed in accordance with Annex A, and new values of RF_{ID} established.

7.5.2.3 Report the results of the statistical analysis, as well as the mean values for the product qualification testing and the QA testing.

7.5.3 Creep-Rupture Testing for Prediction of Creep Limit:

7.5.3.1 For creep evaluation, the four creep-rupture points, one at a load level that results in an approximate rupture time, after time shifting, of 500 hours, and three at a load level that results in an approximate rupture time, after time shifting, of 100 000 hours on the rupture envelope obtained for initial product qualification purposes, shall be compared to the creep data obtained for initial product qualification purposes. The log of the rupture time for each of these four rupture points shall be equal to or greater than the 95 percent lower prediction limit of the variable, log time, established by Student's *t*-test of the original product qualification data set.

7.5.3.2 The prediction limit for the regression performed for initial product qualification is given by (Wadsworth, 1998):

$$\log t_L = \log t_{\mathrm{reg}} - \left[t_{\alpha/2,n-2} \sqrt{1 + \frac{1}{n} + \frac{\left(P - \bar{P}\right)^2}{\sum \left(P_i - \bar{P}\right)^2}} \right] \times \sigma \qquad (4)$$

and

$$\sigma = \sqrt{\frac{\sum \left[\log t_i - \log \bar{t}\,\right]^2 - \dfrac{\left\{\sum \left[\left(P_i - \bar{P}\right)\left(\log t_i - \log \bar{t}\,\right)\right]\right\}^2}{\sum \left(P_i - \bar{P}\right)^2}}{n-2}} \qquad (5)$$

where:

$\log t_L$ = lower bound prediction limit;

t_{reg} = time corresponding to the load level from the initial product qualification creep rupture envelope at which QA creep tests were performed (e.g., at 500 and 100 000 hours after time shifting);

$t_{\alpha/2,n-2}$ = value of the Student's *t*-distribution determined from applicable Student's *t*-table (or from the Microsoft EXCEL function TINV(α,*n*–2)) at $\alpha/2 = 0.05$ and *n*–2 degrees of freedom (this corresponds to the 95 percent one-sided prediction limit);

n = the number of rupture or allowable run-out points in the original test sample (i.e., for initial product qualification);

P = load level obtained at t_{reg} from the regression line developed from the initial product qualification testing;

$\bar{P}$ = the mean rupture load level for the original test sample (i.e., all rupture or run-out points used in the regression to establish the rupture envelope for initial product qualification);

P_i = the rupture load level of the *i*th point for the rupture points used in the regression for establishing the rupture envelope for initial product qualification;

$\log \bar{t}$ = the mean of the log of the rupture time for the original test sample (i.e., all rupture or run-out points used in the regression to establish the rupture envelope for initial product qualification);

t_i = the rupture time of the *i*th point for the rupture points used in the regression for establishing the rupture envelope for initial product qualification.

7.5.3.3 The comparison between the QA test results and the initial product qualification test results is illustrated conceptually in Figure 1. Once $\log t_L$ has been determined at each specified load level, compare this value to the log rupture time (i.e., $\log t_{\text{QA}}$) obtained for each QA creep-rupture test at the specified load level (e.g., 500 and 100 000 hours). If $\log t_{\text{QA}} < \log t_L$ for any of the QA creep-rupture test results, perform two additional tests at the load level P for the specified t_{reg} where this QA criterion was not met and compare those results to $\log t_L$. If, for these two additional tests, this criterion is not met, perform adequate additional creep-rupture testing to establish a new rupture envelope for the product in accordance with initial product qualification requirements (Annex B). This new rupture envelope will form the baseline for any future QA testing.

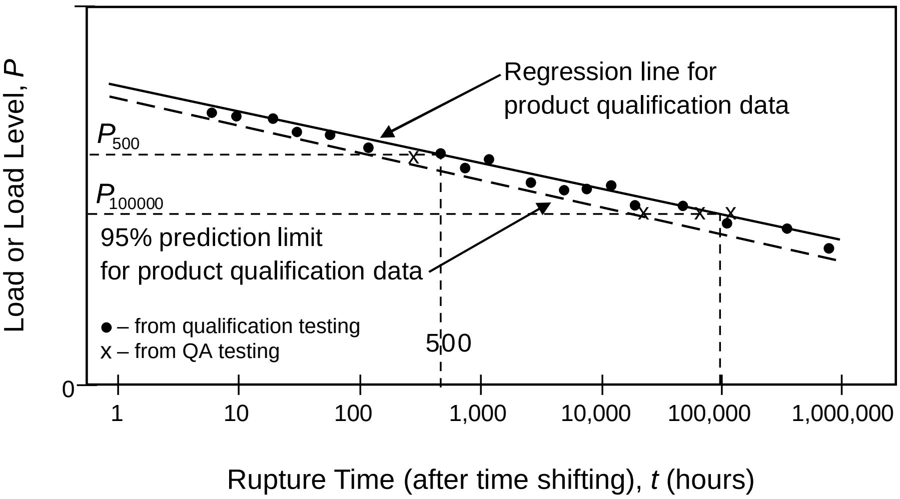

Figure 1—Conceptual Illustration of the Comparison of QA Creep-Rupture Test Results to Initial Product Qualification Creep-Rupture Test Results

7.5.3.4 Report a plot of the QA data in comparison to the product qualification test results as shown in Figure 1, and the QA creep-rupture load levels and time to rupture in comparison to the 95 percent prediction limit calculated at the load levels used to obtain the QA creep-rupture data.

7.5.4 Assessment of Creep Stiffness at Low Strain:

7.5.4.1 The comparison between the creep data obtained for the initial product qualification testing and the QA creep data shall be performed at a specified strain, in this case 2 percent unless otherwise specified by the agency or owner. Where the selected strain level intersects each creep curve, determine the time required to reach the specified strain. Plot the load level as a function of the logarithm of time to reach the specified strain for the initial product qualification data, and perform a regression for this data set. The log times to the specified strain level for the QA creep data shall be determined at a load level that corresponds to 1000 hours on the initial product qualification creep curve. The estimated time to reach the same specified strain for each of the two QA creep data points shall be equal to or greater than the 95 percent lower prediction limit of the variable, log time, established by the Student's *t*-test of the original product qualification data set, using Equations 4 and 5.

7.5.4.2 Once $\log t_L$ has been determined at the specified load level, compare this value to the log time to reach the specified strain (i.e., $\log t_{\mathrm{QA}}$) obtained for each QA creep test at the specified load level (e.g., 1000 hours). Report these values for the product qualification testing and the QA testing. If $\log t_{\mathrm{QA}} < \log t_L$ for any of the QA creep-rupture test results, perform two additional tests at the same load level P for the specified strain and compare those results to $\log t_L$. If, for these two additional tests, this criterion is not met, perform adequate additional creep testing to establish a new low strain creep stiffness value for the product in accordance with initial product qualification requirements (Annex B). This new low strain creep stiffness value will form the baseline for any future QA testing.

7.5.5 Durability Testing:

7.5.5.1 For UV resistance (all polymers), molecular weight and CEG (PET only), and oven aging (PP and HDPE), the QA test results shall meet the minimum requirements provided in Table 1. For the oven aging tests (polyolefins only), compare the tensile strength retained (i.e., strength after oven exposure divided by the strength of the control specimens to the strength observed during initial product qualification testing). The maximum difference between the values of the changes shall be no greater that what is defined as statistically insignificant based on a one-sided Student's *t*-distribution at a level of significance of 0.05, as determined using Equation 3. In this case, $\bar{P}_1$ and $\bar{P}_2$ are defined as the strength retained after oven aging.

7.5.5.2 The $t_{\alpha/2,n_1+n_2-2}$ calculated using Equation 3 shall be no greater than t determined from the applicable Student's *t*-table (or from the Microsoft EXCEL function TINV(α,n–2)) at $\alpha/2 = 0.05$ and n–2 and $n_1 + n_2$–2 degrees of freedom. If this is not true, and the difference between $\bar{P}_1$ and $\bar{P}_2$ is determined to be statistically significant and $\bar{P}_1 > \bar{P}_2$, two additional samples from the same roll of material shall be tested in accordance with ISO 13438:1999 and $\bar{P}_2$ recalculated and statistically compared to $\bar{P}_1$. If the QA test results are still unacceptable, or if the product loses more than 50 percent of its tensile strength during the QA test, a more complete investigation shall be performed in accordance with Annex C. Report $\bar{P}_1$ and $\bar{P}_2$ for the product qualification and QA testing.

7.5.5.3 If long-term performance durability testing was conducted to justify the use of a lower RF_D or to justify use in aggressive environments for initial product qualification, the statistical methodology and criteria provided above for index oven aging (i.e., that there is no statistically significant difference between the initial product qualification test results and the QA test results at a level of significance of 0.05) shall be applied to the oxidation or hydrolysis performance test results at the maximum exposure time and environmental conditions used for the QA testing. Report $\bar{P}_1$ and $\bar{P}_2$ for the product qualification and QA testing.

ANNEX A

(Mandatory Information)

A1. PRODUCT SPECIFIC TESTING AND DATA INTERPRETATION REQUIREMENTS TO DETERMINE RF_{ID} FOR GEOSYNTHETIC REINFORCEMENTS

A1.1. *General*:
The effect of installation damage on geosynthetic reinforcement strength and deformation shall be determined from the results of full-scale installation damage tests in accordance with ASTM D 5818, except as modified herein:

A1.1.1. Place and compact 150 mm (6 in.) or more of soil (same soil as used to cover the geosynthetic) on a flat, level, relatively incompressible subgrade. The compacted layer shall simulate the roughness and compressibility of the backfill conditions in which the geosynthetic layer is likely to be placed in full-scale structures.

A1.1.2. Place the geosynthetic on top of the compacted soil pad. The geosynthetic shall be pulled taut with no wrinkles or folds. It may be necessary to pin the corners of the geosynthetic to maintain its position as soil is placed over the geosynthetic.

Note A1—In addition to the removal requirements described in ASTM D 5818, a lifting plate may be placed below the compacted soil pad below the geosynthetic layer as described in Sprague and Allen (2003) to facilitate easy removal of the soil above the geosynthetic.

A1.1.3. If the installation damage test is conducted for a specific project, the actual backfill material planned for use in the geosynthetic structure should be used for the test. If the purpose of the installation damage testing is to generate RF_{ID} values for general use for future projects (i.e., the testing is not intended to be project specific), a range of soil backfill gradations/types shall be used in the testing. The range of backfill materials selected should permit interpolation as needed to match to a project specific soil used as reinforced soil backfill. In general, the backfill materials tested should range from soil classified as a sand to coarse gravel (e.g., d_{50} sizes ranging from 0.5 to 25 mm). The backfill materials selected should be angular to subangular and shall be durable. The coarse sand and gravel portions of the backfill material should have a Los Angeles Wear (LA Abrasion) percent loss after 500 revolutions (T 96) of no more than 35 percent. Additional installation damage tests may be conducted with a less durable backfill material, at the discretion of the manufacturer and the approval authority. If tests are conducted using a backfill material that does not meet the LA Abrasion requirement stated above, the condition of the backfill shall be evaluated for changes in angularity and gradation after each use. If changes in these two parameters are observed, the aggregate shall be immediately replaced with fresh material. This gradation/angularity evaluation should be conducted periodically even for more durable backfill material. Note that if the backfill materials available in the region for which the approval authority has jurisdiction consistently cannot meet the maximum LA Abrasion requirement of 35 percent loss, a less durable aggregate may be used for all the backfill materials tested, at the discretion of the approval authority.

A1.1.4. The first nine prenumbered specimens identified on the exhumed sample shall be selected for testing. If any of these specimens were damaged due to the exhumation process, that specimen(s) shall be skipped, and the next consecutively numbered specimen(s) shall be selected for testing. If the coefficient of variation for the tensile test results of these first nine prenumbered specimens is greater than 5 percent, the required number of specimens shall be recomputed using the one-sided

Student's t-distribution as required by ASTM D 4595 or D 6637. The additional specimens shall be selected from the next consecutively numbered specimens.

Note A2—An alternative predetermined numbering scheme may be used to ensure that the sample locations are not biased within the sample with regard to damage patterns, provided that bias due to the visual appearance of specimen damage is eliminated.

A1.1.5. Geosynthetic Testing:

Samples subjected to installation damage shall be tested for tensile strength and deformation characteristics in accordance with ASTM D 4595 (geotextiles) or ASTM D 6637 (geogrids). The number of specimens tested should be in accordance with ASTM D 4595 or D 6637. Single-rib tests such as GRI-GG1 shall not be used for installation damage evaluation, as it is difficult to assess the effect of severed ribs on the strength and stiffness of damaged materials. Test results from damaged specimens shall be compared to tensile test results obtained from undamaged (i.e., not exposed to installation conditions) control specimens.

A1.1.6. Data Analysis and Report:

A1.1.6.1. The installation damage reduction factor RF_{ID} is determined as follows:

$$P = \frac{T_{\mathrm{dam}}}{T_{\mathrm{baseline}}} \qquad (A1\text{-}1)$$

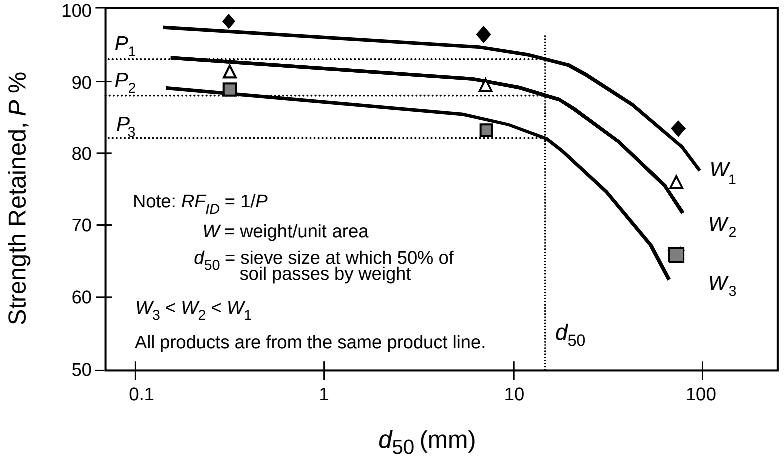
where:

T_{dam} = the average roll specific tensile strength after installation. In no case should RF_{ID} be less than 1.05; and

T_{baseline} = the average roll specific tensile strength before exposure to installation (baseline tensile strength for the installation damage test).

A1.1.6.2. To select an appropriate reduction factor for design, the project site installation conditions must be related to the installation test conditions. To relate the installation damage test conditions to the actual site conditions, primary consideration shall be given to the backfill characteristics (d_{50} particle size, potential for oversize material, particle angularity, and overall gradation) and, to a lesser degree, the method of spreading the backfill over the geosynthetic, the type of compaction equipment, and initial backfill lift thickness over the geosynthetic, provided that the initial lift thickness is 150 mm (6 in.) or more. The actual installation conditions used in the test must be clearly stated in the test report, specifically identifying any deviations from typical geosynthetic reinforcement installation practices in full-scale structures, and the impact those deviations have on the values of RF_{ID} determined.

A1.1.6.3. A repeatable interpolation procedure to estimate RF_{ID} for soils that fall between the soil gradations tested and for the products in the product line not tested (if not all the products in the product line are tested for installation damage resistance) shall be developed. Values of RF_{ID} may be estimated for a specified soil gradation using interpolation as illustrated in Figure A1-1. The d_{50} size of the soil has commonly been used for interpolating between soil backfills for determination of RF_{ID}. Other combinations of soil particle size and factors that account for soil angularity and durability may be considered for this correlation and interpolation procedure per mutual agreement between the geosynthetic manufacturer and the approval authority. The range of backfill gradations, angularity, and durability will affect the range of applicability of the RF_{ID} values obtained from the testing. RF_{ID} values should not be extrapolated beyond the coarsest backfill soil tested.



Note: $RF_{ID} = 1/P$

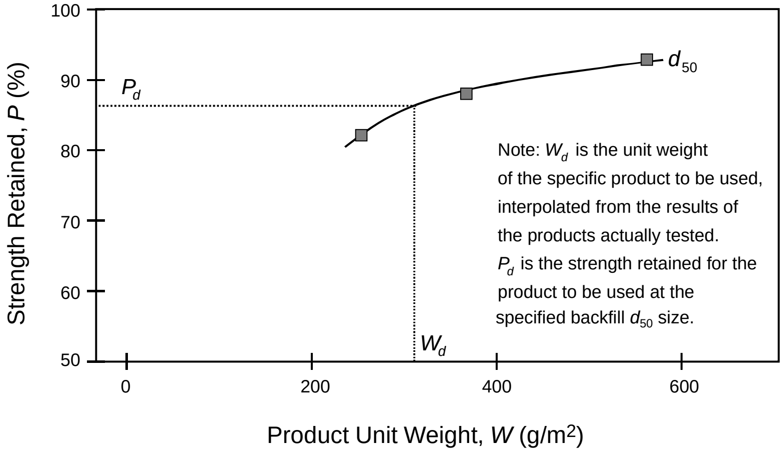
W = weight/unit area

d_{50} = sieve size at which 50% of soil passes by weight

$W_3 < W_2 < W_1$

All products are from the same product line.

Figure A1-1—Example of Installation Damage Data for Several Products That Represent a Product Line When a Strong Relationship between a Product Index Property (e.g., Weight/Unit Area, *W*) and Strength Retained Is Observed



Note: W_d is the unit weight of the specific product to be used, interpolated from the results of the products actually tested.

P_d is the strength retained for the product to be used at the specified backfill d_{50} size.

Figure A1-2—Example of Installation Damage Data Presentation That Can Be Used to Interpolate Values of Strength Retained for Products Not Installation Damage Tested When a Strong Relationship between a Product Index Property and Strength Retained Is Observed

A1.1.6.4. If not all the products within a product line are tested for installation damage, interpolation between products to estimate RF_{ID} is required. The interpolation procedures used depend on whether or not there is strong relationship between a product property (e.g., weight/unit area, tensile strength) and the product's ability to resist damage. As a minimum, the weakest (lightest) and strongest (heaviest) products within the product line, plus at least one additional intermediate strength (weight) product (i.e., the product selected as the primary product for product line characterization) should be used to characterize RF_{ID} for the product line. If the installation damage resistance of each product in the product line can be correlated to a product property, the interpolation procedure provided in Figure A1-2 may be used.

If the installation damage resistance of each product in the product line cannot be strongly correlated to a product property, the interpolation/RF_{ID} product line assessment procedures for backfill gradation and product characteristics in Figures A1-3 and A1-4 may be used.

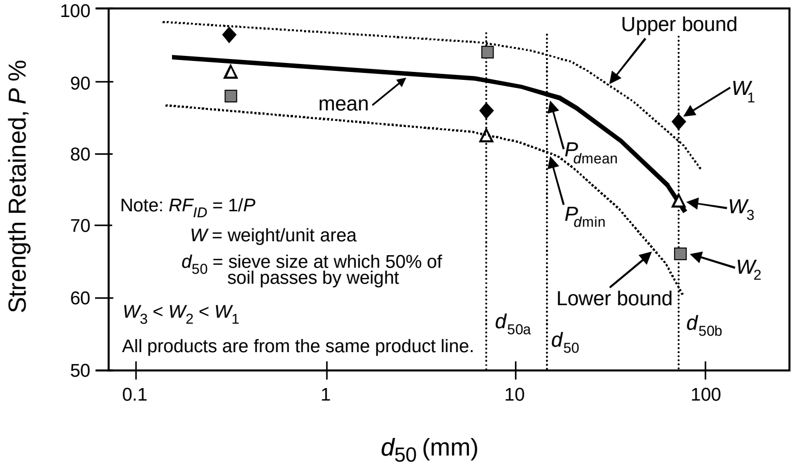


Figure A1-3—Example of Installation Damage Data for Several Products That Represent a Product Line When a Weak Relationship between a Product Index Property and Strength Retained Is Observed

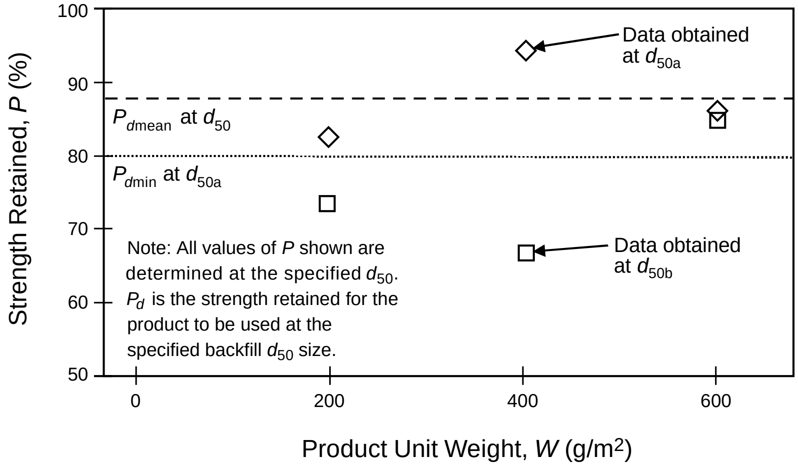

Figure A1-4—Example of Installation Damage Data Presentation That Can Be Used to Interpolate Values of Strength Retained for Products Not Installation Damage Tested When a Weak Relationship (or No Relationship) between a Product Index Property and Strength Retained Is Observed

If it is determined that the RF_{ID} values obtained for a product line are not correlated with product weight per unit area, undamaged tensile strength, coating weight, or some other product parameter, and the variance of RF_{ID} between any two products in the product line is 0.1 or more, then each product in the product line shall be tested. If, in this case (i.e., no correlation could be found), the variance of RF_{ID} between any two products in the product line is less than 0.1 and the upper bound value of RF_{ID} is selected for all products in the product line, not all products in the product line need to be tested.

For coated polyester geogrids, typical properties such as weight/unit area or tensile strength usually do not correlate well to installation damage and the magnitude of RF_{ID}. In that case, the coating thickness or coating mass per unit area relative to the mass per unit area of the product should be considered for the purpose of correlating RF_{ID} between products rather than product unit weight or tensile strength alone.

Note A3—For coated geogrids, the weight of coating placed on the fibers or yarns may influence the amount of installation damage obtained (Sprague, et al., 1999). It is acceptable to obtain the coating mass/unit area through the use of manufacturer QC data on the lot specific mass/unit area of the uncoated material (i.e., the weight of the “greige-good”), subtracting that mass/unit area from the total mass/unit area of the finished product. The total mass per unit area of the sample used in the installation damage testing should be obtained in accordance with ASTM D 5261.

ANNEX B

(Mandatory Information)

B1. CREEP TESTING AND EXTRAPOLATION PROCEDURES TO DETERMINE RF_{CR} FOR GEOSYNTHETIC REINFORCEMENTS

B1.1. *General*:

B1.1.1. The effect of long-term load/stress on geosynthetic reinforcement strength and deformation characteristics shall be determined from the results of product specific, controlled, long-term laboratory creep tests conducted for a range of load levels and durations, adequate for extrapolation purposes to the desired design life, carried out to rupture of the geosynthetic when possible.

B1.2. *Creep Testing Requirements*:
Creep testing, unless otherwise specified herein, shall be conducted in accordance with ASTM D 5262 or D 6992.

B1.2.1. Creep testing in accordance with ASTM D 5262, carried out to rupture when feasible, and at elevated temperatures for the purpose of creep extrapolation using time–temperature superposition principles, is identified herein as the “conventional method.” ASTM D 6992 (Stepped Isothermal Method, or SIM) is also identified herein as an alternative accelerated creep testing method.

B1.2.2. For both test methods, unless otherwise specified or mutually agreed upon by the geosynthetic supplier, the testing laboratory, and the owner, a baseline testing temperature of 68°F (20°C) shall be used for this testing. Higher test temperatures shall be considered as elevated temperatures to be used for the purpose of time extrapolation, unless a higher baseline temperature is needed to match the effective design temperature for a specific site.

B1.2.3. ASTM D 5262 requires that the testing temperature be maintained at +3.6°F (2°C). For some polymers, this degree of variance could significantly affect the accuracy of the shift factors and extrapolations determined in accordance with this annex. For polymers that are relatively sensitive to temperature variations, this issue should be considered when extrapolating creep data using time–temperature superposition techniques, or minimized by using a tighter temperature tolerance.

B1.2.4. Specimens shall be tested in the direction in which the load will be applied in use.

Single ribs for geogrids, or yarns or narrow width specimens for woven geotextiles, may be used for creep testing for the determination of RF_{CR} provided that it can be shown through a limited creep testing program conducted as described in Section B1.7 that the rupture behavior and envelope for the single-rib, yarns, or narrow width specimens are the same as that for the full width product as defined in ASTM D 5262. This comparison must demonstrate that there is no statistical difference between the full width product creep-rupture regression line and the single-rib, yarn, or narrow width specimen regression line at a time of 1000 hours using Student's *t*-distribution at a confidence level of 0.10 (see Equation B1-3).

B1.3. *Overview of Creep Extrapolation Approach*:

B1.3.1. Test results shall be extrapolated to the required structure design life. Based on the extrapolated test results, for ultimate limit state design, determine the highest load level, designated T_l, that precludes both ductile and brittle creep rupture within the required lifetime. T_l should be determined at the required design life and at the design site temperature. Creep test results shall also be extrapolated (not necessarily to the structure design life) to estimate the long-term stiffness of the geosynthetic as specified in Section B2.

B1.3.2. The details of the creep extrapolation approach depend on whether stress rupture or creep strain data are used. To determine T_l, the objective is to predict the rupture limit. Obviously, extrapolating stress rupture data is the most direct way to estimate T_l. However, it is possible to estimate T_l using creep strain data without detailed time to rupture data as discussed herein. Extrapolation of creep strain data is also necessary to estimate the long-term stiffness of the geosynthetic.

B1.3.3. If elevated temperature is used to obtain accelerated creep data, minimum increments of 10°C should be used to select temperatures for elevated temperature creep testing. The highest temperature tested, however, should be below any transitions for the polymer in question. If one uses test temperatures below 70 to 75°C for PP, HDPE, and PET geosynthetics, significant polymer transitions will be avoided. If higher temperatures must be used, the effect of any transitions on the creep behavior should be carefully evaluated.

Note B1—At high temperatures, significant chemical interactions with the surrounding environment are possible, necessitating that somewhat lower temperatures or appropriate environmental controls be used. These chemical interactions are likely to cause the creep test results to be conservative. Therefore, from the user's point of view, potential for chemical interactions is not detrimental to the validity of the data for predicting creep limits. However, exposure to temperatures near the upper end of these ranges could affect the stress-strain behavior of the material due to loss of molecular orientation, or possibly other effects that are not the result of chemical degradation. Therefore, care needs to be exercised when interpreting results from tests performed at temperatures near or above the maximum test temperatures indicated above. In general, if the stiffness of the material after exposure to the environment is significantly different from that of the virgin material, the stress-strain properties, and possibly the strength, of the material may have been affected by the exposure temperature in addition to the chemical environment. If the stiffness has been affected, the cause of the stiffness change should be thoroughly investigated to determine whether or not the change in stiffness is partially or fully due to the effect of temperature, or alternatively not use the data obtained at and above the temperature where the stiffness was affected. The SIM does use temperatures above 75°C, and, at least for PET geosynthetics, test temperatures above this level have not adversely affected the accuracy of the SIM extrapolations.

B1.3.4. This annex provides extrapolation procedures for both stress rupture test data and creep strain data. Two creep extrapolation techniques are provided herein for creep rupture and creep strain data evaluation: the conventional method, which utilizes a simplified visual/graphical approach, temperature acceleration of creep, regression techniques, and statistical extrapolation, and the SIM. This does not mean that the more complex mathematical modeling techniques cannot be used to extrapolate creep of geosynthetics, per agreement with the parties involved; however, they are simply not explained herein.

B1.4. *Extrapolation of Stress Rupture (Creep) Data*:

B1.4.1. Conventional Method:

B1.4.1.1. Plot the stress (creep) rupture data as log time to rupture versus log load level (i.e., log-log plot) or just load level (i.e., semi-log plot), as shown in Figure B1-1. Do this for each temperature in which creep-rupture data are available. The plotting method that provides the best and most consistent fit of the data should be used. A minimum 12 to 18 data points (i.e., combined from all temperature levels tested to produce the envelope for a given product, with a minimum of four data points at each temperature) are required to establish a rupture envelope. The data points should be evenly distributed through each log cycle of time. Rupture points with a time to rupture of less than 5 hours, in general, should not be used, unless it can be shown that these shorter duration points are consistent with the rest of the envelope (i.e., they do not contribute to nonlinearity of the envelope).

Note B2—As a guide, three of the test results should have rupture times (not shifted by temperature acceleration) of 10 to 100 hours, four of the test results should have rupture times between 100 and 1000 hours, and four of the test results should have rupture times of 1000 to 10 000 hours, with at least one additional test result having a rupture time of approximately 10 000 hours (1.14 years) or more. It is recommended that creep strain be measured as well as time to rupture, since the creep strain data may assist with conventional time–temperature shifting and in identifying any change in behavior that could invalidate extrapolation of the results.

B1.4.1.2. Extrapolate the creep-rupture data. Elevated temperature creep-rupture data can be used to extrapolate the rupture envelope at the design temperature through the use of a time shift factor, a_T. If the rupture envelope is approximately linear, the single time shift factor a_T should be adequate to perform the time–temperature superposition.

Note B3—This time–temperature superposition procedure assumes that the creep-rupture curves at all temperatures are linear on a semi-logarithmic or double logarithmic scale and parallel.

Use of a single time shift factor to shift all the creep-rupture data at a given temperature, termed "block shifting," assumes that the shift factor a_T is not highly stress level dependent and that the envelopes at all temperatures are parallel, allowing an average value of a_T to be used for all of the rupture points at a given temperature.

The time to rupture for the elevated temperature rupture data is shifted in accordance with the following equation:

$$t_{\text{amb}} = (t_{\text{elev}})(a_T) \qquad (B1\text{-}1)$$

where:

t_{amb} = the predicted time at the ambient or temperature to reach rupture under the specified load,

t_{elev} = the measured time at elevated temperature to reach a rupture under the specified load, and

a_T = the time shift factor.

The time shift factor, a_T, can be estimated approximately by using a visual/graphical approach as illustrated in Figures B1-1 and B1-2. The preferred approach, however, is to use a computer spreadsheet optimization program to select the best shift factors for each constant temperature block of data to produce the highest R^2 value for the combined creep-rupture envelope to produce the result in Figure B1-2.

Note B4—Incomplete tests may be included, with the test duration replacing the time to rupture, but should be listed as such in the reported results, provided that the test duration, after time shifting, is 10 000 hours or more. The rule for incomplete tests is as follows. The regression should be performed with and without the incomplete tests included. If the incomplete test results in an increase in the creep limit, keep the incomplete tests in the regression, but if not, do not include them in the regression, in both cases for incomplete tests that are 10 000 hours in duration after time shifting or more. Record the duration of the longest test that has ended in rupture, or the duration of the longest incomplete test the duration of which exceeds its predicted time to failure: this duration is denoted as $t_{\max}$.

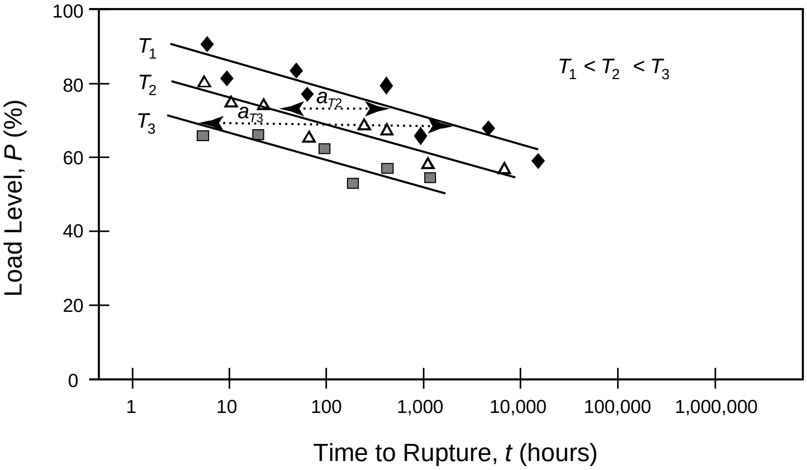

Figure B1-1—Typical Stress Rupture Data for Geosynthetics, and the Determination of Shift Factors for Time–Temperature Superposition

B1.4.1.3. It is preferred that creep-rupture data not be extrapolated statistically beyond the elevated temperature time shifted data. However, if statistical extrapolation is necessary, it shall be accomplished using regression analysis (i.e., curve fitting) up to a maximum of one log cycle of time for all geosynthetic polymers (greater extrapolation using only statistical methods is feasible, but uncertainty in the result increases substantially and must be taken into account). Therefore, adequate elevated temperature data should be obtained to limit the amount of statistical extrapolation required.

Note B5—There may be situations in which extrapolation to create a creep-rupture envelope at a lower temperature than was tested is necessary. Situations in which this may occur include the need to elevate the ambient temperature to have greater control regarding the temperature variations during the creep testing (i.e., ambient laboratory temperature may vary too much), or for sites where the effective design temperature is significantly lower than the "standard" reference temperature used for creep testing (e.g., northern or high-elevation climates). In such cases, it is feasible to use lower bound shift factors based on previous creep testing experience to allow the creep-rupture envelope to be shifted to the lower temperature, as shift factors for the materials typically used for geosynthetic reinforcement are reasonably consistent. Based on previous creep testing experience and data reported in the literature (Chow and Van Laeken, 1991; Thornton, et al. 1998; Thornton, et al., 1998a; Lothspeich and Thornton, 2000; Takemura, 1959; Bush, 1990; Popelar, et al., 1990; Wrigley, et al., 1999; Takaku, 1981; Thornton and Baker, 2002), shift factors for HDPE and PP geosynthetics are typically in the range of 0.05 to 0.18 decades (i.e., log cycles of time) per 1°C increase in temperature (i.e., a 10°C increase would result in a time shift factor of 12 to 15) and 0.05 to 0.12 decades per 1°C increase in temperature for PET geosynthetics. It is recommended that if shifting the creep-rupture envelope to temperatures below the available data is necessary, a shift factor of 0.05 decades per 1°C increase in temperature for PP, HDPE, and PET be used. This default shift factor should not be used to shift the creep-rupture data more than 10°C.

B1.4.1.4. Once the creep data have been extrapolated, determine the design, roll specific, creep limit load by taking the load level at the desired design life directly from the extrapolated stress rupture envelope as shown in Figure B1-2. If statistical extrapolation beyond the time shifted stress rupture envelopes (PP or HDPE), or beyond the actual data if temperature accelerated creep data are not available, is necessary to reach the specified design life, the calculated creep load T_l should be reduced by an extrapolation uncertainty factor as follows:

$$T_l = \frac{P_{cl}}{(1.2)^{x-1}} \qquad (B\text{-}2)$$

where:

P_{cl} = the creep limit load taken directly from the extrapolated stress rupture envelope, and

x = the number of log cycles of time the rupture envelope must be extrapolated beyond the actual or time shifted data and is equal to $\log t_d - \log t_{\max}$ as illustrated in Figure B1-2.

The factor $(1.2)^{x-1}$ is the extrapolation uncertainty factor. If extrapolating beyond the actual or time shifted data less than one log cycle, set "x–1" equal to "0". This extrapolation uncertainty factor only applies to statistical extrapolation beyond the actual or time shifted data using regression analysis and assumes that a "knee" in the rupture envelope beyond the actual or time shifted data does not occur.

Note B6—A condition on the extrapolation is that there is no evidence or reason to believe that the rupture behavior will change over the desired design life. It should be checked at long durations and at elevated temperatures, if used:

- There is no apparent change in the gradient of the creep-rupture curve.
- There is no evidence of disproportionately lower strains to failure.
- There is no significant change in the appearance of the fracture surface.

Any evidence of such changes, particularly in accelerated tests, should lead to the exclusion of any reading in which either the gradient, strain at failure, or appearance of the failure is different from those in the test with the longest failure duration. Particular attention is drawn to the behavior of unoriented thermoplastics under sustained load, where a transition in behavior is observed in long-term creep-rupture testing (i.e., the so called "ductile to brittle transition" – Popelar, et al., 1991). The effect of this transition is that the gradient of the creep-rupture curve becomes steeper at the so-called "knee" such that long-term failures occur at much shorter lifetimes than would otherwise be predicted. The strain at failure is greatly reduced and the appearance of the fracture surface changes from ductile to semi-brittle. If this is observed, any extrapolation should assume that the "knee" will occur. For the method of extrapolation, reference should be made to ISO/FDIS 9080:2001, ASTM D 2837, and Popelar, et al. (1991).

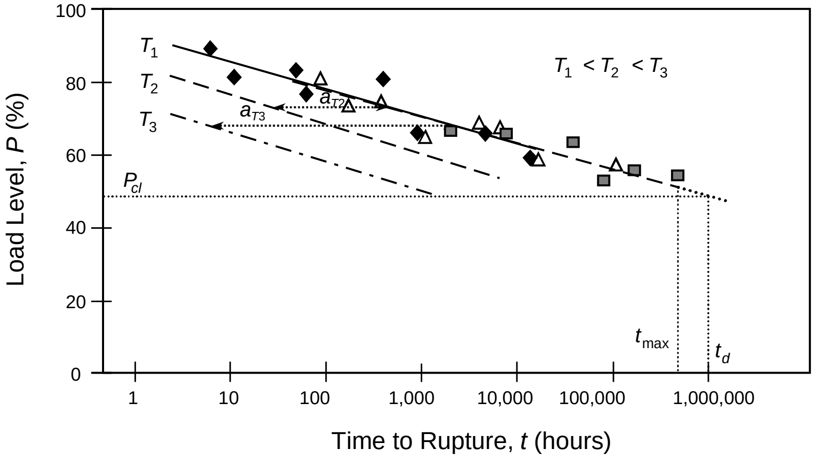

Figure B1-2—Extrapolation of Stress Rupture Data and the Determination of the Creep Limit Load

B1.4.1.5. The extrapolation uncertainty factor also assumes that the data quality is good, data scatter is reasonable, and that approximately 12 to 18 well distributed data points define the stress rupture envelope for the product. If these assumptions are not true for the data in question, this uncertainty factor should be increased. This extrapolation uncertainty factor should be increased to as much as (1.4)x if there is the potential for a “knee” in the stress rupture envelope to occur beyond the actual or time shifted data, or if the data quality, scatter, or amount is inadequate. Furthermore, if the data quantity or distribution over the time scale is inadequate, it may be necessary to begin applying the extrapolation uncertainty factor before the end of the time shifted data.

Note B7—Based on experience, the R^2 value for the composite (i.e., time shifted) creep-rupture envelope should be approximately 0.8 to 0.9 or higher to be confident that Equation B1-2 will adequately address the extrapolation uncertainty. If the R^2 value is less than approximately 0.6 to 0.7, extrapolation uncertainty is likely to be unacceptably high and additional testing and investigation should be performed. In general, such low R^2 values are typically the result of data that is too bunched up, unusually high specimen-to-specimen variability, or, possibly, poor testing technique.

B1.4.2. Stepped Isothermal Method (SIM):

B1.4.2.1. The testing and analysis shall be conducted in accordance with ASTM D 6992.

B1.4.2.2. The SIM may be used to generate and extrapolate geosynthetic creep and creep-rupture data provided this method is shown to produce results that are consistent with the “conventional” extrapolation techniques recommended in Section B1.4.1. To this end, creep-rupture testing shall be conducted using conventional tests (ASTM D 5262) and SIM tests (ASTM D 6992). At least six SIM rupture tests and six conventional rupture tests shall be conducted on one of the products in the product line being evaluated. Typically, the product tested is the one defined as the primary product in Section 6.3.2. Of the six SIM rupture tests, four shall have rupture times (shifted as appropriate) between 100 and 2000 hours and two shall have rupture times greater than 2000 hours. For the conventional (ASTM D 5262) creep tests, a distribution of rupture points similar to that described for the six SIM rupture points should be used. All of the conventional creep-rupture points shall be obtained at the reference temperature (i.e., not temperature shifted). For both the SIM and conventional creep-rupture tests, the test with the longest rupture time should have a rupture time that is approximately 10 000 hours. Creep-rupture plots shall be constructed, regression lines computed, and the log times to rupture determined at a load level that corresponds with 1000 hours and 50 000 hours on the conventional creep-rupture envelope, for the two data sets. The log time to rupture for the SIM regression at this load level shall be within the upper and lower 90 percent confidence limits of the mean conventional regressed rupture time at the same load level using Student’s *t*-test.

B1.4.2.3. The confidence limit for the regression performed for the conventional creep-rupture data is given by (Wadsworth, 1998):

$$\log t_L = \log t_{\mathrm{reg}} \pm \left[t_{\alpha,n-2} \sqrt{\frac{1}{n} + \frac{\left(P - \bar{P}\right)^2}{\sum\left(P_i - \bar{P}\right)^2}} \right] \times \sigma \qquad (B1\text{-}3)$$

and

$$\sigma = \sqrt{\frac{\sum\left[\log t_i - \log \bar{t}\right]^2 - \dfrac{\left\{\sum\left[\left(P_i - \bar{P}\right)\left(\log t_i - \log \bar{t}\right)\right]\right\}^2}{\sum\left(P_i - \bar{P}\right)^2}}{n-2}} \qquad (B1\text{-}4)$$

where:

$\log t_L$ = lower and upper bound confidence limit. The + or – term in Equation B1-3 results in the lower and upper bound confidence limits, respectively.

t_{reg} = time corresponding to the load level from the conventional creep-rupture envelope at which the comparison between the two envelopes will be made (e.g., at 1000 and 50 000 hours after time shifting).

$t_{\alpha,n-2}$ = value of the Student's *t*-distribution determined from applicable Student's *t*-table (or from the Microsoft EXCEL function TINV(α,n–2)) at $\alpha = 0.10$ and n–2 degrees of freedom (this corresponds to the 90 percent two-sided prediction limit).

n = the number of rupture or allowable run-out points in the original test sample (i.e., the conventional creep-rupture data).

P = load level obtained at t_{reg} from the regression line developed from the conventional creep-rupture testing.

$\overline{P}$ = the mean rupture load level for the original test sample (i.e., all rupture or run-out points used in the regression to establish the conventional creep rupture envelope).

P_i = the rupture load level of the *i*th point for the rupture points used in the regression for establishing the conventional creep-rupture envelope.

$\log \overline{t}$ = the mean of the log of rupture time for the original test sample (i.e., all rupture or run-out points used in the regression to establish the conventional creep-rupture envelope).

t_i = the rupture time of the *i*th point for the rupture points used in the regression for establishing the conventional creep-rupture envelope.

Once $\log t_L$, both upper and lower bound, has been determined at the specified load level, compare these values to the log rupture time (i.e., $\log t_{\mathrm{SIM}}$) obtained for the SIM creep-rupture envelope test at the specified load level (e.g., 1000 and 50 000 hours). The value of $\log t_{\mathrm{SIM}}$ at the two specified load levels must be between the upper and lower bound confidence limits ($\log t_L$). If this requirement is not met, perform two additional SIM tests at each load level P for the specified t_{reg} where this comparison was made, and develop a new SIM creep-rupture envelope using all of the SIM data. If, for the revised SIM regression envelope resulting from these additional tests, this criterion is still not met, perform adequate additional conventional creep-rupture testing to establish the complete rupture envelope for the product in accordance with this annex.

B1.4.2.4. If the criterion provided above is met, the SIM testing shall be considered to be consistent with the conventional data, and SIM may be used in combination with the conventional data to meet the requirements of Section B1.4 regarding the number of rupture points and their distribution in time and maximum duration. Therefore, the combined data can be used to create the creep-rupture envelope as shown in Figure B1-2. In that figure, the SIM data shall be considered to already be time shifted. Equation B1-2 is then used to determine T_l. If, for a given product or product line, SIM has been previously demonstrated to be consistent with the conventional creep data, and it is known that the product or product line has not changed significantly with regard to the polymer and the product processing, SIM data may continue to be used without performing a new comparison between the SIM and conventional data.

B1.5. *Extrapolation of Creep Strain Data*:
While it is possible to use creep strain data to estimate T_l, it generally provides no practical advantage over taking creep test specimens to rupture to develop a creep-rupture envelope. Therefore, detailed procedures to use creep strain data for this purpose are not provided in this standard practice. See WSDOT T 925 for additional information and discussion on use of creep strain data for this purpose, as well as other related information and guidance on handling creep strain data.

B1.6. *Determination of RF_{CR}*:

B1.6.1. The creep reduction factor, RF_{CR}, is determined by comparing the long-term creep strength, T_l , to the ultimate tensile strength (ASTM D 4595 or ASTM D 6637) of the sample tested for creep (T_{baseline}). The sample tested for ultimate tensile strength should be taken from the same roll of material used for the creep testing. The strength reduction factor to prevent long-term creep rupture is determined as follows:

$$RF_{CR} = \frac{T_{\text{baseline}}}{T_l} \qquad (B1\text{-}5)$$

where:

T_{baseline} = the average roll specific ultimate tensile strength (ASTM D 4595 or ASTM D 6637) for the roll of material used for the creep testing.

B1.6.2. This creep reduction factor takes extrapolation uncertainty into account, but does not take into account variability in the strength of the material. Material strength variability shall be taken into account when RF_{CR} is applied to T_{ult} to determine the long-term allowable tensile strength, using the minimum average roll value or minimum value for T_{ult}.

B1.7. *Evaluation of Product Lines with Regard to Creep Data*:

B1.7.1. For creep evaluation of a new product not part of the original product line, but, based on the definition of a product line in Sections 3.18 and 6.3.1, considered as part of the original product line, this limited testing program should include creep tests taken to at least 1000 to 2000 hours in duration before time shifting if using the “conventional” creep testing approach, with adequate elevated temperature data to permit extrapolation to 50 000 hours or more. If it has been verified that the use of SIM is acceptable for the product line in accordance with Section B1.4.2.2, durations after time shifting due to elevated temperature up to a minimum of 50 000 hours are required. A minimum of four data points per temperature level tested should be obtained to determine time shift factors and to establish the envelope for the new product. The data points, after time shifting, should be as evenly distributed along the time axis as possible. This comparison between the creep rupture data obtained for the original product line and the creep data for the new product shall demonstrate that there is no statistical difference between the regression lines for the existing product line and the new product at a time of 1000 hours (not temperature accelerated) and 50 000 hours (after time shifting) using Student’s *t*-distribution at a confidence level of 0.10 (see Section B1.4.2.3, specifically Equation B1-4). If no statistical difference is observed, the results from the full testing program for the original product line could be applied to the new product. If this is not the case, then a full testing and evaluation program for the new product should be conducted (i.e., treat it as a primary product as defined in Section 6.3.2).

B1.7.2. For extension of the creep data obtained on one product in the product line (i.e., the primary product tested, which is typically a product in the middle of the range of products in the product line) to the entire product line as defined herein, a limited creep testing program shall be conducted on at least two additional products in the product line. The combination of the three or more products should span the full range of the product line in terms of weight and/or strength. The limited test program described in Section B1.7.1 shall be applied to these additional products. The loads obtained for the data in each envelope should then be normalized by the roll specific ultimate tensile strength, T_{baseline}. All three envelopes should plot on top of one another, once normalized in this manner, and the two additional product envelopes should be located within the confidence limits for the product with the more fully developed creep-rupture envelope (i.e., the “primary” product) as described in Section B1.7.1. If this is the case, then the creep reduction factor for the product line shall be the lesser of (1) the reduction factor obtained for the product with the fully developed rupture envelope, and (2) the envelope of all three products combined. Normalization using the ultimate tensile strength shall be considered acceptably accurate if this is the case. If this is not the case, then the creep-rupture envelopes for the other two products, plus enough other products within the product line, to establish the trend in RF_{CR} as a function of product weight or ultimate tensile strength, so that the RF_{CR} for the other products within the product line can be accurately interpolated. Furthermore, T_{al} must be determined in accordance with Note B8.

Note B8—Note that normalization using the ultimate lot specific tensile strength may not be completely accurate for some geosynthetic products regarding characterization of creep-rupture behavior, and other normalization techniques may be needed (Wrigley, et al., 1999). In such cases, individual creep reduction factors for each product in the product line may need to be established through fully developed creep-rupture envelopes for representative products obtained at the low-, middle-, and high-strength end of the product series. Once the creep limited strength, P_{cl} and the creep reduction factors are established for each product, in this case, product variability must still be taken into account. In such cases, T_{al} must be the lesser of the determination from Equation 1 and the following determination:

$$T_{al} = \frac{P_{95}}{RF_{ID} \times RF_{D}}$$

where:

P_{95} = the tensile strength determined from the 95 percent lower bound prediction limit for the creep rupture envelope at the specified design life (see Equations 4 and 5 in Section 7.5.3.2.

B2. ESTIMATION OF CREEP STIFFNESS FOR WORKING STRESS DESIGN

B2.1. *General*:

Strains for working stress design, such as when using the K-Stiffness Method (Allen et al., 2003) are typically small (i.e., approximately 2 percent). Since reinforcement stiffness is generally a nonlinear function of strain, it is important to obtain the creep stiffness at the appropriate strain level. Therefore, unless otherwise specified per agreement of the parties involved, the creep stiffness should be determined at a strain level of 2 percent. The stiffness value to be used for geosynthetic structure design should be determined at the end of construction (J_{EOC}) or at the end of the structure design life (J_{DL}). Either "conventional" creep testing may be used, or SIM may be used to estimate the stiffness if SIM is determined to be consistent with the conventional creep strain, especially at low strain levels. If comparison between SIM creep strain data and "conventional" creep strain data at low strain levels has not been conducted, then comparison testing between the two approaches will be needed if it is desired to use SIM for the products tested at low strain levels. J_{EOC} should be determined at 1000 hours from creep data, unless another time period is specified by the parties involved to match the actual or anticipated time required to construct the geosynthetic structure for which the stiffness values are to be used.

Note B9—The primary purpose of this stiffness calculation is to provide input data for working stress methods such as the K-Stiffness method (Allen, et al., 2003; WSDOT, 2006), or for more sophisticated analyses such as finite element or finite difference numerical simulations. The time period upon which the stiffness value J_{EOC} is to be based is typically 1000 hours, or the time required to construct the geosynthetic structure. See Walters, et al. (2002) and Allen and Bathurst (2002) for a detailed explanation regarding the time period that should be used to determine J_{EOC}. For J_{DL}, the stiffness should be determined at a time equal to the structure design life (typically 75 years).

B2.2. *Creep Stiffness Testing and Analysis Requirements*:

B2.2.1. The load application rate during creep load ramp up should be consistent with the application rate used in the governing tensile test method (e.g., ASTM D 4595 or D 6637). If it is not possible to accurately apply the load at a specified rate (e.g., if dead weight is applied through the use of a jack), the actual application rate should be measured and recorded.

B2.2.2. The slack tension, T_o, applied to the specimen based on the governing tensile test (e.g., ASTM D 4595 or D 6337) will likely be too large for creep stiffness testing due to the very low loads that are likely for this type of testing. A maximum slack tension of approximately 10 percent of the anticipated load at 2 percent strain or 9 N (2 lbf), whichever is less, should be used for single-rib or narrow width specimens. For full width specimens (i.e., per ASTM D 5262), a maximum slack tension of approximately 10 percent of the anticipated load at 2 percent strain or 70 N (15 lbf), whichever is less, should be used. Since these maximum slack tension values differ from what is specified in ASTM D 4595 and ASTM D 6637, a special set of tensile tests may need to be conducted for use with the low strain creep stiffness testing program. ASTM D 4595 and D 6637 allow both the slack tension and the slack displacement, d_o, to be set to zero for calculation purposes. For low strain creep stiffness testing, the slack displacement should be set to zero, but the slack tension should be left at its full value for stiffness calculation purposes.

B2.2.3. If it has been shown that single-rib/narrow width specimens can be used in lieu of full width specimens for creep testing at high load levels (see Section B1.2.5), single-rib/narrow width specimens may also be used for low strain creep stiffness testing if respective short-term tensile tests also indicate no significant specimen width effects. The maximum difference between the mean values of the load at 2 percent strain in the single-rib/narrow width tensile tests and the full width tensile tests must be no greater than what is considered statistically insignificant based on a one-sided Student's *t*-distribution at a level of significance of 0.05, as determined using Equation 3 in Section 7.5.2.1.

B2.2.4. Obtain creep strain data for at least one load level low enough to produce a strain level at the end of structure construction (assume to be 1000 hours unless otherwise specified by the approval authority). Per agreement between the approval authority and the reinforcement manufacturer, load levels to produce additional 1000-hour strain levels may be tested. A minimum of two specimens per product at each load level shall be tested.

B2.2.5. To establish the load levels needed to produce the desired 1000-hour strains for each product, conduct a series of 1000 second R+H tests. An initial estimate of the load levels needed for the R+H tests may be obtained from the tensile tests used to establish T_{baseline} for each product tested. Test a load level that is likely to produce a strain of approximately 2 percent at 1000 hours, and then two other load levels to bracket the 2 percent load level (e.g., at load levels that would yield approximately 1 percent strain and 3 to 4 percent strain at 1000 hours). Do three replicate R+H tests at each of those load levels, plotting the load level as a function of the estimated strain at 1000 hours, assuming a log linear extrapolation is valid for the R+H test results. The creep data extrapolation and analysis process is illustrated in Figures B1-3 and B1-4. Perform a regression analysis of that data to obtain a more accurate estimation of the load level required to produce a strain of 2 percent at 1000 hours, and run three replicate R+H tests at that load level. If one of the load levels used for the R+H tests does not produce an estimated strain of 2 percent at 1000 hours, a fourth set of three replicate R+H tests may be needed, estimating the load level based on a regression of the R+H tests for the first three load levels. Then conduct two full 1000-hour creep tests at the R+H load level that results in the closest estimate to 2 percent strain at 1000 hours.

Note B10—It is desirable to conduct the full 1000-hour creep tests at the R+H load levels tested so that a direct comparison can be made between the 1000-hour creep tests and the R+H tests. If the creep observed in the 1000-hour creep tests is, in fact, log linear, the R+H tests can then be used for quality assurance testing in the future.

B2.2.6. If log linear extrapolation of the short-term creep data is not feasible, create creep stiffness curves at the desired constant strain level (typically 2 percent) as shown in Figures B2-1 and B2-2, but without using R+H tests to establish the creep stiffness as a function of strain at the desired time (i.e., all creep curves must instead be taken to at least 1000 hours without log linear extrapolation). Elevated temperature extrapolation should not be necessary if the "conventional" approach is used. Be sure that the creep stiffness curve is developed at the desired effective design temperature.

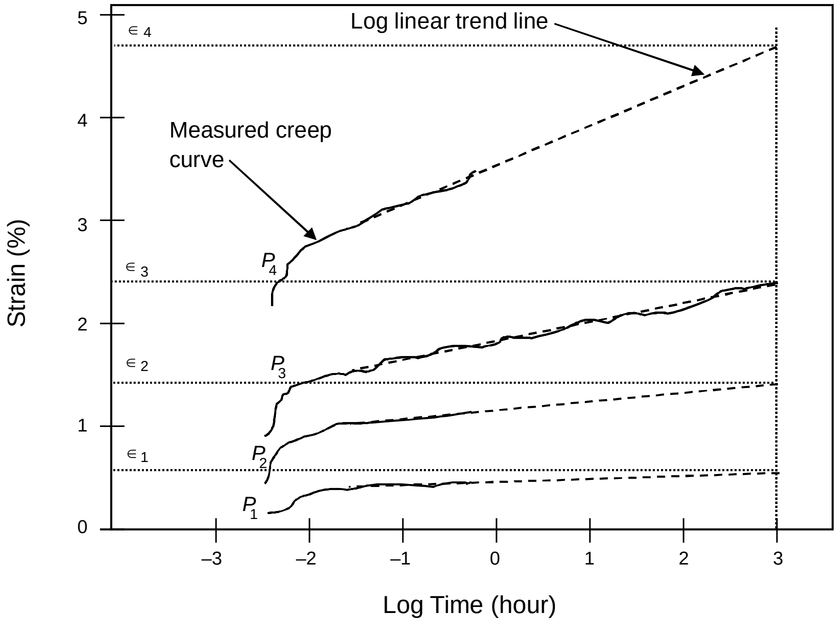

Figure B2-1—Strain Versus Time for Short-Term, Low Strain Creep Tests Used to Estimate Secant Stiffness

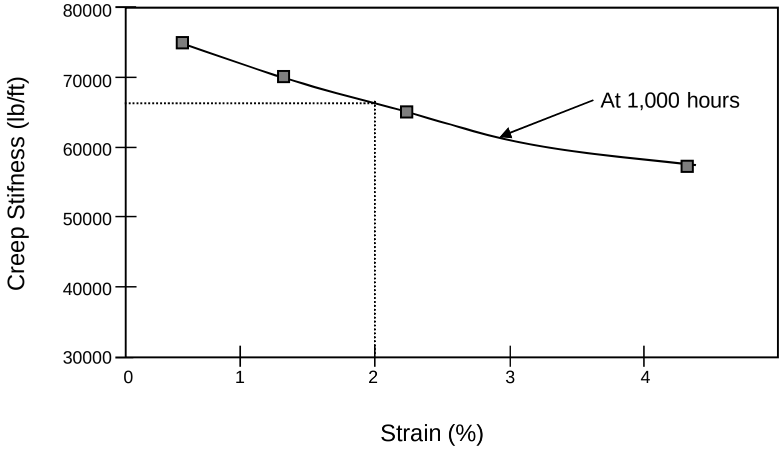

Figure B2-2—Creep Stiffness Determined from the Creep Curves at the Specified Time (see Figure B2-3) as a Function of Strain

B2.2.7. Obtain the creep stiffness at the desired time from the creep stiffness curve as shown in Figure B2-2. The creep stiffness from each creep test at the specified time is calculated as follows:

$$J = \frac{P \times T_{\text{baseline}}}{\in} \tag{B2-1}$$

where:

J = the secant creep stiffness determined at the specified strain level and time,
P = the load level expressed as a percent of T_{baseline},
T_{baseline} = the roll specific tensile strength of the sample used for the creep testing, and
$\in$ = the strain in percent.

These *J* values are then used to generate the plot shown in Figure B2-2.

B2.2.8. To extend the creep stiffness values obtained from the testing to the rest of the product line, a minimum of three products in the product line spanning the range of products in the line (i.e., the primary product, and the low and high end of the line in terms of strength) shall be tested as described in Section B1.7.2. To interpolate to other products between the products tested, determine T_{baseline} for each product tested, plotting the creep stiffness values obtained in Section B2.2.5 as a function of T_{baseline}, as illustrated in Figure B2-3. Creep stiffness values for other products in the product line not tested may be interpolated based on their baseline tensile strengths, if the relationship illustrated in Figure B2-3 is observed for the product line. If not, product specific testing should be conducted for all products in the product line.

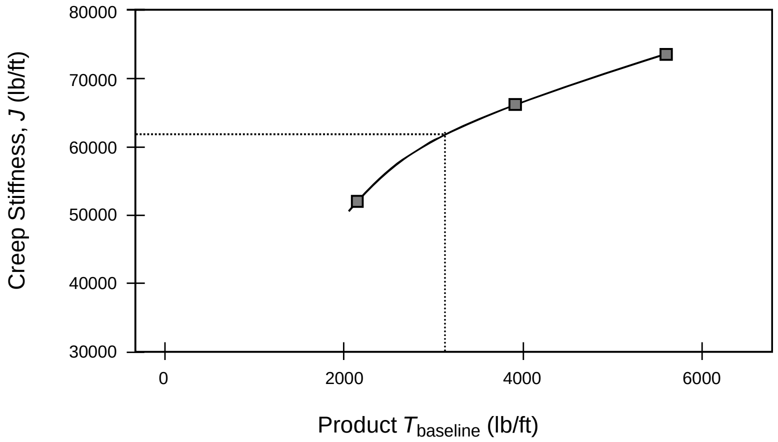

Figure B2-3—Example of Creep Stiffness, *J*, as a Function of T_{baseline}

B2.2.9. Once the values for the creep stiffness are determined for each product in the product line, the stiffness values need to be adjusted to reflect the MARV or minimum value for the geosynthetic, so that a minimum stiffness that accounts for uncertainty in the strength of the material is determined, similar to what is done for the determination of T_{al}. Calculate the design stiffness value as follows:

$$J_{\text{design}} = \frac{J \times T_{\text{MARV}}}{T_{\text{baseline}}} \tag{B2-2}$$

where:

J_{design} = the low strain design stiffness value at the specified time (e.g., J_{EOC}, J_{DL}, etc.);

J_{design} accounts for the variability in the product tensile strength through the use of T_{MARV}. Note that T_{min} may be used in lieu of T_{MARV}.

ANNEX C

(Mandatory Information)

C1. PRODUCT SPECIFIC TESTING AND DATA INTERPRETATION REQUIREMENTS TO DETERMINE RF_D FOR GEOSYNTHETIC REINFORCEMENTS

C1.1. *General*:

C1.1.1. This annex provides guidance regarding the performance of long-term product specific durability testing that may be conducted for product qualification in lieu of the durability index testing as described in Section 6.4.5. The procedures that follow are required if it is desired to use a value of RF_D less than the default minimum of 1.3, or to determine RF_D for environments that are defined as aggressive.

C1.1.2. This annex has been developed to address PP, PE, HDPE, and PET geosynthetics. While the chemical and biological durability procedures and criteria provided herein may also be applicable to other polymers (e.g., hydrolysis testing as described herein is likely applicable to PA and PVA geosynthetics), additional investigation will be required to establish a detailed protocol and acceptance criteria for these other polymers. These other polymers may be considered for evaluation using this protocol once modifications to the chemical/biological durability aspects of this protocol have been developed and are agreed upon by the approval authority.

C1.2. *Durability Testing Requirements*:

C1.2.1. The product specific durability studies for the determination of RF_D should be conducted in or, if necessary, extrapolated to, the chemical/biological environment anticipated in the reinforced backfill. The anticipated temperature of the environment is also a key variable in assessing the durability of a given product, as temperature can have an exponential effect on the rate of product property change. Higher design temperatures may need to be considered for structures with southern exposures. The effective design temperature will be assumed to be 20°C (68°F).

Therefore, determine RF_D at a temperature of 20°C (68°F) unless otherwise specified and agreed upon by the parties involved.

C1.2.2. Standards are currently not available for determining the effect of chemical/biological activity on long-term geosynthetic reinforcement strength. However, long-term product specific durability testing can be conducted in a manner that is likely to produce safe results.

C1.2.3. Geosynthetic durability may be evaluated using either retrieval and testing of geosynthetics in actual installations or through long-term accelerated laboratory testing. Use of field retrieval data from actual installations requires that the baseline, in terms of tensile strength before and immediately after installation, and possibly other properties, be known with certainty, and that the observation period be of sufficient length to permit extrapolation to the desired design life.

Note C1—The field retrieval approach, in general, is fraught with practical and technical difficulties (see Allen and Elias, 1996; Elias, 2000; and Elias, 2001). Furthermore, long periods of time may be needed for polyolefins to establish trends that can be extrapolated due to the presence of antioxidants, as no loss in strength will be observed until the antioxidants are used up. Elias (2001) suggests that 30 years of in-service time may be required to obtain adequate observational data for polyolefins, and even PET products may require 20 years of in-service observations or more to accomplish this. Because of the very long observation periods required, long-term laboratory durability testing is the more practical approach to dealing with the durability issue. An overview of an appropriate laboratory testing approach for each geosynthetic polymer type is provided herein.

C1.2.4. For polyolefin products in which the fibers/ribs do **not** exhibit micro-cracks or crazes as manufactured, long-term chemical durability testing may consist of elevated temperature oven aging tests to evaluate potential for oxidation effects (FHWA, 1997; Elias, et. al., 1997; Salman, et al., 1998; Elias, et al., 1999). A magnification of ×2,000 to ×3,000 may be needed to observe whether or not micro-cracks or crazes are present (Salman, et al., 1997). If micro-cracks or crazes are present, elevated temperatures may significantly affect the molecular structure of polyolefins in the vicinity of the micro-cracks/crazes, making extrapolation of elevated temperature oxidation behavior to the behavior of the as-manufactured product at ambient temperatures very difficult (Salman, et al., 1998). For polyolefins in which the fibers/ribs exhibit micro-cracks or crazes, a means other than elevated temperature should be considered to accelerate oxidation behavior.

C1.2.5. Oven Aging for Thermo-Oxidation Potential for Polyolefin Geosynthetics:

C1.2.5.1. If oven aging tests are conducted, a forced-air oven is strongly recommended to keep the environment inside the oven as uniform as possible during the entire test duration and to keep oxidation products from building up inside the oven, considering the long durations that are likely to be required. Temperature uniformity inside the oven should be maintained at +1 percent. An oven with horizontal air flow is recommended. Specimens should be placed in the oven parallel to the air flow and spaced no closer together than 13 mm (0.5 in.) apart.

C1.2.5.2. The specimens should not be framed to prevent shrinkage as doing this will create load in the specimen, making the resulting data difficult to interpret.

C1.2.5.3. Oxidation testing using forced-air ovens will produce conservative estimates of long-term product strength due to the rapid air circulation and the relatively high oxygen content in the oven relative to the oxygen content in the ground.

C1.2.6. Hydrolysis Testing for Polyester Geosynthetics:

C1.2.6.1. For polyesters, long-term chemical durability testing should consist of elevated temperature immersion tests to evaluate potential for hydrolysis effects. A reactor similar to that illustrated in Elias, et al. (1999) is recommended for incubating the geosynthetic specimens. A description of the test protocol is provided by Elias, et al. (1999). The reactor should be capable of maintaining temperature uniformity (+1 percent) and stability during long-term use. A minimum solid-to-liquid ratio of 1:40 should be used to size the reactor and to determine the maximum number of specimens that can be placed in the reactor.

C1.2.6.2. Measures should be taken to minimize possibilities for oxidation and reaction with carbon dioxide during the long-term incubation (e.g., replace any air inside the reactor with nitrogen, use de-aired water, keep system well sealed, etc.).

C1.2.6.3. Specimens should be suspended in the solution on a hanger made of a material that will not react with or contaminate the immersion fluid and specimens (e.g., Teflon, stainless steel, etc.). The specimens should not be framed to prevent shrinkage so that an unknown amount of tension is not placed on the specimens. Specimens should each be separated by a distance of at least 13 mm (0.5 in.).

C1.2.6.4. The solution should be intensively stirred to ensure solution uniformity.

C1.2.6.5. For coated polyester products, the immersion tests should be conducted without the coating or the coated specimen ends should not be recoated (i.e., the ends of the core polymer should be left exposed to the immersion liquid).

C1.2.6.6. Elevated temperatures should be used to accelerate the degradation process, which allows the data to be extrapolated to the desired design life.

C1.2.6.7. Hydrolysis data should be submitted for the product at a pH of approximately 7 (i.e., neutral conditions—distilled water), at a pH of 9 or more, and at a pH of 4 or less to facilitate the determination of RF_D. RF_D should be determined at a pH of 7 and at an alkaline pH (i.e., a pH of 9) as a minimum. If very acidic soils are anticipated (i.e., a pH near the bottom limit of pH = 4 for conditions defined as nonaggressive), RF_D should be determined at a pH of 4 as well.

Note C2—EPA 9090 testing or the ASTM equivalent (ASTM D 5322) is not considered adequate for a laboratory testing program to provide an estimate of RF_D. However, EPA 9090 or ASTM D 5322 testing can be used as a first cut screening tool. That is, if any significant degradation of the strength of the product in question is observed for the chemical environment tested, the product would be disqualified for use in that chemical environment unless longer term testing conducted in accordance with this annex is performed. EPA 9090 testing (or ASTM D 5322) could also be used verify the effects of certain environmental variables that are known, based on the literature, to not significantly affect the given material. For example, based on the literature, low or high pH is known to have little effect on polyolefins. This type of testing could be used to verify that the low or high pH does not affect the tensile strength of a polyolefin product, to allow that product to be used in environments that have a pH outside the range defined as a nonaggressive environment.

C1.3. *Requirements for Durability Laboratory Test Parameters and Data Interpretation*:

C1.3.1. Incubation temperatures for the testing should be high enough to adequately accelerate the degradation process, but below any major transitions in polymer behavior (e.g., glass transition, melting). Maximum recommended test temperatures to avoid major transitions are on the order of 70 to 75°C for PP, HDPE, and polyester, except as discussed above for polyolefin products that have micro-cracks or crazes as manufactured. However, exposure to temperatures near the upper end of these ranges could affect the stress-strain behavior of the material due to loss of molecular orientation, or possibly other effects that are not the result of chemical degradation. Therefore, care needs to be exercised when interpreting results from strength testing after exposure to temperatures near the maximum test temperatures indicated above.

C1.3.2. In general, if the stiffness of the material after exposure to the environment is significantly different from that of the virgin material, the stress-strain properties, and possibly the strength, of the material may have been affected by the exposure temperature in addition to the chemical environment. If the stiffness has been affected, the cause of the stiffness change should be thoroughly investigated to determine whether or not the change in stiffness is partially or fully due to the effect of temperature or, alternatively, not use the data obtained at and above the temperature where the stiffness was affected. It is additionally recommended that the Arrhenius plot of the data be checked for linearity (see the discussion of Arrhenius modeling in Sections C1.3.8 and C1.3.9). As a minimum, two to three data points above and below the suspected transition should be obtained and the plot checked for linearity through the entire range of temperatures, if it is desired to validate the use of data above the suspected transition for Arrhenius modeling and extrapolation purposes.

C1.3.3. A minimum of four test temperatures is recommended, typically spaced monotonically at 10°C increments (e.g., see ASTM D 3045), except as discussed above for some polyolefin products.

Note C3—At the lowest test temperature (e.g., 30 to 50°C), incubation times of 2 to 4 years should be anticipated to get data adequate for long-term extrapolation.

C1.3.4. Enough retrievals (e.g., a minimum of four retrievals) should be made at a given test condition to adequately define the property loss as a function of incubation time.

C1.3.5. As a minimum, degradation should be tracked using the tensile strength of the specimens retrieved from the incubation chambers. Full wide width (ASTM D 4595 or D 6637) specimens are preferred; however, single-rib or yarn specimens may be used.

C1.3.6. It is recommended that degradation be tracked by chemical means, if possible, as well as through the use of scanning electron microscope (SEM) micrographs to verify the significance of the mechanical property degradation observed.

C1.3.7. The statistical variation of the measured properties after degradation is likely to be greater than what would be observed for the virgin material. This may require that the number of specimens per retrieval be greater than what the property variation for the virgin material would indicate.

C1.3.8. Extrapolation of chemical durability data for polymers typically utilizes an Arrhenius approach, though there is evidence which suggests that the Arrhenius model does not always work well for geosynthetics. Assuming Arrhenius modeling is appropriate, the slope of the strength degradation versus time plots (transformed mathematically to be linear through zero, first, or second order Arrhenius equations) may be used to characterize the degradation behavior as a function of temperature, allowing the slope at the desired design temperature to be estimated through the Arrhenius extrapolation. The equation order that best fits the data should be used (see Salman, et. al., 1998, for details). The strength retained at a given time at the design temperature can be calculated directly from the linear equation with the extrapolated slope. Note that Arrhenius modeling may also be conducted as a function of reactant (oxygen) concentration and pressure instead of temperature (Shelton and Bright, 1993; Salman, et al., 1998). The extrapolation concept would be similar to that used for temperature. See Shelton and Bright (1993); Salman, et al. (1997); Salman, et al. (1998); Elias, et al. (1999); and Elias (2000) for guidance on Arrhenius modeling techniques as applied to geosynthetics. Also note that since the extrapolation is being conducted over several log cycles of time, uncertainty in the data should be considered when determining the retained strength at the design life and design environment.

C1.3.9. For polyolefin oxidation, Arrhenius modeling will likely need to be conducted in two steps, as there are two main phases in the oxidation process for polyolefins: (1) the induction phase, in which antioxidant consumption is the primary activity and little, if any, product strength loss occurs, and (2) the main polymer oxidation phase, in which oxidative degradation of the polyolefin occurs, resulting in strength loss, and can generally be described by the kinetics of a Basic Auto-oxidation Scheme (Salman, et al., 1997; Elias, et al., 1999). An Arrhenius model for the first phase should be developed so that the induction period t_{ind} at the design temperature or reactant (i.e., oxygen) concentration can be estimated. A second Arrhenius model should then be developed using only the data after the induction period, and time in this case would begin at the end of the induction period at each temperature or reactant concentration tested. This second Arrhenius model is then extrapolated to the design temperature or reactant concentration to estimate the strength loss anticipated at the desired design life minus the induction period. Analysis of the remaining antioxidant content provides an additional method of measuring the duration of the phase 1 oxidation process, particularly at lower temperatures and long durations, since changes in the antioxidant content take place ahead of the reduction in strength. Note that if the estimated induction period at the design environment is greater than the desired design life, this second phase Arrhenius modeling is unnecessary.

C1.3.10. Once the tensile strength at a given design life and design temperature has been estimated from the test data, determine RF_D as follows:

$$RF_D = \frac{T_{\mathrm{baseline}}}{T_D} \qquad (C1\text{-}1)$$

where:

T_{baseline} = the average roll specific ultimate tensile strength for the roll of material used for the durability testing; and

T_D = the extrapolated (i.e., to the required design life) lot specific tensile strength after degradation based on the laboratory aging tests.

In no case should RF_D be less than 1.1.

Note C4—Biological degradation has not proved to be a serious factor in the service life of geosynthetics. This is because the high molecular weight PE, polyester, polypropylene and PA used are not easily broken down by bacteria and fungi. The high tensile strength of soil reinforcements prevents them from damage by roots or burrowing animals such as rabbits. For this reason, in general, it is not necessary to consider biological degradation in defining RF_D. However, the possibility of biological degradation should be reviewed if new polymers other than those described are used. Biological durability, if specifically requested by the approval authority, should be evaluated based on ASTM D 3083-89, except the test should be modified to use ASTM D 4595 or D 6637 as the tensile test method. If any significant tensile strength loss is observed, as determined using ASTM D 4595 or D 6637, additional longer term testing should be performed before the product is further considered for use in reinforcement applications (see Bright, 1993).

C1.4. *Evaluation of Product Lines with Regard to Durability Data*:

C1.4.1. For evaluation of a new product that was not part of the original product line, but, based on the definition of a product line in Sections 3 and 6.3.1, should be considered as part of the original product line, this limited testing program should include laboratory aging tests with a 1000 to 2000-hour incubation period in the same environment used for the full testing program conducted previously, conducted at a temperature near but slightly below any major property transitions. These limited durability test results must show that the durability performance of the product is equal to or better than the performance of the product(s) previously tested. If so, the results from the full testing program used to characterize the product line could be used for the new product. If not, then a full testing and evaluation program for the new product should be conducted.

C1.4.2. For extension of the laboratory aging data obtained on one product in the product line (i.e., the primary product tested, which is typically a product in the middle of the range of products in the product line) to the entire product line as defined herein, a limited laboratory aging program shall be conducted on at least two additional products in the product line. The combination of the three or more products should span the full range of the product line in terms of weight and/or strength. Alternatively, if the primary product tested is the weakest/lightest weight product in the product line, only one secondary product need be tested to characterize the product line. The limited test program described in Section C1.4.1 shall be applied to these additional (secondary) products.

Standard Method of Test for

Determining Dynamic Modulus of Hot Mix Asphalt (HMA)

AASHTO Designation: TP 62-07 (2009)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Dynamic Modulus of Hot Mix Asphalt (HMA)

AASHTO Designation: TP 62-07 (2009)[1]

1. SCOPE

1.1. This test method covers procedures for preparing and testing hot mix asphalt (HMA) to determine the dynamic modulus and phase angle over a range of temperatures and loading frequencies.

1.2. This standard is applicable to laboratory-prepared specimens of mixtures with nominal maximum size aggregate less than or equal to 37.5 mm (1.48 in.).

1.3. *This standard may involve hazardous material, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

3. DEFINITIONS

3.1. *complex modulus* (E^*)—a complex number that defines the relationship between stress and strain for a linear viscoelastic material.

3.2. *dynamic modulus* (|*E**|)—the normal value of the complex modulus calculated by dividing the maximum (peak-to-peak) stress by the recoverable (peak-to-peak) axial strain for a material subjected to a sinusoidal loading.

3.3. *phase angle* (ϕ)—the angle in degrees between a sinusoidal applied peak stress and the resulting peak strain in a controlled stress test.

4. SUMMARY OF METHOD

4.1. A sinusoidal (haversine) axial compressive stress is applied to a specimen of asphalt concrete at a given temperature and loading frequency. The applied stress and the resulting recoverable axial strain response of the specimen is measured and used to calculate the dynamic modulus and phase angle.

4.2. Figure 1 presents one schematic of the dynamic modulus test.

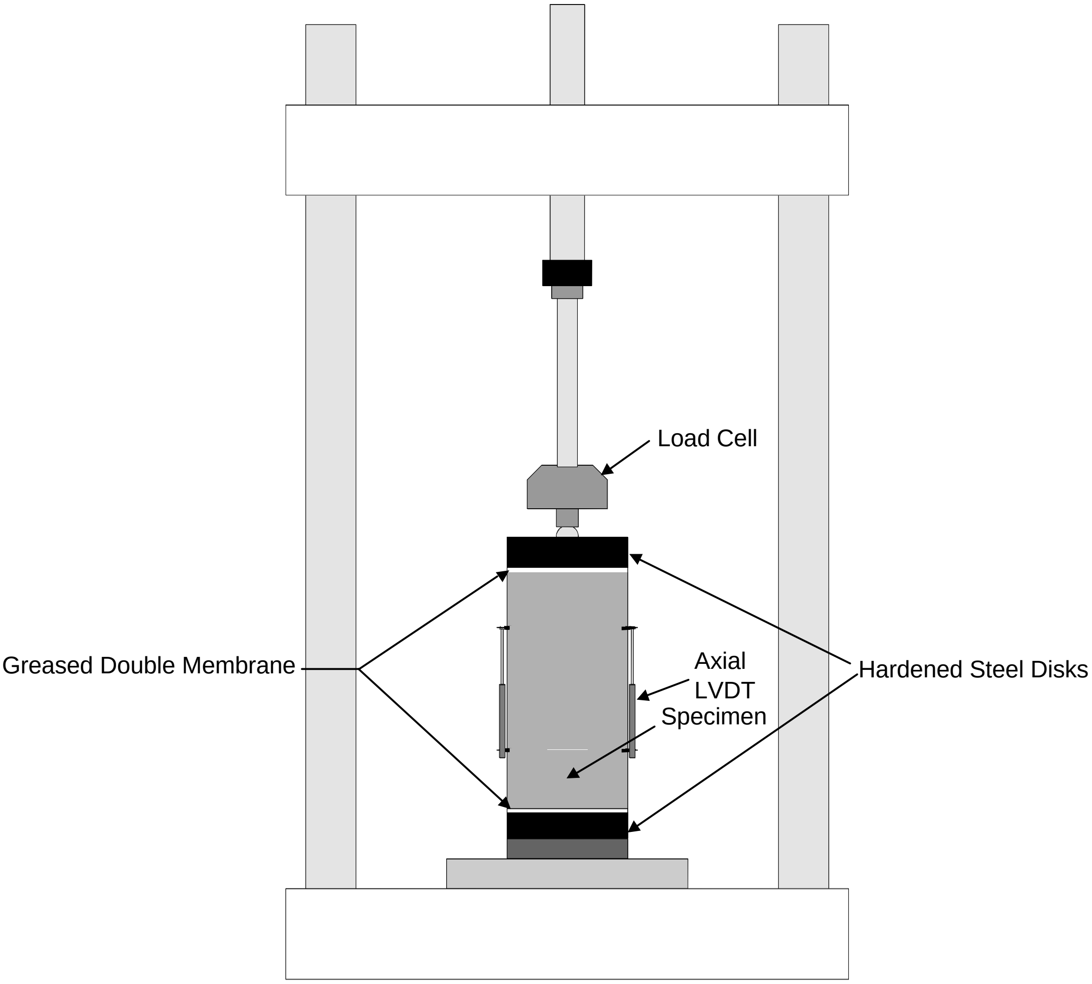

Figure 1—General Schematic of Dynamic Modulus Test

5. SIGNIFICANCE AND USE

5.1. Dynamic modulus values measured over a range of temperatures and frequencies of loading can be shifted into a master curve for characterizing asphalt concrete for pavement thickness design and performance analysis.

5.2. The values of dynamic modulus and phase angle can also be used as performance criteria for HMA design.

6. APPARATUS

6.1. *Dynamic Modulus Test System*—A dynamic modulus test system consisting of a testing machine, environmental chamber, and measuring system.

6.2. *Testing Machine*—A servo-hydraulic testing machine capable of producing a controlled haversine compressive loading. The testing machine should have a capability of applying load over a range of frequencies from 0.1 to 25 Hz and stress level up to 2800 kPa (400 psi). For sinusoidal loads, the standard error of the applied load shall be less than 5 percent. The standard error of the applied load is a measure of the difference between the measured load data and the best-fit sinusoid. The standard error of the load is defined in Equation 1.

$$se(P) = \sqrt{\frac{\sum_{i=1}^{n}\left(x_i - \hat{x}_i\right)^2}{n-4}}\left(\frac{100\%}{\hat{x}_o}\right) \qquad (1)$$

where:

$se(P)$ = standard error of the applied load,

x_i = measured load at point *i*,

$\hat{x}_i$ = predicted load at point *i* from the best-fit sinusoid,

n = total number of data points collected during test, and

$\hat{x}_o$ = amplitude of the best-fit sinusoid.

6.2.1. *Environmental Chamber*—A chamber for controlling the test specimen at the desired temperature. The environmental chamber shall be capable of controlling the temperature of the specimen over a temperature range from –10 to 60°C (14 to 140°F) to an accuracy of ±0.5°C (±1°F). The chamber shall be large enough to accommodate the test specimen and a dummy specimen with thermocouple mounted at the center for temperature verification.

6.2.2. *Measurement System*—The system shall be fully computer-controlled, capable of measuring and recording the time history of the applied load and the axial deformations. The system shall be capable of measuring the period of the applied sinusoidal load and resulting deformations with a resolution of 0.5 percent. The accuracy and resolution of measurements are summarized in Table 1.

Table 1—Accuracy and Resolution of Measurement System

Measurement	Range	Accuracy	Resolution
Load	0.12 to 25 kN	Error ≤0.0 percent	≤0.0012 kN
Deformation	≥1 mm	Error ≤0.0025 mm	≤0.0002 mm
Inherent Phase Lag between Load and Deformation	Not specified	≤1 degree	Not specified

6.2.2.1. *Load*—The load shall be measured with an electronic load cell in contact with one of the specimen caps. The load cell shall be calibrated in accordance with ASTM E 4. The load measuring system shall have a minimum range of 0 to 25 kN (0 to 5600 lb) with a resolution of 1.2 N (0.24 lb).

6.2.2.2. *Axial Deformations*—Axial deformations shall be measured with linear variable differential transformers (LVDT) mounted between gauge points glued to the specimen, for example, as shown in Figure 2.

The deformations shall be measured at two locations 180 degrees apart, three locations 120 degrees apart, or four locations 90 degrees apart. The measurement setup that calls for four locations set at 90 degrees apart has an advantage over the other two options in that, in case one LVDT does not function properly, LVDT and the LVDT on the opposite side can be dropped, and the remaining two LVDTs can be used to determine the average deformation. The LVDTs shall have a range of ±0.5 mm (±0.02 in.). The deformation measuring system shall have auto zero and selectable ranges as defined in Table 2.

Table 2—Deformation Measuring System Requirements

Range, mm (in.)	Resolution, mm (in.)
±0.5 (0.01969)	0.0100 (0.00039)
±0.25 (0.00984)	0.0050 (0.00020)
±0.125 (0.00492)	0.0025 (0.00010)
±0.0625 (0.00246)	0.0010 (0.00004)

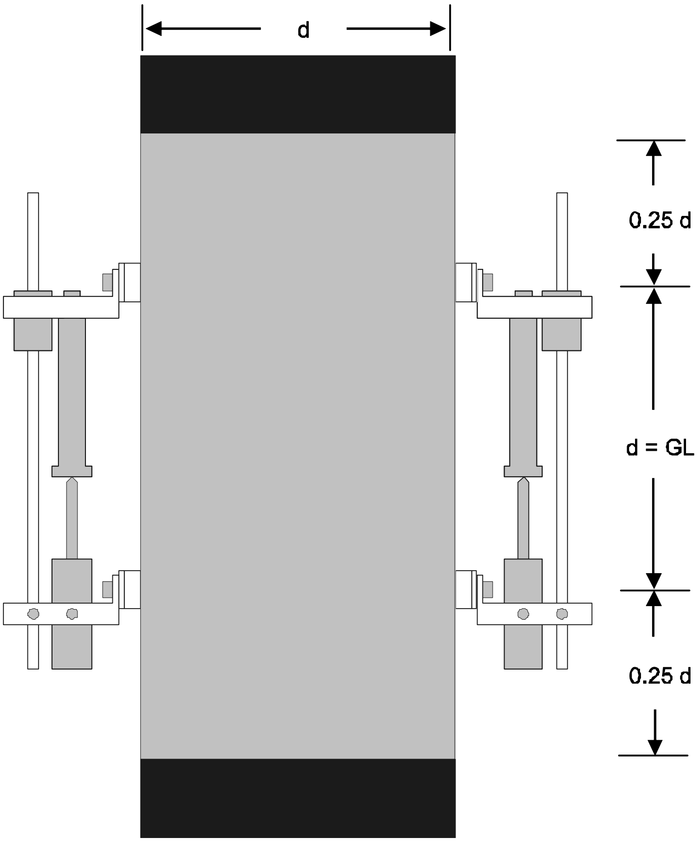

Figure 2—General Schematic of Gauge Points (Not to Scale)

6.2.3. *Loading Platens*—Loading platens, sized 104.5 ± 0.5 mm, are required above and below the specimen to transfer the load from the testing machine to the specimen. Generally, these platens should be made of hardened or plated steel, or anodized high-strength aluminum. Softer materials will require more frequent replacement. Materials that have linear elastic modulus properties and hardness properties lower than that of 6061-T6 aluminum shall not be used.

6.2.4. *End Treatment*—Friction-reducing end treatments shall be placed between the specimen ends and the loading platens. The end treatments shall consist of two Teflon® sheets or two 0.5-mm (0.02-in.) thick latex membranes separated with silicone grease.

6.3. *Superpave Gyratory Compactor*—A gyratory compactor and associated equipment for preparing laboratory specimens in accordance with T 312. The compactor shall be capable of compacting 170-mm (6.7-in.) high specimen.

6.4. *Saw*—A machine for sawing test specimen ends to the appropriate length is required. The saw shall have a diamond cutting edge and shall be capable of cutting specimens to the prescribed dimensions without excessive heating or shock.

Note 1—A diamond masonry saw greatly facilitates the preparation of test specimens with smooth, parallel ends. Both single- or double-bladed diamond saws should have feed mechanisms and speed controls of sufficient precision to ensure compliance with Sections 9.5 and 9.6 of this method. Adequate blade stiffness is also important to control flexing of the blade during thin cuts.

6.5. *Core Drill*—A coring machine with cooling system and a diamond bit for cutting nominal 101.6-mm (4.00-in.) diameter test specimens.

Note 2—A coring machine with adjustable vertical feed and rotational speed is recommended. The variable feeds and speeds may be controlled by various methods. A vertical feed rate of approximately 0.05 mm/rev (0.002 in./rev) and a rotational speed of approximately 450 RPM has been found to be satisfactory for several Superpave mixtures. Use of a standard electric core drill with a holder for the specimen is also acceptable.

7. HAZARDS

7.1. Observe standard laboratory safety precautions when preparing and testing hot mix asphalt (HMA) specimens.

8. TESTING EQUIPMENT CALIBRATION

8.1. The signal conditioning and data acquisition device of the testing system shall be checked to ensure that there is no excess phase shift between load and displacement channels.

8.2. The testing system shall be calibrated prior to initial use and at least once a year thereafter or per manufacturer requirements or per every 200 tests.

8.3. Verify the capability of the environmental chamber to maintain the required temperature within the accuracy specified.

8.4. Verify the calibration of all measurement components (such as load cell and specimen deformation measurement device) of the testing system.

8.5. If any of the verifications yield data that do not comply with the accuracy specified, correct the problem prior to proceeding with testing.

9. TEST SPECIMENS

9.1. *Size*—Dynamic modulus testing shall be performed on test specimens cored from gyratory 150-mm (4-in.) compacted mixtures. The average diameter of the test specimens shall be between 100 and 104 mm (3.94 and 4.1 in.) with a standard deviation of 1.0 mm (0.04 in.). The average height of the test specimen shall be between 147.5 and 152.5 mm (5.81 and 6.00 in.).

9.2. *Aging*—Laboratory-prepared mixtures shall be temperature-conditioned in accordance with the 4-hour short-term oven conditioning procedure in R 30. Field mixtures need not be aged prior to testing.

9.3. *Gyratory Specimens*—Prepare 170-mm (6.7-in.) tall specimens to the required air void content in accordance with T 312.

Note 3—Testing should be performed on test specimens (101.6-mm (4.0-in.) diameter) meeting specific air void tolerances. The gyratory specimen (152.4-mm (6.0-in.) diameter) air void content required to obtain a specified test specimen air void content must be determined by trial and error, achieved by using less or more mixture and compacted to the same height in the gyratory compactor. Generally, the test specimen air void content is 1.5 to 2.5 percent lower than the air void content of the gyratory specimen when the test specimen is removed from the middle as specified in this test method.

9.4. *Coring*—Core the nominal 101.6-mm (4.0-in.) diameter test specimens from the center of the gyratory specimens. Both the core drill and the gyratory specimen should be adequately supported to ensure that the resulting test specimen is cylindrical with sides that are smooth, parallel, and free from steps, ridges, and grooves.

9.5. *Diameter*—Measure the diameter of the test specimen at the mid-height and third points along axes that are 90 degrees apart. Record each of the six measurements to the nearest 1 mm (0.04 in.). Calculate the average and the standard deviation of the six measurements. If the standard deviation is greater than 2.5 mm (0.10 in.), discard the specimen. For acceptable specimens, the average diameter reported to the nearest 1 mm (0.04 in.) shall be used in all material property calculations.

9.6. *End Preparation*—The ends of all test specimens shall be smooth and perpendicular to the axis of the specimen. Prepare the ends of the specimen by sawing with a single- or double-bladed saw. The prepared specimen ends shall meet the tolerances described below. Reject test specimens not meeting these tolerances.

9.6.1. The specimen ends shall have a cut surface waviness height within a tolerance of ±0.05 mm (±0.002 in.) across any diameter. This requirement shall be checked in a minimum of three positions at approximately 120-degree intervals using a straightedge and feeler gauges approximately 8.1 to 12.5 mm (0.32 to 0.49 in.) wide or an optical comparator.

9.6.2. The specimen end shall not depart from perpendicular to the axis of the specimen by more than 1 degree, equivalent to 2.7 mm in 152.4 mm (0.11 in. in 6.10 in.). This requirement shall be checked on each specimen using a machinist's square and feeler gauges.

9.7. *Air Void Content*—Determine the air void content of the final test specimen in accordance with T 269. Reject specimens with air voids that differ by more than 0.5 percent from the target air voids.

Note 4—Considerable time can be saved if the cored test specimens were treated as wet, and the weights in water and saturated surface dry were measured immediately or within a short time period after coring. The test specimens can then be left to dry overnight, the dry weight can be measured the next day, and then they can be immediately prepared for testing.

9.8. *Replicates*—The number of test specimens required depends on the number of axial strain measurements made per specimen and the desired accuracy of the average dynamic modulus. Three replicate specimens should be tested to obtain a desired accuracy limit (e.g., less than ±15 percent of the true dynamic modulus). Table 3 summarizes the estimated accuracy associated with the number of specimens.

Table 3—Estimated Accuracy Related to the Number of Specimens

LVDTs per Specimen	Number of Specimens	Estimated Limit of Accuracy
2	2	±18.0%
2	3	±15.0%
2	4	±13.4%
3	2	±13.1%
3	3	±12.0%
3	4	±11.5%

9.9. *Sample Storage*—If test specimens will not be tested within 2 days, wrap specimens in polyethylene and store in an environmentally protected storage area at temperatures between 5 and 15°C (40 and 60°F). Specimens shall not be stacked during storage.

Note 5—To eliminate effects of aging on test results, it is recommended that specimens be stored no more than 2 weeks prior to testing.

10. TEST SPECIMEN INSTRUMENTATION

10.1. Attach mounting studs for the axial LVDTs to the sides of the specimen with epoxy cement. Figure 3 shows details of the mounting studs and LVDT mounting hardware.

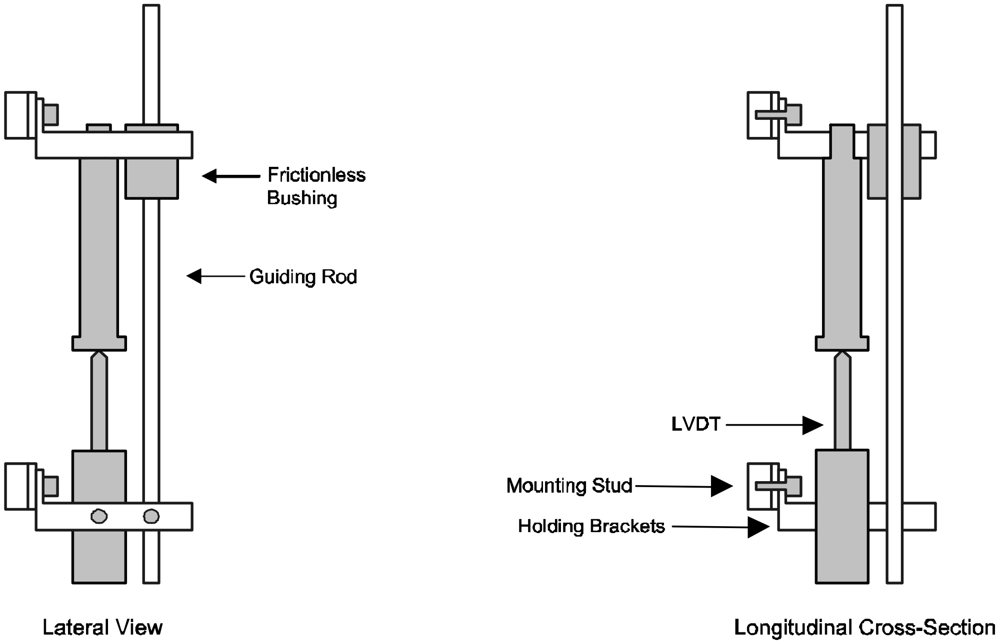

Figure 3—Mounting Hardware Details

Note 6—Quick-setting epoxy, such as Duro Master Mend Extra Strength Quick Set QM-50, has been found satisfactory for attaching studs.

10.2. The gauge length for measuring axial deformations shall be 101.6 mm ± 1 mm (4.00 in. ± 0.04 in.). Suitable alignment and spacing fixture shall be used to facilitate mounting of the axial deformation measuring hardware. The gauge length is measured between the stud centers.

11. PROCEDURE

11.1. The test series for the development of master curves for use in pavement response and performance analysis shall be conducted at –10, 4.4, 21.1, 37.8, and 54°C (14, 40, 70, 100, and 130°F) at loading frequencies of 0.1, 0.5, 1.0, 5, 10, and 25 Hz at each temperature. Each test specimen, individually instrumented with LVDT brackets, should be tested for each of the 30 combinations of temperature and frequency of loading starting with the lowest temperature and proceeding to the highest. Testing at a given temperature should begin with the highest frequency of loading and proceed to the lowest.

11.2. Place the test specimen in the environmental chamber and allow it to equilibrate to the specified testing temperature ±0.3°C (±1°F). A monitoring specimen with a thermocouple mounted at the center shall be used to determine when the specimen reaches the specified test temperature. Minimum recommended equilibrium temperature times are provided as a guideline. Note that these guidelines for equilibrium times are recommended when testing two to four replicates at a time.

Table 4—Recommended Equilibrium Times

Specimen Temperature, °C (°F)	Time from Room Temperature, h 25°C (77°F)	Time from Previous Test Temperature, h
–10 (14)	Overnight	Overnight
4 (40)	Overnight	4 hours or overnight
21 (70)	1	3
37 (100)	2	2
54 (130)	3	1

11.3. Place one of the friction-reducing end treatments on top of the hardened steel disk at the bottom of the loading frame. Place the specimen on top of the lower end treatment, and mount the axial LVDTs to the hardware previously attached to the specimen. Adjust the LVDT to near the end of its linear range to allow the full range to be available for the accumulation of compressive permanent deformation.

11.4. Place the upper friction-reducing end treatment and hardened steel disk on top of the specimen. Center the specimen with the hydraulic load actuator visually in order to avoid eccentric loading.

11.5. Apply a contact load (P_{min}) equal to 5 percent of the dynamic load that will be applied to the specimen. It is acceptable to increase the applied contact stress to 20 kPa to improve machine control effectiveness by applying a load that will maintain positive contact with the specimen but will not damage the specimen.

11.6. Adjust and balance the electronic measuring system as necessary.

11.7. Apply sinusoidal (haversine) loading (P_{dynamic}) to the specimen in a cyclic manner. The dynamic load should be adjusted to obtain axial strains between 50 and 150 microstrain.

Note 7—The dynamic load depends upon the specimen stiffness and generally ranges between 15 and 2800 kPa (2 and 400 psi). Higher load is needed at colder temperatures. Table 5 presents typical dynamic stress levels based on temperature.

Table 5—Typical Dynamic Stress Levels

Temperature, °C (°F)	Range, kPa	Range, psi
–10 (14)	1400 to 2800	200 to 400
4 (40)	700 to 1400	100 to 200
21 (70)	350 to 700	50 to 100
37 (100)	140 to 250	20 to 50
54 (130)	35 to 70	5 to 10

11.8. Test the specimens from lowest to highest temperature, that is, from –10°C (14°F) to 54°C (130°F). At each temperature, apply the loading from highest to lowest frequency, that is, from 25 Hz to 0.1 Hz. At the beginning of testing, precondition the specimen with 200 cycles at 25 Hz at stress level corresponding to Table 5. Then load the specimen as specified in Table 6. A typical rest period between each frequency run is 2 minutes. This rest period shall not exceed 30 minutes for any two frequency runs.

Table 6—Number of Cycles for the Test Sequence

Frequency (Hz)	Number of Cycles
25	200
10	200
5	100
1	20
0.5	15
0.1	15

11.9. The specimen shall be discarded at the end of any testing series at each temperature period. If the cumulative unrecovered permanent strain was found to be greater than 1500 micro units of strain, reduce the maximum loading stress level to half. Keep the test data up to this last resting period, discard the specimen, and use a new specimen for the rest of testing periods under reduced load conditions.

12. CALCULATIONS

12.1. This section presents a standard procedure for calculating both the dynamic modulus, $|E^*(\omega)|$, and the phase angle, $\theta(\omega)$, using data from a specific loading frequency, ω. It also defines four measures of data quality that should be used with the limits in Section 13 to evaluate the reliability of test data.

12.2. The general approach used here involves the least squares fit of a sinusoid, as described by Chapra and Canale in *Numerical Methods for Engineers* (McGraw-Hill, 1985, pp. 404–407). Regression is used because it is easy for most engineers and technicians in the paving industry to understand and apply effectively. This approach is easily performed on a spreadsheet.

12.3. The data produced from each dynamic modulus test at frequency ω_0 are stored in the form of several arrays, one for time $[t_i]$, one for stress $[\sigma_i]$, and one for each of the $j = 1, 2, 3, \ldots m$ strain transducers used [$\in_j$]. The number of i = 1, 2, 3…n points in each array will be equal and will depend upon the number of data points collected per loading cycle and on the total number of cycles for which data has been collected. It is recommended that 50 points per cycle and 5 cycles be used for a total of 250 data points.

12.4. *Analyze Stress Data*. The first step in the analysis is to analyze the data in the stress array. The data analysis is performed on centered stress data which is computed from the raw stress data by subtracting the average stress.

12.4.1. Determine the average stress as:

$$\overline{\sigma} = \frac{\sum_{i=1}^{n} \sigma_i}{n} \qquad (2)$$

where:

$\overline{\sigma}$ = average stress,

σ_i = raw stress point i in the data array, and

n = number of points in the data array.

12.4.2. Then compute the centered stresses by subtracting the average stress from each of the stress measurements:

$$\sigma_i' = \sigma_i - \overline{\sigma} \qquad (3)$$

where:

σ_i' = centered stress at point i in the data array,

σ_i = raw stress point i in the data array, and

$\overline{\sigma}$ = average stress.

12.4.3. From the centered stress data, compute three stress coefficients: offset, in-phase magnitude, and out-of-phase magnitude.

$$A_{\sigma 0} = \frac{\sum_{i=1}^{n} \sigma_i'}{n} \qquad (4)$$

$$A_{\sigma 1} = \frac{2}{n} \sum_{i=1}^{n} \sigma_i' \cos\left(\omega_0 t_i\right) \qquad (5)$$

$$B_{\sigma 1} = \frac{2}{n} \sum_{i=1}^{n} \sigma_i' \sin\left(\omega_0 t_i\right) \qquad (6)$$

where:

$A_{\sigma 0}$ = stress offset coefficient, kPa (psi);

σ_i' = centered stress at point i in the data array;

$A_{\sigma 1}$ = stress in-phase magnitude coefficient, kPa (psi);

ω_0 = frequency of applied stress, rad/s;

t_i = time at point i in the data array, s; and

$B_{\sigma 1}$ = stress out-of-phase magnitude coefficient, kPa (psi).

12.4.4. From the stress coefficients, compute the stress magnitude and the stress phase angle.

$$|\sigma^*| = \sqrt{A_{\sigma 1}^2 + B_{\sigma 1}^2} \tag{7}$$

$$\theta_\sigma = \arctan\left(-\frac{B_{\sigma 1}}{A_{\sigma 1}}\right) \tag{8}$$

where:

$|\sigma^*|$ = stress magnitude, kPa (psi);

$A_{\sigma 1}$ = stress in-phase magnitude coefficient, kPa (psi);

$B_{\sigma 1}$ = stress out-of-phase magnitude coefficient, kPa (psi); and

θ_σ = stress phase angle, degrees.

12.4.5. Compute an array of predicted centered stresses and the standard error of the applied stress.

$$\hat{\sigma}_i' = A_{\sigma 0} + A_{\sigma 1}\cos(\omega_0 t_i) + B_{\sigma 1}\sin(\omega_0 t_i) \tag{9}$$

$$se(\sigma) = \sqrt{\frac{\sum_{i=1}^{n}\left(\hat{\sigma}_i' - \sigma_i'\right)^2}{n-4}}\left(\frac{100\%}{|\sigma^*|}\right) \tag{10}$$

where:

$\hat{\sigma}_i'$ = predicted centered stress at point *i*, kPa (psi);

$A_{\sigma 0}$ = stress offset coefficient, kPa (psi);

$A_{\sigma 1}$ = stress in-phase magnitude coefficient, kPa (psi);

ω_0 = frequency of applied stress, rad/s;

t_i = time at point *i* in the data array, s;

$B_{\sigma 1}$ = stress out-of-phase magnitude coefficient, kPa (psi);

$se(\sigma)$ = standard error for the applied stress, percent;

σ_i' = centered stress at point *i* in the data array;

n = number of points in data array; and

$|\sigma^*|$ = stress magnitude, kPa (psi).

12.5. *Analyze Strain Data*. The second step in the analysis is to perform a similar analysis on the data from each of the strain transducers. However, in this case the data are corrected for drift caused by permanent deformation during the test, and centered data based on the average strain for the transducer.

12.5.1. To estimate the drift in the strain data, search each strain transducer array and determine local maximum and minimum values and the time when they occur for each loading cycle. Then determine the slope of the local maximum and minimum values with respect to time using linear regression. The average of these two slopes is the rate of drift D_j for strain transducer *j*.

12.5.2. Determine the average strain for each strain transducer as:

$$\overline{\in}_j = \frac{\sum_{i=1}^{n} \in_{j_i}}{n} \tag{11}$$

where:

$\overline{\in}_j$ = average strain for transducer *j*;

$\in_{j_i}$ = raw strain for transducer *j* at point *i* in data array; and

n = number of points in the data array.

12.5.3. Correct and center the strain data for each transducer by subtracting from the measured strains the rate of drift times the loading time and also subtracting the average strain for that transducer:

$$\in_{j_i}' = \in_{j_i} - D_j t_i - \overline{\in_j} \tag{12}$$

where:

$\in_{j_i}'$ = corrected and centered strain for transducer *j* at point *i* in data array,

$\in_{j_i}$ = raw strain for transducer *j* at point *i* in data array,

D_j = rate of drift for transducer *j*,

t_i = time for point *i* in data array,

$\overline{\in_j}$ = average strain for transducer *j*, and

12.5.4. From the corrected and centered strain data for each strain transducer, compute three strain coefficients: offset, in-phase magnitude, and out-of-phase magnitude.

$$A_{\in j0} = \frac{\sum_{i=1}^{n} \in_{j_i}'}{n} \tag{13}$$

$$A_{\in j1} = \frac{2}{n} \sum_{i=1}^{n} \in_{j_i}' \cos\left(\omega_0 t_i\right) \tag{14}$$

$$B_{\in j1} = \frac{2}{n} \sum_{i=1}^{n} \in_{j_i}' \sin\left(\omega_0 t_i\right) \tag{15}$$

where:

$A_{\in j0}$ = offset coefficient for strain transducer *j*;

$\in_{j_i}'$ = corrected and centered strain for transducer *j* at point *i* in data array;

$A_{\in j1}$ = in-phase magnitude coefficient for strain transducer *j*;

ω_0 = frequency of applied stress, rad/s;

t_i = time for point *i* in data array, s; and

$B_{\in j1}$ = out-of-phase magnitude coefficient for strain transducer *j*.

12.5.5. From the strain coefficients, compute the strain magnitude and the strain phase angle for each transducer.

$$\left|\in_j *\right| = \sqrt{A_{\in_{j1}}^2 + B_{\in_{j1}}^2} \qquad (16)$$

$$\theta_{\in_{j1}} = \arctan\left(-\frac{B_{\in_{j1}}}{A_{\in_{j1}}}\right) \qquad (17)$$

where:

$|\in_j *|$ = strain magnitude for strain transducer *j*;

$A_{\in_{j1}}$ = in-phase magnitude coefficient for strain transducer *j*;

$B_{\in_{j1}}$ = out-of-phase magnitude coefficient for strain transducer *j*; and

$\theta_{\in_j}$ = phase angle for strain transducer *j*, degrees.

12.5.6. For each strain transducer, compute an array of predicted corrected and centered strains and the standard error of the strain data.

$$\hat{\in}_{j_i}' = A_{\in_{j0}} + A_{\in_{j1}}\cos\left(\omega_0 t_i\right) + B_{\in_{j1}}\sin\left(\omega_0 t_i\right) \qquad (18)$$

$$se(\in_j) = \sqrt{\frac{\sum_{i=1}^{n}\left(\hat{\in}_{j_i}' - \in_{j_i}'\right)^2}{n-4}}\left(\frac{100\%}{\left|\in_j *\right|}\right) \qquad (19)$$

where:

$\hat{\in}_{j_i}'$ = predicted corrected and centered strain for strain transducer *j* at point *i*;

$A_{\in_{j0}}$ = offset coefficient for strain transducer *j*;

$A_{\in_{j1}}$ = in-phase magnitude coefficient for strain transducer *j*;

ω_0 = frequency of applied stress, rad/s;

t_i = time for point *i* in data array, s;

$B_{\in_{j1}}$ = out-of-phase magnitude coefficient for strain transducer *j*;

$se(\in_j)$ = standard error for strain transducer *j* response, percent;

$\in_{j_i}'$ = corrected and centered strain for transducer *j* at point *i* in data array;

n = number of points in data array; and

$|\in_j *|$ = strain magnitude for strain transducer *j*.

12.5.7. Calculate the average phase angle, strain magnitude, and standard error for all *m* strain transducers, along with two uniformity coefficients representing the variation among the strain transducers:

$$\overline{\theta_{\in}} = \frac{\sum_{j=1}^{m}\theta_{\in_j}}{m} \qquad (20)$$

$$\overline{\left|\in^*\right|} = \frac{\sum_{j=1}^{m}\left|\in_j{}^*\right|}{m} \tag{21}$$

$$se(\in) = \frac{\sum_{j=1}^{m} se(\in_j)}{m} \tag{22}$$

$$U_{\in} = \sqrt{\frac{\sum_{j=1}^{m}\left(\left|\in_j{}^*\right| - \overline{\left|\in^*\right|}\right)^2}{m-1}}\left(\frac{100\%}{\overline{\left|\in^*\right|}}\right) \tag{23}$$

$$U_{\theta} = \sqrt{\frac{\sum_{j=1}^{m}\left(\theta_{\in_j} - \overline{\theta_{\in}}\right)^2}{m-1}} \tag{24}$$

where:

$\overline{\theta_{\in}}$ = average phase angle for all strain transducers, degrees;

m = number of strain transducers;

$\overline{\left|\in^*\right|}$ = average strain magnitude;

$se(\in)$ = average standard error for all strain transducers, percent;

$U_{\in}$ = uniformity coefficient for strain transducers, percent; and

U_{θ} = uniformity coefficient for phase angle, degrees.

12.6. *Compute Phase Angle and Dynamic Modulus*. The final step in the data analysis is to calculate the overall phase angle, $\theta(\omega)$, in degrees, and the complex modulus, $|E^*(\omega)|$, kPa (psi), at the selected frequency, ω:

$$\theta(\omega) = \overline{\theta_{\in}} - \theta_{\sigma} \tag{25}$$

$$\left|E^*(\omega)\right| = \frac{\left|\sigma^*\right|}{\overline{\left|\in^*\right|}} \tag{26}$$

where:

$\theta(\omega)$ = phase angle between applied stress and strain for frequency ω, degrees;

$\overline{\theta_{\in}}$ = average phase angle for all strain transducers, degrees;

θ_{σ} = stress phase angle, degrees;

$|E^*(\omega)|$ = dynamic modulus for frequency ω, kPa (psi);

$|\sigma^*|$ = stress magnitude, kPa (psi); and

$\overline{\left|\in^*\right|}$ = average strain magnitude.

13. DATA QUALITY

13.1. In addition to the dynamic modulus and phase angle, a product of the data analysis described in Section 12 has four data quality indicators: (1) standard error of the applied stress, (2) average standard error for the strain measurements, (3) uniformity coefficient for the strain measurements, and (4) uniformity coefficient for the phase angle measurements.

13.2. These data quality indicators can be used to access the reliability of the data. Table 7 presents recommended limits for the data quality indicators.

Table 7—Recommended Limits for Data Quality Indicators

Indicator	Symbol	Equation	Limit
Standard error of the applied stress	$se(\sigma)$	9	≤10%
Average standard error of the measured strains	$se(\in)$	21	≤10%
Uniformity coefficient for the strain measurements	$U_{\in}$	22	≤20%
Uniformity coefficient for the phase angle measurements	U_{θ}	23	≤3 degrees

Note 8—Recommended limits based on research completed in NCHRP Project 9-29 may be revised in the future.

14. REPORT

14.1. Report the following for each specimen at each combination of temperature and frequency tested:

14.1.1. Test temperature,

14.1.2. Test frequency,

14.1.3. Dynamic modulus (from Equation 26),

14.1.4. Average phase angle between applied stress and measured strain (from Equation 25),

14.1.5. Average strain magnitude (from Equation 21),

14.1.6. Stress magnitude (from Equation 7),

14.1.7. Standard error of the applied stress (from Equation 10),

14.1.8. Average standard error of the measured strains (from Equation 22),

14.1.9. Uniformity coefficient for the strain measurements (from Equation 23), and

14.1.10. Uniformity coefficient for the phase angle measurements (from Equation 24).

APPENDIX

(Nonmandatory Information)

X1. PURPOSE

X1.1. This Appendix presents a procedure for assessing the uniformity of the air void content in test specimens produced for dynamic modulus testing.

X1.2. The approach tests the significance of the difference in mean bulk specific gravity between the top and bottom third of the specimen relative to the middle third.

X1.3. The procedure can be used to determine the height for preparing gyratory specimens with a specific compactor to minimize within sample variations in air voids.

X2. SUMMARY

X2.1. Three test specimens are prepared as described in Section 9 from gyratory specimens produced with the same mixture mass and compacted to the same height.

X2.2. The test specimens are cut into three slices of equal thickness, and the bulk specific gravity of each slice is determined.

X2.3. A statistical hypothesis test is conducted to determine the significance of differences in the mean bulk specific gravity of the top and bottom slices relative to the middle.

X3. PROCEDURE

X3.1. Prepare three test specimens following Section 9 to a target air void content of 5.5 percent. All three specimens shall have air void contents with the range of 5.0 to 6.0 percent.

X3.2. Label the top, middle, and bottom third of each specimen, then saw the specimens at the third points.

X3.3. Determine the bulk specific gravity of each of the nine test section slices in accordance with T 166 for dense- and gap-graded mixtures or T 269 for open-graded mixtures.

X3.4. Assemble a summary table of the bulk specific gravity data where each column contains data for a specific slice, and each row contains the data from a specific core.

X3.5. For each column, compute the mean and variance of the bulk specific gravity measurements using Equations X3.1 and X3.2.

$$\overline{y} = \frac{\sum_{i=1}^{3} y_i}{3} \qquad (X3.1)$$

$$s^2 = \frac{\sum_{i=1}^{3} \left(y_i - \overline{y} \right)^2}{2} \qquad (X3.2)$$

where:

$\bar{y}$ = slice mean,

y_i = measured values, and

s^2 = slice variance.

X3.6. *Statistical Comparison of Means*—Compare the mean bulk specific gravity of the top and bottom slices to the middle slice using the hypothesis tests described below. In the descriptions below, subscripts *t*, *m*, and *b* refer to the top, middle, and bottom slices, respectively.

X3.6.1. Check the top relative to the middle.

X3.6.2. *Null Hypothesis*—Mean bulk specific gravity of the top slice equals the mean bulk specific gravity of the middle slice:

$$\mu_t^2 = \mu_m^2$$

X3.6.3. *Alternative Hypothesis*—Mean bulk specific gravity of the top slice is not equal to the mean bulk specific gravity of the middle slice:

$$\mu_t^2 \neq \mu_m^2$$

X3.6.3.1. *Test Statistic*:

$$t = \frac{(\bar{y}_t - \bar{y}_m)}{0.8165(s)} \qquad (X3.3)$$

where:

$$s = \sqrt{\frac{s_t^2 + s_m^2}{2}} \qquad (X3.4)$$

$\bar{y}_t$ = computed mean for the top slices,

$\bar{y}_m$ = computed mean for the middle slices,

s_t^2 = computed variance for the top slices, and

s_m^2 = computed variance for the middle slices.

X3.6.3.2. *Region of Rejection*—For the sample sizes specified, the absolute value of the test statistic must be less than 2.78 to conclude that bulk specific gravity of the top and middle slices are equal.

X3.6.4. Check the bottom relative to the middle.

X3.6.4.1. *Null Hypothesis*—Mean bulk specific gravity of the bottom slice equals the mean bulk specific gravity of the middle slice:

$$\mu_b^2 = \mu_m^2$$

X3.6.4.2. *Alternative Hypothesis*—Mean bulk specific gravity of the bottom slice is not equal the mean bulk specific gravity of the middle slice:

$$\mu_b^2 \neq \mu_m^2$$

X3.6.4.3. *Test Statistic*:

$$t = \frac{(\bar{y}_b - \bar{y}_m)}{0.8165(s)} \tag{X3.5}$$

where:

$$s = \sqrt{\frac{s_b^{\ 2} + s_m^{\ 2}}{2}} \tag{X3.6}$$

$\bar{y}_b$ = computed mean for the bottom slices,

$\bar{y}_m$ = computed mean for the middle slices,

s_b^2 = computed variance for the bottom slices, and

s_m^2 = computed variance for the middle slices.

X3.6.4.4. *Region of Rejection*—For the sample sizes specified, the absolute value of the test statistic must be less than 2.78 to conclude that bulk specific gravity of the bottom and middle slices are equal.

X4. ANALYSIS

X4.1. Significant differences in the bulk specific gravity of the top and bottom slices relative to the middle indicate a systematic variation in density within the specimen.

X4.2. Specimens with differences of bulk specific gravity for the top and/or bottom slices relative to the middle slices on the order of 0.025 have performed satisfactorily in the dynamic modulus tests.

X4.3. Changing the height of the gyratory specimen can improve the uniformity of the density in the test specimen.

Standard Method of Test for

Density of In-Place Hot Mix Asphalt (HMA) Pavement by Electronic Surface Contact Devices

AASHTO Designation: TP 68-04 (2008)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Density of In-Place Hot Mix Asphalt (HMA) Pavement by Electronic Surface Contact Devices

AASHTO Designation: TP 68-04 (2008)[1]

INTRODUCTION

This test method describes the procedures for determining the in-place density of hot mix asphalt (HMA) by an electronic surface contact device.

1. SCOPE

1.1. This method covers the in-place determination of the total density and relative compaction of HMA pavements by measuring changes in the electromagnetic field resulting from the compaction process.

1.2. The equipment referenced in this method is a surface contact device that is relatively unaffected by the surface moisture and surface variances in temperature typically encountered during HMA paving operations. If needed, it should include circuitry to measure/compensate for moisture and temperature variances during the material compaction process.

1.3. *This procedure does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens

3. SIGNIFICANCE

3.1. The test method described is useful as a rapid nondestructive technique for determining the in-place density and relative compaction of compacted HMA mixtures.

3.2. The density results obtained by this test method may be applied using three method applications, Method A—Relative, Method B—Screed Calibration, and Method C—Core Calibration. Method C is the most accurate and requires a correlation with a known density sample of the material being measured.

4. INTERFERENCES

4.1. The composition of the HMA mix being tested may significantly affect the measurements. The device should be calibrated to the specific mix design being used in the field.

4.2. This test method exhibits spatial bias. Oversize aggregate particles in the area of the sensor path may cause variations in density readings. The average of at least four measurements at each test location is recommended.

4.3. The surface texture of the material being tested may cause lower than actual density readings.

4.4. Electromagnetic force fields, such as those caused by overhead high tension power lines or large metal objects near the device, may interfere with the device reading.

5. APPARATUS

5.1. *The device shall meet requirements outlined below*:

5.2. The device shall be housed in an enclosure of heavy-duty construction, and designed for taking *in situ* density measurements of HMA pavements.

5.3. The device shall function in the temperature and moisture levels experienced during the placement of HMA pavements.

5.4. The device shall include the internal circuitry suitable for displaying individual measurements to allow operators to record the results.

5.5. The device shall include a continuous measurement mode of operation.

5.6. The device shall employ suitable electronic circuitry to provide power and signal conditioning to the sensor to provide the data acquisition and readout function, and allow calibration of the unit over the expected range of application conditions and materials.

6. TEST SITE PREPARATION

6.1. Since surface conditions can have a significant effect on density measurements, a smooth surface with no excess water (roller water is acceptable) is required for proper testing. The optimum condition for general testing would be a dry, smooth surface, with total contact between the bottom surface of the device and the surface being tested.

6.2. Select a flat, relatively smooth test area on the HMA mat. Brush the surface clear of any sand or stones, which would prevent contact between the surface and the measuring device.

7. CALIBRATION PROCEDURE

7.1. Calibrate the device for each mixture prior to performing tests on materials that are different from the material types used in establishing the most recent calibration. Calibrate a newly acquired or repaired device.

If available, a standard plate or reference base shall be used to ensure that the device is within the manufacturer’s specifications.

7.2. The device should be calibrated on the HMA mat at compaction temperature ranges allowing subsequent readings to be taken as paving progresses at this temperature range. For calibration using core samples, follow the procedure in Section 7.4.3 and refer to manufacturer’s recommended procedures.

7.3. Maneuver the device as per the manufacturer’s recommendations. Several single measurements are averaged to calculate a reading. The location and number of measurements used to calculate a reading will depend on manufacturer’s specifications.

7.4. Calibrate the device following the procedure for Method A, B, or C. All data used for calibration shall be recorded for each mix formula.

7.4.1. *Method A*—This is the relative method. It may be used to track the compaction process during the establishment of roller patterns.

7.4.1.1. Place the device on the asphalt mat at the test location and draw an outline around the probe of the unit, and record compaction measurements and average reading of the un-compacted material exiting the screed.

7.4.1.2. After each roller pass, place the device within the outline and record compaction measurements and average reading.

7.4.1.3. When readings no longer increase with additional passes, record this value and the number of passes.

7.4.1.4. Repeat steps in Sections 7.4.1.2 and 7.4.1.3 after each roller type where compaction is to be monitored.

7.4.2. *Method B*—This is the screed calibration method. It utilizes the percent compaction obtained by the screed to calculate a starting density. This method requires the operator to estimate the percent compaction obtained by the screed; routinely this number is 75–85 percent of the maximum theoretical or voidless density. Operator experience will contribute to the accuracy of the compaction estimate and the success of this method.

7.4.2.1. Estimate the percent compaction obtained by the screed.

7.4.2.2. Multiply the maximum theoretical density of the material by the percent compaction obtained by the screed, in decimal form. Example: the voidless density is 2468 kg/m^3 (154 pcf); the screed compaction is 0.81 percent. The gauge should read 1999 kg/m^3 (124.7 pcf) behind the screed ($2468 \times 0.81 = 1999$ kg/m^3).

7.4.2.3. Measure the density of the mixture exiting the screed and offset the device to obtain the reading calculated in Section 7.4.2.2. Follow manufacturer’s specific recommendations to input the offset.

7.4.3. *Method C*—This is the core calibration method. It uses actual core densities to calibrate the device. This is the most accurate and detailed method and should be reviewed for a general understanding of the calibration process.

7.4.3.1. Identify one to five test locations on the HMA mat. For establishing a control strip, five core locations should be used. For pavement monitoring or quality control, the operator's discretion and manufacturer's recommendations should be followed.

7.4.3.2. Place the device on the asphalt mat at the test location and draw an outline around the probe of the unit. Record the measurements and average reading.

7.4.3.3. Cut a 150-mm (6-in.) diameter core from the area within the device outline where the reading was taken.

7.4.3.4. Repeat steps in Sections 7.4.3.2 and 7.4.3.3 at additional test locations if applicable.

7.4.3.5. In the laboratory, determine the density of each 150-mm (6-in.) diameter core in accordance with T 166 or other applicable methods, and record the results.

7.4.3.6. Record the numeric difference between the average reading obtained with the device and the corresponding core density for each test location.

7.4.3.7. Average the numeric differences from the step in Section 7.4.3.6, and record the average numeric difference.

7.4.3.8. Adjust the device, following the manufacturer's procedures, to account for the average numeric difference. This will calibrate the instrument to the asphalt mat by adding (or subtracting) the average numeric difference.

8. PROCEDURE OF OPERATION

8.1. Ensure that the device is calibrated in accordance with Section 6 of this specification for the site conditions and HMA mixture being used.

8.2. Locate the measurement area away from any known sources of electromagnetic interference such as overhead high-tension power lines or large metal objects. For best results avoid surfaces with large temperature extremes.

8.3. Place the device firmly on the test surface (prepared in accordance with Section 6 of this standard) and trace an outline around the probe (base) of the unit.

8.4. Record the density measurements given by the device. For quality control or pavement monitoring, the number of measurements taken at a location is less critical. More measurements are required when quality assurance applications or where companion cores will be taken. The number of measurements required will depend on the manufacturer's recommendation based on the device capabilities. The number of measurements should be supported with precision statements obtained from similar sites.

8.5. Average the measurements from an individual location to obtain an average density reading.

8.6. Record data in accordance with Section 9 of this standard.

9. RECORDING RESULTS

9.1. Job site identification and test site location data in accordance with standard contractor protocols.

9.2. Device calibration data as specified in Section 7.

9.3. *Immediately record*:

9.3.1. Individual density measurements at each test location, together with the calculated average density reading for the location.

9.3.2. Temperature of the HMA mat at the time of readings, if taken.

9.3.3. Any qualitative observations of testing or material conditions that may affect the accuracy or interpretation of test results.

9.4. Corresponding core density data (if taken) for each test location.

9.5. Dated signature by the test operator.

---

Standard Method of Test for

Multiple Stress Creep Recovery (MSCR) Test of Asphalt Binder Using a Dynamic Shear Rheometer (DSR)

AASHTO Designation: TP 70-10

1. SCOPE

1.1. This test method covers the determination of percent recovery and non-recoverable creep compliance of asphalt binders by means of the Multiple Stress Creep Recovery (MSCR) test. The MSCR test is conducted using the Dynamic Shear Rheometer (DSR) at a specified temperature. It is intended for use with residue from T 240 (Rolling Thin-Film Oven Test (RTFOT)).

Note 1—The majority of the development work on this test method was performed on material conditioned according to T 240 (RTFO).

1.2. The percent recovery value is intended to provide a means for determining the elastic response and stress dependence of polymer modified and unmodified asphalt binders.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2.2. *ASTM Standard*:

- D 8, Standard Terminology Relating to Materials for Roads and Pavements

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. Definitions of terms used in this practice may be found in ASTM D 8, determined from common English usage, or combinations of both.

3.2. *Definitions of Terms Specific to This Standard*:

3.2.1. *creep and recovery*—a standard rheological test protocol whereby a specimen is subjected to a constant load for a fixed time period and then allowed to recover at a constant zero load for a fixed time period.

3.2.2. *non-recoverable creep compliance* (J_{nr})—the residual strain in a specimen after a creep and recovery cycle divided by the stress applied, kPa^{-1}.

4. SUMMARY OF TEST METHOD

4.1. This test method is used to determine the presence of elastic response in an asphalt binder under shear creep and recovery at two stress levels at a specified temperature. For performance-graded (PG) asphalt binders, the specified temperature will typically be the PG high temperature from MP 19, Table 1.

4.2. Asphalt binder is first conditioned using T 240 (RTFOT). A sample of the RTFO-conditioned asphalt is tested using T 315 (DSR). The 25-mm parallel plate geometry is used with a 1-mm gap setting. The sample is tested in creep at two stress levels followed by recovery at each stress level. The stress levels used are 0.1 kPa and 3.2 kPa. The creep portion of the test lasts for 1 second, which is followed by a 9-second recovery. Ten creep and recovery cycles are tested at each stress level.

5. SIGNIFICANCE AND USE

5.1. This method is designed to identify the presence of elastic response in a binder and the change in elastic response at two different stress levels while being subjected to ten cycles of creep stress and recovery. Non-recoverable creep compliance has been shown to be an indicator of the resistance of an asphalt binder to permanent deformation under repeated load.

6. APPARATUS

6.1. Use the apparatus as specified in T 315.

7. PROCEDURE

7.1. *Conditioning*—Condition the asphalt binder in accordance with T 240 (RTFOT).

7.2. *Sample preparation*—The sample for the MSCR test is prepared the same as samples for T 315 using 25-mm plates. The temperature control will also follow the T 315 requirements.

7.2.1. This test may be performed on the same sample that was previously used to determine the DSR properties of the RTFO residue as specified in M 320. When using the previously tested sample to perform this test, a 1-minute relaxation period between the tests is required before running this test. When using a new sample to perform this test, the 1-minute relaxation period is not required.

7.3. *Test protocol*—The test is performed at the selected temperature using a constant stress creep of 1.0-second duration followed by a zero stress recovery of 9.0-second duration. The test is performed at two stress levels, 0.1 kPa and 3.2 kPa. Ten cycles are run at each of the two stress levels for a total of 20 cycles. The commanded full stress for each creep cycle shall be achieved within 0.03 second from the start of the creep cycle as certified by the equipment manufacturer. The stress and strain shall be recorded at least every 0.1 second for the creep cycle and at least every 0.45 second for the recovery cycle on an accumulated basis such that, in addition to other data points, the data points at 1.0 second and 10.0 second for each cycle's local time are explicitly recorded. If the DSR does not record the strain at exactly 1.00 and 10.00 seconds, then the software shall extrapolate prior data to determine the strain value at 1.00 second and 10.00 seconds. Extrapolated data shall include a measured data point no more than 0.05 second prior to the required time for a creep cycle and no more than 0.30 second prior to the required time for a recovery cycle. There are no rest periods between creep and recovery cycles or changes in stress level. The total time required to complete the two-step creep and recovery test is 200 seconds.

7.4. *Analysis*—Analyze and record the creep and recovered percent strain for the 0.1 kPa and 3.2 kPa creep stress levels as follows:

7.4.1. For each of the ten cycles, record the following:

7.4.1.1. The initial strain value at the beginning of the creep portion of each cycle. This strain shall be denoted as $\in_0$.

7.4.1.2. The strain value at the end of the creep portion (i.e., after 1.0 second) of each cycle. This strain shall be denoted as $\in_c$.

7.4.1.3. The adjusted strain value at the end of the creep portion (i.e., after 1.0 second) of each cycle ($\in_1$), which is calculated as follows:

$$\in_1 = \in_c - \in_0$$

7.4.1.4. The strain value at the end of the recovery portion (i.e., after 10.0 second) of each cycle. This strain shall be denoted as $\in_r$.

7.4.1.5. The adjusted strain value at the end of the recovery portion (i.e., after 10.0 seconds) of each cycle ($\in_{10}$), which is calculated as follows:

$$\in_{10} = \in_r - \in_0$$

7.4.2. For each of the ten cycles, calculate the following at the creep stress level of 0.1 kPa:

7.4.2.1. Percent recovery $\in_r(0.1, N)$ for $N = 1$ to 10:

$$\in_r \left(0.1, N\right) = \frac{\left(\in_1 - \in_{10}\right) \times 100}{\in_1}$$

7.4.3. For each of the ten cycles, calculate the following at the creep stress level of 3.2 kPa:

7.4.3.1. Percent recovery $\in_r(3.2, N)$ for $N = 1$ to 10:

$$\in_r\left(3.2, N\right) = \frac{\left(\in_1 - \in_{10}\right) \times 100}{\in_1}$$

---

8. CALCULATION

8.1. Using the results obtained in Sections 7.4.2.1 and 7.4.3.1, determine the average percent recovery for the asphalt binder at creep stress levels of 0.1 kPa and 3.2 kPa as shown in the following equations:

8.1.1. Calculate average percent recovery at 0.1 kPa:

$$R_{0.1} = \frac{SUM\left[\in_r\left(0.1, N\right)\right]}{10} \quad \text{for } N = 1 \text{ to } 10$$

8.1.2. Calculate average percent recovery at 3.2 kPa:

$$R_{3.2} = \frac{SUM\left[\in_r\left(3.2, N\right)\right]}{10} \quad \text{for } N = 1 \text{ to } 10$$

8.1.3. Calculate percent difference in recovery between 0.1 kPa and 3.2 kPa:

$$R_{diff} = \frac{\left[R_{0.1} - R_{3.2}\right] \times 100}{R_{0.1}}$$

8.2. Using the results obtained in Sections 7.4.2.1 and 7.4.3.1, determine the non-recoverable creep compliance between 0.1 kPa and 3.2 kPa as shown in the following equations:

8.2.1. For each of the ten cycles at a creep stress of 0.1 kPa, calculate the non-recoverable creep compliance, $J_{nr}(0.1, N)$, kPa^{-1}, as strain/stress:

$$J_{nr}\left(0.1, N\right) = \frac{\in_{10}}{0.1}$$

8.2.2. For each of the ten cycles at a creep stress of 3.2 kPa, calculate the non-recoverable creep compliance, $J_{nr}(3.2, N)$, kPa^{-1}, as strain/stress:

$$J_{nr}\left(3.2, N\right) = \frac{\in_{10}}{3.2}$$

8.2.3. Calculate the average non-recoverable creep compliance at 0.1 kPa, $J_{nr_{0.1}}$, kPa^{-1}:

$$J_{nr_{0.1}} = \frac{SUM\left[J_{nr}\left(0.1, N\right)\right]}{10} \quad \text{for } N = 1 \text{ to } 10$$

8.2.4. Calculate the average non-recoverable creep compliance at 3.2 kPa, $J_{nr_{3.2}}$, kPa^{-1}:

$$J_{nr_{3.2}} = \frac{SUM\left[J_{nr}\left(3.2, N\right)\right]}{10} \quad \text{for } N = 1 \text{ to } 10$$

8.2.5. Calculate the percent difference in non-recoverable creep compliance between 0.1 kPa and 3.2 kPa, $J_{nr_{diff}}$:

$$J_{nr_{diff}} = \frac{\left[J_{nr_{3.2}} - J_{nr_{0.1}}\right] \times 100}{J_{nr_{0.1}}}$$

9. REPORT

9.1. *Report the following information*:

9.1.1. Sample identification;

9.1.2. PG grade and test temperature, nearest 0.1°C;

9.1.3. Average percent recovery at 0.1 kPa, $R_{0.1}$;

9.1.4. Average percent recovery at 3.2 kPa, $R_{3.2}$;

9.1.5. Percentage difference between average percent recovery at 0.1 kPa and 3.2 kPa, R_{diff}.

9.1.6. Non-recoverable creep compliance at 0.1 kPa, $J_{nr_{0.1}}$, to two significant digits, kPa^{-1};

9.1.7. Non-recoverable creep compliance at 3.2 kPa, $J_{nr_{3.2}}$, to two significant digits, kPa^{-1}; and

9.1.8. Percent difference between non-recoverable creep compliance at 0.1 kPa and 3.2 kPa, $J_{nr_{diff}}$, to nearest 0.1 percent.

10. PRECISION AND BIAS

10.1. *Precision*—The research required to develop precision estimates has not been conducted.

10.2. *Bias*—The research required to establish the bias has not been conducted.

11. KEYWORDS

11.1. Asphalt binders; creep and recovery; creep compliance; Dynamic Shear Rheometer (DSR); elastomer identification; Multiple Stress Creep and Recovery (MSCR) Test; percent recovery; polymer modification.

APPENDIXES

(Nonmandatory Information)

X1. SAMPLE CALCULATIONS

X1.1. A typical test data plot consisting of ten cycles of creep and recovery at 0.1 kPa creep stress is shown in Figure X1.1. The plot for 3.2 kPa creep stress is similar to Figure X1.1 and will not be shown here. Test data from cycle number 9 are plotted in Figure X1.2 for further clarification.

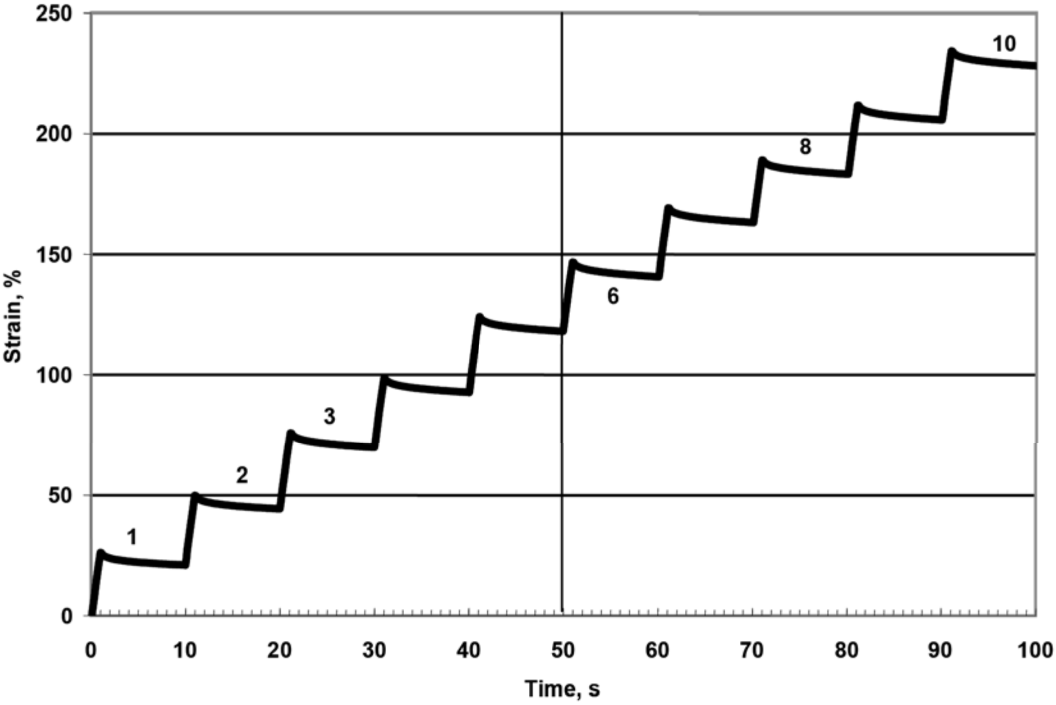

Figure X1.1—Test Data Plot Showing Typical Ten Cycles of Creep and Recovery at Creep Stress of 0.1 kPa

X1.2. *Sample Calculations*:

X1.2.1. Calculation of percent recovery for cycle number 9 (see Figure X1.2):

1. Determine strain at the start (initial strain): $\in_0 = 183\%$
2. Determine strain at 1-second creep end time point: $\in_c = 212\%$
3. Determine adjusted creep end strain at 1-second point: $\in_1 = (\in_c - \in_0) = (212 - 183)\% = 29\%$
4. Determine strain at 10-second recovery end time point: $\in_r = 206.0\%$
5. Determine adjusted recovery end strain at 10-second point:

$$\in_{10} = (\in_r - \in_0) = (206 - 183)\% = 23\%$$

6. Determine percent recovery for cycle number 9 at 0.1 kPa creep stress, $\in_r(0.1, 9)$:

$$\in_r\left(0.1,\,N\right)=\frac{\left(\in_1-\in_{10}\right)\times 100}{\in_1}$$

For cycle number 9 at a creep stress level of 0.1 kPa, the percent recovery will be:

$$\frac{(29-23)\times 100}{29.0}=21\%$$

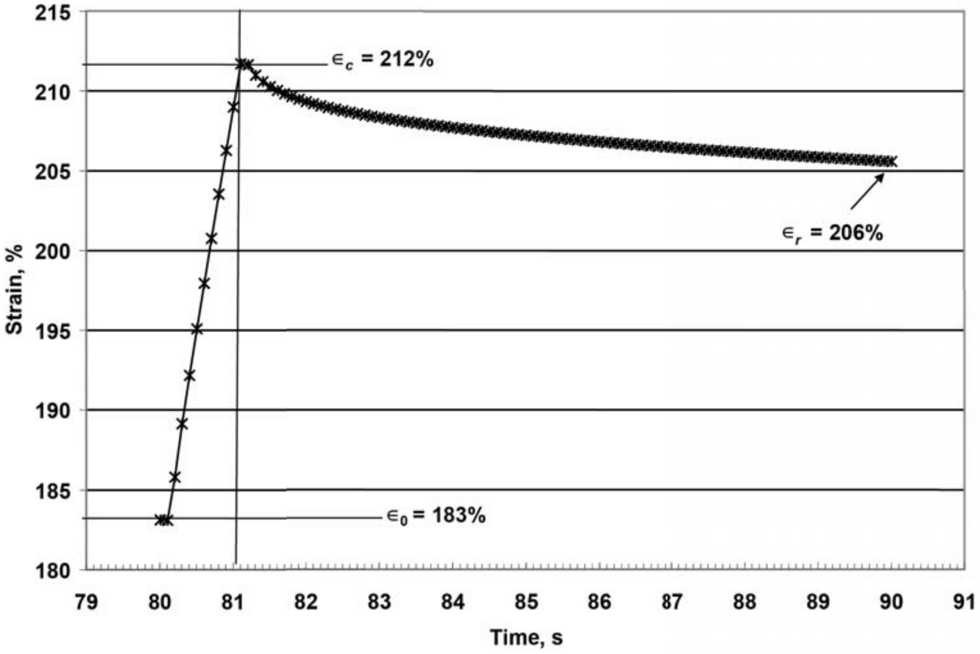

Figure X1.2—Test Cycle No. 9 Data Plot Showing Creep and Recovery at Creep Stress of 0.1 kPa

X1.3. Follow the above example to calculate percent recoveries for all ten cycles for both creep stress levels of 0.1 kPa and 3.2 kPa.

X2. INDICATIONS OF ELASTIC RESPONSE

X2.1. The percent recovery is intended to provide a means for determining the presence of elastic response and stress dependence of polymer modified and unmodified asphalt binders. Figure X2.1 may be used as an indicator of the presence of an elastomeric polymer.

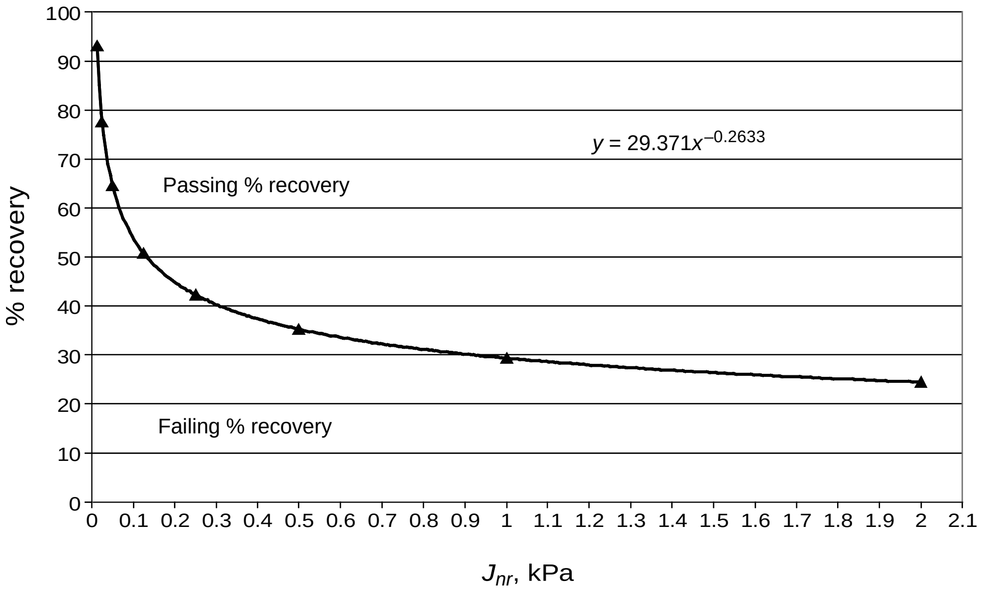

Figure X2.1—Non-recoverable creep compliance versus percent recovery

X2.2. On the graph in Figure X2.1, plot the average percent recovery at 3.2 kPa, $R_{3.2}$, versus the average non-recoverable creep compliance at 3.2 kPa, $J_{nr3.2}$, measured at the same temperature.

X2.3. If the plotted point falls above the line on the graph, the indication is that the asphalt binder is modified with an acceptable elastomeric polymer. If the plotted point falls below the line on the graph, the indication is that the asphalt binder is not modified with an elastomeric polymer.

Standard Method of Test for

Evaluation of Superpave Gyratory Compactor (SGC) Internal Angle of Gyration Using Simulated Loading

AASHTO Designation: TP 71-09[1]
ASTM Designation: D 7115-05

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Evaluation of Superpave Gyratory Compactor (SGC) Internal Angle of Gyration Using Simulated Loading

AASHTO Designation: TP 71-09[1]
ASTM Designation: D 7115-05

1. SCOPE

1.1. This practice covers the procedure for the evaluation of the Superpave Gyratory Compactor (SGC) internal angle of gyration using an instrument capable of simulating loading conditions similar to those created by a hot mix asphalt (HMA) specimen.

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standard*:

- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

3. TERMINOLOGY

3.1. *external angle*—the angle formed between the external mold diameter and a stationary reference/axis of the machine frame.

3.2. *internal angle*—the angle formed between the internal mold diameter and a mold end plate as a mold is gyrated in an SGC.

3.3. *top internal angle*—the angle formed between the internal mold diameter and the upper mold end plate as a mold is gyrated in an SGC.

3.4. *bottom internal angle*—the angle formed between the internal mold diameter and the lower mold end plate as a mold is gyrated in an SGC.

3.5. *effective internal angle*—the average of the top internal angle and the bottom internal angle.

3.6. *tilting moment*—a force (F) acting at one end of an SGC mold platen in a direction parallel to the axis of gyration, but acting at some distance (e) away from that axis. The tilting moment at one end of the mold platen is computed as the product of this distance (e) and force (F).

3.7. *total moment*—the sum total (M) of the tilting moment acting at the top of the mold and the tilting moment acting at the bottom of the mold.

3.8. *eccentricity*—the distance (e) away from the axis of gyration at which a force (F) is acting at one end of an SGC mold. This use of the term *eccentricity* is consistent with previous published reports describing the mechanics of gyratory compaction.[2]

3.9. *standard SGC volumetric specimen*—a standard-sized HMA specimen prepared using an SGC for purposes of volumetric mix design. Such a standard specimen, prepared in accordance with T 312, has a diameter of 150 mm and a final compacted height of 115 ± 5 mm.

4. SUMMARY OF PRACTICE

4.1. The internal angle of gyration of an SGC is measured dynamically with an instrument inserted into the SGC mold.

4.2. A load (moment) is induced on the SGC while the internal angle is simultaneously measured. The simulated loading conditions are similar to those created by compaction of a standard SGC volumetric specimen.

4.3. The internal angles at each end of the mold are measured and then averaged to obtain the effective internal angle of gyration.

5. SIGNIFICANCE AND USE

5.1. SGCs are used to produce hot mix asphalt (HMA) mixture specimens in the laboratory to assess and predict pavement performance. In the fabrication of an SGC specimen, loose HMA is placed inside a metal mold, which is then placed into an SGC. A constant consolidation pressure is applied to the sample while the mold gyrates at a nominally constant angle (referred to as the angle of gyration) and rate. Consistency in the density of the HMA specimens produced is very important to the validity of the tests performed. Specimens of a consistent density are produced when an SGC maintains a constant pressure and a known constant angle of gyration during the compaction process.

5.2. There are several manufacturers and models of SGC. Each model employs a unique method of setting, inducing, and maintaining the angle of gyration. Each model also employs a unique calibration system to measure the external angle of gyration. These existing calibration systems cannot be used universally on all of the different SGC models commercially available. Inconsistencies in HMA specimens produced on different SGC models have been attributed to variations in the angle of gyration.

5.3. This practice describes instruments and processes that can be used to independently measure the internal angle of gyration of any manufacturer's SGC model under simulated loading conditions. The external shape of the instrument chassis assures that the points of physical contact between the mold end plates and the instrument occur at a fixed and known distance away from the axis of gyration. As a result, the vertical load is applied at these fixed points, creating tilting moments at each end of the mold.

5.4. Unless otherwise specified, tilting moments corresponding to an eccentricity of 22 mm shall be used to simulate the loading conditions of a standard SGC volumetric specimen.

6. INTERFERENCES

6.1. Debris on the SGC mold, base plates, ram head, reaction surfaces, or on the instrument can cause errant measurement results. Extreme care should be taken to thoroughly clean the SGC, mold, instrument, and any work areas that will be utilized during the measurement procedure. Scarring or irregular surfaces on mold walls and end plates is also known to cause incorrect results. Do not use any equipment that shows signs of damage. The precision required in the execution of this practice necessitates that extreme care must be taken to avoid errors from damaged or improperly maintained equipment.

7. APPARATUS

7.1. The instrument should be capable of being gyrated inside an SGC mold which induces tilting moments at each end of the SGC mold while simultaneously measuring an internal angle of gyration.

7.1.1. *Data Acquisition*—The timing of the data acquisition system may be automatically triggered by the start of the gyration process. Provision for excluding a known number of initial gyrations from the angle measurement may be provided (*initial delay period*), and the angle shall be measured throughout a known number of subsequent gyrations (*data acquisition period*). The durations of the initial delay and the data acquisition periods may be programmable or fixed.

7.1.2. *Display Options*—The angle measurement result(s) may be viewable on a display built into the instrument chassis and/or retrievable from the instrument via a communications port.

7.1.3. *Temperature Measurement*—The instrument may optionally have a means for displaying, recording, or otherwise indicating its internal temperature during the angle measurement process.

7.1.4. *Static Angle Gauge*—A NIST-traceable angle gauge device machined with one or more known angles and used to calibrate and verify the calibration of the angle measurement instrument.

7.1.5. *Wear Protection Plates*—Thin steel plates (optional) which protect the SGC mold end plates from any cosmetic damage by the contact rings.

7.2. *Superpave Gyratory Compactor* (SGC) and associated equipment as described in T 312. The SGC shall be in good repair, with the compaction pressure, specimen height measurement system, and gyration rate verified to be within specifications. The mechanisms used to induce and maintain the angle of gyration shall be set and maintained within the manufacturer’s guidelines.

7.2.1. The SGC molds, mold end plates, base platens, and ram head surface smoothness shall be confirmed to be within the specifications of T 312. Any equipment not meeting these requirements shall not be used.

8. HAZARDS

8.1. Use standard safety precautions and protective clothing for working in a hot mix asphalt laboratory.

9. CALIBRATION AND STANDARDIZATION

9.1. The angle measurement instrument requires periodic verification, calibration, or both. The system shall be standardized prior to initial use and at least once every 12 months. This annual verification is generally considered a factory calibration and includes the following:

9.1.1. Verification of the static angle gauge with a NIST-traceable measurement system.

9.1.2. Verification of the angle measurement instrument.

10. PREPARATION OF APPARATUS

10.1. Before each use of the angle measurement instrument (i.e., on a daily basis), verify the angle measurement system using the static angle gauge. The static angle gauge, which can apply one or more known angles to the instrument, is used to confirm that the instrument is operating within calibration.

Note 1—The instrument and the static angle gauge must be at the same uniform, stable temperature for the verification to be accurate.

10.2. Be sure the probe tips and contact rings on the angle measurement instrument are free of debris.

10.3. Prepare a clean compaction mold assembly.

Note 2—Accumulation of HMA on one or more of the mold surfaces, mold end plates, base platens, or ram head surfaces directly impacts the instrument's ability to accurately measure the angle of gyration. Use mineral spirits or another appropriate solvent to clean these surfaces.

10.4. If the angle measurement is to be made at an elevated temperature, place the SGC mold in an oven at the desired temperature ±5°C for a minimum of 45 minutes prior to making the first angle measurement. Do not place the angle measurement instrument in the oven.

Note 3—The SGC manufacturer may recommend measurement of the angle at an elevated temperature for those SGC models where the angle changes with mold temperature.

Note 4—Instruments typically have a limited operating temperature range. After use in a hot mold, the angle measurement instrument can be cooled by using a fan to blow ambient air over the instrument or by placing it in front of an air conditioner. Elevating the instrument above the table surface so as to permit maximum airflow over the entire instrument will increase the rate of cooling. Do not cool the instrument below room temperature.

10.5. Verify the settings on the compactor. Unless noted otherwise, the SGC shall be initialized to provide specimen compaction using a consolidation pressure of 600 ± 18 kPa and a gyration rate of 30 ± 0.5 rpm.

10.6. Set the number of gyrations on the SGC in accordance with the recommendations of the manufacturer of the angle measurement instrument.

11. PROCEDURE

11.1. The average internal angle is based on four individual angle measurements as follows:

11.1.1. The top internal angle is measured twice. If the two results do not match within 0.02 degrees, discard the results and repeat this step again.

11.1.2. The bottom internal angle is measured twice. If the two results do not match within 0.02 degrees, discard the results and repeat this step again.

11.2. Each of the four individual angle measurements is performed as follows:

11.2.1. Arm the angle measurement instrument for collecting data.

11.2.2. Place the angle measurement instrument inside the SGC mold. Orient the instrument probes or reference base as appropriate to measure the top or bottom angle.

Note 5—The operator may wish to use a mold extruder to elevate the bottom mold plate to a position where insertion of the angle measurement instrument into the SGC mold is easier.

11.2.3. Place the SGC mold inside the SGC.

Note 6—For some SGCs, it may be more convenient to first place the mold in the SGC, and then place the angle measurement instrument in the mold.

11.2.4. Initiate the compaction process. For most SGCs, this is an automatic process consisting of pressing a button to start the compaction process. The SGC automatically applies the ram pressure, induces the angle, and gyrates the mold to the specified number of gyrations.

Note 7—Certain models of Superpave Gyratory Compactor may exhibit erratic behavior when applying compaction pressure to a simulated load device. Consult SGC manufacturer recommendations regarding the use of simulated load devices and specific procedures for initiating and completing the compaction process.

11.2.5. Remove the angle measurement instrument from the SGC mold.

Note 8—Use caution when removing the instrument, especially when using a power extruder. Take care that the instrument does not get caught or damaged during the extrusion process.

11.2.6. Record the angle result reported by the instrument (to the nearest 0.01 degree). Record which angle (*top* or *bottom*) and which replicate (1 or 2) was measured.

12. CALCULATION

12.1. Calculate the average top internal angle as follows:

$$\text{average top internal angle} = \frac{(\text{top internal angle 1} + \text{top internal angle 2})}{2} \tag{1}$$

12.2. Calculate the average bottom internal angle as follows:

$$\text{average bottom internal angle} = \frac{(\text{bottom internal angle 1} + \text{bottom internal angle 2})}{2} \tag{2}$$

12.3. Calculate the effective internal angle as follows:

$$\text{effective internal angle} = \frac{(\text{average top internal angle} + \text{average bottom internal angle})}{2} \tag{3}$$

13. REPORT

13.1. The report shall contain the following information:

13.1.1. *SGC Information*—Manufacturer, model number, serial number, owner, location, number of gyrations, and consolidation pressure used during the angle measurement process;

13.1.2. *Angle Measurement Instrument Identification*—Manufacturer, model number, serial number, date of calibration;

13.1.3. *Due date for next calibration and eccentricity*;

Note 9—Consult the instrument manufacturer's manual for determination of the applied eccentricity for the particular instrument used.

13.1.4. *Results from each of the individual angle measurements*—Express each angle measurement to the nearest 0.01 degree, with notations indicating top or bottom angle; and

13.1.5. *Effective internal angle*.

13.2. The technician performing the test shall sign and date the report.

Note 10—A sample report is provided in Appendix X1.

14. PRECISION AND BIAS

14.1. *Precision*—The precision is based on an ASTM Interlaboratory Study (ILS #151) that was conducted in 2007. ILS #151 involved 27 laboratories, which featured five Troxler (DAVII-HMS) and six Pine Instrument AFLS1 (RAM) internal-angle measuring instruments and the following SGC models: Troxler Electronics 4140, 4141, and 414x; Pine Instrument AFG1, AFG2, AFGB1, and AFGC125X; IPC ServoPac; and Interlaken. Within the study, the internal angle measurements ranged from 1.014 to 1.290 degrees. ILS #151 indicated that the two internal-angle measuring device types (DAVII-HMS and RAM) produced similar results on all SGC models listed.

14.1.1. *Single-Instrument Precision*—The single-operator standard deviation (1s limit) of a single test result has been found to be 0.011 degrees. Therefore, results of two properly conducted measurements by the same operator with the same internal-angle measuring instrument in the same SGC should not differ by more than 0.03 degrees (d2s limit).

14.1.2. *Multi-Instrument Precision*—The multi-instrument standard deviation (1s limit) of a single test result has been found to be 0.015 degrees. Therefore, the results of two properly conducted measurements by different operators using different internal-angle measuring instruments in the same SGC should not differ by more than 0.04 degrees (d2s limit).

14.2. *Bias*—Since there is no accepted reference device suitable for determining the bias in this method, no statement of bias is made.

15. KEYWORDS

15.1. Angle; asphalt; compaction; gyratory; Superpave.

Standard Method of Test for

Quantitative Determination of the Percentage of Lime in Hot Mix Asphalt (HMA)

AASHTO Designation: TP 72-08

1. SCOPE

1.1. This method covers the quantitative determination of the percentage of lime in hot mix asphalt (HMA) by calculation of the calcium hydroxide, $Ca(OH)_2$, recovered from a sample of the mixture. A specimen is obtained through drilling into the HMA and collecting the drilling dust. The specimen is subjected to an acid filter boil and wash and is analyzed using either Atomic Absorption (AA) or Ion Exchange Chromatography (IEC).

1.2. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 308, Determining the Asphalt Binder Content of Hot Mix Asphalt (HMA) by the Ignition Method

2.2. *ASTM Standard*:

- C 25, Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime

3. SIGNIFICANCE AND USE

3.1. This test method is useful for determining the amount of lime added to an HMA mixture.

3.2. If the coarse aggregate contains limestone, the limestone aggregate will be dissolved by the acid used in this method and can yield an unrealistically high result. If limestone is present in a relatively minor amount, it is possible to run a background analysis on the raw aggregate. An adjustment can then be made based on the background analysis in order to better approximate the actual results. If the aggregate in the HMA contains an appreciable amount of limestone, this test method is not suitable. Depending upon the concentration, the calcium content of any added lime could be masked by the aggregate concentration. This effect would lead to a significant error in overestimation of the amount of lime added.

4. APPARATUS

4.1. *Atomic Absorption (AA) or Ion Exchange Chromatography (IEC)*—These methods are able to measure the concentration of chemical elements, in this case calcium, in aqueous solutions. AA Spectrometry measures the intensity of a characteristic color imparted to a flame by the presence of calcium ions in the test solution. IEC measures the change in electrical conductivity of the solution. IEC can identify components of mixtures; AA Spectrometry can only measure one element at a time.

4.2. *Balance*—An analytical balance conforming to M 231, Class B.

4.3. *Heating Device*—A small hot plate or other suitable device shall be available for supplying sufficient heat under the flask to bring the solution to a boil. Suitable shields, baffle plates, or sand baths shall be used on the surfaces of the hot plates to minimize localized overheating.

4.4. *Rotary Hammer*—An industrial size hammer drill with a $^{3}/_{8}$-in. carbide drill bit.

4.5. *Miscellaneous Equipment*:

4.5.1. *Automatic Pipette*—Eppendorf or equivalent of adequate capacity to obtain a 1.0-mL sample.

4.5.2. *Filter Funnel*—Buchner or equivalent and filter paper, filter flask, and a vacuum source.

4.5.3. *Glassware*—100-mL and 250-mL flasks.

5. TEST SPECIMENS

5.1. Test specimens may be either laboratory-mixed HMA or sampled from HMA pavements.

5.2. Pavement specimens shall be taken from pavements with a core drill, diamond or carborundum saw, or by other suitable means. Specimens will be further prepared as noted in Section 6.1.

5.3. Specimens shall be free from foreign materials such as foundation material, soil, paper, foil, etc.

5.4. If the core contains more than one pavement layer, it is recommended that the layers be separated by sawing or other suitable means.

6. PROCEDURE

6.1. *Preparation of Specimen*:

6.1.1. A specimen is obtained from the drilling dust of a pavement core or laboratory-mixed HMA sample. Stand the core on a thick piece of wood and use a heavy-duty rotary hammer with a $^{3}/_{8}$-in. carbide bit to drill into the sample.

Note 1—A rotary hammer that utilizes SDS, SDS Max, or spline shank bits is recommended. Devices utilizing straight shank bits have been found to be insufficient. Depending upon the number of samples, it may be worthwhile to make a frame to hold the core.

Note 2—It is recommended to wear safety glasses and protective gloves.

6.1.2. Drill to the depth of the drill flutes. This depth will yield about 15 g of dust. Discard any lumps of the core that may break off.

6.1.3. Take the 15 ± 0.5 g of dust and determine its mass to the nearest 0.01 g. Place the dust in a 250-mL conical flask. Add 100 mL of 4 percent acetic acid and boil the mixture for 30 to 45 min. Filter the mixture through a filter funnel (Buchner or equivalent) and wash the insoluble dust with distilled water.

6.1.4. Transfer the filtrate to a 250-mL volumetric flask. Rinse the filter flask with distilled water and add the washings to the contents of the volumetric flask. Add distilled water to the flask until the total volume of its contents reaches 250 mL. Place a stopper in the flask, and shake it well to mix the contents.

6.1.5. Use a pipette (an Eppendorf automatic pipette or equivalent) accurate to 0.1 mL to take a 1.0-mL aliquot from the volumetric flask, and transfer this specimen to a 100-mL volumetric flask. Fill the flask with distilled water until the total volume of its contents reaches 100 mL. Place a stopper in the flask, and shake it well to mix the contents.

6.2. *Analyze the drilling dust to determine the level of calcium ions present*:

6.2.1. Run AA Spectrometry or IEC (according to the manufacturer's recommendations) on the specimen prepared in Section 6.1.5. Run calcium standards before and after the specimen analysis. If using AA Spectrometry, do not add lanthanum salts.

Note 3—Theories exist that calcium is subject to interference with AA Spectrometry and this condition can be overcome by adding lanthanum salts. However, in this procedure, it has been found to provide an artificially high lime result.

6.2.2. The calcium ion concentration in the specimen should be in the range of 1 to 5 mg/L. If the concentration is outside this range, it indicates the possible presence of limestone aggregate (see Section 3.2).

---

7. CALCULATION OF RESULTS

7.1. *Calculate the percentage of lime in the HMA as follows*:

$$L = [[C \times 46.25]/[10 \times W_d \times ((100 - AC)/100)]]/L_c \qquad (1)$$

where:

L = percentage of lime;

C = concentration of calcium from AA or IEC (mg/L);

W_d = mass of the dust, g;

AC = percentage of the binder in the mix, determined by AASHTO T 308; and

L_c = percentage of calcium in the lime from ASTM C 25 to the nearest 0.001 (e.g., 0.955).

7.1.1. Derivation of Equation 1:

The calcium content of the original solution is:

$C \times 100/4$ mg/L or $C \times 25$.

Hydrated lime is calcium hydroxide $Ca(OH)_2$ with a molecular weight of $40 + 2(16 + 1) = 74$.

To convert from mg/L of calcium to mg/L of lime multiply by 74/40 or 1.85.

Therefore, the hydrated lime content is:

$C \times 25 \times 1.85$ mg/L or $C \times 46.25$ mg/L

Hydrated lime is added to the mix as a percentage of the aggregate; therefore, the mass of the aggregate in the dust specimen is included as $[1000 \times W_d \times (100 - AC)/100]$ in grams or $[10 \times W_d \times (100 - AC)/100]$ in milligrams.

---

8. REPORT

8.1. *The report shall include the following information*:

8.1.1. Type of specimen tested (obtained from a laboratory-mixed sample or pavement core sample);

Note 4—For core specimens, the height of each test specimen in millimeters (or inches) should be reported.

8.1.2. Date of the test;

8.1.3. Asphalt mixture identification;

8.1.4. Percentage of asphalt binder to the nearest 0.1 percent; and

8.1.5. Percentage of lime to the nearest 0.01 percent.

9. PRECISION AND BIAS

9.1. No precision and bias statements are available at this time.

10. KEYWORDS

10.1. Atomic Absorption Spectrometry; hot mix asphalt; Ion Exchange Chromatography; lime.

Standard Specification for

Detecting the Presence of Phosphorous in Asphalt Binder

AASHTO Designation: TP 78-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Detecting the Presence of Phosphorous in Asphalt Binder

AASHTO Designation: TP 78-09[1]

1. SCOPE

1.1 This qualitative test method can be used to identify the presence of polyphosphoric acid (PPA) in asphalt binder or residue. If PPA is present in the binder, a blue color is developed in approximately 5 minutes. The test method is not quantitative, but it can detect PPA at concentrations as low as 0.1 percent. The test method can only determine the presence of phosphorus. It is not specific for the presence of PPA. A positive test result assumes that the phosphorus is from PPA. Any additive that contains phosphorus will give a false positive for the presence of PPA.

1.2 The values stated in SI units are to be regarded as the standard.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- T 40, Sampling Bituminous Materials

3. SUMMARY OF TEST METHOD

3.1 Butyl alcohol is used to extract some of the acid present from the asphalt. The extracted acid is then transferred to the water phase. The presence of phosphoric acid is detected by reaction with ammonium molybdate, potassium antimonyl tartrate, and ascorbic acid to form a blue color.

4. SIGNIFICANCE

4.1 Phosphoric acid may be added to asphalt binder to modify the physical properties of the binder. This test method detects the presence of phosphoric acid in the asphalt binder but is not a quantitative test. The result is either positive or negative that phosphoric acid is present.

5. APPARATUS

5.1 *Pipette*—Disposable, plastic transfer pipettes.

5.2 *Containers*—One-ounce cans, test tubes, or small beakers. Disposable cans or glassware are recommended to avoid contamination. If glassware is reused, it must be washed with hot (1 + 3) hydrochloric acid (1 part hydrochloric acid to 3 parts distilled water) and rinsed with distilled water. Commercial detergents should not be used to clean the glassware because they may contain phosphates, which will interfere with the results.

Note 1—One agency found that the cans they were using for this test had been lubricated during the manufacturing process with a lubricant containing phosphates. This resulted in a positive result in this test even with the empty can. If there is doubt about the condition of the containers being used, then take the precaution of running a blank test with no asphalt.

6. REAGENTS AND MATERIALS

6.1 *Antimonyl Tartrate/Ammonium Molybdate Solution*—Dissolve 0.13 g of potassium antimonyl tartrate hydrate [$C_8H_4K_2O_{12}Sb_2 \cdot H_2O$] in 50 mL of distilled water. Add 5.6 g of ammonium molybdate [$(NH_4)_6Mo_7O_{24} \cdot 4\ H_2O$] and swirl until dissolved.

6.2 *Sulfuric Acid Solution*—1 N solution of sulfuric acid [H_2SO_4]. Sulfuric acid solution can be purchased in 1-L polyethylene bottles.

6.3 *Stock Solution*—Mix the antimonyl tartrate/ammonium molybdate solution from Section 6.1 with approximately 950 mL of 1 N sulfuric acid solution. This can be done by adding the solution from Section 6.1 to 1 L of 1 N sulfuric acid if there is sufficient space in the bottle. The exact amount of sulfuric acid is not critical. This solution is stable for 1 year.

6.4 *Ascorbic Acid Color Reagent*—Dissolve 0.50 g of L-ascorbic acid [$C_6H_8O_6$] in 100 mL of the stock solution from Section 6.3. Prepare the reagent fresh daily as needed.

6.5 *Butyl Alcohol*—Isobutanol [$(CH_3)_2CHCH_2OH$] or *n*-butanol [$CH_3(CH_2)_3OH$] may be used.

7. SAMPLING

7.1 Sample the material in accordance with T 40. See Note 2 regarding potential concerns regarding contamination of sampling container.

8. PROCEDURE

8.1 Heat the asphalt and pour 1 to 2 g into a 1-oz can or other small container.

8.2 Place the container in an oven set at 163 ± 10°C for 10 minutes to ensure the asphalt is fluid.

8.3 Remove the container, and immediately add 2 mL of butyl alcohol while stirring the container.

8.4 Continue to stir the container and add 2 mL of distilled water.

8.5 While still stirring the container, add 2 mL of the ascorbic acid color reagent. After the addition of the color reagent, stop stirring and allow the sample to sit for 5 to 10 minutes.

8.6 If phosphoric acid is present in the asphalt, a blue color will develop within 5 to 10 minutes. Decant the solution into a second container if unable to see the color.

Note 2—After 30 minutes, the results are not reliable. The color may either fade or intensify after 30 minutes.

8.7 If a blue color appears, the sample is reported as “positive”. The sample is reported as “negative” if it does not turn blue.

Note 3—The blue color, if present, will be in the aqueous phase, which will be at the bottom. Often the top layer has a brown or green color.

8.8 When new reagents are prepared, prepare and run a blank (asphalt with no phosphoric acid).

9. REPORT

9.1 *This report shall include the following*:

9.1.1 Identification of sample.

9.1.2 “Positive” or “Negative” result.

10. PRECISION AND BIAS

10.1 *Precision*—The research required to develop precision estimates has not been conducted.

10.2 *Bias*—This test method has no bias since the values determined can only be defined in terms of this test method.

11. KEYWORDS

11.1 Asphalt; phosphoric acid; PPA.

---

Standard Method of Test for

Determining the Dynamic Modulus and Flow Number for Hot Mix Asphalt (HMA) Using the Asphalt Mixture Performance Tester (AMPT)

AASHTO Designation: TP 79-10[1,2]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining the Dynamic Modulus and Flow Number for Hot Mix Asphalt (HMA) Using the Asphalt Mixture Performance Tester (AMPT)

AASHTO Designation: TP 79-10[1,2]

1. SCOPE

1.1 This standard describes test methods for measuring the dynamic modulus and flow number for hot mix asphalt (HMA) using the Asphalt Mixture Performance Tester (AMPT). This practice is intended for dense- and gap-graded mixtures with nominal-maximum aggregate sizes up to 37.5 mm.

1.2 *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- PP 60, Preparation of Cylindrical Performance Test Specimens Using the Superpave Gyratory Compactor (SGC)

2.2 *Other Publication*:

- Equipment Specification for the Simple Performance Test System, Version 3.0, Prepared for National Cooperative Highway Research Program (NCHRP), October 16, 2007

3. TERMINOLOGY

3.1 *dynamic modulus*, |E*|—the absolute value of the complex modulus calculated by dividing the peak-to-peak stress by the peak-to-peak strain for a material subjected to a sinusoidal loading.

3.2 *phase angle*, δ—the angle in degrees between a sinusoidally applied stress and the resulting strain in a controlled stress test.

3.3 *permanent deformation*—the non-recovered deformation in a repeated-load test.

3.4 *confining pressure*—the stress applied to all surfaces in a confined test.

3.5 *deviator stress*—the difference between the total axial stress and the confining pressure in a confined test.

3.6 *flow number*—the number of load cycles corresponding to the minimum rate of change of permanent axial strain during a repeated-load test.

4. SUMMARY OF METHOD

4.1 This test method describes procedures for measuring the dynamic modulus and flow number for HMA.

4.2 In the dynamic modulus procedure, an HMA specimen at a specific test temperature is subjected to a controlled sinusoidal (haversine) compressive stress of various frequencies. The applied stresses and resulting axial strains are measured as a function of time and used to calculate the dynamic modulus and phase angle.

4.3 In the flow number procedure, an HMA specimen at a specific test temperature is subjected to a repeated haversine axial compressive load pulse of 0.1 s every 1.0 s. The test may be conducted with or without confining pressure. The resulting permanent axial strains are measured as a function of the load cycles and numerically differentiated to calculate the flow number. The flow number is defined as the number of load cycles corresponding to the minimum rate of change of permanent axial strain.

5. SIGNIFICANCE AND USE

5.1 The dynamic modulus is a performance-related property that can be used for mixture evaluation and for characterizing the stiffness of HMA for mechanistic-empirical pavement design.

5.2 The flow number is a property related to the resistance of HMA to permanent deformation. It can be used to evaluate and design HMA with specific resistance to permanent deformation.

6. APPARATUS

6.1 *Specimen Fabrication Equipment*—For fabricating dynamic modulus test specimens as described in PP 60.

6.2 *Dynamic Modulus Test System*—Meeting the requirements of the equipment specification for the Simple Performance Test (SPT) System, Version 3.0.

6.3 *Conditioning Chamber*—An environmental chamber for conditioning the test specimens to the desired testing temperature. The environmental chamber shall be capable of controlling the temperature of the specimen over a temperature range from 4 to 60°C to an accuracy of ±0.5°C. The chamber shall be large enough to accommodate the number of specimens to be tested plus a “dummy” specimen with a temperature sensor mounted in the center for temperature verification.

6.4 *Teflon Sheet*—0.25 mm thick, to be used as a friction reducer between the specimen and the loading platens in the dynamic modulus test.

6.5 *Latex Membranes*—100-mm diameter by 0.3 mm thick, for use in confined tests and for manufacturing “greased double latex” friction reducers to be used between the specimen and the loading platens in the dynamic modulus and flow number tests.

6.6 *Silicone Grease*—Dow Corning "Stopcock Grease" or equivalent, for manufacturing "greased double latex" friction reducers.

6.7 *Balance*—Capable of determining mass to the nearest 0.01 g. The balance is used to determine the mass of silicone grease during fabrication of "greased double latex" friction reducers.

7. HAZARDS

7.1 This practice and associated standards involve handling of hot asphalt binder, aggregates, and HMA. It also includes the use of sawing and coring machinery and servo-hydraulic testing equipment. Use standard safety precautions, equipment, and clothing when handling hot materials and operating machinery.

8. STANDARDIZATION

8.1 Items associated with this practice that require calibration or verification are included in the documents referenced in Section 2.2. Refer to the pertinent section of the referenced documents for information concerning calibration or verification.

9. PROCEDURE A—DYNAMIC MODULUS TEST

9.1 *Test Specimen Fabrication*:

9.1.1 Testing shall be performed on 100-mm diameter by 150-mm tall test specimens fabricated in accordance with PP 60.

9.1.2 Prepare at least two test specimens at the target air void content ±0.5 percent and with the aging condition in accordance with PP 60. Use Table 1 to select an appropriate number of specimens based on the uncertainty that can be tolerated in the analysis.

Note 1—The coefficient of variation for properly conducted dynamic modulus tests is approximately 13 percent. The coefficient of variation of the mean dynamic modulus for tests on multiple specimens is given in Table 1.

Table 1—Coefficient of Variation for Mean of Dynamic Modulus Test on Replicate Specimens

Number of Specimens	Coefficient of Variation for Mean, %
2	9.2
3	7.5
4	6.5
5	5.8
6	5.3
7	4.9
8	4.6
9	4.3
10	4.1

9.2 *Test Specimen Instrumentation (Standard Glued-Gauge-Point System)*:

9.2.1 Attach the gauge points to the specimen in accordance with the manufacturer's instructions.

9.2.2 Confirm that the gauge length is 70 mm ± 1 mm, measured center-to-center of the gauge points.

9.3 *Loading Platens and End-Friction Reducers*:

9.3.1 For the dynamic modulus test, the top platen shall be free to rotate.

9.3.2 Either “greased double latex” or Teflon® end-friction reducers can be used in the dynamic modulus test.

9.3.2.1 Teflon end-friction reducers are made from 0.25-mm thick Teflon sheet, cut to a size slightly larger than the loading platen.

9.3.2.2 “Greased double latex” friction reducers are fabricated from 0.3-mm thick latex membranes as described in Annex A.

9.4 *Procedure*:

9.4.1 *Unconfined Tests*:

9.4.1.1 Place the specimens to be tested in the environmental chamber with the “dummy” specimen and monitor the temperature of the “dummy” specimen to determine when testing can begin.

9.4.1.2 Place platens and friction reducers inside the testing chamber. Turn on the AMPT; set the temperature control to the desired testing temperature, and allow the testing chamber to equilibrate at the testing temperature for at least 1 h.

9.4.1.3 When the “dummy” specimen and the testing chamber reach the target temperature, open the testing chamber. Remove a test specimen from the conditioning chamber and quickly place it in the testing chamber.

9.4.1.4 Assemble the specimen to be tested with platens in the following order from bottom to top: bottom loading platen, bottom friction reducer, specimen, top friction reducer, and top loading platen.

9.4.1.5 Install the specimen-mounted deformation-measuring system on the gauge points per the manufacturer’s instructions. Ensure that the deformation-measuring system is within its calibrated range. Ensure that the top loading platen is free to rotate during loading.

9.4.1.6 Close the testing chamber and allow the chamber temperature to return to the testing temperature.

9.4.1.7 Procedures in Sections 9.4.1.3 through 9.4.1.6, including the return of the test chamber to the target temperature, shall be completed in 5 min.

9.4.1.8 Enter the required identification and control information into the dynamic modulus software.

9.4.1.9 Follow the software prompts to begin the test. The AMPT will automatically unload when the test is complete and will display the test data and data quality indicators.

9.4.1.10 Review the data quality indicators as discussed in Section 9.5. Retest specimens with data quality indicators above the values specified in Section 9.5.

9.4.1.11 Once acceptable data have been collected, open the test chamber and remove the tested specimen.

9.4.1.12 Repeat procedures in Sections 9.4.1.3 through 9.4.1.11 for the remaining test specimens.

9.4.2 *Confined Tests*:

9.4.2.1 Assemble each specimen to be tested with the platens and membrane as follows: place the bottom friction reducer and the specimen on the bottom platen. Stretch the membrane over the specimen and bottom loading platen. Install the lower “o-ring” seal. Place the top friction reducer and top platen on top of the specimen and stretch the membrane over the top platen. Install the upper “o-ring” seal. When performing confined tests, the specimen must be vented to atmospheric pressure through the drainage lines. Ensure that the friction reducers have holes to allow air to be vented from inside the membrane.

9.4.2.2 Encase the “dummy” specimen in a membrane.

9.4.2.3 Place the specimen and platen assembly in the environmental chamber with the “dummy” specimen and monitor the temperature of the “dummy” specimen to determine when testing can begin.

9.4.2.4 Turn on the AMPT; set the temperature control to the desired testing temperature, and allow the testing chamber to equilibrate at the testing temperature for at least 1 h.

9.4.2.5 When the “dummy” specimen and the testing chamber reach the target temperature, open the testing chamber. Remove a test specimen and platen assembly and quickly place it in the testing chamber. When performing confined tests, the specimen must be vented to atmospheric pressure through the drainage lines. Properly connect the drainage lines to the loading platens, and ensure they are vented to atmospheric pressure through the bubble chamber to identify leaks.

9.4.2.6 Install the specimen-mounted deformation-measuring system outside the membrane on the gauge points per the manufacturer’s instructions. Ensure that the deformation-measuring system is within its calibrated range. Ensure that the top loading platen is free to rotate during loading.

9.4.2.7 Close the testing chamber, and allow the chamber temperature to return to the testing temperature.

9.4.2.8 Procedures in Sections 9.4.2.5 through 9.4.2.7, including the return of the test chamber to the target temperature, shall be completed in 5 min.

9.4.2.9 Enter the required identification and control information into the dynamic modulus software.

9.4.2.10 Follow the software prompts to begin the test. The AMPT will automatically unload when the test is complete and will display the test data and data quality indicators.

9.4.2.11 Review the data quality indicators as discussed in Section 9.5. Retest specimens with data quality indicators above the values specified in Section 9.5.

9.4.2.12 Once acceptable data have been collected, open the test chamber and remove the tested specimen.

9.4.2.13 Repeat procedures in Sections 9.4.2.3 through 9.4.2.12 for the remaining test specimens.

9.5 *Computations and Data Quality*:

9.5.1 The calculation of dynamic modulus, phase angle, and the data quality indicators is performed automatically by the AMPT software.

9.5.2 Accept only test data meeting the data quality statistics given in Table 2. Table 3 summarizes actions that can be taken to improve the data quality statistic. Repeat tests as necessary to obtain test data meeting the data quality statistics requirements.

Table 2—Data Quality Statistics Requirements

Data Quality Statistic	Limit
Deformation drift	In direction of applied load
Peak-to-peak strain	75 to 125 μstrain for unconfined tests
	85 to 115 μstrain for confined tests
Load standard error	10%
Deformation standard error	10%
Deformation uniformity	30%
Phase uniformity	3º

Note 2—The data quality statistics in Table 2 are reported by the AMPT. If a dynamic modulus test system other than the AMPT is used, refer to the equipment specification for the Simple Performance Test (SPT) System, Version 3.0, for algorithms for the computation of dynamic modulus, phase angle, and data quality statistics.

Table 3—Troubleshooting Guide for Data Quality Statistics

Item	Cause	Possible Solutions
Deformation drift not in direction of applied load	Gauge points are moving apart	Reduce LVDT spring force. Add compensation springs. Reduce test temperature.
Peak-to-peak strain too high	Load level too high	Reduce load level.
Peak-to-peak strain too low	Load level too low	Increase load level.
Load standard error >10%	Applied load not sinusoidal	Adjust tuning of hydraulics.
Deformation standard error >10%	1. Deformation not sinusoidal 2. Loose gauge point 3. Excessive noise on deformation signals 4. Damaged LVDT	1. Adjust tuning of hydraulics. 2. Check gauge points. Reinstall if loose. 3. Check wiring of deformation sensors. 4. Replace LVDT.
Deformation uniformity >30%	1 Eccentric loading 2. Loose gauge point 3. Sample ends not parallel 4. Poor gauge point placement 5. Non-uniform air void distribution	1. Ensure specimen is properly aligned. 2. Check gauge points. Reinstall if loose. 3. Check parallelism of sample ends. Mill ends if out of tolerance. 4. Check for specimen non-uniformity (segregation, air voids). Move gauge points. 5. Ensure test specimens are cored from the middle of the gyratory specimen.
Phase uniformity >3º	1. Eccentric loading 2, Loose gauge point 3. Poor gauge point placement 4. Damaged LVDT	1. Ensure specimen is properly aligned. 2. Check gauge points. Reinstall if loose. 3. Check for specimen non-uniformity (segregation, air voids). Move gauge points. 4. Replace LVDT.

9.6 *Reporting*:

9.6.1 For each specimen tested, report the following:

9.6.1.1 Test temperature.

9.6.1.2 Test frequency.

9.6.1.3 Confining stress level.

9.6.1.4 Dynamic modulus.

9.6.1.5 Phase angle.

9.6.1.6 Data quality statistics.

9.6.2 Attach the AMPT dynamic modulus test summary report for each specimen tested.

10. PROCEDURE B—FLOW NUMBER TEST

10.1 *Test Specimen Fabrication*:

10.1.1 Testing shall be performed on 100-mm diameter by 150-mm tall test specimens fabricated in accordance with PP 60.

10.1.2 Prepare at least three test specimens at the target air void content ±0.5 percent and with the aging condition in accordance with PP 60.

Note 3—The coefficient of variation for the "permanent deformation before flow" in the flow number test is approximately 15 percent. The coefficient of variation for the flow number is approximately 20 percent. The coefficient of variation of the mean for tests on multiple specimens is given in Table 4.

10.2 *Loading Platens and End-Friction Reducers*:

10.2.1 For the flow number test, the top platen shall not be free to rotate.

10.2.2 Prepare two "greased double latex" end-friction reducers for each specimen that will be tested using the procedure specified in Annex A. It is recommended that new friction reducers be used for each test.

Use Table 4 to select an appropriate number of specimens based on the uncertainty that can be tolerated in the analysis.

Table 4—Coefficient of Variation for Mean of Properties from Flow Number Test

	Coefficient of Variation for Mean, %	
Number of Specimens	Permanent Deformation before Flow	Flow Number
2	10.6	14.1
3	8.7	11.5
4	7.5	10.0
5	6.7	8.9
6	6.1	8.2
7	5.7	7.6
8	5.3	7.1
9	5.0	6.7
10	4.7	6.3

10.3 *Procedure:*

10.3.1 *Unconfined Tests*:

10.3.1.1 Place the specimens to be tested in the environmental chamber with the "dummy" specimen and monitor the temperature of the "dummy" specimen to determine when testing can begin.

10.3.1.2 Place platens and "greased double latex" friction reducers inside the testing chamber. Turn on the AMPT, set the temperature control to the desired testing temperature, and allow the testing chamber to equilibrate at the testing temperature for at least 1 h.

10.3.1.3 When the "dummy" specimen and the testing chamber reach the target temperature, open the testing chamber. Remove a test specimen from the conditioning chamber and quickly place it in the testing chamber.

10.3.1.4 Assemble each specimen to be tested with platens in the following order from bottom to top: bottom loading platen, bottom "greased double latex" friction reducer, specimen, top "greased double latex" friction reducer, and top loading platen.

10.3.1.5 Close the testing chamber and allow the chamber temperature to return to the testing temperature. Ensure that the top loading platen is not permitted to rotate during loading.

10.3.1.6 Procedures in Sections 10.3.1.3 and 10.3.1.5, including the return of the test chamber to the target temperature, shall be completed in 5 min.

10.3.1.7 Enter the required identification and control information into the flow number software.

10.3.1.8 Follow the software prompts to begin the test. The AMPT will automatically unload when the test is complete.

10.3.1.9 Upon completion of the test, open the test chamber and remove the tested specimen.

10.3.1.10 Repeat procedures in Sections 10.3.1.4 through 10.3.1.9 for the remaining test specimens.

10.3.2 *Confined Tests*:

10.3.2.1 Assemble each specimen to be tested with the platens and membrane as follows: place the bottom "greased double latex" friction reducer and the specimen on the bottom platen. Stretch the membrane over the specimen and bottom loading platen. Install the lower “o-ring” seal. Place the top “greased double latex” friction reducer and top platen on top of the specimen, and stretch the membrane over the top platen. Install the upper “o-ring” seal. When performing confined tests, the specimen must be vented to atmospheric pressure through the drainage lines. Make sure that the friction reducers have holes to allow air to be vented from inside the membrane.

10.3.2.2 Encase the “dummy” specimen in a membrane.

10.3.2.3 Place the specimen and platen assembly in the environmental chamber with the “dummy” specimen and monitor the temperature of the “dummy” specimen to determine when testing can begin.

10.3.2.4 Turn on the AMPT, set the temperature control to the desired testing temperature, and allow the testing chamber to equilibrate at the testing temperature for at least 1 h.

10.3.2.5 When the “dummy” specimen and the testing chamber reach the target temperature, open the testing chamber. Remove a test specimen and platen assembly and quickly place it in the testing chamber. When performing confined tests, the specimen must be vented to atmospheric pressure through the drainage lines. Properly connect the drainage lines to the loading platens, and make sure they are vented to atmospheric pressure through the bubble chamber to identify leaks.

10.3.2.6 Close the testing chamber and allow the chamber temperature to return to the testing temperature. Ensure that the top loading platen is not permitted to rotate during loading.

10.3.2.7 Procedures in Sections 10.3.2.5 and 10.3.2.6, including the return of the test chamber to the target temperature, shall be completed in 5 min.

10.3.2.8 Enter the required identification and control information into the flow number software.

10.3.2.9 Follow the software prompts to begin the test. The AMPT will automatically unload when the test is complete.

10.3.2.10 Upon completion of the test, open the test chamber, and remove the tested specimen.

10.3.2.11 Repeat procedures in Sections 10.3.2.5 through 10.3.2.10 for the remaining test specimens.

10.4 *Calculations*:

10.4.1 The calculation of the permanent strain for each load cycle and the flow number for individual specimens is performed automatically by the AMPT.

10.4.2 Compute the average and standard deviation of the flow numbers for the replicate specimens tested.

10.4.3 Compute the average and standard deviation of the permanent strain at the load cycles of interest.

10.5 *Reporting*:

10.5.1 Report the following:

10.5.1.1 Test temperature.

10.5.1.2 Average applied deviatory stress.

10.5.1.3 Average applied confining stress.

10.5.1.4 Average and standard deviation of the flow numbers for the specimens tested.

10.5.1.5 Average and standard deviation of the permanent strain at the load cycles of interest.

10.5.2 Attach AMPT flow number test summary report for each specimen tested.

11. KEYWORDS

11.1 Dynamic modulus; flow number; permanent deformation; phase angle; repeated load testing.

ANNEX A—METHOD FOR PREPARING "GREASED DOUBLE LATEX" END-FRICTION REDUCERS FOR FLOW NUMBER TEST

(Mandatory Information)

A1. PURPOSE

A1.1. This annex presents a procedure for fabricating "greased double latex" end-friction reducers for the flow number test.

A1.2. These end-friction reducers are mandatory for the flow number test.

A2. SUMMARY

A2.1. "Greased double latex" end-friction reducers are fabricated by cutting two circular latex sheets from a latex membrane used for confining specimens, applying a specified mass of silicone grease evenly over one of the latex sheets, then placing the second latex sheet over the first.

A3. PROCEDURE

A3.1. Cut a 0.3-mm-thick latex membrane along its long axis to obtain a rectangular sheet of latex. The sheet will be approximately 315 by 250 mm.

A3.2. Trace the circumference of the loading platen on the sheet of latex; then cut along the tracing to form circular latex sheets that are slightly larger than the loading platen. Four circular latex sheets are needed to fabricate friction reducers for the top and bottom of the specimen.

A3.3. Place one circular latex sheet on the balance, and apply 0.25 ± 0.5 g of silicone grease onto the middle of the latex sheet.

A3.4. Spread the silicone grease evenly over the latex sheet by rubbing in a circular motion from the center to the outside of the sheet.

A3.5. Place the second circular latex sheet on top of the silicone grease.

A3.6. If the friction reducer will be used in confined tests, cut or punch a hole through both latex sheets at the location of the vent in the loading platen.

---

[1] This provisional test method was adopted and first published in 2009. Revised in 2010.

[2] This provisional test method was developed from NCHRP Project 9-29, Simple Performance Tester for Superpave Mix Design. The name of the device has been changed to the “Asphalt Mixture Performance Tester”. To obtain research documents, refer to the Simple Performance Tester.

Standard Method of Test for

Bulk Specific Gravity of Compacted Bituminous Mixtures Using Water Displacement Measured by Pressure Sensor

AASHTO Designation: TP 82-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Bulk Specific Gravity of Compacted Bituminous Mixtures Using Water Displacement Measured by Pressure Sensor

AASHTO Designation: TP 82-10

1. SCOPE

1.1 This test method covers the determination of bulk specific gravity of compacted bituminous mixtures.

1.2 This method can be used with samples that contain open or interconnecting voids or absorb more than 2.0 percent of water by volume, or both (Note 1).

Note 1—Water absorption by volume is determined using T 166; this specification does not contain a direct determination of the water absorption by volume.

1.3 The bulk specific gravity of compacted bituminous mixtures may be used in calculating the unit mass of the mixture.

1.4 The values stated in SI units are to be regarded as the standard. Unit equivalencies are included for reference and informational purposes only.

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 166, Bulk Specific Gravity of Compacted Hot Mix Asphalt (HMA) Using Saturated Surface-Dry Specimens
- T 245, Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus
- T 312, Preparing and Determining the Density of Hot Mix Asphalt (HMA) Specimens by Means of the Superpave Gyratory Compactor

2.2 *ASTM Standard*:

- D 5581, Standard Test Method for Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus (6 inch-Diameter Specimen)

3. TERMINOLOGY

3.1 *bulk specific gravity (of solids)*—the ratio of the weight in air of a unit volume of a permeable material (including both permeable and impermeable voids normal to the material) at a stated temperature to the weight in air of equal density of an equal volume of gas-free distilled water at a stated temperature.

3.2 c*onstant mass*—the mass at which further drying at 52 ± 3°C (125 ±5°F) does not alter the mass by more than 0.05 percent with weighed at 2-h intervals.

---

4. TEST SPECIMENS

4.1 Test specimens may be either laboratory-compacted asphalt mixtures or cylindrical cores sampled from asphalt pavements.

4.2 *Size of Specimens*—It is recommended that: (1) the diameter of cylindrically compacted or cored specimens shall be at least equal to four times the maximum size of the aggregate; and (2) the thickness of specimens be at least one and one-half times the maximum size of the aggregate.

4.3 Specimens shall be (1) compacted in accordance with T 245, T 312, or ASTM D 5581, or (2) taken from asphalt pavements with a core drill, diamond or carborundum saw or by other suitable means. Care shall be taken to avoid distortion or cracking of specimens during and after removal from the mold or pavement. Specimens shall be stored in a cool, safe place.

4.4 Specimens shall be free from foreign materials such as seal coat, tack coat, foundation material, soil, paper, or foil.

4.5 If desired, specimens may be separated from other pavement layers by sawing or other suitable means. Care should be exercised to ensure separation does not damage the specimens.

---

5. APPARATUS

5.1 *Weighing Device*—The weighing device shall have sufficient capacity, be readable to 0.1 percent of the sample mass or better, and conform to the requirements of M 231.

5.2 *Water Displacement Measurement Apparatus*—The water displacement measurement apparatus shall be of sufficient size to accept a 100-mm (4-in.) or 150-mm (6-in.) diameter laboratory-molded or field-cored specimen. It shall have the depth adequate to immerse the bituminous specimen throughout its height. The water displacement measurement apparatus must be capable of calculating and displaying the bulk specific gravity based on the displaced water volume and the dry mass of the asphalt sample within 30 s to avoid the influence of absorbed water during the rapid measurement of displacement.

---

6. STANDARDIZATION

6.1 The water displacement measurement apparatus requires periodic verification. The unit should be verified once each day before bulk specific gravity measurements are taken. Refer to the manufacturer's recommendations for the verification procedure.

---

7. PROCEDURE

7.1 Dry the asphalt specimen to a constant mass (Note 2). Allow the specimen to cool to room temperature, 25 ± 5°C (77 ± 9°F). Weigh and record the dry mass of the specimen to the nearest 0.1 g. Allow the unit to initialize with the appropriate 100-mm (4-in.) or 150-mm (6-in.) sample holder in the chamber. After initialization, enter the dry mass of the asphalt specimen to the nearest 0.1 g on the keypad, and slide the sample holder out of the water. Place the specimen between the holder's rails, and slowly immerse the specimen into the chamber. Samples saturated with water shall initially be dried overnight at 52 ± 3°C (125 ± 5°F) until constant mass is reached. Recently molded laboratory samples, which have not been exposed to moisture, do not require drying.

Note 2—Specimens exposed to moisture shall initially be dried overnight in an oven at 52 ± 3°C (125 ±5°F) to constant mass. Recently molded laboratory samples which have not been exposed to moisture do not require drying.

7.2 Record the bulk specific gravity displayed on the screen of the measurement device, or export the sample data to a printer or computer.

8. REPORT

8.1 *The report shall include the following*:

8.1.1 Bulk specific gravity reported to the nearest 0.001.

9. PRECISION

9.1 Research to develop estimates for the precision of this bulk specific gravity measurement has not been completed.

Standard Method of Test for

Apparent Viscosity of Hot-Poured Bituminous Crack Sealant Using Brookfield Rotational Viscometer RV Series Instrument

AASHTO Designation: TP 85-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Apparent Viscosity of Hot-Poured Bituminous Crack Sealant Using Brookfield Rotational Viscometer RV Series Instrument

AASHTO Designation: TP 85-10

1. SCOPE

1.1 This test method outlines the procedure for measuring the apparent viscosity of hot-poured bituminous crack sealant at elevated temperature from 150 to 200ºC using a rotational viscometer.

1.2 The rotational viscometer is a rotating spindle-type viscometer that meets the requirements of T 316. This test method can be used for general specification and is especially convenient for use in a field laboratory or a plant site.

1.3 *This standard may involve hazardous material, operations, and equipment. This standard does not purport to address all of the safety problems associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the application of regulatory limitations prior to use.*

- SC-6, Method to Evaluate Sealant Extensibility at Low Temperature by Direct Tension Test
- SC-8, Blister Method to Predict the Adhesion of Bituminous Sealants

3. TERMINOLOGY

3.1 *hot-poured crack sealants*—hot-poured modified asphaltic materials used in pavement cracks and joints.

3.2 *apparent viscosity*—the ratio of shear stress to shear rate for a liquid. This parameter is a measure of the resistance to flow of the liquid. The SI unit of viscosity is the Pascal second (Pa·s).

4. SUMMARY OF METHOD

4.1 Crack sealant material is homogenized according to ASTM D 5167, cut into cubes no larger than 5 mm by 5 mm, and placed into standard containers. Apparent viscosity is measured utilizing the Brookfield viscometer using Spindle #SC4-27; the spindle shall be attached to the rigid hook attachment and rotates at the speed of 60 rpm. The test shall be conducted at the manufacturer's recommended installation temperature.

5. SIGNIFICANCE AND USE

5.1 This test is intended for bituminous sealants applied to roadway joints and cracks.

5.2 This procedure is designed to simulate the viscosity of crack sealants while pouring the sealant into the cracks.

5.3 Sealants must be homogenized (ASTM D 5167) before measuring the apparent viscosity by this method.

6. APPARATUS

6.1 Brookfield rotational viscometer RV Series Instrument.

6.2 *Brookfield Thermosel*—Maintaining a temperature ranging from 170 to 193°C ± 1°C.

6.3 *Laboratory Oven*—Any laboratory standard oven capable of producing and maintaining a temperature ranging from 170 to 193°C ± 1°C.

6.4 Rigid hook attachment especially designed as an attachment in Brookfield viscometer to measure hot-poured crack sealant viscosity.

6.5 Disposal aluminum containers or standard Brookfield containers.

6.6 The rotational viscometer contains sensors that monitor the applied torque and automatically displays the calculated apparent viscosity. The keypad on the instrument is used to enter the spindle number, zero the signal, and run the test at a selected speed. Torque and viscosity can be recorded manually, or an interface can be used to send the signal from the instrument to a personal computer. Optional software is also available that can be used to program preselected thermal profiles. This software is not needed for the specification test. However, the Thermosel must be used to control the temperature and thereby obtain acceptable reproducibility.

7. HAZARDS

7.1 Standard laboratory caution should be used in handling hot sealant in accordance with ASTM D 5167, and when using the Brookfield Thermosel. Required safety procedures should be followed when chemical agents are used.

8. PREPARATION OF APPARATUS

8.1 The rotational viscometer must be leveled to function properly. A bubble-type level is normally located on top of the viscometer and is adjusted by using leveling screws located on the base. Preparing the device, leveling and aligning of the viscometer on the stand, and setting the temperature of the Thermosel are explained in the operation instructions provided by the manufacturer. The detailed steps for testing are specified in the T 316.

9. CALIBRATION AND STANDARDIZATION

9.1 Temperatures of the ovens should be calibrated in accordance with each user’s quality assurance program.

9.2 Thermometer (temperature detector) should be calibrated every 6 months to ensure precision of ±1°C.

9.3 The accuracy of the viscometer should be checked annually using a certified reference fluid of known viscosity following the procedure recommended by the manufacturer.

10. PREPARATION OF SAMPLES AND TEST SPECIMENS

10.1 All apparent viscosity measurements must be performed on homogenized sealant. Sealant homogenization is conducted in accordance with the procedure presented in ASTM D 5167.

10.2 Once homogenized, hot sealant should be cooled down to room temperature and stored for 24 hours before usage. It is recommended that a can or plastic-lined box be used as a container during the cool-down period. The container must be of sufficient size so that the sealant depth is no greater than 100 mm to allow for rapid cooling.

10.3 Cut 10.5 g of the homogenized sealant into small cubes no larger than 5 mm by 5 mm, and place the cubes in aluminum chambers. Disposable chambers installed in the Thermosel shall be used.

10.4 Preheat Thermosel to test temperature and, unless otherwise noted, use the temperature recommended by the manufacturer.

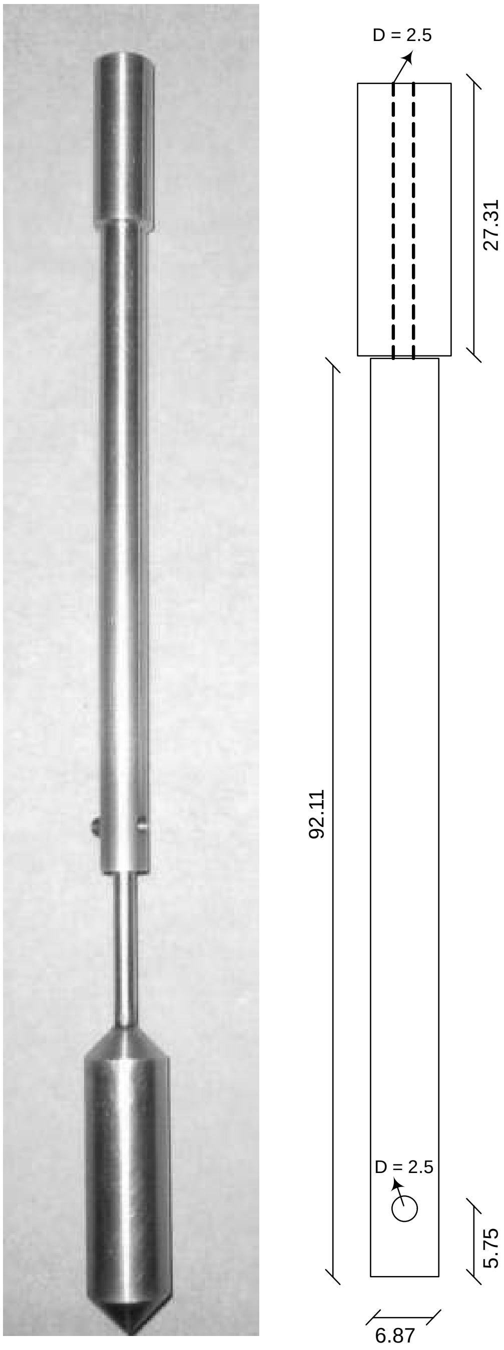
10.5 Place aluminum chamber containing sealant in Thermosel.

10.6 Turn on the viscometer and zero it.

10.7 Allow 5 minutes for sealant to melt.

10.8 Assemble spindle #SC4-27 and attach the spindle to a rigid rod (see Note 1).

Note 1—The current hook which is used for asphalt cement should not be applied to asphalt binder that contains rubber fillers, which would affect the spindle's rotation. Figures 1 through 3 illustrate the spindle and the rigid rod.



(a) (b)

Figure 1—(a) Rigid rod with Spindle Assembled, (b) Schematic of Rigid Rod

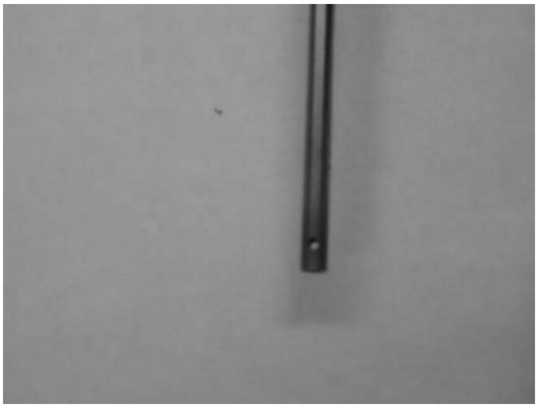


Figure 2—Lower Opening of 2.5 mm to Screw the Spindle to the Rigid Rod

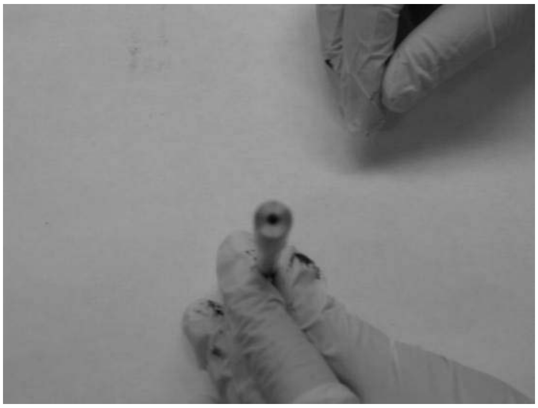

Figure 3—Upper Opening of 2.5 mm to Screw the Rod to the Viscometer Head

10.9 Allow 20 minutes to stabilize the temperature; adjust stirring speed of the spindle to 60 rpm.

10.10 Start testing and record the data right after 30 seconds of stirring. After the data are recorded, stop the test, clean the spindle, and remove the aluminum chamber.

10.11 Insert the next specimen and repeat steps 10.5 to 10.10 until four replicates are tested for each sealant.

11. CALCULATION OF RESULTS

11.1 The viscosity is reported as the average of the best three out of four readings. The Brookfield viscometer measures the apparent of viscosity in centipoise. The measured viscosity may be converted to Pascal seconds by using the conversion factor 1 cps = 0.001 Pa·s.

12. REPORT

12.1 *Report the following information*:

12.1.1 Sealant identification and supplier,

12.1.2 Lot number,

12.1.3 Date received,

12.1.4 Date of apparent viscosity measurement,

12.1.5 Recommended pouring temperature,

12.1.6 Safe heating temperature, and

12.1.7 Any deviations from test temperature.

13. PRECISION AND BIAS

13.1 *Single-Operator Precision (Repeatability)*—The figures in Column 2 of Table 1 are the coefficient of variation that have been found to be appropriate for the conditions of the test described in Column 1. Two results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the value given Table 1, Column 3.

13.2 *Multilaboratory Precision (Reproducibility)*—The figures in Column 2 of Table 1 are the coefficient of variation that have been found to be appropriate for the conditions of the test described in Column 1. Two results submitted by two different operators testing the same material in different laboratories shall not be considered suspect unless the difference in the two results, expressed as percent of their mean, exceeds the values given in Table 1, Column 3.

13.3 The rotational viscometer test is T 316. The reader is referred to the standard method for points of caution and details regarding the test method.

13.4 Viscosity data obtained with this test method are used to ensure crack sealant's apparent viscosity is low enough to fill cracks and, at the same time, high enough not to flow out of the crack. Ideally, the shear rates during the test should match the shear rates sealant experiences during installation. The rotational speed of the spindle was selected at 60 rpm to resemble field pouring conditions. Changing spindle sizes and rotational speeds affect both the shear rate and the measured apparent viscosity.

13.5 Data should be collected after a specific rotation time. Excessive mixing may cause segregation, especially in the case of a rubber-modified sealant.

13.6 Excessive heating may cause volatiles to be lost from the sample or polymer chains to be degraded, both of which lead to a reduction in measured apparent viscosity. In general, during testing, the sample should not be heated to temperatures greater than the pouring temperature recommended by the manufacturer.

Table 1—Precision Estimates

Condition	Coefficient of Variation, (1s%)[a]	Acceptable Range of Three Test Results, (d2s%)[a]
Single-Operator Precision:		
Average Viscosity (Pa·s)	1.62	5.4[b]
Multilaboratory Precision:		
Average Viscosity (Pa·s)	5.90	16.9

[a] The precision estimates given in Table 1 are based on the analysis of test results from seven sealants with a wide range of rheological properties. The data analyzed include results from seven laboratories that conducted each test in four replicates.

[b] As an example, two tests conducted on the same material yield viscosity results of 3.12, 3.05, 3.15 Pa·s, respectively. The average of these three measurements is 3.11 Pa·s. The acceptable range of results is then 5.4 percent of 3.11 or 0.17 Pa·s. As the greatest difference between each two, 0.1 is less than 0.17, the results are within the acceptable range.

14. KEYWORDS

14.1 Apparent viscosity rotational viscometer; crack; fillers; hot-poured bituminous sealant; joint.

Standard Method of Test for

Accelerated Aging of Bituminous Sealants and Fillers with a Vacuum Oven

AASHTO Designation: TP 86-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Accelerated Aging of Bituminous Sealants and Fillers with a Vacuum Oven

AASHTO Designation: TP 86-10

1. SCOPE

1.1 This method applies to bituminous crack sealants and fillers used in the construction and maintenance of roadways.

1.2 The method covers the accelerated aging of the bituminous materials by means of elevated temperatures and vacuum.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish and follow appropriate health and safety practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

- SC-6, Test Method to Evaluate Sealant Extensibility at Low Temperature by Direct Tension Test
- SC-8, Blister Method to Predict the Adhesion of Bituminous Sealants

3. TERMINOLOGY

3.1 *bituminous sealants and fillers*—polymer- or rubber-modified bitumens most often formulated with a mineral filler.

4. SUMMARY OF METHOD

4.1 Crack sealant material is placed in a stainless steel pan and aged at 115°C for 16 hours under a vacuum of 29.9 in. of mercury.

5. SIGNIFICANCE AND USE

5.1 This procedure is designed to simulate the aging and weathering of bituminous sealants and fillers.

5.2 Materials aged with this procedure are best used to evaluate sub-zero characteristics.

5.3 For materials with different bitumen source, polymer grade, and filler types and content, there is no unique correlation between the accelerated conditions and the time of in-service weathering. The accelerated aging leads to sealant rheology typical of sealants weathered 1 to 10 years in the field.

5.4 Sealants must be remixed before being aged by this method.

6. APPARATUS

6.1 *Vacuum Oven*—Oven with a vacuum valve, a bleed valve, and a pressure gauge in inches of mercury. The oven must be capable of maintaining a vacuum of 29.9 in. of mercury and a uniform temperature of 115 ± 1°C. Refer to ASTM E 145 to verify temperature uniformity. The oven should be of a size sufficient to accommodate a minimum of eight sample pans of 6 in. on two shelves.

6.2 *Vacuum Pump*—A one or two-stage mechanical pump capable of achieving a vacuum of 99.9 percent or better in 10 minutes or less. See Note 1.

Note 1—At sea level, the achievable vacuum is 29.92 in. of mercury. See the appendix for the effect of elevation on the achievable vacuum reading.

6.3 *Laboratory Oven*—Calibrated Type IIA oven specified in ASTM E 145. This oven can produce and maintain a temperature of 180 ± 0.5°C.

6.4 *Stainless Steel Pans*—Pans of sufficient dimensions such that 30 g of melted sealant will provide a film about 2 mm thick. See Note 2.

Note 2—PAV pans, used in ASTM D 6521, work well for the purpose of Section 6.4.

7. HAZARDS

7.1 Standard laboratory caution should be used in handling and remixing hot sealant in accordance to ASTM D 5167.

8. VERIFICATION AND CALIBRATION

8.1 Temperature and vacuum control of the ovens should be calibrated according to each user's quality assurance program.

8.2 *Temperature Detector*—Verify the calibration of the temperature-sensing device to 0.1°C every 6 months.

8.3 *Vacuum Gauge*—Calibrate the vacuum gauge to an accuracy of 1percent every 6 months.

8.4 Verify that the sought temperature is obtained within 1 hour after the application of vacuum. An example is shown in Figure 1.

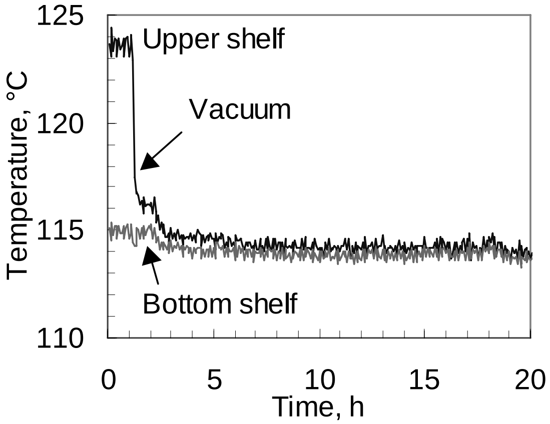

Figure 1—Typical Change in Temperature over Time at a Top and Bottom Shelf of a Vacuum Oven before and after Evacuation

9. PREPARATION

9.1 Apply vacuum and preheat the vacuum oven to 115 ± 1°C. This typically takes 2 to 4 hours.

9.2 Preheat the laboratory oven to 180 ± 5°C.

9.3 Remix 400 to 500 g of material according to ASTM D 5176. Pour 30 ± 0.5 g of hot material into a stainless steel pan. This provides a sealant film about 2 mm thick. See Note 3.

Note 3—At the same time, samples can be poured for other tests, including the tracking test (TP 85 [SC-2]), the low-temperature tests (TP xx [SC-4] and TP 87 [SC-5]), and the adhesion test (TP 88 [SC-6]).

10. PROCEDURE

10.1 Close the vacuum valve on the vacuum oven and slowly open the bleed valve. Once atmospheric pressure is reached, open the door and place the sealant pan in the oven. The oven door must be left opened for less than 1 minute. Re-apply vacuum by opening the vacuum valve. See Note 4.

Note 4—During this step, the vacuum pump must be left running.

10.2 Start timing once the vacuum has reached 29 in. of mercury. Maintain a vacuum better than 29 in. of mercury and a temperature of 115 ± 1°C for 16 hours ± 10 minutes.

10.3 After 16 hours, slowly release the vacuum with the bleed valve, and transfer the pan to the oven preheated to 180°C. Heat the sealant for 5 minutes or until it is sufficiently fluid to pour into shape for the tests according to SC-2, SC-4, SC-5, or SC-6. Pans may be scraped to collect maximum amount of sealant. See Note 5.

Note 5—Allow 24 hours at room temperature before an evaluation of the properties according to TP xx, TP 87, or TP 88 [SC-4, SC-5, or SC-6].

11. REPORT

11.1 *Report the following information*:

11.1.1 Sealant name and supplier,

11.1.2 Lot number, date received,

11.1.3 Date aged,

11.1.4 Aging temperature and vacuum,

11.1.5 Total aging time in hours and minutes, and

11.1.6 Any deviations from test temperature and vacuum.

12. PRECISION AND BIAS

12.1 The precision and the bias for this method of test have not been measured.

13. KEYWORDS

13.1 Aging; cracks; guidelines; joints; maintenance; pavement; roadways; sealant; specification.

APPENDIX

(Nonmandatory Information)

X1. EFFECT OF ELEVATION ON THE ACHIEVABLE VACUUM READING

X1.1. The vacuum reading on the oven gauge depends on the atmospheric pressure outside the oven, which depends on elevation (excluding the effect of weather on pressure). The maximum achievable vacuum reading (P) at an elevation h is given by

$$P(h) = P_0 \exp(-mgh/kT)$$

where:

P_0 = the pressure at sea level,
m = the average molar mass of dry air,
g = the acceleration due to gravity,
k = the Boltzmann constant, and
T = the temperature in Kelvin.

X1.2. Considering a laboratory temperature of 22°C and vacuum readings in inches of mercury, the above equation can be simplified to

$$P(h) = 29.92 \exp(-hc)$$

where:

h = the elevation in ft, and
c = 0.000351 ft^{-1}.

If the elevation is taken in meters, *c* is 0.0001151 m^{-1}.

As examples, in Denver, CO, the elevation is 5433 ft and the maximum attainable vacuum is 24.7 in Hg. In Edmonton, AB, with an elevation of 650 m, the achievable vacuum is 27.8 in Hg; and in Ottawa, ON, the elevation is 188 m, so the achievable vacuum is 29.3 in Hg.

---

[1] These standards were developed through a pooled-fund study sponsored by several AASHTO member departments, the University of Illinois, Virginia Polytechnic Institute and State University (Virginia Tech), and the National Research Council of Canada. The Sealant Consortium is the designation given to this pooled-fund study. For availability of the individual research reports, see Section 14, References.

Standard Method of Test for

Measure Low-Temperature Flexural Creep Stiffness of Bituminous Sealants and Fillers by Bending Beam Rheometer (BBR)

AASHTO Designation: TP 87-10

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Method of Test for

Measure Low Temperature Flexural Creep Stiffness of Bituminous Sealants and Fillers by Bending Beam Rheometer (BBR)

AASHTO Designation: TP 87-10

1. SCOPE

1.1 This method applies to bituminous sealants used in the construction and maintenance of roadways.

1.2 The method is used to determine the bituminous sealant flexural stiffness. It can be used on unaged material or on material aged using TP 86. The test apparatus is designed for testing within the temperature range from –4 to –40°C.

1.3 The values stated in SI units are to be regarded as the standard.

1.4 This standard covers the determination of flexural stiffness in bituminous sealants using the bending beam rheometer and by conducting the creep test.

3. TERMINOLOGY

3.1 *bituminous sealants*—hot-poured modified asphaltic materials used in pavement cracks and joints.

3.2 *Definitions of Terms Specific to This Standard*:

3.2.1 *contact load, n*—the load, P_c, required to maintain positive contact between the test specimen, supports, and the loading shaft, 35 ± 10 mN.

3.2.2 *flexural creep compliance, D(t), n*—the ratio obtained by dividing the maximum bending strain in a beam by the maximum bending stress. The flexural creep stiffness is the inverse of the flexural creep compliance.

3.2.3 *flexural creep stiffness, S(t), n*—the creep stiffness obtained by fitting a second order polynomial to the logarithm of the measured stiffness at 8.0, 15.0, 30.0 60.0, 120.0, and 240.0 seconds and the logarithm of time.

3.2.4 *measured flexural creep stiffness,* $S_m(t)$, *n*—the ratio obtained by dividing the measured maximum bending stress by the measured maximum bending strain. Flexural creep stiffness has been used historically in asphalt technology while creep compliance is commonly used in studies of viscoelasticity.

3.2.5 *average creep rate*—the average creep rate obtained by fitting the power law model of the logarithm of the strain versus the logarithm of time. The average creep rate is the absolute value of the exponents of the power law model.

3.2.6 *test load, n*—the load, P_t, of 240 seconds duration is used to determine the stiffness of the crack sealant being tested, 980 ± 50 mN.

---

4. SUMMARY OF PRACTICE

4.1 The bending beam rheometer is used to measure the midpoint deflection of a simply supported prismatic beam of bituminous crack sealant subjected to a constant load applied to the midpoint of the test specimen. The device operates only in the loading mode.

4.2 A prismatic test specimen is placed in the controlled temperature fluid bath and loaded with a constant test load for 240.0 seconds and unloaded for 480.0 seconds. The test load (980 ± 50 mN) and the midpoint deflection of the test specimen are monitored versus time using a computerized data acquisition system.

5. SIGNIFICANCE AND USE

5.1 This test is intended for bituminous sealants applied to roadway joints and cracks.

5.2 The test temperature is determined as the lowest temperature experienced by the pavement surface in the geographical area for which the sealant is intended.

5.3 The flexural creep stiffness or flexural creep compliance, determined from this test, describes the low-temperature stress-strain-time response of crack sealant at the test temperature.

5.4 The average creep rate determined from this test gives an indication of the rate of deformation of crack sealant at the test temperature.

5.5 Sealants must be homogenized before being used to conduct this test.

6. APPARATUS

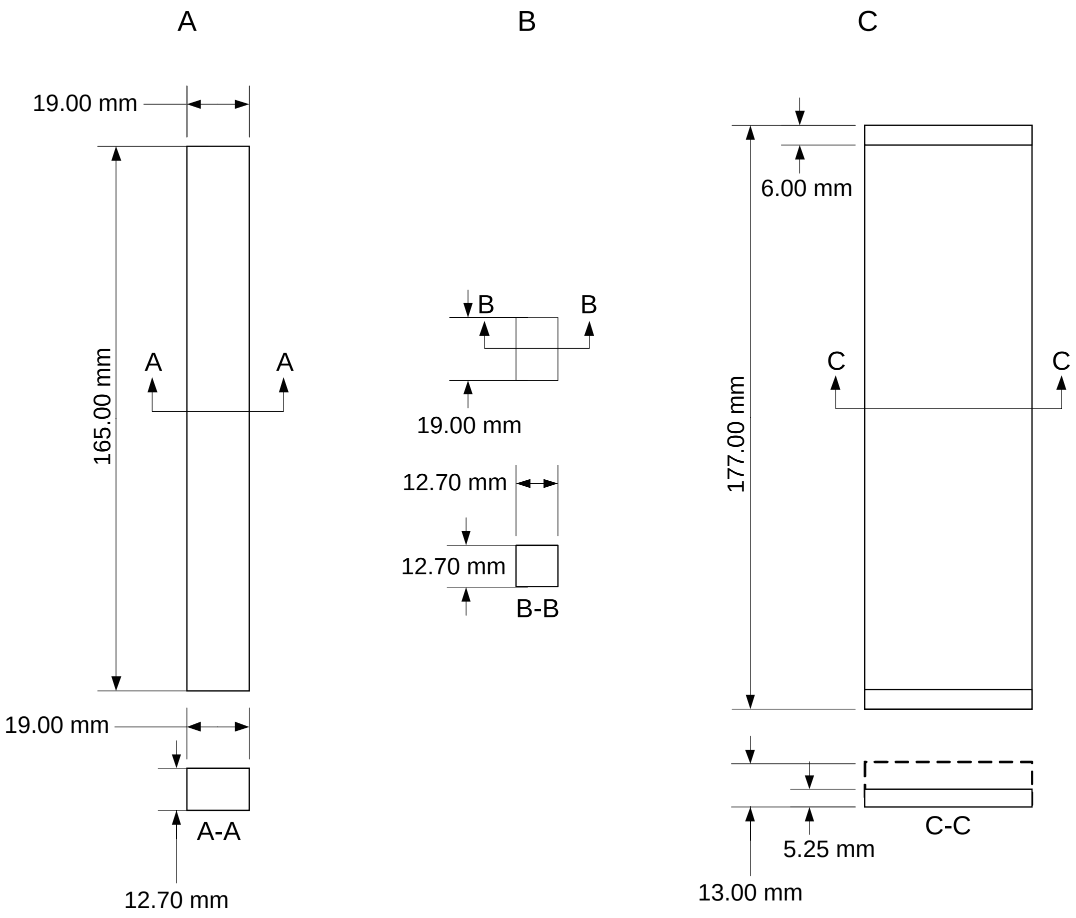
6.1 A crack sealant bending beam rheometer (CSBBR) test system consists of the following: (1) a modified bending beam rheometer with a controlled temperature liquid bath that maintains the test specimen at the test temperature, (2) test specimen molds, and (3) items for verifying and calibrating the system.

6.2 *Modified Bending Beam Rheometer*—A CSBBR is modified from a typical BBR. The CSBBR has a modified loading frame system that can accommodate a specimen 12.7 mm in height to operate a three-point bending beam test that applies a constant test load for 240.0 seconds and unloads for 480.0 seconds. The specification required by the CSBBR system is in accordance with T 313. The updated version software can be obtained from the instrument manufacturer.

6.3 *Test Specimen Molds*—Test specimen molds with interior dimensions of 12.70 ± 0.05 mm wide by 12.70 ± 0.05 mm deep by 102.0 ± 0.5 mm long and fabricated from aluminum or stainless steel (Figure 1).

6.3.1 The thickness of the two spacers used for each mold (small end pieces used in the metal molds) shall be measured with a micrometer and shall not vary from each other in thickness by more than 0.05 mm.

Note 1—Small errors in the thickness of the test specimen can have a significant effect on the calculated stiffness because the calculated stiffness is a function of the thickness, h, raised to the third power.



IT	QTY	DESCRIPTION
A	2	Side Bar
B	2	Spacer Bar
C	1	Bottom Plate

Figure 1—Dimension for Crack Sealant Bending Beam Rheometer Mold and Modified Specimen Support

6.4 *Items for Calibration*—Items remain the same as T 313 except for the thickness dimension of the stainless steel beam used for calibration. The new calibration kits can be obtained from the instrument manufacturer.

6.5 *Calibrated Thermometers*—Calibrated liquid-in-glass thermometers to verify the temperature transducer of suitable range with subdivisions of 0.1°C.

6.6 *Laboratory Ovens*—Two standard laboratory ovens capable of producing and maintaining a temperature of 200 ± 0.5°C.

7. REAGENTS AND MATERIALS

7.1 *Bath Fluid*—A bath fluid that is not absorbed by or does not affect the properties of the crack sealant being tested. The bath fluid shall be optically clear at the test temperature.

7.2 *Binder Clip*—A binder clip is used to hold the aluminum mold to maintain the size of the sample to prevent shrinkage during sealant cooling.

7.3 *Release Agent*—A proper release agent prevents bituminous crack sealant from sticking to the mold. Using a spray type silicon-based release agent is recommended.

7.4 *Solvent*—A solvent can properly clean the molds, end tabs, and plates. The parts cleaned by the solvent shall be submerged in the ethanol prior to use. Cleaning ensures the proper bond between sealant and end tabs.

7.5 *Cleaning Cloths*—Cloths for wiping molds, end tabs, and plates.

8. HAZARDS

8.1 Standard laboratory caution should be used in handling hot bituminous sealant in accordance with ASTM D 5167, and required safety procedures should be followed when chemical agents are used.

9. VERIFICATION AND CALIBRATION

9.1 *Bending Beam Rheometer (BBR)*—Follow the procedure as stated in T 313.

9.2 *Oven and Freezer*—Calibrate the temperature with a thermometer that meets the requirements of ASTM E 1. The thermometer calibration can be verified according to ASTM E 77.

10. SAMPLES PREPARATION

10.1 *Preparation of Molds*:

10.1.1 Spread a very thin layer of release agent on the interior faces of four mold sections to prevent the crack sealant from sticking to the metal end pieces. Assemble the mold and use binder clips to hold the pieces of the mold together.

10.1.2 Preheat the oven to a temperature 50°C lower than recommended pouring temperature at least 1 hour before testing. Place the mold on the ceramic tiles into the oven 15 minutes before pouring the crack sealant.

10.2 *Preparation of Test Specimens*:

10.2.1 Laboratory-aged samples shall be obtained in accordance with appropriate test methods.

10.2.2 Heat four cans of bituminous crack sealant, which contain 35 g of bituminous sealant each, in an oven set at the sealant manufacturer-recommended pouring temperature until the sealant is sufficiently fluid to pour. (Do not heat the sealant more than 30 minutes.) Each can of sealant will be poured into its own mold.

10.3 *Molding Test Specimens*—Prepare four replicates for each tested sealant. Prior to pouring the sealant, take one preheated mold and one ceramic tile from the oven. With the preheated mold on the ceramic tile, firmly stir the sealants prior to pouring into the molds to ensure the homogeneity of the sealant. Begin pouring the sealant from one end of the mold and move toward the other end, slightly overfilling the mold. When pouring, hold the sample container 20 to 30 mm from the top of the mold, pouring continuously toward the other end in a single pass. Repeat the same procedure for the other three molds. With the filled mold still on the preheated ceramic tile, allow to cool for 1 hour to room temperature. After cooling to room temperature, trim the exposed face of the cooled specimens even with the top of the mold using a hot knife.

10.4 *Storing and Demolding Test Specimens*:

10.4.1 Store all test specimens in their molds at room temperature prior to testing. Testing shall be completed within 4 hours after specimens are poured.

10.4.2 Just prior to demolding, cool the molds containing the test specimens in a cold fluid bath that has the same temperature as the selected test temperature for no longer than 5 minutes and only long enough to stiffen the test specimen so that it can be readily demolded without distortion. A 15-minute interval between each sample is desired prior to placing the sample into the cold chamber bath. Do not cool the molds containing the specimens in the test bath because it may cause temperature fluctuations in the bath to exceed ±0.2°C.

10.4.3 Immediately demold the specimen when it is sufficiently stiff to demold without distortion, by disassembling the mold. To avoid distorting the specimen, demold the specimen by sliding the metal side pieces from the specimen.

Note 2—During demolding, handle the specimen with care to prevent distortion. Full contact at specimen supports is assumed in the analysis. A warped test specimen may affect the measured stiffness.

11. PROCEDURE

11.1 All sealants to be tested must undergo the aging process. Follow the procedure described TP 86. It is recommended that a minimum of 150 g of bituminous sealant be prepared for a set of tests.

11.2 Select the appropriate test temperature for the crack sealant specimen. After demolding, immediately place the test specimen in the testing bath and condition it at the testing temperature. The test specimen shall remain submerged in the bath fluid at the test temperature ±0.1°C for the entire 60 ± 5 minutes.

11.3 Check the adjustment of the contact load and test load prior to testing each set of test specimens. The 12.7-mm thick stainless steel beam shall be used for checking the contact load and test load.

11.3.1 Place the 12.7-mm steel beam in position on the beam supports. Using the test load regulator valve, gently increase the force on the beam to 980 ± 50 mN.

11.3.2 Switch from the test load to the contact load and adjust the force on the beam to 35 ± 10 mN. Switch between the test load and contact load four times to ensure that the load is stable.

11.3.3 When switching between the test load and contact load, watch the loading shaft and platform for visible vertical movement. The loading shaft shall maintain contact with the steel beam when switching between the contact load and test load, and the contact load and test load shall be maintained at 35 ± 10 mN and 980 ± 50 mN, respectively.

11.4 Enter the specimen identification information, including the elapsed time the specimen has been conditioned in bath at the test temperature, and other information, as appropriate, into the computer that controls the test system.

11.5 After conditioning, place the test specimen on the test supports and gently position the back side of the test specimen against the alignment pins. Initiate the test.

11.6 The bath temperature shall be maintained at the selected test temperature ±0.1°C during the test; otherwise the test shall be rejected.

11.7 The contact load shall be applied by gently increasing the load to 35 ± 10 mN. While applying the contact load, the load on the beam shall not exceed 45 mN, and the time to apply and adjust the contact load shall be no greater than 10 seconds.

11.8 With the contact load applied to the test specimen, activate the automatic test system, which is programmed to proceed as follows:

11.8.1 Apply a 980 ± 50 mN seating load for 1 ± 0.1 seconds.

11.8.2 Reduce the load to the 35 ± 10 mN contact load, and allow the test specimen to recover for 480 ± 0.1 seconds. At the end of the test, the operator shall monitor the computer screen to verify that the load on the test specimen returns to 35 ± 10 mN. If it does not, the test shall be rejected.

11.8.3 Apply a 980 ± 50 mN test load to the test specimen. The software shall record the test load at 0.5-second intervals from 0.5 to 240 seconds and calculate the average of the recorded load values. Between 0.5 and 5 seconds, the test load shall be within ±50 mN of the average test load and, for the remaining times, within ±10 mN of the average test load. The actual load on the test specimen as measured by the load cell shall be used to calculate the stress in the test specimen.

11.8.4 Remove the test load, return to the 35 ± 10 mN contact load, and collect the data for 480 seconds.

11.8.5 Remove the specimen from the supports and proceed to the next test.

12. CALCULATIONS

12.1 *Deflection of an Elastic Beam*—Using the elementary bending theory, the midspan deflection of an elastic prismatic beam of constant cross section loaded in three-point loading can be obtained by applying Equations 1 and 2 as follows:

$$\delta = PL^3/48EI \qquad (1)$$

where:

δ = deflection of beam at midspan, mm;

P = load applied, N;

L = span length, mm;

E = modulus of elasticity, MPa; and

I = moment of inertia, mm^4.

and

$I = bh^3/12$ *(2)*

where:

b = width of beam, mm; and

h = thickness of beam, mm.

Note 3—The test specimen has a span-to-depth ratio of 10 to 1, and the contribution of shear to deflection of the beam can be neglected.

12.2 *Elastic Flexural Modulus*—According to elastic theory, calculates the flexural modulus of a prismatic beam of constant cross section loaded at its midspan. Therefore:

$E = PL^3/4bh^{3\delta}$ *(3)*

where:

E = flexural creep stiffness, MPa;

P = load, N;

L = span length, mm;

b = width of beam, mm;

h = depth of beam, mm; and

δ = deflection of beam, mm.

12.3 *Maximum Bending Stress*—The maximum bending stress occurs at the top and bottom of the beam at its midspan. Therefore:

$\sigma = 3PL/2bh^2$ *(4)*

where:

σ = maximum bending stress in beam, MPa;

P = constant load, N;

L = span length, mm;

b = width of beam, mm; and

h = depth of beam, mm.

12.4 *Maximum Bending Strain*—The maximum bending strain in the beam occurs at the top and bottom of the beam at its midspan. Therefore:

$\in = 6\delta h/L^2$ mm/mm *(5)*

where:

$\in$ = maximum bending strain in beam, mm/mm;

δ = deflection of beam, mm;

h = thickness of beam, mm; and

L = span length, mm.

12.5 *Linear Viscoelastic Stiffness Modulus*—According to the elastic-viscoelastic correspondence principle, it can be assumed that if a linear viscoelastic beam is subjected to a constant load applied at $t = 0$ and held constant, the stress distribution in the beam would be the same as that in a linear elastic beam under the same load. Further, the strains and displacements depend on time and are derived from those of the elastic case by replacing E with $1/D(t)$. Since $1/D(t)$ is numerically equivalent to $S(t)$, rearranging the elastic solution results in the following relationship for stiffness:

$$S(t) = PL^3/4bh^3\delta(t) \qquad (6)$$

where:

$S(t)$ = time-dependent flexural creep stiffness, MPa;
P = constant load, N;
L = span length, mm;
b = width of beam, mm;
h = depth of beam, mm;
$\delta(t)$ = deflection of beam, at time t, mm; and

$\delta(t)$ and $S(t)$ indicate that the deflection and stiffness, respectively, are functions of time.

13. REPORT

13.1 *Report the following information*:

13.1.1 Sealant name and supplier;

13.1.2 Test sample ID;

13.1.3 Date of aging (dd/mm/yy);

13.1.4 Date of test (dd/mm/yy);

13.1.5 Time of demolding (hour, minute);

13.1.6 Time of conditioning (hour, minute);

13.1.7 Time test load applied for each sample (hour, minute);

13.1.8 Test temperature;

13.1.9 Maximum and minimum temperature during the test;

13.1.10 Any deviations from test load and temperature;

13.1.11 Measured stiffness modulus; and

13.1.12 Average creep rate.

14. PRECISION AND BIAS

14.1 Confidence intervals of 95 percent should be constructed around the average of the calculated stiffness from the results of the four replicates. The closest three measurements will then be used to calculate the coefficient of variation while the fourth replicate will be discarded. A coefficient of variation less than 10 percent is desirable.

15. KEYWORDS

15.1 Average creep rate; crack; creep compliance; direct tension test; hot-poured bituminous sealant; joint; stiffness.

[1] These standards were developed through a pooled-fund study sponsored by several AASHTO member departments, the University of Illinois, Virginia Polytechnic Institute and State University (Virginia Tech), and the National Research Council of Canada. The Sealant Consortium is the designation given to this pooled-fund study. For availability of the individual research reports, see Section 16, References.

Standard Method of Test for

Evaluation of the Low-Temperature Tensile Property of Bituminous Sealants by Direct Tension Test

AASHTO Designation: TP 88-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Evaluation of the Low-Temperature Tensile Property of Bituminous Sealants by Direct Tension Test

AASHTO Designation: TP 88-10

1. SCOPE

1.1 This test method applies to bituminous sealants used in the construction and maintenance of roadways.

1.2 The test method is used to determine the extensibility and strain energy density (SED) of sealants at low temperature. It can be used with un-aged material or with material aged using TP 86. The test apparatus is designed for testing within the temperature range from –4 to –40°C.

1.3 This standard covers the determination of extensibility and percent modulus decay in bituminous sealants with the use of direct tension testing and by applying the tensile stress-strain test.

3. TERMINOLOGY

3.1 *bituminous sealants*—hot-poured modified asphaltic materials used in pavement cracks and joints.

3.2 *effective gauge length*—elongation of a standard dog bone-shaped test specimen due to an applied axial load P is equivalent to that of a simple rectangular specimen with the same cross-sectional dimensions of the restricted section. Effective gauge length, L_e, is defined as the length of the simple rectangular specimen and has been determined to be 20.3 mm.

3.3 *tensile stress*—tensile load divided by the true area of cross section of the specimen.

3.4 *tensile strain*—change in the effective gauge length by the application of tensile load divided by the original unloaded effective gauge length.

3.5 *brittle material*—the stress-strain curve is linear up to fracture at about 1 to 2 percent elongation.

3.6 *brittle-ductile material*—the stress-strain curve is curvilinear and the stress is gradually reduced after the peak point. The failure happens by gradually breaking the molecular bond within the material.

3.7 *ductile material*—the material does not rupture in the direct tension test but elongates due to high strain.

3.8 *rubbery behavior*—materials that exhibit rubbery behavior can be stretched to extreme elongation without rupture.

3.9 *percent modulus decay*—the percentage modulus deduction after 10 seconds of loading.

---

4. SUMMARY OF PRACTICE

4.1 This practice contains the procedure to measure the extensibility and the strain energy density of a bituminous sealant or filler using direct tension test (DTT). The material is bonded between two end tabs made of Plexiglas and subjected to a constant strain rate at a specific temperature.

4.2 The test method is developed to select the bituminous sealant at temperatures where they exhibit rubbery behavior.

4.3 A linear variable differential transformer (LVDT) is used to measure the elongation of the test specimen as it is pulled in tension at a constant strain rate of 6 percent/minute (1.2 mm/minute). A load cell is used to monitor the load during the test. The stress and strain at the point of rupture or peak load are reported.

5. SIGNIFICANCE AND USE

5.1 This test is intended for bituminous sealants applied to roadway joints and cracks.

5.2 The test temperature is determined to be the lowest temperature experienced by the pavement surface in the geographical area for which the sealant is intended.

5.3 The sealant extensibility is a parameter of the capacity of sealant to sustain large deformations due to crack expansion at low temperature without fracture.

5.4 The percent modulus decay is an indication of how fast the sealant can release the imposed loading. A higher percentage decay represents that the sealant can relax the load faster.

5.5 This method is intended for aged sealants, which could become stiffer or softer with age.

6. APPARATUS

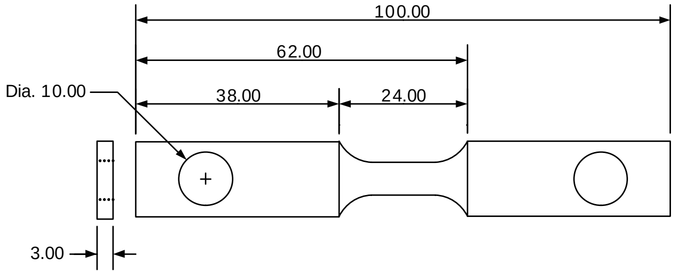
6.1 *Direct Tension Test (DTT) Device*—The DTT system consists of two metal grips to hold the specimen, an environment chamber, a loading device, and a control and data acquisition system. The instrument must meet the requirements stated in T 314.

6.2 *Specimen End Tabs and Gripping System*—End tabs made from Plexiglas material having dimensions as described in Figure 1 that shall be bonded to both ends of the test specimen to transfer the tensile load to the sealant. The manufacturing requirement of the end tabs and the gripping system shall meet the requirement in T 314.

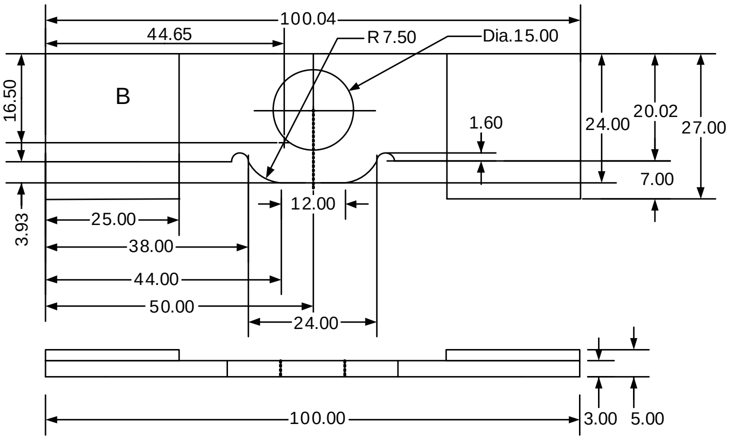
6.3 *Chiller and Test Chamber*—A calibrated circulated temperature control system shall have temperature range from –4 to –40°C. The insulated test chamber shall be capable of maintaining a temperature of ± 0.1°C.

6.4 *Specimen Molds*—The specimen molds should be made from aluminum. Molds shall have dimension as specified in Figure 1. A silicon-based release agent as described later in Section 7.2 shall be used to prevent sealant from adhering to the aluminum molds.

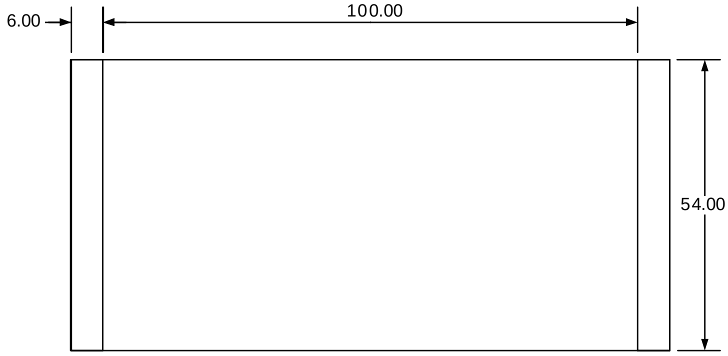
6.5 *Laboratory Ovens*—Two forced-air convection ovens capable of producing, reaching, and maintaining a temperature of 200 ± 0.5°C for heating sealant and molds.



End Insert



Mold Half



Mold Base

Figure 1—Dimension for DTT, End Insert, and Mold

7. REAGENTS AND MATERIALS

7.1 *Fluid for Test Chamber*—A fluid that is not absorbed by or does not affect the properties of the crack sealant being tested. The bath fluid shall be optically clear at the test temperature. Ethyl alcohol is suggested to use as a fluid for temperature control. The aqueous mixture of potassium acetate and deionized water used in T 314 has been found to form turbid solution at temperature of –40°C.

7.2 *Release Agent*—A proper release agent to prevent crack sealant sticking to the mold. A silicon-based released agent is recommended.

7.3 *Solvent*—A solvent can properly clean the molds, end tabs, and plates. The parts cleaned by the solvent shall be submerged in the ethyl alcohol prior to use. This ensures the proper bond between sealant and end tabs.

7.4 *Cleaning Cloths*—Cloths for wiping molds, end tabs, and plates.

8. HAZARDS

8.1 Standard laboratory caution should be used in handling hot sealant in accordance to ASTM D 5167, and required safety procedures should be followed when chemical agents are used.

9. VERIFICATION AND CALIBRATION

9.1 *DTT*—Follow the procedure as stated in T 314.

9.2 *Oven and Freezer*—Calibrate the temperature with a thermometer that meets the requirements of ASTM E 1. The thermometer calibration can be verified according to ASTM E 77.

10. SAMPLES PREPARATION

10.1 Sample and prepare sealant according to ASTM D 5167. See Note 1.

Note 1—It is advantageous to sample about 500 g of sealant and sequentially pour specimens for all the tests, including the aging test (SC-3), the low-temperature tests (SC-4 and SC-5), and the adhesion test (SC-6).

10.2 Anneal the sealant from which the test specimen is obtained by heating for 30 minutes. After 15 minutes, place the sealant in the oven, remove the sealant from the oven shortly, and stir the sealant by spatula to prevent segregation.

10.3 Follow the procedure in Sections 9.2 to 9.6 of T 314 with the following modification. See Notes 2 and 3.

Note 2—If spray-type silicon-based release agent is used, start from one side of the mold and slowly move toward the other side. Only one spray should be applied to the mold.

Note 3—Place the molds and end tab assembly on top of a ceramic tile heated to 50°C lower than sealant pouring temperature. The ceramic tile should be placed in the preheated oven for 15 minutes.

11. CONDITIONING

11.1 Follow the procedure as stated in T 314.

12. PROCEDURE

12.1 Bring the DTT chamber to the test temperature (see Note 4).

Note 4—Select test temperatures in accordance with the material specification, e.g., SC-1, ASTM D 6373-99.

12.2 Prepare four test specimens according to Section 10.

12.3 Follow the procedure in Sections 12.2 to 12.3 of T 314 with the modifications in Notes 5 and 6.

Note 5—Adjust the load frame to allow 20-mm traveling distance; then place the specimen on the loading pin. Remove the slack between the specimen and the loading pins.

Note 6—Manually adjust the thumb wheel on the control box to apply tension in the specimen until a load of 1 ± 0.5 N is shown on the screen. Then calibrate the stroke and load back to zero.

12.4 Set the strain rate to 6 percent/minute (1.2 mm/minute) and start the test.

12.5 After the specimen fractures, degradation is observed, or maximum traveling distance is reached (whichever comes first), stop the test and remove the specimen from the loading frame.

12.6 *The extensibility is identified as follows*:

12.6.1 When the specimen fractures (breaks into two pieces), the extensibility is easily identified as the strain at peak load (maximum stress).

12.6.2 When the specimen does not fracture, but reaches a maximum stress and then flows without fracture, the extensibility is recorded as the strain corresponding to the maximum stress.

12.6.3 When the specimen does not fracture or load reduction is not observed, the extensibility is recorded as the strain at the end of the traveling distance.

12.7 Repeat steps 12.3 to 12.6 for the remaining three specimens.

12.8 After testing is complete, discard the bituminous portions of the spent specimens and clean the end tabs by soaking them in solvent and wiping with a soft cloth. After wiping the end tabs, use a detergent soap solution to remove any oil film residue left by the cleaner material. Alternatively, use a degreasing spray cleaner. Clean the end tabs thoroughly. A grease film on the sealant bonding area can create a weak bond causing bond failures.

13. CALCULATIONS

13.1 For each test result, calculate the engineering stress-strain:

$$\sigma_f = \frac{P_f}{A_0} \quad (1)$$

$$\varepsilon_f = \frac{\Delta L_f}{L_e} \quad (2)$$

where:

σ_f = peak stress;

P_f = measured load at peak;

A_0 = original cross-sectional area (= 18 mm^2);

ε_f = measured strain at peak load;

ΔL_f = measured elongation at failure (ΔL); and

L_e = effective gauge length (= 20.3 mm).

13.2 For each test result, calculate the true stress-strain:

$$\tilde{\varepsilon} = \frac{\Delta L_f}{L_0} \tag{3}$$

$$\tilde{\sigma} = \frac{P_f}{A_i} + \frac{P \times e^{(\dot{\varepsilon} t)}}{A_0} \tag{4}$$

where:

$\tilde{\varepsilon}$ = true strain;

ΔL_f = measured elongation at failure (ΔL); and

L_0 = effective gauge length (= 20.3 mm).

$\tilde{\sigma}$ = true stress;

P_f = measured load at peak;

$\dot{\varepsilon}$ = strain rate; and

A_0 = original cross-sectional area (= 18 mm^2).

13.3 The extensibility is identified as $\tilde{\varepsilon}$.

13.4 Select the three test results that give the best coefficient of variation of the extensibility. Calculate the mean and standard deviation for SED from the selected three test results.

13.5 *Calculate the percent modulus decay*:

13.5.1 From the Boltzman superposition principle, the stress-strain relationship for a viscoelastic material can be expressed as Equation 5.

$$\sigma(t) = \int_0^t E(t - t') \frac{d\varepsilon(t')}{dt'} dt' \tag{5}$$

where:

$\sigma(t)$ = stress history;

$E(t)$ = the relaxation modulus; and

$\varepsilon(t)$ = strain history.

13.5.2 The Prony series (generalized Kelvin model) is used to describe the viscoelastic behavior of hot-poured crack sealants as presented in Equation 6.

$$E(t) = E_0 - \sum_{i=1}^{K} E_i \left(1 - e^{-t/\tau_i}\right) \tag{6}$$

where:

$E(t)$ = the relaxation modulus at time t,

E_i = material constants, and

τ_i = retardation times.

13.5.3 Substituting Equation 6 into Equation 5, the expression of the stress becomes:

$$\sigma(t) = E_0\varepsilon(t) - \int_0^t \sum_i^N E_i \left(1 - e^{\frac{-(t-t')}{\tau_i}}\right) \frac{d\varepsilon(t')}{dt'} dt' \qquad (7)$$

13.5.4 In the DT test, sealant is subjected to a constant strain rate beginning at time zero, $\varepsilon(t) = \begin{Bmatrix} 0 \text{ for } t < 0 \\ \\ \dot{\varepsilon}t \text{ for } t \ \geq \ 0 \end{Bmatrix}$, with $\dot{\varepsilon}$ as the strain rate. The above convolution integral can then be solved as follows:

$$\sigma(t) = E_0\varepsilon(t) - \sum_i^N E_i R \left[t - \tau_i \left(1 - e^{\frac{-t}{\tau_i}}\right)\right] \qquad (8)$$

13.5.5 The equation is used to fit the experimental data by means of the nonlinear least squares (NLS) technique to obtain the material constants E_0, E_i, and τ_i.

13.6 The percent modulus reduction after 10 seconds of loading is calculated as follows:

$$M_{10} = \frac{E(10) - E(0)}{E(0)} \times 100 \qquad (9)$$

14. REPORT

14.1 *Report the following information about the material*:

14.1.1 Sealant name and supplier,

14.1.2 Lot number,

14.1.3 Date received, and

14.1.4 Date sampled according to ASTM D 5167.

14.2 *Report the following information about the test procedure*:

14.2.1 Date and time of test,

14.2.2 Test temperature,

14.2.3 Rate of elongation,

14.2.4 Average extensibility,

14.2.5 Average SED and their standard deviation,

14.2.6 Peak load, and

14.2.7 Type of fracture (fracture or no fracture).

15. PRECISION AND BIAS

15.1 Confidence intervals of 95 percent should be constructed around the average of the calculated extensibility from the results of the four replicates. The closest three measurements will then be used to calculate the coefficient of variation while the fourth replicate will be discarded. A coefficient of variation less than 15 percent is desirable.

16. KEYWORDS

16.1 Crack; direct tension test; extensibility; hot-poured bituminous sealant; joint; low temperature; pavement maintenance; strain energy density.

[1] These standards were developed through a pooled-fund study sponsored by several AASHTO member departments, the University of Illinois, Virginia Polytechnic Institute and State University (Virginia Tech), and the National Research Council of Canada. The Sealant Consortium is the designation given to this pooled-fund study. For availability of the individual research reports, see Section 17, References.

Standard Method of Test for

Measuring Adhesion of Hot-Poured Crack Sealant Using Direct Adhesion Tester

AASHTO Designation: TP 89-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Measuring Adhesion of Hot-Poured Crack Sealant Using Direct Adhesion Tester

AASHTO Designation: TP 89-10

1. SCOPE

1.1 The direct adhesion test is used to determine the adhesion strength of hot-poured crack sealant at the application temperatures.

1.2 The adhesion test is a test of fracture. The object of the test is to apply tensile forces to the interface between sealant and aluminum end pieces. Sealant is confined between two half-cylindrical aluminum end pieces. The applied force and displacement can be recorded as functions of time. Energy required to break the bond can be calculated by measuring the area under the load-displacement curve. This energy can be considered a measure of bonding. In addition, the maximum force to failure can be reported as adhesion strength.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish and follow appropriate health and safety practices and determine the applicability of regulatory limitations prior to use.*

3. TERMINOLOGY

3.1 *hot-poured crack sealants*—hot-poured modified asphaltic materials used in pavement cracks and joints.

3.2 *adhesion*—the maximum force and energy required to separate bituminous sealant from a standard substrate.

4. SUMMARY OF METHOD

4.1 Crack sealant material is homogenized, following the procedure given in ASTM D 5176. For each test including four replicates, cut 40 g of sealant and heat to the manufacturer's recommended pouring temperature. Sealant will be poured in the mold placed between the two half-cylindrical aluminum end pieces. The mold confines the sealant at the bottom and between the two aluminum end pieces at the sides.

5. SIGNIFICANCE AND USE

5.1 This procedure is designed to measure the adhesion of hot-poured sealant to aggregate.

5.2 Sealants must be re-homogenized (ASTM D 5176) before measuring the adhesion by this method.

6. APPARATUS

6.1 Modified Direct Tension Tester (DTT) machine;

6.2 Chiller that can reach –40 ± 0.5°C;

6.3 *Laboratory Oven*—Any standard laboratory oven capable of producing and maintaining temperature ranging from 170 to 193°C ± 0.5°C;

6.4 Release Agent; and

6.5 Four test setups, four molds, and a rubber band.

7. HAZARDS

7.1 Standard laboratory caution should be used in handling hot sealant in accordance to ASTM D 5167, and when using the Direct Tension Tester (DTT). Required safety procedures should be followed when chemical agents are used.

8. PREPARATION OF APPARATUS

8.1 The DTT bath must be adjusted to specific temperature. The sitting posts must be leveled to function properly.

9. CALIBRATION AND STANDARDIZATION

9.1 Temperature of the ovens should be calibrated according to each user's quality assurance program.

9.2 Temperature of the chiller should be calibrated according to each user's quality assurance program.

9.3 *Thermometer (temperature detector)*—Verify the calibration of the temperature-sensing device to ±0.1°C every 6 months.

10. PREPARATION OF SAMPLES AND TEST SPECIMENS

10.1 All adhesion strength measurements must be performed on re-homogenized sealant. Follow the procedure for homogenization given in ASTM D 5176. It is recommended that a minimum of 400 g of sealant be homogenized.

10.2 Once homogenized, hot sealant should be molded, cooled, and stored for later use. To store the sealant, it is recommended that a can or plastic-lined box be used as a container. The mold must be of sufficient size that the sealant depth is no greater than 100 mm to allow for rapid cooling.

10.3 Adjust the oven's temperature to recommended pouring temperature for sealant being tested.

10.4 Turn on the DTT machine, load the program, and cool the chiller to test temperature.

10.5 Place a half cylinder of aluminum end piece in each grip and tighten it.

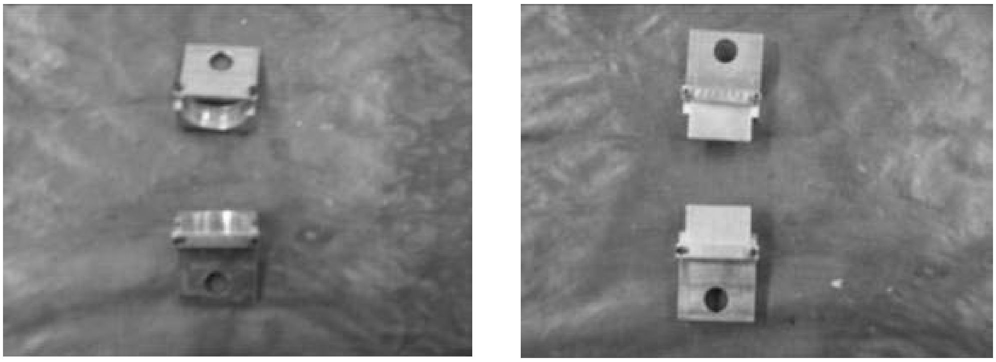

Figure 1—Place Each End Piece in One Grip and Tighten It

Figure 2—Spray Release Agent on the Mold

10.6 Assemble the setup, which is composed of an aluminum end piece on each side and an aluminum mold in between. Wrap a rubber band around the setup to keep all the components in place.

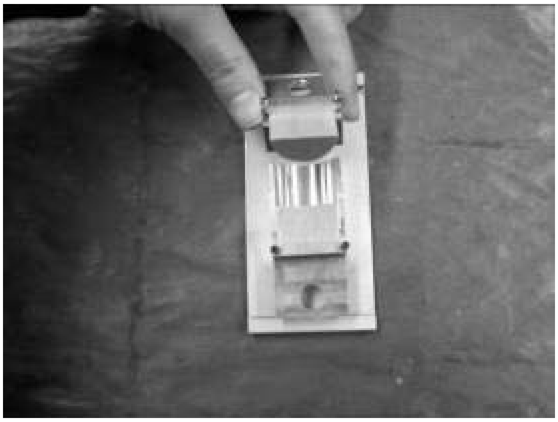

Figure 3—Place Two End Pieces on the Mold

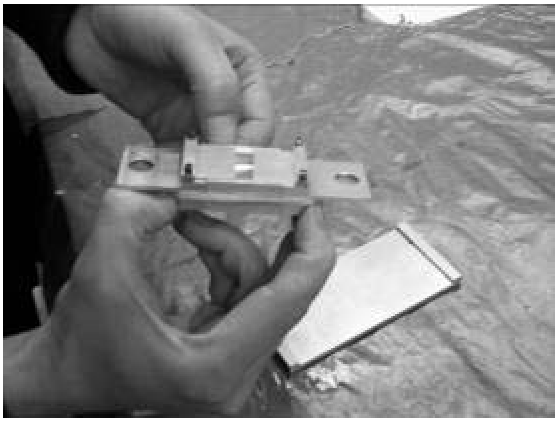

Figure 4—Using a Rubber Band, Hold the Assembly in Place

10.7 Place the notch on the edge of one of the aluminum end piece.

10.8 Prepare a can of sealant by cutting 35 g of homogenized sealant for each set of four samples.

10.9 Place the can in the oven for 15 minutes, remove it from the oven, stir the sealant thoroughly, and place it back in the oven for another 15 minutes.

Figure 5—Heat 35 g of Homogenized Sealant at Recommended Pouring Temperature for 30 minutes.

10.10 Remove the can from the oven, stir the sealant thoroughly, and pour into all the assembled setups. Use four replicates for each sealant. Care should be taken in filling up the molds to prevent any trapped air bubbles in the sample.

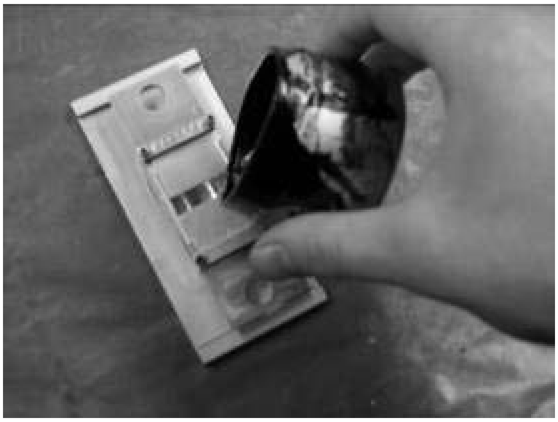

Figure 6—Remove the Sealant from the Oven, Mix Thoroughly, and Pour It in the Mold from One Corner

10.11 Let samples set 1 hour at room temperature.

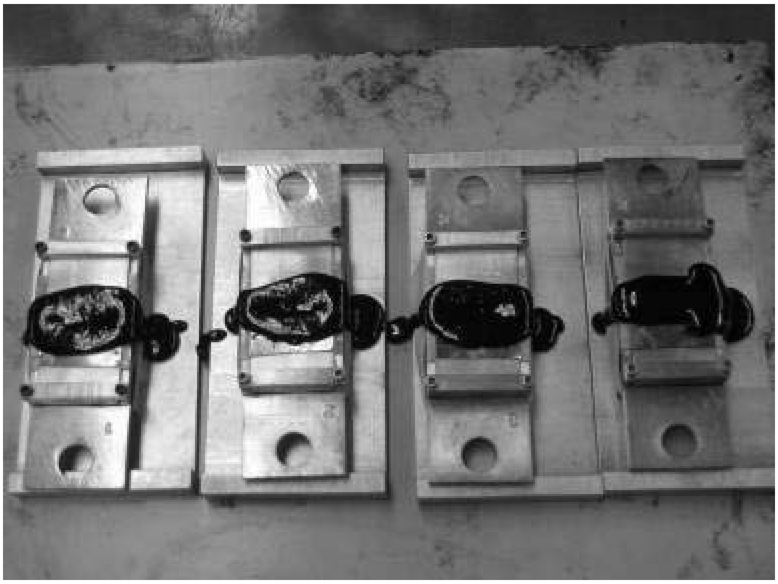

Figure 7—Let Sealant Set for 1 Hour at Room Temperature

10.12 Trim the excessive sealant away with a hot spatula. Move spatula once over and parallel to the interface of the sample; trimming direction shall not be changed during trimming. Use well-heated spatula to prevent any shearing of the sealant.

Figure 8—Trim the Extra Sealant Away Using a Heated Spatula

10.13 Use two tongs to grab the plate underneath the specimen, and place the specimens in the cooling bath.

Figure 9—Grab the Base Plate with Two Tongs, and Place It in Cooling Bath

10.14 Remove the plates underneath each specimen, and leave specimens in the bath for 15 minutes.

Figure 10—Remove the Base Plates

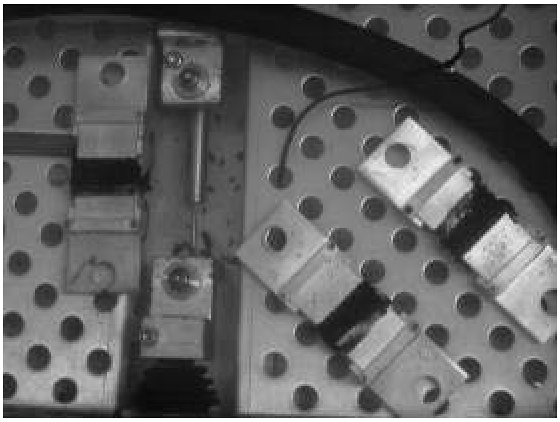

Figure 11—Leave the Specimens in Cooling Bath for 15 minutes.

10.15 Remove one specimen at a time from the bath; place it on a flat surface.

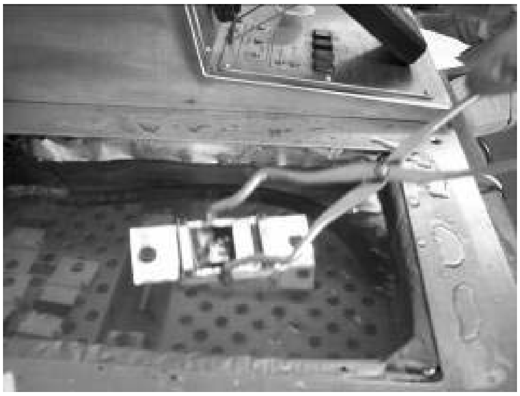

Figure 12—Holding Its Center with Tongs, Remove One Specimen at a Time

10.16 Flip the specimen, remove the rubber band, and keep the two end pieces in place using the index fingers. Remove the mold with your thumb.

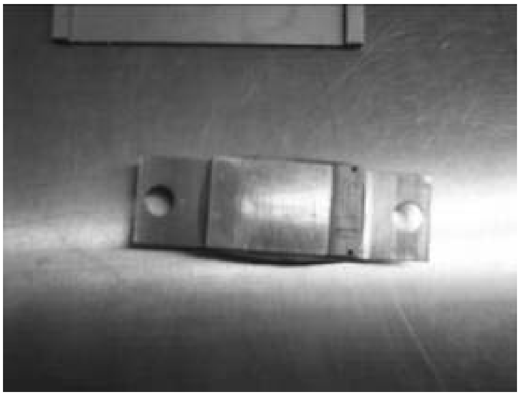

Figure 13—Flip the Specimen on a Flat Surface

Figure 14—Remove the Rubber Band

Figure 15—Remove the Mold While Keeping the Two End Pieces in Place

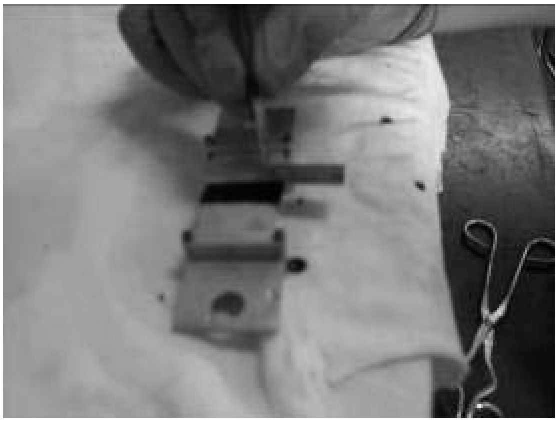

Figure 16—Flip Back the Specimen, and Push the Notch Horizontally Until It Comes Off

10.17 Place the specimen back in the bath.

Figure 17—Grab the Specimen from Two Corners, and Place It Back in the Bath

10.18 Repeat step 8.16 until all specimens are de-molded.

10.19 Leave the samples for 45 minutes in the bath prior to testing.

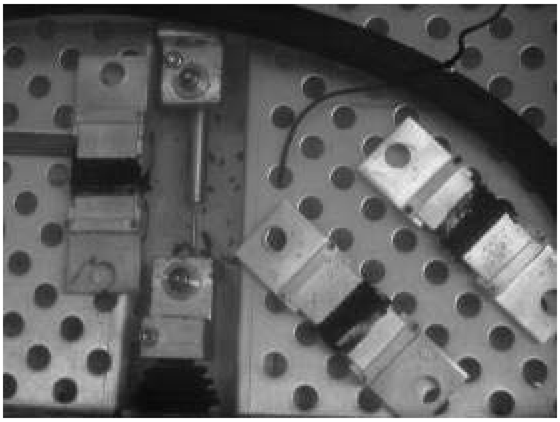

Figure 18—Leave the Specimens for 45 minutes in the Bath

10.20 Open the DTT's test builder program, adjust the machine so the sample can sit freely on the posts, and place the specimen on the posts. Care should be taken not to disturb the specimen.

10.21 Run the test and record the data.

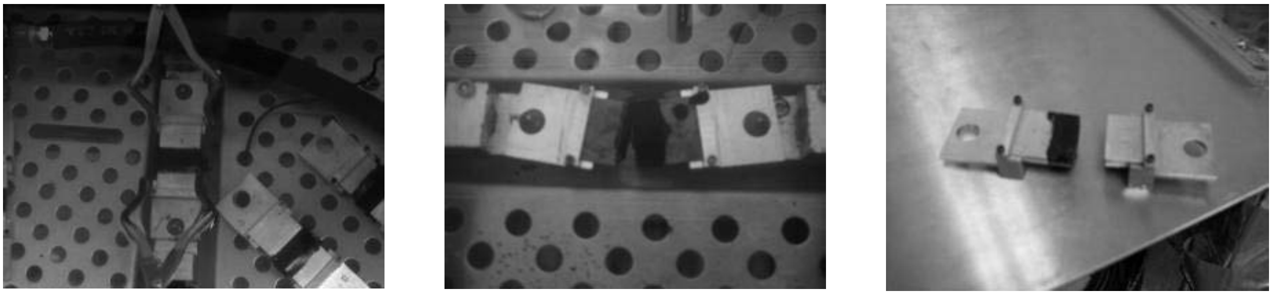

Figure 19—Turn on the DTT Machine, Load Adhesion Program, Mount the Specimen, Tare the Load to Zero, Run the Test, and Record the Data

11. CALCULATION OF RESULTS

11.1 Find the maximum load ($P_{\max}$) to failure and its correspondent displacement.

11.2 Find the bonding energy (E), by calculating the area under the load-displacement curve up to the maximum load and dividing it by the cross-section area of the aluminum end piece.

11.3 Report the $P_{\max}$ and E as the selection thresholds.

12. REPORT

12.1 *Report the following information*:

12.1.1 Sealant identification and supplier,

12.1.2 Lot number,

12.1.3 Date received,

12.1.4 Date of apparent viscosity measurement,

12.1.5 Recommended pouring temperature,

12.1.6 Safe heating temperature, and

12.1.7 Any deviations from test temperature.

13. PRECISION AND BIAS

13.1 *Single Operator Precision (Repeatability)*—The results obtained in the same laboratory, by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the value given Table 1.

Table 1—Precision Estimates

Condition	Coefficient of Variation, (1s%)[a]
Single-Operator Precision:	
Average Viscosity (Pa·s)	19.3

[a] The precision estimates given in Table 1 are based on the analysis of test results from seven sealants with a wide range of rheological properties. The data analyzed include results from two operators in the same laboratories who conducted each test in four replicates.

14. KEYWORDS

14.1 Adhesion; bond; crack; fillers; hot-poured bituminous sealant; joint.

[1] These standards were developed through a pooled-fund study sponsored by several AASHTO member departments, the University of Illinois, Virginia Polytechnic Institute and State University (Virginia Tech), and the National Research Council of Canada. The Sealant Consortium is the designation given to this pooled-fund study. For availability of the individual research reports, see Section 15, References.

Standard Method of Test for

Measuring Interfacial Fracture Energy of Hot-Poured Crack Sealant Using a Blister Test

AASHTO Designation: TP 90-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Measuring Interfacial Fracture Energy of Hot-Poured Crack Sealant Using a Blister Test

AASHTO Designation: TP 90-10

1. SCOPE

1.1 The blister test is used to determine the interfacial fracture energy (IFE) of hot-poured crack sealant at the application temperatures.

1.2 The blister test is a test of fracture. The object of the test is to apply tensile forces using hydrostatic pressure at the interface between sealant and aluminum. Sealant is molded on top of an aluminum disk. The applied hydrostatic pressure and displacement can be recorded as functions of time. Interfacial fracture energy required to break the bond can be calculated using the load-displacement curve through fracture energy concept. This energy can be considered a measure of bonding.

1.3 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish and follow appropriate health and safety practices and to determine the applicability of regulatory limitations prior to use.*

- SC-6, Method to Evaluate Sealant Extensibility at Low Temperature by Direct Tension Test
- SC-7, Test Method for Measuring Adhesion of Hot-Poured Crack Sealant Using a Direct Adhesion Test

3. TERMINOLOGY

3.1 *hot-poured crack sealants*—hot-poured modified asphaltic materials used in pavement cracks and joints.

3.2 *interfacial fracture energy (IFE)*—the energy required to separate bituminous sealant from a substrate.

4. SUMMARY OF METHOD

4.1 Crack sealant material is homogenized following the procedure given in ASTM D 5167. For each test, including four replicates, cut 320 g of sealant and heat to the manufacturer's recommended pouring temperature. Sealant will be poured in the mold assembled on top of an annular-shaped disk of substrate. An aluminum plug will be inserted into the orifice of the substrate to close it. The sealant will be poured on top of the plugged substrate to provide a film of 4.6 mm thickness.

5. SIGNIFICANCE AND USE

5.1 This procedure is designed to measure the adhesion strength of hot-poured sealant to aggregate.

5.2 Sealants must be re-homogenized (ASTM D 5167) before measuring adhesion by this method.

6. APPARATUS

6.1 Modified direct tension test (DTT) machine;

6.2 Chiller that can reach –40 ± 0.5°C;

6.3 *Laboratory Oven*—Any standard laboratory oven capable of producing and maintaining temperature ranging from 170 to 193°C ± 0.5°C;

6.4 Release agent; and

6.5 Four test setups, four molds, four plugs, and four rubber bands.

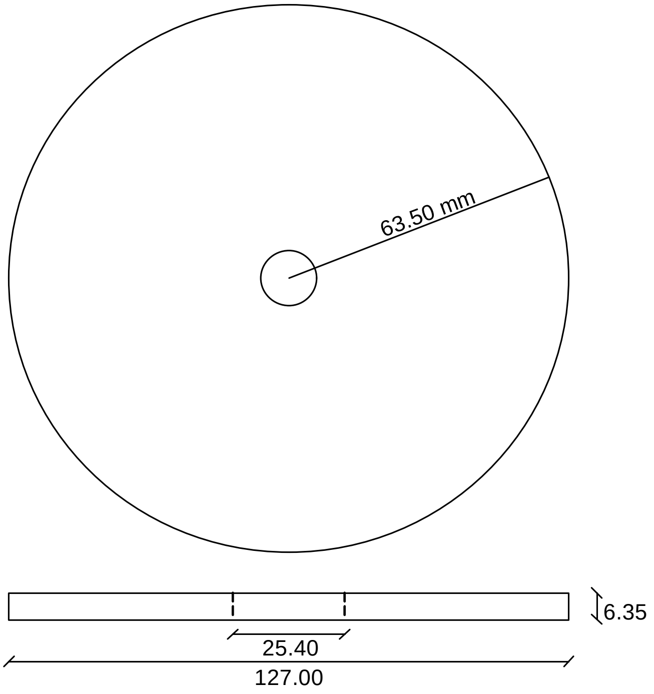

Figure 1—Schematic of the Aluminum Disk

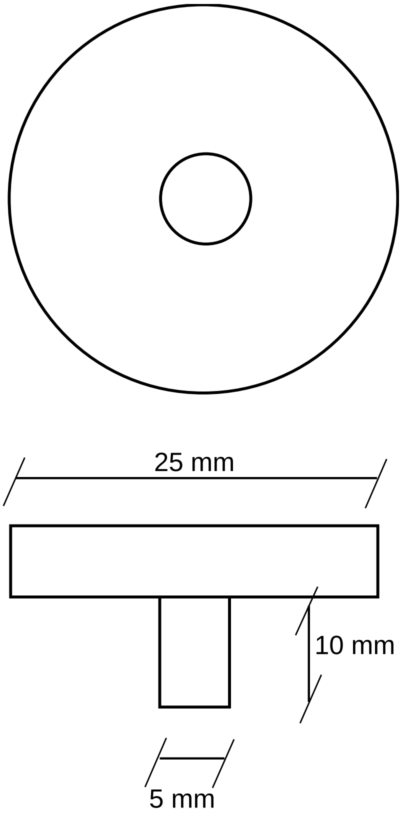

Figure 2—Schematic of the Plug

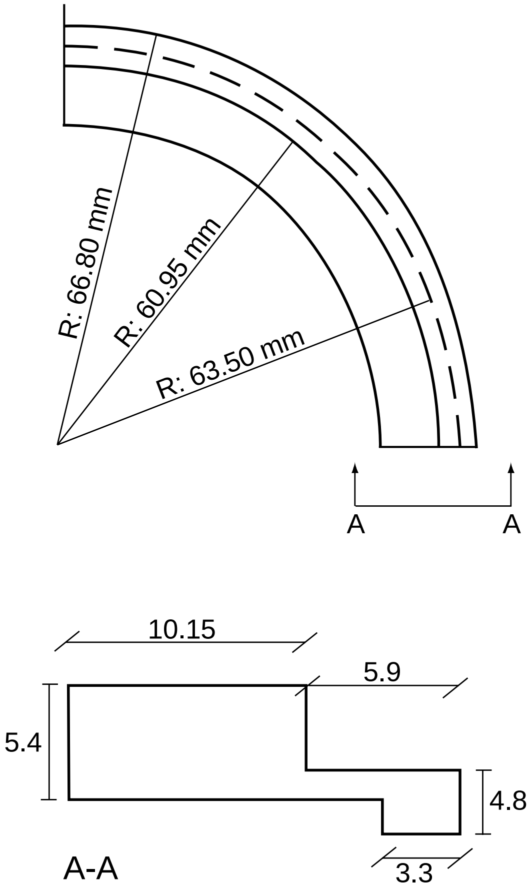

Figure 3—Schematic of One Section of the Four-Piece Mold

7. HAZARDS

7.1 Standard laboratory caution should be used in handling hot sealant in accordance to ASTM D 5167, and when using the Direct Tension/Blister Tester (DTT/Blister). Required safety procedures should be followed when chemical agents are used.

8. PREPARATION OF APPARATUS

8.1 The DTT bath must be adjusted to specific temperature. The test setup must be leveled to function properly.

9. CALIBRATION AND STANDARDIZATION

9.1 Temperature of the ovens should be calibrated according to each user's quality assurance program.

9.2 Temperature of the chiller should be calibrated according to each user's quality assurance program.

9.3 *Thermometer (temperature detector)*—Verify the calibration of the temperature-sensing device to ±0.1°C every 6 months.

---

10. PREPARATION OF SAMPLES AND TEST SPECIMENS

10.1 All adhesion strength measurements must be performed on re-homogenized sealant. Follow the procedure for homogenization given in ASTM D 5167. It is recommended that a minimum of 400 g of sealant be homogenized.

10.2 Once homogenized, hot sealant should be molded, cooled, and stored for later usage. To store the sealant, it is recommended that a can or plastic-lined box be used. The mold must be of sufficient size that the sealant depth is no greater than 100 mm to allow for rapid cooling.

10.3 Adjust the oven’s temperature to recommended pouring temperature for sealant being tested.

10.4 Turn on the DTT/Blister machine, load the program, and cool the chiller to test temperature.

10.5 Use a compass to draw a circle 27 mm in diameter on adhesive-backed fluoropolymer (FEP) film.

10.6 Punch out the circle using a sharp manual punch.

10.7 Peel the FEP film and place it on a level surface, adhesive side up.

10.8 Place the needle on the center (marked with the compass) of the FEP film.

10.9 Place the flat side of the plug on top of the needle and let the needle go through the plug.

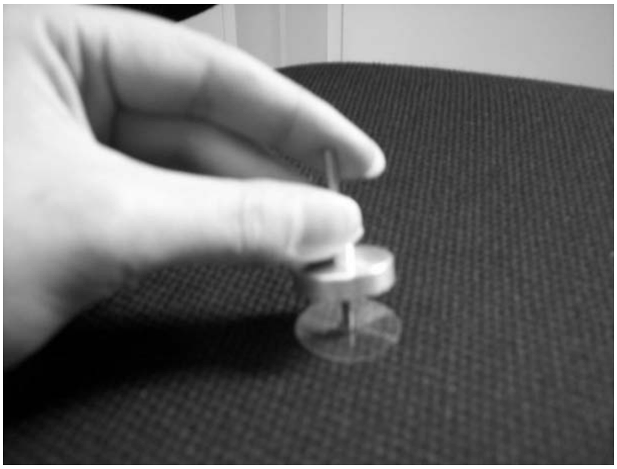

Figure 4—Performing Steps 10.7 through 10.9

10.10 Press the plug on the film gently to make sure it has adhered to the film.

10.11 Spray release agent on the plug while keeping it inclined.

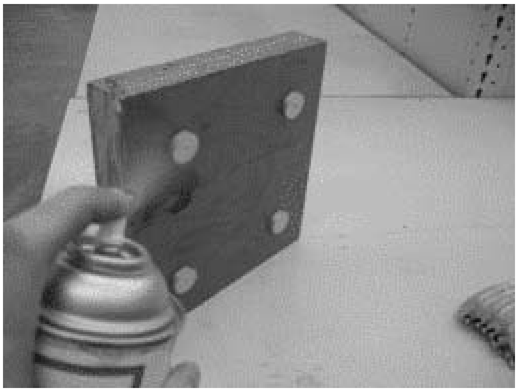

Figure 5—Spraying Release Agent on the Plugs

10.12 Taking care not to contaminate the surface of the disk, place the plug on top of annular disk.

Figure 6—Placing the Plug on the Annular Disk and Pulling It from Underneath until the Disk Fits in the Orifice and the Film Edges Set on the Disk

10.13 Place the aluminum disk and the plug on a setting board.

10.14 Spray release agent on the molds.

Figure 7—Spraying Release Agent on the Molds

10.15 Assemble the mold on top of the disk.

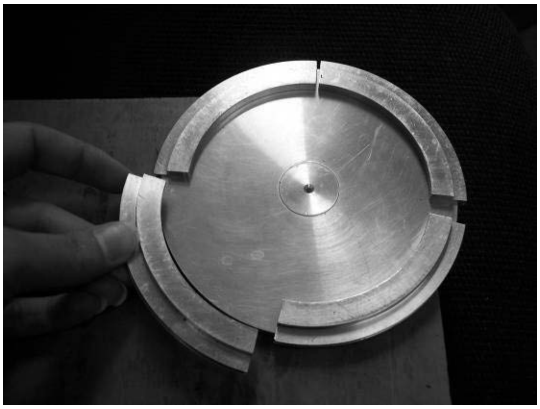

Figure 8—Assembling the Molds on Top of the Disk

10.16 Wrap the mold with a rubber band stretched through the groove around the mold, to keep the components in place.

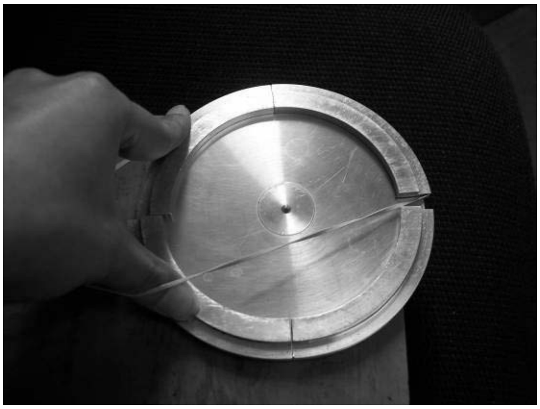

Figure 9—Using Rubber Band to Keep the Mold Together

10.17 Prepare four cans of sealant by cutting 80 g of homogenized sealant for each.

10.18 Place the can in the oven for 15 minutes, remove it from the oven, stir the sealant thoroughly, and place it back in the oven for another 15 minutes.

Figure 10—Heating 35 g of Homogenized Sealant at Recommended Pouring Temperature for 30 min.

10.19 Remove the can from the oven, stir the sealant thoroughly, and pour into all the assembled setups. Use four replicates for each sealant; care should be taken in filling up the molds to prevent any trapped air bubbles in the sample.

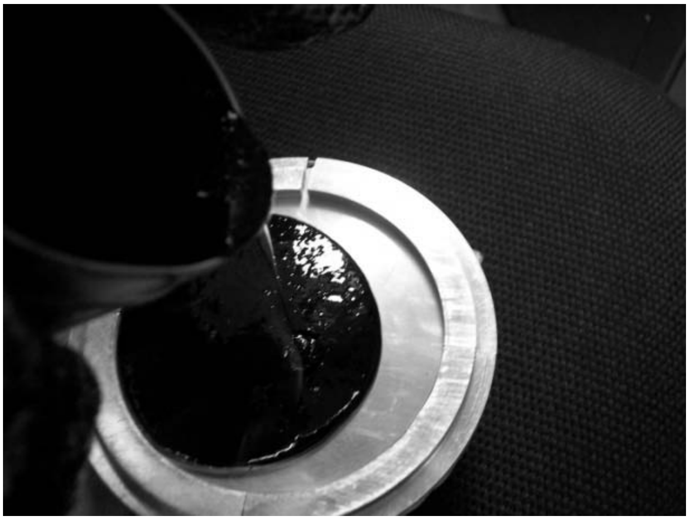

Figure 11—Pouring Sealant onto the Center Top of the Plug so that the Sealant Flows to Fill the Mold

10.20 Let samples set 1 hour at room temperature.

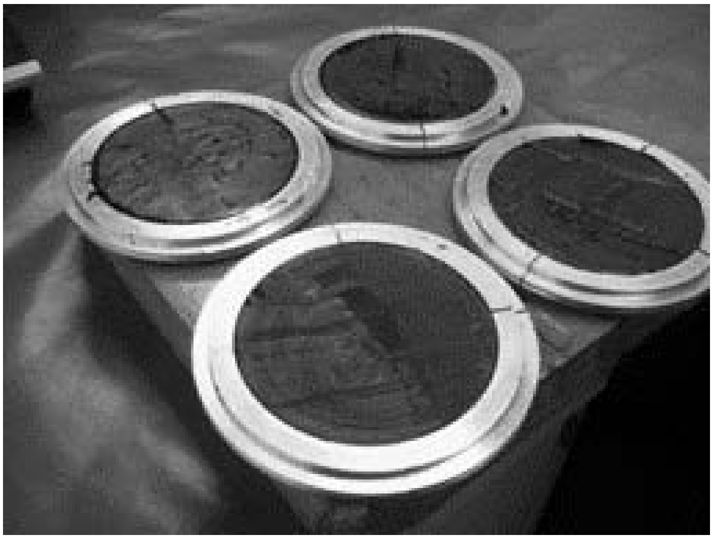

Figure 12—Sealant Setting for 1 Hour at Room Temperature

10.21 Trim the excessive sealant away with a heated putty knife. Move putty knife once over and parallel to the interface of the sample; trimming direction shall not be changed during trimming. Use well-heated putty knife to prevent any shearing of the sealant.

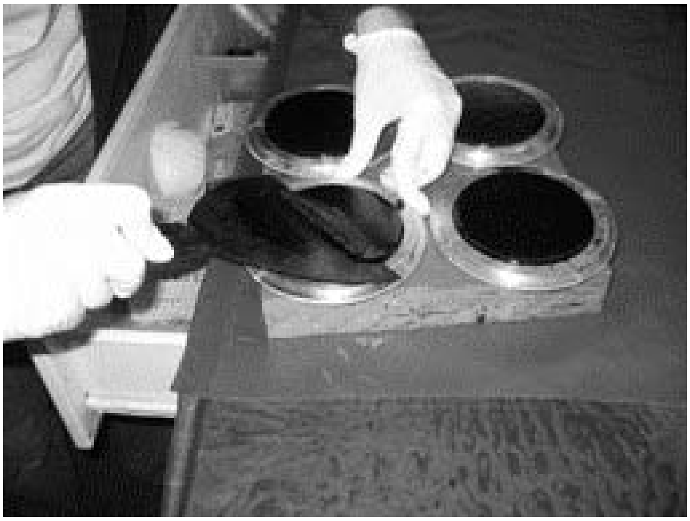

Figure 13—Trimming Excess Sealant with a Heated Putty Knife

10.22 Place the specimens on the cooling rack. Care should be taken not to disturb the specimen.

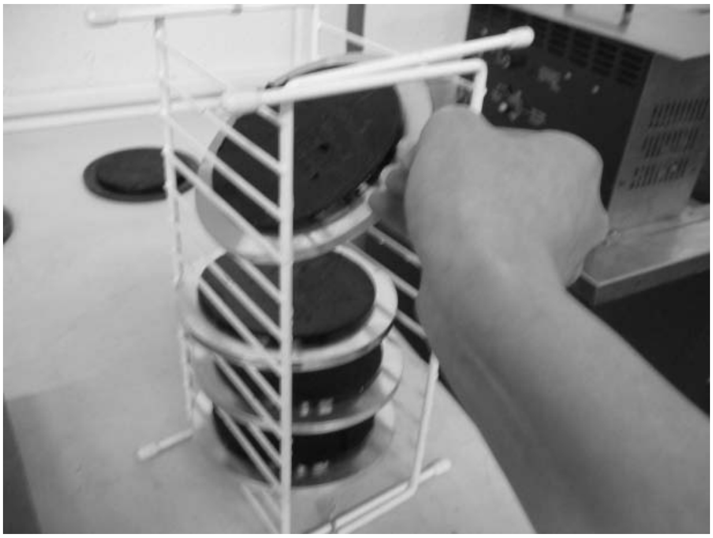

Figure 14—Placing the Disks on the Rack with Clearance between Each Specimen

10.23 Place the rack in the cooling bath for 15 minutes.

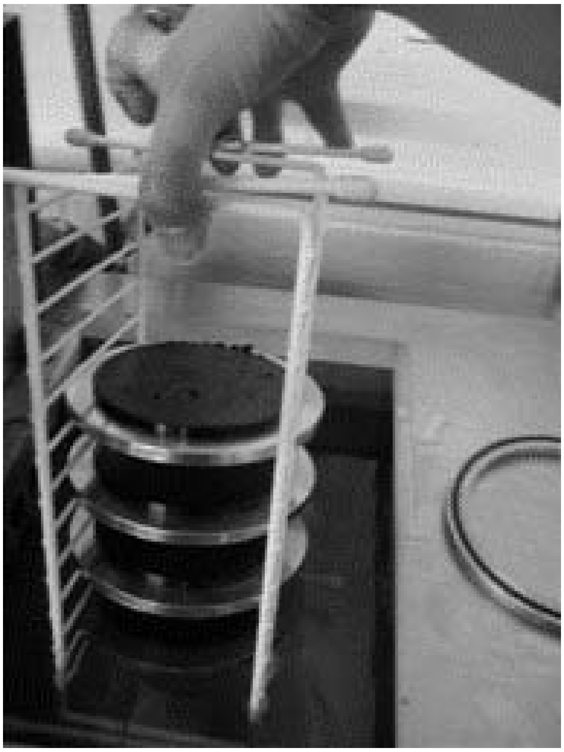

Figure 15—Placing the Rack in the Bath for 15 minutes.

10.24 Remove the rubber band and disassemble the mold gently.

Figure 16—Removing the Molds

10.25 Remove the plug and place the specimen back in the bath.

Figure 17—Removing the Plug from Each Specimen

10.26 Repeat steps 10.24 and 10.25 until all specimens are de-molded.

10.27 Leave the specimens in the cooling bath for 45 minutes before running the test.

10.28 Open the DTT/Blister's test builder program; open the outlet valve to prevent pressure from being applied to the specimen before the test starts. Place the specimen on the setup and clamp the specimen tightly.

10.29 Run the test and record the data.

Note 1—It is recommended that failure surfaces be examined for each replicate to ensure adhesive failure occurred. If sealant breakage occurred, discard the data.

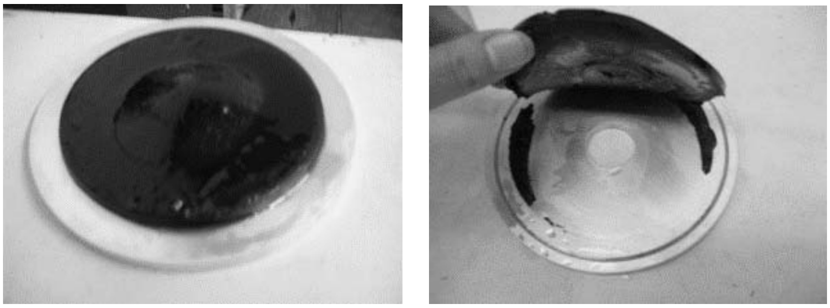

Figure 18—Removing the Specimen and Verifying that the Type of Failure Was Adhesive Failure, in which Sealant Separates from the Disk

11. CALCULATION OF RESULTS

11.1 Find the maximum load ($P_{\max}$) to failure and its correspondent displacement.

11.2 Find the IFE by multiplying half of the maximum load and corresponding displacement.

11.3 Report the IFE as the selection thresholds.

12. REPORT

12.1 *Report the following information*:

12.1.1 Sealant identification and supplier,

12.1.2 Lot number,

12.1.3 Date received,

12.1.4 Date of apparent viscosity measurement,

12.1.5 Recommended pouring temperature,

12.1.6 Safe heating temperature, and

12.2 Any deviations from test temperature.

13. PRECISION AND BIAS

13.1 *Single-Operator Precision (Repeatability)*—The results obtained in the same laboratory by the same operator using the same equipment, in the shortest practical period of time, should not be considered suspect unless the difference in the two results, expressed as a percent of their mean, exceeds the value given Table 1.

Table 1—Precision Estimates

Condition	Coefficient of Variation (1s%)[a]
Single-Operator Precision:	
Average IFE (J/m^2)	8.77

[a] The precision estimate given in Table 1 is based on the analysis of test results from 12 sealants with a wide range of rheological properties. The data analyzed include results from two operators in the same laboratory who conducted each test in four replicates.

14. KEYWORDS

14.1 Adhesion; blister; bond; crack; fillers; hot-poured bituminous sealant; interfacial fracture energy; joint.

[1] These standards were developed through a pooled-fund study sponsored by several AASHTO member departments, the University of Illinois, Virginia Polytechnic Institute and State University (Virginia Tech), and the National Research Council of Canada. The Sealant Consortium is the designation given to this pooled-fund study. For availability of the individual research reports, see Section 15, References.

Standard Specification for

Steel-Reinforced Polyethylene (PE) Ribbed Pipe, 300- to 900-mm (12- to 36-in.) Diameter

AASHTO Designation: MP 20-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Steel-Reinforced Polyethylene (PE) Ribbed Pipe, 300- to 900-mm (12- to 36-in.) Diameter

AASHTO Designation: MP 20-10

1. SCOPE

1.1. This specification covers the requirements and methods of tests for steel-reinforced polyethylene (PE) ribbed pipe, couplings, and fittings for use in surface and subsurface drainage applications.

1.1.1. Nominal sizes of 300 to 900 mm (12 to 36 in.) are included.

1.1.2. Materials, workmanship, dimensions, pipe stiffness, impact resistance, tensile strength of seams, shape stability, joining systems, and form of markings are specified.

1.2. Steel-reinforced PE ribbed pipe is intended for surface and subsurface drainage applications where soil provides support to its flexible walls. Its major use is to collect or convey drainage water by open gravity flow as culverts, storm drains, etc.

Note 1—When PE pipe is to be used in locations where the ends may be exposed, consideration should be given to protection of the exposed portions due to combustibility of the PE and the effects of prolonged exposure to ultraviolet radiation.

1.3. This specification only deals with this pipe's materials requirements. There is no currently accepted AASHTO design methodology for this pipe, and the users of this pipe must assure themselves that this pipe material will perform adequately under installation and design methods chosen by the user. This specification does not include requirements for bedding, backfill, or earth cover load. Successful performance of this product depends upon proper type of bedding and backfill, and care in installation. Appropriate construction and installation procedures are provided by Section 30 of the *AASHTO LRFD Bridge Construction Specifications.* Upon request of the user or engineer, the manufacturer shall provide profile wall section detail required for a full engineering evaluation.

1.4. *Units*—The values stated in SI units are to be regarded as standard. Within the text, the U.S. Customary Units are shown in parentheses and may not be exact equivalents.

1.5. The following precautionary caveat pertains only to the test method portion, Section 9, of this specification. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

- D 3212, Standard Specification for Joints for Drains and Sewer Plastic Pipes Using Flexible Elastomeric Seals
- D 3350, Standard Specification for Polyethylene Plastics Pipe and Fittings Materials
- F 412, Standard Terminology Relating to Plastic Piping Systems
- F 477, Standard Specification for Elastomeric Seals (Gaskets) for Jointing Plastic Pipe
- F 2136, Standard Test Method for Notched, Constant Ligament-Stress (NCLS) Test to Determine Slow-Crack-Growth Resistance of HDPE Resins or HDPE Corrugated Pipe

3. TERMINOLOGY

3.1. The terminology used in this standard is in accordance with the definitions given in ASTM D 883 and ASTM F 412 unless otherwise specified.

3.2. *crack*—Any break or split that extends through the wall.

3.3. *crease*—An irrecoverable indentation, generally associated with a loss in shape stability.

3.4. *delamination*—A gap extending through the welded lap seam between two adjacent wrap widths.

3.5. *encapsulation thicknesses*—The thicknesses of the high density polyethylene (HDPE) covering on both sides of the steel reinforcement as well as the thickness of the closure at the top (outside) of the rib and the thickness of the profile directly under (inside) the reinforcement (see Figure 2).

3.6. *gravity flow*—A condition in which liquid flow through a piping system results from a downward pipeline slope, but flow is less than full, except during conditions when the system may become temporarily surcharged, in which case the system is subject to temporary internal hydrostatic pressure that is limited to 74 kPa.

3.7. *polyethylene (PE) plastics*—Plastics based on polymers made with ethylene as essentially the sole monomer (ASTM D 883).

3.8. *reworked plastic*—A plastic from a processor's own production that has been reground, pelletized, or solvated after having been previously processed by molding, extrusion, etc. (ASTM D 883).

3.9. *seam*—The portion of the helically wrapped strip that overlaps and is fused to adjacent helically wrapped strips (see Figure 1).

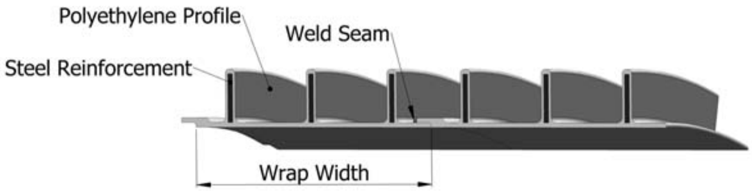

Figure 1—Cross-Section of Profile

3.10. *shape stability*—A general measure of the pipe's ability to maintain geometric and structural stability while deflected and carrying a load equal to or greater than 75 percent of its peak load carrying capability. Peak load-carrying capability is identified as the maximum load in the load/deflection curve as measured during the flattening test as described in Section 9.2.

3.11. *steel-reinforced thermoplastic pipe*—Ribbed thermoplastic pipe with steel reinforcing strips encapsulated within the ribs (see Figure 1).

3.12. *slow crack growth*—A phenomenon by which a stress crack may form. A stress crack is an external or internal crack in plastic caused by tensile stresses less than its short-term mechanical strength.

3.13. *virgin polyethylene material*—PE plastic material in the form of pellets, granules, powder, floc, or liquid that has not been subject to use or processing other than required for initial manufacture.

3.14. *wrap width*—The width the helically wrapped strip covers when measured across the strip, perpendicular to the ribs (see Figure 1).

3.15. *waterway wall*—The minimum wall thickness separating the inner and outer surfaces of the pipe wall, which is measured between pipe ribs (see Figure 2).

4. CLASSIFICATION

4.1. The steel-reinforced PE ribbed pipe covered by this specification is classified as follows:

4.1.1. *Type S*—This pipe shall have a full circular cross section with an essentially smooth inner wall.

4.1.2. *Type SP*—This pipe shall be Type S with perforations.

4.2. Perforations are described in Section 7.5.

5. ORDERING INFORMATION

5.1. Orders using this specification shall include the following information as necessary to adequately describe the desired product:

5.1.1. AASHTO designation and year of issue;

5.1.2. Perforation, if applicable (Section 7.5);

5.1.3. Diameter and length required, either total length or length of each piece and number of pieces;

5.1.4. Certification, if desired (Section 12.1); and

5.1.5. Type of pipe joint (Section 7.12.1).

6. MATERIALS

6.1. *Polyethylene Materials*:

6.1.1. *Pipe and Fittings*—Pipe and fittings shall be made of virgin PE, conforming to the requirements of ASTM D 3350 and having a cell classification of 334452 C or E. Resins that have higher cell classifications in one or more properties are acceptable provided the product requirements are met.

6.1.2. *Rotational Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE, conforming to the requirements of ASTM D 3350 and a having a cell classification of 213320 C or E. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met. For slow crack resistance, acceptance of resins shall be determined by using the notched, constant ligament-stress (NCLS) test according to the procedure described in Section 9.6. The average failure time of the five test specimens must exceed 24 hours with no single test specimen's failure time less than 17 hours.

6.1.3. *Injection Molded Fittings and Couplings*—Fittings and couplings shall be made of virgin PE, conforming to the requirements of ASTM D 3350 and having a cell classification of 324452 C or E. Resins that have higher cell classifications in one or more properties are acceptable provided product requirements are met.

6.1.4. *Carbon Black Content*—The carbon black content shall not exceed 4 percent of the total PE compound weight.

6.1.5. *Other Materials*—It is permissible to use materials other than the cell classification in Section 6.1.1 as part of the welding processes, provided these materials have higher cell classifications in one or more properties and in no way compromise the performance of the pipe products in the intended use.

6.1.6. *Rework Plastics*—In lieu of virgin PE, it is permissible to use clean reworked plastic generated from the manufacturer's own pipe production, provided that it meets the cell class requirements as described in Section 6.1.1.

6.2. *Steel Materials*:

6.2.1. *Steel Material*—The steel material shall be cold- or hot-rolled, formable steel meeting the requirements of ASTM A 653, meeting the strength requirements of Table 4 for the grade defined by the manufacturer as required for their pipe's design. The steel shall have a galvanized coating. All steel materials shall be galvanized per the requirements of ASTM A 653/A 653M with a G60 minimum coating weight.

Note 2—The actual strength of the steel and the rib dimensions are dependent on the manufacturer's design. If requested by the purchaser, the manufacturer shall provide before purchase and delivery their pipe design and certify with delivery that the grade of steel and rib dimensions in the pipe supplied conform to their design...

6.2.2. *Gaskets*—Elastomeric gaskets shall meet the requirements of ASTM F 477.

6.2.3. *Industrial Sealant*—Sealants, such as moisture cure urethane or asphalt-based sealant materials used for repairs or assembly of the internal coupling joint, as recommended by the manufacturer, may be used.

7. REQUIREMENTS

7.1. *Workmanship*—The pipe and fittings shall be free of foreign inclusions and visible defects as defined herein. Visible defects shall not affect the wall integrity or the encapsulation of the steel reinforcement. The steel reinforcing materials shall not be exposed.

7.2. *Visible Defects*—Cracks, creases, delaminations, and unpigmented or nonuniformly pigmented pipe that are visible by the unaided eye are not permissible in the pipe or fittings.

7.3. There shall be no evidence of delamination when tested in accordance with Section 9.2.

7.4. *Pipe Dimensions and Tolerances*:

7.4.1. *Inside Diameter*—The tolerance on the inside diameter shall be ±2.0 percent, when measured in accordance with Section 9.8.1. Pipe dimensions (for both perforated and nonperforated pipe) shall comply with Table 1.

7.4.1.1. Other diameters that are within the range of pipe sizes shown in Table 1 are permissible. The minimum wall thickness and other properties shall be interpolated from the adjacent values given in Table 1.

Table 1—Nominal Pipe Sizes, Inside Diameters, and Minimum Waterway Wall Thicknesses

Nominal Pipe Size, mm (in.)	Inside Diameter, mm [in.] [a]	Minimum Waterway Wall Thickness, t_1, mm [in.]	Minimum Encapsulation Thickness (Bottom), t_2, mm [in.]
300 (12)	300 [11.81]	1.1 [0.043]	0.9 [0.035]
375 (15)	375 [14.76]	1.2 [0.047]	1.0 [0.039]
450 (18)	450 [17.72]	1.3 [0.051]	1.3 [0.051]
600 (24)	600 [23.62]	1.5 [0.059]	1.5 [0.059]
750 (30)	750 [29.53]	1.5 [0.059]	1.5 [0.059]
900 (36)	900 [35.43]	1.7 [0.067]	1.7 [0.067]

[a] Conversions of SI units to U.S. Customary units in this table are "soft" conversions; i.e., the metric measurement is mathematically converted to its exact (or nearly exact) equivalent in inch-pound measurement.

7.4.2. *Waterway Wall*—Minimum waterway wall thickness shall be as required in Table 1 when measured in accordance with Section 9.8.2.

7.4.3. *Length*—The pipe shall be sold in any length agreeable to the user. Length shall not be less than 99 percent of the specified length, when measured in accordance with Section 9.8.3.

7.4.4. *Encapsulation Thickness*—The minimum thickness of the HDPE encapsulation at the sides, top (outside), and bottom (inside) of the reinforcement shall be as shown in Figure 2. Factory cut pipe ends shall have the cut rib ends encapsulated to meet the requirements of Figure 2 for the top (outside) of the ribs. Encapsulation thicknesses shall be measured in accordance with Section 9.8.4.

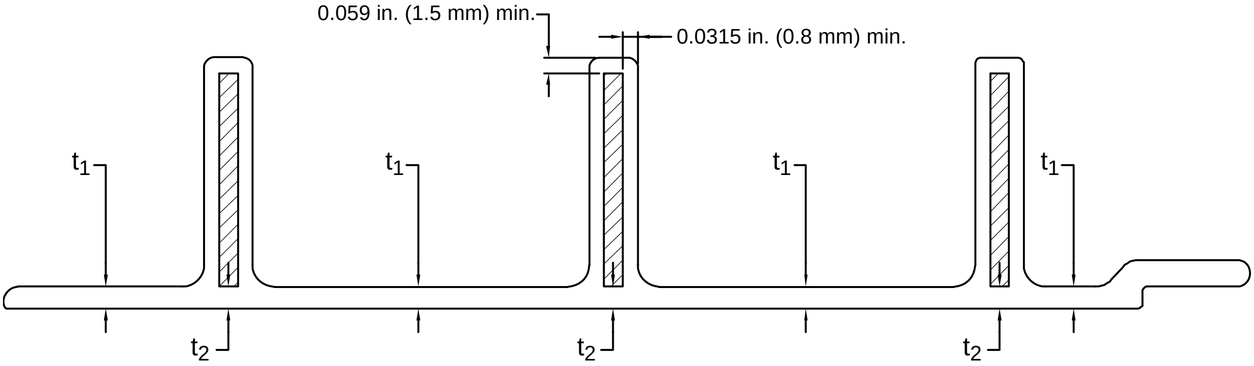

Figure 2—Schematic Representation of Steel-Reinforced Thermoplastic Pipe Profile

7.5. *Perforations*—When perforated pipe is specified, the perforations shall be cleanly cut and uniformly spaced along the length and circumference of the pipe. Circular perforations shall be a minimum of 5 mm (0.2 in.) and shall not exceed 10 mm (0.4 in.) in diameter. The water inlet area shall be a minimum of 30 cm^2/m (1.5 $in.^2$/ft) for pipe sizes 300 to 450 mm (12 to 18 in.) and 40 cm^2/m (2.0 $in.^2$/ft) for pipe sizes larger than 450 mm (18 in.). All measurements shall be made in accordance with Section 9.8.5. The perforations shall be cleanly cut so as not to restrict the inflow of water. Pipe connected by bell and spigot joints may not be perforated in the area of the bells and spigots. Perforations shall be located in the waterway wall portion of the pipe between the ribs and shall not cut into encapsulation of the reinforcement, the radius between this encapsulation and the waterway wall, or the fused seam. The reinforcing steel material shall not be exposed by these perforations.

7.6. *Pipe Stiffness*—The pipe shall have minimum pipe stiffness at 5 percent deflection as listed in Table 2. Pipe stiffness shall be tested in accordance with Section 9.1.

Table 2—Pipe Stiffness and Shape Stability Limits

Nominal Inside Diameter, mm (in)	Pipe Stiffness, kPa [psi] [a]	Shape Stability Limit, %
300 (12)	345 [50]	20
375 (15)	290 [42]	20
450 (18)	276 [40]	20
600 (24)	234 [34]	20
750 (30)	193 [28]	20
900 (36)	152 [22]	20

[a] Conversions of SI units to U.S. Customary units in this table are “soft” conversions; i.e., the metric measurement is mathematically converted to its exact (or nearly exact) equivalent in inch-pound measurement.

Note 3—The 5 percent deflection on criteria was selected for testing convenience and should not be considered as a limitation with respect to in-use deflection.

7.7. *Pipe Flattening*—There shall be no evidence of splitting, cracking, or breaking when tested in accordance with Section 9.2. Additionally, there shall be no separation or delamination of the spiral seam or the rib at the top of its junction with the waterway wall of the pipe when tested in accordance with Section 9.7.

7.8. *Shape Stability*—In the flattening test described in Section 9.2, the load shall not decrease with increasing deflection until after the percentage shape stability limit tabulated for the relevant diameter (in Table 2) has been exceeded. Additionally, if the peak load is reached before 20 percent deflection, the load at 20 percent deflection shall be a minimum of 75 percent of the peak load. Shape stability limit is calculated as follows:

$$SSL = \frac{\Delta Y}{ID} \times 100\%$$

where:

SSL = shape stability limit

ΔY = change in vertical deflection

ID = inside diameter of pipe

7.9. *Impact*—There shall be no evidence of splitting, cracking, or breaking when tested in accordance with Section 9.3. Additionally, there shall be no separation of the spiral seam or the rib at its junction with the waterway wall when tested in accordance with Section 9.7.

7.10. *Tensile Strength of Seam*—There shall be no breaking or separation of the weld when tested in accordance with Section 9.4.

7.11. *Fitting Requirements*:

7.11.1. Only fittings supplied or recommended by the manufacturer shall be used. Fabricated fittings shall be supplied with joints compatible with the overall system requirements. A bell-and-spigot joint is an example of a typical design.

7.11.2. All fittings shall be within an overall length dimensional tolerance ±12 mm (0.5 in.) of the manufacturer's specified dimensions when measured in accordance with Section 9.8.3.

7.11.3. The fittings shall not impair the overall integrity or function of the pipe.

7.11.4. Common fittings include in-line joint fittings, reducers, and branch or complimentary assembly fittings such as tees and wyes. These fittings shall be installed or coupled to the pipe by various methods.

7.11.5. Fittings shall not reduce the inside diameter of the pipe being joined by more than 12 mm (0.5 in.). Reducer fittings shall not reduce the cross-sectional area of the small size diameter by more than 3 percent.

7.12. *Jointing Requirements*:

7.12.1. Pipe joints and couplings shall be bell and spigot or screw-on collar. Only couplings supplied or recommended by the manufacturer shall be used. Couplings shall be supplied with joints compatible with the overall system requirements.

7.12.1.1. Other types of couplings or fastening devices that are equally effective as those described in Section 7.12.2.1 and that comply with the soil-tight joint performance criteria of the *AASHTO LRFD Bridge Construction Specification*, Section 26.4.2.4, may be used when approved by the purchaser. An example of another type of coupler is a split-collar coupling, which shall match the pipe profile and shall provide sufficient longitudinal strength to preserve pipe alignment and prevent separation at the joints. Split-collar couplings shall engage at least three full ribs on each pipe section.

7.12.1.2. *Internal Coupling, Sealant Type*—Joint seal is affected by applying an industrial sealant between the external surface of the coupling and the internal surface of the pipe. This jointing system may be used when approved by the purchaser.

7.12.1.3. Other types of jointing methods such as flanging, internal coupling (gasket type), extrusion welding, electro-fusion, butt fusion, and others may be used when approved by the purchaser.

7.12.2. *Joint Tightness*—The pipe or fitting joint shall meet the requirements defined as one of the following types:

7.12.2.1. *Soil-tight Joints*—Soil-tight joints are specified as a function of opening size (maximum dimension normal to the direction that soil may infiltrate), channel length (length of the path along which the soil may infiltrate), and backfill particle size. If the size of the opening exceeds 3 mm ($^1/_8$ in.), the length of the channel must be at least four times the size of the opening. No opening may exceed 25 mm (1 in.). Backfill material containing a high percentage of fine-graded soils requires investigation for the specific type of joint to be used to guard against soil infiltration.

7.12.2.2. *Silt-Tight Joints*—A silt-tight joint is resistant to infiltration of particles that pass the No. 200 sieve. Silt-tight joints are specified to provide protection against infiltration of backfill material containing a high percentage of fines, and typically utilize some type of filtering or sealing component, such as an elastomeric rubber seal or geotextile wrap. Geotextile wraps are manufactured to tolerances that assure silt will not pass through them. The successful performance of these wraps in the field is dependent on their installation. If a geotextile wrap is specified for use, the material specified should meet M 288, with an Apparent Opening Size (AOS) > 70.

For joints that utilize an elastomeric rubber seal, silt-tight performance shall have been demonstrated in a laboratory test to meet the hydrostatic requirements of ASTM D 3212, with the exception that the hydrostatic test pressure shall be a minimum of 14 kPa (2 psi).

7.12.2.3. *Leak-Resistant Joints*—Leak-resistant joints shall be bell and spigot and utilize an elastomeric rubber seal meeting the requirements of ASTM F 477. Alternative methods of joining (e.g., external joint wraps) shall be allowed provided the requirements of Section 7.12.2.3.1 are achieved.

7.12.2.3.1. Leak resistance shall be verified in the lab by meeting all of the requirements of ASTM D 3212. The hydrostatic test pressure and vacuum specified in the test method shall be 74 kPa (10.8 psi).

7.12.3. *Special Design Joints*—Special design joints shall include joints requiring special strength in bending or shear, pull-apart capabilities, or unusual features such as restrained joints placed on severe slopes, welded joints, flanged and bolted joints for high pressures, high heads, or velocities. Watertight joints that provide zero leakage for a specified head or pressure application are included in this type of joint.

7.13. *Stub Compression Test*—Profile compression capacity in any specimen in the stub compression test shall not be less than 50 percent of the gross cross section of the steel reinforcing area times the minimum specified yield strength of the steel when tested in accordance with Section 9.9. The stub compression test, T 341, shall be a material and wall design qualification test conducted once a year or whenever there are changes in wall design or material distribution. Computing the minimum capacity requires determining the cross-sectional area of the pipe wall. This can be accomplished conveniently by optically scanning the profile and determining the section properties using a computer drafting program.

8. CONDITIONING

8.1. *Conditioning*—Condition the specimen prior to test at 21 to 25ºC (70 to 77°F) for not less than 24 hours in accordance with Procedure A in ASTM D 618 for those tests where conditioning is required, and unless otherwise specified.

8.2. *Conditions*—Conduct all tests at a laboratory temperature of 21 to 25ºC (70 to 77°F) unless otherwise specified herein.

9. TEST METHODS

9.1. *Pipe Stiffness*—Select a minimum of two pipe specimens and test for pipe stiffness $F/\Delta y$, as described in ASTM D 2412, except for the following conditions:

1. The length of the test specimen shall be a whole number of wraps, with a minimum length of four wrap widths or half the pipe diameter, whichever is greater.
2. Randomly orient each specimen in the loading machine.
3. Testing speed of the specimens shall be 12.5 mm per minute (0.5 in. per minute) for testing up to 5 percent deflection. For flattening beyond 5 percent deflection (see Section 9.2), it is permissible to increase test speeds up to 125 mm per minute (5 in. per minute).
4. The deflection indicator shall be readable and accurate to ±0.02 mm (0.001 in.).
5. The beginning point for deflection measurement shall be at a load of 20 ± 5 newtons (4.5 ± 1.1 lbf). The point shall be considered as the origin of the load deflection curve.

9.2. *Flattening*—Flatten the two pipe samples from Section 9.1 until the vertical inside diameter is reduced by 20 percent. The length of the test specimen and the rate of loading shall be the same as in Section 9.1. Examine the specimen with the unaided eye for cracking, splitting, or delamination. It is permissible for the ribs to lean during this test only to the extent that neither the above requirements nor the shape stability requirements (Section 7.8) are failed.

9.3. *Impact*—Test pipe specimens in accordance with ASTM D 2444 except that six specimens shall be tested. Specimens shall be at least four wrap widths in length and impact points shall be at least 152 mm (6 in.) from the end of the specimen. Impact resistance shall not be less than 136 J. Tup B and a flat plate specimen holder shall be used. Condition the specimens for 24 hours at a temperature of 0 ± 1°C (32 ± 2°F), and conduct all tests within 60 seconds of removal from this atmosphere.

9.4. *Tensile Strength of Seam—Test in accordance with ASTM D 638, with the following conditions*:

1. The sample shall be prepared according to the dimensions for Type I specimens, with the weld seam arranged centrally and perpendicular to the tensile test axis.
2. All steel reinforcement shall be removed from the profile.
3. It is permissible to reduce the height of the HDPE ribs to no less than 2.5 mm (0.1 in.) if required to facilitate testing.

9.5. *Joint Integrity*—Assemble each fitting or coupling to the appropriate pipe in accordance with the manufacturer's recommendations. Use pipe samples at least 300 mm (12 in.) in length. Assemble a specimen at least 600 mm (24 in.) in length with the connection at the center. Load the connected pipe and fitting between parallel plates at the rate of 12.5 mm per minute (0.5 in. per minute) until the vertical inside diameter is reduced by at least 20 percent of the nominal diameter of the pipe. Inspect for splitting, cracking, delamination, or other damage while at the specified deflection and after load removal.

9.6. *Slow Crack Growth Resistance of Resin Compounds*—Test basic resin compounds for stress crack resistance in accordance with the ASTM F 2136, the NCLS test, except for the following modifications:

9.6.1. The applied stress for the NCLS test shall be 4100 kPa (600 psi).

9.6.2. Resin test specimens shall be plaques molded from the reground resin from the rotomolded or injection-molded parts.

Note 4—The notched depth of 20 percent of the nominal thickness of the specimen is critical to this procedure.

9.7. *Delamination*—Test the fusion of the weld between the inner and outer wall of the wrap width with a probe or knife point. It shall not be possible to separate cleanly the two walls at the lap seam weld. Test samples at eight equally spaced points around its circumference.

9.8. *Dimensions*:

9.8.1. *Inside Diameter*—Measure the inside diameter of three specimens, each a minimum of 300 mm (12 in.) long with any suitable device accurate to 0.8 mm (0.03 in.), at two positions, namely, any point in the circumferential direction and 90 degrees from this point, and average the six measurements. Inside diameter shall meet the requirements of Section 7.4.1.

9.8.2. *Waterway Wall*—Locate and measure the wall thickness between the ribs at four equally spaced locations around the circumference of the pipe, in accordance with ASTM D 2122.

9.8.3. *Length*—Measure pipe with any suitable device accurate to ±6.0 mm in 3 m (±0.25 in. in 10 ft). Make all measurements on the pipe while it is resting on a relatively flat surface, in a straight line, with no external tensile or compressive forces exerted on the pipe. These measurements may be taken at ambient temperatures.

9.8.4. *Encapsulation Thickness*—Locate and measure the encapsulation thickness by cutting a cross section and measuring in accordance with ASTM D 2122.

9.8.5. *Perforations*—Measure dimensions of perforations on a straight profile specimen with no external forces applied. Make linear measurements with instruments accurate to 0.2 mm (0.08 in.).

9.9. *Stub Compression Capacity*:

9.9.1. Determine the stub compression capacity of the pipe section in accordance with T 341. Conduct four tests on specimens cut from the same ring of pipe at 90 degree intervals around the circumference.

10. INSPECTION AND RETEST

10.1. *Inspection*—Inspection of the material shall be made as agreed upon by the purchaser and the seller as part of the purchase contract.

10.2. *Retest and Rejection*—Retesting in the event of a test failure shall be conducted on samples from the failed lot only under an agreement between purchaser and seller. There shall be no changes to the test procedures or the requirements.

11. MARKING

11.1. *All pipe shall be clearly marked at intervals of no more than 3.5 m (11.5 ft) as follows*:

11.1.1. Manufacturer's name or trademark.

11.1.2. AASHTO MP 20.

11.1.3. Nominal inside diameter.

11.1.4. The plant designation code.

11.1.5. The date and location of manufacture or an appropriate production code. If a date code is used, a durable manufacturer sticker that identifies the actual date of manufacture shall be adhered to the inside of each length of pipe.

Note 5—A durable sticker is one that is substantial enough to remain in place and be legible through installation of the pipe.

11.2. Fittings shall be marked with the designation number of this specification, AASHTO MP 20, and with the manufacturer's identification symbol.

12. QUALITY ASSURANCE

12.1. A manufacturer's certificate that the product was manufactured, tested, and supplied in accordance with this specification, together with a report of the test results and the date each test was completed shall be furnished upon request. Each certification so furnished shall be signed by a person authorized by the manufacturer.

APPENDIX

(Nonmandatory Information)

X1. QUALITY CONTROL/QUALITY ASSURANCE PROGRAM

X1.1. *Scope*:

X1.1.1. As required in Sections 10 and 12, the acceptance of these products relies on the adequate inspection and certification agreed to between the buyer and the seller/manufacturer. This appendix should serve as a guide for both the manufacturer and the user. It places the responsibility on the manufacturer to control the quality of the material they produce and to provide the quality control.

X1.2. *Program Requirements*:

X1.2.1. The manufacturing company must have a quality control plan approved by the specifying agency.

X1.2.2. The manufacturing plant must have an approved quality control plan.

X1.2.3. The plant must have an approved laboratory, either within the company or an independent laboratory.

X1.2.4. The manufacturing plant(s) must have a designated quality control technician.

X1.3. *Quality Control Plan*:

X1.3.1. The manufacturer must supply to the specifying agency a written quality control plan that shows how the producer will control the equipment, materials, and production methods to insure that the specified products are supplied. The following information must be included in the plan:

X1.3.1.1. Titles of the personnel responsible for production quality at the plant(s).

X1.3.1.2. The physical location of the plant(s).

X1.3.1.3. The methods of identification of each lot of material during manufacturing, testing, storage, and shipment. The method of identification shall allow the specifying agency to trace the finished product to the material provider.

X1.3.1.4. The method of sampling and testing of raw materials and of finished product, including lot sizes and types of tests performed.

X1.3.1.5. A plan for dealing with nonconforming product, including how the manufacturer plans to initiate immediate investigation and how corrective action will be implemented to remedy the cause of the problem.

X1.4. *Approved Laboratory*:

X1.4.1. All tests must be conducted at laboratories approved by the specifier. Each manufacturer may establish and maintain its own laboratory for performance of quality control testing or may utilize an approved independent laboratory. Records of instrument calibration and maintenance and sample collection and analysis must be maintained at the laboratory.

X1.5. *Quality Control Technician*:

X1.5.1. All samples must be taken and tested by quality control technicians designated by the manufacturer. The designated quality control technicians will be responsible for overall Quality Control at the manufacturing plant.

X1.6. *Annual Update*:

X1.6.1. An annual update may be required. The annual update may be submitted by the manufacturer to the specifying agency by December 31 of each calendar year.

X1.7. *Plant Approval*:

X1.7.1. The plant approval process requires the manufacturer to submit an annual update to the specifying agency. The update must identify the specific product manufactured at the plant.

X1.7.2. The specifying agency will review the manufacturer's written quality control plan, and a plant inspection may be scheduled. This inspection will verify that the quality control plan has been implemented and is being followed and that at least one designated quality control technician is on-site and will be present when material is being produced under this program. The laboratory will be inspected and approved if it meets the requirements.

X1.8. *Sampling and Testing*:

X1.8.1. The quality assurance plan approved for each manufacturer, or manufacturer's location, or both, shall detail the methods and frequency of sampling and testing for all raw materials and products purchased or manufactured at that location. All testing shall be in accordance with current specifications and procedures referenced in MP 20.

X1.8.2. Samples of materials and pipe may be taken by the specifying agency.

X1.8.3. The specifying agency may require an annual third-party independent assurance test.

X1.9. *Sample Identification and Record Keeping*:

X1.9.1. Manufacturer's quality control samples are to be uniquely identified by the producing plant.

X1.9.2. Quality control and quality assurance data are to be retained by the manufacturer for 2 years and made available to the specifying agency upon request.

X1.9.3. Quality control test reports shall include the lot identification.

X1.9.4. Unless requested at the time of ordering, test reports do not have to be filed for specific projects.

X1.9.5. Reports shall indicate the action taken to resolve nonconforming product.

Standard Practice for

Pipe Joint Selection for Highway Culvert and Storm Drains

AASHTO Designation: PP 63-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Pipe Joint Selection for Highway Culvert and Storm Drains

AASHTO Designation: PP 63-09[1]

1. SCOPE

1.1. Pipe joint design considerations are a critical component for the overall performance of culvert and storm drain installations. Experience has shown that the component responsible for many culvert and sewer performance problems and failures can be traced back to the pipe joint. The structural and hydraulic performance of the joint affects the stability of backfill and soil envelope around the pipe, the line and grade of the culvert, integrity of the overlying embankment and pavement, and compliance to storm and sanitary sewer permits. This practice is to provide clear definitions of joint performance terms, rational design methodology to determine appropriate joint performance requirements, and uniform criteria for manufacturers’ joint qualification and contractors' post-installation pipe joint testing.

1.2. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *brownfields*—abandoned industrial or commercial sites with some soil contamination from previous use, now available for new construction.

3.1.2. *erodible conditions*—soil or backfill materials or conditions where the soil or backfill surrounding the pipe may be removed by the flow of liquid (water) leaking from the pipe or pipe joint.

3.1.3. *exfiltration*—the passage of fluid from a pipe section through small openings or leaks in the pipe wall or in the joint. Fluid that enters the pipe backfill may change the structural characteristics of the backfill or cause migration of the backfill or surrounding soils.

3.1.4. *infiltration*—the passage of fluid into a pipe section through small openings in the pipe wall or in the joint. Extraneous flow entering a pipe system may cause migration of the backfill or surrounding soils into the pipe and change the structural characteristics of the backfill.

3.1.5. *leakage rate*—an amount of infiltration or exfiltration within the pipe system. A maximum leakage rate may be established as a condition of project compliance to assure structural quality and proper installation.

3.1.6. *leak resistance*—Leak resistance refers to a system that is not completely (100 percent) watertight, but allows some defined allowable rate of water leakage into and out of the system.

3.1.7. *leak-resistant joint*—a joint that limits water leakage at a maximum rate of 200 gallons/inch-diameter/mile/day for the pipeline system for the project specified head or pressure.

3.1.8. *post-installation test*—leakage test conducted after pipe installation and backfill utilizing air or water to verify project specification compliance when required as a condition of project acceptance.

3.1.9. *proof of design*—laboratory or in-plant tests for leakage through the pipe or pipe joint under pressure or vacuum that verifies the performance of the pipe joint in a specific test. This type of test may not directly correlate to field performance.

3.1.10. *restrained joints*—joints used for applications in which the joint may be subject to significant tensile and shear forces and moments. Examples of these applications are installations on slopes, sites where differential settlement may occur, and pipes for high pressures and high heads or velocities.

3.1.11. *silt-tight joint*—a joint that is resistant to infiltration of particles that are smaller than particles passing the No. 200 sieve. Silt-tight joints provide protection against infiltration of backfill material containing a high percentage of fines, and typically utilize some type of filtering or sealing component, such as an elastomeric rubber seal or geotextile.

3.1.12. *silt-tightness*—refers to a pipe system's resistance against fine soil migration through the openings of the joint.

3.1.13. *soiltight joint*—a joint that is resistant to infiltration of particles larger than those retained on the No. 200 sieve. Soiltight joints provide protection against infiltration of backfill material containing a high percentage of coarse grain soils, and are influenced by the size of the opening (maximum dimension normal to the direction that the soil may infiltrate) and the length of the channel (length of the path along which the soil may infiltrate).

3.1.14. *soiltightness*—refers to a pipe system's resistance to coarse grained soil migration through the openings of the joint.

3.1.15. *special design joint*—joints requiring special strength in bending or shear, pull-apart capabilities, or unusual features such as restrained joints placed on severe slopes, welded joints, or flanged and bolted joints for high pressures, high heads, or velocities, etc., typically described within special provisions of the project specifications.

3.1.16. *watertight joint*—a joint that provides zero leakage of water infiltration and exfiltration for a specified head or pressure application. Watertight joints typically utilize a resilient rubber seal of some type and are capable of passing a laboratory hydrostatic pressure and vacuum test of at least 10.8 psi without leakage.

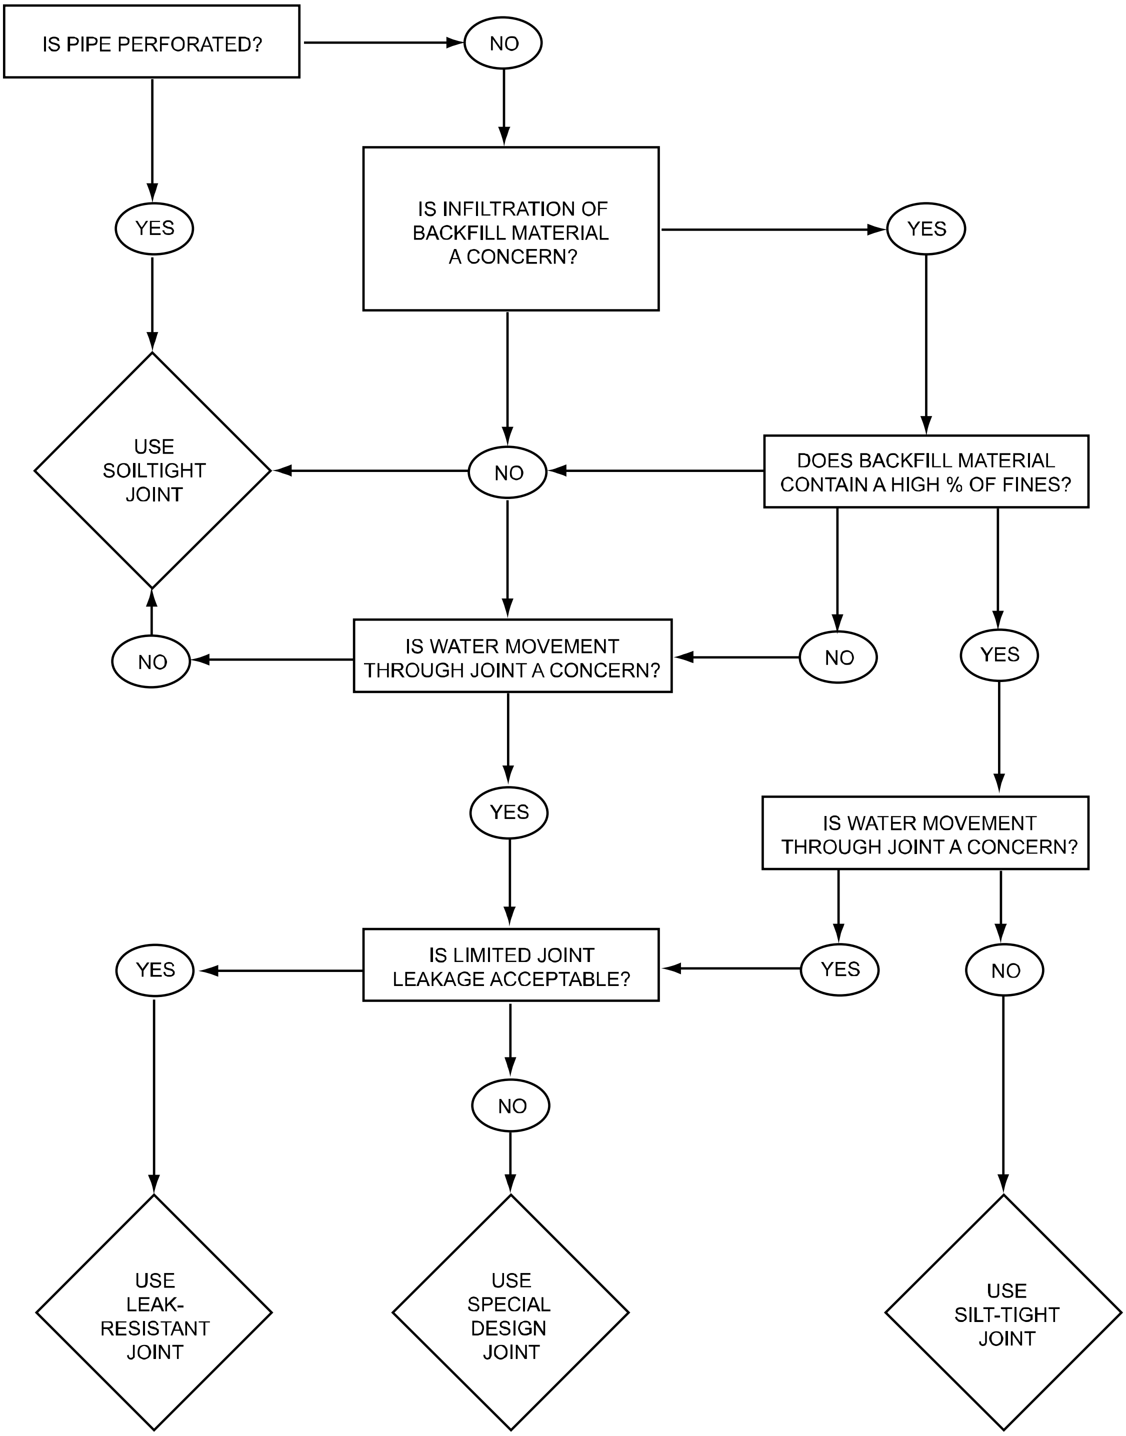
3.1.17. *watertightness*—refers to a system that has zero leakage or infiltration. This is most commonly applied to joints when lab-tested hydrostatically to a specified pressure and/or vacuum specified by the joint standard.

4. SUMMARY OF PRACTICE

4.1. This practice establishes accepted definitions and performance criteria for the joints of buried pipe. Guidance is provided on the selection process for the appropriate joint, and the standard procedures for verifying performance of the joint, both at the plant and in the field when specified, to ascertain that it meets the required performance criteria. The purpose of this practice is to produce consistent performance levels regardless of the piping material used on the project.

5. PROCEDURE

5.1. Examine the Pipe Joint Selection Process Flowchart in Figure 1. The first consideration in the pipe joint selection decision process is to determine whether the pipe for the application is solid or perforated. If the pipe is perforated, then the joint shall have openings no larger than the perforations in the pipe wall.



LEAKAGE RATE (MAXIMUM)
–200 gal/in.-dia/mi/day

Figure 1—Pipe Joint Selection Process Flowchart

5.1.1. For non-perforated pipe, a determination must be made as to the acceptability of allowing infiltration and/or exfiltration through the pipe joint. If infiltration of backfill material is not a concern and water movement through the joint is not a concern, then the default or soiltight joint should be selected for this type of application. The purpose of the soiltight joint is to maintain backfill integrity and pipe alignment and to join the ends/sections of pipe together to allow a continuous flow of water while maintaining the interior required gap between sections. This joint will limit the infiltration of soil particles in the backfill material to particles that will pass through a No. 200 sieve.

5.1.2. For non-perforated pipe where infiltration of backfill material is a concern, the designer should examine the composition of the backfill material. If there is a high percentage of soil fines (Note 1) finer than the No. 200 sieve, then a silt-tight joint should be selected for most applications.

Note 1—A high percentage of fines are defined as more than 35 percent passing the No. 200 sieve.

5.1.3. If water movement through a joint is a concern, a leak-resistant joint or a special design joint should be selected.

5.1.4. If limited joint leakage is acceptable, a leak-resistant joint shall be specified. This joint will limit water leakage at a maximum rate of 200 gallons/inch-diameter/mile/day for the pipeline system for a specified head or pressure.

5.1.5. If limited joint leakage is not acceptable, a special design joint shall be specified.

5.2. Sections 8 and 9 should be consulted once the type of joint has been selected. These sections present various methods for constructing a soiltight, silt-tight, leak-resistant, or special design joint for each type of pipe material.

5.3. To ensure proper joint performance, the pipe joint integrity shall be established by the pipe joint manufacturer prior to shipping the pipe, and further verified in the field by the contractor as witnessed by the project inspector. The manufacturer shall perform plant verification tests when specified in accordance with the Plant Test Requirements for the appropriate pipe material in Section 6. This will ensure a suitable pipe joint is being delivered to the job site. Upon completion of the installation of the pipe, field verification of any leakage requirements by visual inspection or applicable testing shall be performed by the contractor and/or engineer when specified in accordance with the Field Test Requirements outlined for the appropriate pipe material in Section 7. Failure to pass either one of these requirements when specified is cause for rejection of the pipe.

6. PLANT TEST REQUIREMENTS

6.1. *Soiltight Joint*:

6.1.1. Soiltight joints are specified as a function of opening size (maximum dimension normal to the direction that soil may infiltrate), channel length (length of the path along which the soil may infiltrate), and backfill particle size. If the size of the opening exceeds $^1/_8$ in., the length of the channel must be at least four times the size of the opening. No opening may exceed 1 in.

6.1.2. *Concrete Pipe*:

6.1.2.1. Concrete pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications.

6.1.2.2. Plain joints utilizing mortar, mastic, external geotextile wraps, and rubber gaskets are all considered soiltight joints when assembled correctly in the field.

6.1.3. *Corrugated Metal Pipe*:

6.1.3.1. Corrugated metal pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications.

6.1.3.2. Externally banded corrugated or partially corrugated metal pipe bands that are a minimum of 7.5 in. wide and used with annularly corrugated pipe ends are considered soiltight when the assembled dimensions meet the requirements of the *AASHTO LRFD Bridge Construction Specifications*, Section 26.

6.1.3.3. Corrugated metal pipe joints with a bell and spigot configuration conforming to Section 9.1.7 of M 36 are considered soiltight when assembled dimensions meet the requirements of *AASHTO LRFD Bridge Construction Specifications*, Section 26. Pipe shall be visually inspected to verify minimum requirements.

6.1.4. *Plastic Pipe*:

6.1.4.1. Plastic pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.2. *Silt-Tight Joint*:

6.2.1. A silt-tight joint is resistant to infiltration of particles that pass the No. 200 sieve. Silt-tight joints are specified to provide protection against infiltration of backfill material containing a high percentage of fines, and typically utilize some type of filtering or sealing component, such as an Elastomeric rubber seal or geotextile wrap. Geotextile wraps are manufactured to tolerances that assure silt will not pass through them. The successful performance of these wraps in the field is dependent on their installation. If a geotextile wrap is specified for use, the material specified should meet M 288 with an Apparent Opening Size (AOS) > 70.

6.2.2. *Concrete Pipe*:

6.2.2.1. Concrete pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.2.2.2. Concrete pipe joint designs meeting silt-tight joint requirements that utilize a rubber gasket or mastic filler as the sole method of sealing shall verify compliance to the silt-tight requirements by requiring the joint design be subjected to a production pipe proof test by a plant hydrostatic test described in Section 6.2.2.3. Upon successful proof testing of the joint design, further joint acceptance of the pipe to be furnished to the project shall be based on joint dimensional verification and certification that the joint configuration and gasket or mastic filler conforms to the approved joint.

6.2.2.3. *Plant Proof-of-Design Test*—Plant proof-of-design test for silt-tight joints shall be in accordance with M 315 (ASTM C 443) except the maximum hydrostatic test pressure shall not be greater than 2 psi for the straight and deflected position.

6.2.2.4. Concrete pipe joint designs meeting silt-tight joint requirements that utilize an external joint wrap as the sole method of sealing shall verify compliance to the silt-tight requirements by having the joint design include the placement around the entire circumference of the joint by either (a) external sealing bands per ASTM C 877 or (b) 12-in. wide geotextile separation fabric meeting requirements of Section 6.2.1 of this standard.

6.2.3. *Corrugated Metal Pipe*:

6.2.3.1. Corrugated metal pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.2.3.2. Corrugated metal joints, including the bell and spigot configuration, are considered silt-tight when they are wrapped around their entire circumference with a minimum 12-in. wide geotextile separation fabric meeting the requirements of Section 6.2.1 of this standard. Pipe shall be visually inspected to verify minimum requirements.

6.2.3.3. Externally banded corrugated or partially corrugated metal pipe bands that are a minimum of 10.5 in. wide and fully corrugated with annularly corrugated pipe ends are considered silt-tight when the assembled dimensions meet the requirements of the *AASHTO LRFD Bridge Construction Specifications*, Section 26.

6.2.3.4. Bell and spigot joints that use an elastomeric gasket as the sole means of sealing the joint shall meet the performance requirements of ASTM D 3212, with the exception that the maximum hydrostatic test pressure shall be a minimum of 2 psi.

6.2.3.5. Silt-tight joints shall meet the requirements of *AASHTO LRFD Bridge Construction Specifications*, Section 26 for erodible soils.

6.2.4. *Plastic Pipe*:

6.2.4.1. Plastic pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.2.4.2. Silt-tight joints shall utilize an elastomeric rubber seal meeting the requirements of ASTM F 477. Alternative methods of joining (e.g., external joint wraps) shall be allowed provided the requirements of Section 6.2.4.3 are achieved.

6.2.4.3. Silt-tight performance shall be verified by meeting the requirements of ASTM D 3212, with the exception that the hydrostatic test pressure shall be a minimum of 2 psi.

6.3. *Leak-Resistant Joint*:

6.3.1. A leak-resistant joint is specified when water leakage into or out of the pipeline system is a concern. Leak-resistant joints limit water leakage at a maximum rate of 200 gallons/inch-diameter/mile/day for a specified head or pressure.

6.3.2. *Concrete Pipe*:

6.3.2.1. Concrete pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.3.2.2. Concrete pipe joint designs meeting leak-resistant joint requirements that utilize a rubber gasket or mastic filler as the sole method of sealing shall verify compliance to the leak resistant requirements by having the joint design, represented by a production pipe, proof tested by a plant hydrostatic test described in Section 6.3.2.3. Upon successful proof testing of the joint design, further joint acceptance of the pipe to be furnished to the project shall be based on joint dimensional verification and certification that the joint configuration and gasket conforms to the approved joint.

6.3.2.3. *Plant Proof-of-Design Test*—Plant proof-of-design test for a leak-resistant joint shall be in accordance to M 315 (ASTM C 443), with the maximum test pressures of 10.8 psi in the straight alignment and 10 psi in the deflected alignment.

6.3.2.4. Concrete pipe joint designs meeting leak-resistant joint requirements and utilizing an external joint wrap as the sole method of sealing shall verify compliance to the leak-resistant requirements by requiring that the joint design include the placement around the entire circumference of the joint by an external sealing band as specified by ASTM C 877 Type 1 or Type 2.

6.3.3. *Corrugated Metal Pipe*:

6.3.3.1. Corrugated metal pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications.

6.3.3.2. *Plant Proof-of-Design Test*—AASHTO standards have not yet been developed to demonstrate a plant proof-of-design test for corrugated metal pipe. A suitable plant proof-of-design test is recommended to be provided by the manufacturer. This plant proof-of-design should test the leak-resistant joint under conditions more severe than expected in the field in order to allow for the greater installation variables that occur in the field compared with plant testing. Pipe pressures for the plant proof-of-design test are recommended to be on the same order as required for concrete pipe and plastic pipe.

6.3.4. *Plastic Pipe*:

6.3.4.1. Plastic pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.3.4.2. Leak-resistant joints shall be bell and spigot and utilize an elastomeric rubber seal meeting the requirements of ASTM F 477. Alternative methods of joining (e.g., external joint wraps) shall be allowed provided the requirements of Section 6.3.4.3 are achieved.

6.3.4.3. *Plant Proof-of-Design Test*—Plant proof-of-design test for leak resistance shall be verified in the lab by meeting all of the requirements of ASTM D 3212. The hydrostatic test pressure and vacuum specified in the test method shall be 10.8 psi.

6.4. *Special Design Joint*:

6.4.1. *Concrete, Corrugated Metal, and Plastic Pipe*:

6.4.2. Special design joints are joints requiring special strength in bending or shear, pull-apart capabilities, or unusual features such as restrained joints placed on severe slopes, welded joints, flanged and bolted joints for high pressures, high heads, or velocities. These joints are typically described within the special provisions of the project specifications. Watertight joints that provide zero leakage for a specified head or pressure application are included in this category.

6.4.3. Special design pipe joints shall be inspected to ensure dimensions and tolerances are in accordance with the design joint. Pipe, gaskets, wraps, and all other material used to make and seal the joint shall be inspected for compliance to their respective specifications. All measurements shall be made in accordance with AASHTO and ASTM standards.

6.4.4. Special design pipe joints shall be tested in accordance to the project specifications.

7. FIELD TEST REQUIREMENTS

A minimum of five percent of all installed pipe joints will be inspected unless otherwise specified by an agency.

7.1. *Soiltight Joints*:

7.1.1. *Concrete, Corrugated Metal, and Plastic Pipe*:

7.1.1.1. Installed pipe joints shall have a visual or video inspection in the field to ensure compliance to the project specifications. Open joints or joints that are flowing particles larger than those particles retained on a No. 200 sieve shall be repaired or replaced as necessary to comply with the requirements of this standard. (See *AASHTO LRFD Bridge Construction Specifications*, Sections 26, 27, and 30 on cracks and joint defects.)

Note 2—If particles larger than those retained on a No. 200 sieve are restricted from passing through the joint, then the joint has performed its intended design function. However, if there is a significant presence of particles smaller than those retained on a No. 200 sieve passing through the joint, it may mean that the initial design assumption of a soiltight joint requirement was incorrect, and remedial action may need to be taken.

7.2. *Silt-Tight Joints*:

7.2.1. *Concrete, Corrugated Metal, and Plastic Pipe*:

7.2.1.1. Installed pipe joints shall have a visual or video inspection in the field to ensure compliance to the project specifications. Open joints or joints showing sediment as a result of flowing infiltration or exfiltration of particles shall be repaired or replaced as necessary to comply with the requirements of this standard. (See *AASHTO LRFD Bridge Construction Specifications*, Sections 26, 27, and 30 on cracks and joint defects.)

7.3. *Leak-Resistant Joints*:

7.3.1. *Concrete, Corrugated Metal, and Plastic Pipe*:

7.3.1.1. Installed pipe joints shall have a visual or video inspection to ensure compliance to the project specifications. Open joints or joints showing sediment as a result of measurable infiltration or exfiltration shall be repaired or replaced as necessary to comply with the requirements of this standard. If joints are showing leakage or the pipeline is required by specification to be tested, they shall be tested in accordance with the specific project specifications. Testing procedures that may be used for concrete, corrugated metal, or plastic pipe sections are listed below. (See *AASHTO LRFD Bridge Construction Specifications*, Sections 26, 27, and 30 on cracks and joint defects.)

7.3.1.2. Installed pipe joints shall be tested to meet the performance requirements of a leak-resistant joint as specified in accordance with ASTM C 969.

7.3.1.3. As an alternative, concrete pipe joints may be tested in accordance with ASTM C 924. Concrete pipelines with diameters of 27 in. or greater are permitted to utilize successful completion of ASTM C 1103 to verify compliance to project specifications.

7.3.1.4. As an alternative, plastic pipe joints may be tested in accordance with ASTM F 1417.

7.4. *Special Design Joint*:

7.4.1. *Concrete, Corrugated Metal, and Plastic Pipe*:

7.4.1.1. Pipe joints shall have a visual or video inspection in the field to ensure compliance to the project specifications. Open joints or joints showing sediment as a result of measurable infiltration or exfiltration, when prohibited by project specification, shall be repaired or replaced as necessary to comply with the requirements of this standard.

7.4.1.2. Installed pipe joints shall be tested in accordance with project specifications.

7.4.1.3. *AASHTO LRFD Bridge Construction Specifications*, Section 26 covers standard and special strength requirements for use with soft foundations, slope drains, and curvilinear installations. Strength and performance limits beyond these may be specified as required.

7.4.1.4. When restrained joints are required, separation of the joint shall not exceed the limit specified on the project plans or in the specifications.

8. ENGINEERING DESIGN CONSIDERATIONS

8.1. *Joint Selection Criteria*—Joint selection should be based on the following criteria:

8.1.1. *Soiltight Joint*—Soiltight joints may be specified where the passage of water through the joint to or from the surrounding soil is acceptable or even desirable, and where the migration of backfill or soil through the joint is not likely due to the backfill gradation or low migration probability of the soil. Openings in the joint should be of such size that the surrounding material could not pass into the pipe. Perforated pipe may have soiltight joints provided the openings in the joint are no larger than the perforations in the pipe. Perforated pipe utilizing a geotextile wrap should have the wrap extend over the entire joint assembly.

8.1.2. *Silt-tight Joint*—Silt-tight joints may be specified where the passage of water through the joint to or from the surrounding soil is acceptable, but the infiltration or fines from the surrounding backfill or soil is precluded. Silt-tight joints can incorporate an appropriate geotextile wrap, a rubber gasket, or both. Silt-tight joints that employ a rubber gasket as the sole means to seal the joint to silt-tightness should pass a 2 psi laboratory test utilizing the test specified in Section 6.

8.1.3. *Leak-resistant Joint*—Leak-resistant joints may be specified where only very limited joint leakage is acceptable. These joints should be required when it is undesirable to allow leakage of storm water from the pipe into the surrounding soil, or leakage of groundwater from the surrounding soil into the pipe. The acceptable leakage rate should be shown in the project specifications as defined by the design engineer. Leak-resistant joints provide additional assurance against soil migration into the pipe.

8.1.3.1. Leak-resistant joints require careful inspection to assure compliance to allowable leakage rate. If any visible leakage is seen or if required by project specifications, additional field leakage testing is required. Successful completion of this testing is required for pipeline acceptance.

8.1.3.2. The designer should be aware of sewer projects that may require allowable leakage rates less than the leak-resistant joint described herein due to specific permit requirements or local ordinances. Some examples are sanitary sewers, pipelines in potable water well-head protected areas, or conduits buried in or transporting hazardous effluents. In such cases, special joints will be required.

8.1.4. *Special Joints*—Special joints may include restrained joints, welded joints, or any special configuration required to meet specific project demands not described in this practice.

8.1.4.1. Restrained joints may be required when pipe is installed on a steep slope or where internal pressure or force may generate pull-apart forces. Installations such as slope drains may require some restraint to prevent pull-apart. Restraints are normally mechanical in design, utilizing restraining systems across the pipe joint or by employing corrugated pipe bands for corrugated metal pipe.

8.1.4.2. Welded joints may be required where leakage is completely unacceptable. Field welding of steel pipe should be done as specified by M 36, Sections 7.4 and 7.6. Thermoplastic pipe may be welded using butt fusion, extrusion welding, or resistance welding.

8.2. *Joint Testing*—Pipe joint test requirements are divided between manufacturer's laboratory (plant) proof-of design testing and joint specification verification tests, and post-installation testing to verify pipeline performance and project specification compliance. Basic requirements are given in Table 1.

Table 1—Proposed AASHTO Pipe Joint Descriptions and Test Procedures

Joint Type	Joint Description	Laboratory Test	Field Test
Soiltight	Soiltight joints prohibit the migration of soil larger than No. 200 sieve through the joint. Soil-tight joints are specified as a function of opening size, channel length, and backfill particle size. If the size of the opening exceeds 3 mm, the length of the channel must be at least four times the size of the opening. Soiltight joints may utilize connecting bands, elastomeric rubber seals, geotextile wrap, or applied bulk mastic sealant.	Assemble a typical joint and measure openings.	Visual for proper assembly.
Silt-tight	Silt-tight joints prohibit the migration of soil smaller than No. 200 sieve through the joint. Silt-tight joints may utilize connecting bands, elastomeric rubber seals, geotextile wrap, or all of these.	Geotextile wrap shall meet AASHTO M 288, Table 2, with an Apparent Opening Size (AOS) > 70. Gasket shall meet respective pipe joint standard. Joints utilizing gasket only as silt-tight seal shall be designed to pass a laboratory test of 2 psi.	Visual for excessive leakage or leakage carrying soil fines.
Leak-Resistant	Leak-resistant joints are specified where only very limited joint leakage is acceptable The allowable rate is to be shown in the project specifications. Leak-resistant joints may utilize connecting bands, elastomeric rubber seals, impervious wrap, or all of these.	Impervious wraps shall meet ASTM C 877 Type 1 or 2. Gaskets shall meet respective pipe joint standard. Joints meeting leak - resistant criteria shall be designed to pass a laboratory test/proof-of-design test that demonstrates compliance with the leakage rate at the specified head or pressure.	Visual for leakage and/or specified standard test methods for installation acceptance of gravity sewer lines using low-pressure air or water, or vacuum.
Special	Special joints are any joint system or performance requirements not mentioned within this practice. These joints typically require a special provision to be written into the project specifications to cover the unique aspects of the joint system needed. Some examples of special joints are pressure-rated joints, restrained joints, welded joints.	As specified in project documents.	As specified in project documents.

9. RATIONALE

9.1. Joint specifications for the various pipe materials have been developed largely independent of one another. While many similarities exist among the separate joint specifications, there are also key differences due to the differing joint configurations and designs of the various pipe materials. Though each pipe material may have its own plant or laboratory verification test, it is important that all pipes in a given joint classification perform to a defined and consistent level once installed.

9.2. Upon installation, joints may be tested to a specified performance level. In the past, buried pipes have been specified as meeting soiltight, silt-tight, or watertight joint performance requirements. However, due to the vague definition of these performance levels for the various pipe materials, verification of joint performance in the field has been difficult. The purpose of this practice is to standardize the definitions of the performance levels of joining systems for all pipe materials and the means by which that specified performance level is verified.

9.3. More consistent specification of pipe joints will result when all parties involved understand the process of selecting the correct pipe joint for each particular application, and the criteria that must be met as a result of the definition of that particular type of joint. This practice establishes accepted definitions and performance criteria for the joints of buried pipe.

APPENDIX

(Nonmandatory Information)

X1. JOINT TESTING CRITERIA

X1.1. To assist the designers' knowledge regarding various joint testing criteria established by existing ASTM standards or employed by other departments within AASHTO, this listing and testing protocols are provided. These Department Of Transportation test methods are for informational purposes and are not necessarily the recommended specifications of the Subcommittee on Materials.

X2. STANDARD LEAKAGE TEST METHODS

Note X1—This section could include any other testing standard or information not previously discussed within the body of this practice.

X2.1. *Departments of Transportation Test Methods and Requirements*:

X2.1.1. *Washington State Department of Transportation*:

7-04.3(4) Cleaning and Testing

7-04.3(4)A General

Storm sewers and appurtenances, where required in the Plans, shall be cleaned and tested after backfilling by either the exfiltration or low-pressure air method at the option of the Contractor, except where the ground water table is such that the Engineer may require the infiltration test.

All work involved in cleaning and testing sewer lines between manholes or rodding inlets as required shall be completed within 15 working days after backfill of sewer lines and structures. Any further delay will require the written consent of the Engineer. The Contractor shall furnish all labor, materials, tools, and equipment necessary to make the test and clean the lines. The Contractor shall perform the tests in the presence of the Engineer. Precautions shall be taken to prevent joints from drawing during tests, and any damage resulting from these tests shall be repaired by the Contractor at no expense to the Contracting Agency. The manner and time of testing shall be subject to approval by the Engineer.

All wyes, tees, and stubs shall be plugged with flexible jointed caps, or acceptable alternate, securely fastened to withstand the internal test pressure. Such plugs or caps shall be readily removable, and their removal shall provide a socket suitable for making a flexible jointed lateral connection or extension.

If the Contractor elects to test large-diameter pipe one joint at a time, leakage allowances shall be converted to per joint by calculating the allowable leakage as described in Section 7-04.3(4)B or 7-04.3(4)C and then dividing by the number of joints in the tested section. If leakage exceeds the allowable amount, corrective measures shall be taken and the line then retested to the satisfaction of the Engineer.

If any storm sewer installation fails to meet the requirements of the test method used, the Contractor shall determine the source or sources of leakage and shall repair or replace all defective materials and/or workmanship at no expense to the Contracting Agency. The complete pipe installation shall meet the requirements of the test method used before being considered acceptable.

7-04.3(4)B Exfiltration Test—Storm Sewers

Prior to making exfiltration leakage tests, the Contractor may fill the pipe with clear water to permit normal absorption into the pipe walls, provided the leakage test shall be completed within 24 hours after such filling.

Leakage shall be not more than 5 liters per hour per meter of diameter per meter of storm sewer pipe, with a minimum test pressure of 2 meters column above the crown at the upper end of the pipe or above the active ground water table, whichever is higher as determined by the Engineer. The length of pipe tested shall be limited so that the pressure on the invert of the lower end of the Section tested shall not exceed 5 meters of water column. For each increase in pressure of 0.5 meter above a basic 2 meters measured above the crown at the lower end of the test section, the allowable leakage shall be increased by 10 percent.

7-04.3(C) Infiltration Test—Storm Sewers

Whenever the ground water table is above the crown of the higher end of the pipe Section at the time of testing, an infiltration test may be performed in lieu of the exfiltration test upon written permission of the Engineer. The maximum allowable limit for infiltration shall be 4 liters per hour per meter of diameter per meter of length with no allowance for external hydrostatic head.

7-04.3(4) D Low Pressure Air Test—Storm Sewers

Low pressure air testing may be used for pipes 750 millimeters in diameter and smaller in accordance with the following:

The first Section of pipe not less than 100 meters in length installed by each crew shall be tested in order to qualify the crew and material. Successful tests for this Section shall be a prerequisite to further pipe installation by said crew.

Immediately following the pipe cleaning, the pipe installation shall be tested with low-pressure air. Air shall be slowly supplied to the plugged pipe installation until the internal air pressure reaches 28 kilopascals greater than the average backpressure of any ground water that may submerge the pipe. At least two minutes shall be allowed for temperature stabilization before proceeding further.

The pipeline shall be considered acceptable when tested at an average pressure of 21 kilopascals greater than the average backpressure of any ground water that may submerge the pipe. The allowable rate of air loss shall be 1.8 liters per minute per square meter of internal pipe surface, but the total calculated air loss shall not be less than 55 liters per minute nor more than 200 liters per minute.

The requirements of this specification shall be considered satisfied if the time required in seconds for the pressure to decrease from 24 to 17 kilopascals greater than the average back pressure of any ground water that may submerge the pipe is not less than that computed according to the Standard Plan.

7-04.3(4) F Other Test Allowances—Storm Sewers

All lateral or side storm sewer branches included in the test Section shall be taken into account in computing allowable leakage. An allowance of 2.5 liters per hour per meter of head above invert shall be made for each manhole included in a test section.

X2.1.2. *Michigan Department of Transportation Test Method (MTM 723)*

1. *Scope*:
    1.1 This test method describes the requirements for independent laboratory testing of culvert and sewer joints, up to 24 in. (600 mm) in diameter, to verify WATERTIGHTNESS. Laboratory test results will be considered valid for five years once they have been reviewed and accepted by MDOT. Retesting will be required during this five-year period whenever the joint configuration or materials are changed.

1.2 Testing may be conducted by the manufacturer when witnessed and certified by an authorized representative of an independent laboratory. This authorized representative must verify the design and calibration of the testing apparatus.

1.3 Two procedures are included in this MTM either of which may be used to verify the WATERTIGHTNESS of sewer and culvert joints. The rate of water leakage from the test section or the rate of air pressure drop in the test section may be measured.

2. *Referenced Documents*:

2.1 *ASTM Standards*:

- C 924M, Standard Practice for Testing Concrete Pipe Sewer Lines by Low-Pressure Air Test Method (Metric)
- C 969M, Standard Practice for Infiltration and Exfiltration Acceptance Testing of Installed Precast Concrete Pipe Sewer Lines (Metric)
- C 1091, Standard Test Method for Hydrostatic Infiltration Testing of Vitrified Clay Pipe Lines
- F 1417, Standard Test Method for Installation Acceptance of Plastic Gravity Sewer Lines Using Low-Pressure Air

3. *Significance and Use*:

3.1 Culvert and sewer joints, 24 in. (600 mm) or less in diameter, tested and approved in accordance this MTM will be placed on the Qualified Products List.

4. *Apparatus*:

4.1 Testing may be carried out using either air pressure or hydrostatic pressure. Provide plugs capable of sealing the sewer or culvert test section for the appropriate test method.

4.2 The pressure gauge used, for either method, shall have a range of 0 to 10 psi (70 kPa). The gauge shall read to the nearest 0.07 psi (0.5 kPa) with an accuracy of +0.01 psi (0.1 kPa).

4.3 The pressure test apparatus must include a 6.0 psi (40 kPa) pressure relief device.

4.4 When testing plastic pipe, the pipe shall be deflected five percent (5 percent) during the entire testing period to represent the maximum allowable deflection at the time of field installation. The apparatus described in ASTM F 949 shall be used to deflect the plastic pipe.

5. *Test Section*:

5.1 The pipe section to be pressurized using the air or hydrostatic test procedure described in Section 6 shall consist of either two standard length pipe sections for the diameter being tested or two pipe segments each having a minimum length of ten feet, properly connected in accordance with the watertight joint design.

5.2 Jointing procedures used in the laboratory must be readily adaptable for use in the field to allow verification testing.

5.3 The test section shall be clean and free of debris at the time of testing.

6. *Test Procedure*:

6.1 The test procedures presented have been adapted from ASTM field installation acceptance methods for hydrostatic (ASTM C 969M, C 1091) and air pressure (ASTM C 924M, F 1417) testing.

6.2 *Hydrostatic Pressure Testing*

6.2.1 Plug the ends of the test section to provide a watertight seal and provide bracing to withstand the expected test pressure. Bracing shall not create longitudinal compressive forces within the test section. One of the plugs shall be fitted with an orifice through which water can be introduced into the test section. A water supply line shall be fitted with suitable control valves and a pressure gauge allowing continuous monitoring of the hydrostatic pressure at the top of the pipe.

6.2.2 Fill the test section completely with water.

6.2.3 For concrete and clay pipe, the water-filled test section is to stand for a minimum of four hours and a maximum of 72 hours to allow for water absorption by the pipe material. Refill the test section as necessary before continuing with testing.

6.2.4 Bring the hydrostatic pressure in the test section to 4.0 psi (28 kPa) and begin timing the test. Measure the leakage from the pipe joint while maintaining 4.0 psi (28 kPa) for 20 minutes.

6.3 *Air Pressure Testing*

6.3.1 Plug the ends of the test section to provide an airtight seal and provide bracing to withstand the expected test pressure. Bracing shall not create longitudinal compressive forces within the test section. One of the plugs shall be fitted with an orifice through which air can be introduced into the test section. An air supply line shall be fitted with suitable control valves and a pressure gauge allowing continuous monitoring of the air pressure.

6.3.2 Pressurize the pipe to 4.0 psi (28 kPa). Allow a minimum of two minutes for the air pressure to stabilize to between 3.5 psi (24 kPa) and 4.0 psi (28 kPa). If necessary, add air to the test section to maintain the pressure between 3.5 psi (24 kPa) and 4.0 psi (28 kPa).

6.3.3 After the air pressure has stabilized between 3.5 psi (24 kPa) and 4.0 psi (28 kPa), close the air supply valve so that no additional air may enter the test section.

6.3.4 Record the air pressure and begin timing the test. Record the time required for the air pressure to decrease 1.0 psi (7.0 kPa).

7. *Basis of Acceptance*:

7.1 *Hydrostatic Pressure Verification*

The method of jointing is considered acceptable when the leakage is less than or equal to 200 gallons per inch of inside diameter per mile per day (20 liters per millimeter of inside diameter per kilometer of pipe per day).

7.2 *Air Pressure Verification*

The method of jointing is considered acceptable when the time required for the air pressure to decrease 1.0 psi (7.0 kPa) exceeds the minimum times listed in Table 723-2.

8. *Report*:

8.1 Independent laboratory test reports must be submitted which document that a minimum of three passing tests (either three hydrostatic or three air pressures) have been performed for each type of pipe jointing system and each diameter of pipe being submitted for approval as a Qualified Product.

8.2 *Each report must include the following information*:

- pipe and joint component manufacturer’s name,
- specific product name(s),
- description of joint configuration,
- material,
- specification for each component,
- the diameter of pipe joint tested,
- standard pipe section length for pipe joint tested,
- joint assembly procedure used in laboratory testing,
- the date and location of testing,
- observed leakage rate (hydrostatic) or time for 7.0 kPa pressure drop (air),
- field assembly diagram sufficient to allow identification of all joint system components, and
- certification statement by authorized representative of independent laboratory if testing is conducted by manufacturer and independently witnessed.

Table 723-1

Maximum Leakage for Various Pipe Diameter and Standard Pipe Section Lengths for Twenty-Minute Test Interval

Pipe Diameter, in. (mm)	Length of Pipe Section, ft (mm)	Allowable Leakage, oz (L)
12 (300)	8 (2400)	6.8 (0.20)
	10 (3000)	8.5 (0.25)
	12 (3600)	10.0 (0.30)
	15 (4500)	12.8 (0.38)
	18 (5400)	15.2 (0.40)
15 (375)	8 (2400)	8.5 (0.25)
	10 (3000)	10.5 (0.31)
	12 (3600)	12.5 (0.37)
	15 (4500)	15.9 (0.47)
	18 (5400)	18.9 (0.56)
18 (450)	8 (2400)	10.1 (0.30)

Standard Practice for

Match Curing of Concrete Test Specimens

AASHTO Designation: PP 54-06[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Match Curing of Concrete Test Specimens

AASHTO Designation: PP 54-06[1]

1. SCOPE

1.1. This recommended practice covers procedures for making and curing cylindrical concrete specimens at the same temperature as that measured in a concrete member.

1.2. The concrete sample used to make the specimens shall be taken from the concrete being placed in the same member where the temperature is to be measured.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- M 205M/M 205, Molds for Forming Concrete Test Cylinders Vertically
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 119M/T 119, Slump of Hydraulic Cement Concrete
- T 141, Sampling Freshly Mixed Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method
- T 196M/T 196, Air Content of Freshly Mixed Concrete by the Volumetric Method

2.2. *ASTM Standards*:
- C 125, Standard Terminology Relating to Concrete and Concrete Aggregates
- C 1064/C 1064M, Standard Test Method for Temperature of Freshly Mixed Hydraulic-Cement Concrete

3. TERMINOLOGY

3.1. For definitions of terms used in this practice, refer to ASTM C 125.

4. SIGNIFICANCE AND USE

4.1. This method provides a procedure for curing concrete cylinders at the same temperature as that monitored at a specific location in a concrete member. Consequently, the compressive strength of the cylinder more accurately represents the in-place concrete strength of the member. The method is particularly useful for determining the concrete compressive strength at early ages in the fabrication of precast concrete members or for determining the compressive strength of concrete at a critical location in a structural member.

5. APPARATUS

5.1. The apparatus shall consist of a monitoring and heating system capable of maintaining concrete cylinders at a temperature within ±2°C (±4°F) of the temperature of the concrete at a specific location in the member. A satisfactory system may include a temperature sensor in the member, a controller, special insulated cylinder molds with built-in heating systems, and a temperature sensor in the molds.

5.2. *Temperature Sensor in the Member*—Temperature sensors shall be placed at the most critical locations for strength development. The purchaser shall determine the critical locations for temperature sensors in each type of member and show the locations on the project drawings or the contractor shall submit drawings showing proposed locations to the purchaser for approval.

5.2.1. Temperature sensor wire shall be durable enough to withstand the wear associated with construction operations and shall have a size of 20 awg or larger in diameter (Note 1).

Note 1—In locations where electrical interference may affect the measured data, shielded wire should be used.

5.3. *Controller*—The controller shall be capable of monitoring the temperatures of the member and cylinders and controlling the heating system to maintain the cylinder temperature within ±2°C (±4°F) of the temperature measured in the member. Proper operation of the system shall be verified on a regular basis in accordance with the manufacturer's recommendations.

5.4. *Cylinder Molds*:

5.4.1. Cylinder molds shall conform to the requirements of M 205M/M 205 for reusable molds and shall be fitted with watertight lids to prevent moisture loss.

5.4.2. Cylinder molds shall have inside dimensions of 100 by 200 mm (4 by 8 in.) or 150 by 300 mm (6 by 12 in.)

5.4.3. When heated cylinder molds are used, they shall have built-in thermocouples that sense the temperature of the concrete specimens. Each cylinder mold shall have a heating element that surrounds the core of the mold, provides uniform heat to the concrete specimen, and is capable of maintaining a cylinder temperature that matches the temperature of the concrete member within the stated tolerance (Note 2).

Note 2—Because the match-curing system only provides heat to the cylinder and cannot cool it, the temperature of the cylinder may exceed that of the member if the temperature of the member decreases at a greater rate than that of the cylinder.

6. TEST SPECIMENS

6.1. Test specimens shall be cylinders of concrete cast and hardened in an upright position, with a length equal to twice the diameter. When the nominal maximum size of coarse aggregate does not exceed 50 mm (2 in.), the cylinder may be 150 by 300 mm (6 by 12 in.). When the nominal maximum size of coarse aggregate does not exceed 25 mm (1 in.), the cylinder may be 100 by 200 mm (4 by 8 in.).

6.2. A minimum of two 150 by 300 mm (6 by 12 in.) or three 100 by 200 mm (4 by 8 in.) cylinders shall be made for each strength test when the specified strength does not exceed 34 MPa (5000 psi). A minimum of three cylinders shall be made for each strength test when the specified strength exceeds 34 MPa (5000 psi).

7. PROCEDURE

7.1. *System Installation*—Prior to concrete placement, the temperature sensors in the member shall be securely fixed at the specified locations. The sensor tips shall be installed such that they do not have direct contact with steel reinforcement. Prior to concrete placement, proper operation of the match-curing system shall be verified in accordance with the manufacturer's recommendations.

7.2. *Sampling Concrete*—The samples used to fabricate test specimens under this standard shall be obtained in accordance with T 141 unless an alternative procedure has been approved. The concrete sample shall be taken from concrete placed as close as practical to the temperature sensor in the member.

7.3. *Slump, Air Content, and Temperature*:

7.3.1. *Slump*—Measure and record the slump of each batch of concrete from which specimens are made, immediately after remixing in the receptacle as required by T 119M/T 119.

7.3.2. *Air Content*—Determine and record the air content in accordance with either T 152 or T 196M/T 196. The concrete used in performing the air content test shall not be used in fabricating test specimens.

7.3.3. *Temperature*—Determine and record the concrete temperature in accordance with ASTM C 1064/C 1064M.

7.4. *Molding Specimens*—Test specimens shall be molded using the procedures of T 23.

7.5. *Match Curing*:

7.5.1. *Covering after Finishing*—Immediately after finishing, precautions shall be taken to prevent evaporation and loss of water from the specimens. Cover specimens with a nonabsorbent, nonreactive plate or a sheet of impervious plastic.

7.5.2. *Specimen Storage*—During match curing, molds and specimens shall be shielded from direct rays of the sun, other heating devices, rain, and wind. All molds controlled by the same controller shall be stored together (Note 3).

Note 3—Because the match-curing system only provides heat to the cylinders, better temperature control is obtained when the cylinders are stored in an environment that is cooler than the temperature of the concrete in the member.

7.5.3. Connect the molds to the controller and match cure for the specified length of time.

7.5.4. Following the match-curing period, the cylinders shall be removed from the molds and subsequently stored in a similar temperature and moisture environment as the member unless stated otherwise in the project specifications.

7.5.5. When match-cured cylinders are used to determine concrete release strengths, it is recommended that match curing be continued for as long as possible and until the cylinders are stripped for testing.

---

[1] Approved in January 2006, this standard was first published in 2006.

Standard Practice for

Static Segregation of Hardened Self-Consolidating Concrete (SCC) Cylinders

AASHTO Designation: PP 58-08

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Static Segregation of Hardened Self-Consolidating Concrete (SCC) Cylinders

AASHTO Designation: PP 58-08

1. SCOPE

1.1. This method covers procedures for determining the static segregation resistance (stability) of self-consolidating concrete (SCC) using hardened test specimens.

1.2. The concrete used to make the molded specimens shall be sampled after all on-site adjustments have been made to the mixture proportions, including the addition of mix water and admixtures.

1.3. The text of this standard references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables and figures) shall not be considered as requirements for this standard.

1.4. The values stated in SI units are to be regarded as the standard.

1.5. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 205M/M 205, Molds for Forming Concrete Test Cylinders Vertically
- T 22, Compressive Strength of Cylindrical Concrete Specimens
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 141, Sampling Freshly Mixed Concrete

3. SIGNIFICANCE AND USE

3.1. This method provides a visual assessment of static segregation resistance of SCC using a Hardened Visual Stability Index (HVSI) rating to evaluate molded or cored hardened concrete cylinders cut lengthwise in two.

3.2. If the specimens are made and cured as specified herein, the resulting static segregation test data are able to be used for the following purposes:

3.2.1. Acceptance testing for specified static segregation limits,

3.2.2. Checking the adequacy of mixture proportions to resist static segregation, and

3.2.3. Quality control.

4. APPARATUS

4.1. *Molds, Cylinder*—150 by 300 mm (6 by 12 in.) cylinder molds for casting concrete test specimens shall conform to the requirements of M 205M/M 205.

4.2. *Small Tools*—Hand-held wood or metal float or trowel.

4.3. *Saw*—The saw shall have a diamond or silicon-carbide cutting edge and shall be capable of cutting specimens without excessive heating or shock.

4.4. *Core Drill*—The core drill shall conform to the requirements of T 24M/T 24.

4.5. A suitable container for filling specimen molds with SCC.

Note 1—Experience has shown pails and plastic cylinder molds to be suitable containers.

5. SAMPLING CONCRETE

5.1. Samples of freshly mixed SCC used to fabricate test specimens under this standard shall be obtained in accordance with T 141.

5.2. Cored test specimens taken from hardened self-consolidating concrete under this standard shall be obtained in accordance with T 24M/T 24, except for the following:

5.2.1. Cored test specimens may be taken so that the axis is perpendicular or parallel to the concrete as it was originally placed, and

5.2.2. Cored test specimens shall have a minimum diameter of 50 mm (2 in.) and sufficient length to assess extent of static segregation resistance.

5.3. Record the identification of the test specimens with respect to the location of the concrete represented and the time of casting.

6. MOLDING AND CURING SPECIMENS OF FRESHLY MIXED SCC

6.1. *Making Specimens*:

6.1.1. A minimum of two fresh test specimens shall be molded as near as practicable to the place where they are to be stored. If it is not practicable to mold the specimens where they will be stored, move them to the place of storage immediately after strike off. Place molds on a rigid surface free from vibration and other disturbances. The supporting surface shall be level to within 20 mm/m (0.25 in./ft).

6.1.2. Specimen molds shall be filled in one lift, poured using a suitable container without vibration, rodding, or tapping.

6.1.3. Strike off the surface of the concrete level with the top of the mold using a float or trowel.

6.2. *Curing*:

6.2.1. Immediately after molding and finishing, the specimens shall be capped with a plastic cylinder lid and stored for a period up to 24 h at a minimum temperature of 16°C (60°F).

7. PROCEDURE

7.1. Before subjecting the specimens to sawing, they either shall have a minimum curing period of 24 h or shall attain a minimum compressive strength of 6200 kPa (900 psi) according to T 22.

7.2. Specimens shall be sawn lengthwise down the center. If a specimen cannot be satisfactorily sawed smooth for lack of curing, then the remaining specimen(s) shall remain undisturbed for an additional minimum curing period of 24 h before being subjected to sawing.

7.3. Make a visual assessment of the cut planes of the hardened concrete cylinder or core using the criteria in Table 1 and illustrated in Figures 1 through 8. The cut planes shall be wetted to facilitate visual inspection. For cores taken perpendicular to the concrete as it was originally placed, the "top" and "bottom" of the cut plane shall be oriented parallel to the direction of placement.

Table 1—Hardened Visual Stability Index (HVSI) Rating Criteria

Rating	Criteria
0, stable	No mortar layer at the top of the cut plane and no variance in size and percentage area of coarse aggregate distribution from top to bottom.
1, stable	No mortar layer at the top of the cut plane but slight variance in size and percentage area of coarse aggregate distribution from top to bottom.
2, unstable	Slight mortar layer, less than 25 mm (1 in.) tall, at the top of the cut plane and distinct variance in size and percentage area of coarse aggregate distribution from top to bottom.
3, unstable	Clearly segregated as evidenced by a mortar layer greater than 25 mm (1 in.) tall or considerable variance in size and percentage area of coarse aggregate distribution from top to bottom, or both.

8. REPORT

8.1. *Report the following information*:

8.1.1. Identification number,

8.1.2. Location of concrete represented,

8.1.3. Date and time of molding,

8.1.4. HVSI rating for each hardened specimen, and

8.1.5. Results of any other tests on the fresh concrete and any deviations from the standard test methods.

Standard Method of Test for

Determining Air Content of Hardened Portland Cement Concrete by High-Pressure Air Meter

AASHTO Designation: TP 59-00 (2007)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Determining Air Content of Hardened Portland Cement Concrete by High-Pressure Air Meter

AASHTO Designation: TP 59-00 (2007)[1]

1. SCOPE

1.1. This test method covers laboratory determination of the air content of hardened portland cement concrete with the use of the high-pressure air meter. This determination is made from the observation of change in linear piston movement with a specimen in the test chamber from that of the linear piston movement with no specimen in the test chamber. This change is due to a replacement of specific volume of compressible air by a specific volume of incompressible water.

1.2. *This procedure may involve hazardous materials, operations, and equipment. This procedure does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitation prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *linear piston movement* (LPM)—the travel of the hydraulic piston with a specimen in the test chamber.

3.1.2. *initial value* (INIT)—the stabilized travel of the hydraulic piston with no specimen in the test chamber.

3.1.3. *saturated surface dry* (SSD)—the saturated surface dry mass (weight) of the specimen.

4. SIGNIFICANCE AND USE

4.1. This test method covers determination of the air content of hardened concrete exclusive of any air that may be inside voids within aggregate particles. Therefore, determination of an aggregate correction factor, in accordance with the applicable requirements of T 152, is required.

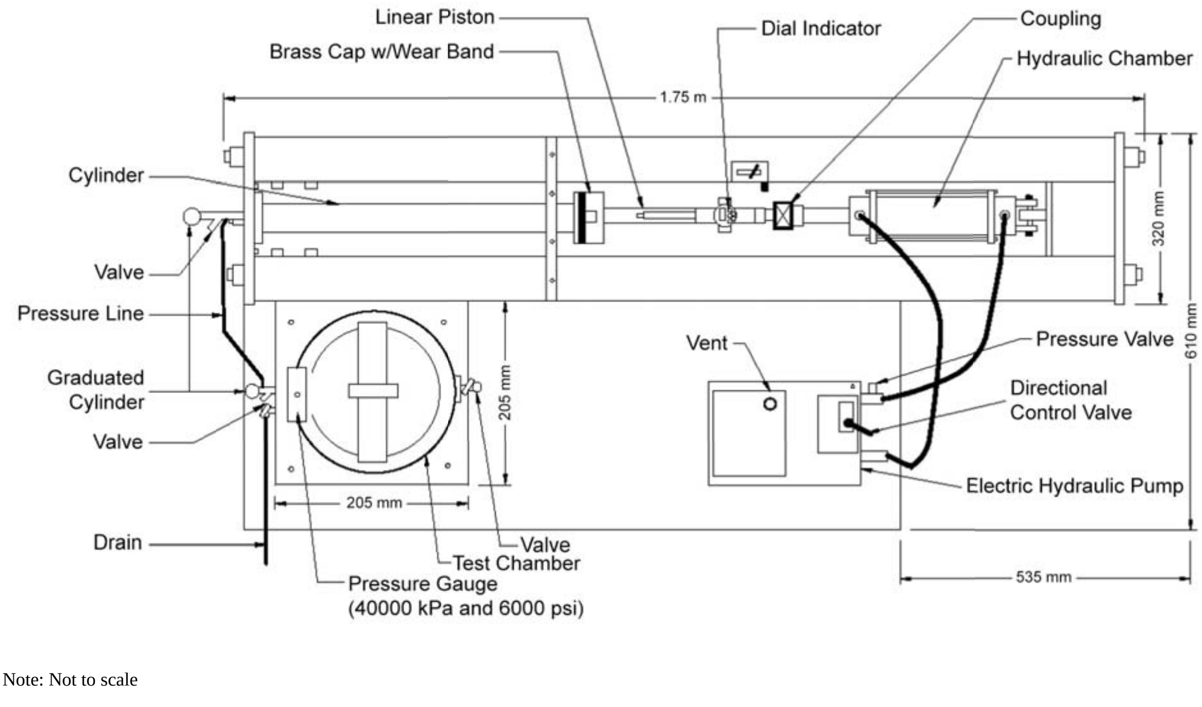
5. APPARATUS

5.1. *High-Pressure Air Meter* (see Figure 1):

5.1.1. *Hydraulic Pump and Hydraulic Cylinder*—A specially designed unit combining a hydraulic pump and a hydraulic cylinder employed to supply the 34470 kPa (5000 psi) load required to force water into a concrete specimen in the test chamber. The unit is supplied hydraulic pressure, which is converted to water pressure by movement of the hydraulic piston.

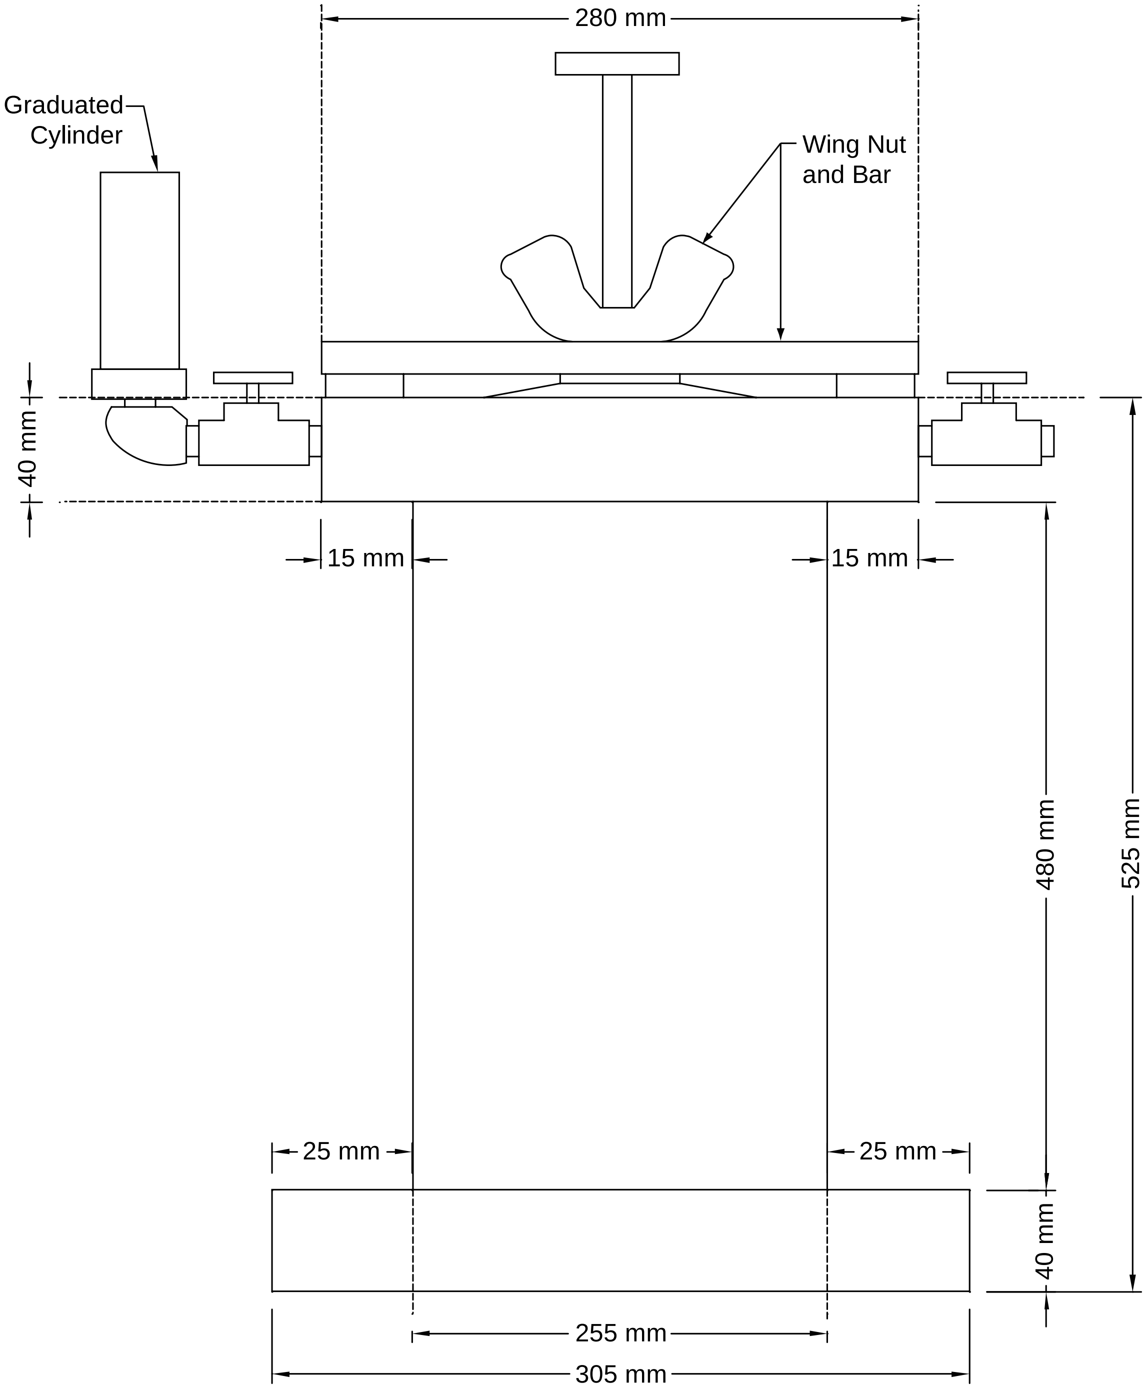
5.1.2. *Test Chamber* (Figures 2, 3, and 4)—A specially designed stainless steel seamless tube secured with a stainless steel plate at the bottom and a stainless steel lid at the top. This chamber is designed to contain water under pressure.

5.1.3. *The System*—The cylinder, of known volume, is attached to the test chamber, of known volume, that is completely filled with deionized water. This is done in order to enable load from the hydraulic pump to be applied to the test chamber. The system is equipped with a dial gauge accurate to 0.0254 mm (0.001 in.), in order to measure the movement of the hydraulic piston. Volume displacement is determined by the measured movement of the hydraulic piston.



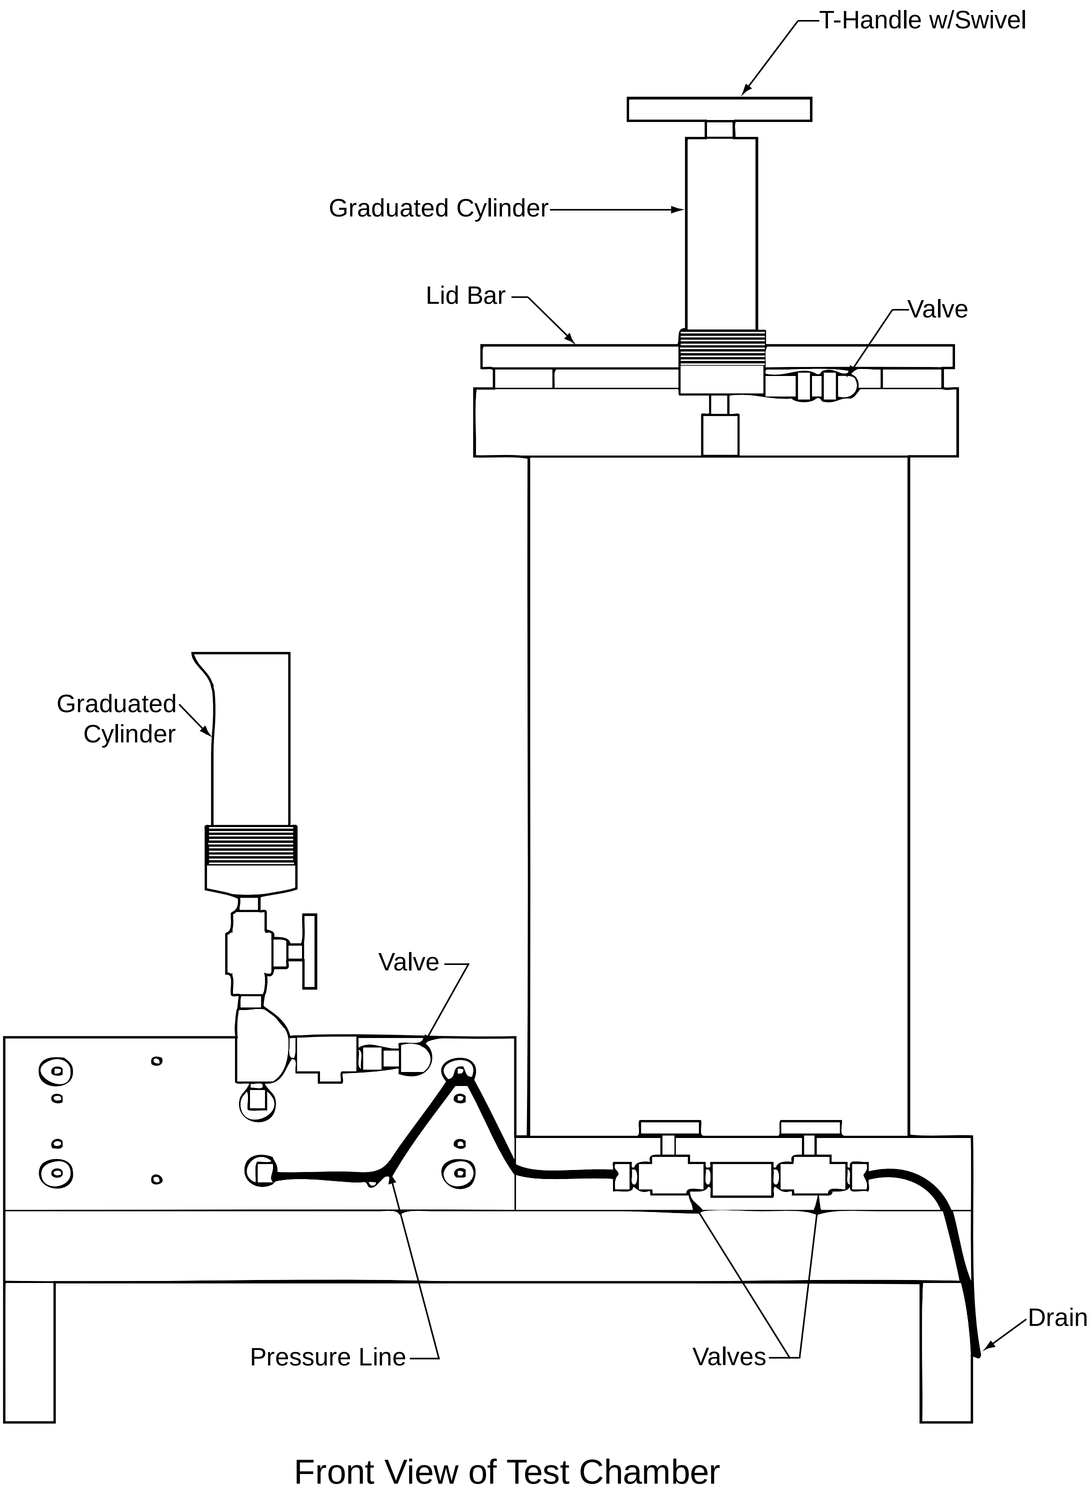
Note: Not to scale

Figure 1—High-Pressure Air Meter (Plan View)



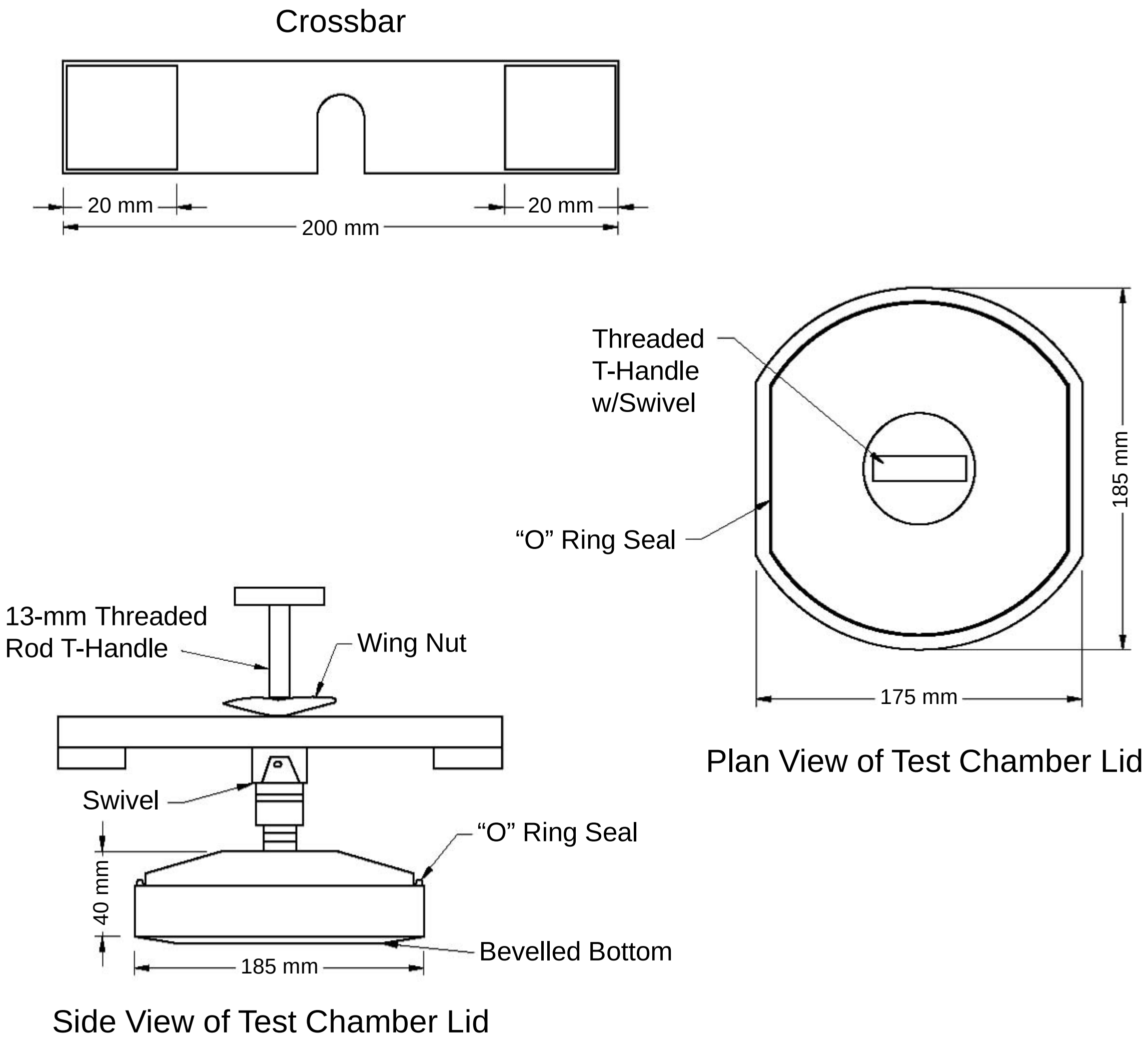
Note: Not to scale

Figure 2—Test Chamber



Note: Not to scale

Figure 3—Test Chamber (Front View)



Note: Not to scale

Figure 4—Test Chamber Lid

6. SAMPLING

6.1. Obtain a sound concrete sample free of steel reinforcement. The sample must be of suitable size to fit into the test chamber. The diameter of the stainless steel lid is 173 mm (6.8 in.) and the depth of the seamless tube is 480 mm (16.9 in.).

7. PREPARATION OF THE TEST SPECIMENS

7.1. *Oven Drying*—Oven dry the specimens for 72 hours at 138–149°C (280–300°F).

7.2. *Saturation*—After the specimens have been oven dried, saturate in 21 ± 6°C (70 ± 10°F) water for a period of 40 to 48 hours.

7.3. *Unit Mass (Weight)*—Determine the unit mass (weight) of the concrete sample in accordance with T 121M/T 121.

8. PREPARATION OF TEST EQUIPMENT

8.1. *Preconditioning the Water*:

8.1.1. Prior to opening the test chamber, close all valves except the valve positioned between the test chamber and the hydraulic cylinder. Remove the lid of the test chamber by loosening the wing nut at the top, thereby releasing the steel crossbar used to secure the lid. Tilt the lid and remove it from the chamber by aligning the flat sides of the lid with the flat sides of the test chamber.

8.1.2. Completely fill the test chamber with deionized water. Remove the pressure gauge and replace it with a plug capable of withstanding a 101 kPa (30 in Hg) vacuum. Apply Teflon® tape to the plug, prior to installation. Place the vacuum lid over the top of the test chamber. It may be necessary to apply vacuum grease to the O-ring of the vacuum lid to prevent leakage.

8.1.3. Engage the vacuum by turning on the power and opening the valves connecting the vacuum lid to the vacuum hose and the vacuum hose to the vacuum. The vacuum gauge should read approximately 91 kPa (27 in Hg). Apply the vacuum until air bubbles being pulled to the surface are no longer visible; this may be done overnight. The vacuum is applied to remove as much air as possible prior to the determination of an initial value.

8.1.4. Disengage the vacuum by closing the valves previously opened and turning off the power. The gauge should return to zero. Apply Teflon® tape to the pressure gauge and replace the plug with the pressure gauge. Replace the vacuum lid with the test chamber lid, do not secure the lid.

8.2. *Bleeding the System*—The system is bled to remove all entrapped air bubbles that may have developed throughout the workings of the high-pressure air meter. This is done by forcing water through the system.

8.2.1. Close the valve positioned between the test chamber and the hydraulic cylinder. Open the drainage valve positioned at the bottom of the test chamber. Allow water to freely flow from the drainage hose to ensure no entrapped air. Close drainage valve, and secure chamber lid by placing the crossbar over the top of the lid and tightening the wing nut.

8.2.2. Open the valve connected to the graduated cylinder located at the top of the test chamber. Fill the graduated cylinder with water. Open the valve opposite this valve and allow gravity to force water through the test chamber. Do not allow water to splatter onto the high-pressure air meter. Continue until no air bubbles are visible and the height of the water in the graduated cylinder reads 50 mL or below. Do not allow the water to completely drain. If this does occur, repeat Section 8.2.1. Close the valve opposite of the valve attached to the graduated cylinder.

8.2.3. Open the valve positioned between the test chamber and the hydraulic cylinder. Use the hydraulic pump, in the load position, to force water through the system. Water will be forced into the graduated cylinder, continue in the load position until the graduated cylinder is filled. Reverse hydraulic pump to release position and drain the graduated cylinder. Continue process until no air bubbles appear in the graduated cylinder. Close valve attached to the graduated cylinder. The valve positioned between the test chamber and the hydraulic cylinder must remain open.

9. PROCEDURE

9.1. *Determination of Initial Value*:

9.1.1. Place the hydraulic pump in the load position. Apply the load until the pressure in the test chamber is exactly 34470 kPa (5000 psi). Record the initial value read from the dial indicator attached to the hydraulic ram in Figure 5. Release the load very slowly, if the load is released quickly, the well holding the hydraulic fluid will overflow. Bleed the system as described in Section 8.2.2.

9.1.2. Repeat this process until the difference in subsequent movement is 0.0762 mm (0.003 in.) or less. This value is considered the INIT. Record all readings on the data sheet given in Figure 5.

Method of Test for
High-Pressure Air Content of Hardened Portland Cement Concrete
INIT DETERMINATION

RECORDER ____________________
DATE ____________________
INIT ____________________

LPM	TIME	COMMENTS

Figure 5—Initial Value Determination (Data Record)

9.2. *Testing Hardened Concrete Specimen*:

9.2.1. Remove the lid of the test chamber. Open the drainage valve to release volume of water approximately equal to volume of the test specimen. Place test specimen in the test chamber using forceps; it is crucial that the water in the test chamber is disturbed as little as possible. This is to prevent introduction of air into water within the test chamber. Bleed the system as identified in Section 8.2, beginning at Section 8.2.2. Place the lid on the test chamber and secure it.

9.2.2. Check all valves, except the valve positioned between the test chamber and the hydraulic cylinder, to make certain that they are tightly closed. The valve positioned between the test chamber and the hydraulic cylinder must remain open. Apply load until pressure in the test chamber is exactly 34470 kPa (5000 psi).

9.2.3. Immediately record the value read from the dial indicator identifying the LPM. Record the time of the reading and hold the 34470 kPa (5000 psi) load. The LPM measured via the dial indicator must be recorded at 5-minute intervals. This value should only be read when the pressure in the test chamber is at 34470 kPa (5000 psi).

9.2.4. It will be necessary to reapply the pressure lost due to the compression of air, in the test specimen, within the first 5 minutes of testing. It may be necessary to reapply pressure at subsequent 5-minute time intervals to maintain the 34470 kPa (5000 psi) load. Maintain the 34470 (5000 psi) load until the movement of the piston remains the same for 15 minutes. Record this stabilized value on the data sheet given in Figure 6.

9.2.5. Record the INIT value obtained in Figure 5.

10. COMPLETION OF THE TEST PROCEDURE

10.1. Open the lid of the test chamber and remove the specimen from the test chamber.

10.1.1. If the testing is complete, replace the water removed from the test chamber and close the lid of the test chamber.

10.1.2. If additional testing is required, repeat the process beginning with Section 8.2.

11. CALCULATIONS

11.1. Compute volume of this test specimen to the nearest one decimal place according to the requirements of the data form given in Figure 7.

Method of Test for
COMPUTING VOLUME OF TEST SPECIMEN

Metric volume s	=		kg	/		kg/m^3 * (1000 mm/m)^3		
		SSD			Unit mass (weight)			
Volume s	=		mm^3					
English volume s	=		kg	/	0.4535924 kg/lb * (12 in./ft)^3]	/		pcf
		SSD					Unit mass (weight)	
Volume s	=		in.^{3}					

Figure 7—Volume of Test Specimen (Data Form)

11.2. Compute the hardened air content of the test specimen according to the procedure given in data form in Figure 8. The values are to be calculated to the nearest one decimal place.

Method of Test for
COMPUTING HARDENED AIR CONTENT OF TEST SPECIMEN

Metric air content	=	{[462121.65 *	(	–	)	]/	}	+ 1.46 –	
			LPM		INIT		Volume		Agg. correction
Air content	=		percent						
English air content	=	{[716.29 *	(	–	)	]/	}	+ 1.46 –	
			LPM		INIT		Volume		Agg. correction
Air content	=		percent						

Note: The coefficient 1.46 is a calibration factor based on Report No. 6-286, Corps of Engineers, U.S. Army Engineer Waterways Experiment Station.

Figure 8—Hardened Air Content of Test Specimen (Data Form)

11.3. *Calculate the plastic air content of the specimen as follows in Equation 1*:

$$\text{Plastic Air Content} = (\text{Hardened Air Content} - 1.53)/0.9 \qquad (1)$$

12. REPORT

12.1. Report the hardened concrete air content, nearest percent.

13. PRECISION AND BIAS

13.1. No precision or bias statements are available at this time.

14. KEYWORDS

14.1. Air content; hardened portland cement concrete.

Washington, D.C. 20001

Standard Method of Test for

Predicting Chloride Penetration of Hydraulic Cement Concrete by the Rapid Migration Procedure

AASHTO Designation: TP 64-03 (2007)[1]

1. SCOPE

1.1. This procedure is for the rapid evaluation of chloride penetration resistance of concrete, from non-steady-state migration experiments.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:
- R 39, Making and Curing Concrete Test Specimens in the Laboratory
- T 23, Making and Curing Concrete Test Specimens in the Field
- T 24M/T 24, Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- T 277, Electrical Indication of Concrete's Ability to Resist Chloride Ion Penetration

2.2. *ASTM Standard*:
- D 1193, Standard Specification for Reagent Water

3. DEFINITIONS

3.1. *Terminology*:

3.1.1. *chloride penetration depth*—the distance between the surface exposed to chloride solution and the chloride penetration front where the color changes from white to brown after spraying of 0.1 N silver nitrate solution.

3.1.2. *diffusion*—the movement of molecules or ions under a gradient of concentration, or more strictly speaking, chemical potential, from a high concentration zone to a low concentration zone.

3.1.3. *migration*—the movement of ions under the action of an external electrical field.

4. SUMMARY OF TEST METHOD

4.1. This test method uses electrical migration to accelerate the movement of chloride ions into a concrete specimen and a colorimetric indicator to measure the extent of chloride penetration. An external potential is applied axially across the specimen to force the chloride ions to migrate into the specimen. After a defined test duration, the specimen is axially split and a silver nitrate solution (colorimetric indicator for chloride) is sprayed on one of the fresh split surfaces. The chloride penetration depth is measured from the extent of the visible white silver chloride precipitate. From this penetration depth, the rate of chloride ion penetration is determined and used to rate the concrete.

5. SIGNIFICANCE AND USE

5.1. The results of this test can be used to rate concrete according to the relative ease with which chloride ions can penetrate into the concrete. This in turn gives an indication of the potential for corrosion of reinforcing steel due to chloride intrusion.

6. APPARATUS

6.1. Water-cooled diamond saw, capable of making cuts perpendicular to the axis of 100-mm diameter concrete cylinders or cores.

6.2. *Conditioning Equipment*:

6.2.1. *Vacuum desiccator*—250-mm diameter or larger (capable of containing at least three specimens), allowing two hose connections, each of which must be equipped with a stopcock.

6.2.2. *Vacuum pump*—capable of maintaining a pressure of less than 5 kPa (37 mm Hg) in the desiccator.

Note 1—Since vacuum will be drawn over water, the pump should be protected with a cold trap, or pump oil should be changed after each use.

6.2.3. *Vacuum gauge or manometer*—capable of reading vacuum levels as low as 1 kPa (5 mm Hg).

6.3. Migration apparatus shown schematically in Figure 1 (Note 1). Detailed drawings may be found in Annex A1.

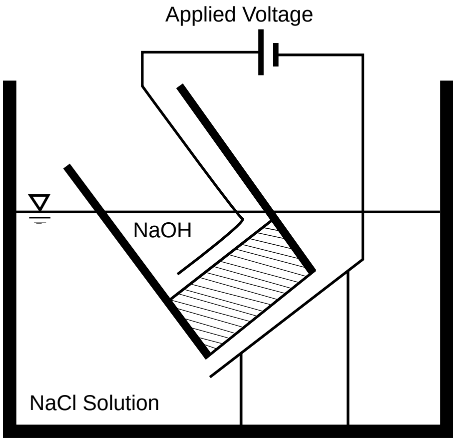

Figure 1—Schematic of Migration Apparatus

6.3.1. *Silicon rubber sleeve*, inner/outer diameter 100/115 mm, about 150 mm long.

6.3.2. *Two stainless steel clamps*, 20 mm wide with diameter range 105–115 mm. (See Figure 2.)

6.3.3. *Plastic container* (catholyte reservoir), 370 by 270 by 280 mm (L by W by H).

6.3.4. Plastic support with 0.5-mm thick stainless steel plate (cathode) attached. (See Figures A1.1–A1.5.)

6.3.5. *Stainless steel mesh or plate* (anode) with holes, about 0.5 mm thick. (See Figure A1.5.)

Note 2—Other designs are acceptable provided that temperatures of the specimen and solutions during the test can be maintained in the range of 20 to 25°C. Test cells for T 277 have been used successfully in this procedure. Use of T 277 cells requires test specimens to be coated as specified in T 277 before conditioning.

6.4. Power supply capable of supplying 0–60 V DC regulated voltage with the accuracy ±0.1 V.

6.5. *Ammeter,* capable of displaying current to ±1 mA.

6.6. *Thermometer or thermocouple,* with readout device capable of reading to ±1°C.

6.7. Any device suitable for splitting the specimen longitudinally, e.g., compression testing machine with split tensile test apparatus.

6.8. *Slide caliper,* with 0.1-mm resolution and ruler for measuring.

7. REAGENTS AND MATERIALS

7.1. *Purity of Reagents*—Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society where such specifications are available. Other grades may be used provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

7.2. *Purity of Water*—Unless otherwise indicated, water shall be reagent quality water as defined by Type III of ASTM D 1193.

7.3. *Reagents*:

7.3.1. Sodium chloride solution, 10 percent by mass—dissolve 100 g sodium chloride (NaCl) in 900 g tap water.

7.3.2. Sodium hydroxide solution, 0.3 N—dissolve approximately 12 g sodium hydroxide in 1 L distilled or deionized water.

7.3.3. Silver nitrate ($AgNO_2$) solution, 0.1 M.

7.4. *Sealant*:

7.4.1. Five-minute epoxy or other suitable sealant for coating specimen sides, if required by the test apparatus. (See Note 2.)

8. SAMPLING, TEST SPECIMENS, AND TEST UNITS

8.1. The method requires cylindrical specimens with a diameter of 100 mm and a thickness of 50 mm, sliced from cast cylinders or drilled cores with a minimum original length of 100 mm. The cylinders or cores should meet the requirements described in R 39, T 23, or T 24M/T 24. Three specimens should be used in the test.

8.2. *Obtaining Test Specimens*:

8.2.1. If a drilled core is used, an outer (i.e., closest to the original surface) layer of the concrete (approximately 10~20 mm thick) should be cut off (Note 3), after which a 50 ± 2 mm thick slice should be cut from the remaining core length to be used as the test specimen. The end surface of the test specimen that was closest to the original surface (i.e., the end surface that was adjacent to the discarded outer layer) should be exposed to the chloride solution (catholyte).

8.2.2. If a cast cylinder is used, an outer (i.e., closest to the troweled surface) layer of the concrete approximately 25 mm thick should be cut off (Note 3), after which a 50 ± 2 mm thick slice should be cut from the remaining length of the cylinder to be used as the test specimen. The end surface closest to the original troweled surface should be exposed to the chloride solution (catholyte).

8.2.3. The thickness should be measured to the nearest 0.1 mm with a slide caliper at four locations equally spaced around the specimen. All four thickness measurements shall be 50 ± 2 mm.

Note 3—The term “cut” here means to saw perpendicularly to the axis of a core or cylinder by means of a water-cooled diamond saw.

9. CONDITIONING

9.1. Brush and wash away any burrs from the surfaces of the specimen. Wipe excess water from the surfaces of the specimens.

9.2. Coat specimen sides with 5-minute epoxy or other suitable sealant, if required. (See Note 2.)

9.3. *Preconditioning (Vacuum Saturation)*:

9.3.1. Place surface-dry specimens in the vacuum desiccator. Both end surfaces must be exposed.

9.3.2. Seal the desiccator and start the vacuum pump. The absolute pressure in the desiccator should decrease to a range of 1 to 5 kPa (7.5 to 37 mm Hg) within a few minutes. Maintain vacuum for 3 hours.

9.3.3. With the vacuum pump still running, open the water stopcock and fill the desiccator with de-aired tap water to cover the specimens. Close the water stopcock and maintain the vacuum for 1 additional hour.

9.3.4. Close the vacuum line stopcock and turn off the vacuum pump. Re-open the vacuum line stopcock to allow air to reenter the desiccator. Maintain the specimens in this condition for 18 ± 2 hours.

10. PROCEDURE

10.1. *Set Up (Note 4)*:

10.1.1. Measure the temperature of the NaOH and NaCl solutions. If the temperatures are not within the range 23 ± 2ºC, bring the temperatures of the NaOH and NaCl solutions to 23 ± 2ºC before starting the test.

10.1.2. Place the plastic support (cathode) in the catholyte reservoir and fill the reservoir with about 12 L of NaCl solution.

10.1.3. For each of the three test specimens, place a rubber sleeve around the specimen as shown in Figure 2 (Note 4). Place clamps as shown in the figure and tighten snugly.

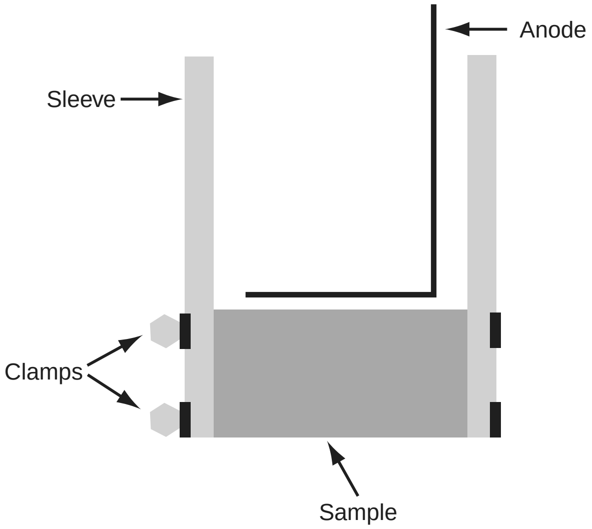

Figure 2—Assembly of Specimen in Rubber Sleeve and Placement of Anode

Note 4—If using an apparatus different than the one described here (e.g., T 277 cells), set up the apparatus in accordance with the applicable standard or the manufacturer's instructions.

10.1.4. Fill each sleeve with distilled water to check for leaks, and tighten clamps further if necessary (Note 5). Empty the water and place the specimens on the slanted plastic support (cathode) in the catholyte reservoir (Note 6).

Note 5—If the curved surface of the specimen is not smooth, or if there are significant defects (e.g., large voids or honeycombs) on the curved surface that may result in significant leakage, apply a strip of silicon sealant to improve the watertightness.

Note 6—If the concrete has been allowed to dry substantially after preconditioning, immerse it in tap water for a few minutes to re-saturate before placing it on the slanted plastic support (cathode) in the catholyte reservoir.

10.1.5. Fill the sleeve above the specimen with 300 ml of NaOH solution. Immerse the anode in the NaOH solution.

10.2. *Application of Voltage*:

10.2.1. Connect the cathode and anode to the negative and positive poles of the power supply, respectively. Turn on the power, set the power supply to a potential of 60.0 ± 0.1 VDC, and record the initial current (A) through each specimen to the nearest .001 A.

10.2.2. Check the current ranges in Table 1 and, if necessary, reset the potential according to the values in the table. If the potential is reset, record new values of initial current for each specimen. If the initial current is greater than 800 mA, do not continue with the test.

Table 1—Test Conditions

Initial Current at 60 V (mA)	Applied Voltage (V)	Test Duration (Hours)
<120	60	18
120–240	30	18
240–800	10	18
>800	Do Not Test	Do Not Test

10.2.3. For each specimen, measure and record the initial temperature in the anolyte solution using a thermometer or thermocouple.

10.2.4. After 18 hours, record the final current and temperature for each specimen, and record the temperature of the catholyte solution. Turn off the power supply.

10.2.5. Disassemble the test apparatus and remove test specimens.

10.3. *Measurement of Chloride Penetration*:

10.3.1. Rinse the specimens with distilled water. Wipe excess water from the surfaces of the specimen. Using a suitable device, split the specimen longitudinally into two pieces. Choose one piece for the penetration depth measurement.

10.3.2. Spray 0.1 M silver nitrate solution on the fresh-split surface. When the white silver chloride precipitate on the split surface is clearly visible (after about 15 minutes), use a ruler to measure the penetration depths at intervals of 10 mm, starting 10 mm from the edge, as shown in Figure 3 (Notes 7, 8, and 9). The depth should be read to the nearest millimeter. At least five valid depth measurements should be obtained.

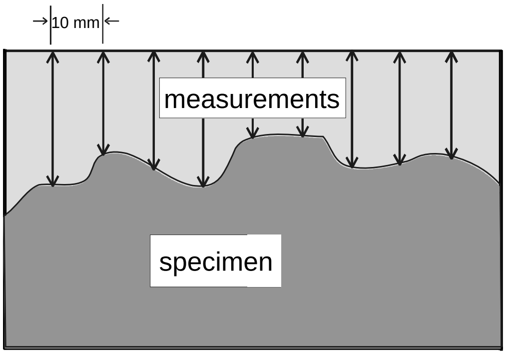

Figure 3—Measurement of Chloride Penetration Depth on Split Face of Specimen

Note 7—If the penetration front to be measured is obviously blocked by the aggregate, move the measurement to the nearest front where there is no significant blocking of aggregate, or alternatively, discard this depth if there are more than five valid depths.

Note 8—If the presence of a defect in the specimen (e.g., large void or honeycomb) results in a penetration front much larger than the average, measurement(s) should not be made at this location. Note such defects in the test report.

Note 9—To eliminate possible edge effects due to non-homogeneous degree of saturation or possible leakage during the test, no depth measurement should be made within 10 mm of the edge. (See Figure 3.)

11. CALCULATIONS

11.1. For each test specimen, the depth of penetration is determined by discarding the high and the low value and taking the mean of the remaining measurements.

11.2. The rate of penetration is calculated by dividing the depth of penetration (mm) by the product of the applied voltage (V) and the test duration (hr).

12. REPORT

12.1. *Report the following information*:

12.1.1. Name and address of the testing laboratory;

12.1.2. Date and identification number of the test report;

12.1.3. Name and address of the organization or person who ordered the test;

12.1.4. Name and address of the manufacturer or supplier of the tested object;

12.1.5. Date of arrival of the tested object;

12.1.6. Description of the tested object including sampling, composition, and curing age;

12.1.7. Purpose of the test;

12.1.8. Test method;

12.1.9. Any deviation from the test method;

12.1.10. Name and address of the person who performed the test;

12.1.11. Date of the test;

12.1.12. Test information including the specimen dimensions, applied potential, initial and final currents, and initial and final temperatures;

12.1.13. Average (for three specimens) penetration depth and rate of penetration as well as individual penetration depth measurements for each specimen;

12.1.14. Any unusual observations, such as significant defects in the specimens or a large penetration front due to a defect or leakage;

12.1.15. Inaccuracy or uncertainty of the test results; and

12.1.16. Date and signature.

13. PRECISION AND BIAS

13.1. *Precision*:

13.1.1. *Single-Operator Precision*—The single-operator coefficient of variation of a single test result (where a test result is, as defined in this test method, the average of three separate measurements) has been found to be 8.8 percent according to the results from the Nordic round-robin test between six laboratories.[2] Therefore, results of two properly conducted tests (each consisting of the average of three individual measurements) by the same operator on concrete samples from the same batch should not differ by more than 25 percent.

13.1.2. *Multilaboratory Precision*—The multilaboratory coefficient of variation of a single test result (where a test result is, as defined in this test method, the average of three separate measurements) has been found by Hooton et al.[3] to be 16 percent for plain portland cement concrete or concrete blended with silica fume, and by Tang and Sorenson to be 23.6 percent for concrete blended with slag. Therefore, results of two properly conducted tests (each consisting of the average of three individual measurements) should not differ by more than 45 percent for portland cement concrete or concrete blended with silica fume, or 67 percent for concrete blended with slag.

13.2. *Bias*—Since there is no accepted reference material suitable for determining the bias in this test method, no statement on bias is made.

14. KEYWORDS

14.1. Concrete; corrosion; chloride penetration; electrical migration.

ANNEX

(Mandatory Information)

A1. APPARATUS DESCRIBED IN SECTION 6

A1.1. This Annex contains drawings for the apparatus as described in Section 6 of this standard.

APPENDIX

(Nonmandatory Information)

X1. INTERPRETATION OF RESULTS

X1.1. Table X1.1 shows recommended ranges of the rate of penetration measured by this test method (mm/V-hr) corresponding to different grades of high-performance concrete (HPC) proposed by Goodspeed et al.[4] The recommended ranges for the rapid migration test are based on laboratory research by Hooton et al.[3] in which the rapid migration test was compared to the T 277 test. The rapid migration test result limits shown below correspond to ranges of charge passed in T 277 used to define HPC grades based on chloride penetration. Those ranges are: Grade 1—2000 to 3000 coulombs, Grade 2—800 to 2000 coulombs, and Grade 3—less than 800 coulombs.

Table X1.1—Recommendations for Chloride Penetration Rate Corresponding to FHWA HPC Performance Grades

	FHWA HPC Performance Grade		
	1	2	3
Rate of penetration (mm/V-hr)	$0.034 \geq x > 0.024$	$0.024 \geq x > 0.012$	$0.012 \geq x$

Standard Method of Test for

Slump Flow of Self-Consolidating Concrete (SCC)

AASHTO Designation: TP 73-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Slump Flow of Self-Consolidating Concrete (SCC)

AASHTO Designation: TP 73-09[1]

1. SCOPE

1.1. This test method covers determination of slump flow of self-consolidating concrete (SCC), both in the laboratory and in the field. SCC is defined as a highly workable concrete that can flow through densely reinforced or complex structural elements under its own weight without vibration and adequately fill voids without experiencing segregation or excessive bleeding.

1.2. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with this standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 119M/T 119, Slump of Hydraulic Cement Concrete
- T 141, Sampling Freshly Mixed Concrete

3. SUMMARY OF TEST METHOD

3.1. A sample of freshly mixed SCC is placed in an inverted mold shaped as the frustum of a cone. The mold is raised, allowing the SCC to spread radially. After flow has ceased, the diameter of the SCC is measured in two perpendicular directions. The average of the two measured diameters is the slump flow.

4. SIGNIFICANCE AND USE

4.1. This test method is applicable to SCC, defined in Section 1.1.

4.2. This test method is intended to provide the user with a procedure to assess the horizontal free flow of SCC in the absence of obstructions. The test gives an assessment of filling ability and may give some indication of resistance to segregation, but it gives no indication of the ability of the SCC to pass between reinforcement without blocking.

4.3. This test method is applicable to SCC having coarse aggregate up to 25 mm [1 in.]. If the coarse aggregate is larger than 25 mm [1 in.], the test method is applicable when it is performed on the fraction of concrete passing a 25-mm [1-in.] sieve, with the larger aggregate being removed in accordance with Section 6 of T 141.

5. APPARATUS

5.1. *Mold*—The SCC shall be placed in an inverted slump cone mold conforming to the applicable requirements of T 119M/T 119.

5.2. *Base Plate*—The base plate shall be made of a stiff, nonabsorbing material, at least 820 mm [32 in.] square and marked with both a circle indicating the central location for the slump cone and a concentric circle with a diameter of 500 mm [20 in.].

5.3. Scoop.

5.4. Strike-off bar.

5.5. Tape measure containing increments of 6 mm [0.25 in.] or less.

5.6. Stopwatch.

6. SAMPLING

6.1. Approximately 6 L [0.2 ft^3] of SCC is needed to perform the slump flow test, sampled normally.

6.2. The sample of concrete shall be obtained in accordance with T 141.

7. PROCEDURE

7.1. Moisten the base plate and the inside of the slump cone.

7.2. Place the base plate on a level, stable surface and the inverted slump cone centrally on the base plate, and hold down firmly (Figure 1).

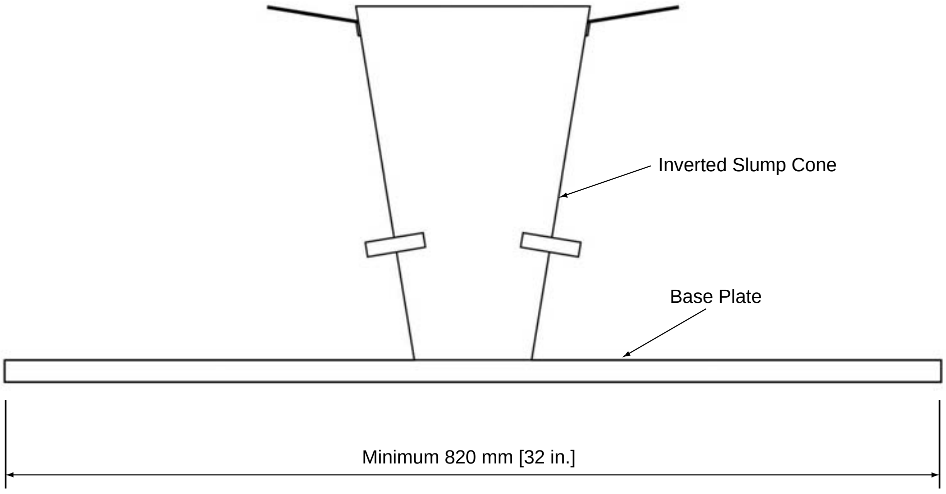

Figure 1—Mold and Base Plate for Slump Flow Test

7.3. From the sample of concrete obtained in accordance with Section 6, fill the entire mold continuously. The mold shall be held firmly in place during filling.

7.4. Do not rod or tamp the SCC. Do not tap or vibrate the cone.

7.5. Use the strike-off bar to strike off the SCC level with the top of the cone.

7.6. Remove any spilled or struck off SCC from around the base of the cone to preclude interference with the flowing SCC.

7.7. Raise the cone vertically 230 mm ± 75 mm [9 in. ± 3 in.] above the base plate with no lateral or torsional motion within a time period of 3 s ± 1 s, and allow the SCC to flow out freely from within. Complete procedures in Sections 7.3 through 7.7 within $2^1/_2$ min.

7.8. Simultaneous with the lifting of the cone, start the stopwatch. Record the time required for the first contact of the SCC slump flow patty with the 500-mm [20-in.] ring on the base plate. This is the T-50 time.

7.9. After the concrete flow has stopped, measure the final diameter of the SCC in two perpendicular directions to the nearest 6 mm [0.25 in.] (Note 1). The average of the two measured diameters is the slump flow in millimeters (inches). Any halo shall be included in the slump flow diameter.

Note 1—Measure the largest diameter of the slump flow as one diameter and the perpendicular diameter as the second to ensure consistency between tests. If the two values differ in diameter by more than 51 mm [2 in.], the test is considered invalid and must be repeated because it is likely that the cone was raised with lateral motion.

8. REPORT

8.1. Record the final diameter of the SCC in two perpendicular directions. The average of the two measured diameters is the slump flow in millimeters (inches) to the nearest 5 mm [0.25 in.].

8.2. Record the T-50 time, the time required for the slump flow patty to reach the 500-mm [20-in.] ring on the base plate.

9. PRECISION AND BIAS

9.1. No precision and bias statements are available at this time.

10. KEYWORDS

10.1. Cone; flowability; plasticity; SCC, self-consolidating concrete; slump; workability.

Standard Method of Test for

Passing Ability of Self-Consolidating Concrete (SCC) by J-Ring

AASHTO Designation: TP 74-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Passing Ability of Self-Consolidating Concrete (SCC) by J-Ring

AASHTO Designation: TP 74-09[1]

1. SCOPE

1.1. This test method covers determination of the passing ability (Note 1) of self-consolidating concrete (SCC) by the J-Ring method, both in the laboratory and in the field. SCC is defined as a highly workable concrete that can flow through densely reinforced or complex structural elements under its own weight without vibration and adequately fill voids without experiencing segregation or excessive bleeding.

Note 1—Passing ability is defined as the ability of SCC to flow through openings such as the spaces between reinforcing bars without segregation or without aggregate blocking. Blocking is defined as the condition in which pieces of coarse aggregate combine to form elements large enough to obstruct the flow of the SCC between reinforcing bars or other obstructions in the concrete formwork.

1.2. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 119M/T 119, Slump of Hydraulic Cement Concrete
- T 141, Sampling Freshly Mixed Concrete
- TP 73, Slump Flow of Self-Consolidating Concrete (SCC)

3. SUMMARY OF TEST METHOD

3.1. The J-Ring apparatus consists of a rigid ring connecting 4-in. vertical smooth bars. The ring is held to a base plate, and an inverted slump cone is placed in its center. A sample of freshly mixed SCC is allowed to flow from the inverted slump cone through the bars of the J-Ring apparatus. The final average diameter of the slump flow patty after flowing through the bars compared to the average slump flow measured without the J-Ring is a measure of the passing ability of the SCC, and the difference in height of the SCC inside and outside of the ring provides an indication of blocking.

4. SIGNIFICANCE AND USE

4.1. This test method is applicable to self-consolidating concrete (SCC), defined in Section 1.1.

4.2. This test method is intended to provide the user with a procedure to assess the passing ability without blocking of SCC. The test gives an indication of the ability of the SCC to flow around and between reinforcement without blocking.

4.3. This test method is applicable to SCC having coarse aggregate up to 25 mm [1 in.].

5. APPARATUS

5.1. *J-Ring Apparatus*—The J-Ring consists of a rigid ring connecting 4-in. vertical smooth bars. The J-Ring shall be of dimensions shown in Figure 1, with tolerances as shown in Table 1. The J-Ring shall be made of steel or some other rigid, non-absorbent material not readily attacked by the cement paste. The 16 vertical round bars shall be spaced as shown in Figure 1 and of diameter of 16 mm [$^{5}/_{8}$ in.]. Connections of the round bars to the ring may be of any type that provides sufficient rigidity to maintain consistent clear spacing between the bars. Threaded, welded, or interference fit connections may be suitable, but care should be taken that heat deformation during welding does not deform the ring and lead to out-of-plumb bars with incorrect clear spacing.

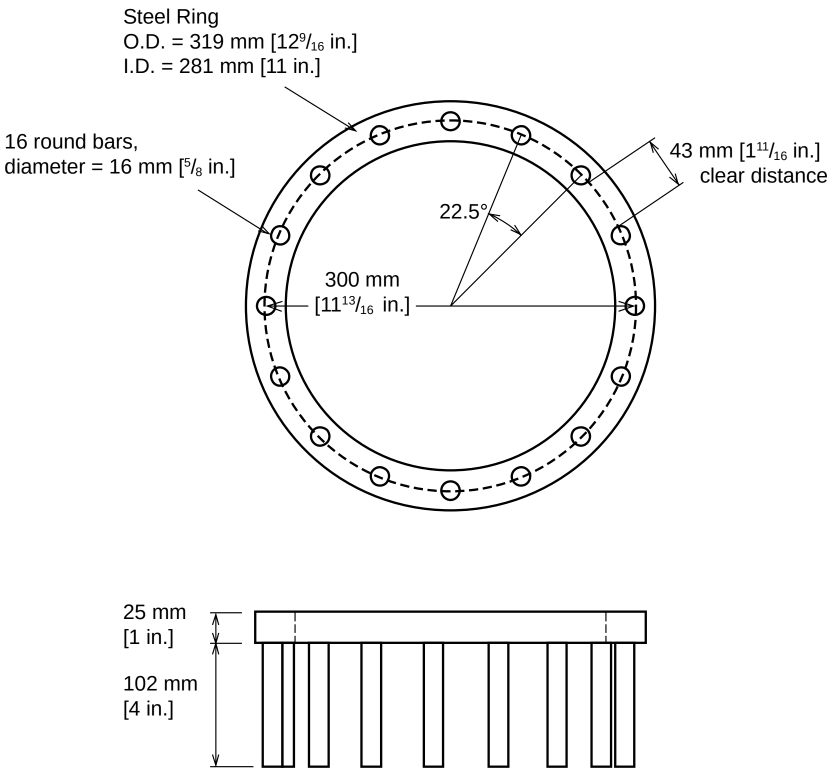

Figure 1—J-Ring Dimensions

Table 1—J-Ring Dimensions and Tolerances

Dimension	in.	mm
Ring diameter (centerline)	$11^{13}/_{16} \pm {}^{1}/_{8}$	300 ± 3.3
Ring width	$1^{9}/_{16} \pm {}^{1}/_{16}$	38 ± 1.5
Bar diameter	${}^{5}/_{8} \pm {}^{1}/_{32}$	16 ± 3.3
Bar spacing (clear distance)	$1^{11}/_{16} \pm {}^{1}/_{32}$	43 ± 1.0
Ring thickness	$1 \pm {}^{1}/_{16}$	25 ± 1.5
Bar length	$4 \pm {}^{1}/_{4}$	102 ± 6.0

5.2. *Slump Cone Mold*—The SCC shall be placed in an inverted slump cone mold conforming to the applicable requirements of T 119M/T 119.

5.3. *Base Plate*—The base plate shall be made of a stiff, nonabsorbing material, at least 820 mm [32 in.] square and marked with both a circle indicating the central location for the slump cone and a concentric circle with a diameter of 500 mm [20 in.].

5.4. Scoop.

5.5. Strike-off bar.

5.6. Tape measure containing increments of 6 mm [0.25 in.] or less.

6. SAMPLING, TEST SPECIMENS, AND TEST UNITS

6.1. Approximately 6 L [0.2 ft^3] of SCC is needed to perform the slump flow and J-Ring test, sampled normally.

6.2. The sample of concrete shall be obtained in accordance with T 141.

7. PROCEDURE

7.1. Moisten the base plate and the inside of the slump cone.

7.2. Place the base plate on a level, stable surface. Place the J-Ring centrally on the base plate and the inverted slump cone centrally inside it (Figure 2).

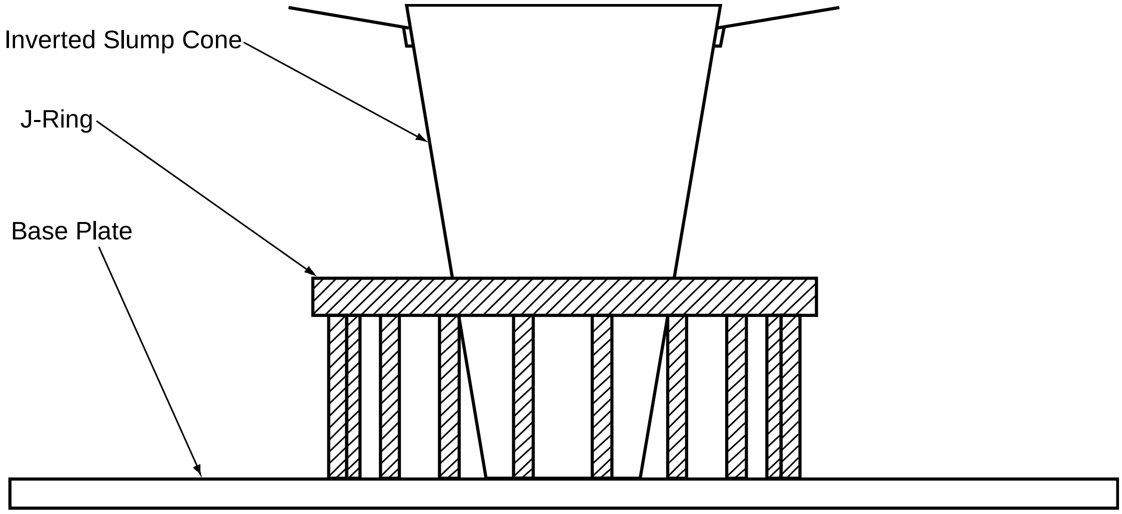

Figure 2—J-Ring Test Apparatus

7.3. From the sample of concrete obtained in accordance with Section 6, fill the entire mold continuously. The mold shall be held firmly in place during filling.

7.4. Do not rod or tamp the SCC. Do not tap or vibrate the cone.

7.5. Use the strike-off bar to strike off the SCC level with the top of the cone.

7.6. Remove any spilled or struck off SCC from around the base of the cone to preclude interference with the flowing SCC.

7.7. Raise the cone vertically 230 mm ± 75 mm [9 in. ± 3 in.] above the base plate with no lateral or torsional motion within a time period of 3 s ±1 s, and allow the SCC to flow out freely from within. Complete procedures in Sections 7.3 through 7.7 within $2^1/_2$ min.

7.8. After the concrete flow has stopped, measure the final diameter of the SCC in two perpendicular directions to the nearest 6 mm [0.25 in.] (Note 2). The average of the two measured diameters is the slump flow in millimeters (inches). Any border of mortar without coarse aggregate or a bleed water "halo" shall be included in the slump flow diameter.

Note 2—Measure the largest diameter of the slump flow as one diameter and the perpendicular diameter as the second to ensure consistency between tests. If the two values differ in diameter by more than 51 mm [2 in.], the test is considered invalid and must be repeated because it is likely that the cone was raised with lateral motion.

7.9. Measure the height of the SCC just inside the ring at four locations to an accuracy of 6 mm [0.25 in.] (heights are designated h_{a1} through h_{a4}). Measure the height of the SCC just outside the ring at four locations to an accuracy of 6 mm [0.25 in.] (heights are designated h_{b1} through h_{b4}). A flat bar or tamping rod placed horizontally across the top of the J-Ring apparatus may be used as a reference to determine the height of the SCC.

7.10. Measure the difference in height between the slump flow patty at the center of the ring (h_1) and just inside the ring at four locations to accuracy of 6 mm [0.25 in.]. A flat bar or tamping rod placed horizontally across the top of the J-Ring apparatus may be used as a reference to determine the height of the SCC.

7.11. Conduct the standard test, TP 73, using SCC from the same sample as used for this J-Ring test so that the results of the J-Ring test may be compared with the results from the slump flow test.

8. CALCULATION OF RESULTS

8.1. Calculate the average of the two measured diameters of the SCC patty after flowing through the J-Ring apparatus. This average value is the J-Ring flow. In general, greater J-Ring flow values indicate greater passing ability.

8.2. Calculate the average of the two measured diameters of the SCC after unrestricted flowing, without the J-Ring in place, by TP 73. This average value is the slump flow.

8.3. Calculate the difference between the J-Ring flow and the slump flow. This value is an indication of the passing ability of the SCC. A difference of less than 25 mm [1 in.] indicates good passing ability, and a difference greater than 51 mm [2 in.] indicates poor passing ability.

8.4. Calculate the average of the four measured heights inside the ring as ham and calculate the average of the four measured heights outside the ring as h_{bm}. Calculate the difference in mean heights between the inside and the outside of the J-Ring as $h_{ab} = (h_{am} - h_{bm})$.

8.5. Calculate the difference between the height of the SCC at the center of the ring and the mean height of the SCC inside the ring as $(h_1 - h_{am})$.

8.6. Calculate the J-Ring test value, J, as $2(h_{ab}) - (h_1 - h_{am})$. A J-Ring test value less than 15 mm [0.6 in.] indicates satisfactory passing ability without blockage.

9. REPORT

9.1. Record the J-Ring flow to the nearest 6 mm [0.25 in.].

9.2. Record the slump flow (without the J-Ring in place) measured by TP 73.

9.3. Record the difference between the J-Ring flow and the slump flow to the nearest 6 mm [0.25 in.].

9.4. Record $h_{ab} = (h_{am} - h_{bm})$, the difference in mean heights between the inside and the outside of the J-Ring, to the nearest 6 mm [0.25 in.].

9.5. Record $(h_1 - h_{am})$, the average of the four measured differences in height between the SCC at the center of the ring and the SCC just inside the bars, to the nearest 6 mm [0.25 in.].

9.6. Record the J-Ring test value, $2(h_{ab}) - (h_1 - h_{am})$, to the nearest 6 mm [0.25 in.].

10. PRECISION AND BIAS

10.1. No precision and bias statements are available at this time.

11. KEYWORDS

11.1. Flowability; passing ability; reinforcement; SCC; self-consolidating concrete; workability.

Standard Test Method for

Air-Void Characteristics of Freshly Mixed Concrete by Buoyancy Change

AASHTO Designation: TP 75-08[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Test Method for

Air-Void Characteristics of Freshly Mixed Concrete by Buoyancy Change

AASHTO Designation: TP 75-08[1]

1. SCOPE

1.1. This test method covers the determination of characteristics of the air-void system of fresh concrete using a sample of mortar. Spacing factor, specific surface, and entrained air content are determined by capturing air bubbles released from a mortar sample.

1.2. The sample will only be representative of the depth of the concrete within approximately 60 mm (2.5 in.) below the level at which the sampling is begun. This method is applicable to fresh concrete with a minimum slump of 10 mm (0.4 in.) and air content between 3.5 and 10 percent by volume. Only air voids less than 3 mm (0.1 in.) in diameter are measured by this method.[2] The test must be performed in sheltered, stable conditions.

1.3. The values stated in SI units are to be regarded as the standard.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- M 231, Weighing Devices Used in the Testing of Materials
- T 119M/T 119, Slump of Hydraulic Cement Concrete
- T 121M/T 121, Density (Unit Weight), Yield, and Air Content (Gravimetric) of Concrete
- T 141, Sampling Freshly Mixed Concrete
- T 152, Air Content of Freshly Mixed Concrete by the Pressure Method
- T 196M/T 196, Air Content of Freshly Mixed Concrete by the Volumetric Method

2.2. *ASTM Standard*:

- C 457, Standard Test Method for Microscopical Determination of Parameters of the Air-Void System in Hardened Concrete

3. SUMMARY OF TEST METHOD[3]

3.1. This method determines the air-void characteristics of fresh concrete by expelling all air bubbles present in a given mortar sample, collecting the air bubbles and recording their quantities, and calculating their size distribution. According to Stokes' law, larger bubbles rise faster than smaller ones. Thus, for bubbles rising a known distance, the size of the bubbles can be determined from the time of their arrival at the surface of the liquid. The air voids of a sample of fresh concrete mortar are released as bubbles by mixing the mortar with a viscous liquid. The bubbles then emerge from the viscous liquid, rise through an overlying column of water, and collect under a submerged dish. As the bubbles accumulate under the dish, the buoyancy of the dish changes. The change in buoyancy of the dish, as measured by a change in weight and recorded as a function of time, can be related to the number of bubbles of different sizes by an empirical correlation. Specific surface, spacing factor, and air content as specified by ASTM C 457 may be calculated from this data with the use of an algorithm.

4. SIGNIFICANCE AND USE

4.1. An adequate air-void system in hardened concrete protects the cement paste from damage during freezing and thawing cycles under moist conditions. This air-void system can be characterized by the volume of entrained air, spacing between air voids, specific surface, and void-size distribution.

4.2. This buoyancy change test method is capable of testing the air-void system of concrete *in situ*, reflecting the history of the concrete as it is in place, not as it is prepared in a sample for testing.

4.3. The primary function of the buoyancy change method is to provide air-void size and distribution information for concrete mixture designs. This test method could be used by the mix designer to evaluate various mix proportion options during prequalification. The effect of admixture combinations and admixture dosages on the air-void system can be evaluated. It can also be used by the approving agency as a quick laboratory check on mixes offered to them for approval.

4.4. During production, the adequacy of the air-void system can be verified for acceptance and feedback can be provided for manufacturing control. This method also allows rapid assessment of the effect of production changes in the mixture or equipment, or variations in placement conditions such as temperature, slump, and pumping on the air-void system. Characterization of the air-void system of the concrete shortly after production provides an assessment of the durability of the cement paste. Results are usually obtained within two hours, allowing adjustments in the subsequent production.

4.5. This method yields results that generally correlate well with the results of a linear traverse measurement on hardened concrete, as prescribed in ASTM C 457 for characteristics of the air-void system. Discrepancies between the results of this method and the results of ASTM C 457 may be due to coalescence of bubbles in the analysis liquid or due to errors in the ASTM C 457 test. The buoyancy change method does not give a total air content result that can be directly correlated with the results of T 152 and T 196M/T 196.

4.6. For further discussion of the significance of characteristics of the air-void system, see ASTM C 457, Section 5, Significance and Use.

5. APPARATUS[4]

5.1. *Analysis and Data Collection Apparatus*—This assembly, the sampling equipment and materials, are designed and built to function as an integrated system that has been demonstrated by the manufacturer to accurately measure and calculate air-void distribution in fresh air-entrained concrete.

5.1.1. *Riser Cylinder*—A clear plastic cylinder with a base and a collar approximately as shown in Figure 1. The base shall have an integral heating element capable of maintaining the analysis liquid at 23 ± 2°C (73 ± 4°F) and entry holes for the plastic rod and the sample syringe with gaskets to make a watertight seal.

5.1.2. *Magnetic Stirrer*—A magnetic stirrer capable of maintaining 300 rpm during mixing.

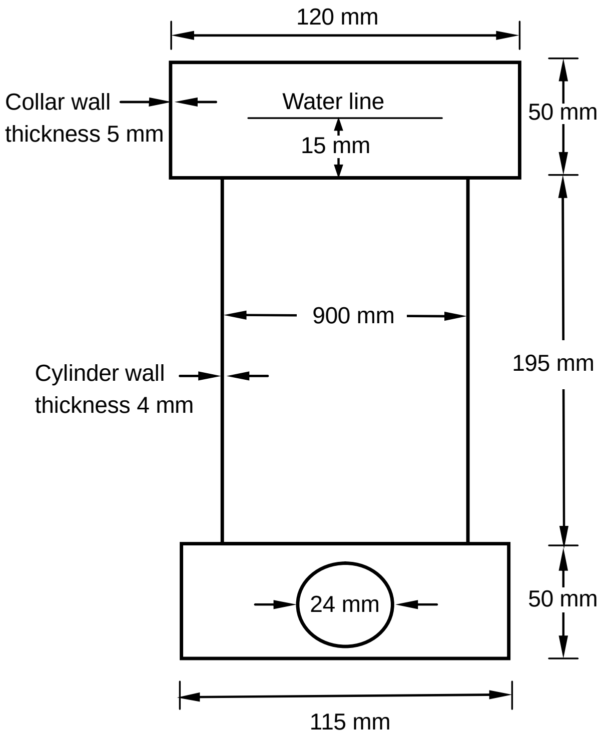

Figure 1—Riser Cylinder

5.1.3. *Balance*—The electronic balance shall meet the requirements of M 231, Class G1. The balance shall also have an integral arm from which the dish can be suspended.

5.1.4. *Cabinet*—The cabinet shall house the riser cylinder, magnetic stirrer, and balance as shown in Figure 2.

Figure 2—Typical Apparatus with Riser Cylinder, Cabinet, and Computer

5.1.5. *Stirrer Rod*—A ferromagnetic steel rod approximately 6 mm (0.25 in.) in diameter and 62 mm (2.5 in.) in length.

5.1.6. *Temperature Sensor*—The temperature sensor shall detect the temperature of the analysis liquid at the bottom of the cylinder. The temperature sensor shall be capable of measuring the temperature to within 0.5°C (1.0°F) in the range of 15 to 30°C (59 to 86°F) and of transmitting such measurements to the computer through an appropriate interface.

5.1.7. *Syringes*—20-ml plastic syringes, with the tapered end removed, calibrated and marked for collecting the specified sample volume as shown in Figure 3.

5.1.8. *Plastic Rod*—The cylindrical plastic rod shall be at least 35 mm (1.5 in.) longer than the width of the base. The outside diameter of the body of the rod is the same as the syringes used in the test. A 1-mm length at the end of the rod shall have a reduced diameter that fits tightly within the inside diameter of the syringe as shown in Figure 3.

5.1.9. *Dish*—The clear, shallow dish shall be large enough to cover the entire area of the cylinder, retain the rising bubbles, and fit within the collar. The dish shall have an opening on the side to allow entrapped air to be removed.

Note 1—An inverted Petri dish with an appropriate slot, as shown in Figure 3, can fulfill these requirements.

5.1.10. *Suspension Device*—A device to suspend the dish from a balance arm by a single wire as shown in Figure 3.

Figure 3—Petri Dish, 20 ml Syringe, and Temperature Sensor

5.1.11. *Control System*—A computer, software, and interface system capable of controlling the test, recording data, and displaying data at least once per minute during the test. It shall also calculate, display, and record the air content(s), air-void spacing factor, and specific surface of the air-void system.

5.2. *Sampling Equipment*:

5.2.1. *Sampling Assembly*—The sampling assembly shall hold the syringe and a wire cage and vibrate at approximately 50 Hz with an amplitude that allows the mortar to flow into the wire cage.

Note 2—A drill operating at 3000 rpm with an eccentrically weighted, forked assembly as shown in Figure 4 can fulfill these requirements. The hammering function of the drill can be used as needed in stiffer concrete mixes.

Figure 4—Wire Cage and Funnel

5.2.2. *Wire Cage*—The cage shall be of sufficient size to obtain a sample of fresh concrete mortar, similar to Figure 4. The cage wires shall have a clear spacing of 6 mm (0.24 in.).

5.2.3. *Plastic Plate*—A rigid, clear plastic plate approximately 250 by 250 by 3 mm (10 by 10 by $^1/_8$ in.) with a center hole of a diameter approximately 3 mm ($^1/_8$ in.) greater than that of the wire cage.

5.3. *Miscellaneous Tools*:

5.3.1. *Funnel*—A calibrated funnel marked for measuring a specified amount of analysis liquid similar to that shown in Figure 4. The funnel shall be capable of introducing the analysis liquid into the bottom of the water-filled riser cylinder with a minimum of mixing.

5.3.2. *Spatula*—A spatula to trim the mortar sample flush with the end of the syringe.

5.3.3. *Water Container*—A container with a 4-L (2-gal) minimum capacity.

Note 3—A 19-L (5-gal) portable insulated drinking water cooler is useful for repeated testing.

5.3.4. *Heating Element*—An immersible heating element capable of maintaining the water in the container at approximately 23 ± 2°C (73 ± 4°F).

5.3.5. *Thermometer*—A thermometer accurate to ±0.5°C (±1.0°F) over the range of 10 to 30°C (50 to 86°F).

5.3.6. *Brush*—A brush with an angled head and a handle longer than the riser cylinder is tall.

5.3.7. *Insulated box.*

Note 4—An insulated "cooler-type" lunchbox is useful.

5.3.8. *Sealable Plastic Bags*—Commercially available in pint and quart sizes.

6. MATERIALS

6.1. *Analysis Liquid*—The analysis liquid shall have physical and chemical properties such that the air-void bubbles remain discrete. The viscosity of the analysis liquid must remain constant over the range of temperatures found in the test and be compatible with the apparatus and the control system. The viscosity of the analysis liquid used shall provide a measurable separation in time between the arrivals of bubbles of different sizes at the top of the water column. The analysis liquid and its viscosity shall be specified by the equipment manufacturer.

Note 5—A commercially available solution of glycerol in water can fulfill these requirements. A mixture of 4 parts glycerol to 1 part distilled water has been known to work well.

6.2. *De-aerated Water*—The water shall be potable and shall have been maintained at atmospheric pressure and approximately 23 ± 2°C (73 ± 4°F) for a minimum of 12 hours before use.

Note 6—Properly de-aerated water is crucial to this test. The solubility of air in water increases as pressure increases and temperature decreases. The change in dissolved air content due to temperature occurs slowly; thus, the water must be maintained at constant temperature for a minimum of 12 hours before use. De-aerated water also reabsorbs air when cooled. If the water is not de-aerated correctly or if it is used shortly after reheating, air may be liberated in the riser cylinder. Air bubbles may form in the riser cylinder and on the dish, and may have a considerable effect on the specific surface and spacing factor results.

6.3. *Ice or Freezer Packs*—Ice as needed in cubes or chips or frozen re-freezable ice packs or cubes.

7. SAMPLING

7.1. Take samples as soon as possible after the concrete is in the desired state. The sampling location depends on the purpose of the test. Samples can be extracted from concrete *in situ* (pavements, structural members, decks, etc.), from concrete sampling containers such as unit weight buckets, beam molds, or cylinder molds, or from other locations.

7.2. Insert a syringe into the sampling assembly and mount the wire cage onto the sampling assembly. Fully collapse the syringe.

7.3. Place the plastic plate in good contact with the surface of the concrete to be sampled. Begin the vibration of the sampling assembly. Lower the wire cage through the hole in the plastic plate into the concrete. The vibration will cause the mortar fraction of the concrete to flow into the wire cage. Advance the wire cage into the concrete at a rate such that the concrete surface under the plate and the surface of the mortar within the cage remain at approximately the same level at all times. Avoid filling the cage with surface mortar by pressing the plastic plate against the fresh concrete. The pressure is adequate when the air bubbles under the plastic plate do not move towards the hole while sampling.

7.4. Advance the wire cage into the concrete until the end of the syringe plunger is in full contact with the surface of the mortar. While maintaining the vibration, push the syringe cylinder smoothly into the mortar at such a rate that the wire cage remains full of mortar until the syringe is fully extended. Stop the vibration and withdraw the wire cage and syringe from the concrete.

7.5. Remove the wire cage and the syringe from the sampling assembly saving the excess mortar from the wire cage. Pack this excess mortar around the end of the syringe to be used to displace any large air bubbles from the syringe.

7.6. Immediately place the sample in a plastic bag on ice or freezer packs in the insulated box to retard the onset of initial set. Testing must begin before the initial set of the concrete.

7.7. If large air bubbles are present at the base of the syringe, remove the plunger and pack enough excess mortar through the opposite end of the syringe to remove the air bubble. Replace the plunger to contact the mortar. Remove the excess mortar from the outside of the syringe and clean the outside of the syringe with a damp cloth. Advance the plunger to the mark corresponding to the specified sample volume and trim the mortar flush with the end of the syringe cylinder using the spatula. Retract the plunger approximately 1 mm (0.04 in.) to allow room for the recessed end of the plastic rod. This step may be performed at any time before step 9.9, seating the syringe on the plastic rod. If the air bubble is larger than 2 ml, discard and resample.

Note 7—2 ml is approximately the distance from the end of the plunger to the calibration mark when the plunger of the syringe is fully extended. The 2 ml of material is packed into the opposite end of the syringe. This material is then forced back out of the syringe when the plunger is advanced to the calibration mark.

8. PREPARATION OF APPARATUS

8.1. Bring the analysis liquid and at least 2 L (0.5 gal) of de-aerated water to a temperature of 23 ± 2°C (73 ± 4°F) without altering other characteristics of the liquids.

Note 8—Using ice in sealed plastic bags or freezer packs to cool the liquids is acceptable.

8.2. Select a test location protected from any wind, vibration, or movement that may affect the balance readings. Place the cabinet on a stable and level surface. Allow the balance to stabilize so that it does not drift more than 0.01 g in four minutes. If the balance has auto-zeroing capability, place a small load on the balance to obtain a non-zero reading in order to observe the variation of the reading.

8.3. Connect the control system.

Note 9—Place the control system so that if the plastic rod is accidentally removed from the base of the riser cylinder the contents of the riser cylinder will not spill onto the control system.

8.4. See Appendix X4 for additional hints on preparation of apparatus.

9. PROCEDURE

9.1. Enter all required data into the control system.

9.2. Place the stirrer rod flat on the bottom of the riser cylinder. Insert the plastic rod through the hole on the wider side of the base of the riser cylinder so the full diameter of the plastic rod protrudes though the hole on the opposite (narrower) side of the base.

Note 10—Using a light coat of waterproof grease on the rubber o-rings will improve the seal between the plastic rod and the base of the riser cylinder.

Note 11—When testing low-viscosity materials such as self-consolidating concrete, it is permissible to tilt the riser column to seat the syringe on the plastic rod before the liquids are added to the riser column.

9.3. Fill the riser cylinder with de-aerated water to about 15 mm (0.5 in.) above the bottom of the top collar. Use the brush to remove all bubbles from the stirrer rod, the plastic rod, and the riser cylinder.

Note 12—Rotating the plastic rod can be helpful in ensuring that all bubbles are removed.

9.4. Mount the riser cylinder in position on the cabinet. It is permissible to fill the riser cylinder with the water after positioning the riser cylinder on the cabinet.

9.5. Fill the funnel with the manufacturer's specified amount of the analysis liquid.

9.6. Insert the analysis liquid into the bottom of the riser cylinder using the funnel to minimize the mixing of the analysis liquid with the de-aerated water. Replace the stopper once the specified amount of analysis liquid has been discharged. Remove the funnel from the riser cylinder and discard any remaining liquid in the funnel.

9.7. Connect the integral heating element of the riser cylinder and the temperature sensor to the control system.

9.8. Insert the dish into the riser cylinder collar. Submerge the dish in the de-aerated water and tilt to allow all entrapped air to escape through the opening. Suspend the dish from the balance arm in such a way that it is approximately centered and does not touch the walls of the riser cylinder collar. Only a single wire of the suspension device may break the surface of the water. Add more de-aerated water if necessary.

9.9. Seat the syringe containing the sample on the reduced end of the plastic rod. Move the syringe and plastic rod together through the riser cylinder base until the junction of the syringe and plastic rod is at the nearest inside edge of the riser cylinder. Leaving the syringe in position, continue withdrawing the plastic rod until the reduced end is flush with the opposite inside edge of the riser cylinder.

Note 13—To make positioning the plastic rod and syringe with respect to the riser cylinder easier, mark the correct position on the plastic rod and note the position of the syringe before starting the test. If moving the plastic rod and syringe is difficult, use a small amount of waterproof grease or analysis fluid on the gaskets and use a twisting motion.

9.10. Remove enough of the air that may have risen during the separation of the syringe and the plastic rod from under the dish so the dish is neither touching nor close to the wall of the riser cylinder collar.

9.11. When the temperature of the analysis liquid as measured by the temperature sensor is 23 ± 2°C (73 ± 4°F), inject the mortar from the syringe into the riser cylinder. Immediately start the mixing and data collection.

9.12. If any of the recorded temperature readings are outside the range of 23 ± 2°C (73 ± 4°F), discard the test.

9.13. If unusual variations that may be due to vibration or disturbance are noted in the data, discard the test.

9.14. Analyze samples as soon as possible. However, samples may be used whenever they can be completely dispersed in the analysis liquid by the stirring action.

10. REPORT

10.1. *The report shall include the following information*:

10.1.1. Project identification;

10.1.2. Test identification number;

10.1.3. Date of test;

10.1.4. Sampling location;

10.1.5. Slump by T 119M/T 119 (if known);

10.1.6. Air content by T 152 or T 196M/T 196 (if known);

10.1.7. Unit weight by T 121M/T 121 (if known);

10.1.8. Mortar (material less than 6 mm) volume, percent, as calculated from the mix design;

10.1.9. Paste volume, percent, as calculated from the mix design;

10.1.10. Sample volume, ml;

10.1.11. Test temperature range, °C (°F);

10.1.12. Air content(s), percent;

10.1.13. Spacing factor, mm (in.); and

10.1.14. Specific surface, mm^2/mm^3 ($in.^2/in.^3$).

11. PRECISION AND BIAS

11.1. *Precision*—The existing data from this method are not sufficient to develop a precision statement. The necessary data could be generated by performing a “round robin” test using several devices at a single facility.

11.2. No bias statement has been developed. There is no accepted reference material suitable for determining bias from the true air-void characteristics of concrete.

12. KEYWORDS

12.1. Air content; air-void characteristics; air-void parameters; air-void system; fresh concrete; spacing factor; specific surface.

APPENDIXES

(Nonmandatory Information)

X1. VERIFICATION

X1.1. To correlate the air-void characteristics (spacing factor, entrained air content, or specific surface) as determined by the buoyancy change method from fresh concrete with those obtained by ASTM C 457 from hardened concrete, compare a minimum of five pairs of samples. Each pair of samples of the fresh and hardened concrete should be from the same batch of concrete, placed and consolidated uniformly, of comparable depth, and located as close together as possible without including any of the area disturbed during sampling the fresh concrete in the hardened sample. Calculate the percentage difference of the buoyancy test results from the ASTM C 457 results for each pair, and then average these percentage differences. The average of the percentage differences of the five pairs should be 20 percent or less for the results to be considered equivalent. Average percentage differences greater than 20 percent may arise from ASTM C 457 testing errors such as mistaking fly ash spheres or voids left by sand grains plucked from the polished surface of the specimen during sample preparation for air voids in the concrete paste. Sampling errors, testing errors in the buoyancy change method, admixtures that affect the viscosity or the miscibility of fresh concrete, or other factors may also cause some variation. The buoyancy change method is less likely than ASTM C 457 to overestimate the quantity and quality of the air voids in any given concrete. In the buoyancy change method, bubbles may coalesce after release into the fluid, and the portion of entrained air associated with the coarse aggregate is excluded from the sample. Thus, the buoyancy change method will tend to give a lower specific surface and higher spacing factor than ASTM C 457.

X2. EQUIPMENT HANDLING REQUIREMENTS

X2.1. The commercially available Germann Air Void Analyzer does not require special handling when it is packed securely in its metal carrying case. The Kansas Department of Transportation’s Air-Void Analyzer has been transported in its case and set up at remote locations at least twice a week for three construction seasons with few deleterious effects.

X3. REPEATABILITY

X3.1. Although each buoyancy test requires a unique sample and therefore cannot be duplicated exactly, researchers at the Kansas Department of Transportation have found that pairs of samples obtained within 0.5 m of each other in the field vary 10 percent from each other on average.

X4. SET UP HINTS

X4.1. Several steps can be taken to reduce the amount of time necessary to set up the buoyancy testing equipment.

X4.1.1. Preparing the de-aerated water and the bottle of analysis liquid in an insulated water container at least one day before testing occurs will save time. If the water container will be stored in an area that is cooler than the specified temperature, set the immersible heater to the correct temperature and put it into the covered water container. If the room temperature is slightly higher than the specified temperature, uncovering the container will allow the water to cool approximately 3°C (5°F). If the room temperature is much higher than the specified temperature, a sealed bag of ice or freezer packs placed in the covered water container the night before testing will generally result in the correct water and analysis fluid temperature.

X4.1.2. After the water has been brought to the proper temperature, care should be taken to keep the temperature as constant as possible. Protect the water container from temperature extremes, such as may be encountered in an enclosed vehicle.

X4.1.3. Obtaining a constant balance reading at the beginning of the test may take a significant amount of time if the equipment is set up in an unstable location. Mobile work trailers that are resting on their tires are generally not stable enough. Any movement by people in the trailer can move the trailer enough to disturb the apparatus and render the test unusable. Generally, only trailers that have been put up on blocks so they are not sitting on their tires are at all acceptable, and only as a last alternative.

X4.1.4. Isolating the test equipment from vibration will reduce the time necessary to obtain a constant balance reading at the beginning of the test. One or two anti-vibration pads may be used under each corner of the cabinet to attenuate shock and vibration.

Standard Method of Test for

Visual Stability Index (VSI) of Self-Consolidating Concrete (SCC)

AASHTO Designation: TP 80-10[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Visual Stability Index (VSI) of Self-Consolidating Concrete (SCC)

AASHTO Designation: TP 80-10[1]

1. SCOPE

1.1. This test method covers determination of the visual stability index of self-consolidating concrete (SCC), both in the laboratory and in the field. SCC is defined as a highly workable concrete that can flow through densely reinforced or complex structural elements under its own weight without vibration and adequately fill voids without experiencing segregation or excessive bleeding.

1.2. The values stated in either SI units or inch-pound units are to be regarded separately as standard. Within the text, the inch-pound units are shown in brackets. The values stated in each system are not exact equivalents; therefore, each system shall be used independently of the other. Combining values from the two systems may result in nonconformance with the standard.

1.3. *This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

- T 141, Sampling Freshly Mixed Concrete
- TP 73, Slump Flow of Self-Consolidating Concrete (SCC)

3. SUMMARY OF TEST METHOD

3.1. The Visual Stability Index (VSI) is a visual rating of the resistance to segregation of an SCC mixture and may be determined when performing the Slump Flow Method of Test in TP 73. A sample of freshly mixed self-consolidating concrete is placed in a mold shaped as the inverted frustum of a cone. The mold is raised, allowing the SCC to spread radially. The stability of the mixture is then rated visually and assigned a Visual Stability Index based on the criteria in this document.

4. SIGNIFICANCE AND USE

4.1. This test method is applicable to self-consolidating concrete (SCC), defined in Section 1.1.

4.2. This test method is intended to provide the user with a procedure to assess the stability of SCC. The stability (or segregation resistance) of an SCC mixture is the ability of the mixture to remain homogeneous in composition during transport, during placement, and subsequent to placement. The VSI does not quantify a property of the concrete mixture, but is useful for quality control/consistency testing.

4.3. This test method is applicable to SCC having coarse aggregate up to 25 mm [1 in.].

5. APPARATUS

5.1. *Mold*—The SCC shall be placed in an inverted slump cone mold conforming to the applicable requirements of T 119M/T 119.

5.2. *Base Plate*—The base plate shall be made of a stiff nonabsorbing material, at least 820 mm [32 in.] square, marked with a circle indicating the central location for the slump cone, and a concentric circle with a diameter of 500 mm [20 in.].

5.3. *Scoop*—A scoop of a size large enough so each amount of concrete obtained from the sampling receptacle is representative and small enough so it is not spilled during placement in the mold

5.4. *Strike-Off Bar*—A flat straight bar of steel or other suitable metal at least $^1/_8$ in. (3 mm) thick and $^3/_4$ in. (20 mm) wide by 12 in. (300 mm) long.

5.5. Tape measure containing increments of 5 mm [0.25 in.] or less.

6. SAMPLE

6.1. Approximately 6 L [0.2 ft^3] of SCC is needed to perform the slump flow and VSI tests, sampled normally.

6.2. The sample of concrete shall be obtained in accordance with T 141.

7. PROCEDURE

7.1. Moisten the base plate and inside of the slump cone.

7.2. Place the base plate on a level stable surface and the inverted slump cone centrally on the base plate and hold down firmly (Figure 1).

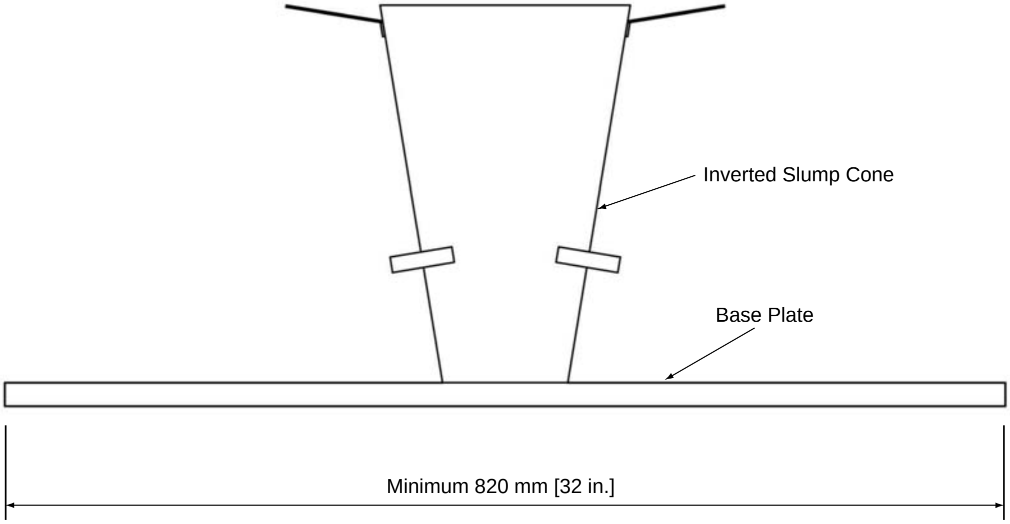

Figure 1—Mold and Base Plate for Slump Flow Test (Inverted Cone Orientation)

7.3. From the sample of concrete obtained in accordance with Section 6, fill the entire mold continuously. The mold shall be held firmly in place during filling.

7.4. Do not rod or tamp the SCC. Do not tap the sides of the cone or vibrate.

7.5. Use the strike-off bar to strike off the SCC level with the top of the cone.

7.6. Remove any spilled or struck off SCC from around the base of the cone to preclude interference with movement of the flowing SCC.

7.7. Immediately raise the cone vertically 230 ± 75 mm [9 ± 3 in.] above the base plate with no lateral or torsional motion within a time period of 3 ± 1 s, and allow the SCC to flow out freely from within. Complete the steps described in Sections 7.3 through 7.7 within $2^1/_2$ min.

7.8. If the Slump Flow test of TP 73 is being performed, diameters of the patty may be measured at this point.

7.9. Using the guidelines in Section 8, rate the stability of the mixture in 1.0 increments by visual examination of the SCC on the base plate and in the wheelbarrow or mixer.

8. INTERPRETATION OF RESULTS

8.1. In the case of severe segregation, most of the coarse aggregate may remain in the center of the slump flow patty of SCC. A border of mortar without coarse aggregate or a bleed water “halo” may occur at the edge of the slump flow patty of SCC.

8.2. Refer to Table 1 and Figures 2 through 8 for assignment of Visual Stability Index.

Table 1—Criteria for Visual Stability Index (VSI) of SCC

Rating	Criteria
0	No evidence of segregation in slump flow patty or in mixer drum or wheelbarrow.
1	No border of mortar without coarse aggregate in the slump flow patty, but some slight bleed or air popping on the surface of the concrete in the mixer drum or wheelbarrow.
2	A slight border of mortar without coarse aggregate (<10 mm [$^3/_8$ in.]) and/or aggregate pile in the slump flow patty and highly noticeable bleeding in the mixer drum and wheelbarrow.
3	Clearly segregating by evidence of a large border of mortar without coarse aggregate (>10 mm [$^3/_8$ in.]) and/or large aggregate pile in the center of the slump flow patty and a thick layer of paste on the surface of the resting concrete in the mixer drum or wheelbarrow.

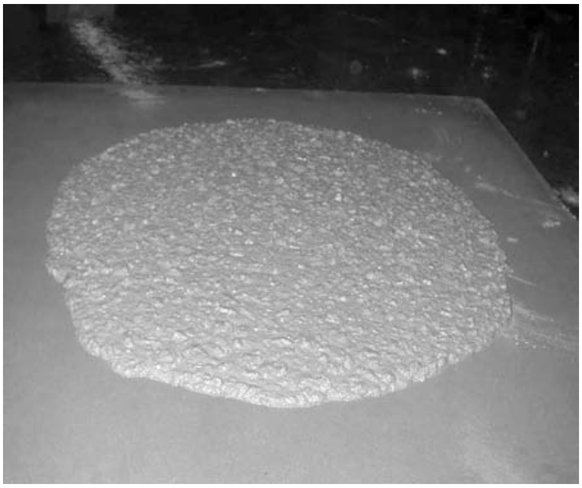

Figure 2—Visual Stability Index = 0

Figure 3—Visual Stability Index = 1

Figure 4—Visual Stability Index = 1

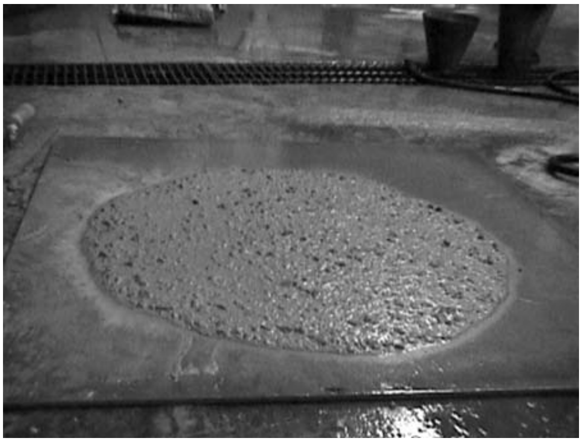

Figure 5—Visual Stability Index = 2

Figure 6—Visual Stability Index = 2

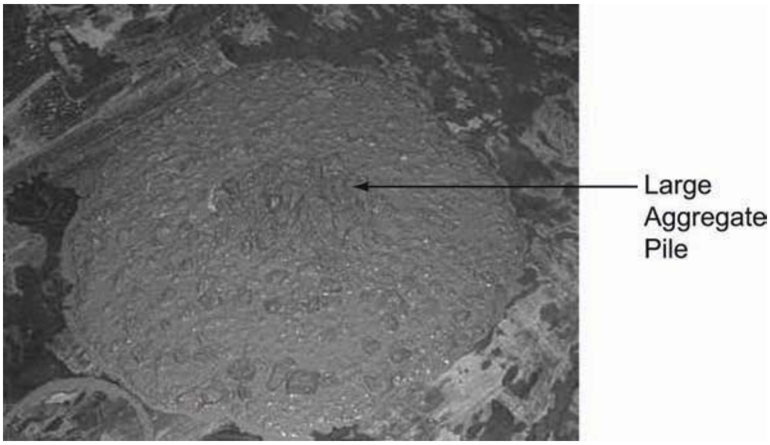

Figure 7—Visual Stability Index = 3

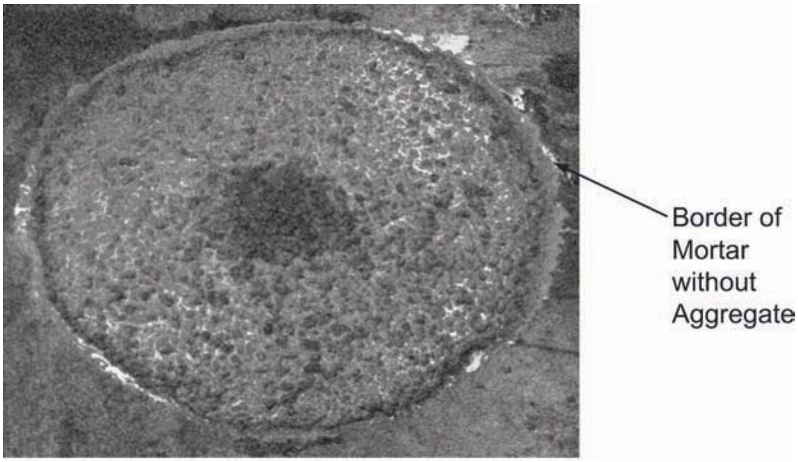

Figure 8—Visual Stability Index = 3

9. REPORT

9.1. Record the Visual Stability Index of the mixture.

10. PRECISION AND BIAS

10.1. No precision and bias statements are available at this time.

11. KEYWORDS

11.1. Halo; SCC; segregation; self-consolidating concrete; slump flow; stability; Visual Stability Index; VSI; workability.

[1] This test method was adopted and first printed in 2009. Revised in 2010.

Standard Method of Test for

Sampling and Fabrication of 50-mm (2-in.) Cube Specimens Using Grout (Non-Shrink) or Mortar

AASHTO Designation: TP 83-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Sampling and Fabrication of 50-mm (2-in.) Cube Specimens Using Grout (Non-Shrink) or Mortar

AASHTO Designation: TP 83-10

1. SCOPE

1.1. This method covers field sampling and fabrication and initial curing of 2-in. (50-mm) cube specimens of non-shrink grout or mortar materials, or both.

1.2. The values stated in either inch-pound or SI units shall be regarded separately as standard. The inch-pound units are shown in parentheses. The values stated might not be exact equivalents; therefore, each system must be used independently of the other.

Note 1—Unit weight was the previous terminology used to describe the property determined by this test method, which is mass per unit volume.

1.3. The text of this test method references notes and footnotes that provide explanatory information. These notes and footnotes (excluding those in tables) shall not be considered as requirements of this test method.

1.4. *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.*

Warning—Fresh hydraulic cementitious mixtures are caustic and may cause chemical burns to skin and tissue upon prolonged exposure.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 106M/T 106, Compressive Strength of Hydraulic Cement Mortars (Using 50-mm or 2-in. Cube Specimens)
- T 141, Sampling Freshly Mixed Concrete

2.2. *ASTM Standards*:

- C 109/C 109M, Standard Test Method for Compressive Strength of Hydraulic Cement Mortars (Using 2-in. or [50-mm] Cube Specimens)
- C 1107/C 1107M, Standard Specification for Packaged Dry, Hydraulic-Cement Grout (Nonshrink)

3. TERMINOLOGY

3.1. *Definitions of Terms Specific to This Standard*:

3.1.1. *plastic mix*—material viscous enough that an indentation will be left in the surface of the grout after tamping.

3.1.2. *fluid mix*—material fluid enough that little or no indentation will be left in the surface after puddling.

4. APPARATUS

4.1. *Specimen Molds Including Cover Plate(s)*—The 2-in. (50-mm) cube specimen molds shall be tight-fitting and made of brass or other suitable material. This material shall not be susceptible to attack by the cement mortar. The mold portion shall have not more than three cube compartments and shall be separable into not more than two parts. The parts of the molds (mold halves and cover plate(s)), when assembled, shall be positively held together. The working surface of the cover plate(s) shall be plane and shall be positively attached to the side walls of the mold. The interior faces of the molds shall conform to the tolerances of Table 1.

Table 1—Permissible Variations of Specimen Molds

Parameter	2-in. Cube Molds		50-mm Cube Molds	
	New	In Use	New	In Use
Planeness of sides	<0.001 in.	<0.002 in.	<0.025 mm	<0.05 mm
Distance between opposite sides	2 in. ± 0.005 in.	2 in. ± 0.02 in.	50 mm ± 0.13 mm	50 mm ± 0.50 mm
Height of each compartment	2 in. + 0.01 in. to –0.005 in.	2 in. + 0.01 in. to –0.015 in.	50 mm + 0.25 mm to –0.13 mm	50 mm + 0.25 mm to –0.38 mm
Angle between adjacent faces[a]	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°	90 ± 0.5°

[a] Measured at points slightly removed from the intersection. Measured separately for each compartment between all the interior faces and the adjacent face and between interior faces and top and bottom planes of the mold.

4.2. *Tamper*—A nonabsorptive, nonabrasive, nonbrittle material such as a hard rubber compound having a Shore A durometer hardness of 80 ± 10. The tamper shall have a cross section of about $^1/_2$ in. by 1 in. (13 mm by 25 mm) and a length of 5 to 6 in. (125 to 150 mm). The tamping face shall be flat and at right angles to the length of the tamper.

4.3. *Trowel*—Steel bladed, 4 to 6 in. (100 to 150 mm) in length, with straight edges.

4.4. *Watertight Container*—A 6-in. by 12-in. (150-mm by 300-mm) concrete cylinder mold with lid.

4.5. *Other Equipment*—Rubber gloves, scoop, clamps to secure the cover plate, light release oil for oiling the molds, small brush or lint-free cloth for applying and removing excess release oil, and burlap or wrapping cloth capable of retaining moisture.

5. SAMPLING

5.1. Samples shall be obtained in accordance with T 141 when the batch equals or exceeds 1 yd^3 (1 m^3). When the batch is less than 1 yd^3 (1 m^3), sample from the batch after discharge. If remixing is required, sample after remixing. Begin molding the specimens within an elapsed time of not more than $2^1/_2$ minutes from completion of the mixing.

Note 2—This test is to be used only for grouts with 100 percent passing the $^{3}/_{8}$-in. (9.5-mm) sieve.

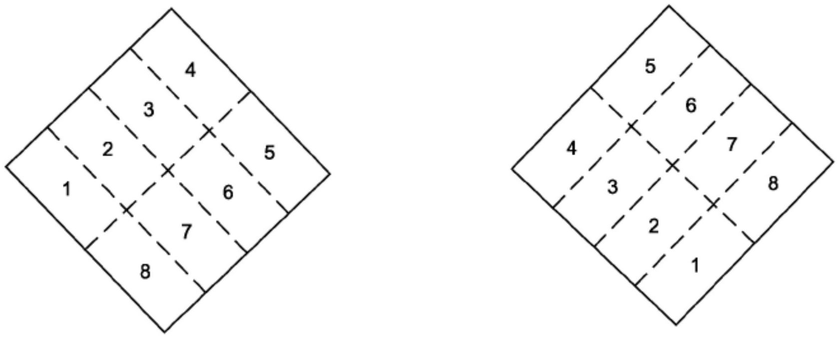
5.2. Obtain a representative sample of the mix. Samples shall be a minimum size of 4 lb (2000 g) for each set of three cubes to be fabricated.

6. PROCEDURE

6.1. Assemble both portions of the mold and the bottom cover plate. All joints shall be watertight. If not watertight, seal the surfaces where the halves of the mold join by applying a coating of light cup grease (non-water-soluble). The amount should be sufficient to extrude slightly when the halves are tightened together. Repeat this process for attaching the mold to the bottom cover plate. Remove any excess grease. Apply a thin coating of release agent to the interior faces of the mold and the bottom cover plate. Wipe the mold faces and base plate as necessary to remove any excess release agent and to achieve a thin, even coating on the interior surfaces. Adequate coating is that which is just sufficient to allow a distinct fingerprint to remain following light finger pressure.

6.2. Place a layer of grout about 1 in. (25 mm) (approximately one-half of the depth of the mold) in all of the cube compartments. Consolidate according to the consistency (plastic or fluid) of the mix.

6.2.1. For plastic mixes, tamp the lift in four rounds of 8 tamps for a total of 32 tamps with the rubber tamper in 10 seconds. See Figure 1 for tamping sequence of each round. Rounds 1 and 3 and Rounds 2 and 4 shall be the same.



Rounds 1 and 3

Rounds 2 and 4

Figure 1—Tamping Sequence

6.2.2. For fluid mixes, puddle the lift 5 times with a gloved finger. See Figure 2 for puddling sequence.

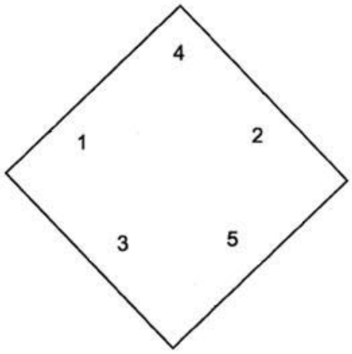


Figure 2—Puddling Sequence

6.3. Place the second lift in each of the cube compartments, slightly over-filling each compartment. Consolidate the material in the same fashion as the first lift with the additional requirement that, during consolidation of the second lift, any grout forced out onto the top of the mold after each round will be pushed back onto the compartment by means of the tamper or gloved fingers, or both, before the next consolidation round. When consolidation of the grout is completed, material should extend slightly above the top of the mold. After the last round, push any grout forced onto the top of the mold back into the compartment with the trowel.

6.4. Smooth off the cubes by drawing the flat side of the trowel (with the leading edge slightly raised) once across the top of each cube at right angles to the length of the mold. Then, for the purpose of leveling the mortar and making the mortar that protrudes above the top of the mold of more uniform thickness, draw the flat trailing edge of the trowel (with leading edge slightly raised) once lightly along the length of the mold. Cut off the mortar to a plane surface flush with the top of the mold by drawing the straightedge of the trowel (held nearly perpendicular to the mold) with a sawing motion over the length of the mold. The material shall be flush with the top of the mold.

6.5. Immediately secure the top cover plate to the cube mold.

6.6. Place the molds in a secure location away from vibration and as close as possible to the structure for initial curing. Cover with wet burlap, towels, or rags; seal it in a plastic sack in a level location out of direct sunlight; and record the time. These samples shall remain undisturbed and protected from freezing or overheating for a period of 24 ± 4 hours.

6.7. At the end of the initial curing period as required by the agency, either:

6.7.1. Place the sealed plastic sack into a watertight container. Transport the cube samples immediately to the location of final curing. During transport, the cube samples shall be protected from jarring, freezing, and moisture loss; or

6.7.2. Disassemble the mold and carefully remove the cube samples. Using a permanent marker, identify the cube samples. Handling the cube samples very carefully, wrap them in wet burlap or wet towels and place them into a watertight container. Transport the cube samples immediately to the location of final curing. During transport, the cube samples shall be protected from jarring, freezing, and moisture loss.

6.8. Final curing shall consist of removing the samples from the transport container and immersing the cube samples in a lime-saturated water storage tank. They are to remain in the storage tank until time of test. (Curing cube samples of material other than hydraulic cement shall be in conformance with the manufacturer’s recommendations.) The storage tank shall be made of noncorroding materials.

Standard Specification for

Detectable Warning Surfaces

AASHTO Designation: MP 12-04

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Detectable Warning Surfaces

AASHTO Designation: MP 12-04

1. SCOPE

1.1. Detectable warnings provide a distinctive surface of truncated domes detectable by cane or underfoot to alert people with vision impairments of the transition to vehicular ways. These warnings compensate for the sloped surfaces of curb ramps that remove a tactile cue provided by curb faces.

1.2. It is not the intent of this specification to relieve the supplier from the final responsibility to provide an appropriate product for the intended function, nor is it intended to specify all the design details. The objective is to provide a sufficiently detailed specification that the function is clearly defined to provide a standard geometry of the detectable warning surface.

2. REFERENCED DOCUMENTS

2.1. The Access Board, *Accessibility, Guidelines and Standards,* "Draft Guidelines for Accessible Public Rights-of-Way," November 23, 2005, www.access-board.gov/prowac/draft.htm.

3. TERMINOLOGY

3.1. *detectable warning*—A surface feature built in or applied to walking surfaces or other elements to warn of hazards on a circulation path.

4. DETECTABLE WARNING SURFACES

4.1. *General*—Detectable warnings shall consist of a surface of truncated domes aligned in a square grid pattern and shall comply with the following requirements:

4.1.1. *Dome Size*—Truncated domes in a detectable warning surface shall have a base diameter of 0.9 in. (23 mm) minimum to 1.4 in. (36 mm) maximum, a top diameter of 50 percent of the base diameter minimum to 65 percent of the base diameter maximum, and a height of 0.2 in. (5 mm).

4.1.2. *Dome Spacing*—Truncated domes in a detectable warning surface shall have a center-to-center spacing of 1.6 in. (41 mm) minimum and 2.4 in. (61 mm) maximum, and a base-to-base spacing of 0.65 in. (16 mm) minimum, measured between the most adjacent domes on square grid.

4.1.3. *Contrast*—Detectable warning surfaces shall contrast visually with adjacent walking surfaces either light-on-dark or dark-on-light.

4.1.4. *Size*—Detectable warning surfaces shall extend 24 in. (610 mm) minimum in the direction of travel and the full width of the curb ramp, landing, or blended transition.

4.2. *Location*:

4.2.1. *Curb Ramps and Blended Transitions*—The detectable warning surface shall be located so that the edge nearest the curb line is 6 in. (150 mm) minimum and 8 in. (205 mm) maximum from the curb line.

4.2.2. *Rail Crossings*—The detectable warning surface shall be located so that the edge nearest the rail crossing is 6 in. (150 mm) minimum and 8 in. (205 mm) maximum from the vehicle dynamic envelope.

4.2.3. *Platform Edges*—Detectable warning surfaces at platform boarding edges shall be 24 in. (610 mm) wide and shall extend the full length of the platform.

Standard Specification for

Stainless Clad Deformed and Plain Round Steel Bars for Concrete Reinforcement

AASHTO Designation: MP 13M/MP 13-04 (2006)

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Stainless Clad Deformed and Plain Round Steel Bars for Concrete Reinforcement

AASHTO Designation: MP 13M/MP 13-04 (2006)

1. SCOPE

1.1 This specification covers the stainless steel clad concrete reinforcement bars in cut lengths or coils, deformed and plain round. The standard sizes and dimensions of deformed bars and their number designations shall be those listed in Table 1 [Table 2].

Note 1—For coils of deformed bars, the capacity of industrial equipment limits the maximum bar size that can be straightened.

1.2 Bars are of three minimum yield levels: namely, 300 MPa [40000 psi], 420 MPa [60000 psi], and 520 MPa [75000 psi], designated as Grade 300 [40], Grade 420 [60], and Grade 520 [75], respectively.

1.3 Hot-rolled plain rounds, in sizes up to and including 50.8 mm [2 in.] in diameter in coils or cut lengths, when specified for dowels, spirals, and structural ties or supports, shall be furnished under this specification in Grade 300 [40], Grade 420 [60], and Grade 520 [75] (Note 2).

For ductility properties (elongation and bending), test provisions of the nearest nominal diameter deformed bar size shall apply. Those requirements providing for deformations and marking shall not be applicable.

Note 2—The weight for plain rounds smaller than 9.5 mm [$^3/_8$ in.] in diameter shall be computed on the basis of the size in ASTM A 510.

1.4 Welding of the material in this specification should not be attempted since no experience has been demonstrated regarding weldability of this product. Mechanical coupling should be specified for bars requiring continuous longitudinal connection. Mechanical couplings must conform to ASTM A 276, UNS S31803.

1.5 This specification is applicable for orders in either SI units (MP 13M) or in inch-pound units (MP 13). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to MP 13.

Table 1—Deformed Bar Designation Numbers, Nominal Masses, Nominal Dimensions, and Deformation Requirements, SI Units

		Nominal Dimensions[a]			Deformation Requirements, mm		
Bar Designation No.[b]	Nominal Mass, kg/m	Diameter, mm	Cross-Sectional Area, mm^2	Perimeter, mm	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
10	0.560	9.5	71	29.9	6.7	0.38	3.6
13	0.994	12.7	129	39.9	8.9	0.51	4.9
16	1.552	15.9	199	49.9	11.1	0.71	6.1
19	2.235	19.1	284	59.8	13.3	0.97	7.3
22	3.042	22.2	387	69.8	15.5	1.12	8.5
25	3.973	25.4	510	79.8	17.8	1.27	9.7
29	5.060	28.7	645	90.0	20.1	1.42	10.9
32	6.404	32.3	819	101.3	22.6	1.63	12.4
36	7.907	35.8	1006	112.5	25.1	1.80	13.7
43	11.38	43.0	1452	135.1	30.1	2.16	16.5
57	20.24	57.3	2581	180.1	40.1	2.59	21.9

[a] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same mass per meter as the deformed bar.

[b] Bar designation numbers approximate the number of millimeters of the nominal diameter of the bar.

Table 2—Deformed Bar Designation Numbers, Nominal Weights, Nominal Dimensions, and Deformation Requirements, U.S. Customary Units

		Nominal Dimensions[a]			Deformation Requirements, in.		
Bar Designation No.[b]	Nominal Weight, lb/ft	Diameter, in.	Cross-Sectional Area, in.^{2}	Perimeter, in.	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
3	0.376	0.375	0.11	1.178	0.262	0.015	0.143
4	0.668	0.500	0.20	1.571	0.350	0.020	0.191
5	1.043	0.625	0.31	1.963	0.437	0.028	0.239
6	1.502	0.750	0.44	2.356	0.525	0.038	0.286
7	2.044	0.875	0.60	2.749	0.612	0.044	0.334
8	2.670	1.000	0.79	3.142	0.700	0.050	0.383
9	3.400	1.128	1.00	3.544	0.790	0.056	0.431
10	4.303	1.270	1.27	3.990	0.889	0.064	0.487
11	5.313	1.410	1.56	4.430	0.987	0.071	0.540
14	7.65	1.693	2.25	5.32	1.185	0.085	0.648
18	13.60	2.257	4.00	7.09	1.58	0.102	0.864

[a] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same weight per foot as the deformed bar.

[b] Bar designation numbers are based on the number of eighths of an inch included in the nominal diameter of the bars.

3. TERMINOLOGY

3.1 *Definition of Terms Specific to This Standard*:

3.1.1 *completed bar*—steel bar with stainless cladding and deformations (if deformed).

3.1.2 *deformed bar*—steel bar with protrusions; a bar that is intended for use as reinforcement in reinforced concrete construction.

3.1.2.1 *Discussion*—The surface of the bar is provided with lugs or protrusions that inhibit longitudinal movement of the bar relative to the concrete surrounding the bar in such construction. The lugs or protrusions conform to the provisions of this specification.

3.1.3 *deformations*—protrusions on a deformed bar.

3.1.4 *metallurgical bonding*—the joining of metals so as to form a permanent joint between the mating surfaces. The principal requirements of joining two metals to achieve a metallurgical bond are thoroughly clean surfaces, heat energy, and mechanical pressure.

3.1.5 *plain bar*—a round, square, or hexagonal steel bar without protrusions.

3.1.6 *rib*—longitudinal protrusion on a deformed bar.

3.1.7 *stainless clad bar*—steel bar with stainless cladding for corrosion protection.

3.1.7.1 *Discussion*—The stainless cladding on the surface of the bar is provided by means of metallurgical bonding with the base steel. The stainless cladding offers corrosion protection to the level provided by the thickness of the alloy furnished. The stainless steel cladded reinforcement shall conform to the provisions of this specification.

4. ORDERING INFORMATION

4.1 Orders for material under this specification should include the following information:

4.1.1 Quantity (mass) [weight],

4.1.2 Name of material (stainless clad deformed and plain round steel bars for concrete reinforcement),

4.1.3 Size,

4.1.4 Cut length or coils,

4.1.5 Deformed or plain round,

4.1.6 Grade,

4.1.7 Packaging (see Section 19),

4.1.8 AASHTO designation and year of issue,

4.1.9 Certified mill test reports (if desired), and

4.1.10 Country of origin, which identifies producer and where material was produced.

Note 3—A typical ordering description is as follows: 10 000 kg , stainless clad deformed and plain round steel bars for concrete reinforcement, No. 25, 18 m long, deformed, Grade 420, in secured lifts, to MP 13M/MP 13-__. Certified mill test reports are required. Metric: Bundles shall have tags identifying producer, heat/lot number, and where material was manufactured. [10 tons, stainless clad deformed and plain round steel bars for concrete reinforcement, No. 8, 60 ft 0 in. long, deformed, Grade 60, in secured lifts, to MP 13M/MP 13-__. Certified mill test reports are required.] Customary: Bundles shall have tags identifying producer, heat/lot number, and where material was manufactured.

5. MATERIALS AND MANUFACTURE

5.1 The bars shall be rolled from properly identified heats/lots of stainless clad and core steel billets.

6. CHEMICAL REQUIREMENTS OF BAR

6.1 The manufacturer shall make an analysis of each heat/lot of steel from test samples taken preferably on the finished product. The percentages of required elements identified in Table 3 shall be determined along with identification of stainless alloy cladding, and conformance of its analysis with ASTM A 276, Type 316 or Type 316L.

6.2 The purchaser may make an analysis from finished bars. The product analysis of the core steel of the finished bars may vary from the heat analysis requirements of Table 3 by the percentages listed for each element as per Table B of ASTM A 6/A 6M.

Table 3—Chemical Requirements of Core Steels

Element	% of Element by Weight
Carbon	0.45 max
Manganese	1.40 max
Phosphorus	0.040 max
Sulfur	0.050 max
Silicon	0.04–0.40
Chromium	—
Nickel	—
Copper	—
Molybdenum	—
Vanadium	—

Note: Where a dash appears, there is no requirement.

7. REQUIREMENTS FOR STAINLESS STEEL CLADDING

7.1 Stainless steel cladding shall meet the requirements of ASTM A 959 [A 276], UNS S31600, or UNS S31603. These are austenitic, nonmagnetic stainless steels and will allow for the use of magnetic thickness gauges in determining coating thickness.

7.2 Stainless steel cladding shall be applied prior to the rolling of the completed bar.

7.3 *Cladding Thickness*:

7.3.1 For acceptance purpose, at least 90 percent of all recorded thickness measurements of the cladding on the completed bar shall be a minimum of 175 μm [0.007 in.] on the completed bar. Thickness measurements below 125 μm [0.005 in.] shall be considered cause for rejection.

7.3.2 A single recorded thickness measurement is the average of three individual readings obtained between three consecutive deformations (or within a 50-mm [2-in.] section for smooth bar). A minimum of five recorded measurements evenly spaced along each side of the test bar (a minimum of ten recorded measurements per bar) shall be obtained.

7.3.3 The cladding thickness shall be measured on the body of a straight length of bar between the deformations (or within a 50-mm [2-in.] section for smooth bar).

7.3.4 Cladding thickness measurements shall be taken on the full section of the bar as rolled.

7.3.4.1 Measurements shall be made in accordance with ASTM G 12, following the instructions for calibration and use recommended by the thickness gauge manufacturer. Pull-off or fixed probe gauges shall be used. “Pencil-type” pull-off gauges that require instantaneous readings (i.e., do not record the reading) shall not be used.

7.3.4.2 If a specimen for cladding thickness fails to meet the specified requirements, two retests shall be permitted on two random specimens from the same heat/lot for each failed test. If the results of both test specimens meet the specified requirements, the heat/lot shall be accepted.

7.4 *Bond Strength*—The cladding/core shall have minimum bond strength of 20 ksi per ASTM A 264.

---

8. REQUIREMENTS FOR DEFORMATIONS

8.1 Deformations shall be spaced along the bar at substantially uniform distances. The deformations on opposite sides of the bar shall be similar in size, shape, and pattern.

8.2 The deformations shall be placed with respect to the axis of the bar so that the included angle is not less than 45 degrees. Where the line of deformations forms an included angle with the axis of the bar from 45 degrees to 70 degrees inclusive, the deformations shall alternately reverse in direction on each side, or those on one side shall be reversed in direction from those on the opposite side. Where the line of deformation is greater than 70 degrees, a reversal in direction is not required.

8.3 The average spacing or distance between deformations on each side of the bar shall not exceed seven-tenths of the nominal diameter of the bar.

8.4 The overall length of deformations shall be such that the gap between the ends of the deformations on opposite sides of the bar shall not exceed 12.5 percent of the nominal perimeter of the bar. Where the ends terminate in a longitudinal rib, the width of the longitudinal rib shall be considered the gap. Where more than two longitudinal ribs are involved, the total width of all longitudinal ribs shall not exceed 25 percent of the nominal perimeter of the bar; furthermore, the summation of gaps shall not exceed 25 percent of the nominal perimeter of the bar. The nominal perimeter of the bar shall be 3.14 times the nominal diameter.

8.5 The spacing, height, and gap of deformations shall conform to the requirements prescribed in Table 1 [Table 2].

---

9. MEASUREMENTS OF DEFORMATIONS

9.1 The average spacing of deformations shall be determined by measuring the length of a minimum of ten spaces and dividing that length by the number of spaces included in the measurement. The measurement shall begin from a point on a deformation at the beginning of the first space to a corresponding point on a deformation after the last included space. Spacing measurements shall not be made over a bar area containing bar-marking symbols involving letters or numbers.

9.2 The average height of deformations shall be determined from measurements made on not fewer than two typical deformations. Determinations shall be based on three measurements, per deformation, one at the center of the overall length and the other two at the quarter points of the overall length.

9.3 Insufficient height, insufficient circumferential coverage, or excessive spacing of deformations shall not constitute cause for rejection unless it has been established by determinations on each heat/lot tested that typical deformation height, gap, or spacing do not conform to the minimum requirements prescribed in Section 8. No rejection may be made on the basis of measurements if fewer than ten adjacent deformations on each side of the bar are measured.

---

10. TENSILE REQUIREMENTS

10.1 The material, as represented by the test specimens, shall conform to the requirements for tensile properties prescribed in Table 4 [Table 5].

Table 4—Tensile Requirements, SI Units

	Grade 300[a]	Grade 420	Grade 520[b]
Tensile strength, min MPa	500	620	690
Yield strength, min MPa	300	420	520
Elongation in 203.2 mm, min %

10	11	9	—
13, 16	12	9	—
19	12	9	7
22, 25	—	8	7
29, 32, 38	—	7	6
43, 57	—	7	6

[a] Grade 300 bars are furnished only in sizes 10 through 19.

[b] Grade 520 bar are furnished only in sizes 19 through 57.

Table 5—Tensile Requirements, U.S. Customary Units

	Grade 40[a]	Grade 60	Grade 75[b]
Tensile strength, min psi	70000	90000	100000
Yield strength, min psi	40000	60000	75000
Elongation in 8 in., min %			
Bar Designation No.:			
3	11	9	—
4, 5, 6	12	9	—
7, 8	—	8	—
9, 10	—	7	—
11, 14, 18	—	7	6

[a] Grade 40 bars are furnished only in sizes 3 through 6.

[b] Grade 75 are furnished only in sizes 11, 14, and 18.

10.2 The yield point or yield strength shall be determined by one of the following methods:

10.2.1 The yield point shall be determined by arrest of the digital load readout, or marked change in the linearity of the elastic stress-strain line, or halt of the pointer, or drop of the beam, as described in Section 13.1.1 of T 244.

10.2.2 Where the steel tested does not exhibit a well-defined yield point, the yield point shall be determined at extension under load using an autographic diagram method or an extensometer as described in Sections 13.1.2 and 13.1.3 of T 244.

10.2.3 The extension under load shall be 0.005 mm/mm [0.005 in./in.] of gauge length (0.5 percent) for Grade 300 [40] and Grade 420 [60] and shall be 0.0035 mm/mm [0.0035 in./in.] of gauge length (0.35 percent) for Grade 520 [75]. When material is furnished in coils, the test sample must be straightened prior to placing it in the jaws of the tensile machine. Straightening shall be done carefully to avoid the formation of local sharp bends and to minimize cold work. Insufficient straightening before attaching the extensometer can result in lower-than-actual yield strength readings.

10.2.4 The percentage of elongation shall be as prescribed in Table 4 (Table 5) when tested in accordance with Section 13.4 of T 244.

10.2.5 Tension test specimens shall be the full section of the bar as rolled. The unit stress determinations on full-sized specimens shall be based on the nominal bar area. If any tensile property of any tension test specimen is less than that specified, and any part of the fracture is outside the middle third of the gauge length, as indicated by scribe scratches marked on the specimen before testing, a retest shall be allowed.

10.2.6 If the results of an original tension specimen fail to meet the specified minimum requirements and are within 14 MPa [2000 psi] of the required tensile strength, within 7 MPa [1000 psi] of the required yield point, or within two percentage units of the required elongation, a retest shall be permitted on two random specimens for each original tension specimen failure from the heat/lot. If all results of these retest specimens meet the specified requirements, the heat/lot shall be accepted.

11. BENDING REQUIREMENTS

11.1 The bend-test specimen shall withstand being bent around a pin without cracking, wrinkling, or splitting of the cladding when tested in accordance with T 285. The requirements for angle of bending and sizes of pins are prescribed in Table 6 [Table 7]. When material is furnished in coils, the test sample must be straightened prior to placing it in the bend tester. The bend-test specimens shall be the full section of the bar as rolled.

11.2 The bend test shall be made on specimens of sufficient length to ensure free bending and with apparatus that provides:

11.2.1 Continuous and uniform application of force throughout the duration of the bending operation.

11.2.2 Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate.

11.2.3 Close wrapping of the specimen around the pin during the bending operation.

11.3 Other acceptable methods of bend testing may be used, such as:

11.3.1 Placing the bar specimen into a lubricated guided bend fixture, as defined by ASTM E 190.

11.3.2 Placing the bar specimen across two pins free to rotate, and applying the bending force with a central rotating pin, and adhering to the size and clearance requirements of Figure 1 of ASTM E 190.

11.3.3 If a bend test fails for reasons other than mechanical reasons or flaws in the specimen as described in Section 13.3.1, a retest shall be permitted on two random specimens from the same heat/lot. If the results of both test specimens meet the specified requirements, the heat/lot shall be accepted. The retest shall be performed on test specimens that are at air temperature, but not less than 16ºC [60ºF].

11.4 When failures occur under more severe methods, retests shall be permitted under the bend test method prescribed in Section 11.2.

Table 6—Bend-Test Requirements, SI Units

Bar Designation No.	Pin Diameter for Bend Test[a]		
	Grade 300	Grade 420	Grade 520
10, 13, 16	$3^1/_2$ *d*[b]	$3^1/_2$ *d*	—
19	5 *d*	5 *d*	5 *d*
22, 25	—	5 *d*	5 *d*
29, 32, 36	—	7 *d*	7 *d*
43, 57, (90°)	—	9 *d*	9 *d*

[a] Test bends 180° unless noted otherwise.

[b] *d* = nominal diameter of specimen.

Table 7—Bend-Test Requirements

Bar Designation No.	Pin Diameter for Bend Test[a]		
	Grade 40	Grade 60	Grade 75
3, 4, 5	$3^1/_2$ *d*[b]	$3^1/_2$ *d*	—
6	5 *d*[b]	5 *d*	—
7, 8	—	5 *d*	—
9, 10	—	7 *d*	—
11	—	7 *d*	7 *d*
14, 18, (90°)	—	9 *d*	9 *d*

[a] Test bends 180° unless noted otherwise.

[b] *d* = nominal diameter of specimen.

12. PERMISSIBLE VARIATION IN MASS [WEIGHT]

12.1 The permissible variation shall not exceed 6 percent under nominal mass [weight]; except for bars smaller than 9.5 mm [$^3/_8$ in.] plain round, the permissible variation in mass [weight] shall be computed upon the basis of the permissible variation in diameter in ASTM A 510M [ASTM A 510]. Reinforcing bars are evaluated on the basis of nominal mass [weights]. In no case shall the overmass [overweight] of any bar be the cause for rejection.

12.2 The specified limit of variation shall be evaluated in accordance with ASTM E 29 (rounding method).

13. FINISH

13.1 The bar shall be free of detrimental surface imperfections.

13.2 Seams, surface irregularities, or mill scale shall not be cause for rejection, provided they are not signs of improper cladding operations.

13.3 Weight, dimensions, cross-sectional area, and tensile properties of a hand wire-brushed test specimen shall not be less than the requirements of this specification (Note 4).

Note 4—Deformed bars destined to be mechanically spliced may require a certain degree of roundness in order for the splices to adequately achieve strength requirements.

13.3.1 Surface imperfections other than those specified in Section 13.2 shall be considered detrimental when specimens containing such imperfections fail to conform to either tensile or bending requirements. Examples include, but are not limited to, laps, seams, scabs, slivers, cooling or casting cracks, and mill or guide marks.

14. NUMBER OF TESTS

14.1 For bar sizes No. 10 to 57 [3 to 18], inclusive, one tension test and one bend test shall be made of each size rolled from each heat/lot.

14.2 Tests for cladding thickness shall be made on a minimum of three bars of each size from each heat/lot unless otherwise specified by the purchaser.

15. INSPECTION

15.1 The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer's works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests (except product analysis) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

15.2 *For Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein and may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification, where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

16. REJECTION

16.1 Unless otherwise specified, any rejection based on tests made in accordance with Section 6.2 shall be reported to the manufacturer within 20 working days from the day the samples were tested by the purchaser.

17. TEST REPORTS

17.1 When specified in the purchase order, report the following information, on a per heat/lot basis. Additional items may be reported as requested or desired.

17.2 Chemical analysis shall include the composition of the stainless alloy cladding, and the elements carbon, manganese, silicon, phosphorus, and sulfur for core steel.

17.3 Tensile properties.

17.4 Bend-test results.

17.5 Cladding thickness results.

17.6 Origin of materials and manufacturing processes for verification of “Domestic Origin” requirements.

18. MARKING

18.1 When loaded for mill shipment, bars shall be properly separated and tagged with the manufacturer’s heat/lot or test identification number.

18.2 Each producer shall identify the symbols of his marking system.

18.3 All bars produced to this specification, except plain round bars, which shall be tagged for grade, shall be identified by a distinguishing set of marks legibly rolled into the surface of one side of the bar to denote, in the following order:

18.3.1 *Point of Origin*—Letter or symbol established as the producer’s mill designation.

18.3.2 *Size Designation*—Arabic number corresponding to bar designation number of Table 1 [Table 2].

18.3.3 *Type of Steel*—Letter C indicates that the bar was produced to this specification.

18.3.4 *Minimum Yield Designation*—For Grade 420 [60] bars, either the number 4 [60] or a single continuous longitudinal line through at least five spaces offset from the center of the bar side. For Grade 520 [75] bars, either the number 5 [75] or two continuous longitudinal lines through at least five spaces offset each direction from the center of the bar. (No marking designation for Grade 300 [40] bars.)

19. PACKAGING

19.1 When specified in the purchase order, packaging shall be in accordance with the procedures in ASTM A 700.

19.2 The stainless steel clad bar shall be handled and shipped such that carbon steel bars, lifting straps, tiedown cables, or chains do not come in contact with clad bars.

19.3 *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be as specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

20. KEYWORDS

20.1 Concrete reinforcement; deformations (protrusions); steel bars.

ANNEX

(Mandatory Information)

A1. GUIDELINES FOR JOB-SITE PRACTICES

A1.1. When handling stainless steel clad bars, care shall be exercised to avoid damage to the bundles.

A1.2. Equipment for handling stainless steel clad bar shall have protected contact areas.

A1.3. Stainless steel clad bars shall be off-loaded as close as possible to their points of placement or under the crane so that the bars can be hoisted to the areas of placement to minimize rehandling.

A1.4. When handling stainless steel clad bars, care shall be exercised to avoid damage to the bundles.

A1.5. Stainless steel clad bar shall be stored off the ground on protective cribbing, and timbers placed between the bundles when stacking is necessary. Space supports sufficiently close to prevent sags in the bundles.

A1.6. Stainless steel clad bar shall be stored separately from regular steel.

A1.7. Long-term outside job-site storage shall be minimized or the material shall be stored indoors.

A1.8. Stainless steel clad bar shall not be flame cut.

A1.9. Placed stainless steel clad bars shall be inspected for damage prior to placing concrete. Damage to bars, which exhibit active corrosion (red-rust), shall be evaluated. Bars that have damage exceeding 2 percent of the surface area in any 0.3-m [1-ft] length shall be replaced.

A1.10. When placing stainless steel clad bar, all wire supports, spacers, and tying wire shall be plastic, plastic coated, or Type 316 stainless steel.

A1.11. Stainless steel clad bar in contact with black steel shall be minimized or eliminated where possible.

A1.12. Cut ends of stainless clad bars shall be epoxied and capped according to manufacturer’s recommendations with either stainless steel caps or plastic caps. Caps shall be sealed to prevent the intrusion of moisture.

Standard Specification for

Uncoated, Corrosion-Resistant, Deformed and Plain Alloy, Billet-Steel Bars for Concrete Reinforcement and Dowels

AASHTO Designation: MP 18M/MP 18-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Uncoated, Corrosion-Resistant, Deformed and Plain Alloy, Billet-Steel Bars for Concrete Reinforcement and Dowels

AASHTO Designation: MP 18M/MP 18-09[1]

1. SCOPE

1.1. This specification covers uncoated, corrosion-resistant, deformed and plain alloy, billet-steel concrete reinforcement and dowel bars in cut lengths or coils, where corrosion-resistant performance may be essential (Notes 1 and 2). The standard sizes and dimensions of deformed bars and their number designations shall be those listed in Table 2 [Table 3].

Note 1—For coils of deformed bars, the capacity of industrial equipment limits the maximum bar size that can be straightened.

Note 2—The degree of corrosion-resistance needed for a specific use is dependent on both the project's environmental conditions and its application.

Comparative corrosion performance data in accordance with Section 11 and Annex A shall apply only when specified by the purchaser.

1.2. Bars are of three minimum yield levels: 420 MPa [60000 psi], 520 MPa [75000 psi], and 690 MPa [100000 psi], designated as Grade 420 [60], Grade 520 [75], and Grade 690 [100], respectively.

1.3. Hot-rolled plain rounds, in sizes up to and including 50.8 mm [2 in.] in diameter in coils or cut lengths, when specified for dowels, spirals, and structural ties or supports, shall be furnished under this specification in Grade 420 [60], Grade 520 [75], and Grade 690 [100] (Note 3).

For ductility properties, test provisions of the nearest nominal diameter deformed bar size shall apply. Those requirements providing for deformations and marking shall not be applicable (Note 3).

Note 3—The weight for plain rounds smaller than 9.5 mm [$^3/_8$ in.] in diameter shall be computed on the basis of the size in ASTM A 510.

Note 4—Welding of the material in this specification should be approached with caution since no specific provisions have been included to enhance its weldability. When the steel is to be welded, a welding procedure suitable for the chemical composition and intended use or service should be used.

1.4. This specification is applicable for orders in either SI units (as Specification MP 18M) or in inch-pound units (as Specification MP 18). SI units and inch-pound units are not necessarily equivalent. Inch-pound units are shown in brackets in the text for clarity, but they are the applicable values when the material is ordered to MP 18.

3. TERMINOLOGY

3.1. *Description of Terms Specific to This Standard*:

3.1.1. *deformed bar*—steel bar with protrusions; a bar that is intended for use as reinforcement in reinforced concrete construction.

3.1.1.1. *Discussion*—The surface of the bar is provided with lugs or protrusions that inhibit longitudinal movement of the bar relative to the concrete surrounding the bar in such construction. The lugs or protrusions conform to the provisions of this specification.

3.1.2. *deformations*—protrusions on a deformed bar.

3.1.3. *plain bar*—steel bar without protrusions.

3.1.4. *rib*—longitudinal protrusion on a deformed bar.

3.1.5. *lot*—bars of one bar number and pattern of deformation contained in an individual shipping release or shipping order.

4. ORDERING INFORMATION

4.1. Orders for material under this specification should include the following information:

4.1.1. Quantity (Mass) [weight];

4.1.2. Name of material (uncoated, corrosion-resistant, deformed and plain alloy, billet-steel bars for concrete reinforcement and dowels);

4.1.3. Size;

4.1.4. Cut length or coils;

4.1.5. Deformed or plain;

4.1.6. Grade;

4.1.7. Packaging (see Section 22);

4.1.8. AASHTO designation and year of issue; and

4.1.9. Certified mill test reports (if desired).

Note 5—A typical ordering description is as follows: 10 Mg, uncoated, corrosion-resistant, deformed and plain alloy, billet-steel bars for concrete reinforcement and dowels, No. 25, 18-m long, deformed, Grade 520, in secured lifts, to MP 18M-__. Certified mill test reports are required. [10 tons, uncoated, corrosion-resistant, deformed and plain alloy, billet-steel bars for concrete reinforcement and dowels, No. 8, 60 ft 0 in. long, deformed, Grade 75 in secured lifts, to MP 18-__. Certified mill test reports are required.]

5. MATERIALS AND MANUFACTURE

5.1. The bars shall be rolled from properly identified heats of mold cast or strand cast steel.

6. CHEMICAL REQUIREMENTS

6.1. The chemical analysis of each heat shall be determined in accordance with ASTM A 751. The manufacturer shall make the analysis on test samples taken preferably during the pouring of the heat. The percentages of carbon, chromium, copper, manganese, molybdenum, nickel, nitrogen, phosphorus, silicon, sulfur, and vanadium shall be determined and reported as required in Section 20.

6.2. The analysis of the heat shall be made by the manufacturer and shall conform to the analysis tolerances specified in Table 1 of ASTM A 484/A 484M when compared to the chemistry reported in Annex A, Section A1.6.3.

6.2.1. A product check made by the purchaser shall conform to the analysis tolerances specified in Table 1 of ASTM A 484/A 484M when compared to the chemistry reported in Annex A, Section A1.6.3.

6.3. The chemical composition as shown by heat analysis shall be limited by Table 1.

Table 1—Maximum Chemical Constituents (Weight %) Except as Indicated

Element	Amount
Carbon	0.15%
Chromium	9.2% (Minimum)
Manganese	2.0%
Nitrogen	0.20%
Phosphorus	0.045%
Silicon	1.0%
Sulfur	0.030%

7. REQUIREMENTS FOR DEFORMATIONS

7.1. Deformations shall be spaced along the bar at substantially uniform distances. The deformations on opposite sides of the bar shall be similar in size, shape, and pattern.

7.2. The deformations shall be placed with respect to the axis of the bar so that the included angle is not less than 45 degrees. Where the line of deformations forms an included angle with the axis of the bar from 45 to 70 degrees inclusive, the deformations shall alternately reverse in direction on each side, or those on one side shall be reversed in direction from those on the opposite side. Where the line of deformation is greater than 70 degrees, a reversal in direction is not required.

7.3. The average spacing or distance between deformations on each side of the bar shall not exceed seven-tenths of the nominal diameter of the bar.

7.4. The overall length of deformations shall be such that the gap between the ends of the deformations on opposite sides of the bar shall not exceed 12.5 percent of the nominal perimeter of the bar. Where the ends terminate in a longitudinal rib, the width of the longitudinal rib shall be considered the gap. Where more than two longitudinal ribs are involved, the total width of all longitudinal ribs shall not exceed 25 percent of the nominal perimeter of the bar; furthermore, the summation of gaps shall not exceed 25 percent of the nominal perimeter of the bar. The nominal perimeter of the bar shall be 3.14 times the nominal diameter.

7.5. The spacing, height, and gap of deformations shall conform to the requirements prescribed in Table 2 [Table 3].

Table 2—Deformed Bar Designation Numbers, Nominal Masses, Nominal Dimensions, and Deformation Requirements, SI Units

		Nominal Dimensions[b]			Deformation Requirements, mm		
Bar Designation No.[a]	Nominal Mass, kg/m	Diameter, mm	Cross-Sectional Area, mm^2	Perimeter, mm	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)
10	0.560	9.5	71	29.9	6.7	0.38	3.6
13	0.994	12.7	129	39.9	8.9	0.51	4.9
16	1.552	15.9	199	49.9	11.1	0.71	6.1
19	2.235	19.1	284	59.8	13.3	0.97	7.3
22	3.042	22.2	387	69.8	15.5	1.12	8.5
25	3.973	25.4	510	79.8	17.8	1.27	9.7
29	5.060	28.7	645	90.0	20.1	1.42	10.9
32	6.404	32.3	819	101.3	22.6	1.63	12.4
36	7.907	35.8	1006	112.5	25.1	1.80	13.7
43	11.38	43.0	1452	135.1	30.1	2.16	16.5
57	20.24	57.3	2581	180.1	40.1	2.59	21.9

[a] Bar numbers approximate the number of millimeters of the nominal diameter of the bar.

[b] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same mass per meter as the deformed bar.

Table 3—Deformed Bar Designation Numbers, Nominal Weights, Nominal Dimensions, and Deformation Requirements, U.S. Customary Units

		Nominal Dimensions[b]			Deformation Requirements, in.		
Bar Designation No.[a]	Nominal Weight, lb/ft	Diameter, in.	Cross-Sectional Area, $in.^2$	Perimeter, in.	Maximum Average Spacing	Minimum Average Height	Maximum Gap (Chord of 12.5% of Nominal Perimeter)

[a] Bar numbers are based on the number of eighths of an inch included in the nominal diameter of the bars.

[b] The nominal dimensions of a deformed bar are equivalent to those of a plain round bar having the same weight per foot as the deformed bar.

8. MEASUREMENTS OF DEFORMATIONS

8.1. The average spacing of deformations shall be determined by measuring the length of a minimum of ten spaces and dividing that length by the number of spaces included in the measurement. The measurement shall begin from a point on a deformation at the beginning of the first space to a corresponding point on a deformation after the last included space. Spacing measurements shall not be made over a bar area containing bar marking symbols involving letters or numbers.

8.2. The average height of deformations shall be determined from measurements made on not fewer than two typical deformations. Determinations shall be based on three measurements per deformation, one at the center of the overall length and the other two at the quarter points of the overall length.

8.3. Insufficient height, insufficient circumferential coverage, or excessive spacing of deformations shall not constitute cause for rejection unless it has been clearly established by determinations on each lot tested that typical deformation height, gap, or spacing do not conform to the minimum requirements prescribed in Section 7. No rejection may be made on the basis of measurements if fewer than ten adjacent deformations on each side of the bar are measured.

9. TENSILE REQUIREMENTS

9.1. The material, as represented by the test specimens, shall conform to the requirements for tensile properties prescribed in Table 4 [Table 5].

9.2. The yield point or yield strength shall be determined by the offset method (0.2 percent offset), described in Section 13.2 of T 244. When material is furnished in coils, the test sample must be straightened prior to placing it in the jaws of the tensile machine. Straightening shall be done carefully to avoid the formation of local sharp bends and to minimize cold work. Insufficient straightening before attaching the extensometer can result in lower-than-actual yield strength readings.

9.3. The percentage of elongation shall be as prescribed in Table 4 [Table 5] when tested in accordance with Section 13.4 of T 244.

Table 4—Tensile Properties Requirements, SI Units

	Grade 420	Grade 520	Grade 690

14, 18	7	6	6

10. BENDING REQUIREMENTS

10.1. The bend-test specimen shall withstand being bent around a pin without cracking on the outside of the bent portion when tested in accordance with T 285. The requirements for angle of bending and sizes of pins are prescribed in Table 6 [Table 7]. When material is furnished in coils, the test sample must be straightened prior to placing it in the bend tester.

Table 6—Bend-Test Requirements, SI Units

	Grade 420	Grade 520	Grade 690
Bar Designation No.	Pin Diameter for Bend Tests[a]		
10, 13, 16	3.5*d*[b]	3.5*d*	3.5*d*
19	5*d*	5*d*	5*d*
22, 25	5*d*	5*d*	5*d*
29, 32, 36	7*d*	7*d*	7*d*
43, 57 (90°)	9*d*	9*d*	*c*

[a] Test bends 180° unless otherwise agreed.

[b] *d* = nominal diameter of specimen

[c] These bars are only used in straight lengths.

Table 7—Bend-Test Requirements, U.S. Customary Units

	Grade 60	Grade 75	Grade 100
Bar Designation No.	Pin Diameter for Bend Tests[a]		
3, 4, 5	3.5*d*[b]	3.5*d*	3.5*d*
6	5*d*	5*d*	5*d*
7, 8	5*d*	5*d*	5*d*
9, 10, 11	7*d*	7*d*	7*d*
14, 18 (90°)	9*d*	9*d*	*c*

[a] Test bends 180° unless otherwise agreed.

[b] *d* = nominal diameter of specimen

[c] These bars are only used in straight lengths.

10.2. The bend test shall be made on specimens of sufficient length to ensure free bending and with an apparatus that provides:

10.2.1. Continuous and uniform application of force throughout the duration of the bending operation.

10.2.2. Unrestricted movement of the specimen at points of contact with the apparatus and bending around a pin free to rotate.

10.2.3. Close wrapping of the specimen around the pin during the bending operation.

10.3. Other acceptable more severe methods of bend testing, such as placing a specimen across two pins free to rotate and applying the bending force with a fixed pin, may be used. When failures occur under more severe methods, retests shall be permitted under the bend-test method prescribed in Section 10.2.

11. COMPARATIVE CORROSION RESISTANCE PERFORMANCE (PURCHASER SPECIFIED)

11.1. Comparative corrosion performance data for chromium containing steels (e.g., ASTM A 955/A 955M and ASTM A 1035/A 1035M) shall be furnished, based on mutual agreement between the manufacturer and the purchaser, as described in Annex A.

12. PERMISSIBLE VARIATION IN MASS [WEIGHT]

12.1. The permissible variation shall not exceed 6 percent under nominal mass [weight] except for bars smaller than 9.5 mm [$^3/_8$ in.] plain round. The permissible variation in mass [weight] shall be computed upon the basis of the permissible variation in diameter in ASTM A 510M [ASTM A 510]. Reinforcing bars are evaluated on the basis of nominal mass [weights]. In no case shall the overmass [overweight] of any bar be the cause for rejection.

12.2. The specified limit of variation shall be evaluated in accordance with ASTM E 29 (rounding method).

13. FINISH

13.1. The bar shall be free of detrimental surface imperfections.

13.2. Seams, surface irregularities, or mill scale oxidation shall not be cause for rejection, provided the weight, dimensions, cross-sectional area, and tensile properties are not less than the requirements of this specification.

13.3. Surface imperfections other than those specified in Section 13.2 shall be considered detrimental when specimens containing such imperfections fail to conform to either tensile or bending requirements. Examples include but are not limited to laps, seams, scabs, slivers, cooling or casting cracks, and mill or guide marks (Note 6).

Note 6—Deformed bars intended to be mechanically spliced or butt-welded may require a certain degree of roundness in order for the splices to adequately achieve strength requirements.

14. TEST SPECIMENS

14.1. Tension test specimens shall be the full section of the bar as rolled. The unit stress determinations on full-sized specimens shall be based on the nominal bar area.

14.2. The bend-test specimens shall be the full section of the bar as rolled.

15. NUMBER OF TESTS

15.1. For bar sizes No. 10 to 36 [No. 3 to 11], inclusive, one tension test and one bend test shall be made of the largest size rolled from each heat. If, however, material from one heat differs by three or more designation numbers, one tension and one bend test shall be made from both the highest and lowest designation number of the deformed bars rolled.

15.2. For bar sizes No. 43 and No. 57 [No. 14 and No. 18] bars, one tension test and one bend test shall be made of each size from each heat.

16. RETESTS

16.1. If any tensile property of any tension test specimen is less than that specified, and any part of the fracture is outside the middle third of the gauge length, as indicated by scribe marks on the specimen before testing, a retest shall be allowed.

16.2. If the results of an original tension specimen fail to meet the specified minimum requirements and are within 14 MPa [2000 psi] of the required tensile strength, within 7 MPa [1000 psi] of the required yield point, or within two percentage units of the required elongation, a retest shall be permitted on two random specimens for each original tension specimen failure from the lot. If all results of these retest specimens meet the specified requirements, the lot shall be accepted.

16.3. If a bend test fails for reasons other than mechanical reasons or flaws in the specimen as described in Sections 16.4 and 16.7, retest shall be permitted on two random specimens from the same lot. If the results of both test specimens meet the specified requirements, the lot shall be accepted. The retest shall be performed on test specimens that are at air temperature but not less than 16°C [60°F].

16.4. If a mass [weight] test fails for reasons other than flaws in the specimen as described in Section 16.7, a retest shall be permitted on two random specimens from the same lot. Both retest specimens shall meet the requirements of this specification.

16.5. If any test specimen fails because of mechanical reasons such as failure of testing equipment or improper specimen preparation, it may be discarded and another specimen taken.

16.6. If a corrosion resistance test fails for reasons other than flaws as described in Section 16.7, a retest shall be permitted on two random specimens from the same lot. Both retest specimens shall meet the requirements of this specification.

16.7. If any test specimen develops flaws, it may be discarded and another specimen of the same size bar from the same heat may be substituted.

17. INSPECTION

17.1. The inspector representing the purchaser shall have free entry, at all times while work on the contract of the purchaser is being performed, to all parts of the manufacturer’s works that concern the manufacture of the material ordered. The manufacturer shall afford the inspector all reasonable facilities to satisfy him that the material is being furnished in accordance with this specification. All tests (except product analysis) and inspection shall be made at the place of manufacture prior to shipment, unless otherwise specified, and shall be so conducted as not to interfere unnecessarily with the operation of the works.

17.2. *For Government Procurement Only*—Except as otherwise specified in the contract, the contractor is responsible for the performance of all inspection and test requirements specified herein and may use his own or any other suitable facilities for the performance of the inspection and test requirements specified herein, unless disapproved by the purchaser at the time of purchase. The purchaser shall have the right to perform any of the inspections and tests at the same frequency as set forth in this specification, where such inspections are deemed necessary to assure that material conforms to prescribed requirements.

18. REJECTION

18.1. Unless otherwise specified, any rejection based on tests made in accordance with Section 6.3 shall be reported to the manufacturer within five working days from the receipt of samples by the purchaser.

18.2. Material that shows injurious defects subsequent to its acceptance at the manufacturer's works will be rejected, and the manufacturer shall be notified.

19. REHEARING

19.1. Samples tested in accordance with Section 6.2 that represent rejected material shall be preserved for 2 weeks from the date rejection is reported to the manufacturer. In case of dissatisfaction with the results of the tests, the manufacturer may make claim for a rehearing within that time.

20. TEST REPORTS

20.1. Test reports should include the following:

20.1.1. Chemical analysis, including percentages of carbon, chromium, copper, manganese, molybdenum, nickel, nitrogen, phosphorus, silicon, sulfur, and vanadium;

20.1.2. Tensile properties;

20.1.3. Bend test;

20.1.4. Comparative corrosion performance data (if appropriate); and

20.1.5. *Qualification test*—Annex A (Purchaser specified) with chemical analysis tolerances conforming to Section 6.2.

21. MARKING

21.1. When loaded for mill shipment, bars shall be properly separated and tagged with the manufacturer's heat or test identification number.

21.2. Each producer shall identify the symbols of his marking system.

21.3. All bars produced to this specification, except plain round bars, which shall be tagged for grade, shall be identified by a distinguishing set of marks legibly rolled into the surface of one side of the bar to denote, in the following order:

21.3.1. *Point of Origin*—Letter or symbol established as the producer's mill designation.

21.3.2. *Size Designation*—Arabic number corresponding to bar designation number of Table 2 [Table 3].

21.3.3. *Type of Steel*—Letters "CS" indicating that the bar was produced to this specification.

21.3.4. *Minimum Yield Designation*—For Grade 420 [60] bars, either the number 4 [60] or a single continuous longitudinal line through at least five spaces offset from the center of the bar side. For Grade 520 [75] bars, either the number 5 [75] or two continuous longitudinal lines through at least five spaces offset each direction from the center of the bar. For Grade 690 [100] bars, either the number 6 [100] or three continuous longitudinal lines through at least five spaces offset each direction from the center of the bar.

21.3.5. It shall be permissible to substitute a metric size bar of Grade 420 for the corresponding inch-pound size bar of Grade 60, a metric size bar of Grade 520 for the corresponding inch-pound size bar of Grade 75, and a metric size bar of Grade 690 for the corresponding inch-pound size bar of Grade 100.

22. PACKAGING

22.1. When specified in the purchase order, packaging shall be in accordance with the procedures in ASTM A 700.

22.2. *For Government Procurement Only*—When specified in the contract or order, and for direct procurement by or direct shipment to the U.S. Government, material shall be preserved, packaged, and packed in accordance with the requirements of MIL-STD-163. The applicable levels shall be as specified in the contract. Marking for shipment of such material shall be in accordance with Fed. Std. No. 123 for civil agencies and MIL-STD-129 for military agencies.

23. KEYWORDS

23.1. Alloy steel bars; concrete reinforcement; corrosion-resistant; deformations (protrusions); dowels.

ANNEX A

(Mandatory Information)

(The following shall apply only when specified in the purchase order.)

A1. TEST METHOD FOR COMPARATIVE QUALITATIVE CORROSION CHARACTERIZATION OF STEEL BARS USED IN CONCRETE REINFORCEMENT

Note A1—This test method aims to emphasize the key differences in the corrosion behavior of corrosion-resistant steels (CRS) as compared to carbon steel, namely the enhanced resistance to chlorides and lower pH environments. The test protocols apply only to solid uncoated monolithic bars and are divided into two main categories. Considering that chloride attack and carbonation are typically the most important causes of corrosion initiation in steel-reinforced concrete structures, two test types are included to evaluate the corrosion performance of the CRS alloy as a function of (1) pH of the environment and (2) concentration of chloride ions, in particular the $[Cl^-]/[OH^-]$ threshold ratio.

A1.1 *Scope*:

A1.1.1 This test method describes procedures to evaluate the comparative qualitative corrosion performance of CRS alloy steel bars to those of M 31M/M 31, utilizing electrochemical polarization resistance and potentiodynamic polarization measurements in various test solutions.

A1.1.2 Bars tested in accordance with these test procedures shall be characterized as corrosion-resistant when both:

A1.1.2.1 The ratio of the polarization resistance (R_p) measured at pH = 10 to the polarization resistance measured at pH = 13 is greater than or equal to (≥) 0.5; i.e.,

$[R_p \text{ at } (\text{pH} = 10)]/[R_p \text{ at } (\text{pH} = 13)] \geq 0.5$, and

A1.1.2.2 The measured pitting potential is greater than or equal to (≥) 250 mV vs. Ag/Ag Cl reference electrode at a $[Cl^-]/[OH^-]$ ratio equal to 2.

A1.2 *Referenced Documents*:

A1.2.1 *AASHTO standards*:

A1.2.2 *ASTM standards*:

- G 3, Standard Practice for Conventions Applicable to Electrochemical Measurements in Corrosion Testing
- G 59, Standard Test Method for Conducting Potentiodynamic Polarization Resistance Measurements
- G 102, Standard Practice for Calculation of Corrosion Rates and Related Information from Electrochemical Measurements

A1.3 *Test Equipment and Materials*:

A1.3.1 *Containers*—500-mL capacity polypropylene (PP) beaker, or equivalent. The solutions used are characterized by a high pH value, hence, glass containers shall not be used.

A1.3.2 *Voltmeter*—High impedance voltmeter (at least one Mohm), measuring to 0.001 mV.

A1.3.3 *Potentiostat*—Potentiostat with 20 V compliance voltage (e.g., Gamry Instruments series G 750).

A1.3.4 *Reference Electrode* (i.e., Ag/AgCl reference electrode or Accumet #13-620-52 Calomel Reference Electrode).

A1.3.5 *Wire*—16-gauge [1.5-mm^2] insulated copper wire is used to make the electrical connections to the bars.

A1.3.6 *Test Solution*—Test solution, compatible with material under test (see Section A1.5.4 for solution preparation).

A1.4 *Test Method*:

A1.4.1 *Description of Tests*—Two well-established types of corrosion tests are included: Linear Polarization Resistance and Potentiodynamic Polarization curves. This section presents a brief overview of each test, similar to test procedures and measurements described in ASTM G 3, G 59, and G 102.

A1.4.1.1 *Linear Polarization Resistance*—The linear polarization resistance technique, or simply polarization resistance, involves measuring the change in the open-circuit potential of the electrolytic cell when an external current is applied to it. For a small perturbation about the open-circuit potential (OCP), there is a linear relationship between the change in applied voltage (ΔE) and the change in the measured current per unit area of electrode (Δi). The ratio $\Delta E/\Delta i$ gives the polarization resistance (R_p) term, which is inversely related to the corrosion performance of the alloy.

A1.4.1.2 *Potentiodynamic Polarization*—In this test, the potential is made to change at a constant rate over a wide range, typically from a very cathodic to a very anodic potential, while the corrosion current density is measured. The test indicates the potential regions where there is electrode activity, and provides a variety of information about the corrosion behavior of the sample. Active, passive, and transpassive regions, for instance, can be readily identified. When chlorides are present, the test can be used to identify the concentration in which pitting corrosion is initiated.

A1.5 *Experimental Procedure*:

A1.5.1 *Steel Sample Preparation*—Test samples of approximately 1-in. length and $^5/_{16}$-in. diameter must be machined from the rebar to be tested, taking care not to overheat or unintentionally induce microstructural changes to the alloy. A screw thread is drilled and tapped (e.g., 6-32 by $^3/_{16}$ in.) into one end of the specimen, to enable electrical contact to be made. The surface of the test specimen shall be polished with SiC paper down to 1000 grit. Electrical contact shall be made to the specimen with a threaded rod long enough to extend outside of the electrochemical cell.

A1.5.2 *Electrochemical Cell*—A standard three-electrode electrochemical cell shall be used. The body of the cell must be made of plastic in order to avoid glass etching due to the elevated pH of the test solutions (a 500-ml PP beaker can be used, for instance).

A1.5.3 *Electrochemical Cell and Sample Assembly*—The specimen shall be covered with adhesive-lined dual-wall heat-shrink tubing in such a way that only approximately $^1/_2$ in. in length of the specimen is left exposed; the remaining length of the specimen as well as the contacting rod must be covered with heat-shrink tubing. The electrical insulation shall be applied with care to provide a crevice-free seal. The exposed surface area shall be measured and recorded. Before testing, after the equipment is set up and the electrochemical cell is ready to receive the test specimen, the exposed area of the specimen shall be repolished, degreased with acetone, and cleaned with methanol and deionized water.

A1.5.4 *Test Solution Preparation*—Test solution shall be prepared with deionized water and certified reagent chemicals. Ideally, the experiments should be controlled by an automated potentiostat and corresponding software, such as a Gamry Instruments series G 750 potentiostat or another equivalent model.

A1.5.4.1 *Polarization Resistance*—Before performing the polarization resistance experiment, the test specimen as prepared according to the procedure in Section A1.5.1 shall be placed in the electrochemical cell and exposed to the aqueous solution for 30 minutes. The OCP shall be measured. A potential variation of –15 mV to +15 mV over OCP shall be applied at a scan rate of 0.125 mV/sec, and the corresponding changes in the current density (in $\mu A/cm^2$) shall be recorded. The polarization resistance term R_p is then calculated based on this data. In order to properly evaluate the corrosion behavior of the corrosion-resistant steel (CRS), and particularly to demonstrate the fundamental difference between the CRS and carbon steels, the polarization resistance tests shall be performed for two different pH levels (e.g., pH = 13 and pH = 10), while maintaining the ionic strength (I_S) of the solutions constant. Naturally aerated aqueous solutions shall be prepared immediately before the test.

Note A2—Carbon steel typically loses its passive film at pH values between 11 and 10, while CRS is expected to maintain its corrosion resistance at lower pH levels.

Note A3—A lower pH solution (i.e., pH = 9) can be used; however, the buffering capacity for such a solution is low. During testing, the pH value shall be monitored to assure that no significant drop in pH occurs.

Note A4—Ionic strength (I_S) is defined as one-half the summation of the product of the concentration of each ion and its charge squared, as shown in the equation $I_S = {}^1/_2 \Sigma c_i z_i^2$ (Lehmann et al., 1996).[2]

Table A1.1 illustrates the composition of aqueous test solutions.

Table A1.1—Polarization Resistance Aqueous Test Solutions

pH	NaOH (mol/l)	I_S	NaOH (g/l)	K_2SO_4 (mol/l)	K_2SO_4 (g/l)
13	0.1	0.1	4	—	—
10	0.0001	0.1	0.004	0.0333	5.8042

A1.5.4.2 *Potentiodynamic Polarization*—After preparing the test sample as described in Section A1.5.1, the specimen shall be immediately placed in the electrochemical cell and conditioned at –1200 mV (vs. Ag/AgCl reference electrode) for 2 minutes in order to reduce any possible air-formed oxide film. Then the potential shall be gradually increased from –1200 mV at a scan rate of 1 mV/s. If a cyclic scan is desired, the potential shall be taken to the beginning of the transpassive region (about +550 mV vs. Ag/AgCl when no chlorides are present) and reversed back to the starting potential.

In the presence of chlorides, the onset of pitting corrosion is detected by a shift of the transpassive region to lower potential values during the forward (anodic) scan. This new potential value is referred to as the pitting potential (for a particular chloride concentration). Pitting corrosion is initiated when a chloride threshold value (as represented by the ratio between Cl^- and OH^- ions prepared in solution) is exceeded. A simulated concrete pore solution with a constant $[OH^-]$ (0.55M KOH + 0.16M NaOH, as described by Taylor, 1997)[3] shall be prepared. The concentration of Cl^- ions shall be changed to a desired level by adding NaCl salt (see Table A1.2 for examples). In order to verify and demonstrate the enhanced corrosion performance of CRS in highly aggressive environments, it is recommended that potentiodynamic polarization curves be measured in at least two environments: (1) simulated concrete pore solution with no chlorides, and (2) the same aqueous solution with a high concentration of chlorides (e.g., ratio $[Cl^-]/[OH^-] = 2$ or higher).

Note A5—Carbon steel rebar typically presents chloride threshold ratios between 0.2 and 0.85, with 0.6 being the most commonly referenced value.

Table A1.2 below illustrates the chemical composition of simulated concrete pore test solutions.

Table A1.2—Simulated Concrete Pore Solutions for Potentiodynamic Polarization Tests

$[Cl^-/OH^-]$	[KOH] (mol/l)	KOH (g/l)	[NaOH] (mol/l)	NaOH (g/l)	$[OH^-]$ (mol/l)	$[Cl^-]$ (mol/l)	[NaCl] (mol/l)	NaCl (g/l)
0	0.55	30.86	0.16	6.40	0.71	0.00	0.00	0.00
1	0.55	30.86	0.16	6.40	0.71	0.71	0.71	41.49
2	0.55	30.86	0.16	6.40	0.71	1.42	1.42	82.98
3	0.55	30.86	0.16	6.40	0.71	2.13	2.13	124.48

Note A6—The two sets of tests described above can clearly demonstrate the corrosion behavior of a selected CRS and show how it compares to regular carbon steel rebar when test parameters, such as pH values and $[Cl^-]$ levels (both considered excessively aggressive in the case of carbon steels), are controlled.

A1.6 *Report*:

A1.6.1 *Polarization resistance*—Report the polarization resistance R_p at pH = 10 and R_p at pH = 13 for test solutions prepared in accordance with Table A1.1 for the comparison bar material (M 31M/M 31) and the uncoated CRS test bar material. Evaluate the ratio of $R_p(\text{pH} = 10)/R_p(\text{pH} = 13)$.

A1.6.2 *Potentiodynamic Polarization*—Report the pitting potential in mV (vs. standard hydrogen electrode and vs. the reference electrode used in the test) at $[Cl^-]/OH^-] = 0$ and $[Cl^-]/OH^-] = 2$ for test solutions prepared in accordance with Table A1.2 for the comparison bar material (M 31M/M 31) and the uncoated CRS test bar material.

A1.6.3 *Chemical Constituents*—Report chemical analysis percentages for the following elements: carbon, chromium, copper, manganese, molybdenum, nickel, nitrogen, phosphorus, silicon, sulfur, and vanadium.

Standard Practice for

Overcoating Field Test Program for Evaluating Protective Coatings on Existing Bridges or Salvaged Beams

AASHTO Designation: PP 55-06 (2009)[1]

1. SCOPE

1.1. This field testing program has been established to provide the end user with test results which can be used to make performance judgments on one-, two-, or three-coat systems for maintenance overcoating previously painted steel structures.

1.2. This field testing program is intended to apply to maintenance overcoating, herein defined as the practice of cleaning and painting over an existing coating which is largely intact but has areas of corrosion or peeling paint in need of repair. This practice usually includes the spot preparation of rusted or degraded areas, feathering edges of existing paint, power washing the entire structure, priming bare or repaired areas, applying an intermediate coat over the repaired areas or entire structure, and the optional step of applying a full topcoat over the entire structure, or a similar variation of these procedures.

1.3. This field testing program evaluates the performance of protective coatings applied to existing painted steel surfaces with various degrees of surface preparation and condition, including surfaces hand tool cleaned (SSPC SP 2), surfaces cleaned by conventional power tools (SSPC SP 3), surfaces power tool cleaned to bare metal (SSPC SP 15), and industrial blast (SSPC SP 14).

1.4. The coating materials in the field testing program are applied to previously painted steel surfaces of existing bridges or salvaged bridge beams after proper surface preparations, as described herein, and thereafter evaluated annually, unless otherwise agreed, for a period of 3 years.

1.5. All of the elements of this field testing program shall be performed in accordance with applicable local, state, and national regulations governing environmental and worker protection. Specific references to material, environmental, and worker protection requirements are not necessarily made in this document since these regulations are widely known and compliance with these regulations is standard practice in the bridge painting industry.

1.6. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this procedure to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

3. DISCUSSION

3.1. The purpose of this program is to provide a basis for comparing the performance of coating systems applied with existing painted structures under similar conditions of weathering exposures. There are a number of variables, issues, and risks involved with overcoating an existing painted structure. The intent of this test is not to address all of these issues, but rather to create test conditions under which coating systems can be applied and evaluated to provide a basis for evaluating coating performance.

3.2. To provide comparability of field testing and results, all test sites shall use the same testing methods described herein and all field testing and evaluation shall be administered by a qualified representative of the specifying agency selected by and reporting to the agency.

3.3. Recommended reference for additional guidance can be found in ASTM D 5064, Standard Practice for Conducting a Patch Test to Assess Coating Compatibility; the SSPC TU 3, Technology Update on Overcoating; and the AASHTO *Guide for Painting Steel Structures*.

4. CANDIDATE TEST SITES FOR FIELD TESTING

4.1. The candidate test sites (existing bridges or salvaged steel bridge beams) should be in a condition requiring maintenance overcoat painting and not total repainting. If bridges are used, they should permit access for field testing and evaluation with a minimum of rigging and traffic control requirements.

4.2. The field test program, if possible, shall include a total of four test sites that are representative of the conditions in the agency's jurisdiction.

4.3. The candidate test sites should have existing paint(s) representative of paints commonly used in the past, such as lead-pigmented oil alkyds, etc.

4.4. The owner of a candidate test site may provide basic support services to the representative of the specifying agency as determined by site conditions and by the requirements of the agreement, such as traffic control and access. Support services are voluntary and on an as-available basis. Test bridges shall be exempted from maintenance painting activities of the host state during the length of the test. See Section 9.6.

4.5. The candidate structural steel shall preferably be rolled beams or welded girders offering uniform and continuous areas for dividing into test areas.

5. PRETEST STRUCTURE INSPECTION

5.1. Prior to surface preparation and paint application, each test area (as described in Section 7) will be characterized in terms of the following properties to provide a basis of comparison among test sites and for proper evaluation of new coating performance.

Note 1—Chloride testing shall also be performed after surface preparation. See Section 8.4.5.

5.1.1. History of existing coating and photographs of test areas.

5.1.2. Visible rusting in accordance with ASTM D 610.

5.1.3. Visible blistering in accordance with ASTM D 714.

5.1.4. Coating degradation estimated percent.

5.1.5. Chalking of topcoat in accordance with ASTM D 4214.

5.1.6. Checking of topcoat in accordance with ASTM D 660.

5.1.7. Coating thickness using magnetic thickness gauge in accordance with ASTM D 7091.

5.1.8. Number of coats in accordance with ASTM D 4138 (Test Method A).

5.1.9. Adhesion in accordance with ASTM D 3359 Method A cross cut.

5.1.10. Adhesion in accordance with ASTM D 4541, Pull-off adhesion, Annex A.2, Pneumatic Adhesion Test Instrument.

5.1.11. Character of substrate, i.e., mill scale, blasted, corroded, etc.

5.1.12. Chloride contamination (see FHWA RD-91-011, Appendix F).

5.1.13. Environmental Exposure Climatic Region: hot/dry; cold/dry; hot/wet; cold/wet; compass orientation of test areas; and exposure to UV: high, moderate, or low.

5.2. It is advisable to select candidate bridge or salvaged beam test sites for overcoat field testing that have existing coating characteristics that yield an "OK" or "Low Risk" recommendation from Table 1, Risk of Salvaging Existing Coating Based on Adhesion/Thickness Characteristics, of the SSPC TU 3 (overcoating). However, if the specifying agency and the coating manufacturer agree a lower rating is acceptable for application of the coatings for test, criteria other than adhesion and thickness of coating may be considered and documented.

6. MATERIALS REQUIREMENTS

6.1. An analysis of the coating system properties required in Sections 6.2, 6.3, 6.4, and 6.7 shall be performed by a contracted independent testing lab and submitted to the agency within six months of the start of field testing.

6.2. The Volatile Organic Compound (VOC) level of overcoat paint systems shall be stated by the manufacturer on the product data sheets and shall be classified according to the maximum recommended VOC after thinning of the coating as applied. This level shall be stated for each coat in the system and shall meet the requirement of the agency.

6.3. Each coating (primer, intermediate, and top coat) submitted for field testing shall be tested to determine its total lead content. The total lead content shall be determined using a dry film sample in accordance with ASTM D 3335. The percentage of total lead in each coating shall not exceed 0.01 percent (100 ppm).

6.4. The properties of each coating (as determined in a mixed condition) shall be stated on the certified Product Data Sheet, including the following:

6.4.1. Total solids, percentage by mass in accordance with ASTM D 2369.

6.4.2. Pigment, percentage by mass in accordance with ASTM D 2371.

6.4.3. Metallic zinc content, percentage by mass in primer shall be determined in accordance with ASTM D 6580. An optional test method is T 337.

6.4.4. Total solids, percentage by volume in accordance with ASTM D 2697.

6.4.5. Mass per volume (grams per liter) in accordance with ASTM D 1475.

6.4.6. Viscosity (Stormer at 25°C) KU in accordance with ASTM D 562 (not suitable for viscosities above 143 KU).

6.4.7. Viscosity (Brookfield at 25°C) cP in accordance with ASTM D 2196. The spindle size and revolutions per minute shall be reported.

6.4.8. Pot life in hours, at specified temperature and specified humidity.

6.4.9. Sag resistance (Lenata) in micrometers wet film thickness, in accordance with ASTM D 4400.

6.4.10. Recommended minimum and maximum dry film thickness in micrometers.

6.4.11. Theoretical coverage (e.g., m^2/liter for 25 micrometers dry film thickness or micrometer/m^2/liter, whichever is appropriate for the particular coating).

6.4.12. Minimum drying time set to touch, dry hard, tack free time, and dry through (and maximum when applicable) in accordance with ASTM D 5895 at 25°C and 50 percent relative humidity.

6.4.13. Mixing ratio for multi-component coatings by volume, mass, or a combination of mass and volume. This is not required for a pre-mixed (all in one) zinc primer.

6.4.14. Mixing ratio for multi-component coatings, by mass.

6.4.15. Shelf life of each component stored at 25°C.

6.4.16. Infrared analysis by using Fourier transform infrared (FTIR) spectroscopy, as specified in Section 6.7.

6.4.17. Heavy metals testing for mixed coatings in accordance with ASTM D 3335 and D 3718. Heavy metals to be tested will include lead, chromium, and cadmium.

6.4.18. Dry film analysis for leachable heavy metals shall include arsenic, barium, cadmium, chromium, lead, mercury, selenium, and silver for each coating. The dried film shall be removed from a non-metallic glass test panel and pulverized to pass through a 250-μm (No. 60) sieve. The pulverized film passing the 250-μm (No. 60) sieve shall be extracted in accordance with the TCLP, Method 1311 of EPA SW-846. The extract shall then be analyzed for heavy metals using the appropriate EPA SW-846 test method for each metal.

6.4.19. The manufacturer shall supply chemical test results that will define the character and nature of the coating system being submitted. Actual results shall be verified by the qualifying laboratory and shall be part of the qualifying laboratory's written report. The type of information provided by the coating manufacturer should include, but not necessarily be limited to, the following: epoxide values (for the epoxy component of two component epoxy coatings), amine values (for that component of epoxy coatings which contains amine or amidoamine cross-linkers), isocyanate group content (for that component of a polyurethane coating that contains the isocyanate component), and identification of hindered amine light stabilizers (for any topcoat that contains such additives). Note that for epoxy coatings cross-linked with polyamide resin, there is currently no standardized test method for determining amide content.

Note 2—If a manufacturer's standard Product Data Sheet does not contain all of the above required information, a supplemental sheet and/or an MSDS with the additional information shall be provided.

6.5. For testing purposes the color of the final topcoat shall be designated by the specifying agency. If used, the color of the intermediate coat shall be a contrasting color.

6.6. *Application Requirements*—The following information shall be supplied by the coatings manufacturer:

6.6.1. The minimum and maximum surface profile requirements (height in micrometers);

6.6.2. Application requirements for ambient temperature, surface temperatures, material temperature, and humidity;

6.6.3. Requirements for application by spray, brush, or roller.

6.7. *Coating Identification Tests*:

6.7.1. An analysis of vehicle solids by FTIR spectroscopy consisting of 16 scans minimum per sample shall be performed as follows:

6.7.1.1. For zinc primer solvent-based coats, infrared spectrum (2.5 to 15 micrometers) of each liquid vehicle component via the potassium bromide sandwich technique.

6.7.1.2. For two component solvent-based topcoats, infrared spectrum (2.5 to 15 micrometers) of each single component via the potassium bromide sandwich technique and of the mixed and dried components in appropriate mixing ratios (dried film) via the potassium bromide pellet technique, or alternatively by the IR card sampling technique, which is called the PTFE technique.

6.7.1.3. For zinc primer water-based coats, infrared spectrum (2.5 to 15 micrometers) of the liquid vehicle component after drying and applying the potassium bromide pellet technique, or alternatively by using the IR card sampling technique, which is called the PTFE technique.

6.7.1.4. For two component water-based coats, infrared spectrum (2.5 to 15 micrometers) of each single component after drying and applying the potassium bromide single-pellet technique, or alternatively by the IR card sampling technique, which is called the PTFE technique; and also of the mixed and dried components in appropriate mixing ratios (dried film) via the single-pellet technique, or alternatively by using IR card sampling technique, which is called the PTFE technique.

6.7.2. The VOC shall be determined in accordance with ASTM D 3960 for primer and topcoats. If exempted solvents are part of the formulation, the manufacturer is responsible for listing those solvents and the percentage of the volatile material in the mixed coating that they represent. The manufacturer may specify an alternative induction time as permitted by U.S. EPA Reference Method 24 when the coating is submitted by test. If the manufacturer does not specify an induction time, the test will be conducted with an induction period of 1 hour.

7. TEST AREAS

7.1. Each test coating will be applied on four test areas at each test site. Each test area will be a minimum of four linear feet of beam. The test areas for all coatings in the testing program will be randomly distributed about the entire testing site. The test area on a steel beam will include both sides of the web and “wrap around” the bottom flange. Two of the four areas shall be covered with a simulated deck. The test areas should be different, if the candidate structure allows, such as interior beam vs. sun-exposed fascia, expansion area vs. midspan, etc. When practicable, salvaged steel beams at test sites should be oriented to achieve different exposures. Each candidate test site will have two control test areas. For the control coating system, the same number of coats and film thickness will be used at all test sites. The control coating system should be selected by the agency. Base this selection on field performance that has been documented in the state where the testing is performed. If the candidate structure allows, the two application sites selected for the control coatings system should be different.

8. SURFACE PREPARATION

8.1. All test areas shall be power washed with potable water using 4500–5000 psi pressure with a zero-degree rotary nozzle placed no more than 8 in. from the surface and held perpendicular to it to remove residual dirt, debris, and contaminants. It may be necessary to catch water used for this purpose using filtering screens or tarps to collect any paint debris removed during cleaning. The structure will be allowed to dry prior to any mechanical surface preparation.

8.2. All non-adherent paint and rust will be removed, collected, and properly disposed of.

8.3. Test areas shall be spaced with an approximate 3-in. clear gap between adjacent test areas.

8.4. The following description is a suggested division of each test area into sub-areas for evaluation of various surface preparation methods. The specifying agency may elect to evaluate other methods of surface preparation and develop a specific matrix of these methods to suit proposed methods in its state.

8.4.1. One half (approximately) of each test area will be cleaned in accordance with SSPC SP 2, Hand Tool Cleaning, using a wire brush and dull putty knife. Edges of intact paint will be worked with a dull putty knife with reasonable effort.

8.4.2. The other half (approximately) of each test area will be cleaned in accordance with SSPC SP 3, Power Tool Cleaning, using needle guns, rotary peening tools, and disc sanders fitted with non-woven abrasive pads. All power tools used will be fitted with shrouding devices and vacuum attachments and used in conjunction with a suitably powered HEPA vacuum to collect dust and debris generated during cleaning. Edges of intact paint will be “feathered” using the disc tool. Care shall be taken not to burnish bare metal surfaces.

8.4.3. A continuous “strip” of bare metal (approximately 4–5 in. wide) shall be placed through the length of the sub-areas described in Sections 8.4.1 and 8.4.2 and prepared to SSPC SP 15 cleanliness using a rotopeen tool.

8.4.4. A continuous “strip” of bare metal (approximately 4–5 in. wide) shall be placed through the length of the sub-areas described in Sections 8.4.1 and 8.4.2 and prepared to SSPC SP 14 cleanliness.

8.4.5. Perform chloride testing before and after surface preparation using the same chloride detection methodology and in the same locations. Surface chloride measurements shall be below 7 $\mu g/cm^2$ prior to the application of the coating.

9. PAINT APPLICATION

9.1. Paint application shall conform to the requirements of SSPC PA 1, except as amended herein or as recommended by the paint manufacturer.

9.2. Prior to painting, the appropriate atmospheric conditions will be documented, including air and surface temperature and relative humidity.

9.3. Paint may be applied by brush, roll, or spray, as determined by the agency. All reasonable attempts will be made to achieve specified film builds.

9.4. Application, dry time, time-to-recoat, and environmental conditions for painting shall comply with the manufacturer's recommendations. All application procedures outlined in Section 6.6.3, including wet film thickness, shall be documented for each coat by the representative of the specifying agency.

9.5. Within two days after the paint has been applied and cured, each test area shall have two vertical scribes cut to bare metal in each test area. The scribes shall be placed approximately three to four inches from the edge of each sub-area described in Sections 8.4.1 and 8.4.2. The scribe shall extend through the strips described in Sections 8.4.3 and 8.4.4. The total length of a vertical scribe shall extend for most of the height of the test area. The scribes shall conform to the cutting requirements of ASTM D 3359. (See Figure 1.)

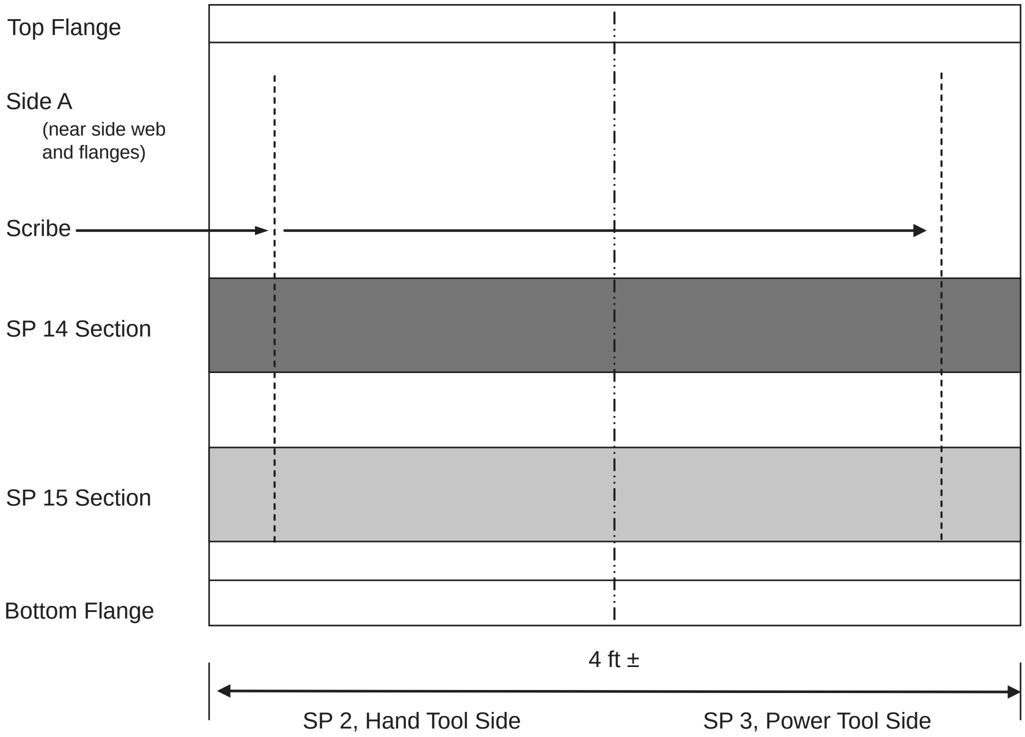

Figure 1—Sketch of Test Patches

9.6. If and when the host state agrees to perform this task, the corrosion process shall be accelerated by applying a dilute solution of salt water by spray to each test area bi-weekly for the winter months or at some other agreed-upon frequency. Application(s) of the salt water solution shall be documented and summarized in the final report. The percentage of sodium chloride in the dilute solution shall be as agreed between the agency and the host state.

10. EVALUATION

10.1. All test areas shall be evaluated annually (unless otherwise specified) and documented by the representative of the specifying agency.

10.2. Each of the sub-areas of surface preparation in each test area (i.e., SSPC SP 2, SSPC SP 3, SSPC SP 14, SSPC SP 15, and scribe) shall be evaluated and rated separately. All areas shall be evaluated visually for rust, coating adhesion, and overall appearance and condition. Evaluation criteria shall include, but not be limited to, the following for each system applied:

10.2.1. Percentage of visible rust for each type of surface preparation for each test area, averages of same for each test site, and averages of same for all sites in accordance with ASTM D 610.

10.2.2. Visible blistering in accordance with ASTM D 714 for each type of surface preparation for each test area, averages of same for each test site, and averages of same for all sites.

10.2.3. Assessment of chalking of topcoat in accordance with ASTM D 4214 at the end of 3 years.

10.2.4. Checking of topcoat in accordance with ASTM D 660.

10.2.5. Adhesion in accordance with ASTM D 3359, Method A Cross Cut, three tests at the end of 3 years for each type of surface preparation for each test area, averages of same for each test site, and averages of same for all sites.

10.2.6. Adhesion in accordance with ASTM D 4541, Annex A.2, Pneumatic Adhesion Test Instrument, three tests at the end of 3 years for each type of surface preparation for each test area, averages of same for each test site, and averages of same for all sites.

10.2.7. Scribe undercut average measurement for each test area with an average for all test sites at the end of 3 years. At the conclusion of the test period, scrape the scribes and measure and report cutback.

10.2.8. Written assessment of the overall performance of each coating at the end of 3 years, noting the limitations and benefits of each system.

10.3. The representative of the specifying agency shall issue a report of the testing. The report shall document the environmental exposure of the test areas and include the coating properties, pre-test conditions, application procedures, annual and final evaluations, and photographs after cleaning and after each evaluation. The representative of the specifying agency will evaluate coating performance by an appropriate rating system and compare and rank all coatings involved in testing accordingly, including the control. Suitable consideration shall be given for differing conditions between test sites. The evaluation information shall be summarized for all systems in a spreadsheet format that is easily understood and approved by the agency.

10.4. The coating testing and performance ratings will be reviewed by the agency for acceptance.

11. ENVIRONMENTAL AND WORKER PROTECTION

11.1. Personnel preparing the field testing shall use appropriate respirators, eye protection, hearing protection, protective clothing, and hygiene necessary to meet the requirements of OSHA and the governing agency.

11.2. Vacuum-assisted power tools and appropriate tools and equipment shall be used as necessary to collect paint debris and protect the ground and water surfaces in the vicinity of the test sites.

Standard Method of Test for

Evaluation of Adhesive Anchors in Concrete Under Sustained Loading Conditions

---

AASHTO Designation: TP 84-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Evaluation of Adhesive Anchors in Concrete Under Sustained Loading Conditions

AASHTO Designation: TP 84-10

INTRODUCTION

Adhesive anchor systems have widespread use in transportation structures such as bridge widening, concrete repair and rehabilitation, barrier retrofitting, utility installation on existing structures, and tunneling. These systems are used to anchor threaded rod and reinforcing bars in concrete. This test method determines an adhesive anchor's ability to withstand sustained tensile loads under normal conditions.

1. SCOPE

1.1. This test method applies to structures used in AASHTO applications and is applicable to adhesive anchor systems with steel anchors in predrilled holes in concrete.

1.2. This test method determines the time to failure for adhesive anchors in concrete at various levels of sustained loading.

1.3. The static load test is developed from ASTM E 488 and the sustained load (creep) test is modified from ASTM E 1512 and ICC-ES AC308.

1.4. This test method only addresses the effect of sustained loads on adhesive anchors. Numerous other factors affect the load capacity of adhesive anchors and a complete battery of tests is essential to evaluate an adhesive anchor. Refer to ICC-ES AC308 for a listing of some of the many factors and related test methods that apply to adhesive anchors.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- A 193/A 193M, Standard Specification for Alloy-Steel and Stainless Steel Bolting Materials for High Temperature or High Pressure Service and Other Special Purpose Applications
- C 31/C 31M, Standard Practice for Making and Curing Concrete Test Specimens in the Field
- C 39/C 39M, Standard Test Method for Compressive Strength of Cylindrical Concrete Specimens
- C 42/C 42M, Standard Test Method for Obtaining and Testing Drilled Cores and Sawed Beams of Concrete
- D 907, Standard Terminology of Adhesives
- D 2990, Standard Test Methods for Tensile, Compressive, and Flexural Creep and Creep-Rupture of Plastics

- E 488, Standard Test Methods for Strength of Anchors in Concrete and Masonry Elements
- E 1512, Standard Test Methods for Testing Bond Performance of Bonded Anchors

2.2. *International Code Council Standards*:

- ICC-ES AC308, Acceptance Criteria for Post-Installed Adhesive Anchors in Concrete Elements

---

3. TERMINOLOGY

3.1. Refer to ASTM D 907 for a complete listing of terminology related to adhesives.

3.2. *Definitions of Terms Specific to This Standard*:

3.2.1. *adhesive anchor*—a post-installed anchor that transfers load to concrete through an adhesive compound embedded in a hole in hardened concrete. The adhesive materials used include epoxy, cementitious material, polyester resin, and others.

3.2.2. *Adhesive anchor system*—for the purposes of this standard, the adhesive anchor system is composed of the following components: adhesive anchor; proprietary adhesive compounds in combination with a mixing and delivery system; accessories for cleaning the drilled hole, such as wire brushes, air nozzles, etc.; and printed instructions for the adhesive anchor installation, including hole preparation, injection, and cure.

3.2.3. *creep*—the deformation or displacement of an adhesive over time due to stress.

3.2.4. *embedment depth*—distance from the surface of the structural member to the end of the installed anchor.

3.2.5. *linear variable differential transformer (LVDT)*—an electronic instrumentation device used for measuring displacement.

3.2.6. *static load test*—a test in which a load is slowly applied at a specified rate for one cycle until failure.

3.2.7. *sustained load (creep) test*—a test in which a constant load is continuously applied until failure due to creep.

3.2.8. *test specimen*—the structural member, anchor rod, and adhesive.

3.2.9. *Symbols*:

- d = nominal anchor diameter, in. (mm)
- d_o = nominal diameter of drilled hole in concrete, in. (mm)
- f'_c = specified compressive strength of concrete, psi (MPa)
- h_{ef} = effective depth of embedment of an anchor, in. (mm)

---

4. SIGNIFICANCE AND USE

4.1. *This test method provides a means of*:

4.1.1. Determining the mean static load of an adhesive anchor,

4.1.2. Determining acceptable loads to apply to an adhesive anchor based on the lifetime of the structure, and

4.1.3. Determining an adhesive anchor's ability to endure sustained loads.

4.2. The stress versus time-to-failure graph is useful to the practicing engineer in selecting and designing adhesive anchors.

4.3. A stress versus time-to-failure graph can give an indication of the reduction in capacity of an adhesive anchor due to sustained load at a given design lifetime.

4.4. This test method provides a means for comparing adhesive anchor products for sustained loading applications.

4.5. The test methods in this standard should be followed in order to ensure reproducibility of test results.

5. TEST APPARATUS

5.1. *Instrumentation and Data Collection*:

5.1.1. All laboratory instrumentation (electronic load, displacement, temperature, and humidity sensors, etc.) must be calibrated with certified equipment.

5.1.2. A load cell or other load-measuring device must be able to measure forces to within ±1 percent of the anticipated peak load.

5.1.3. As an alternative, a load cell is not required for monitoring the sustained load (creep) test if the test apparatus has a stiffness that is sufficiently low to ensure accuracy of 1 percent of the applied sustained load at the maximum anchor creep displacement and if a stiffness-displacement relationship can be established to determine the load applied with reasonable confidence.

5.1.4. Displacements should be measured continuously by LVDTs, linear potentiometers, or an equivalent device with an accuracy of at least 0.001 in. (0.025 mm).

5.1.5. The instrumentation must be placed in a way that does not interfere with the anchor or testing apparatus. The instrumentation should measure the vertical displacement and load on the anchor relative to the test specimen. The instrumentation should be placed in such a way that it will remain parallel to the axis of the anchor and will not be affected by the deflection or failure, or both, of the anchor or test specimen.

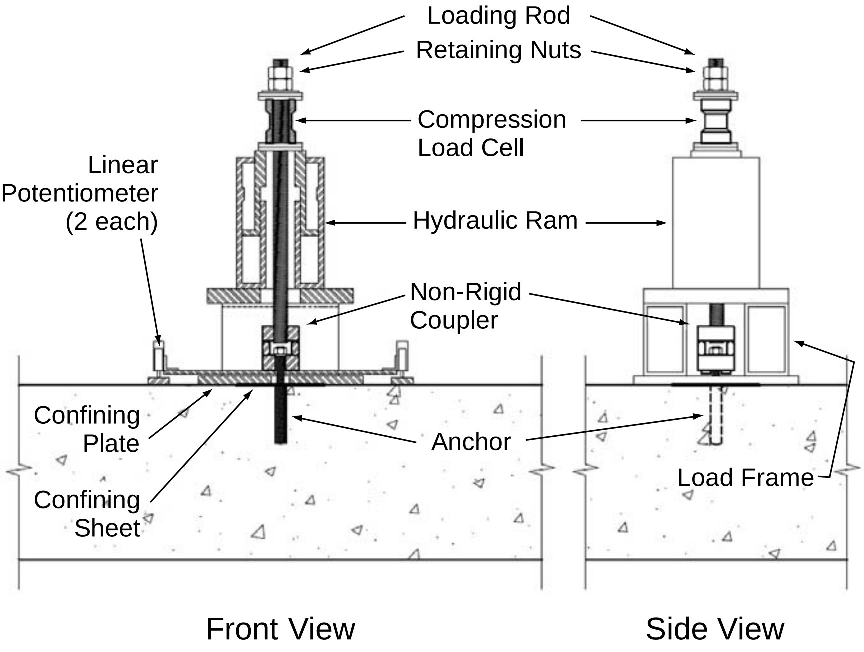
5.1.6. Two displacement measuring devices shall be placed equidistant and sufficiently far away from the anchor to not be within the potential failure surface. The two displacement values shall be averaged to obtain the actual displacement. One displacement measuring device may be used if it is placed centered on the anchor's axis and can be shown to produce acceptable confidence.

5.1.7. *Static Load Test*—The measuring devices and the data collection system must be able to gather data points at least twice per second for the static load test.

5.1.8. *Sustained Load (Creep) Test*—The measuring devices and the data collection system must be able to gather data points according to a progressively reducing frequency as discussed in Section 9.4.6.2 and Note 4.

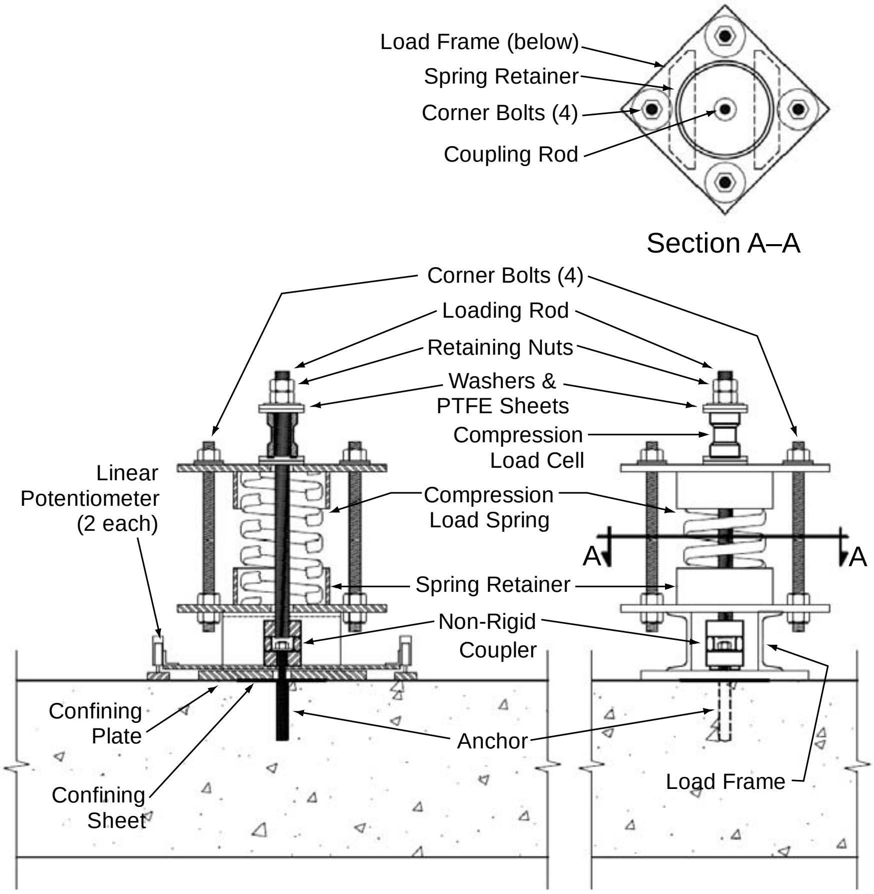
5.2. *Test Apparatus*:

5.2.1. Examples of suitable test apparatus for static and sustained load (creep) tests are shown in Figures 1 and 2, respectively.



Source: Modified from Cook et al. [14.2]

Figure 1—Static Load Test Apparatus



Source: Modified from Cook et al. [14.2]

Figure 2—Sustained Load (Creep) Test Apparatus

5.2.2. The test apparatus must be of sufficient capacity so as to not yield during testing.

5.2.3. *Coupler*—A coupler shall be used between the anchor and the test loading rod, providing a nonrigid connection that does not transfer bending forces.

5.2.4. *Confining Plate*:

5.2.4.1. The thickness of the confining plate should be greater than or equal to the nominal anchor diameter $\pm{}^{1}/_{16}$ in. (±1.5 mm).

5.2.4.2. In order to account for surface irregularities, a sheet of tetrafluoroethylene, polytetrafluoroethylene, fluorinated ethylene propylene, or perfluoroalkoxy of up to 0.06 in. (0.15 mm) of the same shape and dimensions of the confining plate shall be placed between the confining plate and the surface of the concrete.

5.2.4.3. The confining plate and the confining sheet shall be large enough to ensure that the pressure on the concrete underneath the plate does not exceed $0.40\,f'_c$.

5.2.4.4. The hole in the confining plate and the confining sheet shall be 1.5 d_o to 2.0 d_o. The shape of the hole shall match the anchor's cross-section. The size and shape of the hole shall be maintained in all tests.

6. TEST SPECIMEN

6.1. *Anchorage System*—The anchorage system used in the tests should be representative of that used in the field.

6.2. *Anchor Placement*—Spacing of anchors to be tested should be sufficient to permit placement of the test apparatus without interference from adjacent anchors.

6.3. *Structural Member*:

6.3.1. The structural member shall have sufficient dimensions to permit placement of test anchors at least $2h_{ef}$ from any edge and to avoid splitting failure during testing.

6.3.2. Reinforcing steel can be used, but only what is necessary for handling, and shall not interfere with the anchor. Reinforcing cannot be located within an imaginary cone projecting from the end of the embedded anchor to the loaded face of the structural member with an internal vertex angle of 120 degrees.

6.3.3. The depth of the structural member should be at least $1.5h_{ef}$.

6.3.4. The length and width of the structural member shall be large enough to ensure proper placement of the anchors in accordance with minimum spacing and edge distances.

6.3.5. The surface of the structural member shall be formwork or steel-trowel finish.

6.3.6. The concrete compressive strength at time of testing shall be from 2500 psi to 4000 psi (17 MPa to 28 MPa), unless otherwise specified. The aggregate should be of river gravel or crushed rock with a maximum aggregate size of $^3/_4$ or 1 in. (19 or 24 mm). The concrete mixture shall not include any materials such as blast furnace slag, fly ash, silica fume, limestone powder, or admixtures, unless otherwise specified.

6.3.7. Cure the concrete for a minimum of 28 days, ensuring proper moisture for hydration.

6.3.8. Concrete cylinders shall be made in accordance with ASTM C 31 and cured in similar conditions as the structural member. Cylinders shall be de-molded at the same time as form removal.

6.3.9. Test concrete compressive strength in accordance with ASTM C 39 for concrete cylinders or ASTM C 42 for concrete cores if insufficient cylinders were cast. Concrete strength at any point can be determined from a concrete strength-age relationship curve constructed from a sufficient number of compression tests conducted at regular intervals. It is also permitted to linearly interpolate concrete strength from compression tests conducted at the beginning and end of a test series.

7. ADHESIVE AND ANCHOR INSTALLATION AND CURING

7.1. Prior to anchor installation, condition the test specimen to 75 ± 10ºF (24 ± 5ºC) and 50 ± 10 percent relative humidity.

7.2. *Hole*:

7.2.1. Drill holes in accordance with the manufacturer's specifications and document any deviations. Drilled holes must be perpendicular (±6 degrees) to the face of the concrete test specimen.

7.2.2. In order to more easily compare data, the embedment depth, h_{ef}, should be 4.5 ± 0.1 in. (115 ± 2.5 mm) unless otherwise specified. A shallower embedment depth may be used if it is determined that a steel failure would occur prior to bond failure.

7.2.3. For anchors with a diameter, d, the minimum embedment depth, h_{ef}, shall conform to Table 1.

Table 1—Minimum Embedment Depth

d	$h_{ef,\ \mathrm{min}}$
$^1/_2$ in.	$2^3/_4$ in.
$^5/_8$ in.	$3^1/_8$ in.
$^3/_4$ in.	$3^1/_2$ in.
≥ 1 in.	4 d

7.2.4. Clean the holes in accordance with the manufacturer's specifications and document any deviations.

7.3. *Adhesive*:

7.3.1. Prepare and install the adhesive in accordance with the manufacturer's specifications and document any deviations.

7.3.2. Cure the adhesive according to the manufacturer's specifications and document any deviations.

7.4. *Anchor*:

7.4.1. Install the anchor in accordance with the manufacturer's specifications and document any deviations.

7.4.2. To ensure bond failure, use a high-strength steel (minimum strength equivalent to ASTM A 193 Grade B7).

7.4.3. In order to more easily compare data, anchors shall be $^5/_8$ in.—11 UNC (16 mm) threaded rod unless otherwise specified.

8. SPECIMEN CONDITIONING

8.1. Begin conditioning of the test slabs to their final environmental condition upon completion of the manufacturer's specified curing time for the adhesive and initiate testing and within 7 ± 5 days.

8.2. Do not begin tests until the temperature and humidity of the test specimens have stabilized for at least 24 hours.

Note 1—Depending on the size of the structural member, it might take several days to raise and stabilize the concrete temperature to the final elevated temperature.

9. TEST PROCEDURE

9.1. The test procedure consists of two types of tests [static load test and sustained load (creep) test]. Static load tests are conducted initially to determine the mean static load. Subsequently, several sustained load (creep) tests are conducted at various percentages of the mean static load.

9.2. *General Requirements*:

9.2.1. All tests will be confined tests as shown in Figures 1 and 2.

9.2.2. The tests will be conducted at specified temperature and humidity. The temperature shall be monitored via thermocouples or temperature sensors placed in the concrete test specimen. The thermocouples or temperature sensors can be either cast-in-place or installed in a maximum $^1/_2$-in. (12-mm) diameter hole and sealed to ensure accurate concrete temperature readings. The thermocouples or temperature sensors ideally should be placed at the mid-depth of the anchor, but not deeper than $4^1/_2$ in. (114 mm).

9.2.3. The use of thermocouples is not required if it can be experimentally demonstrated that the test procedure will consistently produce test member temperatures in accordance with the target temperatures.

9.3. *Static Load Test*:

9.3.1. *Environmental Conditions*—Conduct the static load tests at a minimum temperature of 110 + 10ºF/– 0ºF (43 + 5ºC/– 0ºC) and below 40 percent relative humidity. Following the required adhesive curing time, raise the temperature to the minimum elevated temperature of 110ºF (43ºC). Do not begin testing until the temperature and humidity of the test specimen have stabilized for at least 24 hours.

9.3.2. *Number of Test Specimens*—A minimum of five anchors shall be tested and their results averaged.

9.3.3. *Test Setup*:

9.3.3.1. Ensure that the test apparatus and instrumentation comply with the requirements of Section 5.

9.3.3.2. Ensure that the test apparatus is centered over the anchor and that the force applied is acting through the center of the anchor and perpendicular to the structural member.

9.3.3.3. Place the confining sheet around the anchor as discussed in Section 5.2.4.2.

9.3.3.4. Place the confining plate over the confining sheet, assuring that there is full bearing with the structural member around the anchor.

9.3.3.5. Connect the loading rod to the anchor by means of a non-rigid connecting coupler (one that does not transfer bending moments from the loading rod to the anchor) and ensure that it is acting in-line with the anchor.

9.3.3.6. The amount of pre-tensioning to the apparatus during test setup shall be uniform for all samples.

9.3.4. *Loading*:

9.3.4.1. *Initial Load*—Apply an initial load not exceeding 5 percent of the estimated ultimate load capacity of the anchor system in order to bring all members of the test apparatus into bearing. Zero the displacement readings.

9.3.4.2. *Rate of Loading*—Two loading rates are allowed by ASTM E 488, the Continuous Load Rate and the Incremental Load Rate. The continuous load rate is the only load rate allowed in this test method for the calculation of mean static load and for inclusion in the stress versus time-to-failure graph. Apply a uniform load rate such that failure ideally will occur at 2 minutes. Failure shall not occur in less than 1 minute or greater than 3 minutes.

Note 2—The incremental load rate can be used in optional additional tests as a method to (1) provide an indication of an adhesive's displacement sensitivity to load at the higher stress levels, and (2) determine appropriate stress levels to test at for the sustained load (creep) tests. This method is discussed in further detail in Appendix X1.

9.3.5. *Data Collection*—Collect load and displacement readings according to Section 5.1.7.

9.3.6. *Determination of Failure*—See Appendix X2 for a description of the various failure modes and methods to determine static load strength.

9.3.7. *Calculations*—Determine and record the mean static load by averaging the individual static load strengths from each test series.

9.4. *Sustained Load (Creep) Test*:

9.4.1. *Environmental Conditions*—Conduct the sustained load (creep) tests at a minimum elevated temperature of 110 + 10ºF/– 0ºF (43 + 5ºC/– 0ºC) and below 40 percent relative humidity. Following the required curing time, raise the temperature to the minimum elevated temperature of 110ºF (43ºC). Do not begin the test until the temperature and humidity of the test specimen has stabilized for at least 24 hours.

9.4.2. *Test Series*—Conduct a minimum of two series of sustained load (creep) tests within two load ranges (PL1 and PL2) based on the *mean static load* from the static load test:

9.4.2.1. Percent load level range 1 (PL1) is suggested to be between 70 percent and 80 percent of *mean static load*.

9.4.2.2. Percent load level range 2 (PL2) is suggested to be between 60 percent and 70 percent of *mean static load*.

9.4.2.3. It is not necessary that all test specimens be tested at the same percent load level, but that they lie within the ranges and the averages of the two test series should vary by at least 10 percent of mean static load.

9.4.3. *Number of Test Specimens*—A minimum of five anchors per series shall be tested.

9.4.4. *Test Setup*:

9.4.4.1. Ensure that the test apparatus and instrumentation comply with the requirements of Section 5.

9.4.4.2. Ensure that the test apparatus is centered over the anchor and the force applied is acting through the center of the anchor and perpendicular to the structural member.

9.4.4.3. Place the confining sheet around the anchor as discussed in Section 5.2.4.2.

9.4.4.4. Place the confining plate over the confining sheet, assuring that there is full bearing with the structural member around the anchor.

9.4.4.5. Connect the loading rod to the anchor by means of a nonrigid connecting coupler and ensure that it is acting in-line with the anchor.

9.4.4.6. The amount of pre-tensioning to the apparatus during test setup shall be uniform for all samples.

9.4.5. *Loading*—Apply an initial load not exceeding 5 percent of *mean static load* in order to bring all members of the test apparatus into bearing. Zero the displacement readings. Apply the remainder of the sustained load within 2 minutes ± 1 minute in as smooth a manner as possible.

Note 3—A suggested modification to the sustained load (creep) test apparatus shown in Figure 2 is presented in Appendix X4 to provide for smooth load transfer.

9.4.6. *Data Collection*:

9.4.6.1. *Temperature*—Record the concrete specimen temperature at a maximum 1-hour interval. Alternatively, the concrete specimen temperature can be recorded at 24-hour intervals if the test chamber temperature is recorded at 1-hour intervals.

9.4.6.2. *Displacement*—The frequency of displacement readings can be reduced over time.

Note 4—The following schedule is a suggestion: every 3 seconds during loading, every minute for the first hour following loading, every 10 minutes for the next 9 hours, and every hour thereafter.

9.4.7. *Determination of Failure*—Failure for the sustained load (creep) test will be determined as the onset of tertiary creep. A discussion of tertiary creep and a method to determine its onset can be found in Appendix X3.

9.4.8. *Calculations*—Determine and record the time to failure and load level at failure for each specimen.

10. CALCULATIONS AND INTERPRETATION OF RESULTS

10.1. Determine the five individual static load strengths from each static load test. Methods to determine the static load strength can be found in Appendix X2.

10.2. Determine the *mean static load* by averaging the individual values from the static load tests.

10.3. Determine the time to failure for each sustained load (creep) test series as the initiation of tertiary creep. A procedure to locate the onset of tertiary creep can be found in Appendix X3.

10.4. Determine the failure load level for each sustained load (creep) test series at the initiation of tertiary creep.

10.5. Normalize the load levels for the sustained load (creep) test to a percent of the *mean static load* from the static load tests.

10.6. Plot the normalized values from the static load test and the sustained load (creep) test on a stress versus log of time-to-failure graph.

10.7. Extend a linear trendline through the 15 points plotted.

10.8. A stress versus time-to-failure graph can give an indication of the reduction in capacity of an adhesive anchor due to sustained load at a given design lifetime.

11. REPORT

11.1. *Data Collection*—Report the type of test (static load or sustained load) and the following applicable information:

11.1.1. Date of test and date of report.

11.1.2. Test sponsor and test agency.

11.1.3. *Anchor Information*—manufacturer, model, type, material, finish, shape, dimensions, and other relevant information.

11.1.4. *Adhesive Information*—manufacturer, model, type, lot, material, application method, and other relevant information.

11.1.5. *Structural Member Information*—description, dimensions, reinforcing, mix design of concrete, aggregate type, curing method, concrete strength at time of test, age of concrete at time of test.

11.1.6. *Installation Information*—description of the procedure, tools, and methods used to install the adhesive anchor. Include the drilling and cleaning of the holes as well as the installation of the adhesive and anchor. Document any deviations from the manufacturer's specifications.

11.1.7. *Adhesive Curing Information*—temperature and humidity conditions, duration of cure, time when conditioning of test specimen began.

11.1.8. Temperature and humidity conditions at time of installation and during adhesive cure, conditioning, and final testing.

11.1.9. Embedment depth and diameter of hole of installed anchors.

11.1.10. *Test Information*—description of test method, amount of initial load, and actual rate of loading.

11.1.11. Number of samples tested per series.

11.1.12. *Static Load Test Data*:

11.1.12.1. Individual and average load values per anchor and coefficient of variation.

11.1.12.2. Individual and average displacement values at maximum load.

11.1.12.3. Load versus displacement curves per anchor.

11.1.12.4. Load versus time curves per anchor.

11.1.13. *Sustained Load (Creep) Test Data*:

11.1.13.1. Individual time-to-failure values per anchor.

11.1.13.2. Individual load values and percent mean static load values at failure per anchor.

11.1.13.3. Individual displacement values at failure per anchor.

11.1.13.4. Load versus displacement curves per anchor.

11.1.13.5. Displacement versus time curves per anchor.

11.1.13.6. Load versus time curves per anchor.

11.1.13.7. Stress versus time-to-failure curve.

11.1.14. Photographs, sketches and descriptions of failure modes observed.

11.1.15. Summary of findings.

11.1.16. Listing of observers of tests and signatures of responsible persons.

12. PRECISION AND BIAS

12.1. *Precision*—No precision has been established for this test method.

12.2. *Bias*—No bias can be established because no reference material is available for this test.

13. KEYWORDS

13.1. Adhesive anchors; anchors; bonded anchors; creep test; concrete; post-installed anchors; static load test; sustained load test; test methods; time-to-failure test.

APPENDIXES

(Nonmandatory Information)

X1. INCREMENTAL LOAD RATE

X1.1. The incremental load rate is a method that applies the load in several load steps, holds the load for 2 minutes, and then increases to the next load level. Apply the load in steps with the first increment not greater than 50 percent of the estimated ultimate load and each increment thereafter not exceeding 15 percent of the estimated ultimate load. Maintain each load increment within a tolerance of ±2 percent for 2 minutes.

X1.2. This method can provide an indication of an adhesive's sensitivity to sustained loading at higher load levels.

X1.3. Figure X1.1 shows a load-versus-displacement curve and a time-versus-displacement curve for an anchor under incremental loading.

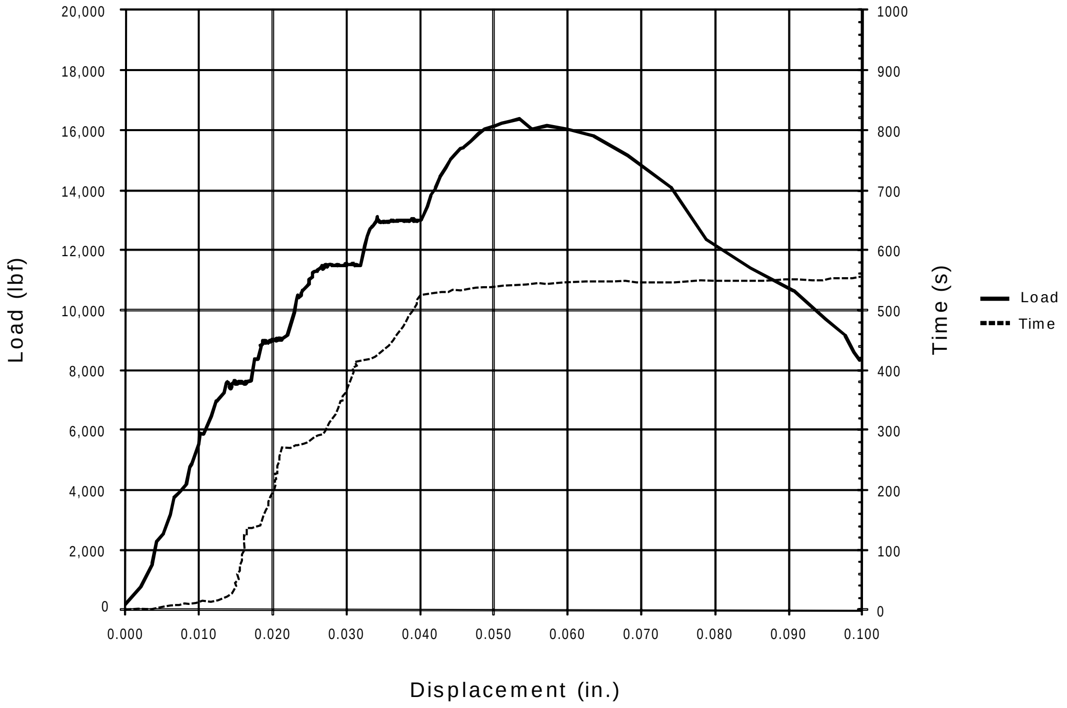

Figure X1.1—Load-Displacement and Time-Displacement Curves with Incremental Loading

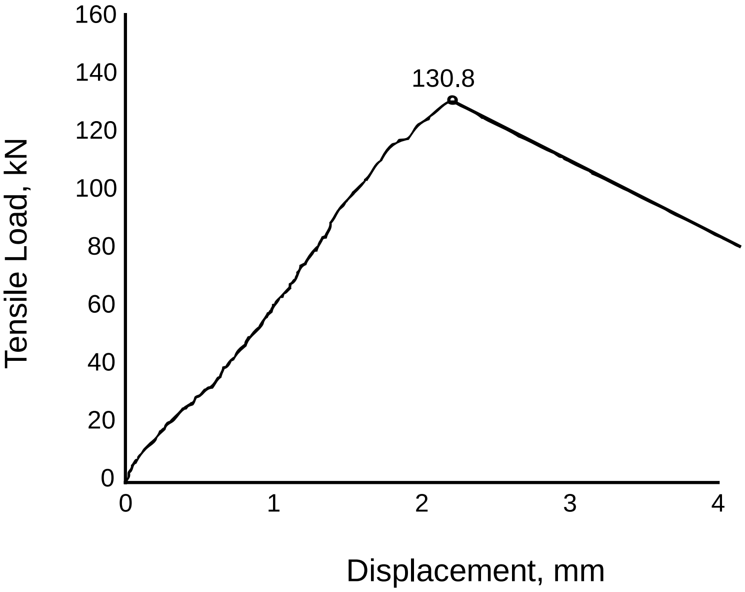
X1.4. As shown in Figure X1.1, as the load is held constant, the anchor in this graph displays more displacement at the higher load steps.

X1.5. Figure X1.1 also shows that, at the lower load levels, the displacement tends to stabilize. Additionally, at the higher load levels, the anchor continues to displace. This is indicated by the slope of the time-displacement curve.

X2. DETERMINING STATIC LOAD STRENGTH

X2.1. Cook and Konz [14.1] classify three types of load-displacement response (strength-controlled, stiffness-controlled, and displacement-controlled) for adhesive anchor systems. These three types of responses and methods of their analysis are summarized below:

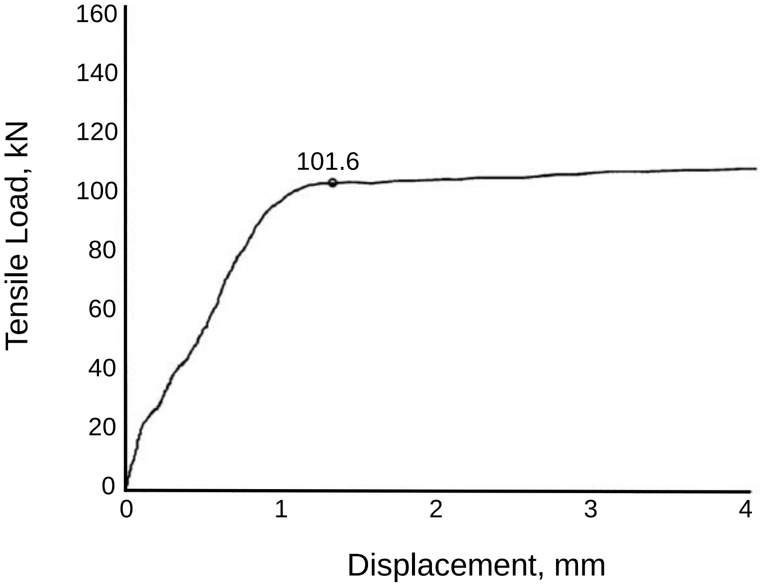
X2.1.1. *Strength-controlled*—This failure mode is defined by a very sharp peak in the load-displacement curve. There is a drastic reduction in the stiffness of the adhesive anchor beyond the peak. The static load strength is determined to be at the peak on the load-displacement graph. Figure X2.1 shows a typical curve of a strength-controlled failure.



Source: Cook and Konz [14.1], Reprinted with permission of ACI

Figure X2.1—Typical Strength-Controlled Failure

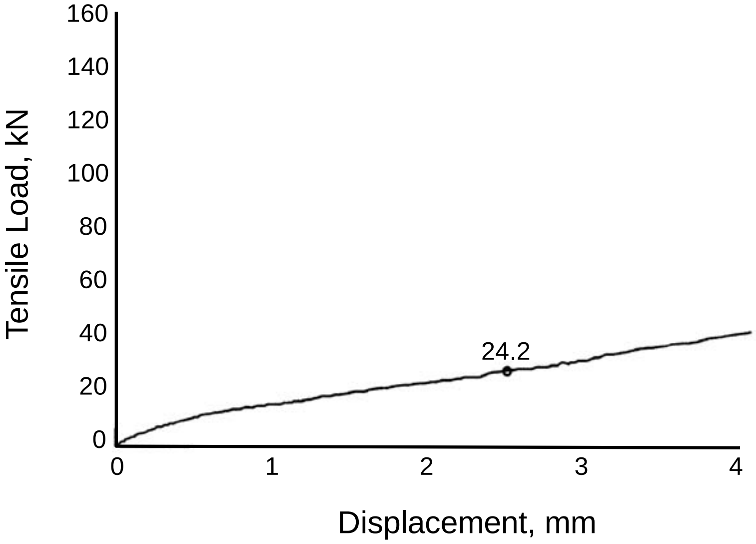
X2.1.2. *Stiffness-controlled*—This failure mode is defined by a large initial stiffness and a drastic change in stiffness that does not decrease, but rather continues to increase at a lower slope. Due to the lack of “peak” in the curve, the static load strength is determined by finding the point at a tangent stiffness of 30 kip/in. (5 kN/mm). The tangent stiffness (slope) at a given data point can be approximated by calculating the slope between a point five data points after and five data points before. Figure X2.2 shows a typical curve of a stiffness-controlled failure.



Source: Cook and Konz [14.1], Reprinted with permission of ACI

Figure X2.2—Typical Stiffness-Controlled Failure

X2.1.3. *Displacement-controlled*—This failure mode has a load-displacement curve with a relatively constant stiffness above the stiffness-controlled threshold of 30 kip/in. The maximum load occurs at very high, and impractical, displacements. In this case, the static load strength is set at a point with a displacement of 0.1 in. (2.5 mm). Figure X2.3 shows a typical curve of a displacement-controlled failure.

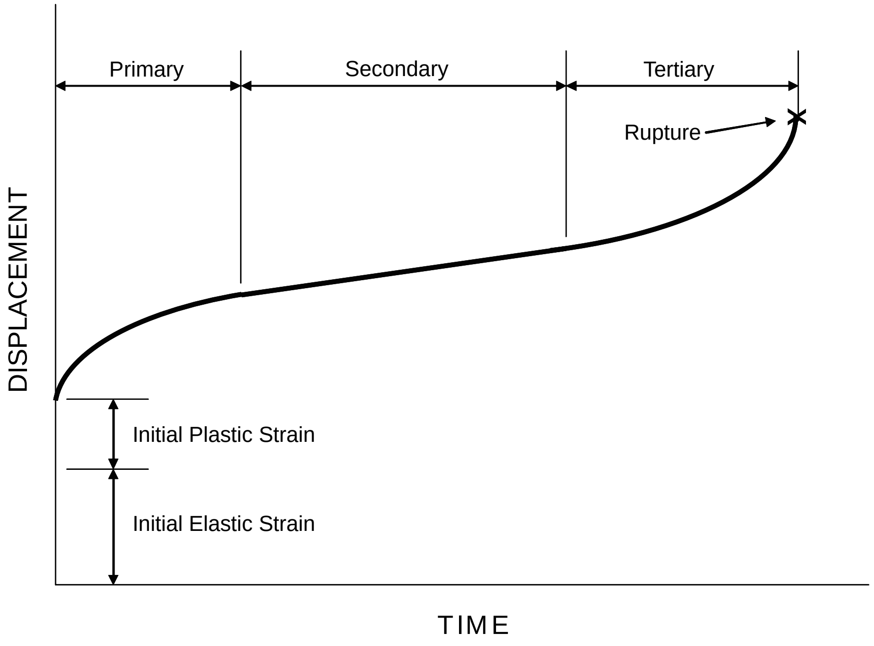


Source: Cook and Konz [14.1], Reprinted with permission of ACI

Figure X2.3—Typical Displacement-Controlled Failure

X3. DETERMINING ONSET OF TERTIARY CREEP

X3.1. As discussed in the appendix of ASTM D 2990, the displacement-versus-time curve will display three regions. Region 1 is the primary creep region and is characterized by an initial rapid decrease in the creep rate. Region 2 is the secondary creep region and is characterized by a relatively steady slope. Region 3 is the tertiary creep region and is characterized by a rapid increase in creep, ending in rupture. Figure X3.1 shows these three regions for a hypothetical sample.



Adapted from ASTM D 2990-01

Figure X3.1—Regions on the Creep Curve

X3.2. The onset of tertiary creep is found by analyzing the change in the slope of the creep curve:

X3.2.1. This method calculates the slope at a given point as the slope between itself and the prior data point.

X3.2.2. The change in slopes between the given point and the following data point is plotted and examined over the region just prior to rupture. It is suggested that this examination be conducted on a normal graph (not log time). The rupture point is easily identified on the displacement-versus-time graph. A suggested range for examining the change in slope is from 80 to 100 percent of time to rupture. Due to minor fluctuations in the displacement readings, the slope might change from positive to negative several times over this range.

X3.2.3. Tertiary creep is defined as the time the change in slope becomes positive for the last time prior to rupture. Figure X3.2 shows a sample graph for determining the initiation of tertiary creep.

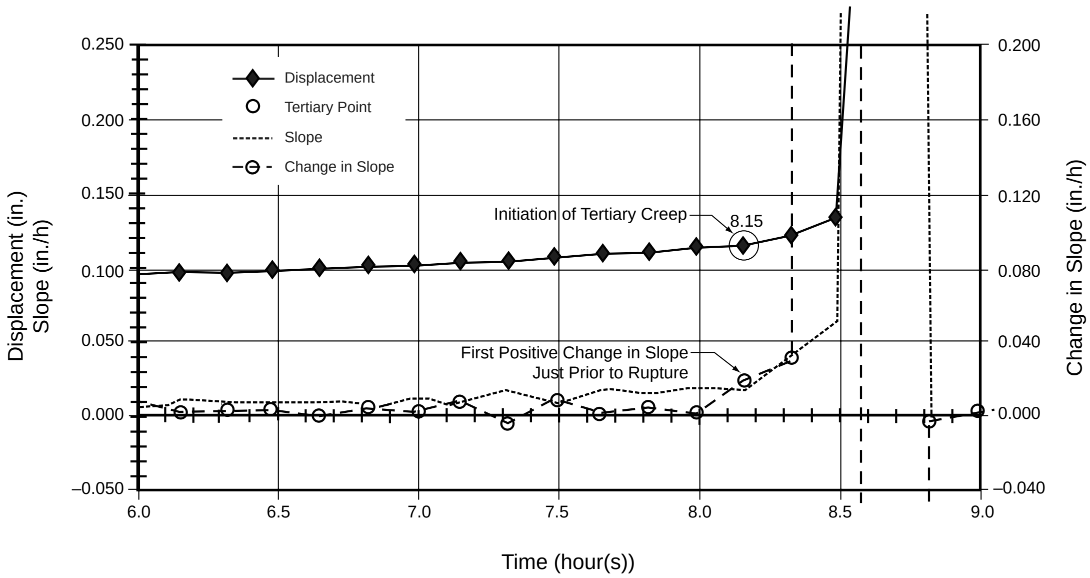


Figure X3.2—Sample Graph Showing Initiation of Tertiary Creep

X3.3. Failure for the sustained load is defined as the initiation of tertiary creep. The failure point for each sustained load test is plotted on the stress versus time-to-failure graph. Figure X3.3 shows a sample stress versus time-to-failure graph.

X3.4. A stress versus time-to-failure graph can give an indication of the reduction in capacity of an adhesive anchor due to sustained load at a given design lifetime.

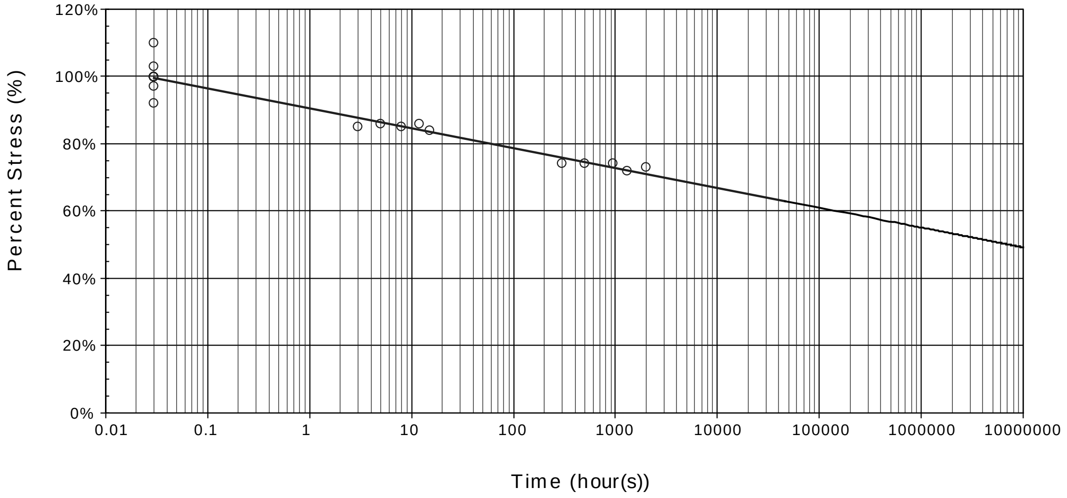

Figure X3.3—Sample Stress vs. Time-to-Failure Graph

X4. SUGGESTED SUSTAINED LOAD (CREEP) TEST APPARATUS FOR SMOOTH LOAD TRANSFER

X4.1. It is important that the load to the anchor be applied in a smooth manner. This can be accomplished with a hydraulic ram.

X4.2. Figure X4.1 shows a modified test apparatus for the sustained load (creep) test incorporating a hydraulic ram that reacts against a plate connected to the existing test apparatus by means of four threaded couplers. The ram and the upper plate can be removed following tightening of the loading rod nut.

Standard Specification for

Smoothness of Pavement in Weigh-in-Motion (WIM) Systems

AASHTO Designation: MP 14-08[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Specification for

Smoothness of Pavement in Weigh-in-Motion (WIM) Systems

AASHTO Designation: MP 14-08[1]

1. SCOPE

1.1. Weigh-in-motion (WIM) is the process of measuring the dynamic forces of moving vehicle tires on pavements and estimating the corresponding tire loads of the static vehicle. The dynamic forces of moving vehicles include the effects of road surface roughness and are modified by vehicle characteristics such as spring and un-spring mass, tire inflation pressures, out-of-round or dynamically unbalanced wheels and tires, suspension damping, and the vehicles' aerodynamic characteristics. The smoothness of the pavement surface in WIM systems directly affects the scale's ability to accurately estimate static loads from measured dynamic forces. Lack of smoothness creates difficulties in calibrating WIM equipment and may cause poor results from subsequent vehicle weight data collection efforts.

1.2. WIM system pavement smoothness is characterized by the output of a Class I profiler collecting data at 25-mm [1-in.] intervals. The data produced by such a profiler will approximate the actual perpendicular deviation of the pavement surface from an established horizontal reference parallel to the lane direction in the wheel tracks.

1.3. The specification requires field collection of pavement profile information of a WIM system or of a candidate WIM site. Computer software is then used to calculate indices of long- and short-range pavement surface roughness that have been correlated to distributions of tandem axle and gross vehicle weight error levels through extensive simulations of truck dynamic loading over measured profiles. Acceptable index levels are based on ensuring to a 95 percent level of confidence that the WIM system roughness will not produce errors that exceed the tolerance level limits recommended by ASTM.

1.4. The profiler test vehicle, as well as all attachments to it, shall comply with all applicable state and federal laws. Necessary precautions imposed by laws and regulations, as well as vehicle manufacturers, shall be taken to ensure the safety of operating personnel and other traffic.

3. TERMINOLOGY

3.1. *Definitions*:

3.1.1. *dynamic axle load (kg or lb), n*—the component of the time-varying forces applied perpendicularly to the road surface by the tires of any one axle of a moving vehicle.

3.1.2. *index, n*—a number or formula expressing some property, form, ratio, etc. of the relation or proportion of one amount or dimension to another.

3.1.3. *roughness, n*—vertical deviation of a pavement surface from a horizontal reference along a wheel track with characteristics that effect vehicle dynamics, including dynamic axle loads.

3.1.4. *profile record, n*—a data record of the surface elevation or slope along one or both wheel tracks of the road surface.

3.1.5. *weigh-in-motion (WIM), n*—the process of estimating a moving vehicle's gross weight and the portion of that weight that is carried by each wheel, axle, or axle group, or combination thereof, by measurement and analysis of dynamic vehicle tire forces. (See Terminology, ASTM E 867.)

3.2. *Definitions of Terms Specific to This Standard*:

3.2.1. *short-range roughness, n*—vertical deviations of the pavement surface from a horizontal reference within a range of pavement from 2.8 m [9.2 ft] preceding a WIM scale to 0.5 m [1.6 ft] beyond it.

3.2.2. *long-range roughness, n*—vertical deviations of the pavement surface from a horizontal reference within a range of pavement from 25.8 m [84.6 ft] preceding a WIM scale to 3.2 m [10.5 ft] beyond it.

4. TEST METHOD TO EVALUATE THE SMOOTHNESS OF PAVEMENT IN A WIM SYSTEM

4.1. *Performance Requirements*:

4.1.1. Functional performance requirements for Types I and II WIM systems were established and tabulated within ASTM E 1318. Table 1 summarizes the tolerance limits for 95 percent probability of conformity to WIM accuracy standards for axle loads, axle-group loads, and gross vehicle weights. Karamihas and Gillespie have developed short- and long-range profile-based indices that can predict the potential WIM error level due to roughness of the pavement. The development and use of these are documented within Annex A1.

4.1.2. Each Type I WIM scale location shall be chosen so that the short- and long-range roughness indices calculated from the pavement profile record of the WIM system do not exceed 0.5 m/km [31.7 in./mi] for either of the wheel tracks. Each Type II WIM scale location shall be chosen so that the short- and long-range roughness indices calculated from the pavement profile record of the WIM system do not exceed 1.25 m/km [79.2 in./mi] and 0.9 m/km [57.0 in./mi], respectively, for either of the wheel tracks. The achievement of these values is needed to ensure that a WIM site is likely to produce load estimates that meet the requirements of ASTM E 1318. When location requirements dictate scale placement in rough pavement, the existing pavement can be modified (overlaid, ground, etc.) or replaced to meet these smoothness requirements.

4.1.3. The very presence of a WIM scale will often create localized roughness within the pavement in its vicinity. If this localized roughness is just outside the range of the Short-Range Index (SRI) (2.8 m [9.2 ft] preceding a WIM scale to 0.5 m [1.6 ft] beyond it), then it will elevate the WIM error levels without any affect on the SRI value. To correct this, a Peak SRI value shall be calculated. This value is defined as the maximum value of SRI for all locations from 2.45 m [8.0 ft] ahead of the scale to 1.5 m [4.9 ft] beyond the scale. For Peak SRI, 0.75 m/km [47.5 in./mi] should be used as the acceptable threshold for Type I WIM and 1.6 m/km [101.4 in./mi] should be used for Type II WIM. Values below these figures are needed for both wheel tracks to ensure that a WIM site is likely to produce load estimates that meet the requirements of ASTM E 1318.

Table 1—Functional Performance Requirements for Types I and II WIM Systems

Function	Tolerance for 95% Probability of Conformance	
	Type I	Type II
Wheel Load	±25%	—
Axle Load	±20%	±30%
Axle-Group Load	±15%	±20%
Gross Vehicle Weight	±10%	±15%

4.1.4. In addition to the initial calculations of short- and long-range roughness indices for WIM scale location acceptance, the pavement smoothness of each existing WIM scale shall be verified annually. Profile records shall be collected and indices recalculated each year to ensure that the scale remains likely to produce load estimates that meet the functional performance requirements of ASTM E 1318.

4.1.5. In specifying a location for a WIM scale with more than one sensor on a single wheel track (typical with piezoelectric WIM equipment), the position of the scale shall be defined as the point midway between the sensors. SRIs and long-range indexes (LRIs) are to be referenced to this midway point.

4.1.6. Under certain conditions, jointed concrete pavement surfaces may exhibit significant changes in roughness due to variations in the temperatures of the pavement. Profile records of these pavements shall be taken at least twice, at times that correspond to approximate extremes of temperatures that are likely to be experienced at the candidate location. The location for a WIM scale shall be chosen so that the short- and long-range roughness indexes calculated from either of these profile records do not exceed the limits.

4.2. *Summary of Practice*—Test methods for evaluating the smoothness of pavement in an existing WIM system are presented herein. These procedures are applicable for determining whether either short-range or long-range roughness levels are at levels that would indicate a WIM scale is likely to produce acceptable levels of weighing error as defined in Table 1. The smoothness tests require the collection of longitudinal profile data with a sampling rate of 25 mm [1 in.] (Class I) according to the procedures in ASTM E 950. Computer analysis of these profiles serves to create indices of short- and long-range roughness that will be compared to acceptable threshold values.

4.3. *Significance and Use*—Karamihas and Gillespie conducted a correlation of calculated SRI and LRI values to WIM scale error for a large-scale study of pitch-plane simulations of 3S2 vehicles. Karamihas and Gillespie further verified this study of simulations of WIM scale errors associated with three-axle single-unit trucks. This correlation allows the indexes to be used to determine whether the WIM system pavement smoothness is sufficient to achieve weight measurements of 3S2 trucks (five-axle tractor-semi-trailers) and three-axle single-unit trucks that fall within ASTM error tolerance levels. The calculation of short- and long-range roughness indexes that fall within those that correlate to the scale measurement tolerances specified in Table 1 means that the scale is very likely to produce an acceptable level of weighing error.

4.4. *Procedure*:

4.4.1. *Profile Records*—Obtain profile records of both left and right wheel paths according to the procedures outlined in ASTM E 950 for Class I profilers using a 25-mm [1-in.] longitudinal sampling interval. These records should begin at least 122 m [400 ft] prior to the WIM scale sensor and extend to 30 m [100 ft] after the scale sensor. For WIM scales that are comprised of two or more sensors, the location of the scale will be defined as the longitudinal midpoint of the locations of the two outermost sensors. Record the WIM scale location as an Intermediate Feature Location Marker within the profile record as per Section 6.3.4 of ASTM E 950. Obtain a total of three records, compare the outputs for each, and evaluate each for equipment-related spikes. Continue collecting profile records until the operator is satisfied that at least one error-free record has been obtained.

4.4.2. *Calculation of Indexes*—A complete description of the procedure to calculate short- and long-range smoothness indices is described in Annex A1—Computation of Profile-Based Short- and Long-Range Indices. The procedure has been coded within the WIM Smoothness Index software available from FHWA's Long-Term Pavement Performance (LTPP) Program Product Delivery Team. This nonproprietary software performs the computations from Annex A1 with either R 57 or ERD text file versions of the profile records from any longitudinal profiler as inputs. Source code is available from FHWA's LTPP Product Delivery Team. Perform 'Site Evaluation' analysis of the WIM system pavement with the WIM Smoothness Index software. SRI, LRI, as well as peak SRI, values will be calculated for both left and right wheel paths of the WIM system.

4.4.3. Although including pavement features located more than 26 m [85 ft] ahead of a WIM scale does not improve its predictive ability, the LRI criterion might fail to screen out WIM sites with a major disturbance just beyond this range if the rest of the pavement is smooth. Although this is unlikely to occur in practice, a useful way to protect against very rough pavement features that are not captured by the LRI value at the scale location is to inspect the value of LRI for 30 m [100 ft] upstream of the scale to ensure that it does not exceed the lower threshold over this range.

4.5. *Interpretation of Results*—Lower threshold values of long-range, short-range, and peak short-range indexes are those below which a WIM system is very likely to produce an acceptable level of weighing error. Upper threshold values of these indexes are those above which a WIM system is very likely to produce an unacceptable level of weighing error. Threshold values for each of these three indexes for Types I and II WIM scales are tabulated in Table 2 and Table 3, respectively. An acceptable LRI value is required for a minimum of 30 m (100 ft) prior to the chosen location.

Table 2—Roughness Index Thresholds for Type I WIM

Index	Lower Threshold, m/km [in./mi]	Upper Threshold, m/km [in./mi]
Long Range	0.5 [31.7]	2.1 [133.1]
Short Range	0.5 [31.7]	2.1 [133.1]
Peak Short Range	0.75 [47.5]	2.9 [183.7]

Table 3—Roughness Index Thresholds for Type II WIM

Index	Lower Threshold, m/km [in./mi]	Upper Threshold, m/km [in./mi]
Long Range	0.9 [57.0]	3.8 [240.8]
Short Range	1.25 [79.2]	5.7 [361.2]
Peak Short Range	1.6 [101.4]	6.6 [418.2]

4.6. *Precision and Bias*—This is a test method that produces pass or fail results. The precision of the test is related to the degree of correlation between calculated index values and errors in measured values of tandem axle and cross vehicle weights. Since these relationships exhibited some scatter in a simulation study, conservative values for index cut-off values were chosen such that there was 95 percent confidence that a scale that met the index criteria would produce levels of weighing error that meet the ASTM E 1318 standards in the study.

5. TEST METHOD TO EVALUATE THE SMOOTHNESS OF PAVEMENT TO DETERMINE THE OPTIMAL WIM SYSTEM LOCATION

5.1. *Summary of Test Method*—A test method for determining the optimal position for a WIM scale within a limited site is presented herein. The procedures are applicable for determining a precise placement of a WIM scale within the linear distance covered by a profiler record that will result in minimum short-range and long-range roughness levels. The smoothness tests require the collection of longitudinal profile data with a sampling rate of 25 mm [1 in.] (Class I) according to the procedures in ASTM E 950. Computer analysis of these profiles at varying longitudinal scale placements serves to place the WIM scale in a location that will minimize short- and long-range roughness. Comparison of these values with acceptable threshold values will indicate whether the site is suitable. To protect against very rough pavement features that are not captured by the LRI value at the scale location, inspect the value of LRI for 30 m (100 ft) upstream of the scale to ensure that it does not exceed the lower threshold over this range.

5.2. *Significance and Use*—A correlation of calculated SRI and LRI values to WIM scale error was conducted for a large-scale study of pitch-plane simulations of 3S2 vehicles. This correlation allows the indexes to be used to determine whether the WIM system pavement smoothness is sufficient to achieve weight measurements of 3S2 trucks (five-axle tractor-semi-trailers) and three-axle single-unit trucks that fall within ASTM error tolerance levels. The calculation of short- and long-range roughness indexes for each candidate scale location within a profile record may be used to determine the correct positioning of a scale to maximize its likelihood of producing acceptable levels of weighing error as outlined in Table 1.

5.3. *Test Methods*:

5.3.1. *Profile Records*—Obtain profile records of both left and right wheel paths according to the procedures outlined in ASTM E 950 Class I profilers using a 25-mm [1-in.] longitudinal sampling interval. These records shall meet the minimum requirements for vertical measurement resolution outlined in ASTM E 950 for Class I profilers and should cover the entire longitudinal extent of roadway to be considered for the WIM scale placement. Obtain a total of three records, compare the outputs for each and evaluate each for equipment-related spikes. Continue collecting profile records until the operator is satisfied that at least one error-free record has been obtained.

5.3.2. *Calculation of Indexes*—A complete description of the procedure to calculate short- and long-range smoothness indices is described in Annex A1—Computation of Profile-Based Short- and Long-Range Indexes. The procedure has been coded within the WIM Smoothness Index software available from FHWA's LTPP Product Delivery Team. This nonproprietary software performs the computations from Annex A1 with ERD text file versions of the profile records from any longitudinal profiler as inputs. Perform 'Location Selection' analysis of the WIM system pavement with the WIM Smoothness Index software. Short- and long-range as well as peak SRI values for both left and right wheel paths will be calculated and graphed for each potential WIM scale location within the record.

5.4. *Interpretation of Results*—Lower threshold values of long-range and short-range indexes are those below which a WIM site is very likely to produce an acceptable level of weighing error. Upper threshold values of these indices are those above which a WIM site is very likely to produce an unacceptable level of weighing error. Threshold values for the long- and short-range indexes for Types I and II WIM scales are tabulated in Table 2 and Table 3, respectively. A location shall be chosen that will result in acceptable index values. An acceptable LRI value is required for a minimum of 30 m [100 ft] prior to the chosen location.

5.5. *Precision and Bias*—See Section 4.6.

ANNEXES

(Mandatory Information)

A1. COMPUTATION OF PROFILE-BASED SHORT- AND LONG-RANGE INDEXES

A1.1. *Four-Pole Butterworth Filter*:

A1.1.1. A pre-filter shall be applied. An elevation profile for each wheel track is replaced with a slope profile, obtained point-by-point by subtracting adjacent elevation values and dividing by the sample interval.

A1.1.2. An ideal band-pass filter passes some range of frequencies without distortion and suppresses all other frequencies. A Butterworth filter fulfills these needs. The exclusion of very short and very long wavelengths minimizes the effects of high amplitude, short wavelength change in the profile at the edges of the spatial weighting function. It also prevents absolute elevation or grade from influencing index values by filtering very long wavelength signals. The transfer function for the frequency response for this filter can be written as:

$$P\left(s^2\Omega_h^2\right) = F\left(\left(s^2 + 2\zeta\Omega_l s + \Omega_l^2\right)\left(s^2 + 2\zeta\Omega_h s + \Omega_h^2\right)\right) \qquad (A1.1)$$

where:

$P(x)$ = input function and $F(x)$ is the filtered profile,

Ω_h = high spatial cutoff expressed as a wavelength,

Ω_l = low spatial cutoff expressed as a wavelength, and

ζ = dimensionless damping ratio, set at 0.707 for a Butterworth filter.

Replacing *s* in the theoretical transfer function with the derivative operation $sy = \frac{\partial y}{\partial x}$, the frequency response can be expressed as an equation:

$$b_2 \frac{\partial^2 P}{\partial x^2} = \frac{\partial^4 F}{\partial x^4} + a_1 \frac{\partial^3 F}{\partial x^3} + a_2 \frac{\partial^2 F}{\partial x^2} + a_3 \frac{\partial F}{\partial x} + a_4 F \qquad (A1.2)$$

where:

$$b_2 = \Omega_h^2$$

$$a_1 = 2\zeta\left(\Omega_l + \Omega_h\right)$$

$$a_2 = \Omega_l^2 + 4\zeta\Omega_l\Omega_h + \Omega_h^2$$

$$a_3 = 2\zeta\Omega_l\Omega_h\left(\Omega_l + \Omega_h\right)$$

$$a_4 = \Omega_l^2\Omega_h^2$$

or in matrix form:

$$\frac{\partial F(x)}{\partial x} = AF(x) + BP(x) \qquad (A1.3)$$

where:

$$F(x) = \begin{bmatrix} F(x) \\ \dfrac{\partial F(x)}{\partial x} \\ \dfrac{\partial^2 F(x)}{\partial x^2} \\ \dfrac{\partial^3 F(x)}{\partial x^3} \end{bmatrix}, \quad A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -a_4 & -a_3 & -a_2 & -a_1 \end{bmatrix}, \text{ and } \quad B = \begin{bmatrix} 0 \\ b_2 \\ -a_1 b_2 \\ (a_1^2 - a_2)b_2 \end{bmatrix}$$

The $F(x)$ matrix is analogous to the array of state variables of the quarter car filter that completely describes the state of the simulated system. A state transition matrix, describing the response of the system over the interval between points i–1 and I, can be used to solve the differential equations for the Butterworth filter. The response is:

$$F_i = SF_{i-1} + PP_i \qquad (A1.4)$$

S and P can be calculated:

$$S = e^{At} \qquad (A1.5)$$

and $P = A^{-1}(S - I)B$ *(A1.6)*

where:

t = time interval between profile samples,

I = 4 by 4 identity matrix.

The calculation of S requires taking e to a matrix power. This may be done through a Taylor series expansion:

$$e^{At} = I + \sum_{i=1}^{N} \frac{A^i t^i}{i!} \qquad (A1.7)$$

where:

N = number large enough to obtain the required accuracy.

To solve differential equations such as Equation A1.3, it is necessary to estimate the values of the state variables at a starting time. To initialize the Butterworth filter, the elements of the F array for I = 1 shall be set as:

$$F_1 = \left[0,\ 0,\ -\Omega_h^2 (p_{L_0/\Delta} - p_1) / L_0,\ 2\zeta\Omega_h^2 (\Omega_h + \Omega_l)(p_{L_0/\Delta} - p_1) / L_0 \right] \qquad (A1.8)$$

where:

$p_{L_0/\Delta}$ = the elevation point that appears at the initialization length,

L_0 = the initialization length,

Δ = the interval between profile samples, and

p_1 = the first profile elevation point.

A2. SPATIAL WEIGHTING OF THE FILTERED SIGNALS

A2.1. A ‘box’ spatial weighting function is applied to the band-pass filter output. Such a function has a value of unity within its boundaries and zero outside of them. The boundaries of this function will be set at the values tabulated in Table A2.1. This weighting function shall be applied after the filter, meaning that the filter response rather than the profile is weighted. The result is that profile features outside the weighting function window can influence the index.

Table A2.1—Weighting Function Boundaries

	Preceding Scale Location	Beyond Scale Location
Short-Range Index	3.0 m [10 ft]	0.3 m [1 ft]
Long-Range Index	25.0 m [82.0 ft]	3.0 m [10 ft]

A3. AVERAGE-RECTIFIED INDEX ACCUMULATION

A3.1. Following the application of a weighting function, individual SRI and LRI values are to be calculated by accumulating over the range of weighting function boundaries.

$$\text{Index} = \left[\frac{1}{N_2 - N_1 + 1} \sum_{i=N_1}^{N_2} abs(F_i \bullet W_i)^P \right]^{1/P} \qquad (A3.1)$$

where:

F = filtered profile,

N_1 = sample number of the first spatial weighting function boundary,

N_2 = sample number of the second spatial weighting function boundary,

W = weighting function, and

P = accumulator exponent (set to 1 for average-rectified accumulation).

Standard Practice for

Quantifying Cracks in Asphalt Pavement Surfaces from Collected Images Utilizing Automated Methods

AASHTO Designation: PP 67-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Quantifying Cracks in Asphalt Pavement Surfaces from Collected Images Utilizing Automated Methods

AASHTO Designation: PP 67-10

1. SCOPE

1.1 This practice outlines the procedures for quantifying cracking distress at the network level in asphalt pavement surfaces utilizing automated methods. Detailed specifications are not included for equipment, instruments, or the associated software used to process the images. According to these specifications, any equipment that can be adequately validated to meet the functionality stipulated herein is considered acceptable. The goal is to achieve a significant level of standardization, which will contribute to the production of consistent pavement condition estimates while not unduly limiting innovation.

1.2 The automation level covered by this standard involves minimal human intervention in the process. It is understood that the current level of technology requires significant human review of the automation process to provide Quality Control/Quality Assurance (QC/QA) of the results and to detect and correct outliers. It is anticipated that the required level of human intervention will decline over the next few years.

1.3 Collect the images to be processed according to PP 68.

1.4 Sampling of images from the data collection standard process is acceptable before proceeding with the analysis process in this standard. The data sample is to be large enough to provide the confidence level required by the agency. Sample size and spacing will depend on construction practices and numerous other factors that impact pavement continuity. A 100 percent sample is recommended until a sampling method can be supported by statistical analysis.

1.5 *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standards*:

- PP 68, Collecting Images of Pavement Surfaces for Distress Detection
- PP 70, Collecting the Transverse Pavement Profile

2.2 *ASTM Standard*:

- E 1656, Standard Guide for Classification of Automated Pavement Condition Survey Equipment

2.3 *Other Standard*:

- *Distress Identification Manual for the Long-Term Pavement Performance Program*, FHWA Report RD-03-031

3. TERMINOLOGY

3.1 *crack*—a fissure of the pavement material at the surface with minimum dimensions of 1-mm (0.04-in.) width and 25-mm (1-in.) length.

3.2 *crack length*—the length is measured between crack termini. If a terminus was created due to reaching the maximum length, a new crack begins at the terminus.

3.3 *crack orientation*—the angular measurement in degrees between the direction of travel and a line drawn between the ends of the crack as measured within the measurement zone of interest.

3.4 *crack position*—the coordinates of the midpoint of the crack measured perpendicular to the shoulder edge of the pavement and the longitudinal location relative to the starting collection point.

3.5 *crack terminus*—the point at which the crack width goes below and remains less than 1 mm (0.04 in.) for a 10-mm (0.4-in.) length, or the intersection with another crack, or when the maximum of 3.67 m (12 ft), is reached or the end of a summary section is reached.

3.6 *crack width*—the average gap in mm between the two edges of a crack measured at points along the gap with a minimum spacing of 3 mm (0.12 in.).

3.7 *inside wheelpath*—a longitudinal strip of pavement 0.75 m (30 in.) wide and centered 0.875 m (34 in.) from the centerline of the lane toward the adjacent lane.

3.8 *longitudinal crack*—a crack at least 0.3 m (12 in.) long and with a crack orientation between +10 and –10 degrees.

3.9 *measurement zone*—one of the five strips of pavement created by the wheelpaths and the areas between and outside the wheelpaths.

3.10 *outside wheelpath*—a longitudinal strip of pavement 0.75 m (30 in.) wide and centered 0.875 m (34 in.) from the centerline of the lane toward the shoulder.

3.11 *pattern crack*—a crack that is part of a network of cracks that form an identifiable grouping of shapes. For this practice, this includes all cracks that are not defined as transverse or longitudinal.

3.12 *summary section*—a portion of a pavement lane over which the data are summarized.

3.13 *transverse crack*—a crack at least 0.3 m (12 in.) long and with a crack orientation between 80 and 100 degrees.

4. SIGNIFICANCE AND USE

4.1 This practice outlines the procedures for quantifying cracking distress at the network level in asphalt pavement surfaces utilizing automated methods.

4.2 The level of development of the current technology requires that the collection and analysis processes be linked together. It is hoped that in the future, a standard set of images may be created by the collection equipment from a “standard pavement distress simulation package” yet to be developed and used to evaluate and control the performance of this method.

5. DATA COLLECTION

5.1 Data are collected according to PP 68.

6. DATA REDUCTION—CRACK DETECTION

6.1 The system that detects the presence of a pavement anomaly that is commonly considered a crack typically involves one or more image analysis software routines.

6.2 It is anticipated that future detection processes may involve the analysis of images of multiple characteristics to improve the reliability of the detection process.

6.3 The detection process is clearly dependent on the quality of the images to be analyzed. Currently, there is no reliable method to independently measure the performance of the collection and analysis processes. The criteria listed herein therefore represent the requirements of the total collection and analysis system. It is anticipated that a reliable method will be developed to independently establish the image quality so that, in the future, each process can be evaluated separately.

6.4 *An acceptable result of this process is a crack map in which at least*:

6.4.1 Thirty percent of the cracks less than 3 mm (0.12 in.) and 50 percent of cracks from 3 mm (0.12 in.) to less than 5 mm (0.2 in.) wide are mapped (see Note 1).

6.4.2 Eighty-five percent of the cracks 5 mm (0.2 in.) or wider are mapped (see Note 1).

6.4.3 A crack is considered mapped if at least 85 percent of its length is detected (see Note 1).

6.4.4 Utilizing images clear of distresses and without discontinuities, or pavement markings, the system should report less than 3 m (10 ft) of total false cracking length in 50 m^2 (540 ft^2) of pavement (see Note 1). The determination of this capability will be made utilizing five 0.1-km (0.06-mi) samples of various pavement types that meet the criteria.

Note 1—These values are the estimates of a panel of experts. Ongoing research and equipment developments will better define these values over the next few years. As capabilities are better defined, separate levels of performance may be established for two or three classes of equipment and software.

7. DATA ANALYSIS—CRACK CLASSIFICATION AND VALUATION

7.1 The summary section distance for cracking data is 0.1 km (0.06 mi).

7.2 Detected pattern cracks (neither longitudinal nor transverse) are separated into five measurement zones across the pavement.

7.2.1 Zone 1 is between the inside wheelpath and the lane edge at the adjacent lane.

7.2.2 Zone 2 is the inside wheelpath.

7.2.3 Zone 3 is the space between the wheelpaths.

7.2.4 Zone 4 is the outside wheelpath.

7.2.5 Zone 5 is between the outside wheelpath and the lane edge at the shoulder.

7.3 *Pattern Cracks Will Be Summarized by*:

7.3.1 The sum of the lengths in meters (feet) of all pattern cracks in the summary section shall be the extent of pattern cracking for each zone within the section.

7.3.2 The average width in millimeters (inches) of all pattern cracks in the summary section shall be the severity of pattern cracking for each zone within the section.

7.4 *Longitudinal Cracks Will Be Summarized by*:

7.4.1 The sum of the lengths in meters (feet) of all longitudinal cracks in the summary section shall be the extent of longitudinal cracking for each zone within the section.

7.4.2 The average width in millimeters (inches) of all longitudinal cracks within the summary section shall be the severity of longitudinal cracking for each zone within the section.

7.5 *Transverse Cracks Will Be Summarized by*:

7.5.1 The sum of the lengths in meters (feet) of all the transverse cracks in the summary section shall be the extent of transverse cracking in each zone within the section.

7.5.2 The average width in millimeters (inches) of all transverse cracks within the summary section shall be the severity of transverse cracking in each zone within the section.

7.6 Detected cracks greater than 25 mm (1 in.) wide may reflect that a narrower crack is present and was sealed. Since current technology cannot separate these conditions, it is recommended that the system flag these occurrences for technician analysis. This analysis can be supported by input from the data collection operator by flagging when crack sealing is present.

8. DATA REPORTING

8.1 The calculated extent of each crack category (Zones 1–5 pattern, Zones 1–5 transverse, and Zones 1–5 longitudinal) in meters (feet) shall be the reported extent value for each category.

8.2 The calculated severity of each category in millimeters (inches) shall be the reported severity value for that category.

Note 2—Therefore, each summary section will have 30 values that characterize the cracking contained therein.

8.3 Each of these values may be first normalized to a scale of 0 to 10 with 10 being the most severe. Those with a value equal to or exceeding the average value of the worst (highest extent and severity values) 10 percent of the historical, agency-wide population for the past 10 years would get a 10 and the remainder values linearly transferred to the normalized scale. The normalized values may then be combined in various ways to provide a reduced data set for reporting (a) more general cracking index(es) for each section at the agency's discretion.

Note 3—In this proposed normalization method, the resulting normalized values would get more sensitive to the amount of distress as the worst 10 percent of the pavements have improved values. An effective distribution is thus maintained over the entire scale but at the expense of sacrificing absolute comparison capability. Since a 10-year average is used and system changes tend to be very slow, the shifting effect will be extremely slow and thus should not affect short-term comparisons. Also, since each system will be normalizing to itself, any attempted comparison between systems would be erroneous.

9. DATA INTERPRETATION

9.1 The agency is free to utilize the reported data as best fits its pavement management needs.

9.2 Any increase in the extent and severity of cracking in Zones 2 and 4 above that in Zone 3 is expected to typically reflect the impact of traffic loading.

9.3 Agencies are alerted that dividing the scalar extent and severity values into level categories or bins can result in erratic results. When values are near the bin limits, natural variation in the data will cause dramatic shifts in results. Such converting can be useful, however, for general comparison to previously collected data in which bin limits were used.

10. SYSTEM VALIDATION

10.1 The process of calibrating and checking the performance of the crack detection and analysis process is left to the agency. Generally, the agency should follow the manufacturer's recommendations for calibrating and verifying the performance of the process. The following considerations should be included in any program.

10.2 The interrelationship between the supplied images and the performance of the processing system is evident.

10.3 A standard set of images from the collection equipment should be created that challenge the processes with the full range of crack types, extents, and severity. The ground truth for these images is to be determined by manually surveying 100 percent of the pavement sections themselves (not their images). Manual examination of the images should only be used as a diagnostic if unsatisfactory results are obtained. These standard images can be used repeatedly until the collection process is modified, necessitating the collection of a new set.

10.4 The standard images created according to Section 10.3 should be used to verify performance of the detection and analysis processes on a routine basis. The frequency depends on the system's past performance and the risk associated with having to reprocess all data since the last check, should a failure occur.

10.5 Generally, performance can be divided into two sections: the ability to create an acceptable crack map, and the ability to properly analyze the created map.

10.6 The ability to create an acceptable map is considered the most challenging and therefore should be checked most frequently. The results of the analysis portion should correlate with trained observers reviewing the images better than 95 percent.

11. VALIDATION/ACCEPTANCE REPORT

11.1 The detection performance report should present, in tabular form, the ground truth values and the values that the automated detection process derived for each severity category listed in Section 6.4 with the percent of success. It should also report the length of false cracks detected per each 50 m^2 (540 ft^2) of pavement.

11.2 The analysis performance report should compare the values in each crack reporting category with the values derived by trained observers utilizing the crack map generated by the automated detection process. The test sections should be the same ones used for the verification of the analysis process.

12. CHECKING THE PERFORMANCE

12.1 A recommended check of the performance of the entire crack collection, detection, and analysis process is to routinely process the data from one or more validation sites. The validation sites should represent most of the data collection variables that the system is expected to encounter during routine data collection. Results are then compared for reasonableness with previous runs. A typical implementation of this process would involve 5 km (3 mi) of collected data and be performed monthly.

Washington, D.C. 20001

Standard Practice for

Collecting Images of Pavement Surfaces for Distress Detection

AASHTO Designation: PP 68-10

1. SCOPE

1.1 This practice outlines the procedures for collecting images of pavement surfaces utilizing automated methods for the purpose of distress detection for both network- and project-level analysis. Detailed specifications are not included for equipment or instruments used to collect the images. According to this standard, any equipment that can be adequately validated to meet the functionality stipulated herein is considered acceptable. The goal is to achieve a significant level of standardization that will contribute to the production of consistent pavement condition estimates while not unduly limiting innovation.

1.2 The images are to be collected utilizing a platform traveling at or near the prevailing highway speed.

1.3 The data collected should cover the entire driven lane in the travel direction.

1.4 *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- PP 67, Quantifying Cracks in Asphalt Pavement Surfaces from Collected Images Utilizing Automated Methods

2.2 *ASTM Standard*:

- E 1656, Standard Guide for Classification of Automated Pavement Condition Survey Equipment

2.3 *Other Standard*:

- *Distress Identification Manual for the Long-Term Pavement Performance Program*, FHWA Report RD-03-031

3. TERMINOLOGY

3.1 *crack*—a fissure of the pavement material at the surface with minimum dimensions of 1 mm (0.04 in.) width and 25 mm (1 in.) length.

3.2 *crack width*—the average gap in millimeters (inches) between the two edges of a crack measured at points along the gap with a minimum spacing between the measurement points of 4 mm (0.16 in.).

3.3 *pavement distress*—external indications of pavement defects or deterioration.

3.4 *pavement image*—a presentation of the pavement that describes a characteristic (gray scale, color, temperature, elevation, etc.) of a matrix of points (pixels) on the pavement.

4. SIGNIFICANCE AND USE

4.1 This practice outlines the procedures for collecting images of pavement surfaces utilizing automated methods for the purpose of distress detection. Its purpose is to produce consistent data collection.

4.2 It is recognized that the requirements for the collected image(s) listed below are linked to the capability of the associated distress detection system. This linkage is seen as necessary due to the current immaturity of the technology. It is hoped that future developments will provide for a more objective method of measuring performance that is independent of the detection system and easier to implement. There are methods to determine certain limited aspects of the collection processes such as the ability to collect images of 1-, 2-, 4-, 7-, and 10-mm (0.04-, 0.08-, 0.16-, 0.28-, and 0.4-in.) diameter rods placed on the pavement at various angles and positions. These processes can be particularly helpful in determining whether there have been any major changes in equipment performance.

5. DATA COLLECTION

5.1 *General Guidelines*—Each agency shall designate the lane(s) and direction(s) of travel to be surveyed or rated based on sound engineering principles and management needs within the agency. The following guidelines are recommended as minimums to provide a necessary database and for long-term uniformity.

5.2 *Survey*:

5.2.1 Reported images at least 4.0 m (13 ft) wide. Preferably, the images should be 4.25 m (14 ft) wide to include an additional 250 mm (10 in.) on the shoulder side so that pavement edge distress beyond the marking can be captured. Typically, vehicle wander requires that images at least 300 mm (12 in.) wider than the required image width be collected in order to report full width data. Data beyond the required image width may be discarded.

5.2.2 Image length in the travel direction shall be not greater than 100 m (325 ft).

5.2.3 The lanes for which the data are collected will depend on final use. Typically, network data are collected in the outside travel lane, and project-level collection covers all lanes.

5.2.4 For network data collection, it is desirable to collect the data in the same travel direction on each cycle.

5.3 *Pavement Image*:

5.3.1 The images must provide sufficient difference among data points representing distressed and nondistressed areas that subsequent distress detection techniques can delineate a minimum of 30 percent of all cracks under 3 mm (0.12 in.), 50 percent of all cracks present from 3 mm (0.12 in.) and under 5 mm (0.2 in.) wide and 85 percent of all cracks 5 mm (0.2 in.) wide or wider regardless of orientation or type (see Note 1). The determination of this capability will be made utilizing five 0.1 km (0.06 mi) samples containing an average of at least ten such cracks per sample.

5.3.2 The images should be sufficiently clear of erroneous differences in data points that a section of pavement without distress, discontinuities, or pavement markings that less than 3 m (10 ft) of total false cracking length is detected in 50 m^2 (540 ft^2) of pavement (see Note 1). The determination of this capability will be made utilizing five 0.1 km (0.06 mi) samples of various types that meet the criteria.

Note 1—These values are the estimates of a panel of experts. Ongoing research and equipment developments will better define these values over the next few years. As capabilities are better defined, separate levels of performance may be established for two or three classes of equipment.

5.3.3 Detected average crack width for each crack detected in Section 5.3.2 must be within 20 percent or 1 mm (0.04 in.), whichever is larger, of the actual width with at least 85 percent confidence.

5.3.4 Pavement images may be visible or infrared video that is either illuminated or passive. It may also be a dimensional map, or any combination of technologies that achieves sufficient distress detection reliability stated in Section 5.3.

6. DATA REPORTING

6.1 The location (latitude and longitude) of the first shoulder side data point of each image should be reported as a minimum, along with a unique image identifier.

6.2 The image scale should be equal in both directions and the value reported.

6.3 Other useful comment data that can affect image analysis, such as the presence of crack seal, railroad tracks, or excessive pavement marking, should be reported with the image.

7. SYSTEM VALIDATION

7.1 The process of calibrating and checking the performance of the measurement equipment is left to the agency. Generally, the agency should follow the manufacturer's recommendations for calibrating and verifying the performance of the equipment. The following considerations should be included in any program.

7.1.1 Location accuracy:

7.1.1.1 Distance measuring instrument accuracy;

7.1.1.2 Latitude–longitude accuracy.

7.1.2 Crack width and length in all orientations.

7.1.3 Crack delineation (sensitivity to the characteristic(s) that define(s) a fissure).

7.1.4 Minimum resolution vs. delineation level.

7.1.5 Minimum resolution vs. crack angle.

7.1.6 System platform stability and environmental impacts (moisture/wind/temperature):

7.1.6.1 Performance at various sun angles and intensities;

7.1.6.2 Performance at various speeds;

7.1.6.3 Performance at various vehicle attitudes and distances relative to the pavement;

7.1.6.4 Performance at various humidity and temperature levels;

7.1.6.5 Performance at different wind conditions;

7.1.6.6 Performance under various lighting conditions;

7.1.6.7 Resolution versus position of cracks due to optical distortion.

7.2 Ground truth for system calibration and verification shall be the close physical examination of the pavement surface by trained technicians with measurement instruments during a lane closure.

7.3 *Validation/Acceptance Report*:

7.3.1 The ground truth report is a crack map depicting each crack in the section and its unique identifier. Included with the map is a table listing the crack identifiers along with the location, length, and average width of each crack in each summary section.

7.3.2 The validation report will tabulate the cracks from the ground truth report into severity categories based on average width and present a comparison to those detected by the automated system in each category. It will also present the length of false cracking reported by the automated system.

7.4 The operator and driver (optional) are critical components of the total measurement system. They must be trained in equipment operation, including instrument failure detection and system management. Smooth, precise operation of the instrument platform is necessary for optimum results.

7.5 *Quality Control/Quality Assurance (QC/QA)*:

7.5.1 The formal calibration and performance verification program may be supplemented with a validation program in which the equipment traverses defined portion(s) of pavement on a regular basis. The validation site should represent most of the data collection variables that the system is expected to encounter during routine data collection. Results are then compared for reasonableness with previous runs. A typical implementation of this process would involve 5 km (3 mi) of data collection and be performed monthly.

8. KEYWORDS

8.1 Asphalt pavement surface; automated data collection; pavement distress; pavement images; pavement management.

Standard Practice for

Determining Pavement Deformation Parameters and Cross Slope from Collected Transverse Profiles

AASHTO Designation: PP 69-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Determining Pavement Deformation Parameters and Cross Slope from Collected Transverse Profiles

AASHTO Designation: PP 69-10

1. SCOPE

1.1 This practice outlines a method for deriving pavement deformation parameters such as rut depth and cross-slope in pavement surfaces utilizing a transverse profile. Detailed specifications are not included for equipment or software used to make the calculations. According to this standard, any approach that can be adequately validated to meet the functionality stipulated herein is considered acceptable. The goal is to achieve a significant level of standardization that will contribute to the production of consistent pavement condition estimates without unduly restricting innovative methods.

1.2 The data will typically be processed utilizing a collection of algorithms in a computer.

1.3 *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCE DOCUMENTS

2.1 *AASHTO Standard*:

- PP 70, Collecting the Transverse Pavement Profile

2.2 *ASTM Standard*:

- E 1656, Standard Guide for Classification of Automated Pavement Condition Survey Equipment

2.3 *Other Standard*:

- *Distress Identification Manual for the Long-Term Pavement Performance Program*, FHWA Report RD-03-031

3. TERMINOLOGY

3.1 *Cross-slope*—the average transverse slope of the pavement surface expressed in percent.

3.2 *inside wheelpath*—a longitudinal strip of pavement 0.75 m (30 in.) wide and centered 0.875 m (35 in.) from the centerline of the lane toward the adjacent lane.

3.3 *lane*—the traveled surface between the inside edges of the pavement markings or, in the absence of markings, an equivalent portion of the pavement surface.

3.4 *outside wheelpath*—a longitudinal strip of pavement 0.75 m (30 in.) wide and centered 0.875 m (35 in.) from the centerline of the lane toward the shoulder.

3.5 *percent deformation*—the difference between the straight-line length and the profile length of a section of pavement divided by the straight-line length multiplied by 100.

3.6 *rut*—a broad longitudinal depression in the wheelpath of the pavement surface with a depth of at least 2 mm (0.080 in.), a width of at least 0.3 m (1.0 ft), and with a longitudinal length of at least 30 m (100 ft).

3.7 *summary section*—a longitudinal length of a pavement lane over which the data are summarized.

3.8 *transverse profile*—the vertical deviations of the pavement surface from a horizontal reference perpendicular to the lane direction.

3.9 *lane center*—a location halfway between the inside edges of the pavement edge markings. If no markings are present, a location 20 percent of the total pavement width from the pavement middle on two-lane roads and a location at the middle of the road on one-lane roads.

4. SIGNIFICANCE AND USE

4.1 The method outlines a set of procedures to calculate several measures of pavement deformation related to the transverse profile. The adoption of these procedures will help produce consistent data for pavement analysis.

4.2 This method reflects a balance between extreme calculation complexity and resultant accuracy. It is not expected to give the correct values for each individual deformation condition but to provide data that, taken in aggregate, will provide an accurate picture of the deformation involved. Likewise, there will be unusual transverse contours that will not calculate correctly. It is expected, however, that their occurrence will be minimal.

5. DATA COLLECTION

5.1 Typically, the transverse profile is to be collected according to PP 70. Other collection protocols may be followed if the data requirements of PP 70 are met or exceeded.

6. DATA REDUCTION

6.1 All calculations are made for each transverse profile reported. For network-level data, the processed profiles should not be more than 3 m (10 ft) apart and for project level, no farther apart than 0.5 m (1.5 ft).

6.2 The raw transverse profile data should be processed to first remove outlier values, and then to smooth the data. An example of smoothing involves the application of an approximately 50-mm (2-in.) moving average filter. The resultant profile is used for all subsequent calculations.

6.3 A system should be established to determine the lane location and width within each profile and correlate this information with the profile data.

6.4 *Establish the Cross-Slope*:

6.4.1 Utilizing the lane width and location from Section 6.3, determine the middle of the lane and locate the associated middle data point in the profile.

6.4.2 Determine the average elevation for each half lane.

6.4.3 The percent cross-slope is the difference in the average elevations divided by one-half the lane width multiplied by 100.

6.5 *Calculate Percent Deformations*:

6.5.1 Establish edge-points for the portion of the profile under consideration (see Section 3.3) by averaging the three closest elevation points and calculate the straight-line distance between them.

6.5.2 Add the section length of all the segments between the two edge points to approximate the profile length.

6.5.3 Subtract the straight-line length from the profile length and divide the result by the straight-line length and multiply by 100.

6.5.4 Potentially useful deformation portions for reporting would be: total lane, inside half, outside half, and middle third.

6.5.5 Deformation criteria can be used to select profiles for more detailed analysis, such as water entrapment or cross-sectional area.

6.6 *Determine Five Key Data Zones in the Lane*:

6.6.1 Define the lane edge utilizing lane pavement marks, construction history, or other means, if not already defined during collection.

6.6.2 Locate and determine values at five spots across the lane.

6.6.2.1 *Spot 1 is the lane center elevation*—Its elevation is the average of the elevation data points measured in the center 75 mm (3 in.) of the pavement lane. Its location is the center of the lane.

6.6.2.2 *Spot 2 is the inside wheelpath elevation*—Its elevation is the average of the elevation data points in the lowest 10 percent of the inside wheelpath. Its location is the midpoint of the selected points.

6.6.2.3 *Spot 3 is the inside edge elevation*—Its elevation is the average of the elevation data points within 100 mm (4 in.) of the inside pavement edge. Its location is 50 mm (2 in.) from the inside lane edge.

6.6.2.4 *Spot 4 is the outside wheelpath elevation*—Its elevation is the average of the elevation data points in the lowest 10 percent of the wheelpath. Its location is the midpoint of the selected points.

6.6.2.5 *Spot 5 is the shoulder elevation*—Its elevation is the average of the elevation data points within 100 mm (4 in.) of the outside pavement edge. Its location is 50 mm (2 in.) from the outside pavement edge.

6.7 *Calculate Rut Depth*:

6.7.1 Convert the percent cross-slope to an angle.

6.7.2 Rotate the profile about spot 3 by the angle above, thus leveling the profile.

6.7.3 Shift the profile so that the value of spot 3 is zero.

6.7.4 Proceed to center depression rut depth calculation if the value of spot 1 is more than 5 mm (0.2 in.) below the average of spots 2 and 4.

6.7.5 Normal rut depth calculation:

6.7.5.1 Rotate the profile about spot 3 until spot 1 is 0. The revised absolute value of spot 2 is the depth of the inside rut.

6.7.5.2 Rotate the lane half between spots 1 and 5 about spot 1 until spot 5 is zero. The revised absolute value of spot 4 is the depth of the outside rut.

6.7.6 Center depression rut depth calculation:

6.7.6.1 Rotate the profile about spot 3 until spot 5 is zero. The revised absolute value of spot 1 is the depth of the center depression.

6.8 *Calculate Rut Cross-Sectional Area*:

6.8.1 After completing the step in Section 6.7.5.1, scan the profile in both directions from spot 2 until three values equal to or greater than zero are reached, and record the location of the first one encountered in each direction. These locations are the rut edges.

6.8.2 The area can be approximated by adding all the elevation values between the edges and multiplying the sum by the data point interval.

6.8.3 Repeat the same process around spot 4 after completing the step in Section 6.7.5.2.

6.8.4 For center depressed pavements, the same process can be applied around spot 1.

6.9 *Calculate Water Entrapment Depth*:

6.9.1 Further smooth the profile with a 200-mm (8-in.) moving average filter.

6.9.2 For positive cross-slope (spot 5 filtered elevation less than spot 3) and zero cross slopes, scan the profile from spot 3 toward spot 5 for locations in which a filtered elevation is not equal to or at a lower filtered elevation than any previous filtered elevation plus 2 mm (0.08 in.).

6.9.3 Should such a point be encountered, continue scanning until three sequential filtered elevations that are lower than their predecessor are encountered. Take the filtered elevation at the highest point of the three (the lip) and subtract the lowest filtered elevation previously encountered. The difference is the water entrapment depth of the discovered depression. The location of the lowest point should also be recorded.

6.9.4 Beginning at the lip found in Section 6.9.3, continue scanning until the profile is completed. (It is quite likely to have multiple water entrapment depths encountered.) They can be sorted by location to determine their relationship to the wheelpaths.

6.9.5 For negative cross slopes (spot 3 filtered elevation less than spot 5), the profiles are scanned from spot 5 toward spot 3 in a similar fashion.

7. DATA REPORTING

7.1 *For network collection, each summary section shall be 10 m (33 ft) and have reported*:

7.1.1 The average cross-slope percentage;

7.1.2 The average rut depth for each wheelpath (normal or center) in millimeters (inches);

7.1.3 The maximum rut depth for each wheelpath in millimeters (inches).

7.2 For project level activity, each summary section shall be 2 m (7 ft) and have reported:

7.2.1 The items in Section 7.1 over the shorter summary section of the project level collection;

7.2.2 The water entrapment depth for each third of the lane width averaged over the profiles in the section; and

7.2.3 Average rut cross sectional area in square meters (square feet).

8. DATA INTERPRETATION

8.1 The agency is free to utilize the reported data as best fits its pavement management needs.

8.2 Agencies are alerted that dividing the scalar depth and percentage indexes into level categories or bins can result in erratic results. When values are near the bin limits, natural variation in the data will cause dramatic shifts in results. Such converting can be useful, however, for general comparison to previously collected data in which bin limits were used.

9. SYSTEM VALIDATION

9.1 The process of checking the performance of the analysis process is left to the agency. Generally, the agency should follow the manufacturer's recommendations for verifying its performance. The following considerations should be included in any program.

9.1.1 Multiple transverse profiles that reflect the conditions encountered in the real data collection world. These should include the profiles collected as part of the equipment verification process.

9.1.2 It is planned that a standard set of profiles will eventually be developed to verify the performance and highlight the limitations of the processing method.

10. KEYWORDS

10.1 Asphalt pavement surface; automated data collection; cross-slope; pavement management; rut.

Standard Practice for

Collecting the Transverse Pavement Profile

AASHTO Designation: PP 70-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Collecting the Transverse Pavement Profile

AASHTO Designation: PP 70-10

1. SCOPE

1.1 This practice outlines a method for collecting pavement transverse profile, including its relationship to a level horizontal reference in pavement surfaces utilizing automated measurement devices. The profile can subsequently be used to quantify cross-slope and pavement distresses such as transverse deformation, rut characteristics, water entrapment, or edge drop-off. Detailed specifications are not included for equipment or instruments used to make the measurements. Equipment that can be adequately validated to meet the functionality stipulated herein is considered acceptable. The goal is to achieve a standardized data set that supports a wide variety of interpretation methods to characterize pavement transverse profile characteristics to capture properties of engineering significance, without unduly restricting innovative methods.

1.2 This standard addresses data collection utilizing a measurement device traveling at or near the posted speed limit.

1.3 *This practice does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations related to and prior to its use.*

2. REFERENCED DOCUMENTS

2.1 *AASHTO Standard*:

- PP 69, Determining Pavement Deformation Parameters and Cross Slope from Collected Transverse Profiles

2.2 *ASTM Standard*:

- E 1656, Standard Guide for Classification of Automated Pavement Condition Survey Equipment

2.3 *Other Standard*:

- *Distress Identification Manual for the Long-Term Pavement Performance Program*, FHWA Report RD-03-031

3. TERMINOLOGY

3.1 *report interval*—the travel distance between the reported data.

3.2 *transverse profile*—vertical deviations of the pavement surface from a level horizontal reference perpendicular to the lane direction of travel.

3.3 *transverse measurement width*—distance between the first and last measurement point in the transverse profile.

3.4 *vertical measurement resolution*—the smallest distance of measurement in the vertical axis stored by the measure device.

3.5 *vertical measurement accuracy*—the difference between the vertical distance reported by the measuring device and a standard reference measurement.

4. SIGNIFICANCE AND USE

4.1 This standard provides guidelines for collecting transverse pavement profile for the subsequent extraction of selected pavement characteristics such as rut, cross-slope, deformation, and edge drop-off.

4.2 Two data reporting intervals are to be selected based on the level of detail required in the subsequent analysis. The longer interval is typical of network data collection while the shorter is more often related to project-level data acquisition.

5. DATA COLLECTION

5.1 *General Guidelines*—Each agency shall designate the lane(s) and direction(s) of travel to be surveyed or rated based on sound engineering principles and management needs within the agency. The following guidelines are recommended as minimums to provide a necessary database and for long-term uniformity.

5.2 The report interval between collected transverse profiles should not exceed 3.0 m (10 ft) for network-level collection and 0.5 m (1.5 ft) for project-level collection.

5.3 For network-level collection, at least one direction should be surveyed on undivided roads and both directions on divided highways. On undivided roads, measurements on the side carrying the heaviest truck loads are desired, when this knowledge is available in advance of the survey.

5.4 It is desirable to survey the same direction of travel and the same lane during subsequent survey cycles.

5.5 The transverse profile shall have a minimum width of 4.0 m (13 ft) for detecting distresses in the lane (between the longitudinal lane markings, when present) and 4.3 m (14 ft) if interpretation of edge drop-off is desired. The extra width should be on the shoulder side of the lane, beyond the edge marking. These widths include 400 mm (16 in.) beyond the normal requirements to account for vehicle wander. Data measured outside the location of interest may be discarded before reporting if a lane identification algorithm is employed at the collection stage.

6. DATA REQUIREMENTS

6.1 The transverse profile shall have data points with separation of less than or equal to 10 mm (0.4 in.).

6.2 Vertical measurement resolution shall be less than or equal to 1 mm (0.04 in.).

6.3 *Vertical measurement accuracy shall be less than or equal to*:

6.3.1 3 mm (0.12 in.) relative to the average elevation of that same profile;

6.3.2 5 mm (0.20 in.) relative to true level horizontal reference.

6.4 The profile shall be measured along a transverse line that deviates less than 10 degrees perpendicular to the lane centerline.

7. SYSTEM VALIDATION

7.1 The process of calibrating and checking the performance of the measurement equipment is the responsibility of the agency. Agencies should evaluate and confirm the manufacturer's recommendations for calibrating and verifying the performance of the equipment relative to their intended data use.

7.2 *Measurement System Elements to Be Validated*—The following elements of the measurement system should be validated:

7.2.1 Distance measuring instrument accuracy.

7.2.2 Data point spacing.

7.2.3 Transverse measurement width.

7.2.4 Vertical measurement resolution and accuracy relative to the vehicle.

7.2.5 Vertical measurement accuracy relative to a level horizontal reference.

7.2.6 Effect of operational and environmental variables, including:

7.2.6.1 Sun angle, intensities, shadows, temperature, and precipitation on the pavement surface; and

7.2.6.2 Measurement speed variability.

7.2.7 Pavement cross-slope, vertical grade, roughness, and horizontal curvature.

7.3 Validation reference for certification is manual measurements of surveyed lane sections made by trained technicians on suitable test sections designated by the agency. Multiple 3-m (10-ft) long test sample interval sections should be employed. One manual reference transverse profile measurement is performed in each test sample interval. The manual transverse measurement interval should not exceed 25 mm (1 in.). The test sample sections should be as uniform as possible along their length to reduce differences in exact measurement location. The longitudinal measurement interval of the manual reference transverse profiles should not be more than 150 mm (6 in.). Artificially manufactured artifacts with known dimensions, such as steel plates or wires, placed through the length of the test sections, may be used to assess system resolution and accuracy. All validation reference values must be measured to a true level reference. The variability in the reference measurement process needs to be assessed. When possible, at least three repeat manual reference transverse profile measurements should be performed on at least three test sections.

7.4 *Validation/Acceptance Report*:

7.4.1 The validation reference report will include assessments from multiple transverse elevation profiles.

7.4.2 The acceptance report should tabulate the data from at least five equipment runs and the validation reference values. It should also include the results from the resolution tests performed in at least four locations across the pavement.

7.4.3 The effects of operational and environmental variables investigated in the validation.

7.5 The operator and driver are critical components of the total measurement system. They must be trained in equipment operation including instrument failure detection and system management. Smooth, precise operation of the instrument platform is necessary for optimum results.

7.6 The formal validation and performance measurements should be supplemented with a routine operational check program in which the equipment measures a standard set of test sections on a regular basis. The check sites should be representative of the pavement system being measured. Time series analyses are used to check for changes in the measurement system not caused by changes in the road being measured. A typical implementation of this system check process would involve monthly measurements on a defined set of sections where the agency has knowledge of maintenance, construction, or other activities that could change the transverse profile of the test sections.

8. KEYWORDS

8.1 Automated pavement data collection; pavement cross-slope; pavement distress; pavement edge drop-off; pavement evaluation; pavement management; pavement monitoring; pavement surface; pavement transverse profile; rut; rutting.

Standard Method of Test for

Measurement of Tire/Pavement Noise Using the On-Board Sound Intensity (OBSI) Method

AASHTO Designation: TP 76-10

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Method of Test for

Measurement of Tire/Pavement Noise Using the On-Board Sound Intensity (OBSI) Method

AASHTO Designation: TP 76-10

1. SCOPE

1.1. This test method describes the procedures for measuring tire/pavement noise using the on-board sound intensity (OBSI) method and the procedures for verification of the measurement system. The test method provides an objective measure of the acoustic power per unit area at points near the tire/pavement interface.

1.2. The OBSI measurement method described herein permits the tire/pavement sound intensity to be measured directly and allows various pavements and textures to be directly compared.

1.3. This method is expected to be subject to revision as experience increases and research results are implemented.

1.4. *This standard may involve hazardous materials, operations, and equipment. This standard does not purport to address all of the safety concerns associated with its use. It is the responsibility of the user of this standard to consult and establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use*.

2. REFERENCED DOCUMENTS

2.1. *ASTM Standards*:

- D 2240, Standard Test Method for Rubber Property—Durometer Hardness
- F 2493, Standard Specification for P225/60R16 97S Radial Standard Reference Test Tire

2.2. *ANSI Standards*:

- S1.9, Instruments for the Measurement of Sound Intensity
- S1.11, Specification for Octave-Band and Fractional-Octave-Band Analog and Digital Filters
- S1.40, American National Standard Specifications and Verification Procedures for Sound Calibrators

2.3. *IEC Standards*:

- IEC 60942, Electroacoustics—Sound Calibrators
- IEC 61043, Electroacoustics—Instruments for the Measurement of Sound Intensity—Measurement with Pairs of Pressure Sensing Microphones
- IEC 61260, Electroacoustics—Octave-Band and Fractional-Octave-Band Filters
- IEC 61672, Electroacoustics—Sound Level Meters

3. TERMINOLOGY

3.1. *on-board sound intensity (OBSI) method*—a measurement procedure to evaluate the tire/pavement noise component resulting from the interaction of an ASTM F 2493 Standard Reference Test Tire (SRTT) on a pavement surface. Sound intensity measurements are taken at defined locations near the tire/pavement interface.

3.2. *overall sound intensity level*—the A-weighted level corresponding to the sum of broadband sound intensity within the one-third octave band ranges from 400 to 5000 Hz in dB(A) with a reference value of 1×10^{-12} W/m^2. A-weighting shall conform to ANSI S1.42.

3.3. *power train noise*—the noise from the power train, including the vehicle engine, exhaust system, air intake, fans, transmission, differential, and axles.

3.4. *pressure-intensity index (PI index)*—defined by the arithmetic average of the sound pressure levels (SPL) of both microphones on the probe minus the sound intensity level, as given by the following equation:

$$PI = SPL_{\mathrm{Avg}} - SIL$$

3.5. *run*—a single measurement traverse of a test section.

3.6. *sound intensity*—the acoustic energy flowing through a unit area in a sound field in W/m^2. As such, it is a vector quantity with an associated direction of propagation.

3.7. *sound intensity level (SIL)*—the logarithmic time average of the sound intensity in dB with a reference sound intensity of 1×10^{-12} W/m^2.

3.8. *sound pressure level (SPL)*—the logarithmic time average of the sound intensity in dB with a reference sound pressure of 20 µPa.

3.9. *standard reference test tire (SRTT)*—as defined in ASTM F 2493.

3.10. *system*—for this standard, refers to the entire system used to measure the sound intensity using the on-board method. This equipment includes the matched microphone pairs, preamplifiers, cables, sound analyzers, probe holders, and associated items mounted on the test vehicle or test trailer.

3.11. *test section*—a given length of pavement over which a sound intensity measurement is made.

3.12. *tire/pavement noise*—the sound generated by the interaction of the tire with the pavement surface as it traverses a specific length of pavement.

3.13. *traffic noise*—the overall noise emitted by the vehicles running over the road being evaluated.

3.14. *vehicle noise*—the total noise from a vehicle, including a combination of noise generated by tire/road interaction (tire/pavement noise), air turbulence, and the power train.

4. SIGNIFICANCE AND USE

4.1. This test method provides an objective measure for on-board determination of sound intensity at defined points near the tire/pavement interface to quantify the noise generated at the tire/pavement interface and the acoustical performance of pavements.

4.2. This test method should not be used to replace the pass-by (wayside) method for determination of vehicle noise.

4.3. The frequency analysis of the measured sound intensity is performed using one-third octave band resolution. During measurements, the frequency range of 200 to 10 000 Hz (center frequencies of one-third octave bands) is typically included. One-third octave bands with center frequencies of 400 to 5000 Hz consistently provide repeatable results. The one-third octave band filters should conform to ANSI S1.11. Directly measured or derived A-weighted values shall be described in the report.

5. GENERAL REQUIREMENTS

5.1. This test method measures the sound intensity emitted in close proximity to the SRTT. A-weighted SILs are reported in one-third octave frequency bands along with the overall SIL.

5.2. One-third octave band levels shall be measured and reported for standardized speeds depending upon the facility type. Equipment that is used for these measurements is described in Annex A4.

6. SELECTION OF TEST SECTION

6.1. A test section shall have the same nominal material and surfacing for its length. During testing, the test tire must be positioned such that it travels entirely on the test surface. The test section shall be dry and free of debris to the extent practical.

6.2. The test section should be a tangent (straight) section of the roadway. Horizontal curves should be avoided when possible. Roadway geometry and approximate grade shall be noted.

6.3. The condition of the road should be documented and pictures included of the typical surface when possible. It is recommended that historical data of the roadway surface, if available, be provided.

6.4. Test sections should be located away from large roadside objects within 2 ft (0.6 m) of the edge of pavement. If measurements must be made with an object(s) nearby, the location of the object(s) should be documented.

7. MEASURING PROCEDURE

7.1. *Measurement Locations*—Measurements shall be made alongside the leading edge and trailing edge of the SRTT contact patch on the passenger (right-side) wheel path (see Annex A5 and Figure A5.1). Figure A5.1 includes the specified locations for the microphone probes during measurement. If measurements are taken at both the leading and trailing edge locations in the same test run, care should be taken to reduce turbulence wake effects from causing a measurable bias in the data.

7.2. *Verification*—At the beginning of the test, and following all warm-up procedures specified by the manufacturer, the overall accuracy of the sound level measurement system (including the microphones) shall be checked and recorded using an acoustic calibrator or piston phone.

7.2.1. At a minimum, verification shall be conducted no more than 1 hour before and no more than 1 hour after the measurement period. Additional verification shall be conducted during the course of the measurements so that the maximum period between verification checks does not exceed 4 hours.

7.2.2. The measurement system shall be adjusted for accuracy according to the manufacturer's instructions. The results of all measurement system accuracy checks shall be recorded in the test report. If the results of any two subsequent verification checks during the measurement period differ by more than 0.5 dB, the testing between those checks shall be considered invalid.

7.2.3. The sound calibration device shall meet Class 1 requirements of ANSI S1.40. (Note that some calibrators require correction for environmental conditions. The manufacturer's specifications should be consulted.) The microphones and calibrator shall be calibrated in accordance with the manufacturer's specifications and ANSI S1.9 and S1.40, respectively.

7.3. *Measurement Period and Averaging*—The measurement defining a test section shall be an energy average over 440 ± 10 ft (134 ± 3 m) of pavement surface. Based on the nominal test speed, the following are the test durations that shall be used to approximately correspond to this distance:

■	60 mph (96 km/h)	5.0 ± 0.1 s
■	45 mph (72 km/h)	6.7 ± 0.1 s
■	35 mph (56 km/h)	8.6 ± 0.2 s
■	25 mph (40 km/h)	12.0 ± 0.2 s

The signals shall be A-weighted prior to digitization in order to prevent overload of the recording system. If a single probe is used, SILs from multiple runs shall be arithmetically averaged for the leading and trailing edges separately. The leading and trailing edge averages shall then be averaged on an energy basis. If dual probes are used, the SILs of two probes shall be energy averaged for each run. The averages for all runs shall then be averaged together arithmetically.

7.4. *Number of Runs*—At a minimum, two runs shall be performed per probe position. If any criterion below is not satisfied with the first two runs, additional runs are required until the criterion is satisfied.

7.4.1. The standard deviation of the overall SILs between the first two runs shall be no greater than 0.6 dB(A). If needed, additional runs shall be conducted until the standard deviation of the overall SIL is no more than 0.6 dB(A).

7.4.2. The standard deviation of the SIL between the first two runs within any one-third octave band with a center frequency between 400 and 5000 Hz shall be no greater than 1.2 dB(A). If needed, additional runs shall be conducted until the standard deviation of the SIL within each one-third octave band level with a center frequency between 400 and 5000 Hz is no more than 1.2 dB(A).

7.4.3. The PI index shall be less than 5 dB in each one-third octave band with a center frequency between 400 and 5000 Hz. Any run in which this criterion is not satisfied shall be rejected and not used in any averages of the runs.

7.4.4. The direction of the sound intensity vector (sound power flow per unit area) must be positive (sound energy propagating away from the tire) for each one-third octave band with a center frequency between 400 and 5000 Hz. Any run in which this criterion is not satisfied shall be rejected and not used in any averages of the runs.

7.4.5. The coherence of sound pressure between the two microphones of the sound intensity probe shall be equal to or greater than 0.8 for each one-third octave band with a center frequency between 400 and 4000 Hz. Any run in which this criterion is not satisfied shall be rejected and not used in any averages of the runs.

7.5. *Recording Data*—The sound should be recorded for later analysis. Recording instrumentation shall meet Class 1 requirements of ANSI S1.9.

7.6. *Compromised Data*—Data from measurements that are obviously influenced by any other source or that were recorded improperly shall be discarded.

7.7. *Air Density Parameter*—Measures shall be taken to accommodate the actual air density during measurement as part of the fundamental sound intensity calculation. Ideally, the manufacturer's documentation should be consulted for how to include this parameter. Alternatively, the sound intensity values can be measured with an assumed/programmed air density of 0.0755 lb/ft^3 (1.21 kg/m^3). A manual correction can then subsequently be made to the levels as follows:

$$\text{SIL Corrected (dB)} = \text{SIL Measured (dB)} + 10 \times [\text{Log}_{10}\,(0.0755\ \text{lb/ ft}^3) - \text{Log}_{10}\,(\text{actual air density during measurement in lb/ft}^3)]$$

$$(\text{SIL Corrected (dB)} = \text{SIL Measured (dB)} + 10 \times [\text{Log}_{10}\,(1.21\ \text{kg/m}^3) - \text{Log}_{10}\,(\text{actual air density during measurement in kg/m}^3)])$$

If not measured directly, air density can be estimated using measurements of ambient air temperature and barometric pressure.

7.8. *Reporting Results*—Measured SILs shall be reported to the nearest 0.1 dB(A).

7.9. *Frequency Spectrum Measurement*—Reporting shall be done in one-third octave band frequency spectra according to ANSI S1.11.

7.10. *Test Vehicle Operating Conditions*:

7.10.1. *Test Speed Variation*—During the test, the vehicle shall travel with constant speed [±1 mph (±1.6 km/h)] over the test section in an appropriate gear setting.

7.10.2. *Standard Speed*—60 mph (96 km/h) shall be used unless conditions do not permit. If a speed other than 60 mph (96 km/h) is used, it shall be clearly designated in the reporting of all SILs. Acceptable alternative measurement speeds include 45, 35, and 25 mph (72, 56, and 40 km/h, respectively).

7.10.3. *Tested Speed*—For each test, the speed shall be measured with any instrument that provides the required accuracy of ±1 mph (±1.6 km/h).

7.10.4. *Tire Inflation*—Cold tires should be inflated to 30 ± 2 psi (207 ± 14 kPa).

7.10.5. *Tire Mounting*—The SRTT shall be used with rotation in the same direction for each test for the life of the tire.

7.10.6. *Tire Inspection*—Remove small stones from the tread grooves prior to test runs. A tire with uneven wear and damage that may affect the noise measurement shall not be used.

7.11. *Temperature Measurement*—Limitations on temperature are equipment specific, and manufacturer specifications should be followed. The temperature of the ambient air and the surface of the pavement test section should be measured at 60-minute intervals.

7.12. *Check of Moisture in Porous Surfaces*—Water in porous surfaces is known to affect measurements. For porous surfaces, procedures should be applied to verify that the pores are dry.

7.13. *Barometric Pressure*—The barometric pressure during the course of the measurements shall be recorded.

7.14. *Tire Hardness*—The hardness of the tire rubber shall be evaluated within a month of the test run using a durometer per ASTM D 2240 and ASTM F 2493.

8. REPORTED DATA

8.1. *The test report shall include the following data*:

8.1.1. Time and date of measurement;

8.1.2. Organization and operators responsible for the measurement;

8.1.3. Pavement lane in which the tests are taken;

8.1.4. Vehicle speeds tested;

8.1.5. Components of the measurement system, including serial numbers, if applicable;

8.1.6. Instrumentation used to collect speed and meteorological data;

8.1.7. Date of last equipment calibration; and

8.1.8. Location of object(s) greater than 6 in. (150 mm) in height above the pavement that are within 2 ft (0.6 m) of the edge of pavement; and

8.1.9. Most recent measurement result of tire hardness and the date it was measured.

8.2. *The following acoustical measurement information shall be reported*:

8.2.1. Measured overall SILs for each good run and the average of the good runs;

8.2.2. Measured SILs by one-third octave bands with center frequencies between 400 and 5000 Hz for each good run and the average of the good runs;

8.2.3. Verification (calibration) results from all instances before, during, and after the measurement period;

8.2.4. Run-to-run differences of levels or standard deviations, or both, for the overall SIL and one-third octave bands with center frequencies between 400 and 5000 Hz;

8.2.5. PI index, sound intensity vector direction, and coherence check results; and

8.2.6. The air density input to the analyzer, temperature, and barometric pressure inputs to the analyzer to estimate air density, and the values of temperature and barometric pressure, or both, used in the subsequent estimation of air density.

8.3. *The test report should include the following data, if recorded*:

8.3.1. Representative photo(s) or video of the surface with a texture dimension reference (e.g., coin or scale);

8.3.2. Air temperatures during the measurement period and their average;

8.3.3. Road temperatures during the measurement period and their average;

8.3.4. Observations of roadway geometry, grade, and cross-slope; and

8.3.5. Observations of roadway condition.

9. PRECISION AND BIAS

9.1. *Precision*—Repeatability of measured results. Precision means obtaining the same answer for the same conditions but does not necessarily indicate accuracy. (Not available at this time.)

9.2. *Bias*—An error trend in the data caused by procedures, equipment, or local characteristics. (Not available at this time.)

10. KEYWORDS

10.1. Close proximity; noise measurement; on-board sound intensity; pavement noise; sound intensity; tire/pavement noise.

ANNEXES

(Mandatory Information)

A1. SCOPE

A1.1 The objective of this Annex is to define the required attributes of equipment to measure tire/pavement noise using the OBSI method. This equipment uses amplitude and phase matched microphones, mounted near a test tire to measure this isolated tire/pavement noise.

A1.2 It is not the intent of this Annex to relieve the supplier from the final responsibility to provide an appropriate product for the intended function nor is it intended to specify all the design details. The objective is to provide a sufficiently detailed specification such that the function is clearly defined. It is intended to be sufficiently detailed such that the data collected from multiple systems will be substantially identical.

A2. REFERENCED DOCUMENTS

A2.1 *The following references were used or referred to in the preparation of this text*:

A2.1.1 *ASTM Standards*:

- D 2240, Standard Test Method for Rubber Property—Durometer Hardness
- F 2493, Standard Specification for P225/60R16 97S Radial Standard Reference Test Tire

A2.1.2 *ANSI Standards*:

- S1.9, Instruments for the Measurement of Sound Intensity
- S1.11, Specification for Octave-Band and Fractional-Octave-Band Analog and Digital Filters
- S1.40, American National Standard Specifications and Verification Procedures for Sound Calibrators
- S1.42, American National Standard Design Response of Weighting Networks for Acoustical Measurements

A2.1.3 *IEC Standards*:

- IEC 60942, Electroacoustics—Sound Calibrators
- IEC 61043, Electroacoustics—Instruments for the Measurement of Sound Intensity—Measurement with Pairs of Pressure Sensing Microphones
- IEC 61260, Electroacoustics—Octave-Band and Fractional-Octave-Band Filters
- IEC 61672, Electroacoustics—Sound Level Meters

A. GENERAL SYSTEM REQUIREMENTS

A3.1 *General Design*—The test vehicle may be a passenger vehicle (automobile). It is desirable that the wheel well for the test wheel be open (tire not covered on the outboard side) or an absorptive treatment be used to avoid reflections and conflict in calculating the sound intensity using the OBSI method. Trailers with test tire loading (similar to that of a passenger vehicle [850 ± 100 lb (385 ± 45 kg)]) are also possible for use but are not directly described in this methodology. If a trailer is used, the requirements noted herein must be observed. There shall be one appropriately instrumented SRTT for each test run. Pictures of typical setups are shown in Figures A5.2 through A5.5. The test tire shall be mounted on a non-driven, non-steering wheel (i.e., a wheel not directly driven by the power train or steering assembly).

A3.2 *Special Considerations*—The use of wind screens on the probes is necessary to minimize wind noise contamination in the lower frequency ranges. Wind screens shall be open-cell-structure foam, spherical, and 3.3 to 3.6 in. (84 to 91 mm) in diameter.

A3.3 *Recording Instrumentation*—A recording device is recommended but not required. If used, the quality must meet Class 1 requirements of ANSI S1.9. Methods that result in undistorted playback of recorded data are required. Digital Audio Tape (DAT) recorders that have been manufactured to meet recording industry standards are preferred because of the standardization that has occurred. Other digital recording methods may also be used if the overall sound recording characteristics are equivalent or better than those attainable with a conventional DAT recorder. (There is no standardization for other digital recording methods, and they should, therefore, be used with caution. Methods that utilize lossy data compression (e.g., MP3) must not be used.) Documentation on the recording equipment should accompany report or, alternatively, be available upon request.

A3.4 *Verification of the Test Vehicle and Measurement System*—The test vehicle and measurement system shall be checked for proper performance. This evaluation should determine if unwanted noise is occurring from the following sources:

- improperly operating vehicle,
- bearing or brake noise,
- microphone wind screen flutter, or
- equipment mount vibrations.

A3.5 *Quality Checks*—The spectral content of data collected from multiple tire/pavement combinations should be reviewed to determine if any frequency band does not appear to vary. Constant frequency band data is an indication that noise other than tire/pavement noise is present. The audio track should be carefully examined to determine if any unusual noise is present.

A4. EQUIPMENT

A4.1 *Sound Intensity Measurement System—for the OBSI method shall consist of the following*:

A4.1.1 For each sound intensity probe, two microphones shall be selected such that they comply with the Class 1 requirements of ANSI S1.9. If measurements at the leading and trailing edge are made concurrently, two probes shall be used that meet these requirements. Upon installation of the probes alongside the test tire, care must be taken to avoid unwanted turbulence and effects on the trailing set of microphones.

A4.1.2 Preamplifiers affixed to each individual microphone are required for signal amplification.

A4.1.3 Windscreens on each probe shall be used to control wind noise. The use of wind noise control devices, such as nose cones, is not necessary.

A4.1.4 A two-channel analyzer (minimum) that meets the Class 1 requirements of ANSI S1.9 shall be used.

A4.1.5 An acoustic calibrator or piston phone that meets the Class 1 requirements of ANSI S1.40 shall be used.

A4.1.6 A sound intensity calibrator or methodology as supplied by the equipment manufacturer for specific equipment should be used.

A4.1.7 Headphones should be used during measurement.

A4.1.8 Associated cabling and power supplies shall be used as necessary.

A4.1.9 *Vehicle Speed Measurement Instrumentation*—Any equipment with accuracy of ±1 mph (±1.6 km/h) may be used. Vehicle speedometers cannot be used to meet this requirement unless a verification of the accuracy is made prior to testing.

A4.1.10 *Temperature Measurement Instrumentation*—The temperature-measuring instruments for both the ambient and pavement temperatures shall have an overall accuracy of at least ±2.0°F (±1.2°C).

A4.1.11 *Frequency Analysis Instrumentation*—Equipment used must provide measurement of individual one-third octave frequency bands. The instrumentation used should meet the Class 1 requirements of ANSI S1.9.

A4.1.12 *Barometric Pressure*—The barometric pressure measuring instrument shall have an accuracy of ±0.75 in.Hg (±25 hPa).

A5. MOUNTING AND INSTALLATION REQUIREMENTS

A5.1 *Probe Position*—The sound intensity probes should be positioned as defined herein and illustrated in Figure A5.1. The point located between the two microphone diaphragms on a given probe shall have a fixed position relative to the tire, such that the horizontal distance from the plane of the nearest tire sidewall is 4.0 in. (102 mm). Exact orientation of the microphones should be as shown in Figure A5.1 at a height above ground level of 3 in. (76 mm). The spacing between the probes shall be 8.25 in. (209.6 mm), centered about the hub (4.125 in. (104.8 mm) on each side of hub). All of these positions shall have a tolerance of ±0.25 in. (±6.3 mm). Figures A5.2 through A5.5 show typical arrangements.

A5.2 *Microphone Spacing*—The pair of microphones on any sound intensity probe shall be separated in such a way that the center-to-center spacing between the two diaphragms is 0.63 ± 0.04 in. (16 ± 1 mm).

A5.3 *Positions Checks*—The microphones must be mounted in the same position for each test. All wiring associated with a probe should not be changed. The microphones on any given probe shall be parallel to each other and to the sidewall of the tire. This position can be checked at the time of installation.

A5.4 *Tire Balance and Alignment*—Proper balance and alignment of the SRTT should be verified. The camber angle and toe-in must comply with the vehicle specifications and be verified by a qualified mechanic for the specific vehicle type. During this same process, all mechanical parts such as brakes and shocks should be inspected for deterioration, improper operation, and any condition that could cause unwanted sound or vibration.

Standard Practice for

Evaluating the Engineering and Environmental Suitability of Recycled Materials

---

AASHTO Designation: PP 56-06 (2008)[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Evaluating the Engineering and Environmental Suitability of Recycled Materials

AASHTO Designation: PP 56-06 (2008)[1]

1. SCOPE

1.1. This practice is to provide a general evaluation framework for assessing the feasibility to use recycled materials in the highway environment.

1.2. This document was developed using the *Framework for Evaluating Use of Recycled Materials in the Highway Environment*.

2. GENERAL PROVISIONS

2.1. It is recommended that the *User Guidelines for Waste and Byproduct Materials in Pavement Construction* be referred to before using this practice, as many common recycled materials for highway uses have already been evaluated with this method and are documented in the User Guidelines.

2.2. AASHTO resolution PR-14-01, Use of Recycled Materials, encourages the use of recycled materials in transportation applications where engineering, economic, and environmental conditions warrant their use.

3. SUMMARY OF THE PRACTICE

3.1. The evaluation framework is illustrated in a flowchart format as shown in Figure 1. There are five steps in the framework and three screening stages. The framework provides for combining or skipping steps if it is clear that such action is appropriate. The framework also provides, as part of the stepwise evaluation process, the means to modify or beneficiate materials that do not meet criteria so that there is an opportunity to revise the application based on new data obtained during the evaluation process.

3.2. *Framework Limitations*—This document is an attempt to provide an overall comprehensive evaluation framework that decision makers can use in evaluating recycled material use in highway applications. Although much progress has been made in the development of these procedures, the complexity associated with defining evaluation procedures and criteria demands that the evaluator select the best test methods and criteria subject to local conditions and that the criteria and test methods presented be continually updated as new information is made available. The multi-disciplinary engineering and environmental efforts involved in implementing the steps outlined in the framework will require that state engineering and environmental agencies forge cooperative efforts, pooling the necessary resources to undertake the evaluation effort. Only through such cooperative efforts can the complex issues that need to be addressed receive proper attention and ensure the appropriate use of recycled materials in the highway environment.

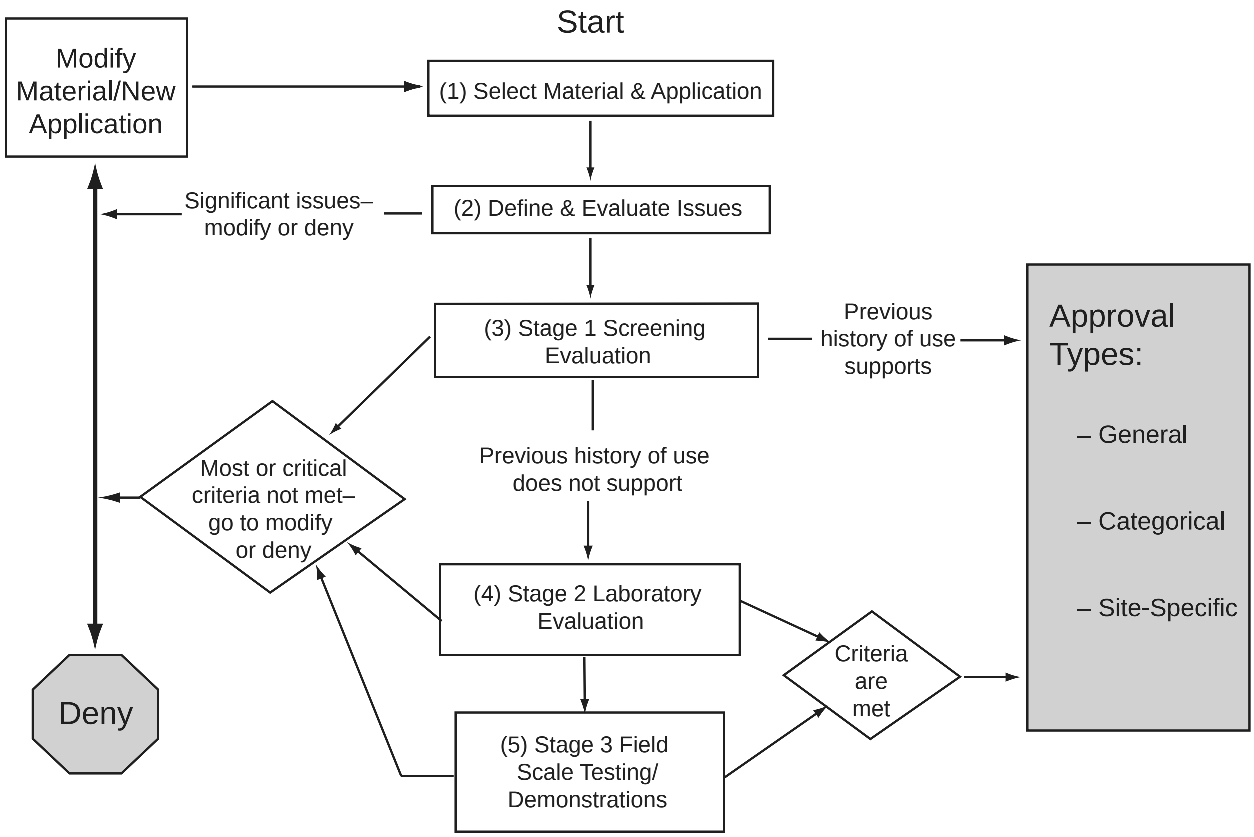

Figure 1—Evaluation Framework Flow Process

4. PROCEDURE

4.1. *Step 1—Select Material and Application*—The first step in the framework process is to select a material and a specific application (e.g., use blast furnace slag in embankment construction) that will be evaluated.

4.2. *Step 2—Define and Evaluate Issues*—The second step is to collect all relevant information that can provide input into the decision-making process. This includes, for the material and its proposed application; all related historical data; engineering and material property data; environmental, health, and safety data; implementation constraints; recycling issues; and economic issues.

The purpose of this step is to define all issues that may warrant more detailed examination and, in particular, those issues that may be problematic insofar as approval of the material for use may be concerned. A flowchart that can be used to identify the key issues in any material-application proposal is presented in Figure 2. Recommended checklists to ensure that the proper information is collected for such an evaluation are provided in Tables 1 through 6.

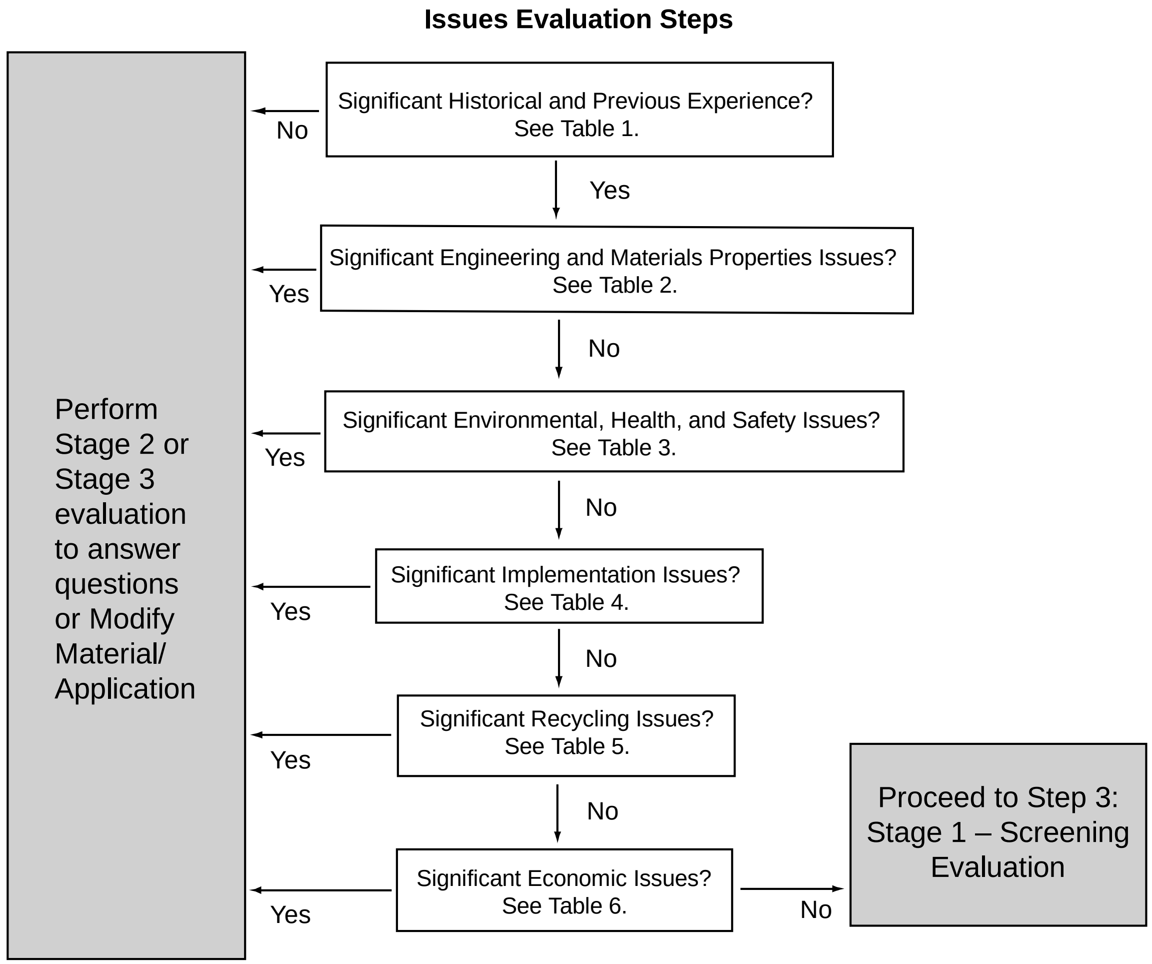

Figure 2—Issues Flowchart

Table 1—History and Previous Experience Questions

General Area	General Questions[a]		
History	1. Has the recycled material been used anywhere? If so, identify uses.	Y	N
	2. Is information available about the source of the recycled material? If so, collect it.	Y	N
	3. Has this recycled material been previously used for transportation applications? If so, identify applications.	Y	N
	4. Has this recycled material been used in geographically diverse locations? If so, identify locations.	Y	N
	5. Has this recycled material been used previously in a similar application? If so, identify location.	Y	N
	6. Has this recycled material been used in other agencies? If so, identify these agencies.	Y	N
	7. Have other agencies approved for this use? If so, identify these agencies.	Y	N
Previous Experience	1. Is information available about important prior experiences (previous use, prior objections, and similarity with other materials)? If so, collect the information.	Y	N
	2. Are there experts available to discuss prior experiences? This can include regulators, scientists, practitioners, waste generators, and associations. If so, contact the experts.	Y	N
	3. Is there any published literature about prior experiences? If so, obtain the information.	Y	N

[a] Y = Yes, N = No

Table 2—Engineering and Material Properties Questions

General Area	General Questions[a]		
Engineering	1. Is information available about the engineering properties of the recycled material? This could include information about gradation, bulk density, durability, and compaction data. If so, collect the pertinent information.	Y	N
	2. Is the recycled material appropriately characterized with respect to time-dependent engineering properties? This could include time-dependent variation in gradation, bulk density, durability, and compaction. If so, collect the pertinent information.	Y	N
	3. For the proposed application, are there appropriate engineering criteria for the product? This could include durability, grain size, and compaction requirements. If so, collect the pertinent criteria.	Y	N
	4. Is engineering information available about important prior experiences (previous use, prior performance criteria, and similarity with other materials)? If so, assemble the pertinent information.	Y	N
Material Properties	1. Is information available about the material properties of the recycled material? This could include information about loss on ignition, mineralogy, and pozzolanic activity of the waste material. If so, summarize the data.	Y	N
	2. Is the recycled material appropriately characterized with respect to time-dependent materials properties? If so, summarize the data.	Y	N
	3. For the proposed application, are there appropriate material properties criteria for the product? If so, identify the criteria.	Y	N

[a] Y = Yes, N = No

Table 3—Environmental, Health, and Safety (EHS) Properties Questions

General Area	General Questions[a]		
Environmental	1. Is information available about the environmental properties of the recycled material? This could include information about total elemental composition, total available elemental composition, and volatile and semi-volatile organics composition data. If so, collect the pertinent information.	Y	N
	2. Is the recycled material appropriately characterized with respect to time-dependent environmental properties? This could include time-dependent variation in total elemental composition, total available elemental composition, and volatile and semi-volatile organic composition. If so, collect the pertinent information.	Y	N
	3. For the proposed application, are there appropriate environmental criteria for the product? This could include leaching data, total content data, particle size, etc. If so, collect the pertinent criteria.	Y	N
	4. Is environmental information available about important prior experiences (previous use, prior performance criteria, and similarity with other materials)? If so, assemble the pertinent information.	Y	N
	5. Have there been any environmental assessments undertaken relative to the use of the proposed material? If so, summarize the information.	Y	N
Public Health	1. Are there any Materials Safety Data Sheets (MSDS) for the recycled materials? If so, collect the sheets.	Y	N
	2. Have there been health risk assessments (HRA) undertaken relative to the proposed use of the material? If so, summarize the information.	Y	N
Safety	1. Have there been prior Occupational Safety and Health Administration (OSHA) issues for generation, processing, storage, and use in previous efforts? If so, summarize the information.	Y	N

[a] Y = Yes, N = No

Table 4—Implementation Issue Questions

General Area	General Questions[a]			
Implementation	1. Are there any apparent political constraints? If so, describe them.	Y	N	U
	2. Are there any apparent regulatory constraints? If so, describe them.	Y	N	U
	3. Are there any apparent public acceptability constraints? If so, describe them.	Y	N	U

[a] Y = Yes, N = No, U = Unknown

Table 5—Recycling Issue Questions

General Area	General Questions[a]			
Recycling	1. Are there likely recycling or life-cycle issues? If so, identify them.	Y	N	U
	2. Has the recycled material or its application been reused within other areas of the highway environment? If so, identify them.	Y	N	U

[a] Y = Yes, N = No, U = Unknown

Table 6—Economic Issue Question

General Area	General Question[a]			
Economic	1. Are there any apparent economic constraints? If so, identify them.	Y	N	U

[a] Y = Yes, N = No, U = Unknown

4.3. *Step 3—Stage 1 Screening Evaluation*—The third step in the process is a Stage 1 screen. The purpose of a Stage 1 screen is to determine whether the data collected in Step 2 are sufficient to approve (or reject) the proposed application without additional study. A Stage 1 approval means that the evaluator has a high degree of certainty that there is sufficient information to justify acceptance of the proposed material and application. This typically involves demonstrating that the proposed material is sufficiently similar to reference materials, which have been used successfully, to warrant approval. A Stage 1 screen should include an assessment of all existing data pertaining to engineering data, environmental, health, and safety data, recycling issues, implementation concerns, political issues, and economic issues to ensure that the data are sufficient to permit a responsible decision. Recommended screening checklists with evaluation criteria are presented in Tables 7 through 11.

Table 7—Stage 1 Engineering Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]			
Material Source	Determine whether the proposed material is generated from similar source materials and the same process or operation as the reference material.	1. Will the quality of feedstock materials to be used in the production or generation of the proposed material be sufficiently similar to that used to produce or generate the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
		2. Will the operating conditions associated with the production or generation of the proposed material be sufficiently similar to those of the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
		3. Will the post-production operations (e.g., material processing, handling, and storage) associated with the production or generation of the proposed material be sufficiently similar to the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
Engineering Properties	Assess whether there are sufficient data to compare the engineering properties of the proposed material and reference material, and whether the respective properties are sufficiently similar to approve the proposed material for use.	1. Are appropriate engineering property data available for both the proposed and reference materials, and are the data reliable?	Y	N	U
		2. Can it be determined that the proposed and reference materials have statistically similar engineering properties that are in conformance with the specifications of the proposed application, and are they comparable?	Y	N	U
Field Performance	Determine whether the reported historical data for the reference material provided give reasonable assurance that the proposed material will provide satisfactory performance in the intended application.	1. Is there a sufficient and reliable historical performance record available?	Y	N	U
		2. Are there experienced personnel available with whom to review the results of the historical performance data, and have the above-referenced contacts provided positive feedback regarding the application?	Y	N	U
		3. Is the historical performance data of the material sufficient to warrant a Stage 1 approval?	Y	N	U

[a] Y = Yes, N = No, U = Unknown

Table 8—Stage 1 Environmental, Health, and Safety Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]			
Material Source	Determine whether the proposed material is generated from similar source materials and the same process or operation as the reference material.	1. Will the quality of feedstock materials to be used in the production or generation of the proposed material be sufficiently similar to that used to produce or generate the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
		2. Will the operating conditions associated with the production or generation of the proposed material be sufficiently similar to those of the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
		3. Will the post-production operations (e.g., material processing, handling, and storage) associated with the production or generation of the proposed material be sufficiently similar to the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y	N	U
Environmental Properties	Assess whether there are sufficient data to compare the environmental properties of the proposed material and reference material, and whether the respective properties are sufficiently similar to approve the proposed material for use.	1. Are appropriate environmental property data available for both the proposed and reference materials, and are the data reliable?	Y	N	U
		2. Can it be determined that the proposed and reference materials have statistically similar environmental properties that are in conformance with the specifications of the proposed application, and are they comparable?	Y	N	U
Field Performance	Determine whether the reported historical data provided give reasonable assurance that the proposed material will provide satisfactory performance in the intended application.	1. Is there a sufficient and reliable historical performance record available?	Y	N	U
		2. Are there personal contacts (regulators or scientists with experience) available with whom to review the results of the historical performance data, and have the above-referenced contacts provided positive feedback regarding the application?	Y	N	U
		3. Were there any specific problems or difficulties reported, and were the reported problems satisfactorily addressed in previous investigations to warrant a Stage 1 approval?	Y	N	U

[a] Y = Yes, N = No, U = Unknown

Table 9—Stage 1 Recycling Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Engineering Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the engineering quality of the product if used in a secondary application at the completion of its useful service life?	1. Could the proposed material adversely impact the production process during a post-service life application?	Y N U
		2. Could the proposed material properties be altered during either its service life or post-service life processing to such an extent that it could significantly impact the properties of the secondary material?	Y N U
Environmental Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the environmental quality of the product if used in a secondary application at the completion of its useful service life?	1. Could the proposed material adversely impact the environment (air, water, or soil quality) during post-service life processing if introduced into a secondary application?	Y N U
		2. Could the proposed material adversely impact the environment (air, water, or soil quality) during its post-service life use if introduced into a secondary application?	Y N U
		3. Could the proposed material adversely impact the environment (air, water, or soil quality) if disposed of as construction and demolition debris after its initial service life?	Y N U
Worker Health and Safety Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the worker health and safety properties of the product if used in a secondary application at the completion of its useful service life?	1. Could harmful fugitive dust or volatile gaseous emissions resulting from the use of the proposed material impact worker health or safety during post-service life processing or construction activities?	Y N U
		2. Could the use of the proposed material create a hazard to the physical safety of workers during post-service life processing or construction activities?	Y N U

[a] Y = Yes, N = No, U = Unknown

Table 10—Stage 1 Implementation Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Institutional Acceptability	Consider the probability that the regulatory community will approve and the technical community will accept and utilize the material in the proposed application.	1. Rate the degree of difficulty that can be anticipated in obtaining approval to incorporate the material-application match into existing construction specifications.	H M L
		2. Rate the degree of difficulty that can be anticipated prior to the receipt of environmental approvals from regulatory agencies.	H M L
		3. Rate the degree of reluctance that engineers might have in specifying the material in the proposed application.	H M L
		4. Rate the degree of reluctance that contractors might have in utilizing the material in the proposed application.	H M L
Political Acceptability	Consider the degree to which public officials will support or impede the proposed application.	1. Rate the degree to which political opposition could impede the application.	H M L
Public Acceptability	Assess the degree to which the public will accept the proposed material-application strategy.	1. Rate the degree to which the public opposition due to perceived environmental, health, safety, or economic impacts could impede the application.	H M L

[a] H = High, M = Medium, L = Low

Table 11—Stage 1 Economic Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]		
Material Cost	$C_{DP} = P_{RM} + C_{PR} + C_{ST} + C_{LD} + C_{TR} + P$ (*1*) where: C_{DP} = Delivered price of the proposed material, P_{RM} = Price of the raw proposed material (F.O.B.), C_{PR} = Cost of processing the material, C_{ST} = Cost of stockpiling the material, C_{LD} = Cost of loading the material, C_{TR} = Cost of transporting the material, and P = Profit.	Is $C_{DP} \leq C_{DC}$? where: C_{DC} = Delivered price of conventional material	Y	N
Installation Cost	$C_{IP} = C_{DR} + C_{DP} + C_C + T_{RP}$ (*2*) where: C_{IP} = Cost of installation using the proposed material, C_{DR} = Cost for design of application with the recovered material, C_{DP} = Delivered price of the proposed material (see Eq. 1), C_C = Cost for construction with the recovered material, and T_{RP} = Cost of testing and inspection for the proposed application.	Is $C_{IP} \leq C_{IC}$? where: C_{IC} = Cost of installation using conventional material	Y	N
Life-Cycle Cost	$A_{CP} = C_{IP} \times CRF(i,n) + C_{AM}$ (*3*) where: A_{CP} = Annual life-cycle cost using the proposed material, C_{IP} = Cost of installation using the proposed material (see Eq. 2), $CRF(i,n)$ = The capital recovery factor with an interest rate of *i* percent and an expected service life of *n* years, and C_{AM} = Annual maintenance cost.	Is $A_{CP} \leq A_{CC}$? where: A_{CC} = Annual cost using conventional material	Y	N

[a] Y = Yes, N = No

4.4. *Step 4—Stage 2 Laboratory Evaluation*:

4.4.1. A Stage 2 laboratory evaluation is recommended if a Stage 1 review determines that existing information is insufficient to either accept or reject the application.

4.4.2. The Stage 2 evaluation screen is intended to characterize (1) the engineering and materials properties and (2) the environmental, health, and safety properties of the proposed recycled material and its application product. These data can then be compared with established criteria or with the performance of reference materials using available laboratory and analytical engineering and environmental protocols.

4.4.2.1. In a Stage 2 engineering and materials properties evaluation, a laboratory testing program must be developed that will provide sufficient data to demonstrate that the proposed material is suitable for use in the proposed application. Inherent in the evaluation is that laboratory testing requires assessment of the engineering and materials performance of the proposed material as well as the engineering and materials performance of the product or the application it will be used in.

4.4.2.2. In a Stage 2 environmental, health, and safety laboratory evaluation, a laboratory testing program must be developed that will provide sufficient data to demonstrate that the proposed material is suitable for use in its intended application. Inherent in the evaluation is that laboratory testing requires assessment of the environmental performance of the proposed material as well as the environmental performance of the product.

4.4.2.3. It is important to consider engineering and materials performance and environmental performance in potential post-service life utilization scenarios. While these reuse scenarios cannot be precisely described, it is important to identify, to the extent possible, future engineering and environmental issues that may arise if the recycled material is reused.

4.4.3. To undertake a Stage 2 laboratory evaluation, it is recommended that (1) a test plan be prepared that delineates the samples to be tested and the tests to which the sample will be subjected, (2) acceptable specifications or performance criteria be identified that can be used as a means for evaluating the results of the test plan, and (3) the data be statistically evaluated to determine whether specifications are met or performance is similar to appropriate reference materials.

4.4.4. The most critical steps in a Stage 2 evaluation are development of the test plan and establishment of performance criteria. The referenced *Framework for Evaluating Use of Recycled Materials in the Highway Environment* document provides a description of engineering and environmental parameters that will typically be of interest when evaluating the use of proposed materials in specific applications and provides detailed lists of applicable laboratory test methods that can be used in the evaluation.

4.5. *Step 5—Stage 3 Field Scale Testing/Demonstrations*:

4.5.1. The Stage 3 screen, the next step, is intended to provide field-scale data on (1) engineering and materials properties and (2) environmental, health, and safety properties of the proposed recycled material and its application product. These data can then be compared with established performance criteria, with reference materials (e.g., a control section), or with appropriate standards or regulatory limits.

4.5.2. The Stage 3 field testing stage is most applicable in situations where (1) the proposed recycled material has not been used historically so there is little or no field data, (2) there is little or incomplete historical data for the recycled material and more field data are needed, or (3) the proposed recycled material is being considered for new use in applications and there is no pertinent field data. Both short-term and long-term monitoring activities may be required.

4.5.2.1. Short-term monitoring activities are designed to evaluate how the new material might affect the application during the end-product production process, such as asphalt or portland cement concrete production, and during and/or immediately after construction.

4.5.2.2. Long-term monitoring activities are designed to evaluate how the proposed application performs during the post-construction period and can involve a time period ranging from several years up to the design life of the application.

4.5.3. To undertake a Stage 3 evaluation, it is recommended that (1) a demonstration test plan be prepared that delineates the field monitoring requirements, (2) acceptable specifications or performance criteria be identified to evaluate results of the field demonstration, and (3) the data be statistically evaluated to determine whether specifications are met or performance is similar to that of appropriate reference materials. Field monitoring activities will differ, depending on the type of application being proposed. Recommended engineering and environmental field monitoring activities are presented in the “Framework” document.

4.6. *Modify Material/New Application*:

4.6.1. *Modification Points in the Flowchart*—During each step in the evaluation process, the evaluator should be cognizant of conditions that suggest that the proposed material and its intended application have or are likely to encounter problems in gaining acceptance and that a reevaluation of the proposed strategy is in order. This reevaluation can result in the withdrawal or modification of the proposed recycled material and the proposed application. This reevaluation step is reflected in the Figure 1 flowchart, where at each node in the review process, the material and/or application may be modified.

4.6.2. *Beneficiation*:

4.6.2.1. Modifications can be made to improve the engineering suitability or the environmental suitability of the proposed recycled material in the selected application. This approach is termed *beneficiation*.

4.6.2.2. Engineering modifications could include such items as (1) modifying the proposed percentage of material to be used in the application, (2) requiring additional material processing, such as screening or crushing, to remove problematic fractions, or (3) requiring the introduction of additional reagents to mitigate any anticipated problem with the application. As a simple example, if an applicant proposes to introduce 30 percent foundry sand as an aggregate substitute material into a hot mix asphalt pavement, and such a mix design is unable to meet the aggregate gradation specification of the mix, then prior to rejecting the application, it would seem reasonable to request that the applicant modify the proposed mix design to comply with the gradation specification. As an additional example, suppose it is reasonable to introduce foundry sand at levels of approximately 25 percent, but during laboratory testing, stripping tests show that the pavement might be susceptible to water damage, then it would be reasonable to suggest that anti-stripping agents be incorporated into a foundry sand mix or that additional processing occur to reduce the stripping factor present in the spent foundry sand.

4.6.2.3. Environmental modifications could include such items as (1) adding moisture conditioning for dust control, (2) using chemical fixation or stabilization technologies to reduce the availability of contaminants of concern, (3) limiting the location of the proposed application, or (4) suggesting that removal of certain components of the proposed materials (e.g., fines) be undertaken prior to use. Environmental modifications can similarly be incorporated into a review process. For example, a proposal to use unconditioned (dry) coal fly ash as an embankment material might raise some concerns during a screening process because of the potential for fugitive dust emissions during transport and placement. Conditioning (moisture addition) to control these emissions would be a reasonable modification that could be incorporated into the process. If there is additional concern regarding erosion of the embankment, then a vegetative cover could be a reasonable modification.

4.6.3. *New Applications*—If an intended application does not meet certain criteria and if the recycled material cannot be modified, then another application may need to be explored. The evaluator can explore the use of the recycled material in an alternative application. For instance, if problems are expected with the percolation leaching of a mineral processing waste in an embankment, it may be more appropriate to consider its use as an aggregate substitute in an asphalt paving application where the asphaltic material produces a monolithic product with a reduced cumulative release of constituents from monolithic leaching.

4.7. *Approval Process*:

4.7.1. *Approval Points in Flowchart*—Approval can occur at Stages 1, 2, or 3 of the evaluation process. Approval or rejection will depend on the performance of the recycled material in the proposed application compared with criteria and specifications used by the decision maker. Much of the actual approval process will require, by use of common statistical measures, that the measured engineering and environmental properties of the recycled material or the product meet these criteria or specifications.

4.7.2. *General, Categorical, and Site-Specific Approvals*—When a proposal is submitted for consideration, an evaluation to completely accept or completely reject the proposed application is not required. A number of different types of approvals can be considered. These types are referred to in this document as general, categorical, and site-specific approvals.

4.7.2.1. *General*—General approvals are approvals in which minimal, if any, conditions are imposed on the applicant. Such approvals would be used where there is an overwhelming preponderance of data and history showing that the recycled material and application can be employed without adverse engineering or environmental consequences. General approvals would be appropriate for traditional highway materials in traditional applications, such as the recycling of asphaltic pavements or portland cement concrete pavements back into new pavement construction or pavement reconstruction. It may also be used for traditional recycled material in traditional applications, such as the use of coal fly ash or ground, granulated blast furnace slag as a supplementary cementitious material in portland cement concrete pavements. Finally, in some instances, it may be used for traditional recycled materials in new applications, such as the use of coal fly ash in a flowable fill mix for backfill applications.

4.7.2.2. *Categorical*—Categorical approvals impose more restrictive limits on where and how a material may be used than for general approvals. For example, such approvals might limit the use of a recycled material to a specific environment (e.g., a defined distance above the groundwater table), or a specific section of subapplication (e.g., base course as opposed to a wearing course pavement). For example, the use of blast furnace slag as a granular base below asphalt pavement in locations that are a minimum of 61 cm (2 ft) above high groundwater would be a categorical approval. Such approvals can be used where there is sufficient historical, laboratory, or possible field data showing that the recycled material and application can be employed without adverse engineering or environmental consequences in the specific environment. Categorical approvals are appropriate for traditional recycled materials in new applications, new materials in traditional applications, or new materials in new applications.

4.7.2.3. *Site-Specific*—Site-specific approvals are one-time approvals and require a new evaluation for the next project. These types of approvals normally require field monitoring to obtain additional information to assist the decision maker in assessing the suitability of the material. Site-specific approvals are normally associated with new material use in either traditional or new applications.

5. REFERENCES

5.1. *User Guidelines for Waste and Byproduct Materials in Pavement Construction*—This document provides information about the use of 19 waste and byproduct materials in six major highway applications. Each material is described (origin, current management options, market sources, and general uses). Detailed information is also given about their use in specific highway applications (performance records, processing, requirements, engineering properties, design considerations, construction procedures, and unresolved issues). The document also lays out conceptual evaluation guidance issues (framework, environmental, and costs) and describes the six major highway applications. Dr. Warren H. Chesner of Chesner Engineering, P.C., Robert J. Collins of Robert J. Collins and Associates, and Michael H. MacKay and John Emery of John Emery Geotechnical Engineering Ltd. are the authors. This work was funded through cooperative agreement DTFH61-95-C-00035 to Chesner Engineering, P.C. from FHWA. It is also available as publication number FHWA-RD-97-148 and can be seen online at http://tfhrc.gov/hnr20/recycle/waste/begin.htm.

5.2. *Waste and Recycled Materials in the Transportation Industry NCHRP 4-21 Database*—This database contains information on 21 waste and recycled materials. Information includes photographs of the materials, general information, production and use data, engineering properties data, environmental properties data, suitable highway applications, laboratory testing, field testing, references, and points of contact. The work was sponsored by AASHTO in cooperation with the FHWA and conducted under the auspices of the National Highway Cooperative Research Program, which is administered by the Transportation Research Board of the National Research Council. The authors are Dr. Warren H. Chesner, P.E., Christopher Stein, Robert J. Collins, and Lynette Van Helden of Chesner Engineering, P.C. Supporting technical information was provided by Michael H. MacKay, P.E., of John Emery Geotechnical Engineering Ltd. The work was conducted under NCHRP contract HR4-21 to Chesner Engineering.

5.3. *Framework for Evaluating Use of Recycled Materials in the Highway Environment*—This document, a follow-on to the User Guidelines and NCHRP 4-21 projects, provides a consensus framework for state transportation and environmental regulators to evaluate the prospective use of recycled materials in the highway environment. A logical framework is provided with issues identification, preliminary screening, laboratory testing, and field testing stages. A variety of approval and material modification steps are also offered. Extensive test methods and applicable standards or criteria (both materials and environmental) are given for the laboratory and field testing stages. An Expert Review Panel, consisting of experts from the highway community and state agency personnel, helped craft the approach. The document was authored by Dr. Taylor Eighmy of the University of New Hampshire (UNH) and Dr. Warren H. Chesner of Chesner Engineering, P.C. This work was funded by cooperative agreement DTFH61-97-X-00020 to UNH from the FHWA and can be seen online at http://www.rmrc.unh.edu.

APPENDIX

(Nonmandatory Information)

X1. FRAMEWORK EXAMPLE

X1.1. Appendix X1 presents an example of the evaluation process. It provides a step-by-step application of the framework process outlined in Figure 1 and the evaluation checklists introduced in this document. It is assumed in this example that an applicant submits an application to a State DOT and that the DOT initiates a joint review of the subject application with the State environmental agency. Together, the two agencies constitute the decision maker or evaluator. A State DOT could also initiate this review without an outside applicant request.

X1.2. *Step 1—Select Material and Application*—The applicant submits an application to the State DOT to use an industrial slag as an aggregate substitute in hot mix asphalt base courses.

X1.3. *Step 2—Define and Evaluate Issues*—The State DOT evaluator notifies the State environmental regulatory agency counterpart that an application has been submitted. A meeting is set up in which the applicant is requested to provide responses to the issues evaluation checklist questions:

- Historical experience (Table X1.1)
- Engineering properties (Table X1.2)
- Environmental properties (Table X1.3)
- Implementation issues (Table X1.4)
- Recycling issues (Table X1.5)
- Economic issues (Table X1.6)

The applicant submits the completed issues evaluation checklist tables, which (for example purposes) are presented in Tables X1.1 through X1.6.

Table X1.1—History and Previous Experience Questions

General Area	General Questions[a]	
History	1. Has the recycled material been used before? If so, identify uses.	N
	2. Is information available about the source of the recycled material? If so, collect it.	Y
	3. Has this recycled material been previously used? If so, identify applications.	N
	4. Has this recycled material been used in geographically diverse locations? If so, identify locations.	N
	5. Has this recycled material been used previously in a similar application? If so, identify location.	N
	6. Has this recycled material been used in other jurisdictions? If so, identify jurisdiction.	N
	7. Have other jurisdictions granted use? If so, identify jurisdictional province.	Y
Previous Experience	1. Is information available about important prior experiences (previous use, prior objections, and similarity with other materials)? If so, collect the information.	Y
	2. Are there experts available to discuss prior experiences? This can include regulators, scientists, practitioners, waste generators, and associations. If so, contact the experts.	N
	3. Is there any published literature about prior experiences? If so, obtain the information.	Y

[a] Y = Yes, N = No

Table X1.2—Engineering and Material Properties Questions

General Area	General Questions[a]	
Engineering	1. Is information available about the engineering properties of the recycled material? This could include information about gradation, bulk density, durability, and compaction data. If so, collect the pertinent information.	Y
	2. Is the recycled material appropriately characterized with respect to time-dependent engineering properties? This could include time-dependent variation in gradation, bulk density, durability, and compaction. If so, collect the pertinent information.	N
	3. For the proposed application, are there appropriate engineering criteria for the product? This could include durability, grain size, and compaction requirements. If so, collect the pertinent criteria.	N
	4. Is engineering information available about important prior experiences (previous use, prior performance criteria, and similarity with other materials)? If so, assemble the pertinent information.	N
Material Properties	1. Is information available about the material properties of the recycled material? This could include information about loss on ignition, mineralogy, and pozzolanic activity of the waste material. If so, summarize the data.	N
	2. Is the recycled material appropriately characterized with respect to time-dependent material properties? If so, summarize the data.	N
	3. For the proposed application, are there appropriate material properties criteria for the product? If so, identify the criteria.	Y

[a] Y = Yes, N = No

Table X1.3—Environmental, Health, and Safety (EHS) Properties Questions

General Area	General Questions[a]	
Environmental	1. Is information available about the environmental properties of the recycled material? This could include information about total elemental composition, total available elemental composition, and volatile and semi-volatile organics composition data. If so, collect the pertinent information.	Y
	2. Is the recycled material appropriately characterized with respect to time-dependent environmental properties? This could include time-dependent variation in total elemental composition, total available elemental composition, and volatile and semi-volatile organic composition. If so, collect the pertinent information.	N
	3. For the proposed application, are there appropriate environmental criteria for the product? This could include leaching data, total content data, particle size, etc. If so, collect the pertinent criteria.	Y
	4. Is environmental information available about important prior experiences (previous use, prior performance criteria, similarity with other materials)? If so, assemble the pertinent information.	Y
	5. Have there been any environmental assessments undertaken relative to the use of the proposed material? If so, summarize the information?	N
Public Health	1. Are there any Materials Safety Data Sheets (MSDS) for the recycled materials? If so, collect the sheets.	N
	2. Have there been health risk assessments (HRA) undertaken relative to the proposed use of the material? If so, summarize the information.	N
Safety	1. Have there been prior OSHA issues for generation, processing, storage, and use in previous efforts? If so, summarize the information.	N

[a] Y = Yes, N = No

Table X1.4—Implementation Issues Questions

General Area	General Questions[a]	
Implementation	1. Are there any apparent political constraints? If so, describe them.	U
	2. Are there any apparent regulatory constraints? If so, describe them.	U
	3. Are there any apparent public acceptability constraints? If so, describe them.	U

[a] Y= Yes, N= No, U = Unknown

Table X1.5—Recycling Issues Questions

General Area	General Questions[a]	
Recycling	1. Are there likely recycling or life-cycle issues? If so, identify them.	U
	2. Has the recycled material or its application been reused within other areas of the highway environment? If so, identify them.	N

[a] Y= Yes, N= No, U = Unknown

Table X1.6—Economic Issue Question

General Area	General Questions[a]	
Economic	1. Are there any apparent economic constraints? If so, identify them.	N

[a] Y= Yes, N= No, U = Unknown

X1.3.1. A summary of the results of the issues evaluation checklist analysis is presented in Table X1.7. The reviewing agencies determine whether any significant issues warrant modification or dismissal of the permit request; however, the absence of adequate environmental data means that, at a minimum, a Stage 2 environmental, and perhaps health and safety, step will be necessary. A Stage 1 screen is initiated.

Table X1.7—Industrial Slag as an Aggregate Substitute in an Asphalt Base Course Issues Evaluation

Area of Evaluation	Identified Issue
Historical Experience	The industrial slag from the applicant's facility has not been previously used in any application. Similar materials from other facilities have been used as an aggregate substitute material in asphalt pavements.
Engineering Properties	The applicant has gathered a significant amount of relevant engineering and material property data.
Environmental Properties	The applicant has inadequate environmental data.
Implementation Issues	No problematic issues were identified.
Recycling Issues	No problematic issues were identified.
Economic Issues	No problematic issues were identified.

X1.4. *Step 3—Stage 1 Screening Evaluation*—The Stage 1 screen is undertaken in accordance with the checklist outlined in Section 4.3 Step 3—Stage 1 Screening Evaluation:

- Engineering properties (Table X1.2)
- Environmental properties (Table X1.3)

X1.4.1. *Stage 1 Engineering Properties Screen*—The applicant is requested to provide data to demonstrate statistically that the engineering data submitted for the slag material will be consistent with time and that the engineering properties of the slag are statistically similar to reference materials (similar material that the applicant claimed has been successfully used in the past). Table X1.8 outlines the Stage 1 engineering evaluation.

Table X1.8—Stage 1 Engineering Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Material Production	Determine whether the proposed material is generated from the same process or operation as the reference material.	1. Will the quality of feedstock materials to be used in the production or generation of the proposed material be sufficiently similar to that used to produce or generate the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y
		2. Will the operating conditions associated with the production or generation of the proposed material be sufficiently similar to that of the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y
		3. Will the post-production operations (e.g., material processing, handling, and storage) associated with the production or generation of the proposed material be sufficiently similar to the reference material so that the engineering properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	Y
Engineering Properties	Assess whether there are sufficient data to compare the engineering properties of the proposed material and reference material, and whether the respective properties are sufficiently similar to approve the proposed material for use.	1. Are appropriate engineering property data available for both the proposed and reference materials, and are the data reliable?	Y
		2. Can it be determined that the proposed and reference materials have statistically similar engineering properties that are in conformance with the specifications of the proposed application, and are they comparable?	Y
Field Performance	Determine whether the reported historical data for the reference material provided give reasonable assurance that the proposed material will provide satisfactory performance in the intended application.	1. Is there a sufficient and reliable historical performance record available?	Y
		2. Are there personal contacts (engineers with experience) available with whom to review the results of the historical performance data, and have the above-referenced contacts provided positive feedback regarding the application?	Y
		3. Is the historical performance data of the material sufficient to warrant a Stage 1 approval?	Y

[a] Y = Yes, N = No, U = Unknown

X1.4.1.1. Based on the information provided, the decision maker determines that the engineering properties of the slag will be consistent throughout the year and that the properties of the slag are statistically similar to that of the reference material.

X1.4.2. *Stage 1 Environmental, Health, and Safety Screen*—The applicant has inadequate environmental data for the industrial slag. Table X1.9 outlines the Stage 1 environmental evaluation. A Stage 2 laboratory analysis will be required.

Table X1.9—Stage 1 Environmental, Health, and Safety Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Material Source	Determine whether the proposed material is generated from the same process or operation as the reference material.	1. Will the quality of feedstock materials to be used in the production or generation of the proposed material be sufficiently similar to that used to produce or generate the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	U
		2. Will the operating conditions associated with the production or generation of the proposed material be sufficiently similar to that of the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	U
		3. Will the post-production operations (e.g., material processing, handling, and storage) associated with the production or generation of the proposed material be sufficiently similar to the reference material so that the environmental properties of the proposed material will not be significantly impacted and will still be comparable to the reference material?	U
Environmental Properties	Assess whether there are sufficient data to compare the environmental properties of the proposed material and reference material, and whether the respective properties are sufficiently similar to approve the proposed material for use.	1. Are appropriate environmental property data available for both the proposed and reference materials, and are the data reliable?	N
		2. Can it be determined that the proposed and reference materials have statistically similar environmental properties that are in conformance with the specifications of the proposed application, and are they comparable?	N
Field Performance	Determine whether the reported historical data provided give reasonable assurance that the proposed material will provide satisfactory performance in the intended application.	1. Is there a sufficient and reliable historical performance record available?	N
		2. Are there personal contacts (regulators or scientists with experience) available with whom to review the results of the historical performance data, and have the above-referenced contacts provided positive feedback regarding the application?	N
		3. Were there any specific problems or difficulties reported, and were the reported problems satisfactorily addressed in previous investigations to warrant a Stage 1 approval?	N

[a] Y = Yes, N = No, U = Unknown

X1.4.2.1. The applicant submits supporting data to assist the evaluators in completing the remaining Stage 1 evaluation, which are shown in Tables X1.10 through X1.12.

X1.4.3. *Stage 1 Recycling Evaluation*—The decision maker and applicant define the likely reuses of the recycled base course that will contain the industrial slag. The potential engineering and environmental issues are evaluated for each reuse scenario. Table X1.10 outlines the Stage 1 recycling evaluation. Although no engineering issues were identified, the absence of adequate environmental data means that recycling from an environmental perspective could not be fully assessed.

Table X1.10—Stage 1 Recycling Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Engineering Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the engineering quality of the product if used in a secondary application at the completion of its useful service life?	1. Could the proposed material adversely impact the production process during a post-service life application?	N
		2. Could the proposed material properties be altered during either its service life or post-service life processing to such an extent that it could significantly impact the properties of the secondary material?	N
Environmental Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the environmental quality of the product if used in a secondary application at the completion of its useful service life?	1. Could the proposed material adversely impact the environment (air, water, or soil quality) during post-service life processing if introduced into a secondary application?	U
		2. Could the proposed material adversely impact the environment (air, water, or soil quality) during its post-service life use if introduced into a secondary application?	U
		3. Could the proposed material adversely impact the environment (air, water, or soil quality) if disposed of as construction and demolition debris after its initial service life?	U
Worker Health and Safety Acceptability	If the proposed material is incorporated into the engineered product, could it significantly impact the worker health and safety properties of the product if used in a secondary application at the completion of its useful service life?	1. Could harmful fugitive dust or volatile gaseous emissions resulting from the use of the proposed material impact worker health or safety during post-service life processing or construction activities?	U
		2. Could the use of the proposed material create a hazard to the physical safety of workers during post-service life processing or construction activities?	U

[a] Y = Yes, N = No, U = Unknown

X1.4.4. *Stage 1 Implementation Evaluation*—The implementation screen defines potential institutional, political, and public issues that may arise from the proposed use of the industrial slag. Table X1.11 outlines the Stage 1 implementation evaluation. The absence of environmental data at the current stage of the evaluation limits the ability of the decision maker to adequately assess this issue.

Table X1.11—Stage 1 Implementation Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Institutional Acceptability	Consider the probability that the regulatory community will approve and the technical community will accept and utilize the material in the proposed application.	1. Rate the degree of difficulty that can be anticipated in obtaining approval to incorporate the material-application match into existing construction specifications.	H
		2. Rate the degree of difficulty that can be anticipated prior to the receipt of environmental approvals from regulatory agencies.	H
		3. Rate the degree of reluctance that engineers might have in specifying the material in the proposed application.	H
		4. Rate the degree of reluctance that contractors might have in utilizing the material in the proposed applications.	H
Political Acceptability	Consider the degree to which public officials will support or impede the proposed application.	1. Rate the degree to which political opposition could impede the application.	L
Public Acceptability	Assess the degree to which the public will accept the proposed material-application strategy.	1. Rate the degree to which the public opposition due to perceived environmental, health, safety, or economic impacts could impede the application.	L

[a] H = High, M = Medium, L = Low

X1.4.5. *Stage 1 Economic Evaluation*—The results of the economic screen, presented in Table X1.12, suggest that a significant economic incentive exists to utilize the material.

Table X1.12—Stage 1 Economic Screening Checklist

Parameter	Test Method	Evaluation Criteria[a]	
Material Cost	$C_{DP} = P_{RM} + C_{PR} + C_{ST} + C_{LD} + C_{TR} + P$ (*1*) where: C_{DP} = Delivered price of the proposed material, P_{RM} = Price of the raw proposed material (F.O.B.), C_{PR} = Cost of processing the material, C_{ST} = Cost of stockpiling the material, C_{LD} = Cost of loading the material, C_{TR} = Cost of transporting the material, and P = Profit.	Is $C_{DP} \leq C_{DC}$? where: C_{DC} = Delivered price of conventional material	Y
Installation Cost	$C_{IP} = C_{DR} + C_{DP} + C_C + T_{RP}$ (*2*) where: C_{IP} = Cost of installation using the proposed material, C_{DR} = Cost for design of application with the recovered material, C_{DP} = Delivered price of the proposed material (see Eq. 1), C_C = Cost for construction with the recovered material, and T_{RP} = Cost of testing and inspection for the proposed application.	Is $C_{IP} \leq C_{IC}$? where: C_{IC} = Cost of installation using conventional material	Y
Life-Cycle Cost	$A_{CP} = C_{IP} \times CRF(i,n) + C_{AM}$ (*3*) where: A_{CP} = Annual life-cycle cost using the proposed material, C_{IP} = Cost of installation using the proposed material (see Eq. 2), $CRF(i,n)$ = The capital recovery factor with an interest rate of i percent and an expected service life of n years, and C_{AM} = Annual maintenance cost.	Is $A_{CP} \leq A_{CC}$? where: A_{CC} = Annual cost using conventional material	Y

[a] Y = Yes, N = No

X1.4.6. A summary of the results of the Stage 1 screen is presented in Table X1.13. The reviewing agencies determine that the submitted engineering data are adequate.

Table X1.13—Stage 1 Screen Results

Evaluation Area	Evaluation Results
Engineering	The engineering evaluation did not identify any problematic issues. The industrial slag meets all required engineering criteria, and the production process meets required quality control criteria. No further engineering evaluation is required.
Environmental, Health, and Safety	Due to the lack of data, a Stage 1 evaluation could not be performed. A Stage 2 analysis is required.
Recycling	Due to the absence of environmental data, analysis of recycling issues could not be fully assessed.
Implementation	Due to the absence of environmental data, analysis of implementation issues could not be fully assessed.
Economic	It is economically practical to utilize the slag in the proposed application.

X1.5. *Step 4—Stage 2 Laboratory Testing*

X1.5.1. On the basis of the results of the Stage 1 screen, the decision maker prepares an environmental test plan and criteria for evaluation. Table X1.14 provides an outline of the Stage 2 environmental test plan, criteria, and results. The sequence of environmental tests presented in Table X1.14 is consistent with the environmental properties and tests outlined in Chapter 5, Table 5-2 of the "Framework" document for aggregate substitutes in bound applications.

Table X1.14—Stage 2 Environmental Testing Results

Environmental Property	Criteria	Results
Regulatory Testing of Aggregate Substitute	40 CFR, Part 261.21 40 CFR, Part 261.22 40 CFR, Part 261.23 40 CFR, Part 261.24	Nonignitable Noncorrosive Nonreactive Nontoxic
Inorganic Composition of Aggregate Substitute	Soil reference guidelines	The concentrations of arsenic and chromium were approximately one order of magnitude above the soil reference standards.
Organic Composition of Aggregate Substitute	—	Not required by decision maker since the material has undergone a high-temperature process.
Particle Size of Aggregate Substitute	—	Not required by decision maker since the material is a glassy substance and <1% of the material passes a No. 200 sieve. Fugitive dust emissions are not expected.
Mineralogical Composition of Aggregate Substitute	—	Not required by decision maker because the material has a low dusting potential and a low crystalline silica content.
Inorganic Leaching of Aggregate Substitute	U.S. EPA[a] drinking water standards	A distilled water leaching test was used to determine the inorganic leaching properties of the industrial slag. All leachate concentrations were below drinking water criteria but the upper 90% confidence limit for arsenic exceeds the criteria. A sample statistical calculation is presented in Table X1.15.
Organic Leaching of Aggregate Substitute	—	Not required by decision maker since material has undergone a high-temperature process.
Acid-Base Behavior of Aggregate Substitute	Soil reference guidelines	Results indicate increased leaching of arsenic under acidic conditions.
Product Inorganic Leaching	U.S. EPA[a] drinking water standards	Product inorganic leaching was determined using a distilled water leaching test and the TCLP[b] protocol on crushed product containing the industrial slag. All leachate concentrations were below drinking water criteria.
Product Organic Leaching	—	Not required by decision maker since the material has undergone a high-temperature process.
Product Abrasion	—	Not required by decision maker since material will be in binder course.
Product—Volatile Emissions	—	Not required by decision maker since the material has undergone a high-temperature process.

[a] United States Environmental Protection Agency

[b] Toxicity Characteristic Leaching Procedure

X1.5.2. The applicant is requested to undertake regulatory tests, inorganic composition tests, inorganic leaching tests, acid-base leach tests, and product inorganic leach tests.

X1.5.3. The results of these tests indicate that the slag is nonhazardous but contains concentrations of arsenic and chromium that were one order of magnitude higher than soil reference guidelines (cleanup guidelines). Leachate concentrations from distilled water leaching tests for inorganic constituents were all less than drinking water standards but the 90 percent confidence limit for arsenic exceeded the drinking water criterion as shown in Table X1.15. Acid-base leaching tests revealed higher arsenic concentrations in higher acid (low pH) solutions. Product testing was undertaken by preparing a design mix in which the slag was incorporated into the hot mix product. The product was subjected to a distilled water leach test and to TCLP testing protocols to assess the potential for leaching of the product in an aggressive leaching environment. All leachate concentrations were found to be below drinking water criteria.

Table X1.15—Stage 2 Environmental Testing Sample Statistical Calculation

Sample Arsenic Concentrations (µg/L): 38, 55, 51, 39, 42
Arsenic Drinking Water Criteria (µg/L): 50
Average Concentration (µg/L): 45
Standard Deviation: 7.58
N: 5
t: 2.132

The Upper Concentration Limit (UCL) can be calculated using a *t* statistic at = 0.05 for *n*–1 degrees of freedom (4) which is 2.132.

$UCL = 45 + 2.132\ (7.58/(5)^{1/2})$
$UCL = 52.2$

Here, the UCL of 52.2 exceeds the criteria of 50, and the material is deemed to exceed the criteria even though the average is 45.

X1.6. *Approval Process*—Upon review of the Stage 2 environmental test results, the decision maker determines that there is minimal potential risk to the environment if the slag is used in the proposed application. Nonetheless, to ensure environmental protection, the decision maker issues a categorical approval for the proposed application, which provides a number of test requirements and application limitations. The decision maker requires the following:

- The slag may be used in a hot mix base course at levels not to exceed 10 percent by weight of aggregate.
- A monitoring program is established to test for levels of arsenic and chromium in the slag product and a limiting level (one order of magnitude above the soil guidelines) is established. Any concentration above such levels would result in material rejection.

---

[1] Approved in December 2005, this provisional standard was first published in July 2006. Reconfirmed in 2008.

Standard Practice for

Establishing Requirements for and Performing Equipment Calibrations, Standardizations, and Checks

AASHTO Designation: PP 57-06 (2009)[1]

**American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001**

Standard Practice for

Establishing Requirements for and Performing Equipment Calibrations, Standardizations, and Checks

AASHTO Designation: PP 57-06 (2009)[1]

1. SCOPE

1.1. This document contains general criteria and guidelines for establishing requirements for and performing equipment calibrations, verification of calibrations, standardizations, and checks.

2. REFERENCED DOCUMENTS

2.1. *AASHTO Standards*:

- T 176, Plastic Fines in Graded Aggregates and Soils by Use of the Sand Equivalent Test
- T 201, Kinematic Viscosity of Asphalts (Bitumens)
- T 245, Resistance to Plastic Flow of Bituminous Mixtures Using Marshall Apparatus

2.2. *International Standards*:

- *International Vocabulary of Basic and General Terms in Metrology* (VIM), second edition. International Organization for Standardization, Geneva, Switzerland, 1993.
- ISO/IEC 17025, General Requirements for the Competence of Testing and Calibration Laboratories
- *ISO Guide to the Expression of Uncertainty in Measurement* (GUM). International Organization for Standardization, Geneva, Switzerland, 1995. The U.S. edition of the GUM is entitled *American National Standard for Expressing Uncertainty—U.S. Guide to the Expression of Uncertainty in Measurement*, ANSI/NCSL Z540-2-1997.

3. TERMINOLOGY

3.1. *accuracy of measurement*—closeness of the agreement between the result of a measurement and a true value of the measurand (VIM, Section 3.5).

3.1.1. *Discussion*—Part 1 of the international standard ISO 5725-1 on the accuracy of measurement methods and results defines accuracy as the closeness of agreement between a test result and the accepted reference value. This definition is supplemented by a note which states that the term accuracy, when applied to a set of test results, involves a combination of random components and a common systematic error or bias component. Accuracy is thus viewed as a characteristic of a measurement process consisting of precision as well as bias components. A process is considered to be accurate only if it is precise as well as unbiased.

The expanded uncertainty of a measurement, discounting the bias, is equivalent to the accuracy of the measurement after a correction or correction factor is applied.

3.2. *calibration, n*—a set of operations that establish, under specified conditions, the relationship between values of quantities indicated by a measuring instrument or measuring system, or between values represented by a material measure or a reference material, and the corresponding values realized by standards (VIM, Section 6.11).

3.2.1. *Example*—Balances (measurement instrument), Dynamic Shear Rheometer (measuring system), Pycnometer (material measure).

3.2.2. *Discussion*—The purpose of calibration is to ensure that measurements made by the laboratory are traceable to the International System of Units (SI). Where traceability of measurements to SI units is not possible or relevant, measurements must be traceable to certified reference materials, agreed methods, or consensus standards. Uncertainty estimates obtained during calibration are used to judge if an instrument is suitable for its intended purpose. There is a need to re-establish traceability or recalibrate only when instrument measurements drift out of control [as determined through verification of calibration (Section 3.10)].

3.3. *check, n*—a specific type of inspection and/or measurement performed on the physical properties of equipment and materials to determine compliance or otherwise with stated criteria.

3.4. *correction, n*—value added algebraically to the uncorrected result of a measurement to compensate for systematic error (VIM, Section 3.15).

3.4.1. *Discussion*—Since the systematic error cannot be known perfectly, the correction can only be an estimate.

3.5. *correction factor, n*—numerical factor by which the uncorrected result of a measurement is multiplied to compensate for systematic error (VIM, Section 3.16).

3.5.1. *Discussion*—Since the systematic error cannot be known perfectly, the correction factor can only be an estimate.

3.6. *standard, n*—material measure, measuring instrument, reference material, or measuring system intended to define, realize, conserve, or reproduce a unit of one or more values of a quantity to serve as a reference (VIM, Section 6.1).

3.7. *standardization, n*—a process that determines (1) the correction or correction factor to be applied to the result of a measuring instrument, measuring system, material measure, or reference material when its values are compared to the values realized by standards, (2) the adjustment to be applied to a piece of equipment when its performance is compared with that of an accepted standard or process.

3.7.1. *Discussion*—Standardization in case (1) is a simplified form of calibration that estimates systematic error but does not identify random error. Standardization, therefore, does not address all of the elements of uncertainty of measurement and does not lead to traceable measurements. An example of case (2) standardization is adjusting the number of blows of a mechanically operated hammer so it applies the energy equivalent to that of a manually operated hammer.

3.8. *traceability, n*—the property of the result of a measurement or the value of a standard whereby it can be related to stated references, usually national or international standards, through an unbroken chain of comparisons all having stated uncertainties (VIM, Section 6.10).

3.8.1. *Discussion*—There is a need for traceable measurements. Measurements, not the instrument, can be traceable. Measurement traceability is established through calibration. Measurement traceability is maintained through verification of calibration (a regular check of instrument output using a control standard).

3.9. *uncertainty of measurement, n*—parameter, associated with the result of a measurement, that characterizes the dispersion of the values that could reasonably be attributed to the measurand (VIM, Section 3.10).

3.9.1. *Discussion*—The uncertainty of a measurement is required in order to establish its traceability. An evaluation of the uncertainty of measurement is conducted to determine if measurement equipment is fit for purpose.

The expanded uncertainty of a measurement, discounting the bias, is equivalent to the accuracy of the measurement after a correction or correction factor is applied.

3.9.2. The definitions of various uncertainty terms used in the GUM are:

- *Standard uncertainty*—uncertainty of the result of a measurement expressed as a standard deviation.
- *Combined standard uncertainty*—standard uncertainty of the result of a measurement when that result is obtained from the values of a number of other quantities, equal to the positive square root of the sum of the terms, the terms being the variances or covariance of these other quantities weighed according to how the measurement result varies with change in these quantities.
- *Expanded uncertainty*—quantity defining an interval about the result of a measurement that may be expected to encompass a large fraction of the distribution of values that could reasonably be attributed to the measurement.
- *Coverage factor*—numerical factor used as a multiplier of the combined standard uncertainty in order to obtain an expanded uncertainty. The coverage factor *k* is typically in the range of 2 to 3.

3.10. *verification of calibration, n*—a process that establishes whether the results of a previously calibrated measurement instrument, measurement system, material measure, or reference material are in control.

3.10.1. *Discussion*—Verification of calibration is used to maintain the traceability of a measurement and to determine when to recalibrate. Control charts should be used to plot verification results and determine if instrument measurements have drifted out of control.

3.11. *verification of standardization, n*—a process that establishes whether the results of a previously standardized measurement instrument, measurement system, material measure, or reference material are in control.

3.11.1. *Discussion*—Verification of standardization is used to indicate when a shift in the population average occurs and when it is time to re-standardize. Control charts should be used to plot verification results and determine if instrument measurements have drifted out of control.

4. SIGNIFICANCE AND USE

4.1. Construction material test standards can be improved if equipment calibrations, standardizations, and checks are properly specified and if each activity and its requirements are understood.

4.2. The guidance in this document is intended to be used by standards developers in the selection of terms used in methods and in the establishment of appropriate requirements for equipment calibrations, standardizations, and checks.

4.3. The guidance in this document can also be used by laboratories for performing equipment calibrations, standardizations, and checks.

5. GUIDANCE FOR STANDARDS DEVELOPERS

5.1. *Calibration or Standardization versus Checking*—Most measuring instruments, measuring systems, and material measures should be either calibrated or standardized. Checking applies to test equipment that is not a measuring instrument, measuring system, or material measure such as an oven, straightedge, or specimen mold.

5.2. *Determining if Equipment Checks Are Necessary*—The primary consideration in deciding whether a piece of test equipment should be checked is the equipment's influence on the test result. If the physical properties of a piece of equipment could significantly influence the test result, then routine checks to determine compliance or otherwise with stated criteria are essential. However, if the physical properties of a piece of test equipment are not likely to affect the test result, routine equipment checks are not necessary.

5.3. *Calibration versus Standardization*—The two primary considerations for making the decision to calibrate or standardize a measuring instrument, measuring system, or material measure are (1) the measurement's influence on the test result and (2) the probability that the uncertainty of measurement could exceed the accuracy requirement of the measurement. Refer to Table 1 for guidance for determining whether to specify equipment calibration, standardization, or nothing.

Table 1—Guidance for Determining Whether Equipment Shall Be Calibrated, Standardized, or Neither

		Probability That the Uncertainty of Measurement Could Exceed the Accuracy Requirement of the Measurement		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Standardize	Calibrate	Calibrate
	Moderate	Standardize	Standardize	Calibrate
	Low	Nothing	Standardize	Standardize

5.4. *Selecting and Specifying Intervals for Equipment Calibrations, Standardizations, and Checks*—Equipment calibration, standardization, and check intervals shall be specified in the test methods (Notes 1 and 2). The two primary considerations for determining an acceptable interval are (1) the probability that time and/or usage will affect the instrument or device and (2) the measurement's or device's influence on the test result. Refer to Table 2 for guidance for determining intervals between calibrations, standardizations, and checks.

Note 1—When the risk associated with using inaccurate equipment or nonconforming equipment is high, equipment should be monitored frequently. When the risk is low, less frequent monitoring may suffice.

Note 2—Since the user may have verification of calibration data to support extending a calibration interval beyond the interval specified, the following wording is suggested for use when specifying calibration intervals: "In the absence of verification of calibration data to support the extension of the interval between calibrations, the interval between calibrations shall not exceed ______ months."

Table 2—Determining the Interval between Equipment Calibrations, Verification of Calibrations, Standardizations, and Checks

		Probability That Time or Usage Will Affect the Instrument/Device		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)	Frequent Monitoring (High Risk)
	Moderate	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)
	Low	Infrequent Monitoring (Low Risk)	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)

Note 3—Intervals for frequent monitoring should be between 1 month and 4 months; intervals for moderate monitoring should be between 4 and 12 months; intervals for infrequent monitoring should be between 12 and 24 months.

6. GUIDANCE FOR LABORATORIES THAT CHOOSE TO EXTEND CALIBRATION OR STANDARDIZATION INTERVALS BEYOND THE INTERVALS SPECIFIED IN STANDARDS

6.1. *General*—A laboratory may use the calibration and standardization intervals specified in a standard or may extend calibration and standardization intervals beyond the intervals specified in the standards. To extend calibration and standardization intervals beyond those specified, a laboratory must establish and implement a program for continual verification of equipment calibrations and standardizations.

6.2. Appendix X1 gives an example of an acceptable "verification of calibration" program. A "verification of standardization" program would be similar to the "verification of calibration" program.

7. REQUIREMENTS FOR LABORATORIES PERFORMING CALIBRATIONS, STANDARDIZATIONS, AND CHECKS

7.1. *General (the Risk)*—When the results of equipment calibrations, standardizations, or checks indicate that the equipment is out of conformance with specified requirements, the user shall evaluate the significance of the nonconforming work. The user shall review all test results reported since the previous calibration, verification of calibration, standardization, or check and notify clients if the validity of reported test results is in doubt.

7.2. *Calibrations*—Calibrations specified in a test method shall be performed by an accredited calibration service provider (see Note 4) or by a calibration service provider that has provided evidence that it conforms to the applicable requirements of ISO/IEC 17025.

Note 4—The National Voluntary Laboratory Accreditation Program (http://ts.nist.gov/standards/scopes/programs) and the American Association for Laboratory Accreditation (http://www.a2la.org) accredit calibration service providers.

7.2.1. Standards used to calibrate equipment shall be certified reference materials or standards calibrated by an accredited calibration laboratory (see Note 4).

Note 5—The expanded uncertainty of the standard used for equipment calibration purposes should be no greater than one half of the required accuracy of the equipment.

Note 6—Certificates that accompany standards used for calibrating equipment should include estimates of expanded uncertainty, the calibration conditions, and a reference to the calibration method.

7.2.2. The calibration process shall include an estimation of the uncertainty of measurement.

Note 7—Some of the factors that contribute to the uncertainty of measurement are the reference standard, the measurement method, repeatability of the instrument, resolution of the instrument, operator, and environmental conditions.

7.2.3. All calibrations shall be concluded with a comparison of the uncertainty of measurement with the required accuracy to determine whether the instrument is fit for purpose.

Note 8—Measurement uncertainty can be reduced by choosing a better reference standard and/or improving the calibration method.

7.2.4. The interval between equipment calibrations shall be no greater than the intervals specified in a method unless the laboratory has implemented a verification of calibration program. Where intervals are not specified, the interval between calibrations established by the laboratory shall be dictated by (1) equipment usage and the risks associated with making inaccurate measurements (see Table 2) or (2) the results of verification of calibration data (see Note 9) obtained at intervals chosen to minimize the risk of making inaccurate measurements.

Note 9—The interval between verification of equipment calibrations should also be dictated by equipment usage and the risks associated with making inaccurate measurements.

Note 10—Ideally, equipment should only be recalibrated when there is evidence to suggest that measurements are unstable.

7.3. *Standardizations*—Standards used to standardize equipment shall be reference materials or standards calibrated by an accredited calibration laboratory (see Note 4).

Note 11—The expanded uncertainty of the reference standard used for conducting standardization should be no greater than one half of the required accuracy of the equipment.

7.3.1. All standardizations shall be concluded with a comparison of the systematic error with the required accuracy to determine whether a correction or correction factor is necessary.

7.3.2. The interval between equipment standardizations shall be no greater than the interval specified in a method unless the laboratory has implemented a verification of standardization program. Where an interval is not specified, the interval between standardizations established by the laboratory shall be dictated by equipment usage and the risks associated with making inaccurate measurements (see Table 2).

7.4. *Checks*—The interval between equipment checks shall be no greater than the interval specified in the method unless such equipment is checked before each use or the laboratory has documented evidence to show that, for a specific level of usage, the conformance of the equipment to specification requirements would not be likely to change (see Note 12). Where an interval is not specified, the interval between equipment checks established by the laboratory shall be dictated by equipment usage and the risks associated with using nonconforming equipment.

Note 12—Measurement instruments used to make equipment checks should be calibrated and should have an expanded uncertainty of no greater than one half of the specified equipment tolerance.

Note 13—Equipment check intervals may be extended provided that equipment check data indicates that the equipment wear is predictable over time. Analysis of the equipment check data may indicate that the interval should be decreased to ensure that the equipment consistently meets the specification requirements or is removed from service when appropriate.

APPENDIXES

(Nonmandatory Information)

X1. EXAMPLE OF A VERIFICATION OF CALIBRATION PROGRAM FOR LABORATORIES

X1.1. *General*—Laboratories interested in extending calibration intervals beyond the intervals specified in the standards and those interested in establishing a Laboratory Equipment Assurance Program should establish and implement a program for the continual verification of equipment calibrations.

X1.2. *Requirements*:

X1.2.1. *Artifact check standard*—A device for controlling the bias and long-term variability of the process once a baseline for these quantities has been established from historical data on the check standard. A stable artifact, such as a steel mass, might be an appropriate check standard for a verification of calibration program for balances.

X1.2.2. Graphing software, such as Microsoft Excel®.

X1.3. *Example*—A laboratory currently pays a calibration service to calibrate all of its balances every 12 months. The laboratory has decided to implement the following verification of calibration program for its balances in an effort to eliminate unnecessary recalibrations, reduce the cost of calibrations, and improve their mass measurements. The laboratory followed these steps:

- Establish artifact
- Take repeat measurements
- Collect readings in spreadsheet
- Calculate subgroup mean and subgroup range
- Draw average (x-bar) and range (R) charts
- Evaluate charts

Note X1—The process is in statistical control if the points in the control chart are distributed randomly and between the control limits. The WECO rules (Western Electric Company Rules) are a good indicator that the process may be out of control. [Visit the National Institute of Standards and Technology (NIST) website for more information: http://www.itl.nist.gov/div898/handbook/pmc/pmc.htm].

WECO Rules:

Any Point Above +3 Sigma
-- +3 σ LIMIT
2 Out of the Last 3 Points Above +2 Sigma
-- +2 σ LIMIT
4 Out of the Last 5 Points Above +1 Sigma
-- +1 σ LIMIT
8 Consecutive Points on This Side of Control Line
== CENTERLINE
8 Consecutive Points on This Side of Control Line
-- –1 σ LIMIT
4 Out of the Last 5 Points Below – 1 Sigma
-- –2 σ LIMIT
2 Out of the Last 3 Points Below –2 Sigma
-- –3 σ LIMIT
Any Point Below –3 Sigma

Trend Rules: 6 in a row trending up or down, 14 in a row alternating up and down.

Note X2—An out-of-control condition in the average (x-bar) chart indicates a shift in the population average and could be due to the measuring equipment going out of calibration or some problem with the check standard itself. An out-of-control condition in the range (R) chart indicates an increase in the dispersion of the repeat observations, which could be attributed to inadequate control of the environment or incompetence of the operator involved in the measurements.

X1.4. *Data*—A laboratory places a nominal 2000 g mass on a balance each morning and takes five readings. The measurements are recorded and then collected in a spreadsheet. Each set of five readings is considered a subgroup. Subgroup averages and ranges are calculated. The average of the subgroup averages and the average of the subgroup ranges are calculated after approximately twenty subgroups. See the example spreadsheet and control charts below. The interval between verifications could remain daily or be extended to weeks, months, or greater (see Note X3).

Note X3—The interval between verification of equipment calibrations should also be dictated by equipment usage and the risks associated with making inaccurate measurements.

Table X1.1—Verification of Calibration Data for Balance

Reading 1	Reading 2	Reading 3	Reading 4	Reading 5	Subgroup average	Max	Min	Subgroup range
2000.2	2000.4	2000.2	2000.2	2000.3	2000.3	2000.4	2000.2	0.2

X1.5. *Control Charts*:

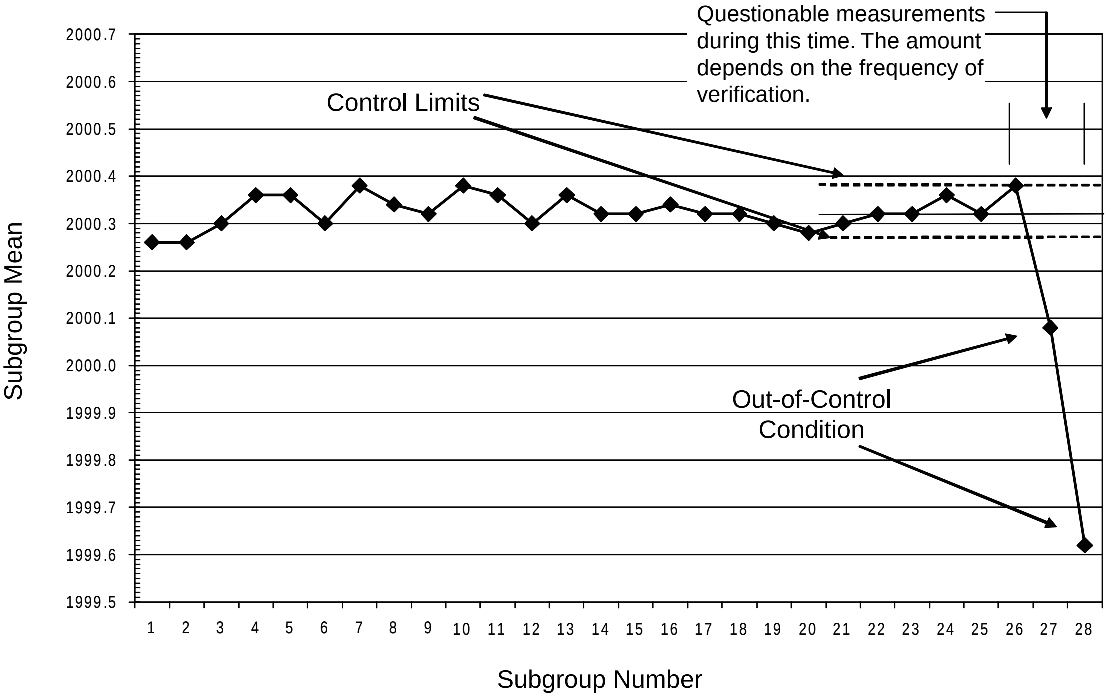

Figure X1.1—Average (X-bar) Chart for Verification of Balance Calibration

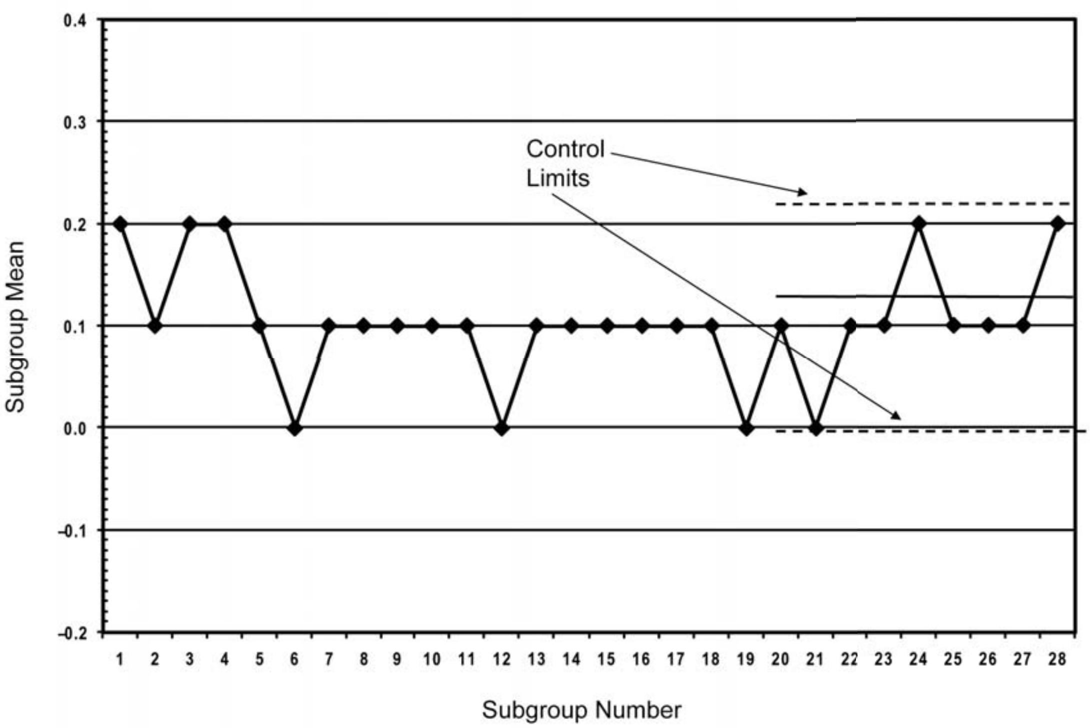

Figure X1.2—Range (R) Chart for Verification of Balance Calibration

X2. EXAMPLE OF A CALIBRATION REQUIREMENT FOR MEASURING EQUIPMENT

X2.1. *Decision to Calibrate the Equipment*—AASHTO T 201 (Kinematic Viscosity of Asphalts) states that a "…liquid-in-glass thermometers of an accuracy after correction of 0.02°C (0.04°F) can be used or any other thermometric device of equal accuracy."

This thermometer sits in a water or oil bath which holds the viscometer and the asphalt. The viscosity of asphalt is highly dependent on temperature. Additionally, since the accuracy requirement for the thermometer is small, the probability that the uncertainty of the temperature measurement could exceed the accuracy requirement for temperature is high. Therefore, the decision should be made to specify calibration for the thermometer.

		Probability That the Uncertainty of Measurement Could Exceed the Accuracy Requirement of the Measurement		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Standardize	Calibrate	Calibrate
	Moderate	Standardize	Standardize	Calibrate
	Low	Nothing	Standardize	Standardize

Figure X2.1—Guidance for Determining Whether Equipment Shall Be Calibrated, Standardized, or Neither

		Probability That Time or Usage Will Affect the Instrument/Device		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)	Frequent Monitoring (High Risk)
	Moderate	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)
	Low	Infrequent Monitoring (Low Risk)	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)

Figure X2.2—Determining the Interval between Equipment Calibrations, Verification of Calibrations, Standardizations, and Checks

X2.2. *Specifying Calibration*—"A liquid-in-glass thermometer or other thermometric device calibrated at the desired test temperatures shall be used. Each test temperature shall have an expanded uncertainty of measurement of 0.02°C (0.04°F) or less after applying any corrections."

X2.3. *Selecting the Calibration Interval (Standards Developer)*—As stated previously, the viscosity of asphalt is highly dependent on temperature. Additionally, most temperature measuring devices, especially liquid-in-glass thermometers, are susceptible to change with time and usage. Therefore, this instrument should be subjected to frequent monitoring.

X2.4. *Specifying the Calibration Interval*—"The thermometer used in this test shall be recalibrated at least every 4 months."

X2.5. *Selecting a Calibration Interval (Laboratory)*—A laboratory has two options in this case: accept the interval specified in the method (4 months) or implement process control through a verification of calibration program.

X2.5.1. Laboratory "A" performs many tests each day and chooses to implement a process control plan by comparing the test temperature of the working thermometer against that of a calibrated reference thermometer having an uncertainty of measurement of 0.01°C every month. Laboratory "A" records the difference in temperatures on a control chart and plans to recalibrate the working thermometer only if the plot of temperature differences indicates that the working thermometer has become unstable.

X2.5.2. Laboratory "B" performs a test once a week and plans to send their working thermometer to a local accredited calibration service provider for recalibration every 4 months.

X3. EXAMPLE OF A STANDARDIZATION REQUIREMENT FOR MEASURING EQUIPMENT

X3.1. *Decision to Standardize the Equipment*—AASHTO T 245 (Marshall Method) specifies thermometers for water baths that are sensitive to 0.2°C (0.4°F).

The water bath is used to heat the specimens to test temperature (60°C) before they are tested. The temperature of the specimens has a moderate effect on the test result. Additionally, there is a moderate probability that the uncertainty of the temperature measurement could exceed 0.2°C (0.4°F). Therefore, the decision should be made to specify standardization for the thermometer.

		Probability That the Uncertainty of Measurement Could Exceed the Accuracy Requirement of the Measurement		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Standardize	Calibrate	Calibrate
	Moderate	Standardize	Standardize	Calibrate
	Low	Nothing	Standardize	Standardize

Figure X3.1—Guidance for Determining Whether Equipment Shall Be Calibrated, Standardized, or Neither

X3.2. *Specifying Standardization*—"Thermometers for water baths shall be standardized at the test temperature. Corrections shall be applied to compensate for any systematic error."

X3.3. *Selecting the Standardization Interval (Standards Developer)*—Moderate to high risk exists as the temperature measurement has a moderate influence on the test result and there is a moderate to high probability that time or usage will affect the thermometer.

		Probability That Time or Usage Will Affect the Instrument/Device		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)	Frequent Monitoring (High Risk)
	Moderate	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)
	Low	Infrequent Monitoring (Low Risk)	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)

Figure X3.2—Determining the Interval between Equipment Calibrations, Verification of Calibrations, Standardizations, and Checks

X3.4. *Specifying the Standardization Interval*—"Thermometers for water baths shall be standardized at the test temperature at least every 6 months. Corrections shall be applied to compensate for any systematic error."

X4. EXAMPLE OF A "NOTHING" REQUIREMENT FOR MEASURING EQUIPMENT (NO CALIBRATION OR STANDARDIZATION)

X4.1. *Decision to Specify Nothing*—AASHTO T 176 (Sand Equivalent Test) specifies the use of a clock or watch (reading in minutes and seconds) for timing approximately 30 seconds for the hand-shaking method. This measurement has a very small influence on the test result, and there is no specified accuracy requirement. Even if one assumed an accuracy requirement of 1 second, the probability that the uncertainty of the time measurement could exceed 1 second is low. Therefore, the decision should be made to specify neither calibration nor standardization.

		Probability That the Uncertainty of Measurement Could Exceed the Accuracy Requirement of the Measurement		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Standardize	Calibrate	Calibrate
	Moderate	Standardize	Standardize	Calibrate
	Low	Nothing	Standardize	Standardize

Figure X4.1—Guidance for Determining Whether Equipment Shall Be Calibrated, Standardized, or Neither

X5. EXAMPLE OF AN EQUIPMENT CHECK REQUIREMENT

X5.1. *Decision to Check the Equipment*—AASHTO T 245 (Marshall Method) specifies that the internal diameter of the compaction mold shall be 3.995 in. to 4.005 in. This is not a requirement of the output of the device but rather is a requirement of its physical properties (dimensions). Therefore, a decision should be made to specify a check of the mold.

X5.2. *Specifying an Equipment Check*—"The internal diameter of mold cylinders shall be checked to determine whether they conform to the details shown in Figure 1 [of T 245]."

X5.3. *Selecting an Equipment Check Interval (Standards Developer)*—The mold's influence on the test results (stability and flow) is low. The probability that usage will affect the mold is moderate to high. Therefore, not checking the molds would lead to moderate risk.

		Probability That Time or Usage Will Affect the Instrument/Device		
		Low	Moderate	High
Measurement's Influence on the Test Result	High	Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)	Frequent Monitoring (High Risk)
	Moderate	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)	Frequent Monitoring (High Risk)
	Low	Infrequent Monitoring (Low Risk)	Infrequent Monitoring (Low Risk)	Moderate Monitoring (Moderate Risk)

Figure X5.1—Determining the Interval between Equipment Calibrations, Verification of Calibrations, Standardizations, and Checks

X5.4. *Specifying an Equipment Check Interval*—"The internal diameter of mold cylinders shall be checked at least every 12 months to determine whether they conform to the details shown in Figure 1 [of T 245]."

X5.5. *Selecting an Equipment Check Interval (Laboratory)*—A laboratory has two options, adopt the check interval specified in the method or establish a process control program that allows it to predict when the mold will cease to meet specification requirements.

X5.5.1. Laboratory "A" develops a process control plan by predicting the average life of each mold and extending the intervals for checking.

Date	Mold #1 (in.)	Mold #2 (in.)	Mold #3 (in.)
Dec. 1997	3.998	4.001	3.996
Dec. 1998	3.998	4.001	3.997
Dec. 1999	3.999	4.002	3.998
Dec. 2000	4.000	4.002	3.998
Dec. 2001	4.001	4.003	3.999
Wear Rate	0.0006/yr	0.0004/yr	0.0006/yr
Avg. wear rate = 0.0005 in./yr			

X5.5.2. Laboratory "B" performs only a few tests each month. The laboratory chooses to adopt a 12-month schedule for checking the internal diameter of their molds. In addition, they plan to record and analyze mold usage data and the results of the equipment checks and determine if it is feasible to extend the check interval beyond 12 months with minimal risk of using nonconforming equipment.

---

[1] Approved in December 2005, this standard was first published in July 2006. Reconfirmed in 2007, 2008, and 2009.

Standard Practice for

Coal Combustion Fly Ash for Embankments

AASHTO Designation: PP 59-09[1]

American Association of State Highway and Transportation Officials
444 North Capitol Street N.W., Suite 249
Washington, D.C. 20001

Standard Practice for

Coal Combustion Fly Ash for Embankments

AASHTO Designation: PP 59-09[1]

1. SCOPE

1.1. This practice covers the use of coal combustion fly ash (typically but not limited to non-self-hardening ash) as a fill material for the construction of embankments.

1.2. When properly processed, hauled, spread, and compacted on a prepared grade to appropriate density standards, coal combustion fly ash used alone, or blended with traditional soil aggregate or other approved aggregate materials, can be expected to provide a lighter-than-normal weight fill material (85 to 100 pcf, 1360 to 1600 kg/m^3) with adequate stability and load support for use as road or highway embankment.

1.3. The technique described in this practice uses containment berms, cover fill material, and sometimes a liner and leachate system to isolate the fly ash and any resulting effluent. This is a conservative approach to the environmental issues raised by the use of fly ash as fill, and may not be required for all fly ashes or for all regulatory requirements.

1.4. This practice recognizes that since fly ash is a by-product of the burning of coal in electricity- and steam-generating facilities, various state, county, and local environmental laws and regulations apply if fly ash is used as an alternative embankment material. Aspects of fly ash that are of environmental concern are identified. Therefore, this standard discusses elements such as impermeable layers and leachate collection, as they may be required according to the environmental regulations affecting the proposed installation.

1.5. More specific guidance for the detailed use of fly ash as embankment material may be found in ASTM E 2277.

1.6. The values stated in SI units are to be regarded as the standard.

3. GENERAL DESCRIPTION

3.1. Fly ash is the finely divided residue that results from the combustion of coal. Fly ash is the airborne residue that exits a coal combustion chamber with the flue gas and is removed from the flue gas by electrostatic precipitation, baghouses, or other particulate control devices prior to the introduction of scrubber reagents. It contains siliceous and aluminous materials.

3.2. For purposes of this practice, fly ash is divided into two types. One is self-hardening and the other is non-self-hardening. Both types contain siliceous or siliceous and aluminous materials, which in the presence of lime or portland cement and water react to form a cementitious material.

3.2.1. *Self-hardening fly ash (Class C)*—For the purpose of this practice shall mean fly ash that will form cementitious material in the presence of water alone.

3.2.2. *Non-self-hardening fly ash (Class F)*—For the purpose of this practice shall mean fly ash that requires the presence of lime or portland cement and water to form a cementitious material. It is likely that fly ash used in accordance with this practice will commonly be the non-self-hardening type, as it is less desirable for other uses.

3.3. Additional definitions relative to fly ash and other coal combustion by-products are provided in ASTM E 2201.

3.4. The very fine-grained nature of fly ash, similar to that of natural silt-sized materials, makes it susceptible to vertical capillary water migration. Capillary water migration in embankments could lead to embankment saturation and instability under loading or frost heaving due to the development of ice lenses. As such, this practice recommends that a layer of open-graded granular material be constructed at the base of the fly ash embankment, and a layer of cover material be constructed on top of the embankment to prevent frost penetration into the fly ash in frost-prone locations.

3.5. Aqueous solutions that percolate through fly ash or fly ash containing admixtures could exhibit pH values that fall outside the range of 5 to 9. The engineer is cautioned that aqueous solutions with pH values that fall outside this range could result in corrosive conditions detrimental to concrete or metal conduit structures.

3.6. For cases where applicable laws and regulations raise concern regarding the quality of the leachate from the fly ash embankment, this practice includes a liner and leachate collection system.

3.7. The definitions of fill material and other soil aggregate terms are provided in M 146.

4. FLY ASH ORDERING INFORMATION

4.1. *The purchaser or specifier of coal fly ash shall include the following information in the purchase order or contract documents*:

4.1.1. Reference to this standard, including year;

4.1.2. Reference to the requirements of state, local, or both, environmental protection agencies;

4.1.3. Requirements for grading, blending, or both;

4.1.4. Type or types of fly ash specified (self-hardening fly ash is commonly referred to as Class C ash and non-self-hardening fly ash is referred to as Class F); and

4.1.5. Exceptions or additions to this standard.

5. PHYSICAL AND CHEMICAL PARAMETERS

5.1. *Fly Ash*:

5.1.1. Fly ash shall meet the requirements set forth in the contract documents in regard to gradation, blending, and type of fly ash.

5.1.2. If not otherwise stated in the contract documents, fly ash supplied as an embankment material shall have 100 percent of the material pass the 12.7-mm ($^1/_2$-in.) sieve.

5.1.3. The loss on ignition (LOI) of the fly ash should not exceed 20.0 percent when tested in accordance with ASTM C 311. This guide limit on LOI has been established to allow fly ashes to be used for fill that have LOIs that are typically too high for use in concrete, without allowing such a high LOI that environmental impacts and buried energy issues become too large.

5.1.4. Fly ash may be combined with other approved embankment materials or admixtures as approved by the engineer. Mixing shall be accomplished by the use of mechanical interlock systems (pug mills), conveyor belt blending, or by other methods approved by the engineer. The supplier shall maintain actual production blending of fly ash and other approved embankment material within a tolerance of ±5 percent of the approved proportion.

5.1.5. Blends of fly ash and other approved embankment materials must be free of deleterious substances. Fly ash or blended products should be free of pyrites and other metal sulfides as determined by ASTM C 295. In particular, the presence of pyrites or other metal sulfides should be investigated when coal combustion bottom ash is added to a blended mix due to their potentially expansive nature. Other potentially expansive compounds, such as sulfur trioxide, could be present in certain coal combustion by-product sources. It is recommended that the engineer investigate the source material and blended product to ensure that excessive expansion will not be a problem.

5.1.6. If chemical stabilization of the fly ash is specified, the contractor should submit a mix design to the engineer for approval. The materials should be mixed in a mechanical interlock system (pug mill) or other approved method. The use of certain stabilizing agents may elevate pH values of aqueous solutions that may contact the stabilized fly ash. The engineer is reminded that aqueous solutions that percolate through fly ash or admixtures containing fly ash could exhibit pH values greater than 9 or less than 5, which could result in corrosive conditions detrimental to concrete or metal conduit structures.

5.2. *Containment Berms*:

5.2.1. Material used to construct the containment berms for the fly ash embankment shall meet the requirements of the specifying agency. Containment berm material should provide adequate strength to retain the fly ash fill during compaction.

5.3. *Cover for Fly Ash Embankment*:

5.3.1. Material used to construct the cover for the fly ash embankment shall meet the material requirements of the specifying agency. The cover material should be dense-graded so as to minimize infiltration of surface water and be placed of a thickness such that it will prevent freezing temperatures from reaching the fly ash fill. Fly ash materials, being very fine-grained, are naturally frost-susceptible and will likely heave if frozen. In some cases, it may even be desirable to specify a geomembrane over the top of the fill.

5.4. *Liner and Leachate Collection System*:

5.4.1. Where specified, material used to construct a liner beneath the fly ash embankment shall meet the material requirements of the specifying agency. In areas where a liner is not specified, consideration should be given to the installation of a capillary break such as recommended in Section 3.4 to prevent the rise of groundwater into the embankment.

5.4.2. Where specified, material for the components of a leachate collection system constructed beneath the fly ash embankment shall meet the material requirements of the specifying agency.

6. FIELD APPLICATIONS

6.1. *Site Preparation*:

6.1.1. Clear and grub the existing site in accordance with the applicable specification. All unsuitable material shall be removed. Compact the ground surface as per the agency’s specifications.

6.1.2. Place and compact a layer of open-graded granular material where necessary to meet lines and grades shown in the contract plans.

6.2. *Liner and Leachate Collection System*:

6.2.1. Where specified, construct the liner and leachate system in accordance with, and to the lines and grades shown in the contract plans.

6.3. *Containment Berms*:

6.3.1. Before construction of fly ash embankments begins, construct containment berms having a trapezoidal cross section and side slopes of 2:1 or less and a width of at least 1.8 m (6 ft) at the top of each containment berm segment. The first containment berm segments should be located on the outside limits of the embankment footprint. As the embankment is constructed upward, containment berms should be placed on the outside of each new tier before placing fly ash.

Note 1—For narrow embankments, such as ramps, the engineer may consider narrower containment berms because smaller equipment will be required.

6.3.2. The material used to construct containment berms should be placed in loose lifts having a maximum thickness of 200 mm (8 in.). Each lift should be compacted as required by the specifying agency.

6.4. *Fly Ash Placement*:

6.4.1. The delivery, placement, spreading, and compaction of fly ash should be planned so the work can proceed from one step to the next without delay.

6.4.2. Non-self-hardening fly ash should be conditioned for dust control and to reduce the potential for erosion by the addition of 10 to 15 percent water by weight at the source site prior to delivery, and subsequent storage (stockpiling) of the fly ash for a period of 24 hours or more until the water is evenly dispersed. If the supplier can demonstrate that water is evenly distributed throughout the fly ash, then stockpiling may not be required or the duration may be reduced. Self-hardening fly ash must be kept dry until placement to avoid hardening before compaction.

6.4.3. Delivery of fly ash must be in closed or covered trucks.

6.4.4. Large-scale storage of fly ash shall not be permitted at the project construction site. Small amounts of fly ash, such as a day’s supply for the project, may be stored for short periods of time to facilitate construction when stockpiling is done in accordance with the project sediment and erosion control plan.

6.4.5. Fly ash, delivered to the project site, should be unloaded directly inside the contained embankment area where it will be used.

6.4.6. Fly ash material should be spread into loose lifts approximately 200 mm (8 in.) thick. The engineer may consider thicker lift dimensions if it can be satisfactorily demonstrated with a test section that adequate compaction can be achieved over the full depth of the thicker lift.

6.4.7. If necessary for proper compaction, water should be added to the fly ash by the use of water distribution tank trucks. The water and fly ash should be mixed using a rototilling mixer or other approved method. At the time of compaction, the fly ash should have a moisture content that will result in an after-compaction dry density that complies with the requirements of the project specifications.

6.4.8. The fly ash embankment should be compacted as required by the specifying agency. This will normally be to a minimum density criteria. This material should be compacted much like a natural silt material.

Note 2—The first pass in the compaction process may be accomplished by the method known as tracking. This involves the use of a bulldozer track to accomplish initial compaction. The bulldozer is moved progressively across the fly ash embankment until the entire area is tracked. The fly ash embankment should then be compacted using pneumatic tired, vibratory, or other types of compaction equipment. Best results are often obtained when the equipment works from the edge of the embankment toward the center.

6.4.9. At the completion of each day's work, the surface of the fly ash embankment should be sealed. This is a preventative measure in which the compacted surface is crowned and graded for positive drainage so that rain would tend to flow off the embankment rather than penetrate into the embankment material.

6.4.10. The contractor should make available and use water, if necessary, to control the generation of dust due to drying of the fly ash.

6.4.11. Continue the placement and compaction of fly ash to the lines and grades shown in the contract plans.

6.5. *Finished Embankment*:

6.5.1. Following completion of the placement of fly ash, the final grade of the embankment should be accomplished by the placement of at least 600 mm (24 in.) of compacted natural soil material or selected clay material, depending on the requirements of the specifying agency, on top of the fly ash volume. The material should be placed in 200-mm (8-in.) loose lifts, or as required by the specifying agency. Greater thicknesses of cover material may be required where local frost penetration conditions are greater (see Section 5.3).

6.5.2. The entire embankment structure, with the exception of the roadway pavement structure, should be covered with at least 200 mm (8 in.) of topsoil and seeded, or otherwise covered in accordance with the requirements of the specifying agency.

6.5.3. In the event that impermeable containment above or below the fly ash embankment is required, then such containment shall be accomplished in accordance with the permeability requirements of the specifying agency.

---

[1] This provisional practice was adopted and first published in 2009.

AASHTO PROVISIONAL STANDARDS

This is the fourteenth edition of the *AASHTO Provisional Standards*. The publication includes a complete set of current protocols containing a total of 60 Provisional Standards. A chronology of the year-to-year status of the Provisional Standards during the past eight years is included immediately following the Table of Contents. A complete chronology is available on our website at http://downloads.transportation.org/chronological_summary.pdf.

All Provisional Standards are approved for publication by the AASHTO Highway Subcommittee on Materials. The format for the Provisional Standards was developed by AASHTO in 1993, with an objective of providing a mechanism for early distribution of materials specifications and test methods resulting from SHRP and other research. Provisional Standards are standards which have been adopted by the Highway Subcommittee on Materials on a temporary basis for a maximum of eight years. At any time during the eight-year period, the Subcommittee can ballot to convert a Provisional Standard into a Full Standard.

A Provisional Standard is initially approved for two years by a vote of the Subcommittee. At the end of two years and four years after the initial approval, the Technical Section of the Subcommittee responsible for the Provisional Standard can extend its life by a voice vote or letter ballot for an additional two years. At the end of six years and seven years after the initial approval, the Subcommittee can extend the Provisional Standard’s life by a voice vote or letter ballot for an additional one year. If a Provisional Standard fails any extension vote, it is discontinued. At the end of eight years, the Subcommittee can ballot a Provisional Standard for adoption as a Full Standard or the Provisional Standard is discontinued.

The time period used to maintain the provisional status is used for the refinement of these standards on the basis of the comments received from the users and other reviewers. It is planned that the Provisional Standards contained herein will be considered by the Highway Subcommittee on Materials for inclusion in future editions of the *Standard Specifications for Transportation Materials and Methods of Sampling and Testing*, either as “Provisional Standards” or possibly as “Full Standards” as presented or in amended form, if the Subcommittee so decides in its balloting.

The Subcommittee, so far, has converted 67 Provisional Standards into Full Standards. These Standards are now regularly published in AASHTO’s *Standard Specifications for Transportation Materials and Methods of Sampling and Testing*. At the same time, over a period of 16 years, 37 Provisional Standards did not receive the Subcommittee’s approval. These standards, therefore, are excluded from this publication.

Future editions of *AASHTO Provisional Standards* will be published and released, as necessary.

In keeping with the concept of *AASHTO Provisional Standards*, comments on the Provisional Standards included in this edition are welcome and should be directed to AASHTO at the address stated below.
