State-funded military infrastructure contributed to city's growth and modernization, added aesthetic value to city landscape and provided locals with jobs at construction sites. Growing military population gave local trade and services a boost (Urbaniak, 2012). Furthermore, large concentration of the military stimulated frequent visitations from high state officials which further added to the prestige. Through generations, historic army barracks were a reminder of past splendor for the citizens, but to the outsiders this urban code was unintelligible.

Military compounds changed the face of the city in more ways than one and left a lasting impression. They were usually situated on the outskirts, where enough space was available for spacious complexes, large drill squares and shooting ranges. Their development required towns to provide infrastructure and amenities, which stimulated the sprawl of these towns towards the outskirts, where the barracks were situated. Streets leading to military facilities were named by thankful citizens in honor of military units that occupied them, e.g. *An den Kasernen* (at present Jagiełły Street in Wrocław) which leads to the former Burgess Barracks, *Kaserne Strasse* (presently Adama Mickiewicza Street in Namysłów leading to the former Dragoon Barracks), *Einundfünfziger Strasse* (at present Długa Street in Wrocław) which took its name from the 51st Infantry Regiment stationed there or *Grenadier Strasse* (at present Hutników in Legnica) (Rudnicka-Bogusz, 2015). Barracks were usually accompanied by extensive shooting ranges and paddocks. When the military vacated the premises they became the foundation for municipal parks, such as Park Leśny (Forest Park) in Lubin – a former shooting range or *der Hag* (a meadow in Municipal Park in Legnica) also once a shooting range.

The bond between communities and the units implanted in them was strong. The rhythm of city life fitted itself to the dynamics of army marching in, marching out or marching through. At the beginning the relation was antagonistic. Before the construction of the barracks, soldiers were traditionally billeted in private homes (Lepage, 2009), which met with general resentment (Davies & Moorhouse, 2009). Gradually the relationship became warmer. Eventually, every time the troop got back to town from a campaign it received a warm welcome. The townspeople organized a feast and decorated their houses with the colors of the regiment or founded frescos for mess halls, etc. (Paetzold, 1998).

3 TYPOLOGY AND STYLISTICS OF MILITARY COMPOUNDS

State-funded investments, which were implemented in provincial cities, were one of the most iconic and prestigious. There were no limitations in resources, when it came to their form and appearances that were supposed to express privilege and authority. Municipalities relayed plots for those investments free of charge, so their gauge was not restricted by shortages of terrain (Bińkowska, 2012). Their construction was a prestigious endeavor and was financed by the state. The edifices, representing central government in local communities, were well funded and strongly built. The barracks, either through evolution or by design, housed several battalions. The troop was accommodated in a single building or a complex. Most compounds comprised numerous buildings of various purposes, organized around a central courtyard. Administrative buildings, such as command and commissariat, were positioned at street front. The complexes were hieratic, compact and spatial. Individual buildings often assumed the appearance of a city palace, whereas complexes constituted of several buildings tended to derive its layout from *entre cour et jardin* palace type or reminisce Godin's *Familistere*. They formed tight, self-sufficient blocks, emulating strongholds.

The increase in construction of barrack complexes falls into two periods, and so the architecture bears features characteristic of these two periods. The first one coincides with the reign of William Frederick I of Prussia, during which the prominence of the military in the Kingdom of Prussia steadily rose up to a point when it became the first power of the state. Buildings from that period represent the stylistic of historicism, usually the neo-Gothic with elements of Romanesque Revival, which brought to mind the basic association of knighthood and strongholds. They were designed in a manner that made them stand out against the background, to emphasize their significance and indicate their purpose. The examples here are the so called Red Barracks in Oleśnica built at the turn of the 20th century, quarters for the Dragoon Regiment in Oleśnica built in the 1870s, Ranger Battalion barracks complex in Jelenia Góra built around 1880 or Grenadier Regiment of King William I barracks in Legnica. More prestigious objects, such as officers'

mess in Oleśnica (built around 1880) or Cuirassier Barracks in Wroclaw were designed in neo-Renaissance to resemble *palazzos*.

The layout of the collective residential buildings utilized the most functional solutions and constructions known at that time. Foot-soldiers lived in two-bay buildings: rooms, accommodating up to 10 bunk beds, opened up to a corridor that ran along one side of the building and led to staircases. There was usually a main, open staircase situated at the center, which led to a spatial vestibule and two auxiliary staircases. Officers and their families lived in multi-staircase buildings, allowing them to maintain more privacy. Additionally, the compounds were comprised of stables, mess halls, armories, lazarettos, baths and watch-houses.

Similarly, Nazi Germany, while steeling itself for armed conflict, developed and tightened the security grid of military training facilities and military barracks in the east of the country. Functionalism – widely utilized at that time for multi-family dwellings - was not overlooked in military architecture. The barracks usually had a multi-staircase layout, occasionally a three-bay layout with rooms extending on both sides of a central corridor. In their urban design, military complexes also utilized improvements introduced in the 1920s and 1930s in the settlements of building cooperatives associated with *Werkbund* movement, such as linear plan, however incorporated in well-tried hieratic block layouts. The most prominent feature was still a central courtyard, around which all the buildings were arranged in a form of a dense compound.

4 REGENERATION OF MILITARY COMPOUNDS IN LEGNICA – EXAMPLES

After 1945 some parts of Lower Silesia underwent a complete exchange of population and alteration of nationality. After these territories were resettled, the objects that were most venerated by the natives became unfamiliar and irrelevant for the newcomers. Due to their function, the military installations were inhabited by the Polish or Soviet army. As strategic objects, they were, in most cases, properly maintained. When the Russian troops were withdrawn in 1993 and the Polish Army was restructured, many properties were looted and abandoned. Unused, they degraded. What was once a focal point for town's social life, now became a collection of discarded ruins, with little sentimental value.

Among many Lower Silesian cities Legnica is the one that was mostly influenced by its relationship with the army. Since the end of the first Silesian War in the summer of 1742 until the withdrawal of the Russian Army in 1993, Legnica was a garrison for various branches of the military. Throughout the ages the city owed its privileged administrative position and its economic situation to the presence of the army (for the central budget the army is a liability and expense, but it generates substantial income for the local budget).

Figure 3. Eastern façade of the Grenadier Complex after regeneration.

For example, the grandiose compound of *Grenadier Kaserne* in Hutników Street was built entirely from brick manufactured locally by Gottfried Bienwald's brickyard and laid by local masons; the post-war army music competition held in Legnica was renown in the whole of the Eastern Block, etc.

The military facilities are a token of "little homeland" to three ethnic groups and generations of Legnica citizens. For German compatriot associations from Legnica (*Liegnitz*) these objects are a sentimental reminder of the splendor of their lost homeland (Tomczak, 1997). To the Russian military and their families it's a subsidiary home they once inhabited (wroclaw.wyborcza.pl). To the Poles who settled in the city – a part of town they reclaimed with the withdrawal of occupational army and with proper regeneration of which the city may again achieve prestige (fakty.lca.pl). The care given to the facilities by Polish authorities is a sign of good intention and will of reconciliation, as well as an investment in future good relations with their former inhabitants.

As in other garrison towns in East Prussia and later Germany – e.g. Wrocław (*Breslau*), Brzeg (*Brieg*), Koźle (*Cosel*) – Legnica barrack compounds were distributed on the outskirts of town, creating a ring around it (Figure 1). Nowadays, due to urban sprawl, they are located downtown. The complexes were connected to main exit-roads, some conveniently positioned near main railway hubs. They covered 17 km^2 and comprised of over 1200 properties, amongst which were not only dormitories, but also warehouses, hospitals, schools and an airport, all located in downtown Legnica. Since the barracks occupied such prestigious locations, their degradation became a serious problem for the city officials. A good example is the largest hospital in town – the lazaretto in Złotoryjska Street. On the southern outskirts of town, just off the road, hidden in a tangle of trees, stands an abandoned extensive complex of military hospital. The edifice was constructed in 1937 and comprised of a hospital, a medical school and recuperation center.

The oldest among the compounds is *Grenadierkaserne* – Grenadier Regiment barracks of King Wilhelm I – constructed in the years 1874–1888 right outside the Old Town, at the main western exit-road (Figure 2). The construction of this compound was the key factor that influenced the urban pattern of this part of the downtown (Rodak, 2015). The complex was built on a rural plot of land (Grajewski, unpubl.). The first street that was plotted in this area was the *Grenadierstrasse* (presently Hutników Street), that ran in front of the main building of the complex. In 1889, after the compound was completed, another new street was marked out to run along the southern perimeter of the complex.

The compound consists of three dormitories and a supplementary building – encompassing a vast drill square – and some auxiliary buildings at the back of the premises. The barracks represent a type of monumental, multi-store and three-wing building whose main body is accentuated on central axis and quoins by *avant-corps* surmounted with turrets or machicolations. The *corps de logis* faces the street and the side wings are propelled into the courtyard. As can be seen on archival plans, such stylistics was commonly utilized for military facilities at that time, for instance in Bierutów, Kluczbork or Wrocław – e.g. barracks on Kępa Mieszczańska, Szczepin Barracks (Eysymontt, 1998).

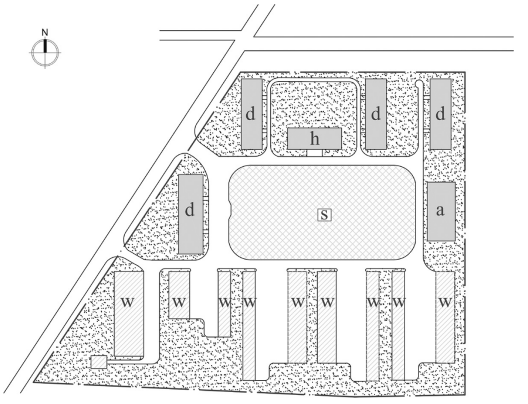

Figure 4. The complex in Złotoryjska Street – (a) auxiliary training facility, (d) dormitory, (h) headquarters, (s) drill square, (w) workshops & warehouses.

Elevations of the buildings are made of red bricks which are diversified with ceramic, sometimes colorfully glazed moldings, cornices, friezes and window casings. The outer walls are formed tectonically, undulating in depth and height, with varying textures. The buildings are two-bay, with a corridor, leading to auxiliary entrances, running along back elevation. In each of the buildings main entrance leads to a spacious vestibule with an open stairwell.

The complex was vacated in 1993 and in 1998 the premises were handed over to a community colleague. In the following years school authorities allotted around 20,000,000 PLN to the regeneration of the compound. Two out of three dormitories were included in the regeneration project, which involved restoration of elevations and woodwork, adaptation of interior, reconstruction of the historic fence. The preconditions were ideal for establishing a school. Spacious dormitory rooms were easily converted to lecture rooms partially thanks to the large windows letting enough light in and partially thanks to the high ceiling, allowing installation of suspended ceiling that accommodates all the extra amenities. The wide corridor, designed to enable instantaneous marching out of a large troop comes in handy during breaks and is essential to meeting the requirements of fire department safety regulations. The voluminous drill square is a perfect place for student meetings and recreation. The stylistic of the complex matches the required grandeur of a scholarly facility as well (Figure 3).

There are however week points to this project as well. Due to safety concerns the buildings can only be accessed via the inner courtyard – through back entrances – while the main representative portals stay shut. The drill square is used as a parking lot, which makes an unpleasant impression and takes up space from area of possible student activity. Moreover the third, southern dormitory remains a ruin.

Figure 5. Unfortunate stylistic choices visible in the façade of the barracks.

In 1935 on the south side of the city, in a park dedicated to a World War One monument, a complex of barracks for antitank defense units – *Kaserne Siegeshöhe* – was built (Figure 4). It comprised six administrative and residential buildings in the west, north and east of a drill square, as well as nine auxiliary sheds, garages and workshops in the south. The buildings were almost ideally situated on a north-south axis, practically making up a layout of a functionalist linear settlement.

Alike other military compounds it was vacated in 1993. In 2006, a social housing association (TBS) began regeneration and adaptation of the complex and in 2010 first users inhabited their new flats. The three-bay barrack was ideally suited to becoming an apartment building. A spatial corridor linked rooms running along eastern and western elevations to two entrances opening to the inner courtyard. The house had three stories, a basement and an attic. During adaptation on each floor, the corridor was divided in two, creating two separate units with autonomous entrances. Large common bedrooms were subdivided into independent flats and equipped with bathrooms and kitchens. The building was retrofitted with amenities: entrances were supplemented with huts and ramps for the disabled, the apartments were given balconies. The attic was partitioned by an additional ceiling, creating *entresol*. The result was around 2800 m^2 of living space and preservation of the compound.

However, even though most of the original tissue was preserved, in the process of adaptation almost all architectural features were forsaken for the comfort of future users and only the original urban pattern is visible today. Originally, the brick walls were covered with plaster and painted in modest beige (liegnitz.pl). The roofs were covered with flat, red terracotta tiles. Windows had wooden frames with muntin and were painted white. The attic was illuminated by means of dormers neatly distributed on every second window axis. The walls were accentuated by brick socle and expressionist ceramic moldings, e.g. in portals. All those features have been discarded. The walls were insulated with Styrofoam, plastered and painted in bright yellow and green. The brick socle was replaced by textured plaster. Wooden windows were exchanged for plastic with no internal subdivisions. The dormers were taken out. To let light into the penthouses the roof was riddled with roof windows and *porte-fenetres*. Raw flat tiles were replaced by glazed molded tiles.

It stands to reason, that the social housing associations operate on a tight budget and cannot afford building materials of the highest quality. Nevertheless, alterations to elevations, roof and questionable coloristic are a matter of style rather than finances (Figure 5). In the case of regeneration of military compounds, just as in the regeneration of post-industrial districts, the strongest point is the charm of historic architecture (Bryx & Jadach-Sepioło, 2009), which in this case seems to have been neglected.

Legnica is an excellent example of all chances and perils of regeneration process. A successful regeneration can bring back not only the objects but also the *genius loci* back to the life of a community. A careless adaptation, even though it returns the objects back to the society, obliterates their context and historic values – its only value is economic.

5 CONCLUSION

Barrack complexes complete the cultural landscape of garrison towns constituting an account of their past and an explanation for the manner in which they evolved. Without them the cultural landscape becomes vague. That is why it is essential that we preserve as many of them as possible. Obviously it would be counterproductive to petrify and preserve these complexes without reintroducing them into the urban space. Luckily, military installations can be easily adapted for various purposes. They are pre-facilitated with necessary infrastructure, which decreases initial costs of any potential investment. Since they include objects of versatile functions – houses, offices, warehouses, chow halls – they provide many possibilities of adaptation.

However, historic buildings, including military compounds, should be dealt with according to the monument preservation regulations, even if they are not regarded as monuments. A successful revitalization must satisfy the criteria of unity and integrity of quality (deriving from setting, function, design, materials, workmanship and condition) (ICOMOS, World Heritage Criteria, 1976). A building cannot be detached from its context, i.e. built environment (a group of buildings with which it formed a complex) or its surrounding landscape. First of all, the compounds should be regarded as a whole, should not be broken up into separate buildings. All the surviving buildings from the original complex design should be maintained, or if they were destroyed in the course of history – they should be represented by neutral objects of the same gauge. Second of all, beside economic and sentimental value, the complexes possess a scientific value – a typological potential – that can place them

in a larger context. Thus, the original features of the architecture should be preserved above all.

There are cases of both positive and negative practices among the many examples of adaptation. That is why regeneration of such military installations should be properly supervised, so that they are not deprived of their original characteristics, but serve as evidence of history while fulfilling their new functions. Barrack complexes form a separate genre in architectural typology, which is why it is important to find a specific recipe for their regeneration.

ABSTRACT: Contemporary societies have multiple forms of inter-relation between space and culture which are re-signified in the context of the recent and rapid changes occurring in the technological, economic and social spheres. This context sheds light onto the following question: how do museums and cultural facilities, in their material and symbolic dimensions, unfold dynamics and vicissitudes of such process in local e global levels? This is the core question that guides a research project, conducted by a group of Brazilian and Portuguese researchers, based on a comprehensive approach, embedded on interdisciplinary knowledge yielded by Architecture and Urban Planning and by Social Science. This article presents the first results of a field research conducted in cultural centers located in Lisbon (Portugal) and Brasilia (Brazil). In both cities, the cultural facilities that were chosen as the scope of the research, where a variety of significant cultural events are staged, sometimes are similar and sometimes are different as they highlight social, economic and technological changes through the cultural objects they shelter and exhibit, as well as their own architecture.

1 INTRODUCTION

Museums and cultural facilities have always been stages for significant cultural events of any society, as they exhibit social, economic, technological changes, both by means of the cultural objects they shelter and display, and through their own physical constitution, in their architecture. In contemporary times, these facilities are even more outstanding and an evidence of the relevance taken by culture and the architectural field in post-modernity. Thus, the purpose of this article is to present in detail contemporary forms of inter-relations between space and culture based on an analysis of museums and cultural facilities in their material and symbolic dimensions.

For such, we chose as empirical objects two cultural facilities located in two different cities: the Tile Museum in Lisbon, the historical capital city of Portugal and the Live Museum of Candanga[i] Memory, in Brasilia, the modernist city, capital of Brazil. The scope of both museums are the expressions of grassroots cultures and constructive techniques and they include in their collections significant iconographic records of the histories of these two cities. The methodology of the research was to substantiate the study by connecting two fields: space and culture, through an interdisciplinary approach, based on the knowledge produced by Architecture and Urban Planning and by Social Sciences.

2 CULTURAL FACILITIES IN THE FACE OF GLOBALIZATION

Despite the emergence of the great media-based museums in the last decades of the 20th century, their consolidation as the type of museology that best represents contemporary times (due to its bond to the capitalized circulation of information via technological means) did not prevent, obviously, the permanence and continued adoption of a variety of museums, appearing in other historical moments. And some of them becoming even more necessary today, precisely because they provide several needs observed in the great contemporary museums. Apparently, many of

[i] Candango is the term informally utilized to name the workers who migrated to the region where Brasilia, the capital, would be built, in order to participate in the construction efforts.

the new institutions, inspired in former models, are reinterpretations that were adapted to their new scene of usage, such as the great contemporary museums, which also assume the specificities of past times, with a different semantics according to the new objectives they are aimed at.

And, it is precisely within this wide range of cultural facilities, implemented in the context of the financial capital and therefore shaped according to the needs of such a system to circulate, that we intend to deal here with the sphere of their creation and way of working in the present. These places, providers of knowledge, due to their powerful and historical relations settled between the spacialties they were conceived to meet and the cultural objects they display, consist in our view of excellent objects for study both of the past, the present and even of the future possibilities, in the sight of such relations between space and culture that are preserved, displayed and crystalized in them, in addition to so many promotions, recreations and omissions.

In fact, as many have already noted (Choay, 2001, Ghirardo, 2002, Huyssen, 1994, 2000, Montaner, 2003, Motta, 2000, Ribeiro, 2004), during the neoliberal economic boom taking place after the turn of the 1980's, several features of that moment were favorable to the dissemination of great spatial facilities in the form of museums, such as the hegemonic reorganization of the capital and its proximity with the cultural industry, the technological innovations and their utilization in the architectonic field, the information apparatus of visual nature and its connection with registry and memory, multiculturalism and a number of demands for cultural representativeness, the gradual valuation of educative activities and experiences of self-representation, the implementation or improvement of public policies to foster culture, the growth of leisure and international tourism, the instability of the financial market and the stability of the art market. In addition, of course, to the programmatic expansion of the museums themselves or exhibit facilities taken as places of encounter as well as places to acquire knowledge of the potentialities of contemporary architecture.

However, it is still too early to assess the durability of the success of such contemporary museological dissemination. This uncertainty arises from the fact that there appeared a number of criticisms to the economic formula to which mainly the mega museums were added to, increasingly more sumptuous and costly, due to the attempt by many local governments to reactivate economy by means of disputable public-private partnerships and questionable cultural approaches. Facts such as the fret and loss of attractiveness arising from this huge spectacular presence, which had already become a common practice expected in the new mega projects, began to spawn cases of new and increasingly premature re-openings, new alterations or even franchises in an effort of keeping the great public that had been initially attracted. Moreover, the cyclical economic crises, as that of 2008, affected and threatened not only the viability of several projects of already famous museums, even before implementation, but also the great museums, recently built or being expanded by means of traditional donations which, since then, had their funds diminished, with cases where millionaire expenses were reduced, additional funds were suspended, debts were accrued and some museums happened to be shut down. But, even before such crisis had erupted, critiques and celebrities from the milieu in which such institutions were now competitors, had already exposed the weakness of such utilization of the museums as tools of economic recovery (Arantes, 2000).

In fact, this scenario calls into question how comprehensive and how intense is the process of dissemination that the term "culture" has been going through in the last few decades, supported on economic and technological basis with potential high profitability and reproducibility (Guattari, 2000). This dynamics has enabled different cultural expressions to take on a core and strategic adding up to its power as a provider of citizenship, generation of economic development and the strengthening of a contemporary imagery associated with technology à, as one of the most important means of social representation at this moment, on the verge of transforming its representative spaces into icons of the world architecture. It is precisely due to this reality that, in our view, it seems justifiable and necessary to renew the attention to the different factors – conceptual, formal, and functional – that interact in such objects of study.

In light of this, we also understand that it is more coherent in our investigation to adopt as object of study an architectonic program rather than a building – starting with the external and public areas that are additional to the buildings up to the display rooms, with all of its diversity. Obviously we take them as referents to the topic we are dealing with, to the party adopted or also the spatial arrangement – due to the comparative possibilities that this genre may provide our research with, pushed into the global phenomenon of media dissemination and apparent cultural valuation under a hegemonic economic system.

3 THE CITIES OF LISBON AND BRASILIA IN THE MUSEUM

In order to analyze this scene that becomes consolidated in several cities around the world, the objects chosen in the cities of Lisbon and Brasilia are facilities which are, not incidentally, representative of grass-root cultures, making up the grounds for research, considering cultural multiplicity as an assumption for a broader understanding of Brazil's sociocultural complexity.

The objects chosen were observed in the sight of the history of the creation of such places, their urban implementation, the origin and preservation of their collections; these aspects were reviewed in a both material and symbolic perspective.

This choice also included a number of possibilities in terms of the symbolic potential represented by the two capitals, Brasilia and Lisbon, both in the wake of the competition for a good standing in the hierarchy of the global cities. Naturally, cultural facilities in other cities, in Brazil and abroad, might be addressed here as potential aids of comparative nature in sight of similarities and differences.

In Brasilia, Brazil's federal capital, among dozens of museums located in the planned area of its "pilot plan", a number of them focus on themes associated with the spheres of power regulation in the country and in the city. Looking at the museums located within this plan it is possible to see differences that are fruitful to investigate in relation to their architecture, scale, management and audience. Considering just the monumental axis and its surroundings there are almost 20 museums in Brasilia, most of them are modern projects of monumental nature or operating within a public building. From this set, a case study was selected due to the importance given to a specific component of the history and the culture of the federal capital, that is, the various social segments that served as physical labor force that supported and allowed the dream of the capital to become true, represented in the Live Museum of Candanga Memory, located at the fringe of the city's pilot plan.[ii]

Devised to be the first hospital of the nation's future capital conceived by the then President Juscelino Kubitschek, Brasilia, next to the lodgings for employees, this architectonic project was built in wood in only two months' time and opened in 1957. As a great deal of the adjoining area had been settled by other residents, resulting in the so called Cidade Livre (free city), today the Bandeirante Core, the initial intent of "undoing" such buildings after the inauguration of the modernist city was an idea that was abandoned as the hospital went on in operation and its support facilities remained in use until 1974, when they were finally shut down because the new District Hospital was being built, today the Base Hospital. As it became one of the few remaining architectural representations of the time when the new Brazilian capital was built, the cultural heritage protection securing this complex within the woods where it is located and its change into a museum, the Live Museum of Candanga Memory, which expresses constructive techniques utilized early in the local settlement and by the physical labor of anonymous builders who immigrated to the site under such circumstances (the so called candangos), shelters today settings of the grass-root facilities at the time, reproductions of projects proposed to the capital, exhibits of first photographic images of the capital, a library and, also, artistic workshops are conducted in it. The distinction of this physical place in the city in regard of so many modernist works that are now symbolic landmarks of the capital and of the country and its explicit increasing valuation, especially the new assimilation of the grass-root culture and its representations around the world in the last decades, not only as the result of cultural recognition itself but also as the appropriation of the most distinct representations as new sources of economic capitalization.

In Lisbon, the Portuguese capital, the case study was defined with the main purpose of providing comparative analysis. Out of so many traditional and recent cultural complexes of great impact on to the urban landscape of the city, the choice was the National Tile Museum, managed by the General Administration of the Cultural Assets, located in the premises of the former Monastery of the Mother of God, an architectural construction dating back to the 1500s. Such museum, dedicated to glazed tiles (azulejos), is a highlight as an "artistic expression that draws a distinction of the Portuguese culture in the world" (http://www.museudoazulejo.pt). Over and above the expositive activities, the museum has also the mission of fostering the knowledge of ceramics intended for coating and covering and its production as well as to support the preservation of the existing heritage.

The Museum is located in Xabregas, in the Eastern part of Lisbon, a former area with convents and villas, which turned into an industrial zone with dockings and working-class dwellings along the last century. Now it is facing a period of decline and marginalization associated with the process of de-industrialization and changes in the Port of Lisbon.

The National Tile Museum one of the most representative cultural facilities in Portugal due to its subject, the glazed tile – ceramics for covering and coating use – which became an icon of the covering/coating technique in construction which consolidated itself as a specific expression of the Portuguese grass-root culture in the field of construction, especially after the Portuguese culture merged with the Moorish and Mozarabic cultures.

Since the old monastery was built and founded in 1509 by queen D. Leonor, there was a constant transportation and storage of the most diverse pieces of glazed tile on the site in order to supplement the inner decoration of the building. Indirectly, this yielded a significant collection of such constructive technique. After the monastery was shut down, successive actions were taken within the premises in order to preserve such collection.

In 1980, the collection was integrated into the National Museum of Ancient Art and went through works of conservation and restoration funded by the Calouste Gulbenkian Foundation, thus achieving its emancipation as the National Tile Museum. This great collection, together with several pieces by anonymous makers and its exhibition facilities and also the increasing support activities provided by the institution, embodies a complex which – in a nation known for the valuation of traditions – emphasizes the importance of the grass-root culture both as an element of identity representativeness of this social segment and as a support to consolidate the images of works typical

[ii] Informações complementares, http://www.museuvirtualbrasil.com.br/museu_brasilia/modules/news3/article.php?storyid=73

of socio-cultural groups of stronger economic power. After all, as in the case of the old monastery in question, the popular technique of covering walls with glazed tiles was then also adopted in many buildings where the monarchy, the clergy and the bourgeoisie lived. More recently, such facility began to serve as an auxiliary mechanism in the process of economic revival sought by a variety of cities around the world by linking the cultural, entertainment and touristic domains.

4 CONCLUSION

The context outlined above ignites the following question: How do museums and cultural facilities, in their material and symbolic dimensions, reveal dynamics and vicissitudes of these processes on the local and global level? Among a variety of possible lines of study of museums (from the Greek mouseion: temple of muses), as are generally called the several places where material cultural is displayed, we will highlight their potential as a semeiophoros object, that is, something whose value may be measured either by its material condition or by its symbolic potential as a holder of meanings.

From a material viewpoint, new museums have taken an outstanding presence as actual spectacular mega projects, seen as the movie stars of the architecture world, icons of the present; also, architectonic facilities built in early times, became steady cultural references of their historical moments (Lourenço, 1990). In this context, the most increasing studies of such facilities and their functioning highlight the rise of phenomenon called "museum mania", originating from a sphere of more political-economic than cultural nature (Motta, 2000). This thread has been a source for questioning by a variety of critical sectors, from the cultural and urban fields, who claim it is necessary to argue both the legitimacy of the discourses imposed onto the cities, as well stressed by David Harvey (1996), and the relevance of the cultural representations they display, by lenses that disfigure their essence, as in the cases of exhibits that subtly manipulate their original meanings (Crimp, 2005). The reason why several criticisms emerged lies in the fact that a great deal of the success of these mega projects comes not exactly from the cultural objects they shelter but rather from the ostentation around the creation of a distinguished spatiality, or from the aesthetic aspects in reconfiguring places made representative of an era (Stevens, 2003), such as railway stations, dock and port buildings or industrial complexes that were shut down in the face of new demands guiding the changes in urban configuration (Ghirardo, 2002).

Regarding the second issue of this analysis, the symbolic potential of museums and cultural centers, we highlight the approach by Pierre Bourdieu (2005), for whom culture consists of a field where symbolic battles are fought and by which the inequality between the social classes is maintained. Museums, due to their cultural status, tend to convey feelings of belonging to some people and of exclusion to others, because of the repertoires represented and the languages exposed (Mariani, 1999). Such consideration has been valid for various phases taking place in these facilities along history, since the guardian museums keeping the loot acquired in the imperialist and colonizing expansions in the 17th century, the showcase museums that legitimate the aristocratic and dominant ideology of the States under construction in the 19th century, to the times of the mega museums of the 21st century, devised by municipalities and sponsored by financial corporations (Montaner, 1990).

Considering the dimensions of space that can be analyzed, this article was an attempt to intertwine these sociocultural levels that are perceived in such facilities. As already stated as the purpose of this work, it is essential to get to know the relationship between space and culture arising from the lived experience in such cultural facilities, since the brand of the contemporary societies is the convergence of language between the economic and the cultural spheres by employing especially technology and its visual information multimedia apparatus (Canclini, 2005).

Confronting these empirical objects, analyzed in a comparative fashion and made explicit herein, allows us to understand the dynamics and vicissitudes depicted by some cultural practices in the spaces where they express themselves.

In spite of the great distance in space and time, both museums we have analyzed are similar in terms of their material and symbolic dimensions. Powerful representatives of the culture experienced by the exiting lower class in their specific societies, in the scope of this subject, such museums resemble in many issues commonly found in the field of grass-root cultures. After all, neither of them was built as a cultural facility to display and preserve such representativeness; they were rather turned into cultural facilities as a result of the value they were assigned afterwards. It should be noted that the location of both facilities are a highlight in their own city, seen as museums of grass-root culture; Xabregas, in Lisbon, became very much industrialized during the 20th century and today there is a steep drop in density in terms of population and function; the Bandeirante. Core was informally populated in the fringes of Brasilia's pilot plan. They exist outside the elite's urban circuits, and this tells a lot from a material and symbolic perspective, that is, popular art and culture, for ages segregated and today (re)valued. It is not casual, therefore, that not only in these cases, they are located literally at the margins of the city and society.

These remarks may obviously serve as guidance for further and better considerations about such cultural facilities as well as about the cities that shelter them and the societies that maintain and utilize them.

Toward a sustainable city-territory in a diffused context: The potential of internal limits

Guillaume Vanneste
Université catholique de Louvain, Louvain-la-Neuve, Belgium

ABSTRACT: In a context of territories almost entirely artificialized by Man, seeking to distinguish urban from nature might seem not relevant anymore. The urban condition tends to become globalized and decentralized everywhere. Among those context, the diffuse city is made of fragments of heterogeneous urban materials densely inhabited on an 'infrastructured' layer of transport and well equipped with various city's functions. Knowing this, the city's edge condition, which once was facing the countryside frankly, continuously and often peripherally, has also become globalized, decentralized. City's edge is everywhere and nowhere at the same time. And yet, the city and the countryside remain operative concepts in the collective imaginaries. What happened to the urban and natural features in the contemporary city and what are their transformations today? Through the theme of internal limits, this paper will investigate the contemporary relationships between elements of the territory, mainly between the open ones and the built ones towards project strategies for sustainable and ideal urban future.

1 INTRODUCTION

1.1 *An artificialized environment*

The urban question, in the limelight during the recent decades, is today at a crossroad. A United Nations report in 2014 speaks of more than 50% of the world population who lives now in the city. In the twenty-first century, environmental conditions of human being have become mostly urban and spread everywhere on the globe. The context of the contemporary city is new. It occurs through mechanisms and speeds that we barely start to know.

The recent Anthropocene paradigm pushes humans to face their responsibilities regarding the environmental and social conditions of the ecosystem. The paradigm of the Anthropocene (Crutzen and Stoermer, 2000), demonstrates the significant impact of human activity, now able to influence the "Earth system" in the same way than earlier geological forces (Bonneuil and Fressoz, 2013). Indeed, environmental transformations change our relationship to "nature". The soils and open spaces of our territory could hence be considered as a spatial and natural capital. As this Anthropocene paradigm also question the relation between city and countryside inherited from the classical, industrial and modern city, it leads to reconsider design strategies and tools in urbanism.

The 2014 biennale of Rotterdam edition, 'Urban by Nature' did point out this new urban condition as humankind new "natural environment". Nature, among other human artefacts no longer claims to have a pristine character. The nowadays global urban fact acts as a new environment, a second nature, a frame for the development and the relationship between humans (Gugger and Macaes e Costa, 2015). This hybrid condition does not necessarily raise the issue of city countryside as an antagonism anymore but rather as a relationship between elements. This planetary or decentralised urban condition (Brenner, 2014) is the topic of intense urban studies since at least the beginning of the second half of the twentieth century.

Starting from a reading of existing researches on diffuse city in Belgium, this paper will go through the following steps showing how a critical acceptance of the staggered urbanisation can lead to new ways of designing the territory. The hypothesis is to look at limits as materials that can be described and designed to characterise the diffuse city and its territories. Through a short exploration of the dispersed area in the south of Belgian urban sprawl, we will then identify the hints for structuring the transformations of the territory in its relation to open spaces. The ambition is to understand the mechanisms at work and put them into perspective for a more sustainable construction of the territory today.

2 DISPERSION: A DESCRIPTIVE URBANISM

2.1 *Territories of dispersion*

Among those widespread urban conditions, some are characterized by an intense urban sprawl. I will name territories of dispersion those urban situations that have undergone an important descriptive work in urban planning. The European territories of dispersion began with the creation of dwellings, of production areas and of their communication networks, most often in the fertile lower plains. The various studies around

those constitute now a body of researches that has built a common but specific and contextual knowledge of a globalized phenomenon. From this corpus, some readings and resulting models have been used for the exploration of the study area because of their methodology's relevancy, their geographical localisation or for their historical significance.

In Italy, Veneto region's descriptions are exemplary of this descriptive work of the late twentieth century. Since the definition of the so-called c*ittà diffusa* by Francesco Indovina in 1990, in an economical study realized by the department DAEST of the University of Venice IUAV, several other researches have contributed to this understanding effort of the transformations of this horizontal sprawl. In this respect, the work of Munarin & Tosi and Secchi & Viganò, of the University of Venice (IUAV) happened to be pioneers in Europe. "The città diffusa has therefore been constituted from the original centralities of towns and villages: in the outskirts of the village, along the main road, a few modern houses are implanted, a craft warehouse or a middle size commercial area" (Indovina, 1990). The interest of Indovina's research lies in a frame shift which isn't centred on main cities but intends to describe the sprawl without references to any centre or hierarchy.

Such work has been realised about other territories as well. Thomas Sieverts studied the *Zwischenstadt* in Germany, Bauer and Roux the *rurbanisation* in France and before them, Gottman worked on the *megalopolis* on the east coast of the United-States. Beyond usual chaotic characterisation of those places, they proceed with a close reading trying to explain the rationalities and processes at work in these territories. They have led to various precise theoretical and practical studies about sprawl, aiming to define its forms and logics and proposing different definitions such as suburban, *peri-urbain, banlieue*, *megalopolis*, desakota, etc. They have enriched each other with shared concepts. This paper will refer more specifically to the tradition and literature of the diffuse city.

2.2 *Studies in Belgium*

In Belgium, dispersion occurs yet during the Middle Ages but more widely during the industrial period. The developments of railways and tramways' infrastructures coupled with policies on commuting displacement and on individual housing in social laws have been sustaining the building up of a dispersed territory (Seebohm Rowntree, 1910).

Later, during the post-war period, an Arcadian image of individual housing was forged in the collective imaginary. Supported by a law facilitating access to property, each family aspired to build its own detached house on its property. This welfare state context is well described in the text *la banlieue radieuse* (Smets, 1986).

In "Patching up the Belgian landscape", Bruno Demeulder (1999) describes Belgium as "[…] a land of laissez-faire, where the cacophonic juxtaposition of designs delivers surprise after surprise, where an intense poetry lurks side by side with a nauseating banality behind the common place of everyday habitation". Juxtaposition illustrates the neighbouring of projects, side-by-side but unconnected and without relations. Indeed, land privatization and the strong tendency to willing to be owner, are building a disparate landscape, based on suburban individual housing.

On her side, Bénédicte Grosjean, in "Urbanization Without Urbanism" (2010) explains the fine process of construction of the diffusion in so-called "nor urban nor rural" areas. For her, dispersion is based on transportation networks and on worker's cheap-housing access policy.

In "Brussels 2040", a prospective study on the future of the Brussels metropolis published in 2012, the "linear of contact" is developed by Studio as a measuring index, in linear meter, of the contact between built and open areas per inhabitant (Studio Secchi Viganò, 2012). The value of this index is then compared to the one of other metropolis showing its special feature through the relation of this metropolis with its open space. According to this comparison, Brusselian would actually be more in contact with the open space than Parisian.

In addition, the mismatch between the physical limits and administrative boundaries in Brussels Capital District makes its case paradigmatic. The landscape ecology, which underlies the territories, oversteps management's tools and policy of the capital region (Roland, 2013).

This non exhaustive body of descriptive studies demonstrated, each with its assumptions, the importance since the nineteenth century of processes that led to a dispersion of urbanisation, namely through transport system, social laws or a complex administrative and federal apparatus detached from the ground rationalities. It is through these inventive representations and acute descriptions of the city that a knowledge has been built up, being the base for theoretical research and practical transformations.

3 A POST DIFFUSED CITY POSTURE

3.1 *Critical acceptance: from diffuse city toward horizontal metropolis*

The position of urban planning, and even of some urban policy, through the studies quoted here above has evolved towards what one could call a post diffused city posture. Dispersion is not simply stigmatised anymore and a return to the compact city is no longer the only antidote to this so-called pandemic disease. On the contrary, this condition is accepted as an existing data to work with. Almost like an amnesty (Dehaene, 2012), we find traces of this acceptance in papers, conferences or seminars essentially emphasizing the quality of the living environment but questioning the sustainability of this form of urbanisation.

Acceptance allows one to deal and design with this current and existing condition, trying to modify it, to iterate it, rather than to seek its concentric counterpoint

or ideal antithesis. However, this acceptance does not imply the validation of the system as such. In this regard, two prospective ideas try to draw the guidelines, starting from the existing towards an urban ideal: the Horizontal Metropolis and the "ecological re-edition" of dispersed metropolis.

3.2 *Horizontal metropolis and ecological re-edition*

The origin of the horizontal metropolis concept can be found in the prospective vision "Brussels 2040", which one of three parallel studies was made by Studio Secchi Viganò in 2012 (the two other teams where KCAP and 51N4E): "what we call horizontal metropolis is both an image and a concept: it is about a reality where rural and urban, communication, transport and economical systems, are closely linked and interpenetrated". The horizontal metropolis is a theoretical construction analysing the territory as a superposition of layers enabling to imagine the diffuse city's transformation on the basis of its existing rationalities as "spatial and natural capital". It suggests a horizontal organisation of the society as a project for the diffuse city

On the other hand, the critical reading of a potential ecological and economical project for the horizontal metropolis proposed by Michiel Dehaene in the book "Gardening in the Urban Fields" (2012) offers additional finesse that one needs to keep in mind when dealing with what is already there and its future transformations. "This reflection on the horizontal city is not a plea for sprawl or uncontrolled development, but rather for the continued development of the existing patterns of urbanization; not suddenly choosing another model, but rather continuing to garden carefully in the existing urban field". He names these potential transformations an "ecological re-edition", emphasizing the work to be done starting from the previous edition, like an author would add a preface or rephrase paragraphs in a book.

4 FRAGMENT, HETEROGENEITY AND INTERNAL LIMITS: KEYS OF READING

In order to accept to rethink this city-territory, let's try to understand its specific constitutive elements. The image of internal limits refers to open, productive or recreational spaces, inside of the metropolis. Moreover, it insists in a second sense, on the inner morphological resource for potential transformation that lies within the territory itself.

4.1 *The form of the territory*

Unlike compact cities, identifying these territories' form is not easy. Their shapes, however, are not generic, and their descriptions gives access to a form of knowledge and of understanding (Viganò, 2012). The territories of dispersion are characterized by a configuration that disseminates the various urban functions and materials, supported by topographic, hydrographic, geological rationalities and whose flows, dynamics and movements are organized through large communications networks, including roads and railways.

Within this scattered portrait, fragments are still recognizable. Contemporary city's increasing development is often driven by individual, capitalist or private logic. The growth of 'pieces of cities' has been made with little or no regard to issues of public spaces and relations to the context. Those fragments and heterogeneous urban materials with large linear developments increase their mutual contacts but they also generate in-between spaces and leftovers. Paradoxically, the resulting relations between elements are impoverished, materialized by fences, barriers or lack of public spaces. Nevertheless, the fragmentation of the contemporary space generates a specific urban structure presenting unusual situations carrying a lot of potentialities.

4.2 *The internal limits: open spaces inside the metropolis*

A particular attention will be given to the "open" elements with the intuition that this "non-urban" plays a fundamental roll in the characterization of this type of city. According to Gilles Novarina, "the contemporary city is like the black spots of a leopard skin. It surrounds, inside it's mesh, cultivated farmland, woods and wasteland. The nature and the countryside, until then situated outside of the compact city, become integral parts of the *città diffusa*." The incorporation of this urban nature within the diffuse city makes it particular regarding limits' concerns since dispersion "abolishes the boundaries between town and country" (Novarina, 2003). The research assumes that this special condition from the point of view of fragmentation, of the proliferation of limitations and intimate interweaving between built and open space, is an ideal observation field to investigate urban and nature relations nowadays. Within this framework, the research to investigate a study area in its particular relation to the urban nature's limits into a prospective purpose.

4.3 *A study area between Brussels and Charleroi*

A study case will be chosen to support our arguments. This is a part of the Belgian diffuses city located between Brussels and Charleroi, deliberately leaving these urban centralities out of frame to focus on the description of the area in-between.

Dispersion of urbanisation within Belgian territory appears as a large oval shape around Brussels metropolis, extending from the Euregio Lille Kortrijk Tournai to the west to the province of Limburg to the east, and from northern Antwerp city to southern Walloon Brabant province and the necklace of post-industrial cities situated in the coal mining valley on the bottom of the illustration.

This drawing shows pattern of urbanisation represented as long filaments joining denser points and creating together a mesh, a continuous network of artificialized spaces. It is not uniform and one can

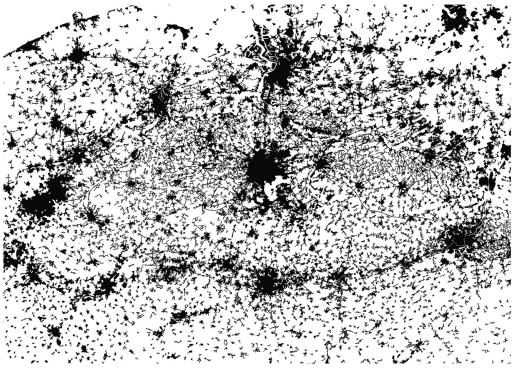

Figure 1. Diffuse city in Belgium, frame 200 × 100 km (Source: drawing elaborated by the author based on corine land cover 2006).

distinguish in figure 1 the differences between northern and southern parts. Notably, in Flanders (north), building plots are saturated and new conditions of dwelling are being defined in order to preserve open space. In Wallonia (south), open space is still a resource but its management could be enhanced.

Showing on a higher resolution the Walloon region land uses (COSW, *carte d'occupation du sol en Wallonie*), the figure 2 delayers its main features: built areas, forest and green spaces, cultivated land and agricultural land. Analysing this part of territory, south of Brussels, one can observe an important plots, parcels and land use fragmentation and an interweaved mix of built spaces and open spaces. Networks are willingly left aside to focus on the opposition between built and open environments. Those should be further investigated both as connectors and barriers, acting on a larger scale.

The agricultural and forest areas which are and which are not in direct contact with a built parcel, are pointed out above one another in figure 3. This starts to reveal a figure for a project. The spatial capital and the intimate relation between those elements can be the carrier of a territorial project, facing question of sustainability or public spaces.

Crossing this cartographic overview with a fieldwork on site, on can figure out that current urban mechanisms are supporting a way of conceiving limits that share responsibility in the constitution of a low quality interface between different allocation areas. These specific findings are making clear the need to reconsider more widely some urban design tools and to question the limits on this specific territory.

These succinct delayering of the territory allows to list several assertions about morphological situation and some hints for structuring the transformations of territory in its relation to open spaces.

– Few parcels of open spaces (agricultural or green spaces) don't have contact with built neighbourhood.
– Reciprocally, many built plots have contact, view or access to open spaces.

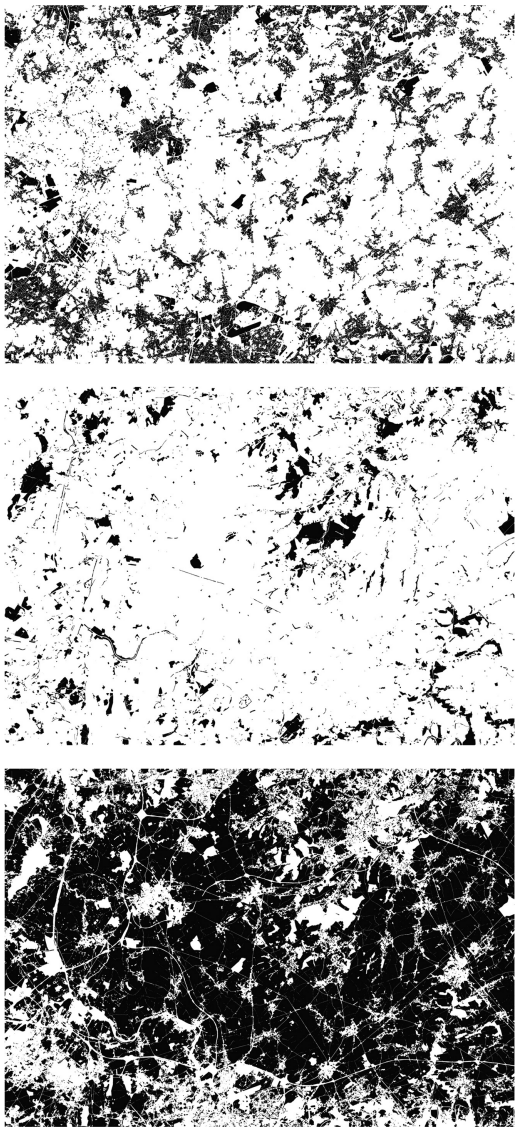

Figure 2. Delayering of territorial elements: built, green and agriculture. Frame 40×20 km. Area between Brussels and Charleroi (Source: drawing elaborated by the author based on cosw).

– These plots are equally distributed throughout the territory and not really grouped into one place, but rather spread all over, like the leopard skin or like pointillism. Only bigger patches of cultivated land can be found in the centre, due to the higher plateau in between the Senne valley (Brussels) and the Samber valley (Charleroi)
– It also presents a continuity valuable as an ecological and sustainable quality. Such as corridor, continuity allows species to flow and moves through, brings air to temperate some places through green areas and foster soft mobility and recreative path.

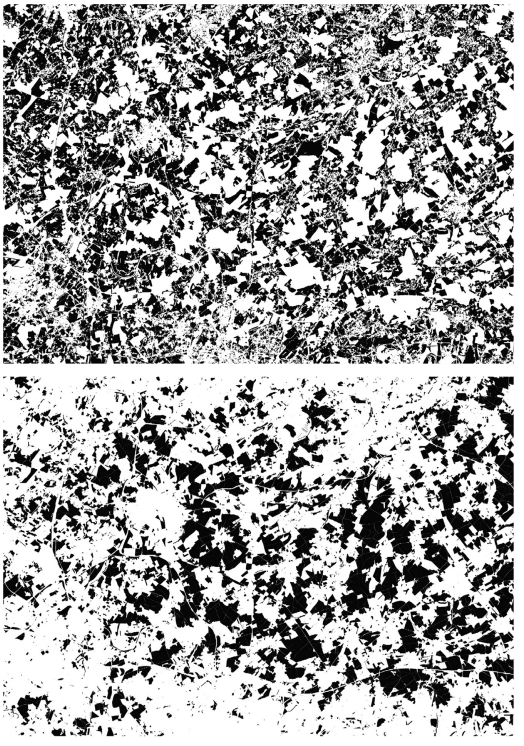

Figure 3. The internal limits. Frame 40×20 km (Source: drawing elaborated by the author based on cosw).

5 LIMIT AS A PROJECT: PROSPECTIVES AND TRANSFORMATIONS

This short analysis seeks to show that urban-rural relationship, in its contemporary reconfiguration, both asks and brings hints for a conceptual shift into design concepts, strategies and tools in order to transform the existing situation into a wished urban environment.

5.1 *A conceptual tool*

More than a physical reality, limit is also a widely used concept that has been developed in urban planning in issues such as city's form, growth, densification, spatial justice or environmental quality. Beyond the fact that limits act as spatial, sociological and anthropological "devices" of separation and ownership (parcels, defensive walls, etc.), the concept of limit is present in the social organisation of territories and of course in the urbanistic field, explicitly or not, within conceptual tools, regulations or policies. However, instead of being the monopoly of urban planning limits as a concept, its constitution benefits of a large amount of contributions from other disciplines and some theoretical fields have greatly enriched the meaning of this concept: the fragment, the edge, the *lisière* (Vanbutsele, 2015); or even concepts such as inversion (Cogato Lanza, 2005), porosity, or isotropy, convened in various urban projects are clearly underpinned by the theme of the limit.

Figure 4. Relation between open and built elements of the territory (Source: pictures of the author).

A contrario, spatial barriers and social injustices only increase in today's societies. Some gaps seem stronger than ever, building a city cleaved between poor and rich people, not without that the planners have

had some responsibility in it (Secchi, 2013). These trends are building very contrasting cities producing simplistic shaped intervention whatsoever offering few urban quality.

Social and spatial relations organised on a territory are represents through physical marks on its ground and in its soil. André Corboz speaks of the territory as a product, a project and a form (2001). Indeed, the actors of the ecology at work on a territory are producing, drawing and designing its form everyday through the transformation of our living realm. The territory is hence a support, both built artefact and intellectual project. It is in this sense that we propose to rethink the question of limits no more as a barrier, an edge or a line, but more like a frontier, an area of exchanges, a deep and porous space.

5.2 *Transformation on the edge of the metropolis*

In urban planning today several iconic or ordinary projects as well as urban processes and dynamics are at work in the transformation of our cities. The question or urban nature is being reconceptualised through those projects dealing with edge issues. But, they are mostly taking places within the periphery, in the margins of big cities or in the outskirts of metropolis, and seldom in the "internal limites" of the territories.

Among landscape or urban projects, concepts such as Michel Desvignes' *thick edge*, Bernard Reichen's *limit as a concept* for the SCOT of Montpellier (Masboungi, 2005), Studio Secchi Viganò's *antipark*, or the Metropolitan Landscape studied by Bas Smets leave some room for thinking. Some large urban visions and consultations, recently commissioned like Le Grand Paris, BXL2040, The Great Moscow, or the CUB in Bordeaux also defined the edges of extensions area of these big metropolis (figure 5).

Each of these examples make use of scenarios, visions or projects to imagine the wished urban future of these metropolis, based on a specific relation to void, open spaces or to the city-territory. Proposals are often quite innovative and conceptually powerful, allowing to drastically rethink an urban way of living more in adequacy with natural rationalities. Nonetheless, it must be noted that such examples only take place in high-density area or mid-size metropolis. Less dense contexts show a lack of policy, project or thinking. Some first hint should then be proposed for the diffuse city.

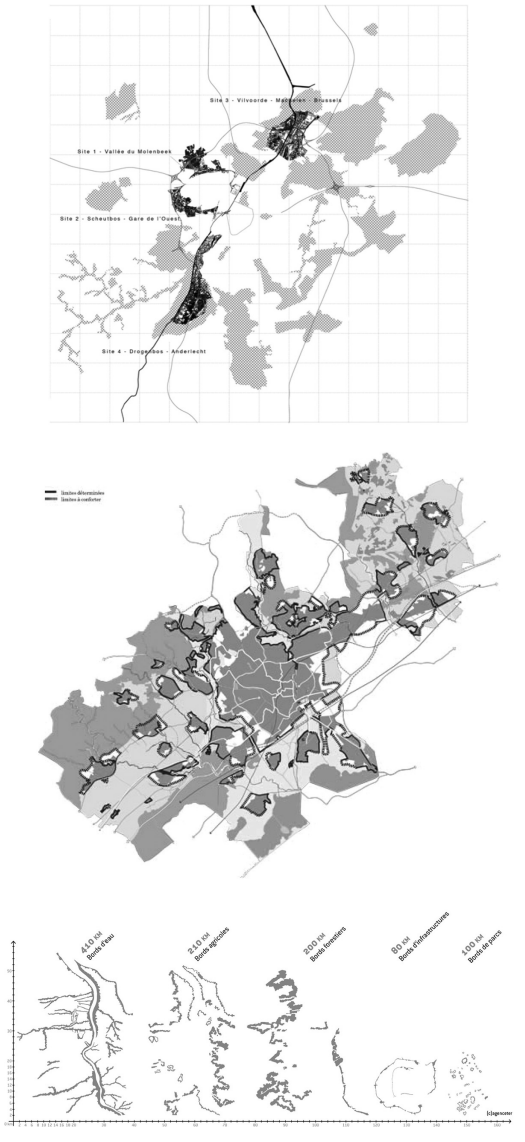

Figure 5. Limit as a project, examples of project dealing with metropolis' edges (Metropolitan Landscapes Brussels, SCOT Montpellier, CUB Bordeaux).

5.3 *Transformation in the diffuse city*

One of the challenges of this research lies in the conceptual construction of the object "limit" as a dynamic element and working agent, able to undergo the changes and to welcome synergies, rather than being the secondary result of two elements. Especially in a context of scattered urbanization where it seems that no vision or project is at work for its development.

As stated above, by borrowing some models in other disciplines as landscape, environmentalism or agrological and biological sciences, the concept of limit has been transformed and can still evolve. If we consider for example the concepts of *lisière* or ecotone, the notion of edge becomes a thicker line, able to manage flows, exchanges and dynamic processes, a thick boundary. The first reading of the area between Brussels and Charleroi has shown how numerous are the situations of confrontations of different land use. We see in this morphology a potential for projects. We can even extend this re-reading to the territorial scale and to the relation between different urban elements, joining the proposition of "ecological re-edition" of Michiel Dehaene: the existing horizontal territory is taken itself as a resource for its own "ecological re-edition."

Besides, I sought to show the intuition that most of those territories are built today out of the theoretical discourses presented above. And if one recognizes that individualisation of today' society is a key feature of the diffuse city, one must consider that the limits are not only considered between heterogeneous fragments but also between homogeneous elements, from one to another, between a house and the next one, an individual to another. The interface between territory's materials is an issue whose importance is increasing generating the need of a territorial reflection on the management of open space as a common resource. And looking at the actual construction and evolution of the diffused territory, we think that there is an urge for it to be socially, economically and environmentally more sustainable.

6 CONCLUSION

As a conclusion, let's see how this argumentation can help to identify the hints for structuring transformations with the ambition to tend towards a more common and sustainable construction of the territory for tomorrow.

First, the emergence of an important descriptive work on situations of diffused urbanization has been presented and how this work has sought to describe urban-rural relations. In addition, the descriptive look to the study area, helps us to understand what has become of the atavistic relation between city and countryside.

Second, I developed the posture of a post diffused city, showing the models of the horizontal metropolis and of the ecological re-edition of the territory, as possible ways to work with the existing rationalities and morphology for design the city and territory.

Third, the figure of the fragment in the contemporary city has been underlined and the multiplication of edges, barriers and gates issues as they build a fragmented territory. Nevertheless, the particular configuration of the Belgian dispersed territory, in its fragmentation and individualisation, generates a double potential: a spatial and natural capital and a possible conceptual shift about diffused issues.

Then, I enlighten the existing way to rethink limit as a project through the benchmarking of edge projects for the metropolis. Those models or methods should then be confronted to situations of sprawl in order to point the ideal future of that kind of urbanity. In a further step, the research could be continued in the form of research by design project by reflecting on scenarios and specific cases. The ecological and collective re-issue of the territory can summarize this general thinking.

Finally, among the specificities of the contemporary city, I believe that places of limits are a space of differences and potentials, especially in the post diffused territories, aware of their rich and hybrid condition, no longer trying to solve a city-country opposition. The "internal limits" summarise this point, using the term internal to describe both the open spaces geographically situated within the metropolis and the fact that the resource for this potential transformation lies within the territory itself. This perspective tends to design a more sustainable metropolis offering horizontal relations between elements and individuals and pursuing a stronger ideal for a *vivre ensemble*.

Imbricate ecologies: Rethinking the city-nature relational challenge

Wissam Mansour
Notre Dame University, Lebanon

ABSTRACT: The overlapping of the urban and the rural under planetary urbanization presents a welcome challenge to the relationship under which the city and nature are thought: As this overlapping upsets the simple liberal relationships of integration and opposition that were possible through the historical distance between city and nature, their overlapping presents morphological and ecological imbrications –natural, human, and urban- that bring back to the fore urban-nature relations of particular relevance to urban sociology and urban ecology. This research adopts a socio-ecological approach to rethink early modern urban definitions that yielded desolate ecologies and versions of Darwinism to isolated or metaphorical studies of human and natural ecologies. It relinks the urban definition and production to the spatial dynamics inherent from the geo-ecological relationships between overlapping urban-natural dimensions. Canonical models for thinking city-nature relationships are excavated for urban-natural, socio-spatial imbrications under planetary urbanization.

1 INTRODUCTION

Among the images that planetary urbanization produces, two images stand out in their significance to the study of the nature of this urbanization: The first image is central to urban growth and is exemplified by urban movements to reclaim urban parks and natural areas within cities such as the Gezi Park protests in Istanbul during the 2013 summer, and the civil movements that reclaimed Beirut's historical pine forest as a public space. The second image is spatially peripheral to urban growth. Instances of this image are found in china's expanding urban centers: The growth of conurbations in china and the transformation of neighboring villages into fast growing cities – like Shenzhen and Guangzhou – with urban villages of their own brings Geddes' concept of the regional city to ironic dimensions where natural regions disappear, as it literally takes today a whole region to make a city.

While the first image emphasizes and confirms the importance of natural areas within cities for sustaining healthy urban living, the second – that of the gradual disappearance of the country side – shows offset outlook of nature from an urban vantage. Their central and peripheral locations within urban growth illustrate protracted tensions in the sustainability of the relationship that binds nature with urbanization. The fact that these anecdotal images flank the ecological relationship between cities and nature illustrates the persistence of such a problematic relationship radially across urbanization processes, where remedying solutions are mostly sought on urban levels while urban-natural confrontations peripherally persist.

While urban sociologists first signaled modern civilization by the growth of great cities (Wirth 1930), the advent of this contemporary growth as described above is depicted in images that are not categorically dissimilar from Sumner's description of primitive societies as human groups scattered over a vast territory. The major transformation in this latter image towards planetary urbanization is a scaling up of human groups into cities and towns that coalesce rather than scatter to cover vaster territories, and the subsequent disappearance of nature under this urbanization cover. The natural spatial tenet of modern civilization being the settlement of nomadic people (Wirth 1930) under such a covering is today unfounded. Also, the simple distinction between city and nature is no longer possible as the city is no longer this rough jewel on the breast of nature as Geddes described it a century ago (Geddes 1915). Rural-urban overlaps under planetary urbanization complicate the relational patterns between urban and natural environments beyond the morphological and the social transformations that permeated the disappearance of the rural as the modern cities first outgrew their peri-urban extensions. These overlaps call for an analysis of some of the urban models that thought growth processes to date, and the ecological relations that had bound nature and city. While acknowledging canonical models such as the urban concentric expansion as a natural growth process (Burgess 1925), or other socially centered urban dynamics like Harvey's movement of dispossession by international capitalism (Harvey 2008), this analysis seeks to question the following:

– First, The ecological approach to the growth of modern cities as inherited through modern urban sociological theories especially as these were influenced by post-Darwinian evolutionary theories. It is questioned here whether the human ecological approaches to theorizing urban growth have

emphasized the human metaphorical aspect of the evolution of species over more complete ecological readings of city growth.
– Second, the human outlook, or the transformation of such an outlook to the relation that historically bound cities to nature as characteristically distinct, until cities as social and built environments culminated to second natures (Lefebvre 1976). Consequently, this puts into question whether or not social revolutions must be urban, or ecological.

The paper will approach these two questions from various urban, sociological and ecological approaches with the aim of spotting tendencies for severing the spatial relationship between cities and nature, especially as influenced by growth. Latent permutations of dematerialized demarcations between city and nature will be mapped under their respective ecologies towards an assessment of the nature of the ecology of growth. Ecologic morphologies that thought city and nature – like Geddes' Valley Section (Fig. 1) and Leon Krier's rural-urban Transect (Fig. 2) will be revisited as ecological imbrication models under the changing nature of urban growth.

2 MODERN CITIES AND HUMAN ECOLOGY

2.1 *Ecology, economy and socio-urban theory*

Ecology had dominated socio-urban thinking in early sociological writings on cities since the establishment of the Chicago School. As it will be further shown, the impact of the partial ecological approach by the human ecologists isolated to a large extent the human centered ecological study of cities from their natural environments. This was, however, due to the integration of ecological thinking within socio-urban research through the economic dimension. The economic accent of social thought in early modern writings on cities was impacted by an emerging pecuniary and statistical analysis of cities and citizen. It streamed urban ecology more towards a human than a geographically centered ecological thinking.

Georges Simmel's influential analysis of the metropolis and the psychology of the cosmopolitan heavily draws on the transformation of society under a capitalist economy. His description of such an urban character under the influence of economic exchange defines the psychology of the individual as an ambiguous accommodation in continuous adjustments to external socio-economic forces. His adaptation of the Durkheim's social *anomie* is based on the comparative analysis of rural life versus the metropolitan way of life, which displayed for Simmel an environment of threatening currents and discrepancies (Simmel 1903). Simmel describes an ecological transformation in the relationship to environment from rural to metropolitan habitats: Under feudal ages, the freedom of men was simultaneously bound up with the law of the land and the corresponding feudal social orbit. The unfree man was the one with mere feudal associations. This relationship with environment together with its social implications is rendered for Simmel superfluous under the metropolitan way of life that offers richer social contacts and associations by virtue of the narrow spatial proximities. In Simmel's description of this relationship between personal freedom and the spatial environment he correlates the enlargement of social circles and the personal freedom together in transcending the visible expanse of the city, which expands on conceptual and economic bases to dominate its hinterland. As such, in its expansive domination of its natural extensions, as well as in the socio-economic forces it exerts on citizen, the city's self centeredness ignores nature under the economic premise of early urban modernity.

Simmel's conception of the city was a sober correspondence between the calculative exactness of the modern economy and a scientific sociological preference to transform the world into an arithmetic problem that could be solved. His approach to the city as transcended by the urbanite and as itself transcending its limits is commensurable with later developments in ecological readings of the city that took a strictly human ecological turn.

2.2 *The city, numbers and human ecology*

Numbers constituted the sociological gate to a human ecological approach to urban environments during the twenties. They formed the basis for socio-urban studies of cities with various urban and ecological implications. For Ernest W. Burgess, the analysis of urban elements that are subject to numerical measurement was key in identifying urban growth. The introduction of the concentric zone model of the city, and succession as a metabolic growth process drew organic metaphors from plant ecology to pass city growth and a latent social disorganization as natural processes within the city. Growth and succession together ultimately defined mobility as the natural pulse of urban life. However, mobility remained for Burgess a tool to measure land values and describe city growth, as a wayfinding tool for citizens to organize their life patterns in the city, and find their congenial social worlds (Burgess 1925). Despite his awareness of the appearance of vast urban aggregates – conurbations – in Europe, America and China as "a new feature in the distribution of man over the earth" (Burgess 1925), his ecological outlook was directed more towards metropolitan areas than towards this new distributive feature and its wider ecological impact.

Another numerically inherent reading of the city was Louis Wirth's definition of an urban theory based on population size, density and heterogeneity. Wirth saw in the human concentrations in gigantic urban aggregations a "distinctive feature of man's mode of living in the modern age" (Wirth 1930). His seminal essay Urbanism as a Way of Life acknowledges continuous variations between rural and urban ways of life, yet subordinates an "ecological order" within his urban theory to the physical structure of cities that mainly comprised for him of a dense population,

typical patterns of social relations, and typical forms of collective behaviors. Greatly influenced by Simmel, Durkheim's social theory and Darwinism, Wirth built his urban theory on the effect of numbers and densities in the production of differentiation and specialization within socio-urban structures. Population numbers and density as objective indices permeate Wirth's ecological perspective of urbanism. He accounts to their effect the organizational and the functional facilities of cities, which in their turn account for the dominance of the city over its hinterland (Wirth 1930). For Wirth, The increasing population of great American cities with their social contrasts and biological characteristics defined the thinking of cities and their growth. This human ecology dominated Wirth's urban theory at the Chicago School of urban sociology.

In his Theories of Urbanism, Claude S. Fischer contrasts this determinist ecological approach with a compositional – or nonecological – theory that attributes differences between urban and rural ways of life to the composition of different populations. He distinguishes between determinist and compositional theories in their disagreement on the relationship of urbanism to the viability of the personal milieus that form the experiences and behaviors of individuals (Fischer 1976). Fischer's differentiation of these two urban theories points out a major discrepancy in the conception of the relationship between social life and environment. While determinist theory develops an urban approach based on the city as milieu for social organization, the nonecological or compositional theory describes social organization as social worlds protective of ethnic mosaic and of vulnerable individuals.

Herbert Ganz, a major proponent of the compositional theory argued that Wirth's urban theory is based on demographic factors – numbers, density and heterogeneity – rather than ecological factors. He proposed an urban definition based on social characteristics like class and life cycle, rendering the Wirthian relationship between settlement type and the way of life spurious. For Ganz, "the sociologist cannot, therefore, speak of an urban or suburban way of life" (Ganz 1968). He suggests that concepts like urban or suburban are not especially relevant for the understanding of the ways of life, but are rather – together with number, density and heterogeneity – "ecological concepts which describe human adaptation to the environment" (Ganz 1968).

2.3 *The dematerialization of the relation to geographic environment*

The disappearance of such a distinction between society and its habitat under geo-sociological predicates is then strongly linked to the growing economical basis of urban living. It reaches its peak in John Friedman's World City Hypothesis. There, the city and its growth are connected to global economic forces more than to local dynamics or regional extents. There, we find the second level of the removal of an urban ecology from its relationship to nature. The industrial city still maintained its dependence and growth along harbors and river basins as Saskia Sassen explains in The Urban Impact of Economic Globalization. While the industrial city still maintained the mirror of its economic growth in the city itself including its industrial and banking service cores, global cities today are primarily characterized by international financial flows (Sassen 2000). These flows, for Sassen, have overshadowed both in terms of values and power the industrial as well as the commercial sites of global urban environments and relocated these relational values from the parts of the city to global financial markets. She argues that the transformation of the economy of cities from a material to a financial and service based economy transforms the geography of global economy and strengthen the role of cities (Sassen 2000).

Sassen describes a narrowing down of the geography of the global economy due to the concentration nature of a growing direct foreign investment. She shares together with John Friedman a common perspective of this new geography along an East-West axis. As the trading of raw materials ceded between African and Latin American countries on one hand, and on the other hand, northern countries in Europe and the United States in favor of financial flows with centers in Asia, North America and Western Europe; the latter formed an east-west urban growth axis following global economic growth patterns, despite peripheral hierarchies with centers of secondary growth.

For Friedman, such a world city formation brings along spatial and class polarization on different scales relevant to the position of a nation within the hierarchy of the world city formation, but equally on the metropolitan level. Friedman attributes the various forms of spatial polarization – the ghettos, suburban squatters, ethnic enclaves – to class polarization, which is commensurable with huge income gaps, large-scale immigration from rural areas or from abroad, and to the evolution of jobs.

The transformation of the economic basis of societies under global economies, therefore, augments socio-spatial metropolitan problems and produces similar spatial types to the urban environment of early modern cities. The ghetto, urban sprawl and Urban Villages persist throughout various economic bases of cities – industrial, commercial and financial – as economy unsettles the relationship between a society and its habitat.

2.4 *What is natural about human ecology?*

The naturalization of such problematic areas of the city was theorized since the foundation of urban sociology. In "The Natural Areas of the City" Harvey Zorbaugh advocates a human ecology as an urban anatomy that composes the city of different unplanned natural areas as a response to their growth (Zorbaugh 1926). Such an organization is brought about by the competition of communities who are segregated as the city overgrows natural areas into natural groups. Zorbaugh invites those who would like to control the city's growth to

take into account the ecological facts that are inherent from this natural ecology: competition for position, segregation over natural areas, and succession. His discussion of the Chicago zoning ordinance's attempt to control land value reveals the importance of considering natural organizations and natural groupings as they intersect with injected blocks or use districts. He suggests a futility of an attempt to control the growth of the city and its inevitable succession, but rather sees a potential success in an urban economy that recognizes the natural organization of the city, population grouping, and a natural process of city growth (Zorbaugh 1926).

Similarly in his essay titled "Human Ecology" for the American Journal of Sociology, Robert Park attributes the natural functional areas of the city to the factors of dominance and competition. He breaks, however, from social Darwinism in his acknowledgement of the cultural level that distinguishes the human society from a plant and animal society. The human ecological basis of the city accounts for Park neither to a purely economic nor to a purely geographic ecology, but to "symbiotic society based on competition and a cultural society based on communication and consensus" (Park 1936). Park leaves room for a biotic competition in urban environments – mediated by other men, technology, and by institutional structures – and another cultural superstructure – a sublimated symbiotic society – that limits competition and the freedom of the individual by customary culture. Such sublimation enhances the weakening of a geo-ecological approach to studying urban environments and rather elevates an already diluted human ecological approach to the city into a cultural super structural level. While the inherent dualism within such a human ecology – competition and consensus – removes the toll of its association with social Darwinism, it nevertheless justifies urban inequalities and natural areas as natural processes subject to competition and succession, and further removes the regulation of these processes from the natural environment and endorses it in cultural institutions which themselves become the common habitat. Despite their difference, the determinist and the compositional theories advocate a human adaptation to urban environment. They equally alleviate the accent put on competition and what it justifies under social Darwinism – exclusion, colonialism – and relocate it either in the city or in the citizen. The human ecologists looked to humanize the city by naturalizing it.

3 CONTIGUOUS NATURES

3.1 *City-nature integration and opposition*

In the socio-urban tradition as analyzed above, the struggle to humanize the industrial cities of the early twentieth century dominated the work of urban sociologists, and dissociated the city from its environment. Robert Park notes an isolation model upon which nature rested until its destruction by commerce (Park 1936). Economy as we have seen had justified theories that thought the ecological struggle that dominated modern urban sociology and made necessary the rethinking of the biotic basis of the new modern world. These theories lacked more contiguous approaches of nature and city and isolated cities from nature.

This isolation did not, however, prevail all early modern urban thought. At the horizon of Patrick Geddes' thinking of the evolution of cities, for example, stands healthy living as the completeness of environmental, functional and social relations. With great clarity Geddes posited the urban ecological challenge as a coexistence challenge: "Cities in evolution and people in evolution must thus progress together" (Geddes 1915).

Yet, this parallel evolution is not ready-at-hand within the relationships that historically bound city and nature. Relations of distinction and sometimes opposition of city and nature often maintained their respective ecologies theoretically distinct. The shortcomings of a partial thinking of city and nature were, however, mainly addressed in urban ecology, where these distinct natures – city and nature – came to contiguous relations.

Anne Whiston Spirn maps the historical roots of ecological urbanism to the contributions of landscape architects and urban theorists. These took various approaches to the place of nature within cities, and the other way around. Landscape infrastructure, including urban parks were largely adopted by Frederick Law Olmsted to promote healthy urban environments through assistive processes to natural infrastructure (Spirn 2011). This has developed to the distinct discipline of landscape urbanism, which seeks to design geographic territories of augmented socio-political, economic and environmental outreaches. The Golden Horn Cultural Valley Project in Istanbul is an example of such an infrastructural culture-led approach to cities and their natural environments. It illustrates how the restoration of an estuarial ecosystem improves urban livelihood and economic growth. The premise of such landscape urbanism projects augments urban-natural contiguity hand in hand with economic growth.

Ebenezer Howard's Garden City model is another relevant model that brought nature and the city together. The debate over the Garden City model as Spirn explains is of a sustainable nature: To build new cities in nature or to re-naturalize existing cities. Lewis Mumford, like Patrick Geddes, emphasized the natural, historical and cultural relevance of cities within their regional context. McHarg revolutionized the evolutionary approach to ecology. His perspective of nature as process and of place as a morphological evolution resulted in an evolutionary approach to ecological urban design.

Under ecological urbanism, cities become part of the natural world. They are habitat, but are also ecosystems that make adaptive participation in larger, enduring ecosystems (Spirn 2011).

3.2 *The axis and the patch: The geometry and the politics of the relation between habitat and outgrown nature.*

Ecological contiguity has as co-requisite prolonged ecological imbrications like the ones found in Leon Krier's European Transect model (Fig. 1). This model and its application into the rural-urban Transect by Andrés Duany and Elizabeth Plater-Zyberk emphasize fractal overlaps between natural and built environments along various community development zones, with a strong sense of investment towards urban centers to minimize urban sprawl. In contrast, the suggested east-west linear growth axis under the World City Hypothesis evasively end-runs prolonged imbrications and urban densification. It promises no less dangerous ecological consequences than other forms of complete urbanization. The advents of the latter would inevitably be towards the limits of complete urbanization the reduction of nature and its complete replacement by the urban second nature: The future world of the generalized socially produced urban (Lefebvre 1976).

Whether cities are thought of as equally natural, or nature as a concept rather than a thing or a place (Spirn 2011), cities under complete urbanization would have to live under adverse ecological conditions; like in Mike Davis' apocalyptic ecological prospects of sprawling, decadent Los Angeles (Davis 1999), or drawn under the crushing weight of the produced urban space. The image of the activist pleading for the preservation of the urban park dreads and subscribes to both hypotheses. There belong all efforts to render cities sustainable. The patch as the trace of growth and nature reduction remains very significant for such ecological resistance.

Research spanning two decades in Stockholm demonstrates the significance of the patch to urban green infrastructure in remedying the effects of urban growth on the widening distance between urban consumers and the ecosystems supporting them.

In providing a space for human interaction with nature, patches generate ecosystem services that help connect cities to the biosphere (Andersson et al. 2004). The patch also is commensurable with urban practices that develop landscape within cities along heritage walks and urban parks, like the Freedom Trail in Boston. The Garden City apotheosized this natural integration too. Yet, the garden city is also prone to disappear, like the rural becomes peri-urban and urban, as is the case in Beirut's peri-urban transformation. What remains of this level is the patch: With grim prospects, under-pollinated, and together with the remnants of rural houses to which they belonged, they command a respectful grin as they persist under the smear of urban dioxide. The patch is inspiring and cities should not let it go.

Or, should the east-west growth axis theory go unhindered, then a biospherical split is imminent: North and south of the east-west growth belt. The Sci-Fi prospects of such a split are open, including apocalyptic natural disasters and environmental wars.

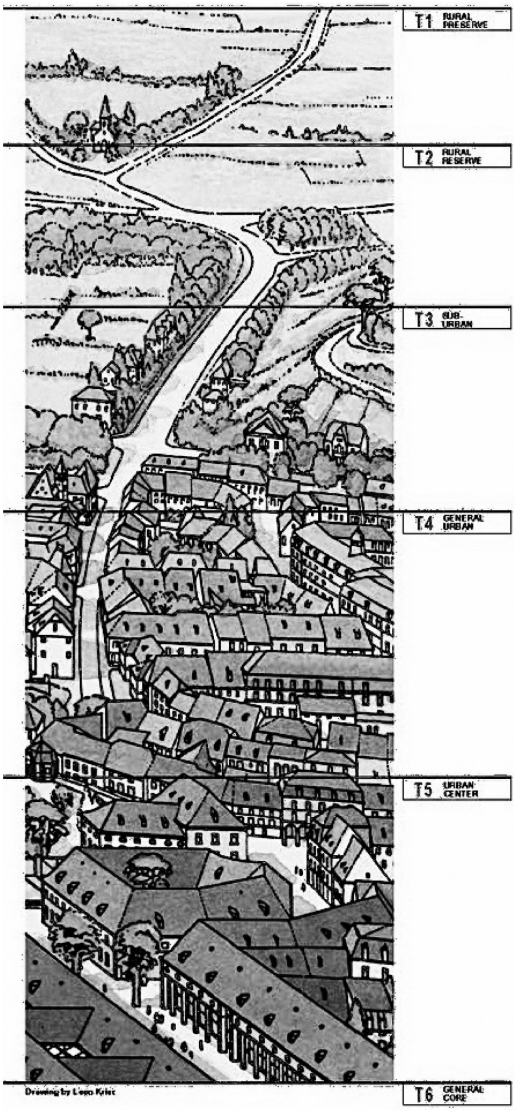

Figure 1. European Transect (Krier, 1978).

Together with this, an other socio-cultural split might well occur, whereby nature lovers would inhabit the peripheries of the belt, and in the core-belt strands of agglomerated conurbations would be financial enterprises, economic agglomerations, urbanites. And probably somewhere in between, the slums of working immigrants might one day coalesce and finally revolt. This is the triumph of the concentric zone model, of the radial growth model perfecting its realization: The up scaling of the ideal republic with its indifferent separation from the nature that surrounded it becoming one global second nature. Like Fifth Avenue draws a line between Central Park and New York, so would a line be drawn between a world city and nature, should the approach to scattering new urban centers across countries like china become a common practice

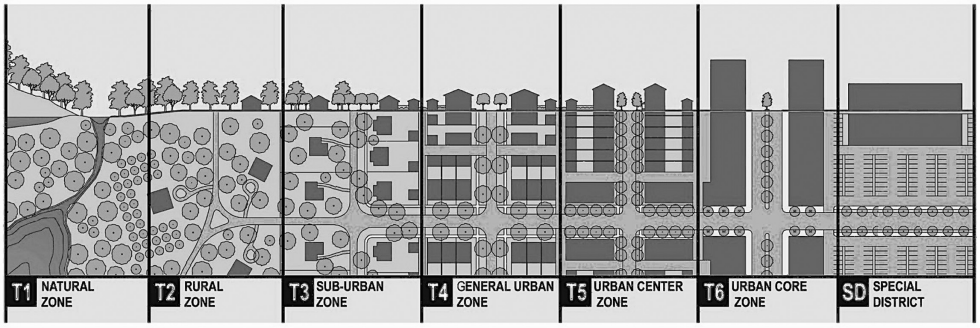

Figure 2. Rural-Urban Transect (Duany Plater-Zyberk & Company, 2008).

under pretexts of regional development and comparable urban rural growths that aim towards economic equity rather than ecological equity.

4 IMBRICATE ECOLOGIES

4.1 *Naturalization models*

Growth processes considerably sever the maintenance of nature, including the small natural patches in the city. Densification, for example, problematizes the possibility of maintaining a small-scale imbrication that weaves together city and nature. The economically driven nature of growth is in conflict with the economy of small natural patches. Densification maximizes built up areas to save rural lands. However, with densification, the green patches in the city disappear. Ecologically sustainable chances are considerably higher when socio-cultural awareness is raised as to the importance of urban natural imbrications across all scales of nature. The protests for reclaiming urban parks in cities like Beirut and Istanbul become useful tools against the disappearance of small-scale natural patches due to the transformation towards more urban ways of life. They are occasioned by infrastructural transformations, which isolate areas of the city, including natural areas and urban parks from their historical natural extensions.

This question preoccupied Geddes in his analysis of the evolution of cities. In his description of growing regional constellations he emphasizes the importance of regional surveying to determine the nature of growth. He pointed out two natural scales in face of this growth: The remaining natural reserves that may separate the growing towns and villages into conurbations, and any remaining possible gardens. (Geddes 1915). This vision differs from Duany's transect planning model insofar as the latter suggests a presupposed natural continuum intersected with transitory, yet fixed zoning categories and static growth. As these sparse along the transect section, they pertain from outside in to the hamlet and the village going in towards the city with its urban core. Yet there is no assurance as to immobilize the growth of this core and the destruction of the fractal model across which nature penetrates the section of Duany's transect (Fig. 2).

This growth phenomenon is a notorious reason for the severing of ecological wellbeing of cities across the world. Barcelona, Istanbul, Paris and Beirut among others are examples of cities that outgrew their centers to connect with nearby towns and villages, eating up significant natural lands. Rural emigration further contributes to the longevity of this ideal model. Therefore, the transect scenario suggests a static imbrication of natural and urban areas, but not an imbrication of the natural, human and urban ecologies which are at play within such morphological imbrication. Also, suggestions to scatter new urban centers as means to even urban-rural developments in China and elsewhere in the world present challenges to the thinking of such a sought after imbrication of the ecologies. One of these pressing challenges is the possibility that these new towns may occasion the same conditions that necessitated their creation in the first place: uneven development of rural and urban areas, and the accompanying urban malaise and neglect of rural ways of life; the creation of the slums and emigrant enclaves. Together with financial economical systems and foreign investment, this inevitably leads to increased land values and building booms, which leads back to city growth. Saskia Sassen argues that the globalization of economic activity and the generalized trends towards urban dispersal do not preclude the creation of territorial nodes, which are still needed for the accommodation of the management and the infrastructure of financial systems (Sassen 2007).

The other challenge that new towns present is a diminishing regional relevance of cities. This regional relevance, in addition to history created for Geddes masks through which cities reveal their spirit at each period of their evolution (Geddes 1915). The mask, however, is also lost in the creation of new cities as cities lose their unique place within their regional constellations. As the relationship of work and place lose their significance, the valley section (Fig.3) in which Geddes draws the regional relevance of cities from the primacy of occupation to natural contexts also loses significance.

Nevertheless, the chances that new urban insertions as substitutes for the growth of global cities is a prospect worth investigating, especially if it could enhance the imbrication of their latent ecologies

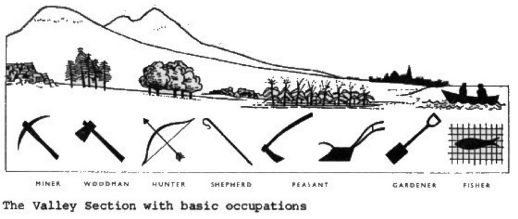

Figure 3. The Valley Section (Geddes 1909).

through the creation of new growth poles. These may enhance the control of growth through the introduction of linearity through polarization.

Like the complete separation between nature and city, which results in the replacement of a natural ecology by a human, similarly, the seamless overlap of natural and urban areas is likely to reproduce growth models. Yet, the possibility that scattered growth may enhance the imbrication of ecologies renders linear growth or other models worth studying. Models of relationships between urban and natural ecological environments that valorize the integrative objectives of the transect model and the patchy relevance of the city within nature, and at the same time nature within the city on the smaller scale of integration should be sought. While geometric propositions are possible, the interest of this paper is rather to signal the relevance of studying relations that bind geometric relational patterns between city and nature and, on the other hand, ecological separations or imbrications as byproducts of such geometric relations under dynamic ecological conditions.

4.2 *Nature, city and revolution*

A central problem faces such a thinking of imbricate ecologies. This problem under the theory of complete urbanization is the ungraspable boundaries of urban environment. As cities grow, their boundaries disappear, and cities become their own environments. Henri Lefebvre marks the complete urbanization of the world as a moment in the history of the transformation of the notion of place. The ultimate transformation at the horizon of urbanization is into a critical urban phenomenon that subordinates the agrarian to the urban, under the complete urbanization of the world (Lefebvre 1970). This ultimate transformation informs an urban centered revolution for Lefebvre. He describes the urban as a virtual world that assumes the concentration of everything, including nature, within temporal, and socio-spatial differences internalized within it, and detached from nature. Urban revolution as an axis stretching from pure nature to complete urbanization presents for Lefebvre the theoretical need for an analysis of urban society, towards the formulation of an urban practice as a concrete need. It should be no news then, that the importance of urban thought today is more pressing than ever. Harvey agrees with Lefebvre that revolutions today must be urban. However, the internalization of the concept of environment within the urban, and consequently, the urban nature of revolution are not in conflict with the environmental relevance of revolutions. Henri Thoreau's civil and nature contributions exhibit a balanced concern of civilization and nature that inspired both environmentalists, as well as key political figures like Leo Tolstoy and Gandhi. His concept of nonviolent resistance rests on the exclusion of the self from the need of governmental power, which originated in Thoreau's nature retreats. As such, civil revolutions have environmental underpinnings.

The fifth assessment report of the Intergovernmental Panel on Climate Change identified evidence that extended territorial emissions from developed countries – which include all GHG emissions within a city's territory – are substantially high (Seto et al. 2014). The report forecasts significant emission raises in China by 2040 due to population growth and urban expansion. The report proposes spatial planning as a tool for climate change mitigation. This includes macro strategies like regional planning, urban containment, and complete communities, in addition to other mitigation scales including urban planning and design strategies, like urban regeneration, infill development, and traditional neighborhood design, among others. Two things become clear: First, that urban planning and design are today more necessary than ever. Second, that environmental and urban revolutions are not dissimilar at their horizon. Protests to reclaim the natural patches of the city are symptomatic of urban and environmental longevity. Yet, the other image that concerns the urbanization of urban periphery requires a more silent urban revolution at the level of urbanism.

5 CONCLUSION

This research studied the theoretical axis that spans central relations between nature and cities under planetary urbanization. It was shown how the economy-centered approach of urban sociology naturalized the modern city under Human Ecology. The dematerialization of the relation between the city as a human economic habitat and its geographic environment dominated socio-urban thought throughout post-human urban ecologies concurrent with urban phenomena like the world city hypothesis. The various urban ecological approaches to locate cities as habitats back within a larger enduring ecosystem were largely conceptualized through radial sectional strategies, permeated by the idea of growth and natural re-integration. It was argued that such strategic models suggest static natural-urban morphologies that are easily destroyed by densification, rather than dynamic ecological overlaps. Landscape infrastructure and other small-scale infrastructural models like the patch were suggested as ecological models resistant to urban growth. While these should be of interest to architecture and urbanism, their mode of resistance to planetary urbanization inspire revolutionary overlaps that are urban and equally environmental.

Urban biophilic environments-a novel lexicon for trans-disciplinary practice

D.S. Nicholas, Rita Truoncgao, William Char & Shivanthi Anandan
Drexel University, Philadelphia, Pennsylvania, USA

ABSTRACT: The interdisciplinary research group, URBN STEAMLAB, integrates evidence based design with fundamental research processes in science, engineering and technology to create novel strategies and solutions for sustainable urban living and architectural interior spaces. Here, trans-disciplinary research is conducted to lead to new built outcomes and urban living spaces that are sustainable and include natural systems. This paper details a novel project driven by such concerns. *Algal Biophilic Interior Environments* is an in-home architecturally integrated hydroponics system that addresses the issues of healthy food availability in the urban environment and is the product of novel working methods. The design includes sustainable, effective, and testable interior systems that are suitable for growing algae cultures and plants on a small scale in the urban row home interior. These small-scale consumer-sized interior growing units will act as interactive infrastructural units in an urban row home.

1 INTRODUCTION

1.1 *Interactive space*

Design research is shifting the language of the built environment. Trans-disciplinary research is conducted to lead to new built outcomes and a growth of urban environments that are sustainable and include natural spaces. This paper details the fluctuation of design lexicons to produce architectural solutions for the urban environment that are sustainable and research driven, and includes a novel project driven by such concerns. The research lab, URBN STEAMLAB, integrates evidence based design with fundamental research processes in science, engineering and technology to create novel strategies and solutions for built sustainable urban living and architectural solutions within that environment. The research team combines the use of traditional STEM-based (Science, Technology, Engineering and Mathematics) innovation and research methods with STEAM-based (Science, Technology, Engineering, Arts and Mathematics) design methodologies to provide opportunities for problem solving and discovery for both scientists and designers in service to a new type of interactive interior, one that serves and augments users health.

Usman Haque, in his essay "Architecture, Interaction, Systems", codifies all interactive architectural experiences as one of three types: "reactive", "single loop" or "multiple loop". Each experience is defined by user interface with the environment and the growing complexity of these transactions. He claims that the more complex the interaction, the more satisfying the space to the users. This complexity and interaction between inhabitants and the systems of the building creates a kind of intimacy and control for the users that can be quite satisfying. (Haque, 2006) This assertion taken a step further can encompass projects such as those discussed in this paper. There is a necessity to have interaction in our architectural and interior environments: one that is created through the ever complex and varying needs of users and environments. Haque draws on Gordon Pask's work and the thesis that "*We can consider … architectural systems in which the occupant takes prime role in configuring the space s/he inhabits, a bottom-up approach which would result in a more productive relationship to our spaces and to each other."* (Haque, 2006).

We can look to the environmental theory of user affordances developed by Gibson and detailed by both Lang and Kopec. In addition, the idea that behavior settings which allow users to control their environments can allow these users to have a positive or negative reaction to spaces (Kopec, 2012). Haque is proposing more than control, however- he is proposing a relationship with space that is dynamic and complex (Haque, 2006). This theory of space making is one that the *Algal Biophilic Interior Environments* project detailed here falls firmly within. The team believes that this view of space-making draws us ever closer to a complexity that our current climate necessitates in all design. As such, the design of interior environments as multidisciplinary problem solving becomes paramount to creating space in the 21st century.

This thesis has led to the examination of new typologies for urban living. Thus, the design of sustainable materials, products and strategies for long term, environmentally friendly city living is crucial for the overall health of the planet and its human population.

2 COLLABORATIVE METHODS

2.1 *S.T.E.M. + design*

Current research shows that exposure to natural systems can improve human health. (Frumkin, 2001) The URBN STEAMLAB working processes and the *Algal Biophilic Interior Environments* project discussed here respond to this challenge through prototyping a process for innovation in sustainable urban living with a practice/research and collaborative process that examines bench science outcomes and tests prototypes in physical environments. This practice is part of the shifting lexicon of design practice towards human centered and "hard" research based approaches.

At the current time, traditional STEM fields are struggling to retain a competitive edge in the United States. Acknowledging this, the federal government has made STEM education a national priority for the coming years, recognizing that the US needs to produce one million more STEM professionals than are predicted to graduate over the next decade. Addressing the recruitment of students into STEM fields, a 2014 conversation with trainees in STEM fields at the Northeast Scientific Training (NEST) Programs Retreat proposed some solutions to this situation: 1) include a social justice component in the students' training, 2) train the students in communicating STEM to non-scientists, 3) train the students in STEM to STEAM (Science, Technology, Engineering, Arts and Mathematics) technologies, and 4) provide access to invested mentors. URBN STEAMLAB uses innovative methodologies and processes to incorporate these solutions into its activities. By introducing design into the traditional STEM disciplines, this program orients researchers to the possibilities of engaging with STEAM disciplines as a way of creating innovation. It also addresses a social justice component by exploring one of the major problem solving challenges of our age – the growing need for sustainable urban living solutions in today's cities. In 2000, the Environmental Protection Agency (EPA) concluded in the report "Our Built and Natural Environments" that urban ecosystems directly affect natural habitats and ecosystems, endangered species and water quality via habitat fragmentation, consumption of land and the replacement of natural ground cover with synthetic, impenetrable surfaces. Thus, the design of sustainable materials, products and strategies for long term, environmentally friendly city living is crucial for the overall health of the planet and the human population. In general, the silos of discipline have created a lack of exposure for designers to traditional STEM research and for STEM researchers to design opportunities. Both groups lack opportunities that might be relevant to the future technologies deployed in the marketplace. In addition, the design of spaces must now be more research driven than ever. In their book "Design Informed" Chong, Grant and Martin assert that design professionals are not exposed to research methods as part of their training or practice. This creates limitations for them in today's complex practice environment. (Chong et al., 2010).

2.2 *Informed design*

"Few design professionals are trained as researchers or even sensitized to critically evaluate research quality. Our academic settings and professional practice rarely place value on rigorous methodologies for creating and interpreting the information used to inform design. Even the basic steps of scientific method—define the problem, create a hypothesis, test, and document—are seldom followed by designers. Hopefully, the profession will make clear to our educational system that we demand some level of research knowledge as part of basic design education, because it will be as important to our professional success as design and technical capability. In the interim, we can share experience to establish a baseline of professional credibility in Evidence Based Design." (Chong et al., 2010).

The novel process of work described here creates a cycle in which STEM team members are gaining exposure to creativity, design and iterative practice, while the STEAM team members gain exposure to evidence based thinking and research practices that are valuable and unique. All team members work through human centered research practices which include building empathy for users and closely examining their needs and outcomes – this is necessary for operating in an innovative environment. In this way the conception of how participants interact with the environment and how the environment can create opportunities and resources for them builds on Haque's original, more subtle conception of space and interaction for experiential richness.

2.3 *Team and processes*

URBN STEAMLAB is made up of Scientists, Engineers, Architects and Designers. The current project is a collaboration between a bench scientist, an architect and design professor, a masters student in Interior Architecture and an engineering student, with input from other students, researchers in engineering and public health. The novel work process creates opportunities for students, faculty and researchers to work in an interdisciplinary manner on projects using a set of engagements that involve bench science, laboratory based processes, human centered empathy building and iterative studio based development. Team members start through learning skills in both design thinking and laboratory experimentation. The Science based team member maintains a bench science laboratory into which URBN STEAMLAB student participants are trained to follow protocols and culture micro organisms. At the same time, the team is given a set of iterative design thinking exercises to grapple with. These start as simple brainstorming techniques and end with systematic matrices that create ongoing diagrams of possible ideas and directions. In addition, deep dive techniques including interview, shadowing,

and personas are explored. The outcome is that the team learns to combine both iterative design thinking and laboratory experimentation. For the science based participants this creates new modes of creativity; for the design based participants this allows them to explore evidence, research and design as engines for these new types of spaces.

Following both practices in their thinking, the science work is lead by the exploration of micro-algal cultures and the ways that it can survive with multiple environmental factors in play. Team members are then are asked to deep dive into the human problems in the urban environment, especially those in neighborhoods that are underserved in terms of health, food and nutrition. As the solutions grow in complexity team members "flow" together with roles being assumed by lead researchers that have conceived of positive directions. In addition, the process exposes undergraduate students to the cultural and social aspects of the relationship between research, design and problem-solving.

By doing so, this project brings the STEM to STEAM practice of design, innovation and research into strategies for sustainable urban living. Those participating in this course as novice recruits will be exposed to this STEM to STEAM way of practicing, which will enrich and broaden their learning experience. Mishra et al. weave a vision of multidisciplinary learning that leads to creativity and enhanced problem-solving, sustained by opportunities for interactions between disciplines that support creative thinking through both technology and human interaction (Mishra et al., 2013). This research group is both process and outcomes driven and the chart below illustrates the working methods deployed by the group.

Novel Processes in URBN STEAMLAB	
Activity	**Objectives + Outcomes**
Theme: Paths and Trajectories. Build project goals and team	Develop faculty/student/mentor relationships
Theme: Gathering and Identifying. Research users and precedents. Engage in initial design thinking exercises.	Develop research/ innovation skills. Targeted research/ design proposal.
Theme: Users and Stakeholders Focus on human users. Deep dive techniques for empathy are deployed. Hands-on research/design	Develop research/ innovation skills through human centered design. Identify strategies for engaging with user groups.
Theme: Synthesis and reframing. Discussion and implementation of creative thinking and problem solving strategies	Develop familiarity with research/ innovation/ design tools.
Theme: Brainstorm initial solutions and ideas. Ideation: matrices development.	Develop ideas for prototyping/ research.
Theme: Development. Initial discussion of prototyping modes and skills, development of idea matrix	Develop individual research/design skills. Prototypes
Theme: Prototype Examination and Ideation. Prototyping and visualization exercises.	Develop initial physical prototypes/ collect data. Create and deploy group prototypes.
Theme: User Testing and Synthesis. Prototype revision.	Initial and revised prototypes/ models both physical and envisioned. Test prototypes in the field.
Theme: Synthesis Presentations and discussions	Prototypes and research notebooks that track research progress.

Figure 1. URBN STEAMLAB Novel Processes and outcomes.

3 PROJECT DEPLOYMENTS AND PROTOTYPING

3.1 *Project description and parameters*

The current URBNSTEAMLAB challenge is the design of sustainable, effective and testable consumer hydroponics systems that are suitable for growing algal cultures and plants on a small scale in the urban interior. The project, *Algal Biophilic Interior Environments,* seeks to create opportunities to ameliorate the urban food deserts currently in force in many urban areas through education and exposure to food production. According to the US Department of Agriculture (USDA), food deserts are low-income communities, with households living on tight budgets, that lack large grocery stores and supermarkets selling fresh produce and healthy food options like fresh fruits, vegetables, meats, and dairy products (USDA, 2015). The outcome of the project will be a new typology for urban living, one that includes a self-contained building system and interface that allows the inhabitants to produce food, clean the air, and through the deployment of double skin and passive wall systems to augment the heating or cooling of their spaces. The urban row home is the natural locus for the project and the architectural implication of introducing this new research-driven technology into this historic building type are considered as part and parcel of the solution to the urban issues in our environment.

With its impetus in the examination of ways to test the feasibility of algae micro-ponds to create nitrogen rich water fertilizer used in an indoor setting this project – *Algal Biophilic Interior Environments* – has

evolved into creating in-home architecturally integrated hydroponics systems to address the issues of healthy food availability in the urban environment. The design includes sustainable, effective, and testable consumer hydroponics systems that are suitable for growing algae cultures and plants on a small scale in the urban interior, including the design and prototyping of small-scale consumer-sized interior growing units that can act as interactive infrastructural units in an urban row home. Thus far the team has identified four (4) typologies that they are working towards: stackable units, window units and two types of panel units. These typologies have been classified through an examination of the interior space and types of row home in the urban area adjacent to the team's practice and a STEM-based analysis of the growing habits of the algae culture. We have deployed consumer grade 3D printers to create initial prototypes. Initial laboratory tests included small units to support algal growth, these micro ponds as we call them. Cyanobacteria being photosynthetic organisms like plants, require light (either artificial or natural) for growth. Cyanobacteria were introduced into nutrient media in the micro-ponds at a defined concentration, placed either in a growth chamber, on the laboratory bench far from a window, or on the window sill of the lab. Their growth was monitored daily. The micro-ponds supported the growth of the cyanobacteria for several days – as shown by the absorbance rates in figure 2. The project deploys algal cultures in service to the fertilization and production of food. For this project we install cyanobacteria, which are bacterial organisms that are critical for the primary productivity of their environments. Certain cyanobacterial species carry out nitrogen fixation, a process that enzymatically converts nitrogen gas obtained from the air to nitrate. This process enriches the nutrient availability of the surrounding cyanobacterial environment. Many cyanobacteria grow well in aquatic environments, and have been used as genetic and physiological test model systems for increasing food production by plants.

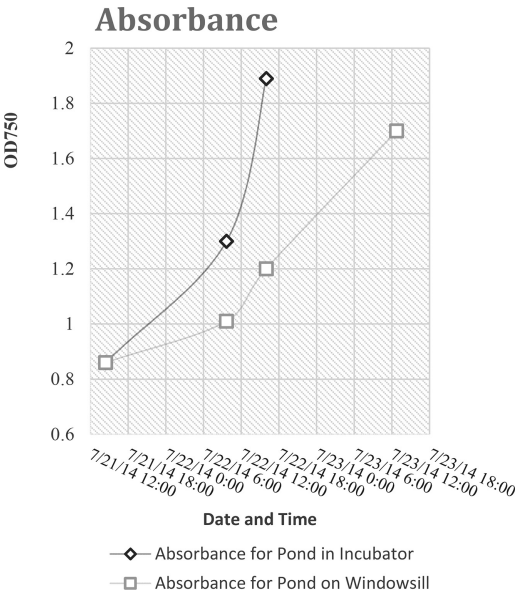

Figure 2. Measuring growth of algae over a 3 day period using optical density (OD_{750}) measurements.

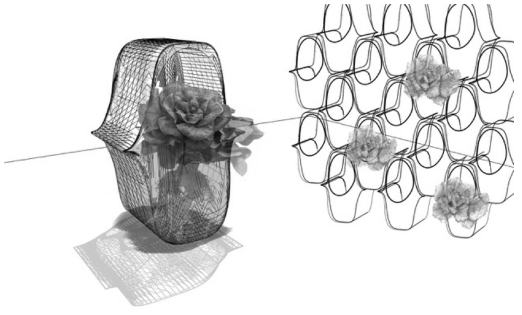

Figure 3. Initial Rendering showing the latest closed prototype.

3.2 *Prototyping*

This project began as a way to test the feasibility of using algal micro-ponds to create nitrogen-rich liquid fertilizer in an indoor setting, garden or yard. It has evolved into creating an in-home hydroponics system to address the issues of food production in the urban environment, and models the use of design thinking processes in basic research. This portion of the larger project includes designing and prototyping small-scale consumer sized portable interior growing units that can act as decorative and interactive units in an urban row home, while still growing cyanobacteria to generate fertilizer. URBN STEAMLAB teams worked on designing and generating a prototype pond system and testing cyanobacterial growth in it. The image below shows successive prototypes and an initial rendering of the latest unit.

The prototyping process was integrated into the lab-based cyano growing phase and the forms adjusted in response to the growth of the microalgae. The project has migrated from an open design to a closed upright unit as the absorption and the evaporation of the medium has shown that the algal culture will not grow as well when the water surfaces are completely exposed.

The team believes that this prototyping process will become more and more exacting as they continue to culture algal strains and move into the growth of plants. The introduction of sensors and interactive technology in the project will afford the users new possibilities in the production of food in their interior urban environment and may lead to methods for ameliorating the lack of availability of fresh produce in the underserved environment. This project aims to synthesize design, innovation and research and to link and utilize them in terms of real life process and experience. Charles Owen has spoken and written about the strength for science and design processes in tandem with each other in service to innovation, as each discipline brings certain

Figure 4. Printed Prototypes showing the evolution towards more closed design lower right.

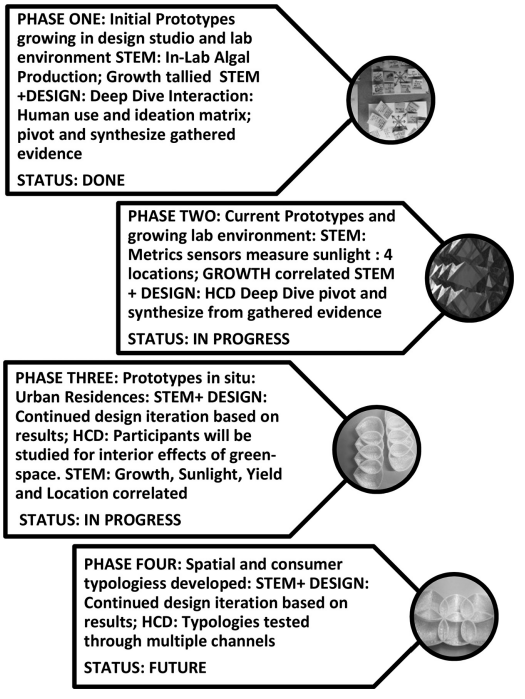

Figure 5. Project Process chart.

strengths due to the inherent nature of their objectives and approaches (Owen, 2007).

The argument has long been made that design, when included as an early part of problem-solving, leads to more satisfactory levels of creativity in dealing with complex problems. URBN STEAMLAB aims to create experiences in which the basic tenets of design thought become part of the non-designer's lexicon when experimentally approaching the realm of novel solutions for sustainable living in the urban environment. This approach, coupled with mentor engagement, will move projects in directions previously unimagined and expose students to innovation in ways that will serve them in their chosen academic and professional paths.

3.3 *Plants and interior environments*

In J. Benton Jones's marvelous compendium on hydroponic growth, *Hydroponics: A Practical Guide for the Soil-less Grower*, he lists the advantages and disadvantages of soil-less growing as explored by both Jenkins and Wignarajah. The team found that the positives of this type of growth, which included: no need for soil, no labor required for working the soil, high density high yield possibilities, conservation of water, and the easy control of disease (Jones; 2012) aligned perfectly with the urban condition, which includes lack of space, lack of land and the need for dense production. In addition, the process of growing in the interior environment creates the opportunity to introduce natural features into the residential environment in the urban grid. As stated above, natural elements have a health-enhancing effect (Frumkin, 2001) and this effect will be measured through prototypes placed within the community. Produce collected will be tracked carefully to understand the possible impact on eating habits. Certain health metrics for the volunteer participants will be tracked to see if there is any overall outcome in terms of heart rate weight and diet. The project process program and plans for integration of research and design are shown in the process chart Figure 5.

In this project, we also explore the development and use of novel materials and structures for the construction of the algal hydroponic growing units. As this work progresses we envision developing materials and micro-ponds that contain embedded or built-in sensors that monitor cyanobacterial growth. This self-contained system will allow users to monitor cyanobacterial growth without removing the algae from the medium for measurements. Prototypes have cycled through many forms: the current prototype will stack and integrate into the exterior wall on the interior surface as a way of insulating, producing food and creating the health enhancing Biophilic effects of natural space in the urban environment.

4 CONCLUSION

4.1 *Interior intervention/façade intervention*

"The facade is one of the most significant contributors to the energy budget and the comfort parameters

of any building. As energy and other natural resources continue to be depleted, it has become clear that technologies and strategies that allow us to maintain our satisfaction with the interior environment while consuming fewer of these resources are major objectives for contemporary facade designs." (Aksamija; 2013)

This project is essentially seen as becoming part of the interior surface of the façade of an urban row home: as such the next critical phase will include situating the prototype in the street and rear-facing interior walls of the row home building type. The project team is currently exploring a prototype that allows both stacked units and a stack effect for the spaces, thereby creating double skin facade-like effects in the interior. In this next phase the effects of an additional heat gathering and radiating surface, such as the stacked growing units, could act as an inner skin and, if vented correctly, augment the energy outlook for the conventional row home. (Aksamija; 2013) This project creates user interactivity, affords control of the interior and creates a bio wall for residential use that will produce food. Its future permutations will explore the façade and energy effects of the proposed system as well.

The neighborhood in which this next phase will take place, Mantua, is a community in Philadelphia that lacks access to fresh food as stated above. Predominantly an African American community, Mantua has a poverty rate of 43.2% (The Philadelphia Inquirer, 2016), which is much higher than the national's average of 15% (US Census Bureau, 2015). The average income of Mantua residents is $30,995 with an 18.2% unemployment rate (The Philadelphia Inquirer, 2016). In 2014, Mantua was singled out by President Obama as one of five economic "Promise Zones" across the country that will receive federal backing for community revitalization through the Promise Zones Initiatives (Moraff, 2014). As a site for initial prototyping Mantua holds within it the possibility for being a prototypical urban row home application with a real need for fresh food that will drive the outcomes for users in their residences. *Algal Biophilic Interior Environments* contextualizes project-based work in relationship to the future language of new practices in the built environment and the inculcation of STEM based research practices and human centered processes for built innovation. The project described here embodies new practices in the built environment and the urban communities that need fresh food, energy efficiency, and calm, healthy interiors. Novel outcomes that lead to new thresholds of human/environment relationships will continue to be explored in this project, due to a process that is inherently cross-disciplinary, and the practice "space" of a team including both bench scientists and designers has been laid out as a possible model for future application. The *Algal Biophilic Interior Environments* project activates the interior terrain of the row home, along the lines of Haque and Pask mentioned earlier, and posits a brave new interior – with the activation of self-sufficient urban living conditions.

Out in the open

S. Morgado
CIAUD and Faculty of Architecture, University of Lisbon, Lisbon, Portugal

ABSTRACT: Open space, especially before the variety and diversity of the built environment, seems to be the most identifiable and distinctive approach towards an efficient and reliable guaranty to control metropolitan sprawl. Act-ing at different levels of planning and design, as well as crisscrossing various fields from landscape to urban, from environmental to societal sciences, from heavy infrastructures to intangible flows, the open space system may provide high quality places accessible to all. The links between morphological evolution and the main urban models used in the planning process are pinpointed, giving evidence of to the role of open space in the process of land transformation. Chelas was specifically addressed for its key role in various levels of planning and design. This paper examines the final results of a research conducted at the Faculty of Architecture, University of Lisbon and at the School of Architecture in Barcelona (ESTAB-UPC), funded by the FCT.

1 THE POTENTIAL RING OF METROPOLITAN LISBON

Lisbon, as a municipality and city, plays a key role in functional terms and in a broader metropolitan context, since the metropolitan axes of greatest opportunity converge in its crown. Whereas at a metropolitan scale the Lisbon crown stems from the formation of an infrastructural ring, the intensification of uses and infrastructure that interconnect there contribute to a specific impact on the forms of growth of its urban fabric. This is particularly important in areas open space, which are stimulated by the urbanization of Lisbon and at the same time requested by the dynamics induced by its metropolitan area, contributing to situations of further fragmentation, fringes and incomplete fabrics.

At the intersection between these phenomena and scales, Chelas acquires paramount importance, particularly due to the potential role it plays in a latent axial relationship with Barreiro, which is likely to develop as a result of changes in the rail network.

Considering the need to highlight the role of open space in the evolution of Lisbon's fabric, the identification and characterization of morphologies – in progress in space and time – result from careful observation of the available cartography and graphical representation, taking into account the internal structure regarding the way open space relates to the buildings and the infrastructure network, defining their limits and the explanation of its use through spatial characteristics. In these circumstances, understanding how the changes of this *metropolitan kneecap* occur can contribute to consolidating more specific knowledge of both the metropolitan configuration and functional structure and of the morphological elements.

2 CHELAS: FROM A BASIS TO A FABRIC

The Chelas Valley is part of the potential crown of Lisbon, in the Olivais-Chelas sector, which stands out due to the pre-existence of rustic areas and the urban development of the twentieth century, where some of the most important experiences of Portuguese modern urbanism can be found.

The process of the city's division into sectors, mainly due to the axial development of its urbanization towards the north through *Avenidas Novas*, contributed vastly to the autonomy and circumscription of this area of intricate urban formation, in which the open space has always played a key role: a rural setting increasingly filled by extensive areas of shacks, houses, infrastructure and, more recently, becoming a large public space of the city.

The area under study is a rustic space that was progressively urbanized. It stands out in Lisbon due to the spatial discontinuities that are fundamentally a result of intermittent urban intervention in the twentieth century, albeit relevant as to the innovation of the proposals and the architects and authors involved. It is an eastern area characterized by social conflict, miscegenation of uses and urban forms, which originated in the contrasts between the industrial riverfront (Marvila), the discontinuities between occupied zones (Chelas) and the new interventions in the proximity (Parque Expo).

Due to its adjacency to the planned Terceira Travessia do Tejo[1] (Third Tagus Crossing), it was expected it would become an important international central

[1]A bridge which, had it been built, would connect Barreiro to Lisbon, thus materializing a possibility long considered.

point, taken into account in the Lisbon Municipal Master Plan.

Having always been considered an infrastructural reserve, the available space, together with its central position in Lisbon, a municipality that has been losing population and economic importance (e.g. to Oeiras), the greater connectivity opportunities are provided by the following:

– At present, the direct connection to the main road network (particularly roads with motorway profile), railway beltline and proximity to the conventional speed railway line to Porto and the current Portela Airport,
– In the future, the proximity to the high-speed railway Gare do Oriente, in Lisbon, and consequent direct access to the new airport on the south bank and link to Europe.

This allows us to identify a new metropolitan axis that will reorganize, from a functional point of view and due to its hierarchy and nature of its centrality, the very metropolitan area, which encompasses Barreiro, in itself equally well positioned as an area of opportunity.

Its location, which is key in terms of extended metropolitan structure – in the Lisbon potential crown and bordering the remaining metropolitan area – provides an opportunity to study an area which, although always present in the urban plans for Lisbon, had not attracted much scientific attention, not always for positive reasons. Existing papers have almost always addressed either social issues or housing public policies, specifically its Urban Plan, focusing on *built-up areas*. That is, works that have suppressed the base structure that liaises (or not) with the space of the city.

Thus, this analysis aims to contribute to the study of Chelas' urban formation, making its morphological characterization, identifying the transformation processes that gave rise to its current configuration, and giving prominence to the space that is unoccupied. This work is based on a diachronic interpretation defined by a *window* that allows examining the morphogenesis of Chelas at three stages of its urban development (1991, 1950 and 2008).

The systematization of the identified morphological classes allowed highlighting three distinct, parallel, and complementary processes prevalent in specific moments and present in the transformation of the selected sample in Chelas:

1 *Parcelling as the basis for transforming the territory,* in a still relatively traditional way, clearly opposing the rural to the urban and with diverse morphological classes, which is directly linked to the Lisbon rural crown circumscription process; in this case, pre-existing structures and the way they are adapted play a key role.
2 *The modern paradigm and the segregation of open space:* disjunction and specialization – spatial and functional – as the key open space segregation agents as a whole, using fewer morphological classes, which is aided by the axial urbanization of the city and corresponding sectorization; in this case, with emphasis on the introduction of urban concepts that are remote, as much as possible, from existing strata, giving them new forms and meanings.
3 *A new protagonist in the Project of the City* – with particular emphasis on open spaces, acknowledging their potential in terms of comprehensive ability to structure the city itself, resorting to the use of large-scale architectural elements, such as parks and spaces separating areas with very different characteristics.

The empirical observation of the city space and the field visits, supported by other documents, notably city plans, enabled outlining an approach, also theoretical, regarding the culture of contemporary European cities.

Although this analysis applies to a specific situation in Chelas, the study conducted in Lisbon makes us believe that the methodology, processes and identified morphological classes are sufficiently representative and can be applied to future studies, understandably with some reservations given the local specific conditions.

Despite all the hitches and detours, one can say that almost all of the *Chelas Urbanization Plan* has been accomplished. This includes the construction of urban parks and the final details to ensure urban continuity.

3 A NEW PROTAGONIST IN THE DESIGN OF THE CITY

The urgent housing allocation contributed to a focus on the *built areas* of the Plan, which only recently have been supplemented – functionally and spatially – with elements that allow an authentic *idea of city*.

Whereas modern design urban fabrics are characterized by functional specialization and spatial disjunction, the idea of the city endorsed in the post-industrial period highlight, in the first instance, the problems relating to the maintenance and conversion of obsolete fabrics that are emptied of their functions and, more recently, the notion of a metropolitan city in which open and built spaces alternate and mutually potentiate programmes, forms and projects with transversal features.

It is therefore evident that the city does no longer have an exclusively urban nature in the process of occupation of rural areas or in ongoing *urban development*. Rather, it is the result of multiple induction processes relating spaces with different characteristics, which the literature of the last decade has generalized as *metropolization*.

As soon as the city started to undergo large-scale development, several authors, such as McHarg (1969), Gregotti (1972) and Dematteis (1995), have explained the need to seek ways of intervention using projective concepts and thorough knowledge of each territory – i.e. the basis of the metropolis, rather than resorting to a functional rationale.

In the US, *Landscape Ecology* (Forman et al.), a school with roots in Germany from the early twentieth

century that has spread throughout Europe, is also referred to. More recently and specifically focusing on open space as the protagonist of the metropolis project, the concept of *Landscape Urbanism* (Waldheim, 2006) and *Metropolitan Landscape* (Tatom, 2009) emerged advanced by landscape architects and urban planners whose cross-cutting interventions focus on interface and transition areas, also contributing to the renewal of the assumed aesthetic parties of contemporary urban design (i.e. the landscape architects working in urban projects James Corner, Enric Battle or João Nunes).

These issues have been integrated into various interventions in cities like Barcelona, especially with regard to the relationship between the compact fabric of the city and areas of scenic interest developed using various forms, such as interventions to mitigate the impact of major roads on urban spaces. Reference is particularly made to public space projects, such as the motorway junction in Trinidad Nova, by Enric Battle, and the Agrarian Parks in their relationship with the land use of metropolitan space (Sta Maria del Gallecs and Llobregat), as well as the urban reform of the Besós River (Clos, 2008), similar to interventions made in Italy and France (Llop, 2009).

These are crucial topics in the approach to city design since, on the one hand, they enhance open space as an inalienable element of a consistent and effective urban planning and, on the other, consolidate new approaches to it, in a period that immediately follows the emergence of strategic planning in Portugal[2].

Following formal urbanization and physical and functionalist planning, new mechanisms have been introduced aiming at making the intervention in the city more flexible by seeing plans as processes. However, in the case of Lisbon, the Strategic Plan (1992) was accompanied by a Municipal Master Plan (1994) using instruments also inherited from a modern base, namely through the definition of *Planning and Management Operating Units*, quite rigid zoning and urban parameters that were no answer to multi-scalar situations and did not allow the effective coordination between various levels of planning and the actors involved. These issues became, in the last decade, essential factors for a change in the approach to planning (Faludi, ed, 2008).

Likewise, it was found that the dissociation of urban fabrics from fabrics associated with open space, with a relevant and necessary focus on urgent issues of urban renewal and housing, accentuated dislocation and fragmentation situations regarding open areas, which were gradually taken up, sometimes without the necessary global view of the city.

Therefore, the key issues focus on areas of transition and infrastructural overlap, especially regarding the relationship between settlements and ring structures that have been acting as city limits at different times from the mid-nineteenth century onwards, following an industrial rationale. In this case, this means the ring roads and the railway beltline in which the five centralities provided by the revision of the Master Plan of Lisbon are anchored: Alcântara, Sete Rios, Praça de Espanha, Chelas and Estação do Oriente (CML, 2010).

Following recent changes in EU's policy and programmes, as well as some intervention strategies that have introduced a new model in terms of city design (i.e. London and Barcelona), the review process of the Municipal Master Plan of Lisbon introduces a new approach to the city's project, which, in this case, is particularly interesting for i) an architectural combination of the various elements that compose it and ii) an integrated and reciprocal view between urban and open areas, as opposed to the previous period when open space issues were not necessarily and directly related with urban planning issues[3].

Specifically in Chelas and with regard to the role of open space perceived as a city design booster, the analysis of its urban transformation process allowed identifying two different aspects: i) potential uses, consisting of areas of opportunity for future interventions, although fragmented and resulting from the overlapping of higher capacity infrastructure; and ii) open space project, integrating the areas subject to qualified interventions, provided for in plans and projects contributing to the overall consistency of the city.

It should also be noted that, at various times, the area under study was considered in urbanization plans with reasonably distinct goals and limits – Urban Plan of Chelas and the Valley of Chelas, in 1965 and 1998, respectively – although always relevant and necessary, or resorting to models of occupation of areas confined to zones or neighbourhoods (Bairro dos Alfinetes and Quinta do Marquês), under the various programmes aimed at housing and urban renewal (*PimP, PER, Viver Marvila*).

The latest debate includes detailed plans with greater structuring ability, such as the Hospital Group, whose developing preliminary proposal[4], despite the weaknesses that are typical of urban design with too much focus on isolated built areas, gains a new dimension for giving prominence to open space as a binding element of Chelas' various *built zones*.

Two situations arise dialectically: identifying areas of potential uses that stimulate new centralities; and the emerging approach to the Open Space Project as a built support of the city, which will be discussed below.

3.1 *Open space design*

The design of the open space merges with the actual city project. It presupposes an architectural and urban approximation that enables, in the project's approach to the city itself, the various components – urban, rural and more hybrid ones – to meet, exploring new forms

[2]The prestigious Valmor prize in Lisbon started to distinguish interventions in landscape architecture in 2003, which clearly shows its growing importance in the context of the city.

[3]Previously allocated to various Municipal Departments.

[4]Project: CML, Pedro Falcão de Campos, NPK and ABAP, 2009.

of intervention and promoting, in the process, not only a critical view, but also a conceptual one, through which the aesthetic dimension of the metropolitan landscape is also renewed. After all, the aim is to find among the fragments the opportunities to rebuild a mosaic of continuities tinted by cohesive fabrics from different origins.

In a way, this view is close to the notion of *porous city* (Équipe Studio09, Bernardo Secchi and Paola Vigano, 2009b: 3), which explains the need to design the support of the city itself[5] , giving continuity to other city projects developed from a global intervention perspective.

The analysis of the various planning and management documents available (Table 6: *Instrumentos de Planeamento e Gestão, Acções e programas com incidência na área de estudo* – Planning and Management Instruments, Actions and Programmes focusing on the area under study), indicates that open public space – in its various components and scales – is repeatedly mentioned as a key element, especially in the area under study, but only recently operated upon, or so considered.

The actual *Chelas Urbanization Plan – Plano de Urbanização de Chelas* (GTH, 1965: 87) considered the *free areas* as key, offering them a total of 291.16 ha, or nearly 57% of the total intervention area. Free areas comprised walking areas, parks and playing fields, including Parque Oriental, Parque do Vale Fundão, Clube Oriental de Lisboa, and urban gardens.

It was anticipated that the green areas would play various roles: i) creation of collective public recreation comprising sports and cultural equipment and the framework for certain routes for pedestrians (GTH 1965: 82); ii) protection against the consequences of the proximity of polluting industries, establishment of slope areas and the edging of fast transit routes (GTH 1965: 82). The analysis pointed to the three forms of open space design which, nevertheless, are interconnected in space and time, resulting in a dynamic system using the following:

– structural elements of the city in terms of planning and urban design, such as sports facilities and fields and urban parks;
– collective spaces close to buildings, thus to people, in the various activities and programmes from the perspective of urban renewal, such as the areas identified as infrastructural finishing features;
– gardens associated with notable buildings, more reserved and of limited access.

It can also be concluded that despite the various trends and urban models referring to open space as essential to the city design and later the actual Chelas Urbanization Plan, the investment in the areas of the park and the completion of the network of public spaces is only recently starting to be a reality, finally allowing acknowledging this area as a city.

3.1.1 *Result of planning and urban design*

The analysis of the plans shows that the intervention, in terms of the open space project, began by sticking to the emergence of reserved nature spaces (*gardens associated with noteworthy buildings*) in erudite architectural sets, with the notion of public equipment in the marginal area of Lisbon being introduced later.

Since the urban fabrics of Marvila were modest in terms of typological range due to its popular and industrial origin, the emergence of playing fields adjacent or linked to the residential areas of the working class and factories, which still persist nowadays, stands out. While very poorly equipped, these sports fields represented an innovation in relation to the concept of urban equipment, albeit at the expense of a network of public spaces, which in this case were rare, in a space that was becoming densely built.

Their location favoured their relationship with the Marvila and Picheleira older fabrics. In the case of the former, the field close to Fábrica Nacional de Sabões and *Clube Oriental de Lisboa* in the former Bairro Chinês, located in Quinta do Marquês de Abrantes, to the south and north, respectively, of Marvila station and Azinhaga dos Alfinetes, one of the main lines of rustic urbanization of this area of the city, stands out.

Until now, this type of equipment has been gaining ground in the city's fabrics. From simple playing fields, they evolved into more elaborate sports areas and include fields for sports practice aimed at more advantaged populations, such as tennis in Mata de Alvalade or golf at the Bela Vista Park, occupying a significant area of open space. With regard to these two types, their location and contribution to the rehabilitation of the area, then provided for in the Chelas Urbanization Plan as Parque Oriental de Lisboa, must be emphasised.

As a complement, in the *built-up areas* associated with equipment, the system of collective spaces is also being equipped with playing fields, mainly those included in the school equipment areas, such as D. Diniz High School in zone I or the Amendoeiras/Olival Neighbourhood. It is, after all, a fragile situation in a city marked by serious social and economic problems.

The *Chelas Urbanization Plan* carefully addresses open space as a fundamental element of urban design. However, its non-execution led to a perception that these changes did not differentiate much from high density suburban areas of other municipalities of the Metropolitan Area of Lisbon, promoted publicly or privately, only focusing on the full urbanization of rustic properties directly connected to road intersections.

Thus, although the process has been quite different – in this case there was a conceptual decision to integrate its various areas – what stands out in the face of the long-running process is, in practice, the exclusion of spaces that have become increasingly reduced due to the overlapping of built-up areas and

[5] Le projet de la ville poreuse ce n'est pas le projet d'une ville, mais le projet du support de cette ville. […] Le projet d'une ville poreuse élargit la section des rivières, utilise les espaces non utilisés, sous-utilisés ou résiduels pour créer ou renforcer les zones humides. […] La ville poreuse est une ville où la biodiversité percole et où les parcs ne séparent pas.

large infrastructures, contributing to an *indifferent* landscape.

This process contributed to an intermittent landscape of the city, in many ways similar to areas like Odivelas, Damaia or Pragal. Paradoxically, the resumption of place names of the old estates to introduce an idea of "neighbourhood" (Lóios, Armador, Amendoeiras, Olival, Condado, Alfinetes, and Flamenga) coincided with the logic, probably associated with real estate marketing, adopted in areas of more diffuse or extensive metropolitan occupation (i.e. urbanization of Quinta da Ramada in Odivelas, among many other examples in the Lisbon Metropolitan Area), as well as with a certain socio-political view of city space.

More than being an opportunity for action, this situation illustrates the urgent need for qualified intervention in these areas, which is why some of the newer parks in the city are located in Chelas, helping to strengthen the idea that there will be more urban parks in the eastern side of Lisbon than in its western side, very still dominated by the Monsanto Forest Park.

In the adjacent areas, Parque do Vale do Silêncio and Quinta Pedagógica stand to the north, both in Olivais, and Parque José Gomes Ferreira, also known as Mata de Alvalade, is located in the west, close to the Bela Vista Golf Club, and Parque or Mata da Madre de Deus stands in the south.

Indeed, the location and characteristics of the parks in Chelas result from its physiographic characteristics, with two privileged areas making up the wet system and the structuring corridors system of the city (CML, 2009e, *Plan 2 – Planta de Ordenamento: Estrutura Ecológica Fundamental/Planning Plan: Ecological Fundamental Structure)*, making the first interpretation of the physical geography of the place: Chelas and Vale Fundão valley systems. This situation is guaranteed by the *Estrutura Ecológica Integrada*/*Ecological Integrated Framework* (CML, 2009e, *Plan 3*).

The organization of a large area over the Chelas valley system becomes thus clear – Bela Vista, Quinta da Montanha and Frades Vicentes – between Avenida Gago Coutinho and Alvalade, to the west, Olaias to the south and the Armador, Flamenga and Lóios neighbourhoods to the east.

It is an area of scenic and environmental value, as set out in the Lisbon *Plano Verde/* Green Plan and later included in the review of the Municipal Master Plan (CML, 2009 and 2010), consisting of several concatenated parks and forming the City Eastern Park, as initially proposed in the Chelas Urbanization Plan.

The Chelas Urbanization Plan set out that the planned green spaces included two key issues. On the one hand, the provision of equipped green spaces or collective recreational public parks, and, on the other, the necessary protection from nearby polluting industries close to highways. In addition to the proximity benefits for the new populations, it was also advantageous to the city, since this equipment would address needs, especially in the eastern area, by preventing the spreading of industrial pollution in specific weather conditions (GTH 1965: 82). The plan foresaw the City Eastern Park and the Fundão Valley Park with an occupancy of 16% and 7%, respectively, of the total area under intervention. (Map 19: *Ocupação do Solo*/Soil Occupation, GTH, 1965).

The City Eastern Park would be located in the west, on the western strip most strongly restricted of the intervention area. Apart from the steep slopes, very much changed by erosion and extraction of sand, partially classified in the *Plano Verde/Green Plan*[6] and referred to in the PDM review as Geo-monument (CML, 2009e, Plan 6 – *Planta de Ordenamento: Património Geológico e Arqueológico*/Planning Plan: Geological and Archaeological Heritage), it was a very limited area due to its proximity to Portela International Airport.

This was the hilliest part in the intervention area of the Chelas Urbanization Plan, with percentages above 15%, which prevented other type of occupation, especially built-up areas. Despite these constraints, the sunny orientation to the east, south and west, together with the panoramic view of the city and the river enabled by the higher points, indicated the need for a landscape study coordinated with the Plan (GTH, 1965: 83), with the slope between Picheleira and Casal Vistoso being considered a particularly sensitive area.

In recent years, the Bela Vista Park (*Parque da Bela Vista. Plano Geral da Zona Central/*General Plan of the Central Zone, 2005) was set up there, adjacent to the Golf Club on the north and the Bela Vista South Park (*Parque da Bela Vista – Sul, Zona Central/Bela Vista Park – South, Central zone*, 2008).

Bela Vista Park (85.0 ha) is divided, through Avenida Marechal Spínola, which prolongs Avenida Estados Unidos da América, into a central and south areas. Still retaining some traces of the old estates, including sections of Azinhaga da Belavista and a water mill, it offers wooded areas of meadow and lawn, with the highest points being privileged viewpoints over the city. It also includes sports facilities and maintenance circuits (CML, 2010).

The valley area bordering the southern railway line on both sides is expected to be subject to scenic intervention, which this work considers to be of *potential use*. Pre-existing sections include Quintas da Fonte do Louro in the north (severed by the construction of the railroad) and Quinta da Montanha.

To the south, Frades Vicentes Valley, between Olaias and Picheleira, is an area that is also expected to be requalified with regard to its landscape (Preliminary Proposal, *Plano de Pormenor do Parque Hospitalar Oriental*/*Detailed Plan of the Eastern Hospital Group*). This area of the park will be extended to involve the Chelas Convent, contributing to the heritage significance of its architectural complex.

The completion of planned interventions will enable finishing a continuum of interesting landscape in the

[6] Proposal for a preliminary municipal ecological structure.

eastern area of Lisbon, strengthened by the proximity to Mata de Alvalade. Mata de Alvalade (21 ha), or José Gomes Ferreira Park, has its origin in the Charca and Narigão estates, which were expropriated to create the Alvalade neighbourhood. It is characterized by a relatively dense forest, whose clearings accommodate several facilities, such as picnic parks, viewing points, playgrounds, and a fitness circuit (CML, 2010).

The Vale Fundão Park (9.0 ha) has urban features and is characterized by an open forest area with large clearings (Parque do Vale Fundão – Concurso público internacional de manutenção e limpeza/Vale Fundão Park – Cleaning and Maintenance International Public Tender, 2008). It is an area of scenic interest, with some sports equipment, such as a football field, a sports centre and public swimming pool, surrounded to the east by the Amendoeiras/Olival neighbourhood. It has traces of the Alfundão or Lebre and Val Fundão old estates, such as a water mill and some paths, facing urban gardens zones in the south and east. Its eastern boundary is a section of the channel of the Alviela rivulet, an interesting pre-existing feature from a heritage viewpoint duly protected by a protocol between the CML and EPAL (CML, 2010).

Regarding housing, school equipment and local commerce, by 1991 only zones I, N2 and J, i.e., the current neighbourhoods of Amendoeiras/Olival, Lóios and Condado had been built, for which reason the transversal links between these zones and the completion of the proximal exterior and public spaces were vital (DCH 1991: 37). The need for a quick-start of the infrastructure and architectural projects for the M zone (Armador neighbourhood) was also considered to be primordial to attain an urban balance.

It was in the context of the Chelas Plan[7] review that *Parque Urbano do Vale Central*/*Central Valley Urban Park* was proposed. It is an area surrounded by the N1 and N2 zones, today Lóios and Flamenga, respectively. The proposal for the Central Valley Urban Park had as main objectives the creation of a close by free recreational area, where maintenance charges were to be as low as possible, so as the green structure was close to existing natural conditions (DCH 1991: 53). The park ended up not being accomplished, although the place encompasses an extensive area of urban vegetable gardens (2008. Chelas) that require planning in future and fulfil, in practice, the role that was attributed to them.

In the late twentieth century, Chelas resumed a key role in the planning strategies of the eastern area of Lisbon, especially considering the upcoming Expo '98, thus renewing the possibility that a bridge to Barreiro would indeed be built (Silva Dias, Francisco 1991: 9–11).

Anticipating that Chelas' central area would become an area of *Estruturação Urbanística Terciária*/*Tertiary Urban Structure,* as identified by the Municipal Master Plan (*Classificação do Espaço Urbano/Urban Area Classification*, CML, 1994b), which would contribute to defining the U.O.P. 27 titled *Centro de Chelas*/*Centre of Chelas*, the main concerns were focused on the interstitial and incomplete areas of the built-up areas (*Unidades Operativas de Planeamento e Gestão/Planning and Management Operating Units*, CML, 1994b, PDM). This is evident, especially in the urgent cross-connection to the city and the establishment of a *centre* for diverse uses that encompassed the Zone O of the Chelas Urbanization Plan and whose allotment would be developed by Ambelis, in the proposal for the Central Area of Chelas (CML, 1995), or *Quadra Central*/*Centre Court*.

In the studies conducted at the DCH – *Departamento de Construção de Habitação*/*Department of Housing construction*, prior to the intervention in the Chelas Central Area[8], the project would materialize, somehow in a hard way, through a large-scale built structure based on a plan for a highway intersection. This area had already been regarded as essential, especially as a means to overcome the central valley[9].

As a complement to the planned park areas, at the time still important degraded spaces, such as the Relógio Neighbourhood and the area of Quintas Fonte do Louro and Montanha, the preparation of this study shows mainly a concern with the planning and the attainment of outdoor green spaces integrated into the *built-up areas*, using proposals for that purpose.

3.1.2 *Infrastructural finishing features*

The infrastructural finishing features arise out of the predominance of a highway system both in the perimeter of the area under study, expected to act as a parkway, and in the fasciculate collective spaces separating the area for motor vehicles and the spaces for pedestrian circulation. In the case of the latter, there is also an area that just finalizes a specific infrastructural channel, usually with a paved or green area, not always promoting its exclusive use by pedestrians.

This is particularly important in some areas of Chelas, in the form of a central space of built-up areas, accentuating barriers and the difficult circulation between different areas. Examples include the main axes of Zone I (Amendoeiras/ Olival), Zone M (Armador) and Zone J (Condado), which, despite some uneven passages, are different from the others, such as the Chelas Central Avenue (Avenida Central de Chelas), because they are urban areas with functional interest and are directly related to the built environment and housing. They are mere space-channel or kneecap areas, usually sufficiently reduced so as not to open future opportunities for use, such as the area north of Chelas Central Avenue, which may in future

[9] Study by Architects Elias Rodrigues and Helder Tércio (DCH, 1991: 37).

be part of the Parks system, finishing off the Zone N2 (Lóios) to the north.

3.1.3 *Gardens associated with outstanding buildings*

Gardens associated with notable buildings are qualified spaces of erudite origin in conjunction with notable buildings due to their typology, like a palace or monastery. That is, it means an architectural approach to a set where the garden has a recognizable aesthetic value. It was found that many of these situations have evolved from private property with very limited access in terms of public occupation.

Although the gardens continue to be restricted with regard to access, in terms of design they are confined spaces of architectural interest built on higher density areas, deserving special mention. Their location on the urban fabric allows us to identify situations and peculiarities we would not normally notice otherwise, like in Rua do Açúcar.

One notes that this type of garden is found predominantly i) along the old beach road, today known as Açúcar, naturally in accordance with the most architecturally notable buildings, such as the Mitra Palace; or ii) associated with the noble buildings of the estates with a close relation with the fabric of Marvila, such as *Quintas das Salgadas*, *Alfinetes* or Marquês de Abrantes.

These examples characterize various moments in the history of the gardens, ranging from the formal parterre ones that benefitted from being at different heights (Mitra Palace) to organic sets that used existing water to create natural reflection pools (*Quinta das Salgadas*).

The analysis of Silva Pinto's cartography also allows concluding that some farms did not have a true formal garden. However, the alignments of trees along direct paths formalizing noble entrances and agricultural fields offered a form of landscape architecture adequate to the central buildings, such as Quinta do Armador, or Quintas das Teresinhas and da Graça further north, since then included in housing spaces as equipment, which the maps show to have been progressively enriched with trees or new spaces associated with leisure and contemplation (Quinta do Leal).

Despite the densification and the urban expansion over the rural areas, especially on the front of Marvila, Beato and Poço do Bispo, the areas left open as public parks, gardens or marginal occupation spaces (such as Quinta do Ourives) are the areas whose increased permeability is critical because they coincide with important water lines or traces of marshes that no longer exist.

From structures to landscapes – towards re-conceptualization of the urban condition

Lucyna Nyka
Faculty of Architecture, Gdańsk University of Technology, Poland

ABSTRACT: This paper presents an original approach towards the phenomena of re-naturalization of cities and indicates its possible consequences for the urban design and planning strategies. It focuses on the ongoing shift "from structures to landscapes" in understanding urban conditions. While modern architecture introduced geometric compositions against the background of nature, early modern theories of architects and sociologists started the pursuit toward a new perception of urban reality. Studies of later researchers supported by emerging philosophical re-interpretations continued questioning the oppositional character of natural and artificial, and juxtaposed the rigidness of a plan with the direct experience of urban geography. It contributed to an important shift towards understanding the city as a landscape, and consequently urbanism as landscape urbanism. The processes of re-naturalization of cities are influenced by this shift, which results in new genres of public spaces and building typologies based on the inseparability of the natural and the built.

1 INTRODUCTION

The problem of re-naturalization of cities today is both important and complex. Cities are changing and most of them are expanding, often chaotically into suburban territories. Many are growing at a pace that could not have been predicted even one decade ago. Economic, social and cultural changes provoke mass migrations, resulting in more than half of the human population living in cities. It would be hard to suppose that the need for contact with the elemental qualities of nature, an environment delineated by meadows, forests or green hills, which have been kept for thousands of years in the most archetypical memory of human beings, will disappear with these processes. Actually, it is not hard to notice that nature is introduced and re-introduced to our cities.

The question remains though, how to find an intellectual interpretation of the re-naturalization processes and how to re-conceptualize this new condition. The ways in which nature appears in cities goes beyond solutions that could be traced back to the concepts of John Claudius Loudon, Frederick Law Olmsted, Daniel Burnham or other great masters who undoubtedly gave an important impulse to the advancement of landscape design as a creative discipline. Some forms in which nature is re-introduced to our cities resonate with the heroic land art works of Richard Morris, Robert Smithson or Walter de Maria, who revealed new territories for artworks located between culture and nature, while stimulating the artistic and architectural imagination of the next generations.

Not denying the influence of the above-mentioned sources, this paper provides argumentation that the true shift, which has changed the forms of the presence of nature in our cities, came with the more general re-interpretations that took place at the verge of the nineteenth and twentieth centuries. Early modern theories of Georg Simmel, Walter Benjamin or Siegfried Kracauer marked the first steps in a pursuit toward a new perception of urban reality in which the natural and the man-made started to be perceived as an inseparable whole. Blurring the borders between the natural and the built, integrating objective knowledge with direct experience and accepting the city as an active environment contributed to the conceptualization of the city as a landscape. This was a pivotal concept that opened new perspectives toward forms in which nature manifests itself today in our cities.

2 TOWARD "CITY AS LANDSCAPE"

2.1.1 *Green parks in cities*

It became clear in the nineteenth century that densely populated and rapidly growing cities demand new solutions that focus on introducing nature into the urban fabric. John Claudius Loudon was one of the first who believed in the necessity of long term planning for providing a coherent urban system of green spaces. His plans for green belts for London and settlements immersed in nature, published in 1829, predated Ebenezer Howard's ideas and the Garden City movement for more than half a century. Almost three decades later, in 1857 Frederick Law Olmsted and Calvert Vaux proposed a project for the Central Park in New York, starting the practice of leaving green areas in cities as a common value, which marked a new

era in urban planning in America. Urban parks were supposed to compensate for the harshness of rapidly developing cities. Rocky slopes, vast plains and idyllic scenes were rooted in imaginary visions of rural scenarios and had to bring relief to hard-working people. In landscape planning architects paid a lot of attention to the composition of elements and the coherence of the final effect. It is important to notice however, that in their relation to the structure of the city, parks were defined as clearly delineated and usually fenced green islands surrounded by urban fabric.

This definition was to be changed for the first time in Chicago in 1893, when John Wellborn Root, Daniel Burnham and Frederick Law Olmsted for the World's Columbian Exposition redesigned the vast areas south of the city centre. A new conceptual challenge appeared – to create neither a green park nor a group of pavilions, but a coherent whole, a new harmony between built structures and re-shaped nature. A whole new environment was created: new buildings were erected, marshlands were dredged and sculptured into lagoons, and canals were cut through the city structure that led to a large water reservoir with an artificial island. The fair was supposed to be a case study for the future look of American cities, but in fact, this romantic vision clashed with common social problems and the visual chaos of a rapidly growing city (Kostof 1985). Daniel Burnham and Edward H. Bennett continued the ambitious redesign of the Chicago lakefront in 1909, proposing landfills to extend shoreline parks into the bay area, freely sketching their new boundaries between land and water. Nevertheless, with the Great Depression and political threats those plans gradually lost their impact and popularity.

2.1.2 *Early modern theories of movement*

While concepts of Loudon, Olmsted, Vaux, Bennett and other great masters still remain clearly visible in currently applied landscape design strategies, today's processes for re-naturalizsation of cities have been deeply influenced by an important shift that took place at the end of the nineteenth and the first decades of the twentieth century. Interestingly, it was not focused on nature. With the emergence of early modern theoretical concepts, architects, sociologists or even filmmakers launched the pursuit toward a new perception of urban reality – the city as a landscape. Urban space started to be perceived in motion, from the perspective of walking – a concept embraced by Charles Baudelaire and later expanded by Georg Simmel, Walter Benjamin and many others. There is a strong interrelation between the specific "wandering practice" and the emergence of landscape experience in the urban environment, as Heinz Paetzold highlights (Paetzold 1998). Anthony Vidler (2000) indicates that a wanderer "sought to recapture the primal resonances of natural paths in the urban labyrinth". Urban space resembling "volcanic landscapes" was cut with "nomadic routes" (Vidler 2000). Walking through the streets, creating new paths and discovering yet unknown places, resulted in the application of certain geographical metaphors and techniques for depicting "urban topographies", as for example "urban mapping". This noticeable change in the vocabulary marked a very specific launch toward the conjoined presence of the natural and the built in urban form, and also created conditions for understanding many different components constituting urban environment as one whole.

The shift toward denying the opposition between culture and nature has been related to questioning the long lasting dichotomy between objective and subjective in the perception of the city. Urban space sublimed into the notion of landscape was no more a neutral scenario but rather a concept constructed in the eyes and mind of the observer. Consequently, the act of walking through cities not only provided neutral knowledge based on purely visual stimuli but also became the source of a closer, haptic perception. Such ideas were rooted in the late nineteenth century theories of Alois Riegl, who delved into relations between movement in space and perception, distinguishing between close perception in movement – *haptic* and the static, distant one – *optic* (van de Ven 1980).

Since then, the impact that space exerts on the walking observer has become an irreducible factor in many descriptions of urban territories. It also became a fertile leitmotif in early modern cinematography, investigated at that time by such filmmakers as Siegfried Kracauer, Sergei Eisenstein, or Fritz Lang. As Guliana Bruno (2001) points out, the moving insights into the life of the early modern city, so well conveyed by cinematic images of that time, were a powerful source of experiences which made them parallel to walks through eighteenth century gardens. Moreover, as Bruno points out, "Historically, the activity of site-seeing developed largely through garden strolling, especially through picturesque gardens". In both environments the landscape "moves" the observer, both in the literal and metaphorical sense, letting the internal and external geographies overlap (Bruno 2001). At this point it is worth noticing that the eighteenth century gardens could be considered as brave experiments on achieving the unity of the constructed environment by integrating nature and architecture, often by means of in-between elements like grottos or fragments of walls.

2.1.3 *Modernistic compositions*

In spite of the potential of those ideas, modernism marked a strong comeback to rationalistic suggestions and solutions for urban planning that offer sober compositions of geometric blocks against the background of nature. It is true however, that a significant part of modern strategies dealt with the issue of the re-naturalization of cities. Construction on pillars left an abundance of space beneath the building, which at least theoretically allowed the nature to smoothly pass through. High-rise buildings allowed the possibility of leaving vast open spaces around, which could be conceived as green areas and aimed at compensating the lack of nature in cities. There were masterpieces built, like Lafayette Park in Detroit designed in 1956

by Ludwig Hilberseimer and Ludwig Mies van der Rohe, which even today still offers a very interesting quality of life "halfway between the city and the countryside" (Del Bo 2013). On the other hand, it is important to notice that the modern approach to nature was extremely anthropocentric, as Wolfgang Welsch argues (2002). According to Le Corbusier's declaration issued in 1925, architecture has to be a "seizure of nature by man" and "an act of man against nature". As Welsch comments, it is one of the manifestations of the "hopelessly misguided modern picture" that could be expressed as "man against the rest of the world" (Welsch 2002).

2.1.4 *Environmental concepts*

While modernism was thriving and geometrically perfect plans were admired from the bird's eye view, the quest toward blurring the opposition between nature and culture, objective and subjective, man and the environment had continued. The idea of "kinaesthetic consciousness" with the concept of the body as the centre of experience presented in Husserl's phenomenological writings, along with the later investigations of Marcel Merleau-Ponty, formed the influential background for critical re-interpretations of the relation between human being and the urban reality. Equally important were the pragmatic theories of John Dewey. According to this philosopher, while experiencing we are immersed in the environment, not distanced from it. Dewey's ideas undertaken later by Arnold Berleant gave impact to the emergence of environmental aesthetic in the last third of the twentieth century (Wilkoszewska 2006). Environmental aesthetics goes beyond the appreciation of the isolated object of art proposing aesthetic appreciation of both natural and human environments (Carlson 2011).

Although environmental thinking had rather limited influence on the twentieth century urban planning, it was an important factor in the emergence and development of art in the sixties and seventies, mainly Process Art, Environmental Art and Land Art. Hans Haacke's words can be regarded as symptomatic for artists' aspirations of the time: "make something (…) which always looks different, the shape of which cannot be predicted precisely, make something that cannot "perform" without the assistance of its environment" (Robins 1984). Artists such as Michael Heizer, Richard Morris or Robert Smithson renounced the construction of art objects "in favour of the creation of experiences related to the environment" (Lailach 2007). Sculptures were not created as "independent configurations" but "as a way of intensifying, of making the landscape itself into another space" (Robins 1984). Heizer's "Double Negative" project of two deep cuts through the plain of the desert invited the visitor to experience the impact of such "another space". Artists were experimenting with elements – with massive earthen forms, geometrical shapes covered by grass, water, qualities of light, or the energy of lightening.

Noticeably, walking was recognised as the most sublime artistic act. George Trakas constructed

Figure 1. Broken Circle by R. Smithson, Emmen, The Netherlands. Photo L. Nyka.

"transforming passages" and let the viewers travel along articulated artistic paths. Some artists like Nancy Holt or Robert Smithson became involved in the idea of making passages though or over the aquatic pools. Smithson stressed the importance of the physical presence of water. In order to cumulate this experience in his Broken Circle project, the viewer walks along the shoreline and continues the journey along a circular structure, gradually discovering the situation of remoteness and isolation (Fig. 1). Fading paths, stones carefully arranged in lines, and cuttings through the earth for creating subdued passages marked the new forms of artistic expression. Artistic endeavours were not focused on creating art objects against the background of landscape but rather on making an intervention seamlessly integrated with it. Most of the works were experiments on the unclear borderline between the natural and the built. As such, they revealed original paths toward discovering new relations between architecture and nature that are manifested so remarkably today in the landscape of the city.

3 RE-NATURALIZATION OF CITIES

3.1.1 *From urbanism to landscape urbanism*

In the last two decades of the twentieth century perception in motion, the value of connecting paths, and understanding the city as a changing environment became visible in urban interpretations once again. Researching philosophical and anthropological interpretations of everyday practices, Michel de Certeau analyses the "rhetoric of walking" and argues that making shortcuts, poaching on others' territories, or creating individual paths could be interpreted as opposition to modern strategies dedicated to the masses (Certeau 1984). Recognising different spatial narratives has become a stimulating source of concepts both in research and education. As Vaso Trova notices, "sequencing, setting boundaries, revealing or concealing, gathering, opening, etc. are common cultural practises with strong spatial character found in all kinds of urban contexts, as well as in design projects at different scales (Trova 2008). As a result, a new set of aspirations has appeared even in the official

documents issued by municipalities, as for instance: how to make a walk through the city "kinaesthetic" and "haptic" (Abbate 2005).

The idea of movement as a source of urban experience and conceptualization of the city itself as an active and changing environment has resulted in the re-emergence of the concept of urban space as landscape (Nyka 2006). This shift from structures to landscapes in understanding urban condition brings about important redefinitions. Firstly, it opens new ways toward incorporating many different factors, from environmental conditions to social and cultural forces into design project. It should be emphasized that urban planning is not isolated in this regard – the notion of a landscape is evoked nowadays in many fields of research, from archaeology to the humanities. Referring to the construct of landscape enables understanding of many facts and places, shaking them off from their analytical isolation, as Christopher Tilley argues (Tilley 1994).

In effect, elements of nature along with their visible and invisible influences are discovered as valuable components of urban landscapes, and they are being re-introduced to cities. Sound, as an integral component of any environment, is consciously integrated into architectural forms (Borucka 2015). Water appears inside to support the elemental qualities of architecture (Nyka 2007). Natural and built integrate in conceptually new ways, challenging the long-lasting opposition between culture and nature. Accepting the integration of natural elements and the man-made structures in urban design contributes to the formation of hybrid landscapes. Urbanism transforms into landscape urbanism and becomes a powerful notion. It is based on the assumption that there is no juxtaposition of the object and its environment – they are intertwined into one inseparable whole, being a part of both, a cultural and environmental context. Consent for the open coexistence of the natural and the built in the constructed urban landscapes gives new insights into the idea of re-naturalization of cities.

The ongoing process of re-naturalization manifests itself in different layers and can be seen in many scales, both in urban planning and design strategies, and also in original design solutions for buildings. This issue has a long tradition of research carried out within the Master Programme design studio in the Faculty of Architecture, at Gdansk University of Technology in Poland.

3.1.2 *Buildings as landscapes*

Students have answered the question of topographic characteristic of the built form on the basis of individual design concepts. In many cases public spaces of buildings have been conceptualized as paths, spread between interior and exterior, organized as the connecting lines that lead the observer through different environments. Projects have been focused on investigating the characteristics of the interior pathways, the way they constitute public space of the object, and relate it to the surrounding. One of the basic findings

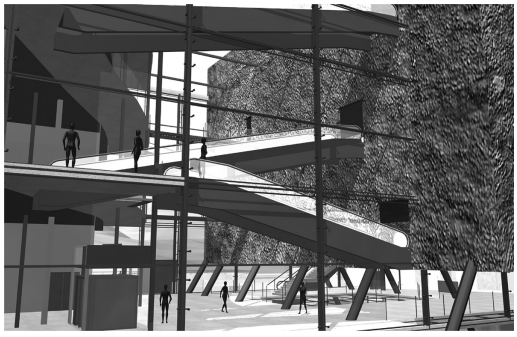

Figure 2. Shi-ga Museum. MA diploma project, author: P. Szewczyk, supervisor: L. Nyka. Gdañsk University of Technology.

Figure 3. Himalayas Expeditions Museum. MA diploma project, author: M. Skołucka, supervisor: L. Nyka.

was that the organization of spaces along the connecting lines dissolves the boundaries between inside and outside.

With unclear contours between the inside and outside, buildings are designed as landscapes. Walking through buildings becomes parallel to walking through geographical formations – valleys, plateaus, or passes (Fig. 2). Greenery is allowed to pass through interior spaces, architectural structures merge in their composition with the tectonics of land, interweaving with natural elements. This reference to the characteristics of landscape is fully interrelated with the search for haptic qualities of architecture. In the Himalayas Expeditions Museum project, the visitor is gently guided along stony walls, exposed to wide openings directed toward the high mountains scenery. Then the way continues among topographical formations, including the icy climbing block located in the hall (Fig. 3 & 4). In such a situation the building is not only located in the environment, but takes its sense from it. It is shaped to encompass the surrounding and invites it to the interplay with simple concrete walls.

While these kinds of architectural experiments have initially been implemented predominantly in situations with open landscape, they are gradually being introduced to cities. A good example of this is the design proposal for the Design Factory, which is to be located on the Gdansk University of Technology campus (Fig. 5). Design Factory will be a space where students can conceive, develop and implement interdisciplinary and transdisciplinary group projects. In the presented

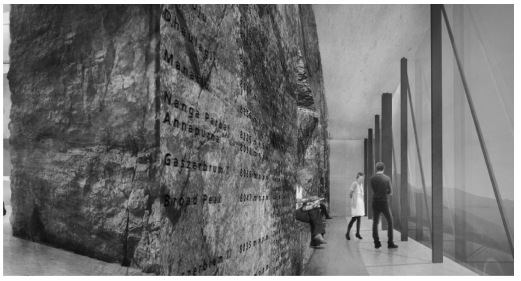

Figure 4. Himalayas Expeditions Museum. MA diploma project, author: M. Skołucka, supervisor: L. Nyka. Gdańsk University of Technology.

Figure 5. Design Factory. Architectural design studio. Authors: P. Puciłowska, M. Gerszewski, R. Gajda. Studio leader: L. Nyka. Gdańsk University of Technology.

design solution, an ascending path connects two parts of the campus and gently cuts through the green hills. This simple gesture gives the designer an opportunity to engraft into the slope a barely visible architectural structure. Cultural context, time-related programmes and environmental conditions – particularly the necessity to interconnect the existing green spaces into a coherent system – were integrated into the design concept. It is believed that the hybrid spatial characteristics of this object based on the presence of greenery that pours into the building, earth formations, and minimalistic geometry of the interior structure, will stimulate students' imagination, providing an inspiring scenario for innovative projects.

Numerous experiments on the re-naturalization of cities through architecture involve applying media and interactive technologies. It has already been proved that technology may effectively support the sensorial qualities of space (Urbanowicz, Nyka 2012). Moreover, it could be noticed that the strong urge toward re-introducing nature to cities coincides with the interest in exploring the role of media images in urban landscapes. When properly implemented they can collaborate with the environmental characteristic of buildings and urban spaces.

3.1.3 *Constructed urban topographies*

Numerous processes of transformation that take place in post-industrial areas provide inspiring opportunities for undertaking experiments on landscape urbanism. Development plans for such territories are not only focused on creating continuities of public spaces that would reconnect them with the city centres, but also on strengthening ecological systems. This gives a chance for the creative re-invention of relationships between built form and nature. These issues became dominant in the project focused on urban renewal of the former port territories located north of Gdansk on the Vistula River in close proximity to Wisloujscie Fortress.

The student's objective was to locate there a Media Technology Institute with a whole set of accompanying spaces both open and enclosed. The Institute was supposed to serve not only the students but also a broader community of people willing to visit exhibitions, attend some courses, or just come by while walking along the neighbouring shoreline areas.

To answer these demands different patterns of paths were sketched as a first step toward integrating various parts of the area together and relating them to the system of pedestrian circulation routes. Subsequently, the concept revolved around the ecological forces that have been shaping the area for ages. In fact, the boundary between land and water has been changing here many times throughout history, which became very inspiring. Firstly, alluvial deposits brought along by waters had been altering the shape of the riverbed, creating temporary islands and shallows. Moreover, the land was cut by differently shaped water moats built as a part of fortification systems. Those waterlines were often accompanied by monumental bastion formations. Referring to this history of changes, the Institute has been designed as a set of geomorphic volumes spread over the area, incrusted with new waterlines and a whole set of artificial islands (Fig. 6). Not only are the geomorphic forms in some way site-specific in this place, but they also do not compete with the Wisloujscie Fortress. Moreover, the green areas that spread along shorelines and continue to the roofs of the buildings increase the amount of biologically active surfaces. In effect, it could appear that located on the blurred boundaries between the natural and the built a new genre of urban environment is emerging.

This pursuit of the site-specific characteristics of cities is supported by the ongoing ecological shift. There is a strong surge in urban planning to go beyond the methods of, as De Meulder (2008) expresses, "clean urbanism" – devoid of any influence of primal natural conditions (De Meulder & Shannon 2008). Today architects and urban designers are relating their projects to characteristic geomorphologies, with water flows or ecological continuities. This strategy goes beyond the idea of decorating the city by means of introducing nature.

Wolfgang Welsch warns that the oversimplified strategy of decorating the city with nature leads to failure. "Nature, or other transhuman aspects, is not to be additional ornament, but must be inherent to, must co-determine the very form of architecture" (Welsch 2002). All this contributes to the perception of a city

Figure 6. Multimedia Art Center. MA diploma project, author: A. Popławska, supervisor: L. Nyka. Gdańsk University of Technology.

as a site-specific construct negotiated in particular geographic and topographic conditions.

In effect, even small parcels in the city can be understood as a part of the broader ecological systems. The role of an architect is to make the environment visible by means of both built structures and natural elements. In this meaning, the environment is constantly re-discovered and re-created by the architect and urban designer. Nature is consciously and willingly involved in this re-creation of cities. This situation extends the traditional vocabulary of architects who work on artificial topographies, green corridors and passages through urban structure, or reclaim historical water canals and reservoirs. Importantly, re-conceptualizing the urban condition as landscape condition involves understanding it not so much in terms of picturesque image, but most of all as a human environment with its potential to foster creativity and to stimulate both personal and collective experience.

3.1.4 *Between anthropocentrism and ecocentrism*

At this point it is important to look closer at the ongoing conflict between anthropocentrism and ecocentrism – two opposite approaches relating to the presence of nature in cities. The ecological one is often criticized for its too narrow perspective, which is reduced mainly to the recovery of biodiversity and care for ecological systems. Unfortunately, as many landscape designers comment, nature is recognized within this approach in a very limited and traditional way. Environmental advocates continue to attend to an objectifable nature that they believe remains external to culture, James Corner indicates (Corner 1999). At the same time followers of the anthropocentric approach tend to neglect natural qualities of the environment – as opponents argue.

It seems however, that no matter if the attitude toward landscape is conservative or advancing the discipline, there is a growing agreement that there is no such thing as nature; nature is being constantly transformed by man (Wilkoszewska 2006). In this context the two approaches, although different in background and objectives, may not be in direct conflict. Even with growing sensibility toward ecological values, it is hard to imagine returning urban areas to their former ecosystems. Equally hard is to believe in a convincing and culturally ambitious landscape project created in isolation from natural flows and forces.

4 CONCLUSIONS: NEW LANDSCAPES AND SOCIETAL CHALLENGES

We can see clearly today that we introduce to cities our concepts of nature. In urban environments we may encounter adventurous nature augmented by media images, or engrafted into intermediate elements that are neither buildings nor topographies, and which are in some ways analogous to those introduced almost three centuries ago by Alexander Pope and William Kent. In the processes of re-naturalization of cities it is important to realize that there is no such thing as nature, there are different natures: naturalistic barren lands, pastoral scenes, green passages cutting through buildings and technologically enhanced ephemeral gardens. By understanding and taking advantage of this situation of an under-defined or openly defined nature, architects may shape the urban environment so it has the power to inspire us and make our lives more creative.

While the new genres of public spaces and building typologies are emerging, a crucial question appears as to how this refers to social changes. First of all, it is critical to realize that landscape does not only respond to social changes; landscape is a mirror of a changing society. Through history there has been a convergence between artistic vision of the landscape and social changes that transform cultural landscapes, as Denis Cosgrove argues (Cosgove, 1998). Landscape is a way of perceiving the world. Landscape is a social product; it is a consequence of the collective human transformation of nature (Frydryczak 2014).

As Cosgrove (1998) points out, the idea of landscape evolved and was elaborated for a long time as a product of elite consciousness, until its impoverishment in the late nineteenth century; "The significance of landscape declined again during the period of major social change in the late nineteenth century. (...) It no longer carries the burden of social or moral significance attached to it during the time of its most active cultural evolution" (Cosgrove 1998). It seems however that this decline was rather a crisis, the unavoidable erosion marking the starting point for its transformation and reappearance in urban conditions. Landscape appears today as an important category for the interpretation of urban spaces and a powerful tool for their integration. Conceived in different scales, it fosters the emergence of new methods for stimulating urban renewal with new genres of public spaces and building

typologies based on the inseparability of the natural and the built. Nowadays, landscape can be seen in this process of reappearance as a creative environment for human activities, with its power to stimulate people and support their identity within the particular cultural and geographical conditions in which they live.

Transdisciplinary design framework and a NZE future for the city

Constance C. Bodurow
College of Architecture + Design, Lawrence Technological University, Southfield, MI, USA

ABSTRACT: Our Transdisciplinary Design (TDD) mode of inquiry has evolved over eight years and is globally transferable, replicable, and scalable. Our conceptual framework for TDD encompasses hybridized progression, co-production, and manifestation. Building on the body of transdisciplinary scholarship, we call our framework "Speculative Normativism". Built on a foundational, "comprehending vision", linear in the temporal dimension, highly integrative, and shaped by complex contextual perceptions, capacities, and flows, the method is made operative within the "Territory of Hybridization and Co-Production" where design agency, transformative action, and co-production moves past singular disciplinary expertise toward projective contributions. To illustrate our framework, we tell the story of co-production among academics, students, professionals, and the community to address grand challenges, create a Net Zero Energy (NZE) prototype structure which collects solar energy, rainwater, creates a public realm to support active learning and training, and generates energy, educational opportunities, and equity in Detroit. The prototype represents a catalytic act in a larger vision to achieve a NZE future for the city, and launch a next generation in TDD.

1 INTRODUCTION

1.1 *Transdisciplinarity in action*

We wish to share the story of our evolving transdisciplinary framework and associated method, and a now eight year collaboration between architects, urbanists, engineers, and STEAM educators at both the University and Elementary level, funders, partners, and in co-production with the Detroit community (broadly defined). The research, pedagogy, and design is led by studio [Ci] and collaborating faculty in the Colleges of Architecture + Design and Engineering at Lawrence Tech University (LTU) in partnership with the Detroit Public Schools (DPS), the Tireman neighborhood of Detroit.

Our Transdisciplinary design collaborative is inspired by and contextualized within an emergent paradigm of architecture and urbanism labs and firms which embrace systemic and hybridized methods and engage diverse disciplines and partners to address sustainability through infrastructure networks at the scale of the ecosystem, including rvtr (Thun et al., n.d.), Lateral Office (White, 2012), and P-Rex (Berger, 2009). Currently, studio [Ci] is in the process of implementing a Net Zero Energy (NZE) project to advance the design and technical disciplines by generating not only renewable energy, water, and waste reduction, but also scalable and replicable public realm, educational and training opportunities, and a new economic model for the Tireman neighborhood of Detroit. The prototype project evolved out of a broader vision to make a 20 sq mile (5038.3 hectare) neighborhood of Detroit a NZE community, to achieve an alternative, equitable, and sustainable ecosystem for the city, and design generative infrastructure interventions for energy, density, and nature. We proposed an "energy farm" which hybridizes photovoltaic energy and rainwater collection systems into an innovative canopy and public realm that achieves shared goals for the cultivation of the next generation, and achievement of urban sustainability, growth, and equity (Bodurow, 2010).

To test the vision, our transdisciplinary team has designed a NZE structure which collects solar energy and rainwater and supports education and training in an outdoor classroom with learning gardens. The prototype will allow us to test our design for large scale generative NZE infrastructure at the Sampson Webber Leadership Academy (SWLA), a pre K–8 Detroit Public School (DPS), and surrounding neighborhood context (designated Innovation Ecological in the Detroit Future City Framework). The Team has designed, modeled, and will eventually build and test the [sw]LAB NZE prototype (Figure 1) with seed

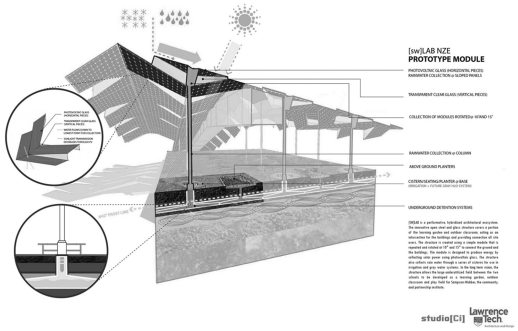

Figure 1. NZE prototype: Illustrative section.

Figure 2. Long term vision (studio[CI] 2014).

funding from a Ford C3 grant and other supporting funders.

1.2 *Background and goals*

The prototype is part of a phased, long term vision for DPS/Sampson, the site, and the Tireman Neighborhood, and represents a catalytic act in what will be a larger, replicable intervention across the DPS system and city of Detroit, reinforcing NZE/STEAM lesson plans for school children and community members, and support the long term vision of a NZE neighborhood. Our design method requires that the prototype achieve aesthetic, performative and equity goals. The project, part of a larger, long term vision, creates an "energy farm" by hybridizing photovoltaic energy and rainwater collection systems into an innovative canopy structure. The more ambitious long term vision includes a NZE canopy, neighborhood scale, collectivized micro grid, a partnership research and training institute, and enhanced public realm (Figure 2).

The prototype was scheduled to be installed in spring 2016 and is designed to be a replicable prototype to generate renewable energy, conserve and manage water, and reinforce sustainability lesson plans which engage children and train community members through active learning. The prototype is designed to generate more than energy: it has catalyzed the stabilization and sustainability of the school and neighborhood. The Team's transdisciplinary approach incorporates "hands-on" involvement, education, and training into a project advancing not only the technical disciplines and trades, but allow students, teachers, and residents to engage in and be empowered by the initiative.

Through our TDD mode of inquiry, we asked:

- How can elements of renewable energy, water management, and outdoor learning and training be hybridized into a NZE structure and replicated to create NZE Farms?
- Can we create a neighborhood energy district (micro-grid), cooperatively owned by residents?
- Could our design intervention encourage a new educational trajectory for Detroit school children and our students through exposure to STEAM/NZE and transdisciplinary lesson plans and active learning in the public realm?
- Might we impact the disparity between wealth and poverty in Detroit and move to a more sustainable economic model?

The prototype is the result of six previous years of extensive applied research, dissemination, and design/development. Detroit's vacancy perpetuates entrenched social, economic and environmental disparities and inequities. We speculate that vacancy can be generative: of energy, wealth, and educational opportunities through NZE infrastructure.

Detroit is positioned to leverage vacancy as an asset (Bodurow, 2010). We believe our NZE, generative use design can provide a criteria-based approach for collective decision making and sustainable growth; and our design progression and interventions tested in the Tireman neighborhood, can serve as a replicable model for the entire city. This approach proposes a new economic model transferring and repurposing publicly held vacant property into a cooperative model of ownership and management for residents, generating training opportunities for the emergent renewable energy/knowledge based economy and wealth for the neighborhood. We intend this project to serve as a catalyst for the eventual sustainable redevelopment of Detroit.

The overall goal of our project is to create a unique hybridized, generative infrastructure. The NZE prototype has provided opportunities to advance the scholarship of several disciplines, for students to learn about transdisciplinary and NZE design, and to encourage the economic transformation of a resource constrained urban community. The primary objectives of our co-production include:

- Hybridize disciplinary knowledge and methods through a new conceptual framework to address several grand challenges of urban sustainability (energy independence, poverty, and equity).
- Achieve Projected Performance: prove that the energy and water collection metrics can be achieved and sustained; prove that the garden beds will thrive through the integrated drip irrigation system.
- Create an "outdoor classroom" that reinforces and supports lesson plans which provide educational opportunities for Pre K-8 school children and training opportunities for community members in NZE and for the knowledge-based economy.
- Accomplish a successful experiment and test. This prototype/pilot project will confirm the potential for replicability across the DPS system, the neighborhood, and the City of Detroit and beyond and support new research and design trajectories.

2 ANALYSIS

2.1 *Theoretical framework*

The origins of Transdisciplinarity in research and education can be traced to 1970 (Balsiger, 2004) through the social and political sciences, and the humanities. In 1987, Romanian born Basarab Nicolescu, a

theorist physicist, founded the nonprofit CIRET (the Centre International de Recherches et Etudes Transdisciplinaires) and eventually the UN study group on transdisciplinarity. Nicolescu describes transdisciplinarity as "the science and art of discovering bridges between different areas of knowledge and different beings" identifying three pillars: complexity, multiple levels of reality, and the logic of the included middle." (Klein, 2004). However, Nicolescu is critical of societal stakeholder involvement, which the Network of Transdisciplinary Research has prioritized. (I2S, n.d.)

Julie Thompson Klein, perhaps the most prolific scholar in transdisciplinarity over three decades, states "Transdisciplinary approaches" are far more comprehensive in scope and vision" and "with "transdisciplinarity"… gaps between the real and the ideal are most apparent (Klein, 1990). Initially the purview of European academics, today the method is referenced in all regions of the world (Lawrence, 2015). Increasing, transdisciplinarity, because of its essentially holistic systemic approach, is a method used to address the grand challenges facing the globe (climate change, poverty, et.al), is equated with efforts to achieve sustainability, and has moved into the design and spatial disciplines. In the first peer reviewed journal on transdisciplinarity (Lawrence and Després, 2004), and the subsequent 2015 update, architects and urban planners were included. In 2011, Springer published a volume addressing Architecture and Urbanism (Doucet and Janssens, 2011). This volume also contains a thorough definition of transdisciplinarity as distinct from other methods of combining expertise for knowledge production (multi-, inter-, post-, cross-, supra-, meta- et al.). "Transdisciplinarity is at once between disciplines, across disciplines and beyond any discipline, thus combining all the processes of multidisciplinarity and interdisciplinarity." (Lawrence and Després, 2004) A review of all recent scholarship reinforces the proliferation of transdisciplinarity in the last decade. As Klein asserts: "The current ascendency of transdisciplinarity (TD) is marked by an exponential growth of publications, a widening array of contexts, and increased interest across academic, public and private sectors." (Klein, 2014).

Our approach, framework, and methods are clearly transdisciplinary, if we are to accept the nature of previously described transdisciplinary research – which are characterized by "hybrid nature … tackles complexity … accepts local contexts and uncertainty … oriented toward action … addresses societal problems but also contributes to their solutions … bridging the gap between research and decision making in society". (Lawrence and Després, 2004) and (Doucet and Janssens, 2011) We operate in a context (primarily Detroit, MI, USA) "where social, technical, and economic developments interact with elements of value and culture, including … energy … sustainable development, and urban land and waste management … quality of life." (Haberli, et al., 2004). Our own working definition of Transdisciplinary Design (TDD) is "an immersive, collaborative, and integrative design centered entrepreneurial pedagogic, research, and practice approach, expanding diverse disciplinary boundaries to address complex systems, and to achieve urban sustainability through resultant design interventions from the scale of the structure to an [urbanized] ecosystem." (Bodurow, 2013).

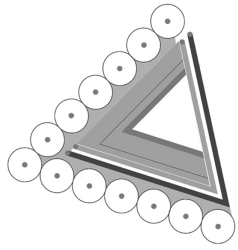

Figure 3. Transdisciplinary Design (TDD).

The notion of "gaps" (ala Klein) informs our definition and framework. We embrace the notion of expanding disciplinary boundaries and believe identifying the new territories for design agency and action is essential to our TDD framework (Figure 3). It has proven critical in moving all contributors past their singular disciplinary expertise toward projective contributions, trajectories, and ultimate manifestations. As the Holistic Education Network states, transdisciplinary inquiry 'involves multiple disciplines and the space between the disciplines with the possibility of new perspectives 'beyond' those disciplines … focusing on the inquiry or issue itself." (Hent.Org accessed 17 FEB). Indeed it is in this "space between": the new TDD territory where innovation is born and thrives in our collaborations.

> speculation, n.
> 1. The faculty or power of seeing; sight, vision, esp. intelligent or comprehending vision. Now arch.
> a. The exercise of the faculty of sight; the action, or an act, of seeing, viewing, or looking on or at; examination or observation. Obs. 4. a. The contemplation, consideration, or profound study of some subject.
> Etymology: < late Latin speculātiōn-em, noun of action < speculārī to speculate v.
> Oxford English Dictionary (accessed 21 FEB 2016)

2.2 *Conceptual framework*

We are inspired and challenged by the observation that "many contributions during the last 10 years lack a conceptual framework." (Lawrence, 2015). We offer our own conceptual framework for Transdisciplinary Design (TDD): that of "Speculative Normativism", which we have evolved over the last eight years, with more intense maturation in the last three.

In our experience, the TDD method is essentially speculative, not merely responsive, reflexive, or

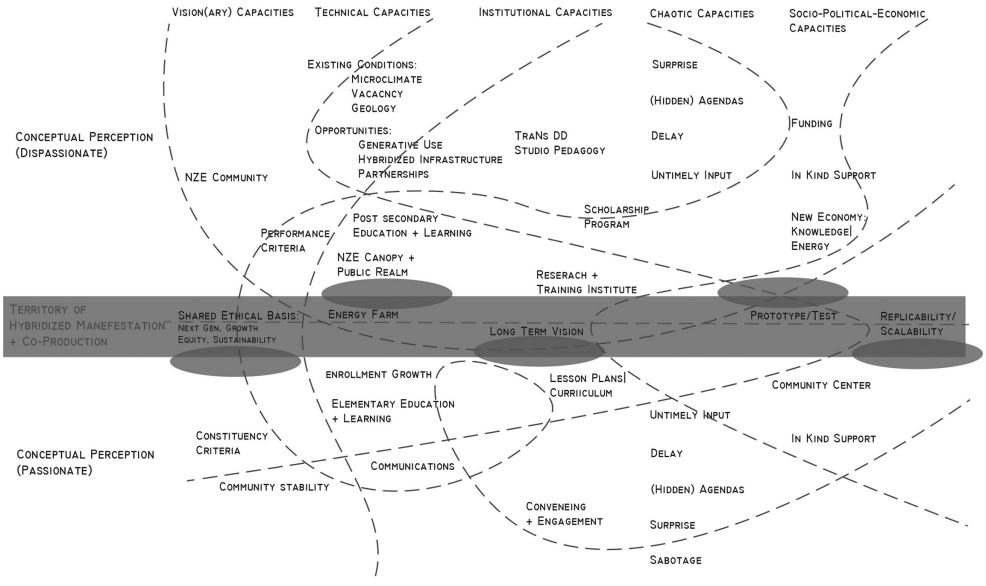

Figure 4. TDD: a new Speculative Normativism.

reflective as Schon and others have proposed (Schön, 1983). I mean no disrespect to this extensive body of knowledge, nor the scholars who created and propagated these theories (Schon was one of my first Professors at MIT and shaped my intellectual and professional future). But in order to make transdisciplinary mode of inquiry operative with an eye toward relevant manifestation outside the academy, we have included transformative action in multiple contexts (in the lab, the classroom/studio, and in the field). Our approach goes beyond the typical methods of inquiry in the spatial disciplines (drawing, modeling, etc.) to incorporate diverse generative techniques and settings, paired with active learning and co-production with diverse team and community members who bring additional capacity and expertise. Further, we do not define our method as "problem solving" or even "problem seeking", as framed by Dunne and Raby, though we do operate "between reality and the impossible" (Dunne and Raby, 2013). We have found the need for a "comprehending vision", which builds on indigenous critical mass and capacities, unites disciplines and diverse participants, allow for the integration of inputs and, eventually, co-production and successful manifestation. Our interpretation is supported by Klein, who asserts: "Transdisciplinarity requires deconstruction, which accepts that an object can pertain to different levels of reality, with attendant contradictions, paradoxes, and conflicts." (Klein, 2004).

We call our conceptual framework "Speculative Normativism" with an eye toward creating that "comprehending vision" of what is not only possible, or probable, but what should be. We feel that TDD must simultaneously have a basis in contextual and conventional social norms, yet also be prescriptive in nature, leading to an ideal standard or model. Our conceptual framework is inspired by what Klein identifies in her writing as "post-normal science and wicked problems that break free of reductionist and mechanistic approaches" (Klein, 2014). As designers, we wish our vision and expertise to result in built form. More importantly, we aspire to generate not only transformative action, but replicability, and therefore, an enduring paradigm. Linear in the temporal dimension, our TDD progression is highly integrative, influenced and shaped by multifarious contextual perceptions, capacities (including vision(ary), technical, institutional, chaotic, and socio-poli-econ) and the flows which deliver select outcomes to the territory of "hybridized manifestation" and ultimately implementation.

We have created an illustration of our conceptual framework of "Speculative Normativism" (Figure 4). Our observations are that there at least two "Contextual Perceptions" or realities in TDD: Dispassionate and Passionate. These exist on opposing sides of what we have named the "Territory of Hybridized Manifestation+Co-Production". The two quadrants are not necessarily divergent, though generally, the "Dispassionate" quadrant (and its associated inputs, forces and, production) is comprised of more technical methods, and the knowledge and experiences which are derived from these. The "Passionate" quadrant is, generally, comprised of more qualitative methods, knowledge and experiences. However, the two quadrants occasionally intersect and overlap, and participants operating within each share operative methods. The resultant co-production, illustrated on the central axis, are the manifestations which actually carry forward into implementation. Thus, this central axis represents not only intersection, but the "Territory of Co-Production".

capacity, n.
Etymology: 15th cent. capacyte, <French capacité , <Latin capācitāt-em

Oxford English Dictionary (accessed 25 FEB 2016)

1. a. Ability to receive or contain; holding power. Obs. (in general sense).

4. Mental or intellectual receiving power; ability to grasp or take in impressions, ideas, knowledge.

5. Active power or force of mind; mental ability, talent.

6. gen. The power, ability, or faculty for anything in particular. Constr. of, for, or inf.

We have identified five "Capacities" on the upper axis: Vision(ary), Technical, Institutional, Chaotic, and Socio-Political-Economic. The notion that capacity implies not only volume, but power, both individual and collective, justifies the terminology. Each of the five capacity categories contain diverse and rich talents, inputs, and forces which, in general, provide positive momentum to drive the TDD progression forward (and sometimes, keep it in stasis or present friction). On the matrix, we have arrayed in each quadrant for purposes of explanation, the specific "dispassionate and passionate" methods, inputs, and deliverables from our own NZE project. Visionary capacities are essential, as asserted, for speculation of a projected and prescribed future state. In our NZE project example, vision originated in the dispassionate quadrant, but was enriched and expanded by input from the passionate quadrant. Technical Capacities included many spatial disciplines (as described below, and also including structural and geotechnical engineers) and elementary, primary and secondary administrators and educators. Institutional Capacity came from a variety of players: Lawrence Technological University, Detroit Public Schools, and the public, private, and NGO sectors in Detroit, each with their own power. Chaos is ever present (it governs the universe!), sometimes occurring in small quantities, sometimes overwhelming. Indeed, dealing with chaos, ambiguity, and uncertainty is *de rigueur* in TDD. Examples include: (hidden) agendas, political and economic obstacles, extended timeframes, escalating costs, constant fundraising, irrational decision making, exhaustion, defection, etc. Socio-Political-Economic Capacities represent the dual blessing and curse of funding, funders, in-kind donations, and partnerships. Most positively expand co-production, but often divert focus and exert uneven influence. This capacity category also intersects with the vision(ary) category, in our case, the intention of creating a new knowledge/energy economy for the neighborhood and city. Note: all capacities are illustrated in equal size and weight, though in reality, these capacity categories fluxuate and exert their power unevenly throughout the TDD progression. Similarity, inputs and forces possess inherent dualities, and often transgress capacity boundaries.

Nature reminds us that "while matter cycles, energy only flows" (Callenbach, 2008) and is then converted from one form to another. Flows are illustrated in the matrix to acknowledge the limitations of two dimensional diagramming of such a complex, four dimensional endeavor as TDD. Flows also portray the integrative nature of our TDD progression and reveal the cross-cutting influence of the five capacities categories and their associated outcomes on the hybrid territory.

The "Territory of Hybridized Manifestation + Co Production" (again, the territory of TDD) is linear and temporal, implying origin and a projected future. This territory contains the consensus manifestations which generally move forward into implementation. An example is "Ethical Basis", which was the result of discussing and documenting shared values and goals. In our experience, inputs from either quadrant often stand alone as discreet and complete, while the manifestations which migrate to the hybrid territory tend to evolve and eventually manifest. While these consensus manifestations are generally discreet (e.g., the NZE Prototype) some have associated "gray zones" implying potential for additional trajectories, and so are illustrated as such.

2.3 *Analysis [method, empirical research]*

Our method is influenced by Mason White's notion of Disciplinary Thievery "of co-opting strands of a discipline's operative or, possibly more severe, a discipline's nomenclature, language, and identity." (White, 2012). We aspire to create new territory for architectural research and practice and new roles for designers through this melding of disciplinary expertise. Building on seven years of collaborative research, design, and co-production with each other, our students, and community constituencies, our NZE project has engaged designers in diverse pedagogic, research lab, and generative settings.

Founded as a transdisciplinary design collaborative (addressing environmental and grand challenges requires it), studio[Ci] authored the "Convergence of Intensity" [Ci] methodology and unique GeoDesign interface which enables the "coming together: of metrics [criteria] in three categories: Human [inhabitation]; Cultural [place]; and Infrastructural [ecosystem], into a spatial convergence." From 2008–2010, we collaborated with the 20 square mile (51.8 square kilometers), 100,000+ resident, Southwest Detroit (SWD) neighborhood on the Value Densification Community mapping project, which created the foundation for our current NZE project (Bodurow et al., 2009). We are primarily humanists and urbanists, but are also influenced by geography and landscape methodologies, such as Corner's "agency of landscape" which has helped shape our approach to vacancy in Detroit. While trained in scientific and technical fields, studio[Ci] is primarily expert in the spatial disciplines related to infrastructure and the built and natural environments (architecture, urban

planning, urban design, landscape architecture, civil engineering, environmental and mechanical engineering) and the agency each brings in addressing the grand challenges facing the globe. However, not all academics, practitioners, and students are predisposed to our TDD method, so recruitment and selection of team members are carefully curated. While we seek colleagues who are experts in their respective disciplines, more important are characteristics of intellectual curiosity, openness, and patience (as time expands to support the TDD collaborative environment and address the inevitable obstacles). As Pinson observes, "a precondition for transdisciplinarity: identifiable disciplines capable of a constructive dialogue with other domains of knowledge." (Pinson, 2004) Close and extended collaboration is required, what Despres called "mediation space and time" or Horlick-Jones and Sime called "border work" (Lawrence and Després, 2004). Klein adds: "Margaret Mead suggested that "analogic" thinkers may be more successful at handling integrative tasks than "digital" thinkers, who may be too narrow to deal with cross-cutting issues." Further, the best-suited faculty are "academic intellectuals…accountable to a wider audience, academic intellectual may have experience with concepts and problems outside academe." (Klein, 1990). This tracks studio[Ci]'s foundational values of relevance, rigor, and integrity. As Klein asserts: "there is no transdisciplinary *Esperanto*". It is "a generative form of communicative action that is context specific". (Klein, 2004). Transdisciplinarity "is simultaneously an attitude and a form of action." (Klein, 2004).

In 2010, we claimed we could make SWD neighborhood a NZE community, and then, with funding support, spent the next two years proving it could be achieved (Bodurow et al., 2012). We created a "Manifesto" based upon context, theory (Ci), and approach (Transdisciplinary Urbanism). Strongly research based, we created an emergent TDD framework, which, at the time, was more iterative in nature in order to conduct foundational research and analysis, make propositions to achieve NZE, and establish process and co-production between our team and representatives of the community.

Through our 2010–2012 effort, we observed that vacancy in SWD concentrated and arrayed itself around infrastructure and institutions, which became the basis for several specific design interventions in what we call "generative infrastructure" hybridized with nature, energy, and density. Our proposed "Energy Farms" design intervention in the Tireman Neighborhood was most favored by the community, and offered opportunities for the large scale generation of solar and geothermal energy and the engagement of many potential partners. (Bodurow, 2010) Since fall 2013, studio[Ci] has engaged in research, teaching, design, evaluation, construction, testing, and monitoring for the implementation of a prototype Net Zero Energy (NZE) structure which will be fully installed by June 2016. This evolved TDD progression is illustrated in Figure 5, with capacity (institutional, community

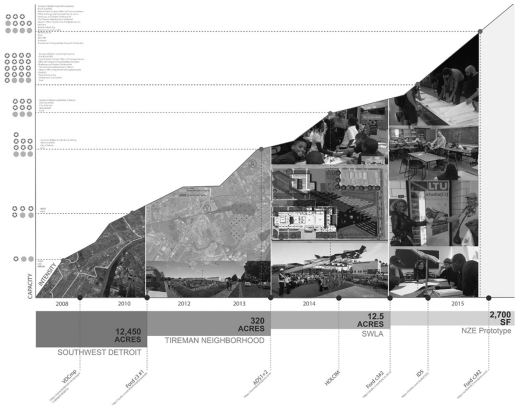

Figure 5. Method: time, capacity, intensity, geography (Bodurow et al., 2015).

and funding) on the Y axis, time and geography on the X axis, and intensity on the Z axis. The project evolved over time in its capacity (existing and emergent professional and community expertise), intensity (the form and modes of intellectual and emotional investment, creative production, and the demands of multivariate performance criteria) and geography (from city to neighborhood scale to site and built intervention. It is interesting to note that as our capacity and the intensity of our co-production increased, the geography of our intervention compressed, from 12,450 acres (5038.3 hectares) to 2,700 sf (250.8 square meters).

2.4 *Co-production and knowledge transfer*

Our team's goal was to experiment with, innovate, and hybridize NZE technologies; create and test a unique prototype structure; and work at the boundaries of our disciplines, thereby advancing them individually and collectively. Our team asked: What if students learned about NZE in elementary school? What if residents were trained and empowered to generate their own energy? What if vacancy could be generative – of energy, wealth, educational opportunities? What would this mean for the stabilization of a neighborhood, the city, their future?

The TDD method is about knowledge production, but also focused on knowledge transfer. As educators first and foremost, we have created vehicles for student engagement, both in more traditional forms and non-traditional forms, such as the development of an innovative TDD studio pedagogy, and establishment of a NZE Team Room at SWLA, allowing engagement of elementary school children in active learning around NZE (Figure 6). Learning objectives for students included gaining awareness and knowledge of transdisciplinary method in support of Net Zero Energy goals and performance metrics; acquisition of skills in the design, construction, and installation of hybridized photovoltaic and water collection systems; and direct

Figure 6. NZE Team Room at DPS/Sampson.

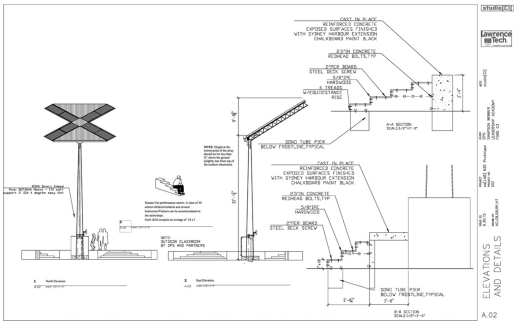

Figure 7. DD/CD set for NZE Prototype.

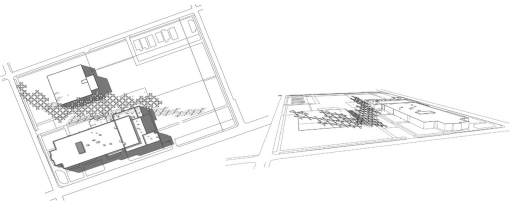

Figure 8. Array, module and canopy studies modeled on site.

experience in issues of social justice and the agency of design in addressing the grand challenges.

Co-Production is integral to our TDD progression, so we agree with "the intentional involvement of stakeholders in the definition of problems and those criteria, objectives, and resources used to analyse and resolve them." (Klein, 2015) Our transdisciplinary progression emphasizes the importance of critical thinking and altering designs to respond to dynamic conditions. We incorporate awareness, education, and training into a replicable model which allow all team members to engage in co-production.

Our TDD method encourages the integration and resolution of diverse expertise, perspectives, and values. We assemble and engage a diverse array of talented and passionate constituents. These co-producers form a team lead by faculty to realize a generative, hybridized NZE architecture and infrastructure. Complexity is assumed, and an entrepreneurial spirit and commitment to expanded time and space for interaction and integration is essential. As in all design research, risk taking, failure, patience, and persistence have equal importance to intellect, skill, and expertise. Challenges and pressures influence process and outcomes in unexpected ways.

We required that the prototype achieve aesthetic, performative and equity goals. Staying within a tight budget encouraged students to make each design iteration with care. The transdisciplinary progression emphasizes the importance of critical thinking and altering design to respond to dynamic environmental and urban conditions. Students are engaged in all aspects of the design and implementation work both on campus and in the community. Students held roles in detailed design through testing array alternatives, engaging in making; and creating details for bid and construction (Figure 7).

Architecture, Urban Design, and Engineering students engaged the project through a transdisciplinary method including curricular, co-curricular, technical, and research assistant roles and benefitted from cross college collaboration. In spring 2015, students refined a CAD Design Development/Construction Documentation (DD/CD) set and physical and digital models for the prototype. Students researched local, state and federal regulations regarding solar and water harvesting projects and interacted with the city, DPS, DFC and other partners. Students supported the bid process with local fabricators and installers and the bid set to which they contributed was the basis for our final design/structural set. Aggressive deadlines required sustained effort by the entire team, including process with DPS, the community, final design, approvals and permitting, installation, testing and evaluation.

Students advanced work on the long term vison utilizing parametric modeling to replicate the prototype array into twenty array modules, and eventually projecting the overall canopy on site (Figure 8). Students engaged project constituencies and diverse publics. In spring 2016, one Masters level student lead a weekly class of 6th graders in the design and construction of the Outdoor Classroom element, providing tutorials in 3D software and basic woodworking. Students engaged with the community and then summarized progress and created summaries for social media posts, keeping University, School, partners, funders, the general public, and the surrounding community informed. These uploads illustrate progress on implementing the prototype. ("s'CiLTUFordC3," n.d.). Using survey tools, we plan to gather data on impact to student and teacher thinking and approach. Through a prescribed monitoring protocol, we will document performance metrics and evaluate costs.

3 CONCLUSIONS

Our TDD conceptual framework of "Speculative Normativism" has evolved over eight years, served to address several grand challenges, and advanced studio[Ci]'s efforts to achieve our NZE Prototype. Our operative method has identified the "Territory of

Hybridization and Co-Production". Identifying this new territory for architectural research and practice, transformative action, and co-production has proven essential to our TDD method. We have expanded design agency, and created new roles for designers through this melding of disciplinary expertise. Any transdisciplinary method is imperfect, but we believe our mode of inquiry and transformative action is globally transferable, replicable, and scalable in resource constrained communities, and so, in our experience, the results justify the means. As important to realizing the prototype, we aspire to launch a next generation of design and engineering students who are inspired to explore Transdisciplinarity and NZE beyond their insular disciplinary boundaries in the quest for hybridized, and therefore more sustainable, design solutions.

Our NZE prototype represents a catalytic and transformative action in a much broader, long term vision for the city. Through the completion of the project and future monitoring, we intend to advance inquiry for:

- Feasibility and optimization analysis on canopy and structural systems for digital fabrication;
- Economic and financial feasibility studies for the creation of a neighborhood energy district (micro grid) cooperatively owned by residents;
- A new educational trajectory for Detroit's children and our students through exposure to NZE and transdisciplinary lesson plans;
- Work force development to train Detroit residents for jobs in the emergent renewable energy/ knowledge based economy;
- Approaches to impact the spatial inequities which entrench disparity between wealth and poverty in Detroit, moving toward a more sustainable economic model.
- Evolution of our TDD conceptual framework and method in pursuit of in order to achieve sustainability and a NZE future for cities.

Regenerative design for achieving net-zero energy commercial buildings in different climate types

A. Aksamija & Y. Wang
University of Massachusetts Amherst, Massachusetts, USA

ABSTRACT: This article discusses feasibility of achieving net-zero energy goals in retrofitting existing commercial buildings in different climate types. The objective of the research was to study how to integrate passive design strategies and energy-efficient building systems to improve building performance and reduce energy consumption of existing buildings, and to reach net zero energy goals by utilizing renewable energy sources. Based on extensive energy modeling and simulations, multiple design considerations were investigated, such as improvements to building envelope, retrofitting of HVAC and lighting systems, occupancy loads, and application of renewable energy sources for commercial buildings located in cold, mixed and hot climates. The comparative analysis of simulation results was used to determine how specific techniques lead to energy savings in different climate types and for buildings of various shapes and orientations. The research results show that it is possible to meet net-zero energy use with appropriate design manipulations and comprehensive utilization of renewable energy sources.

1 INTRODUCTION

1.1 *Background*

Net-zero energy buildings (NZEBs) contribute to reduction of energy consumption in the building sector, mitigating the environmental impacts brought by constructing and operating buildings. In the U.S., commercial and residential buildings account for approximately 40% of total energy consumption. The total end-use emissions of CO_2 from the commercial building sector was 897.9 $TgCO_2Eq$ in the U.S. in 2012, constituting 18% of the total emissions (EIA 2015). High demand for fossil fuels needs to be controlled and CO_2 emissions need to be decreased to mitigate climate change and enhance urban resiliency. To achieve this goal, one of the strategies is to reuse and effectively adapt existing buildings to improve their environmental impacts.

Retrofitting existing buildings is a viable approach for decreasing energy consumption associated with the building stock. Vast majority of commercial buildings in the U.S. (81.5%) were built before 1999, and 60% of them were built before 1979 (CEBCS 2012). This indicates that most of the existing buildings were built before the energy codes were established and extensively enforced (Laustsen 2008). Effective and reliable energy efficiency measures are able to ensure enhanced energy performance in the long run and improved occupant comfort by increasing the natural light, optimizing temperature controls, and introducing healthy building operation and maintenance systems (Tobias 2010).

Regenerative design is a design approach for existing buildings, which utilizes comprehensive sustainable, energy-efficient and resilient design methodology (Aksamija 2015). In building retrofits, regenerative design is conceived as exploration and improvement of buildings' functionality, aesthetics, human comfort, and energy performance. Different from historic preservation, regenerative design of existing buildings can be applied extensively for retrofits and adaptive reuse, allowing buildings of different types, functionalities, and sizes to be upgraded efficiently and cost-effectively.

Taking the idea of NZEB into regenerative design requires integrated passive and active design strategies, as well as renewable energy sources into existing buildings' redesign to meet the net-zero energy consumption objectives. The NZEB concept has been widely explored during the last few years as a way to achieve energy efficiency in the building sector and encourage on-site renewable energy incorporation. Considering the significant portion that commercial buildings take in the U.S. building stock and their high energy consumption level, involving NZEB methodologies into commercial retrofits will benefit the preservation of embodied energy in original construction and the reduction of operational energy.

1.2 *Literature review*

Significant research exists relating to building retrofits; however, the rate for existing buildings' upgrade continues to be low, representing only around

2.2% of existing building stock (Ma 2012). Current sustainable retrofit techniques include renovating building envelope, HVAC and lighting systems, as well as upgrading building functions, materials and building use. The challenge and barriers relating to regenerative design include existing building's size, quality and equipment (Wilkson 2012), as well as tenants and owners' acceptability, which is critical in the decision-making process for sustainable retrofit practice. Building performance is the core issue involved in the evaluation, and assessment of potential energy savings and costs must be taken into consideration. The integration of regenerative design and net-zero energy goals in retrofit projects provides challenges to practice, but offers an opportunity to embed a strengthened performance-based design approach and global energy conservation.

The fundamental objective of net-zero energy concepts is to use low-cost, locally available, nonpolluting and renewable sources to satisfy building's energy requirements. The commonly applied accounting methods are net-zero site, net-zero source, net-zero costs, and net-zero emissions (Torcellini 2006). Recent research extends the net-zero energy building methodological framework to introduce the life-cycle perspective in the energy balance, thus allowing the building's embodied energy and its components to be included in the discussion (Cellura 2014). For retrofit projects, life-cycle energy balance calculation method could be applied to acquire the true environmental influence with respect to both the consumption of energy during operation and the preservation of energy embodied in the buildings' materials, structure, and technical installations (Marszal 2011). However, the methodology to fulfill the building energy assessment and rating extension for embodied energy calculation still has uncertainties in handling the socio-economic aspects of building construction, which needs to be further explored and investigated (Hernandez 2011). In this paper, net-zero energy building is defined as a building which is able to achieve zero balance for annual energy budget with on-site renewable energy sources. Commercial office retrofit buildings were set as the study target. The study was conducted by investigating the effects of sustainable retrofit strategies on buildings' energy efficiency in different climate types and introducing renewable energy sources to meet the annual energy needs.

1.3 *Objectives*

The main goal of this research was to examine the possibility of achieving net-zero energy goals in commercial retrofit projects located in different climate types through regenerative design. The utilized research methods consisted of several aspects, including conducting multiple simulations of common commercial building prototypes under different climate conditions to test their energy use and establish baseline energy usage, and applying multiple energy saving retrofit strategies. Also, renewable energy design considerations were investigated to explore the feasibility for achieving net zero energy goals. This paper addresses these following research questions:

(1) What are the main characteristics of existing commercial buildings in the U.S.? What is the baseline energy usage for buildings located in different climates? What is the effect of shape and orientation on energy consumption?
(2) What are the appropriate strategies for improving energy efficiency for building retrofits located in different climate types? How to apply retrofit design strategies to maximize energy savings?
(3) How to make net-zero energy goal possible through adopting regenerative design method? What are the applicable renewable energy sources and how can they be used to meet net-zero goals?

The research methods included data analysis, energy consumption calculations through energy modeling and investigation of applicable renewable energy technologies. Based on the analysis of properties and characteristics of commercial buildings located in different climate zones in the U.S., energy simulations were used to investigate baseline energy usage and the effects of regenerative design methods on energy consumption. Further calculations and explorations of renewable energy sources were performed to investigate methods for achieving net-zero energy goals. The following sections describe research methods and results in detail.

2 CHARACTERIZATION OF EXISTING COMMERCIAL BUILDINGS

2.1 *Building size*

Chicago, Baltimore, and Phoenix were selected to represent three different climate zones (cold, mixed, and hot). According to the data from 2012 Commercial Building Energy Consumption Survey (CBECS), common features of commercial building within these three climate zones were determined to develop the energy models for simulations. CBECS database provides actual data about the commercial building sector in the U.S., hence allowing us to accurately analyze the building characteristics (Griffith 2008).

The survey results show that approximately 88% of total commercial buildings are less than 2,300 m^2 (25,000 ft^2), which means that most commercial buildings are medium to small size. The mean square area for all the regions in the U.S. fluctuates between 930 m^2 (10,000 ft^2) to 2,300 m^2 (25,000 ft^2) (Figure 1). The mean area per building in Chicago is 1,608 m^2 (17,300 ft^2). As the second largest seaport in middle Atlantic, Baltimore's mean area is 2,100 m^2 (22,300 ft^2). Phoenix is located in southwestern part of the U.S., and the mean area per building is about 1,400 m^2 (14,500 ft^2). Based on this data analysis, we developed prototypes and the simulation models as 1,300 m^2 (15,000 ft^2) buildings to represent the general

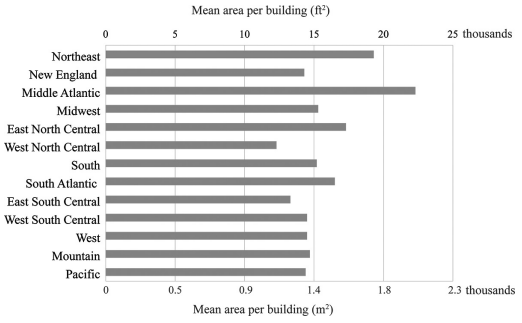

Figure 1. Mean area of commercial buildings in the U.S.

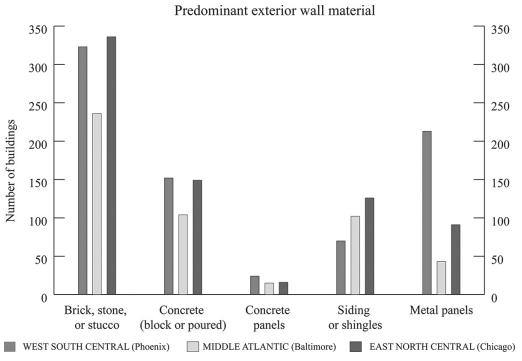

Figure 2. Predominant exterior wall materials.

condition of existing commercial building stock in the U.S. market.

2.2 *Building envelope*

To construct the energy models and set the inputs for building envelope treatment, occupancies, building systems and construction methods for existing commercial offices, CBECS data was analyzed to determine the details for each building component. For Chicago, Baltimore, and Phoenix, exterior walls for most buildings are constructed of brick, stone, or stucco, while concrete and shingle siding serves as the secondary important exterior wall material in Chicago and Baltimore. In Phoenix, metal panels and concrete are also major materials used for building envelope (Figure 2).

Roof's construction is another critical issue in determining building's energy performance. Currently, most commercial buildings located in Phoenix have metal roofing. Asphalt, fiberglass, or other shingles are the predominant roof materials in Chicago and Baltimore (Figure 3). Shallow pitch roof and flat roof are predominant roof types in West South Central, Middle Atlantic, and East North Central areas (Figure 4).

2.3 *Building systems and equipment*

Optimizing the control and efficiency of building equipment used for HVAC and lighting systems plays

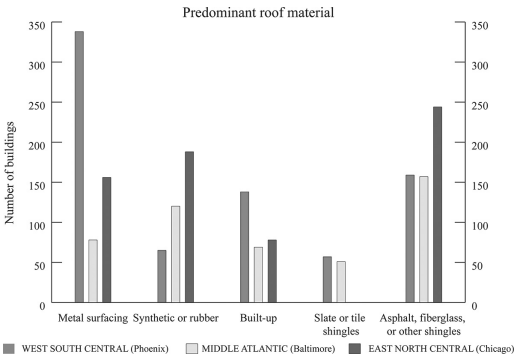

Figure 3. Predominant roofing materials.

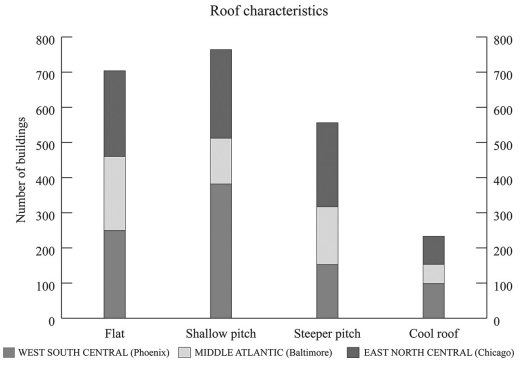

Figure 4. Roofing characteristics.

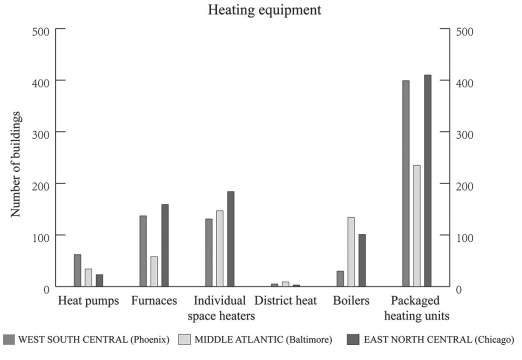

Figure 5. Heating equipment (more than one may apply).

an important role in reducing energy consumption during building operation. Packaged heating units are the most popular heating system in existing commercial buildings, based on CBECS data (Figure 5). Some other types of heating equipment, such as boilers, individual heaters, and furnaces are also widely used for heating purposes.

When it comes to the cooling equipment, packaged air conditioning units are dominant cooling systems, which are used in existing commercial properties in Chicago and Phoenix. In Baltimore, individual air conditioners are the third type of cooling equipment

extensively used in commercial offices. Furthermore, considering that lighting accounts for a large portion of commercial office's electricity's consumption, the CBECS database was analyzed to determine typical lighting equipment. According to the survey results, standard fluorescent fixtures are widely used, as well as incandescent and compact fluorescent fixtures.

3 ENERGY MODELING AND RENEWABLE ENERGY

3.1 *Simulations and energy modeling*

Energy simulation program eQuest was used in this research, where baseline models were created, as well as models representing regenerative design strategies as alternative runs. Since the building form and orientations may vary according to specific site constraints, 14 prototypes were created to represent different shapes, forms and orientations (Figure 6). For each prototype, three different models were created, representing the baseline model, and two alternative runs (low-impact and deep retrofit design options). Energy modeling was performed for all of these scenarios, and for buildings located in different climate types (Chicago, Boston and Phoenix). Therefore, 42 different energy models were developed.

The test model is described as 1,400 m^2 (15,000 ft^2) commercial office building with four stories above ground. The inputs for baseline models located in cold climate (Chicago) were selected according to the 2012 CBECS survey data for East North Central Region. The average energy use intensity (EUI) was calculated to be 398 kWh/m^2 (126 kBtu/ft^2). This high EUI suggested that most of the existing commercial office buildings in Chicago are not highly energy-efficient. The first alternative run was based on an improved model with thermally improved exterior walls, roof and windows, lower window to wall ratio for west and east facades, lower lighting power density (LPD) for functional rooms, and more energy efficient HVAC system. The results indicated that these strategies would reduce energy consumption by approximately 30% compared to baseline models. For the building envelope, adding insulation would increase the R-value of exterior walls and the roof to better control heat transfer through building envelope. For Chicago area, brick is the major exterior wall material currently used. The retrofitting measure of adding insulation to improve the R-value of existing exterior walls would have an effect on the energy efficiency and durability. Adding insulation and air/vapor barrier would increase thermal resistance of exterior walls, control moisture transport and eliminate possible thermal bridging. Building envelope upgrade also considered replacing windows, adding exterior shading and interior light shelves, contributing to energy efficiency, and improving daylight and visual comfort. Manipulation of window to wall ratio was also applied as a method to help improve the energy performance of building envelope. The model's window to wall ratio was set to 40%, in order to ensure an appropriate exterior appearance, enough access to natural light, and a well-functioning building facade system in terms of providing expected thermal performance and achieving energy efficiency. Retrofitting interior lighting fixtures to reduce lighting power density is an effective way to lower electricity consumption for lighting, and was included as one of the retrofit design strategies. Installing occupancy sensors to control interior lighting and adding daylight harvesting are also feasible measures, which were incorporated into this study. Moreover, upgrades to existing HVAC systems were included, specifically increasing the efficiency of service systems and widening zone temperature ranges for operation and set points.

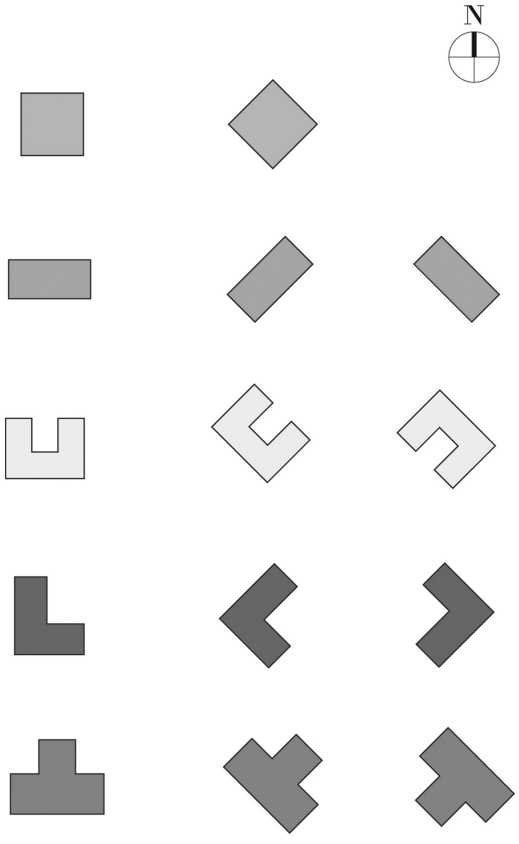

Figure 6. Building prototypes.

To achieve significantly lower end uses for heating, cooling, and ventilation, deep retrofit measurement could be taken into account, such as completely retrofitting HVAC systems. For example, radiant systems are much more energy efficient than typical VAV systems. Radiant systems also provide improved thermal comfort with lower energy consumption (Rhee 2015). The deep retrofit strategy considered retrofitting of HVAC equipment and integration of radiant systems. The modeling of radiant system in eQuest is approached by setting the system type as

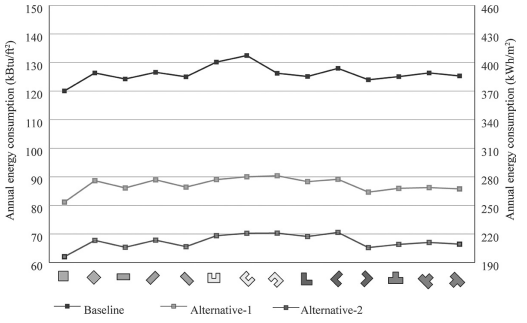

Figure 7. EUI comparison of three runs for Chicago commercial office buildings.

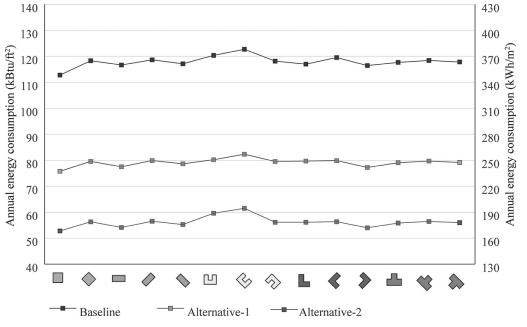

Figure 8. EUI comparison of three runs for Baltimore's commercial office buildings.

4-pipe fan coil with hot water heating. The second alternative run results were obtained after using radiant system, and they indicate almost 50% energy reductions compared to baseline run results (Figure 7).

The effects of building shape and orientation on the total energy consumption is evident in the fluctuations of EUI values. The results demonstrate that for the buildings of same size and identical systems, square shape with north-south orientation has lowest EUI, while the U-shape and T-shape buildings have higher EUI. This finding indicates that compact shape and reduced surface area benefit buildings in terms of energy performance. Also, north-south orientation for identical building shapes results in lower EUI than other orientations.

Further analysis was conducted to determine energy consumption of commercial office buildings in Baltimore and Phoenix. Baltimore has mixed climate. The results indicate that commercial buildings in this climate generally have lower EUIs than buildings in Chicago. The estimated average EUI for commercial building sector in Baltimore is approximately 370 kWh/m^2 (117 kBtu/ft^2), and deep energy retrofit could lower EUI's to 177 kWh/m^2 (56 kBtu/ft^2), shown in Figure 8. This means that 268,160 kWh (915,000 kBtu) energy could be saved for a 1400 m^2 (15,000 ft^2) commercial building on an annual basis.

The same research method was applied to study the existing commercial building stock in Phoenix.

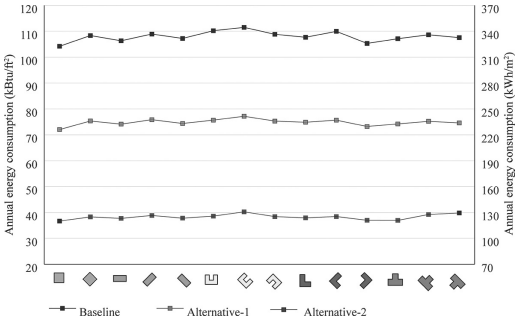

Figure 9. EUI comparison of three runs for Phoenix's commercial office buildings.

Phoenix's climate type is hot and dry, so energy demand for heating in Phoenix's commercial office buildings is not as high as for Chicago and Baltimore. Rather, cooling interior air is critical for providing comfortable thermal environment. The baseline run demonstrates that average EUI of a typical commercial office building in Phoenix is approximately 341 kWh/m^2 (108 kBtu/ft^2). Without high energy demand to maintain heating system, energy usage of commercial offices' is relatively lower compared to the computed values for Chicago and Baltimore, and mostly consist of cooling, equipment and lighting loads (Figure 9).

The energy modeling of typical existing commercial office buildings located in different climates (Chicago, Baltimore and Phoenix) and regenerative design strategies uncovered how low-impact and deep retrofit design methods would influence energy consumption. Also, energy consumption swings that are caused by building shapes and different orientations indicates that neutralizing the building envelope is a key element in energy efficient design (Hootman 2012). Improving building envelope, upgrading HVAC and lighting systems, and integrating advanced building technologies would drastically reduce energy consumption of existing buildings. Net-zero energy goals can only be achieved by lowering energy consumption as much as possible, and providing the remaining energy needs with renewable sources.

3.2 *Renewable energy sources*

Renewable energy technologies, such as photovoltaics, wind turbines, geothermal, biomass, hydropower and fuel cells can be used for buildings' energy demand. Since the monthly usage of electricity and gas was calculated through energy simulations and modeling, renewable energy sources were identified to make up the energy gap and meet net-zero goals.

The widely accepted method is to integrate high efficiency commercial photovoltaics and install on buildings' roofing system. Rooftop PV arrays enable conversion of solar power into electricity to meet the buildings' electric requirements. For commercial

retrofit projects, using grid-connected PV systems has certain benefits and drawbacks. On one hand, PV products have relatively simple configuration, so installment and maintenance are not complicated. On the other hand, the fact that most commercial buildings might have very limited space to add new components or limited roof area might reduce potential for energy generation from PVs. For a square shaped 1,400 m^2 (15,000 ft^2) commercial building in Chicago, a series of 14 PV panels, which cover 350 m^2 (3,750 ft^2) roof area, would produce approximately 70,334 kWh (240,000 kBtu) energy annually. This energy accounts for around 25% of the total energy the building needs on a yearly basis, indicating that it is difficult to achieve net-zero energy consumption with only PV system.

One alternative renewable energy source that can be considered is wind power. Building-integrated wind turbines with vertical axis are becoming more widely adopted as they can be designed as part of the building systems without occupying large area. Creative integration of wind installations is closely related to the building shape, site, wind availability and urban fabric, therefore posing challenge to existing building's retrofit (Bobrova 2015).

Hydropower system could be a possible choice for commercial buildings close to water sources. For small to medium size commercial buildings, adding site-based micro hydro system can be considered if site and location are favorable. Incentives for micro system applications are widespread, which can offset a significant part of the cost for equipment purchase and instalment (Jenkins 2013).

Fuel cell technology also has an important role in renewable energy systems. By converting the energy of chemical reaction into usable energy, fuel cells serve as renewable energy devices with battery characteristics. When it comes to implementation in the building stock, fuel cell systems could be incorporated into modular building components. The modularity potential of fuel cell lends this renewable energy source significant advantages, since flexible applications and cost-saving maintenance are possible.

To successfully achieve net-zero energy consumption, integrated design approach is required, where multiple renewable energy sources are implemented. Different from initiating a new building, retrofitting existing buildings and regenerative design have more limitations and restrictions. The orientation and the main structure of the building can hardly be modified, and the potential return on investment for new applications is critical in the decision making process. Plus, when it comes to employing renewable energy technologies, the barriers often lie in lacking local resources and installation space. For instance, hydropower systems require accessibility to on-site resources. Limited rooftop space and shading from adjacent buildings could significantly impact the usage of photovoltaic panels and their performance. Therefore, realizing net-zero energy goal in commercial retrofit projects requires the combination of passive and active design strategies, full analysis of local resources and feasibility studies, and application of multiple renewable energy systems.

Figure 10. Case study building (prior and post-retrofit).

3.3 *Case study*

In order to illustrate application of the framework and methods discussed in this paper, a case study is briefly presented to demonstrate regenerative design methods to reach net-zero energy goals for an existing commercial building. The study was conducted by authors and previously published (Aksamija 2015).

An 18,500 m^2 (200,000 ft^2) old paper mill located in Holyoke, Massachusetts was the target for the study. The climate is heating-dominated, although cooling is also needed in the warm seasons. The original building was built in 1895, and underwent several additions and retrofits over time. Currently, only 20% of the building is still used for commercial functions, and majority of the building is abandoned.

The first step in adaptive redesign was to analyze massing of the existing building, structure, and spatial organization. It was determined that parts of the building will be demolished (mainly, parts of the second and third floor), and that two additional floors will be added to accommodate new building program, which includes offices, classrooms, museum, retail space, and a restaurant (Figure 10). The middle part of the building was redesigned into a courtyard. With this retrieved courtyard, daylighting and natural ventilation were integrated as passive design techniques to reduce energy consumption. Building envelope upgrade was also achieved by improving the exterior wall insulation. Expanded polystyrene (EPS) rigid insulation panels and fiberglass batt insulation within the framing cavity were added to resist the heat flow and increase the R-value of the wall assemblies. For the top two floors, a new facade system was designed. Curtain wall system and exterior horizontal sunshades system were combined to achieve environmental optimization and energy efficiency. Biomass heating system was integrated into the building's HVAC system by combusting biomass fuels, which add to significant cost-saving, environmental, and social benefits. Since wood, agriculture residues, and crops are the most common fuels for biomass energy systems, easy accessibility to these organic matters in this region would lead to reduced delivery and storage cost. Commercial HVAC smart control system was taken into the HVAC system retrofit to facilitate intelligent integration and optimization of HVAC system components in the building.

Using simulation software eQuest to build and analyze energy model of this commercial building, it was possible to understand the energy consumption quantities, explore the energy saving potentials, and evaluate different sustainable design alternatives. The baseline simulation showed high annual energy consumption, with EUI of 379 kWh/m^2 (120 kBtu/ft^2). Deep retrofit measures incorporated control of internal loads and operating schedules, lighting, improvement in the building envelope, and retrofitting of HVAC systems. For museum, classrooms, stores and offices, different demand for interior lighting environment and occupancy schedules were taken into considerations. Lighting power density (LPD) was reduced for all spaces in the building. After applying all the possible energy saving strategies, an alternative simulation run was conducted to acquire a comparison analysis, lowering the EUI value to 164 kWh/m^2 (52 kBtu/ft^2).

According to the simulation results, it was evident that renewable energy sources are necessary to achieve net-zero energy goals. Comprehensive thinking towards energy conversion ratio, feasibility, accessibility, and cost contributed to the decision of selecting four types of renewable energy systems to work together, generating enough energy to support the operation of the building. High efficiency commercial photovoltaics were considered to be placed on the roofs. The design of PV arrays involved a series of 240 PV panels, covering 4,600 m^2 (50,000 ft^2) roof area to provide approximately 1,170,000 kWh (4,000,000 kBtu) energy annually. In addition, wind turbines were considered to be installed on top of the building to capture wind energy on site. Medium vertical axis wind turbines with 2KW generator were selected to be installed on the roof to generate about 528,000 kWh (1,800,000 kBtu) energy per year. The reasons for choosing this type of wind turbines included their high efficiency, possibility to catch wind from all directions and simplicity in mechanical configuration. Biomass and hydropower were also used in the design of renewable energy systems based on the consideration of the availability of resources. Holyoke is located in western Massachusetts area, which has rich agricultural resources, so it is cost-efficient to collect and deliver biomass materials. The last renewable energy source that was considered for the retrofit design of the building's energy system is hydropower. The location of this building was the primary reason for including hydropower. This particular building has a great potential for hydropower due to its proximity to canal and existing hydropower turbines. For this building scale, a micro hydro system is suitable for placement on the site. Combination of solar and wind energy, biomass and hydroenergy would make this retrofit building reach net-zero energy goals. Solar energy would account for 45% of the energy demand, wind energy for 20%, biomass for 12% and hydroenergy for 20%. The results show that this commercial building is able to meet net-zero energy goals after appropriate design manipulations and use of several renewable energy sources, and also illustrates methodology for regenerative design of existing buildings to meet net-zero energy goals.

4 CONCLUSION

Based on the comprehensive analysis of current commercial buildings in the U.S., their energy use and impacts of design retrofit strategies, this paper explored the possibility of taking regenerative design into commercial offices' retrofit practice to achieve net-zero energy consumption. The energy performance of existing commercial buildings needs to be improved to address energy consumption associated with buildings and address climate change. General strategies for retrofitting design include enhancement of the building envelope and optimization of the building systems. It is important to integrate high performance building envelope, advanced lighting systems, and energy efficient HVAC systems into existing commercial buildings to lower their energy consumption. Implementation of renewable energy sources to reach net-zero goals should be considered only after deep retrofit strategies are adopted to significantly lower the buildings' EUI. Importantly, net-zero energy goals typically cannot be accomplished with only one renewable energy system. Integration of multiple renewable energy systems is essential in successfully reaching net-zero energy goals. Besides the widely adopted photovoltaic systems, other renewable energy technologies must be adopted, such as fuel cells, wind turbines, hydropower, etc. However, the barriers to execute deep retrofit design still exist. Financial consideration and economic impacts are one of the most important challenges. Building owners may be reluctant to make substantial investments for the retrofit analysis, design and construction. There is a lack of research and available resources towards the cost comparison of building new and retrofitting old structures, so it is complex for most building owners to take all the potential costs into account during the decision making process. Also, insufficient knowledge of advanced sustainable design strategies, applications to retrofitting projects, as well as their benefits in the long run lead to the preference towards constructing new buildings rather than retrofitting existing buildings in some cases. It is important to improve understanding and perception of net-zero retrofits and encourage more practice to test different net-zero energy retrofit measures and verify their feasibility. Further explorations need to be made to overcome the barriers relating to commercial retrofits, identifying cost-effective and performance-based design techniques. The considerations for combining net-zero energy design strategies into commercial retrofits include the payback and investments for renewable energy systems, as well as the impacts of various design strategies on energy consumption and their costs. Net-zero design strategies are initiated by including energy saving components and advanced building systems, but their advanced functions can hardly be fully exploited if

proper management lacks in the operation. Therefore, integrated design that improves energy consumption, advanced building technologies and systems, renewable energy sources, and improved building operation are required for regenerative design of existing buildings to meet net-zero energy goals.

Tall buildings, high expectations, towering responsibilities: Critically considering skyscrapers, urbanism and sustainability

Fahad Alotaibi
University of Calgary, Canada
Qassim University, Saudi Arabia

Brian R. Sinclair
University of Calgary, Canada + Sinclairstudio Inc.

ABSTRACT: Skyscrapers loom large in our urban centers, defining skylines, consuming blocks and shaping social fabric (Alotaibi & Sinclair, 2015). They contain our businesses, incorporate our shopping malls and increasingly include our homes. Cities around the world engage constantly in a frantic race towards the heavens. Whose buildings will be the tallest? Where does function end and vanity begin? What contributions do these emerging edifices make to the civic realm? And, what potential do they hold for improving our quality of life? The race upwards dates back to the late 19th century when the first skyscraper was erected in Chicago, with New York City taking the lead a few years later, resulting in this typology of building dramatically evolving as time marched ahead. Until now the tall building has been considered, albeit with ample controversy and debate, a prominent symbol of a city's growth and prosperity; also representing land efficiency, economic value, corporate ambition, individual power, and great potential for more sustainable environments. The future reaches even higher while the demand for skyscrapers burgeons. However, to better meet shifting expectations, demands and responsibilities, this typology needs to be critically considered, redefined, reinterpreted and redesigned through the inter-related lenses of environmental psychology, building performance and urban planning. Moreover, there are numerous challenges confronting the tall building: issues of vertical transportation; aspects of human interaction with the building, including satisfaction of occupants' psychological and physiological needs; and attention to the urban realm, including how to better integrate the building with the city's fabric in a way that adds more value. Advanced technology in building construction and elevator systems, among others, pave the way for skyscrapers to grow taller and taller. Today's super-tall buildings are no longer single purpose skyscrapers, rather they are considered mixed-use vertical cities with many facilities and functions available to occupants & users. Structures such as the Burj Khalifa, Shanghai Tower, and Kingdom Tower, as cases in point, take the typology in unprecedented directions. Many aspects of this new breed of building need to be evaluated and explored, such as the concept of sky-streets that provide a sense Based on statistics from the Council for Tall Buildings and Urban Habitat (CTBUH, 2015), approximately 90% of future super-tall buildings will be built in these two international regions. The authors review current practices associated with tall buildings, and interpret the advanced and cutting-edge technologies realized through the development of exemplary contemporary towers. Following an assessment of a range of case study towers the researchers present a holistic approach to the design, delivery & occupation of tall buildings, bringing together different of place to the occupants and link outdoor with indoor, sky-bridges connecting towers & communities, and the inter-woven structural, regulatory, sociological, psychological, environmental, and urban ethos of such buildings. The present paper moves beyond conventional technological aspects of the tall building in order to pursue more culturally, psychologically and socially-engaged buildings. This paper addresses the present challenges and future possibilities of tall buildings by first focusing on two main geographical areas that globally dominate tall building construction: Asia and the Middle East. perspectives, and constructively considering perception, performance and place-making as central contributors to the innovation and emergence of a next generation of this remarkable architectural typology.

Keywords: Skyscrapers, Design, Planning, Place-Making, Asia, Middle East, Systems Thinking

1 INTRODUCTION

Tall building design is a complex and demanding task. There are multiple facets and factors that make this building typology unique and intricate, and thus the challenges that face designers are varied in their scope & direction. However, from the authors' view the approach used to tackle these challenges has been

proved to be narrower and more specific than it should be. There is a crucial need for integration and a holistic approach in architecture in general, and especially in tall building design. Brian R. Sinclair (2015) noted:

> "Accompanying and inter-related with fragmentation is the increasing push for narrowness and specialization. Rather than viewing and managing the world in an inclusive and holistic manner, the path today is too commonly one of the selfishness, taking care of individual before communal needs, seeking information and securing solution with a "point-of-sale" mentality, and looking almost exclusively to the short term."

The rapid development of tall buildings around the world has stressed the need to gain great clarity and understanding of the big issues facing tall buildings. There has been a preoccupation with the empirical, the measurable and the technical. The authors, however, believe that place-making, urban integration, and sustainability issues stand as neglected and essential parts of the future of tall buildings, and need careful consideration from all designers, developers and stakeholders.

1.1 *Tall building and place-making*

"Creating the sense of place is the first task of Architecture" Juhani Pallasma (2012)

The dramatic increase of populations around the world, and the migration from rural to urban areas, give reasonable justification for building tall. Tall buildings promise to achieve a greater level of density, to reduce building footprints in favour of public space, and to encourage the use of public transit – all of which will help cities to grow sustainably in the era of climate change, resource scarcity and dramatic urbanization.

From the beginning, in the late 18th century, the skyscraper as a typology was derived most notably from economic and identity factors, which led the skyscraper to generate wealth and shape a distinctive image of the city. The economic factor is related to land value, especially in the case of Chicago, in which the value of land in The Loop neighbourhood increased dramatically from $130,000 per acre in 1880 to $900,000 per acre in 1890 (Douglas, 1995). The other driving factor which was articulated in the first generation of tall buildings was the power of meaning and image-making. Rybczynski (2002) pointed out that the first generation of American skyscraper designers, especially Raymond Hood, developed a unique approach to tall building design: Nietzschean symbolism for corporate power, or architecture as advertisement. From that time onwards every step upwards was conceived as symbol of power and prestige, and cities engaged in a competitive race to have the tallest building, without which a city would lack status (Gottmann, 1966).

The two sectors that dominated the first generation of tall buildings were newspapers and insurance corporations, both seeking image and power in the city. Domosh (1988) pointed out the symbolic role of skyscrapers as a reflective image of economic paradigm changes:

> "These first tall buildings need to be understood as attempts by this new economic class to fulfill two parallel goals – to find appropriate expression for its new power and to legitimize that power by placing it within the constructs established by the more traditional elite, thereby conveying a civic as well as a commercial message."

From the beginning, the image of the skyscraper was an integral part of skyscraper design. The dilemma at present is that many designers ignore this capacity of power, and design their towers in aesthetic manners that avoid, dilute or deny cultural and social forces. In this regard, Huxtable (1984) clarified the problem that dominates the design of tall buildings: "Today architects are looking at some very big buildings in some very small ways".

The authors do not seek to classify tall buildings based on their style, but rather look to encourage ways in which tall buildings might better integrate with and reflect a more meaningful image of a city. The combination of efficiency and iconicity is a huge task for achieving the balance needed to provide a sense of place for tall buildings (Polo, 2007). For instance, Albahar Tower (Alotaibi, 2015) proves a strong example, designed in a sensitive way for its context and functioning well in numerous ways. This genuine quality is perhaps what differentiates the true image of tall buildings, over fakery, which appears in some places in Asia where the façades are ornamented aimed at uniqueness and expressionism, without any serious function (Polo, 2007). In his seminal work, Hough (1992) explained the forces that shape distinctive places and argued for the important roles of indigenous materials, basic needs, natural forces, cultural history, and changing technologies in the uniqueness of locality.

Tall buildings have become an important phenomenon in cities for many reasons; among others, they reflect specific economic activities and work as distinctive landmarks for/in a city's landscape (Gottmann, 1966). Despite the importance of the symbolic role in the built environment, and tall buildings in particular, only a few studies have sought to examine tall buildings' architecture as cultural artifacts (Rapaport, 1969, 2005; Appleyard, 1979; Harvey, 1985).

Based on question-driven inquiry rather than a problem-solving approach, the present researchers sought to examine the current situation regarding tall buildings in the developing areas of Asia and the Middle East – and especially from the perspectives of place-making, the image of a city, and identity. As well, the authors explored how those factors are embodied in the design process and reflect on the buildings' symbolism, and how the designers in both regions balance the experiential and functional needs of the occupants, developers, users and stakeholders.

1.2 *Where the towers meet the ground*

Tall buildings play a huge role in the 'living' fabric of the city – the real issue today is not about how tall buildings shape the skyline, but rather how tall buildings meet the ground and integrate with the urban realm. Tall buildings as a typology were initially and fundamentally conceived as a sky element. Thus, historically designers paid great attention to the last portion of the tower, where the tower meets the sky (i.e., where it "scrapes" the sky). On the other hand, the way the tower is developed & delineated on the ground has garnered far less attention from designers. Maybe this shortcoming is related to the visual impacts of the building's height and how people see the tower, since usually the first thing people do when they encounter something tall, is to look upward. But the city arguably benefits more from attention to the ground plan of the tower than from its interface with the heavens. An aim of the current research was to consider how best to add greater livability to the urban fabric, versus fragmenting it even further.

The way a tall building is situated in its context is integral to mediating this potent building type with the urban realm. The direct and non-direct impacts of towers on the city are huge – they can either attempt to create vivid areas at grade it or work as isolated objects that divide the city into fragmented zones that prove counter to livability aspirations. The context, relationship to transportation, permeability, microclimate or local environment, and contribution to public spaces are among the areas that need to be seriously investigated with regard to the impacts of tall buildings in/on the urban realm (Short, 2012).

Firely (2011) suggested in his study of the relationship between tall buildings and cities that it is important how these buildings are placed in the city, whether singly, in clusters, or as vertical districts. In many cases such towers are placed in ways that prevent meaningful and effective connection between activities at street level. These towers frequently operate in dehumanized and dehumanizing ways. The relationship between the inside (i.e., the tower itself) and the outside (i.e., the street level) should be treated in ways that encourage people to engage and experience, and that invite te people to use and enjoy the spaces at ground level. Regarding this point, Whyte (1980) asserted that:

> "A good integral space should not be blocked off by bland walls, it should be visible from the street; the street and its surroundings should be highly visible from it; and between the two, physically and psychologically, the connections should be easy and inviting."

The urban approach of placing the tall buildings in their context is varied: for instance the Europe approach is very different from the North American one. In Europe tall buildings are often clustered in areas out of the core of the city, which tend to be dominated by historic buildings. In cities such London we see the development of Canary Wharf and Paris the creation of La Défense. In Asia and the Middle East there are combinations of these two distinct approaches; in some cases the towers puncture the urban core based on public transit routes, such as in Tokyo, where there is no central 'downtown' for clusters of tall buildings, but where distribution depends on the infrastructure and transportation system (Polo, 2007). In the Middle East, for example in the case of Riyadh, Saudi Arabia, both approaches work together: tall buildings appear in clusters (e.g., the King Abdullah Financial District) which contain more than 66 towers with appropriate infrastructure and public transportation hubs. In contrast to this, the rest of the towers in Riyadh are distributed on the city's main roads without any due consideration to the way they are placed or to the provisions of the public transit system.

The current dilemma with tall buildings and their integration with the urban realm caused architect Moshe Safdie (2015) to raise a fundamental question that helps to frame our inquiry. In a piece entitled How to Build a Better City, Safdie questions:

> "How crowded should or can cities get? What should be driving tower design, be it residential, commercial or mixed use? Are our current planning and zoning regulations adequate in guiding this growth, in mitigating the impact of density? Or do we need new tools for a new era of mega-scale construction?"

The need for careful integration of tall buildings with the urban fabric is crucial, and the success of this integration is based on many factors such as being connected to public transportation, careful design of the podium, examining how to meet the ground plane, considering the social life of the in-between spaces that work to link the fabric of the city, and addressing the micro-climate and its direct effect on the people on the street. In the last decade there has been increasing awareness about the importance of the integration between tall buildings and urban areas, with the CTBUH recently launching an award in this category to encourage designers to pay more attention to this vital aspect of tall buildings.

1.3 *Tall and green*

Tall buildings are considered huge consumers of energy, and this reality has attracted concern from designers and developers alike. In fact the major concern is not on the general environmental performance of buildings but rather has tended to focus on one aspect: energy-saving. The present authors advocate for a much broader + more robust understanding of environmental performance versus a narrow view on energy reduction/savings. Some scholars (e.g., Goncalves, 2011) underscore the importance of real-life data to support environmental claims, and urge an examination of the validity of the figures that designers typically present to highlight savings on buildings' energy bills. The urgency here is to link together

the physical components of sustainability with cultural and social ones, and for them to inform each other (Tabb, 2013). We should work in "responsive cohesion", a term coined by Warwick Fox "to describe a state in which the various elements of a thing or process exhibit a reciprocal interaction between elements that constitute it, and the context in which it is located" (as cited in Williamson, 2003).

Thoughtful consideration of active and passive energy approaches is pivotal to create a sustainable environment, and tall buildings have a great potential to deliver this goal. Designers have many routes of action. For example, by adapting this typology of building to its particular context great strides can be realized – for example, ensuring that skyscrapers contribute to microclimates in positive ways. Sky gardens, roof gardens, elevator buffer zones, climatic-responsive façades, and solar voltaic panels are some of the principles that can be deployed in tall buildings to help to reduce energy, lessen carbon impacts, and heighten environmental responsibility.

Ken Yeang, a Malaysian ecologist and architect, is a pioneer in redefining tall buildings as a green option for future cities. He sought to adapt this type of building during a time of impending climate change, and designed early "bioclimatic skyscrapers" in the 1990s. One striking example of his integration of towers and the environment is the IBM Tower (Wood & Parker, 2013). This building was designed according to the bioclimatic approach, which relies on passive methods of generating energy, and results in a better integration with the environment. This simple system ultimately results in a pleasant and comfortable environment for its occupants (Cheung & Chau, 2005). Another watershed venture moving us towards sustainability and energy-saving is the innovative design of the Commerzbank Tower in Frankfurt [1997], by Norman Foster. This project provides a good example of the application of passive techniques to create pleasant spaces for users. The tower's 'Nine Skycourts' provide natural light and fresh air for its occupants and utilizes stack affect techniques, which help to achieve a high level of natural ventilation of 80% over the span of a year. This tower has been recognized as the first truly "Green" skyscraper (Wood & Parker, 2013).

These examples of exceptional environmental performance raise vital questions: "What is the appropriate evolution for tall building environmental performance that moves us beyond the quantitative to meaningfully consider the triple bottom line of sustainability, (i.e., technological, economic, and socio-cultural)?", and "How should the designers of tall buildings deal with the more human, softer, qualitative and experiential aspects of sustainability when building tall?"

The tendency to reduce sustainability to one of these three pillars seems to be quite prevalent in architectural practice. And the low-hanging fruit seems to inevitably be around scientific and readily measurable aspects therein. There is a strong belief in the capability of technology to solve the environment problems (Adhya, Plowright, 2015). The need, however, for a critical re-interpretation of 'sustainable' architecture, is essential. It is crucial to move beyond the empirical to also embrace the social and ecological parts of the sustainable development equation. As Adhya & Plowright state:

> "Sustainable architectural design should understand its disciplinary priorities through human well-being, integrated fitness landscapes, social development, and social hope…. This ecological approach can be catalytic in promoting sustainability as a shared 'dialogic space', where things can function in relation to others, and among various critical agencies of the society."

Sustainability is a contested terminology, with definitions posited different ways in different fields. (Guy, Farmer, 2001) sought to reinterpret sustainable architecture – they ended up classifying sustainable architecture into six logics of typology: Eco-technic, Eco-centric, Eco-aesthetic, Eco-cultural, Eco-medical, and Eco-social. This variety of typologies emphasizes the urgency of seeing sustainable architecture as a multi-scalar entity, which then compels designers to move beyond the technological sphere.

2 ANALYSES

The present research considered critical examination of two very active regions for building tall, namely Asia and the Middle East. Specific projects in these regions were examined in terms of design and development approaches as well as built outcomes (including urban integration). Learning from the consideration of cases in the regions, the researchers conceived of and crafted a conceptual framework for building tall that incorporates a much broader spectrum of facets that is propagated via the status quo (i.e., business as usual).

2.1 *Asia context*

From 1970 onward, major Asian cities transformed into remarkably globalised cities: for example Shanghai, Beijing, Hong Kong, and Tokyo. For instance, in the Chinese context, planning systems were changed from a centrally planned economy to a market economy, resulting in cities sharing the principles of neoliberal cities (Wu, 2008). Ren (2011) deliberately illustrated this phenomenon of building globalization in China by focusing on transnational architecture production, or how the governments of emerging cities in China used renowned international architects to design "branded" buildings. As stated in (5), "Chinese cities are not alone in their pursuit of prominent international architects for city branding and promotion. From Bilbao to Chicago, urban governments have competed with one another to use prestigious international architects to put their cities on the map."

However, although various architects have worked to adapt Western architecture to the Chinese culture,

Figure 1. The Shanghai World Financial Centre (courtesy Leslie E. Roberston Associates).

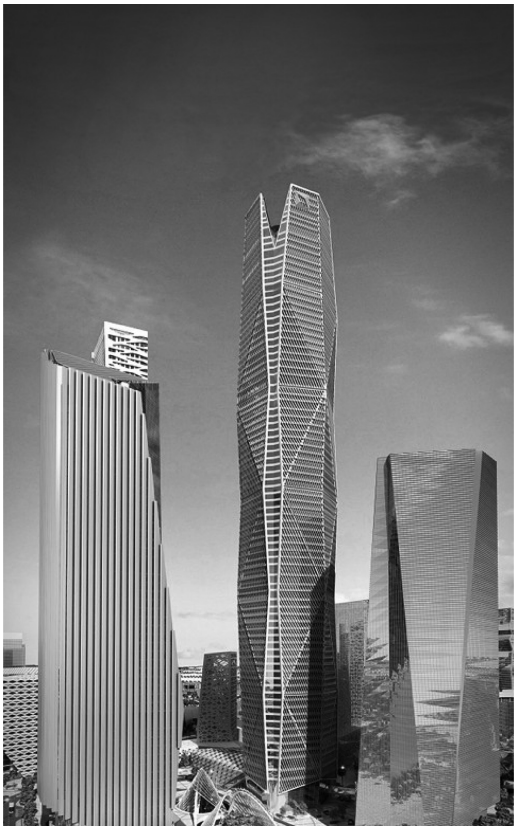

Figure 2. The Capital Authority Tower looms as the tallest building in the KAFD (courtesy HOK).

the works of Y.C. Lee stand as prominent examples for achieving better balance between the modern and the traditional. Many of his buildings were tall buildings, designed to reflect spirit of place based on his interpretations of many sources of Chinese architecture: poetry, art, and traditional architecture. Lee developed his architectural language to be inspired by local traditions. An exemplar in this regard is 'Taipei 101' – a skyscraper that deployed and successfully manifests his adaptive architectural language.

The Shanghai World Financial Centre (SWFC) stands out as a symbolic icon of Shanghai's and China's endeavours towards producing the vertical city. Rising to 492 meters, located in the Pudong District, next to Jin Mao Tower, the two towers compete in the sky to reflect the city's attitudes and ambitions. The elegant form of the SWFC results from a careful configuration of function and form. The towers' form begins with a square prism at the base with the plan tapering as it reaches heavenly.

This form expresses the ancient Chinese symbolism of heaven and earth (Wood, 2008). The bold features of the towers are the simplicity of form that symbolize the city's culture in an elegant way, and the innovative manner in which the structure was developed from a more conventional one into a novel system, thereby reducing weight by 10% and reducing materials – together making the buildings more environmentally friendly (Wood, 2008).

2.2 *Middle East context*

Emerging Arab cities have been undergoing a huge transformation, especially in changing from conventional low settlements into vertical urban centers that hold second place only to Asia concerning the total number of tall buildings constructed. Dubai launched the region's race to the sky in the early 1970s, with British architect John R. Harris (designer of the city's master plan) design of the first tall building in the region (Dubai World Trade Center). This tower was the tallest building in the Arab World from 1979 until 1999 (Alotaibi, Sinclair, 2015). In comparison Riyadh, the capital of Saudi Arabia, was conceived by the renowned planner Constantinos Doxiadis as a low-rise city. That said, the city quickly embraced the race to the sky, with the past decade seeing more than 50 towers designed and built in Riyadh. Most of these skyscrapers were placed in the new financial zone

King Abdullah Financial District (KAFD). This impressive district is a multi-phased mixed-use development, comprising 34 towers with more than 3 million square of space (O'sullivan, 2011). The master

plan for the development was designed by Henning Larsen, with directions inspired by cultural references and site geographical features – the main theme of the district was based on the passages known as "wadi" (urban elements of traditional Arabian cities) which is manifest as a rich network of interconnected alleys (Becker, 2015).

The Capital Authority Tower looms as the tallest building in the KAFD, with a height of 385 meters and comprised of 80 stories. This tower is designed in sensitive way that reacts to the intense desert climate in Saudi Arabia – this responsiveness to climatic issues is manifest in numerous sustainable features including a high-performance integrated enclosure system that incorporates solar shading, photovoltaics, façade lighting, and an innovative façade system (Soto & Al-Shihabi, 2015). The podium of the tower was conceived to provide good access for the public and to better link the towers with the urban amenities (including connecting the building to the district's notable alley system). From the current authors' perspective, urban integration is an essential aspect for successfully designing tall buildings. One compelling example for placing a tall building in ways that contributes to the city is Sowwah Square in Abu Dhabi, United Arab Emirates. Sowwah Square is mixed-used development comprising 4 towers and one low-rise office building (i.e., Stock Exchange Building). The development is located in a distinctive setting within Al Maryah Island, the four towers dramatically frame the Stock Exchange Building which is placed in the center as the heart of the project. The landscape of the area is well designed, the project is well connected to urban fabric and in strong relationship to the Gulf coast. These projects act to illustrate some of the success stories in the region.

In both the Asia and Middle Eastern context the above-noted case studies are more of an exception than the rule. The present authors underscore that the majority of towers tend to be rather disconnected from the urban fabric, tend to stand alone as sculptural objects versus community players, and focus unreasonably on technical solutions rather than holistic and integrated components of the broader city. In response the researchers engaged in an act of synthesis based on findings from the literature and the case analysis – resulting in the creation of a conceptual framework that challenges convention and aims to raise awareness (and the bar) around more complete ways of designing, developing, constructing and using tall buildings.

2.3 *The Alotaibi-sinclair framework for integrative tall building design*

In reaction to their research into and critique of conventional approaches to building tall, the authors shaped a conceptual framework intent on much greater holism and integration. The framework functions as an instrument to provoke and precipitate greater understanding of the tall building phenomenon. It is proposed as an alternative approach based on greater integration and more holistic ways of thinking. Sinclair (2015) stressed that "Integration is a vital aspect of the equation for a more sustainable environment. Our modern world is fraught with fragmentation. Communication between departments, disciplines, governments, corporations, and individuals is commonly strained and often dysfunctional. Western culture, in particular, emphasizes dualistic thinking and acting, and seeks to classify and categorize anything and everything. Increasingly, specialization of knowledge is sought and rewarded. Discrete knowledge is promoted, bounded, and protected. Silos of information and containers of knowledge are cautiously and aggressively guarded. The end result is often systems that break down, approaches that are isolated, problem-solving that is limited, and solutions that are less than effective." The present framework serves to counter such fragmentation and separation – breadth and comprehensive consideration is vital to designing tall buildings under greater pressure and facing heightened complexities.

As illustrated in Figure 3, the current situation for skyscrapers has treated these buildings as isolated sculptural objects, looming in a way to express power and prestige. End goals are primarily achieved through the implementation of technological aspects while ignoring the other essential parts of the equation. The present authors readily admit that advanced technology is inherent in the tall building typology. However, other factors such as urban, social and cultural dimensions are equally important. As mentioned previously, present architectural approaches have migrated towards narrowness and specialization – and in the instance of tall buildings, practices have focused on overly-constricted views towards some technical aspects, such as structure, envelope, and environmental systems. Furthermore the authors believe that emerging and different forces will shape the future of tall buildings, such as climate change, embrace of mixed-use models, and rapid urban growth. Also, the way that decisions on these buildings are made are highly complex, involving more input than just the designers – in fact, interdisciplinary engagement of architects, bankers, politicians, engineers, contractors and community agents, is now the norm. Thus, considering the authors' framework, tall building design must not be distilled down to fundamentally technical/technological emphases, but also must philosophically, meaningfully and operationally embrace ecology, psychology, sociology, and urbanism as equally urgent.

3 CONCLUSIONS

Tall buildings have a huge impact on the environment, playing crucial roles in creating the image of the city and offering immense potential to contribute positively to the urban fabric of our cities. A wealth of factors, including scale of construction and scope of programming, make this building typology intricate and unique. Architects assume significant responsibility to pay attention to the design process and innovate

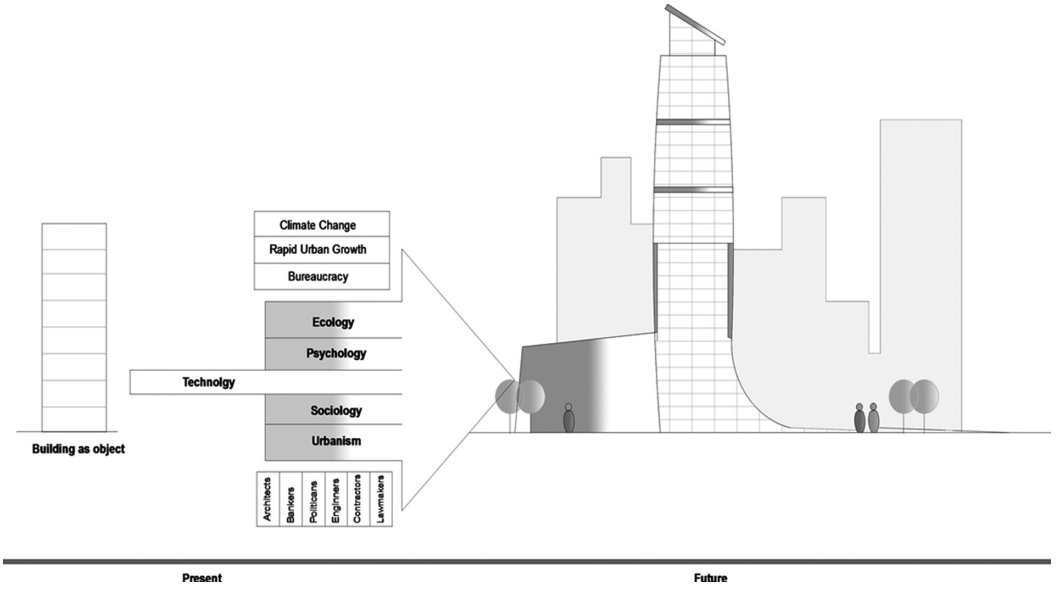

Figure 3. Alotaibi Sinclair Framework for Integrative Tall Building Design.

ways in which such projects are conceived and realized. The stakes are very high indeed. The authors stress that the approach for designing this remarkable building type is to date incomplete and lacking. Moving forward the strategies for design and development must be comprehensive, integrative, holistic and far for responsive (i.e., socially, psychologically, culturally). Examples of tall buildings in Asia and the Middle East, showcased in the present paper, illustrate movement towards higher levels of environmental performance, urban integration, and place-making. The conceptual framework presented aims to propel tall building design and development forward on a trajectory well beyond technical matters. Future studies by the researchers will continue to place emphasis on the holistic approach rather than focusing on more measurable, empirical and quantitative aspects of building tall. The surge towards even more tall buildings globally compels environmental design professionals to critically examine the role of the tall building, and in response to devise and shape the typology as significant contributors to our cities and as meaningful solutions to address our needs.

ABSTRACT: Cities are at the core of current environmental problems and, conversely, host the solutions for them. Design has a great potential to reshape cities transforming them for improved living conditions and balanced ecological systems. Among the cities' elements that contribute to sustainability are green spaces. Therefore, this paper focuses on criteria for designing and evaluating contemporary sustainable landscape located in urban areas. First, the role of urban green spaces is defined, followed by the criteria for sustainable design and performance of urban landscape architecture and architecture. Then, Washington Canal Park is evaluated as a case study, as it is a comprehensive example of contemporary urban green space with a broad approach to sustainability. The paper concludes discussing how the comprehension of landscapes designed for sustainability informs new design decisions, considering the high potential for advancing further with possibilities of integrating buildings and landscapes for multi-layered performance.

1 INTRODUCTION

Cities are the everyday environment for the majority of the global population (Haase et al. 2014). More than half of the world's population is living in urban areas (United Nations 2014). Cities are continuously growing in terms of geographical area, number of buildings, and population (Pozo Gil 2013). This growth of cities and population is increasing the demand and impact on natural resources and energy, and, thereafter, the challenges for ensuring human welfare and for preventing the increasing loss of soil, habitats, resources, and biodiversity (Haase et al. 2014; Gómez-Baggethun et al. 2013).

The endless environmental damages hitting our planet are consequences to our way of living that have been sacrificing our lives and health and, also, of all other species, while exhausting the ecosystem capacity to support human impact (Ryn et al. 2007). Cities are at the core of current environmental problems and, conversely, host the solutions for them (Griffith & Berdague 2006; Haase et al. 2013; Gómez-Baggethun et al. 2013).

Among the cities' elements that contribute to sustainability are green spaces. Since the nineteenth century the importance of green spaces in cities and towns is recognized; at that time, they were a special contribution to escape from air pollution (Swanwick et al. 2003). After the 1990s, both the quality and the quantity of green spaces became relevant as a consequence to the significant growth of the cities and the transition of the world to an urban one (Swanwick et al. 2003; Lee & Maheswaran 2011).

Therefore, green spaces play a fundamental role in cities for a more sustainable urban environment as they may provide social, economic and environmental benefits (Ignatieva et al. 2011). The effort of having urban green spaces providing multiple benefits is in consonance with contemporary high demand for multifunctional landscapes (Lovell & Taylor 2013).

In this context, design has a great potential to re-shape cities transforming them for improved living conditions and balanced ecological systems. Therefore, most projects claim for sustainable solutions, aiming for net zero carbon, water and energy, more biodiversity, and quality of life. Though, assessment of the built project is necessary to measure how successful the design solution is and to inform new solutions. Evidence and measures related to sustainable performance are imperatives, as evidence-based design is a powerful means to justify and prove the benefits of sustainability (Hamilton & Watkins 2009).

For this study, first, the role of urban green spaces as multifunctional landscapes is defined. Then, a collection, analysis, and comparison of criteria for sustainable landscape architecture is presented, considering design and performance. The criteria for sustainable design are drawn from evaluation platforms, in particular: Leadership in Energy and Environmental Design (LEED) and Sustainable Sites Initiative

Figure 1. View of Washington Canal Park (Olin 2016).

(SITES) Rating Systems; whereas the criteria for assessing sustainable performance are drawn from Landscape Performance Series (LPS).

Second, a case study is applied to Washington Canal Park. Built on a brownfield, Canal Park is a comprehensive and informative example of contemporary urban green space with a broad approach to sustainability (Figure 1). It received the AIA|DC Chapter Design Award 2013; it is certified both by LEED and SITES, and, also, assessed, in terms of its performance, through LPS. Thus, the project's claims toward sustainability and its performance after construction are compared. The data gathered from this case study is interpreted, interrelated and evaluated. Existing interrelations between design and performance for sustainability are defined and discussed.

Through these research steps, recommendations for evidence-based designs are extracted which bridge science and design, discourse and practice, while improving the means for sustainable design in a practical and reasonable approach. This provides designers with solutions for sustainable design that are informed by monitoring and assessment of projects in operation.

The paper concludes with discussing how the comprehension of landscapes designed for sustainability informs new design decisions in the field of sustainability, which in a broader scale contributes with the paradigm shift towards an evidence-based environmentally friendly designed world.

2 URBAN GREEN SPACES AS MULTIFUNCTIONAL LANDSCAPES

Landscape architecture deals with balancing the built and natural environments through a multidisciplinary approach ranging between science, design and art (ASLA 2016). Urban green spaces are among the tasks of landscape architects and architects, as they include not only parks, street trees, urban agriculture, residential lawns, but, also, green roofs and walls (Kabisch & Haase 2014).

Green spaces are a major component of cities with a huge significance in enhancing the urban environment and the quality of life in cities (Ignatieva et al. 2011). Indeed, the contemporary agenda for urban areas is related to social inclusion, health, sustainability, and urban renewal (Swanwick et al. 2003). Therefore, urban green spaces have a positive impact and contribution.

Urban green spaces provide great benefits such as social, health, economic, and environmental benefits. The health benefits of green spaces are related to outdoor exercises, stress reduction and relaxation, and primary contact with biodiversity and natural environment (Swanwick et al. 2003). Some of the social benefits of green spaces are environmental education, child development, social inclusion and interaction (Swanwick et al. 2003). The environmental benefits include: preservation and enhancement of the biodiversity, fresh air availability, noise reduction, climate extremes mitigation, sustainable urban drainage systems, carbon dioxide absorption, and opportunity for applying and demonstrating sustainable management principles and practices (Swanwick et al. 2003). Finally, urban green spaces bring economic benefits, including direct employment, revenue generation, valorization of property prices, and business and tourist attraction (Swanwick et al. 2003).

A landscape supporting multiple benefits is considered a multifunctional landscape. Multifunctional landscapes may be understood as supporting both the diversity of human needs and ecosystem functions (Canfield & Bo 2014). Therefore, multifunctional landscapes may deliver as many ecosystem services as possible. Ecosystem services are defined as components of nature, directly enjoyed, consumed, or used to yield human well-being (Boyd & Banzhaf 2007). They are the product of ecological processes and functions that support life as a result of the interaction of living and non-living elements (Miller & Spoolman 2009; Myers 2013).

The four categories of ecosystem services are: (1) *provisioning services*, which provide food, water, timber, and fiber; (2) *regulating services*, which regulate climate, floods, diseases, wastes, and water quality; (3) *cultural services*, which include recreation provision, aesthetic, and spiritual benefits; and, (4) *supporting services*, which include soil formation, photosynthesis, and nutrient cycling (Millennium Ecosystem Assessment 2005).

In this sense, multifunctional landscapes should provide global and local climate regulation; air and water cleansing; water supply retention; erosion and sediment control; hazard mitigation; pollination; habitat functions; waste decomposition and treatment; human health and well-being; food and renewable non-food products, and; cultural benefits (SITES 2014).

The concept of ecosystems services provision is in many ways embedded in the concept of sustainability. Currently, one established practice of ensuring sustainable practices in design projects is the adoption of rating systems. Therefore, follows the criteria for sustainable design and performance of urban landscape architecture and architecture.

3 CRITERIA FOR SUSTAINABLE DESIGN AND PERFORMANCE OF URBAN LANDSCAPE ARCHITECTURE AND ARCHITECTURE

3.1 *LEED v4 for building design and construction*

LEED is a rating system for project certification toward green buildings and communities in terms of design, construction, maintenance and operation. It is the green building certification program that is most recognized and used across the world. For the purpose of this work, LEED v4 (version 4) for Building Design and Construction (BD+C) and New Construction (NC) is considered. It is important to mention that Canal Park was LEED BD+C: NC v3 2009 certified. However, comparisons between the two versions were made which showed that there are not substantial differences for our analysis purpose.

In LEED, each subject being evaluated has some requirements and credits. After attending all the requirements, and depending on the amount of credits scored, a project may be certified, when it achieves from 40 to 49 points; it may be classified as LEED Silver, meaning that it scored from 50 to 59 points; LEED Gold, from 60 to 79 points; and, LEED Platinum, if scoring from 80 to 110 points.

Besides supporting an integrative design process, LEED v4 for BD+C: NC is related to design decisions about location and transportation; sustainable sites; water efficiency; energy and atmosphere; materials and resources; indoor environmental quality; innovation; and, regional priority.

Evaluating a project for its location and transportation means valuing sensitive land protection; sites with development constraints; density and diverse uses; access to quality transit; bicycle facilities; reduced parking footprint; and, green vehicles. In terms of sites sustainability, construction activity pollution prevention is required, while credits are related to site assessment; site development considering habitat protection or restoration; open space; rainwater management; heat island reduction; and, light pollution reduction (USGBC 2015).

In relation to water efficiency, a LEED certified building must have outdoor and indoor water use reduction, and building-level water metering, while credits include, again, water reduction, cooling tower water use, and water metering. About energy and atmosphere, it is required that a project presents a fundamental commissioning and verification, minimum level performance, building-level energy metering, and fundamental refrigerant management. Besides, there are credits for enhanced commissioning, optimized energy performance, advanced energy metering, demand response, renewable energy production, enhanced refrigerant management, and green power and carbon offsets (USGBC 2015).

Materials and resources are approached toward sustainable design by requiring storage and collection of recyclables, and construction and demolition waste management planning. In addition, credits are scored by considering building life-cycle impact reduction; building product disclosure and optimization, in terms of environmental product declarations, sourcing of raw materials, and material ingredients; and, construction and demolition waste management (USGBC 2015).

For indoor environmental quality, minimum in-door air quality performance and environmental tobacco smoke control are required. Credits are related to enhanced indoor air quality strategies, low-emitting materials, construction indoor air quality management plan, indoor air quality assessment, thermal comfort, interior lighting, daylight, quality views, and acoustic performance. Finally, extra credits may be scored when projects demonstrate any innovation, regional priority, and a LEED Accredited Professional (USGBC 2015).

In the LEED v4 for BD+C: NC, from the total of 110 possible points, most possible points are related to energy, which represents 30% of total. Second most ranked subjects are location and transportation, and indoor environmental quality, which are worthy 14.5% of total points each (Table 1).

Table 1. Criteria topics of LEED v4 for BD+C: NC.

Topics	Requirements	Points	Points (%)
Integrative Process	0	1	10
Location and Transportation	0	16	14.5
Sustainable Sites	1	10	9.1
Water Efficiency	3	11	10
Energy and Atmosphere	4	33	30
Materials and Resources	2	13	11.8
Indoor Environ. Quality	2	16	14.5
Innovation	0	6	5.5
Regional Priority	0	4	3.6
Total		110	100

3.2 *Sustainable SITES initiative*

SITES is a comprehensive rating system for sustainable landscapes. It is similar to LEED, indeed the U.S. Green Building Council, LEED's developer, is a supporter and stakeholder of SITES. In addition, SITES supports and encourages projects that have buildings to apply simultaneously for LEED.

SITES' Guiding Principles for sustainable landscape design advocate for protecting existing ecosystem services on site and its surroundings; applying the precautionary principle to avoid irreversible damages; designing with nature and culture; using a decision-making hierarchy of preservation, conservation, and regeneration; providing regenerative systems as intergenerational equity; supporting a living process; using a systems thinking approach; using a collaborative and ethical approach; maintaining integrity in leadership and research; and, fostering environmental stewardship (SITES 2014). By incorporating these principles

to design, SITES values the creation of regenerative systems embedded with resiliency; provision of future resource supply and climate change mitigation; market transformation; and, enhancement of human well-being and communities (SITES 2014).

For SITES certification, projects are assessed similarly to LEED in terms of requirements and credits. The subjects considered are site context; pre-design assessment and planning; site design and water; soil and vegetation; materials selection; human health and well-being; construction; operations and maintenance; education and performance monitoring; and, innovative design solutions or exemplary performance (SITES 2014).

For site context, it is required limiting development on farmland; protecting floodplain functions; conserving aquatic ecosystems and habitats for threatened and endangered species. Points are scored if redeveloping degraded sites; locating projects within existing developed areas; and, connecting to multi-modal transit networks (SITES 2014). Pre-design assessment and planning requires using an integrative design process; conducting a pre-design site assessment; and, designating Vegetation Soil and Protection Zones. Credits are scored by en-gaging users and stakeholders (SITES 2014).

For site design and water, it is required management precipitation on site and reduction of water use for landscape irrigation. In addition, there are credits for management of precipitation beyond baseline, outdoor water use reduction, functional storm water features designed as amenities, and aquatic ecosystems restoration (SITES 2014). Sustainability in site design in relation to soil and vegetation requires the creation and communication of a soil management plan; the control and management of invasive plants; and, the appropriate use of plants. More sustainable solutions lead to scored points, such as conserving healthy soils; appropriate and special status vegetation; and, not only conserving, but also using and restoring native plants and their communities; optimizing biomass; reducing urban heat island effects; using vegetation to minimize building energy use; and, reducing the risk of catastrophic wildfire (SITES 2014).

For human health and well-being, there is no requirement for a sustainable site design, but several possibilities of credit scoring. Among them are the protection and maintenance of cultural and historic places; provision of optimum site accessibility; safe-ty and wayfinding; promotion of equitable site use; mental restoration, physical activity, and social connection support; on-site food production; light pollution reduction; fuel efficient and multi-modal transportation encouragement; minimization of exposure to environmental tobacco smoke; and, local economy support (SITES 2014). In terms of construction, it is required communication and verified sustainable construction practices; controlling and retaining of construction pollutants; and, restoration of soils disturbed during construction. Additionally, a project scores points if restoring soils disturbed by previous development; diverting construction and demolition materials, and, reusable vegetation, rocks, and soil, from disposal; and, by protecting air quality during construction (SITES 2014).

Table 2. Criteria topics of SITES v2.

Topics	Requirements	Points	Points (%)
Site Context	4	13	6.5
Assessment + Planning	3	3	1.5
Water	2	23	11.5
Soil + Vegetation	3	40	20
Materials Selection	1	41	20.5
Human Health	0	30	15
Construction	3	17	8.5
Operations + Maintenance	2	22	11
Education + Monitoring	0	11	5.5
Innovation (Bonus)	0	9	4.5
Total	18	200	100

The requirements for operations and maintenance are planning for sustainable site maintenance and provision for storage and collection of recyclables. Then, points are scored if considering organic matter recycling; minimization of pesticide and fertilizer use; reduction of outdoor energy consumption; use of renewable sources for landscape electricity needs; and, protection of air quality during landscape maintenance (SITES 2014). Education and performance monitoring are not required. Their criteria are: promotion of sustainability awareness and education; development and communication of a case study; and, planning for monitoring and reporting site performance (SITES 2014). In conclusion, SITES rating system offers a possibility of scoring bonus points in case of innovation and exemplary performance (SITES 2014).

The two most scored subjects in SITES are related to soil, vegetation, and materials selection in site design, that all together represent approximately 40% of total possible points. And the subjects that have more requirements are site context, assessment and planning, soil and vegetation, and construction (Table 2).

3.3 *Landscape performance series*

The Landscape Architecture Foundation through two programs, being Landscape Performance Series (LPS) and Case Study Investigation, is playing an important role on research about landscape performance of built projects. These programs are based on case studies of high-performing multifunctional landscapes. They focus on landscape quantitative and qualitative data and the health of its ecosystems, people, and economies.

Landscape performance is defined as a measure of effectiveness with which landscape solutions fulfill their intended purpose and contribute to sustainability. Evaluating the performance of built projects may

contribute to improve the quality of designed and planned landscape toward sustainability. Landscape performance measures aim to inform design decisions and knowledge, public policy, to reduce investor risk, and to improve return on investment (LAF 2016).

LPS provide resources about sustainable land-scape performance through case study briefs, facts library, metric tools, and theme collections. Through these means, they are contributing to enhancing sustainable landscape design and to disseminate sustainable landscape value.

There is no rating system in LPS. For measuring landscape performance benefits, LPS offers a set of measurement tools which are related to one or more benefits. These tools are online calculators that may be comprehensive when able to measure several benefits, or very specific (LAF 2016). The benefits from landscape performance may be estimated during design process or when actual measurements of built projects are not available. The evaluated benefits are land; water; habitat; carbon, energy and air quality; materials and waste; social; and, economic (LAF 2016).

The benefits related to water are: stormwater management, water conservation, water quality, flood protection, and water body/groundwater recharge. Habitat benefits measure populations and species richness. Land benefits consider soil creation, preservation, and restoration. Benefits related to carbon, energy and air quality measure energy use, air quality, temperature and urban heat island, carbon sequestration and avoidance. Reused and recycled materials together with other strategies for waste reduction are other valued benefits for landscape performance (LAF 2016).

Considering the concepts from these three systems for enhancing sustainable practices, Washington Canal Park will be the following object of study.

4 WASHINGTON CANAL PARK

Washington Canal Park is a model of contemporary sustainable urban park located in Washington DC designed and built from 2009 to 2012. It stretches over three linear blocks, summing 3 acres from approximately 1,000 feet long and 100 feet wide. It is a former brownfield, that served as a parking lot for school buses, transformed into a vital and sustainable urban environment.

The park is named after Washington Canal that ran in that area back in the 1800's. Three pavilions were designed also as a site historical reference to floating barges that were a common feature of the old canal (AIA DC 2013). The pavilions host a café and dining area with 65-seat, a stage, and a storage room. Olin Studio designed the park while Studios Architecture designed its buildings.

Canal Park offers a very diverse programming besides the restaurant and the stage. It has an interactive fountain with programmable jets in the summer, ice rink in the winter, lawn and gravel areas, sculptures, an interactive light cube where art work and other things are displayed, and social and cultural events (Canal Park 2016).

The park's major environmental aspect is to collect and manage storm water from the site and its surroundings while satisfying most of the park's water needs. It has a rain garden that works as a storm water collection basin filtering and directs the water to an underground storage tank. It was also designed to collect storm water from the roofs of adjacent buildings. Cisterns hold up to 80,000 gallons of runoff. With this system, recycled storm water is reused for majority of park's irrigation, toilets, fountains and making ice demands (Figure 2).

In addition, it has 28 geothermal wells that contribute to reducing the park's demand on energy, together with the use of energy efficient lighting (Olin 2016). The park's buildings were built with harvested wood; they also have green roofs, natural ventilation through operable screen panels, and they may rely on reused water for the toilets (AIA DC 2013). The park presents a strong educational component for sustainability. Also, it became a social reference in the neighborhood where people take their pets for a walk, office workers have lunch, families attend for playing with water or ice features.

Washington Canal Park is an endeavor of public-private collaboration that enhanced the value of existing and future real state development in its surroundings. The fact that the park is close to a metro station makes it accessible to other people from the city and allows the use of public transportation contributing for traffic, air pollution, and fossil fuel consumption reduction. It is important to mention that the park offers electric car charging stations, which contributes to make this technology publicly accessible.

Washington Canal Park was awarded two certifications, being LEED and SITES. After construction, its performance has been measured and the results for that are presented in the LPS. Considering these facts, Washington Canal Park is assessed through the lens of those evaluation systems.

4.1 *Canal Park, LEED, SITES and LPS*

Canal Park was certified as LEED Gold (LEED for New Construction and Major Renovations v2009) on 2014. It achieved 65 points of 110 points which means 59% of possible points. In this system, the project scored all points possible for water efficiency and innovation; and, 24 of 26 points possible for sustainable sites. It also scored high in terms of indoor environmental quality, 11 of 15 possible points. It received almost one-third of total points for energy and atmosphere, and approximately one-fourth of total possible points for material and resources. Finally, it did not score anything in regional priority and integrative process (USGBC 2014).

The park also received SITES Three-Star Level Pilot Certification. It scored 164 points of 250 possible

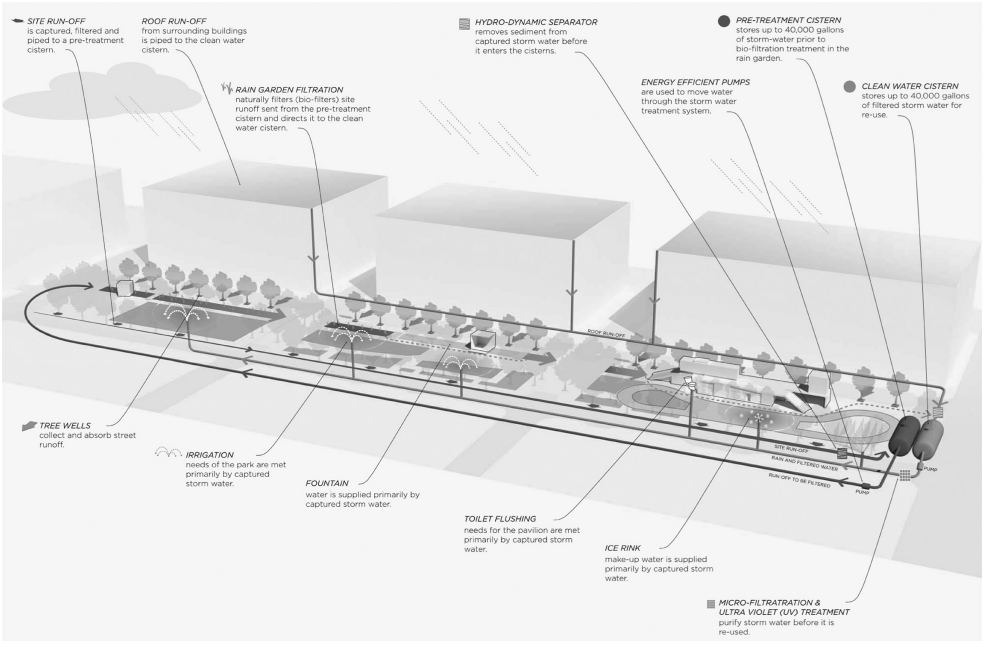

Figure 2. Stormwater management system (Olin 2016).

points, which means approximately 66%. Therefore, it is SITES certified in a close percentage range as it did in LEED.

In SITES, the park scored the total points for site selection, assessment and planning, and monitoring and innovation. For human-health and well-being, it scored 27 of 32 possible points. However, it only scored 25% for materials selection; and approximately half of possible points for site design and water, site design and soil and vegetation, construction, and operations and maintenance (SITES 2013).

LPS highlights Canal Park's many sustainable performance benefits. Being the environmental benefits mostly related to the high efficiency of the stormwater management system, as it captures and treats 95% of average annual runoff from the site and neighboring streets with perspectives for collecting and treating also the storm water from surrounding buildings roofs. Consequently, 88% of potable water is saved with stormwater reuse, which may reach 100% as stormwater from surrounding buildings roof are collected. In addition to environmental benefits, there is an energy consumption reduced by 12.6% with the use geothermal energy for heating and cooling of the large pavilion that hosts the restaurant and with efficient light fixtures throughout the park. Finally, 100% of residual concrete, brick, block, and asphalt from construction was recycled, which contributed to greenhouse gas emissions reduction (Salazar et al. 2015).

Social benefits of the park are reflected by the high number of visitors with an average of 58 visitors daily and 28,000 visitors for one-year long. Also, the park is perceived as well-designed by most of its visitors, while providing inviting spaces for social interaction. Further more, the park contributes to safety perception on site and neighborhood, and to 18% decrease of vehicular speed in the street sections that cross the park (Salazar et al. 2015).

Economic performance benefits sum up 43 jobs provision for low-income people and members of the local community; the generation of 100% of the funds needed for park's operation through the events, ice skating rink revenues, and rentals; and, increased property values in 1% more than the rest of the city during the same period of time. While contributing to the growth and development of the neighborhood, the park is also contributing to the generation of more tax revenue and jobs. In addition, by reducing potable water consumption, water cost is saved. On the other hand, the use of certified wood increased the cost of the project in relation of conventional wood. However, in a macro scale it contributed to savings with broader sustainable benefits (Salazar et al. 2015).

5 DISCUSSION

5.1 *About LEED and SITES*

Comparing SITES and LEED, it is observed that the emphasis on energy is considerably higher in the latter. Energy efficiency is mentioned four times in different topics in SITES, but the system does not have a specific topic dedicated to energy, neither any requirement for energy efficiency. Although it is known that energy consumption is not as critical as water consumption in green spaces, it should be highly considered as a great collaboration for the surrounding buildings through

energy production, for example. About water, both systems consider it with approximately same weight in the total of possible scoring. In terms of materials, SITES awards two times more percentage points than LEED.

In addition, while LEED values sustainable sites with several possible points related to this topic, SITES does not consider sustainable building construction on-site for scoring. Making it part of the formal SITES rating system would definitely make a difference for valuing and considering all the built elements of a site toward sustainability.

Both systems consider the importance of multimodal transportation, but only LEED awards points to parking footprint reduction. This is intriguing as parking lots are a critical element against good and sustainable urban landscape architecture. LEED does not have any educational component, nor consideration for on-site food production, while SITES does. There should be a greater incentive for educational purpose in buildings. As people tend to spend more time in buildings than in open spaces, the former could offer a potential approach for increasing the perception and enhancing the behavior for sustainability.

On the other hand, SITES does not mention acoustic performance, as LEED does. Acoustic performance could be considered in both rating systems, while LEED may continue evaluating it for indoor environmental quality, SITES could consider it for noise reduction in urban open spaces.

5.2 *About canal park*

LPS highlights many of Canal Park's ecosystem benefits. However, it does not mention anything about heat island reduction, or any relation with climate mitigation, besides storm events. Adding to that, biodiversity or habitat issues are not mentioned either. Even being a small park, it provides green spaces, which certainly have some contribution to both climate mitigation and habitat provision. Canal Park was assessed according to the criteria proposed by LPS, which are based on the ecosystem services. However, most data related to the park's performance are directly linked to the project and documentation from LEED and SITES within their boundaries and requirements. In this sense, LPS should make it clear how comprehensive or specific is each case study they present in relation to the broad approach and criteria for ecosystem services that they propose.

Despite limitations of methods and application of the post-occupancy evaluation conducted by Olin and Capitol Riverfront BID, it has a positive aspect for the project after construction, especially because it demonstrates the sensibility about the importance of monitoring performance. Olin's research was part of the requirements from SITES, however the methods for monitoring social performance could be enhanced for a more comprehensive understanding of the social mechanisms and more conclusive results.

Some issues about the park's performance are related to systems that are not working as designed and predicted, such as water reuse for toilet flushing. The appearance of the reused water in the toilets did not satisfy the users. Even with explanation about the sustainable system and its safety, public dissatisfaction conduced the park's manager to switch the toilets for city water use. In this sense, there is a relevant need to overcome the cultural barrier for water reuse in toilets. In addition, the collection of stormwater from adjacent buildings' roofs was not implemented. Some buildings have been redeveloped after the park's construction and they were not connected to the park's system as proposed by the park's project.

6 CONCLUSION

There is a high potential for advancing further with possibilities of integrating building and landscape for efficient and comprehensive environmental performance, such as exemplified in the Canal Park proposed system for stormwater collection from adjacent buildings' roofs.

Canal Park definitely has more benefits then the ones presented by LPS. Probably because of time limitations for conducting the performance research, not all benefits were able to be explored and measured. Also, it should be taken into consideration that the impact and benefits of an urban green space goes beyond its site, as it is one element of a bigger interrelated ecosystem. Canal Park is a small urban park, but if considered as part of a green network other benefits could be highlighted from its performance.

While acknowledging cities' dynamics and constant changing and adaptation, for urban sustainability, it is necessary to have regular monitoring of projects that should be responding to changes without losing their sustainable characteristics. Therefore, urban spaces design for sustainability is about accepting adaptation, through flexibility of systems and program, without losing sustainable performance, or better, enhancing performance.

An autopsy of an environmental tragedy: 1995 Chicago heat wave

A. Sharag-Eldin, K. Atchison, C.B. Heller, S. Gharehgozlou, H. Haji Molana & W. Lucak
Kent State University, Kent, OH, USA

ABSTRACT: In July 1995, a heat wave struck the City of Chicago causing 739 heat-related deaths in few days. This paper provides a comprehensive analysis of the outdoor and indoor environmental conditions that occurred in July of 1995. We selected three sites in which two residents have perished which represent different architectural and urban conditions. Site climate data were synthesized using microclimate simulation. The generated climate data is then used to estimate the internal conditions. Estimated interior conditions have shown a two-day time lag between the outdoor and indoor peak heat stress. This research established that heat-related fatalities are likely to occur in extreme heat episodes if the air-conditioning fails and the residents were frail, unable, or unwilling to spend the nights elsewhere. The results also demonstrated that trees and vegetation may reduce the impact of Urban Heat Island (UHI), but will not negate the extraordinary conditions created by a heat wave.

1 INTRODUCTION

1.1 *Chicago heat wave 1995*

In July 1995, a heat wave struck the City of Chicago causing 739 heat-related deaths in eight days. According to the Bulletin of the American Meteorological Society (Kunkel et al. 1996), a brief but intense meteorological incident occurred in the Midwestern United States. By July 13th, the air temperature peaked at 41°C (106°F). In the next five days (11th–15th), the temperature kept rising. A weak cool front slowly began to provide relief the Midwest from the 15th–17th (Kunkel et al. 1996). Due to the high demand for electricity, the city suffered from widespread power disruptions (Klinenberg 2002). These power outages that left over 49,000 citizens without air-conditioning (Thomas 2015) had devastating consequences on the health and safety of the most citizens of Chicago.

Starting with three victims on the 13th, the numbers climbed the next two days quickly to 181 (Whitman et al. 1997; Semenza et al. 1996). The death toll resulting from direct heat-related causes between the 14th to the 20th amounted to 485 residents of Chicago. Finally, after the event ended and the epidemiologist compiled their statistics, over 739 excess deaths were counted. During this brief period, there were 1072 (11%) more hospital admissions than average and 838 (35%) more than expected among patients aged 65 years and older (Semenza et al. 1996).

1.2 *Heat stress*

The Cook County Medical Examiner Office (CCMEO) defines heat-related death as one that occurs with "no history of trauma or evidence of fatal injury."

Table 1. Demographics of the Victims*.

Age	Non-Hispanic White	Non-Hispanic Black	Total
<55	27	42	73
55–64	19	44	69
65–74	62	62	125
75–84	87	63	176
>84	47	45	258
Total	242	256	514

*Data expressed in excess deaths which accounts for morality figures above observed in July 1995. Source: (Whitman et al. 1997).

The definition requires that the measured body temperature was 40.6°C (105°F) or higher before or immediately after death (Whitman et al. 1997). Significant to this study, the CCMEO suggestion that there should be evidence that the environmental conditions at the death scene reached 37.8°C (100°F) or more (Whitman et al. 1997). Since the majority of these deaths happened indoors, the estimation of air temperature could be used to verify the CCMEO stipulation.

Table 1 shows that the majority of the victims were elderly males, who lived alone (Klinenberg 2002; Whitman et al. 1997). A study conducted in Epidemiology Program Office and the National Center for Environmental Health using multivariate analysis showed that more than 50% of the deaths could have been prevented if the victims had a working air-condition system (Semenza et al. 1996). Other risk factors include bed confinement, ambulatory restriction, and lack of companionship (professional or familial). The study showed that individuals with

pre-existing medical conditions accounted for a significant percentage of the deaths (Semenza et al. 1996). For a heat-wave episode to cause this level of mortality, evidence showed that a series of environmental and societal conditions have to prevail. In fact, sociologists attribute the large number of victims to urbanization, poverty, overwhelmed city emergency infrastructure, and safety (Sheridan & Dolney 2003; Dolney & Sheridan 2006; Ebi et al. 2006).

A number of comprehensive studies have linked morbidity during heat waves to heat stress index (Hartz et al. 2012; Kaiser et al. 2007). Heat stress index is a two-parameter environmental index that estimates an equivalent temperature by combining the effects of dry bulb temperature and relative humidity (Belding & Hatch 1955). However, thermal comfort is a complex physio-psychological phenomenon that necessitates the inclusion of multiple environmental parameters such as; dry bulb temperature, relative humidity, ambient mean radiant temperature, air and movement with human metabolic rate and clothing insulation (Fanger 1970). It is defined as "condition of mind that expresses satisfaction with the thermal environment" (ISO 2005). Thermal sensation and thermal comfort are related phenomena. On a scale of −3 cold, −2, cool, −1 slightly cool, 0 neutral, 1 slightly warm, 2 warm, 3 hot, values of 2 and 3 represent heat sensation levels that may cause heat stress. Fanger identified three parameters to achieve thermal comfort; heat balance, sweat rate, and mean skin temperature (Fanger 1970). Deviation from the full achievement of these parameters causes discomfort (Epstein & Moran 2006). Sensitive populations – elderly and those with preexisting vascular diseases – tend to be more likely to be affected by local thermal discomfort. A study conducted in the school of Medicine, University College London found that the elderly demonstrated poor judgment of ambient temperature and consequently were unable to control the temperature. These studies demonstrate a clear connection between the indoor environmental conditions and the elderly as a group vulnerable to heat stress. The body of vulnerable persons responds to high thermal stress conditions by increasing their heart rates, increasing body temperature, thus stressing their respiratory function beyond its capacity to adapt.

Individuals exposed to thermally stressful conditions may have their health severely affected and may lead to death. Upon stress, the thermoregulatory system that distributes heat throughout the human body fails to accommodate the need for the competing organs including the blood flow to the skin. (Parsons 2003). With sweating, the human body loses sodium and potassium (Niosh 2013). If this condition persists, the sweat glands will begin to swallow if the air is humid (Niosh 2013). Prolonged exposure to this leads to a decrease in sweating which consequently causes the skin temperature to rise. In turn, the core body temperature rises rapidly (Parsons 2003; Patz et al. 2000). At 38°C–39°C (100.4°F–102.2°F), the individual exposed may collapse, at 40°C (105.8F) core temperature, heat stroke will likely occur (Abderrezak & P. 2002). Men over 40 years old represent over 50% of fatal heat stroke cases and 25% of the non-fatal cases (Niosh 2013).

1.3 *Research questions*

Despite the rich body of research work connecting heat waves and morality, it became evident to the authors that the impact of individual structures and urban conditions remain largely unstudied. Based on extensive review of the literature, the research team developed the following research questions:

a) Was the temperature at the building sites where individuals died differently from those measured at the airport due to the Urban Heat Island?
b) Was building type, height, or urban morphology significant factors affecting the outdoor environments adjacent to where the victims lived and died?
c) Did the individual building design affect the indoor environmental conditions conducive to heat stress?

The intent of this study is to estimate through computational methods and simulation the indoor environmental conditions prevailing during the heat wave. The resultant data will be used to gauge the potential human stress caused by these circumstances.

2 RESEARCH DESIGN

2.1 *Climatic data*

Historical climatic data measured at O'Hare Airport were collected from NOAA's website. The data were measured on an hourly basis but a few hours were missing. The researchers used fourth order polynomial curve-fit routines to construct complete hourly data sets (dry bulb temperature, relative humidity, wind speed and direction, and cloud cover).

2.2 *Sites selections*

Three sites were selected in the city of Chicago to represent three morphological conditions; dense urban, less dense urban, and suburban. The other criterion for site selection was that at least two victims died at the same address. This data was collected from the Chicago Deadly 1995 Heat Wave: an Oral History website (Thomas 2015).

Site #1 is located in a northeastern area of Chicago. It is a brick four-story building with multi-family residential units. The area is fully covered with concrete pavement, asphalt roads and parking lots (Figure 1). The only vegetation on the site in 1995 were mature deciduous trees on the streets and alleyways. The trees create deeply shaded areas near and at the back of the residence of concern. Due to privacy issues the research team cannot identify the specific buildings

Figure 1. High-density Urban Site #1. Source: Google Earth.

Figure 2. Low-density Urban Site #2. Source: Google Earth.

or the residents who perished in it. The two individuals who died in this neighborhood died on the 18th of July.

Site #2 is located in a neighborhood on the Southside of Chicago (Figure 2). The majority of the deaths in this neighborhood occurred on July 15th–17th. The apartment building is located on a broad right of way containing a four lane street and two one-way streets. Approximately 50% of the site surface is covered with structures, 35% with dirt and vegetation, and 15% with asphalt and concrete. Most of the other structures are also four-story apartment buildings except a church and two residential towers at the Southeast corner of the site. One tower is 50 meters high, and the other is 72 meters (236 ft.) high. Site #2 is representative of lower income, residential neighborhoods that are a mix of medium and high-density apartments in a fairly open urban setting. Vegetation (Trees and green lawns) are sparse but provide comprehensive coverage of the buildings in the general area.

Site #3 represents an impoverished low-density neighborhood with suburban-like single-family pattern (Figure 3). The site is covered with grass (front and backyard) and some street trees. Additionally, some mature trees are located near the house under investigation. The lot is surrounded by neighboring houses and is located on the main road with a secondary road located behind it. The unit studied is about five meters high (15 ft) and represents a typical residence in this neighborhood. Deaths occurred at the site on July 14th.

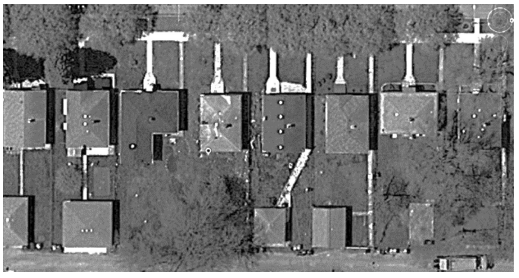

Figure 3. Suburban Site #3. Source: Google Earth.

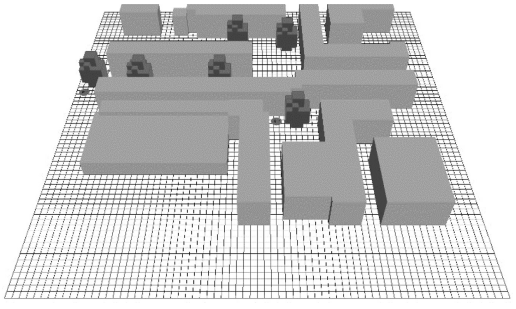

Figure 4. Envi-Met Model for Site #1 (Example).

2.3 *Preparing models for microclimatic simulation*

Three-dimensional models were constructed in Envi-Met. Building dimensional data were collected using Google SketchUp Pro. Envi-Met is a non-hydrostatic microclimate modeling system that is used to simulate surface-plant-building interaction in urban spaces. It uses a simple one-dimensional radiative transfer model with vegetation model (Bruse & Fleer 1998; Huttner et al. 2008). The program uses a uniform mesh with a maximum of 250 × 250 × 30 cells.

2.4 *Microclimatic modeling*

The research team used historical weather data for the period of July 10th–20th in the simulation of the three sites. The data was collected from O'Hare Airport using NOAA website. Data for each day were entered, and the program ran for 24–48 hours per day and configuration. Each of the models used a 100 × 100 × 40 cell models. The resulting outdoor conditions were then compared to the airport data (Figure 5).

The comparison of the resulting environmental data showed that a relatively small variance existed between the airport and the other sites. However, site-specific physical conditions such as overshadowing of a neighboring building, vegetation, and wind obstructions created unique and distinguishable microclimatic conditions for each site.

The research team replaced the three calculated hourly meteorological data (Dry Bulb Temperature, Relative Humidity, and Wind speed) by Envi-Met at

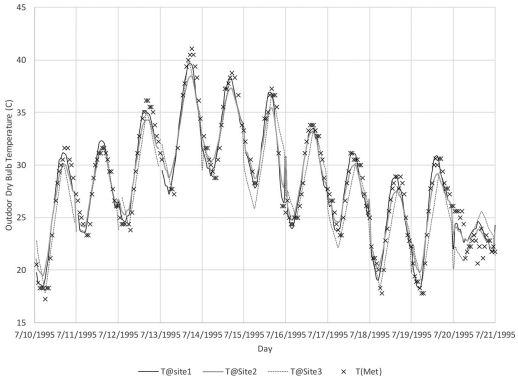

Figure 5. Dry bulb temperature calculated for the three sites at 1.0–1.8 m show variation from the airport readings.

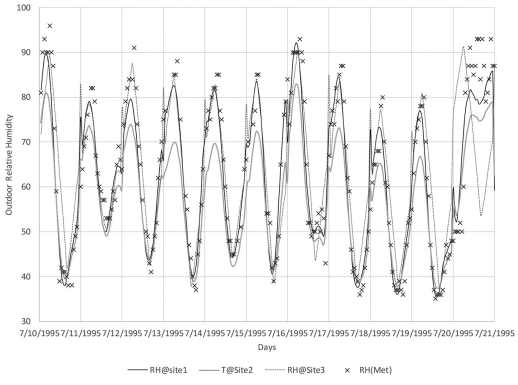

Figure 6. Comparison between the calculated Relative Humidity and the historical data at O'Hare Airport.

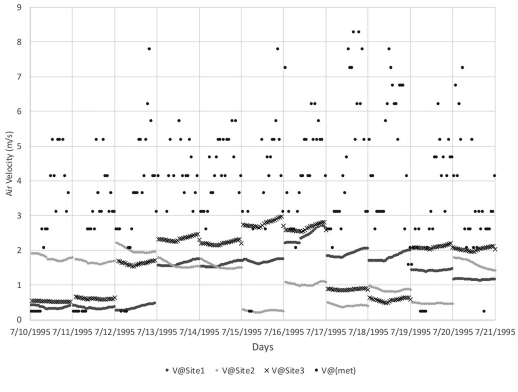

Figure 7. Air velocity at the airport is much higher than those calculated at the three sites. Site #1 had the lowest street level air velocities where Site #3 had the highest.

the three sites for the period of July 10th–20th in place of the climate data available for energy simulation programs. The modified climate files were used in the simulation of the indoor conditions.

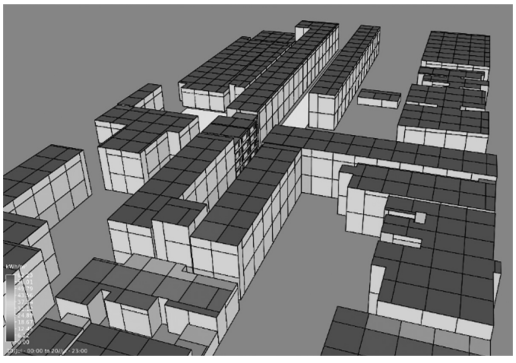

Figure 8. The least amount of solar intensities incident on the roof and wall areas were calculated for the apartment on site #1.

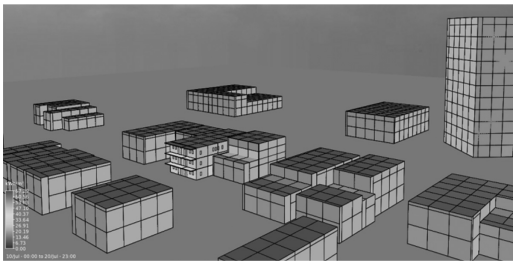

Figure 9. The average density Site #2 showed high roof surface incident solar radiation intensities while wall surfaces were exposed to average solar intensities.

2.5 *Indoor condition modeling*

Integrated Environmental Solution (IES) program Virtual Environment (VE) was used to simulate the indoor conditions for the buildings in the three sites. Before running the energy simulation, we ran the Solar Shading Calculations Module to estimate the shading coefficients for the month of July. This data was passed to the Apache Simulation Module.

3 ANALYSIS

This section will focus on the analysis of the outdoor and indoor conditions as well as the estimation of the thermophysiological responses of the occupants during the period from the 10th to the 20th of July 1995.

3.1 *Conditions at the three sites*

The three sites represent different environmental and urban morphological conditions. They also differ in the nature of the ground cover surrounding the buildings of concern. Site #1 had the highest percentage of concrete and asphalt finishes while sites #2 & #3 we had green lawns and trees.

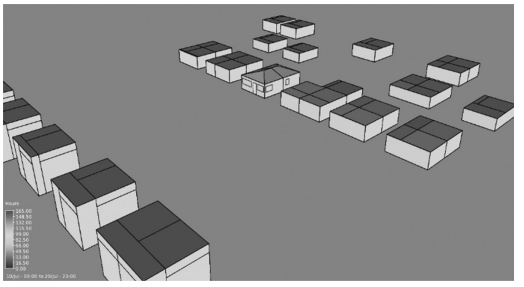

Figure 10. Together with Site #2 the roof surfaces in site #3 received the highest intensity of solar insolation per square meter.

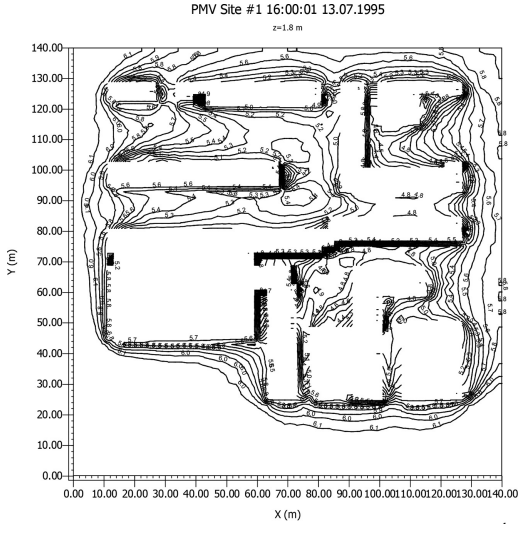

Figure 11. Site #1 Outdoor PMV distribution for July 13th at 4:00p.

3.2 *Comparing the three sites*

This comparison will use the thermophysiological response to include the four environmental parameters and assumes a 65-year-old individual clothed at 0.53 CLO and an estimated work metabolism of 80 W calculated from an average walking speed of 1.2 m/s amounting to a total personal metabolic rate of 154 Watts.

The thermophysiological response metric used in this paper is the PMV. PMV index (Fanger 1970) is one of the most popular biometeorological thermal indices for a broad cross-section of people (Mayer & Höppe 1987; Staiger et al. 2012; Johansson et al. 2014). Point 2 and above on the scale represent a thermal sensation level hot and higher.

Despite the difference in the distribution pattern of the calculated PMV for July 13th at 4:00p, the range of the obtained values remained constant (4.5–6.0) except for Site #1 where the PMV value is lowered to 3.8 between the deep street canyons (Figure 11–Figure 13). The outcome of Site #1 is validated by comparing the calculated PMV value to the measured

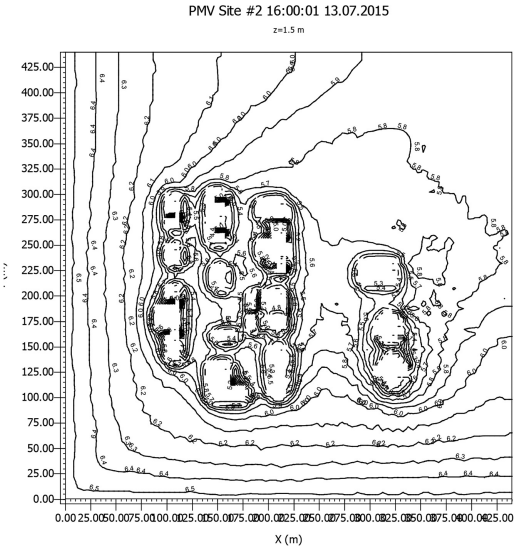

Figure 12. Site #2 Outdoor PMV distribution for July 13th at 4:00p.

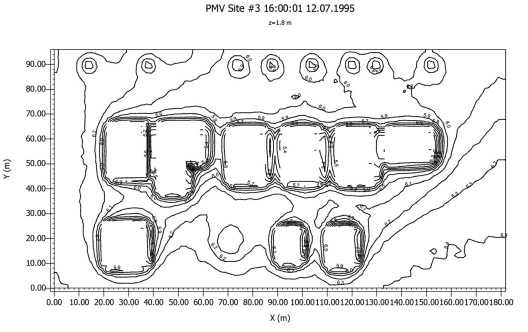

Figure 13. Site #3 Outdoor PMV distribution for July 13th at 4:00p.

and documented data in a research project conducted at the Department of Biometeorology and Applied Meteorology, University of Munich (Mayer & Höppe 1987).

Figure 14 show that the PMV values for the three sites far exceeded the acceptability range. In fact, PMV persisted after the peak temperature on the 13th (Figure 5). It should be noted that despite the extreme heat stress experienced by the residents, the evenings remained tolerable. Images documenting the event showed that many residents slept outdoors in parks and open spaces (Figure 15).

3.3 *Comparing the three interior conditions*

Energy simulation of the interior spaces at the three sites showed a significant variation of environmental conditions indoors. Based on accounts of the events, the majority of the residential units where unconditioned, due to either power outages or the lack of air-conditioning units in the apartments. Other reason

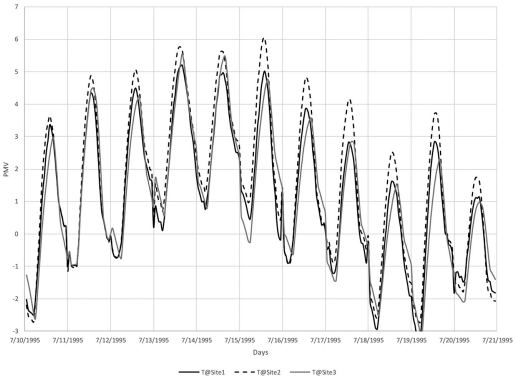

Figure 14. Predicted Mean Vote (PMV) for the three sites outdoor conditions.

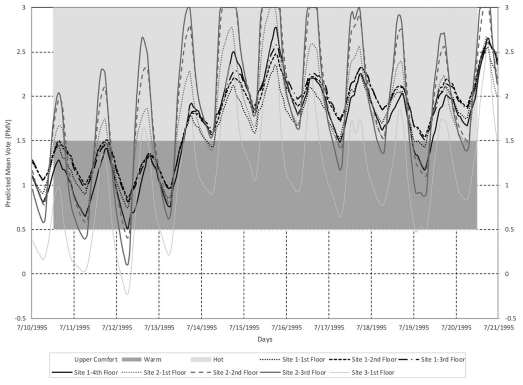

Figure 16. Predicted Mean Vote (PMV) calculated for indoor conditions in all sites and levels.

Figure 15. Sleeping in public parks. Source: https://www.emaze.com/@ALLIZFQR/Chicago-Heat-Wave-1995?autoplay.

included the unwillingness of residents to open their windows for fear of burglary and personal safety. As a result, the indoor simulation was conducted with no ventilation and no air-conditioning.

The resulting indoor air temperatures were highest at Site #2 on the third (top) floor. This floor was exposed to the highest incident solar radiation intensity. Generally, site #2 experienced the highest temperatures. The indoor peak temperature on the top floor reached 40–50°C (104–122°F) in the period between the 12th to the 20th. Heat stress experienced by the residents was extremely high resulting in their deaths on the 15th and 17th. The single residence in Site #3 experienced the highest fluctuation of diurnal temperatures. Despite being the coolest structure, residents were exposed to temperatures over 40°C (104°F) from the 12th to the 18th. Heat-related deaths in the residence occurred on the 14th. Residents on the fourth floor of the apartments in Site #1 were exposed to temperatures close to those in the Site #3. However, because of the relatively high thermal mass and shadows cast by the surrounding buildings the diurnal temperature fluctuations were minimal. As a result, the occupants were exposed to an elevated indoor temperature exceeding 38°C (100.4°F) from the 13th to the 20th. The deaths that occurred in this building on the 18th clearly indicated that the residents suffered for three days, elevated levels of thermal stress without relief. Since the occupants were elderly and opted not to open their windows or leave the apartments to sleep on the street, they likely suffered a long and painful death.

Predicted indoor PMV values (Figure 16) show that the thermal sensation and consequently levels of thermal stress varied between the three sites. While occupants in site #2 experienced the longest period of thermal stress (11th–20th), stress levels of residents in site #3 exceeded acceptability from the 12th to the 20th. Site #1 began to exceed acceptability by the 12th but only continued until the 18th.

4 CONCLUSIONS & DISCUSSION

Even though heat waves are rare meteorological events (Kaiser et al. 2007), valuable lessons are learned by studying them carefully. This research project showed that there is strong evidence that links heat-related deaths to indoor environmental conditions.

Figure 17 proves that the peak and the pattern observed in excess death matched the peak and the pattern of the indoor PMV levels. This was true in all three of the sites.

It should be noted however that the number of excess deaths could be drastically reduced we respond in the following manner;

a. Properly ventilating the residences may have provided relief at night. Especially when many died because of the heat buildup indoors.
b. It is important to understand that the most significant losses occurred days after the peak heat intensity. This time, lag can be attributed to building capacity to retain heat longer than the air. Knowing that could have given the authorities the time to respond.
c. While shading using trees and overshadowing cast by neighboring building reduced solar radiation, air

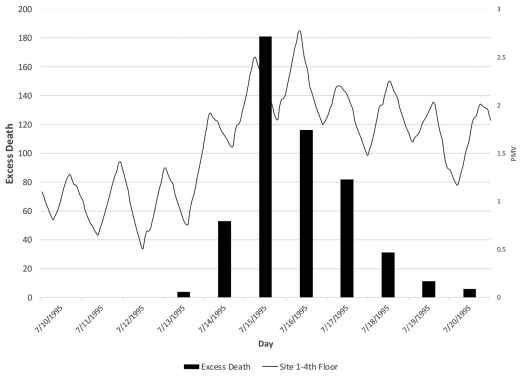

Figure 17. Comparing Heat Related-deaths to calculated indoor PMV. Source: (Whitman et al. 1997).

movement was also significantly reduced thus negatively affecting the residents' thermoregulatory system.

d. Large mature tree canopies provided shade but also reduced air movement in the alleyways and increased the relative humidity above ambient levels.
e. Vulnerable groups in potentially unventilated top floors should be identified and forcibly removed from their residents when predicted weather conditions have the profile experienced in the July 1995 event.
f. Urban heat Island that prevailed at the city during the summer season created the ideal environment for the retention of the heat after the peak and extended to the next few days. That condition was identified as the footprint of the "killer urban heat wave."
g. It is necessary to develop climate scenarios to deal with climatic and weather uncertainty (Goodess et al. 2007).

5 LIMITATIONS OF THE STUDY

The study provided the research team with an insight to the thermal conditions that prevailed in a short but intense point of time in the City of Chicago. However, it should be noted that the causes for mortality due to heatwaves in urban areas is a complex problem and could not be completely explained by estimating the environmental conditions that prevailed indoors or outdoors at the time. Due to the scope of the paper, the authors did not expand upon commonly used Heat Stress indices beyond the thermal comfort metric (PMV).

6 FUTURE RESEARCH

This effort is an on-going project and the outcomes presented in this paper are only a small fraction of the scope of the full project. We are currently working on the following issues.

a. Use of thermal stress indices to relate the biometeorological data to the physiological responses described in the introduction
b. Investigate passive and active ventilation strategies that may reduce the probability of overheating of indoor spaces during extreme heat episodes
c. Test retrofit strategies to reduce overheating of exterior and interior environments
d. Develop an indepth understanding between the Urban Heat Islan and the extension of extreme heat conditions beyond the peak meteorogical temperature
e. Study the impact of climate change on the frequency and intensity of extreme heat episodes

ACKNOWLEDGMENT

The authors would like to express their gratitude for director of the Master of Health Design Dr. Margret Calkins from the College of Architecture and Environmental Design at Kent State University for her insightful review of the manuscript and invaluable feedback.

The people's park: A study of the relationship between design and conviviality in Superkilen

Maria Beltran-Rodriguez & Madlen Simon
University of Maryland, College Park, USA

ABSTRACT: Scholars have traditionally focused on the ecological function of urban parks. Lately though, ecology is playing a secondary role, as demonstrated by many newly awarded parks. The 'people's park' typology, with a strong emphasis on design and program, is seen as a potential everyday space that can promote social wellbeing. This research aims to find out what about design makes the 'people's park' a convivial place. We conducted a pilot study at Superkilen, a 'people's park' in Copenhagen, testing for markers of conviviality. Observations show it is a robustly convivial environment. To test how design can influence the level of conviviality in the people's park we developed a checklist based on scores. The findings at Superkilen show that there are correlations between a park's level of conviviality and the scores obtained. This methodology will be tested in other parks – successful and non-successful – in order to make it generalizable. The significance of the research lies in the development of this methodology or checklist that can serve both in the design phase as well as on the diagnosis to assess the design problems of underperforming parks.

1 THE PEOPLE'S PARK TYPOLOGY – *WHAT?*

Landscapes have hosted social activities and interactions in the 'public' for a very long time. From the private garden at Octavius Quartio House (3rd century BCE) or the hortus conclusus at St. Gall Monastery (9th Century CE) to one of the first public parks, Prince's Park in London (1842). Conviviality as a quality of a landscape being friendly, lively and enjoyable, evolves from being a private phenomenon of an elite, to gradually becoming more public and inclusionary for every citizen. Contemporary urban parks, though, seem to be reflecting a reverse tendency (Zukin 1996).

The concept of urban park as we understand it nowadays, has its origins in the early 19th century, during the Industrial Revolution, when planners recognized their benefits and positive effects (Rogers 2001). Urban parks have since then been highlighted especially for their ecological functions, as well as their experiential and cultural effects (Czerniak 2007). Lately though, the ecological function seems to be secondary, as many new internationally awarded urban landscapes show. Clemens Steenbergen (1993) talks about the development of the city park as a landscape architectural model. One of the turning points he mentions is the appearance of what he calls 'The people's park': "until then the landscape architectural form could be reduced to its origins in nature. The people's park [. . .] became a recreational machine. Instead of nature, the program became the source of unity." (Steenbergen 1993, 122). It is interesting to note that Elizabeth Barlow Rogers (2001) refers to the Victorian Garden also as the "people's park", but in a slightly different sense than Steenbergen does. She was describing the turning point of 19th Century England, when the first public parks were designed, with the provision of land "for the Recreation of the inhabitants" and using "public funds for parkland acquisition and development to pay back this cost with the proceeds from the sale of the adjacent building lots." (Barlow Rogers, 2001, 323). She refers to this phenomenon as "the democratization of landscape design."

Adrian Geuze questions whether urban parks should exist as 'natural' spaces at all. In his essay "Moving Beyond Darwin" he claims: "Green has become a kind of habit. And it has also become a cliché of its own [. . .] there is absolutely no need for parks anymore, because all the 19th century problems have been solved and a new type of city has been created." (Geuze 1993, 38–39). This research will look at this last typology of park, the people's park, highly designed and programmed and not necessarily green in the traditional sense.

We often associate green in cities with health (Le Corbusier 1933). This research, though, is interested also in those aspects that transcend the merely green component of a park, and that talk about the quality of social interaction and integration (conviviality) it can promote. The World Health Organization states "health is a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity." (The World Health Organization Constitution, 1946). This research wants to strengthen this notion of "social well-being" as directly linked to health, and as something that shouldn't be extraordinary (i.e. on holidays or weekends) but ordinary, it should be part of our day to day routine. In the Ottawa Charter, the World Health Organization specified that: "health is created and lived by people within

Figure 1. The 'settlement health map'. Barton & Grant, 2006.

the settings of their everyday life; where they learn, work, play, and love. " (WHO Ottawa Charter, 1986). This must be remembered when designing the public realm and parks are especially important for a high quality of life in cities (Jellicoe 1975). If we look at 'The Settlement Health Map' (Barton and Grant 2006) in figure 1, we can appreciate the determinants of health and well being in our neighborhoods. Our research on the design of urban landscapes falls under the categories of 'activities' and 'built environment', but like this health map explains, it can directly affect 'local economy', 'community', 'lifestyle' and thus 'people'.

2 DIVERSIFYING POPULATION – *WHY?*

The people's park is a particular instance of urban landscapes. In this new family of urban landscapes that puts a larger emphasis on design and program than on ecology, social well being seems to play an important role and is seen as a pertinent aspect to study. Thus, finding out what aspects of design make people feel welcomed and integrated become essential aspects of this research. An important challenge of the people's park typology is to make people feel like at home (i.e. an extension of their living room) and at the same time to promote a tolerant and respectful attitude towards strangers. It's important to look for design solutions that allow inclusive participation by individuals and groups. This becomes an even more important question in demographically, culturally, economically and/or ethnically diverse contexts.

Conviviality is understood in our research not only in a scientific context, but also as an ordinary phenomenon to achieve in our everyday spaces. This is a timely issue, particularly in Europe, which has for a number of years been struggling to accept a diversifying population and even more timely as the current crisis in the Middle East drives refugees to European cities. Today's refugees' movements might have tremendous implications in urban public places and the people's park typology is one of the places where we are going to see this especially play out. European countries had been fairly homogenous and in recent years have been confronting issues of diversity. How design influences the level of conviviality in a people's park becomes an especially critical question in todays diversifying context. Copenhagen is a good example of a diversifying European city, making Superkilen, the park this paper focuses on, an appropriate site for our research.

3 THE STUDY OF CONVIVIALITY THROUGH DESIGN – *HOW?*

In our previous work we have defined conviviality, through a literature review on its synonymous concepts 'sociability' and 'liveliness.' We define convivial landscapes as "physical places that are flexible, changing and adaptable, which are a result of processes and outcomes based in equity, integrity and democracy, and that contain urban uses and solutions that correspond to resident's needs and desires" (Beltran & Simon 2015).

Our current study posits a direct relationship between certain design features in urban landscapes and the conviviality level these promote among its users. If we examine the literature on what makes people interact with each other in public places, we find many factors. We found three inherent design qualities: 'accessible' – as opposed to restricted–; 'inclusive' – as opposed to exclusive–; and 'multi-functional' – as opposed to single-functional; as especially relevant for the study of conviviality in the people's park typology.

3.1 *Main requirements for conviviality*

The three factors for conviviality are used as a measure of how convivial an urban landscape is. They cannot be understood as separate entities, but as part of a sequence or continuum, like figure 2 shows. The three factors are represented in a graph, along the x-axis. Each factor is sub-divided into various design features (see 3.2. for details), which are each given a score. Each score is added vertically, in the y-axis. Instead of placing each score independently, as you move right, each score adds up to the immediate previous one (the one on the left). The reason for this is that you can easily read the overall score for accessibility (x), inclusiveness (y) and multi-functionality (z), as well as the final conviviality score ($x + y + z$) at the right hand side of the graph. You can also eventually compare very easily the graph results on conviviality for various parks.

The most primitive or first factor, 'accessibility', is a necessary condition for people to be in the park in the first place, and therefore a necessary condition for conviviality to even be possible. If an urban landscape

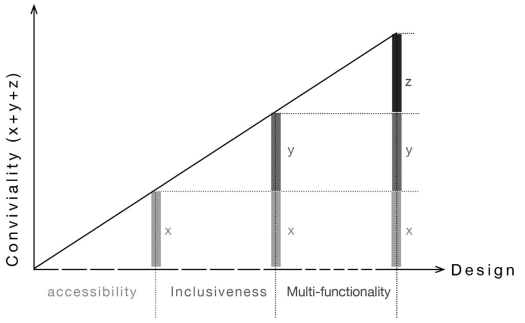

Figure 2. Conceptual graph on the sequence for conviviality in relation to design.

is accessible, it means people, everybody in general, *can* physically access it; it doesn't mean that they will. The next level in the sequence, 'inclusiveness', speaks of the psychological effect a design might have on people, making them feel welcome and comfortable in it. Therefore, once people have the possibility of access, if on top of that they feel attached to that place they will *want* to be there. Lastly, if we look at the third level in the sequence, 'multi-functionality', we talk about people actually interacting in and with that urban landscape, using it and manipulating it.

3.2 *Data: What design features to look for*

The three factors (accessibility, inclusiveness, and multi-functionality) that we think are relevant for peoples' conviviality level have been examined to determine what data to collect. This is reflected in a checklist of design features to study in a people's park (table 1). Many of these design features are recurrent themes in any urban analysis. The novelty of our proposal is to study them together and as directly linked to convivial behavior.

To evaluate accessibility of an urban landscape we must collect data on the following design features: physical boundaries, connectivity and walkability. An urban landscape with very open boundaries will be more accessible than one with very closed margins or fences or with restricted entry times.

In order to evaluate inclusiveness we must collect data on the symbols used, the aesthetic qualities, the type of furniture and the lightning features. All of these might determine whether someone feels welcome or confortable in a place or not. For example, offensive or sectarian symbols might repel certain population sectors and poor lightning might decrease activity or social interaction.

Lastly, to evaluate multi-functionality, the data collected will focus on: number and simultaneity of activities, presence of thematic areas, changes in surface material and variety in vegetation. A larger variety of thematic areas or activities means more opportunities for different people to interact, to get to know each other, and therefore a better chance for conviviality to flourish.

Table 1. Design features for each factor for conviviality and score system.

Design feature	**0 score**	**1 score**	**2 score**
ACCESSIBILITY			
Physical Boundaries	Closed	Semi-permeable	Opened
Connectivity	Poor	Acceptable	Well-connected
Walkability	Low	Acceptable	High
INCLUSIVENESS			
Symbols	Offensive	Neutral	Welcoming
Aesthetic	Sectarian	Anonymous	Inclusive
Furniture	Individual	Collective	Mixed
Lighting	Deficient	Sufficient	Good
M-FUNCTIONALITY			
Number of Activities	None	One or two	Multiple
Simultaneity of Activities	None	Scarce	Preeminent
Thematic Areas	None	One or two	Multiple
Surface Material	1	2	More than 2
Vegetation	homogenous	2 varieties	Varied: according to different uses

Like table 1 shows, each design feature has three distinguishing degrees, from worse to best. These are meant to translate the data collected through the checklist onto a graph of conviviality vs. design (like the one in figure 2). If the park under examination scores the lowest on a given design feature, no points will be awarded in that particular category. If it scores intermediate, 1 point will be awarded and if scores highest, then 2 points will be awarded.

4 SUPERKILEN PARK – *Where?*

This paper focuses on one specific case study, Superkilen park in Copenhagen (Denmark), because 'Superkilen' was found to be especially relevant in the study of conviviality in a diverse urban setting and poses an interesting scenario for studying the affect of design on conviviality. Since its inception, Superkilen's performance has been widely debated for its implications in relation to the increasing expectations of public investments, new modes of participation, collaboration and conflicts (Steiner, 2012). The park was built as a result of a public and private partnership, and represents the challenges and possibilities of a shared yet heterogeneous space, with an emphasis on participatory practices and social integration goals.

The whole City of Copenhagen is developing under a common strategy based on "more urban life for all, more people to walk more, and more people to stay longer." (Steiner 2012, 9). Superkilen is part of a greater urban development project for Nørrebro, an ethnically and socially mixed neighborhood in Copenhagen, with very different ideas on social co-existence. The Project was launched six

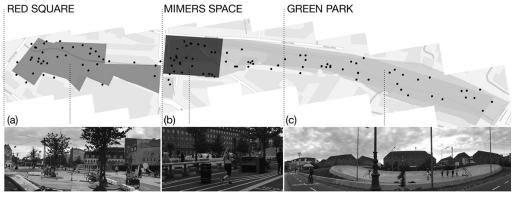

Figure 3. The three conceptual areas in Superkilen (source: the authors).

months after the Mohammed cartoon crisis and people in Denmark were coping with the ambiguities of being tolerant. The city of Copenhagen and Realdania, an association created to invest in creating quality of life in the built environment (www.politiken.dk), launched the partnership project on urban development in Mimersgade in Nørrebro, with a budget of 100 million Danish crowns – 13.4 million euro – for three projects (Nørrebrohallen, Mimer park and Superkilen).

4.1 *Inception*

The following consultant team was responsible for Superkilen's design: BIG (Danish architects), Topotek 1 (German landscape architects), Superflex (Danish artist group), Lemming & Eriksson (Danish consulting engineers) and Help communication (Danish communications consultants). They all worked together with the City of Copenhagen and the local residents. The park has been awarded various international design prizes, such as the 2013 AIA Honor Award in the Regional & Urban Design category by the American Institute of Architects, the mention for Design of the Year by the Design Museum in London as well as for the European Union Prize for Contemporary Architecture. The interest for this research, though, doesn't stem from how it is valued in the design community, but from the effects design might have on residents' and users' ways of interacting with each other, and on their level of conviviality.

The point of departure for the designers was the fact that public spaces are overloaded with conflicting expectations and the commission's brief implicitly asked the designers to deal with the issue of migration in the neighborhood and to ameliorate the situation through the park's design. The official website of Denmark, advertises it as one of the most ethnically diverse and socially challenged neighborhoods in the Danish capital (www.denmark.dk). The design concept organizes the park into three zones, each with its own identifying color (red, black, green), and each containing plantings and artifacts characteristic of the different cultures and countries represented in Nørrebro's population.

The 'Red Square' was conceived as an urban extension of *Nørrebrohallen's*, a cultural and sports center for the neighborhood, inner life. It is composed of various areas for cultural activities and sports and a larger central space, meant as an opportunity given to the community to meet while exercising and/or playing (figure 3a). The red coating extends beyond the limits of the park, into limiting streets and into *Nørrebrohallen*. Furthermore, the adjacent buildings are incorporated into the project visually by painting them the same red as the ground, which appears to fold up creating a three dimensional space. The most prominent example, at the Nørrebrogade boundary of the park creates a sloping curve conceived as sitting area (figure 4). Most of the surface in the red square is built with multifunctional rubber coating, making suitable for activities such as ball games, parades, or as an ice rink in winter, etc. Near *Nørrebrohallen* temporary stands are placed often, to accommodate activities such as open-air cinema and theater or sporting events. On the square's east side there is outdoor seating from the cafe at *Nørrebrohallen's* main entrance. At the north end of the square, areas for playing basketball are fitted into the parking lot.

'Mimers space' (the black area) is conceived as Superkilen's heart. This is designed for locals to meet around the Moroccan fountains, gather under the Japanese cherry trees, or sit on the Turkish bench. There are permanent tables, benches, and barbecue areas that serve as a kind of urban living room, where people cook, eat, read or play chess (figure 5). At the North end of the black square the designers located an elevated south-facing seating area, a hill overlooking the square that serves as a playground (figure 3b).

The green area, the 'Green Park', is conceived as a more traditional park, with paths around rolling hills. It is conceived as a green landscape and playground where families with children can gather for picnics, sunbathing and seating in the grass, as well as accommodating hockey tournaments or badminton matches. The consultant team designed multifunctional spaces, such as a multifunctional hockey and basketball court (figure 3c).

4.2 *Operation and maintenance*

There are two entities responsible for the management of Superkilen. The first one, Copenhagen Municipality's Renovation of Parks & Nature Department, is responsible for operation and maintenance. Because Superkilen was established with the aim to create a framework for a more active life in the neighborhood, a board was established before the park was built, once the winning project was selected, to supervise its realization. Nowadays it operates under the name *Kile* board. This board is the second entity responsible for the management of Superkilen. It is composed of local representatives and acts as a generator and coordinator of activities, events, and happenings in the area. Its main goal is filling Superkilen with activities for the benefit of citizens in the neighborhood, creating synergies with other activities in the city, supporting networks, and collecting experiences concerning the locals. *Kile* also draws from local resources and knowledge to generate feedback on possible future uses for Superkilen.

The Mimersgade Partnership for the neighborhood allocated 1,050,000 DKK (150,000 EUR) for *Kile* during a period of 3 years after Superkilen was built. Kile submits an annual accounting to the secretariat of Nørrebro Local Committee and manages applications to support activities four times a year. The activities and events in Superkilen have public access and are selected according to certain criteria, such as level of visibility, sustainability and health and integration and mutual cultural understanding. This last criterion is key for our research. Not only was Superkilen created under participatory processes broadly representing the multi-ethnic community, but also once in operation, the park took on the mission to provide activities and events involving many different players and citizens, across age and ethnic backgrounds.

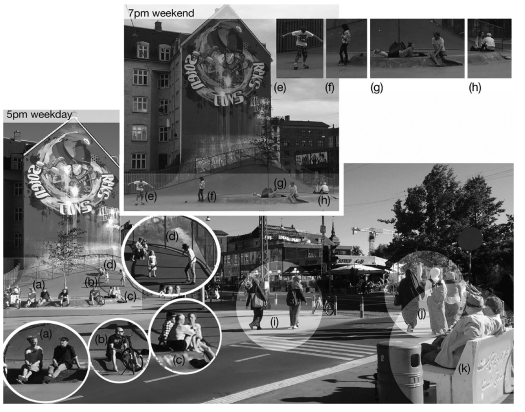

Figure 4. Red Square at different times and days. August 16 7 pm (top) / Aug 18, 5 pm (bottom). Source: photographs taken by paper authors.

5 METHODOLOGY, ANALYSIS & RESULTS

The research methodology has two steps. First we observed and coded park-goers behaviors, in order to identify markers for conviviality. From our analysis of the results we created a checklist of the most prevalent indicators. Next, we ran a study using the checklist. We selected for our study Superkilen, a people's park that was explicitly designed to be a convivial place and was perceived to be convivial by designers, politicians and locals (this was described in section 4). We conducted a pilot study on Superkilen, as the first of a series of studies of parks that make up our larger investigation. We went there and observed users' behavior. We then coded convivial behaviors through photographs (figures 4 and 5). Last, we ran the checklist to measure and diagnose convivial behaviors in Superkilen. Below we summarize the two-step analysis undertaken.

Figure 5. Mimersgade Space (Aug 18, 2 pm). Source: photographs taken by paper authors.

5.1 *Observing and coding conviviality*

The pilot study takes place during August 2015, a very vital time of the year for outdoor activities in Denmark due to climate, holidays, etc. We visited the park for one entire week, Monday through Saturday, three times per day: in the morning, afternoon and evening. Figures 4 and 5 show some of the settings at different days and times. Like the images show, we coded photographs in order to identify convivial behaviors among users and reveal an overall convivial environment in Superkilen.

When we coded the images we identified the following markers for conviviality:

- People doing different activities: chatting (figure 4d), sunbathing (figure 5c), texting (figure 4m), playing (figure 4a), skating (figure 5e), looking (figure 5b), laying down (figure 5g), reading (figure 4g), walking (figure 4k), drinking (figure 5a), among others.
- Varieties in age (figures 4a, 4c, 4d, 4h, 5d, 5k), or race (figures 4b, 4c, 4d, 4e, 4h, 4k, 5i)
- Variety in group size: one (figure 5b), two (figure 5a), three (figure 5c), group (figure 4b)
- Physical comfort (people sitting down)
- Psychological comfort: strangers of different ethnic origin facing at each other (figure 4j), people lying down in public (figure 5g), people sitting very near strangers (figure 4h), among other signs.

The more all of these are intermingled, the more convivial the place. Since conviviality is not an already established phenomenon, we selected these particular markers to identify convivial behavior.

5.2 *Measuring conviviality*

Having confirmed visually that Superkilen was a convivial environment, we ran the checklist, in order to measure conviviality and therefore diagnose the park. The score results can be seen in figure 6. All but one of the design features scored maximum (2 points), meaning that they strongly support conviviality. The exception was 'vegetation', since only two main varieties of plants were found that accommodate to cultural variances in the park's users (1 point).

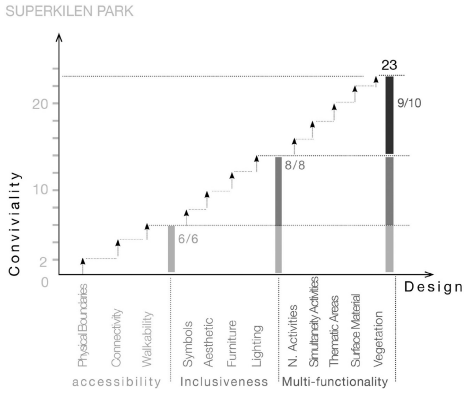

Figure 6. Conviviality vs design graph representing Conviviality scores in Superkilen.

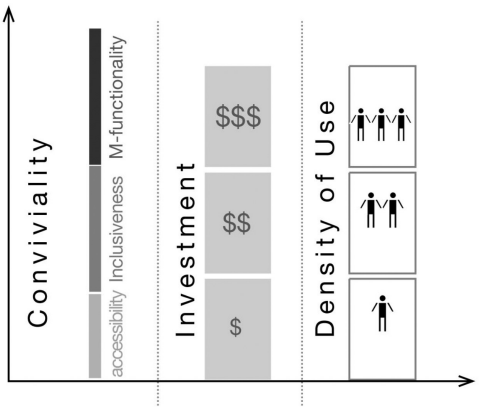

Figure 7. Conceptual graph to compare conviviality levels (accessibility + inclusiveness + multi-functionality), investment and density of use (number of people/size of park).

6 CONCLUSIONS

We selected Superkilen Park, intended from its inception as a place to unify a diverse neighborhood, as a case study for piloting our methodology for diagnosing conviviality in the people's park. We went there to see if we could observe the behavioral results of the designers' decisions. What we observed was a robustly convivial environment, reflected in the coded images. When we measured conviviality according to the checklist, we found correlations between observed conviviality and the scores.

Superkilen has proven to be a good example of a convivial 'people's park', providing a reference measurement for comparison with other parks. In future research we will test this checklist in additional people's parks, including examples anecdotally considered successful and unsuccessful, in order to validate the methodology.

The significance of the research lies in the development of the checklist, potentially useful both in the design process and in post-occupancy evaluation. Designers facing the commission of a new park can use the checklist as a tool. It can also be used to diagnose existing underperforming parks. It can serve as an important tool for diverse communities in the design and evaluation of everyday urban public spaces that foster conviviality.

Since a people's park usually requires a large investment of money, it will also be relevant to compare the conviviality levels obtained in a post-occupancy evaluation with the money directly invested in the design of the park and the density of people ultimately using it. A very straightforward comparison (see figure 7) between the conviviality score, the investment made and the density of use might tell us whether the park is efficient, whether it was a good investment, whether conviviality happens no matter the investment made or whether the three variables have no connection whatsoever. This graph can be used to compare parks of different geographical location or economic/social/political context, to extract useful findings.

This research contributes a small but useful tool, particularly relevant today as communities confront the problems of rapid diversification. As formerly homogeneous neighborhoods take in a more diverse population, it is important to create spaces that welcome diversity and promote tolerant and respectful social interactions. The people's park, designed for conviviality, is a powerful force for building a sustainable social fabric.

Evidence-based design of outdoor learning spaces in winter: Behavioral mapping in a 'Forest School'

A. Rout
Computational Media Design, University of Calgary, Calgary, Canada

P. Galpern
Faculty of Environmental Design, University of Calgary, Calgary, Canada

ABSTRACT: Outdoor learning spaces can be used to support child development where children engage with natural elements as an integral part of their school experience. This naturally facilitates cognitive play: a grouping of behaviors that facilitate cognitive development. The problem is that outdoor learning is particularly challenging in winter due to cold weather. This compromises opportunities for children to benefit from outdoor learning for a large part of the school year in cold climates. Previous studies, using behavioral mapping, have pointed to the role that design elements play in child development; although these studies were conducted in warm weather. Our solution is to map child behaviors in schools where outdoor play is encouraged during winter, to illustrate the role that design elements play in winter outdoor learning, and to enable us to highlight challenges of winter outdoor learning that may be addressed through design interventions. We observed three schools which are dedicated to outdoor learning, during winter in a cold climate, using behavioral mapping, focused observations and photo documentation. Our analysis confirms that outdoor winter environments support cognitive play, and we discuss design interventions that can mitigate challenges faced by schools dedicated to outdoor learning in winter.

1 INTRODUCTION

Numerous studies indicate the benefits for children of playing outdoors in natural settings (Fjørtoft & Sageie 2000, Ozdemir, Corakci, Özdemir, Çorakçi, Ozdemir, Corakci, Özdemir, & Çorakçi 2010). Outdoor play may counteract the public health implications of increasing childhood obesity (Ebbeling, Pawlak, & Ludwig 2002) and concerns that children are suffering from nature deficit disorder, caused by the lack of connection to natural environments (Louv 2008). Changes in outdoor physical activity have been related to season and weather, with reductions in activity particularly evident for children who attend indoor schools during winter months (Tucker & Gilliland 2007). This study investigates the design features of 'Forest Schools' in a cold climate to better understand how design elements can support outdoor play in learning environments during winter. The intention is that the study can be used by designers of schools incorporating outdoor classrooms, and to support child learning in outdoor settings during winter months.

1.1 *Forest School approach*

The Forest School approach, developed in Denmark and Britain over the last twenty years is a response to a perceived nature deficit in early-childhood education (Maynard 2007). More recently these schools are opening in large centers across Canada (Andrachuk, Edgar, Eperjesi, Filler, Groves, Kaknevicius, Lahtinen, Molyneux, Morcom, Petrini, Piersol, Power, & Young 2014). These schools offer programs which engage children in outdoor play in natural settings. Three schools that adopt the Forest School approach operate in both rural and suburban settings in Calgary, Canada, and enable outdoor play throughout the winter. This study looks at these schools to examine how design features support outdoor play in winter, and identify opportunities for new design elements that may further facilitate the objectives of the school.

The Forest School pedagogical approach has been described as social constructivist (O'Brien 2009) in that it enables learning through examination and engagement with the natural environment, and requires students to construct their understanding of curriculum through experience; interacting independently and with one another. The school uses hands-on experiences in a natural woodland setting to build confidence and self-esteem in children. The school's approach enables children to prioritize learning through guided play, rather than instructor-centered activities. In the schools observed, there is no

delineation between "play time" and "learning time", instead the children follow a flexible pattern of activities through the day that is outlined by the teacher, where play and learning occur in tandem.

This study utilizes focused observations using a *fly on-the-wall* approach (Moggridge & Atkinson 2007), behavioral mapping (Moore & Cosco 2010) and photo documentation. The focused observations were used as a qualitative approach to design-research, where a researcher with a design background (architectural design) observed the school activities without interfering.

1.2 *Behavioral mapping and cognitive play*

Behavioral mapping was incorporated as a quantitative method to observe and record the play behaviors of the students in relation to environmental features at the school. The method records cognitive play behaviors as a means to evaluate design features. The United Nations Convention on the Rights of the Child states that all children have the right to play (article 31). Play is important not only for developing physical abilities, or letting off steam (Ozdemir, & Corakci 2010) but is critical for developmental learning (Herrington & Brussoni 2015). Cognitive play is a grouping of play behaviors that allow children to engage with an environment and learn through their interactions with it (Malone & Tranter 2003). The current study uses Rubin's play observation scale to identify five cognitive play behaviors: functional, constructive, dramatic, explorative and games-with-rules (Rubin 2001).

Behavioral mapping has been used as a method for evaluating children's outdoor play areas, and is suggested as a research method that would be useful for designers to gather information about a design project (Moore & Cosco 2010, Ozdemir, & Corakci 2010, Cosco 2006, Herrington & Brussoni 2015, Zamani & Moore 2013). In their study of manufactured elements in preschool settings Zamani and Moore (2008) use behavioral mapping to identify design recommendations to incorporate features that afford cognitive behaviors. In this research mapping is used to evaluate outdoor classroom elements at three Forest School locations, in order to identify opportunities where design interventions would further benefit the objectives of the school.

1.3 *Affordance theory*

Gibson's affordance theory presents the environment in terms of features which afford possibilities for numerous types of actions (Gibson 1979). The theory describes the relationship between an environmental feature and human perception and use. The use or function of an object is dependent on the qualities of the object itself as well as the abilities, perceptions and desires of the human. Environmental features provide opportunities for human engagement – such as a tree with low branches which affords climbing. Affordance theory is usefuline valuating children's outdoor play spaces because it enables a researcher to evaluate certain elements of a design by the behaviors that it affords (Cosco, Moore, & Islam 2010).

Table 1. Environmental Features Categories. Shows groupings of the environmental features that were used in this study.

Environmental Setting	Examples
Bushes	Bushy branches

Affordance theory has been expanded upon by Heft who developed a framework for evaluating environments. Through analysis of multiple behavioral studies of children he designed a preliminary taxonomy of environmental features (Heft 1988). Heft argues that understanding the affordances of an environment is more useful for evaluating a design than simply stating the form of an object. In other words, when designing a play space for children it is more useful to understand a tree as something that is "climb-able", or "hide-behind-able", than it is to say it is a tree. Heft's taxonomy has been used and customized for various environments, and has been applied in the context of interviews (Korpela, Kyttä, & Hartig 2002) and behavioral mapping (Zamani & Moore 2013).

2 ANALYSIS

2.1 *The Schools*

The research was conducted in Calgary, Canada at three schools which incorporate a Forest School approach. There are three locations for the schools. Two are located just south of the city in a rural area, these both utilize a public park near a lake (the Lake Site). One of these utilizes the community hall amenity as a classroom (Preschool 1) and the other has use of a classroom at a private school in the area (Nature

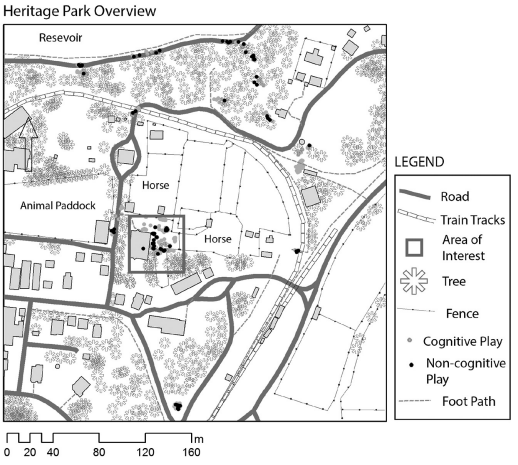

Figure 1. Overview map of Heritage Park showing distance travelled by Preschool 2. Map shows the different locations visited by students and the extent of travel across the site.

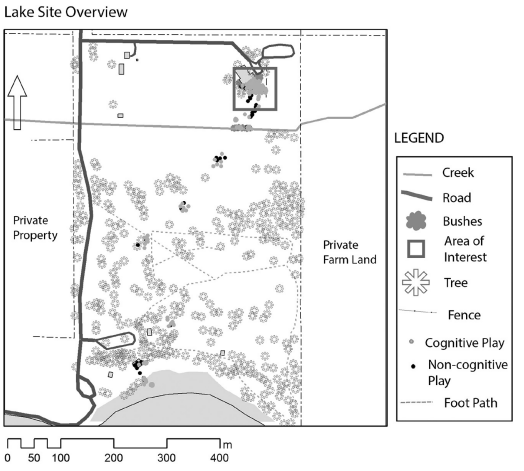

Figure 2. Overview map of the Lake Site, showing distance travelled by Nature Kindergarten and Preschool 1. Map shows extent of excursions travelled by students and the diversity of the landscapes visited. Lake Site is larger than Heritage Park with fewer man-made features.

Kindergarten). The third school is located within the city limits (Preschool 2). It has temporary use of a city-owned cultural amenity called "Heritage Park" for the winter months.

Preschool 1 and 2 provide programs for preschool children age 3–4 from 9:30 am–2:30 pm. Children attend the school for either 1 or 2 days a week. The objective of the school is to encourage outdoor learning, but the school also utilizes indoor classrooms. The Lake Site is a rural prairie landscape with many small patches of trees, some scrub and bushes, a creek and one more densely forested area. Preschool 2 is located in a cultural park, which uses heritage buildings and Park elements, to create a historical museum amenity. The park is not open to the public in winter months and Preschool 2 has access to all outdoor, unfenced parts of the site as well as a building for a classroom. Heritage Park has a large forested area, walkways and open spaces that are used by the school.

The Nature Kindergarten is a kindergarten for children aged 5–6 focused around the objectives of the Forest School. It utilizes the Lake Site, as well as a classroom in a nearby private school. Students attend the school for either a 2 day or a 3 day program. Both the 2 day and the three day spend one day a week almost entirely outdoors, where they are dropped off at the lake edge by their parents and throughout the day they traverse the property to the community hall, and return back to the lake for afternoon pick-up (see Fig. 2).

These schools were selected as a subject for the study because of their inherent interest in engaging children in long periods of outdoor play, even in winter. Even though the schools have heated classroom facilities and spend more time indoors on very cold days, there is a desire to engage children outdoors as much as possible. The three sites are complimentary in that they offer a range of environments within the same climate to support the study outcomes. The study was conducted in January which is, on average, the coldest month of the year in the Calgary region. The study was conducted over two weeks enabling observations to occur with multiple groups of children on the three sites. In total 56 children were observed over eight days.

2.2 *Climate*

The temperature of the days the study was taken ranged from −6 degrees to 9 degrees Celsius. (Environment Canada 2016). There was fresh snow on the ground which changed in consistency and malleability over the course of the study due to night freezing and varying temperatures during the days. Despite a tendency for Calgary to experience Chinooks (unusually warm weather from mountain wind) it is typical for much of the ground to be covered in snow in January. Calgary averages 54.2 days of snowfall a year and for at least 84 days per year (one quarter of the year)it is expected there will be at least 1 cm of snow on the ground.

2.3 *Methods*

The purpose of this study is to evaluate current design features of three Forest Schools, using evidence-based observations, in order to support the school's winter curriculum, and identify opportunities for design improvements. We examine the following research question: Which existing design elements are currently being used to support the Forest School objective of learning through outdoor play? The play behaviors were recorded using Rubin's play observation scale (Rubin 2001) which was slightly adjusted for this study. Behaviors recorded include the five cognitive behaviors described by Rubin as well as the non-cognitive play behaviors recommended in Rubin's

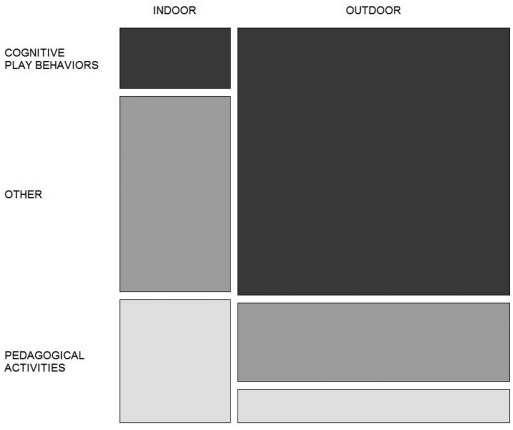

Figure 3. Chart indicating indoor and outdoor play. Area of each rectangle represents the percentage of total time observed displaying a behavior in an environment, demonstrating that outdoors afforded more cognitive play behaviors than indoors, and pedagogical activities were mostly observed indoors.

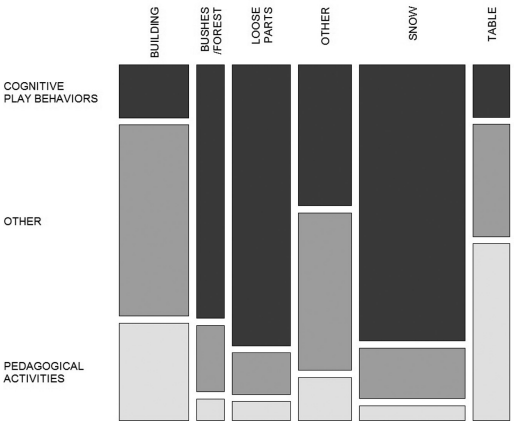

Figure 4. Chart indicating environments and afforded behaviors. Area of each rectangle represents the percentage of total time observed displaying a behavior in an environment, demonstrating that snow afforded the most cognitive behaviors, followed by loose-parts.

method. These include: transitional, onlooker, uncodable, hovering, rough and tumble, aggression, peer conversation, and unoccupied. Three additional activities were also included, these were: eating, instruction and curriculum activities.

The observations were conducted during three days with Preschool 1, two days with the Nature Kindergarten and three days with Preschool 2. *Fly-on-the wall* observations started near the beginning of the school day between 9:30–10:00 am and the close of the day at 2:00–2:30 pm. The observer participated in all class outings and activities while present at the site. The observer, through note-taking and observations looked to identify ways that current design features support the objectives of the school, as well as opportunities where new design features would be of benefit.

The behavioral mapping was conducted at the same time. The observer recorded observations at five minute intervals for one hour in the morning and one hour in the afternoon (between 10:00 am–11:00 am and 1:00 pm–2:00 pm). At every observation each student was observed for 10–15 seconds, their play behavior and environmental feature was recorded with pencil in a record sheet, as well as a location marker on paper maps of the site. Location markers were transferred to GIS software after the study was complete. Between 6–10 children were recorded each day. In total there were 1633 unique spatial and temporal observations collected for 56 children.

The behavior mapping times were carefully selected in conversation with the teachers at the school because they were the most likely times to observe children in active play and learning. Due to the approach taken by the school there is no set "recess time" or set "class time". The two pedagogical activities that were added were "instruction" and "curriculum activities". Instruction was coded as one-on-one instruction from a teacher as well as group instruction.

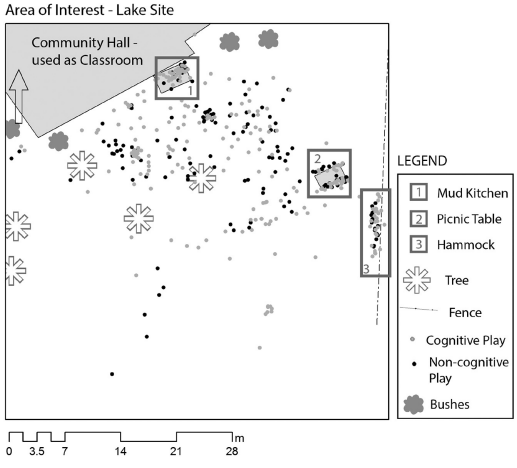

Figure 5. Close up of the Lake Site showing cognitive behaviors at the hammock, picnic table and the mud kitchen, identifying spatial and temporal associations with key design elements.

Curriculum activities included projects or activities provided by the teachers, which were at times optional and at other times conducted as a group activity. A grouping of environmental features was developed specifically for this study (see Table 1). The environmental feature groupings were based on previous studies (Zamani & Moore 2013, Heft 1988, Cosco 2006) and adapted to the available features at the site. GIS locations were recorded and analyzed based on proximity to an environmental feature and the behavior recorded at that site.

Photographs of the overall site, the indoor classrooms and the individual environmental features were taken as a record of the various elements, and as a reference for comparison (not included here). The

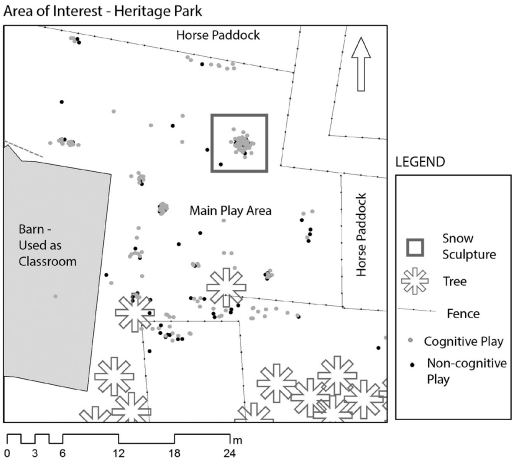

Figure 6. Close up of Heritage Park showing concentration of cognitive behaviors at the 'snow sculpture', a structure built out of snow, by the students, that afforded the most cognitive play behaviors in this environment.

photographs are used to visually describe the characteristics of the available features. Consent for the observations was obtained through emails that were sent out to parents and teachers explaining the intent of the research. Signed consent forms were collected at the school locations. Research was approved through the University of Calgary Conjoint Faculties Ethics Research Board.

2.4 *Results*

Chi-squared test of independence was conducted on behavioral and environmental data. Results reject the hypothesis that there is independence between environments and behaviors ($p < 0.01$, $df = 24$), indicating that there is an association between these elements. The environmental feature that afforded the most cognitive play behaviors was snow, with functional and constructive behaviors being observed the most. This agrees with other studies which cited "natural loose" elements as affording mostly constructive behaviors (Zamani & Moore 2013). The unique features of snow is that is can provide for a wide range of activities, due to its malleability and constructability. Snow was observed being used create structures (constructive play) which were later used to afford functional play (climbing), and dramatic play (playing house) (see Fig. 6). Some challenges with snow were observed during *fly-on-the-wall* observations. Snow is cold and if children lose their mittens or are not dressed appropriately they may want to go inside. When snow melts it is wet, which can cause children to be uncomfortable if their snow clothing is not also waterproof. Snow consistency and maleability changes due to temperature, which meant it could not be depended on for specific activities. In addition snow does not afford fast running or wheeled toys. Despite this, snow afforded the most cognitive behaviors (see Table 2) with functional, constructive and dramatic being the most observed. In addition, the children interacted with snow for the majority of the time spent outdoors (see Fig. 4).

Loose-parts were second in affording cognitive play behaviors (see Fig. 4 and Table 2). It was observed that loose-parts work in combination with snow to provide an environment which affords cognitive play. Common loose-parts were shovels and buckets which were used in constructive and functional play. Hammocks were hung from an existing fence and afforded functional play. The loose-parts element that afforded the most dramatic play was the mud kitchen (Fig. 5). Instruction was observed in all environments, but curriculum activities were most common at a table (see Table 2).

The non-cognitive behavior most observed was transitional time, mostly related to children getting dressed to go outside. The regular routine involves coming indoors to go to the bathroom and eat lunch or snack both at the beginning of the day and in the middle of the day. This results in at least two times a day when children spend time dressing and undressing for the weather. The ability to get oneself dressed in snow gear is a part of the learning process and children are encouraged to get themselves ready. Some children are able to get read in a shorter amount of time, but for safety reasons they wait for their peers or for a teacher to accompany them outside. Travel on the site was observed in all three schools.

Travel in this study refers to an excursion where preparation was required, and the class would travel on foot, as a group, to new environmental landscapes on their site. Travel is far enough from the main classroom that students could not pop-in and out if needed. As seen on the overall maps of the two sites (see Fig. 1 and 2), the students did not remain in the outdoor area near the classroom. 36% of the observed time was spent more than 40 m from the main classroom (see Fig. 7 and 8). It was observed that a 40 m radius from the main classroom indicated the distance that play would occur without travel. Travel across the site was either used to support the pedagogy, or requested by the students as a way to visit their favorite spots. Both the Heritage Park site and the Lake Site have forested areas which required travel to visit. There were days when the students requested to visit the forest but they were unable to go because there was not enough time to walk there and back. Previous research has shown that a variety of landscape features is important in developing child play environments (Fjørtoft & Sageie 2000), and it is felt by the researchers that travel is an important feature of the school's approach to outdoor learning.

Games with rules was the cognitive play behavior that was least observed (see Table 2). This may be due to the age of the children, as well as the lack of available traditional game-type elements such as balls or sports equipment. This may also have been a result of the snow-covered ground. Exploratory was the second lowest observed cognitive play behavior. Exploratory was observed mostly in the forest and in the open. These behaviors were observed including exploring a

Table 2. Percentage of total observed behaviors and environments, indicating the relative observed prevalence of behaviors within each environment category.

Behavior	Building	Loose-parts	Other	Snow	Table
Constructive	0.6	2.3	0.8	7.3	2.0
Dramatic	1.4	3.9	1.7	3.8	0.4
Exploratory	0.6	1.5	5.1	1.0	0.2
Functional	0.5	5.9	4.0	12.3	0.7
Games	0.0	0.0	0.4	0.0	0.0

Other	4.0	1.6	5.9	3.6	3.2

new part of the forest, looking at tracks, looking for something or making new discoveries in the snow or ice due to changes in temperature.

Cognitive play behaviors, as a percentage of time spent in outdoor and indoor spaces, were higher outdoors (see Fig. 3). Chi-squared test of independence was conducted to determine the association between indoor and outdoor environments and observed behaviors. Test results indicate that indoor and outdoor environments are not independent from the observed behaviors, and are therefore associated with each other ($p < 0.01$, $df = 16$). Reasons for this may have been that much of the indoor time was spent in transition (putting coats on) or pedagogical activities. It is unclear whether the reasons for this difference is due to the space being more suitable for structured learning, or whether structured activities are needed indoors to keep the children engaged. Further study is required to explain the reasons for these differences.

2.5 *Discussion*

Outdoor play in natural settings for children in winter landscapes affords a variety of beneficial cognitive play behaviors. Snow, being present only in winter affords beneficial play and in combination with the appropriate loose-parts, winter landscapes can afford all play behaviors for children. This concept is supported both by previous studies which demonstrate the role of natural loose elements and manufactured loose elements, as well as previous Forest School and outdoor play space evaluations (Herrington & Brussoni 2015, Fjørtoft & Sageie 2000, O'Brien 2009, Zamani & Moore 2013, Cosco 2006).

The overall design implications are thus related to enabling children to engage with outdoor natural elements for longer periods of time. This includes being able to travel further distances on the site, and be able to stay there for longer periods of time without returning to the indoor classroom. Elements that are currently used that support playing outside longer were loose-parts, particularly buckets, shovels, hammocks

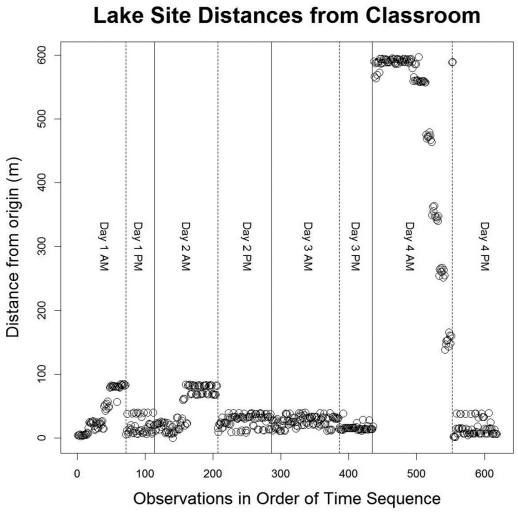

Figure 7. Distances traveled by students at the Lake Site, indicating students raveled up to 600 m from the classroom on Day 4 and 90 m from the classroom on Days 1 and 2.

and sleds. Shelters provided at the Lake Site enable students to eat outdoors which reduces the transition time involved in changing into snow clothes. Design elements that would support staying outside longer could include a deck or intermediate outdoor space between the classroom and outdoors where students could eat, participate in curriculum activities and have shelter from snow and rain without removing snow clothes. Outdoor storage to keep school supplies from weather damage and would allow access from outdoors would also support extended outdoor time. Access to washrooms from outdoors without full removal of snow clothes would lower transitional times. Elements that support curriculum activities outdoors could include seating that is off the ground, and table top surfaces that are flat and sturdy enough to support paint jars and other containers without tipping.

Design features that currently support the students traveling a distance from the buildings include sleds and teacher's backpacks; which carry tools, dry mittens, teacher's supplies, safety equipment, art clipboards and pencils. Features on the site which function as partial shelter are lean-to and tipi-like shelters that have been constructed in previous weeks. Opportunities for design to support students traveling farther from their main classroom include pre-built stations, or portable sled-like elements that would include a place to go to the bathroom, shelter, a chance to warm up or dry off, opportunity to sleep/nap off the ground, seating, storage or tools or equipment, a table surface and mud kitchen elements.

The researchers felt that behavioral mapping was a useful method for collecting quantitative data about the activities of children at the Forest School. The maps provide a visual representation of the daily activities, and information about the distance children traveled. The coding sheet provided adequate data to support

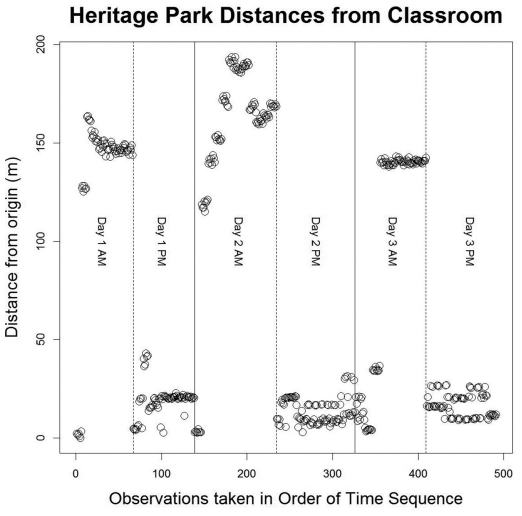

Figure 8. Distances traveled by students at Heritage Park, showing students traveled as far as 198 m from the classroom Day 2 and traveled, at least 145 m from their classroom each other day.

design decisions and statistical analysis, although the researchers felt that the behavioral mapping results were not sufficient to generate new design recommendations without additional observation methods. This is because the mapping results do not indicate the reasons for behaviors, or the role that teachers or pedagogy play in student dynamics. In addition, mapping can only evaluate a current design, but cannot generate new ideas, particularly innovative solutions that have no existing examples to test. It is the opinion of the researchers that observational research should be conducted by designers themselves in order to understand the complexities and subtleties that are difficult to portray in study results. Without being present during the research, it can be challenging for a designer to translate numeric data in a way that gives a holistic picture of design problems or points to innovative solutions. In addition, if a designer is a part of the research process they can help identify research questions that are useful for design, as well as analysis methods that will pin point relevant findings.

2.6 *Limitations of the study*

Limitations of the study include the difficulty in separating free play from pedagogical activities. For this reason it is difficult to determine if environmental feature affordances were the cause of a behavior or if it was influence from a program or teacher. Mapping of the spaces was challenging due to the size of the sites. The role that snow and winter elements play in the study are difficult to compare without a summer baseline study. Despite these limitations it is felt that the study was able to record the activities of the children and demonstrate the ways that the environment supported the objectives of the school. Even though the size of the site made mapping challenging, the resulting graphics were helpful in describing the movement of the students on the site and associated behaviors. Despite not having a previous study conducted in summer to use as a baseline, previous studies conducted through qualitative research and behavioral mapping of children's play areas can function as a comparison.

3 CONCLUSION

Through an observational study of three Forest Schools, this study evaluates two outdoor learning spaces in winter. Educators at these schools have been resourceful in using suburban and rural locations for the program, often repurposing various structures and facilities to serve their needs. Design elements, particularly snow, loose-parts and a natural site with a variety of landscapes, have been successful in meeting the objectives of the school and in engaging learning outdoors in winter. Overall the students were observed engaging in cognitive play behaviours for the majority of their time spent outdoors. Design recommendations revolve around developing built areas around the building, indoor spaces that reduce transition times and pre-built stations on the site to further facilitate child engagement with natural elements.

The study results support the conclusions of previous studies conducted in warmer weather: that outdoor natural play environments afford cognitive play behaviors. Snow was the environmental feature that afforded the most cognitive play behaviors, which indicates that snowy winter environments can support cognitive play and learning. Loose-parts, such as shovels, buckets, hammocks and a mud kitchen, afforded the second most cognitive play behaviors. Games with rules, was the least observed cognitive behavior, suggesting that the available environmental features do not afford these activities. Design interventions that enable outdoor learning in winter will provide opportunities for cognitive play. It is recommended that design solutions be developed that reduce transition time. It is also recommended that design interventions that support children's travel on the site be considered. Behavioral mapping was considered by the researchers as a useful method for evidence based design when used in conjunction with other observational methods.

Re-naturalization of post-war housing estates in Poland. The value of residential green space

E. Przesmycka & Z. Napieralska
Wrocław University of Technology, Wrocław, Poland

ABSTRACT: The authors raise an issue of creation common spaces in the post-war multifamily housing areas in Poland, and how does those common spaces affects on life quality of inhabitants. The subject of studies covers three housing estates in Warsaw, Cracow and Lublin, created between 1940s, 1950s, 1960s in the context of the present trends of transformation and preservation of their spatial, natural and architectural values The article will both present examples of well-functioning, common green areas in multifamily housing complex and also will indicate what are main problems associated with badly solved or lack of common green spaces . Presented residential settlements has derived from the idea of the 'garden city" by Ebenezer Howard. This idea has determined the shape and space quality of those settlements, makes them still attractive places for living.

1 HISTORICAL BACKGROUND OF HOUSE SETTLEMENTS IN POLAND

1.1 *Polish house estates before World War 2*

In 1898, in the publication of the book *"Tomorrow: A Peaceful Path to Real Reform",* Englishman Sir Ebenezer Howard presented a model of a radially-concentric garden city, as a response to the crisis in the second half of the nineteenth century. According to Howard's concept, the Garden City would create favorable living conditions in health and harmony for the entire community, combining the advantages of living in the countryside and in the city (Howard 1902). This idea became the drive for the development of new urban concepts and a solution to social problems. It was implemented for the first time in 1903, in the housing estate of Letchworth, near London, designed by Raymond Unwin and Barry Parker (*Conversation* . . . 2013). Although the housing estate designed in a suburban village failed to fulfill its role in its entirety, the founding ideas of Howard were adopted in various urban planning solutions worldwide. Howard's urban planning concept was in its heyday in Western Europe in the pre-war period, mainly in England. Also in Poland, these concepts were propagated by architects and urban planners designing interwar housing estates in Poland. An example would be the village of Ząbki near Warsaw (designed by Tadeusz Tołwiński) (Tołwiński, 1963), or the Garden City of Młociny near Warsaw (designed by I. Miśkiewicz). According to Professor Tadeusz Tołwiński (1887–1951), one of the most important factors in the urban and architectural creation were natural conditions, among them green spaces, as the basis for good urban planning – from health to aesthetics (Toeplitz 1937). Polish pre-war garden cities were located mostly on forested land, in good natural conditions. More often than whole cities, under the influence of Howard's concept, garden housing estates were implemented in such a manner to form residential facilities for the rapidly growing urban centers (*Creating* . . . 2013). The latest European trends in the design of urban housing estates were already known and used.

In 1932, the Polish Association of Housing Reform (PTRM) was founded. It has popularized the achievements of the new, worldwide, urban planning. In many publications on the development of residential areas, engineer-gardeners drew ways of shaping public green areas, allotments and other green spaces. Solutions of housing estates, where houses were located in a common park, with no private gardens, were presented. This was reflected in the design of newly established housing estates, as a coherent "well-functioning organism" (Przesmycka & Przesmycka, 2005). Both in professional journals and in daily newspapers, the importance of creating harmonious housing estate gardens was emphasized, taking into account their functionality. Garden began to be treated as a continuation of the apartment (Lynch, 1960). The creation of lawns, planting beds of perennials, such as plantings of roses were recommended. At the same time, it pointed to the need to design recreational spaces for the elderly and children's playgrounds, in conjunction with the use of plants that closed these spaces (Gehl, 1971). It was pointed out to the importance of hedges that do not create optical barriers for the observation of green bushes and colours of flowers planted in gardens. The costs of setting up residential gardens were estimated at 5–8% of the building price, which proves attaching great importance to the proper management of the buildings' surroundings. Even then, uniform fencing and flexibility in terms of planting by the inhabitants of their land was proposed.

It was suggested to plant trees according to a uniform plan, which gave the impression of more space.

1.2 *Housing estates in Poland after World War 2*

In the post-war period, Poland was under the influence of the Soviet Union, which translated into a change of the political system, elimination of private property, nationalization of industry and large landed property.

War damage, changing the country's borders, industry development, all resulted in the migration of rural population to urban areas. This necessitated an unprecedented pace of building housing estates. For the purpose of the developing industry, numerous large housing complexes were erected, most frequently occupying the formerly nationalized agricultural lands located on the outskirts of cities. This gave the opportunity to implement the whole residential neighborhoods, often for several or even tens of thousands of residents. Simplified and typified residential buildings originally based on Soviet patterns were positioned in attractive locations, not sparing the area, which allowed for the creation of large housing estates earmarked for playgrounds, recreation and design of green spaces. Fortunately, many contemporary designers were architects educated before the war, who were able to introduce Howard's concepts in the design of large public housing complexes for 30, 40 or 50 thousand residents (Skibniewska 1979). These housing estates were created mostly in the way of architectural competitions until the 1980s.

1.3 *Housing estates in Poland after transformation*

After 1989, Polish political changes began a new era in the urbanization. The ideas of state or cooperative housing estates or housing estates built for employees of industrial plants failed. Political changes also resulted in the transformation of the spatial structure of housing estates erected in the communist period. A change in the legislation allowed for the privatization of individual buildings, and hence the separation of the public space that belonged to them. This resulted in the possibility of compacting the building arrangement at the expense of green areas.

Currently, especially in large cities, the participation of local communities in efforts to shape the neighborhood spaces is increasing. Residents are beginning to appreciate the value of green spaces. The aging population begins to take its own initiative: revitalization of residential spaces (Przesmycka & Przesmycka 2011). Of course, this is being done with varying degrees of success, but it signifies the importance of the social factor in taking the initiative to improve the quality of residential spaces. Both formerly planted high greenery, small ponds, playgrounds no longer meet today's standards, and they need attention. Sometimes residents take the initiative in their own hands – most often in the immediate vicinity of their place of residence. There are many grassroots initiatives that prove the formation of bonds in the local communities that initiate the processes of restoring natural functions and giving them new spatial forms. Of course, these processes do not follow the same pattern in all housing estates. Often it is the city authorities and the administration of estates who decide on what is going to be changed or retained.

Housing estates selected for the analysis of transformations are representative of the different periods of the formation of the urban planning assumptions for housing estates. Post-war housing estates are represented by means of the example of Nowa Huta, currently a residential district of Cracow at Lenin Steelworks (1948). The Sady Żoliborskie housing estate presents an example of design with preservation of natural space, which was found in the cases of implementation of Polish housing estates in the 1960s and 1970s. The third example are the Juliusz Słowacki housing estates in Lublin, designed by Oskar Hansen, where a large role was played by the use of natural conditions (configuration of the terrain and the existing greenery). All housing estates are linked by the problem of "aging" of the residents and inadequacy of public and semi-public spaces to the changing needs of the users. The zoning and segregation of transportation designed at that time allowed collision-free vehicle and pedestrian traffic, but it does not meet many of today's requirements.

2 AIM AND METHODOLOGY OF THE STUDY

The subject of studies covers three housing estates in Warsaw, Cracow and Lublin, created between 1940s, 1950s, 1960s in the context of the present trends of transformation and preservation of their spatial, natural and architectural values. These housing estates are characterized by reference to the concept of garden cities by E. Howard. The authors examine the condition of the ongoing activities in order to maintain their natural and urban planning values and determine the possibility of carrying out the effective re-naturalization processes in the Polish legal and economic conditions. Research is carried out against the background of the historical perspective of the implementation of housing estates in Poland as integral parts of the garden city concepts. They refer to the European implementation of the restoration and creation of a garden city by means of the example of Letchworth Garden City.

3 NOWA HUTA SETTLEMENT, CRACOW

Nowa Huta was founded originally as a satellite town near Cracow. The city was to provide social facilities for the steelworks. Currently, it is a Cracow district.

Nowa Huta and its subsequent housing estates were erected over the period of several decades, representing urban planning and architectural assumptions typical of the period of socialist realism until the late modernism. Over the years, the nature of development,

Figure 1. Nowa Huta, An aerial view from the south, along the main N-S compositional axis. Source: Wikimedia .org https://upload.wikimedia.org/wikipedia/commons/2/2e/Nowa_Huta_jako_idealne_socjalistyczne_miasto.jpg.

Figure 3. Nowa Huta, green, common space between block of flats. Author: E. Przesmycka, 2016.

its intensity and quality of new buildings has changed.

Work on the Nowa Huta design began immediately after the war, in 1948. There were different design groups working on urban plan of Nowa Huta, but the main part of this settlement has designed Tadeusz Ptaszycki with his team. Apart from the obvious attention to recreational and green areas at the planning stage, the city of Nowa Huta primarily formed part of Howard's concept thanks to its urban grid with clearly separated green center, extensive residential complexes, with broad thoroughfares in the form of alleys with planted trees (Fig. 1). Designed green areas of the housing estate combined the elements of the town's historical stylistics (rows of trees) with the ideas of the interwar functionalism (Fig. 2) (Dobrzycki, 1955). The first part of the housing estate was located nearest the plant – Lenin steelworks; this was carried out strictly according to the first, classicising design. The estates were characterized by an intimate scale and a traditional form, modeled on pre-war residential areas. It was dominated by a small residential building pattern for several families in an environment of the designed, diverse vegetation. The favorite tree species were Italian poplars, and beds of roses were planted along the main avenue (Kosiński, 2011).

After 1990, like most of housing estates of that period, Nowa Huta lapsed in lethargy for several years. Lack of management concept, the impoverishment of residents – former employees of the decaying steelworks, were additional factors that contributed to the degradation of the residential space. Over the next several years, the situation faced by Nowa Huta and similar housing estates from 1950s have changed. Nowa Huta began to be perceived as an example of an attractive urban concept. Its attractiveness lies in the presence of green spaces and public spaces between blocks of flats (Fig. 3) (*Lokalny Program* . . . 2008). Also, the aesthetics of the socialist realism architecture is now regarded positively. This change in the public perception of housing estates from the 1950s meant that it is easier to obtain funding for the on-going revitalization. The breakthrough came with Poland's accession to the EU and the opportunity to acquire EU funds, which helped start work on improving the standards of the utility spaces, as well as individual residential buildings. Currently, numerous revitalization projects are being implemented, from improvement of public transport to the recovery of the social infrastructure.

4 SADY ŻOLIBORSKIE HOUSING ESTATE, WARSAW

The housing estate of Sady Żoliborskie in Warsaw is an example of the estate created at the end of the 1950s – i.e. after some easing of the communist regime in Poland.

The housing estate was created in the years 1958–1973 and was very modern. It is characterized by an open form, and it was freely composed – designed for the comfort of living. One of the objectives was the separation of the pedestrian from vehicle communication. Public transport was routed out to the outskirts of the housing estate. The challenge for the designer was

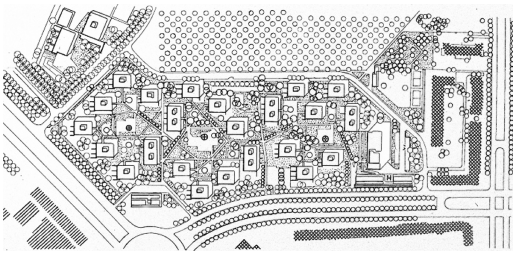

Figure 4. Sady Żoliborskie housing esate, urban plan. Source: H. Skibniewska 1974. *Rodzina a mieszkanie,* PAN, Warszawa.

Figure 5. Sady Żoliborskie housing estate, Warsaw, source: powojennymodernizm.com.

to preserve the tree stand existing on land intended for the construction of the housing estate, and integrating it in the space of residential buildings. Residential houses were designed as three- and four-story buildings, in a clearly rhythmic, spatial layout, split by wide alleys. Orchards, which were on the plot allocated for the construction of the housing estate, constituted the core of its urban planning. The author of the project integrated the line of new residential houses so as to avoid interference in the existing tree stand, and the felling of trees was the last resort (Fig. 4).

'If in the housing estate we are to erect a house and plant a tree at the same time, a resident is forced to wait for the tree twenty-five to thirty years. I know I must preserve everything that grows, because it allows me to quickly create a genuine environment.' (Skibniewska, 1974)

Today Sady Żoliborskie is a place where one can find the concept of the garden city, and residents identify with it. Well communicated with the Warsaw city center, it provides tranquility, green and interesting architecture that is embedded in the greenery. Several years ago, the whole complex underwent a thorough thermo-modernization. The value of the apartments in this neighborhood is high compared to the prices of the apartments in other neighborhoods of the same period and demonstrating similar utility values. This is an example of how the property value is affected by the quality of the urban assumption and natural values of the space, in which residential buildings are located (Fig. 5).

5 JULIUSZ SŁOWACKI HOUSING ESTATE, LUBLIN

In the first years after World War 2, the housing situation of Lublin was very unfavorable. Housing shortage caused by the ravages of war was further compounded by the investment neglect of the interwar period. Post-war Lublin ranked one of the highest cities in Poland in terms of residents per room. In the face of continuous population growth and the increasing housing shortage, the city authorities were interested in an inexpensive and intensive housing construction. The response to this unfavorable housing situation of the city was in the form of housing co-operatives (Przesmycka, 2009). One of the first such cooperatives in post-war Poland was established in Lublin. The new residential district of Lublin formed in so-called Rury Jezuickie. The land allocated for the construction of residential buildings managed by the Lublin Housing Cooperative (Lubelska Spółdzielnia Mieszkaniowa – LSM) occupied approx. 360 ha. Seven housing estates were created there. The first housing estate, erected in 1958 was the Adam Mickiewicz housing estate, while the next one was the Juliusz Słowacki housing estate. The first housing estates were characterized by exceptional care for green spaces. Small, three- and four-storey blocks were distributed quite freely on a hilly terrain. In the 1970s, the housing estate occupied 42 ha, of which 20 hectares were allocated for green areas, giving approx. 38 sq. m of green areas per resident. Importantly, the Adam Mickiewicz housing estate and the entire LSM district, when compared to the latter housing estates, were characterized by the favourable proportion of green areas in relation to the land for other purposes (Przesmycka & Sosnowska 2010). The Juliusz Słowacki housing estate was one of the most interesting urban planning and architectural assumptions created in the 1960s in Poland (Fig. 6). In that period, urban planning and architectural design were subordinated to the "top-down" defined standards and guidelines. These standards limited the size of apartments and housing space per resident, which was to ensure the greatest number of apartments in the building. As a result, buildings and apartments referred to as "typical" were made in the prefabricated and industrialized technologies. The housing estate was to be more densely built-up, cover a smaller area and serve more people. The authors of the housing estate design were Zofia and Oskar Hansen. They implemented it according to Oskar Hansen's original concept of "The Open Form". The designers wanted to make future residents design a layout of walls in their homes and determine the layout of windows and balconies – which in those days was a remarkable extravagance (Hansen 1965). The buildings were formed in such a way that they formed part of the natural, hilly terrain (Fig. 7). An important element of landscaping the public greenery was

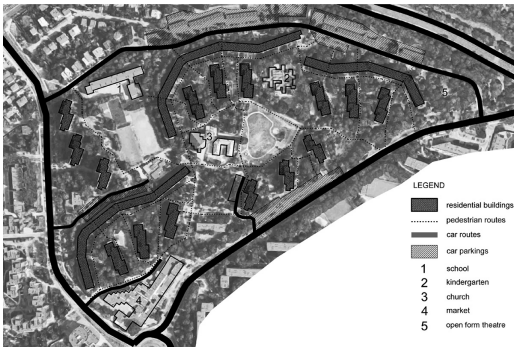

Figure 6. Juliusz Słowacki housing estate. Urban plan. Author: Z. Napieralska.

Figure 7. Juliusz Słowacki housing estate. Author: E. Przesmycka, 2016.

an open-form theater located in the highest part of the housing estate – a square having a sculpturally shaped form. Today, this part of the housing estate is devastated and not used.

In 1966, Hansen developed the Linear Continuous System (LSC) theory, which assumed a band division of the space into zones with different functions and a departure from the traditional division between the center and the periphery. Again, this concept has been applied in the design of the Juliusz Słowacki housing estate, where residential zones are separated by service areas and green areas (Fig. 8). The project assumed that in every place, the residential zone had a different relationship with green and service zones, but it was equal in terms of distance and ease of access (Hansen 1970).

The Open Form concept by Oskar Hansen and the concept of the Garden City are the examples of harmonious design of residential buildings and the natural environment in order to ensure a high quality of life. The Open Form concept assumed an additional opportunity to shape public space by each resident and the breakdown of the artist's supremacy in the design process – according to Hansen, the role of the designer was rather to be a guide (Hansen 2005). He believed that there was no such thing as a "typical person" for a "typical house", despite the ubiquitous typification in the architecture of the socialist era.

6 HOUSING ESTATES IN THE 1970S AND 1980S IN POLAND

The 1970s and 1980s were the peak period for industrialization and intensification of development in the housing sector in the countries of the Eastern bloc. Housing estates implemented in that period lacked a well thought-urban composition, and were characterized by high density of flats with a relatively free layout of buildings, which is not conducive to the formation of social spaces. Extremely little attention was paid to creating residential interiors. Residents gradually ceased to identify with such "dormitory towns" that were distant from the city center, while housing estate administrators paid no attention to the natural values of the settlements. It is hard to find in them traces of Howard's concepts, despite there were plenty of open spaces in housing estates of that period.

A common problem of the most of the housing estates created in the second half of the twentieth century in Poland is the lack of ongoing activities to prevent "the aging of buildings and residential spaces". Paradoxically, the absence of any corrective actions saved the original assumptions of greenery and landscaping elements in most of the housing estates. Today, they are a valuable evidence of the era and in many cases they begin to be perceived as elements of spatial identity of the housing estates.

7 CONCLUSIONS

Currently, we are observing a trend that is very important for the quality of life in post-war housing estates era of the People's Republic of Poland; this trend involved transformation and modernization of the neighborhood spaces (Przesmycka & Sosnowska 2012). The surfaces of sidewalks and roadways are being replaced and the necessary landscaping elements are being added, but these are often temporary measures, showing no traces of conscious design and respecting the existing urban planning concept. At this point, the question arises whether these housing

Figure 9. Letchworth Garden City, Great Britain. Author: E. Przesmycka, 2013.

estates may be saved by a comprehensive revitalization process, with particular emphasis on green areas?

In most of these housing estates, a sense of identification with the place of residence increases as a result of revitalization activities, the most important element of which is the re-naturalization.

In the housing estates of the second half of the twentieth century, greenery has reached the stage, where most of the tree species are in their maximum habits. Trees and shrubs require proper maintenance or replacement. Some forms of greenery (e.g. the so-called rockeries) are no longer fashionable. Over the years, the soil in the city undergoes irreversible sterilization and contamination, which causes dying out of valuable species (shrubs). Random plants planted by the residents often disturb the old landscape assumptions.

Functional and aesthetic arrangements of the greenery are conducive to strengthening neighborly bonds (Beatley, 2000). This is also linked to a sense of security in the area, improvement of natural environment values. Residents who get engaged in activities to improve the quality of their housing environment, identify with this space and feel more and more responsible for it.

The analysis of the presented housing estates demonstrates the need for the re-naturalization of green areas as part of the integrated revitalization processes. These processes have already begun in many cities; however, often they are not adequately managed. The problem is attempts to use the free space for dense arrangement of the buildings or allocating to missing parking spaces. The proper conduct of the revitalization process is conducted with the participation of the local community, which does not relieve the city authorities from responsibility for the natural environment in housing estates (Farr, 2008). Because of the large percentage of natural ecosystems in the urban structures, greenery should be particularly protected and cared for. The revitalization of Letchworth Garden City (Fig. 9) suggests that this is possible and demonstrates the positive effects of coordinated actions to improve the quality of historic housing estates and garden cities.

Industrial ruins. A re-cycling approach in researches for dismissed areas

A. Massarente
Department of Architecture, University of Ferrara, Italy

ABSTRACT: Ruins are one of the configurations through which architecture reveals its multitemporal dimension in a renaturalization process of the contemporary city. A specific character related to that question is readable in brownfield sites, in which is possible to highlight morphological interactions between ruins and buildings in sites involved in regeneration projects. In some research experiences these dismissed areas represent a possible network for testing settlement patterns more suitable for their regeneration and useful to get a more intense dialogue between different stakeholders. Among the possible elements oriented to the definition of such settlement patterns are: sequence of regeneration cycles through energy infrastructures in a multitemporal dimension; the link of these areas to network of networks formed by water infrastructure, roads and railways reinterpreted as new ecological corridors; legal and management subjects, planning tools at urban and regional scale, methods for mapping on a regional, urban and building scale.

1 INTRODUCTION

1.1 *A re-cycling approach*

In this text we will try to understand how a re-cycling approach could be seen as more radical than the re-using one in regeneration processes applied to brownfield sites, through the reference to the multitemporal dimension of ruin, at architectural scale, and to the role of waste landscapes or drosscapes, at territorial scale, in order to define more flexible aesthetic and design strategies.

2 MULTITEMPORAL DIMENSIONS OF RUINS

2.1 *Ruins and constructions*

Ruins are one of the most interesting configurations through which architecture reveals its multitemporal dimension.

Ruins are represented by figures through which it is possible to explore the hidden form, where it reveals not only the ways of its construction, but also the terms of its possible transformation.

In architectural history and theory – for example through the work of Baldassarre Peruzzi, John Soane, August Perre, Louis I. Kahn, Francesco Colonna, Georg Simmel – it is possible to read, in its theories and practices, traces of this fertile relationship between ruins and transformation.

A similar principle is applied, after the Renaissance, from those architects directly involved in archaeological research or interested in it (Tafuri 1980): as for example Giovanbattista Piranesi, Fischer von Erlach, Julien David Leroy, Antoine Desgodetz, Léon Dufourny, Bernard de Montfaucon, Pierre-Adrien Pâris, Giuseppe Valadier, Karl Haller von Hallerstein, Robert Cockerell, John Soane, Luigi Canina, Thomas Leverton Donaldson, Leo von Klenze, August Caristie, Jakob Ignaz Hittorf (Pousin 1993).

Many of these architects describe ancient monuments through representations – sections, prospective sections, elevations in different combinations –, which not only reproduce what you can see of those ruined spaces, but also what is not seen, i.e. the formal and tectonic principles that constitute its architectural space (Pinon 1993).

The theme of ruin has origins dating back at least to Francesco Petrarca, although the representation that opens the aesthetics of ruin (Borsi 1995) is the "destructo et deserto tempio" (Mortier 1974; Vercelloni 1990) described in 1499 by Francesco Colonna in his *Hypnerotomachia Poliphili* (Colonna 1980).

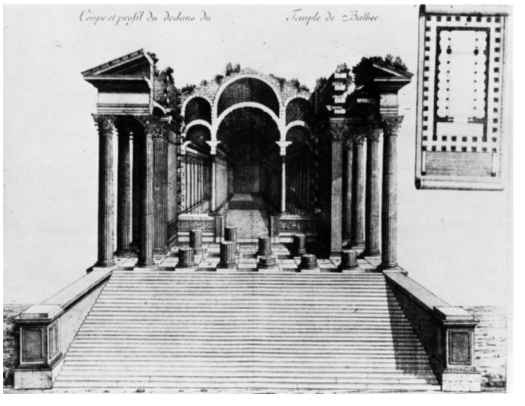

Figure 1. J. Marot, Representation of Bacco's temple in Baalbek, 1680.

Beyond the italian origin, it is in France that the theme of ruins is spreading thanks to Joachim Du Bellay and his work *Les Antiquitez de Rome*, written between 1553 and 1557 (Mortier 1974).

In philosophy, is Georg Simmel that more keenly has treated this issue, defining the ruin, in one of his texts (Simmel 1911), as the phenomenon by which the balance between nature and spirit in architecture is shattered, giving rise to a "new form which, considered from the point of view of nature, is absolutely significant, intelligible, autonomous".

When a building changes his state, and it loses its functional character remaining only a shadow of its form – the new form defined by Simmel, i.e. the ruin –, at that moment is possible to reveal the dichotomy in architecture, which like any system contains order and disorder, construction and deconstruction. Architecture seems to bring in itself the cause of its own degradation and transformation: it is a complex phenomenon, which while resulting in a unit, maintains different levels of complexity and contradictions that may lead to its decay or transformation.

The study of complexities and contradictions in architecture led in the second half of the twentieth century, for example through researches developed by Robert Venturi, to a significant mutation of linguistic references, of the transformation objectives, of the relations between architecture, city and history (Venturi 1966).

The fragment, the unfinished and the complex program reveal different scalar relations in the city, as well as the ruin lets understand some hidden architectural elements. The ruin tends to reveal architecture's configurative structure, i.e. the possible and dynamic relationship between form and content in a multi-temporal dimension.

On the other hand, the use of industrial ruins is quite similar to the recycling practices of greek-roman monuments, which characterized the paleo-christian architecture from V-VIth century A.D. until the so called "protoumanesimo".

As highlighted by several authors (Choay 1992) ancient monuments were primarily subject to two opposite practices: on the one hand the overall reuse, linked to more or less radical modifications; the o-ther, the fragmentation or the despoiling of component parts (columns, ornaments, decorations) later reinserted in new buildings.

Similar practices have characterized the spoliation cases of abandoned industrial complex where existing machines and facilities for production cycles are dismantled and reused in other industrial areas, sometimes thousands of kilometers away, leaving mute ruins on the abandoned site, buildings unable to communicate their origin.

Or even cases in which it is designed and built a reuse of spaces and areas, with new configurations of spaces, new senses and signs.

3 POST-INDUSTRIAL RUINS

3.1 *Ruins and constructions*

It is important to carefully evaluate the potential that the same relation between ruins and constructions reveals in some research experiences in which theories and methods of architectural design can play an important, if not decisive, role.

An obligatory reference is due to researches dedicated to the relationship between archeology and contemporary design, in which interesting expe-riences have been developed by several research groups.

A specific character is readable in research experiences related to the redevelopment of brownfield sites, in which relationships between different disciplinary apparatus – for example, industrial archeology, architectural design, urban regeneration, economic evaluation – highlight morphological interactions between ruins and constructions in sites involved in regeneration projects.

In particular, the field of remediation and redevelopment of contaminated sites, even though not succeeding to take off, in Italy represents a strategic area of great economic and environmental opportunities: 58 sites of national interest for approximately 7000 sq km, representing approximately 2.3% of the national surface, set the framework for testing of settlement models strategically more suitable for regeneration of brownfields, in relation to the specific characteristic of each site.

The current post-industrial phase has seen the relocation, decommissioning and abandonment of areas

Figure 2. Fertilizer's deposit, Agrimont site, Porto Marghera, Venezia (photograph by Angelo Desole).

Figure 3. Sugar refinery's site Delta Po, Porto Tolle, Rovigo (photograph by Angelo Desole).

considered strategic from urban, infrastructural and economic points of view. In this sense, brownfield sites are key elements for urban renewal of entire areas, considering their infrastructure, technology, energy, social and economic characteristics.

Some researches (Bottarelli, Pogutz & Tencati 2005) shows that in the sites of national interest with inherent potentialities the remediation costs represent only a few percentage points in the overall economic budget. So that clean-up costs do not constitute the decisive factor in the productive chain of "remediation and reuse" of contaminated sites, but are the same potentialities of the site which eventually lead to the regeneration. Industrial reclaimed buildings are reduced to modern ruins, leaving only read the skeleton of its original structures, often with the loss of secondary devices: infills, coatings, applications and other material characteristics.

Furthermore reclamation processes, often driven by survey models unable to describe three-dimensional complexity of these industrial sites, inexorably erase the rich complex of infrastructure – roads, railway lines, bridges, cantilever roofs, walkways, conveyors, cranes, water and cooling towers, chimneys, silos – which historically represent the intrinsic reasons of the historical settlement, and in the meantime can be considered as future potential of urban renewal of these areas.

3.2 *Settlement patterns*

In some research experiences developed in our university, these dismissed areas represent a possible network for testing interesting settlement patterns more suitable for their regeneration, in relation to specific characteristics of the site.

Among the possible elements that contribute to the definition of such settlement patterns are: the location of these brownfield sites in an urban context characterized by soil contamination and the possibility to define sequence of regeneration cycles of the same areas through energy infrastructures (i.e. geothermal energy, photovoltaic) in a multitemporal dimension; the link of these areas to "network of networks" formed by water infrastructure, roads and railways, that could be reinterpreted as new ecological and slow mobility corridors in the lanscape; legal and management subjects, planning tools at urban and regional scale, methods for mapping on a regional, urban and building scale, useful to get a more intense dialogue between different stakeholders.

The following paragraphs will describe some experiences of research and teaching activities developed in our universities on these issues.

3.3 *Tools for feasibility studies: ASM*

In the contemporary design of an housing complex the definition of the functional programme (Blanchard 2002) is developed by interdisciplinary groups and has an important part in new residential districts inside existing urban settlements. Often these are hybrid areas, where are visible infrastructural intersections or abandoned precincts of dismissed industrial areas, that become residual ones, then transformed in secondary landscapes (Clément 2004).

In such cases the process of designing the program can enable, through comparison of different scenarios or urban regeneration strategies, to previously define the objectives of regeneration process, to evaluate comparatively the criteria identified to achieve them and to share with other stakeholders different stages of decision-making (Massarente 2012).

As a result of such actions, designing the program can developed in most cases through the tools of feasibility study, which is the platform through which you can: develop dialogue and confrontation between different stakeholders; foster communication of ongoing activities to local communities; define the overall framework of (technical, environmental, economic, financial, procedural) feasibility of interventions; draw up a detailed articulation of the functional program of activities provided through a preliminary design document; identify possible funding opportunities for the design and implementation of interventions; develop the subsequent design levels.

This project was developed since 2010 to 2011 during a research activity, that lead to the definition of a feasibility study on urban rearrangement of an area in Rovigo, a town between Ferrara and Venezia, that was previously a gasometer plant for gas production and lighting, in the second half of XIXth century. Nowadays the same area is the head office of a public company (ASM) that has the management of a

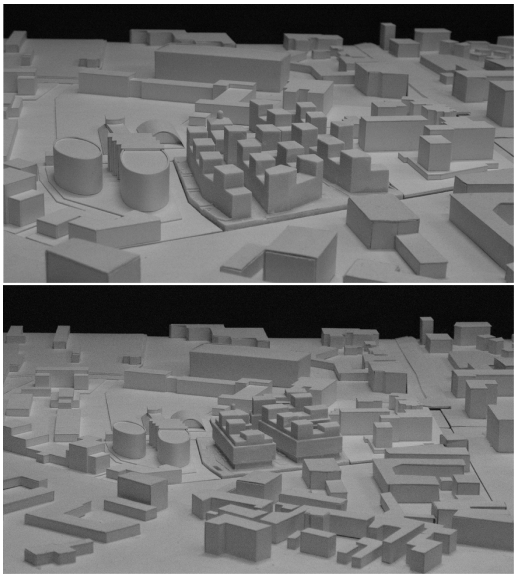

Figure 4-5. Models of two different alternative visions "borgo" and "community" (below), ASM former gasometer area.

series of public territorial services, such as energy distribution, renewable energies, waste treatments, last honours services.

During these research activities were deepened two different alternative visions ("borgo" and "community") which represent two possible urban scenarios for the same area, with different composition criteria for housing, compatible activities (such as co-working, retail trade, coffe-shops) and local services for housing district (health district, meeting places for young people and associations).

The concept of "borgo" vision is based on a sequence of spaces which intertwine the characteristics of square, street and park, becoming an organizing principle of the settlement through urban spaces that expand and shrink, linking public, semi-public and private spaces, and meanwhile trying to connect to existing permeability in the surrounding blocks.

The concept of "community" vision is based on a composition of clusters forming relations between public, semi-public and private spaces with fragments of pre-existing industrial buildings.

These composition criteria, like the profile of possible new clients and dwellings' dimensions, were developed through analysis and samples of direct and indirect sources of local real estate market.

Unfortunately the research project, after its conclusion, was not used by ASM for subsequent decision acts. Contingencies of the real estate market, company policies and administrative constraints in dealing with the municipal administration did not allow, among other factors, to move towards an urban regeneration process.

Nevertheless we believe that this research experience, for tools, methodologies and outcomes, can be a useful reference methodological framework for urban regeneration of areas in which the collaborative relationship between proprietary companies, municipalities and university research centers can be developed with tangible results (Massarente & Verde, in press).

Figure 6-7. Ground floor plan and urban section of vision "community" and (below) perspective of one court, ASM area.

3.4 *Research and didactic interactions: Alc.Este*

Through the experience of the Workshop *Regeneration of productive areas. The case of former distille-ries Alc.Este in Ferrara* it was intended to offer students of the Final Synthesis Studios of the degree course in Architectural Design, University of Ferrara, an educational experience centered on a well-documented case study involved in recent urban redevelopment programs.

Since 2012–13, these Studios are the place where students prepare dissertation through a first phase working on a theme characterizing the Studio, by which students are led to choose the topic of the dissertation, and a second phase of individual study and development.

Each of the 5 Studios are consisting of a characterizing subject (Architectural Design, Architectural Restoration, Architectural Technology, Urbanism, Landscape Architecture), and teaching modules also of other disciplines, aimed at guaranteeing the interdisciplinary nature of each Studio.

The themes of the 5 Studios are related to main research areas to which are referred the professors' and lecturers' teaching activities: Regeneration of abandoned industrial areas, Restoration of Twentieth century architecture, Technological design for architecture, Public spaces and sustainable development, Landscape architecture and infrastructures.

This relationship between training for dissertation and departmental research may trigger virtuous circuits between teaching and research: either through didactic verification of research methodologies (i.e. feasibility studies' tools) tested in applied researches, both through carrying out researches for study cases already discussed, on an experimental basis, during dissertations.

Ferrara School has a steady network with the architectural profession and these virtuous circuits, triggered by this new articulation of Final Synthesis Studios, tend to integrate graduates' professional careers towards the various forms of architectural profession with possible collaborations in research activities by best motivated students, also by attending PhD courses.

The articulation of these Studios also tends to foster various possibilities for postgraduate training, such as master for professional level and postgraduate schools, with which centres and research laboratories have long collaborated, in coordination with professional associations.

This Workshop was attended by students of Master's Degree MPI in *Conservation, management and enhancement of industrial Heritage*, promoted by University of Ferrara in partnership with other Italian universities, and by students of Erasmus Mundus TPTI *Techniques, Patrimoine, Territoires de l'Industrie. Histoire, Valorisation, Didactique*, in collaboration with Université Paris 1 Panthéon-Sorbonne (France), University of Evora (Portugal), University of Padua (Italy).

Following some introductory lessons dedicated to the case study, carried out in the first semester and at the opening of the Workshop (April 2015), students were asked to produce, in few days, a concept related to possible regeneration strategies for the area of the former distillery, to translate into 4 different scenarios of transformation, even through phases, using documents available and methodologies applied during the Workshop.

These strategies and scenarios proposed by students were discussed with Workshop's professors and researchers and were subsequently compared by synthetic multicriterial analysis, which will be briefly described in a short publication in their assumptions, purposes and processing mode.

With this educational experience is intended make interact the students with one of the most complex issues in the processes of regeneration of brownfield sites, that is the definition of the program and its complex relationship with processes of planning, urban regeneration policies and logics of economic enhancement.

Meanwhile it was decided to interlace these educational activities with the experiences of post-graduate training more advanced today in Italy on this subject, trying to refine some results, inevitably limited by time

Figure 8. Buildings and infrastructures, Alc.Este area.

Figure 9. Buildings and infrastrutctures, former distillery Alc.Este area.

Figure 10. Alba cement industry site, Porto Torres, Sassari (photograph by Angelo Desole).

and nature of teaching carried out in the Workshop, through the work of students of the Master MPI.

This educational experience has determined the basis on which were developed some further investigation: at level of a degree thesis in progress, both through a project work by two students of Master MPI, both through the analysis in progress of case study developed as part of a doctoral research in the frame of IDAUP International PhD Architecture and Urban Planning.

3.5 *Regeneration's cycles: RE_loaded buildings*

A recent experience is linked to the presentation of the research project *RE_loaded buildings. innovative technologies for the regeneration of the building stock in abandoned areas*, as part of the financing program POR FESR 2014-2020, axis 1 *Research and Innovation*, action 1.2.2 *Support to the realization of complex projects of research and development activities on a few thematic areas of importance and the application of functional technological solutions to the realization of the strategy S3*, promoted by EU European regional development Fund and Region Emilia Romagna.

The economic crisis of the real estate market in Italy during recent years leaves us a complex scenario, characterized by an increasing availability of brownfield sites, abandoned beyond the threshold time of transformation.

These abandoned areas offer themselves as a basically no more reproducible resource, assimilated to a new state of nature to be exploited, which requires an investment of creativity without precedent.

To face this condition, in this research program it was proposed to use these areas as urban laboratories inside which to test new methods and techniques for urban regeneration, bringing corporate identities and productive cultures, widely disseminated in the city through multiplicity of research and manufacturing centers.

Through the promotion of innovative practices and subsequent development of an overall production chain of regeneration, it is intended to exploit the available and unused real estate asset as business incubator for training of new specialized job profiles in recycling culture of existing urban complexes.

For this purpose this research project aims to promote a strong integration of knowledge, able to cover different prerequisites of regeneration process: remediation of contaminated areas, recycling waste materials, monitoring and seismic safety of structures, energy retrofit of buildings, temporary uses of interior spaces, development of digital meeting platform that fosters the matching of supply and demand for redevelopment and urban regeneration initiatives.

This project intends to develop a coordinated system of specific building sites, allowing the experimentation of processes and products, then promoting an immediate enhancement of the areas through valorisations actions and use, even temporarily, of brownfield sites and its buildings.

The project is divided into 4 working areas that are translated into development objectives: Technical solutions for diagnostics of brownfield sites; Technologies for safety and energy efficiency of built environment; Technological systems for reactivation of spaces; Information systems for planning, design and management of brownfield sites.

In particular, in working area 4 the general objective is the development of data management tools for analysis and design of brownfields, through implementation of geographic information systems and design tools in order to make accessible to different stakeholders data related to diagnostic tests, innovative technologies and phases of temporary use of areas and buildings, through a strong interaction with activities carried out in working areas 1, 2 and 3.

So in this working area, it is expected the development of territorial data management tools from application of innovative technologies (soil reclamation, recycling of inert materials from excavation, waste water treatment, solar and geothermal energy) as part of regeneration cycles of brownfields, as well as informations generated by application of innovative technologies (seismic safety, energy retrofit, acoustic comfort, building systems) as part of redevelopment phases of abandoned areas and buildings.

4 CONCLUSIONS

These research experiences show us that the re-cycling approach could be seen (McDonough & Braungart 2013) as more radical than the previous re-using one, because of its two intrinsic possible processes. The first one is the "up-cycle process", i.e. the valorisation of an object or a site towards a form of higher life through a new creative use and very simple interventions. On the contrary, the second one, called "down-cycle process", foresees a reduction of the original functions of the site, proposing a re-use of its individual components as raw or semi-finished materials for other purposes and in different contexts.

In any case, re-cycling attitude implies the ability to sight, in discarded objects, new potentialities, which

Figure 11. Perspective of one pedestrian space of vision "borgo", ASM area.

Figure 12. Ground floor plan and urban section of vision "borgo", ASM area.

are very different from the original functions for which they have been originally conceived.

Considering industrial dismissed areas as "waste landscapes" or "drosscapes" (Berger 2006) accepting "waste/dross" as a natural part of urban process, could represent a new field of research, in which ruins could be considered as part of the configurative tools of the project.

In fact, according to Alan Berger, "the natural process of the city is not unlike that of living orga-nisms, whose hard parts originated in the expelling and/or managing of waste . . . . Cities are not static objects, but active arenas marked by continuous energy flows and transformations of which landscapes and buildings and other hard parts are not permanent structures but transitional manifestations.

Like a biological organism, the urbanized landscape is an open system, whose planned complexity always entails unplanned dross in accord with the dictates of thermodynamics . . . The challenge for designers is thus not to achieve drossless urbanization but to integrate inevitable dross into more flexible aesthetic and design strategies".

The ripple effect: How saving Yamuna river will save Delhi

Gagan Ishwar Singh Keith
Architecht – Zaeske und Partner Architekten BDA, Wiesbaden, Germany
Passout – International Masters of Landscape Architecture,
Hochschule für Wirtschaft und Umwelt Nürtingen-Geislingen, Germany
Passout – Chandigarh College of Architecture, India

ABSTRACT: Yamuna is dying. One of the holiest rivers of the Hindus that charmed the Mughals to build the Taj Mahal along its banks is reduced to a pale, sickly drain. The paths along the riverfront, which were once the centre of a thriving river culture, have disappeared without a trace. Yamuna has become a cautionary tale of rapid unchecked urbanisation.

In 1912, when Herbert Baker and Edwin Lutyens won the commission to build a new capital for the British Empire's jewel, India, their aim was to create a garden city of 400,000, "with room for endless expansion". That number has now swelled to a staggering 16 million. In the 22 km it flows through Delhi, the river Yamuna dies from a million cuts. For instance, Delhi generates 36 million tonne of sewage, and 50% of it flows untreated into the river. The 22-km stretch of the river through the city — two per cent of its total length — contributes 80% of its pollution load. Delhi is damaged by the going paradigms of the river Yamuna. Since 1993, successive governments have spent over 250 million Euros in 3 phases to revive the river, with little to show for it. Amidst this failure how can we future-proof the desecrated city of Delhi through strategies of spatial and urban planning?

This research-work seeks to find salvation for Yamuna through Green Urbanism, a conceptual model for zero-emission and zero-waste urban design, which arose in the 1990s, seeking to re-engineer existing ci-ties and regenerate the post-industrial city centre. This study concludes that a design that crosses theory to take into account, political, social and economic realities, will help in creating a feasible natural and urban landscape in Delhi. With this new strategy, the future city of Delhi forms a new urban structure where the urban-rural morphology and nature overlap. The study develops a strategy by interpreting the results of various research methods like DPSIR, SWOT, Place-diagram and Stakeholder-analysis for a realistic outcome.

This regeneration strategy for Yamuna is based on a case study of Rhine which flows through Germany. Rhine, which has a catchment area of 200000 km^2 where 58 million people live, was once labeled as the 'Open Sewer in Europe'. A sustainable plan, has transformed the fortunes of Rhine, which received the European River Prize in 2013. A study which brings together sustainable practices and ideas from both professionals and stakeholders is a perfect way to understand the complexity of huge scale urban projects. The outcome of such a study will guide us to a green and sustainable future.

1 INTRODUCTION

To achieve maximum results in the shortest time, I have planned a strategy in an area where Yamuna is effected the worst, i.e. Delhi. Delhi, with a population higher than 22 million, is the world's second most populous and the largest city in India. A mere 2% of Yamuna's total length runs through Delhi and dies along its way. The current population of this rapidly growing city is more than 16,753,235 and has grown more than 10 times over the last hundred years.[1] This makes Delhi one of the fastest growing cities in the world. This has lead to several problems and utter mismanagement which has lead to the severe environmental pollution.

1.1 *Current state of Yamuna*

In the year 1909, Yamuna was distinguishable as "clear blue" as compared to the silt-laden yellow of the Ganga. In 1970–80s Yamuna was regarded as the life line of Delhi. The first 375 kms stretch of Yamuna from Yamunotri to Delhi is of reasonably good quality water, after which the discharge of waste water from 18 drains renders the river severely polluted after Wazirabad in Delhi.[4] Today, Yamuna has become one of the most polluted and toxic rivers in the world.[5] Whatever the state may be, Yamuna is a source of life for millions. Today, the water from the river is abstracted for various purposes. Major part of the water i.e. 94% is used for irrigation, 4% of the water is used for domestic purposes and 2% for industrial usage.[6]

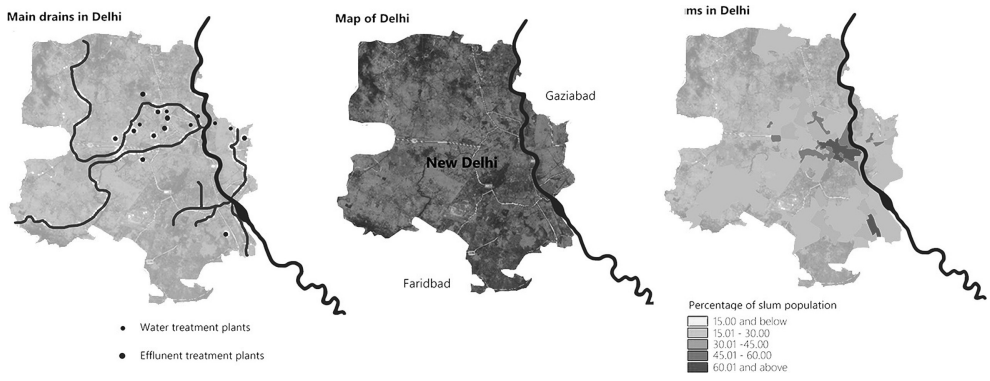

Figure 1. Co-relation – Yamuna River and Slums in Delhi.

Stakeholders	Role of stakeholder	Gain and benefit
People *Slum dwellers and the waste picker community*	Separate waste and wastewater Collect waste from Yamuna	Sell waste for money at canteen bio plant Get low priced meals from canteen & get purified water for reuse Make sustainable homes
Private sector *Comapnies, NGOs, organisations*	Built canteens which run of bio-gas Built STPs with bio plants to produce energy from sludge Buy waste from slum dwellers	Raw material for running the plant from Yamuna Future investment secured
Public sector *Central government, DJB, muncipality*	Create *"Community washing units"*, on-site *"Water treatment plants"* *Designate job titles to waste pickers* *Share responsibility with private companies*	Target of "Clean Yamuna" achieved sooner Work load shared, costs will be reduced The new government will win trust and goodwill of the citizens, make stronger

Figure 2. SWOT Analysis of the curent situation in Delhi: *This explains the How, Who and Why in the two processes. Who all are key Stakeholders, How can they bring a change, how are they related and lastly, Why would it be profitable for them, their city and the enviornment they live in.*

1.2 *How to plan the future of Yamuna*

Apart from the existing government plans and projects which have not shown good results, what I propose is a common solution for the holisistic problem at hand. A SWOT analysis in Figure 2, helps understand what could be part of the next steps in saving Yamuna. This analysis further decided how to proceed with the

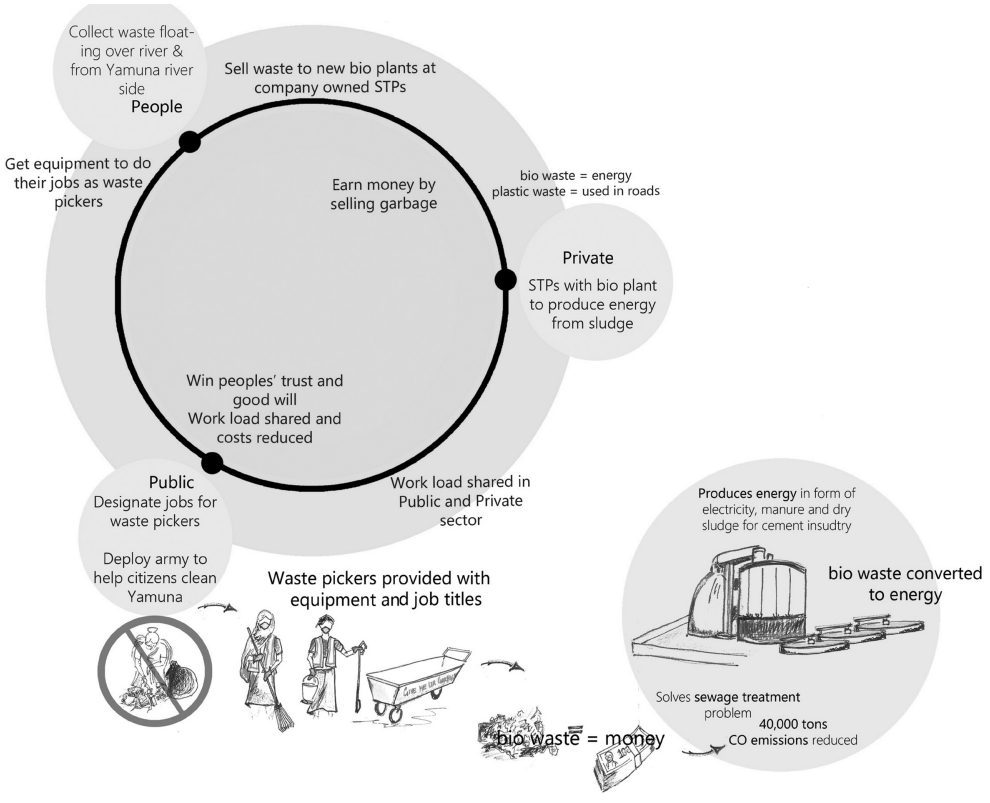

Figure 3. Active Cleaning Process. *Source: https://www.mannheim.de/node/22107*, *https://www.mannheim.de/node/22108 "The rise of the smart city". The New Economy. Retrieved*

strategy proposed to revive the dying river. 52% of the total population living in slums, pollute the Yamuna and if even half of this problem is tackled, it would bring great relief to Yamuna. In my strategy, I propose to take the help of the slum dwellers to clear Yamuna of a majority of its pollution by involving them in the cleaning process.

1.3 *Strategy*

This project concerns Slums around Yamuna and develops these blighted areas. It is crucial to understand the need of slum dwellers, their relation to the urban-natural habitat around them and recognize the problems associated with its existence.

A 'Slum Rehabilitation project' or 'River Revitalization projects' are not just planning or design projects but it is a social response that requires the coordinated effort of the NGOs, Private investors, Citizens, Slum Dwellers and most importantly the Governing Authorities.

But why would everyone work to develop slums unless they understand how it effects the society, economy and environment?

The answer is only if one can profit from saving the Slums and cleaning Yamuna will one work for it! A Stakeholder analysis below will explain Who, Why, How can be a part of Delhi Slum rehabilitation & Yamuna revival project.

All Urban problems in Delhi directly or indirectly relate to the Slums in Delhi and the common solution for this is also a vast change in urban and natural landscape. This can be accomplished. Explained in two phases: Active and Passive Process of cleaning Yamuna and Slum Rehabilitation in Delhi.

2 ACTIVE PHASE

The Active process demonstrates the relation between Yamuna and the Slums. Once this is accomplished all contributors would effortlessly work together in a cleaning and rehabilitation process in Delhi. In this way by empowering the people and specially slum dwellers with the help from the public sector, many social and environmental problems find a common solution.

Thankfully though, citizens of Delhi like some spiritual groups, youth groups, children and students are now taking initiative to clean the river and take part in events to clean the Yamuna. This is a brilliant start of a publicly driven cleaning process and at the same time this can be guided better.

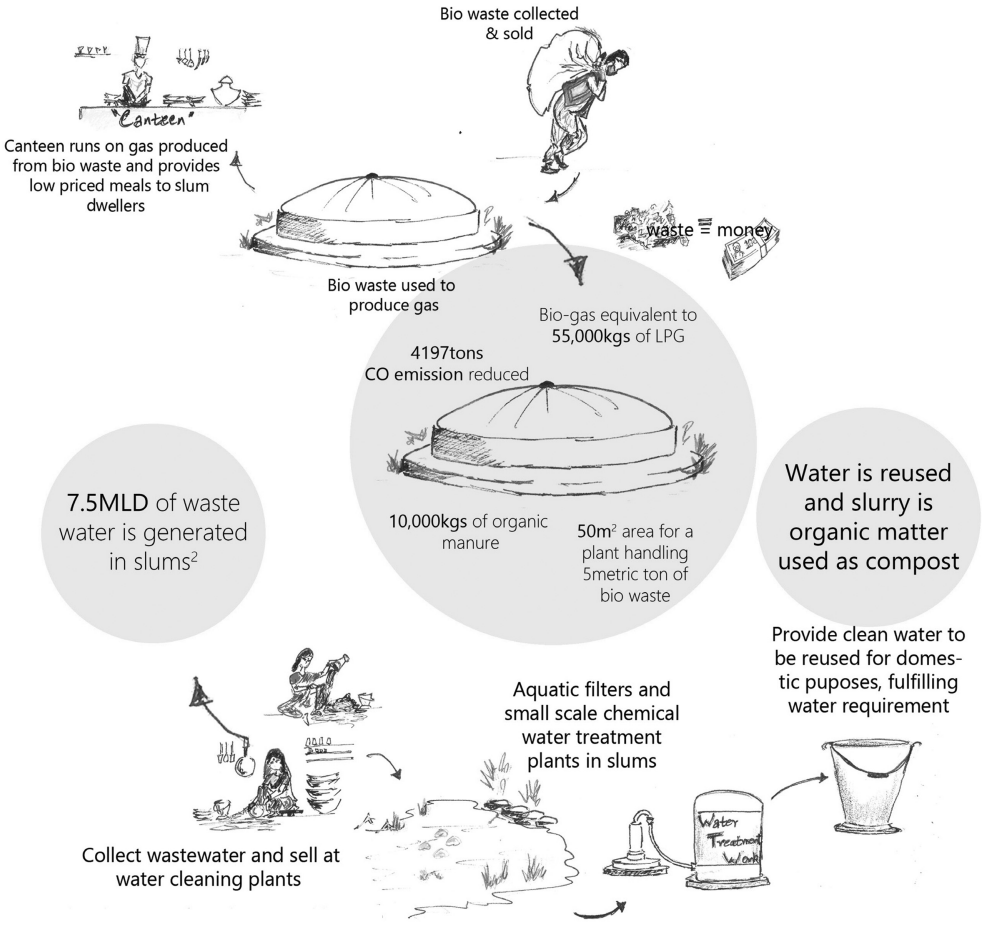

Figure 4. Passive Cleaning Process. *Source: http://www.no-burn.org/waste-pickers-run-biogas-plants-in-mumbai-india-on-the-road-to-zero-waste-blog*

Channelizing this in the right direction and empowering the people with the help from the public sector, a cleaner Yamuna can be achieved.

In this strategy, I again used the 3P's sequence as in the previous phase. The role of each part involved is explained graphically in Figure 3.

2.1 *Passive phase*

The Passive process manages the waste water and bio garbage produced in slums and at the same time providing the slum dwellers with services like clean water, washing area for clothes or utensils and a canteen which offers low priced meals to the slum inhabitants.

This will not only be effective in cleaning Yamuna but a sustainable process as the slum inhabitants can collect and sell bio waste in "Bioplant+Canteen" like in Mumbai. An organized approach with the support of the government will motivate the waste pickers in the slums to collect the waste from Yamuna where on one hand they could sell for a good price. Where don the other the government gets Yamuna cleaned effectively, the slums develop in a sustainable way. It is calculated that the slum in Delhi generates approximately 450,000 kgs of bio waste a day.

3 INTRODUCING A CHANGE

Changing the face of the Yamuna, providing slums with services and creating new infrastructure will take considerable time and resources. This change will not be overnight. A pictorial description of the infrastructure required for this change depicts the magnitude of development required.

3.1 *Scenario method*

A visual explanation of how the Slums, Yamuna and the urban life around Yamuna can be developed is explained in visuals using a Scenario Method.

Current Situation: Here all the urban complexities in Delhi are depicted in context to the Slums, metropolitan region Delhi and the Yamuna. Due to the

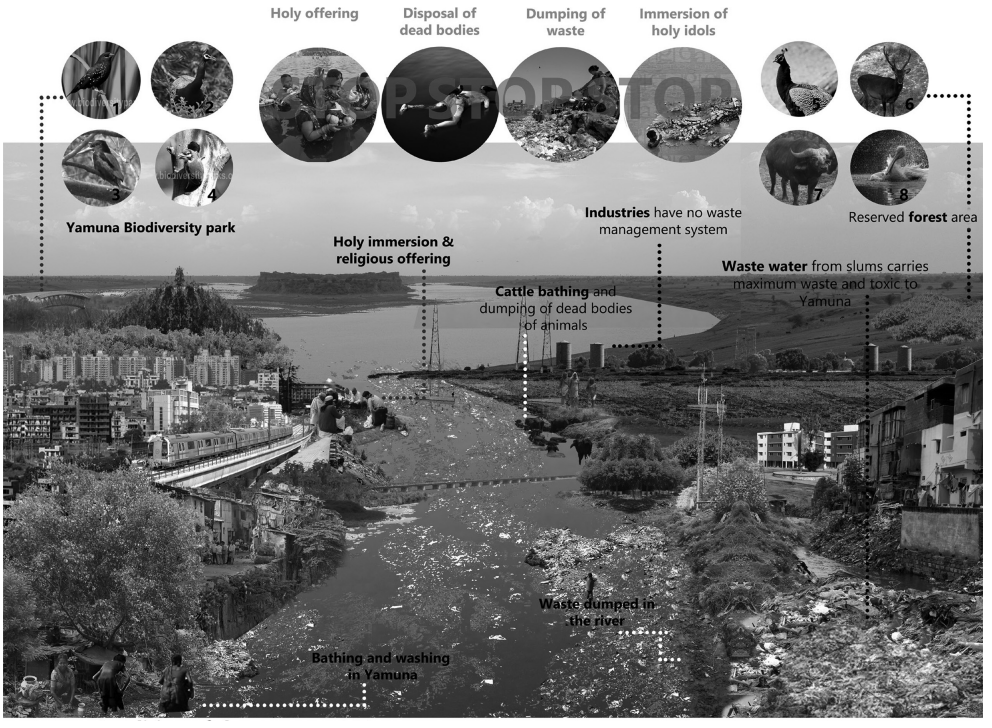

Figure 5. Scenario 1. Current State of Yamuna. If no changes are made the condition will worsen and create hazardous problems in Delhi.

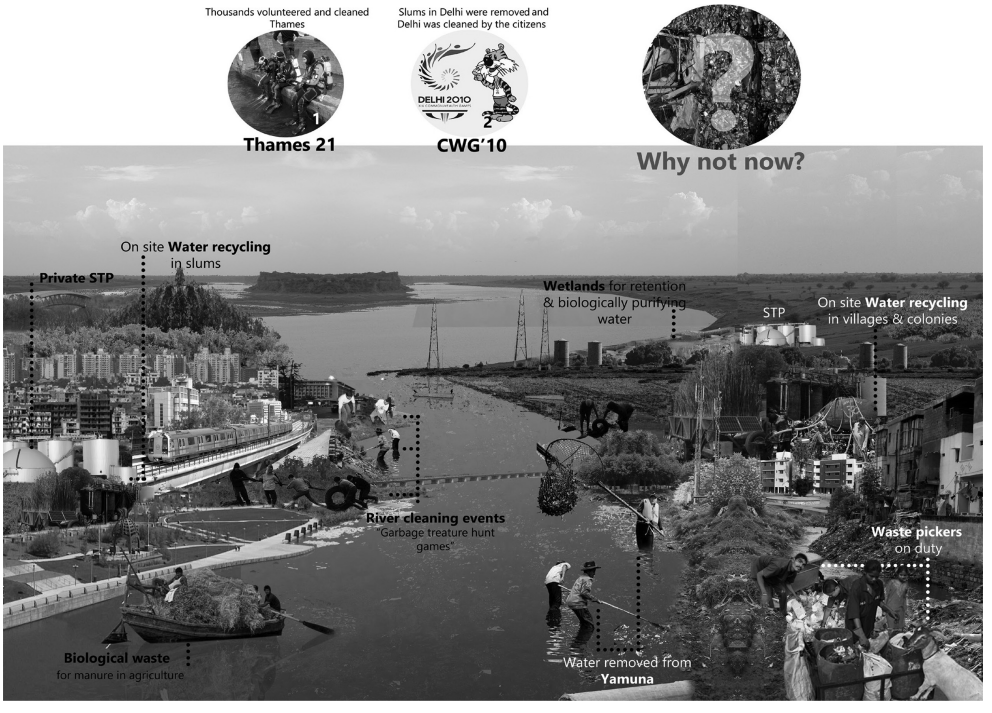

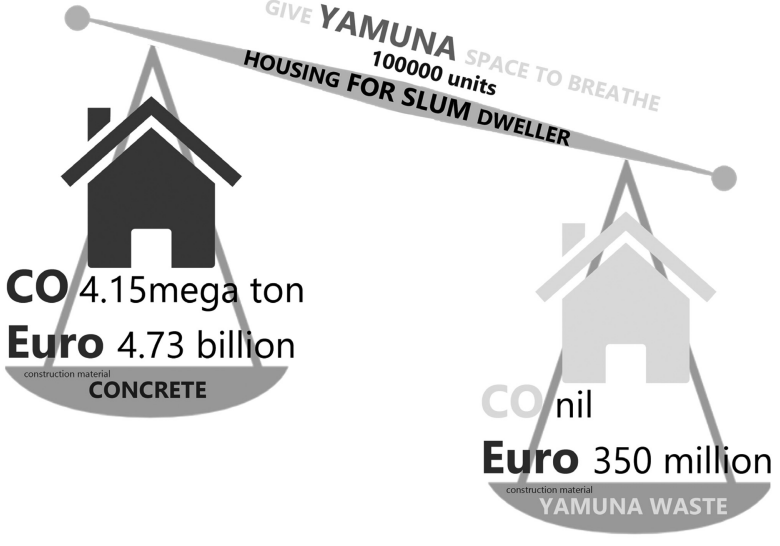

Figure 6. Scenario 2. A united effort. People have to work as one to bring a whole new life into Yamuna.

Figure 7. Scenario 3. A Possible Future.

Creating homes from PLASTIC and RUBBER waste collected from **YAMUNA** solves the problem of waste and pollutans floating over the river and provides **SUSTAINABLE** and **LOW COST HOMES** for the people living in the slums which are built right next to Yamuna. **WASTE** generated in future can be used to make homes for the rest of the people living below poverty line and without proper shelter.

Figure 8. Sustainability of the Strategy. *Source: https://sustainability.water.ca.gov/documents/18/3406693/Estimation+of+CO2+emissions+from+Constructing+Apartments+in+Korea.pdf*

inhumane conditions in which the people live in slums, they are forced to use the river water for the necessary daily work and release the pollutants in the river at the same time. To their misfortune, they do not have an option to think otherwise.

Change in future: For a better future for Yamuna and Delhi, people need to unite together to bring a change. It was seen at the time of the Asian "Common Wealth Games" in 2010, Delhi citizens gathered to clean the streets. Slums were moved for which 200,000 people were given compensation and more than 200 truckloads of garbage was removed from roads. Once Delhi realizes the role of Slums in the city, change will occur.

Yamunalive: With the advanced technological solution and further improvements in these developments, garbage and waste is going to be the resource used to make many interesting inventions.

4 SUSTAINABILITY OF THE STRATEGY

Any kind of human activity produces waste and 'Waste' will be the inevitable outcome in any future. With the rate of growth in Delhi, the generation of bio waste, domestic garbage and sewage will increase in future. Like today, the waste management issue will be a problem if a concrete solution is not developed. This strategy converts the waste polluting Yamuna into energy and sustainable housings. This will be a never ending process as the waste production will neither decrease nor stop.[13]

With this process, massive amounts of CO emissions will be reduced and unlimited resource for energy will be produced. The calculations of these figures for relatively smaller numbers compared to the whole population of Delhi are below.

To revive the Yamuna, one of the major challenges is to move the slums built immediately next to the river and shift them farther away in outskirts or open unusable cheap land. As proposed, with the Active cleaning process the slums can be rehabilitated and sustainable homes can be made from the rubber tyres, plastic bottles and aluminium cans recovered from the waste.[14]

For 100,000 units, the calculated comparison between regular construction and sustainable construction processes is given in Figure 8. The new housing will include on-site water recycling plants and canteens with renewable and sustainable energy like explained in the Passive cleaning process. This will give the river natural space to breathe and the pollution load will be reduced by creating green corridors along Yamuna.

Bartram's bringing boating back: Reviving Philadelphia's Schuylkill River

E.V. Ellis
Drexel University, Philadelphia, Pennsylvania, USA

ABSTRACT: Bartram's Garden is 45 acres of parkland settled by America's first botanist John Bartram in 1728. The garden is located to the southwest of Philadelphia along the west bank of the lower Schuylkill River. To the south at Point Breeze is the location of the largest oil refinery on the East Coast. Although the quality of the river's water has been compromised due to industrial production, there are numerous efforts underway to breathe life back into the river. Bartram's Garden is restoring its freshwater tidal wetland area, cultivating mussels to support the river ecosystem, and is the first to bring public boating recreation back to the river. To follow is a sketch of the history of the Schuylkill River and Bartram's Garden to provide a context for understanding the significance of the Public Boating Program at Bartram's Garden and the work of university, high school and vocational students to help make this vision a reality.

1 INTRODUCTION

In 1683, the surveyor Thomas Holme drafted "A Portraiture of the City of Philadelphia" for William Penn (Fig. 1). Marked by four green public spaces near the corners and punctuated with land for its city hall at the center, the city was laid out spanning the breadth of a peninsula in Pennsylvania bounded by the Delaware River to the east and the Schuylkill River to the west (Fig. 2). The Delaware River became the city's conduit to Europe with its large ships for international trade and the lower Schuylkill River became the locus for industrial production.

In 1728, the third-generation Pennsylvania Quaker John Bartram purchased 102 acres to the south of the city alongside the Schuylkill River from Swedish settlers. A man with a passion for scientific inquiry, Bartram systematically began collecting seeds and plant specimens resulting in the most varied collection of North American plants in the world. He established a trans-Atlantic hub of plant exploration through his exchanges with London merchant Peter Collinson. By 1765, Bartram was so internationally recognized that he was appointed the "Royal Botanist" by King George III. Under the care of three generations of Bartrams, his international plant trade and nursery business survived him and continued to thrive along the Schuylkill River until 1850.

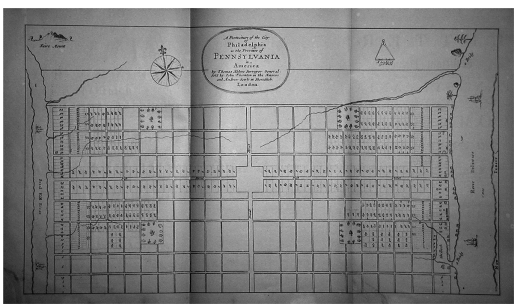

Figure 1. 1683 Thomas Holme, "A Portraiture of the City of Philadelphia" (Historic Maps of Pennsylvania).

A delicate ecosystem named "hidden river" by the Dutch, the east bank of the Schuylkill River was where the city began construction on the Fairmount Waterworks in 1812, the source of the city's drinking water until 1909. A beautiful, picturesque assemblage of buildings modeled after the temples of ancient Greece (Fig. 3), the waterworks pumped water from the river up a hill to a 3 million gallon earthen reservoir that held the city's water. By 1854, downstream at Point Breeze two industries were thriving: the Atlantic Refining Company which shipped nearly one-half of the world's illuminating fluid and the Point Breeze Gas Works which was then considered the largest in the world. By 1891, 35% of all petroleum exported from the U.S. was shipped from this location in Philadelphia. This same year, the City of Philadelphia took possession of the estate to preserve Bartram's Garden and by 1893 the John Bartram Association was created by his descendants. Today, the site is managed by the Association in cooperation with Philadelphia Parks and Recreation.

The water quality of the lower Schuylkill River has been adversely affected over time by numerous industries including sewage treatment facilities near the mouth of the Schuylkill River, scrap metal and waste recycling businesses, and refuse from slaughterhouses. By the end of the 20th century, the delicate ecosystem of this hidden river had become severely compromised. The 21st century has brought a new

vision for the renaturalization of the Schuylkill River resulting in a number of strategies for creating a more healthful water resource for the city, most notably Philadelphia's *Greenworks* program, the *Green Cities, Clean Waters* effort spearheaded by the Philadelphia Water Department, and *The Tidal Schuylkill River Master Plan*.

One of the more prominent projects to activate the river is the Schuylkill River Trail, a multi-use trail in Southeastern Pennsylvania with a projected length of almost 130 miles when complete. This trail will culminate (or begin) at Bartram's Garden to the south near the mouth of the river. Efforts to breathe life back into the river are underway. While the water is not yet drinkable, Bartram's Garden is restoring its wetland area, cultivating mussels to support the river ecosystem, and is the first to bring public boating recreation back to the river. To follow is a sketch of the history of the Schuylkill River and Bartram's Garden to provide a context for understanding the significance of the Public Boating Program at Bartram's Garden.

2 AMERICA'S FIRST BOTANICAL GARDEN

When John Bartram (1699–1777) bought his garden in 1728 in the rural township of Kingsessing, in Philadelphia County, it was located on an idyllic 102 acres along the Schuylkill River. It was the perfect location to establish a North American botanic collection: it faced toward the southeast, was sheltered by low hills to the north and south, and was fortunate to have a great variety of soils (Fry 2004). Located along the boundary between two geographic regions, the coastal plain and piedmont, this was an ideal location for Bartram's botanical garden. The mid-Atlantic climate of Philadelphia was moderate and plants from both the north and the south could survive outdoors (Fry 2008). Approximately four miles from the heart of Philadelphia, Bartram's garden could be reached by crossing the Schuylkill River at Gray's Ferry and traveling through a peaceful countryside down Woodland Avenue and past gracious estates on the way to Darby (Fig. 2).

In September of the following year, John Bartram married his second wife Ann Mendenhall (1703?–1789) after his first wife had unfortunately died two years earlier leaving him with one son. They had nine children, eight surviving to adulthood. They and three generations of their descendants lived in the stone house they built in 1731, which still survives today at the garden (Fry 2004).

Although John Bartram's garden began as a personal garden, it grew to a botanical inventory of native and exotic plants he collected throughout America's eastern seaboard and exchanged with others from abroad. Raised a Quaker in nearby Darby, he was trained to view scientific inquiry as a means of revealing the guiding principle of God in nature (Fry 2010). His trips into the wilds of America were botanical expeditions that in and of themselves served as a school of

Figure 2. 1752 N. Scull and G. Heap, "A Map of Philadelphia and Parts Adjacent" (Historic Maps of Pennsylvania).

botany. He and his family understood North American plants and plant communities from direct observation of the natural environment and by cultivating plants in their garden (Fry 2004).

By 1733, Bartram began corresponding with a fellow Quaker in London, Peter Collinson (1694–1768), a cloth merchant and novice botanist and gardener. Collinson connected Bartram with a disparate group of British gardeners, nurserymen, botanists, scientific collectors, aristocrats, and the owners of some of the most famous gardens of the eighteenth century—Bartram then had new sources for exotic plants to import to his garden and conversely had buyers for his North American plants and seeds (Fry 2004, 2008). This was the beginning of a lucrative business with Europeans who were willing to pay significant sums for rare and valuable North American plants (Fry 2010). By 1765, Collinson lobbied King George III to recognize Bartram for his devotion to botany and natural science. He was rewarded with a royal stipend of £50 per year for the rest of his life and the unofficial title of King's Botanist for North America (Fry 2004).

By the middle of the eighteenth century, Bartram's Garden had the biggest variety of North American plants in the world. Neither publicly funded nor officially recognized, it functioned as a national botanical garden during his lifetime and through to the 1840's. By the middle of the nineteenth century, though, North American plants had become widely cultivated in

Europe and America and were no longer rare or interesting to the horticultural world. Bartram's plants and seeds were now part of the gardening mainstream and could be cultivated in Europe without importing his seeds from America. Ultimately, the Bartram family plant and seed business was dependent upon an elite group of customers who no longer needed their product.

By 1850, Bartram's descendants were forced to sell the house and garden. A railroad industrialist, Andrew M. Eastwick (1811–1879), bought the estate and preserved the historic garden as a private park. Thomas Meehan (1826–1901) tended the garden and ultimately was responsible for leading the movement in Philadelphia to preserve the site as a public park (Fry 2010). In 1891, the City took possession of the estate to preserve Bartram's Garden and by 1893 the John Bartram Association was created by his descendants. In 1892, the editor of *The Horticulturist* John Jay Smith reflected on its significance, "From this garden dates horticulture in America. It should be carefully preserved forever" (Fry 2008).

3 THE SCHUYLKILL RIVER WATERSHED

3.1 *The schuylkill watershed ecosystem*

Bartram's Garden is located within the Schuylkill River watershed. A watershed is the area drained by a river or a river system. A watershed functions as an interconnected system, or *watershed ecosystem*, which includes an intricate network of small headwaters streams and the agriculture, forest, plant, and aquatic communities it serves. The watershed is the irreplaceable source of water for groundwater and the water people drink (TCF 2002).

The largest tributary in the Delaware River Basin, the Schuylkill watershed covers about 1,916 square miles, or over 1.2million acres. The river originates to the northwest at Tuscarora Springs in Schuylkill County and travels approximately 130 miles toward the southeast to its mouth at the Delaware River in Philadelphia. The Schuylkill River drainage network falls into four natural physiographic regions or "provinces" with different geologic, topographic, hydrologic, soil and climatic conditions, which in turn has influenced land use and economic development patterns within the watershed. Bartram's Garden is located within the Atlantic Coastal Plain Province, which is at the southern tip in the City of Philadelphia extending into New Jersey. One of the region's most important groundwater sources is contained in this province (TCF 2002).

Critical elements of a watershed ecosystem are streamside areas and wetlands. Healthy wetlands prevent flooding, sedimentation, habitat degradation and invasive non-native plant species. Almost like a water sponge, the wetland stabilizes the shoreline and prevents erosion. Other benefits are the special habitats they provide for wildlife, some of which can be globally endangered species (TCF 2002).

3.2 *Schuylkill river trail and greening the river*

Although only complete in sections, a multi-use recreational trail follows portions of the entire 130-mile length of the Schuylkill River. There are currently over 60 miles of finished trail for significant lengths along the east bank of the river. Starting at the northern limits, there's a scenic seven-mile stretch from Auburn to Hamburg in Schuylkill County that near Port Clinton intersects with the Appalachian Trail, the national scenic trail that extends from Maine to Georgia. While the Hamburg to Reading section has not yet been built, cyclists can follow a signed on-road route for about 20 miles between the two cities. From Reading, the trail continues another 20 miles to Pottstown where the trail breaks off again and is picked up in Parkerford to connect with a 30-mile stretch to Philadelphia (SRT). At South Street in Philadelphia, there are plans for the Trail to cross the river to the west bank and continue on to Bartram's Garden, which will serve as the southern gateway to the Schuylkill River Trail (MGA).

The Schuylkill River serves as the central spine for Fairmount Park, the largest landscaped city park in the United States. Its name derives from the "Faire Mount" shown at the northwest corner of William Penn's plan of 1682 (Fig. 1). In 1855, the city council passed a resolution to open the land formally to the public as Fairmount Park. In late 1858, the Committee on Public Property invited "Plans for the Improvement of Fair Mount Park". The goal was to combine newly acquired upriver estates, along with other parcels, comprising about 130 acres all together, into a unified park based on New York's Central Park designed by Frederic Law Olmsted and Calvert Vaux. In 1859, the firm of James Clark Sidney (ca. 1819–81) and Andrew Adams (ca. 1800–60) won a public competition for the design of Fairmount Park. Later in 1866, the city invited Olmsted to make a study for the park, which later became a formal proposal for the completion of the park in January 1871. However, in the end the project went to a young German architect, Hermann J. Schwarzmann (1846–91), the park engineer on staff who had been responsible for the ongoing work of park maintenance (Lewis 2006).

Opening in 2000 to the south of Fairmount Park, the Schuylkill Banks recreation area connects the Fairmount Water Works with Locust Street (KSK 2012). That same year, the nonprofit Schuylkill River Development Corporation (SRDC) began a master plan to extend Fairmount Park south through the City to create a new Schuylkill River Park to help mitigate the predominately industrial corridor of the lower Schuylkill River. The goal is to improve public access, promote tourism on the river, reclaim industrial sites for green public space, and acquire land to create greenways that can connect to adjacent residential neighborhoods (TCF 2002).

3.3 *Industrialization of the Tidal Schuylkill River*

The Tidal Schuylkill River is the eight-mile portion of the river and both its land banks located below the

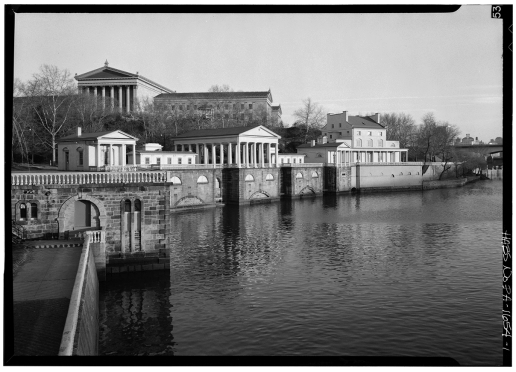

Figure 3. General view from the water with the Philadelphia Museum of Art in the background – Fairmount Waterworks, Aquarium Drive, Philadelphia, Philadelphia County, PA (Library of Congress Prints and Photographs Division Washington, D.C. 20540 USA http://hdl.loc.gov/loc.pnp/pp.print).

Fairmount Dam going south to the confluence of the Schuylkill with the Delaware River. Construction on the Fairmount Water Works began in 1812. The dam was constructed in 1822 to provide higher levels of water for pumping at the water works; to the north of the dam was the source of the City's drinking water and remains so today. The dam also stilled the waters, which encouraged waterborne shipping to come up the river as far as the dam, as well as use of the river for recreation. Surprisingly, the tidal flux of the river is over eight feet daily. Water was pumped from the Schuylkill up the hill to a 3 million gallon earthen reservoir to hold the city's water. By 1909, the quality of the river's water to the south of the dam was no longer suitable for drinking and the bathing establishments along its eastern shore had been driven out of business by the unabated pollution of the river (EDAW 2003). This mound later became the earthen platform for the Philadelphia Art Museum, constructed 1919–1928 (Fig. 3).

From Holme's "Portraiture" of Philadelphia (Fig. 1), it would appear that the City spanned from river to river. While this was William Penn's grand vision, actual settlement was predominately along the western bank of the Delaware River. The area west of Broad Street from the future City Hall (1871–1901) was sparsely settled well into the 19th century. The Delaware River became the location for shipping, the river lined with piers and wharves, many of which are still there today and some of which have been repurposed for parks, housing, and retail. Located at the western "back door" to the City, the hidden Tidal Schuylkill River became the locus for industrial production, especially oil refining.

Early in the 19th century, the Philadelphia Gas Company was located on the east bank of the Schuylkill at the foot of Market Street, several blocks south of the dam. By1836, it was purchased by the City and became consolidated as the Philadelphia Gas Works; its first significant commission was to provide illuminating fuel for the forty-six natural gas street lights along Second Street between Vine and South Streets near the Delaware River wharves. An even larger city-owned gas company was to be located at Point Breeze mid-century, remaining active for a little over a century (Cotter 1992). Soon thereafter, the Atlantic Petroleum Storage Company (now ARCO) established wharves at Point Breeze in 1861 (Fig. 4). Thirty years later, nearly half of the world's illuminating oil was exported from the Atlantic refinery at Point Breeze, which was 35% of all petroleum exported from the U.S. (Weigley 1982). Later in 1903, the Philadelphia Electric Company (PECO) established Generating Station A-1, the first large-scale, centralized power plant in the Philadelphia region near Grays Ferry along the eastern bank of the Schuylkill. Additional generators were added over the years and the area remained in operation by PECO in some capacity or another to generate energy until the end of 2012.

The oil refining business continued to expand in the Tidal Schuylkill River. Just south of Point Breeze at Girard Point, Gulf Oil built its first terminal in 1920. Together, both refineries were processing 69,000 barrels of oil per day by World War II. Sunoco purchased both the Point Breeze and Girard Point refineries, which the company consolidated into one refinery in 1994. Today, Philadelphia Energy Solutions (PES) owns the refining complex, which it operates as two separate domestic refineries with a combined processing rate of 335,000 barrels per day (14 million U.S. gallons) of crude oil. It is the largest oil refining complex on the U.S. Eastern seaboard (PES 2016, Quivik 2015).

Although the Schuylkill River north of the dam at the Fairmount Waterworks is still the source of drinking water for 1.5 million people, 56% of people surveyed believe that their local stream or river is not safe to swim in and 82% never or rarely use the Schuylkill River and its tributaries for recreational purposes (TCF 2002).

4 RECREATING THE HIDDEN RIVER

4.1 *Philadelphia's efforts to green the rivers*

It is not surprising that by 1909 the Fairmount Water Works had ceased to supply the City with its drinking water. The water was so well known to be hazardous that in 1892 the New York Times reported three Philadelphia boaters who set off a fire with the "thoughtless act" of tossing a match into the Schuylkill, which ignited the "thin scum of oil from the adjacent oil works." In 1896, a negligence suit had been brought against the Atlantic Petroleum Storage Company by an exporter whose ship caught fire at Point Breeze. A gas works engineer testified that floating oil "would be all over the river, and sometimes it would be close in along the wharf, according to which way the wind was blowing." Another gas works employee testified that the ground was mostly "clinker and debris" and that "oil will come through it just like a sponge" (Dougherty 2013). Industry blocked attempts to clean up the river until the 1940s when the Schuylkill

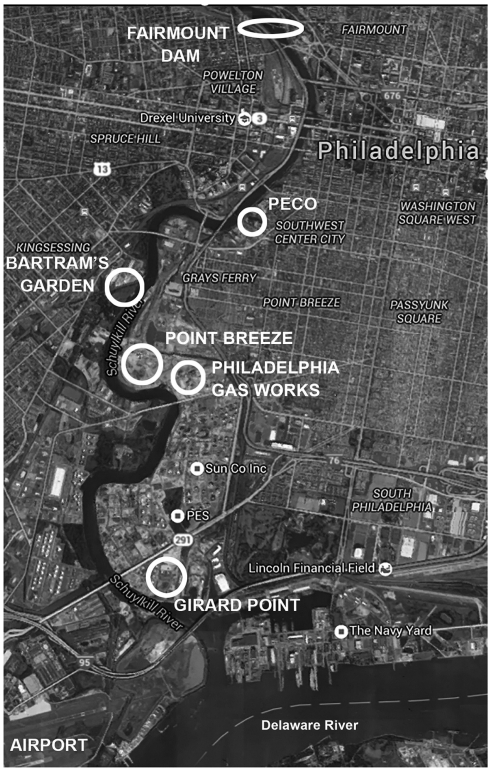

Figure 4. Bartram's Garden location with respect to the oil refineries in Philadelphia (map by google earth with locations identified by author).

River Project, a joint state-federal clean-up effort, was created. The river's water quality was improved with EPA's introduction of the Clean Water Act in the 1970s.

While much had transpired since then, the EPA levied a $1.25 million fine against the Sun Oil Company in 1994 for its violation of the Clean Water Act at its Schuylkill refinery. Sun Oil's fines allegedly resulted from discharging ammonia, nitrogen, chromium and other chemicals into the Schuylkill River. Unified under the name "South/Southwest Philadelphia Environmental Endowment," sixteen groups from neighboring communities discovered that the law allowed for a portion of the fine to go to a community-based Supplemental Environmental Project (SEP). The "Endowment" met with representatives from the Academy of Natural Sciences and Bartram's Garden to devise a SEP remediation plan (Pontarelli 1995). Their solution was to create a 1.5 acre freshwater tidal wetland on the river at the southwest corner of Bartram's Garden, which historically had been the location of a pond near the shoreline (Mueller 1996). It took 18 months for the legal issues to be resolved and another year to get the project going due to the proposed wetlands proximity to a local ball field, Native American archaeological artifacts discovered at the site, and the requirement to test for soil contamination (Howard 1996).

The Philadelphia Airport is located near the mouth of the Schuylkill River where it meets the Delaware River. In 2012, the airport proposed to extend one taxiway to connect with another, which would include the filling and loss of 1.49 acres of emergent non-tidal wetland habitat. As compensation for the wetland loss the airport proposed a wetland enhancement project to expand the tidal wetlands at Bartram's Garden. The proposed plan would include re-grading and excavation to develop a 2.33 acre tidal wetland complex with 1.54 acres of open water and emergent tidal wetland, 0.24 acres of scrub/shrub wetland habitat, 0.23 acres of forested/shrub wetland habitat, and 0.33 acres of upland buffer habitat (US Army Corps of Engineers 2012). The proposal was well-received by Bartram's because the 1997 wetlands were never dedicated as a permanent wetland nor did the wetland include the proper plants to prevent invasive species from overtaking the grounds. Additionally, no funds were set aside for long term monitoring or to purchase and install the plant species needed to anchor the wetland. The rebuilt wetlands were designed to be fully tidal and to accommodate the 8-foot tidal differences, which could make the wetland an ideal spawning ground for larger fish like bass (Hahn 2013). The wetlands underwent a number of design alterations to add the nearly one-acre addition due to the discovery of the 17,233 artifacts that spanned the time periods of Late Archaic through Late Woodland (as long ago as 3000 BCE), and the late seventeenth-century to modern times (Harris 2013).

The freshwater tidal wetlands restoration project at Bartram's Garden is a tangible example of the efforts the City of Philadelphia has expended to make the city a more sustainable urban environment. Inaugurated in 2009 and updated annually since then, *Greenworks Philadelphia* has fourteen targets directed at reducing energy consumption, reducing greenhouse gases, improving air quality, diverting solid waste from landfills, and managing stormwater, among others. A companion document is the *Green City, Clean Waters* program developed by the Philadelphia Water Department. PWD's strategy is to utilize green stormwater infrastructure to help mitigate the effects of Philadelphia's combined sewer overflows that drain to the Delaware and Schuylkill Rivers. Philadelphia's strategy to green its waterways is supported by groups such as the Partnership for the Delaware Estuary, which is a nonprofit organization dedicated to protecting and enhancing the Delaware Estuary, where fresh water from the Delaware River mixes with salt water from the Atlantic Ocean. They and Drexel University's Academy of Natural Sciences have been actively involved with the Bartram's Garden wetland restoration. Their programs support and provide guidelines for freshwater tidal wetlands and freshwater mussel recovery, among others.

4.2 *Freshwater tidal wetlands*

Freshwater tidal wetlands are critically important for both the urban ecosystem and human health. The

Delaware Estuary has the largest freshwater tidal prism of any estuary in the world. Because of the broad salinity gradient from the Atlantic Ocean to the upper reaches of the Delaware and Schuylkill Rivers, it allows for nationally rare freshwater tidal wetlands in the upper estuary. The ecological and economic benefits of a freshwater tidal wetland are multiple: flood protection; nursery, forage and nesting habitats for fish and wildlife; water quality improvement; and carbon and nutrient sequestration (Kreeger 2011). The wetland at Bartram's is significant as an urban ecosystem because in addition to its ability to improve water quality, it could potentially provide habitat for diverse animal species unable to live elsewhere in the city.

4.3 *Mussels restoration*

Mussels are bivalves, which are the best taxonomic group to target for integrating an ecosystem-based approach to conserving, managing, and restoring aquatic resources. In order for mussels to survive, they require a healthy population of suitable fish hosts as well as decent water and habitat quality. Freshwater mussels can live to be 80- to 100-years old and most species do not begin reproducing until 8- to 10-years old. In contrast to other bivalve species, freshwater mussels need a fish host to complete their reproductive cycle: a female with developed larvae propels her baby mussels, or glochidia, into a fish's mouth where they attach to the gills or sometimes the fins. This enables the mussel population to disperse upstream where the larvae could not go on their own. The glochidia remain attached to the fish for approximately 2–3 weeks until they release in a new upstream location. Therefore the life and health of a mussel species is directly dependent on their fish hosts, who can be adversely affected by dams, water quality and habitat degradation (PDE 2012).

Freshwater mussels are critical bioindicators that directly reflect the health of an aquatic system and are one of the best tools for bioassessment of both specific contaminants in the water as well as the overall ecology of a waterway. Since they are large filter feeders, they must process large amounts of water and particles across their soft tissues, which results in greater exposure to contaminants. Because mussels filter copious amounts of water and they do not swim around, their presence in a waterway indicates healthy water. Healthy and abundant freshwater mussel beds provide a multitude of ecological services and are a dominant functional component in aquatic food webs: they stabilize bottom habitats and enrich sediments for other fauna, add habitat complexity and increase water quality (PDE 2012).

A few mussels have been found near Bartram's Garden, which indicates the water quality is likely to be sufficient. One of the goals of the John Bartram Association (JBA) Strategic Plan is to "serve as a model for environmentally responsible practices, work in partnership for revitalization of the Schuylkill Riverfront, and work with the City to … make Philadelphia a vibrant urban green city." One strategy to achieve this goal is to "develop restoration and maintenance plans for Bartram's tidal wetlands" (JBA 2013). JBA has expressed interest to PDE in hosting a mussels production hatchery. Juvenile mussels would be propagated at the hatchery and would be used to reseed streams and rivers in the Delaware watershed where there were once diverse and abundant mussels, but no are longer. A mussels hatchery would also contribute to the habitat restoration and water filtering capability of Bartram's newly restored wetland.

5 RENATURALIZING WITH RECREATION

5.1 *Bartram's urban garden*

Once reached via a country road from Philadelphia on the way to Darby, today Historic Bartram's Garden is hidden from the public, reached circuitously via paved concrete roads marked by trolley rails that snake through a bleak post-industrial complex of buildings that often are in disrepair. On the other hand, Bartram's beautiful garden can also be reached directly via the recently completed Bartram's Mile which connects this historic landscape to the verdant recreational Schuylkill River Trail and the south Philadelphia community.

Cognizant of the unfortunate public perception of the river as a polluted waterway, Bartram's Garden has taken on the challenge of transforming this negative view to a vision of a vibrant urban oasis for recreation for the whole community. In addition to the Bartram's Mile gateway project, their Action Plan includes safeguarding and improving the Garden's environment, enhancing recreational activities, establishing the on-site working farm and orchard as a destination for the urban farming community, developing restoration and maintenance plans for the tidal wetlands—essentially establishing Bartram's as a world-class cultural, heritage and urban green space destination with nutrition and environmental education programs that emphasize awareness and stewardship (JBA 2013). Part of this vision includes activating the waterway—really activating the waterway by putting people on it in boats.

5.2 *NYC boathouses*

Inspiration for recreational boating at Bartram's has come from the numerous successful boathouses the staff has visited in the vicinity of New York City. Apparent from the boathouse mission and activity descriptions to follow is a concern for the environment as an integral part of recreational boating.

The *Yonkers Paddling & Rowing Club*, Inc. is a not-for-profit membership organization whose purposes are to encourage rowing and paddling sports as well as to educate and inform the public about the environment of the Hudson River and the importance of its protection for present and future generations.

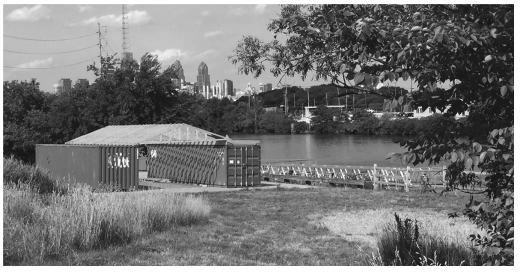

Figure 5. Bartram's Garden Community Boathouse with city skyline in the background (photo by author).

Two of the goals for the *Village Community Boathouse at Pier 40* are: 1) to improve the park's Estuarine Sanctuary through public education, research and habitat enhancement and 2) to provide free or low-cost recreational opportunities for New York City residents.

The *North Brooklyn Boat Club* (NBBC) offers environmental education workshops on site in their "container classroom", regular water testing, as well as small workshops on wooden boat building, restoration and repair. NBBC has two main educational programs, an on-land component and an on water version to better involve citizens with a number of ecological issues facing urban waterways.

Long Island City Community Boathouse is playing a critical part in revitalizing Long Island City by reconnecting residents and local business people with their estuary through its paddling programs and raising awareness about estuary ecology.

In addition to its continuing public boating and youth programs, the *Brooklyn Bridge Park Boathouse* supports appropriate local advocacy initiatives aimed at improving public access and water quality in the harbors and rivers of New York City. They advocate for the reclassification of "designated use" waterways to "primary contact", because human-powered boating exposes people to the same risks of unclean water as swimming. They test the water every Thursday at the popular launch sites for human-powered boaters and publish the results on the Water Trail Association website on Friday. The goal is to provide a reliable database that harbor boaters can use to predict water quality at their preferred launch site.

5.3 *Bartram's bringing boating back*

Inspired by the boating programs in New York City, Bartram's inaugurated their River Program to bring water-based activities to Southwest Philadelphia. Their Community Boathouse opened on June 14, 2015 to the fifth annual RiverFest and second annual Tidal Schuylkill River Boat Parade, a community event that included a floating ice cream parlor, a floating brass band, and a choreographed dance performance on paddle boards. Featuring the garden's history, a Rhododendron Flotilla reenacted Bartram's trip home from Berks County with the first example of the *Rhododendron arborescens*, discovered near the headwaters of the Schuylkill River.

The Community Boathouse (Fig. 5) was the product of a year-long collaboration with Drexel University through their Engineering Partnerships In Community Service (EPICS) program. Staff at Bartram's Garden worked directly with a team of architectural engineering students for their Senior Design project, which included designs for a boardwalk and overlook for the newly restored wetlands, a living shoreline, pier and promenade along the riverfront, the community boathouse, and a floating dock that could accommodate the 8-foot daily tidal flux. These college students worked on site with high school students from a Philadelphia Charter School, The Workshop School, to build the Floating Dock they had designed. The Community Boathouse was designed by the team who detailed a roof truss system over a 20-foot span between two shipping containers and a green roof with rainwater collection system. The shipping containers were donated by a Drexel alum and the roof system was built by the Challenge Program, a vocational school located in Delaware. The shipping containers are used for boat storage and the 20-foot span provides shaded outdoor space for Philadelphia Waterborne, an experiential, project-based educational program for middle- and high-school students that utilizes boat building, maritime history, and environmental education as a way to engage students and enhance student educational outcomes. In total, the Community Boathouse and Floating Dock were the products of educational programming at all levels that used project-based learning as the key educational principle.

6 CONCLUSION

North American settlers were unaware of the gift they had been given when they stumbled upon the pristine, hidden Schuylkill River. Characteristic of human settlement, the river and adjacent land were used to accommodate growth and expansion of the city named after its founder, William Penn. In retrospect, post-industrial societies are recognizing the value that will be lost due to the growth and expansion of cities without consideration of the natural environment. Philadelphia is renaturalizing its city through a number of strategies including wetlands and mussels restoration, green stormwater infrastructure, and bringing recreation back to the river.

ACKNOWLEDGEMENTS

The author would like to thank Danielle Redden, Bartram's Garden River Programs Manager, for collaborating with me, my students and Drexel University on the floating dock and boathouse projects, Joel T. Fry, Curator at the John Bartram Association, for his help with Bartram's Garden research, and Danielle Kreeger, Drexel University colleague and science director at the

Partnership for the Delaware Estuary for assistance with information on the Freshwater Mussel Recovery Program.

Learning from ancient Anatolia: Strategies of naturalization in metropolitan Istanbul

T. Frank
Kennesaw State University, Atlanta, USA

ABSTRACT: The negotiation between the natural and built environment in urban design is one of the more vital aspects facing the practice today. The process of assessing this relationship is facilitated by state-of-the-art simulation tools which enable designers to study the ambient qualities of space and associated multivariate effects such as static rays, fluid flows and thermal gradients. These toolsets pave the way toward alternative strategies in urban naturalization, ones that consider the natural and the constructed as part of a shared ecology in lieu of being diametrically opposed. This paper examines the nature of this exchange in high-density urban situations where adequate access to daylight, fresh air, and view sheds are limited due to over-development. The focus of this research resides in Turkey where historical examples dating back three millennia serve as strong examples for cities today where high-density development has undermined the quality of life for metropolitan inhabitants. This paper reviews outcomes from a cross-disciplinary student workshop, funded by the James Marsden Fitch Foundation, carried out over a nine week period in western Turkey. With the use of computer simulation programs, ancient housing typologies including Ephesus, Priene and Pergama are analytically unpacked and played back in the form of design exercises set in Istanbul. During the research period, simulation tools enable the team to disclose design strategies from ancient settlements and test the reintegration of those strategies within new models of collective development.

1 INTRODUCTION

Urban naturalization, as an established practice, largely focuses on returning the city to a more natural condition through the use of vegetal means native to the region (Urban Naturalization in Canada, 2001). While this approach certainly improves the quality of urban life for all inhabitants, its emphasis lies largely in the benefits provided by the presence of landscape elements, foregoing in-depth examination into how natural states operate to systemically forge the disposition of urban space itself. Understandably, the sublimation of urban development into the dynamics of its natural setting is less pervasive in design because traditional means used to study the characteristics of an urban condition tend to be symptomatically stationary. And yet, in contemporary urban design practice, there is much excitement surrounding new performance modeling and simulation platforms that facilitate the observation of various energy states that constitute a natural environment, especially when used to test design alternatives within its shared domain (Reed and Lister, 2014). These tools pave the way to unprecedented areas of investigation, advancing the very concept of naturalization in urban design through experimental processes that examine the operative principles particular to the natural world. Furthermore, these new processes offer a response to urban theorists who in recent decades have called for interdependence between the natural environment and human intervention in the form of a shared ecological system (Botkin, 1990).

This digitally augmented ecological approach to urban naturalization examines the behavior of renewable resources such as solar and wind inputs through observable models that highlight characteristic climatic factors and the role of design strategies in modulating these fields. With the disclosure of environmental knowledge provided by such an alternative workflow, we are drawn to speculate whether such knowledge is present within classical examples of urbanism. Prior to the invention of active building systems, early populations seemingly achieved atmospheric zoning by putting basic building attributes to task, finely attuning building assemblages to ever-changing environmental factors to provide comfort for inhabitants. Based upon this premise; can analysis of these early forms of urbanism in places like Asia Minor provide insight into how access to natural resources was provided in antiquity? If so, what relevance does this knowledge from ancient sites have in contemporary urban planning? How can this knowledge be used in developing new models of multi-tenant living within the same region at least three millennia later? In this paper, these questions are posed with regard to cases of urbanization that exhibit both

concentrated population groups and the need for adequate access to native resources. The motivation of this research is two-fold; to identify strategies of naturalization and climatization present in urban antiquity and to examine how these strategies offer insight in places like Istanbul where unprecedented growth and subsequent construction patterns have left these resources depleted and its citizens marginalized.

Using simulation operations such as computational fluid dynamics and backward ray tracing enables designers to model systems of climate behavior and intervene within these domains to survey the impact of human influence on these given states (Marsh and Khan, 2011). In modeling the complexity of the physical world using simulation platforms, designers are able to develop new forms of literacy about how the natural world operates around us and how effective our planning strategies are in maintaining these relationships and subsequently improving our quality of life within constructed situations. The potential of this approach translates to improved quality of life for building occupants and accommodated densities dictated by extreme economic demand without forsaking natural resources essential to the ecological dynamics of place. Furthermore, in light of our ongoing climate crisis; simulation tools can help reduce emission of greenhouse gasses and shape a holistic built environment that is more connected to energy resources thus improving comfort levels for occupants as a complete ecological system (Hensen, 2004).

This paper looks at recent research conducted in Turkey where simulation programs are used to disclose design strategies developed by early populations in Asia Minor and test the reintegration of these findings to identify new collective living strategies in rapidly developing metropolitan Istanbul. As simulation platforms generate observable output states, they facilitate assessment of viable high-occupancy housing alternatives against established project goals and objectives. These goals not only include parameters for density targeting occupant concentrations but also standards of performance that comprise of access to uniform daylighting, distribution of fresh air and maintenance of view sheds. The paper reports on how these simulation tools offer new ways to conceptualize space within high-density urban developments by establishing the atmospheric qualities of both individual and shared space from the inside-out in lieu of developing high-rise communities from the outside-in. Outcomes from the research of ancient settlements in Asia Minor are presented which focus on the advancement of spatial organizations that toe the line between interior and exterior; individual and collective; and natural in comparison to constructed. The assimilation of these strategies within new models of collective living are tracked to assess the relevance of these spatial agglomerations in today's urban society as they generate variable atmospheric zones which invite inhabitants to use space collectively and migrate daily activities based upon the ambient disposition of each zone.

2 CASE STUDIES

2.1 *Ancient anatolian settlements*

Strong examples of early urban planning are plentiful along the Aegean coastline in western Turkey, also known as ancient Asia Minor. Sites such as Priene, an Ionian settlement dating back to the 4th century BC, better known for its Hippodamian grid planning; Ephesus, an ancient Greek city dating back to the 10th century BC, best known for its housing complexes terracing from prominent urban promenades; and Pergamon, also an ancient Greek city dating back to the 4th century BC whose citadel is perched atop a prominent promontory all provide early examples of urban planning where space is organized around constraints dictated by both climate and the need for solid defenses from invading factions. The compact composition of living units and the intensified development densities in these settlements adhere to their sloped terrains, creating terraced patterns that establish unique models of collective living, generating spatial gradients from more to least enclosed. In each case, these transitions from public to private zones establish a rich inventory of space types that serve to inflect the daily and seasonal variations of climate along the Aegean coastline (Frank et al, 2014). Furthermore, because these settlements were situated between Greece and Persia they were home to some of the most intense battles in ancient time, giving rise to sophisticated systems of fortification and the need to maximize space developed within the citadel (Nossov, 2009). The spatial disposition within these settlements make them ideal models for passive climatization within high-density complexes as each space type engages the native region in a unique manner. The benefit of this knowledge offers is clear, a concerted language of spatial organization and subsequent strategies of passive climatization that provide insight for contemporary development within the region.

2.2 *Case study methodology*

The methodology associated with this case study analysis advances in a systematic manner with the final output disclosing how ancient design strategies are used to temper varying ambient states present within the extensive environment. Portions of residential complexes within the three aforementioned cities are analyzed using simulation platforms to reveal these signatures of climatic modulation. This process involves three primary steps; modeling, simulation and comparative analysis across key timeframes. In the initial step of the process, each of the residential complexes are digitally modeled using Rhinoceros, a NURBS based 3-D modeling platform developed by McNeel, to create polygonal meshes from archeological reconstruction data. These polygonal mesh models are imported into simulation domains where they are exposed to numerous environmental factors at critical timeframes including the equinox and solstice periods

in the annual cycle. Using regressed climate data from the region, the environmental factors accounted for in the analysis include daylighting, solar radiation, single source view sheds and ventilation. Diva for Rhino, developed at the GSD at Harvard University, uses the Radiance backward ray tracing engine to conduct daylighting and solar radiation studies in the analysis workflow. The isovist component in McNeel's algorithmic modeling plug-in, Grasshopper for Rhino, is used to analyze view sheds from single source points. Simulation CFD, distributed by Autodesk®, is a computational fluid dynamics simulation platform used to survey the be havior of air velocity, path and pressure in the case study analysis. In the third step, initial output from the simulation analysis is compared to ascertain how design strategies such as spatial organization, degree of enclosure and orientation account for changes indicative in the temperate Turkish climate with cool-wet winters and hot-dry summers to provide levels of interior comfort that approximate contemporary standards.

2.3 *Case study outcomes*

Upon completion of the initial round of case study analysis, three signature traits were evident in the ancient settlements studied; thin unit blocks, permeable building masses and mass-void juxtapositions within building complexes. Using the methodology described above, output states from simulation platforms demonstrate degrees of climatization whereby interior comfort is provided through the sole use of naturally renewable sources, namely the climatic context in concert with basic elements of the material enclosure. As evidenced below, this ability to simulate first-principles relationships within ancient settlements provides unprecedented insight into how early populations organized space in concert with climatic constraints, especially where space was at a premium within systems of fortification.

Thin unit blocks are typically one to two rooms wide and elongated in the east-west direction to maximize exposure to solar and wind resources. At Priene, housing units were two rooms wide with the southernmost rooms acting as intermediary space types that work off of central courts, offering varying degrees of light penetration into the enclosed area of the living unit and reflective surfaces that redirect ample daylight into all areas of the plan. The thinness of the plan and loose definition of the southern-most spaces provide daylight uniformity at a rate of 0.54, above the recommended value of 0.4; daylight levels within interior rooms of 300-3,000 lux, within the recommended range of 108–5,400 lux; and daily insolation values of 2 kWh/m^2 on interior surfaces during the winter (Figure 1).

Permeability includes the design of apertures and open spaces within a defined building block which harvest natural resources like wind and daylight while also framing views out to the immediate context. At Pergamon, permeability is achieved through colonnaded

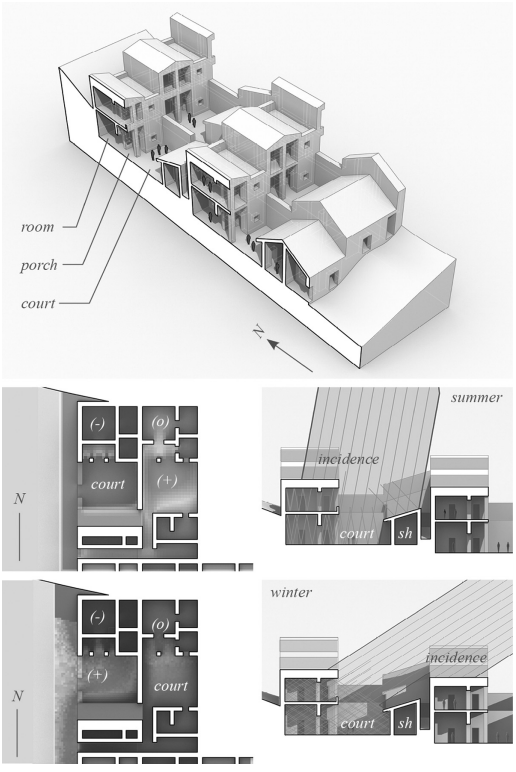

Figure 1. Above: Reconstruction of Priene Insular Row House after Hoepfner. Below (clockwise from upper left): daylighting analysis of the first level, summer solar raytracing, winter solar raytracing and daily insolation analysis of the first level.

arcades, open antechambers and aligned apertures within the peristyle housing blocks. These strategies produce ventilation rates of 1.26 m/s on the interior, just below the maximum allowable air velocity rate of 1.5 m/s; a range of daylight levels situated within the comfort range from 500 to 3,000 lux; and framed visual connections out to the hinter-land from 96% of the occupied floor area (Figure 2).

Mass-void juxtapositions stem from the terracing of housing blocks along inclined terrain. This type of spatial organization places open space below grade and sets loosely enclosed volumes above the ground. At Ephesus, the mass-void juxtaposition happens through the deep two-story courtyard that provides light and air access to subterranean spaces while allowing air and heat to stratify from lower to upper levels of the complex. This approach creates two distinct zones within the compound, an upper zone where light and air velocity levels are more variable at 2,700 lux and 0.3 m/s respectively. In the lower zone there is a much tighter light and velocity range at 1,400 lux and 0.1 m/s (Figure 3).

All three examples provide evidence that historical structures, as reconstructed by those in the field

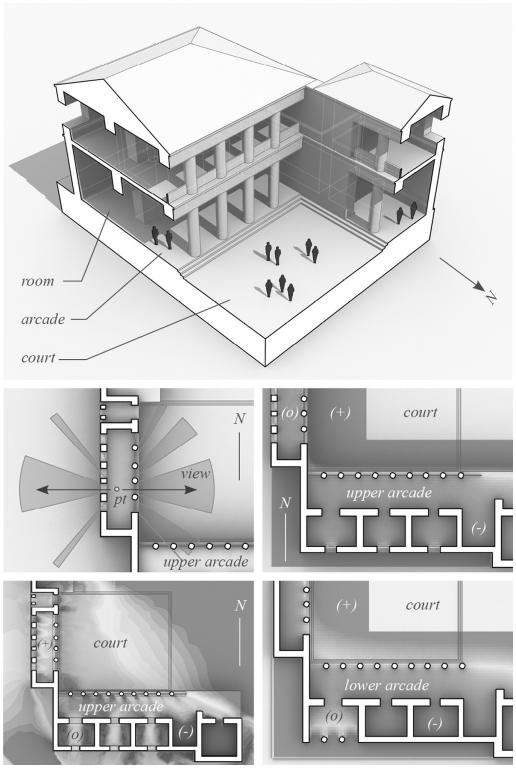

Figure 2. Above: Reconstruction of Pergamon, Group V Complex after Radt. Below (clockwise from upper left): isovist analysis of the upper level, upper level daylighting analysis, lower level daylighting analysis and upper level air velocities.

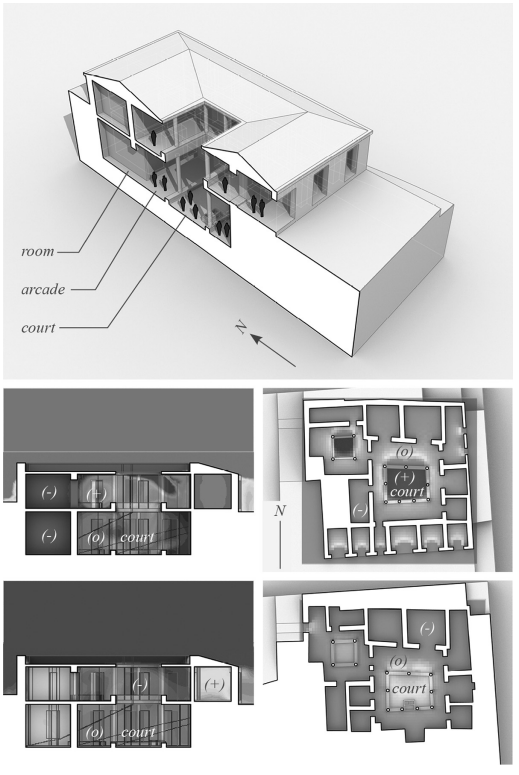

Figure 3. Above: Reconstruction of Ephesus, Terrace 2, Dwelling Unit 2 after Osterreichisches. Below (clockwise from upper left): air velocities in section, upper level daylighting analysis, lower level daylighting analysis and temperature in section.

of archeology, offer insight into how spatial organization, degree of enclosure and orientation contrib- ute to passive climatization. As noted in formative architectural treatise, early populations put material enclosures to task in order to step down climatic extremes so to provide some level of interior comfort for occupants (Pollio, 1960). Expanded knowledge of these strategies opens the door for reuse, in contemporary terms, within metropolitan high-density development where access to view, fresh air and natural light are paramount. In the following section, the research examines the relevance of these strategies when incorporated into models of high-rise construction rapidly taking place in Istanbul.

3 CONTEMPORARY DEVELOPMENT

3.1 *Modern-day Istanbul*

With a population growth rate at 3.45%, Istanbul is the fastest growing city of any nation in the Organization for Economic Co-operation and Development (OECD) and is on pace to reach 24 million inhabitants by 2023 according to the World Population Review (WPR, 2015). Growing pains have ripped through the city where over-building, green space eradication and poorly climatized high-rise structures have resulted in marginalized inhabitants and violent protests. Furthermore, at the time of the research, the warmest month on earth was reported by the National Oceanic Atmospheric Administration, providing further evidence that climate change is an existential threat that requires reassessment of our design and construction processes (NOAA, 2015). In light of these challenges, new development strategies are desperately needed that offer equitable yet equally responsible access to renewable resources for use in rapidly expanding metropolitan areas such as Istanbul.

As highlighted in the previous section, alternative methods of planning embedded within historical settlements in ancient Asia Minor prioritize naturalization and access to renewable resources within concentrated building complexes. Drawing insight from how early populations organized densely populated space in concert with naturally renewable resources is a worthwhile endeavor in light of the design challenges present in metropolitan Istanbul. These insights are specifically relevant if the knowledge extracted from these early examples of urbanism

serve as the basis for experimentation, encompassing new models of naturalization within high-density development.

3.2 *Workshop methodology*

A cross-disciplinary student workshop, carried out over a nine week period in western Turkey, investigates patterns of spatial configuration, atmospheric differentiation and performance within concentrated population densities in Istanbul. In lieu of working solely with a Euclidean definition of space, the workshop advances our understanding of space as comprised of dynamic social and environmental zones. The act of spatial organization in this exercise evolves from the strict regulation of absolute space to the modeling of layers, superimpositions and transformations of phenomena that permeate the built environment. This process is facilitated by the aforementioned performance modeling tools that allow workshop participants to measure the inextricable relationships that exist between systems of spatial enclosure and the fluid state material energies which pervade them. The working methodology during the workshop period parallels the one defined in the case study section above with exception to the feedback loops which openly test a range of spatial configurations and support new lines of inquiry within the process of experimentation. This design process foregrounds the potential of new toolsets for non-linear testing, systematically evaluating design alternatives against established workshop goals and objectives. These goals include parameters for density targeting occupant concentrations of 28 square meters per person where the median floor area of a unit is divided by the household as an indicator of adequacy in the context of overcrowding. Additionally, performance parameters are considered that include abundant access to uniform daylighting with a minimum of 250 lux over 90% of a floor plate; maximized distribution of fresh air to interior spaces with natural ventilation rates ranging from 0.8–1.5 m/s; and maintenance of view sheds to outdoor areas for a minimum of 90% of occupied spaces. These performance metrics parallel those adopted by the building industry which recommend daylight illuminance levels between 108–5,400 lux with a uniformity ratio of at least 0.4 when measuring the minimal daylight level over the weighted illuminance average; interior ventilation rates between 0.2–1.5 m/s; and direct lines of sight to outdoor areas for 75% of regularly occupied floor areas.

Aside from inhabitants that populate a metropolitan area, the physical identity of a city is largely derived by factors that include material, vegetation, terrain, and climate. While all of these factors are influential in defining the specific identity of Istanbul, this research solely focuses upon its characteristics of climate. Istanbul is classified in the Köppen system as temperate with hot and dry summer seasons. This climatic region resides 41 degrees north of the equator and 28 degrees

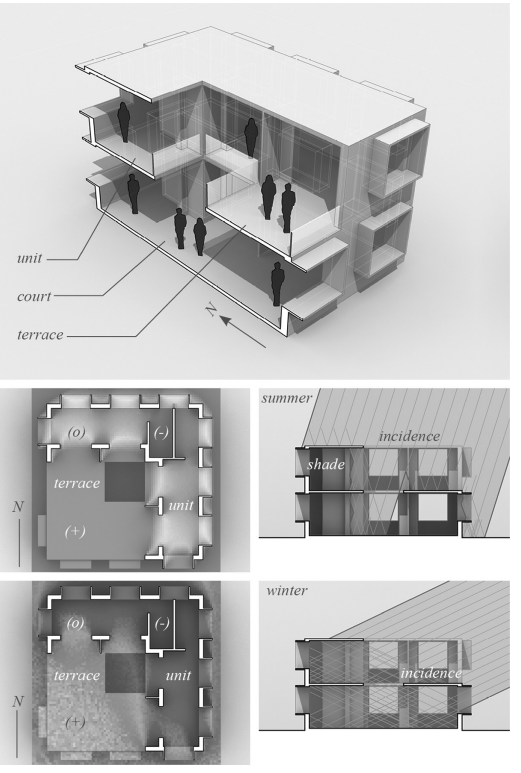

Figure 4. Above: Collective living model with thinness after Sanjaya. Below (clockwise from upper left): daylighting analysis of upper level, summer solar raytracing, winter solar raytracing and daily insolation analysis of upper level.

east of the prime meridian. Significant seasonal variation is present with daytime high-temperature averages in the winter at 7°C and in the summer at 28°C. Prevailing winds in the region generally come out of the north with year-round average speeds ranging from 4–6 m/s with peak velocities in the summer situated at 15 m/s. Additionally, from winter to summer solstice, the sun's elevation angle in the city shifts from 25–75° when measured at noon. The oblique relationship between solar inputs from the south and wind inputs from the north offer unique opportunities in passive climatization from summer to winter within Istanbul's temperate climate.

3.3 *Workshop outcomes*

Outcomes from the workshop demonstrate the cogency of spatial dispositions extracted from ancient structures in developing new models of collective living. Participants reintegrating the aforementioned design strategies including thinness, permeability and mass-void juxtaposition achieved direct connections with the immediate environment, heightened levels of comfort for building occupants and reduced reliance on high grade energy sources for building performance. With the use of simulation platforms, this

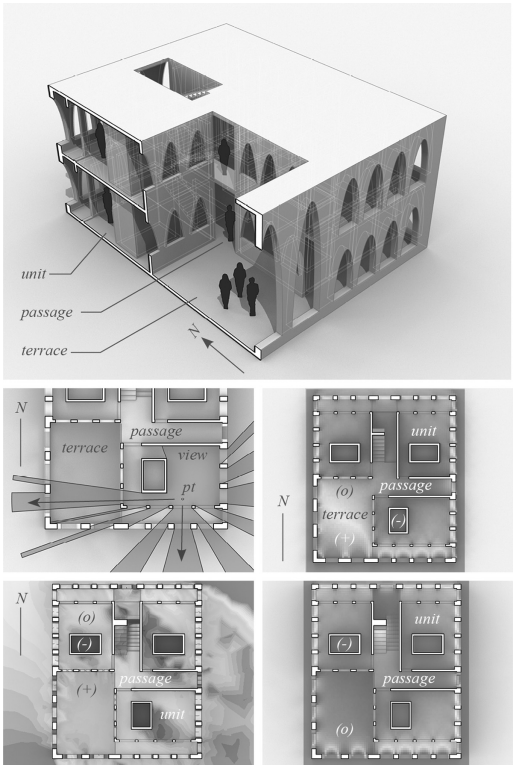

Figure 5. Above: Collective living model with permeability after McDonough. Below (clockwise from upper left): isovist analysis of the upper level, upper level daylighting analysis, lower level daylighting analysis and upper level air velocities.

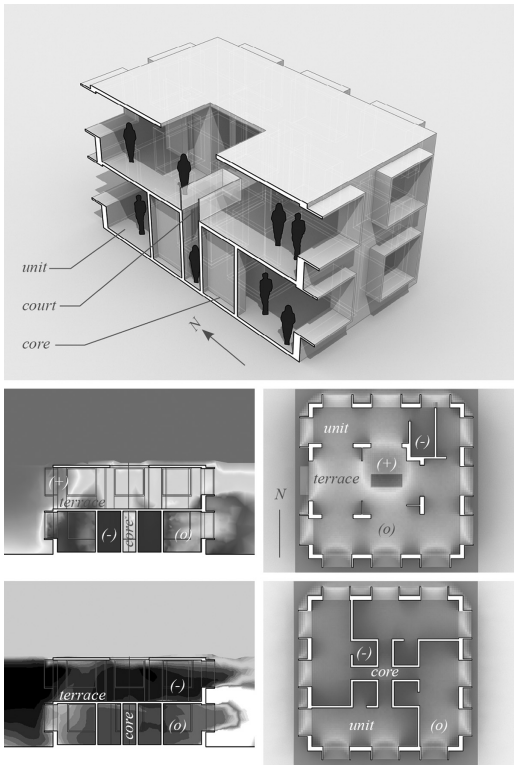

Figure 6. Above: Collective living model with mass-void juxtaposition after Sanjaya. Below (clockwise from upper left): air velocities in section, upper level daylighting analysis, lower level daylighting analysis and temperature in section.

research trajectory re-conceptualizes spatial typologies in urban settings by considering their ambient composition as comprised of an array of natural states. Using simulation domains, participants model natural forces pervading an urban condition and heuristically test alternative spatial dispositions, observing the dynamic interactions present within this shared domain. Through this process, participants track the relative strengths of design alternatives against the well-established metrics of passive building performance, outlined above, in context of constraints dictated by local climate.

Thin unit footprints are proposed in the workshop through the use of centralized spaces and concentrated living areas around the perimeter of a building block. Narrow unit plans and intermediary zones outfit with light shelves along the edges of each unit channel light into the central parts of the living area. The concentration of enclosed private functions along the perimeter with common amenity space central to the residential block provide occupant concentrations of 27 square meters per person. The resultant daylight levels along the central spine of the unit interior reach 925 lux at a minimum while the uniformity of light distribution in the space resides at 0.69 across the interior living area, both superior results against standard performance metrics for illuminance. Additionally, view sheds to the exterior are also provided to 99% of the private and common amenity areas of the complex (Figure 4).

Permeability is projected in the workshop with the introduction of air gaps between enclosed private living areas. These gaps, exposed to the fluid environment serve as common amenity areas, open circulation chases and unit access corridors. These tightly defined passages, set between loosely distributed enclosed private living units and intermixed amenity areas, offer occupant concentrations of 24 square meters per person. With circulation and amenity gaps doubling as ventilation ways, air velocity rates in each living area reside within the recommended range, between 0.5–1 m/s with 5 m/s prevailing winds out of the north. Distributing enclosed living units around the perimeter of each block while maximizing the openness of spaces between offers ample access to light and opportunities to view the surrounding context. Daylight levels central to each living area reside at 1000 lux on average while views to surrounding areas are provided to 96% of the unit floor area which are exemplary against comfort recommendations (Figure 5).

Mass-void juxtapositions are advanced in the workshop with gradually defined spatial zones whose configuration changes from loose to tight. Enclosed service areas, centrally located on certain levels, serve

to insulate living areas around the perimeter while on other levels, a narrow central court maximizes exposure of the enclosed living areas to the natural environment. Due to the shared access to the central court space and the additional area provided by enclosed service zones, occupant concentrations reside at 24 square meters per person. Due to the buoyancy of hot air, upper zones of the juxtaposed configuration need to exhaust hot air through ventilation provisions. With added exposure to the prevailing winds within these upper zones, hot air stratifying can be exhausted with strong ventilation rates of 1.5 m/s when exposed to the 5 m/s prevailing wind out of the northwest. Furthermore, superb daylight levels ranging from 1333 lux to 2000 lux are provided in each of these spatial zones through self-shading and orientation that offers adequate daylight distribution in order to maximize visual comfort for all interior activities (Figure 6).

4 CONCLUSIONS

The research presented here aims to provide an alternative workflow in the design of multi-tenant living models within densely populated metropolitan areas. Looking at ancient case studies as a source of insight, these models focus upon ecological relationships between the natural and constructed elements of a city to assimilate the building into the interworking of the local climate. The process highlighted in this paper opens the door to widespread use of strategies borrowed from antiquity and advances clustered living trajectories that measure the potential of renewable resources in providing comfort for inhabitants while sourcing in a manner that doesn't denigrate the natural ecology. Through the creation of observable simulation models, this research contributes to the future of our changing society by making the climatic conditions less constraining and more invigorating in urban design. As demonstrated in the analysis above, leveraging natural resources toward the betterment of the built environment offers added comfort and connection whereby spatial definition ceases to separate or isolate one from their surroundings but uses simulation models to extend, intensify or proliferate the characteristics of the natural world. Results from both the case study analysis and the collective living workshop produce atmospheric dispositions that reside well within established ranges for adequate interior comfort, offering a quality of life and healthy living situation for all population groups.

Up to this point, the research has explored three principal goals: offering new workflows within the design process that place natural and constructed elements within a shared domain, accommodating the need for population agglomerations in cities and offering improved access to natural resources for all urban inhabitants. While continued assessment of the successes and failures across this array of objectives is needed, the focus of this paper has been to deploy a new mechanism for analysis and design while measuring initial outcomes for relevance and potential impact on society. The expectation moving forward is to advance the research by transitioning from small abbreviated models of collective living to total developments where multiple scales of design are required that include specific unit parameters and tight site constraints. Next steps include the integration of evolutionary solvers within future workflows, continued examination of ancient case studies across the Anatolian region and corresponding workshops that examine high-rise housing complexes within Istanbul where density has resulted in over-development and subsequent tension among its population.

ACKNOWLEDGEMENTS

A city for the eyes of the future – children's visions of the city

R. Pelayo, P. Leal & I. Machado
I2ADS – Universidade do Porto, Porto, Portugal

ABSTRACT: This article addresses the conceptualization of urban areas and intends to approach the delineation of possible ideals for future urban development. It focuses on the idea of the renaturalization of the city understood as a process of making it more human-friendly in opposition to the many known factors that dehumanize urban space today. We depart from the assumption that architectural design is always a projection into the future and that children as citizens of the future should somehow be heard in such a process. Children's vision of urban space emerges from the analysis of 59 collective drawings representing idealized cities executed by about 800 young teenagers and are based on their experiences of living in urban areas. Quantitative data from the analysis of these visual documents allowed us to draw pertinent conclusions to the problem addressed and can now contribute to future urban planning.

1 INTRODUCTION

This article is an attempt to sketch a pertinent answer to the questions the organizers of this congress launched concerning the new ways in which urban areas are being conceptualized today. As they have put it, "urban and rural conditions overlap. Built areas merge with landscape and nature. How can research reconceptualize the urban condition? What will the city of the future look like? What was the presence of Nature in the urban fabric of the past?" We are looking for research that focuses on this transformation process (. . .) and points to possible ideals for future urban development" (Costa et al. 2016).

We address here the conceptualization of the urban areas and intend to approach the delineation of possible ideals for future urban development. In fact, dehumanization of the urban is something that we are being confronted with and it seems to result from the devaluation and neglect of the biological condition of humanity affecting all life forms in Earth. In a sociological viewpoint Lidskog (2001) asks "why do people (. . .) ignore some scientifically based recommendations (e.g. the random issue in dwellings) but totally accept others (e.g. Greenpeace's claim that Shell's plan to sink the oil platform Brent Spar in the North Sea would have ecologically detrimental consequences)?" Renaturalization of the city as a form of urban regeneration is an emergent concern among urban planners who are making efforts to transform the urban fabric focusing on expanding existing natural elements and even creating not only to just add a green area to urban settlements but giving natural elements the core role of structuring and organizing urban reconstruction.

To shed light on these issues from the perspective of the citizen we set up a visual research aiming to understand their urban aspirations. Although that is always a difficult task, it is also a particularly interesting viewpoint to put ourselves in, if we can succeed in gathering reliable information.

Departing from the assumption that architectural design is always a projection into the future we think that children, as citizens of the future, could serve as the perfect interlocutors in the much needed dialogue between the urban planning sphere and citizens. In fact, if the city will be theirs we shouldn't be indifferent to children's existence and find ways to take their visions into account as we responsibly devise our legacy to the next generations. It can similarly be argued that children are already full-fledged citizens and potentially the first victims of urban dehumanizing conditions and that is reason enough to take their city understandings and eventual urban aspirations into account.

Measures designed to overcome dehumanization of urban space specifically concerning children's well being is not new. Measures are being developed and implemented trough initiatives like UNICEF Child Friendly launched in 1996. This organization is growingly acting on the resolution passed during the second United Nations Conference on Human Settlements (Habitat II) which declared that "the wellbeing of children was the ultimate indicator of a healthy habitat, a democratic society and good governance" (Scott, 2011). They advocate listening to children's needs towards the built environment once it "has a significant impact on children and young people's development, their quality of life and their experience and enjoyment of the world. Schools, houses, shops, walkways, railways, parks, recreational and community centers are all part of our built environment" (Scott, 2011).

Expecting to collect data that allows a fresh look on these issues in a pertinent way to the problem addressed, we set up a detailed analysis on a series

Figure 1. Children drawing first drafts at workshop, 2013.

of group drawings made by children representing invented cities. The set of drawings was produced by 786 children aged between 11 and 13 years old that attended one of the 59 editions of the one-day workshop "Uma cidade para os teus olhos" (A city for your eyes) promoted by Universidade do Porto at Faculdade de Arquitectura as part of the much broader program for children "Universidade Júnior" (Junior University) in July 2013, July 2014 and July 2015. The workshop design was created by Professor Raquel Pelayo who is also responsible for its implementation. All authors of this article have worked directly with the children at the workshops and the assumptions deduced from the analysis of the drawings are also consistent with the informal observations made of the youngsters overall performance and what they externalized during the workshops.

Drawing is a process that captures not only conscious deliberate thinking but also unconscious and more profound subjectivities. That is the reason why it is one of the most important art forms and also quite appropriate as means of inquiring children.

The focus of the analysis is on the quantification of urban equipments that children elected to feature on their collaboratively idealized cities, but we realized that other focuses can be implemented in future research once these drawings are quite rich and have several layers of information that go beyond urban equipments. Since 2014 audio recordings of children's oral presentations of the individual first drafts have been done (about 500) within the workshop activities and those documents can be used in future further research, namely to compare the results of this visual inquiry with oral data.

2 VISUAL DATA ANALYSIS

Fifty nine large line drawings made with thick marker pen on newspaper of approximately 113×69 cm (44.5×27 in) executed collectively, in groups of fourteen young teenagers each, representing the city idealized by each group, are the visual documents analyzed in this investigation. We searched for traces of the children's vision of urban space in order to find out what they value in an urban area and the relative importance that they attribute to each of the urban equipments that they have chosen to include in their invented ideal cities.

We depart from the assumption that in what concerns children's drawing each drawn item is meaningful for its author. In this case each item stands for a piece of urban equipment that one of the children's deliberately desired to see in the city. This was not done by chance; they developed personal objective and subjective criteria to meet the workshop challenge i.e. drawing "their desirable city", "the best city ever", "something that would work" and that "they would be proud of".

At the workshops, the groups of 14 children were introduced to the knowledge world of architecture and urbanism, had the opportunity to develop graphic and visual skills, were sensitize for a responsible/active citizenship and reflected upon urbanism from their experiences of living in urban areas. All of that is reflected in their final collective drawings of the group "desirable city".

Note that before the execution of the collective drawing each child has created an individual drawing of the city with graphite pencil on A3 paper as can be seen in Figure 1. Only after completing that task the child has been asked to choose from his or her drawing the most important item(s) and draw them in the collective city in order to create with the co-workers the "ultimate city". These last drawings are the ones we analyzed. The execution of these final drawings has been filmed as part of the workshop. All these videos are available online at: https://www.youtube.com/channel/UCCPyZ3CyXk6n6hTUCXhqtkA and include all the audio recordings mentioned earlier (in portuguese).

The first question to be raised is if the visual documents analyzed are a viable and credible source to inform a theoretical approach to children's vision on urbanism. An example of one of the drawings analyzed can be seen in Figure 2. That depends on how true, coherent and comprehensive the raw quantitative data appears to be. And that is the case for all three conditions because we can confirm children's typical tastes from resultant data, like their preference for ice cream shops and fast-food restaurants – the only ones that appeared - or a relative strong presence of videogames shops. Also regarding entertainment children's preference for circus or funfairs are clear. On the other hand, we can see the presence of all basic life supporters on this planet, like water, light, plants and some animals. Sun and animals were items not considered in the analysis undertaken but almost all cities have a sun in the sky and birds/dogs also appear – as well as a dinosaur!

The portrait the numbers give us on children's vision is not an oversimplified version of the city's complexity, neither is devoid of logical and pragmatic thinking given that many areas and concerns appear, including the most important life maintenance activities, like feeding, health care, security, administration and even honoring the dead. Other main vital areas for surviving within society are present, like transports,

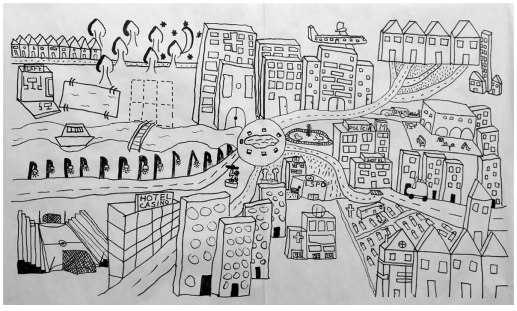

Figure 2. Children's collective final drawing of an imagined city. 2015. Raw data from conducted research.

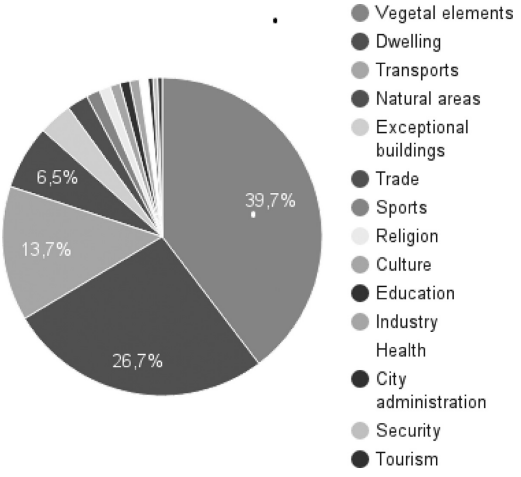

Figure 3. Percentage of urban equipment categories found. Data from conducted research.

schooling, diverse areas of business, entertainment and even cultural, identity and spiritual needs, as we will see. A last word to say that even children's humor, freedom and imagination are all reflected in these drawings for example when visiting UFOs overfly the city and suck-in a peaceful citizen or when a terrible fire ignites somewhere in the city presenting a security risk. We found a total of 3072 items corresponding to components of the 59 collaboratively imagined cities. Natural elements like the sun, the moon, clouds and animals were not taken into account and only the vegetal world has been considered to account for the presence of the natural world. This category is distinct of natural areas which consists in organized natural settings like a riverfront or a garden despite containing eventually some of the green elements that appear in natural areas. The percentages of urban equipment categories we found is represented in Figure 3 chart.

The main categories found are natural elements (1219), which include mainly trees and some flowers and grass. The second more present component is dwelling (821) divided in houses (516) some of them organized in housing estates and apartment buildings (305).

Transport equipments (421) are the last major category found, superior to 10 % of the total items. It includes roads (228), vehicles, like cars, buses, aircraft, helicopters, trains, ships or boats (93) bridges (38), traffic circles (27), railroads (10) and other equipment including airports and parking areas amongst other (25).

These data are surprising in what concerns the presence of nature in these cities. Data points very clearly to the importance children give to their need for nature to be present in their daily life since it not only has the larger amount of all, but also is everywhere and represents almost half the items absorbing 39.7% of all considered items.

Dwelling is an expected frequent feature and is 26.7% of total items. Population rates give us an idea of the size of the city. Once we have a housing value well below 50% of all features one can interpret that children prefer cities that are not giant urban agglomerates, highly populated. Following this preference for a certain equilibrium in the size of the desirable city one can add there is also a preference for one-family houses instead of big vertical buildings to live in. Despite that transportation is a big concern for children, not only in what concerns the circulation within the city, mainly by car – considering the 254 roads and traffic circles that are more than half the sum of all transport items – but also in terms of having connections to go anywhere, given the significant presence of long course transports by air, rail and water, although not by car once there are no highways.

These cities have shown to be quite complex as we proceeded to a more detailed analysis of the remaining 19.9% that splits into twelve different kinds of equipment that includes the following categories in order of higher presence: Natural areas (200), Exceptional buildings (105), Trade (66), Sports (42), Religion (35), Culture (32), Education (30), Health (30), Industry (30), City administration (15), Security (15) and Tourism (14). A chart representing these categories per quantity is at Figure 4.

Once again natural settings lead in number reinforcing the vital importance of it for children's well-being. Natural areas found are very diverse and include backyards (51), parks (38), riverside (31), waterfronts (30–17 lakes and 13 beaches) and adjoining the city there are frequently mountains (29) and forests (21). Water in diverse forms is always expressively present in the drawings. Its number more than triples the number of drawn cities.

Exceptional buildings are a category of constructions with no clear use that stands up for their architectural and symbolical value. It is of two sorts, contemporary buildings (41) and heritage buildings (64), 44 of those are medieval castles and/or fortifications. It's presence in the drawings almost doubles the number of cities. Amongst these historical value items we found quite similar versions of two Eiffel towers, a Palace of Westminster with the Big Ben tower, and even a TajMahal or a White House, but most of

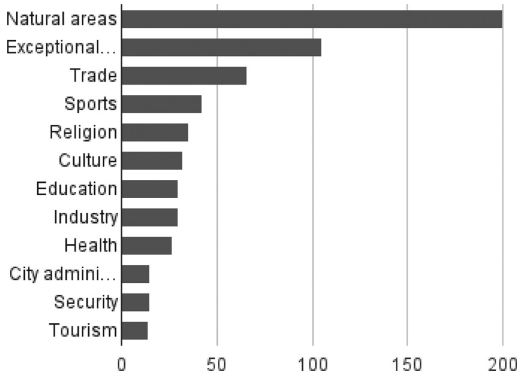

Figure 4. Other urban equipment categories per quantity. Data from conducted research.

these are invented in a blurred classical architectural style. These constructions might have been conceived as museums, offices, headquarters of various sorts, hotels or dwelling buildings but they stand in the city as expression of its cultural high level and historical value, as well as signaling the city's economical power. This leads us to conclude that for these children art as social identity vehicle imbued of cultural value is above all other more utilitarian life aspects present in the drawn cities. Even if those aspects carry survival value like food, health or security.

Trade is the next more frequent group of features. Its presence is similar, but superior to the number of drawn cities analyzed. Trade equipments include shopping centers (6), clothes shops, groceries (15), videogames, music and book shops (7), restaurants (9), bars and ice cream shops and a street food seller (19), banks (4) and post offices (3). Shops and services are usually grouped together in a street or certain area of the city. There is a preference for street shops and services (60) rather than shopping centers (6).

Sports is represented mainly by football fields and stadiums (19) followed by swimming pools (15) and other sport equipments for tennis, basketball, equitation, bowling and a multisport complex (8). What seems significant here is that all these equipments are in open air, favoring nature contact. The number of urban sport equipments is just below the number of city collective drawings.

Religion is the next most present concern in the children's cities. We found mainly churches and chapels (25) but also cemeteries (9) often side by side the churches. They appear in any place within the city. The number of religious constructions is about half the number of drawings meaning that half the cities have it. Also with a similar number we find Culture, Education, Health and Industry.

Culture aggregates open air funfairs (14) circuses (12) and buildings like theatres, music halls or museums (7). Almost as numerous as cultural equipments we found 30 schools, two of them universities and an astronomy research center. Health care is another area that has a fair presence in these cities once about half the cities have it. There are 27 hospitals and 3 pharmacies. The last type found in half the cities analyzed is Industry, which is composed mainly by factories (21) and includes not only two nuclear power plants, a wind turbine and a waste treatment center but also preindustrial equipments like windmills (6) and some other few features connected to agriculture (3).

City administration, Security and Tourism are present but are less frequent, appearing in only about a quarter of the drawings. The need for city management is represented through 15 central town hall buildings. Tourism is also seen as something important in a city. There are 14 hotels – one of them for dogs. Some of those are extravagant buildings, have many stars, swimming pools or a heliport at the top.

Security is the last type of equipment found in the children's drawn cities. There are six police stations and two police teams in action (8), some prisons (3) and four firefighter teams in action but we failed to distinguish their fire station buildings. We interpret that the importance given to security is expressed trough appearing as an ongoing activity rather than by urban equipment quantity.

3 CONCLUSIONS

The study conducted on children's drawings representing cities allowed us to access relevant information about children's space appropriation and aspirations, confirming the use of drawing as a powerful instrument of inquiry as attempted previously in other studies concerning territory (Lynch, K. 1960) and more recently Guerra (2014).

Main findings of this study concern the natural versus constructed balance, the population density and the symbolic value of art and architecture confirming previous conclusions from other studies on children connection to nature and adding identity issue as something that is worthy of further research.

There is no space for doubt in the data collected that the most important children aspiration stemming from the visual documents is for a strong nature presence in their lives and environment. The expressiveness of numbers points out this issue as being a precondition for human life once it is far above any other possible concern, confirming the biological need for more nature-friendly cities. As Lynch (1977, 57) put it "The hunger for trees is outspoken and seemingly universal". These results express the importance of developing policies towards the renaturalization of urban areas. It confirms Lynch (1977) oral collected data from children interviews when participants were asked to imagine the best place to live in, stated frequently trees, and as beautiful places, gardens and parks. It is also in line with other concomitant conclusions of the first explorative studies on how children used and experienced local places beside Lynch seminal work, like Hart (1979) and Moore (1986) researches that uncovered, for the first time, the high value of nature to children. This conclusion

is also supported by more recent studies, so comprehensively reviewed by Chawla (2015), that point to physical and psychological health benefits of nature contact.

Another important finding not unrelated to the previous is the city size in terms of population density per urban area. This is a concern that is shown by a smaller number of dwellings than expected (i.e. matching common cities' reality) associated with the preference for horizontal housing and followed by a frequent but bland presence of the road network, where no highways appear.

The final most relevant finding is not something that concerns physical survival. It expresses the primacy of spiritual and psychological human dimensions over materialistic needs. It is about the importance of art forms for a community. The number of exceptional buildings in the children's cities exceeds all other minor areas of urban equipments (i.e. Trade, Sports, Religion, Culture, Education, Health, Industry, City administration, Security, Tourism). In the analyzed set of drawings children ascribed vital importance to art's power to unite humans in a shared common identity. Be it trough celebrating present life – using new forms of beauty – or by celebrating our ancestry by preserving the past's precious heritage. In fact, the ability to empathize is at the core of every human conglomerate since prehistoric times and even though there are no previous studies pointing to this conclusion it is not alien to Sobel (2002) concept of "affective geography" coined upon Cobb (1959, 540) theory that states that "What a child wanted to do most of all was to make a world in which to find a place to discover a self".

Children's vision on the city points to these three ideals for future urban development concerning nature presence, city size and art and it would be interesting to compare children and adults vision on future cities in future studies.

Children say that without its totems (and what they stand for) or devoid of grow control the city will decay and that without its green shadows and flows of water the city will certainly die. As we all are responsible citizens and active members of communities around this planet we should all listen to our children and take in consideration their vision to see what we can do to leave behind a better and happier world.

A bio-socio integrative approach for future development of waterbodies in Alexandria

R.E. Abdel Galil
The Arab Academy for Science, Technology and Maritime Transport, Egypt

ABSTRACT: Urban areas in many cases irreversibly disrupt and fragment the landscape by imposing built structures and hardscapes, along with damaging human activities. This research is concerned with water bodies as natural elements in urban areas. Water has always been a fundamental attraction for city development. However, nowadays the integrated water-city relationship has weakened. In many cases the public are not engaged with waterfronts, and urban functioning is at odds with the preservation of the natural resource, resulting in neglect and mistreatment. Such is the case in Lake Mariout, Alexandria, Egypt.

The research addresses the fragmented approach to dealing with the Lake and the lack of consensus around its future. It realizes the potential of this natural element and the opportunities afforded by adopting a bio-socio integrative approach, with the aim to repair stressed and disfigured ecosystems while facilitating human development. Various stakeholders and interest groups were surveyed to gauge their views towards future developments and the Lake in order to form a consensual vision. The paper concludes with recommendations for city-nature synergy based on the quadrant of nature, population, built environment and governance.

1 URBAN – NATURE RELATIONSHIP

1.1 *Urban – nature synergy*

The relationship between human agglomerations and nature is one of disruption and stress. Cities are inhabited by a variety of flora and fauna and have become central nodes in the commodification of nature (Swyngedouw & Cook 2014). Urban areas vary in size and their relationship with the natural environment. The discourse on sustainable urban form often advocates urban compactness and criticizes sprawl, referring to earlier attempts of bringing nature closer to the city such as Ebenezer Howard's Garden city. Both Le Corbusier and Frank Lloyd Wright built on the work of Ebenezer Howard. Le Corbusier adopted a centrist vision aimed at increasing open space and improving circulation by increasing urban densities through high rise tower blocks, yet advocating segregation of functions. Wright's 'Broadacres' vision adopted a decentrist vision, considering the opportunities presented by the car and electricity, loosening the city boundaries and allowing densified spread into the countryside. He advocated aesthetically controlled and planned decentralised urban developments but did not anticipate the consequential unplanned sprawl (Vreeker, 2009). Both visions led to current urban patterns of dense mono-development in the city core and dispersed development on the fringe. Concepts, theories and practices such as the compact city, growth management, multifunctional land use, smart growth, new urbanism and transit-oriented design have evolved in response to the dissatisfaction with resultant urban patterns (Vreeker 2009, Ancell & Thompson-Fawcett 2008, Lau et al. 2005, Hall 1998). Recently, 'unsustainability' has risen to the fore in political and public consciousness, with emphasis drawn on the repercussions of urbanizing nature beyond the city and on re-viewing nature as harmonious and desirable (Swyngedouw & Cook 2014, Samiei 2013, Kaika 2005). But how can urban areas be an extension to our natural environment and how can we reach a balanced relationship?

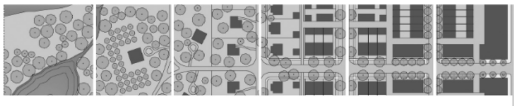

Figure 1. Urban Transect (Duany et al., 2014).

In order to conceptualize the relationship between urban areas and nature, the relative existence of nature in relation to the hierarchical urban spread is to be established. Two approaches are addressed. First, the 'transect' approach (Talen, 2002; Duany et al. 2014) which views the environment as a continuum ranging from rural to urban, aiming to preserve the integrity of both. This approach is useful in solidifying a logical progression from rural to urban with an underlying imperative that urban elements should strengthen rather than stress the immersive environment.

Six zones are specified: natural, rural, sub-urban, general, urban center and urban core (Duany et al. 2014). It is a rather linear conceptualization and does

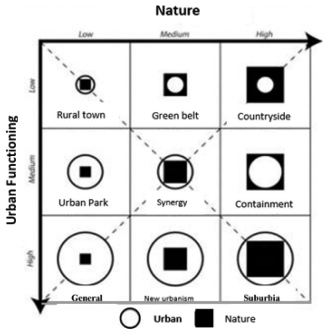

Figure 2. Urban – Nature synergy (adapted from Ducruet, 2007 and Duany et al., 2014).

not highlight issues of dependency. Second, a matrix developed by Ducruet (2007) explains the successive stages of port-city inter-relationship, subsequent spatial separation and the dependency and dominance of one over the other. He describes the relationship in terms of centrality and intermediary, where if an entity is central it holds value in and of itself, whereas if it is of an intermediary status, it is exploited and serves others. Duany et al. emphasize a spatial hierarchy, helpful to discern scale and size whereas Ducruet conceptualizes the inter-relationship between entities, valuable to discern exploitative versus synergistic associations.

Figure 2 shows a developed matrix building on both approaches to conceptualize the urban-nature relationship. Horizontally, nature increases in its dominance over the urban area, whereas vertically, urban functioning rather than density shows the pressure on nature. The diagonal running from the upper left to the lower right shows the hierarchical descent of centrality to intermediacy where nature is exploited in the context of suburbia. The diagonal running lower left to the upper right shows the opposite where the countryside is of value in and of itself and the urban areas develop independently of nature, risking patronage of natural resources. The synergy occurs in the middle where a state of equilibrium and balance can be conceptualized in terms of maintaining the integrity of both nature and the urban areas. This concept is led forward in the next section, informing the approach proposed in the paper.

1.2 *Fragmentation of city and nature*

Cities have long been viewed as disruptive to nature, a place where nature ends and intensive urban functioning begins (see the General city in Fig. 2), an imposition of built structures and hardscapes, not to mention human activities that put immense pressure on the natural environment and the ecosystem (Swyngedouw & Cook 2014, Samiei 2012, Heinonen & Junnila 2011, Yeang 2009, Grimm et al. 2008). Before the industrial revolution, cities were relatively small, few, had controlled population and their impact on the natural world was limited, in other words they were bio regionally embedded (Samiei, 2013). Following, the modernist view depicted the city as a mechanical object (Jones & Wingfield 2010), a view rejected later by many, giving rise to movements such as Metabolism, Landscape Urbanism, Urban Ecology and Eco master planning (Samiei 2013, Jones & Wingfield 2010, Yeang 2009, Yeang 2008, Svane et al. 2006, Kurokawa 1992, Anastasakis unpublished). Metabolism describes the city as a living organism, an evolving system made of parts, each having its function and the integration of the parts creates a whole (Kurokawa 1992). Landscape urbanism calls for closing boundaries between architecture and landscape, where flowing landscape-like building forms closely synchronize with their surroundings (Muller 2007). Urban ecology is an emerging interdisciplinary field that aims to understand how human and ecological processes can coexist in human-dominated systems. Urban ecosystems are perceived as diverse, hosting human activities that sustain human life forms, (infrastructure; roads, dams and buildings) and a biological inventory (plants, wildlife, water systems, food systems and microbes) (Samiei 2013). Eco masterplanning contrasts with conventional masterplanning in that it strives for a seamless and benign integration of the human built environment with the natural environment, retaining the ecosystems' integrity, connectivity and functioning.

These movements focus on the relationship between the city and nature with a focus on the built and natural environment. The human aspect is regarded in so far as it imposes infrastructure and hardscapes to satisfy human activities. More recently, it has been pointed out that the social aspects have perhaps been overlooked, calling for environmental justice, social ecology and equality (Swyngedouw & Cook 2014). Advocates encourage mapping the social activities that take place in the city and the ecological cycles at work in the urban environment (Jones & Wingfield, 2010). Hinging on resilience theory, the inter relationship between people and their environment is highlighted, stating that humans and nature are strongly coupled and co-evolving, and should therefore be conceived of as one 'social ecological' system (Holling cited in Montenegro 2010).

The literature has pointed to the fragmentation of ecosystems caused by mass urbanization which has disrupted natural systems and created unhealthy settlements. As a result, urban dwellers have become increasingly disconnected from nature, oblivious to the concepts of a healthy ecosystem, considering landscape an ornamental feature and superficial embellishment. Moreover, we face a new found uncertainty regarding social and economic pressures in light of widespread global economic instability and climate change which manifest themselves locally, more so in developing countries with the absence of effective mechanisms to deal with the various systems in urban areas.

Bio-integration and social ecology are key concepts to transform the relationship between urban areas and nature. It is by no means an easy task, particularly in developing countries with fragmented institutional structures. Coordinated action will be required for

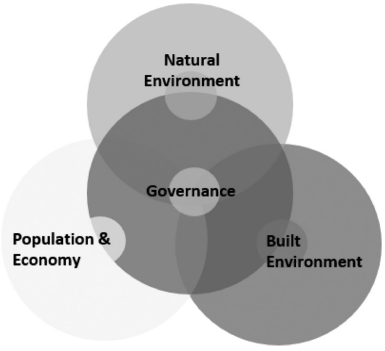

Figure 3. Key dimensions for a bio-socio integrative approach.

such a transformation to occur (Grant 2012). Figure 3 draws on the four key points outlined in the literature. It emphasizes the bio-integration of the Built and Natural Environment, the importance of coupling the natural with the human activities (socio-economic) and the imperativeness of coordination via a governance system to effect transformation. The approach is used to analyze the case study, develop a vision for the area and propose means of effecting this transformation.

2 LAKE MARIOUT CASE STUDY

2.1 *The natural environment*

Lake Mariout is one of the waterbodies in Alexandria city and borders it to the south. The Lake, once the most productive fisheries resource of the four major Egyptian brackish water lakes, in a couple of decades became the least productive (from 11,000 tons in 1976 to 6,378 tons in 2004), receiving primary treated sewage, industrial effluents and agricultural drainage water. The Lake is considered the boundary of the city where urban and rural meet, where agricultural land from the Nile delta form its south banks. The Lake area shrunk from 252 km^2 in 1889 to 71.4 km^2 in 1995 to 60.7 km^2 in 2009.

The Lake has relatively saline soil. Flora covers more than 60%, in the form of reed and water hyacinth, growing exponentially due to organic pollutants, affecting the fisheries. It is historically home to migratory birds, however, loss of habitat and hunting habits have reduced numbers significantly. The ecosystem of the Lake has severely suffered from unplanned human activities affecting its morphological and ecological characteristics. Land desiccation occurs systemically for: city development, heavy industries, agricultural reclamation and informal settlements (14.5 km^2). Motorways and canals led to the division of the Lake to four basins (Fig. 3) with no connections or waterflows, significantly changing the composition of each basin.

There are five informal settlements in the vicinity of the lake, one of which is directly on the shore. Questionnaires were distributed to their inhabitants as

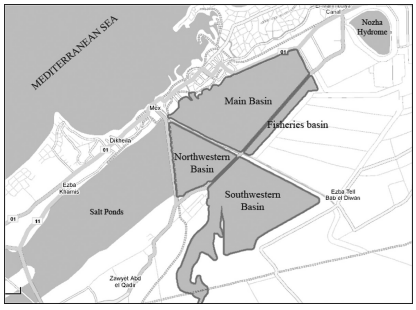

Figure 4. Division of Lake Mariout to four basins.

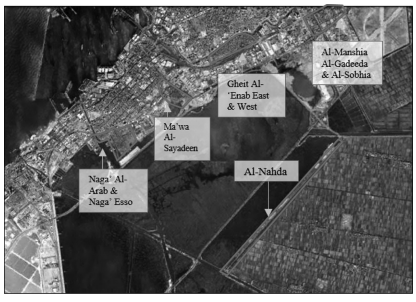

Figure 5. Informal settlements around the main basin.

part of the research (this will be explained further in the next section). 46.6% of the inhabitants prefer lake purification. Reasons varied between its natural existence and preserving the fishermen source of income, Investors use the extreme pollution as an argument for the entire filling of the water body. It is estimated that an economic loss of 5.6–8.5% of the city's GDP is attributed to the environmental degradation of the Lake between health costs, loss of tourism and recreation opportunities and loss of fisheries and wetland (CEDARE 2009). Several projects were initiated in cooperation with the Environmental Affairs Agency to address the pollution problem, however, none were implemented due to administrative reasons (explained in sec. 2.4) managerial and financial reasons. If the Lake, as an important Natural asset, is to be bio-integrated, it should seize to be seen as a backyard and its ecology preserved and harmonized with human activities. It currently has an intermediary status in the dependency relationship, where it only serves as an exploitative asset.

2.2 *Population and economy*

130 questionnaires were distributed to local residents of the area using a simple random sampling method. Five residential quarters were identified spanning three administrative districts.

The importance of the Lake to the respondents, personal attributes affecting their relationship with the Lake, their inclinations towards types of developments, were some of the main interest points. Almost 50% of the population age between 15–45 years and

those above 45 are about 23% (CEDARE 2009). To give an indication of the density, 107,476 people live in the informal settlement at the top left. Average family size is 4–5 members and illiteracy is 25%. The population are composed of fishermen, farmers and poor informal settlers where the latter forms the majority. The percentage of the workforce working in the informal sector is 30%, manufacturing industries 20%, 18% in the trade and equipment maintenance sectors, 12% in the construction sector, 10% in transport and storage, and only 10% of the total number of workforce work in fishing and agriculture (El-Refai 2009). This clearly shows that there are nearly no economic activities related to the Lake. In a neo-liberal market and according to ecological modernization, economic development is unquestionably prioritized and socio-ecological justice is neglected or receives limited consideration (Swyngedouw & Cook 2014, Baker 2007, Keil 2007, Portney 2003). Unless economic opportunities are linked with the Lake, in light of ecological modernization, the Lake might well be filled in and distributed as land plots. Also, those bearing the immediate burden of pollution are the settlers exposed to health hazards and the fishermen whose livelihoods are threatened.

The state of equilibrium and bio-socio integration is farfetched, tending towards the 'general city' (Figure 2), where the natural element has no value to the urban dwellers and is engulfed by urban functioning. This is emphasized in responses where, 51% consider the Lake unimportant to them (93% in one of the informal settlements), 35% are not ambitious about their area and only 38.4% acknowledge living in its vicinity. The Lake needs to be integral to dwellers' everyday activities and opportunities must arise to also attract the wider population of the city, affording society diversified opportunities for economic development, public enjoyment, and civic identity.

2.3 *The built environment (land-use, transportation & infrastructure*

Most of the urbanization is located to the north and west of the Lake. The estimated vacant land is about 5.68 km^2 accounting for 11%, residential uses occupy 8%, industry 18%, services 11% and vegetation 33%. Wetlands, commercial, religious and others occupy 19% (Fig. 5). Of the residential units, those 25–50 m from the shore of the Lake, are slum-like units and the price of land is third of its value compared to land on the roadways. This is obviously the opposite of what should be expected on a water body and confirms that the Lake is hardly seen as a natural asset. Heavy industries dominate the industrial sector accounting for 64% whereas light industries are 23% dominating the urban area to the north and north-west. None of the land uses are related or relevant to the Lake except for fishing. There are no recreational or tourism activities and the residential stock is limited. Land use can be an influential factor in achieving bio-integration where heavy polluting activities, poor housing stock

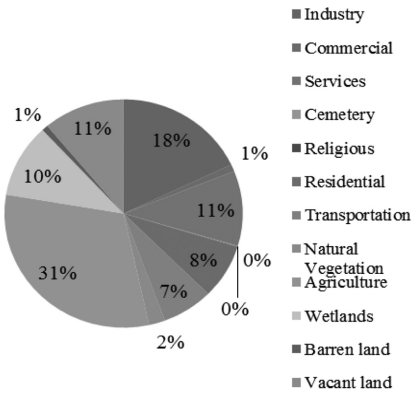

Figure 6. Land uses of the study area.

and limited civic amenities are at odds with urban ecology principles.

The transportation in the study area is one of the main factors that affect the equilibrium of the Lake ecosystem as the transportation network of roads, bridges and drainage routes were constructed in the middle of the Lake dividing it into basins with no openings for the passage of water. This isolated each basin, preventing ecological linkages, affecting its biodiversity and the way it deals with pollutants. The roads range from regional, national to local routes accounting for about 7% of the study area. These roads mostly surround the area rather than penetrate it, causing difficulties and immobility to the residents. Considering that most of the residential stock is informal, the infrastructure network is limited due to the illegality of land. The sanitation network only reaches 69% of households.

The analysis of the built environment reveals an inappropriate distribution of land uses in relation to the Lake, inconsideration of the lake ecosystem in laying the transportation routes and the severe shortage in services and facilities, all amounting to a disruptive urban area in dire need of a transformative approach.

2.4 *Governance*

The governance of Lake Mariout is at the heart of the problem. The Lake is surrounded by 6 administrative districts and managed by 7 national and local authorities, not to mention the secondary stakeholders and interest groups (see Table 1). On the national level, the Ministry of Agriculture owns the Lake, responsible for fish production, the Ministry of Irrigation manages the constancy of water level, the Ministry of Environment is responsible for environmental quality control and the Ministry of Interior enforces the Law and protects the lake from illegal activities and infringements. On the local level, the Governorate is responsible for planning and creating investment opportunities. An authority implements sewage plants, and finally industrial enterprises are ratified by the Investment Commission (Abdel Galil & Al-Din, 2013). Each

Table 1. Primary & Secondary stakeholders (Al-Din 2011, CEDARE 2009).

Primary stakeholders	Secondary stakeholders & interest groups
Alexandria Governorate	Syndicate of Fishermen and fishermen
Ministry of Housing, Utilities, and Urban Communities	Donors working in the same area (mainly World Bank, GEF and EPAP II)
Alexandria Company for Sanitary Drainage (National Organization for Potable Water & Sanitary Drainage)	Developers and Contractors (representation could be assigned to Alexandria Businessmen Association)
Ministry of Agriculture – The General Authority for Fish Resources Development	Ministry of Transportation
Ministry of Industry and Foreign Trade (and Federation of Egyptian Industries & Industry Modernization Program)	Ministry of Investment
Ministry of Petroleum – General Petroleum Organization	Waste Management Contractor (main & sub-contractors & informal labour)
Ministry of Environment – Environmental Affairs Agency (EEAA)	National NGO's (leading: Friends of the Environment, Pioneers of the Environment, and Fishermen Association)
Ministry of Interior – Water Bodies and Environment Police	Research Community in Alexandria (University of Alexandria, National Institute for Ocean Sciences)
Ministry of Health	Professional bodies
Ministry of Tourism	International bodies (World bank, UN)
Alexandria Local Council	Local community around the lake
	Alexandria populace
	Media and others

authority has its sectoral information which is not communicated to other authorities, besides the lack of an integrated management and monitoring plan for the Lake. The level of participation of the secondary stakeholders is minimal (CEDARE 2009).

The interviews conducted with government officials, professional bodies, investors, NGOs as well as the informal interviews with local residents of the lake vicinity (at the study area boundary), revealed varying opinions of the value of the Lake and the synergistic relationship between the development of the area and the natural resource. Rather than having a consensus on the value of the lake, they all agreed that it is in urgent need of purification, either because it can affect future investment prospect or for the livelihoods of the fishermen. NGOs and residents cited affordable ways to do so. However in terms of development, pressing socio-economic needs clearly shape the argument and affiliation with the lake. Bio-integration was only referred to by planning professionals, housing investors and Environmental NGOs. Residents were inclined to maintain the status quo of land desiccation and slum areas with better amenities yet no affiliation to the lake. Only the fishermen suggested changing the Lake's status as a natural reserve. The interviewees seemed unclear on who can effect these changes; for officials realize the limitations of their jurisdiction, NGOs and interest groups realize their limited role in decision making and residents go about their everyday lives depending on their social networks, as the majority are in illegal tenure.

3 BIO-SOCIO INTEGRATIVE VISION

A bio-socio integrative vision is one that considers the natural resources in the area as the foundation for human development based on a co-existing relationship where the contact with a biodiverse world is essential to stimulate the development of emotional, cognitive, and social potential and its lack results in a loss of real ecological knowledge and emotional attachment to nature. This knowledge and attachment can result in living within the limits and ecology of the natural area and informing a compatible type and form of human and built impositions. The role of governance is in fostering the integration and forging mutual relationships with the diverse stakeholders, maintaining environmental justice in order to bring about the transformation to a synergistic relationship.

In order to realize this vision in planning terms, objectives have been drawn for each of the key dimensions laid in Figure 3. Proposed projects for the area are given a priority tag and the responsibility for action is outlined (see tables 2, 3 & 4).

3.1 *The natural environment objective*

Achieving an ecological equilibrium and urban-nature synergy, avoiding human violation whether pollution or land encroachment (see Table 2).

3.2 *Population and economy objective*

Achieving balanced socio-economic structures based on environmental justice and consensual agreements (see Table 3).

3.3 *The built environment objective*

Achieving integration between the built environment and nature by allowing compatible and water-dependent landuses closer to the lake shore and relocating/mitigating harmful landuses. Also striving for environmental and social justice, accounting for social needs (see Table 4).

Table 2. Natural Environment Objective and projects.

Objective: Environmental equilibrium for lake Mariout ecosystem

Sector	Goals	Proposed Projects	Classification	Responsibility	Priority
Lake pollution	Purifying the lake water from the sources of pollution the heavy industries	– Secondary wastewater treatment plants – for the eastern and western plants – Building internal treatment plants for	Service	National Organization for Potable Water & Sanitary Drainage/EAA	High
		– Rework on opening tunnels under the international road and the Alexandria Cairo highway for the water passages	Service	Ministry of Housing and Reconstruction	High
		– The Integrated Management Project (IMP) – The Global Environment Facility project (GEF)	Service	The EAA	Medium
Lake encroachment	Preventing more land encroachments on the lake; through the immediate development on the existing shoreline	– Construction of the future development infrastructure – Promenade, directly on the lake shore	Service/local development	Ministry of Urban Planning/Alexandria Governorate	High
		– Parks and Green Spaces, adjacent to the lake shore	Service/local development	Ministry of Urban Planning/Alexandria Governorate	Medium

Table 3. Population and Economy Objective and projects.

Objective: Upgrading the socioeconomic conditions

Sector	Goals	Proposed Projects	Classification	Responsibility	Priority
Investment	Creating a fertile base of investment in the area	A catalyst project; could include water sports club, fishing clubs, or hotel and healthcare centre	Investment	Investors	High
Slum settlements & facilities	Socially accepted reallocation of the slum inhabitants, while sustaining their existing crafts.	Reallocation of the slum settlements in the same locations	Procedural	Alexandria Governorate/ investors	High
		– Economic housing; required by 30% of the slum inhabitants. (should be with equivalent existing households areas for each family)			
		– Retail complex includes most of the existing crafts and informal activities (craftsmen shops)	Investment	Ministry of Urban Planning/Alexandria Governorate *or* Investors	High
Fishing	Upgrading the socioeconomic conditions of the fishermen and increasing their existence.	– Demolishing the existing fishermen communities and establishing new ones, directly adjacent to the fishing activities	Procedural/ local development	Alexandria Governorate/ Ministry of Urban Planning	High
		– Fish market Transforming the lake, after purifying, into a "natural reserve" (as suggested by one of the interviewees)	Procedural	Ministry of Agriculture/ EAA	Medium

3.4 *Governance objective*

Establishing an Integrated Management Agency for Lake Mariout responsible for coordinating efforts and forging mutual relationships with diverse stakeholders. Decision making in a participatory process is its main responsibility.

The bio-socio integrative vision departs from the rationality and zoning of modernism separating the artificial and the natural environment which in many cases led to the exclusion of nature. It also departs from the purity and immobility of utopian approaches. Bio-socio integration starts from the notion of dependency and synergy developed in section 1.2. It aims for an equilibrium between the built, nature and humans, achieving a synergy in *function* and *size* of the urban area and nature (Fig. 1). The objectives deliver the vision, laying ground for action with seed projects aiming to repair stressed and disfigured ecosystems while facilitating human development.

4 CONCLUSION

The bio-socio integrative approach strives for a seamless and benign co-existence of the human built environment, the natural environment and social activities. The aim is ecologically and socially driven to

Table 4. Built Environment Objective and projects.

Objective: Integration with the natural environment and strive for environmental justice

Sector	Goals	Proposed Projects	Classification	Responsibility	Priority
Polices	Founding governmental guarantees and incentives for future investors	– Detailed, updated, registered land use plan – use of incentives ex. Impact fees, betterment or community infrastructure levy – Firm implementation of the existing land use laws, with increased penalties	Procedural	Ministry of urban planning/ Alexandria Governorate/ Ministry of Interior	High
Existing land uses	Mitigation of land uses that could not be relocated, integration of existing stock with the environment, and relocation.	– Establishing a buffer zone between the future development and the heavy industries	Service	Alexandria Governorate/ Ministry of Urban Planning	High
		– Relocation of the light industries to Borg Al-Arab industrial zone	Procedural/ Investment	Alexandria Governorate/ Investors	Medium
		– Rehabilitation of the old warehouses & encouraging bio-socio integrated projects	Investment	Investors	Medium
Development & Facilities	Establishing future land uses that meets the needs of the local inhabitants, the nature of the area, and economic development	– Water-dependent uses with high integration with water, including fish markets and restaurants, boat yards	Investment	Investors	Medium
		– Water-related uses with medium integration with water, including low density housing, youth centres	Investment	Investors	Low
		– General hospital required by 49% of the area inhabitants. Primary & preparatory schools. Police stations	Service/ Investment	Ministry of Urban Planning/ Ministry of Interior	High
Transportation	Enhancing and adopting the existing transportation network	– Increasing the capacity and quality of the existing transportation network and increasing accessibility	Service/ Investment/ Procedural	Ministry of Housing and Reconstruction	High
Infrastructure	Improving and enhancing the existing infrastructure system, to serve all the available potentials, including the tourism activities	Construction of a motorway connecting the study area with Borg Al-Arab industrial zone and upgrade of the railway (St no 218)	Service	Ministry of Housing and Reconstruction	High
		Increasing the capacity and quality of the existing sewerage and water systems. Roads should allow permeability though basins	Service	National Organization for Potable Water & Sanitary Drainage	High
		Designing a network of roads forming a tourism path to the historical sites in Lake Mariout area (including Wadi Mariout)	Service	Ministry of Housing and Reconstruction/Ministry of Urban Planning	Low

conserve and enhance existing ecosystems and foster a healthy relationship with urban functioning. The result is an urban-nature synergy aspiring for a state of equilibrium. The proposed approach departs from conventional planning and practices which inherently separate the built and the natural. It also departs from ecological modernization which commodifies nature, reducing impacts to tradable carbon units, and in so prioritizes economic development managed through technological fixes and organizational change, downplaying socio-ecological issues.

The case study shows how the current land uses have systematically disrupted and fragmented the landscape by imposing industries, informal settlements and regional highways not to mention dumping primary treated sewage, all destructive to the ecosystem of the Lake. Moreover, a fragmented management has resulted in further deterioration and loss of any interest in the Lake as an opportunity for enjoyment, investment and improved livelihoods. Instead of having a special value for the city, the shore rather than seen as a waterfront is considered as a backyard.

The relationship should be built on the premise of centrality rather than intermediary; the resources are not there to be merely exploited, rather a synergy should be formed. A synergistic relationship promises the development of emotional, cognitive, and social potential whilst maintaining the integrity of the ecosystem. To realize the synergy, a bio-socio integrative approach is presented building on four dimensions 'nature, population, built environment' and 'governance' where the latter fosters the integration between the former three dimensions and forges mutual relationships with the diverse stakeholders. The paper presents a useful conceptualization of the urban – nature relationship and further presents an approach building on the concept. Application on the case study showed how the approach can be taken forward through prioritized projects targeting each sector.

Urban acupuncture as a tool for today's re-naturalization of the city: The non-constructible parcels of municipal Beirut through the case study of Saifi district

D.R. Aouad
Department of Architecture & Design, School of Architecture & Design, Lebanese American University, Beirut, Lebanon

ABSTRACT: This paper builds on a review of approaches towards the concept of appropriation of urban space and leftover spaces in particular. Focusing on re-naturalization as a specific mode of space transformation, it examines the specificities of leftover spaces and the role they could play in relation to urban strategies for municipal Beirut. The current Lebanese urban legislation acknowledges a certain number of parcels as non-constructible; integrating these parcels within the existing urban fabric and implementing a strategy that will allow flexible and innovative space management, would require a process of identification, innovative urban tools, revised legal mechanisms as well private and public actor's involvement. Throughout this paper, building upon the collection and the analysis of non-constructible parcels' data within the study districts of municipal Beirut, a re-naturalization process in the form of urban acupuncture will be proposed and recommendations for eventual urban strategies, urban operations, tools and programs will be developed.

1 INTRODUCTION

1.1 *The context*

As cities struggle to adapt to the changes in society, culture, technology and the economy, new types of urbanism intriguingly manifest themselves as necessary tools for its re-naturalization. Today's understanding of re-naturalization has shifted from the traditional focus on squares, parks and pavements to a broader concept that recognizes the value of less formal leftover spaces and the daily interactions that occur in them. It is through this manifestation and the emergence of a more dynamic, flexible or adaptive urbanism, that the city could become more responsive to new needs, demands and the preferences of its users.

1.2 *The problematic*

Within the context of a growing urbanization on a territory that can no longer accommodate such growth, and the lack in open and public spaces to respond to users' needs, municipal Beirut finds within its realm an urban resource that can no longer be ignored. This paper is an inquiry into the role of leftover space and more specifically non-constructible parcels, regarding their values and potentialities for the re-naturalization of the city, based on their contribution to the public realm. At present, municipal Beirut holds within its urban fabric a high number of residual or leftover spaces that are labeled as non-constructible and the potential of these unexploited urban land resources, resulting mainly of gaps in the laws and regulation system as well as a political and social laissez-faire by the authorities, is yet to be explored.

This paper builds on a review of approaches towards the concept of appropriation of urban space and leftover spaces in particular, focusing on re-naturalization as a specific mode of space transformation. By examining the specificities of leftover spaces, their activation components and the role they could play in relation to urban strategies for small and dense cities such as municipal Beirut, this paper will attempt to examine the impact of these urban transformations on the cities' urban fabric and the sustainable revitalization this form of urban acupuncture might have on society.

Throughout this paper, non-constructible parcels within municipal Beirut, and more specifically the Saifi district, will be identified and analyzed. This paper will show how preliminary results, using GIS and extensive fieldwork, will go through a filtering process in order to achieve final results unveiling the existence of a network of parcels ready to play a role in the city's re-naturalization. Concerns regarding the implementation and urban proposals will be discussed in relation to urban strategies, legal operations, tools and re-naturalization programs. In conclusion, a summary of the findings and recommendations will be presented as part of a long term general tactical strategy for the appropriation and transformation of space.

2 LEFT OVER SPACES AND URBAN ACUPUNCTURE

2.1 *Left over spaces*

Since the 1980's, literature on the subject of leftover and residual spaces can be viewed as a reflection of the evolution of contemporary society in European and American cities. Authors such as Trancik (1986), Bauman (2001) and Koolhas (2002), in their quest to mitigate the shortcomings of modernism's planning, referred to the concept of residual spaces as an undesirable urban situation leading to urban incoherence and emptiness, others throughout their architectural works such as Winterbottom (2000), Knapfel (2001) and Atelier Bow Wow (2002) began to acknowledge their presence as a driving force in the urban fabric and described it in their work.

The publications of Thompson (2002), Studio Urban Catalyst (2003), Wikstrom (2005), Haydn and Temel (2006), Philipp Oswalt, Philipp Misselwitz and Laus Overmeyer (2007) and the more recent works of Sheridan (2008), Hou (2010) and Colomb (2012) did not only describe this urban situation but also acknowledged them as opportunities and proposed solutions and programs while assuming the efficiency and potential of these residual spaces in the city. Put aside their divergent stands on residual spaces, these authors, amongst many others, share a common goal and that is their wills to integrate residual spaces in the urban fabric.

The evolution of the meaning of the term leftover or residual space coincides with changes in each city's economic, social, political and urban situation, and along with those changes, different land uses are associated with the interpretation of these spaces. There were two distinguished approaches to residual spaces within the urban fabric; one that acknowledged these spaces as problematic and undesirable and the other that saw in these situations an opportunity to develop temporary use programs leading eventually to the re-naturalization of the city. Both approaches shared a common concern and that is the integration of these spaces within the urban fabric.

2.2 *Re-naturalization as urban acupuncture and the concept of interim spaces*

In any given urban fabric where strategic punctual interventions are needed to shortcut economic, social, political or legal obstacles, creating new energy and helping desired scenario to be consolidated, assigning a temporary use program to a vacant or underused land with no immediate development demand, the creation of interim spaces could be triggered. This concept of urban acupuncture, just as in the medical approach, will trigger positive chain-reactions, helping cure and enhance the whole system. Lerner (Lerner, 2014), explains that a healthy city must follow a sustained, long-term preventive care process that depends on a good relationship between urban planners, designers and the city itself in the same way as medicine depends on a good relationship between doctor and patient. He maintains that good urban acupuncture is about drawing people out to the streets and creating meeting places, helping the city become a catalyst of interventions between people. In that sense, re-naturalization of the city not only functions on a spatial level, it also acts as a catalyst for those interim spaces to become platforms for citizen participation hence providing an experimental opportunity for an urban platform for democratic action and human expression (Haydn & Temel, 2006). Moreover, Thompson's Loose-fit spaces (Thompson, 2002) implies a re-design of these spaces in order to integrate the urban fabric with unfixed rules of integration that could be defined by the users' need and may change accordingly.

In order to activate those spaces and furthermore implement a given temporary use programs, there are a number of components that need to co-exist. The following section will review these components as well as the drivers and the mechanisms that generate the emergence of interim spaces.

2.3 *The activation components*

2.3.1 *Drivers and pinpricks*

Strategies for city re-naturalization through urban acupuncture and the activation of leftover spaces require the co-existence of certain activation components and pinpricks. Driven by the spatial, social, economical and cultural context, specific small scale interventions mainly aim at enhancing city life. In order to better grasp the various user dependent strategies behind the activation of interim spaces, Bishop and Williams (2012) emphasize that other than uncertainty, there are numerous drivers and conditions for temporary urbanism such as vacancy, the revolution in the workspace, the intensity in the use of space and new technologies.

The existence of biophilic patterns such as visual connection to nature, non-rhythmic sensory stimuli, biomorphic forms and refuge are identified in various projects; Paley Park (Zion, 1967) and the High Line in New York (NYC Parks, 2013), Meanwhile London (Killing Architects, 2008), PlaNYC and Calgary Pop-Up Places (Pfeifer, 2013) have developed and implemented user dependent strategies (urban pinpricks) with spatial arrangements that show a strong correlation between those identified biophilic patterns and increased physical and mental user's well-being. Some have a more ambitious program, are larger in scale and require more effort in terms of funding, collaboration and authorities' involvements; others are easier to implement.

2.3.2 *The legal mechanisms*

On the other hand, and in order to complete the development of strategies for this urban acupuncture implementation, regulatory and legislative mechanisms not currently responding to users' needs, should be adapted, backed up by adequate tools and enthusiastic actors. Increasingly incorporating city

re-naturalization through leftover spaces into official planning processes as phases of development is a good start (Lehtovuori & Ruoppila, 2012). It was exemplified as a part of a long term vision for regeneration in the NDSM project in Amsterdam, where policies were adjusted to developing needs. Another recent project to fall under the same tactical strategy would be the High Line Project in New York and the Meanwhile London Project (Lehtovuori & Ruoppila, 2012). Whether long or short-term strategies were envisioned; resources were or were not available; leaders were local authorities or intermediary agents; or developments were user driven pushing for collaboration or centralized, they all shared a bottom-up strategy starting with the understanding of user's needs and the acknowledgment of the potential of leftover spaces.

Speeding up permits, innovative agreements and contracts, short-term leases and adaptive rental policies, freeing up vacant public space, providing benefits for private owners who support such implementations as well as corporate funding, self-funding and sponsorship all backed up with a positive political will, could provide a favorable context to allocating innovative programs and spaces leading eventually to a better re-naturalization of the city.

2.3.3 *The actors*

Any approach to everyday urbanism involves the collaboration of various entities; from public and private owners, endowments, developers, municipality and local public authorities, all the way to users, NGO's and activists. Different and innovative approaches such as participation, public and private sector collaboration, public-private sector partnership are few amongst new methods in city planning to meet the needs of the community and provide its users a better quality of life.

Mapping the potential of unused and leftover spaces have been a very active operation in cities such as Oslo (Soldeberg, 2011) and Sweden (Wikström, 2005), where many projects have focused on identifying the potential of leftover spaces such as underdeveloped lots, inactive public spaces and abandoned buildings. Municipal Beirut holds within its realm an urban resource that can no longer be ignored as well. The following sections will introduce the study area of municipal Beirut identifying and analyzing leftover space in the form of non-constructible parcels.

3 MUNICIPAL BEIRUT: AN URBAN RESOURCE

The introduction of the 1973 decree n°5550 divides municipal Beirut into 10 different districts (Figure 1) imposing along the way certain restrictions regarding the constructability status of certain parcels. Municipal Beirut is managed by a law-decree n° 118 adopted in 1977, and modified in 1997. The first article of this law-decree states that the municipality is a local administration that manages within the limits of its territory the attributes that are given to it by law. It is financially autonomous and has the power to self-manage its local interests. Two authorities are directly involved in the urban planning regulations: The Higher Council on Urban planning (HCU) and the Directorate General on Urbanism (DGU). Indirectly involved in the urban planning process is the Council for Redevelopment and Reconstruction (CDR) who's mission, back in 1977 when it was created, was to prepare a reconstruction plan for Lebanon.

Figure 1. Municipal Beirut cadastral districts and zoning map.

3.1 *Non-constructible parcels*

The major master plans Beirut was subject to throughout its history, such as the Danger Brothers Scheme in 1932 and the Ecochard scheme in 1943 and 1964 (Verdeil, 2005) combined with an outdated laws and regulations system that manages urban operations, have enriched the urban fabric of Municipal Beirut with a non negligible number of non-constructible parcels. They are leftover spaces found in the shape of small vacant or built spaces in between buildings or around corners (Figure 2). Their sizes do not exceed 250 m^2 depending on the zone they belong to and they can have various land uses such as parking lots for neighboring buildings, vacant plots, dumpsters, brown land, right of ways or other. Some of them are illegally built and as for the un-built ones, they are rapidly being consolidated with larger adjacent plots by developers who are seeking more space for their projects.

3.1.1 *The current legislation*

Since 1954, with the introduction of Article 5 of the decree n° 6285/54, Lebanon's Construction's Law has acknowledged and defined non-constructible surfaces as: (a) a residue of an old road after a new alignment and (b) a result of land consolidation or left-over after planning (El-Achkar E., 1998). Moreover, Article 5 modified by decree n° 5550/73, does not allow construction on narrow parts of parcels for three main reasons (El-Achkar E, 1998): (a) for the intent of visual clearance on street corners and intersections, (b) to

Figure 2. Picture of non-constructible parcel (Plot 634) in between two buildings serving as a junkyard.

Table 1. Minimal dimensions and areas for a parcel to be constructible according to zoning as per Article 2 of the decree n° 5550/73.

Zones	Area m^2	Façade m	Depth m
Zone 1	100	9	7
Zone 2	100	9	7
Zone 3	120	10	8
Zone 4	150	10	8
Zone 5	250	12	14
Zone 6	200	12	8
Zone 7	100	9	7

manage parcel densification and (c) to avoid transferring its odd forms into the volumetric of the buildings (Table 1).

Zones 8 and 10 are subject to special decrees while Zone 9 is a non aedificandi zone and hence do not contain any non-constructible parcels within their urban fabric.

3.1.2 *Methodology*

Since no data regarding non-constructible parcels was available, maps had to be redrawn in order to identify and highlight this type of information. The use of Geographic Informational System Software (GIS) proved to be adequate for this type of query, since it provides a layering system coupled with a geographic referencing system that allows maps from different sources to be stored, manipulated, analyzed and managed. Different attributes were given to non-constructible parcels in order to achieve a clear classification and to isolate the urban characteristics and allow for future comparative analysis. These attributes are: district name, number of parcel, zoning area, nature of use, constructability status, proximity factor and land consolidation potential of each parcel. In order to validate and archive the mapping results some fieldwork was done including photographical survey, updating existing maps, and fact sheets for each parcel. However, as a limitation to this study, few areas classified as military were

Figure 3. Municipal Beirut cadastral districts and zoning map showing non-constructible parcels preliminary distribution.

inaccessible and complete parcel ownership data was difficult to achieve.

3.2 *Preliminary results for districts*

A preliminary count of un-filtered non-constructible parcels and their distribution is shown in Figure 3.

The total number of non-constructible parcels within the boundaries of municipal Beirut is 6039. Zones 3 and 4 hold within their realm the highest number of non-constructible parcels, respectively 2016 and 2008, while zone 7 holds the lowest number with 115. Zone 2 holds 534, zone 6 holds 892 and finally zone 5 holds 474 parcels. However, the raw data at this stage is not yet complete since it doesn't take into account that some of these parcels cannot be exploited as a support for the re-naturalization of the city. It will be called the exploitability factor.

3.2.1 *Exploitability factor*

It was explained earlier (see section 3.1) that non-constructible parcels can have different sizes (not exceeding 250 m2) and can hold different functions. They can also be built; in that case it is most likely that these buildings are illegal (since no construction permit can be given to these parcels), or they can be un-built. Fieldwork have shown that built and un-built parcels have different urban situations as described in Table 2.

This exploitability factor relies on the potential of these parcels to host programs related to the re-naturalization of the city. The rationale behind it is that if an illegal building is badly preserved or abandoned, it could be easier for the municipality to demolish it and give the parcels back its non-constructability status or simply refurbish it. On the other hand, a well preserved building with inhabitants could be more problematic since it requires expropriation and settlements. Vacant plots are easier to manage whether they are publicly or privately owned. In the first case the municipality can be free to use the parcel the way she wishes, while in the second case, a settlement would have to be

Table 2. Different urban situations for non-constructible parcels within municipal Beirut and their exploitability factor.

Urban situation	Built	Unbuilt	Exploitable
Well preserved	x		
Badly preserved	x		x
Light structure	x		x
Consolidated	x		
Built before the law*	x		
Junkyard		x	x

Table 3. Count for exploitable and non-exploitable non-constructible parcels by districts within municipal Beirut.

Districts	Total* n°	Exploitable n°	Exploitable %**	Non-exploitable n°
Mdawar	1140	38	(23%)	130
Rmeil	1725	84	(26%)	238
Achrafieh	3221	615	(50%)	612
Saifi	423	77	(61%)	50
Zokak El Blat	559	151	(71%)	60
Bachoura	809	118	(65%)	62
Mazraa	4928	303	(24%)	951
Moussaytbeh	4387	127	(26%)	362
Ras Beirut	2583	70	(22%)	247
Minet El Hosn	537	18	(67%)	9
Ain El Mreysseh	620	35	(73%)	13

*The total represents all parcels in a given district.
**From the total of non-constructible parcels.

reached with the owner in order to allow his parcel to be used and integrated within the city's re-naturalization network.

The total number of non-constructible parcels ready to integrate the re-naturalization network is 1656 (Table 3) and has a total area of 300,000 m^2. As a comparative scale, this total area is similar to the largest park existing in Beirut, the Pine Forest, located south of the Mazraa district on the periphery of municipal Beirut. Within the realm of a dense city like Beirut, injecting a new life to these parcels could radically change the users' perception on green spaces and open public spaces. By bringing closer to users a flexible and adaptable space, where people can meet, gather and socialize, or simply use according to their needs, Beirut municipality could embrace the concept of re-naturalization through urban acupuncture.

In order to validate the previous encouraging results, it was necessary to further push those findings on a selected district in order to eventually apply one or more urban strategies to meet the objectives of this study.

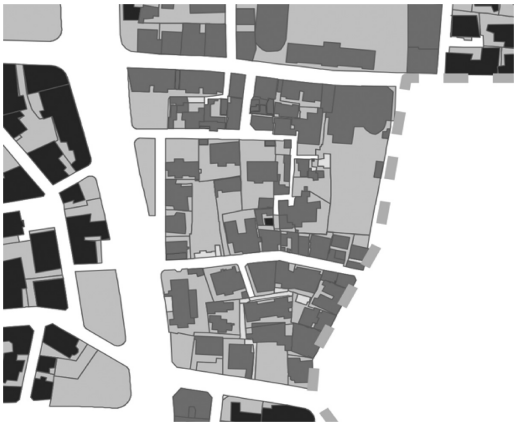

Figure 4. Examples of non-constructible parcels in Saifi district.

4 ANALYSIS OF CASE STUDY: SAIFI DISTRICT

In order to test these results as fairly as possible, it was important to select a district that would be, to a certain extent, representative of the other districts. It was also important that the selected district would have a good number of non-constructible parcels with a high rate of exploitability. Since these parcels would eventually be part of a larger network, it would be interesting that the selected district would be located close to the city center and with some proximity and connection to other districts.

4.1 *The case study area*

Saifi district fits well within the conditions stated above (Figure 4). It has an urban fabric that is quite representative of the other districts. It is situated on the southern edge of the city center and just east of Damascus road, a major axis in the urban fabric of Beirut. It holds within its realm a decent number of non-constructible parcels (77) with a high rate of exploitability (61%). Saifi district is a relatively small district with only 423 parcels in total, which makes it, for the purpose of this paper, a good case study.

4.2 *Identification*

Part of zone 2, this district's non-constructible parcels are guided by the minimal areas and dimensions listed in Table 1. The total area for the 77 non-constructible parcels adds up to 3976 m^2 or 1.5% of the district's total footprint of the built area. Should non-constructible parcels integrate the urban fabric and become interim spaces, accessibility will be an important parameter to study. Moreover, their integration and future use will depend greatly on the spatial, socio-economical and cultural context in which they belong.

Spatially, three types of situations were identified: parcels adjacent to a major road (37%), parcels

adjacent to a secondary road (48%), and parcels that were isolated inside blocks with no connection whatsoever to a road network (15%). While the better connected parcels could play an important role in exposing the network to the public, less exposed parcels could inject life into dense urban blocks in need of some breathing space. The average size of a non-constructible parcel in Saifi district is 44.7 m^2. However, further study of the Saifi district allowed the identification of a category of non-constructible spaces not identified as entities and part of constructible parcels that are acknowledged by the regulations. This urban situation could be added to the already existing reservoir of identified non-constructible parcels and could play an important role in the city.

Beirut is a city haunted by sectarian divide, and Saifi district is no exception to that. However, re-naturalization strategies have proven to have enough social commitments to overcome these divides pushing users and authorities forward to implement, promote and backup innovative urban policies in order to create a better quality of life.

4.3 *Land use*

For a better understanding of the nature of these non-constructible parcels it was necessary to analyze few urban parameters such as the status of the built, the nature of use and the types of occupancy (Table 4). Through fieldwork and data collection, it was identified that the number of vacant parcels is much higher than the illegally built. In a situation where built parcels are more demanding in terms of cost, i.e. rehabilitation and renovation, dealing with residents, and legalizing permit status, it is more cost effective to deal with un-built parcels, should their status allow it because not all un-built parcels are vacant land (see Table 5). Data also shows that the total area of vacant non-constructible parcels accounts for 37.2% of the total number of parcels and 26.4% of the total footprint of the parcels (42 parcels accounting for 1980 m^2). Even though right of ways makes 22% of the total footprint, implementing re-naturalization programs or features can be more delicate for accessibility reasons. There are very few vacant non-constructible parcels being used as gardens and that depicts a major problem in the existing urban fabric, as people have very few spaces in which they could turn to for green areas. Some of these existing parcels are playgrounds and others are just random and unorganized green spaces that need maintenance.

As specified earlier, not all vacant land are actually the same. Fieldwork shows that vacant land is used in some of the cases for: parking spaces, installing neighborhood generators, gardens, junkyards, building entrances and brown land.

On the basis of these findings, Saifi district, might as well be a very fertile ground for the implementation of innovative urban strategies focused on the city's re-naturalization. However, there are many concerns to be raised.

Table 4. Land use and types of occupancy for non-constructible parcels within Saifi district.

Occupancy	n°	m^2
Commercial	2	122
Right of way	10	640
Residential	30	1695
Vacant land	32	1640
Other*	3	134

*These are residual parcels that are part of a new road network.

Table 5. Land use and types of occupancy for non-constructible parcels labeled as vacant land within Saifi district.

Vacant Land	n°	m^2
Parking	7	778
Generators	1	301
Gardens	1	56
Junkyards	1	61
Entrances	2	92
Brown land	20	352

4.4 *The concerns*

Currently, the city under the authority of its municipality, has no vision regarding the implementation of these types of strategies. Apart from the inexistent urban strategy, non-constructible parcels are yet to be acknowledged as potential urban resource. Moreover, developments within the districts, and specifically in Saifi, are still promoter oriented rather than user oriented and no resources or funding are even remotely available to develop such endeavor, rather they still rely heavily on classical and traditional urban tools such as land consolidation and re-parceling. Bureaucratic slowdown and costly permits, as well as a case by case study by the municipality of proposed strategies (even on publicly owned land) are large obstacles for any future developments of such nature.

4.5 *Proposed urban strategies and recommendations*

Spatially, non-constructible parcels are a great opportunity to create usable outdoor spaces, integrating biophilic patterns that contribute to the overall positive health effects on the space. Views of vegetation and greenery such as trees and bushes, sound of splashing water from a waterfall loud enough to drown street noise and neighboring conversations, movable urban furniture for user appropriation of space, dynamic and diffuse light from tree shading and canopies, elevation from sidewalk and limited visual access to street are small interventions that could change the way a user views the space, enhancing it for better appropriation. Small neighborhood parks or loose-fit spaces, open air markets and cultural installations, or simply outdoor spaces that celebrate these biophilic patterns, would

emerge responding to local needs, promoting subculture diversities, hence drawing out people to the streets and creating meeting spaces, ultimately becoming a social catalyst for the city.

Strategic punctual interventions require municipality interference on publicly owned parcels, as well as owner's cooperation on privately owned land. In regards to the tactical urban strategy proposed, those interventions have to be part of a long-term vision to enhance the quality of life for the users in Beirut. Although the municipality should be leading this process and carefully following it up, informal actors should play a key role in the decision-making process and the implementation process. A collaboration of all actors within the framework of this strategy would push the implementation process forward and help its application.

First, the municipality needs to create a unit within its premises, in order to investigate and shortlist the potential non-constructible parcels. In the case where land is publicly owned, the Municipality would grant a permit for the organizer in order to use its vacant lot. The current procedures have limitations and new ones will need to be implemented. The created cell would be in charge of these procedures and would be run by experts in the field of design, events, economics, technology and other city related issues. Permits should be delivered rapidly, and decisions need to be taken on a local level, hence bypassing the municipal authority as it is the case today.

In the case of privately owned parcels, the municipality needs to interfere as well. Owners have to be contacted and notified that their unused property should be made available for a certain period of time. Of course incentives need to be given to owners who support the implementation of these programs, such as tax cuts or other. For the municipality and the owners, it is a win-win situation, since the municipality improves neighborhoods in disrepair by freeing up needed public space, and owners see their property being managed and taken care of. By issuing land procurement contracts, as it was done in Leipzig (Heck & Will, 2007), the municipality promotes private activities by prospecting and using privately owned sites for temporary use programs. Short-term leases and adaptive rental contracts could be negotiated with owners should the duration of the project require so. Moreover, by creating private public partnerships with landowners, the municipality could encourage owners to invest in temporary programs by freeing up their land.

It is clear that the potential of these parcels would not only exist in the entity of each but also in their connection to each other, creating a network of green itineraries and pathways throughout the neighborhood, district, and eventually the city.

5 CONCLUSION

The review of leftover spaces and temporary uses in North American and European cities, has shown that the concept of residual spaces has shifted from being referred to as an undesirable urban situation to being acknowledged as a driving force in the urban fabric and, moreover, as an opportunity for the implementation of re-naturalization programs. In defining the activation components for these interim spaces and highlighting the spatial, socio-economical and cultural contexts it was clear re-naturalization could, through urban acupuncture, become a tool for space transformation, hence serve as a catalyst for the city regeneration. Innovative urban strategies around the world, using mechanisms and tools led by local authorities, owners or other informal actors, share one common thread and that is the user-oriented tactics.

Through different regulatory reforms and tools such as land procurement contracts and authorization agreements, cities managed to reclaim the potential of residual spaces by collaborating with private owners and giving them incentives to encourage temporary use implementation on their property. Municipalities and local authorities have appointed special committees for following up on the process, and by short-listing potential sites, and proposing new programs, they were able to gain the confidence of the owners and implement successful projects.

It was shown that municipal Beirut holds within its realm an urban resource too precious to be ignored. In the context of urban growth and the continuous lack in open and public spaces, non-constructible parcels within municipal Beirut appear as an adequate support for the implementation of re-naturalization programs.

Through data collection and fieldwork, an updated database of the existing non-constructible parcels within municipal Beirut was generated. At first, a preliminary mapping of municipal Beirut parcels, according to their respective district's zoning and constructability limitations, has identified 6039 non-constructible parcels. According to the exploitability factor, it was shown that some of these parcels were not fit to host re-naturalization programs based on their nature of use and status. It was safe to assume that vacant parcels and illegal buildings in decay were better manageable in order to host any future program and easier to be integrated to the re-naturalization network.

The study has shown that after filtering undesirable parcels, the total number of non-constructible parcels added up to 1656 totaling an area of approximately 300,000 m^2, a non-negligible number when compared to the scale of the city. This where the concept of urban acupuncture begins to draw all its meaning. However, it was necessary to validate these results on a district's scale, in order to understand the distribution of these parcels amongst the districts. The case study of Saifi provided a deeper understanding of the nature of these parcels, as well as their distribution and scale. It was found that 1.5% of the district's built footprint or 3976 m2 of land was identified and ready to be integrated within the network. Moreover, vacant land account for 37.2% of the total number of parcels, which is an encouraging value for future implementation.

However, this study showed that were some concerns regarding the non-existent vision of the municipality which reflects on the weak legislative support for this type of operations, and the bureaucratic slowdown for permits delivery. More concerns were raised regarding the promoter oriented rather then user oriented strategies, its complete disregard for this urban resource within its realm and the lack of funding.

On the basis of these revelations, it was proposed that urban strategies dedicated for the city re-naturalization through non-constructible parcels should be of a tactical nature, consistent, focused on the implementation process, where uses are applied as part of a long-term vision for the regeneration of the city with adequate resources to back it up. Spatial arrangements integrating biophilic patterns such as the presence of water and greenery, the use of material connected to nature, elements of safety and some privacy, will increase physical and mental well-being of its users. By adjusting its current policy, involving public and private actors, investing in cells within the municipality to manage those resources and projects, Beirut municipality should strive to meet developing user's needs and push towards the re-naturalization of the city.

ABSTRACT: Can local, micro-level design and cultivation of shared, urban spaces foster stronger intra-sectorial and inter-community links and elevate youth participation levels towards the improvement of the quality of social life of neighborhoods? This paper provides an affirmative answer through the examination of a participatory action research applied in a vulnerable neighborhood in the City of Toronto. This article begins by briefly discussing the context as well as the methodology. Then, it proceeds by presenting the research process and framework, community involvement and participatory design. Finally, it concludes by reporting on the results, thus far, of this project.

1 INTRODUCTION

Alongside numerous large cities around the world at various scales (e.g., Birmingham and its riots, Paris and the "banlieue" unrest, etc.), Toronto has also recently been shocked by cases of indiscriminate youth-related violence in underserved communities.

Studies have found that these vulnerable neighborhoods are characterized by higher levels of youth unemployment and crime, as well as lower levels of family and community integration that together can increase the likelihood of depression and violent behavior. Another factor that impacts communities is health equity. Besides access to jobs and health facilities, residents also need safe recreation spaces to feel less isolated and to have opportunities to interact. Often the remedies discussed involve large-scale, infrastructure-related transformations, which are costly, structure- rather than individual-centered and have a long-term (often unrealized) time horizon. This paper suggests an alternative strategy of targeted micro-level urban interventions, by way of designing and creating participatory gardens in selected locations of a neighborhood with higher levels of youth unemployment, social inequities, and crime. It focuses on the case of the Flemingdon Park in Toronto and the ongoing urban regeneration project that a team of designers, community workers, neighborhood leaders and engaged youth initiated in 2013.

The renaturalization of cities can take different forms—from the development of large scale parks like the Bois de Boulogne and the Parc de Vincennes in Paris which were considered lungs for the city of the 19th century—to planted avenues and planned urban green spaces like those designed and implemented under Alphan who improved the quality of public spaces in the French capital. These strategies contributed to the beautification of Paris and adopted a planned top-down approach.

Recently, we have witnessed an increase in citizens taking action to turn their neighborhoods into more inclusive spaces and attempt to regain access to areas overtaken by vehicular circulation. An interesting exhibition and book that displayed such initiatives was *Actions, What Can You Do with the City* curated by the Canadian Centre for Architecture (Borasi & Zardini 2008). At the local scale, the Flemingdon Urban Fair Committee has been raising awareness about the importance of green spaces in the neighborhood, has been looking for alternatives to activate them, and has been advocating for a community-based farmers market.

This paper focuses on a pilot project that uses a participatory action research approach to engage youth in envisioning and contributing to the renaturalization of parts of their neighborhood by way of gardening. It builds on earlier studies like *Paysage Solidaire* undertaken in vulnerable neighborhoods in Montreal (Farah

& Bhatt 2013) initiated by pioneers like V. Bhatt and other members of the Minimum Cost Housing Group of McGill University.

2 PARTICIPATORY ACTION RESEARCH (PAR)

Studies from a variety of fields have been using the PAR methodology. According to Baum et al. "Participatory action research seeks to understand and improve the world by changing it. At its heart is collective, self-reflective inquiry that researchers and participants undertake, so they can understand and improve upon the practices in which they participate and the situations in which they find themselves (2006 adapted from Minkler 2003 and Wallerstein and Grinch 1999)." (Baum et al. 2006).

When undertaking participatory action research in communities, the researcher helps set a framework and enable participants to contribute to addressing an issue or to a visioning session. Hence, as noted by Gumucio-Dagron (2001), the researcher plays more of a facilitator's role rather than a guide. Overall, the PAR methodology is well suited to engage communities, which is why it is becoming increasingly popular with urban planning, urban design and landscape projects (Deming et al. 2011).

3 FLEMINGDON PARK: A CASE STUDY

3.1 *Background of flemingdon park*

Flemingdon Park is a vulnerable neighborhood, with 30% of its population considered low-income – a high number compared to the City of Toronto's overall average of 19% in 2011 (City of Toronto, Neighbourhood Demographic Estimates, 2014) and the fifth highest unemployment rate (15.3%) out of the 140 neighbourhoods of the city (Centre for Research in Inner City Health, 2014). Since 2014, Flemingdon Park was included in the City of Toronto's *Neighborhood Improvement Areas* (31 neighborhoods have received this designation), and prior to 2014, it was considered a *Priority Neighborhood* (City of Toronto, NIA Profiles).

With regard to its physical layout, Flemingdon Park is niched between two ravines systems (on the West, South and East) and a main road to the North (Eglinton Avenue), hence disconnecting it from the rest of Toronto's urban fabric. Moreover, it is further subdivided due to the passing of the Don Valley Parkway (a major highway running North/South) as well as by the presence of an unbuilt strip that hosts the Hydro Corridor (an infrastructure comprising of elevated electricity transmission poles).

The question we asked was how to engage youth in this socially and geographically underserved location to envision improved pedestrian links-with increased activity as well as natural surveillance of public spaces-between selected community hubs, while also growing food.

3.2 *The research and iterative design process*

In 2015, the design process in Flemingdon Park included the following activities:

1. Meeting with the design team, Youth Outreach Workers and Public Health staff members from the City of Toronto as well as potential partners to discuss the research scope,
2. Creating an inventory of potential sites that could be used to renaturalize the neighborhood and site visits to select a number of eligible sites (shown in figure 1),
3. Collecting data related to the physical environment of the neighborhood (property plans, maps, building heights) through field work and geospatial data,
4. Analyzing the data and preparing visual materials (maps to share information about the site and facilitate the participatory process, as well as selection of urban agriculture (UA) case studies to enrich participants' understanding and illustrate the variety of possibilities),
5. Beginning to meet youth for:
   - Discussions regarding their needs, challenges they faced and their aspirations associated to the neighborhood in general and to specific sites,
   - Broadening their understanding of UA and generating ideas regarding possible implementations on the sites,
6. Engaging and including youth in the participatory design process through design charrettes,
7. Summarizing participants' ideas, elaborating their visions, visualizing the design,
8. Presenting to the community through data visualization, incorporating their feedback and further discussing ways to improve the proposal,
9. Revising the proposal following feedback from community members,
10. Following-up on the project status

Overall, the process was iterative: facilitated by the design team, community members expressed their aspirations; these were digitalized and the design team further illustrated them with the use of renderings, sections or photomontages which were represented to the community for additional feedback and revised accordingly.

As depicted in Figure 1, eight sites were selected because they were key gathering hubs for residents like the community centre, a recreation centre, schools, or the commercial centre. More specifically, they included: 1) Flemingdon Community Centre and Playground Paradise; 2) a city-owned unattractive community park adjacent to the Hydro corridor; 3) the lot of the Dennis R. Timbrell Recreation Centre and Flemingdon Park Library; 4) the Ontario Science Centre; 5) Flemingdon Park shopping centre; 6) the Valley Park Middle School; 7) Marc Garneau Collegiate School; and 8) a health centre with a food bank as illustrated in figures 1 and 7.

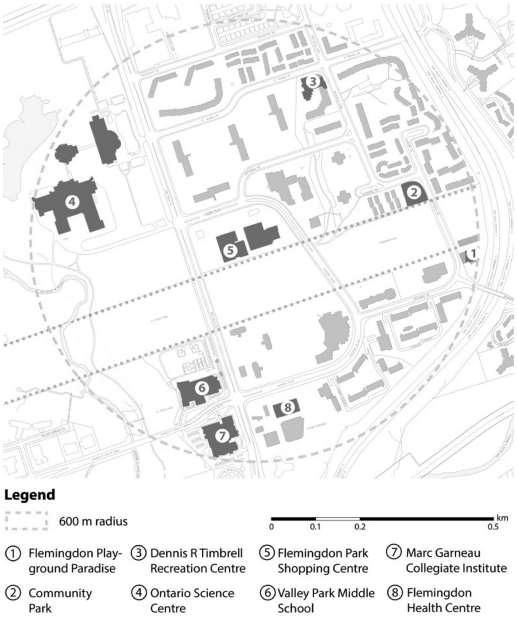

Figure 1. Map of the area of study within the Flemingdon Park neighborhood.
Sources: This map is based on data from the City of Toronto Property Data Maps (2013) available through Ryerson University's Geospatial Map & Data Centre.

The aforementioned sites were lacking a clear connection, hence, we investigated how to link them through pathways and an improved pedestrian realm by way of both gardening and integrating urban agriculture.

The first charrette included seven youth participants from the community. Volunteers were shown examples where urban agriculture was incorporated to public spaces. Then, they were divided into two groups and were asked to make a collage to improve the attractiveness of the park (identified with the number 2 on the maps figure 1 and 7). They were provided with a plan of the park, elements (benches, compost bins, tree bags, growing containers, picnic tables and raised beds), scissors, glue and colours as shown in figure 2. Following this participatory design charrette, youth presented their proposal to each other and we discussed how to move forward. The design team further developed the proposal based on ideas generated through this process, presented the working project for more feedback and then finalised it.

The second charrette combined a background introduction about gardening, urban agriculture and pedestrianization with a visual presentation based on the outputs of the first charrette, as well as an individual drawing exercise. A total of 25 youth participating in the school's summer camp joined this meeting and provided feedback on the working proposal. Their comments on work to date were taken into account towards improving their experience and responding to their interests.

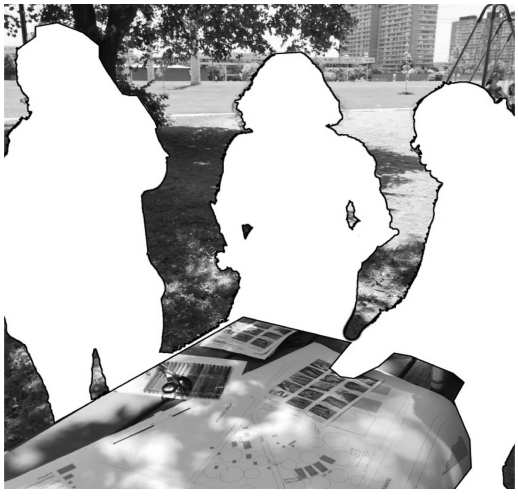

Figure 2. First charrette with community youth envisioning the future of the community park identified with the number 2 in figures 1 and 7.

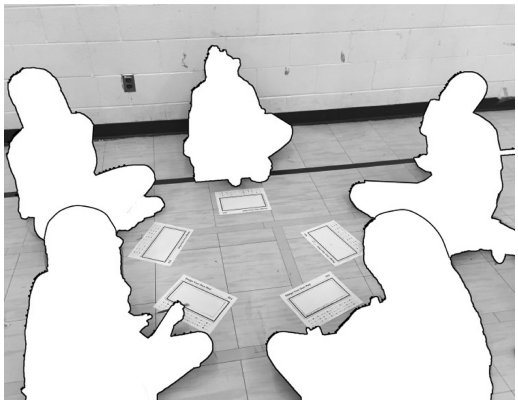

Figure 3. Second Charrette: youth from the community designing the layout of a plot along the Hydro Corridor.

Further, for the charrette component of this meeting, each youth selected a 3 by 6 meters site along the hydro corridor where they could intensify urban agriculture based on their preferences. Then, they gathered in smaller groups as illustrated in Figure 3.

Their ideas were expressed through marker drawings on a sheet comprising of a rectangle (illustrating the plot) and a list of 30 vegetables suitable for cultivation in the area.

3.3 *Designing the connecting trail*

Similar to the large vacant lots in the Flemingdon Park neighborhood, streets and pathways are in general very wide and rather uninspiring due to their scale, the lack of activity, programming and their single use. The envisioned connecting trail, illustrated in figure 4, aimed to improve the natural and social connections in the neighborhood through an enhanced public realm,

Figure 4. Schematic illustration of the proposal for a connecting trail.
Sources: This view is based on data from the City of Toronto Property Data Maps (2013) and Building Height Data (2015) available through Ryerson University's Geospatial Map & Data Centre.

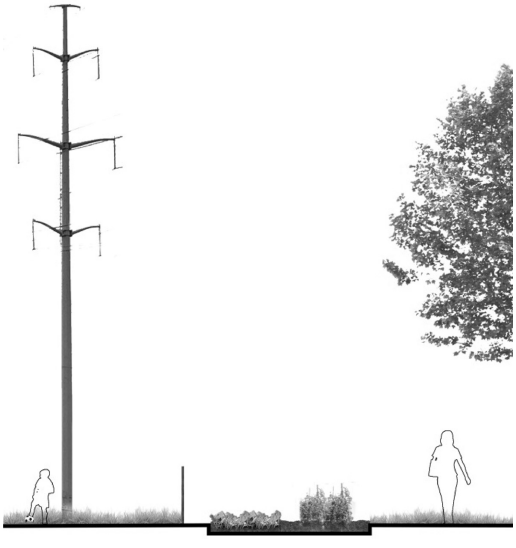

Figure 5. Section of a portion of the hydro corridor illustrating the inclusion of vegetable gardens.

by way of integrating urban agriculture, natural shading and creating an identity to the area engaging both residents and visitors.

To illustrate some proposed connecting pedestrian paths, sections and perspectives, as shown in figures 5 and 6 were used.

Trees, shrubs and ferns were selected based on a list of Toronto native plants (City of Toronto, Tree Planting); in addition, fruits and vegetables were also included.

While the hydro corridor is already used by youth for sports activities, we proposed to further intensify its usage and activate it by way of incorporating a community garden along the northern perimeter as illustrated in the section, Figure 5.

Further, to revitalise the Flemingdon shopping centre area (identified with the number 5 in figures 1 and 7), a wide outdoor space between two key commercial buildings was rethought. Taking advantage of an existing raised bed, we proposed to plant vegetables

Figure 6. Perspective illustrating a proposed aromatic garden in the Flemingdon shopping centre.
Illustration by Chenqi Zhu and Chu Li.

such as tomatoes, cucumbers and peppers (based on youth preferences) as well as crab apple trees – also found along the hydro corridor. As illustrated in figure 6, shaded gathering spaces were introduced under the trees. These urban sitting areas, initially inspired by a bench developed by Cox Architects, address a desire expressed by the youth to have more outdoor community spaces.

Overall, the value of these interventions is not only found in the greening and renaturalizing of part of the neighborhood; they have already engaged youth in the visioning process, and continue to involve them in the implementation. In 2013, our team developed a garden in Vendome Place, a noteworthy Modern housing project developed by Irving Grossman. In 2016, youth inaugurated another garden in front of the Flemingdon Playground paradise. We have also reached out to the Councillor and are in the process of investigating ways to further consolidate this work.

As illustrated in the map Figure 7, by connecting education, community and commercial hubs in a neighborhood, gardening activities can and already do have a larger impact when linked, contributing to a stronger sense of inclusion, cooperation, security and neighborhood identity.

4 CONCLUSIONS

The results from this PAR empirical case illustrate that such gardens can not only improve districts and re-naturalize the city, but also help towards repairing the social and urban fabric in numerous ways. First,

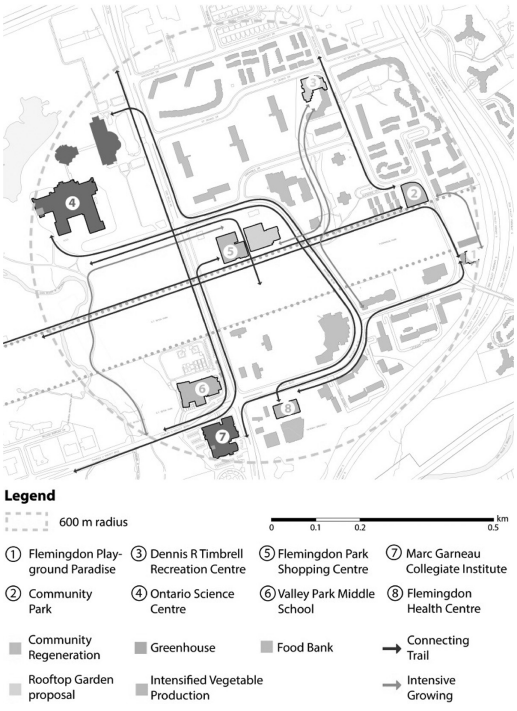

Figure 7. Map showing how a variety of existing and added practices related to gardening and urban agriculture in the neighborhood.

they can distinguish one's neighborhood. Second, the joint element of this effort presupposes, and therefore fosters a community spirit. Third, the building and operating of such a community garden re-engages younger with other community members (allowing for knowledge and advice to be transmitted), benefiting both; fourth by way of channeling some of their energy and time towards a productive and fruitful activity they can be proud of, it ultimately empowers the young.

ACKNOWLEDGMENTS

The authors would like to thank all the youth volunteers who participated in this project, as well as Mariana Pereira Guimaraes, 2013 Research assistant and Chenqi Zhu, 2016 Research assistant with the Mitacs Globalink program who contributed to different phases of this research project.

This research was partly funded by the Mitacs Globalink program and Ryerson University. This project also received a Dean's Research Fund from the Faculty of Engineering and Architectural Science.

Constructing urban habitats: Investigating the ecological potential of integrating natural environments into buildings and landscapes in urban areas

Giancarlo Mangone
Carleton University, Ottawa, Canada

ABSTRACT: The integration of natural environments into urban areas can provide diverse economic, social, and ecological benefits. However, there is scant existing research on nature integrated urban landscape and building design strategies and solutions that effectively improve the ecological integrity of local ecosystems. Through a literature review, this paper investigates the relative ecological performance potential of stand-alone urban landscapes (ULs), incorporating natural environments into buildings (NIBs), and incorporating natural environments adjacent to buildings (NABs). The results indicate that the integration of natural environments into urban areas can substantially improve the ecological integrity of local ecosystems. NABs can be particularly effective, as they can be designed to foster the benefits of both NIBs and ULs, while also offering unique, and generally more effective, ecological benefits. Specifically, NABs can substantially contribute to reducing urban sprawl, in ways that improve the economic and social value of local communities.

1 INTRODUCTION

There is substantial evidence that urban natural environment design solutions *[urban habitats],* such as parks, building site landscapes, and building integrated natural environments, can be designed to make positive, effective contributions to the integrity of local ecosystems, depending on the design solution and context (Snep et al., 2011, Mangone, 2015b). However, there is currently a dearth of research, including effective ecological performance evaluation metrics, on nature integrated urban landscape and building design strategies and solutions that effectively improve the ecological integrity of local ecosystems (Lundholm and Richardson, 2010, Zari, 2012). Without this knowledge, it is difficult for design teams to produce design solutions that positively impact local ecosystems, which is demonstrated by the number of existing ineffective urban habitats, which in some cases negatively impact local ecosystems. For instance, design teams can focus on solving seemingly important issues, such as providing an extensive green roof to foster biodiversity. However, depending on their design and connectivity with local ecological corridors and habitat patches, urban habitats, including green roofs, can function as ecological traps (Battin, 2004).

However, comprehensive ecological performance evaluations of cities are not usually available for building and landscape design teams, or commissioned by municipalities. Thus, it's important to identify the relative value of various building and landscape scale ecological design solutions.

The focus of this paper is to investigate the relative maximum ecological performance potential of natural environments integrated into buildings (NIBs), natural environments integrated into building developments as adjacent, symbiotic environments (NABs), and standalone, exterior natural environments (landscapes), when sited within urban areas. The relative value of these three general types of ecological design solutions are discussed, in terms of their potential to improve the ecological integrity of local ecosystems. These ecological design solutions are based on the results of previous explorative research projects that investigated the maximum ecological performance potential of buildings and urban landscapes, (Mangone and Luscuere, 2012, Mangone, 2015a) as well as literature reviews of the effects of urban areas on local ecosystems, and the potential of urban areas to improve the ecological integrity of local ecosystems (Mangone, 2015b). This discussion provides both a review of existing literature that can be applied to ecological building and landscape design strategies, as well as proposes and assesses the ecological potential of an innovative landscape integrated building design strategy, based on the results of existing literature.

2 METHODS

In order to identify effective design solutions and strategies, it is important to evaluate the ecological performance of various design solutions and strategies at the correct scale. Although design teams tend to focus on the ecological performance potential of the project site, (Zari, 2012) or in some cases the city, (Chrysoulakis et al., 2013) existing research indicates that ecological design solutions at scales smaller than

individual regions, such as at the scale of individual buildings, neighborhoods, and landscapes, tend to be most effective when they address the ecological issues that are most important to consider at the scale of the local region (Schneiders et al., 2012, Kowarik, 2011, Noss, 2000). Thus, it is necessary for design teams to identify the ecological issues that are important to address at the scale of the local region that the site and local city are situated within. After identifying the most important regional ecological performance issues, the design team should assess which issues can most effectively be addressed through their project, given the project constraints, budgets, goals, and other design factors (Mangone, 2015b). Therefore, the ecological performance of the different ecological design strategies within this paper are discussed and assessed in this paper in terms of their potential contribution to regional ecological performance issues, rather than building or landscape scale ecological issues. These discussions and assessments are based on the results of existing literature.

In order to develop and assess ecological design strategies, it is important for design teams to consider a range of existing ecological design strategies. Design strategies that are focused on improving the ecological integrity of local ecosystems can be categorized into three general ecological design strategies: design to foster ecosystem functions, biodiversity, and ecological behavior (Mangone, 2015b). A detailed assessment of the relative value of these design strategies, and comprehensive identification of potential specific design strategies within these broad categories, is outside the scope of this paper. Mangone (2015b) provides a more detailed review. These design strategy categories are used in this paper to categorize the general potential ecological performance of the three general ecological design solutions discussed in Sections 3–5.

3 NATURAL ENVIRONMENT INTEGRATED BUILDINGS (NIBS)

At the building scale, the integration of nature into buildings, such as microforests, can provide a number of direct and indirect benefits to local ecosystems (Mangone, 2015b). However, existing research suggests that, depending on the context, the indirect benefits of nature integrated into buildings tend to be more effective, in terms of improving the ecological integrity of local ecosystems.

The integration of natural environments into buildings can add considerable construction costs to buildings, if the nature space is developed as an additional space to the building that is not used for any required building program areas. This necessitates additional external wall, floor, and potentially roof assemblies, among other additional building system requirements. Within this context, urban landscapes tend to be more cost effective to construct. However, the construction costs of NIBs can be reduced if they are designed to provide space for required building program spaces. In some cases, indoor natural environment spaces have been found to reduce the quantity of spaces needed within a building, thereby reducing building construction costs, while improving occupant work performance and well-being (Mangone, 2015b). NIB's provide unique ecological, social, and economic benefits, such as being accessible throughout the year and in inclement weather, as described in the following sub-sections.

3.1 *NIB ecosystem functions*

There are a number of research and built projects that investigate the use of natural environments within buildings to provide building services. However, in general, the effectiveness of these services tends to be substantially lower than alternate, more technical building system solutions, in terms of cost and quantity of service provided per unit of system area. Natural environment integrated building systems tend to require considerably more area than technical building systems (Lohan et al., 2011, Sproul et al., 2014). Furthermore, in terms of ecological and economic performance, it is generally more effective to provide building services via municipal scale infrastructure systems, such as district heating and cooling plants. These systems can be integrated into buildings, as hybrid infrastructure (Mangone, 2015a). Nevertheless, natural environment integrated building systems have the potential to be integrated into building spaces in ways that provide occupant performance and well-being benefits, promote ecological behavior, as well as reduce operation and construction costs, as discussed in Section 3.3.

In terms of wastewater systems, living machine wastewater filtration systems, which can be designed to provide interior natural environments, have been incorporated into a number of buildings. However, living machines require daylight access, as well as greater treatment area than advanced technical wastewater treatment systems, such as MBBRs. Moreover, living machines have greater initial, operations, and maintenance costs than advanced technical wastewater treatment systems, constructed wetlands, and pond systems per unit of wastewater (Anderson, 2012, Álvarez et al., 2008, Molinos-Senante et al., 2012). Hence, from an ecological performance perspective, it is generally more effective to integrate an advanced technical wastewater treatment system into a building as a form of hybrid infrastructure (Mangone, 2015a).

In terms of energy reduction, natural environments have been used to shade and insulate buildings, as well as filter air, particularly via green walls and roofs. However, besides vegetated shading systems, (Perini et al., 2011, Mangone and Linden, 2014) these benefits can typically be achieved more effectively, in terms of cost and performance, through alternate design strategies, (Joksimovic and Alam, 2014, Snep et al., 2011, Lohan et al., 2011, Sproul et al., 2014) and can avoid potential maintenance and operations issues of green walls and roofs, such as roof water leakage and the

common perception in building system code standards and specifications that vegetation is unreliable and variable in terms of long term operations (Homeowner Protection Office, 2007, Mangone and van der Linden, 2011, Orwell et al., 2006). Vegetation can also reduce building energy consumption via their psychological effects on building occupants. (Mangone and Linden 2014, Mangone et al., 2014) Moreover, in some contexts, the psychological benefits of plants have been found to be more valuable in terms of costs, energy reduction potential, social benefits, and ecological performance, than the physical effects of vegetation on buildings. For instance, dense vegetation work environments have been found to increase the thermal comfort range of building occupants, thereby allowing the heating setpoint to be lowered and the cooling setpoint to be raised (Mangone et al., 2014). The occupancy of a vegetated semi-outdoor courtyard in Accra, Ghana was found to save more than three times as much energy as shading the courtyard (Mangone and Linden, 2014). It is important to note that green walls and roofs tend to be less effective in terms of psychological benefits, due to their limited potential to interact with occupants, as discussed in Section 3.3. Regardless, it is important to consider that from an ecological performance perspective, the quantity of energy reduced through these building scale strategies has a minimal effect on the energy consumption of a region, unless the strategy is integrated in a substantial quantity of buildings in an urban area. However, in terms of improving energy consumption at the regional scale, there are more cost efficient strategies. Moreover, the integration of natural environments into buildings at the regional scale can typically more effectively improve the ecological performance of the region via alternate ecological design strategies. Section 5 describes a nature integrated building design solution that can reduce substantially more energy in some contexts, as well as provide a diverse range of other ecological, social, and economic benefits.

Building integrated food production is increasing in effectiveness, in terms of providing quantities of food that substantially contribute to a region's food demand (Grewal and Grewal, 2012). However, these building integrated agriculture spaces are not considered in this paper, as current effective growth methods are not perceived to be natural environments. Future research into the design potential of interior agriculture could investigate the potential of growing interior agriculture in ways that are perceived by occupants to be natural environments while maintaining growth efficiency, as well as the potential of building occupants of diverse building programs, such as office workers, to have personalized interactions with the crops, which would promote ecological behavior, as discussed in Section 3.3.

3.2 *NIB biodiversity*

The biodiversity potential of NIBs is constrained by their inherent lack of area. Due to their constrained size, building habitat patches tend to have high edge/interior patch quality ratios and a limited potential to provide resources and high quality habitat, thereby limiting their biodiversity potential, as discussed in more detail in Section 4.2. These factors can result in building habitat patches functioning as ecological traps, thereby negatively affecting the urban area's biodiversity (Battin, 2004). The potential of the building site to function as a high quality habitat patch, or positively contribute to the biodiversity of the region in another facet, partly depends on the connectivity potential of the site, as well as a number of design factors (Mangone, 2015b).

Buildings offer unique benefits that have been taken advantage of for centuries to foster biodiversity, such as in Victorian greenhouses. Buildings provide an actively climate conditioned environment that is sheltered from inclement weather, readily accessible for maintenance, and has access to diverse resources (Mangone, 2015b). Buildings can function as gene banks. Depending on the height and location of a building, the building can be designed to disperse locally important species throughout the area. For instance, Edouard Francois' M6B2 Tower of Biodiversity in Paris takes advantage of its dominant height to disperse plant species seedlings via wind dispersal. Protected habitat patches for rare species can be fostered through the high controllability of the interior environment that buildings offer (Mangone, 2015b). Common building skins, such as concrete, are natural analogues of rare natural ecosystems, such as cliffscapes (Lundholm and Richardson, 2010). Green roofs can provide habitat patches as well, although care must be taken to design a roof that provides a high quality habitat patch, as extensive green roofs commonly are low quality in terms of biodiversity (Gilroy and Sutherland, 2007, Battin, 2004). Building habitat patches can also function as support habitat patches for adjacent high quality habitat patches, as well as ecological corridors and nature reserves. They can also function as stepping stone habitat patches to interconnect adjacent high quality habitat patches. In addition, buildings can be designed to protect adjacent habitat patches, from inclement weather and human induced disturbances, such as noise, and depending on the design and interaction of the building with the natural environment, future demolition and development of the natural environment.

3.3 *NIB ecological behavior*

At the individual building scale, the results of existing research suggest that the most effective contribution that building integrated natural environments can make to the ecological performance of the region are typically to promote ecological behaviour, (Mangone, 2015b) unless a given context fosters the opportunity to effectively address a high impact negative performing regional ecological performance parameter. Moreover, ecological behaviour strategies generally can incorporate biodiversity and ecosystem function strategies as well.

Frequent positive experiences in natural environments promote a number of ecological behaviors and increases people's valuation of natural environments (Cheng and Monroe, 2012, Kaiser et al., 2013, Muller et al., 2009). Existing research suggests that direct, personal interactions with natural environments are more effective than indirect experiences (Kahn et al., 2008, Peschardt and Stigsdotter, 2013, Adevi and Mårtensson, 2013). Positive direct interactions with natural environments can also reduce building resource consumption and operating costs, and improve occupant well-being, comfort, and work performance (Mangone et al., 2014, Mangone and Linden, 2014, Vink et al., 2008, Mangone et al., 2015, Hartig et al., 2001). Moreover, depending on the design, natural environments within office buildings can reduce the overall office area, by providing workspace that can be used for diverse work tasks that typically require separate built spaces to accommodate, thereby reducing construction and operation costs (Mangone et al., 2015). Thus, by providing natural environments within buildings, where people spend the majority of their time, (U.S. EPA, 1995) the potential of individuals to have positive interactions with natural environments is increased, thereby promoting ecological behavior. Moreover, the inherent protection of interior environments from inclement weather allows occupants to interact with natural environments throughout the year. However, at the scale of an individual building, the quantity of people that interact with a building integrated natural environment is typically substantially less than an outdoors, public urban natural environment, such as a park.

4 URBAN LANDSCAPES (UL)

Urban landscapes are areas of planted and/or managed native and non-native species, such as public parks and gardens, that are situated within urban areas (Niemelä, 1999). Urban landscapes provide unique ecological opportunities, which are discussed in the following subsections.

4.1 *UL ecosystem functions*

Landscapes can be designed to provide diverse infrastructure services, such as flood protection, urban heat island mitigation, and storm water and wastewater retention, filtration, and infiltration. (Joksimovic and Alam, 2014, American Rivers et al., 2012, Molinos-Senante et al., 2012, Kandziora et al., 2013) In a number of cases, green infrastructure systems are cheaper and require less maintenance, depending on their design. (Muschalla, 2004, American Rivers et al., 2012). In addition, landscapes can typically be designed to provide these infrastructure services while simultaneously providing occupiable space for the local community. For example, the Wakodahatchee constructed wetland in Delray Beach, Florida filters wastewater, provides habitat, and functions as a public park.

4.2 *UL biodiversity*

Landscapes typically afford opportunities to provide larger habitat patches than buildings can offer. Their larger size fosters opportunities to provide more diverse habitats and resources, as well as higher quality and interior habitat patches, depending on the design solution. For instance, existing literature indicates that vegetated areas of less than approximately 1.0 ha typically cannot support self-sustaining habitat patches for a number of species, particularly those that prefer to inhabit the interior areas of habitat patches, such as megafauna (Burgess et al., 1981, Snep et al., 2011). Ecosystems that lack interior habitat patches tend to be less able to support a number of species that prefer interior habitat, including core, rare, and endangered species (McGuckin and Brown, 1995, Collinge, 1996). To this end, existing literature indicates that urban habitat patches tend to have relatively low quantities of interior habitat area, in comparison to natural ecosystems (Cameron et al., 2012, Rudd et al., 2002, Kowarik, 2011). It is important to note that the absence of certain species in urban ecosystems, particularly species that are adverse to edge habitats, such as a number of megavertebrates, has substantial, complex effects on the trophic dynamics of urban ecosystems. However, it is important to note that, particularly within urban areas, individual habitat patches tend to be smaller than existing literature indicates is necessary to generate source habitat patches. Moreover, minimum suitable habitat patch sizes differ by species, ecosystem type, the quality of the patch, resources available within the patch, as well as a number of other contextual and spatial factors. For example, habitat patches as small as 0.3 ha have been found to effectively function as habitat patches for a variety of species, particularly mobile species, even within urban core ecosystems (Goddard et al., 2010, Rudd et al., 2002, Snep et al., 2011).

4.3 *UL ecological behavior*

Public, easily accessible landscapes inherently foster opportunities for greater quantities of people to have positive experiences with natural environments than interior natural environments. However, the occupation of these landscapes can be reduced during inclement weather, depending on the design of the landscape and nature of the weather event. Moreover, the inherent outdoor nature of landscapes, and their larger area, allows for their design to accommodate more activities than an interior nature environment, particularly outdoor recreation activities. By increasing the frequency, quantity, and type of interactions with natural environments, landscapes can be designed to increase diverse ecological behaviors of the local community, as discussed in Sections 3.3 and 5.

5 NATURAL ENVIRONMENT ADJACENT BUILDINGS (NABS)

Direct habitat alteration is the primary cause of damaging the ecological integrity, or health, (Kandziora et al., 2013, Haines-Young and Potschin, 2010) of natural ecosystems. The development and expansion of urban areas is one of the largest drivers of direct habitat alteration (Noss, 2000, Vackár, 2012). Within North America, low-rise housing is a key contributor to urban sprawl and natural ecosystem degradation (Resnik, 2010, Hansen et al., 2005). Low-rise housing communities also tend to negatively affect the well-being of the inhabitants, (Resnik, 2010, Gauvin et al., 2008) and have greater resource consumption and increased infrastructure and public service costs (Holden, 2004, Ewing and Rong, 2008, Norman et al., 2006). Nevertheless, in North America, low-rise housing developments are currently being developed at far greater rates than mid-rise and high-rise housing developments combined (Corporation, 2015, Bureau, 2015).

A transition from low-rise to mid-rise housing communities will help mitigate urban sprawl. Thus, increasing demand for denser communities is an important ecological performance goal, because it's one of the most effective sustainable decisions individuals can make. This single decision outweighs thousands of daily choices to turn off lights, use less heat, or recycle a can. Although there is evidence that preference for dense communities is increasing, particularly among the elderly and young professionals (Wilson et al., 2012, Portland State University, 2015, Myers and Gearin, 2001), the majority of North American residents have preferred low-rise housing communities throughout the last half century (Morrow-Jones et al., 2006, Stewart, 2004, Portland State University, 2015, Myers and Gearin, 2001). Access to permanent vegetated spaces can increase North Americans' preference and valuation of higher density developments, (Morrow-Jones et al., 2006, Geoghegan, 2002, Anderson and West, 2006) and depending on the spatial qualities of the vegetated space, can potentially make denser developments as preferred as low density developments (Morrow-Jones et al., 2006). The integration of natural environments into mid-rise housing developments also provides opportunities to improve the integrity of local ecosystems, as discussed in Sections 2 and 3, as well as generate unique social and economic benefits and amenities for local communities. Thus, the integration of natural environments into mid-rise housing developments may increase people's preferences for mid-rise housing.

Siting mid-rise housing developments adjacent to natural environments promotes positive interactions with natural environments, which can promote ecological behavior and provide a range of benefits to the occupants, as discussed in Sections 3.3 and 4.3. These developments are a type of natural environment adjacent buildings (NABs), which are building developments that integrate the design and function of adjacent landscapes with the design and function of the building, in ways that are mutually beneficial. This is achieved through the provision of views and rapid, easy access to natural environments, for a larger quantity of people than is possible within low density developments. This is important because the majority of visits to natural environments are close to one's home, (White et al., 2013, Lankia et al., 2015) the quantity of human interactions with nature is decreasing, (Pyle, 2003, Baisre, 2013) and the majority of human interactions with nature occur within urban areas, typically with highly cultivated, non-stimulating, and homogenous environments, such as ornamental lawns (Savard et al., 2000, Vackár, 2012). This ongoing 'extinction of experience' limits the access of communities to the benefits that natural environment interactions provide, (Pyle, 2003) and leads to the perception of degraded natural environments as normal, particularly from generation to generation. This diminishes people's expectations regarding the quality and ecological functions of natural ecosystems, which can contribute to further degradation of natural ecosystems. This phenomena is referred to as 'shifting baseline syndrome' (Papworth et al., 2009, Baisre, 2013). By incorporating high quality natural environments into people's daily lives, such as nature integrated mid-rise housing, this trend can be reversed. For instance, the provision of natural environments that provide psychological and physiological benefits to occupants may generate a recursive nature-experience feedback loop, (Mangone, 2015b) by attracting more people to interact with these environments, and promote repeated experiences of these spaces by individuals. If these environments are perceived to be valuable for conducting a range of activities, the perceived value of these spaces would increase, thereby promoting the development of additional natural environments. These effects would increase the quantity of inherent and design dependent benefits and services that natural environments provide the local community, and promote more ecological behaviors among more people, including the restoration and preservation of natural environments, (Cheng and Monroe, 2012, Kaiser et al., 2013) thus fostering natural environment development in multiple ways (Mangone, 2015b).

There is scant existing research on building scale ecological behavior design strategies that have neighborhood or city scale impacts (Mangone, 2015b). Existing research on building scale ecological behavior strategies tend to focus on personal consumption behaviors, such as reducing personal water and energy consumption rates in homes and offices (Abrahamse et al., 2005, Abrahamse et al., 2007, Midden et al., 2007). In terms of personal resource consumption, mid-rise housing residents consume less quantities of several resources than low-rise housing residents (Holden, 2004, Ewing and Rong, 2008, Norman et al., 2006). Yet, design teams tend to focus on the performance of a building and its occupants, rather than the influence of a building on the larger scale community and natural ecosystems (Mangone, 2015b, Zari, 2012).

Nature integrated mid-rise housing is a potential building scale ecological behavior design strategy that has neighborhood/city scale impacts, is applicable to diverse contexts, and can provide diverse economic and social benefits to local communities.

6 CONCLUSION

Thus, the integration of natural environments into urban areas has the potential to substantially contribute to improving the ecological integrity of local ecosystems, while increasing the social and economic value and quality of local communities, depending on the design solution and local context. This finding demonstrates the relative potential value of integrating natural environments within and adjacent to buildings. In particular, the integration of the design of buildings with adjacent landscapes from an ecological performance perspective was found to be particularly effective. The results of this discussion can aid design teams in determining effective ecological design strategies for specific projects, and calls attention to the need for investigations into innovative, more effective ecological design strategies and solutions, as well as methods to evaluate the ecological integrity of local ecosystems and the effectiveness of various potential ecological design strategies and solutions.

Camouflage: Design innovation for "Grey Infrastructures" in the city of the future

O.E. Bellini
Department of Architecture, Built Environment and Construction Engineering (ABC), Polytechnic University of Milan, Italy

ABSTRACT: Nowadays, 'Grey Infrastructures' are in contrast with an increasing demand for eco-friendly and sustainable cities. They have become an ineluctable component of the urban ecosystem, witnessing the divergence between the natural and artificial components of the city. They are undergoing a critical reflection about their environmental compatibility, as well as their aesthetic and functional configuration; for this reason, they could be rethought through a smart use of 'eco-tech-green' solutions. This approach is a precondition for a new environmental planning of contemporary towns, allowing their transformation into "multitasking ecosystems", creating a new aesthetic of *camouflage*. Greenery is also an opportunity to re-naturalize the city, because of the evident benefits that vegetation entails with regard to the environmental issues. This research aims at showing the existence of different design approaches to the urban infrastructures and suggesting the possibility to identify new techniques to re-naturalize these artifacts through the use of *camouflage* techniques.

1 THE DENSITY CITY AND ITS INFRASTRUCTURES

1.1 *The city of the future*

According to an intense debate on life in contemporary towns and their possible renovation, as well as to the more and more crucial role active citizens can play in such process, the European Union has recently adopted measures promoting a sustainable development, based on the needs of territory and people. Such governance model involves common perspectives and long-terms decisions, aiming at managing the ongoing transition and overcoming the problems of contemporary towns (EU, 2011). From the building scale to the urban one, we assist daily to a number of new ways to conceive, plan and build future towns, stimulating further reflections about their possible evolution and the priority decisions to take for this purpose. The aim of such researches is to turn towns into laboratories, setting up networks of anticipatory experiences, namely in the domain of environmental sustainability (Schröpfer, 2015), where nature plays a crucial role in the renewal of resilient towns (EU, 2015).

Recently, in fact, the role of cities in a sustainable development has become much more prominent for several reasons, the most evident ones being the high concentration of the world population in urban areas – more than half live in cities, and this number is expected to increase to 72% by 2030 (UNFPA, 2014) –, urban sprawl and its detrimental effect on the environment. This recognition is the result of the spreading awareness that cities are pioneering actors in increasing the ecologic performances of buildings and other infrastructures. So far, the concept of "sustainable city" has gained significant political momentum worldwide. Nonetheless, cities cannot contribute to the overall sustainability, unless their built environments are sustainable. In fact, planners and policy-makers have given increasing importance to neighborhoods, recognizing their environmental, social, and economic levels as the most meaningful to the citizens' life.

Measures aiming at ensuring the environmental quality in regard to the ongoing densification processes are also taken into account by the scientific debate. Compact cities' habitants are more than others called to find solutions to the problems related to overpopulation: traffic, congestion, pollution, waste production and everything that affects health and wellness.

Densification is assuming, in the collective imagery, an increasingly negative connotation, in that it is ever more associated to an irrational occupation of territory and, consequently, to critical environmental conditions. On the other hand, disciplinary researches tend to focus on new paradigms, such as efficiency, quality and sustainability, envisaging anti-sprawl strategies: long-term densification projects, based on high-quality standards, can allow both land preservation and the mending of urban wounds, involving social and environmental marginality (Ng, 2009).

These assumptions are also crucial aspects of "Sustainable Urbanism", a model longing for a smart "*Green Density*" (Rey, 2013), to bring in processes of renovation and reuse of abandoned interstitial areas. Furthermore, it limits the energetic impact

on the environment and restyles cities, adding new facilities to the existing ones. In this sense, infrastructures are fundamental elements in the concept of "*Urban Metabolism*", introduced by the urban-ecologist G. Herbert, since they can be considered as definitive solutions to the environmental impact of urban areas (Herbert, 1999).

1.2 *A new ecology for grey infrastructures*

The term "infrastructure" encompasses a number of meanings, which differ according to the domains they refer to. In the political discourse, for instance, it implies the various interventions supporting economic and political measures, whereas in urban design it refers to the activities necessary to guarantee the relations between the different modalities of territory occupation. It is thus possible to define infrastructures allowing a higher efficiency of the city functions, namely mobility, leisure and sport, education and culture, health, communication, waste and energy management, etc.

Grey Infrastructures, sometimes referred to as "hard or traditional infrastructures", are man-made, engineered components of a system. They, on the other hand, imply an approach to wet weather management that uses natural systems – or engineered systems that mimic natural processes – to enhance the overall environmental quality and to provide utility services. The term "Green Infrastructure" is relatively new to the lexicon of urban planning and landscape design. It was first used in a 1994 report on land conservation strategies by the Florida Greenway Commision (Firehock, 2010), with the intent to elevate the social worth and functions of natural lands and systems to the same level as Grey Infrastructures.

A second definition of "Green Infrastructure" has recently developed from the need to discuss the aesthetics and the functions of other artifacts of the urban context: according to it, they are systems and practices that use or mimic natural processes to infiltrate, evapo-transpirate (the return of water to the atmosphere either through evaporation or by plants), reuse stormwater or runoff. In contemporary Architecture and Planning, it is possible to identify large-scale and small-scale Green Infrastructures, the former being all over landscape elements such as parks, natural areas, greenways, and working lands (fields and forests), the latter being interventions on circumscribed parts of buildings: green roofs, rain gardens, vegetated swales, pocket wetlands, infiltration planters, vegetated median strips and so on (Sinnett, 2015).

Considering Green Infrastructures from an overall perspective – the landscape one – it is possible to integrate built and natural environments, introducing benefits for the health and well-being of people and wildlife. This perspective envisages Green Infrastructures as a three-dimensional "envelope" surrounding, connecting, and infusing buildings, streets, utilities, etc. As such, they cannot be separated from Grey Infrastructures, with which they interact to create the background on which they exist. The erasure of symbolic boundaries between these two categories compels a holistic and interdisciplinary approach to the infrastructure planning and designing (Rouse *et al.*, 2013).

It is therefore extremely important, for researchers in infrastructures design, to take into account that these highly-heterogeneous artifacts often involve the creation of "infra-places" – defined by the interactions between the city and its infrastructures – and "non-places", low-quality urban areas and buildings. To such purpose, it is necessary to rethink traditional assumptions on the relations between infrastructures, city and architecture, overcoming worn-out paradigms such as that of *non-lieux* (Augé, 1992), shifting focus to the concept of "infra-scape". This term is a crasis between *infra* – a Latin prefix meaning both "below" and "in-between" – and *scape,* which evokes the widespread idea that infrastructures are likely to define new urban perspectives.

In this way, it is possible to turn ongoing researches on Green Infrastructures into the first step of a radical urban renewal, focusing on those ambiguous and undefined elements G. Cléments perfectly described in the 'Manifesto del Terzo Paesaggio' (De Pier, 2005). The new conception of landscape put forward in this volume considers not only all the facilities supporting the city functions, but also "infra-spaces" (*infra-spazi)*: areas generated in the neighborhood of such artifacts, which may be profitably exploited by the community.

One of the possible measures to be taken in order to increase the sustainability and biodiversity levels in high-density areas involves the integration of vegetation into Grey Infrastructures, in a constant dialectic between the city and the countryside, nature and artifacts. In this way, Green Infrastructures can take hold in the urban landscape, involving deep symbolic and concrete transformations: not only do properly designed parks, urban gardens, green roofs and walls contribute to preserve biodiversity and contain climate change; they also improve social cohesion and the quality of the living environment.

We need to stop considering Green and Grey Infrastructures separately: researches on the aesthetics and the function of Grey Infrastructures in relation to sustainability theories are orienting their design towards new paradigms that discuss the benefits they can bring to collectivity in terms of quality of life.

In the design of these new-generation infrastructures, therefore, process and product innovation must combine, in order to allow a shift from mono-tasking to multitasking solutions: Green Infrastructures are in fact connoted by the co-existence of a number of functions and techniques – implying, for instance, natural systems, architectonic methods and digital devices – aiming at creating resilient networks in synergy with the city, the environment and the community (Maksimović, 2015). These more and more widespread practices, besides reducing the increasing aversion people feel towards infrastructures, also

produce significant improvements in the collectivity's quality of life.

On the other hand, the quest for a balance between economic development, environmental safeguard and urban landscape aesthetics – as well as the reconsideration of infra-spaces – is pushing infrastructure design to overcome the traditional ways to conceive, build and manage them.

Infrastructures, no longer playing the role of organizing principles of the urban landscape, seem nowadays apt to new forms of landscape renovation, also thanks to Camouflage (Leach, 2006) and the Aesthetics of Disappearance (Virilio, 1989): the sole solutions permitting to eradicate the repulsion of eco-orthodoxy towards such artifacts.

An approach of this sort is possible thanks to techno-green solutions involving, for instance, the use of manipulated vegetation in order to turn infrastructures into other artifact masks, or to blur their presence in the context they are set in. In this sense, infrastructures cease to be isolated elements in the urban landscape and start being interpreted as elements of nature itself. Nonetheless, to this end, it is necessary to shift focus from the artifact to the context it is in, the most important issue being to understand how infrastructure can be placed, hidden, and put into a network.

Thanks to process and product innovation, we have nowadays access to a wide range of technological solutions allowing the naturalization of urban infrastructures, be they realized *ex novo* or undergoing renewal processes, as put forward by pioneers of ecologic architecture, such as Le Corbusier, F. Hundertwasser and M. Wells.

1.3 *The role of vegetation and eco-tech-green*

Vegetation and eco-tech-green can be employed in a number of ways to enhance the urban environment quality, together with biodiversity preservation, greenhouse gas emissions control, storm-water runoff mitigation, noise reduction, urban heat island control. One further service that vegetation and eco-tech-green can provide the urban context with is the improvement of air quality. Vegetation and eco-tech-green can reduce the presence of air pollutants both by deposition and by affecting the physical transport of polluted air masses, reducing or enhancing ventilation, altering the roughness of the building surfaces.

The extent to which urban vegetation and eco-tech-green can improve air quality has mostly been explored through the use of models. These research concluded that there is a large flux of air pollutants towards urban vegetation and these fluxes did not significantly affect local air pollution concentration, although even apparently slight pollution reductions represent a significant gain in human health. On the other hand, some researchers have maintained that the role of urban vegetation in reducing local air pollution has been exaggerated.

The theme of infrastructure design and renewal plays a crucial role, in order to guarantee high standards in terms of quality of life (Beatley, 2010). Nonetheless, this is only possible thanks to innovative design and building methods, involving the use of eco-tech-green solutions, a new way to implement projects using built-up vegetal material through their manipulation and transformation. The most evident effect it produces is the progressive 'demineralization' of the urban-scape, obtained by the proliferation of vegetal surfaces, be they vertical or horizontal. The implementation of eco-tech-green solutions also represents an interesting opportunity to help the creative reinsertion of open spaces in towns and to open future scenarios that anticipate the 21st century challenge of the "fertile town", which implies the overcoming of the town/country issues through the implementation of agriculture in the urban context.

Nowadays, eco-tech-green implies the adoption of complex technologies and techniques, offering a wide range of systems and products to use vegetation as an element of designing and planning, so as to determine the iconographic outcome of the intervention and to condition its environmental context.

From a technical point of view, it is possible to identify two distinct typologies of interventions: "green cover" and "natural wrapping".

Unlike hanging gardens, which have been more widely experimented, green covers have few applicative variations: the extensive green roof – that needs less maintenance and lower implementation costs, in spite of its low feasibility – and the more traditional intensive roof, that allows the use of a wider range of vegetal elements, be it to improve the aesthetics or to facilitate the use of eco-tech-green (Bellini, Daglio, 2009).

On the other hand, the spectrum of possible solutions for vertical open spaces is also articulated in two macro-typologies of systems/products: green façades, obtained by the use of climbing plants, generally growing from the ground, attaching to supports and frames, and living walls (otherwise called *murs végétalisés*), that generally make use of hydroponic techniques, and that vary according to the nature of the cultivated substratum.

1.4 *The function of 'eco-tech-green'*

Although sustainability and ecological choices are often mistaken for the mere use of green, it is self-evident that vegetation can bring in a number of advantages, some of which are by now put forward by innumerable scientific contributions and recent researches.

Eco-tech-green can carry out a variety of environmental and economic functions, bringing benefits to human health and wellness *tout court*. This is even more evident in high-density urban areas, where open spaces are usually limited and not always accessible.

Benefits issued from eco-tech-green solutions are extrinsic and intrinsic. They consist in hygiene/environment-oriented measures, aiming at determining positive repercussions on the urban microclimate (Foster, 2011). The integration of vegetal elements into Grey Infrastructures contributes to the management of

rainwater: it is in fact possible to control the volume of rainwater flow, reducing surface runoff, thanks to water absorption into the soil. Moreover, green components may also help controlling the infiltration of rainwater into the ground, so as to reduce the volume of the flow in sewer systems, and thus regulate the speed at which underground aquifers are fed. The presence of vegetation on the infrastructure also prevents the transport of pollutants in the surface water: once they have flown into the ground, plants and microbes can in fact naturally filter and destroy common pollutants.

Another important environmental indicator on which vegetation has meaningful effects is the quality of air and, consequently, of the urban microclimate. Three principle factors, affecting such indicators, are positively influenced by vegetation: temperature, humidity and wind speed. Not only do plants capture carbon dioxide through photosynthesis and other natural processes – emitting water vapor and oxygen into the atmosphere, humidifying and refreshing it – they also absorb and destroy smog components, such as fine particles and gas ozone: a gas that can form and react under the action of light, and that is present in two layers of the atmosphere. High up in the atmosphere, ozone forms a layer that shields the Earth from ultraviolet rays but, at ground level, ozone is considered a major air pollutant. Furthermore, a reduction of the thermal energy accumulated on the building surfaces involves both a natural refreshment and the destruction of urban heat island, with the consequent reduction of the demand for energy needed by air-conditioners.

Intrinsic benefits, on the other hand, have an ecological identity and can condition the quality of life of the natural ecosystem. They are a result of specific properties of vegetal systems, such as resilience, resistance and connectivity, and they can be synthetized into the homeostatic capacity of the ecological system.

Moreover, in spite of its limited extension, vegetation manages to create the necessary micro-ecological conditions for the insertion of a number of animals into the surrounding ecosystems, easily recreating forms of biodiversity.

According to *biophilia* theories, the presence of green spaces can positively intervene on human health, in that individuals, being in contact with nature, are better off in terms of productive work, learning and curing diseases (Wilson, 1984). As a consequence, the presence of vegetation in the urban context can also help reduce the level of criminality and violence, with positive repercussions on the sense of community and belonging.

The role and function of the vegetation and eco-tech-green in the density city have been widely documented in scientific literature.

2 GREENERY 'GREY INFRASTRUCTURE'

2.1 *Greenery infrastructure: A new challenge*

The awareness of the interconnectedness of all urban phenomena – definable as "set of possibilities", according to a systemic model – derives from the sciences of complexity (Tenreiro *et al.*, 2011). In the domain of architecture design, this consciousness has been implemented by computer science technologies. Researches on biomorphic architecture based on relational and interactive patterns could privilege the morphogenetic side of design, thus exalting the complexity resulting from the interaction of the forces involved in the formal creation. Interesting theoretical and practical researches are claiming a new conception of artifacts as open and reactive devices according to an ecologic and systemic approach (Feuerstein, 2001). This idea of architecture focuses on information, communication and virtual reality, rather than on physical presence, and yet it can promote positive transformations, turning up as intermediate dimensions in the constant quest for a balance between nature and artifacts.

To some extents, such assumptions can constitute the basis of deep renewal processes, concerning particularly the functions and the aesthetics of Grey Infrastructure: nowadays, their design is no longer bound to the necessity to enhance their formal appearance, but aims at blurring their presence through processes of dematerialization and re-naturalization. This shift is meant to put into effect, on a "mental-environmental level, the developing ecologist consciousness which, in the digital era, is more and more interested in multidisciplinary design perspectives considering arts, landscape and architectures. Similarly, the pioneering researches on *Land art*, *Environmental art*, *Ecological art* carried out by the end of the Sixties, were significantly influenced by environmental sciences, according to a conception of architecture "responsive to change" and to a new environmental awareness: born in response to the early Seventies energy crisis, such prerogatives are now the basis of contemporary eco-oriented design researches. All this contributed to spread the need of a balance between the planet transformations and the limits they impose, and the pursue of the convergence between "*Mind and Nature*" (Bateson, 1979).

Grey Infrastructures are integrant parts of the urban landscape, and for this reason it is necessary that they reflect the various aspects of the context they are set in, communicating their cultural and environmental identity (Wines, 2000). The purpose of ongoing researches on urban infrastructure is to integrate their traditional architectural paradigms with new landscape-based perspectives, in order to turn these artifacts into iconographical "systems of passages": stimulating material and immaterial flows – thanks to the integration of traditional systems with digital devices and the use of vegetal components – it is possible to proficiently include infrastructures into urban eco-systems, overcoming the long-standing issue of the incompatibility between nature and artifacts. In this way, infrastructures are more and more frequently conceived as "interfaces" combining different perspectives – architectural, productive, environmental – cultures and values. In particular, their surfaces no longer define

boundaries, but become mediums between two constantly exchanging domains (Virilio, 1984), osmotic membranes that turn edges into dissimulated thresholds. In the domain of infrastructure design, such dematerialization can be carried out according to four categories:

a) "aesthetics of disappearance": a no-volume architecture reflecting the idea of non-fixation of the image put forward by Virilio and Baudrillard, which is sometimes characterized by light interventions, as in most of the works of K. Kuma, Herzog & de Meuron, T. Ito, J. Nouvel, R. Piano, K. Sejima; other times by underground constructions reproducing the continuous variation of soil and vegetation, as the hearth houses designed by E. Ambasz, Abalos & Herreros, Mecanoo, MVRDV, D. Perrault *et al.*;

b) "nature and artifact overlapping": architectures in which mineral and vegetal components co-exist, as in the SITE residential tower in Mumbai (2004), inspired by the Hanging Gardens of Babylon, or in the Expo 2000 Dutch pavilion, designed by MVRDV: both are concrete realization of theoretical researches on the themes of density and the relation between architecture and landscape.

c) "neo-naturalistic metaphor": architectures aiming at conciliating the organic and the architectural space, through procedures borrowed by the natural world: in this way it is possible to communicate their inclusive identity, as in the sophisticated naturalized constructions designed, just to name a few, by Herzog & de Meuron, T. Ito, Diller Scofidio+Renfro.

d) "naturalistic camouflage": a sort of ecologic maquillage, sometimes turning into hypertrophic ornaments trying to hide architectural alterities (Repishti, 2008) as, for instance, in A. Gueuze's "vertical landscapes", in P. Blanc's "vertical gardens" and, more generally, in the eco-tech-green solutions adopted by E. Ambasz, S. Boeri, E. François & D. Lewis, F. Roche, K. Kuma, J. Nouvel.

Contemporary ecologic theories applied to architecture not only deal with environmental sustainability in terms of "low-tech" and "eco-tech" strategies, involving the use of recycled materials and alternative energetic sources; they start from a general reconsideration of urban infrastructures, trying to overcome their conventional "insular" conception and to establish relations with "infra-spaces".

3 INNOVATIVE DESIGN

Analyzing a different set of Green Infrastructures on the urban scale, it has been possible to identify some common design techniques, differing according to how eco-tech-green solutions were used. Each case study has been considered on the basis of the following paradigms: multi-functionality, connectivity, habitability, resiliency, identity, return on investment. Nonetheless, these considerations showed that the common strategy of the infrastructures examined is the principle of *camouflage*.

If, from a merely visual point of view, this may be intended as a strategy of invisibility, in environmental design it consists in an *artificium* allowing the disguise of bulky – and for this reason often disliked – urban infrastructures (Cesarin *et al.*, 2010). In a sense, infrastructure *camouflage* doesn't differ too much from those strategies used by weak animals in order to escape their predator's attacks, reproducing on their bodies the patterns of the surrounding space (Caillois, 1998).

In the domain of urban infrastructure design, camouflage is meant both to make the *camouflé* subject invisible, transforming its appearance thanks to a vegetated skin, according to techniques experimented in plastic arts, design and architecture. Recent researches carried out in this field have distinguished four environmental design techniques, inspired to camouflage: *Blending Camouflage; Disruptive Camouflage; Breaking into Pieces e Blurring Camouflage.*

3.1 *Blending Camouflage*

Blending Camouflage explores the different uses of vegetal components in order to alter the perceptive relation between objects and their background. In this sense, vegetation can weaken the visual impact of Grey Infrastructures, blurring their presence onto a natural background.

In other words, the artifact being covered with the very same elements of its context loses its artificial nature, and hence its visual impact on the context itself. *Blending Camouflage* is mainly used in landform architecture, namely when the very intention is to innovate obsolete design paradigms.

Combining the urban and the architectonic scales, camouflaged infrastructures are meant to remodel the traditional antithesis between nature and artifacts, figure and background. The transition from landscape to architecture is thus mediated by large, rough naturalized surfaces, defining green intermediate areas often usable by the community.

3.2 *Disruptive camouflage*

Disruptive camouflage alters the infrastructures nature, transforming their representative identity. As many animals do, it is possible to modify their appearance thanks to specific *disruptive patterns*, such as stripes or figures.

In these case, vegetation can be used in such interventions, being applied onto the infrastructure surfaces and edges, so to blur their aspects and disguise their presence. In this way, not only does *camouflage* make the artifact appearance more abstract and less definite, but it integrates its functional identity with renewed ecologic meanings, in antithesis with the negative widespread assumptions tied to this sort of constructions.

An example of *disrupting technique* is provided by vertical gardens grown on specific supports in order to provide infrastructures with a new aesthetic dignity.

3.3 *Breaking into pieces*

Inspired by the animal world, as well as any other camouflage techniques, *Breaking into Piece* consists in changing the infrastructure original appearance covering it with the natural elements of the context it is set in, such as lawns, trees and bushes.

This camouflage technique may be applied to the domain of infrastructures design through the creation of circumscribed vegetated surfaces, partially covering specific parts of the artifact.

By breaking "into pieces" grey, mineralized surfaces through the insertion of natural elements, it is therefore possible to mitigate the artificiality of urban infrastructures, reconciling them with their surrounding contexts.

With this technique the construction becomes carpeted with appropriately studied and valued vegetation insertions in such a way that the construction loses its artificial aggression and assumes a more natural and ecological one.

3.4 *Blurring camouflage*

The last camouflage device current researches have elaborated in the domain of infrastructures design is blurring, to be intended as a way to confuse and cast ambiguity on what goes under it. In other, more concrete terms, it consists in the adoption of specific devices allowing to alter the identity of an object.

In the field of infrastructure design, such purpose can be carried out thanks to those devices which help blur artifacts, partially or totally hiding their presence.

This type of camouflage adopts techniques borrowed from other domains – such as packaging design – for instance installing vegetated skins confusing not only the presence of the artifact, but also its function. Thanks to vegetated components, it is possible to turn infrastructures into something else, only partly recognizable and yet putting forward, with their sole presence, crucial ideas for the sustainability of future cities. This technique, relying on a complete vegetal cover of the construction, creates a sort of natural mask that, faced with the new ecological conscience, tries to hide the presence, rendering it, involuntarily, even more visible.

4 CONCLUSIONS

Green Infrastructures are much more than a living wall, green façade, green roof and forested corridor: they are a different way of thinking or designing infrastructures. Conceived as a multi-scale network

of ecological features and systems providing a number of functions and benefits, they involve a systemic approach to planning and development, which recognizes the value of ecosystem services and aims at integrating them within our built environment. Green Infrastructures is not limited to a particular type of technology or feature carrying out a specific function; they are the result of a complex network of institutions, organizations, agencies, businesses, and citizens bringing ecosystem services back into planning and development. In order to realize the full potential of Green Infrastructure, coordination and collaboration are needed across several domains – political, jurisdictional, agency, organizational, sectoral, disciplinary, professional, to name just a few. The most significant challenge to advance a robust and integrated form of Green Infrastructure may be a bottom-up policy with a collective action from citizens. Both the design of new infrastructures and the renewal of existing ones demand an absolute accuracy and a constant research, in order to overcome their merely techno-functional nature and to involve a general reconsideration of their adjacent areas.

Camouflage devices, in fact, can bring in very interesting opportunities to improve the environmental sustainability of urban contexts and to develop new aesthetic and figurative solutions. Not only can such innovations contribute to spread an increasing acceptance of infrastructures but, as we pointed out throughout this paper, they can turn into pretexts to deeply rethink the function and the aesthetics of *"infra-luoghi"*.

Green camouflage techniques, in fact, are meant to order the chaotic and fragmentary coexistence of buildings, empty spaces, network, systems and infrastructures, not always working synergistically for the good of collectivity.

As a matter of fact, vegetation and eco-tech-green solutions can proficiently help mitigate the environmental and visual impact of unpleasant urban infrastructures; moreover, they are an extraordinary opportunity to provide cities with new green spaces, whose benefits have been demonstrated by this research. Environmental and health issues are, in the domain of Green Infrastructures, indissolubly tied to the processes of landscape reconsideration, in that they both contribute to enhance the quality of urban life: it is self-evident that healthcare and territory resiliency – together with the social and economic benefits they involve – strictly depend on the quantity and the quality of exploitable green spaces.

Natural *camouflage* for urban infrastructures increases environmental sustainability standards,

affecting the primary needs of citizens. Among them, security is to many extents one of the most strongly and transversally perceived as a fundamental right. In the collective imagery though, urban infrastructures and the surrounding areas are often thought as symbols of criminality, social diseases and violence.

Using vegetation and eco-tech-green in the grey infrastructure design, it is possible to move from mono-tasking to multitasking objects, capable of performing multiple functions simultaneously: ecological, environmental, landscape and recreational, for the sustainable city of the future.

Hence, a general reconsideration of environmental design paradigms – involving the adoption of the *camouflage* techniques so far described, as well as deep changes in the legislation and the training of specific professional figures – can be the first step of a profound shift in the collective and individual conception of sustainability in high density cities.

Green infrastructure in New York City: Top down and bottom up initiatives to improve environmental quality

K. Perini
University of Genoa (DSA), Italy

ABSTRACT: European environmental policies so far have achieved important results at both Member State level and internationally. The United States has a different approach to Europe in this field: with a less prescriptive normative framework, several associations, organizations and public bodies work to improve environmental conditions in cities through the integration of green infrastructure. Vegetation can restore the environmental quality of dense urban areas by reducing the Urban Heat Island (UHI) effect, improving air quality and energy performance of buildings, and fostering biodiversity. The main objective of this research is to study initiatives and actions carried out and developed in New York City to help improve environmental and ecological conditions through the wider diffusion of green infrastructure. Top-down and bottom-up initiatives implemented in such dense city, considering the role played by Federal agencies, NYC Departments, and local communities, are analyzed.

1 INTRODUCTION

Environmental problems within cities have significant consequences for human health, citizens' quality of life, and urban economic performance (Commission of the European Communities, 2005). This is due in large part to urban areas' high vulnerability to climate change related flooding and heat waves. Since the majority of the world's population today lives in cities (Luederitz et al., 2013), these are important issues to address. While human lifestyles, consumerism, and unsustainable material production lead to alterations at multiple scales in urban systems, they also generate negative effects in residents' everyday lives (Grimm et al., 2008). Environmental problems and the ecological imbalances related to climate change, including especially biodiversity loss and environmental pollution, demonstrate the need to reduce material and energy flows and lessen environmental impacts (Luederitz et al., 2013; Seto et al., 2012).

Urban areas are responsible for 70% of global carbon emissions and nearly 70% of energy consumption (International Energy Agency, 2008). However, a denser urban environment could reduce the emissions connected to transportation needs and building energy use, and consequently their impact on climate change (Ewing et al., 2008; Hamin and Gurran, 2009); compact development add population to already developed places, concentrating human related activities and helping to protect underdeveloped and sensitive lands and maintaining viable habitats in the remainder (Farr, 2008). Therefore, through sustainable urban design, the negative effects of anthropic activities on the environment can be reduced, and environmental issues for human health and quality of life can be mitigated. After all, "The gamble for ecological survival has always been reliant on technology and design – and when technological limits are obvious, the design adaptation has to be made" (Plunz, 2008).

European environmental policies so far have achieved important results at both Member State level and internationally. The United States has a different approach to Europe in this field; five states have not yet adopted the Department of Energy's Building Energy Codes Program (U.S. Department of Energy, 2014), and several associations, organizations and public bodies work to improve environmental conditions in dense urban areas through the integration of green infrastructure. This community involvement can play a very important role in the field as many initiatives to improve ecological conditions of cities depend on the participation of urban citizens (Francis and Lorimer, 2011).

Urban and building design may aim to reduce environmental imbalances in urban areas and guarantee sustainability: on one hand, buildings consume a significant amount of energy (International Energy Agency, 2012); on the other, working on urban fabric is important considering the surface covered by built areas (e.g. in the case of New York City; www.nyc.gov). Vegetation can restore the environmental quality of dense urban areas by reducing the Urban Heat Island (UHI) effect, improving air quality and energy performance of buildings, and fostering biodiversity (Dunnett and Kingsbury, 2008; Ottelé et al., 2010; Taha, 1997). Therefore, a wider diffusion of vegetated green infrastructure in cities could

contribute to the achievement of several European environmental objectives.

The case of New York City (NYC) is considered in the present research. The main objective is to study and analyze initiatives and actions carried out and developed in New York City. Top-down and bottom-up initiatives to improve ecological and environmental conditions of dense cities through the wider diffusion of green infrastructure are identified; particular attention is paid to top-down initiatives implemented in New York, considering also the role played by Federal agencies in promoting the integration of green infrastructure. The effectiveness of mechanisms related to bottom-up approaches are similarly evaluated, with the concept of environmental justice defined and examples of initiatives implemented by local community organizations, grassroots associations, and citizen groups in the field of urban areas environmental sustainability and green infrastructure provided.

2 METHODS AND TOOLS

With the aim to study and analyze initiatives and actions carried out and developed in New York City to help improve environmental conditions in cities through the integration of green infrastructure, several methods and tools have been used. Bibliographic analysis, evaluation of tools used by public bodies and designers, and site visits allowed for the identification of improved environmental conditions through the integration of green infrastructure. An analysis of plans and regulations provided information on top-down approaches in the field while an overview of local community organizations highlighted bottom-up initiatives.

All the aspects analyzed in this research have also been deepened thanks to consultation with several experts in the field, researchers, experts working at the Federal and local level, and referents from community groups, among others. In parallel the main ecological and environmental imbalances within cities were analyzed, as the concept of environmental justice was. To deeply analyze all the aspects mentioned, both top-down and bottom-up green infrastructure projects will be discussed. These are: the Brooklyn Bridge Park and the Greenstreets program, both developed under Mayor Bloomberg administration in New York City, and the High Line, the Bronx River Greenway project, developed thanks to the efforts of local communities.

3 GREEN INFRASTRUCTURE (GI) IN CITIES

Today, more than 40% of the total land in urban areas is covered by impervious surfaces as roads, parking, and buildings (Benedict et al., 2006). Green infrastructure at city scale can play a key role in improving environmental conditions. When green infrastructure is proactively planned, developed, and maintained, it can guide urban development by providing a framework for economic growth and nature conservation integrating urban development, nature conservation, and public health promotion (Schrijnen, 2000; Tzoulas et al., 2007; Van der Ryn, 1996; Walmsley, 2006).

The term "green infrastructure" was coined in Florida in 1994 in a report to the Governor on land conservation strategies noting that natural systems important components of infrastructure (Firehock, 2010). Infrastructure is commonly defined as the facilities and services necessary for a society, community, and / or economy to function; these facilities and services can be "hard" (e.g. transportation and utilities) or "soft" (e.g. institutional systems such as education, health care and governance). GI is considered "soft" and is important for building capacity improved health, job opportunities, and community cohesion (Rouse, 2013).

GI includes natural, semi-natural, and artificial networks of multifunctional ecological systems within, around, and between urban areas (Tzoulas et al., 2007). This includes waterways, wetlands, woodlands, wildlife habitats, greenways, parks, and other natural areas that support native species, maintain natural ecological processes, sustain air and water resources, and contribute to the health and quality of life for communities and people (Benedict et al., 2006).

Vegetated GI mitigates climate change generally, transforming the CO_2 produced by automobile traffic and heating into carbonhydrates and oxygen; CO_2 is used by plants for the photosynthesis process, creating oxygen and biomass (Getter and Rowe, 2006; Köhler, 2008). Greened paved surfaces intercept solar radiation and can reduce warming of hard surfaces, thus reducing the UHI phenomenon by two to four degrees Celsius (Onishi et al., 2010; Taha, 2008).

Green infrastructure may include greenways, which, if systematically planned, can lead to a reduction of private transportation (use of cars) and, consequently, of their impact on the city environment (Hamin and Gurran, 2009). Vegetation improves environmental conditions in cities by acting on both causes and effects, collecting fine dusts and reducing the concentration of gaseous pollutants (Ottelé et al., 2010; Yin et al., 2011). Water quality can similarly be improved by natural systems filtering pollutants (Benedict and McMahon, 2001). As stated by the Environmental Protection Agency (EPA, 2011), green infrastructure is fundamental for stormwater management and as flood control as the loss of natural systems increases the risk of flooding and natural disasters (Benedict and McMahon, 2001).

The elements and components of green infrastructure are able to improve ecosystem health, defined as the occurrence of normal ecosystem processes and functions, free from distress and degradation, maintaining organization and autonomy over time and being resilient to stress (Costanza et al., 1992; Lu and Li, 2003; Rapport et al., 1998). Species rich heterogeneous habitats are considered more resilient than homogenous habitats in terms of habitats, species

and genes (Loreau et al., 2002), and influence urban ecosystem health by contributing to ecosystem resilience, organization, and vigor (Tzoulas et al., 2007).

4 TOP-DOWN POLICIES

Since 2009, the U.S. Environmental Protection Agency (EPA) under Administrator Lisa Jackson has endorsed the promotion of green infrastructure with the support of the New York State Department of Environmental Conservation (DEC). The EPA, with its mission to protect human health and the environment, writes and enforces regulations based on laws passed by the U.S. Congress, including, among others the Federal Water Pollution Control Act Amendments commonly known as the Clean Water Act (CWA), adopted in 1977, which regulates discharges of pollutants into water and sets quality standards for surface waters (www2.epa.gov\\laws-regulations; New York City Department of Environmental Protection, 2010).

Nowadays, the EPA provides local municipal grants, along with technical support, to cities to support an implementation of GI to fulfill CWA requirements (http://water.epa.gov/grants_funding).

Despite this approach, regulatory aspects at the Federal level also play an important role in the diffusion of GI; cities around the country have begun to manage stormwater runoff using green infrastructure to advance EPA regulatory requirements. This is mainly related to billions of dollars that local municipalities spend to reduce the volume of stormwater runoff in order to meet the regulatory requirements of the CWA to achieve swimmable and fishable waters (Crauderueff et al., 2012).

New York City (NYC) has 25,900 inhabitants per square kilometer, an urban density higher than figures registered in 40 American states and 800 times the population density of the United States (Owen, 2010), meaning that green infrastructure can play a very important role in reducing environmental and ecological imbalances (Rosenzweig et al., 2006).

During administration of Mayor Michael Bloomberg, several policies were developed reduce greenhouse gas (GHG) emissions by 30 percent by 2030, and to improve residents' quality of life, as outlined in PlaNYC, the City's comprehensive sustainability plan released in 2007. PlaNYC was created as a bold agenda to meet challenges related to growing population, aging infrastructure, a changing climate, and an evolving economy and to build a greener, greater NYC (New York Department of City Planning, 2011). The ambitious goal of PlaNYC is to reduce citywide GHG emissions by 30% below 2005 levels by 2030 (known as 30 by 30). According to the "PlaNYC Progress Report" of 2013, in six years, NYC reduced citywide GHG emissions by 16% with a cleaner energy supply, more highly efficient power plants coming online, and less polluting natural gas displacing energy generation by coal and oil. Among the initiatives launched

Figure 1. The Brooklyn Bridge Park, New York City.

to improve infrastructure, create or preserve housing, and reduce emissions related to transportation, green infrastructure received much attention. With the aim of bringing more than 250,000 New Yorkers to within a 10 minute walk of a park, green areas have been built.

The Bloomberg administration's policies played a key role on the implementation of green areas, an example is the Brooklyn Bridge Park. This is among the successful administrative initiatives in transforming and resurrecting public space in New York City. The Bloomberg administration facilitated a recalibrated urban landscape agenda through implementing a renewed emphasis on the importance of providing a citywide, connected public space network. As part of a progressive vision to activate and reconnect the City through the function of open space, the Administration's PlaNYC has been successful from urban and public health perspectives in activating and reconnecting the public realm, from a transportation and an open space perspective, and from an urban design perspective (Flynn, 2013).

Parks and public space importance is recognized for recreational amenities, ecological function, and economic development, as well as trees, green roofs and other forms of ecological infrastructure. NYC has invested in a network of green corridors, streets and other dedicated paths that perform multiple functions, including promoting recreation, capturing stormwater, and cleaning air (New York Department of City Planning, 2011).

Stormwater management also plays a fundamental role in this case, as New York City experiences a tremendous volume of rainwater runoff from rooftops, streets, and other impervious surfaces (New York Department of City Planning, 2011). To comply the Federal Clean Water Act, New York City built 14 sewage treatment plants, which were problematic in some area of the City (e.g. West Harlem), as demonstrated by local community organizations' protests (Angotti, 2008). In other cases, a green infrastructure approach has been adopted to prevent environmental degradation. NYC has launched several initiatives to increase the resilience of the built environment, including a $2.4 billion GI plan intended to better manage rainfall and reduce the impacts of Combined

Sewer Overflow (CSO) (New York Department of City Planning, 2013).

The "PlaNYC Sustainable Stormwater Management Plan" (New York City Department of Environmental Protection, 2008) was issued by an Interagency Best Management Practices (BMP) Task Force and concluded that green infrastructure – including bioswales, green roofs, and subsurface detention systems – was feasible in many areas in the City and could be more cost effective than certain large infrastructure projects such as CSO storage tunnels or tanks; in fact during heavy storms, these can exceed capacity and are designed to discharge a mix of stormwater and wastewater into New York Harbor to prevent treatment plants from becoming compromised (New York Department of City Planning, 2011). In September 2010, the City released its Green Infrastructure Plan, presenting an approach to improving water quality that integrated green infrastructure with investments to optimize the existing system and build targeted and cost-effective gray or traditional infrastructure (New York City Department of Environmental Protection, 2010b).

Among the several initiatives implemented in NYC to increase vegetation via widespread small interventions, the Greenstreets program is notable; transforming unused road space, traffic islands, and industrial areas into green assets, Greenstreets capture stormwater and improve water quality, and serve as important ecological respites within the urban landscape. Since 1996, they have been built throughout the City's five boroughs using specially designed soils and plants (New York City Department of Environmental Protection, 2013).

PlaNYC recognizes the important role played by the community with regard to parks maintenance, and the need to involve the public early in the park development process to engage citizens and community groups in the upkeep of their parks and green infrastructure. According to "PlaNYC Progress Report" (New York Department of City Planning, 2013), maintenance and stewardship are key priorities going forward. As stated in the NYC Green Infrastructure Plan, stakeholder participation is critical to build and maintain green infrastructure, and the New York City Department of Environmental Protection has led the outreach effort to involve community boards, stormwater advocacy and green job non-profit organizations, Citizens Advisory Committees (CACs), civic organizations, other City agencies, environmental justice organizations, and local communities (New York City Department of Environmental Protection, 2010b).

5 BOTTOM-UP POLICIES

Local participation in the United States has a deep rooted tradition (Angotti, 2013). The United States based Environmental Justice Movement (EJM) started its national campaigns in 1980s among a confluence of events that brought about the terms "environmental racism" (the disproportionate effects of environmental pollution on racial minorities) – and "environmental justice" (a social movement that emerged in response to this problem) into the public space (Sze, 2008, 2007).

Figure 2. Greenstreet in New York City.

Environmental justice, with its central concern the disproportionate impact of noxious facilities on communities of low income and of color, brings a progressive approach to sustainability by underlining the role of social justice in environmental and land use planning; as results, many of the current generation of community plans arose from the struggles of this movement (Angotti, 2008).

The EJM was founded to address the inequity of environmental protection in local communities (www.epa.gov/environmentaljustice); the EPA defines environmental justice as, "the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income, with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies". In 1990, the EPA created the Environmental Equity Workgroup (since 1994 the Office of Environmental Justice (OEJ)) to address allegations that, "racial minority and low income populations bear a higher environmental risk burden than the general population". In the same year, New York's first African American Mayor, David Dinkins, took office with the support of a broad coalition of community, environmental, and other social movements (Sze, 2008).

The involvement of community in city planning and design is today widespread. In New York, immediately after his election in 2002, Mayor Bloomberg accepted the basic principle of community planning, as opposed to his predecessor Rudolph Giuliani (Angotti, 2008).

M3project principal Flynn was consulted on the role of the community in a firm activity, and of community boards in the urban design process, and notes that community participation, involvement, and approval has become a fundamental component to complex urban design initiatives and agendas. Successfully engaging the public realm into the design process and, ultimately, into the design solution, can in itself be a complex agenda. Engaging public interest as an initial design element contributes and informs the project's vision, ambition, and goals and in many cases promotes enhanced community support, increased stakeholder investment, and expedited planning processes (Flynn, 2013).

Flynn was part of the team created by James Corner, Field Operations with the firm Diller Scofidio + Renfro, which designed the High Line in New York City, a project that demonstrates the capabilities of productive collaborations that successfully merge architecture, landscape architecture, and urban design.

The High Line is a public park opened in 2009 that is built on an historic freight rail line elevated above the streets. The rail line was built in the 1930s as part of a massive public-private infrastructure project on the West Side of Manhattan and had not been used since 1980. It is owned by the City but maintained and operated by Friends of the High Line, a community-based non-profit group formed in 1999 when the historic structure was under threat of demolition. Friends of High Line works to raise essential private funds to support more than 90 percent of the park's annual operating budget (www.thehighline.org).

Although the High Line project rises in a very different neighborhood compared to, for example, the low income Bronx (analyzed as well in this research), it is an interesting example of a bottom-up project. According to Flynn (2013), the High Line project was a catalyst and product of the Friends of High Line'. From an administrative perspective, the Bloomberg administration was a great advocate and facilitator towards its realization, implementation, and potential, especially since the previous administration, the Giuliani administration, was contemplating tearing it down. The open ideas competition held in 2003 was the platform for demonstrating community interest and true value possessed in the, at the time, decaying and abandoned industrial landscape. During the first years, NYC Parks was not on involved while Friends of High Line was the real initiator and capital facilitator for the project. Although, at the time preceding the High Line's transformation and opening, Chelsea, the epicenter of Manhattan's Gallery District, and the Meatpacking District, were a burgeoning design, the addition of the High Line to its cultural landscape transformed the West Side of Manhattan into what

Figure 3. The High Line, New York City.

it is today. The High Line has given evidence of the importance of green infrastructure within urban landscapes and the profound effect and potential it can have on culture, economy, real estate, and public identity. The story of the High Line is a profound example of the impacts a strong community voice, determined private interest groups, and key private investment can have on the reshaping of our urban environments (Flynn, 2013).

Going back to the environmental justice movement, in New York City, some neighborhoods have seen important struggles carried out by local community organizations, including especially Sunset Park in Brooklyn, West Harlem in Manhattan, and the South Bronx. Planning policies had an enormous impact on these minority-majority and low income communities (Sze, 2007).

Among the most interesting bottom-up projects of urban requalification based on green infrastructure, the Bronx River has to be mentioned. The Bronx River flows through the South Bronx, a neighborhood which has struggled for nearly three decades under the negative connotations of its name as a flash point for violent crime, drugs, and unchecked urban decay; the neighborhood also houses 15 waste transfer stations and four power plants (Loria, 2009).

The Bronx River went from a flourishing and beautiful resource to a contaminated conduit for industrial and residential wastes over the past two centuries. The restoration of the Bronx River started in the 1970s. In 1974, in response to the poor conditions of the Bronx River, local residents formed the Bronx River Restoration Project, Inc. (BXRR) and removed debris from the shoreline of the Bronx River (New York City Department of Environmental Protection, 2010). Since then,

Figure 4. The Bronx River Greenway, South Bronx.

several initiatives were developed to improve the ecological and environmental quality of the river, with plans, protests, appeals. The many restoration measures directly implemented or pushed by the local community resulted in the foundation of the Bronx River Alliance, an organization aimed at the improvement and maintenance of the Bronx River; today, local community organizations and NYC Departments work together to improve the environmental and social conditions of the neighborhood to reduce ecological imbalances of the River, which is surrounded by a greenway and parks (built thanks to the efforts of the community), and is maintained with the efforts of citizen volunteers.

The case of the Bronx River demonstrates how effective a collaboration between local community organizations and public bodies can be in a low income community, and in a neighborhood with many social and environmental issues, while favorable conditions are important, the environmental justice activists of the South Bronx have played the most important role (Angotti, 2013). Following community priorities may bring about important results, providing projects with State and City resources that would not be possible otherwise due to the lack of resources to maintain all the green areas.

6 CONCLUSIONS

Green infrastructure (GI), since when the term was first used in 1994, has gained increasing attention as multifunctional ecological systems. U.S. Environmental Protection Agency (EPA) takes into account the use of GI for stormwater management and flood control, and in general for ecological, economic, and social benefits through natural solutions. The endorsement of EPA of the promotion of green infrastructure plays an important role in its diffusion.

With regard to the case of New York City (NYC), many policies have been implemented in the past 10 years to reduce greenhouse gas (GHG) emissions by 30% by 2030 and to improve the quality of life. The use of GI is considered especially important for maintaining water quantity and quality and bolstering the livability aspects connected to the public space.

Stormwater management is among the most important aspects of recent policies implemented for sustainability. This is due to the evidence of looming ecological imbalances (e.g. Hurricane Sandy) and especially various economic aspects, as green infrastructure can be a cost effective measure to manage stormwater and to meet the swimmable and fishable water quality standards fixed by Federal Government through the Clean Water Act and regulated by the EPA.

To facilitate the management and also creation of green areas, several programs implemented by NYC involve citizens' participation and the City invests significantly in communication and education.

Although the United States normative framework is not prescriptive as the European one, in the case of green infrastructure a local (city and state level) and community based approach reveals to be effective.

Community engagement in NYC is essential to city planning and design and, in addition to community involvement in such top-down initiatives, interesting examples of bottom-up projects were described. The community plays an important role in restoring environmental conditions of urban areas, not only related to functional contributions (e.g. parks maintenance) but also of the scale of environmental justice organizations campaigns that have resulted in improvement of environmental conditions in low income communities. The case of the Bronx River demonstrates how effective a collaboration between local community organizations and public bodies can be in a low-income community, in a neighborhood with many social and environmental issues. In fact, citizens worked since the 70' with NYC Departments to improve social and environmental conditions, reducing the ecological imbalances of the river, which is now surrounded by a green corridor and parks.

Also in other context, as in the case of the High Line, community was able to drive a very successful project. Following the community's priority allowed the creation of green areas in dense and polluted parts of the city.

At the same time, the Bloomberg administration promoted several interesting (green) projects in the city. Thanks to the benefits that vegetation provides, urban heat island mitigation, stormwater management, air quality improvement, contributing ecosystem health, etc. the environmental and social characteristics of the area analyzed were drastically improved. Therefore both top-down and bottom-up projects implemented in New York City in the last 10-20 years played a key role in improving environmental, ecological, and social conditions for citizens' quality of life.

ACKNOWLEDGMENTS

The present research was conducted in 2013 at the Urban Design Lab at the Earth Institute, Columbia

University. It was funded by a Fulbright-Schuman Program grant. Professor Richard Plunz, faculty associate for the research, is acknowledged, as all the experts consulted.

Thinking + making: Digital craft as social project

Shelby Elizabeth Doyle
Iowa State University, USA

ABSTRACT: "That parametricism "goes social" is not a concession to the prevailing winds of political correctness (that divert and dissolve the innovative thrust of architectural discourse). Rather, it is a sign of parametricism's maturity, confidence and readiness to take on the full societal tasks of architecture, i.e. it implies the inauguration of Parametricism 2.0 … After 15 years of muscle flexing it is high time to put these innovations to more serious work." *Patrik Schumaker* (Schumaker, 2015) The 'more serious work' presented here is the presentation of craft, and specifically digital craft, as a historic and theoretic framework that extends the agency of computational thinking and parametric design in the social project of architecture. Ultimately, this paper argues for the development of a more robust theoretical position about the social application of advanced parametric design as a means to expand architectural agency in the discourse surrounding parametric design's relationship to large scale social issues.

1 INTRODUCTION

Architect and theorist Stan Allen notes in his article *Artificial Ecologies* that the practice of architecture has always been in the paradoxical position of being invested in the production of real, concrete matter yet working with tools of abstract representation (drawings, models, computer simulations and so forth). The paradox charges the question: does thinking (and its associated abstractions) or making (and its concrete matter) give architecture its agency? (Allen, 2003).

The capacity to craft, to think through making, instills architecture with an explicit agency to engage outside of the academy and the discipline. The introduction of digital craft into contemporary practice extends, rather than limits, this agency in the social (or political) project of architecture. The process of thinking through making and the accompanying nonlinear methods position architects to identify pathways of thought into contemporary issues, and then make visible that which remains unseen to other disciplines. Craft encourages imagination and through imagination the architect enters into the spheres of life, which are not immediate to personal experience: the social (or political) project of architecture. This imagination is a powerful agent as well. The ability to imagine a better world equipped with the capacity to act, is to craft an object with intentionality and purpose.

As the discipline continues to struggle with self-identity and the direction of its fragmented authority, craft remains the most valuable tool at the architect's disposal. This papers aims to define craft as it relates to architecture and the architect, to position craft as an agent of social and political change, and to identify digital craft as an extension of this agency.

2 DEFINING CRAFT

The term craft is derived from the Middle English *craeft*, meaning strength and skill. Craft can also be associated with the professional affiliation of a guild or trade association. Indeed, it first came into widespread use in conjunction with the advent of guilds – self-protective medieval associations or private clubs of artisans with formally cultivated talents rooted in innate and rare abilities. Craft creates intimate relations between problem solving and problem finding, technique and expression, play and work. (Sennett, 2008) It brings to mind material, matter, repetition, talent, time, pride and dedication. Craft comes burdened with accusations of nostalgia, luddite tendencies and perhaps even a regressive attachment to the past and the pre-industrial. In the mid 17th century Denis Diderot spent the better part of twenty years identifying and documenting crafts. The result: *The Encyclopedia, or Dictionary of Arts and Crafts*, exhaustively recorded how practical things are accomplished and proposed ways to improve them. In *The Encyclopedia* Diderot, places manual pursuits on equal footing with mental labors, asserting that the craftsman's labors were icons of the Enlightenment. He also scorned hereditary members of the elite who did no work and so in Diderot's opinion contributed nothing to society. His definition of craft is as follows:

> *"CRAFT. This name is given to any profession that requires the use of the hands, and is limited to a certain number of mechanical operations to produce the same piece of work, made over and over again. I do not know why people have a low opinion of what this world implies; for we*

depend on the crafts for all the necessary things of life."

Denis Diderot, *The Encyclopedia* 1747–1765.

As can be seen in Diderot's explanation, the idea of craft and its embodiment of the thinking maker produced discomfort as it upset a social order where thinking and making were separated and making subordinate to thinking. This separation is not new; it extends to the very foundations of philosophy. As Jacques Ranciere demonstrates in his book *The Philosopher and His Poor*: "So there is only one principle of exclusion (from political life). Plato's Republic does not decree that one cannot be a shoemaker and a citizen at the same time. It simply establishes that one cannot be a shoemaker and a weaver at the same time…" (Ranciere, 2004) In doing so Plato sets forth that the shoemaker has only been given enough time to do one thing and therefore cannot encroach on the monopoly of thought and leisure that the philosopher enjoys. The thinking-maker disrupts the neat hierarchical social order which preferences the philosopher, as thinker, over the artisan, as laborer.

3 HIERARCHY AND CRAFT: ANIMAL LABORANS AND HOMO FABER

Richard Sennet opens *The Craftsman* with a distinction between making and thinking. Much of Sennet's argument is an extension of Hannah Arendt's *The Human Condition* that "any maker of material things, is not master of his own house; politics, standing above the physical labor has to provide the guidance." To paraphrase Arendt's distinction between *Animal laborans* and *Homo faber*: *Animal laborans* is a "beast of burden" and *Homo faber* "man as maker." Therefore, *Homo faber* is the judge of material labor and practice, not *Animal laborans'* colleague but his superior. (Arendt, 1958) (Sennett, 2008) Sennett argues that Arendt's separation can be repaired through the act of craft:

> "Thinking and feeling are contained within the process of making (craft). What if *Animal laborans* might serve as *Homo faber's* guide? … History has drawn fault lines dividing theory and practice, technique and expression, craftsman and artist, maker and user; modern society suffers from this historical inheritance …"

Arendt's argument has a greater subtlety to it than Sennet allows. She casts labor as necessity and in these terms to labor means to be enslaved by necessity. It is this enslavement, which breeds the contempt of *Homo faber* who has been freed from these necessities by *Animal laborans* labor. Simultaneously *Homo faber is* aware that he has won his freedom by excluding *Animal laborans* from full participation in the political process by granting him only enough time to labor.

But what then of the artisan? What of Ranciere's cobbler who discomforts the philosopher? The dichotomy of productive (cobbling) and unproductive labor (philosophizing) has been a topic of interest for a range of scholars from Adam Smith to Karl Marx, who elevated labor above contemplation, reversing the traditional hierarchy. Arendt as well doesn't let *Homo faber* escape freely with his vision of separateness from the labor of *Animal labors*. She holds *Homo faber* in contempt, not innocent of but complicate in the acts of his counterpart, since he (*Homo faber*) invented the artifice, which initially spawned the labor. (Arendt, 1958) Kenneth Frampton picks up Arendt's argument in his essay "Intention, Crafty and Rationality" from *Building (in) the Future: Recasting Labor in Architecture*. He further elaborates upon Arendt's distinction by quoting again from *The Human Condition*:

> "If the *Animal laborans* needs the help of *Homo faber* to ease his labor and remove his pain, and if mortals need his help to erect a home on earth, acting and speaking men need the help of *Homo faber* in his highest capacity, that is, the help of the artist, of poets and historiographers, of monument-builders or writers, because without them the only product of their activity, the story they enact and tell would not survive at all. In order to be what the world is always meant to be, a home for men during their life on earth, the human artifice must be a place fit for action and speech, *for activities not entirely useful for the necessities of life but of an entirely different nature from the manifold activities of fabrication by which the world itself and all things in it are produced.*" (Frampton, 2010).

Frampton continues his essay by questioning the architectural profession's ability to confront this issue of separation: "the unreal split between the media cult of the individual star and the anonymity of divided labor that realizes the work." For Frampton this challenges the concept of singular authorship and also fails to address "the presence of a totally new breed of young architects-academics capable of working at both an intellectual and a manual-cum-technical level." (Frampton, 2010) Which is the architect: *Homo faber* or *Animal laborans*? And does craft allow an architect to dwell simultaneously in both roles?

4 DEFINING THE CRAFTSMAN

Who then is the craftsman? And how is the craftsman different than the artist? Sennet maintains that an artist claims originality and that originality is the trait of single, lone individuals (Frampton's "media cult of the individual star"). Conversely, craft names a more anonymous, collective and continued practice of authorship. In this case, originality becomes a marker of time and denotes the sudden appearance of something where before there was nothing. (Sennett, 2008) On the other hand, the quality and value of craft is considered to be a shared experiment of collective trial and error. In this sense, good craftsmanship implies socialism. Craft is carried out collectively, at least in spirit,

in a workshop or studio, a productive space in which people deal face-to-face with issues of authority and a gradient of skills. Skills become a source of legitimacy to command or to dignify obedience.

It is here, that the separation of head and hand are realized, not just as intellectual divides, but by social and economic markers. The architect, the master carpenter and the framer all function as craftsmen. However, the architect sets himself atop the hierarchy of makers imposed within the guild, closer to thinker than to maker. Despite the hint of elitism, the architect must also continue the process of making, grappling with Allen's paradox of abstraction and matter. (Allen, 2003) Additionally, the architect may feel contempt for his reliance upon others to enact his designs as it implies a relinquishment of control. Or as Renzo Piano states (italics are author's for emphasis):

> "An architect must be a craftsman. Of course any tools will do. These days the tools might include a computer, an experimental model in mathematics. *However, it is still craftsmanship – the work of someone who does not separate the work of the mind from the work of the hand.* It involves a circular process that draws you from an idea to a drawing, from a drawing to an experiment and from a construction back to an idea again. For me this cycle is fundamental to creative work. Unfortunately, many have come to accept each of these steps as independent. Teamwork is essential if create projects are to come about." (Piano, 1992)

Today's architect-craftsman has adopted technology as a way of bypassing the need for teamwork or reliance upon others to build. Instead of navigating Allen's paradox, this new breed of architect regains control of his craft through the use of the computer and tools of fabrication. However, the act of bypassing the collective and continuous aspect of craft creates a false sense of individuality and originality. As Scott Marble argues in his essay "Imagining Risk":

> "If craft is defined as a skill developed over time and in direct relationship to making and to working with materials, architects have long been disconnected from this skill, relying instead on builders and fabricators to actually carry out their designs. Architects work with abstract processes of representation that lead to abstract processes of making. This is a challenging context within which to position craft, if any conventional definition of the term. For craft to function as a useful concept today, it might best be rethought as a process of mediating not only between tools and the objects that are produced but also between design as a process of imagination and production as a process of technique. In fact, craft has always been mediated through a relationship between humans and technology." (Marble, 2010)

This mediation between ideas and objects is the indispensable aspect of craft, which makes the architect the craftsman of the building process. However, does the contemporary architect-craftsman maintain an element of agency?

5 CRAFT AND AGENCY IMPERILED

The American Institute of Architects provides template contracts to its members. One of the primary objectives of the contracts is to protect the architect from liability by distancing the architect from the making of a building:

> "The Architect shall not have control over, charge of, or responsibility for the construction means, methods, techniques, sequences, or procedures…"
>
> 3.6.1.2 AIA Contract Document B101 Standard Form or Agreement Between Owner and Architect (AIA, 2015)

The advances and proposals made by Marble and others or the arguments set forth in Kieran and Timberlake's seminal *Refabricating Architecture* are undone by the very documents which define the profession as a profession (in the United States) separating *Homo faber* from those who build, *Animal laborans.*

Sennet says of *The Craftsman* "I am writing in a long-standing tradition of American Pragmatism, joining philosophy with concrete practices in the arts and sciences, to political economy, and to religion, to find philosophic issues embedded in everyday life.") (Sennett, 2008) In this sense craft reflects the objects of everyday life. Well-crafted objects inherit the pragmatism of their philosophical foundations and shed the necessity of the omniscient designer. Additionally, craft implies action and its associated physical products, falling in line with the history of American Pragmatism and the country's foundations built upon the Protestant work ethic. Craft usually hints at the concept of expertise, carefully guarded by professionalism, guilds, trades or unions. What happens though when an outsider takes up a craft, someone not ordained by the keepers of the craft?

Architecture Without Architects an exhibit curated by Bernard Rudofsky at the Museum of Modern Art in New York City in 1964 was a study of non-formal, non-classified architecture – architecture without architects. Rudofsky says of the show "for want of a generic label, we shall call it vernacular, anonymous, spontaneous, indigenous, rural…" Rudofsky continues by saying that "vernacular architecture does not go through fashion cycles. It is nearly immutable, indeed unimprovable, since it serves its purpose to perfection." And that "part of our troubles results from the tendency to ascribe to architects – or for that matter, to all specialists – exceptional insight into problems of living when, in truth, most of them are concerned with problems of business and prestige." (Rudofsky, 1964) It is here that Rudofsky's argument ceases to resonate – he assumes that architecture, vernacular or otherwise, is only tasked with solving problems, not with finding and defining problems.

The focus on non-classified architecture leads into a discussion of the architecture of groups underserved by the traditional profession: the other – be that the impoverished (or any otherness).

6 CRAFT'S AGENCY: IMAGINATION AND OBJECTS

Adam Smith argues, in the *Theory of Moral Sentiments*: "As we can have no immediate experience of what other men feel, we can form no idea of the manner is which they are affected by conceiving what we ourselves should feel in a like situation." Therefore, entering into others' lives requires a profound act of imagination. (Smith, 2009)

Impoverishment of any form – physical, emotional, or intellectual – can be interpreted as pain. In *The Body in Pain: The Making and Unmaking of the World* Elaine Scarry remarks on the de-objectifying effect of pain and its consequent destruction of language. On this lack of referential content Scarry says, "…it is not surprising that the language for pain should sometimes be brought into being by those who are not themselves in pain but who speak on behalf of those who are…" However, how do those who speak gain their voice and their agency? For Scarry this happens through the act of imagining. Through imagination, the speaker can enter into the unsharable space between the certainty of pain and the doubt of its objectlessness. (Scarry, 1985)

> "…Imagining may entail a revolution of the entire order of things, the eclipse of the given by a total reinvention of the world, an artifact (a relocated piece of coal, a sentence, a cup, a piece of lace) is a fragment of world alteration. Imagining a city, the human being "makes" a house; imagining a political utopia, he or she instead helps to build a country; imagining the elimination of suffering from the world, the person instead nurses a friend back to health." (Scarry, 1985)

Despite Scarry's conviction that imagination alone produces agency, she does allow that the objects resulting from imagination have their own agency: *"…through tools and acts of making, human beings become implicated in each other's sentience."* (Scarry, 1985) Or as John Ruskin, declared in *The Crown of Wild Olive*: "what we think, or what we know, or what we believe is, in the end, of little consequence. The only consequence is what we do." (Ruskin, 1866) It can therefore be reasoned that a consciousness of things cannot be independent of the things themselves. Through an engaged material consciousness, we become particularly interested in the things we can change.

The craftsman then can be considered a social philosopher at the intersection of practice and talent and this poses a general question about agency: we are minded to believe that engagement is better than passivity. Therefore, if craft gains its agency through action, and architecture its agency through craft, then how can craft beget the engagement of architecture with a larger social project?

Architects as producers of space, can also be producers of ideologies and of capabilities. Imagining a route out of poverty, requires architects to think and to act, to imagine and then to produce objects. These objects hold new ideologies and offer spaces to improve capabilities. This means architecture must offer not just shelter, but systems to operate within, schools to educate, infrastructure to travel, hospitals to heal, stages to perform, studios to paint. We cannot build what we have not first imagined, and architecture is uniquely positioned to do just that.

7 DEFINING DIGITAL CRAFT

> *"Virtual craft still seems like an oxymoron; any fool can tell you that a craftsperson needs to touch his or her work."* Malcolm, McCullough, Abstracting Craft *(McCullough, x)*

What happens then if architecture cedes craft to the digital realm? Or rather, gives up the very thing, which gave it agency in the first place? Is the digital realm an extension of the imaginary space or a replacement for physical space? And does this cyberspace extend architectural agency or limit it? Digital walls do not keep out physical rain or as McCullough states there is "the seeming paradox of intangible craft." Indeed, we may now be entering an age of the master-builder-craftsman or architect-craftsman that John Ruskin sought to revive, but getting there in a way Ruskin could not have anticipated. Issues of dimension, heft, tactility, and materiality remain essential to architecture as built environment, no matter how tantalizing the pixilated world may be. Digital fabrication and its associated tools provide a tactile counterpoint to the image-based environment otherwise prevalent in digital work.

> *"The best way to appreciate the merits and consequences of being digital is to reflect on the differences between bits and atoms."*
> Nicholas Negroponte, Being Digital (Negroponte, 1995)

For the purpose of this paper, the digital turn in architecture occurred in the early 1990s and is defined as the computerization of design, construction, and fabrication processes. This is marked by a transition from designs based upon a Cartesian grid to those constructed from a digital field condition abstracted within computational space. Specifically, the introduction of continuous computational splines that are variable within defined limits and can be notated as parametric functions or mathematical relationship between parts. (Carpo, 9)

Digital craft emerges from computational thinking, digital fabrication and robotic construction; processes that allow the full participation of architects in the

production of buildings and thereby extend architecture's agency to engage in a larger social and political project. A close reading of the *Human Condition* demonstrates that the spheres presented by Arendt: labor, work, and action are interconnected and in the present day are merged through architectural technology to extend the participation of architects in the construction process beyond the cultural and physical confines of bodily practice.

Craft has long been seen as the antithesis of the evils of modernity and industrialization. Against the rigorous perfection of the machine, the craftsmen became an emblem of human individuality, symbolized by the positive value placed on variations, flaws and irregularities in handiwork. However, does craft, like all traditional knowledge, inherit and pass on prejudice? As members of the University of Virginia School of Architecture Faculty wrote in an open letter to the board of visitors, the university administration, and the university community entitled *"What are the Jeffersonian Architectural Ideals?"*

> "Is there a problem in choosing an architecture to stand for the values of a university at the beginning of the twenty-first century when that architecture was inaugurated at an historical moment when racial, gender, social, and economic diversity were less welcome?" (UVA, 2006)

Does craft gain or cede authority by tethering itself to the continuity of human thought and event? Contemporary craft loses it agency when it becomes associated with the Luddite, romantic, or historic. In fairness, craft does not need to be mistreated by these associations. The combination of technology with craft, termed digital craft, prevents craft from this characterization.

David Pye defines craft in *The Nature and Art of Craftsmanship:* "Craftsmanship…means simply workmanship using any kind of technique or apparatus, in which the quality of the result is not predetermined but depends on the judgment, dexterity and care which the maker exercises as he works. The essential idea is that the quality of the result is continually to risk during the process of making…." (Pye, 1968)

If fabrication and digital craft is seen as the completion of an idea that is then constructed by the machine, then indeed the most valuable aspect of craft is lost to over-determination. Simulation can side-step this over-determination but it is a poor substitute for tactile experience. If the digital is used to eliminate the feedback loop of question finding through question answering, then craft itself is at risk. Machines break down when they lose control; whereas people make discoveries, stumble upon happy accidents. There is a nostalgia for a lost space of freedom – free space in which people can experiment, a supportive space in which they could at least temporarily lose control. A radical emancipatory challenge provokes:

> "Power in action requires some largeness and imaginativeness of vision. Men must at least have enough interest in thinking for the sake of thinking to escape the limits of routine and custom. Interest in knowledge for the sake of knowledge, in thinking for the sake of the free play of thoughts is necessary then to the emancipation of practical life – to make it rich and progressive…."
>
> John Dewey *"Concrete and Abstract Thinking" How We Think* (Dewey, 1910)

Therefore, how might digital craft re-engage the best aspects of craft, thinking through making, and the power of the digital realm? First, digital craft must embrace the spatial conditions of the computer environment. The term cyberspace first appeared in William Gibson's 1982 story *Burning Chrome* and was subsequently popularized by his 1984 novel *Neuromancer*. (Gibson, 1984) The concept of other or virtual space is woven throughout history, appearing in literature and cultural commentary from Plato's *Allegory of the Cave* to Descartes' *Evil Demon*. However, the concept of cyberspace is unique in that it offers not just a space of representation and communication but also provides a social setting within which these activities can exist. The resulting social relationships are what give cyberspace its physical presence and thereby architectural ramifications. In architecture, this conceptual space is often considered to be the space of the screen or monitor and therefore simultaneously the space within the computer and the internalized space of perception.

Is it possible, that the future of architecture lies in our ability to make the parametric sensate or to actualize the abstraction of cyberspace into meaningful physical objects? In digital culture, there is a new continuity between subject and the architectural object, with no void between them. As if the distance of vision was abolished by tactility. Craft and its inherent materiality will prevent architecture from falling prey to the complete cognitive internalization of the screen, it will halt the progression toward ocular space primacy, and it will create the interactive corollaries between cyber and physical spaces.

For digital craft to promote the agency of thinking through making, architecture must embrace the aspects of feedback mechanistic processes offer, by expanding the field of information to the tools used in the discipline.

8 CONCLUSION

Digital worlds should not be seen as alternatives or substitutes for the built world, but rather as an additional dimension which allows architects a new freedom of movement in the physical world. In other words, the transcendence of physicality in the digital world allows architects to extend their agency in the physical world. (Carpo, 10)

Digital craft brings together the physical and digital worlds. The historic and theoretic framework presented here aims to move forward the agency of

computational thinking and parametric design in the social project of architecture. The development of a more robust theoretical position about the social application of advanced parametric design will expand architectural agency in the discourse surrounding parametric design's relationship to large scale social issues: Schumaker's 'more serious work'.

Emerging research: The architect's personal research through design competitions

P. Guilherme & S. Salema
CHAIA, Universidade de Évora, Évora, Portugal

ABSTRACT: Architectural Design Competitions is a growing field of research in architecture theory and provide a laboratory view over the dynamics of the production of environmental design quality and the renewing process of culture and knowledge. Design competitions connect academia and praxis, can bring out the best out of architects and is a way to achieve excellence in design. Our argument, following previous research, is that architectural design competitions reflect a procedure of research (derived from the academia but in the praxis), develop personal and field competences, values and abilities, and foster innovation in architecture. In fact, there is evidence that during their professional practice, licensed architects, outside the academia and in praxis, use design competitions as fundamental research opportunities. These facts sustain the importance of the role of architectural design competitions as an important social, cultural and professional field of research that challenge the way we currently see the practice and the education of the architect. Recent research gives relevance to the way design competitions could also contribute to and stimulate Continuing Professional Development (CPD) and should be accepted as such.

1 INTRODUCTION

Architectural Design Competitions is a growing field of research in architecture theory (Rön et all 2010, 2013, Tostrup 1999) and generally provide a laboratory view over the dynamics of the production of environmental design quality, design quality and the renewing process of culture and knowledge.

Design competitions exist for a very long time (Lipstadt 1989, 2000, 2010). There are records of Greek competitions as early as 448bC, they flourished in Renaissance Italy (e.g. Brunelleschi's design for the cupola of Florence Cathedral) and are now major architectural procuring events to achieve the best design service (Kostoff 2000).

Design competition serve as a way to address an architectural or urban problem and to find its best answer. The debate about the value of competition is not only about the equitable distribution of design commissions but also about its important theoretical, ideological and ethical foundations. The openness in the distribution of public funds, the understanding of design process, and the participation in the shaping of the built environment may be better obtained with design competitions (Strong 1996, Spreiregen 1979, Collyer 2004, Chupin et all 2015, Rönn et all 2010, 2013). Other may argue that there are other ways of achieving this (Nasar 2006).

Nonetheless, it constitutes an opportunity for all parties involved (promoters, architects, public) to improve the quality of the built environment.

In this paper we will focus on the architect's point of view and in particular in the way competitions serve as stimulus to researching and improving one's abilities and competences as an architect.

Previous research (Guilherme and Rocha 2013, Guilherme 2014, 2016) has connected the importance and theoretical background of design competitions to the core curriculum of the academia (Malacrida 2010) (at its birth in the Beaux-Arts in Paris) and to the practice (praxis) of the licensed architect. The connection between academia and praxis that occurs during design competitions seem to be a proof of Donald Schön's (2003) "*research-in-action"* and Jeremy Till's (2012) evidence of *"architecture [as] a form of knowledge that can [, is] and should be developed through research"*.

Present research takes into consideration previous data (Guilherme 2016) in order to further link design research and competitions with professional development, thus illustrating the importance of design competitions in design research. It also takes into consideration recent studies and surveys (Van Alen Institute 2015a, 2015b, 2015c, *Forlati and Isopp 2011*) that further describe and give credit to design competitions as being part of a research activity within practice. We will present, discuss and recommend the possible use of design competitions as part of Continuing Professional Development (CPD).

2 ANALYSIS

The education of an architect (Brady 1996, Schön 2003) is not a static endeavor that can be easily defined by fixed and precise characteristics; it evolves with the

demands and developments of society. It must therefore encompass both continuity and change to prepare students to meet the demands of the profession. Given the dynamic and complex nature of architecture, the education of an architect involves not only what constitutes a course of study, but how an architect is educated.

Education is seen as a continuous progression of knowledge, beyond any age limit, and during the working life span of the architect (e.g. Oscar Niemeyer died with 105 and is said to have worked until he died).

To some formal extent (taking a holistic view of the working life span of the architect) it may encompasses three levels (layers) of education (using the Architects' Council of Europe structure):

- An initial formal academic education period with the basic principles of architectural culture and the design process. It may be different according to countries education policies, but may constitute a Bachelor of Architecture, a License Degree in Architecture or a Master Degree. More specific skills can be pursued by post graduations or doctoral programs in architecture;
- A second level of professional experience in contact with the core practice (praxis) of architecture;
- A third level of Continuing Professional Development.

We will elaborate on how architectural design competitions in practice (in the second level of education) may constitute a proof of architectural research thus providing a valuable contribution to continuous education (third level of education).

2.1 *Continuing Professional Development (CPD)*

The Royal Institute of British Architects (RIBA), established in 1838, oversees *"the advancement of architecture and the promotion of the acquirement of the knowledge of the Arts and Sciences connected therewith"* (RIBA 2009). RIBA has helped to develop and apply research-based knowledge of RIBA members, chartered practices and schools of architecture in order to promote links between practice and academia. In order to do so, it has defined key work areas, annual research themes. The objective is to *"raise awareness among practitioners of the benefits, both intellectual and economic, of research in practice"* (Anon. 2016).

Continuing Professional Development is beneficial for you as an individual, as well as to the profession as a whole, as it offers an assurance to the public the professional is up-to-date with the latest industry developments and innovations (Tyler 2016a). CPD enlarges the already acquired academic competences with other newer, recent and potentially more creative knowledge.

To the Architect's Council of Europe *"Continuing Professional Development (CPD) for architects is, at European level, of professional and public interest. Its necessity has been affirmed in directives of the European Union and its relevance is even greater in the enlarged European Union. As the diversity of training and practice has increased, CPD has become a necessary obligation for practicing architects and for the organizations that represent them."* (ACE 2006)

CPD is mandatory for all AIA (US) and RIBA (GB) members and is described by Joni Tyler (Head of CPD at RIBA) as being *"any learning you do under your own initiative, whether structured or informal. It's CPD you arrange, rather than CPD we bring you."* (Tyler 2016b) As a chartered member, architects are obliged each year to:

- Undertake at least 35 hours of CPD. These are the minimum amount of time you need to spend each year maintaining your competence;
- Undertake at least 20 of the required 35 hours from the ten topics in the RIBA CPD Core Curriculum (around two hours per topic per year). This is considered formal CPD;
- Award at least 100 learning points to the individual CPD activities you carry out. Assigning points represents your assessment of what you got out of the CPD activity, and will be the result of the time you spent reflecting on relevant subjects.
- Gain at least half of your CPD from structured learning activities, unless your circumstances prevent it;
- Record CPD activities.

CPD is considered to be a creative learning tool, and any activity from which you can learn – as long as it's relevant to the practice or business of architecture and contributes towards maintaining practice's competence – could count as CPD (Tyler, 2016c). As long one learns from the activity and it influences your professionalism and competence, despite the medium, you may be doing your CPD.

This is a recent profound change over the strict way of formal learning and is linked to professional ethics and to the diversity of competences, attitudes and knowledges needed for the architect. It is the architect's responsibility to attend to its needs for continuing professional development in order to honor its social commitments to the common good and to the profession or art itself.

According to ACE (2006) *"CPD aims to deliver to architects a means to maintain and improve their personal culture, practice and competence and to update their knowledge regarding arts, science and technology, where there is permanent evolution, with due regard for the aesthetic, social and legal regulation of their activities."* According to Joni Taylor (20161, 2016c) unformal learning (outside the minimum 20 hours formal learning and up to 35 hours) can be found in:

- Doing some online or distance learning;
- Working towards an additional relevant qualification;
- Attending local or community courses;
- Bringing CPD or training expertise in house;
- Attending a conference or workshop;
- Listening to podcasts or watch webcasts;

– Engaging in knowledge transfer;
– Attending industry trade shows and exhibitions;
– Undertaking research: informal self-directed research, formal research, or research in practice;
– Or any other informal activities, such as: reading, going on study tours, volunteering, siting on committees, blogging, having discussions on social media, mentoring, visiting exhibitions, learning from colleagues, being a school governor, engaging in reconstruction or disaster relief.

The most important question is in fact how you reflect on learning from your experiences and increase your professional knowledge and skills to your benefit, as well as that of your staff, business, clients and future.

This subject is deeply covered by Donald Schön (2003) with the notions of *reflection-in-action*, and *reflection-on-action*. First it involves looking at the experiences, connecting them with our feelings and attending to our theories in use. It entails building new understandings to inform the actions in the situation that is unfolding. Then testing out the *theories* or *leading ideas* and allowing to developing further responses and moves. The act of reflecting-on-action enables spending time exploring why one acted as one did, what was happening in a group and so on. In so doing new sets of questions and ideas are developed about the activities and the practice.

Thus learning, reflection and change appear to provide opportunities for professional development in praxis, to both ACE, RIBA and AIA.

2.2 *Architectural research*

Jeremy Till's position paper on *What is architectural research?* for RIBA Research Committee (2005) has become theoretically inspiring for those discussing whether by architectural research we mean *research about architecture*, *research through architecture* or *research for architecture*. These three categories, borrowed from the least known Christopher Frayling's pamphlet on *Research in Art and Design* (1993), describe a general theory of design in which the task of solving the problems involves conceptualization and explicit knowledge adaptation to individual design experience.

Ken Friedmen (2008) discusses experience and inquiry stating that *"tacit knowledge is valuable"* and *"central to all human activity, and the background of embodied individual and social knowledge provides the existential foundation of all activities, including intellectual inquiry."* (2008, p. 157) Even though ancient sciences, that have successfully linked empirical observation with inventing theorizing (e.g. Copernicus, Galileo, Newton and others) thru hypothetical and deductive thinking, apparently seem to be less useful in providing useful theories and end up by being scorned by modern science, they constitute the fundamentals of tacit knowledge. Friedman states that *"all knowledge, science and practice rely on rich cycles of knowledge management moving from tacit knowledge to explicit and back again. While the craft tradition of design has relied more on tacit knowledge than on explicit knowledge, it is time to consider the explicit ways in which we can build design theory."* (2008, p. 158).

Some authors (Groat and Wang 2013, Salama 2015) argument that we are familiar with forms of historical and theoretical research about architecture and with the improvement of architectural and design practice as the focus of design research by design practitioners and theorists. However, research through architecture presents us systemic doubts about its methods and legitimacy.

Also Albena Yaneva (2005), following OMA's Whitney project presents the hypothesis of research in practice and with the project at hand.

Current practices at a research PhD program in architecture in the University of Évora (Salema et all 2014) sustain the possibility that *the "project (as a methodology, a process of knowledge or simulation of a 'hypothesis') could be part of an advanced research in architecture"* (p. 471) in academia doctoral programs. The *project* is the subject and the result of the research thesis, and the opportunity of the *project* is motivating and nurturing the academic *scientific* research.

2.3 *Design competitions*

Design Competitions are one of the oldest forms for selecting one architect or one project amongst others. *"Architectural design competitions are quality-based, project-orient selection procedures to procure architectural services. Quality based means that the decisions are made on basis of the quality of the submitted proposal. It is the opposite of a quantity-based, or even solely price-based, decision. Project-oriented means that the decisions are based on expectations for the future, as the basis is the upcoming project, and not on past achievements (as in the case of a team-based selection procedure)."* (Forlati and Isopp 2011, *p.274*).

The submitted entry is part of an educated hypothesis to the solution of the problem posed by the competition brief by the author. It is an individual research (Guilherme & Rocha 2013), sometimes pursued over several design competitions or projects (e.g. Souto de Moura's *Salzburg Hotel* (1987/89) *The Bank* (1993), and *The Burgo Tower* (1991/95 Phase 1; 2003/04 Phase 2; 2007 Construction)) but using the supposed *scientific method* of the academic *atelier* competition first seen at the *Beaux-Arts* (Malacrida 2010), never deeply refuted as the atelier's way to teach architecture between the *enlightened teacher*/*celebrated master architect* and the *apprentice* (Guilherme 2014). The jury system, and the concurrent projects from others challenge the commitment and ideas reaffirming that architecture is not practiced in isolation, but a public art, with public and social responsibilities.

Competitions *"are favored by professionals mainly by its symbolic (social, cultural and professional) capital (Stevens, 1998) as they reflect one's opportunity to prove one's abilities and ascend to those whose dominancy in profession is unquestioned. The main architectural universities (academia) function is to produce professional architects (Stevens, 1995), and to do so it has to reproduce the ways of an architect, and the consecrated privileges of the class. The parallel discussion at universities is the production of knowledge and ways to relate with the profession (praxis). Competitions provide a place and a time when both worlds unite, were the student is expected to learn an important lesson on the status of the architect and learning at the same time, and were the professional reunites, once again, his practice with research."* (Guilherme 2014).

Competitions have been the base pedagogic process for the transmission of symbolic capital by masters to pupils under an organized system of implicit professional knowledge. Competitions ensure that the fundamental hierarchy of the members of the academia (the teachers and juries: who defined what good art and architecture was) and those that would ascend to it (the students: who were prized and hence were the good artists and architects) and perpetuated a secular way to ascend to stardom. We believe architectural competitions provide an opportunity to research in architecture in order to present (using predetermined models and mediums) one's research and its conclusions (statements). Each personal architectural research is in fact subjected to an *informal* (unstated) merit competition (were the teachers take the part of clients, sponsors and juries), to a peer evaluation, in order to prove its author's right to, step by step, become a graduated architect. The research is validated by the competition and assures the originality of the research, its significance and rigor.

Therefore, as previously argued, competitions are opportunities for research (Guilherme & Rocha 2013) and have been used by the academia to foster development in knowledge (Guilherme 2014), thus we firmly believe design competitions may also constitute research in architecture outside the academia.

2.4 *The wonderland manual for emerging architects*

Wonderland – platform for European architecture is a Vienna (Austria) based network for young Europe-oriented architecture practices aiming experience, information and knowledge exchange.

Wonderland takes part in collaboration projects with international teams to foster inter-European exchange, organizes *Project Spaces*, *Blind Dates* and Symposiums, conducts research on current challenges and approaches in the field of architecture as well as urban planning and shares results with members and the public by means of exhibitions and publications. It is an expanding network and is strengthening their presence in Europe.

Wonderland published in collaboration with *A*10 three thematic numbers previous to the *Manual for Emerging Architects: How to Establish and Run an Architecture Practice in Europe* in 2012. This *"accelerating [of] the exchange of information among young architects in Europe"* (Forlati and Isopp 2011) is a speculative manual for reaching to a higher degree of social status within architectural symbolic capital. This manual explains the profession to the young professionals. It includes a coherent amount of information and poll-based surveys on how to conceive, establish, develop and run an architectural practice today.

After addressing how to *get started*, and *making mistakes* – an important part of being creative, of accidental innovation and by stating *trial and error* as a fundamental method of solving problems – the authors affirm the importance of *being public*, *being specialized* or *making competitions (Forlati and Isopp 2011*, p.269–328). Forlatti further develops:

> "*Taking part in a competition is about testing one's abilities outside a predefined setting of personal connections, nationality, office size, or gender. It is about experimenting and developing a personal vision much more directly than in the usual architect-client relationship. And winning a competition is much more than just getting a job! It is about the possibility of growing big in a day, of shortcutting years of slow growth, or of jumping scale in the size of projects the practice deals with, of getting a footing in a different national context, of specializing. And finally it is about publicity and recognition in and beyond the professional context – from colleagues to the general public." (Forlati and Isopp 2011, p.271)*

According to *Wonderlands*' pole-based surveys, an average practice in Europe does around 3 competitions and invests around 2000 hours per year. It achieves a ratio of 4 out of 10 returns of some kind, 2 wins and 2 other prizes, but only one gets realized. In fact, it takes about 8.4 years to realize 2.5 projects won in competitions.

According to *Wonderland* survey: 83% of the respondents sees competitions as a way to develop the architectural thinking in practice; 84% sees competitions as a necessity for clients who want new ideas; 50% uses models to test ideas; 74% has collaborators specialized in competitions in the office; 71% is not so interested in the first-prize money when choosing a competition; and 76% sees the relation between work required and compensation as problematic.

This data confirms the relevance of competitions to research about practice to European architects and its relevance as architectonic events for acquiring (or enlarging) its own symbolic capital.

2.5 *RIBA competitions task group report*

The RIBA Council approved in June 2014 the findings of the RIBA Task Group Review of architectural

competitions (RIBA 2014). The group comprised clients, client advisers, architects and RIBA executives, and was set up by the RIBA in 2013 to review the use of competitions in the UK.

Key recommendations of the review included the promotion of best practice guidance and the celebration and promotion of the benefits of competitions for all types of buildings, which should lead to an increase in the quantity of well-run and well-managed competitions.

Other task group recommendations approved by RIBA Council include improved processes to reduce waste such as design charrettes, standardized prequalification templates and additional services including client mentoring for less experienced clients. These recommendations are intended to challenge both the quantity and the quality of competitions run in England. RIBA has extensive experience in delivering high quality and significant competitions and competitive selection processes. By doing so, it also manages to impose architects as those best suited and responsible for obtaining high architectural quality among the profession.

RIBA Competitions standards include principles of openness, fairness and transparency, as well as protection of copyright, honoraria payments to reflect the amount of design work required, efficient processes including use of digital entry, judging composition, involvement of independent client adviser, and feedback to competitors. These standards are consolidated with a service to approve and promote qualifying third-party competitions. The main recommendations from the task group were (RIBA 2014, pp.14–16):

- Celebrate and promote the benefits of competitions;
- Increase the quantity of well-managed, well-regulated competitions;
- Provide best practice guidance and support to clients;
- Promote best practice and continuous improvement to processes;
- Influence the standards of other competition providers.

During a wider consultation a majority (11/3) responses (RIBA 2014, p. 27) led the Task Group to recommend that "*Competition entries should count towards an architect's CPD requirement"*. In fact, there was an overall idea that competitions could be part or research or training, in particular when new knowledge could be obtained. However, when competitions were only seen as a repeated procuring tool, respondents felt no development could arise, giving credit to the idea of design competitions being directed to major events or uncommon problems and not to ordinary problems.

This relevance is quite clear in relation to key professional development supplementing CPD Core Curriculum, which is the main CPD Study Guide, and is comprised of 10 subjects: (1) Being safe health and safety; (2) Climate: sustainable architecture; (3) External management: clients, users and delivery of services; (4) Internal management: professionalism, practice, business + management; (5) Compliance: legal, regulatory and statutory frameworks and processes; (6) Procurement and contracts; (7) Designing and building it: design, construction, technology and engineering; (8) Where people live: communities, urban + rural design and the planning process; (9) Context: the historic environment and its setting; and (10) Access for all: universal/inclusive design.

By including competitions as unformal CPD the Task Group would be providing a place where all could be tested in the form of a research hypothesis, thus enabling a potential research.

The competition would then become a research experience and therefore would constitute an even greater place for providing the public service RIBA wishes architects could do. By including or selecting competitions as an unformal CPD, British architects would have to work not only to win the commission (and therefore use design competitions as procurement), but also make competitions a place to research (therefore making competitions more innovative oriented).

2.6 *The Van Alen survey*

More recently *Architectural Record* and *Van Alen Institute* (2015a, 2015b, 2016), with support from the Graham Foundation, systematically gathered input on what motivates designers to enter competitions, what they love and hate about the process, and their suggestions for how to make them work better. They released the results with more than 1,400 participations from 65 nations worldwide.

Key findings (Van Alen Institute 2015a) from the anonymous responses highlight some of the most interesting headlines from the survey:

- Designers enter competitions so they can work more creatively than they would be able to in everyday practice, and explore new topics, ideas, collaborations, and skill sets outside of typical constraints. Respondents indicated that the top three reasons for entering competitions are 1) the opportunity to experiment (57,0% of survey entrants); 2) an interesting issue (54,9%); and 3) an opportunity to gain publicity (39,0%).
- The lack of compensation for time and resources spent is a primary limitation to designers participating in competitions. Respondents indicated that the top three limitations to participating in competitions are 1) lack of compensation for time/resources spent (78,6%); 2) low probability of winning (29,4%); and 3) no or low chance of implementation (28,6%).
- Respondents indicated a desire for more feedback (48%). This is especially crucial among students: 65% said it would make entering competitions more appealing. Students were also particularly interested in collaborating with people outside of the design fields.

These key findings support the idea that competitions are fundamentally an optimistic praxis of architecture. It is the most recent and relevant raw data analysis (Van Alen Institute 2015b) proving competitions are fundamental for students and licensed architects as research into practice.

In April 2015 a *Design Competition Conference* took place, sponsored by the *Harvard Graduate School of Design* and *Van Alen Institute*, co-chaired by Jerold S. Kayden and David van der Leer, in order to *"review the state of design competitions today and their impact on competitors, sponsors, design, and the public interest. Using the lens of professional, ethical, business, legal, aesthetic, and public policy perspectives"* (Van Alen Institute 2016d). The conference (Anon. 2015) is a testimony of the *pros and cons* of making competitions and a vivid story of some competition entries.

Some of the respondents assured that *"competition allows to work on otherwise impossible issues or subjects usually reserved for the 50 architects that are known worldwide... It is the best format for architectural research and learning through investigating."* In addition, some spoke how specific competitions more appealing to young architects (less than 40 years old) could be described like being *"[Europan] a catalyst of Urban and Architectural Research"*.

The survey is an unexpected view over the preconceived ideas on competitions, challenging their supposed hierarchy and importance.

3 CONCLUSIONS

We gathered evidence from different sources that present the importance of design competitions to architects and to the public realm. In 2011 *Wonderlands* conducted a European survey and launched a Manual for Emerging architects sustaining the value of competitions to the development of the architect. Four years later the *Van Alen Institute* has produced a worldwide survey about design competitions which ended with a major conference with Harvard University over the fundaments, the theory, the advantages and hazards of design competitions. Both surveys sustain that competitions are seen and used as research opportunities by architects. These researches are evaluated thru their merit by a jury taking into consideration the promoter or public interest. These surveys show that design competitions can be much more than just a way to gain a commission and enlarge the possibility of their use over other subjects of knowledge. No matter whether competition projects are built or not, and despite all waste of time, human or financial resources, the prizes increase the winners' symbolic capital within the architectural field, and the public attention given to competitions raises the prestige of the architectural profession in general.

There seems to exist a link between design competitions and architectural research at the academia and there is a new theoretical corpus of authors sustaining the hypothesis of being able to research thru the design. There is evidence that competitions are potentially research oriented procedures in praxis, and should be taken into account as similar, to some account, to scientific research.

We acknowledge there is evidence of the relevance of continuing professional development in relation to the initial education of the architect and to the practice (praxis) of architecture. Some countries have been updating their vision of what can constitute CPD and have included unformal ways of acquiring new knowledge. RIBA competitions task group has further stated that competitions should be considered as unformal CPD as long as it would influence the professionalism and competence of the architect.

We are convinced that the by doing competitions an architect is researching or *reflecting-in-action* thru design projects which can benefit and influence the way that architect works. Thus design competitions ought to be considered as opportunities for continuing professional development and should become part of CPD core curriculum.

Modern architecture Kuwait: The role of the architect

R. Camacho
College of Arts, Media and Design, School of Architecture, Northeastern University, Boston, USA

ABSTRACT: Upon assigned deputy curator for the first representation of Kuwait at the 13th International Architecture Exhibition of *La Biennale di Venezia*, the author initiated a research work on building production and architectural practice in this country.

In 2012 the author organized, as parallel event to the country's representation,a conference on Modern building heritage which included a series of round-table debates between practitioners and the local community. The success of this event triggered several years of research, on-site and archive visits and interviews with architects, planners, contractors, historians, and former city officials. In 2013, with the support of Kuwait Foundation for the Advancement of Sciences and on behalf of Dar al-Athar al-Islamiyyah initiated in co-authorship a double volume book, "Modern Architecture Kuwait.1949–89," recently published by *Niggli Verlag* as the first systematic analysis on the country's building production.

The paper prompts to expose the research above. Among the major motivations for it are the lack of knowledge and common misconceptions regarding the national architecture production between the collapse of the Ottoman Empire and Saddam Hussein's invasion. Erasing this part of Kuwait's national history is a major loss for the country, and a missed opportunity to investigate the nation's "modern" state foundation. The magnitude of this problem is demonstrated by the fact that since the study began at least three major buildings, all subject of the research work, have been demolished to create space for high-rise office buildings, while others have been deeply modified or covered with shiny aluminium cladding.

1 BUILDINGS AND BUILDING CULTURE IN KUWAIT

The act of build and re-build is part of a post- oil Kuwaiti community behavior, a form of equality, the need for the new home or the fascination with the new. Motivation, that is followed by a delusion of superiority, a seizure or conquest rather than a strategic removal of the existing, the old.

Following the discovery of oil and the colonial disengagement (1952–62), the act of building – a house, a hospital, a mosque or even a *diwaniya* – developed into a continuous need, a social imperative. The community becomes dependent on those modes of social equality and representation. At this point, Architecture and Planning assume the form of "a way to" the new and the modern, that stimulates destructiveness of the old and the construction of the new.

With the "New Town Development" (1952), Sheikh Abdullah Al-Salem Al-Sabah spearheaded the first large planning and infrastructural project of the country, expanding the built beyond the city walls and encouraging the demolition inside. The city itself disappeared. The city once a coherent spatial organization, governed by the continuities of ritual, history and memory, was fragmented and reorganized. Although, the city's instantaneous re-formation by the disappearance of the traditional geometric references did not result in lack of resolution of architectural image, as one could imagine. During the early stages of this reformation (1949-65) the focus on infrastructure and network enhanced the interconnection of various sites and - despite the isolated architectural "masterpieces" that gave a nominal symbolic content to the architecture – tolerates a sort of anonymous state-sponsored Modernism.

The complete demolition of the Old City centre and the comprehensive redesign of the urban form, together with the creation of the new neighbourhood units, catalysed the attention of major international designers working in synergy with local firms and authorities and leaving on the ground important examples of late Modern Architecture. Over a span of 40 years the process of reshaping Kuwait involved designers such as Kenzo Tange, Alison and Peter Smithson, Georges Candilis, Alfred Roth, Sayyed Karim, Hassan Fathy, Dar Al-Handasah, Mohammed Makiya, Rifat Chadirji, Basil Spence, BBPR, Pier Luigi Nervi, Felix Candela, I.M. Pei, SOM and TAC just to name a few.

As Kuwait gained independence and autonomy, the necessity of a new landscape to represent the freshly founded state grew high. A new urban environment was envisioned for a new state, therefore major architectural practices found here the possibility to expand their professional horizons and the challenge to compose an entire city, building by building, almost from

scratch. The urgency for a modern town and the ambition of architects led to the construction of a city made of stand-alone buildings. The diversity of production sources, together with the strong motivation for experimentation, generated and still generates a series of remarkable architectural-urban models.

To this day, the right of the City to take the land ownership with the purpose of providing land assets to its citizens, subsidized access to housing, and the aspirations for "a better future" dominate the social and economic spheres. Kuwait remains a merchant city where promises of industrialization and neoliberalism were defeated by the "affluent individualism" of its citizens and city officials, and by architects devoted to the erection of their own modern monuments. Along with the exposure to the objective possibilities of new building forms, the architects were seduced into the representation of glorified domestic industrial achievements, encouraged as a form of national pride.

2 ARCHITECTS AND THE COMMON PRACTICE IN KUWAIT

"In this period has grown the understanding that the building's action on the shaping of the territory and the spatial shaping of the territory itself should be at the center of our work." (Smithson, 1996)

"We use architects and planners from all over the world (…) We want the best." Qabazard said "and we need their help, not merely to design buildings, but to collaborate with local architects. (…) Sometimes we just want their advice and send them an air ticket." (Gardiner,1983)

Since then architectural authorship is measured by object building and the general consensus within the discipline is that architectural efforts should be visible in the city. After the Invasion (1990) the community goal lays in the far distance, in that other world, the promised *Silk City*, a project initially planned in 1977 to build a new capital city 60km from the northern border with Iraq. Gradually, the idea of direction becomes the most important thing. The more distant the goal the better the prospect of its permanence. The seemingly indispensable principles of growth before invasion, have been replaced by something quite different: by image replica or by repetition.

The post-war reconstruction and beautification process opened a precedent on city development, that is today the urban support for many of the architects and engineers practicing in the country. Issues of instant city, construction of new identities, the tabula rasa condition and questions of environment all will come up and for the first time in 40 years of modernization, a collective motivational ambition to restore the face of the city by referring back to an alleged traditional building culture. Together with this emergent and most likely conservative approach, the exotic lifestyle of a liberated transitory culture became a sort of "image bites" that collapsed traditional forms and complex urban patterns into single, consumable frames. The city developers, who then inherited this rearranged landscape of highways, tall buildings, and parking lots declared the left over voids diseased sites and offered their own, corrected architecture to fill them with yet more buildings. The architects on the other hand believed themselves to be gentle where their predecessors had been ruthless.

In light of such evidence there is ample support for the assumption that the phenomenon of Shiber's "fluid city shell" (Shiber,1964) was no longer related to the implementation of large planning operations, though it has substantial explanatory strength when it comes to the production of individual buildings. This, in turn, reinforces the conceptualization of the architectural process as a mechanism of linkage through which architects, owners, contractors and contexts exert control over integral parts of the city's hierarchies beyond the normative instruments of traditional planning.

3 MODERN ARCHITECTURE OF KUWAIT RESEARCH

"Modern Architecture Kuwait.1949–89," the MAK project in co-authorship with Sara Saragoca and Roberto Fabbri, departs from this conceptualization. These apparently uncorrelated works, described through mostly heretofore unknown information, are fundamental to providing tentative answers to a series of hypothetical questions: How were architectural design processes and practices developed from the early infrastructure of the 1950s to the invasion of 1990? How was architecture practiced in the absence of historical heritage, major local architectural references, strong morphological elements, or a strong urban footprint, and (occasionally) in absence of adequate planning tools or their correct implementation?

The objective of the MAK is to understand these dynamics of practice, rather than to produce a history of Kuwait's urban development. Consequently, the methods applied here concentrate the analysis on the multiple and built elements that compose the modern city, contextualizing the design practices and architectural intentions behind them. Through the understanding of the territory as a loose canvas that allows the physical presence of these elements to be rendered in the urban landscape, it became clear that a survey of buildings was the principal subject of this investigation. The traditional methods of an urban-scale approach were inadequate to the task. Our investigation began therefore with architectural elements as pivotal subjects and with an intensive engagement with over forty years of building production in Kuwait, including on-site visits, photographic surveys, archival research, and interviews with architects, planners, contractors, historians, and former city officials. This work was multiplied by extensive multidisciplinary and multimedia research using old city

plans, building drawings, photographs, film footage, letters, legal documents, architectural and construction press, journals, the popular press, and a range of other documents, including the portfolios and corporate profiles of design firms and contractors, in order to document every possible construction or building project comprised in those years. By focusing on the professional trajectories of these designers and by reading the presence of these buildings in the urban environment at the architectural scale, the research examined and analysed a selection of buildings which is finally presented here as an architectural atlas.

This repertoire of hundreds of buildings is revealed as a collection of specimens, selected for their specific qualitative aspects, as examples of particular design methodologies or typologies, or else for their different adaptations to the severity of local environmental conditions. The method applied here has been to simultaneously read the differing chronologies and geographic linkages of urban and architectural practice in order to understand dynamics of change and innovation in terms of design principles, the city fabric, and construction technology. As a result, a different narrative from that of the chronological survey came to the forefront—what the building actually does, contrary to what it was intended or designed to do. In this way, the project pursues the value of the built object in the city beyond its function or program.

The final building selection involved a complex process of inclusion and exclusion. Some buildings are unequivocally—sometimes rhetorically—considered local landmarks, such as the National Assembly, *the Abraj Al-Kuwait* (the Kuwait Towers) or the State Mosque, while other types, such as single and multi-family dwelling units, exist in such numbers and diversity that they were impossible to account for and characterize in a overview study such as this and for that reason were excluded. With regard to housing, exceptions were made for certain mixed-use typologies, such as Hassawi Residential and the Nugra and Dasman complexes, that are relevant for their authors, their complexity of scale or their importance for understanding the city, as one can also argue in the cases of al-Muthanna or the Rehab complexes. The same approach gradually led the research into the systematic analysis of lesser-known projects, such as the Shuwaikh Power Station and Desalination Plant or the Kuwait Shipping Company offices, as well as unbuilt proposals such as the Sport Centre or the Low-Income Housing Schemes.

In this intricate realm, the availability of sources played a very important role in the selection of buildings. Despite the acknowledged efforts of some major local firms, it was not easy to gain access to primary sources in Kuwait, which are often dispersed or forgotten. Needless to say, some buildings could not be described here given the lack of these supports. On the contrary, the international projects, once discovered, were found to be well documented in archives, but these were scattered all over the world. It took the collaboration of several fellow researchers to collect these documents, creating a long-distance network of exchanges.

The research identified a selection of around 150 projects covering a span of forty years. A major effort was invested in creating a timeline and biographical references of architects, planners and contractors that could put these projects in relation to the region's recent history as well as to the architectural scene of the Middle East.

In a second moment, the project invites other scholars and researchers to develop further a critical understanding of the city and buildings.

3.1 *The role of the building*

In the course of selecting and chronologically mapping the buildings, it became clear that the diversity inherent to architecture and urban practice in Kuwait were over determined by the city's history and geography of modernisation. The chronological organization of the buildings in four chapters in the book allows a reading across historical time of the interactive processes by which the city was gradually generated and, through authored projects, the city's image. Such an organization highlights the role of practices, and of urban architectural knowledge, in the process of generating the city.

3.1.1 *Building as infrastructure*

The first of these chapters reflects the first generation of the country's modern architecture and its foundational principles established by an elite of British designers, contractors and officials. The core of this early development process was made of schools, power plants, hospitals, administrative and governmental offices. Among these, the usage and the construction technology and material are prevailing conditions. Although, projects such as the Southwell Hospital in Ahmadi (1951–60), the Vocational Technical College (1953–54) in Shuwaikh and the Institute for Physically Handicaped (1963–69) preceded later attempts by the Smithsons and Candilis, Josic and Woods to conceptualize low-rise, highly dense building types. Following Alison Smithson's publication on "How to recognise and read mat-building" for the British journal Architectural Design in 1974 and their proposal for the Ministries Complex (1969–72), these typologies became popular referents in many of the design briefs for schools and public institutions in Kuwait during the 1980's.

3.1.2 *Building as national identity*

The projects collected in the second section consider buildings but also some of the medium-scale urban schemes that best represent the Pan-Arab spirit of the "Al-Imara al-Haditha" (modern architecture). The term coined by Ihsan Sherzad for Iraq is commonly used by local scholars and historians to refer to the work of Sayyed Karim's in Kuwait and Shiber's well-known "architectural control"(Shiber, 1964). These principles expressed an ideal and mature Arab state

seeking to establish its own national identity through projects of often larger scale and international projection that could finally render the "City of the Future," a fluid territory in which projects such as the Khaldiya Girls Secondary School or the Governmental Hotel, for example, were allowed to change location or function within the span of a few years. Furthermore, Shiber's efforts to promote the revision of the First Master Plan through zoned and detailed urban plans led to the creation of the Central Business District Areas. In these areas Shiber called for the "rational building" of a "type of architecture suited for Kuwait."(Shiber, 1962) The considerable amount of buildings erected in these districts were either designed by Saba Shiber and his team or through international design competitions, which diversified the design approaches from those discussed in the first chapter. For instance, the "Grand Corniche" and the redevelopment of the old city harbour area constituted proposals for the first large-scale development process that was open to urban design where Shiber pursued the ideal environment for this "City of the Future."(Shiber, 1964).

3.1.3 *Building as cityscape*

The complexity and experiences resulting from such operations prompted a new elite of city officials, such as Hamid Shuaib and Ghazi Sultan, to look into the city's historical layers and read them against the regulation plans. In the third chapter of specimens it becomes clear how the unstable environment of Kuwait's urbanization made conventional methods of planning and urban homogenisation difficult to implement in subsequent years. In 1968 the invitation "to Prepare Urban Form Studies for the Old City," given to Alison and Peter Smithson, Reima and Raili Pietilä, Candilis, Josic and Woods, and BBPR, and the multiple design competitions for Low Income Housing schemes, called for more agile and assertive techniques of intervention. What was expected from these proposed architectures was not simply a vision of future development but the actual capacity to generate physical impact in shaping the city's visual appearance, as well as the functionality of the cityscape itself.

The brief for Al-Riqqa Low-Income Housing, addressed to Jafar Tukan, requested "units of classic Arab design, in harmony with local architecture." Meanwhile, Macklin L. Hancock called for an Islamic-arabic inherited approach to "understand how this can be achieved [considering] materials which will help to keep maintenance costs low [and] effective solutions to technical problems unique to this part of the world"(Hancock, 1969). During the 1970s practices such as Iraq Consult, PACE, KEO, KEG, and Sabah Abi-Hanna (later SSH) initiated a remarkable body of work related to the private development of mixed-used programs which seek, in their own ways, the aesthetic values identified by Hancock.

The functionality of this new cityscape required strategies that were architectural as well as urban. It required urban buildings that engaged the city at the level of the urban plan. In this sense, the Demonstration Areas, identified as consequences of the 1968 "Urban Form Studies for the Old City," fully expressed this condition: "The intention was to illustrate principles by actual buildings for known demands" (Smithson, 1974). This initiative resulted in multiple modern souqs and high-rise buildings scattered all across Kuwait City. The consultant to the Municipality, Roland Kluver, encouraged the idea of a self-contained unit in order to recover the residential component within the city centre. The ambition of the late Sheikh Sabah al Salem al Sabah, was here finally rendered throughout different projects: "Kuwaitis are entranced by the fanciful idea of roofing over Kuwait and air-conditioning it all, with powerful planetariums projecting beautiful skies day and night. This little country has the money to think big." (De Carvalho, 1965)

3.1.4 *Building as program*

Finally, during the 1980s, Kuwaitis' extensive interest in building construction became more of a business matter rather than a welfare policy. The celebration of the building boom uncritically offered the city up to market forces. The capitalization of formal and informal stock exchanges in Kuwait was by 1982 ranked third in the world, behind the US and Japan. But by the summer the Kuwait informal market stopped trading. The Souq Al-Manakh crash, still referred to until recently as "the greatest stock market bubble of all time," revealed the volatility of oil and the speculative finance economy prevalent in the country (Kubo, 2012). In the following year construction in Kuwait dropped by 50%, leading to the interruption of some of the undergoing projects, and eventually to the bankruptcy of contracting firms and designers such as TAC. Within this scenario, the forth chapter covers the remaining interval of production until the Iraqi Invasion in 1990. This time frame of uncertainty represented a new beginning in urban policy, which eventually extended beyond the Invasion. As a result, architects and other building actors were forced to adjust to frequent changes and learned how to instrumentalise these changes in their own interest claiming for the autonomy of the discipline from the building function as an attempt to revive local tradition and culture. In this way, the building program becomes the central argument to provide the spatial nature and capacity to evoke visual imaginaries and aspirations. The architecture elements are then defined by choice of either parties and oscillating between exuberance and some disillusionment with the modern. The Conference Centre in Bayan is a clear reference to this: the architect of 'Sava Centar', the most modern convention centre at the time and once called the technological marvel of Tito in Belgrade, is here reinterpreted in a typology of the past claiming for other architectural roots than those being displayed in the city buildings. Initially without purpose the Conference Centre was the excuse to perform the scale and exuberance aspired.

Under the guidance of well-educated owners or client representatives, building practice often developed into personalized and emotional narratives, proper to a post-modern condition and well described by Krzysztof Wiśniowski, co-author for the Port Authority Headquarters. For this project Wiśniowski recalls the Centre Georges Pompidou being a strong reference in the client's requests, consequentially bringing more analogical arguments into the design process: "the four car ramps were [conceived] as mooring lines that secure a Dhow." The Arab Organizations Headquarters Building in Shuwaikh, developed between 1982–90 by Mohamed Makkiyah in association with Archicentre and completed in 1994 by PACE, is a good example of a design process initiated here and perpetuated to this day.

3.2 *Mapping modernity in Kuwait*

Each specimen was dissected, analysed and presented here as part of the kaleidoscopic heritage of modern architecture in Kuwait. Time-wise, modernism is conventionally situated in the first half of the 20th century and geographically placed, in most cases, in Europe or in the Americas. The definition of Modern Architecture is widely misused, often confused—for example with contemporary—and is not conducive to shaping a close classification, especially if it is understood that a real modern movement never really existed as one tight movement with a single agenda, but rather through multiple contingent collaborations, debates, and confrontation between architects and artists that often shared highly divergent points of view and approaches to design.

Marcel Breuer, whose studio was also involved in Kuwait at a later stage of his career, expresses in an undated note his concern regarding the word modern, for the multiplicity of meanings that it can trigger. He labeled it as an excellent sales term, and as such he tried to elaborate the concept in a way that seemed relevant for this research: "Now, if we use the term 'modern architecture' I mean something quite different. And I should say that I call the most modern architecture the one which longest remains 'modern'. (…) In the sense in which I use this term, modern design or architecture is not a form or a motif, but rather an instinct, or rather, a tendency. (…) As I mentioned before, not the outside characteristics are real significance of this movement but rather the fundamental instincts behind its forms. Going down to the roots of our work, I see three basic principles: First: the direct approach. Second: the tendency for clarity. Third: the tendency to create with truthful elements; (or indifference to create with forms of illusion, or with decorative covering forms)."(Breuer, 1986)

These basic principles also suggest common characteristics among the varieties of different buildings, from different times and by different authors, that have been selected to compose this study. The Kuwaiti architectural context can perhaps be better inscribed in the frame of other modernisms, borrowing the—nowadays frequently used—title of the Do.co.mo.mo (Docomomo International) conference in Turkey 2006, which gave an impulse to reconsider less orthodox forms of modernism.

3.3 *Recovering a lost identity*

Modernization efforts were halted in 1990, and after the Invasion for the first time since the inception of the Antiquities Law in 1960, conservation ideas began to take hold. Nevertheless, following the death of Saddam Hussein in late 2006, the country recovered its trust in a certain future and new initiatives for design and building started without the addition of any critique of the prior standards.

As with other cities in the region, the town center of Kuwait has suffered a gradual deterioration in areas once characterized by their modern architecture, and today faces the challenge of conservation, confronted with the current processes of urban development. The residential urban periphery, although an urban fabric characterized by single-unit structures, includes a number of modern buildings of significant quality that have been modified or are at risk of demolition. In fact, the value of these modern structures is not always understood, so that often the buildings are demolished and replaced. This phenomenon has been encouraged by an elite of politicians, scholars and even architecture and planning practitioners that have labeled these architectures as "foreign" and therefore implicitly indifferent to local history and building tradition. Only recently, under narratives of "nation building" through memory and identity, an emerging community of young, well-educated artists and professionals from the most varied sectors of society has started to project an "archeological status" onto these buildings, urging for their preservation.

4 CONCLUSION

Among the major motivations for conducting this study are the lack of knowledge and common misconceptions of the architecture produced within this timeframe in Kuwait. Kuwaiti citizens often show disaffection and a low sense of belonging to these spaces, and the authorities have taken very few measures in the past to promote the conservation and restoration of this important heritage. Erasing this part of Kuwait's national history, as well as its international architectural heritage, is a major loss for the country, and a missed opportunity to investigate the country's recent past. The magnitude of this problem is easily demonstrated by the fact that since this study began at least three major buildings, all present in this book, have been demolished to create space for brand-new towers, while others have been deeply modified or covered with shiny aluminium cladding. While it is impossible not to feel a deep sense of loss every time a trace of the past has been erased, it is equally impossible to pursue preservation practice or policies without creating

a proper baseline. This requires a scientific, systematic database similar, for instance, to Evangelia Simos Ali's survey of Kuwait's surviving pre-oil structures, conducted in the early 1980s.

Two major goals can be ascribed to the survey presented here. First, to create the first database of the most significant modern architectural specimens in Kuwait, identifying the key players and distinctive features of relevance to both the culture of Kuwaiti citizens and a wider professional audience. Second, to reopen the discussion of building conservation decisions and an examination of emerging approaches related to the rehabilitation and adaptive reuse of modern architecture, nowadays suffering from a lack of recognition and an almost nonexistent framework of legal protection. Contrary to the idea of fossilization in a sort of a modern archaeological park, where every building becomes a monument to itself or a museum, compatible transformations can perhaps bring back life to the abandoned and reestablish new functions for the outdated.

A renewed architectural consciousness has emerged in recent years throughout the several publications, articles, exhibitions, conferences and lectures hosted both in academic and cultural contexts in Kuwait. These efforts have made modern architecture in Kuwait and Middle East the main subjects of academic research for local and international scholars and research institutes, which MAK has acknowledged throughout this research.

A peak of this ongoing process can also be read in the participation of Kuwait in the last two architectural editions of *La Biennale di Venezia*, where the national pavilions were produced by local curators around the subject of national heritage. All of these combined efforts have been capped by the submission of *Abraj Al-Kuwait* to be listed as a UNESCO World Heritage Site. If successful, this will be the first nomination for the modern architectural and urban heritage of Kuwait. The blogosphere, a space in which a mass audience sharing comments and thoughts on the subject of the city in transformation becomes visible, has led to more tangible actions in the street, like the first public protest against the demolition of the old Chamber of Commerce, in 2014. For those who are not familiar with the Gulf, this is not common.

In the authors' intentions this research was never to be an exhaustive representation of forty years of architectural practice in Kuwait. The aspiration is rather to deepen our knowledge of the city's built environment, with the declared intention of informing contemporary architectural and urban practice. A better understanding of this important heritage can open architects, planners and city officials to a different way of doing, providing not only a collection of information, documents and drawings, but a practical tool that could trigger a better use of these buildings.

The architect and interactive buildings: From builder to composer and conductor?

H.H. Achten
Faculty of Architecture, Czech Technical University in Prague, Prague, Czech Republic

ABSTRACT: Three upcoming technologies – Internet of Things, Wearables, and Cloud Computing are seen to converge in support of smart buildings and smart cities. In this paper characteristics of interactive architecture is discussed, and how the mentioned technologies may impact such buildings. The conception, design, and creation of interactive architecture requires a rethinking of the design process by the architect. Some preliminary strategies are outlined to achieve this. The role of the architect moves to a composer- or conductor-like style.

1 THREE DISRUPTIVE TECHNOLOGIES

Technological developments have a large influence on buildings and the urban environment on an increasing wider spectrum of aspects. This concerns not only the widening capabilities in the design process (rapid prototyping, generative design, parametric modelling, design-to-production) but also the world around us itself. Environmental pressures require architects, urbanists, and society to come up with sustainable solutions. Smart Buildings and Smart Cities are coming up that take advantage of advanced control systems (for buildings) and connected networks (for cities) to make more responsive environments which ca n reduce some of these pressures (for example energy, carbon footprint, congestion, and so on).

In this paper we propose that there are three technologies which will have a disruptive effect on architecture: The *Internet of Things*, *Wearables*, and *Cloud Computing*.

The Internet of Things (commonly abbreviated as *"IoT"*) combines physical objects with their computational representation so that the objects can be manipulated by virtual entities. The term was first introduced in Ashton (2009). Intelligence and knowledge about location and state of things is transferred to the objects themselves, and needs no longer be inferred top-down. IoT lowers the boundary between physical and virtual systems and actually allows them to operate in a physical-virtual continuum.

Wearables are simple or more advanced sensing and computing devices that people wear on their body (for an early example, SensVest, see Knight et al. 2005). Wearables often have GPS functionality and track user vital statistics such as heart rate, respiration, caloric burning, and so on. Wearables form a middle layer that can inform smart systems about the physical condition of the user. Additionally, the environment may provide wearables with relevant information for the user (for example training-wearables that get information about smog levels in a city – thus able to advise the user where to take their jogging route).

Cloud computing is a comprehensive set of servers and network technologies that are outsourced and scale with user's needs, meaning transfer of data and computing resources from locally managed systems to network-based services (Buyya et al. 2009). Smart devices may obtain necessary data and computational resources from Cloud services thus reducing the need for large capacity facilities within the devices themselves. Additionally, since most of the services run through virtualized machines, the exact location of the real resources becomes less important. Therefore it is sufficient to connect wireless to local resources, thus reducing bandwidth and transmitting capacity.

In short, we can summarize the effect of the three technologies together as follows: through IoT, building components become more aware of their surroundings. They can infer valuable information about inhabitants through Wearables that people have on them, via direct communication or via Cloud technology. Local inference by the building components themselves, or facilities through Cloud services, allows buildings to respond to user needs. Through this convergence of technologies we can achieve interactive architecture.

There are many technological developments in each of the mentioned fields, and the implications and technical aspects are much wider than we as architects are able to understand, process, or influence. What is important to note however, that it is not necessary to be completely knowledgeable of all things happening in order to take advantage of these developments? Applying IoT, wearables, and Cloud computing to buildings

sets a number of boundary conditions which simplify the application of these technologies:

1. *Location*: buildings are precisely localized, therefore their services are localized as well. Inhabitants are either present in the building (direct interaction), or in a different place (requiring agency of the services in that different place). High accuracy indoor location sensing can be obtained with well-placed RFID tags. Public location-based services can breach privacy (they gather information about place and interest of a user), but this is less the case in the home/occupant relationship. Additionally, because of fixed location devices need only take into account objects and people around them in a limited area.
2. *Characteristics*: Technological requirements for indoor environments are less demanding than for the whole outside world: indoor environments typically have small network size, few users (family members), rechargeable batteries power source, Wifi, 3G, 4G LTE backbone Internet connectivity, local server, RFID and WSN devices, and small bandwidth requirements. For public buildings these services scale up and have to include also anonymous users.
3. *Easier orchestration of services*: the amount of smart objects and services which have to coordinate their tasks in a building context is much less and also more specific than in the general IoT context – which needs to cover the whole outside world.

These technologies by themselves are not enough to reliably and without fault infer what the needs and desires of a building's inhabitant are. It will still take intelligent user profiling and learning algorithms to understand the needs (see for example Wemlinger & Holder 2015). However, the combination of Internet of Things, Cloud computing, and Wearables will lower the information gathering task for an interactive system in a substantial amount. Wearables by themselves monitor physiological data of the user, and most likely will combine this with social data as well (smart phone functions like agenda and so), so an interactive system can simply ask the wearable rather about the condition of the inhabitant. Cloud computing and IoT add locational information to create from which a spatial understanding of both inhabitant and building can be derived.

2 DISRUPTION, THEN WHAT?

The notion of disruption is quite complex and under ongoing development and refinement. It has to be pointed out that it is more proper to speak of disruptive processes rather than technologies – the disruption is not in the technologies but in the (in)abilities of companies to deal with changing technology (Christensen 2006). Nevertheless, in mainstream discussion the term "disruptive" is usually associated with technology, and it has come to mean any game-changer that will have a profound influence on a particular sector.

In the previous section we have argued why the particular combination of IoT, Cloud computing, and Wearables will be disruptive. What will actually be disrupted, is the conventional state of the built environment as a passive object. With cities and buildings acquiring responsive capabilities, we will need design offices, teams, legislative bodies, and the general public to adopt different design thinking, strategies, norms, and expectations. In the further part of this paper we will discuss in particular interactive architecture as a concrete emerging phenomenon from this disruption.

3 INTERACTIVE ARCHITECTURE

Advances in technology are leading to buildings that can autonomously act more of their own and change according to particular settings in a more or less intelligent way. Such buildings have been termed in various ways, for example: *Building Automation System*, *Smart Home*, *Sentient Building*, *Adaptive Building*, *Dynamic Building*, *Interactive Building*, *Kinetic Architecture*, *Intelligent Building*, or *Portable Building* (Achten 2014a). The variety in terminology indicates that much of this is still in preliminary stage, and indeed many of their applications seem like "a *solution* looking for a *problem*" (Maia & Meyboom 2015). The most consistently developed systems at the moment are Smart Homes, which take up most of the references of research in this field (see for example Crowley & Coutaz 2015).

In our research we are interested in the phenomenon of *interactive architecture*. To be precise, for a building to be interactive, we desire of the building (or of the building components) to engage in a meaningful transfer of information with the user, such that the state of the user and the building may be changed after this exchange of information. Therefore many semi-autonomous actions in buildings, such as automatically opening doors, opening or closing blinds, thermal control, and so on that take place without active consideration of the user are *not* interactive in our view.

3.1 *Orientations in interaction*

In today's situation, most interactive environments are either geared towards optimal performance (mostly Smart Homes) or to information or entertainment activities (mostly media facades). We propose that there are more orientations possible for interactive systems, in total *performance*, *sustainability*, *service*, *symbolizing*, and *entertaining*.

1. *Performance*: the interactive system aims to obtain optimal performance according to a set of objective criteria (for example lighting conditions, acoustic requirements, thermal comfort, and so on).

Table 1. Interaction attitudes.

	Instruct	Conversation	Manipulate	Explore
Performance	Trainer	Fellow	Specialist	Explorer
Sustainability	Mentor	Helper	Scout	Discoverer
Service	HAL	Host	Assistant	Technician
Symbolizing	Icon	Peer	Chaplain	Guru
Entertaining	Idol	Buddy	Crew	Entertainer

2. *Sustainability*: the interactive system aims to maximally reduce carbon footprint and other aspects that impact energy consumption (for example use of daylight, heat recovery treatment, operating passive systems, and so on).
3. *Service*: the interactive system aims to provide an optimal set of services for building users (for example pathfinding of visitors, allocation of resources for building functions, adaptively managing elevator and escalator routines combined with user patterns, and so on).
4. *Symbolizing*: the interactive system aims to optimally convey a societal, symbolic, religious, or metaphoric function that deepens community commitment (for example supporting life phases and steps like wedding, baptism, or funeral; events of state, or community).
5. *Entertaining*: the interactive system aims to express an entertaining value to the inhabitant and visitor (for example through display of images and sound, to create illusions or trompe-l'oeil, generate effects to impress or awe visitors, and so on).

We have to note that perhaps the distinction between five orientations may be too fine-grained. There definitely is a distinction between "performance" and "sustainability" (high performance usually comes at the cost of larger energy demands), but maybe "service" could be integrated into "performance." Similarly, "symbolizing" and "entertaining," since they both have representative function may be combined into one category, thus leading to three main orientations rather than five. This is something that can only be assessed through application of the theory, and see where the distinctions make sense.

3.2 *Styles in interaction*

According to interaction design theory (Sharp, Rogers & Preece 2007), interactive systems can try to *instruct* a user, have a *conversation*, *manipulate*, or *explore*.

1. *Instruct*: the interactive system aims to clarify the use of an object or technology to the user (for example how the user has to operate the indoor climate system to obtain thermal comfort while maintaining good energy footprint).
2. *Conversation*: the interactive system exchanges information with the user in a dialogue kind of fashion (for example the building delivers monitoring data about its functioning to the user, or an online security system may inquire about the purpose of a visit).
3. *Manipulate*: the interactive system and user aim to achieve a particular goal through manipulation (for example setting the desired levels of comfort in a building without the user needing to know how this is achieved).
4. *Explore*: the interactive system and user try out various options without clear goal-fulfilling behavior (for example experimenting with lighting settings, or different options for opening and closing blinds, and so on).

Interaction style determine ways how an interactive system may engage with the user in a dialogue. These styles influence for example which information is shown, how consequences are displayed, which options are available, and so on.

3.3 *Attitudes of interactive buildings*

From the combination of orientations (performance, sustainability, service, symbolizing, and entertaining) and interaction styles (instruct, conversation, manipulate, and explore), we can derive 20 possible interaction *attitudes* (Achten 2013) – see Table 1.

By giving the attitudes descriptive names like personalities (trainer, helper, fellow, buddy, etc.) we want to indicate that each attitude has distinctive qualities. It does not mean that these attitudes act like a personality per sé. They form guidelines for the designer rather than a fixed set of norms and values which have to be obtained.

The realization of an attitude can be split up in two parts: the outward part that is visible to the user, and the inward part that controls the mechanics of the interactive system.

The outward part concerns changes in the building like moving objects, different light levels, signals, displayed information, and so on. As the user may infer intentions of the outward part, we may call this the "intentional level" of the attitude. This part will be the main concern of the architect and the design team that have to come up with the interaction concept of a building.

The inward part concerns changes in the sensors, controllers, and actuators that effect the interaction itself. Since the inward mechanics part is usually hidden to the user, we can call this the "cognitive level" of the attitude. This part will be the main concern of the

specialists, programmers, and technicians who build concrete interactive systems. In Achten (2014b) we demonstrated the split between intentional and cognitive level on the hypothetical design for an interactive museum.

3.4 *Keeping things consistent: the narrative*

A noted characteristic of attitude by assigning them a personality is that we want these attitudes to remain consistent in the way they act. It is quite easy to lose this consistency if we treat interaction as a series of unrelated events between inhabitant and building. Lehman (2013) notes that interaction occurs through a series of interaction points (between system and user) that should support the "narrative" of the user – the logical unfolding of a series of events that comply with the user's needs. Users may go through different narratives in the same environment as their needs dictate. For example, in a hospital environment, the user as patient may have several narratives (undergoing therapy, having consultation, getting visitors, and so on). Each of these narratives need to be supported by an interactive environment.

In the same way as Lehman argues for a user-based narrative, we believe that narrative is instrumental for the system side as well. In that sense an "*interaction narrative*" is the logical and consistent unfolding of a series of interaction events in an interactive system. The notion of interaction narrative strengthens the concept of attitude because both focus on consistency. Attitude does this through assigning a 'personality,' and narrative does this through a consistent series of interactions.

4 TOWARDS INTERACTION DESIGN

Who should design our future interactive buildings and environments? We propose that this is not a question to be solved by installation experts, but is something that has to be considered by the architect from the very start. We expect that interaction will have a large impact on the character of buildings, and thus architects need to find an adequate expression for this. There are however, very few theoretical frameworks that can support architects in the design of interactive buildings.

Cedric Price (1934–2003) and Gordon Pask (1928–1996) have to be mentioned as the earliest pioneers who actually tried to realize interactive buildings. In 1971 already, Cedric Price realized the Inter-Action Centre in Kentish Town, UK (Kronenburg 2007: 209). This building was the realization of a more ambitious concept, the Fun Palace, proposed in 1961 in collaboration with theatrical director Joan Littlewood. The Inter Action Centre consisted of an open frame in which modules could be inserted and changed at will. Gordon Pask argued as early as 1969 that architects should design systems rather than buildings. As Pask wrote: "*Another consequence is that architects are required to design* dynamic *rather than* static *entities. Clearly, the human part of the system is dynamic. But it is equally true (though less obvious) that the structural part must be imaged as continually regulating its human inhabitants*." (Pask 1969: 494).

Most of the ideas of those times were ahead of technological possibilities, and this applies even some decades later when the first so-called interactive structures were built – such as the *Tower of Winds* project by Toyo Ito in 1986, Yokohama (Mignonneau & Sommerer 2008: 94). The majority of likewise realized projects focused on some visual representation of dynamics because that was technologically speaking the most feasible way. A widely noted next step of a dynamic structure with actually moving parts was achieved with the so-called *Aegis Hyposurface* installation in 2000, a project lead by Marc Goulthorpe (Liu 2001: 36–41).

In the past decade many sensor-, actuator-, and controller-technologies, as well as easy programming tools became increasingly more available. This allowed many people to experiment with responsive technologies, both in practice and in academia. Trying to summarize who is actively investigating responsive technologies today is a near impossible task. Notable architects who have tried their hand on interactive buildings and installations from the early beginning are for example Michael Fox & Juintow Lin, Tristan d'Estrée Sterk (Orambra), Kas Oosterhuis (Hyperbody & ONL), Chuck Hoberman (Hoberman Associates), and so on. Many experimental practices with younger generation of architects and researchers have a close connection between industry and academia. Examples of such researchers among many others are Omar Khan & Laura Garofalo (Liminal Projects), Jason Kelly Johnson & Nataly Gattegno (Future Cities Lab), Madeline Gannon (Carnegie Mellon University), Alessio Erioli (Co-de-iT, Bologna), Manuel Kretzer (Responsive Design Studio), Andrew Vande Moere (KU Leuven), and so on.

4.1 *Small projects – great expectations*

Many buildings today feature responsive components such as self-regulating blinds, escalators, surveillance systems, and so on. The largest interactive structures in architecture by and far are media facades. Advanced electronics firms like Philips (Aarts & Marzano 2003) and Samsung [1] offer interactive solutions without considerations of the architectural side. Smaller companies, in particular active in home automation, but also office automation, offer specialized products such as virtual sky ceilings [2] and home control hubs like *ivee* [3].

Architects who experiment with interaction usually do not have the backing of an R&D unit that electronics firms have, so mostly they are limited within the resources offered on a project basis or within a research

budget at a school. Sometimes we can see a combination with material investigation due to availability of rapid prototyping technologies and the application of unconventional materials. Most of the time however, materials and interaction are two separate worlds (research groups with strong material research are for example *Institute for Computational Design* Stuttgart (headed by Achim Menges), MIT's *Mediated Matter* (headed by Neri Oxman), MIT's *self-Assembly Lab* (headed by Skylar Tibbits), or *Kokkugia* (headed by Roland Snooks and Robert Stuart-Smith).

The view of the architect that emerges from all this work is an experimentation-involved practice that advances knowledge step-by-step on a project basis. There is a certain ad-hoc character to this experimentation because available means depend on contingencies in budget, available technology, team composition, local authorities, and so on. Consistent lines of inquiry are usually supported in the collaboration or integration in a research unit. Universities (for example those mentioned above, but there are many more) can allow longer timelines of investigation that are separate from practical applications.

It is fair to state that most actually built projects are of modest size. In fact, a complete interactive building yet has to be realized to the best of my knowledge. The Prairie House project (2011) by Tristan d'Estrée Sterk's Orambra [4] comes close but was not built. What is happening however, is that through many projects, installations, new material experimentation, collaboration between architects, scientists, and artists, and so on, the discipline of architecture is building experience and confidence with this very new phenomenon. I sincerely believe it is only a matter of time, within a very short time horizon (within two or five years from now) that a highly interactive building will see the light – chances are it may already be in development somewhere.

4.2 *A changing perspective*

Based on the discussion above, we can see an increasing number of opportunities for architects to experiment with interactive buildings. This is not just a technological story. To successfully design interactive buildings we need a different design process and changes in the design team composition and roles.

The focus of the architect in the design process changes. Rather than designing a static structure, the architect has to compose a dynamic and responsive structure. More than ever, what the architect should be considering first, is the experience of the inhabitant in the building. Designing such an experience is not trivial, because it is no longer based on a user observing a static object. The building's responsiveness and dialogue with the user comes into consideration as well. Furthermore, "the inhabitant" as such is not a single individual, but can be any number of people. Additionally, some of these people will have regular contact with the building, but others may be one-time passers-by and anonymous.

In order to tackle this well, architects should have the following skills:

1. *Analyze dynamics of existing context and future built environment*. This analysis goes beyond traditional analysis of people and traffic movement. Dynamics of existing context deals with energy, material, people, and information flow of all kinds. It is in particular important to identify patterns of density and exchange that can indicate important activities and occurrences in the environment. Additionally, it is important to understand that a future design will influence these patterns. The aim obviously is to create a design which has positive effects, but even with advanced simulation tools these are difficult to predict.
2. *Design a dynamic experience of the building*. More than ever, user experience design becomes an important aspect of a building design. User experience consists of a complex set of interactions of the user with the building, all of which lead to an understanding of the user of the building. This is strongly related with the attitudes listed in Table 1, in order to avoid an ad-hoc collection of unrelated interactive user experiences.
3. *Synchronize the various interactive components* to establish a consistent whole of the building activities. The interaction narrative outlined before organizes the themes of interaction between user and building. These have to form a consistent story so that the user understands and to some extend may anticipate what he or she can do in the building.

In earlier work we have outlined a number of design methods that may assist architects in the design of interactive architecture (Achten and Kopřivá 2010).

Understanding a dynamic future, creating a dynamic experience, and synchronizing components are skills often encountered in *music composers* and *conductors*. Throughout the ages, composers have written scores that provide a particular musical experience. By means of notational system the main music was set down, however, leaving freedom for the actually playing musicians how to interpret the music. In the same way a conductor, dealing with a score, has to decide on an interpretation to make the music really come to life.

Architects arguably are not composers nor conductors. We would claim however, that architects would benefit if they were inspired by some of the sensitivities of composers and conductors to dynamics, transfer of emotions, and orchestrating sounds, timbre, and quality. Such inspiration may come from any composer at any given time period. In particular the American composer John Milton Cage Jr. (1912–1992) seems to be closest to both worlds of music and architecture. In his works he dealt with chance and the absence of control. These are indeed critical points where the parallel between composers and architects is at its weakest. Even the most carefully considered user experience

has to deal with contingency – unexpected occurrences and behavior of people. This is more so when we are dealing with buildings that service large numbers of anonymous users. An alternative way to consider the design of interactive architecture may be game design – a position often claimed by Kas Oosterhuis (Hubers et al. 2001; Oosterhuis and Feireiss 2006).

4.3 *Bottlenecks*

The discussion above cannot be complete without considering bottlenecks that have negative influence on the development of interactive architecture. Currently, most initiatives come from architects who are willing to invest time and resources into this domain. There are a number of bottlenecks that slow down these developments:

1. *Inadequate budget*. Interactivity is not factored in the budget of the building – thus left to less structural funding.
2. *Not included in competency*. When interactivity is considered, it is usually seen as an addition, rather than an integrated feature of the design. Therefore, the interaction design is taken aboard in the design team.
3. *Not included in fee*. The design of an interactive building is not seen as the main job of the architect, and thus not included in the fee.
4. *Missing theoretical framework*. Interactive architects develops on a project-by-project basis without theoretical considerations from the field what interaction is about. Therefore many things are discovered on an ad-hoc basis rather than through systematic inquiry.
5. *No proven performance*. Most examples of interactive architecture do not have obvious positive effects on buildings, thus making investors and architects alike hesitant to explore this direction.

5 DISCUSSION

Buildings are become increasingly knowledgeable about their surroundings and show more and more intelligent behavior. Most of this is developed in the domain of building installations. Additionally we see architects experimenting with responsive technologies that depart from the performance and functional side. We believe that the technologies of Internet of Things, Cloud computing, and Wearables is going to have an accelerating effect on interactive architecture. We have outlined a number of theoretical considerations what this interactive architecture may require. We see the role of the architect changing, and taking on characteristics of composer and conductor, although we are also aware of the limitations of these metaphors.

ACKNOWLEDGEMENTS

The views presented in this paper are the result of ongoing work at the Cabinet of Architectural Modelling at the Faculty of Architecture of Czech Technical University in Prague. The work is inspired by the many people who are experimenting with interactive architecture all over the world – we have mentioned just a few of them in this paper. Their influence and work is greatly acknowledged by the author.

The emerging role of the architect as system designer

Z. Oztoprak
TOBB University of Economics and Technology, Ankara, Turkey

ABSTRACT: This paper offers a possibility of a revised understanding of the position of the architect. First, the new science of our age, biomimetics, and its potential in architecture is examined. The need for a methodological approach for the implementation of biomimetic strategies in architecture is addressed. Second, the nature of general system theory and the introduction of systems thinking in architecture is identified. The link between biomimetics, systems thinking and architecture is clarified. Finally, the focus is put on the changing role of the architect from the form-giver to the designer of the systems that designs a building.

1 MAN AND NATURE

Since the relationship of man and nature is as old as the history of mankind, man always observed nature and tried to find solutions through his experience. Until the very end of 19th century, man has learned shapes and forms from nature through the observation of natural structures. After the industrial revolution, development of new technologies and advanced tools for observation enabled analysis of nature and enhanced man's relationship with nature. In time, the behavior of nature became much more important than how she looks like. Earlier attempts of such a tendency towards nature was seen in the sustainable development of the 1970s, with a global approach to energy and resources. In the end of 20th century, all these resulted in a new branch of science, named as biomimetics.

Biomimetics, in general, implies the study of natural processes and systems for solving problems, creating innovations and developing new technologies inspired from nature. In this regard, biomimetics can be seen as a result of the enhanced relationship of man with nature, through new technologies and advanced tools for observation. Biomimetics differs from sustainability and energy issues being more of an instruction than a prescription. Every time it demands to design a new system abstracting principles from nature. We need to start from the beginning, developing, trying and testing systems inspired by various biological systems as potential prototypes.

Today, with growing impact of biomimetics, we find the promise of a new direction for many fields in the 21st century, such as engineering, manufacturing, material science and even in medicine and fashion. In architecture also, many current approaches are trying to transfer strategies from natural systems. By integrating the logic of nature to digitally-driven design processes, architects are trying to transfer strategies of natural systems from the nano-scale up to design and construction of very large buildings. However, many current approaches to apply biomimetics in architecture are either limited to form based mimicry or synonymous to older notions of sustainability. In order to move beyond these existing attempts and to overcome the challenges of implementing biomimetics in architecture, there is a need for a systematic approach. In this regard it is crucial to provide a systematic and then a system design to analyze complex structures of nature. Then it will be possible to propose new implementations in architecture, as it is in other disciplines that developed their own methods.

2 ARCHITECTURE AS A SECOND NATURE

Since biologist Janine Benyus proposed Biomimetics as a science, the term has been used to address studies that learns from and then emulates natural forms, processes and ecosystems to create more sustainable designs (Benyus 1998). Benyus pointed out that nature has already solved many of the problems we are grappling with. Different from simply observing and mimicking nature, she suggested *"consciously emulating nature's time-tested patterns and strategies"* (Benyus 1998). To solve a problem, instead of looking to a particular species of plant or animal, Benyus explains, biomimicry looks across all classes of organization-bacterium, fungi and plants and animals in order to get a breadth of mechanisms. When these mechanisms are gathered into a catalog of solutions there would appear some commonalities. Eventually this would give some very simple design principles about the problem.

To this end, biomimetics basically provide three fundamental ways to learn from nature in order to solve a specific problem, considering nature as a model, as a measure and as a mentor. Firstly, nature as a model for design implies emulating nature's forms, processes,

systems and strategies to solve human problems. Secondly, as a measure of design, nature is taken as an ecological standard to judge the rightness of man-made innovations. Lastly, nature as a mentor offers a new way of viewing and valuing nature, *"which may introduce an era based on not only what can be extracted from the natural world, but what can be learnt from it"* (Benyus 1998).

In biomimetics, biological structures are analyzed and understood as material hierarchies self-organized into structures that are achieved by a bottom up process of self-assembly, from which their properties and performances emerge. This approach requires looking more deeply into biological materials and structures to see where their success lies. Moreover, it necessitates the recognition of the patterns in the way problems are solved in nature. Since the complex integrated systems exist successfully in all natural organisms, drawing analogy to biological models might provide a deeper insight for the development of new architectural solutions.

At this very point, it will be useful to mention that earlier, the idea of architecture that learns from natural structures and processes seemed impossible since nature builds molecule by molecule, out of responsive, self-repairing materials. Offering the ability of processing massive amount of data and information, computational technologies brought new mindsets that understands the precision and complexity of natural models. Having the potential to encode nature's behavior into algorithms, digital technologies enabled the conception of nature as an operative model rather than a mystical one. Analogous to these advances, the interest has shifted from nature's beauty towards its morphogenetic and adaptive processes, which might provide new insights and solutions for architecture.

In short, today, we have the opportunity to *"learn from nature with advantages of massive scientific knowledge, better tools and aesthetic sensibilities unconstrained by historical dogma"* (Pawlyn 2011). The relations we find in nature and integrated systems of natural organisms can be used for structural, functional and ecologically efficient buildings. It is possible to mimic processes in nature in order to create life-like structures. With the capacity to analyze and simulate nature's behavior through digital tools enables its employment in the early stages of design process with a higher range of precision that was impossible to accomplish before the advent of these tools. Designers now seek to advance nature's principles in structuring matter by designing artificial synthesis of natural materials and substances.

Despite these developments, to date, biomimicry has only been applied to architecture to a fairly limited extend, often relying on straightforward mimicry of natural shapes and forms. This could be seen as a result of challenges in implementing biomimetics in architecture, which can be summarized as: 1) the search for, and the selection of an appropriate strategy or multiple strategies from the large database provided by nature, 2) scaling difficulties of the strategies- a strategy working at one scale might not work at another 3) conflicts between solutions of integrated parts of the concept design (Badarnah Kadri 2012). It would exceed the scope of this paper to argue these challenges in detail. However, the paper suggests introduction of systems theory applies a shift in architecture and enables the translation of inspirations from nature.

The shift implies a dismissal of the view of architecture as a monolithic unity, comprised of entities in static isolation for one which defines architecture as the culmination of independent and interrelated systems which interact with its context. In systems understanding, nothing exists in isolation but it is dependent on a shifting network of other things. With a holistic approach, systems thinking will liberate architecture's dead matter state towards a novel system, redefining architecture's new role as (a) *second nature* (Oxman 2010).

3 SYSTEMS THINKING IN ARCHITECTURE

Even though he understood the parts in isolation, Aristotle laid the first stone in understanding systems as a whole which is more than the sum of its parts. Adding to this, Descartes offered the idea of understanding processes by way of simple causality, with relationships deduced from at most two interacting elements. Later on, in the mid-20th century, Ludwig von Bertalanffy, introduced general systems theory, criticizing deductive methods of classic physics that focus on isolated phenomena. According to him, such methods were inappropriate for biology, since nothing in nature exists in isolation or in simple dependencies, but rather needs to be understood as complex systems of interactions. Challenging the mechanistic world view which was closely related to the domination of machine and rendering living beings as machines, Bertalanffy asserted that concepts of modern scientific developments have their most obvious exemplification in life itself. With this in mind, he aimed to develop *'general systems theory as a universal scientific discipline to decipher the laws which rule the definition of organized wholes'* (Bertalanffy 1968). He described the idea of general system theory as *"trying to derive, from a general definition of system as a complex of interacting components, concepts characteristic of organized wholes such as interaction, sum, mechanization, centralization, competition, finality, etc. and to apply them to concrete phenomena"* (Bertalanffy 1968).

In the 1960s, evolving in parallel with general systems theory, architecture took on board systems theory in particular with the writings of the architect Christopher Alexander. Challenging with traditional design approaches, Alexander tried to visualize the structure of design problems. He claimed that an overall design problem cannot be divided into sub-problems as such it is impossible to arrive at a novel design solution as a summary process of solving individual

problems one after the other. Alexander considered the idea of a system synonymous with the idea of an abstract model of some specific holistic behavior, which is accomplished through *interaction among parts* (Alexander 1968). As defined first by Aristotle and later extended by Bertalanffy, the interaction of the parts is intended to be greater than just their combination. The holistic behavior cannot be understood in the individual part, nor can it be seen with the addition of its parts. In order to speak of something as a system, Alexander identifies, we must be able to state clearly: 1) the holistic behavior which we are focusing on, 2) the parts within the thing, and the interactions among these parts, 3) the way in which this interaction, among these parts, causes the holistic behavior defined (Alexander 1968).

Meanwhile, in the early 1960s, some cyberneticists -Gordon Pask in particular- began to think of architectural design and its numerous interrelations as a cybernetic system. Cybernetics, appeared in 1948, is the theory of control mechanisms in technology and nature and it is based upon the principle of feedback or circular causal traits providing mechanisms for goal-seeking and self-controlling behavior (Bertalanffy 1968). In his 1969 article "The Architectural Relevance of Cybernetics", Gordon Pask identified a significant void in architectural theory and claimed cybernetics as *"a discipline that fills the bill insofar as the abstract concepts of cybernetics can be interpreted in architectural terms (and, where appropriate, identified with real architectural systems) to form a theory (architectural cybernetics, the cybernetic theory of architecture)"* (Pask 1969).

In his article, Pask suggested that architects are *"first and foremost system designers who have been forced to take an interest in the organizational system properties of development, communication and control"* (Pask 1969). Even in this case, he points out, architects were asked to solve problems entailing the regulation and accommodation of human beings; hence, to design systems. For him, they were trapped by the quite rigid codes of architecture and by the conventions of society or the individual practitioner. There were well accepted communication media for conveying instructions, directives and ideas and a metalanguage for talking about all these ideas, for comparing, criticizing and evaluating them. Problems could be solved by the reasonable application of architectural rules. As a result, *"architects did not see themselves as system designers, even though they designed systems"* (Pask 1969).

In Pask's application of cybernetics to design, the antagonism between designer and machine serves to unsettle the traditional top-down hierarchy (Steenson Wright 2014). Pask states, *"But notice the trick…the designer does much the same job as his system, but he operates at a higher level in the organizational hierarchy…Further, the design goal is nearly always underspecified and the controller is no longer the authoritarian apparatus which this purely technical name brings to mind"* (Pask 1969).

The article closes with "a simple cybernetic design paradigm" which could alter the interaction between the designer and the system with which the designer worked*: "Let us turn the design paradigm in upon itself, applying it to the interaction between the designer and the system he designs, rather than the interaction between the system and the people who inhabit it"* (Pask 1969). It could be stated that Pask considered architecture as a problem to be formatted and solved, particularly in the case when the designer uses a computer as his assistant. He argued that computers change the design paradigm by altering the relationship between the architect and the system, not the system and his inhabitants.

It may be argued that Pask's theories on architecture were too far ahead of their time and were not fully grasped by the wider architectural community. However, his theories had a profound influence on different groups of architects, who find completely different areas from Pask's theories relevant to their own work. In the 1960s, Pask worked with the architect Cedric Price on his Fun Palace, where he introduced the concept of underspecified goals to architecture systems. In the 1970s, his influence on Nicholas Negroponte contributed to the philosophy of MIT's Architecture Machine Group, which was focused around the notion of architecture as an enabler of collaboration (Negroponte 1975). Later, in the early 1990s, architects such as John Frazer were particularly interested in how Pask's adaptive systems might be applied to architectural design process in order to evolve building forms and behaviors (Haque 2007).

Computational theories and methods inspired by biological principles have impacted Pask's theory. In the early 1960s, Pask worked on inorganic analogue models of organic growth processes but he had moved on mathematical experimentation on cellular automata in the later 60s, taking advantage of novel mathematical structures, to simulate processes of growth, evolution, and adaptation within the computer. The architect would supply the computer with a 'seed' structure for building, which the computer would then evolve, taking account of co-evolutionary interactions with the building's environment. At the same time, the architect could interfere with this process, in the choice of the seed, by selecting certain vectors of evolution for further exploration, and so on.

It is crucial to state that Pask's work on architecture is not about designing aesthetic buildings or making urban structures more spectacular. Pask's notion of architecture as systems is about designing the system that designs a building. In this way, starting from local relationships and simple units, it allows bottom-up design as opposed to top-down. More importantly, it gives rise to emergent behaviors and forms and to create complexly ordered structure. The geometric definition of the system has to overcome the primacy of shape and related metric, descriptive characteristics. Therefore, the designer has to facilitate the set-up of a computational model not as a particular gestalt specified through a number of coordinates, but

rather as a framework for possible formations affording further differentiation that remains coherent with the behaviour observed and extracted from physical experiments and explorations of the relevant system.

Today, Pask's theories are particularly important since they provide basis for a systems oriented thinking in architecture. In the case when buildings are conceived of systems, every component of the building and its environment interact, adapt and create one another, merging into one holistic system. To put it in another way, while the system of the building is coevolving with its environment, it would also be constantly interacting with its own parts, sending information back and forth. This, in turn, would lead up to an integrated and holistic design approach and eventually it might contribute to the application of biomimetics in architecture.

4 ARCHITECT AS SYSTEM DESIGNER

Without systems thinking in architecture, the attempts to draw analogies between biological entities and built environment cannot go further than simply mimicking natural forms. As it is described above, in order to transfer strategies of organisms in nature to built environment, first it is needed to investigate and analyze these strategies and their dominating principles, then a catalogue of solutions might be created. In order to learn from the multidimensional relationships of nature, the requirements of the system have to be defined, then analogue systems in nature that perform similar functions need to be identified. Computational design generating tools enable the transitions between the domains, in particular the identification of biological analogies and their abstraction. Then the relations we find in nature and integrated systems of natural organisms can be used for the design of architectural systems.

Such a design approach demands new strategies for design, in which form is no longer predetermined. When we see architecture through this perspective, we no longer conceive buildings as monolithic unities but structures constituting multiple and diverse components that operate at different scales and levels. We grapple, then, both independent and interrelated sub-systems co-exist in a building.

In completing the mode of thinking for biomimetics in architecture, the changing position of architect must be addressed. As Oxman denotes, *"the image of the architect as form-giver has dominated the profession for centuries"* (Oxman 2007). Today, this concept is being challenged by increasing involvement of computers in the design process together with potentials of systematic knowledge transfers for the development of biology inspired solutions in architecture. Computation, be it digital or natural, does not function with explicit description of form and finality. With this we see a development in the very nature of the architect from the demiurgic 'form-giver' to the architect as the controller of generative processes, where the final appearance is a product not of the architect's imagination alone, but of the generative capacities of the rules he set up. It is not that the architect here is any less imaginative; rather, *"the architectural imagination has been displaced into a different arena: into the imaginative use of various processes"* (Leach 2009). The idea of conceiving of the architect not only as the designer of buildings but also as the designer of systems that design buildings might open up new horizons in architecture.

Mapping the expanding and fracturing field of architecture

S.M. Golden
Ulster University, Belfast School of Architecture, Belfast, Northern Ireland

ABSTRACT: This paper illustrates and discusses a unique mapping of architecture practice, tracing arrays of critical, compared to commercial, practice approaches. It visually interprets the sociologist and philosopher Bourdieu's theories on the interactions between agents and institutions to the field of architecture. Discussions relate Bourdieu's concepts of habitus and capital to key stages of UK architectural practice from the mid-1950s through 2015. The paper contributes to contemporary knowledge and debates about architects' shifting roles and practice types in privatised, market-led processes by providing a spatial framework to trace the increasingly fractured nature of the profession. Established and emerging areas of architecture, derived from literature reviews and primary sources, are evaluated as practice types in which agents seek – at one end of the field – to preserve, protect, or enhance traditional norms, versus those – at opposite ends – who challenge, and at times subvert traditional practice norms in favour of more critical approaches.

1 INTRODUCTION

Since the late twentieth century, architects increasingly work in larger-scale urban development frameworks, and in more diverse practice types where the private market has impacted the architecture field and the majority of individual architects' roles as creative professionals. This paper examines UK architecture practice-futures through related debates in academic and institutional settings, particularly those within the main UK architectural governing body, the Royal Institute of British Architects (RIBA). The paper sets out concepts underpinning original visual and text-based analysis, part of a larger body of research, which illustrates how architects face increasingly diverse roles as more (visually) prominent but less influential agents in privatised and global design and construction processes.

Beginning with a review of architectural, and sociological literature, the paper discusses practice structures and processes that combine creative and entrepreneurial skills with more explicit intellectual and value-laden action. Key theories about practice, and agent/field interactions are derived from the sociologist/philosopher Bourdieu's treatise of habitus, disposition, and motivation for individual agents in any given field.

Discussions frame conclusions about critical practice, spatial design, autonomy, and contingency in architecture, which are established, emerging, and increasingly divisive topics between individual practitioners and the RIBA.

2 PRACTICE FUTURES IN THE 21ST CENTURY

Architecture remains one of the most publicly visible disciplines working to shape the built environment in the twenty-first century. Despite decreasing levels of influence on urban development decision-making, it is the discipline most often associated with building design and the production of urban space. In reality, most of the key decisions from strategic planning and land acquisition to setting out a particular project brief and its financial parameters are far removed from the influence of the architecture profession.

Debates about where knowledge and training should focus in the future include differences between core creative versus financial or technical skills (Building Futures, 2010a; RIBA, 2005), and between personal ethics compared with practice principles (Young, 2013). Prominent arguments often centre on how the professional field has and should continue to respond to the increasing dominance of private markets, which account for almost half of professional earnings (RIBA, 2013a).

The architecture profession is fragmented by internal debates about how to address the decline of roles valuing architects' creative design skills, and what might be the most appropriate future practice priorities; further supporting commercial and market-led forces as exclusively building design agents or rethinking architects' role as more socially driven agents for the wider public. Oft-cited questions include whether architects can or should be socially responsible, and the

extent to which they can influence change (Crawford, 1991).

Key debates about architects' skills examined here centre around calls for:

- Greater proficiency in commercial and economic skills – to support market-led development (Building Futures, 2010a);
- Calls for more autonomy as aesthetic experts and artists (Schumacher, 2010);
- Other voices, collectively known as transformative spatial agency, promoting alternative or more expansive forms of practice that might engage more with political and social contexts, rather than aligning to the control and values of the marketplace (Awan et al., 2011).

Contemporary arguments for greater architectural autonomy tend to focus on the status quo of architects as design experts with traditional building design/management skills enhanced by new technology (Schumacher, 2010). Technical, commercial, artistic, and activist views compete. Research promoting spatial agency includes international practices and project examples, evaluated for spatial judgement, mutual knowledge, and critical awareness skills that might challenge "strong normalising tendencies of mainstream architectural production" (Awan et al., 2011, pp. 26–27). There is no clear consensus about either the future centre of architectural culture or how to interrogate the status quo, and change it for the better (Awan et al., 2011).

Relative to UK professional context debates about existing and emerging practice types and skills training, the research here sought to first better define and visualise the centre and broader extent of architectural practice from the literature. The following section discusses how the RIBA and other influential bodies perceive the changing nature of the architectural profession to trace and discuss how UK practice has evolved since the post-war period.

2.1 *The RIBA and practice future debates*

Reports commissioned by the RIBA reflect widespread consensus at professional and academic levels that architecture has become less distinctive as both an occupation and a discipline (Building Futures, 2010b; RIBA Practice, 2000). The RIBA continually reviews the breadth of established and emerging practice types as part of it annual monitoring, and its established role to protect and promote the statutory title of architect in the UK.

The Institute's report, *The Future for Architects?,* conceded that practice contexts are "continuing to change so dramatically that the skill sets required must also shift" (Building Futures, 2010b, p. 34). Practice types and work areas continue to be benchmarked in traditional building-related areas for housing, residential, education, mixed-use and offices; a single umbrella category covers all "other project types" (RIBA, 2013a). According to the *Future* report and further research, 93% of the Institute's *Chartered* architects (i.e., only those ARB licenced architects who register and pay annual fees to the RIBA) continue to earn their fees from "full services," meaning from building design and construction contract management.

Additional RIBA research shows that there was a 40% reduction in demand for architects' services between 2007 and 2010, the first years of a global finance and property market recession (Building Futures, 2010a). From all full-service fees in a given year, almost half are reportedly earned by only 3% of Chartered practices (RIBA, 2013a). RIBA guidance suggests architects should adapt pro-actively to changing professional roles as an "opportunity to change attitudes toward development" and to demonstrate how good design is one of the values of the profession in "shaping better places and helping deliver a better quality of life" (RIBA, 2011, p. 01).

Practice types within the field, recognised by the RIBA, have expanded from a Post-WWII establishment view of "full service" designers and contract managers to a diverse, expanding, and contested roles including *local generalists*, *niche specialists* (including both design and technical specialisation), and *larger multi-disciplinary firms*. Additional practice types the RIBA has documented in annual monitoring surveys (Building Futures, 2010a) include:

- General design-led or more commercially-driven consultancy;
- Networked services, focusing on technical or design services;
- Globally networked practices, delivering all services on 24-hour timescales;
- Small metropolitan boutiques, offering "boundary pushing design . . . qualities of the star architect on a smaller scale";
- Entrepreneurial BOOT (Build-Own-Operate-Transfer) design services; and
- Creative Agencies, practices "not committed to architectural services . . . more flexible in following the market."

The definition and measure of practice sizes range from sole practitioners and micro practices of up to five members, to large offices with over fifty members (Building Futures, 2010a). Generally, larger commercial firms continue to dominate over smaller to medium design-led practices, while more traditionally architect-led roles in the design and construction industry are increasingly taken up by outside professions including planning, surveying and project management; bringing uncertainty about the (or any) future meaning and role for architects (Building Futures, 2010b).

The following table (Table 1) illustrates increasingly fractured practice trends from the post-WWII period to the present, interpreted from the literature.

With an increasing focus on systems-led forms of planning and private-led mechanisms for development in the 1960s – 1980s, architects influential roles as

Table 1. Changing professional roles, 1955–2015 (Source: Author).

Key Date/ State of Practice	Established/ Traditional modes and roles	Emergent/ Challenging modes and roles

masterplanners working in the public sector decreased while more market-driven roles emerged. Changes in design team structures initiated by the UK Government during the 1990s led to declining roles for architects as team leaders and full-service designers on larger scale projects; roles increasingly challenged by professionals outside of architecture. In the early millennium, particularly the period following global financial crises and property value collapse after 2007, architects' esteem in roles as starchitects and corporate agents became increasingly challenged from within the profession.

The most recent review of the architecture profession at a strategic/government level in the UK began in April 2013 when the Department for Culture Media and Sport (DCMS) appointed architect Sir Terry Farrell to work with the main professional architectural governing bodies, including the RIBA (DCMS, 2013; RIBA, 2013b). *The Farrell Review*, as it is commonly referred to, was completed in 2014 and represents the first important architect-led Government assessment of the profession and its role in shaping the UK built environment since Rogers' 1999 *Urban Task Force* report (The Urban Task Force, 1999). *The Farrell Review* acknowledged that "the nature, scale and scope of? built environment design have changed beyond all recognition" (*The Farrell Review*, 2014, p. 08). It addressed the following themes: education, outreach, and skills; design quality; cultural heritage; economic benefits; and UK Government built environment policy. Some of the key focus areas included,

- How architecture could be "taught as a business and better connected to the marketplace, engineering and construction";
- Globalisation;
- The role architecture's institutions should play in future practice;
- How to regain trust about design quality and "placemaking" issues in the built environment,
- Increasing architecture's influence at all development scales – "from local improvements to nationally significant projects.";
- Encouraging "leading architects […] to help the broader, more unsuccessful and unloved parts" of the built environment; and
- How to "prepare for the changing world order and rapid urbanisation across the globe in the twenty-first century"

The Review conclusions include recommendations for the profession to "reflect the major shift [in practice] toward two opposing tendencies – greater specialisation and diversified career paths on the one hand, and a greater need for integrating and joining things up on the other" (*The Farrell Review*, 2014, p. 67). The research presented in this paper addresses the above architecture specific challenges through a sociology-based approach, which is set out and discussed in the following section.

3 GAMES IN A FIELD: BOURDIEU'S SPATIAL THEORIES OF PRACTICE AND AGENCY

Bourdieu is regarded as one of the most prominent late twentieth century sociologists, contributing to education, culture, and art theory (Stevens, 1998). He established influential agent-field principles including key concepts about individual-collective structures and interactions in a given field (e.g. education, art, politics), cultural-environmental influenced disposition, *habitu*s, and taste/values, *distinction* (Bourdieu, 2010).

Bourdieu's treatise *Distinction* examines cultural preferences relative to social hierarchies, *capital*,

across the French bourgeoisie, and has been adapted to qualitative/comparative studies in many fields including economics, art, and law (Grenfell, 2008). As architectural discourse has increasingly focused on aspects of agency and architects' interactions with each other and society – beyond a focus upon building outputs and design or theory for its own sake – Bourdieu's reflexive methods to document and evaluate what de Certeau called the genesis of practice – i.e., not what practices produce, but what produces them (de Certeau, 2011) – has become more prominent in architectural research.

Bourdieu's work has been characterised as drawing upon the language of architecture to convey both physical and non-physical spatial aspects of social interaction in everyday life (Dovey, 1996). Fourcade observed spatial references in Bourdieu's writings about financial markets; how, for Bourdieu, "markets are not structured by connections between buyers and sellers (over goods) but by homologies between the 'space of producers,' the 'space of consumers,' and the 'space of goods"' (Fourcade, 2007, p. 1022) The architect and urban theorist Dovey has noted in a related way that Bourdieu's concept of habitus "suggests that the built environment constructs the real as spatial ideology – a congruence between the "division" of space and our "vision" of the world (Dovey, 1999, p. 03).

Bourdieuien theory and methods – set out further in the next sub-section – were selected as particularly suited to this architectural practice-led research, to address how architects, as actors and agents, relate to institutional and social structures, and how culture and society interact (Webster, 2010). Bourdieu's subjectivist and grounded approach to agency-structure research (Stevens, 1998) also corresponds to the research (and researcher's) interpretivist aims and methodology.

3.1 *Field theory: Individual dispositions and professional spheres*

Bourdieu describes fields as "a network, or a configuration, of objective relations between positions, objectively defined, in their existence and in the determinations they impose upon their occupants, agents or institutions" (Bourdieu in Wacquant, 1989, p. 39) He defines fields as bounded spheres and universes of activity and influence over certain people or objects. He identifies people and agents who enter a field as being "at once founded and legitimized [. . .] by their possessing a definite configuration of properties" (Bourdieu and Wacquant, 1992, p. 100) and,

> [B]y their present and potential situation (situs) in the structure of the distribution of species of power (or capital) whose possession commands access to the specific profits that are at stake in the field, as well as by their objective relation to other positions (domination, subordination, homology, etc.) (Bourdieu in Wacquant, 1989, p. 39).

Bourdieu's research addresses individual agents' actions, and motivations to act in a particular field, which he describes as akin to "being in a game," knowing the "rules of the game," and having interest. His concept of interest in relation to action correlates to themes examined in this architectural research, including how architects understandings of professional intention, motivation, and participation correspond to their approach/actions in practice. His metaphor for the norms of a field as a game allows rules to be challenged; thereby potentially affecting the game and those who might be dominant within a field in a given timeframe. Agents in a field, as players in a game, have choices to make relative to disciplinary doxa. Adapted to architecture in this research, it frames the findings about possibilities to challenge perceived material and symbolic norms.

At one end of a given field Bourdieu describes particular agents who "can play to increase or to conserve their capital," meaning they can remain "in conformity with the tacit rules of the game and the prerequisites of the reproduction of the game and its stakes" (Bourdieu and Wacquant, 1992, p. 99). Conversely, he describes how players with a different perspective can also aim to transform, partially or completely, the established rules of the game (Bourdieu and Wacquant, 1992). The latter type of players, what are referred to here as transformative agents, can apply "strategies aimed at discrediting the form of capital upon which the force of their opponents rests (e.g., economic capital) and to valorise the species of capital they preferentially possess" (Bourdieu and Wacquant, 1992, p. 99). In other words, agents including architects – as players – may be constrained and impacted upon by economic and political situations, but they are not trapped in a deterministic setting whereby their actions and position in the field are fixed, or on a stable trajectory.

The concept of play thereby introduces an agent's tacit skill and explicit choice to conform to or transform the tacit rules of the game;

> Social agents are not 'particles' that are mechanically pushed and pulled about by external forces. [. . .] They have the propensity to orient themselves either toward the preservation of the distribution of capital or toward the subversion of this distribution (Bourdieu and Wacquant, 1992, p. 108).

The above themes are synthesised by Bourdieu's *practice-field (capital-habitus)* model (Bourdieu, 1986; Maton in Grenfell, 2008), which sets out a relationship shown in Equation 1, whereby the totality of habitus, individually acquired "systems of disposition," and capital, defined as "one's position in a field," is considered jointly "within the current state of play [doxa] of [a chosen] social arena (field)" (Bourdieu and Wacquant, 1992, p. 102). Capital can refer to an architect's position in the professional field relative to economic, social, or cultural position among other factors.

$$[(\text{habitus}) \times (\text{capital}) + \text{field}] = \text{practice} \quad (1)$$

Bourdieu also set out three "necessary and internally connected moments" to study any given field (Bourdieu and Wacquant, 1992, p. 105):

– "First, analyze the field vis-à-vis the field of power."
– "Second, map out the objective structure of the relations between the positions occupied by the agents or institutions who compete for the legitimate form of specific authority of [the] field"
– "Third, analyze the habitus of agents."

He argues that fields can be examined to "assess how concretely they are constituted, where they stop, who gets in and who does not, and whether at all they form a field" (Bourdieu and Wacquant, 1992, p. 100). He further states that researching fields is an "endless to and from movement," wherein "one must identify the forms of specific capital that operate [and] know the specific logic of the field" in order to "construct [its] forms of specific capital" (Bourdieu and Wacquant, 1992, p. 107).

Within the scope and constraints of this research and the contexts of contemporary UK architecture practice relative to the RIBA, the field of architecture is thus examined through a Bourdieuien lens. The outcomes and conclusions, which are both architecture specific and transferable to other professional fields are set out and discussed in the next section.

4 FINDINGS: MAPPING ARRAYS OF PRACTICE AND PRACTICE TYPES

Arrays of practice refer to unseen as well as more tangible aspects of architects' career trajectories, choices, practice contexts, and other parameters that establish one's professional identity as social, creative agents. The mapping structure and graphics presented herein (Figures 1–4) are the author's adaptation of Bourdieu's well-known and widely published figures, used to display and discuss his research (Bourdieu, 2010, 1998).

Four original diagrams correlate individual architectural practice types and themes to different professional dispositions and relations between individual architects and the collective architectural field from the period following the Second World War into the new millennium. Different sets of axes illustrate arrays of architecture practice, and critical, compared to commercial, practice approaches in a visual format. The visual format provides a spatial framework to understand how architects can adapt to more critical practice in privatised commercial contexts, and to evaluate the research as a unique contribution to debates on the changing architectural profession. The findings reflect the greater diversity of architecture practice, and the increasingly destabilised field, discussed in Section 2.1, and detailed in Table 1.

Figures 1 through 4 trace perceived changes in architecture from a more established (stable) field in the immediate post-WWII era to a fractured (dynamic, contested) field in the new millennium. Different practice types (architects practice roles) and themes (key theories or issues from the literature) are shown relative to the two sets of axes and the indicative centre of the field (representing normative building designled roles). The locations of each practice type, and the centre of the field, shifting over time, are interpreted from the practice and theory literature. The following sub-sections set out and review each mapped stage in detail.

4.1 *1955: Relative stability and widespread capital*

Figure 1 illustrates the field in a more stable and less complex state. The starting date is coincident with an important international milestone for architecture, planning, and what evolved into the separate/related discipline of urban design. As a base point for comparison, the 1955 map aims to capture the state of the UK field prior to the 1958 Conference on Architectural Education, a seminal event that brought in new systems of professional architectural training that remain more or less intact (Roaf and Bairstow, 2008).

The map indicates the traditional building design and contract management centre of the field as firmly established, with some areas or practice emerging during the post-WWII period. Traditional agency is shown balanced on the social/cultural and economic centreline, encompassing "full services" by architects, as artistic and corporate architectural agents, including roles in key land acquisition and planning decisions as well as influence over the design, detail, and management of individual buildings. Urbanism is recognised and incorporated as an emerging, and already integral part of the centre of the field.

Two dotted-line shapes show important changes impacting the traditional centre. These changes include new processes and qualifications for professional academic training (left-hand), in which university based systems increased in intellectual and

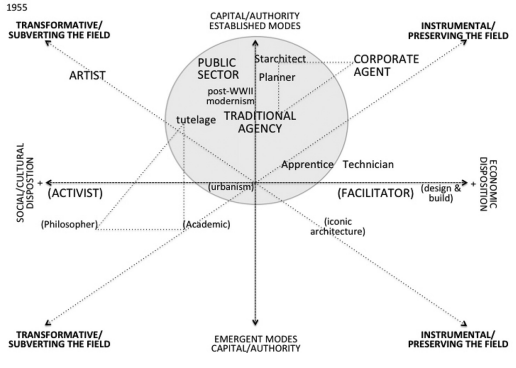

Figure 1. The field of architecture, ca.1955 showing traditional norms (grey) & established practice roles with emergent types.

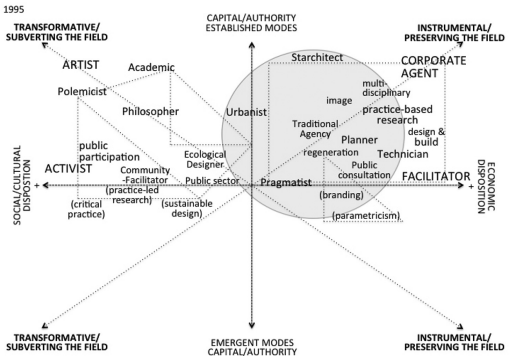

Figure 3. The field of architecture, ca.1995 showing traditional norms (grey) & established practice roles with emergent types.

economic capital, replacing apprenticeships and tutelage as the primary route to professional qualifications. The post-WWII growth of corporate agency, larger international firms is shown as established, and impacting traditional roles for designers, planners, and the twentieth century version of 'starchitects' (important individuals including Mies Van der Rohe, Le Corbusier, Gropius, and others). The next mapping stage, 1975, continues to trace the field's trajectory through a post-Keynesian era, when a resurgence of free-market ideology influenced architects to support increasingly dominant economic forces.

4.2 *1975: Challenging norms; resistance & retreat*

Figure 2 illustrates the field as corporate and free market influences became established across the traditional centre, shifting it in the direction of instrumental practices favouring economic capital over transformative and socially driven ideals. Postmodernism replaced modernism as the dominant theoretical and aesthetic practice by the early 1970s. Public sector roles for architects, and the number of architect-planners trained as spatial designers were both in decline, connected to changing policies for funding urban development and training/practice shifts in the 1960s from spatial to systems-led approaches (Cuff, 2000). Within architecture therefore, the mapping indicates that planning is shifting out of traditional architectural roles, becoming less esteemed (i.e. lower status/capital) and associated with facilitator rather than designer roles.

The mapping reflects the growth of activism and critical theory in architecture, which developed from socio-political and economic periods of protest and civic unrest in the 1960s and early 1970s. The architecture profession was criticised as anachronistic, associated with the failures of large scale urban renewal projects and functionalist modernist housing estates (Papanek, 1985).

Shifts within the profession include an increasing status for both commercial roles and theory-driven academic areas, and emerging roles focused on community and the environment (Dutton and Mann, 1996). Dotted-line shapes here indicate increasing complexity of roles/types in the field, including the emergence of polemical theorist-practitioners and activists, and influences on the centre; denoted as the increasing capital of philosophical/autonomous modes of thought, as well as opposite trends toward economic/instrumental practices, and the approaching era of deregulation.

4.3 *1995: Change and challenge; a fracturing field*

Figure 3 illustrates the impact of resurgent free market urban investment, and urban policy changes, established after 1979 by the Conservative Thatcher-led UK government.The archetypal standing of full-service architectural agency becomes less certain, reflected in the mapping text. Layers of dotted-line shapes show increasingly complex commercial, critical, and communicative aspect of professional practice. Transformative approaches and widening participation became established in professions like planning; emerging from allied social and planning theory into architecture in the mid to late 1990s (Ghirardo, 1991; Gutman, 1988; Healey, 1993; Sorkin, 1991). The traditional centre is shown shifting further toward an economic, instrumental, and self-preservationist trajectory. The mapping thus reflects a fracturing of architectural practice types with new roles commonly aligning toward economic extremes, indicating practice efforts to survive and preserve the field.

During this period important strategic changes included new policies and investment mechanisms for urban development, which remain as larger-scale masterplanning and private-led models of regeneration in the twenty-first century (Bell, 2005; Dietsch, 1995). Both the private sector and government bodies increasingly sidelined architects' status as design-team leaders, and as influential actors in decisions affecting

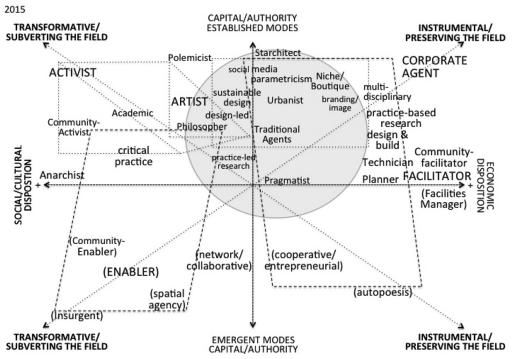

Figure 4. The field of architecture, ca.2015 showing traditional norms (grey) & established practice roles with emergent types.

the built environment (Duffy, 1994). Government-commissioned reports including *Constructing the Team (Latham, 1994)* and *Rethinking Construction (Egan and Construction Task Force, 1998)* contributed to a restructuring of UK design and construction teams, a trend that continued into the millennium period despite dramatic increases in property-led development.

4.4 *2015: Border crossings; a fractured field*

Figure 4 illustrates architecture in the new millennium period of rapid urban development and increasing complexity within architecture practice, both of which define contemporary struggles between the social and economic space of the field. A substantial number of architects left the field or shifted their intended trajectory vis-à-vis the traditional centre during a sustained period of recession and uncertainty after 2007. The density of the mapping, and additional connecting shapes, reflect the fractured nature of practice. Emerging practice types appearing at the transformative/subversive extremes denote the expansion of practice roles beyond the recognised architectural field; a trend to normalise border crossings between architecture and other disciplines that is resisted within the establishment, and the RIBA (Gunkel, 2001). There are increasing calls to remove or blur the boundaries of the field yet the commercial core remains the dominant power.

Two broken-line shapes show a growing divide between agents/practice types seen as preservationist and instrumental, and types seen as promoting opposite aims, to break open the field and its training processes toward more social/transformative ends. Established types of commercial practice at the preservationist end include management, design and build, specialist technical services, while more subversive types include enablers and insurgent architects, network/collaborative forms of practice, and new forms of critical spatial practice (Awan et al., 2011; Hou, 2010). Critical practice has shifted toward more active, real-world, and transformative approaches, in contrast to autopoetic, theory and computer-driven practices (Doucet and Cupers, 2009; Schumacher, 2010). While the traditional centre is shown intact as a space, it has shifted back toward the centre axis and is shown as increasingly congested by different competing practice themes and types, including design/artist-led, commercial, and new media-driven approaches; each vying for varying degrees of capital in the design and construction industry, and influence over the profession's future.

5 CONCLUSION

The mapping relates to the second of Bourdieu's connected moments, necessary to study a given field and the relations between "the positions occupied by the agents or institutions who compete for the legitimate form of specific authority of a field" (Bourdieu and Wacquant, 1992, p. 105). Thus, in the diagrams, a Corporate Agent is shown at opposite economic-socio/cultural scales to an Artist, yet both are shown with similar levels of established capital/status. Activists, an example of both an emerging and established type, are located at the socio/cultural end with increasing levels of status.

Contemporary practice challenges, reflected in the mapping, and in proposed new and redefined practice types "provide a glimpse of a world to come" where there are opportunities for change, and for interested architects to become agents of change (Hardt and Negri, 2012, p. 03). The examples and types, while indicative and subjective in one sense, represent real examples of practice choices available to architects. The findings demonstrate the extent to which other ways of practicing architecture exist, challenging limited skills training, and career guidance available to young practitioners, which overwhelmingly focuses on past norms where architects were full-service designers with high level of influence on development decision-making.

Finally, the research findings reveal a significant trend amongst architects to reframe their future practice and professional training as a means to proactively redress declining levels of influence; learning to adapt their training as designers and managers, to act transformatively, without ignoring or denigrating their innate and learned skills as creative professionals. These findings are supported by the extent to which once peripheral protagonists and practice roles are shown to challenge the status quo of commercial practice for esteem and professional capital.

ACKNOWLEDGEMENTS

The author acknowledges contributions to refine the research writing and diagrams from Dr T.M. Rikala, Prof I. Montgomery, and Prof C. Gormley-Heenan of the Ulster University Faculty of Art, Design & the Built Environment; and Faculty of Social Sciences.

TPCAU professor at National School of Architecture of Lyon

Gérard Mai
Assistant Planning Officer in the town of Ambert

ABSTRACT: To suggest some answers to questions about the future of the living environment of human settlements in rural areas, this article will discuss intensification assumptions adapted to new or rehabilitated housing projects in the rural commune of *Ambert*, administered by the department of Puy-de-Dôme, France. These assumptions are derived from shared education between the two Higher National schools of Architecture in Lyon (an area of study called master AA & CC "Architecture, Ambiances and Constructive Cultures") and Grenoble (an area of study called master A & CC "Architecture and Constructive Cultures"). They are based on the research and partnership of two laboratories of the Grenoble architectural school, the research unit AE & CC (Architecture, Environment and Constructive Cultures, Labex MCC) and the research unit CRESSON (Centre for Research on the SOUND SPACE and the urban environment, UMR CNRS 1563 *Architecture, Ambiance and Urbanity*). This collaboration foreshadows the construction of a solar powered habitat in *Ambert*, showing an approach centered on pleasant surroundings and local building habits.

Keywords: Habitat, Ambiances, Constructive Cultures, sustainability, energy and rural environment

1 THE HABITAT OF THE FUTURE, CAN IT REMAIN LOW-RISE?

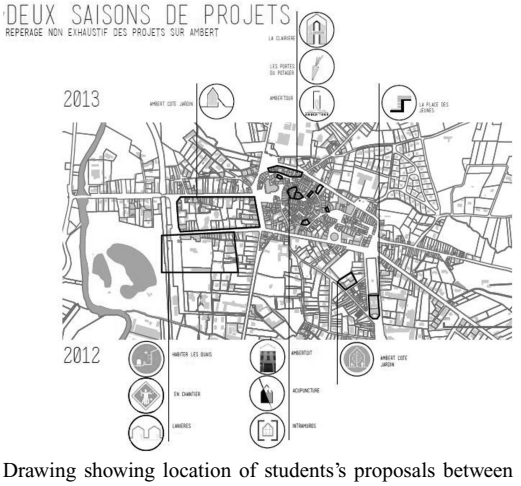
Our world is changing radically. The effective spatial awareness of sustainable development issues due to recent crises (social, environmental, financial and energy) leads to other approaches to habitat, land, social mix and tools to be used within the framework to be built. First of all, in rural areas, this finding prompts the building of an ecological, responsible and economical habitat, attractive for newcomers, reflecting new surroundings in rural conditions, integrating energy issues and ecological thinking, as well as on the level of materials employed and the production line of the components used.

Secondly, and in response to the request of some rural municipalities, the need for density, to avoid urban sprawl, invites us to restore value to all open spaces, on the ground and into the air. The designer is then asked to imagine buildings and environments that combine infrastructure, landscape, architecture, events, society, customs, cultures, energy and local resources. Thirdly, reflection across the territory implies rethinking the inhabitants' logistics mode. We must rethink both the modes of management of natural resources essential for life (such as water), and agricultural space management methods, transport methods between food production areas and consumption areas, and modes of travel between different living areas. A new symbiosis must emerge between agriculture, mechanics and architecture by combining, in a more organic way, available and vacant lands, vehicles, housing and the working place.

Overall, this awareness challenges us about our lifestyles (increase or decrease?) and our major societal choices (centralized or decentralized?). At the political level and at the individual level, however, it is extremely difficult to make these choices without concrete indications of the opportunities available to us. These decisions can obviously not be taken solely on the basis of theoretical reasoning. Therefore, to gain the support of the majority and become effective, and more efficient, these choices should be informed by research and experiments carried out together on the constructive aspects and living ambiances of tomorrow's society, which bring quantified and tangible evidence of the feasibility or consistency of the proposals.

Hence the following proposals that attempt to connect, around the issue of habitat, in the small rural town of *Ambert*: sensitive approaches and technical education, landscape and individual living spaces, perceptions and measurements, sustainable approaches to the territory and expectations of ambiance, all these actions to address the transformation of multiple *Ambert* sites. At the heart of our concerns, the renewal of the rural habitat questions the alternative to the private home and considers density compatible with proximity, multiplicity of services, a gradual decrease in the use of the car, effective pooling of resources, rationalization of transport investment, and a guarantee of quality of life in shared spaces and a relationship with nature.

2 DEMOGRAPHIC CHALLENGES IN THE AREA OF AMBERT



Faced with population decline, the town of *Ambert* (6600 inhabitants) wishes to retain young people and welcome new populations. Many SMEs in the valley have developed in the areas of weaving, the wood industry and chemicals (*Sanofi*). If they have today 2500 industrial jobs, however, they have some difficulties in recruiting or keeping their employees. The obstacles come from the image of a town far away from active centrers where a spouse has trouble finding a job and, specifically, a town without good housing: it appears unsuited to the needs of a population willing to settle there, who seek comfort, air, sun, nature-friendly buildings, and a feeling for the environment.

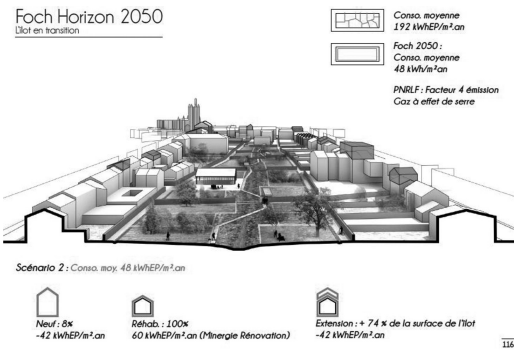
What is this new population? It is primarily well-paid executives. They come first for a year keeping their original housing, or they prefer to rent on site to reduce transport time. They seek a modern lifestyle with outside spaces, light and sunshine: a furnished or unfurnished rental. After the first completed year they move to *Ambert*, enjoying the quality of life, no longer having to make car journeys. They hope to buy a home in an existing or a new building. Of course they can settle in the countryside, but they often need spacious accommodation close to the services offered by the town (leisure, culture and community activities are very lively in *Ambert*). The desire of the municipality is to encourage architecture students to imagine homes that attract: comfortable and contemporary interior architecture opening on to the outside, (not necessarily a privatel garden) but an exterior accessible according to the season; housing in the city centre, bright, spacious, plush, with a history, that is close to services, giving a sense of comfort, particularly in winter.

Secondly there are salaried workers who are hopefully recruited locally. Coming from rural areas they prefer the new or old houses on the outskirts of the town, with a garden (depending on their budget). They live while slowly modernizing their house bought for between 100,000 and 150,000 Euros. The most urban among them accept the shared garden.

Thirdly there are foremen, apprentices and medical aides who come to train for a few months. Numbering two hundred, they generate every year a high turnover of people. These employees' supervisors look for small or shared apartments, comfortable, with terraces and no gardens. The company *Sanofi*, owner of many homes for the reception of workers, converted them into temporary foster homes for foremen. But the houses are lacking and not really suited to employees who want to get away from the workplace and get nearer to the "town". A similar desire exists among the "many care assistants" who have little income and who accept small furnished, shared apartments near the hospital, rehabilitated homes in the town centre. As for apprentices, they would rather find shelter in hostels for young workers that do not exist locally. Some are housed in the local boarding school.

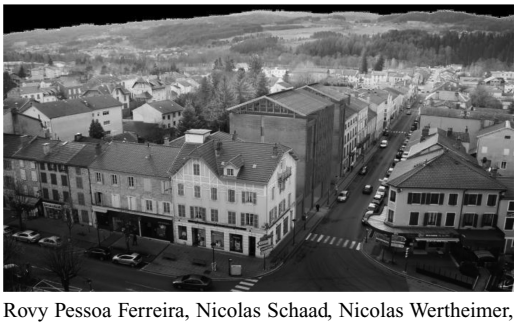
Drawing showing location of students's proposals between 2011 and 2013. *Floriane and Emilie Delesglise Ettori, DEM master AA&CC Promotion 2013.*

The city council finally states that there is a demand for seasonal housing designed for pensioners living in villages or hamlets, and coming downtown in winter "because it is cold and there is nothing to do up there" on the one hand and on the other, for seasonal workers on construction sites and public works.



In conclusion the demands of the new townspeople are numerous and varied. The town centre should suit students, health workers, as well as those who love opulent homes. Today it attracts a few lonely people with small budgets. To reverse this tendency, the architecture students of Lyon and Grenoble were encouraged to offer new comfortable and attractive homes. Around the *Chabrier* garden (see map for location) a new rather up-market development is planned but the municipality wants a social mix. This leads the students to consider a spatial distribution of new inhabitants described above. On the land called "Prairie" in *Ambert*, near the station, would be built, for newcomers, new housing, some furnished rental, as well as seasonal homes. On the island development called "Island Foch", a field on the western edge of the town centre, students propose an alternative to the house in the country by redeveloping an outdoor space, shared by the inhabitants, which would provide social and age diversity, suited to higher density.

3 PROPOSALS FOR THE HABITAT



But when we proposed this, many other issues were raised. What density is really tolerable? Which urban forms are adapted to this density? What former architectural styles allow integration into the existing ecosystem so as to maximize energy performance while preserving social diversity, equal access to services and the privacy of individuals, while addressing responses to fuel poverty? What substances or materials should be used to achieve economical levels while participating in the creation of an environment appropriate to habits and neighborhoods? What symbolic presence and what climatic role can plants have in this built-up environment? Which building systems and construction organizations are best suited to perform these complex assemblies while remaining compatible with the financial means of the majority? Which helpful devices can be envisaged to allow the poor to access housing, to meet the basic right of a roof over one's head?

To submit an early answer to these questions that examine the future of the living environment of human settlement, here are some ideas shared between the national schools of architecture of Lyon and Grenoble.

1/The habitat model which is preferred by 86% of French people, the detached house, is no longer compatible with life in *Ambert* because of transport costs between the home and the "town centre", and between the home and the workplace. A new development located in the quarter called "Foch", just on the edge of the ancient medieval fabric of the sub-prefecture, becomes possible if a large number of spatial sensations of a detached house (360 degree circular vision, neighborhoods a little way off, activities outside extensions, an accessible common garden, the existence of outbuildings …) can be preserved, improved and integrated into the local architecture of the *Foch island* near central town. The "rules" regarding the assumption of vertical densification have to be written so as to remain on a human scale. It is not a model that can be applied systematically, but one that can be adapted as for the *Foch island* built in the nineteenth century, an island with a large interior "garden" belonging to and appreciated by its residents, as the proposal below shows.

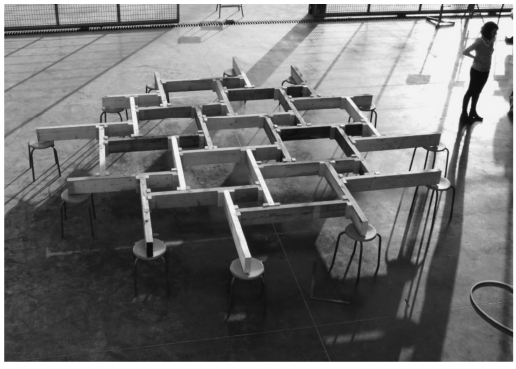
Rovy Pessoa Ferreira, Nicolas Schaad, Nicolas Wertheimer, DEM master AA&CC promotion 2014.

2/In*Ambert*, houses in the medieval town are narrow and have two or three floors. In a new configuration of apartments designed for wealthier people, leading to social diversity, the top floors can be converted into further elevation, to accommodate a laundry, a "sunbathing spot", a summer kitchen, a barbecue, a greenhouse, which would provide an additional common sheltered space for young children to play, get-togethers between tenants on public holidays, that

Rovy Pessoa Ferreira, Nicolas Schaad, Nicolas Wertheimer, DEM master AA&CC promotion 2014.

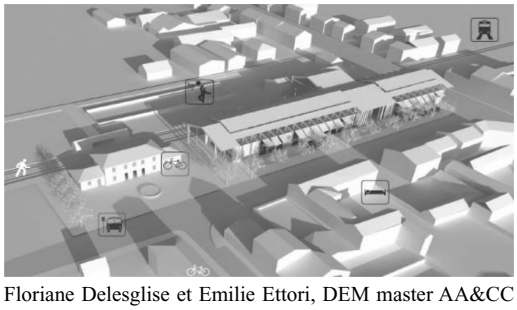
would contribute to the development of the spirit of the spirit of neighbourliness and solidarity.

3/Ground floors of the town houses can easily include small industries or shops, as the sale of fabrics is very much alive in *Ambert*. Hence the idea for offices or business premises comprising a productive diverse urban mix, reducing travel stress for some people, ensuring also the exchange, or sharing of single person transport such as bicycles or electric vehicles.



Anne-Claire Bouvier, Alexandre Chavanne, Aurélie Rodroguez-Fallard, Maud Royer, DEM master AA&CC promotion 2013.

4/The rehabilitation of the town centre can be achieved through a construction system based on a prefabrication of small elements which can easily enter through doors and windows, thus reducing installation costs, increasing the quality control of the construction, both these aspects constituting a critical given for the construction of buildings to "high" energy performance in the current French professional context.



5/Other innovative hypotheses? The idea of a large training workshop shared with a craft cooperative received the Award for Young Architects given by the city of Lyon. This project would help revive local construction procedures, wooden and earth pathways, by involving them in a youth training project.

The erection of buildings for food production has never been part of architectural and landscape proposals in *Ambert*, as it has traditionally been a "service" town. However, a change is taking place for at least two reasons: firstly, because food might give work to one half of a young couple who arrive without jobs. The second reason concerns pensioners and people in isolated hamlets, who "come down" to *Ambert* and are used to a vegetable garden. They could teach gardening to the new young couples. For example, on the outskirts of the town, this meeting between the two generations could totally renew the landscape.

4 CONCLUSIONS

The teaching staff proposed the construction of a solar habitat prototype for *Ambert* in 2015/2017. The municipality has agreed to underwrite the architectural renewal of *Ambert* with renewable energies. It would be designed by a group of students and produced by local entrepreneurs sharing the project. An architect has offered to submit the building permit and supervise the students so that the project can be managed in their own name.

The prototype will have to demonstrate the ability of *Ambert* to survive the energy challenges of tomorrow. It will also demonstrate, once built and tested in situ by locals, the ability to meet local multiple perceptions and significations for number of people. All spatial planning, even the poorest, can be the bearer of meaning; and any construction, even the most complex, can be carried out mechanically. Project management on site might propose a profitable strategy to deliver energy and build a dwelling, but this strategy may be insignificant for people of that area. The meaning is personal and it also focuses on spatial and practical signs recognized by all. How then can we advance in energy saving by ignoring this phenomenon? What meaningful support can this ecological movement bring to *Ambert,* today? Can it be shared between architecture students and resi dents of rural areas?

Delphine Bugaud et Alice Gras, DEM master A&CC promotion 2012.

The reader can see that new issues appear and because they deserve answers, the teaching staff has committed itself to research, funded by the French Office of Architectural and Landscape Research of the Ministry of Culture and Communication.

Exploration of multiple zone daylighting and energy performance for senior housing

Y. Fang & S. Cho
North Carolina State University, Raleigh, North Carolina, USA

ABSTRACT: Building shape and orientation have significant impact on building's daylighting and energy performance. Daylight conditions in buildings have strong association with occupants' health and comfort, especially for seniors. Although numerous studies have been done about building daylighting performance simulation and evaluation, most of them focused on the analysis of a single room or typical rooms. However, in complex multi-story buildings, daylight conditions vary greatly from room to room. Little research has examined this multiple zone daylighting performance variation. This paper demonstrates a simulation and evaluation process that uses several evaluation metrics and statistical methods to compare multiple zone daylighting performances of different designs. The case study is a senior housing project with eleven design options. Great differences in daylighting and energy performance are found, and locations of unsatisfactory units are indicated in building floor plans. The research outcome highlights the importance of daylighting evaluation, and provides design recommendations for architects and property owners.

1 INTRODUCTION

Daylight is essential for occupant's health and life quality, especially in buildings where occupants are more susceptible to environmental impacts, such as hospital inpatient departments, rehabilitation centers, and senior housing. Occupants in this kind of buildings stay in their rooms almost throughout the day, and both their physical and psychological condition are in vulnerable state.

Studies have shown positive impact of daylight on building occupants' health. The effects of daylight mainly fall into two categories: light on the skin and light reaching the retina (Edwards and Torcellini, 2002). Direct sunlight on the skin could stimulate vitamin D production, which has been proved to be linked to many health outcomes, such as increased bone health, reduced risks of cancers, heart disease and autoimmune disease (Holick, 2004). Full-spectrum of light from the sun reaching the retina could affect circadian system, which is found to be related to Seasonal Affective Disorder (Rosenthal et al., 1984), mood and sleep efficiency (Lieverse et al., 2011), alertness, cognitive performance, and affective responses (Vandewalle et al., 2009).

Variation in built environment, including the room orientation, daylight condition, and views would cause a great difference in occupants' health, recovery time, life qualities, etc. A study found that bipolar patients assigned to rooms with more sunlight had an average of 3.67 days shorter hospital stay than patients with the same symptoms in rooms with little or no sunlight (Nelson et al., 2005). Another study of a cardiac intensive care unit found overall a shorter length of stay and lower mortality rates of in the bright rooms than dim rooms (Walch et al., 2005). They also found that patients in sunny rooms used significantly less pain medication, and showed less stress at discharge. Therefore, it is important for designers to consider that all residents of the building should get appropriate and healthy environmental conditions.

The case study project is a senior housing. Countries throughout the world are facing the problem of population aging (Wong, 2008). There is an increasing number of senior housing projects being built worldwide, and the built environment of senior housing is getting people's attention.

Daylighting in senior housing is particularly important for several reasons. First, seniors need two to three times more light than young adults to see clearly (Hebert, 2007). Second, the full-spectrum of light produced by the sun is beneficial for their vision (Hebert, 2007). Third, there is a high frequency of Vitamin D deficiency in seniors because of inadequate sun exposure (Parfitt et al., 1982). Existing senior housing projects have problems of inadequate daylight. It is found that only 45% of the 165 investigated senior housing rooms can comply with the daylight design recommendations (Lewis, 2015). Large-scale senior housing projects often have complex building shapes and rooms with different orientations and daylighting conditions, and the health and life quality of the senior residents of these rooms could be significantly different.

This research explores building designs through the analysis of different daylighting evaluation criteria, and demonstrates how the building design would lead to different performance between buildings and within each building. Design suggestions are made for designers to consider the equal chance for occupants to have good built environment.

2 METHODOLOGY

2.1 *Design introduction*

In this study, a hypothetical senior housing project is to be built on a site of 80 meters by 80 meters. The project is located in Atlanta, Georgia, with a humid subtropical climate. The senior housing should have at least 240 daylight available units. The 240 units could be used as residential rooms, stairs, offices, medical services, storages, etc. For the simplicity of daylighting simulation, all units are modeled as identical residential rooms. There are a restroom and a balcony for each unit, and the dimension of the room is shown in Figure 1. The design model is built in software Rhinoceros.

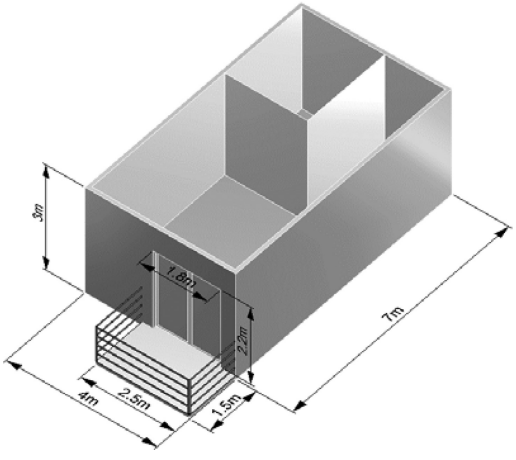

Figure 1. Standard senior housing unit.

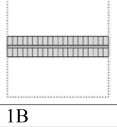

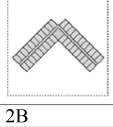

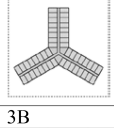

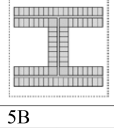

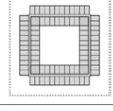

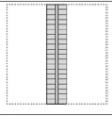

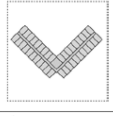

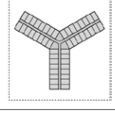

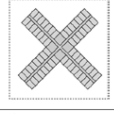

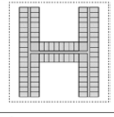

The designs to be tested are prototypical multi-story senior housing in the US. Six most common senior housing building shapes (Perkins, 2004) are chosen for this study, and five of them have two different orientations, so there are totally eleven buildings being analyzed. All buildings are between three to six floors. The building layouts and detailed information are listed in Table 1. For convenience, the buildings are names based on its building number and orientation. For example, 1A means building 1 with the first orientation. Each room is also labeled with a unique number with its building, orientation, floor, and room location.

2.2 *Simulation and analysis process*

The first set of daylighting analysis is indoor illuminance simulation. The daylighting simulation tool is Diva for Rhino with the simulation engine Radiance. Diva for Rhino is a daylighting and energy modeling plugin developed by Solemma LLC for the modeling tool Rhinoceros. The reflectance of the ceiling, floor, interior and exterior walls are respectively 0.8, 0.2, 0.5, and 0.3. The window is assumed to be double pane glazing with visible transmittance of 0.8. Each room is considered as a zone, and four sensors are placed inside each zone as a group. There are 240 groups of sensors in each building. An example of the sensors placement on one floor can be found in Figure 2.

The main performance metrics output are Daylight Factor (DF) and Daylight Autonomy (DA). Daylight Factor is the ratio of the interior illuminance level and the exterior illuminance level. It is usually considered as a static metric, and stays the same throughout the year, whereas Daylight Autonomy is a dynamic metric and is climate-based. It is the percentage of time that the average illuminance of a room that can achieve a baseline on daylight available hours (Reinhart et al., 2006). In this study, the illuminance baseline is set to 300 Lux, and the analysis periods are 6 am to 6 pm each day, with totally 3650 hours per year.

Table 1. Design information.

Building	**1**	**2**	**3**	**4**	**5**	**6**
Building Name	1A	2A	3A	4A	5A	6A
Orientation A						
Building Name	1B	2B	3B	4B	5B	
Orientation B						
Number of floors	6	6	5	4	3	3
Number of Units each floor	40	40	48	60	80	80
Surface area (m^2)	5686	6039	6385	6774	7222	7226
Footprint (m^2)	1280	1345	1792	2176	2816	2820

The second set of daylighting analysis is direct sunlight hours analysis. The tool used is Ladybug (Roudsari et al., 2013), which is an environmental analysis plugin for modeling tool Grasshopper and Rhinoceros. A test point is placed at 0.8 meters above the center of the balcony outside each room. The Sun-Path component (Fig. 3-a) is able to demonstrate the 3650 sun positions from 6 am to 6 pm each day in a year, and Sunlight Hours Analysis component (Fig. 3-b) calculates the hours that the sunlight can directly reach the test points. An evaluation metric is developed called Sunlight Availability, which is the percentage of direct sunlight hours in the total 3650 hours. These two sets of daylighting analysis methods should complement each other in the performance evaluation.

Energy simulation is also considered in this study, and the aim is to compare the heating and cooling loads of different building shapes and orientations, as a support for daylighting analysis. OpenStudio, developed by the National Renewable Energy Laboratory (NREL), is used as the energy simulation tool. OpenStudio is a plugin for modeling tool SketchUp. The energy models use ASHRAE Standard 90.1-2010 mid-rise apartment as a template, and occupancy and plug load changes are made to better represent senior housing energy consumption (Fang and Cho, 2014).

3 RESULTS AND ANALYSIS

3.1 *Traditional daylighting metrics and analysis*

The daylighting simulation results of 11 different building shapes and orientations are shown in Table 2, and these daylight metrics are some of the default outputs. Different metrics can show different aspects of the design features. Mean Daylight Factor and Mean Daylight Autonomy both examine the overall daylighting condition of the building (Fig. 4). The two results also show conflict with each other. For example, Building 5 Orientation A has the highest mean Daylight Factor, but the mean Daylight Autonomy is among the lowest.

To examine the percentages of daylit area in buildings, there are two metrics available in the simulation output: Sensors with Daylight Factor of 2% or higher and Area with DA of 50% or higher. These two metrics show similar trends (Fig. 5) as the previous figure, and same conflicts exist. Using these measures to evaluate daylit area is problematic. Whether the well daylit sensors are in the same room or different rooms make great difference in the evaluation of the building daylight performance, but these measures are not able to

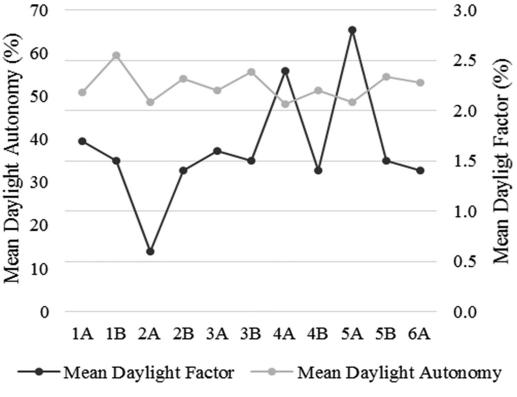

Figure 4. Mean of daylight autonomy and daylight factor.

Table 2. Default daylighting simulation output.

Building Name	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A
Mean Daylight Factor (%)	1.7	1.5	0.6	1.4	1.6	1.5	2.4	1.4	2.8	1.5	1.4
Sensors with Daylight Factor of 2% or higher (%)	27	25	3	24	27	26	45	23	52	24	24
Mean DA (%)	51	60	49	54	51	56	48	51	49	55	53
Area with DA of 50% or higher (%)	56	61	49	60	52	60	49	55	53	55	57

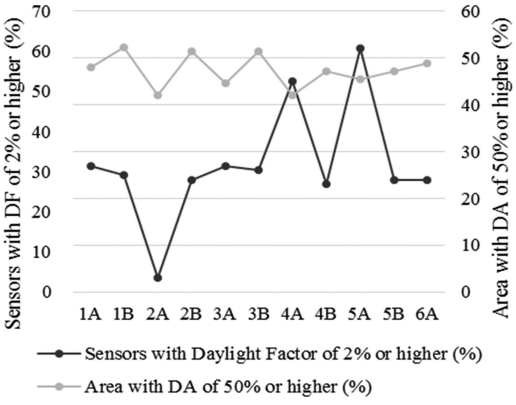

Figure 5. Percentage of daylight area.

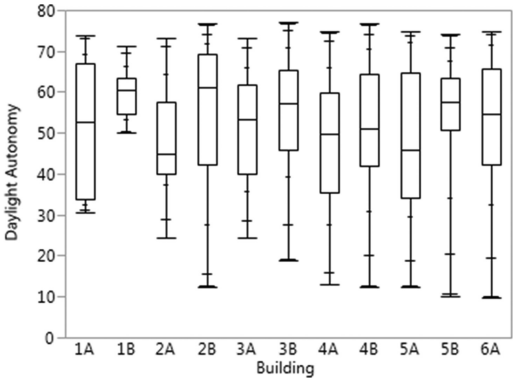

Figure 6. Plots of daylight autonomy.

tell the difference. Therefore, further exploration of the simulation data is needed.

3.2 *Extended daylighting analysis*

Two main daylighting metrics used in this section are Daylight Autonomy and Sunlight Availability. First, box plots are used to graphically present the distribution and variation of daylighting data of the buildings. Figure 6 is the plot of Daylight Autonomy. Each bar shows the distribution of the Daylight Autonomy of 240 units in one building. Great difference is found for different buildings and same building with different orientations. The distributions are skewed to the left, which means most data is relatively large, and there are a few ones with small values. DA spans from 10% to 80%, and the median of the data is between 50% and 60%. As the building shapes get more complicated, the variation gets larger. From building 1A, pure north facing rooms have DA of at least 30%, but in buildings 2A to 6A, there are lots of rooms with much worse DA values to as low as 10%. Figure 7 is the box plots of Sunlight Availability of 11 buildings. The distributions are quite symmetric around the median. Sunlight Availability spans from 0% to 100%, and the median is around 40%.

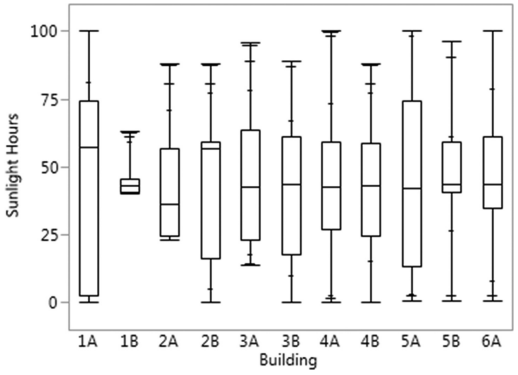

Figure 7. Plot of sunlight availability.

Another method is to directly compare the percentage of rooms in each design that can reach certain daylighting threshold. Four thresholds are proposed, and the data is listed in Table 3. Daylight Autonomy of 50% is considered as moderate target, and 35% is minimum target. Sunlight Availability of 30% is considered as moderate target, and 15% is minimum target. Figure 8 and Figure 9 present the number of units in each building that can reach the minimum and moderate thresholds. It is clear to tell the performance difference between buildings. The results of two metrics generally conform to each other. For the minimum daylighting target, all units in 1B and 2A are able to meet the target, and the other designs with higher performance are 3A, 4B, and 5B. Regarding moderate daylighting target, all units in 1B are still able to meet the target, but only half the units in 2A can meet the target. The other better designs are 5B, 3B, and 6A.

Figure 10 shows the locations of the all the units below the minimum daylighting requirement. All rooms in 1B meet the requirement, thus not displayed in this figure. Because there are no balconies and rooms shading the top floors, top floors rarely have rooms with poor daylighting. The lower floors the more problematic rooms there are.

Daylight Autonomy considers all direct sunlight, diffuse light, and reflect light, whereas Sunlight Availability is only a measure of direct sunlight. The two metrics can identify different rooms in some circumstances. For example, some east, west, and even south facing rooms in building corners can get some hours of direct sunlight, but on average the room illuminance is too low to reach the Daylight Autonomy requirement. On the other hand, for some rooms facing north, northeast or northwest, there is no chance to get enough direct sunlight, but the room illuminance can be enough due to the ambient and reflect light. It need to be mentioned that Radiance runs with stochastic randomness, which means the rays are randomly sent out in each simulation and the simulation output can be inconsistent. That explains why some rooms in the same building locations can have slightly different DA output. However the output of direct sunlight hours is always consistent.

Table 3. Percentage of units reaching daylighting target.

Building Name	1A	1B	2A	2B	3A	3B	4A	4B	5A	5B	6A
Percentage of units DA reach 50% (%)	50	100	40	60	55	67	49	53	45	76	62
Percentage of units DA reach 35% (%)	65	100	95	85	94	96	76	86	72	90	88
Percentage of units Sunlight Availability reach 40% (%)	50	100	49	61	59	67	61	57	53	78	65
Percentage of units Sunlight Availability reach 15% (%)	61	100	100	79	95	79	81	90	75	92	83

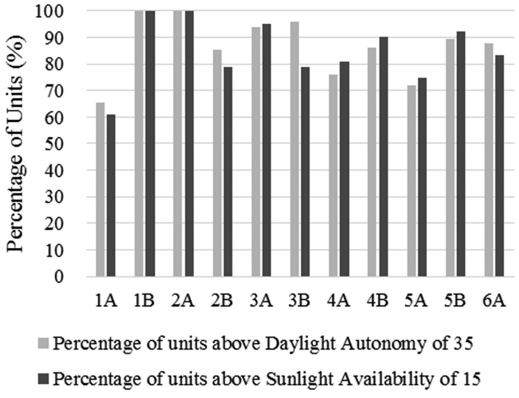

Figure 8. Units reaching minimum daylighting target.

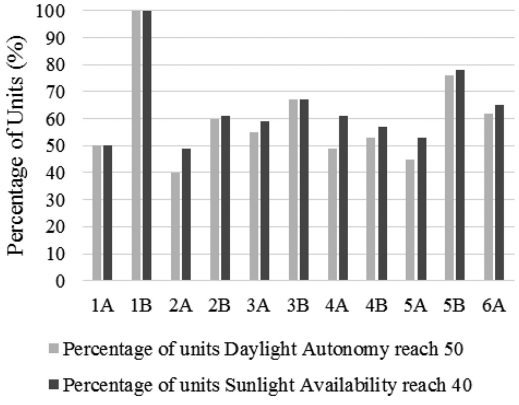

Figure 9. Units reaching moderate daylighting target.

3.3 *Statistical analysis of daylighting performance*

When buildings have a large number of rooms and each room has a different performance metric data, instead of comparing means or medians of the data, there are lots of statistical tests available to tell the building performance difference. R is used in this study to test if the overall daylighting conditions are statistically different between designs. R is an open source software for statistical computing and graphics.

First, Kruskal–Wallis test is used to test the overall difference. Kruskal–Wallis test is a non-parametric method for testing whether samples are from the same distribution. For the Daylight Autonomy, a p-value < 2.2e-16 is found. A p-value of 0.05 or lower indicates a significant difference, and the smaller the p-value, the more significant the difference is, thus there is significant difference between the DA of the 11 buildings. However, a p-value of 0.319 is found for the test of Sunlight Availability, which means there is no significant difference. This could be explained by the similar distributions of Sunlight Availability in Figure 7. When significant difference is found in overall test, the next is pairwise test for multiple comparisons to see which building is significantly different from others. The test used is Conover's-Test (Pohlert, 2014). Table 5 presents the p-values of pairwise comparisons of Daylight Autonomy. Most of the pairs are significantly different, and 1B is different from all other buildings. It is also easy to identify buildings of similar performance, such as 4B and 1A, 3B and 2B.

3.4 *Energy analysis*

Heating and cooling simulation outputs are reported in Table 4 and Figure 11. Different heating and cooling loads are found between building shapes. Same building shape with different orientations also showed big differences. North and south dominant orientations have less heating and cooling load than other orientations. For example, 1A is less than 1B; 4A is less than 4B; 5A is less than 5B. Building 1 requires the least heating and cooling energy, and building 2 requires the most. There is a trend that as the building floors get lower, and building shapes get more compact, there is more requirement of heating energy and less requirement of cooling energy (excludes building 1). The room to room difference in energy requirement and thermal comfort could be the topics in future study.

3.5 *Discussions*

The above analysis shows the daylighting performance difference of residential rooms within each building and between buildings, which could lead to the life quality difference for the senior residents. To guarantee proper daylight condition for all residents, daylighting simulation and analysis is necessary. For new senior housing projects, building shapes and orientations should be considered carefully along with floor layout. For existing projects, the rooms with poor daylighting should not be used as residential units for seniors. Carefully designed artificial lighting could be used to enhance the illuminance condition of residential rooms. Easily accessible public area with

abundant daylight could also be added to compensate the inadequate sunlight in residential rooms.

4 CONCLUSIONS

This paper presents the daylighting and energy performance evaluation process of senior housing designs through simulation and statistical analysis. Advantages and disadvantages of different performances metrics are discussed. Significant differences of daylighting are found between designs. Rooms of poor performance are located in each design, and design suggestions regarding these rooms are proposed. This evaluation process is recommended for comparing building performances in the early design stages. This study is the first step of multiple zone building daylighting optimization, and the next step will include window and shading adjustment based on room daylighting differences.

Forms of the Earth and elements of the city in Muratori's urban projects

G. Tupputi
Department of Architecture and Civil Engineering DICAR, Bari, Italy

ABSTRACT: In the contemporary age, the dialogue that man always leads with nature through architecture has been interrupted.

In the contemporary city, characterized by an open form and an expanded dimension, the techniques of urbanization don't care about the orographic form of the landscape.

This is the major cause of conditions that today hit the city.

However, it is possible to recognize that the city could find the reason of its form in the relationship with the form of nature.

In Italy, over the past century, the theory of the urban project tried to deal with these issues and to define the syntax of urban construction in relation to the form of physical geography.

Some of the more interesting design experiences, in this sense, are those run by Saverio Muratori at the end of the fifties: the projects for the "districts" of Magliana (Rome) and the project "Estuario uno" (Mestre).

1 INTRODUCTION

1.1 *The crisis of contemporary cities*

Over the centuries, civilizations have chosen the places to settle in according to the recognition of specific values and particular characters corresponding to their specific cultures. Every foundation process has always been consequential to a process of interpretation of the territory. Because of this dialectic relationship with the physical substratum, each human settlement has contributed, over time, to exalt the original characters of chosen places.

This interaction has radically changed during the last century. Today, cities assume an "extended" dimension and an "open" form. Infrastructural triangulations split the territory and compare themselves with the elements of wide-open landscape; they absorb large portions of land and agricultural fields. The limits between city and countryside are already indistinguishable and edge urban spaces cannot be considered urban places and, even, places of nature. They are ambiguous spaces.

The form of contemporary cities is no longer compact and well defined like the form of ancient cities, but it is "diffused" and "scattered" on the territory (Arís 2005).

The *town in extension* is about to explode, since the radical change of its structure and of its dimension is not supported by a different way to interpret its relationship with the elements of physical geography.

Urbanization policies seem to be indifferent to the form of natural substratum in which cities are built.

Cities unconsciously grow without direction. The empty space, among the parts of the city, is deprived of its collective value and becomes *junkspace*, residual space, without character, without identity, surrounded by the anonymous buildings of the *generic city. The Joyful Science"*.

1.2 *The role of urban project*

On the basis of the recognition of this crisis, a theoretical reflection should be made in terms of form.

The Mediterranean landscape (the set of cities, country sides, natural places that are the result of a deep and ancient interaction between man and nature), in particular, raises two central questions to the reaffirmation of its own identity: the awareness that the condition of the contemporary *city-territory* ("boundless" and "polycentric") needs a new interpretation of the relationship between city and territory and the acknowledgement of the etymological value that the form of geographic elements assumes as regards to the urban form.

In fact, the city, today, is no longer based on a mutual exclusion principle, as it happened with the ancient city, compact and closed on itself and built in complete opposition to the surrounding rural area, but rather on a "simultaneous presence" of artificial and natural facts (Motta & Pizzigoni 2011).

Significant are the words of Antonio Monestiroli 'we cannot think to built the city like historic centres, like it is only one thing, we have to build it divided into parts' (Monestiroli & Venezia 2011) since the bond of mutual influence between natural facts and urban facts is established when the parts of the scattered city attempt to find a connection with the elements of the landscape to give a new form to the urban structure.

With regard to these considerations, the discipline of urban project should define "new grammars" for the construction of contemporary city. These ones should be able to overcome the indifference of *generic city*, in order to find a possible alternative to the theories that consider natural empty space like "shapeless" space (Moccia et al., in prep.).

In Italy, during the past century, the theory of urban project tried to deal with the objective of defining a new syntax of urban construction, which is elaborated in respect of the form of physical natural substratum.

Saverio Muratori had one of the most significant experiences, during the 50's and 60's. He developed the projects for the Magliana "quarter", in Rome and for the Barene of San Giuliano, in Mestre. These projects represent a significant attempt to define the form of parts of the city, through the acknowledgment of the "generative" value assumed by orography.

2 THE PROJECTS FOR MAGLIANA DISTRICTS, ROME, 1956–1957

The projects for Magliana districts (the ridge-project and the valley floor-project) deal with two different conditions of physical substratum (the hills and the river bend), to which correspond two different "parts of the city", separated by a natural range consisting in hill slopes.

2.1 *The quarter on the hill range (1957)*

In the different versions of the project for "high" quarter, the composition of urban elements (squares, streets, blocks, public buildings) looks for a harmony with the elements of natural landscape (mountain pass, hill ridge, valley floor, plateau).

Saverio Muratori takes advantage of the long-shaped hill ridge to built long perspectival streets, enclosed by two facades of residential buildings. They are not parallel to each other and the pillars of the porches, in the ground floor, articulate them. So, Muratori can define a machine capable to channel the open landscape of Tiber river valley inside the new settlement (Palmieri 2013).

In some places, these streets are interrupted to allow the positioning of specialized buildings, to enable the creation of public spaces that serve the urban sub-units, in which the project is articulated.

In certain variants of the project, parallel blocks and, otherwise, in other variants, courtyard residential buildings are located on the hillsides, between the ridges. They are placed orthogonal to the ridge and define their own dimension on the basis of the conformation of the slopes. Courtyards are sometimes open to the landscape; sometimes they are closed and introverted with an inner character.

The declension of residential buildings types, in the different versions of the project, seems have the purpose of the experimentation of different "characters" that define themselves in relation to the places that they overlook (Monestiroli 2011). The relationship with the territory generates, once again, the character of architecture.

The public spaces, which have to be representative of community life and, so, of human settlement identity, are positioned in the places that have an appropriate character to this function.

Hill saddles and plateaux are focal points due to their particular geomorphological conformation and, for this reason, become the places of the collective spaces. In fact, the streets on the ridges converge in the saddle point on the hills, and it is the perspective focal point of the quarter. For these reasons, it should be deemed to be a place of a great civic value and it becomes, in the different project variants, a natural public space or a great urban square.

The plateaux, however, are easily identified, also at the territory scale, due to their height and to their punctual form. Here, Muratori places isolated public buildings.

2.2 *The quarter on the river bend (1956)*

In the Magliana project on the valley floor, the radiocentric form of urban structure is generated by the Tiber bend.

A great "street-plaza" lies on the bend itself, gathering urban polarities and collective buildings. It represents the central point of the neighbourhood.

This place is chosen once again for its particular geographical configuration, which makes it appropriate to become a public space.

Five radial paths spread from the street alongside the "blend-square" and distinguish four sections, in which the settlement is divided. Each of these urban zones contains a small public area with essential services for the neighbourhood.

At the end of the five principle axes, under the hillside that separate the "down" quarter from the "high" one, the presence of residential towers forms a counterpoint to inner polarities, which are set on the linear square on the river, at the intersections with the five radial streets.

The dialectic between inner and exterior polarities make it possible to visually perceive the dimension of the quarter, and so to strengthen its finiteness nature and, more importantly, to contribute to establishing its unity.

Also in this project, there are different building typologies. From perimeter residential towers to four-storey buildings, which define the fronts of the principle streets of the settlement. And again, there are two-storey row houses, which build the insides of each urban zone and there is the public plaza, in which collective buildings are located on the meandering curve of the river bend.

This composition of building types, along the Tiber, declares once again the etymological value assumed by geographical elements for the construction of these projects.

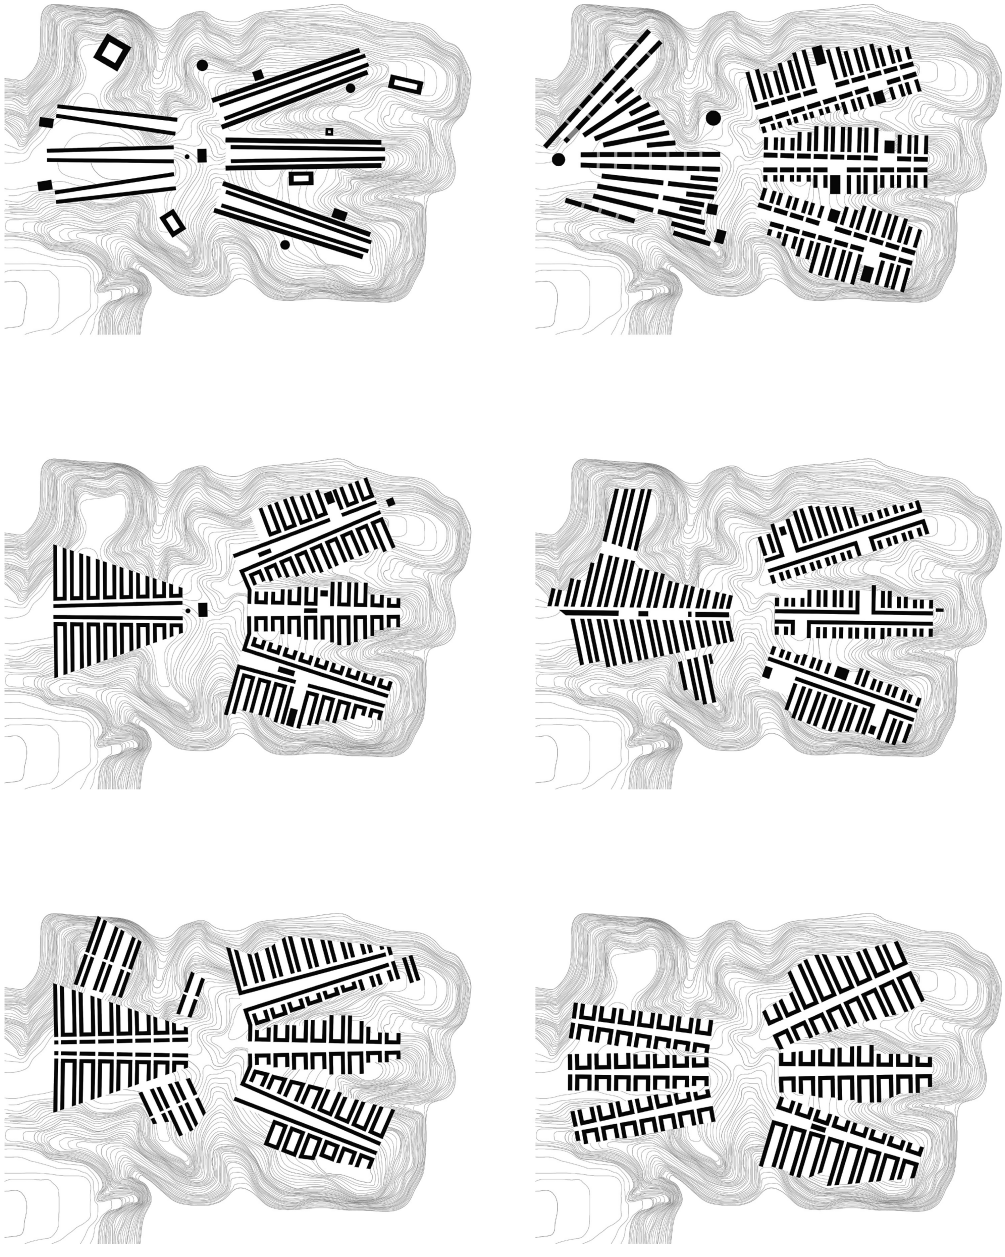

Figure 1. Saverio Muratori, different planning solutions for Ina-Casa quarter, Magliana II. Rome, 1957. Drawing by the author.

3 "ESTUARIO UNO" PROJECT FOR "BARENE DI SAN GIULIANO" COMPETITION, MESTRE, 1956

The purpose of "Barene di San Giuliano" competition was to build a quarter for 40.000 inhabitants, between Venice and Mestre.

On this occasion, as is well known, the group led up by Saverio Muratori elaborated three design concepts, which correspond to the interpretation of three essential moments of Venice urban development. So, he identified the three typical urban systems that characterized Venice urban structure throughout its history: the type with a quadrangular square, the type with a comb-shaped plan and the type with foundations flanked by canals. These paradigms represent the Venice of X–XI centuries, the Gothic Venice and the Renaissance Venice of XVI–XIX centuries, respectively (Maretto 2012).

Figure 2. Saverio Muratori, project for Ina-Casa quarter, Magliana I, Rome, 1956. Drawing by the author.

The project called "Estuario uno" is the most significant for this research, because it assumes the morphology of lagoon archipelago as etymology for the construction of the new quarter.

The form of the "elemental part" corresponds to the dimension of an "urban island" that, through its repetition, builds the whole city.

Each individual island declares its autonomy, by placing itself with its own orientation.

The buildings are organized around a central empty space, called "campo". This place becomes the little square of each island-unit. On one side, there are the buildings for community services, while on the other three sides, residential blocks composed by different building types ("close courtyard", "passing courtyard", "row houses") take place.

Near to the road that connects Venice and Mestre, Muratori builds a great square, which is an exception in the iteration system of urban islands. This long square is able to look on one side at the Venetian lagoon and, on the other side, at the hinterland of Mestre.

Also in this project Muratori develops a complex and hierarchical urban organism and it is undeniable that urban structure is very closely bound up with the character and the form of the place.

The meandering water-space of lagoon stands in opposition to the finiteness of island-units that identifies the archipelago, through their repetition, as a plurality in which individual elements lives together even though they are unavoidably separated.

4 CONCLUSIONS

In the light of the above considerations, the analysis of Saverio Muratori's urban projects becomes very important and makes possible the acquisition of useful tools to build a new "idea of the city", which should allow to deal with the state of being contemporary.

Whereas, in other circumstances, Saverio Muratori carried out his research on urban project in different ways, trying to operate in a spirit of continuity with the formation processes of ancient city (for example through the processual extension of urban fabric and the saturation of empty spaces), instead, in these planning experiences, we can individuate a great intuition, which consists in the recognition that the form of physical geography assumes an etymological value in respect of the urban form.

Other important themes, other significant relationships start from this recognition, such as, for example, the relationship between the parts of the city and the system of open spaces. In these projects, natural interstices (which are peri-urban areas, shreds of untamed nature, uncultivated country sides or even empty spaces produced by decommissioning process) are considered like "intervals" which confer identity to the individual parts and which define them in their finiteness.

These project experiences show us that the empty space of nature, absorbed by the *town in extension*, may acquire a syntactic value in the urban structure and that it makes possible the creation of long-distance relationships between the quarters, making them formally autonomous.

The identity of city-territory may be based on this set of relationships and it will be stronger if the single elements can harmonize with the morphological characters of the Nature and if it the connective value of empty urban spaces is recognized.

Moreover, Muratori carries out experimental studies on the principles of appropriateness of buildings

Figure 3. Saverio Muratori, "Estuario uno" project for "Barene di San Giuliano" competition, Venice, 1959. Drawing by the author.

types trying to make variations depending on the characters of natural places.

Through the use of mixed building typologies, Muratori builds these quarters, as formally autonomous organisms, but they are also strongly hierarchical and complex inside.

Finally, the simultaneous presence of delimitated and compressed urban spaces (in which the character of interior prevails) and of extended and dilated natural spaces (in which the character of esterior prevails) enriches the contemporary city and refers to the complex spatial articulation of ancient city, which is able to evoke different characters (from the collective essence of squares, of streets, to the semi-private essence of courts and alleys).

So, in the different projects, Muratori develops different strategies that take in consideration the idea of a deep dialectical relationship between architecture and Nature and that confer a strong identity and a suggestive character to the different settlements. Theses quarters become, in this way, extraordinary examples of *city-nature* (Moccia 2015).

Therefore it can be said that Muratori's thought, in its theoretical complexity, outlines some guidelines for work that even today offer several suggestions. These ideas might be resumed with interest since they are highly topical and they might be very relevant to the present situation.

These projects contain the seeds of possible developments.

Potentialities therein have a great operational usefulness for the construction of contemporary cities.

This is why I find interesting to analyse and to interpret the urban projects that Muratori defines in '60s, in light of these beliefs; looking for the several fruitful insights that characterized these experiences.

Landscape design and restoration as an educational hub: An experience from Costa Rica

J. Cancela & A. Orozco
Centro de Investigação em Arquitectura, Urbanismo e Design,
Faculdade de Arquitectura da Universidade de Lisboa, Portugal

ABSTRACT: Landscape can be defined as a mirror of the interactions between man and nature trough time. Landscape design is an intentional cultural act to change some elements of those interactions. "Landscape restoration" can be defined as an intentional cultural act to remove and/or add some elements to places and interactions in order to bring them to a more "healthier" state. It's a process where communities, architects and ecologists, politicians and educators must work together. To develop this concept, in October 2015 the first course on "Landscape Conservation" was held in Costa Rica, promoted by the Organization for Tropical Studies. This course linked architects with ecologists, politicians, community leaders, researchers, economists and planners, in the restoration of a protected wetland. All of the participants ranked the experience as very good or excellent, and landscape design and restauration proved to be an important approach to the development of a global working framework, connecting views and skills needed for achieving a more sustainable future. This presentation describes these concepts, experiences, results and desirable future developments.

1 INTRODUCTION

Biological diversity or biodiversity – the variety of life forms that inhabit the planet and the natural patterns that make up between them (ONU, 2010) – is at the limit that humanity can continue to develop and prosper, now and for future generations, without creating abrupt and irreversible environmental changes (Steffen et al, 2015). One of the key problems that the conservation of biological diversity faces is the loss, degradation and fragmentation of habitat (UICN, 1980; ONU, 2010).

Urban growth can lead to loss of habitats of high value, adjacent to cities (Hansen et al, 2005; McDonald et al, 2008; Radeloff et al, 2010) and this in turn can result in high rates of extinction of native species (Kowarik, 1995; Marzluff, 2008). Urban growth therefore can be deeply associated with some of the main causes affecting biodiversity, and this can alter environmental qualities at different scales (Grimm et al, 2008).

As a result of human activities, four of the nine "planetary boundaries" have been crossed. In order of importance and impact, the loss of the integrity of the biosphere, biogeochemical cycles altered, the change of the earth system and climate change. The integrity of the biosphere and climate change have been identified as possess on its own the potential to lead the system of the Earth to a new state, should these be substantially and persistently transgress (Steffen et al, 2015).

In recent years and in growing numbers various researches on this topic have been conducted. For instance, one have concluded that the conservation of urban biological diversity should focus on promoting the preservation and the restoration of native species (McKinney, 2006).

The biodiversity loss and climate change must become fields of interdisciplinary actions, where architects and planners can play a part. For that, it is needed for them to get a global view of the subject and a common language. This article concerns this new field of work, and provides details on how architects and planners can work together with ecologists, local communities, NGOs and public bodies, reflecting on the experience the authors had on the coordination of a course in landscape design and restoration in Costa Rica.

2 LANDSCAPE PLANNING, DESIGN AND RESTORATION

Landscape can be broadly defined as a mirror of the interactions between man and nature trough time (Cancela, 2001). In the year 2000, the member States of the Council of Europe approved the European Landscape Convention, with the aims to promote landscape protection, management and planning, and to organise European co-operation on landscape issues (EU COM2011 244). In the mentioned Convention, landscape is defined as "an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors". In the same document, "landscape protection" means actions to

conserve and maintain the significant or characteristic features of a landscape, justified by its heritage value derived from its natural configuration and/or from human activity; "landscape management" means action, from a perspective of sustainable development, to ensure the regular upkeep of a landscape, so as to guide and harmonise changes which are brought about by social, economic and environmental processes; and finally "landscape planning" means strong forward-looking action to enhance, restore or create landscapes.

For the objectives of the present article, we can define "landscape design" as an intentional cultural act to change some elements of those interactions. "Landscape restoration" can be defined as an intentional cultural act to remove and/or add some elements to places and interactions in order to bring them to a more "healthier" state (Hourdequin & Havlick, 2016). It's a global process where communities, architects and ecologists, politicians and educators must work together to achieve proper results. So, accordingly to the Landscape Convention, the actions leading to the restoration of landscapes can be classified under the global name of "landscape planning". We personally don't agree with this encompassing definition, mainly because landscape planning and landscape design lays on the approach that the system will be manipulated until the original target or design endpoint is reached, whereas landscape restoration is open ended and cannot reach a specific endpoint with a great level of certainty (Clewell & Aronson, 2013), thus leaving more space to accommodate natural changes and evolution. The inference is more "guidance" than "insistence" (Clewell & Aronson, 2013). This evolution strategy seems more appropriate in a world where change and chance are the rule, the future is as unpredictable to other organisms as it is to humans and natural disturbance is to frequent for equilibrium models to be useful (Drury, 1998).

2.1 *Why architects should be involved in landscape design and restoration*

According to the point "E.S. 1.3 Natural and Cultural Heritage" of the 2015 Code of Ethics & Professional Conduct of the American Institute of Architects, "members should respect and help conserve their natural and cultural heritage while striving to improve the environment and the quality of life within it" (AIA, 2015). This is only mandatory for the architects enrolled in that specific professional body but serves as a general guideline for architects worldwide. Due to the fact that architects work mainly in urban environments, and urban development is a great cause of habitat degradation and loss, is obvious that architects that want to comply with the mentioned Code of Conduct should be involved in activities that minimize and restore environmental degradation. This we can call the ethical approach for landscape restoration.

Due to the fact that in the planet most of the natural factors are intertwined, as the global biogeochemical cycles demonstrated (Cain et al, 2011), an effect in a particular place and time can have impacts in other places and times. In a globalised world, architects cannot be confined to the knowledge of their limited spaces and times of intervention, but must comprehend their impact, positive or negative, in a "small world". This we can call the informed approach for landscape restoration.

Well planned and appropriate landscape restorations, compared to loss of ecosystem services, may provide benefit/cost ratios of 3–75 in return of investments and an internal rate of return of 7–79%, depending on the ecosystem restored and its economic context, thus providing in many cases some of the most profitable public investments including generation of jobs directly and indirectly related to an improved environment and health; ecological restoration can further act as an engine of global and local economy and being a source of green employment (Nellemann, 2010). This we can call the economic approach for landscape restoration.

Science and technology shape our world and, as a society, we need to make well-reasoned and scientifically literate choice about everything (NS, 2015); thus for architects the opportunity to work with teams that normally will have a great amount of science and technology careers involved (geologists, engineers, biologists, ecologists, etc.), is a key issue for professional development and scientific improvement. Landscape restoration is a new field of science but already has a specific professional association (the Society for Ecological Restoration), and a good number of journals and conferences of worldwide level. The scientific approach to landscape restoration is an expanding field, in which architects should also thrive and develop the corresponding competences to deal with hard science data that allows them to deal with this issue on other sides of the profession.

2.2 *A particular aspect of landscape design and restoration: wetlands*

Wetlands provide services of near USD 7 trillion every year (Nellemann, 2010); this is roughly the same amount (USD 7.6 trillion) that all "Travel & Tourism" activities (travellers on trips outside their usual environment with a duration of less than one year), generated for the global economy in 2014 (WTTC, 2015). So, from an economic point of view, wetlands have roughly the same value than travel and tourism activities. However, wetlands are at risk of disappearance (due to climate change, pollution, habitat degradation, overexploitation of resources, etc,) and travel and tourism activities are increasing at a steady pace (WTTC, 2015). The services that wetlands present, if they all disappeared, would need the total amount of money generated from travel and tourism activities to be replaced.

Also, from data collected in 2003 in Sri Lanka, the services provided from a local wetland were calculated at more than 2000 USD per hectare, per year, within a

huge range of direct services that included flood attenuation, industrial wastewater treatment, agricultural production, downstream fisheries, firewood, fishing, leisure, domestic sewage treatment, local freshwater supply and carbon sequestration (Nellemann, 2010).

3 THE COSTA RICA EXPERIENCE

In order to develop an approach between architects and ecologists, an "specialty field course" was organized in Costa Rica. This country has 4.98% of the world's biodiversity (Obando, 2007), being considered as one of the top 20 countries in the world within this parameter; this is mainly due to its geographical position in the Mesoamerican isthmus, combined with a varied topography and climate (Kappelle et al, 2002).

The course was developed by the Organization for Tropical Studies (OTS) at "Las Cruces Biological Station and Wilson Botanical Garden". The Organization for Tropical Studies (OTS) is a non-profit consortium of nearly sixty universities, colleges, and research institutions from around the world. In the early 1960's, scientists from U.S. universities forged working relationships with colleagues at the Universidad de Costa Rica in the interest of strengthening education and research in tropical biology. Intense interest, both in the U.S. and in Costa Rica, led to the founding of OTS in 1963. OTS was founded to provide leadership in education, research and the responsible use of natural resources in the tropics. To this end, OTS offers intensive field courses for undergraduates, graduate students, and natural resource professionals in tropical biology and related disciplines in Costa Rica and South Africa. In 1985 OTS was the first organization to receive the Tyler Prize for Environmental Achievement; in 2000 OTS was singled out for Special Recognition and Merit by the Ecological Society of America; and in 2006 OTS was awarded the first Diversity Award from the Organization for Biological Field Stations (www.ots.ac.cr).

Las Cruces Biological Station & Wilson Botanical Garden is located on the southern slope of the Pacific Coast of Costa Rica, in the Puntarenas province, at 1200 meters above sea level and 300 km to the southeast of San Jose – Costa Rican capital – in the canton of Coto Brus (Fig. 1). Las Cruces is part of the La Amistad Biosphere Reserve and is a key site in the study of restoration ecology and biological corridors.

The main objective of this course, was to complement academic formation with interdisciplinary and transdisciplinary professional performance in the area of landscape analysis, design and restoration. Architects interacted with ecologists, the local community, national and international professionals, and local authorities (Fig. 2). This allowed that their future professional intervention proposals share and understand a common ecological language, are designed and developed according to scientific data and are seen as an opportunity to conserve, manage and restore ecosystem services at different scales. Also,

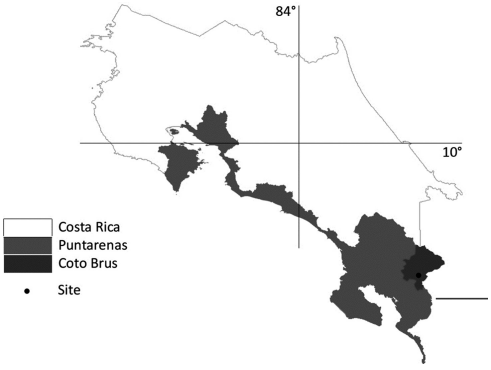

Figure 1. Location of Coto Brus and the wetlands site, in the Province of Puntarenas, Costa Rica.

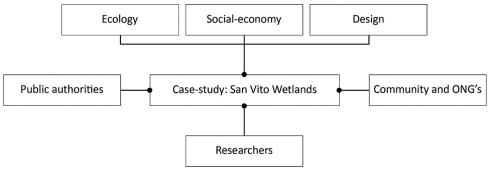

Figure 2. Scheme of interactions for the landscape restoration of the San Vito Wetlands.

Figure 3. San Vito Wetlands, general view.

for ecologists that normally are very able to study and interpret a local ecosystem but might lack the ability to produce good conceptual designs, powerful communications and construction details, to link with architects was a surplus of intervention very much welcomed. According to the experience, to help architects to gain effective knowledge on landscape issues, the comprehension of the factors of time, change, complexity and chance in the "natural" world, were fundamental.

The activities were developed within a theoretical-pratical approach, with an objective and real case study to intervene: the wetlands of San Vito de Coto Brus, a small protected area, with circa 20 hectares, in the periphery of the town of San Vito (Fig. 3). These wetlands are located near the main road from San Vito to Panama and neighboring a small airport. The hydrographic basin is mainly occupied by agriculture and small patches of fragmented forest. These wetlands are important as a food resource for a great variety of birds, and due to its scenic beauty and its proximity to San Vito, has the potential to become an ecological urban park. The course also emphasized the opportunity for

members of the communities around the wetlands and local authorities, to discover the potential of the site as an educational, economic and eco-touristic regional hotspot.

Within this practical learning and applied experience, the architects enrolled in the course were involved in the interpretation of the landscape, proposing integrated solutions within the specific ecological and social context, assuring the development of the place's identity. They were also guided on innovation criteria for design guidelines, with the implementation of scientific data on the conservation, restoration and rehabilitation of the landscape, in order to decrease the loss and fragmentation of habitats, generating a strong conceptual basis about the ecology and landscape connectivity of the site. The more "traditional" approaches of green architecture, respecting the local conditions and the cultural and natural characteristics of the site, were also a point in which architects developed interesting work. All this tasks were seen as a complement to the academic formation and professional experience, developed within a transdisciplinary framework.

4 THE FUTURE ROLE OF ARCHITECTS IN LANDSCAPE DESIGN AND RESTORATION

The EU Biodiversity Strategy aims to halt the loss of biodiversity and ecosystem services in the EU and help stop global biodiversity loss by 2020. It reflects the commitments taken by the EU in 2010, within the international Convention on Biological Diversity. It's an ambitious strategy setting out 6 targets and 20 actions to halt the loss of biodiversity and ecosystem services in the EU by 2020. In particular, the "Target 2 – Maintain and restore ecosystems", states that "by 2020, ecosystems and their services are maintained and enhanced by establishing green infrastructure and restoring at least 15 % of degraded ecosystems" (EU COM2011 244). If this target is to be effectively applied, if only partially, the actions involved will create a huge potential market for ecological studies and monitoring, species and landscape conservation and restoration projects, academic research, ecological rehabilitation and management.

Due to the fact that worldwide nowadays, the landscape is mainly multi-layered or "cultural", architects and planners must be involved, considering this kind of actions inside their professional capability. In fact, as happened to food systems in urban planning that were once called a "stranger to the planning system" (Pothukuchi, 2000) and are now an indispensable issue on urban planning, we believe that biodiversity that is now the new "stranger" to that system, can also become – due to its increasing importance in the technical and political arena – a significant issue on landscape design, planning, management and restoration.

Climate change also plays an important role on this subject, obliging planning to be more adaptive and concerned with the maintenance or creation of natural systems that can act as barriers, sinks or sponges to contain raising water levels at coastal areas. Being these areas the most heavily urbanized, the work of architects and planners on this issue is of primordial importance for the years to come (Costa, 2013).

Due to its specific education and practice, architects already are and will be very important in teams dealing with landscape restoration, biodiversity and climate change issues, as the before mentioned Costa Rican experience has demonstrated, particularly in the capacity of architects to create global visions for an achievable future, change them into graphical documents that interpret and coordinate the work of different team members, produce construction documents and have the skills to supervise and evaluate the work done on site.

But also from the results of the mentioned Costa Rican experience, for architects to become more relevant in these fields, they need to know more about ecology, interpretation of scientific data, global biogeochemical cycles and land ethics.

5 CONCLUSION

Landscape conservation and restoration can be important new fields of work for architects and planners. Biodiversity loss and climate change are two contemporary mega-trends that need to be stopped or mitigated, and for that, need the contribution of all technical disciplines involved in spatial decisions. The Costa Rica course that linked in an practical way architects with ecologists in the restoration of an wetland, proved to be a very effective way to architects rapidly gain basic know-how about these issues and become an important part of teams dealing with landscape restoration, particularly for their capacity to deal with complex spatial data, create coordinated visons, transform them into easily understood communication tools, produce construction documents and potentially supervise the construction of the site. They were very appreciated from other team members with an education on biology or ecology, able to study a site but with less capacity to propose coherent visions, communication and construction documents. As the results of the course showed an appreciation of 75% of the participants considering it as "excellent", we may conclude that this kind of interaction between architects and natural scientists is acknowledge, and a good process to architects to gain fundamental skills to help tackle the global issues of biodiversity loss and climate change, new important fields of work to architects and planners, in order to help to achieve a more sustainable future.

ABSTRACT: The physical world and our bodies act as constraints on the spaces we design, build and use. As process and product, the project underlying this paper is a human-imposed spatial design solution and environment. But as concept, it has some degree of independency or autonomy. It seeks for its own unique identity, crossing natural and man-made patterns. What kinds of space and place can code be designed to make? Or in other words, can the new computational technologies, interpreting the nature's processes, significantly change the role of design in the futures of space conception? This paper will present an urban project proposed for Luanda city outskirts, dealing with specific geographic conditions, common in semi-arid climates, contributing for the idea of a native functional urban development. This proposal intends to create a model able to translate social and cultural particularities of being African, using material systems inspired in singularities observed in African biological diversity as source of inspiring forms and shapes. The complexity of Nature's shapes is built up by modulated repetition of a few basic types of structure. The exploration of biological entities, like the African Anophelines Larvae, as an information source from the viewpoint of evolution, differentiation and self-organization of geometries and shapes was used as a metaphor for the development of this "Urban Species" dwelling project.

1 INTRODUCTION

According to Allen (1992), immaterial ciphers, or codes, are substituted by the material traces that give rise to shapes. Adopting this idea of biological-genetic code that drives differentiation and the emergence of shapes in environment, the aim of Urban Species project is to create a morphogenetic protocol to the implementation of a modular housing aggregate. This project adopts an analogous generative system (Mitchell 1989) looking at an existing system and its operation, in order to interpret it and recreate it under other circumstances: establishing a comparison with the generative power of the Hox genes. This project is not a literal interpretation of any profound knowledge of the Genetics Science. It is an analytical methodology with the support of programming languages applied to design as a metaphor to the complexity underlying the genetic code (Carroll 2007). Particularly the comparison with Hox complexes where gene expression is initiated in the embryo and is responsible for shaping the many biological entities was inspiring to undertake this research. The analysis of site specific conditions for the implementation of the project in a real geographic location, Angola, made us start the concept design looking closely to a particular African larvae, the Anophelines, as a generative source (Monnerat et al. 2002). The complexity of the Anophelines body is built up by modulated repetition of a few basic types of structure (Alberts et al. 2002). Thus, the underlying expression pattern of genes confers on each segment of the larval body a different identity. Hox gene expression is initiated in the African Anophelines Larvae embryo and is responsible for shaping its body (Akam 1994). This way code seems to play an evolutionarily role in patterning the axis of the body. This idea of biological-genetic coding that drives differentiation in environment is used to create a morphogenetic protocol to the implementation of a modular structure for "Urban Species" houses. The genome that determines the geometric pattern of the Larval development is used in this project as a metaphor to design a growth system applied to the housing structures. The success of the housing models will be achieved by the intricate manipulations made from the departure point of the generator elements, or "genes" (Figs 1, 2). Such "genes", or structural elements, are able, through association and repetition to produce complex housing structures.

With this insight it is possible to build an unpredictable variety of spatial organizations. We tried to demonstrate how the discovery of methodological standards – code – could guide the development of constructive and architectural components.

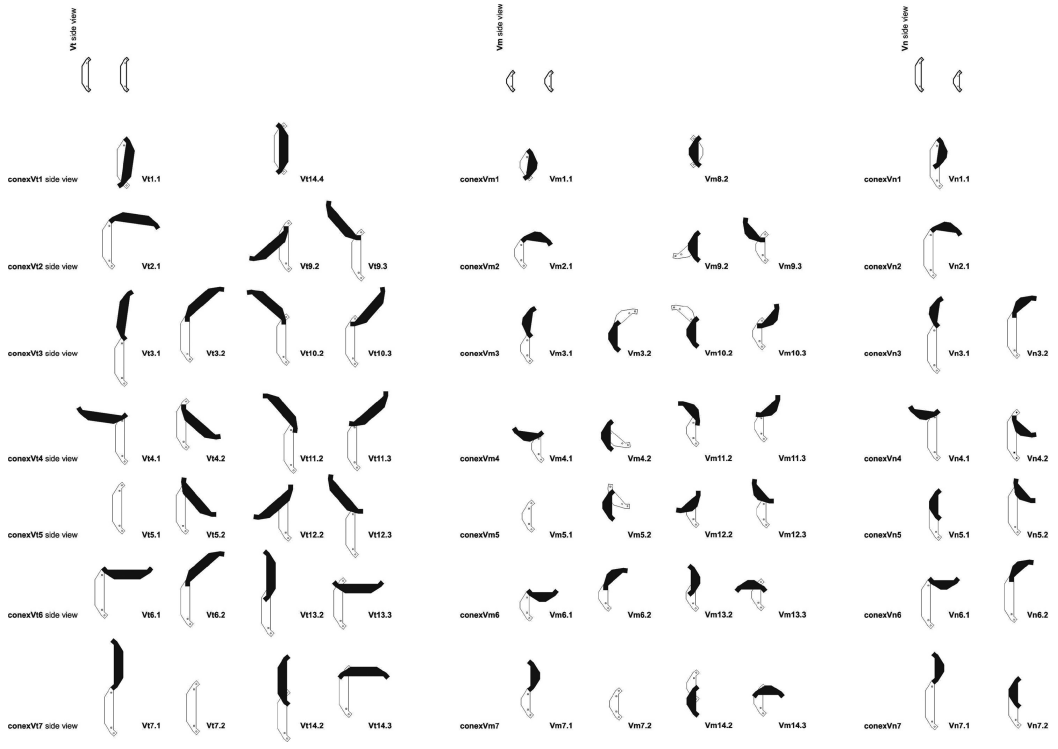

Figure 2. Diagram of possible combinations between the structural elements Vt and Vm.

2 CONTEXTUALIZING GENERATIVE SYSTEMS IN BIOLOGY AND DESIGN

The idea of generative systems and self-organization in the design creative process makes use of interdisciplinary analogies, whether in Biology or other Science fields, addressing different scales of functioning of an ecosystem. The analogy involves the study of self-organization process, rules, constraints and final results, in order to abstract these characteristics and apply them in the context of design.

As described by Camazine (2001), the generative systems are formed as processes through which emerges a global structure, as a result of interactions of the elements forming the system. The rules that specify these interactions are applied to constituent elements to achieve highly complex overall structures. Combinatorial theory and configuring of modular components as generative techniques have been applied extensively in biological systems (Lindenmayer 1968, Flake 1998). But only recently in architectural and urban design, especially with the introduction of computation as an increasingly easy-to-use tool applied to visual graphics applications (Maeda 2001). One of the earliest records on the use of this combinatorial thinking (Mitchell 1978) is found in Aristotle on "Parts of Animals, Book One" in which Aristotle presents a methodology in biology as a combinatory system of

parts that would drive the diversity and differentiation for potential animal making (Barnes 1984). The same methodological approach can be observed in the work of Palladio and the use of grammatical combinations of architectural elements to design space and building geometries (Tafuri 1989). More recently the work of Simon (1968) and Stiny (2006) merging computational procedures, combinatorial optimization and design inspired the new generations of architects making use of the computational power of modern desktop computers. In particular the work of Herbert Simon demonstrated to be inspirational for the development of this research project. Simon presents several strategies in applying combinatory and optimization logics to find alternatives in the design of real world problems. As Afonso & Magalhães (2012), these experimental processes are unlocking architects from the exclusively anthropological point of view in producing architecture. In a time of perceptible technological change, and through the application of the computational force, design is becoming a more experimental practice. Similar to the generative processes in genetics or biology fields, the architecture discipline procedures do not rigidly determine forms anymore, but simply direct and constrain their development.

3 PROCESS, PROJECT BACKGROUND

The metaphor of the genetic code and evolutionary processes has a clear application to the objective of this project: designing a radically cheap-to-build single-family housing system for Luanda, a city under intense demographic pressure and fast urban transformation. In 2013 in Luanda, seven out of ten people was living in slums (Silveira 2013). The housing system should be implemented to tackle this emergent phenomenon. It should allow adaptation in time and the possibility of fast evolution to different family scenarios. The system should be built through self-construction, adapting thus to the processing speed of the Angolan social fabric and life style of low-income populations.

The free interpretation of the genetic code as a generative concept for this project is adapted during this project to specific variables. The definition of a computational generative process, using scripting techniques, is crossed with the project brief and functional needs. In this sense, the paper proposes a housing system as replicable model that reflects the social, economic and cultural specificity of Luanda, making local construction industry technology and current materials of the local architecture.

This project also faces issues of efficiency in the design and construction of architectural structures and deliver of a non-standard product that correspond to the personalized demands of the target users. To respond to the previous brief and simulate the diversity of possibilities underlying the changing lifestyle of the user, the African families in emergency situation, we applied a strategy of high modularity to achieve the adaptability needed to suit unique end user requirements. We simulate this system using the power of high level programming languages as Python, applied to common architecture graphic visualization software. The use of code also simulates a scenario very close to the experience of auto-construction, where the end-users are able to create their own design through simple association of the structural elements Vt and Vm following the connectivity rules as suggested in the Figure 2 mapping diagram. The next section will explore in detail how the power of emergence in generative processes using code has yielded both unpredictable and aesthetic appealing structures.

Table 1. Overall functional areas for a single housing unit.

Gross built area: 100 SQM
Plot area in flat topography surface: 250 SQM
Plot side facing the street: 10 m
Depth of the plot: 25 m

4 PROCESS, FROM CODE TO SHAPES

4.1 *Code as generative strategy for housing structures*

The success of the housing models was achieved by the intricate manipulations made from the departure point of the generator elements, using bottom-up techniques (Jacobson 1994). Within bottom-up strategy, the information processing gives rise to complex systems, by piecing together single elements, "genes". These genes (or construction elements in architecture) were linked to shape larger structures until a desirable top level is achieved. This strategy resembles the behavior of genetic code; in fact each structural element function as a genotype, having this way a specific capacity as generative seedling (Fox et al. 2006). These base elements are combined with the direct input of the designer (or any user running the Python script) during the formation process of the housing models. In that sense the succession of architectural models presented in Figure 3, are the result of applying specific connectivity rules between the wooden structural elements Vt and Vm. The house could then be programmed using the power of scripting or manually constructed by their occupants using the admissible connectivity mapping system (Fig. 2).

With this insight it is possible to build an unpredictable variety of house shapes and functional organizations. It is an alternative design to rigid planning procedures and an antidote against pre-conceived ideas. It is also a possibility to the inhabitants to participate in the construction or even conception process, personalizing and upgrading their own houses. The resulting architecture is a highly combinatory system. Different combinations can be produced ad infinitum by simply adding more elements to the system (Fig. 4). Section by section the house will be shaped and packed by an algorithmic territorial protocol, rather it be analog (human driven) or digitally computed.

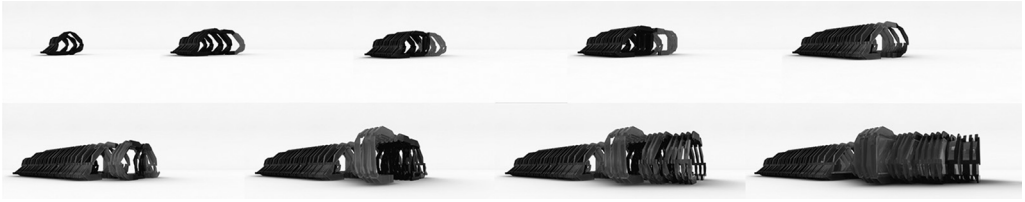

Figure 3. Evolution scenario of the housing model by combination of structural elements. Run script with 70 iterations.

The functionality of the script is shown in the following pseudocode:

– **Definition of Main function**

– Ask the user to select 3 points on the structural elements Vt and Vm
– Take the 3d element (Vt or Vm) to produce copies according to the amount of iterations
– Ask the user the amount of iterations to produce
– Iterate according the desired amount
– Execute the Connect function to produce the final aggregation/housing structure

– **Definition of function Connect**

– Function that connects every component – Vt and Vm – to begin the aggregation or proliferation process
– Shift the elements of the current aggregation to next aggregation content
– The next aggregation list of structural elements will be called recursively
– Loop through the components – Vt and Vm – in the current aggregation
– Generate the connection of components and collect them in the next aggregation set
– Build the geometry of the last aggregation/iteration result

– **Definition of function StructElement**

– Indicate the common points for the connection between elements
– List to collect the points of the new elements to be created according to the number of iterations
– Compute and append the connection points in the list
– Return the newly connected elements

4.2 *Urban species housing script using Python programming language*

```
def connect(VtVm):
        VtVm.newIteration = []
      for curElement in VtVm.curIteration:
      VtVm.newGeneration.append(VtVm.struct
Element (curElement) )
        VtVm.newIteration[-1].render()
        VtVm.curIteration = VtVm.newIteration [:]
def structElement(VtVm, curElement, sharedVertices
= [1,2]):
        newCoord = []
        newCoord.append( curElement.coord[ 2 ] )
        newCoord.append( curElement.coord[ 1 ] )
      vec=rs.VectorCreate(curElement.coordinates[1],
curElement.coord[0])
        temp = rs.VectorAdd(curElement.coord[1],vec)
          newCoord.append(temp)
      vec=rs.VectorCreate(curElement.coord[2],
curElement.coord[3])
        temp = rs.VectorAdd(curElement.coord[2],vec)
          newCoord.append(temp)
        return Element(newCoord)
def Main():
ptOrient = rs.GetObjects("Select the 3 points in the
Structural element to connect and iterate ", rs.filter.
point)
      while len(ptOrient)=3:
      if len(ptOrient)<3 :
      ptOrient = rs.GetObjects ("Select exactly 3 points
in the Structural element to connect and iterate",
rs.filter.point)
      elif len(ptOrient)>3
      ptOrient = ptOrient [0:3]
coord = []
    for ptOrient in ptOrient:
      coord.append( rs.PointCoord(ptOrient) )
      Connection = connect(coord)
iterations = rs.GetInteger("Input number of iterations",
5, 1, 10)
      for i in range(iterations):
        Connection.connect()
Main()
```

The 'infinite' quantity of compositions the algorithmic process may generate, will lead progressively to a more ordered formations applying constraints that selectively reduce suitable possibilities. For example, we can drive the program to generate geometries capable to contain and implement a specific functional demand (host a family with 4 elements) and be adapted to the plot size of 250 SQM. Figure 5 shows a possible housing unit as a result of the scripting techniques. The designer during the process of running the script may take important decisions on the construction of the housing shape. Selection of the contact position of the structural elements Vt and Vm, and the amount of repetitions, or iterations, the program will perform may drive completely distinct geometries. The obtained results are in fact aesthetically unpredictable but in some extent controllable.

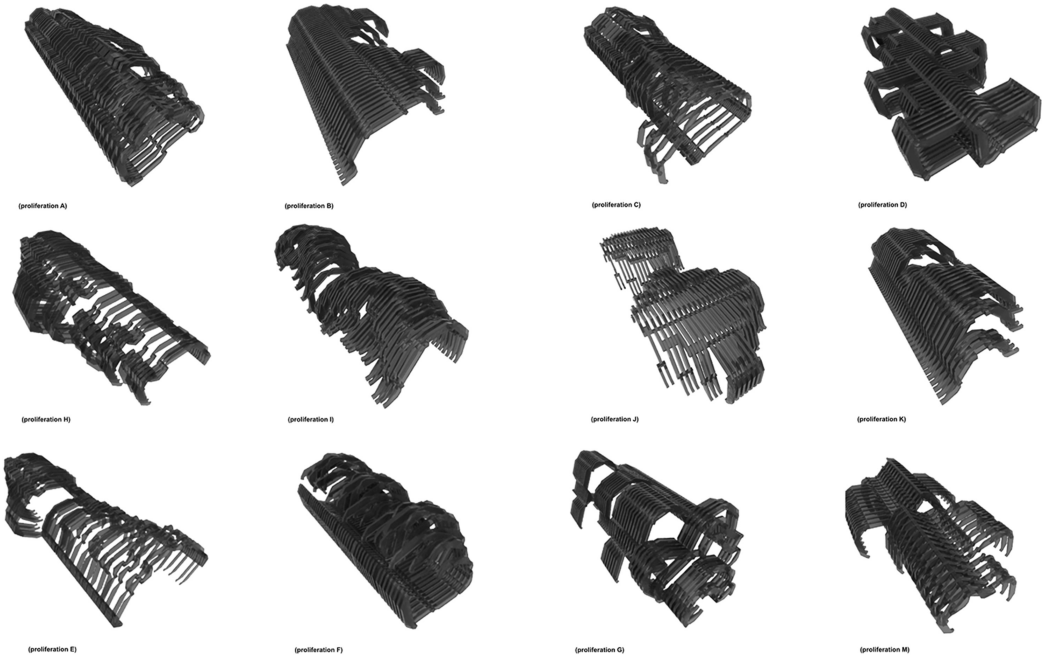

Figure 4. Mapping of different possibilities of housing structures by combination of elements Vt and Vm as structural beams. The diagram is the result of the implementation of the Python scripting language for visual graphics software.

5 PROCESS, FROM CODE TO DESIGN

5.1 *Components, or genes*

In the construction of the Urban Species housing units, every single element is part of an overall system. The three-dimensional generated pattern – or the final geometry of the house – results from combination of simple hardwood elements: the construction components that act like "genes" in our first design concept. Inspired by the information embodied in the development of the African Anophelines Larvae and through experimentation with the first physical prototypes (Fig. 5), we were able to design and fabricate two components (Vt, Vm) but which allowed us to achieve multiple variations morphologies. Those elements were cut from a block of wood using the local resources and contributing to the local industry of wood production. In 2011 Angola was exporting only around 12,000 cubic meters of wooden logs through the main wood industries in the country located in northern part of Angola in Cabinda and in Luanda (Saatchi, 2011). The production of the hardwood construction elements for each housing unit could lead the occupants to plant more trees and sensitizing the Angolan families to the importance of the forestry sector. This is also a possible contribution to forestry conservation of existing protected areas which biological diversity is noticeable.

To develop their proliferation in a system it was then necessary to conduct a thorough investigation of different aspects: (1) the connection between two components, to establish each type of possible connections, (2) the connections between groups of components and how these focus on the final aggregation structures and the possible morphological configurations defining how to use our system, so that clear instructions could be given to non designers in order to assemble a housing unit (Fig. 2), and finally (3) the simulation of the real-time connection of components according to the established rules.

5.2 *Proliferation rules to generate housing structures*

They focus on communication between elements, or the combinatory rules between the generative elements Vt and Vm. Each resulting housing structure has an imbedded code that can be changed and adapted by the user.

This allows us, with appropriate strategies, to generate a new and adaptable concept of modularity, which encourages endless morphological differentiation (as many as the number of potential system users or occupants of the house) but with certain standard layouts. It means that each family may implement and improve its own concept of functional organization. It means also that it is possible to grow the construction just by aggregation of new elements to the house, within defined limits. The system is then evolving in time. This way the emerging "cultural urban structure" is promoted by the social values and the lifestyle of this society, expressed in terms of spatial organization.

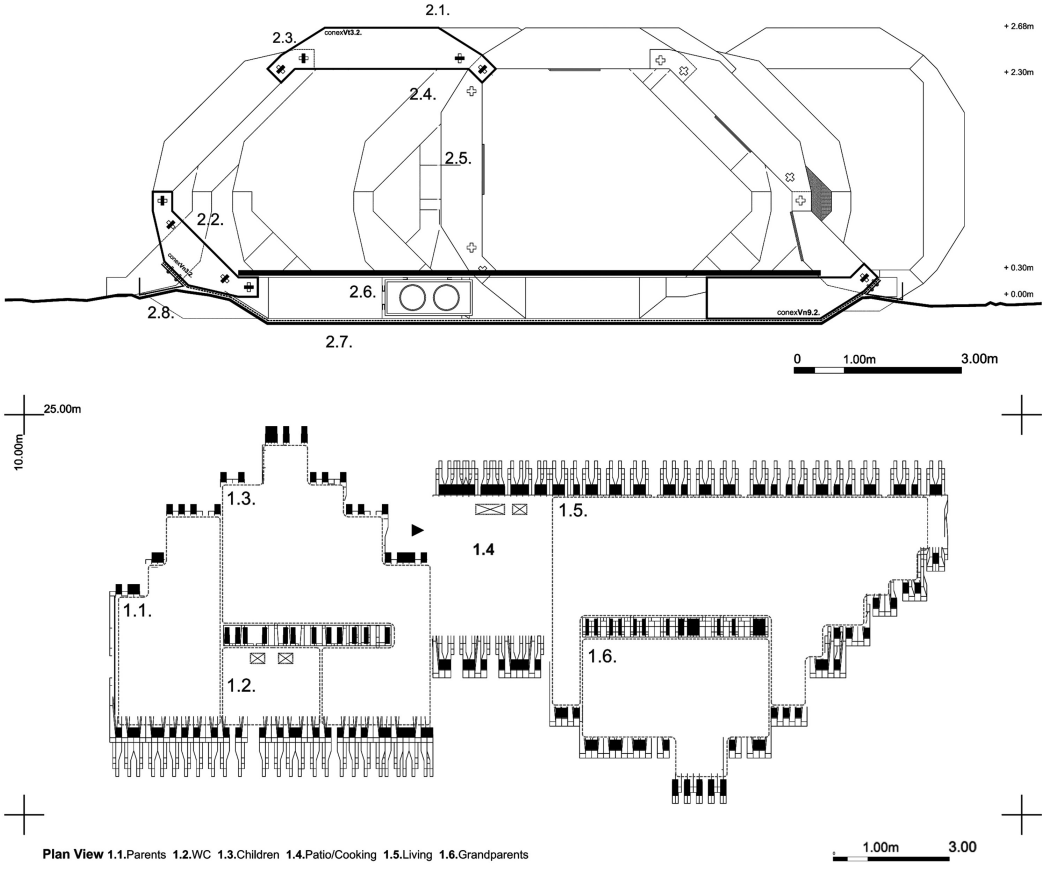

Figure 5. Plan and detail section of a possible housing unit resulting from the running the Urban Species Ptyhon script.

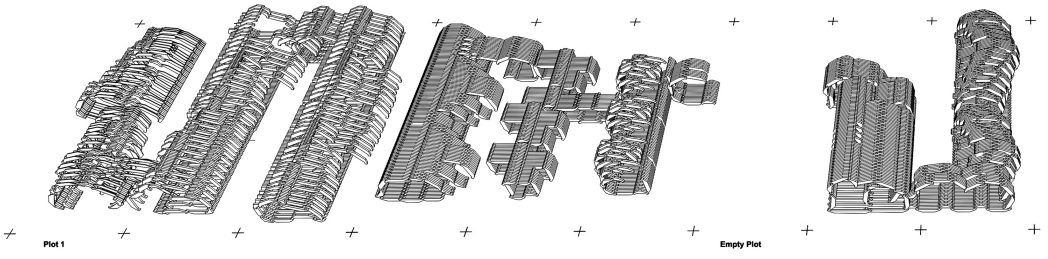

Figure 6. Simulation of a street view. The computational system created introduces the possibility of diversity at the urban scale. This could also be seen as a preview of the street alignment of the self-constructed houses by the end-users.

6 SELF-FABRICATION

6.1 *Do it yourself*

Can we combine traditional construction values of self-sufficiency that preserve local resources with the contemporary technological advances? Cultural and architectural heritage is taken as an active resource and used in the project. The identification of forces and characteristics that shape local architecture and how they may be incorporated into the present: the assessment of human interaction in the appropriation of architectural forms as the end result of social norms and codes, spontaneity or mere instinct to solve the challenges were considered to design a generative process for this project. This anonymous or spontaneous way of building included in the construction process allows an endless formal variation, with the intervention of the end-user (Fig. 6). The system we propose includes the participation of the local population and promotes an architecture developed by the tacit

Figure 7. Final design proposal based on the combinatory power of computational tools. Hypothetical scenario.

"know-how" of this society. This understanding involves the manufacture of modular elements (hardwood beams) adapted to local requirements and specific local wood industry. These construction elements, and the way we can combine them, ensure the principle of adaptability of the buildings to new needs and uses that may evolve over time.

6.2 *Handmade computing*

The self-construction method can be itself seen as a computation. It is a step-by-step process of combination and connection of structural elements to genere an architectural space. It can be performed by the occupants of the house. We tried to design a system of rules and assembly instructions more than just a single housing prototype to be repeated by future contractors and real estate developers. We can call it "handmade computing", and the outcome of this strategy is similar to the geometries produced using scripting techniques. One emergent characteristic of this project is that at some moment it shifted from being developed digitally to being developed physically.

The underlying general guideline for this research is to propose a method in which the conception of architectural space and form generation comprises a logical sequence of combinations of simple structural elements. The system's simplicity makes it accessible to non-designers and can be replicated by the users of the project itself, which in this case actively participate in the design process of their own houses. We still speak of a computational process, but without the use of computers. In both cases (digital and analog processes) formal result is an emergent design induced by the development and intrinsic characteristics of the generative system.

7 CONCLUSION AND DISCUSSION

The goal of this paper is the resolution of an architectural problem, or architectural brief, in order to create a scope of solutions that tackle the several questions rose within the conceptual process. By bringing other fields of knowledge to the architecture working process, this paper tries to question what sorts of design are created through the analogy to the internal logics borrowed from those disciplines. We could call it "scientific imagination" referring Wiener (1964). Such an approach mimicking scientific procedures could be transported to architectural production. The system we tried to develop, based on the idea of generative design, combines the few issues formulated through the working process to create a family of possible solutions. More than just an architecture project, it is a system, as suggested by Weinstock et al. (1998), using generative design as an answer to a specific problem.

This project was conceived as a flexible system that could be easily modified. Developed with Python Scripting components, the main properties of the system are modifiable through parameters that express the functional demand of space but also produce a specific aesthetic quality. This paper seeks for open solutions that permit us to establish networks between the architect and procedural strategies common in other scientific fields, but which are understandable to non-designers.

The identification of biological entities (like the African Anophelines Larvae) as an information source from the viewpoint of evolution, differentiation and self-organization of geometries and shapes was used as a metaphor for the development of this "Urban Species" modular houses. We tried to demonstrate how the use of code can guide the development of constructive and architectural components and how the insertion of this "Genetics" logic of assembly can determine the geometry and functional program of a modular house for Luanda. The ability of our system to achieve endless variations by the active intervention of the end-user, the African families that with their specificity may personalize their houses, is contributing to the general idea of "binding" social aspects with design intentions. The use of these kinds of techniques represents a new way of thinking architecture in terms of computational process. Nowadays, advanced architecture production is not working on traditional themes by using computer tools. Using digital-computational resources we come to a completely revolutionary and surprising pinnacle of architecture (Estévez 2005).

At the other extreme is the total absence of computational tools, or the non-use of desktop computers to generate architecture, but still perform a kind of computation. It is what we tried to simulate by introducing the possibility of self-construction by anonymous people, not designers. Our generative housing system allows the local populations to participate in the design of their own structures, using the predefined construction components and the admissible connection rules of the system. We promote this way a kind of anonymous architecture (Ferretto 2015) but that generates a

sense of place and space with collective history and memory. Figure 7 presents a possible future scene of the adaptation of the housing structures to the real site.

The research has demonstrated the importance of physical implementation of the architectural space. At a time when design studios are increasingly making use of digital technologies, and when architecture is designed digitally, it is important to recognize that space and available resources can impute physical limitations to architecture.

Our future research could involve the study of the optimization of this generative combinatory system and the adaptation to other real scenarios. Also should be studied more in detail the relationship between digital computation and analogue process of self-construction, programing a real-time platform that could help non-designer to participate in the concept design process along with architects, understanding this way the consequences of the making of the architectonic space.

Revisiting forgotten energy technologies – a comparative performance history of a residence with an underfloor air plenum and ground-coupled water-source heat pump

Larry O. Degelman
Texas A&M University, College Station, TX, USA

ABSTRACT: This paper summarizes a 36-year recorded performance history of a ground-coupled water-source heat pump system in a residence in Texas with a ductless underfloor air plenum, known as the Plen-Wood® system. Beginning in 1980 and continuing through 2015, monthly records were kept for the heating and cooling energy consumption, as well as the heat pump's incoming/outgoing water temperatures, outdoor temperatures, and monthly degree days. Measured data during 2013–2014 were also used to validate a heat pump simulation model in an independent research program of monitoring and calibration. Energy consumption from the study home was compared to a reference set of 2.7 million same-sized homes in Texas from the 2009 RECS (Residential Energy Consumption Survey). The study home showed 21.2% less energy use and 19.6% less cost per unit floor area than the reference homes of the same floor area. Attempts to assign savings separately to either the WSHP or the plenum were not undertaken.

1 INTRODUCTION

1.1 *Challenging the status quo*

Environmental control systems (ECS) is a topic quite familiar to architectural educators. To many, it conjures up images of mechanized appliances like compressors, fans, heaters, pipes, ducts, heat pumps and the like. To others, it might also include solar collectors, Trombe© walls, super insulation or low-e windows. The theme in this paper is to discard the notion that ECS is isolated to mechanical gadgets and components, but rather, it must equally include other role players like the building's architecture, its physical features, daylight access and its placement on the site. From ancient times, habitats were configured to accommodate the best of the natural settings – shelter from water and winds, shading from the sun, and/or the admission of sunlight (and heat). The Industrial Revolution of the early 1800's introduced a new paradigm that encouraged a "build anywhere; comfort can be arranged" attitude. This led many designers to adapt to a disregard for early well known approaches and sound fundamentals of environmental control. This paper does not reject the inclusion of mechanized systems; it does include an examination of the performance of a ground-coupled water-source heat pump (WSHP) system, but it also features the performance of the nearly forgotten underfloor air plenum that was promoted in the late 1970's, known as the Plen-Wood® system (NAHB 1978, 1985.)

1.2 *Objectives*

The home featured in this study is an all-electric residence in Texas, built in 1979 and occupied constantly by the same people for 36 years. Records were kept for that period for monthly electricity use, monthly weather conditions of heating and cooling degree days, and the electric utility bills and rates. No gas was available in the subdivision, so all energy use data are in kWh of electricity use.

The objective of this study was to discover if the underfloor air plenum feature would achieve competitive energy-efficiency results when compared to the conventional slab-on-grade residence in the study region. The study home is not special as far as envelope insulation goes, basically meeting the typical energy efficiency standards that were in place in 1979. It does use a solar thermal system for service water heating, but the resulting savings due to the solar system are not factored into the environmental control savings comparisons. As for the HVAC system, the WSHP system is certainly not a new concept, though it is not the common choice for residences in the south central Texas area studied.

The efforts in this study were focused on the impacts, if any, of the combined influences of the WSHP and the underfloor air plenum system. Identifying the savings separately from these two systems was seen as a nearly impossible task, so any savings reported herein are the combination of these two systems working together. The combined

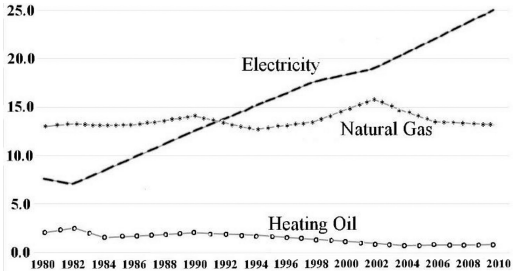

Figure 1. Fuel use in Southern US (in millions of households.).

performance was easy to extract since the kWh consumption of HVAC could be disaggregated from the whole-building electricity use. The electricity uses and monthly heating and cooling degree days were recorded for the entire 36-year period, making for some cause and effect relationship observations.

1.3 *Fuel use trends in southern USA and Texas*

Prior to 1970, the number of homes in the USA using natural gas for heating was approximately equal to the number using electricity, at around 5 million each. By 1980 the gas heated homes had risen to about 13 million while electricity only grew to about 7.5 million homes. Oil heated homes trailed far behind at only 2 to 3 million homes, a trend that continues to this day. Around 1980, however, the number of homes using electricity for heating began to increase dramatically, matching the gas homes in 1991 (at 13 million each). By 2010, electrically heated homes reached 25 million, while gas heated homes remained at around 13.5 million homes. (See Figure 1.)

In Texas, around half the homes still use natural gas for heating or cooking, but more are moving toward electricity as the preferred energy choice. Electrically heated homes have continually evolved from resistance heating (prior to 1970) to heat pump systems, and many of these have evolved from air-to-air heat pumps to water-source heat pumps. Since heat pumps provide air conditioning as well as heating, and air conditioning is already in use in 98% of Texas homes, the water-source heat pump seemed to be a natural and logical choice when the study home was designed in 1978. Water source heat pumps and especially the underfloor air plenum designs, however, are still very rare. Solar water heating does exist in numerous homes, though it is still not the norm.

1.4 *The underfloor air plenum concept*

The underfloor air plenum idea is not the same as the one typically used for computer room floors in office buildings, known as UFAD (underfloor air distribution, Carrier 2006). Rather, it is aimed mainly at residential use. It's based on a simple, proven concept that replaces supply air ducts with a sealed underfloor "crawlspace" plenum to distribute conditioned air to floor registers in the rooms above. The floor is of wood construction, accompanied by sealed and insulated foundation walls. This is depicted in Figure 2 (NAHB 1985). No insulation is placed in the floor that separates the plenum from the rooms above. This permits the floor to act as a radiant panel for both heating (24.2 C ave.) and cooling (22.1 C ave.)

The air plenum is in direct contact with the earth below (separated only by a polyethylene moisture barrier). The earth mass becomes a large capacity thermal storage system that enables daytime heating or cooling to carry over into the nighttime hours. As such, hourly variations in outdoor weather conditions have little impact on indoor temperature and comfort.

The heating and cooling behavior is slightly different than the ducted systems that are designed as air displacement systems. The system does use air as the medium of heat transfer, but an important difference is that the floor acts as a radiant panel. Temperature differences between the floor and the spaces are so slight that occupants have no sensation of this. Instead, the floors are just slightly warmer in winter and cooler in summer – a feature that is openly welcomed by most occupants. The plenum concept is certainly not new; it follows the concepts of the "hypocaust" system invented by the Romans over 2000 years ago to heat rooms in public bath houses through underground chambers (Ring 1996). Similarly, the Korean Ondol has been in use even longer (Kim & Lee 2003).

2 CLIMATE REGION FOR THIS STUDY

Most of Texas can be characterized as having a very warm or hot climate. Average electricity consumption per Texas home is 26% higher than the national average. The average annual consumption is around 85.77 kWh/m^2 (around US$10.50), which is among the highest in the nation, though it is similar to other warm weather states like Florida. Not surprisingly, air conditioning accounts for a greater portion of home energy use (18% compared to 6% nationally) while space heating accounts for a smaller portion (22% compared to 41% nationally). In addition, Texas has an abundance of sunshine, increasing the need for air conditioning, though offering opportunities for solar assisted water heating and PV energy.

Observing the last 36 years, there are indications that the Texas climate is undergoing a gradual increase in average temperatures. Using 15 C as a temperature base, Figure 3 shows a 6-year trailing average of cooling degree days for the years 1980 through 2015, recorded locally in College Station, TX.

Figure 4 indicates a decline of heating degree days for the same period. This observation was not part of the original study plan, but is does add an interesting sidelight about our changing climate nonetheless.

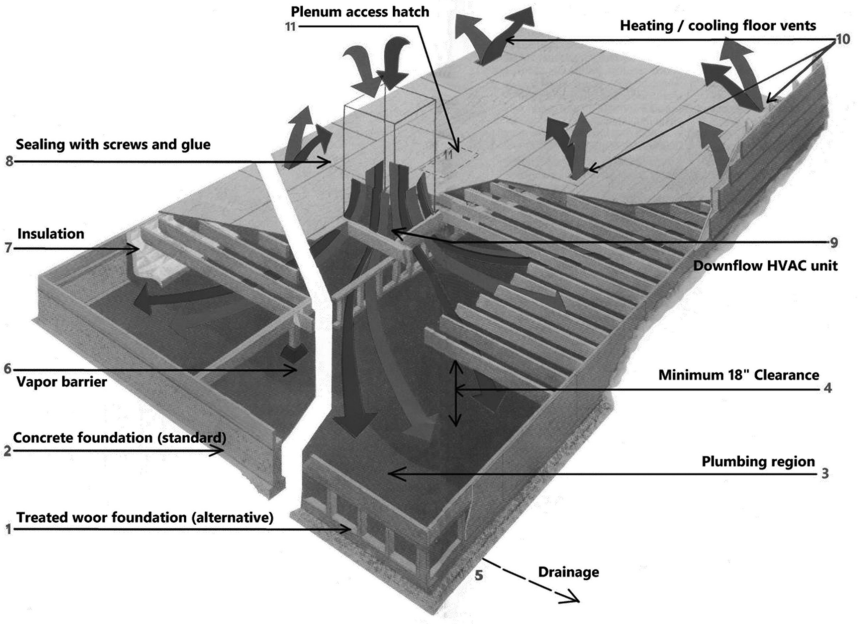

Figure 2. Schematic pictorial of the Plen-Wood system (adapted from NAHB 1985).

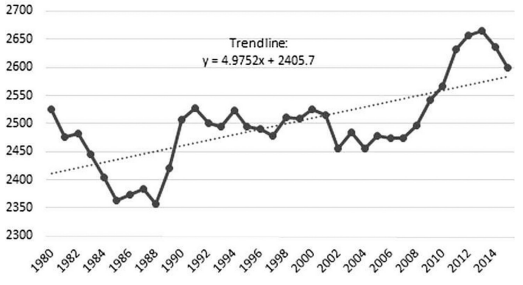

Figure 3. Six-year trailing average of cooling degree days in College Station, TX (Base 15 C, years 1980–2015).

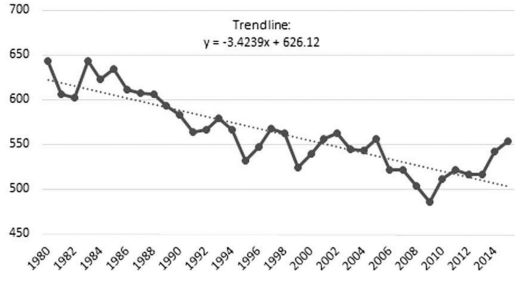

Figure 4. Six-year trailing average of heating degree days in College Station, TX (Base 15 C, years 1980–2015).

3 TYPICAL RESIDENTIAL CONSTRUCTION IN TEXAS

Almost no homes in Texas have basements – due mainly to expansive clay (increases 30% when wet and then back to normal quickly when dry), near-zero frost line making below-grade excavation unnecessary, and mostly level sites leading to lack of drainage due to impenetrable soils. In effect, excavating for basements is typically regarded as an unnecessary and unjustifiable expense by most builders. Slab-on-grade foundations with no slab-edge insulation are the norm. Figure 5 shows a schematic cross-section sketch of the typical home, though the homes can be either one- or two-story.

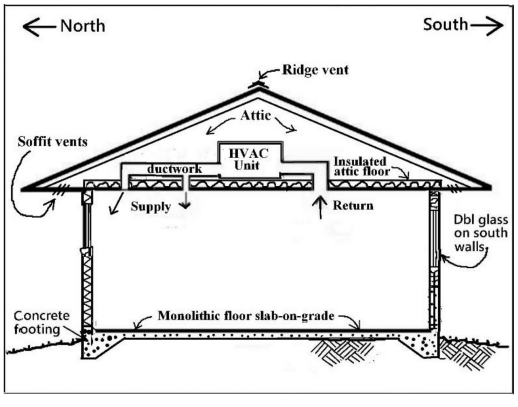

Figure 5. Typical slab-on-grade reference home construction.

The HVAC system in Figure 5 is typically an all-air system with ductwork in the attic, with air being delivered to the living space from ceiling or high wall diffusers. Another typical building feature includes tight fitting air infiltration barriers (not shown), referred

to as house-wrap. That feature was not prevalent in late 1970's homes, but has become more common in recent years. The study home in this project does not have the house-wrap, though it will be contrasted to the reference homes that were built between 1980 and 2015, many of which do have the infiltration barriers installed.

Home builders prefer the traditional slab-on-grade construction mainly for economic reasons. It's simpler and faster; however, a number of features of that approach can cause significant, well-known, drawbacks with regard to energy efficiency. (1) Placement of the HVAC unit and ductwork in the attic leads to air leakage into the attic and conducted heat gains and/or losses through the duct walls. Both of these reduce the heating and cooling efficiencies. (2) Insulation is normally placed on the attic floor in order to minimize the heat losses and heat gains into the living space. This causes the attic itself to become overheated due to the uninsulated roof surface (which is typical of these homes), and thus causes the HVAC unit to be overworked. (3) Attics are typically ventilated via ridge and soffit vents, but this never totally eliminates the excessive heat buildup in the attic space. Often, attic ventilator fans are also used, but this is yet another electricity consumer. (4) Though the air-conditioning season dominates most of the year, there are a few months per year when heating is much needed. During cold outdoor conditions, which can last 3 or 4 days at a time, the cold floor slab presents an uncomfortable condition for occupants, causing some people to raise the thermostat.

The foregoing is not to claim that all traditional homes are inefficient energy hogs. Many have upgraded features of good insulation, solar screens, efficient windows, and high-efficiency HVAC units. However, any home that incorporates the underfloor air plenum system will not encounter any of the aforementioned problems. More details on this will follow.

4 DETAILS OF THE STUDY HOME

4.1 *Main features of the home*

The study home was designed in 1978 to have an underfloor air plenum and a water-source heat pump. Construction was completed in 1979 and the home was occupied on 3 January 1980. A number of "passive" features were incorporated into the design, including orienting the major glass areas due south, placing the home in the shadow of a large tree at its western side, double-glazed windows, and no glass on the west exposure. The east exposure has a greenhouse with removable solar shade screens and a large tree that shades the eastern exposure in summer. The interior has a two-story massive fireplace of concrete and stone construction. South-facing clerestory windows admit daylighting (and direct sun in winter) to all rooms on the north side of the house. Throughout the interior, all

Figure 6. SE general view of the study home.

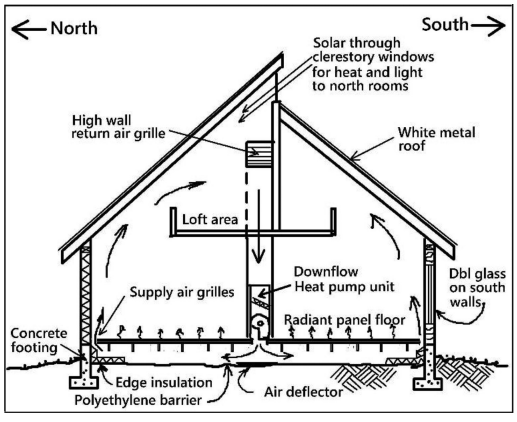

Figure 7. Concept section showing air flow patterns.

spaces have cathedral ceilings, resulting in no attics. The roof is high-reflectance white enamel on galvanized steel backed with Rockwool insulation (R-value 3.87 m^2K/W). The main floor is hardwood and ceramic tile over the closed air plenum crawlspace. Second level floors have carpeting. Walls are insulated 115 mm stone masonry throughout.

The total floor area is around 288 m^2. A solar water heater was installed in 1981 and has operated through the year 2015 constantly. The house has two ground-coupled water-source heat pumps – a larger one (12.3 kW) for the main ground floor area and a smaller one (3.2 kW) for the second floor and master bedroom area, which is not directly influenced by the underfloor air plenum. Both heat pumps have a COP of 13. The home was updated with low-e windows in 2006, converted from incandescent to LED lights in 2015, and heat pumps replaced in 1995 and 2006 – each time with slightly improved system efficiencies. A general view of the home is shown in Figure 6.

A concept section schematic of the study home is shown in Figure 7, illustrating the air distribution patterns. To counteract the effects of temperature stratification, the return air grill is placed high in the center of the house to redistribute the warmer air back to the

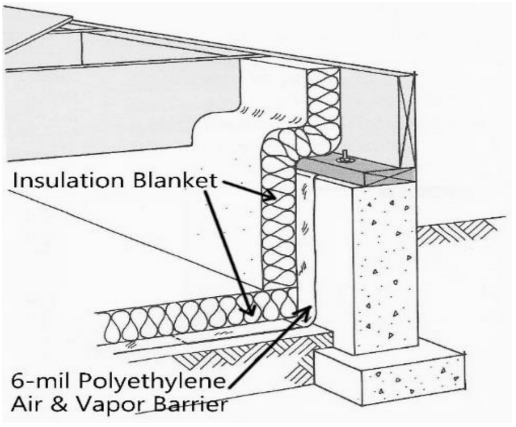

Figure 8. Foundation wall with insulation detail.

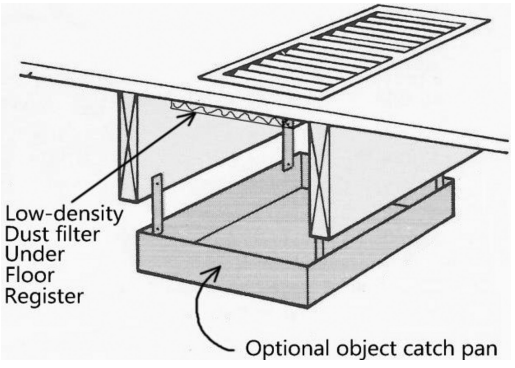

Figure 10. Detail of floor register in wood floor.

plenum. The house acts as a single volume so as to enhance the effectiveness of the plenum air flow.

Figures 8, 9 and 10 show details of the plenum, foundation insulation and floor registers.

4.2 *Mechanical system – WSHP*

The mechanical system is made up of two water-source heat pumps served by a 734 m horizontal closed loop of PVC pipe with 51 mm diameter. The horizontal loop is buried an average of 1.7 m and is in 3 segments: 137 m in earth, 317 m in pond water, and another 280 m in earth. The actual depth of the pipe varies from 1.5 m to 1.8 m throughout the circuit.

A site plan showing the loop layout and the pond is in Figure 11, the top being due North. In the 2013–2014 year, a PhD researcher undertook an independent research project (Do 2014) to validate a heat pump simulation model by comparing simulated performance values to ones obtained by monitoring ground loop water temperatures in the study home.

5 STUDY APPROACH

In order to compare the study home's energy use to the reference homes' energy, two sets of data were obtained: (1) for the study home, the data were 36 years of actual monthly records for electricity use, electricity cost, average temperatures and heating and cooling degree days; (2) for the reference homes, the data were obtained from the ***eia*** (US Energy Information Agency) database called RECS (Residential Energy Consumption Survey, RECS 2009), which covers 30 years of residential energy consumption data for the period 1980 through 2009.

The data for the study home comprised 36 years of monthly records. The electricity use was disaggregated into climate dependent (HVAC use) and non-climate dependent (baseline use, i.e., water heating, washer/dryer, dishwasher, interior lights, exterior lights, 3 refrigerators, 3 air cleaner/purifiers, TVs and computers). Solar collectors provided over 80% of the water heating energy, so that electricity was measured separately and was not considered as part of the HVAC use. It was, however, used in the comparison to the overall energy use in the reference homes since the reference set did include service water heating. The solar collector analysis and electricity used for water heating in the study home has been documented in an earlier publication (Degelman 2005). Baseline electricity use was extracted by documenting the electricity use in months in which there was neither heating nor cooling required. In the 36-year period, the average monthly baseline use was determined to be 1200 kWh; thus, the remaining use was allocated to HVAC use (climate dependent.) The baseline electricity use was further broken down into individual components through use of a portable watt meter that measured specific appliances (computers, TV's, etc.)

The RECS data were selected for homes only in Texas, for the same year of construction, same building floor area, and same fuel type used. Other categories (number of occupants, education level, income level, and owner or renter occupied) were ignored. The RECS data were in overall annual energy consumption and energy use per unit floor area. This measure is called the EUI (energy use intensity), and is expressed in either kWh/m^2 or MJ/m^2. This was the metric used for all the comparisons. The RECS report broke down

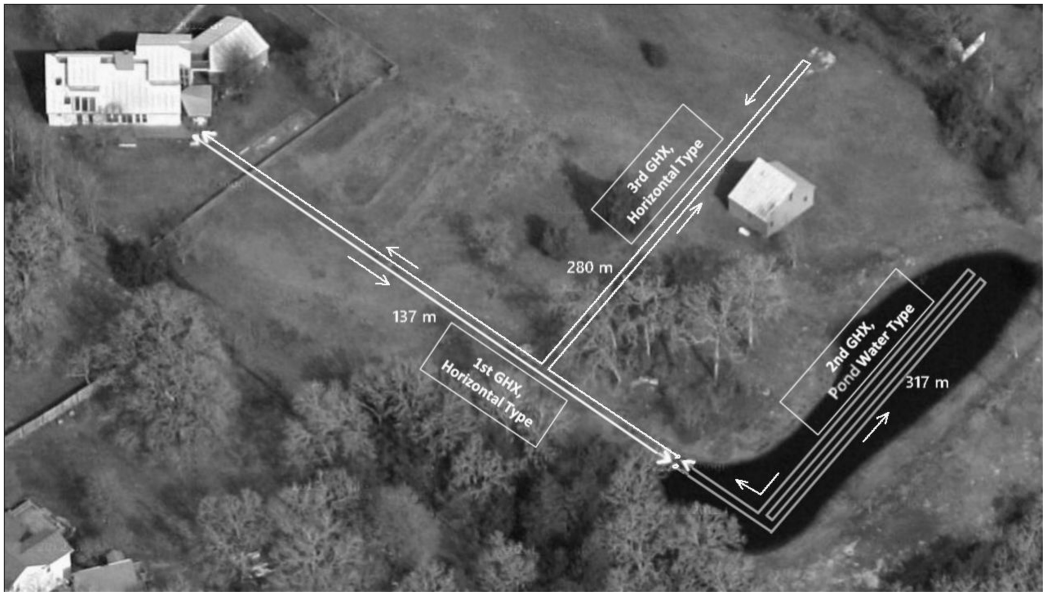

Figure 11. Google Map® site plan showing the ground loop heat exchanger pipe (reprinted with permission from Do 2014).

energy use into categories of heating, water heating, cooling, refrigerators and other appliances, so some non-climate related energy use comparisons could also be made. These breakdowns were only compared out of general interest and had no effect on the HVAC comparisons that are the main focus of this paper.

Results of the study were summarized and are presented in graphs of electricity kWh, broken into categories of energy use: HVAC only and baseline (washer, dryer, dishwasher, lighting, water heating, refrigerators, air purifiers, computers, TVs, other small appliances.) Other graphs were made for the climate data, specifically heating and cooling degree days. Comparisons to the reference data set were then synchronized to the same categories of energy use.

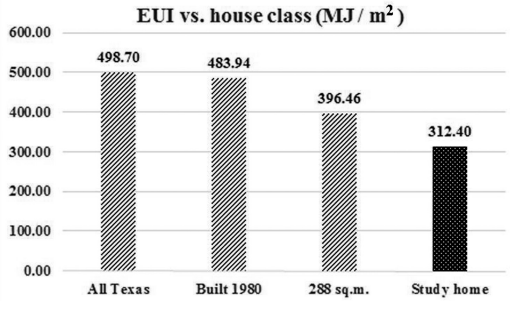

Figure 12. Whole-building EUI comparisons between reference buildings & the study building.

6 RESULTS AND DISCUSSION

The first comparisons were made on the overall EUI values for both the reference homes and the study home. The annual EUI values for the reference homes in the RECS database are in several classifications: all Texas homes, those built around 1980, and those with floor areas around 288 m^2 Figure 12 shows EUI values for those three classes compared to the study home. It seemed that the fairest comparisons should be made to those homes of the same size as the study home. Using that as the criterion, the reference homes annual average EUI was 110.2 kWh/m^2, or 396.5 MJ/m^2, and the 36-year average EUI for the study home was recorded as 86.8 kWh/m^2, or 312.4 MJ/m^2. Therefore, the study home shows a savings of 21.2%. This is for whole-building energy use. To better understand which categories of energy use are credited with the savings, the overall energy was disaggregated, as shown in Figure 13. By isolating the individual energy users, it is revealed that the drop in energy use of heating and cooling alone was from 159 MJ/m^2 for the reference homes to 123 MJ/m^2 for the study home – a savings of 22.6%.

The significant saving for water heating shown in Figure 13 is due to the solar collectors, so these are not credited toward any savings attributed to the plenum or the WSHP. Nonetheless, the heating and cooling alone dropped by 22.6% below the reference homes. Appliance and lighting energy are higher in the study home than the reference homes, but no details are given on how appliance data were collected in the RECS homes.

The issue of annual cost was also examined. Those results are shown in Figure 14, comparing the energy costs in the RECS dataset to the measured utility bills in the study home. Annual energy costs are \$9.42/m^2 for the reference homes and \$7.57 for the study home,

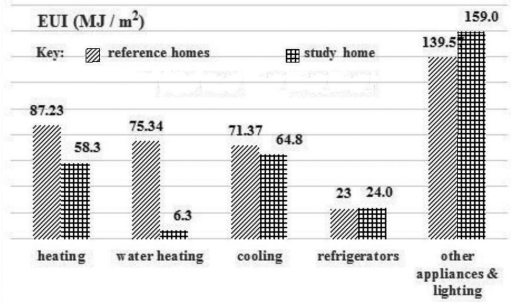

Figure 13. Comparison of EUI for end use categories in the reference buildings & the study building.

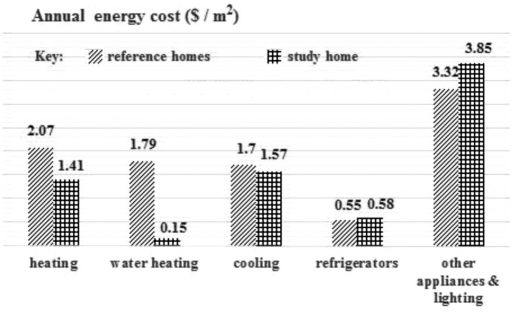

Figure 14. Comparison of annual energy cost for end use categories in reference & study homes.

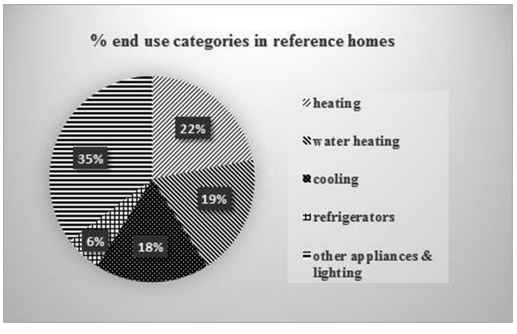

Figure 15. Percent breakdown of energy use in reference homes in Texas.

a savings of 19.6%. The most likely reason that this does not coincide exactly with the percent savings in energy could be related to different electric rates and/or the possibility that gas fuel might be used for heating in some of the RECS homes data.

Aside from annual energy use in absolute terms, it was also interesting to observe the percentage breakdown in the energy end-use categories. Figure 15 shows the breakdowns for the 2.7 million homes in the RECS database. There is a notable difference between these and those in the study home shown in Figure 16.

The study home has extremely small energy use for water heating (due to the solar system), causing a much

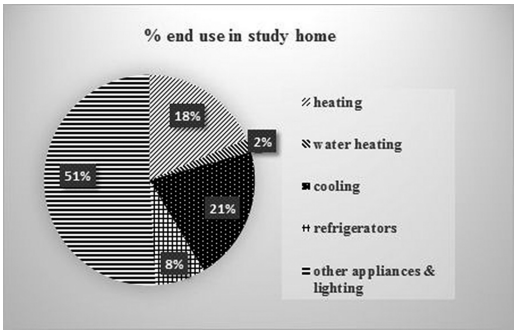

Figure 16. Percent breakdown of energy use in study home.

Table 1. Comparison of features and energy use.

Parameter	RECS homes	study home
Years of records	30	36
Number of homes	2.7 million	1
% of all Texas homes	31.8%	–
Floor area, m^2	288 average	288
Window wall ratio (WWR*)	n.a.	24%
South facing WWR	n.a.	39%
West facing WWR	n.a.	0%
East facing greenhouse WWR	n.a.	31%
Roof color	n.a.	white
Wall material	n.a.	stone
Orientation on site	varies	Due N-S
Energy spent for water heating	19%	2%
HVAC system type	air-to-air a.c.	WSHP
EUI, MJ/m^2	396.5	312.4
Energy savings, %	-0-	21.2%
Annual energy cost, $\$/m^2$	$9.42	$7.57
Annual energy cost saving, %	-0-	19.6%
Annual savings for Heating + Cooling only:		
HVAC only energy, MJ/m^2	159	123
HVAC energy savings, %	-0-	22.6%
HVAC only costs, $\$/m^2$	$3.77	$2.98
HVAC only savings, %	-0-	21.0%

* WWR = 100 × window glass area/wall area.

larger fraction of energy for small appliances and lighting. The fraction of energy use for heating and cooling appears to have changed very little (from 40% to 39%) even though the absolute amount of energy for heating and cooling reduced significantly. The presence of the solar hot water system has impacted the fractional distribution of end uses.

To illustrate the overall comparison of the energy results from this study, Table 1 was developed to summarize all the aspects of the HVAC savings and the other non-climate related used, both for the reference homes and the study home.

The WSHP water loop has 43% of its 734-m length under the pond surface at a depth of around 1.8 m when the pond is full, which is typically all winter. In summer the pond water depth is as low as 1.2 m.

Though heat pump validation was never the focus of this study, some important results are worth noting. From the time that ground-coupled heat pump systems

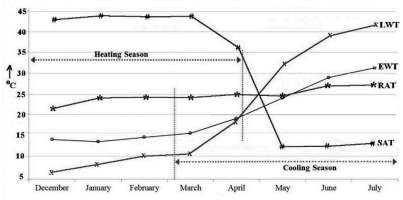

Figure 17. Entering and leaving water temperatures and supply and return air temperatures for the WSHP system.

were introduced, many expressed concerns that the earth (the heat sync for the system) might experience an irreversible temperature saturation over the years that would render the system ineffective. The concern was that increased soil temperatures in summer would defeat the ability of the heat pump to reject heat to the earth, and compromise cooling of the house interior. There was similar concern that the declining soil temperature over the winter would make the heat pump unable to produce the desired warm air inside. Fortunately, none of the issues showed up as problems during the 2013–2014 monitoring phase carried out by Do (2014). Since the system had been operating for 34.5 years, concerns over future performance degradation should not occur. The research project recorded the incoming and outgoing water, as well as the supply air and return air temperatures every 20 minutes covering both cooling and heating seasons. Results are shown in Figure 17 for December through July.

Temperature data of this system showed favorable conformance to the comfort criteria for standard heating and air conditioning equipment. Supply air temperatures (SAT) were around 43 C for the heating season and 12 C for the cooling season. Return air temperatures (RAT) were around 22 C in winter and 27 C in summer. The entering water temperatures (EWT) were about 13 C in winter and 32 C in summer. Leaving water temperatures (LWT) were at 7 C in winter, gradually increasing to 42 C in summer. All temperatures match the performance specs for these particular heat pumps. Do (2014) was able to confirm his simulation models (based on theory and other empirical data from other sources.)

7 CONCLUSIONS

Recorded data suggest that the study house performs somewhat better than the typical Texas home of similar size and period of construction. This was not a surprise since the study home has the solar hot water system, though when that contribution was removed, there were still significant energy savings for the environmental control systems. The interior temperature settings for the study home were constantly at 23 C in winter and 25 C in summer. The second floor had a separate heat pump and had almost no interaction with the underfloor air plenum.

A few side issues of interest were also observed in this study: (1) the 36-year period was sufficient to reveal a trend toward rising annual temperatures, resulting in increased cooling degree days and decreased heating degree days, (2) when set to fan-only mode, the underfloor earth mass showed evidence of daytime charging of large amounts of heat and releasing that to the interior spaces at nighttime – effects being felt for up to 2 days, and (3) measured temperatures in all first-floor rooms were consistently within 0.5 C of each other and within the settings on the thermostat, so comfort was never compromised.

8 SUGGESTIONS FOR FURTHER STUDY

Another worthy endeavor would be to perform a similar study using standard air-to-air heat pumps, in which case any savings accrued could be attributed to the underfloor air plenum system. Incorporating occupancy differences would be an interesting study, but could present new challenges.

Evaluating the energy performance under the LEED-ND criteria by using EnergyPlus

O. Demir & S. Mirianhosseinabadi
North Carolina State University, Raleigh, North Carolina, USA

ABSTRACT: In present era, rapid technological changes are also expended through architectural practice. In this study, we focus on establishing a new framework to integrate the building energy performance evaluation into urban scale evaluation strategies. This study presents the results of a literature review on the principles of LEED for Neighborhood Development and sustainable urbanism. Moreover, two case studies – a commercial building and a small-scale neighborhood – have been simulated using EnergyPlus to evaluate the performance of the building after using the LEED-ND principles for green buildings.

Leadership in Energy and Environmental Design for Neighborhood Development (LEED-ND) is a system for rating and certifying green neighborhoods – developed by the United States Green Building Council (USGBC). LEED-ND integrates the principles of new urbanism, green building, and smart growth into the first national standard for neighborhood design, expanding LEED's scope beyond individual buildings to a more holistic concern about the context of those buildings.

1 INTRODUCTION

According to various approaches, sustainable urbanism makes towns and cities more desirable places for people to live (Beatley, 2012; Farr, 2008; Kelbaugh, 2002; McGeough, Newman, & Wrobel, 2004; Mostafavi & Doherty, 2015; Newman & Jennings, 2008). Those approaches have also helped to shape sustainable cities. Xiufeng Pang, Tianzhen Hong, and Mary Ann Piette (2013) state that implementation of well-developed energy efficiency measures and emerging technologies is slow, even though these to decrease energy consumption in buildings have existed for years. Also, they claim that unmotivated building owners, high implementation costs and operation difficulties are the reasons for the fact.

At the operational level, establishing a context by using accurate energy calculation tool helping building owners in obtaining best approach to improve existing building/s and new developments is the purpose of this study. Mainly, this study establishes a framework that shows flow toward sustainable urbanism aiming to reduce energy consumption in a neighborhood scale throughout LEED criteria by using EnergyPlus tool. Furthermore, best practice is to promote energy efficiency at the urban scale.

Sustainable urbanism requires both a naturalist and orientation to the regional and local ecology and an urban planning emphasis for development to occur. Sustainability occurs successfully when there is a balance among economic, social, and ecological (environmental) characteristics of towns and cities. There are many ways in which sustainability can be applied successfully in urban areas. The principles and elements of sustainability, planning policies, analysis and design methods, and green technology are all part of sustainable urbanism.

With growing population, ecological footprint is increasing accordingly. The amount of land that an individual needs to maintain himself is called an ecological footprint (Bovill, 2015). One of the essential consequences of ecological footprint is higher carbon dioxide emission by energy consumption. McGeough et al. (2004) refer specifically to American problems, such as overpopulation in big cities and unsustainable practices, providing percentage of growth in population and energy usage. This knowledge requires promoting sustainable/renewable energy sources. In fact, a sustainable environment can be created when different strategies are used and integrated into policies, regulations, and systems.

2 LITERATURE REVIEW

2.1 *Sustainable urbanism*

Many environmental issues exist at the different levels such as local, regional, and global. In 1987, the definition of sustainable urbanism was created, and the United Nations World Commission on the Environment and Development published a report called "Our Common Future" (McGeough et al., 2004). Human habitation affects environment in a variety of ways. It leaves behind an ecological footprint that indicates the water, energy, and materials that occupants

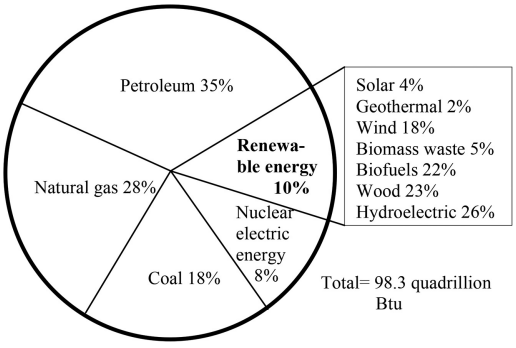

Figure 1. U.S. energy consumption by energy source, 2014 ("Monthly Energy Review," 2015).

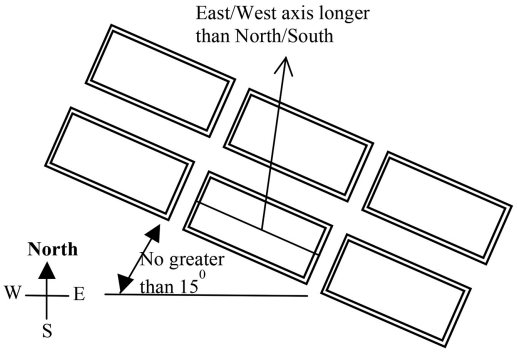

Figure 2. GIB: Solar orientation criterion for solar-oriented blocks (Congress, 2009, p. 97).

have consumed. Overconsumption is a risk for these resources. Therefore, it becomes necessary to integrate new technologies into economic, environmental and social dimensions within the process of sustainable developments. "Sustainable development is the ultimate goal of the energy planning process" (Neves, Leal, & Lourenço, 2015, p. 111).

There are different types of energy that have been used in the US (**Figure 1**) such as petroleum, natural gas, coal, renewable energy (consisting of hydropower, wood, biofuels, biomass waste, wind, geothermal, and solar), and nuclear electric power (2015). According to monthly energy review, residential (22%) and commercial buildings (19%), industry (32%), transportation (28%), and electric power generators are the main energy users (2015). As it has seen non-renewable energy (89%) consumption is higher than renewable (10%) energy.

The most important element of sustainable urbanism is the creation of smart cities, innovative cities, and green cities. Smart technologies include public transportation, district heating, and green building design (Beatley, 2012). According to Beatley (2012), sustainable development starts with the local government. Local activities are the major cause of the problems and solutions. Local governments also can achieve sustainable development within local government programs (Beatley, 2012; Farr, 2008). Farr (2008) states that it would be better if the integration of human and natural systems could take place within sustainable urbanism. In addition, sustainable urbanism supports this balance to create stronger cooperation between the two systems. He proposed a category that aims to support creating high-performance-buildings and neighborhood-scale infrastructure systems containing sustainable (alterative/renewable) energy systems. Fossil-fuel energy usage needs to be reduced, and energy-saving systems need to be commonplace. In this study, we are trying to present how we can make energy-saving systems as commonplace by encouraging LEED-ND certificate program to include accurate calculation tool (EnergyPlus) for energy consumption. This tool will give opportunity to provide results of before and after intervention (after upgrading with renewable energy resources) for building and/or neighborhood.

2.2 *Leadership in Energy and Environmental Design (LEED) for neighborhood development*

LEED-ND stands for Leadership in Energy and Environmental Design for neighborhood development. LEED-ND criteria offer ways to improve livability in the area by means of critical analysis and design practice. The purpose of certified green building is to support green infrastructure improvement in structures and buildings. Building structure needs to follow requirements provided by the IAF accreditation body ISO 17021, ISO/IEC Guide 65 and ISO/ IEC 17065 (Congress, 2009). Some of the LEED-ND criteria that are emphasized in this study are 'minimum building energy efficiency', building energy efficiency', 'solar orientation', 'on-site renewable energy sources' and 'district heating and cooling' under green infrastructure and buildings (GIB) (2009). Certified green building is for energy metric to provide sustainable energy usage for the target area within green building performance. Basically, the criterion serves to support green building practices (2009).

LEED-ND Solar Orientation criterion aims to encourage energy efficiency by generating optimum conditions for the use of passive and active solar approaches (2009, p. 96). The requirement to get one credit either for block or building orientation is to locate the project on existing blocks or design or orient 75% or more. According to this criterion, solar-oriented (**Figure 2** and **Figure 3**) buildings or blocks with east-west lengths (longer axis) should be equal to or greater than north-south axis, and east-west axis within fifteen degrees of geographic east-west (2009, p. 96).

On-site renewable energy sources as a criterion of LEED-ND intend to encourage using renewable energy sources. These energy sources are solar, wind, geothermal, small-scale or micro hydroelectric, and biomass. Earning one credit is dependent on production capacity of used source. At least five percent of buildings' electrical and thermal energy cost must

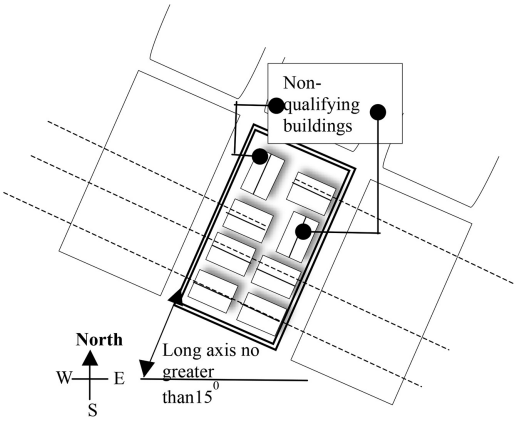

Figure 3. GIB: Solar orientation criterion for solar-oriented buildings (Congress, 2009, p. 97).

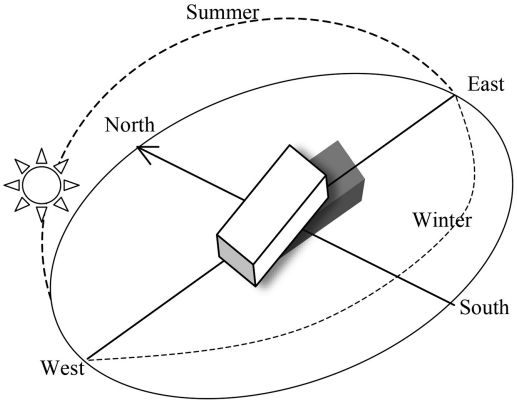

Figure 4. A single building solar orientation.

be supported by renewable energy sources (Congress, 2009).

Sun orientation (Figure 4) of buildings is becoming a crucial for builders to reduce energy costs by using Sun's free energy (Gromicko & Gromicko, n.d.). According to Gromicko and Gromicko, there are several advantages of solar orientation of buildings such as increasing the building's appeal, marketability, and reducing the energy bills. They state that building orientation, along with daylight and thermal mass, are important deliberations of passive solar construction that can be combined into practically any new building design.

Despite an overall view of LEED-ND criteria with a focus on the correlation among elements within each emphasized criteria set has strong basis, within the scope, there is lack of finding necessary data and programs/ software to utilize the criteria. In other words, LEED-ND program should indicate energy efficiency calculation tools such as EnergyPlus to assist projects before implementation. Also, implementation strategies can be shaped based on findings from specified tools. One of the other benefits of indicating specific tool/s is to reduce implementation cost by using various measurements of building and neighborhood to apply best practice.

LEED-ND might encourage public and private sectors to provide data and make it accessible by institutions and development groups. Xiufeng Pang et al. (2013) presents a framework to encourage the large-scale energy efficacy by motivating building owners and decreasing the operational cost through data sharing and amending the process through the cloud-based real-time building energy simulation in their study. In their study, data-sharing process at each individual building is done over three mechanisms such as weather station network and client software and the Energy Management and Control System (EMCS). There is no current weather station network that could provide all the essential constraints. Xiufeng Pang et al. (2013) state, "The emerging low-energy technologies and urban energy systems, such as radiant heating/cooling, demand response, district heating/ cooling and renewable energy, require more weather measurements, e.g. global horizontal solar, direct and diffuse solar, wind speed and direction, to ensure their proper operations."

GIB should be stretched out to correspond larger scale by providing projected framework. In other words, a suggestion for LEED-ND is to resolve scale issues by evaluating criteria suitability depending on this particular framework.

2.3 *EnergyPlus tool*

EneryPlus, which goes beyond DOE-2 (building energy use and cost analysis tool), is the advanced energy modeling tool that is used by the Department of Energy (Bovill, 2015, p. 240). EnergyPlus can help to measure energy efficiency and passive solar design metrics, comparing mechanical system types and operating costs, performing ROI analysis of any sustainable characteristics, such as improved insulation or better windows, performing daylighting analysis of the building, calculating LEED energy reduction credits, showing compliance with ASHRAE 90.1, and so on ("EnergyPlus Energy Modeling," 2016).

2.4 *Establishing the framework*

Within the scope of this study, EnergyPlus tool is used to establish a framework for sustainable urbanism throughout considering LEED-ND criteria (**Figure 5**). This framework is adapted from 'fundamental objectives hierarchy' (Neves et al., 2015). It consists of three dimensions of sustainable urbanism (environmental, economic, and quality of life), related LEED-ND criteria, simulation software (EnergyPlus), and two different cases – one is small-scale neighborhood and one commercial building.

Mostafavi and Doherty (2015) mention two issues: first is affordability of the practices of ecological planning and sustainability; second is scale. The national standard for the evaluation of sustainable buildings is LEED, a program that is used throughout the

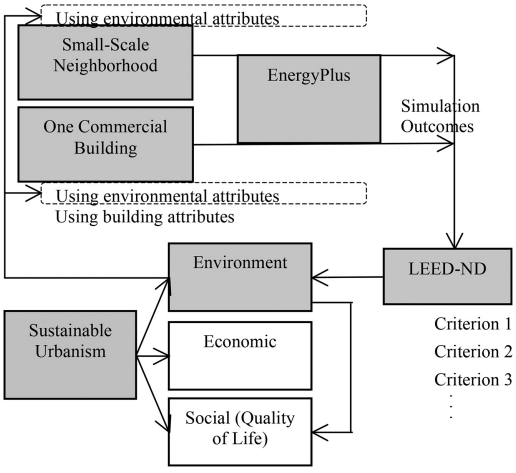

Figure 5. The proposed framework for urban scale energy efficiency regulation (defined attributes are remarked with grey boxes).

country. However, urban systems are designed around a local scale, as opposed to being developed across region. The scope of urban responsibility includes both future and current needs that must be considered for sustainability.

3 METHOD

3.1 *Case studies*

The proposed cases provide a baseline for the LEED-ND program to improve energy efficiency measures to support sustainable urbanism. This study consists of two cases – one commercial building simulation and one small-scale neighborhood simulation – to examine the 'solar orientation' criterion. The case study buildings have been modeled using SketchUp and OpenStudio plugin. In the next step, the geometry files have been imported into the EnergyPlus tool to add the internal heat gains (people, light, and equipment), and HVAC systems to the model and develop the base case models based on the ASHRAE 90.1 2004. The outputs from both models are heating and cooling energy consumption.

The city of Raleigh, North Carolina is chosen as a location for case studies. Raleigh geographically locates on latitude of 35 degree 46 minute and 59 second and longitude of 78 degree 39 minute (Cornwall, Horiuchi, & Lehman, 2016). Both a single commercial building and a small-scale neighborhood were located in regard to similar physical conditions as well as solar orientation in the city of Raleigh locates in mid-Atlantic region.

4 RESULT

The two settings defined in the method section were simulated using the proposed framework and results are presented in this section. The focal objective of these initial results is to understand the energy consumption and energy savings process calculated by EnergyPlus considering solar orientation and on-site renewable energy sources criteria. We aimed to use Raleigh weather data file in EnergyPlus model calculate annual energy saving by taking into account LEED-ND criteria.

Table 1. Pairwise correlations analysis of one commercial building and a small-scale neighborhood.

Variables		N	Coef.	*p*-value
SB cooling	SB heating	365	−0.5614	<.0001*
SN cooling	SB cooling	365	0.9736	<.0001*
SN cooling	SB heating	365	−0.5409	<.0001*
SN heating	SB cooling	365	−0.5809	<.0001*
SN heating	SB heating	365	0.9934	<.0001*
SN heating	SN heating	365	−0.5581	<.0001*

* Correlation is significant at the 0.01 level.
SB: Single commercial building; *SN*: Small-scale neighborhood.

The results of the correlational analysis are presented in Table 1. There was a significant positive correlation between the variables: Single commercial building and small-scale neighborhood' cooling and heating energy use. In contrast, single building heating and small-scale neighborhood's cooling have a negative correlation as well as single building cooling versus small-scale neighborhood heating in terms of energy use.

5 CONCLUSION

This paper presents a framework that can potentially improve scope of LEEN-ND certification program and other urban scale energy efficiency regulations. Sustainable urbanism helps us to understand importance of energy reduction and leaning to renewable energy sources; and EnergyPlus helps us to accurately calculate energy consumption of buildings by using some of the environmental and building attributes. Today, cities that are growing fast need more land, water, energy, and resources to satisfy human needs. It is important to spear out energy efficiency strategies across the nation.

This study provides better understanding of sustainable urbanism elements and emphasizes possibility of replication energy efficiency strategies of single building in the same neighborhood. EnergyPlus software provides accurate results for both single commercial building and small neighborhood scale for the same measurements. The intention of this study was to analyze case studies a commercial building and a small-scale neighborhood's energy performance by using EnergyPlus in order to reduce building energy consumption by promoting energy efficiency measures. This study suggests the improvement in Green Infrastructure and Buildings (GIB) criteria under the

LEED-ND principles that relates to energy efficiency such as ‘solar orientation’ and ‘on-site renewable energy sources’.

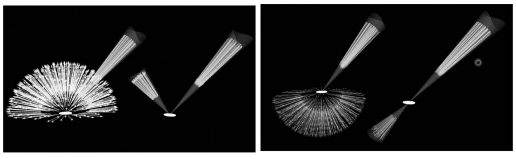
Urban glare and death ray potentials from glass towers

Kyounghee Kim
University of North Carolina at Charlotte, USA
FrontInc, USA

Seung-Hoon Han
Chonnam National University, Korea

ABSTRACT: Glass facades have become popular for contemporary towers in urban settings due to its aesthetic consideration and abilities to maximize view-out and daylighting potentials. Given the increasing popularity of glass facades with issues such as energy transfer and glare controls, close coordination between designers and engineers is indispensable to minimize life cycle energy consumption and to enhance occupant's comfort. Recently, fully glazed facades have been recognized as a possible source of urban glare and death ray problems, introducing a risk to built environment and public health burden. Starting from the Disney concert hall in LA, the Vdara hotel in Las Vegas, to recent examples of the Museum Tower in Dallas and the 20 Fenchurch st. tower in London, those buildings exemplify unforeseen design problems that required remedial solutions after construction. This research paper focuses on theoretical metrics of urban glare and death ray problems and discusses empirical and analytical methodologies that allow designers to identify such problems during the schematic design phase of a building. Architectural design and technological solutions to mitigate urban discomfort were also discussed.

1 INTRODUCTION



Energy efficiency of urban towers largely depend on a great variety of factors such as climate, physical settings, social norms, and user awareness. Passive design strategies including building massing and orientation responding to site climates can make significant improvement in building energy conservation. Physical settings of urban buildings such as density, materials, and geometrical layout affect building energy usages. Building skins incorporating energy efficient façade technologies become critical for reducing energy transfer through building envelopes. Social norms to adopt more stringent energy codes and to implement voluntary energy programs will enhance energy profiles and carbon footprint from the built environment. Finally, human behaviors and awareness of energy conservation will further result in energy conservation.

Glass facades, despite of being a major source of building energy transfer, are becoming widely executed as an architectural element primarily due to the benefits of daylighting and view-out. However, the glass facades of high rise towers in urban settings have been identified as a potential source of urban glares and death rays to nearby drivers, pedestrians and neighborhood buildings. The solar rays falling on a glass facade are absorbed, transmitted, and reflected. Higher the reflectance of a facade, stronger reflected rays adversely affecting urban discomfort. In addition, the problem associated with facade reflection in the urban context is reinforced by the reflectance level of facade materials. Building forms and façade geometry further intensify urban discomfort. The urban glare could adversely affect visibility and visual comfort. The death ray could create additional heat gain that impact thermal comfort and energy bills especially cooling loads. Further, it could impose a risk to neighborhood property, materials and public health. This study discusses case study buildings that exemplify urban glare and death ray as unforeseeable problems during design process, and discussed possible solutions. Further, the research utilizes empirical and analytical methods to validate urban discomfort potentials.

2 URBAN DISCOMFORT: URBAN GLARE AND DEATH RAY

2.1 *Material reflectance and geometrical reflection*

Façade reflectance has implications on energy performance of a building in heating and cooling loads. The visual reflectance is the ratio of reflected visible light to incident visible light on a façade surface, wavelength of 390–700 nm, which affect daylighting transmittance. Solar reflectance accounts for full solar energy spectrum, wavelength of 300–2500 nm (ie. UV-visible light (VL)-infrared (IR)). It is the ratio of reflected solar energy to incident solar energy on

(a) (b)

Figure 1. Diffuse and direct reflectance (a) and transmittance (b) of solar rays. (image source: DiLaura et al., 2011).

a façade surface, and affects heat gain into a building. Architects are typically concerned with the visual reflectance that determines aesthetics of being visually neutral or reflective. A higher visual reflectance will likely cause more urban glares than non-reflective facades. A higher solar reflectance will likely develop more incidences of death rays onto outdoor environment and heat gain onto neighborhood buildings. The visible light spectrum of the solar spectrum attributes to 48% of the energy content while the near IR contains about 50% of energy content with the remaining energy content is attributed to the UV. The solar reflectance consists of diffuse and direct reflectance. Diffuse reflectance reflects solar rays in all directions while the direct reflectance reflect rays with the same incidental angle of the sun (Figure 1(a)). Likewise, solar transmittance is composed of diffuse and direct transmittance. Diffuse transmittance allow solar rays to scatter in all directions while direct transmittance preserves the direction in which the light travels (Figure 1(b)). Depending on surface geometry and texture, diffusivity varies. The albedo refers to the diffuse reflection while the reflectivity represents direct reflection.

The variety of colors, hues, textures of façade materials affect both visual and solar reflectance. Glass material reflects and transmits visible light. Low-e coating on a glass, typically a thin transparent layer of silver, is a spectrally selective coating in that it maximizes visible spectrum yet minimizes the thermal IR. Low-e coating can be reflective or non-reflective depending on aesthetic preferences. It further improves the thermal transmittance (U-factor) by lowering the radiative heat transfer or by reflecting long wavelength radiation due to the low emissivity. It should be encapsulated within the air cavity of a double insulated glass unit (IGU) for durability. The visible reflectance of low-e coating within an IGU varies from 10% reflectance to as high as 65% reflectance. However, the solar reflectance does not necessarily follow the magnitude of visual reflectance because it encompasses a full solar spectrum. Glass reflects, absorbs, and transmits solar energy. Due to advanced coating technologies, a low-emissivity coating in an IGU for example could offer10% visual reflectance and 40% solar reflectance to maximize visible light transmittance while minimizing solar heat gain. Table 2 shows visible and solar reflectance of IGU with different low-e coatings.

Table 1. Visual reflectance and solar reflectance of different low-e coatings according to LBNL standards.

IGU type	Visual reflectance	Solar reflectance
clear glass, 6 mm	8.2%	7.8%
IGU w/o low-e	15.1%	14.2%
IGU w/ ve 2 m	10%	41%
IGU w/ve 65	27%	34%
IGU w/vre46	34%	39%
IGU w/vre38	46%	58%
IGU w/iposol	64%	66%

Table 2. Specular reflectance of opaque materials.

	% specular reflectance
Mirrored and optical coated glass	80–99%
Metalized and optical coated plastic	75–97%
Processed anodized and optical coated aluminum	75–95%
Polished aluminum	60–70%
Chromium	60–65%
Stainless steel	55–65%

Data from http://www.uncg.edu/iar/elight/learn/determine/lc_sub/mat_prop.html

Opaque cladding materials offer both visible reflectance and solar Reflectance. The visible reflectance of an opaque cladding concerns aesthetics while the solar reflectance matters for energy transfer of a building. The reflectance is measured by spectrophotometric meter which determines the reflectance at each different wavelength of solar spectrum. An opaque material can achieve a typical value of 80% solar reflectance with maximum reflectance of 95%. Both reflectance and emittance affect material's ability to reject solar heat. The specular reflectance of a polished anodized aluminum could go up to 95%. Table 2 shows specular reflectivity of opaque materials.

In addition to the reflectance material property, building shapes and geometry of a façade system could exacerbate urban glare and death ray. For example, reflective concave geometry of facades will create a solar convergence point outdoor and adversely affect urban discomfort. The Vdara Hotel in Las Vegas or the 20 Fenchurch st. tower in London are examples of the reflective concentrating geometry. Such geometrical reflections could be mitigated by integrating diffused surfaces such as adding external shading devices or applying diffusive surface treatment. Façade geometries with both convex and flat surface could also cause urban glare and death ray depending on the reflectance level of façades.

The discomfort or disability glares are perceived when viewing angles are aligned with the angle of solar reflection off the facades. Discomfort glare will

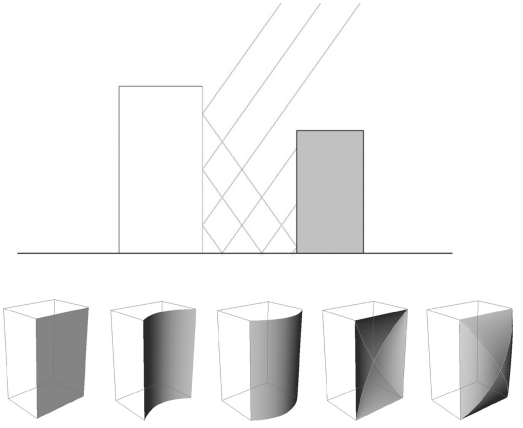


Figure 2. Possible geometrical reflection.

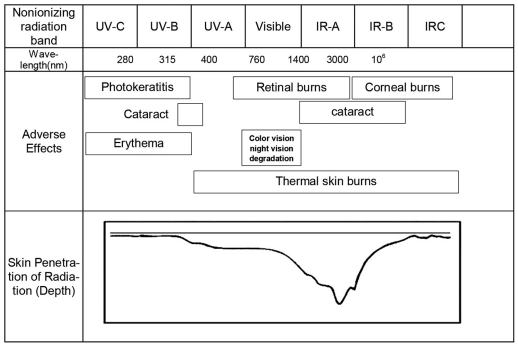

Figure 3. Adverse effect of solar spectrum on ocular hazards (reproduced from Slingy, 2001).

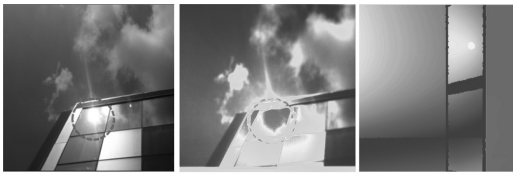
force viewers to look away or change viewing directions. The disability glare reduces visibility due to a bright light source reducing luminance contrast of the retinal image. Therefore, understanding solar positions as a function of solar altitude and azimuth is fundamental when assessing urban glare risks. The photometric and radiometric intensity obeys the inverse square law; therefore, the distance between the intensity of source and effective area should be taken into consideration.

Table 3. Luminance levels on different objects.

Luminance, cd/m2	Representative objects
10	Horizon, overcast sky at sunset
310	LCD computer display max
1000	Scattered clouds
3100	Complete overcast daytime sky
10,000	T8 fluorescent lamp, candle flame
310,000	Blackbody at 1950K
3,10,000	Tungsten lamp filament
10,000,000	Sun at the horizon
100,000,000	Sun at midafternoon



2.2 *Urban glare and health impact*

Scientific evidence suggests that ocular health is correlated to sunlight exposure. Constant exposure to the intense sunlight can lead to impaired vision and eventually blindness. Further, the eye can sustain damage from reflective sunlight to water, sand, or snow as well as eclipse and light sources such as lasers surgery devices or laser pointers [Slingy, 2001]. The ocular exposure over the open water from both direct and diffuse sunlight for example is found to be ,of the order, of 20% of sunlight. The American Optometric Association reported that “Exposure to UV and intense violet/blue visible radiation is damaging to retinal tissue in laboratory experiments, thus scientists have speculated that chronic UV or intense violet/blue light exposure may contribute to aging processes in the retina” [AOA, 2015]. Figure 3 shows adverse effects of solar spectrum on ocular hazards. Photokeratitis is caused in the short wavelength region of the visible spectrum while retinal burns occurs due to the visible spectrum and the infrared A while Corneal burns is caused by the longer wavelength of the infrared region. It is important to mindful of ocular exposure to intense light sources. The use of fully glazed facades has gained popularity in contemporary buildings due to its aesthetics and unique performances such as daylight and view-out. The influence on direct reflection from facades becomes evident in creating environmental problems on pedestrians, drivers and occupants of adjacent buildings. Figure 3 shows an overview of ocular hazards when exposed to different wavelength of solar spectrum.

In addition to the ocular effect due to solar exposure, glare represents visual performance under the presence of light source. Glare occurs when luminance is too high or luminance ratios between minimum and maximum luminance areas are too high. According to CIE definition, glare is defined as two categories: disability glare and discomfort glare. Disability glare is physiological glare and reduces visual performance and visibility. Discomfort glare is psychological glare and produces discomfort without interfering visual performance and visibility. Table 3 shows light intensity measured in cd/m2 on various surfaces. Sun at the horizon and midafternoon can damage eyes.

The luminance level of the sun is estimated to be around 1.6×10^9 cd/m^2. The sky luminance in the daylighting study area considers clear sky, partially cloud and overcast conditions. The highest luminance of the clear sky condition, for example, occurs in the circumsolar region with around 20,000 cd/m2 luminance (DiLaura et al., 2011). More complex sky models are available based on weather data. Solar illuminance measured on a plane normal to solar rays can reach as high as 100,000lux (DiLaura et al., 2011).

The luminance of a façade can be obtained by both physical measurements and simulation (ie Radiance).

(a) (b) (c)

Figure 4. Field taken (a, b) and simulated (c) HDR images of a façade reflecting the sun.

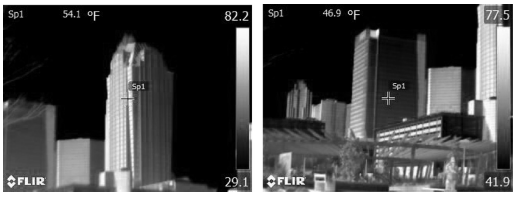


Figure 5. Thermographic images of Charlotte uptown on a winter day.

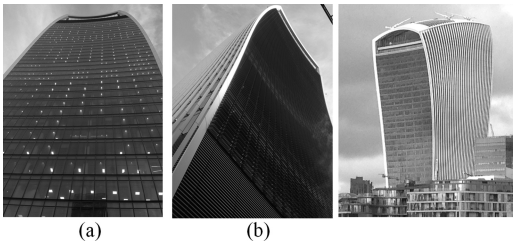

Figure 4 shows hdr images that are field taken or simulated using radiance software. Radiance software uses backward ray tracing and a weather data driven sky model that simulates direct reflection of a glass façade.

2.3 *Urban death ray*

Heat flux reaching on a material consists of reflectance, transmittance, and absorptance. The surface temperature of a material primarily depends on absorptance. Absorptance rate varies depending on material color, emissivity, geometry, and so on. The intensity of solar reflection depends on reflectance rate. Solar reflectance is the ratio of heat flux reflected by a surface to the total heat flux incident on it. Solar transmittance is the ratio of heat flux transmitted by a surface to the total heat flux incident on it. Solar absorptance is the remaining ratio that is not reflected nor transmitted. Therefore, total heat flux equals to summation of reflected, transmitted, and absorptive heat flux (ie. Solar reflectance + transmittance + absorptance = 1).

Urban death ray is caused by solar reflection from reflective facades or reflective concave facades. It adds heat built-up on the ground level or heat gain onto neighborhood buildings. Both solar reflectance level and concave geometry will increase the incidence of death ray problems. Thermographic images of urban buildings can be one way of identifying possible hotspot locations. Simulation techniques such as whole building energy simulation or irradiance analysis can be utilized to understand potential impact on heat gain to neighborhood buildings.

There are a few notable buildings that caused urban discomfort problems after construction, and provided insightful lessons. The Walt Disney Concert Hall (2003) in LA was reported to cause glares and heat to drivers and neighborhood buildings due to the reflective curved stainless steel metal panel. Both the solar reflectance and the curved geometry of the metal panel intensifies glare and death ray. Problematic metal panels were modified with dull finishes to diffuse sunlight. Another example of reflective concave geometry is the Vdara hotel (2009) in Las Vegas. The South facing concave facade with a reflective glass curtainwall intensified solar rays on the pool deck, causing temperatures to reach up to 99 degree C (210 degree F) that burned things on the deck. Trees and umbrellas were added to absorb converged solar rays. The 20 Fenchurch street tower (2015) in London is another example of reflective concave geometry. The parabolic glass curtainwall burned car part on the street and built up heat on pedestrian level. The Fenchurch tower had installed aluminum shading louvers to mitigate sun reflection problems (Figure 6). Lastly, the Museum Tower (2011) in Dallas is a convex glass tower that emitted detrimental sunlight to the Nasher Museum (2003). The reflectance of the convex glass façade is around 45%, and the direct reflection is strong enough to damage curated art work indoor and outdoor. Three different remedy proposals were discussed – 1. to add anti-reflective film on the Museum tower glass curtainwall, 2. to redesign the skylight oculus of the Nasher museum, and 3. to install a free standing sculptural shield. However, none of the proposals have been accepted and implemented due to practical and financial reasons.

3 PRACTICE INVESTIGATION

The Children's Hospital of Philadelphia (CHOP) designed by PCP and Ballinger is a research and office tower located across the Schuylkill river in Philadelphia. The tower is 23story tall with 46,450 sq. meter (500,000 sqft) gross floor area, sitting on a parking podium. The building mass responds to climates, views and neighborhood context. The facades consist of concave and convex geometry with glass curtainwall with around 30% visual reflectance. The lower level of the building is enclosed with terracotta and glass claddings with metallic tube fins. The upper level of the building facades consists of reflective curtainwall with metal tube fins. The metal tube fins along the curtainwall mullions reduces solar gain.

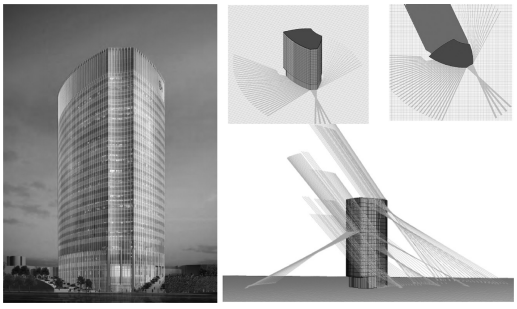

Figure 7. Solar ray analysis using forward ray tracing.

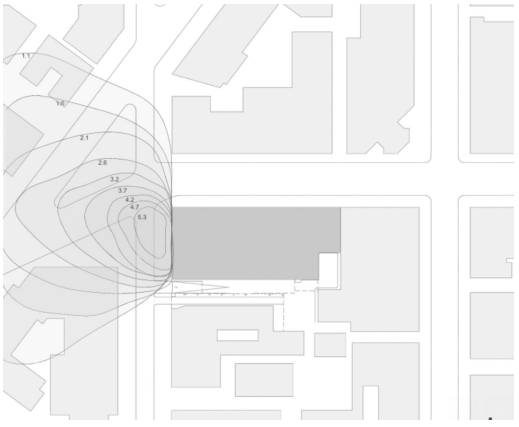

Figure 8. Urban glare analysis that shows an extent of street level glare problems resulted from the west façade.

The solar ray study allowed us to identify solar convergence point from the Eastern concave façade and to visualize the effective area of solar rays that are falling on the ground. Understanding of solar converging areas could suggest potential urban glare and death ray problems. The urban glare study specifically concerns glare to pedestrian and drivers due to the direct reflection from building facades. Death ray in this project specifically concerns thermal comfort at pedestrian level. Figure 7 shows solar ray and glare analysis for the tower.

The 2050M st. office is located in downtown Washington, DC. It is a new construction and its gross floor area is around 37,160 sq.meter (400,000 sq.ft.) The building enclosure consists of flutted glass curtainwall and a concrete wall with punched windows. Due to the concave geometry of the flutted glass panel, it was expected that the curtainwall facade generates multiple reflections from the glass converging on viewers. The solar ray study focuses on defining a solar convergence point to confirm the death ray potentials, and the effective areas on ground that could impose a risk to neighborhood properties, materials and public health. Further, computer tools using Radiance determined maximum luminance level of the flutted glass and glare potentials. Figure 8 shows daylighting study to understand the degree of glare problems imposed by reflected facades.

4 CONCLUSIONS

Glass towers in cities have gained popularity with an intention of aesthetics and access to daylight and view out. However, the glass facades in urban settings have been identified as a potential source of urban discomfort such as glares and death ray to the built environment.

This study discussed scientific matrices of urban glare and death ray, and potential health hazards. The research methodology consists of field measurements and simulation. HDR photography taken in a field allows designers to understand potential glare. Thermographic images assist in identifying hotspots of facades or pedestrian/car roads. Daylight simulation using Radiance is an analytical method to identify luminance and glare level. Solar ray analysis is to assist death ray potentials by using forward ray tracing and identifying solar convergence points. The solar ray analysis also provides the extent of effective areas on ground or neighborhood buildings that may cause glare or death ray problems. The reflective concave geometry intensifies solar rays, and it is important to confirm urban discomfort potentials during the earlier design process. In addition to the geometrical reflectance, the reflectance level of cladding materials also plays an important role in urban glare and hotspot issues. The higher the reflectance is the stronger the reflective solar rays from facades. Façade reflection could adversely affect visual glares, forcing viewers to look away. The death ray from facade reflection could increase cooling energy bills or air conditioning equipment for neighborhood buildings due to additional heat gains. Further it could introduce a risk to properties and public health. Possible mitigation solutions include shading devices, frits, anti-reflective coating/film to reduce reflectance level. Concave or parabolic geometry require special attention. It is important to balance out aesthetic preference, energy performance, and public health.

Statistical analysis of academic performance in Ohio's Green Schools

C.B. Heller & A. Sharag-Eldin
College of Architecture and Environmental Design
Kent State University, Kent, Ohio, USA

ABSTRACT: School buildings are tools used in service of society and should be designed to meet the needs of people serviced by them and paying for them. Surveys have shown the public cares most about academic success in schools. Therefore, the impact of design decisions on student performance should be understood. Research has established lighting, indoor air quality and thermal comfort as the building design elements influencing human performance. The goal of this research was to identify through statistical analysis any significance or priority among these design elements. Ohio is uniquely positioned for such research because it has by far the largest group of green schools in America (over 250). The analysis found that daylighting significantly influenced student performance in the short term, whereas thermal comfort and indoor air quality did not. This study is a unique contribution to the growing body of evidence linking indoor environmental quality and human performance.

1 INTRODUCTION

1.1 *Green design priorities*

It was only a couple of decades ago that the public and the building professions began to work together to define, design and construct green, high-performance buildings. Since then, significant advances have been made in the design of the buildings we spend over 85% of our lives in (Kats, 2003). Today our buildings are more efficient, they are of higher quality and they cost less than the buildings of yesterday. Research has shown that resource efficient building design makes economic sense when all costs and benefits are considered over the life of a building. In 2002, the U.S. Senate Committee on Environment and Public Works and California's Sustainable Buildings Task Force both commissioned reports detailing the costs and benefits of green buildings. The reports completed by the U.S. Green Building Council (USGBC) and private consultants showed the financial benefits of resource efficient design far outweigh the costs (Kats, 2003). Most experts and building professionals now agree that resource efficient buildings are a good investment because research has clearly defined the benefits. In addition, national programs have been successful in educating the public about the benefits of resource efficiency. For example, over 80% the general public recognize the ENERGY STAR label and understands its purpose (USEPA, 2014). Today, decision makers involved in the building process, from the design community, the government and the public, understand the value of building design impacting energy and resource efficiency.

There is also a body of work suggesting the financial benefits of green building design impacting human health and performance may exceed the financial benefits of resource efficient design. For example, a report completed for the Massachusetts Technology Collaborative showed the long term financial benefits of human impact can be 2 to 3 times greater than the financial benefits resulting from energy efficiency (Kats, 2003). However, there is no consensus around the value of improved human health and performance. The financial benefits have not been as clearly defined as they have for resource efficiency. In addition, the public is not well informed of how green design impacts their health and performance. As a result, most building standards and government regulations continue to emphasize resource efficiency over indoor environmental quality. A good example of this is the green building rating system Leadership in Energy and Environmental Design (LEED). LEED is the most popular green building certification in the world with more than 72,000 projects in over 150 countries (USGBC, 2015). Figure 1 shows how resource efficiency is given priority over indoor environmental quality in LEED for Schools 2009.

As shown above, there are 44 credits available for resource efficiency and 19 credits available for indoor environmental quality under LEED for Schools 2009. Since only 40 credits are needed for certification it is possible for buildings to earn the green label without significantly impacting the health and performance of occupants. When designers do decide to address indoor environmental quality they must decide with other stakeholders what to incorporate into the design of the building. Without research clearly defining the benefits of improved human health and performance design priorities can be enigmatic.

Figure 1. The structure of LEED for schools version 2009.

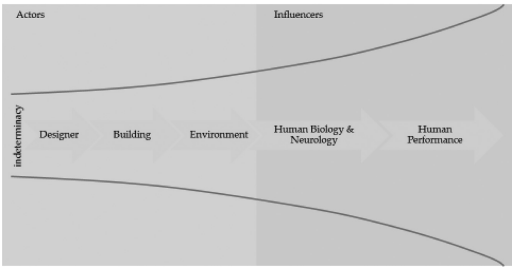

Figure 2. The relationship between designer and human performance.

1.2 *Building design and human performance*

Understanding the impact of design on human performance starts with understanding relationships connecting designers and occupants. While designers talk about designing for human performance the relationship is not a direct one. The designer is an actor and acts on the building. The designer exercises control over the building. The building is also an actor and acts on the built environment. The building exercises control over the built environment. Therefore there is a strong control relationship between the designer and the built environment. Figure 2 illustrates this point.

The built environment is described by qualities such as thermal comfort, lighting and air quality. These are the qualities over which the designer has control. These qualities have been shown to influence human biological and neurological processes which in turn influence human performance.

For example, research has shown there is an optimal temperature range for human productivity in both office and academic environments (Seppänen, 2006; Pepler, 1968). Studies have also shown human performance improves in both office and academic environments as ventilation rates increase (Federspiel, 2004; Wargocki, 2006). Finally, research has shown daylighting improves student performance (Heschong, 1999). Daylighting is the use of natural light to illuminate

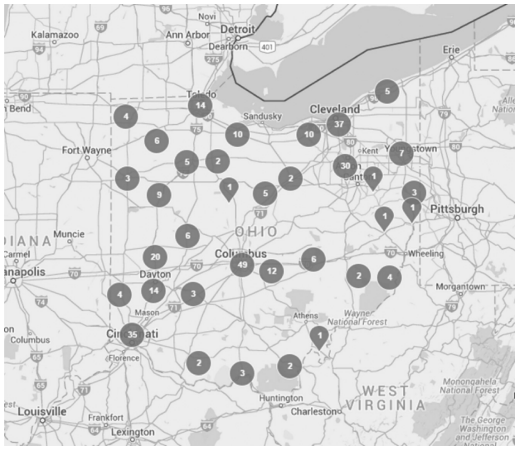

Figure 3. Map of Ohio's green schools courtesy of the green building information gateway (2016).

spaces within a building. The relationships between these qualities of the built environment and influencers of human performance are not strong control relationships. It is difficult to precisely quantify the impact of design on human performance because indeterminacy increases in influencer relationships. However, it may be possible to establish significance or priority among indoor environmental qualities that influence performance.

1.3 *Ohio's Green Schools*

Ohio is a unique and ideal place to study the impact of green building design on human performance. A bit of history helps explain why. Ohio was one of the first states to encourage green design with legislation. The Ohio EnergySmart Schools program was enacted under Governor George Voinovich in 1999 and its structure closely resembled that of LEED, the newly developed green building rating system from the USGBC (Ohio Energy Project, 2000). Ohio's program emphasized resource efficient design because policy makers were looking for an economical, long term solution to the state's infrastructure problems. At the time, Ohio's schools were ranked 48th in the nation for indoor environmental quality and last in overall structural condition (Ohio Energy Project, 2000).

Over the next decade, improving educational infrastructure remained a priority in Ohio and policy makers developed close relationships with the USGBC. In 2007, the state launched the Ohio Green Schools Program which required a minimum of LEED Silver certification for all new school projects receiving state funds (OSFC, 2014). The program included a resolution with language specifically prioritizing credits in the energy and atmosphere section of LEED (OSFC, 2014). As a result, there are now over 250 LEED certified schools in Ohio, making it the national leader, but the impact on student performance is unclear. Figure 3 gives the location of Ohio's green schools.

Since school buildings are tools used in service of society they should be designed to meet the needs of people serviced by them. Surveys have shown parents and taxpayers care most about the academic success of schools (Zeehandelaar, et al, 2003). Therefore, the impact of design decisions on student performance needs to be understood. The group of green school buildings in Ohio provides a unique opportunity to study relationships between building design and student performance. In addition to being the largest sample in the country, most of the buildings earned at least a LEED Silver certification. Therefore most schools addressed indoor environmental quality in some way. Also, most of the buildings were designed using LEED for Schools 2007 and 2009 which have nearly identical indoor environmental quality standards. Finally, Ohio makes standardized student performance data for these schools available through the Ohio Department of Education. By bringing the performance data together with design data this study aims to inform green design priorities for future schools.

2 ANALYSIS OF BUILDING DESIGN AND STUDENT PERFORMANCE

2.1 *Developing the statistical model*

Studies have established which qualities of the built environment influence human performance. Other studies have attempted to quantify the magnitude of the impact of individual environmental qualities on human performance. The goal of this study was to use statistical analysis to identify significance or priority among the design elements influencing human performance.

Since Ohio has chosen to define green schools using LEED it was important to keep the nature of LEED in mind when designing this analysis. Design freedom is a core principle of the LEED program. LEED standards have always been consensus based and voluntary. The relationship between LEED and designers is intended to be symbiotic. Designers make decisions that influence LEED and LEED in turn influences design decisions. The structure of the LEED program (the credit system) can influence design priorities but does not set priorities. Given the variability allowed under LEED for design leading to certification it's possible for buildings to be certified without incorporating various design elements that influence human performance. As shown in Figure 1, these elements are found in the indoor environmental quality sections of LEED. The LEED program also includes prerequisites in some categories. A prerequisite is a design condition that must be met in order to earn certification and therefore is a firm priority. For example, the indoor environmental quality section of LEED for Schools 2009 includes a requirement for minimum indoor air quality performance. However, there are no prerequisites addressing thermal comfort or lighting. In addition to the minimum indoor air quality performance prerequisite, there are 10 voluntary

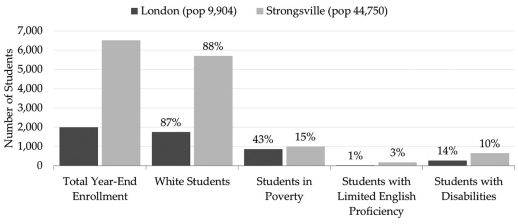

Figure 4. Comparing school district student data 2011.

credits available for indoor air quality. All the credits available for thermal comfort and lighting are voluntary. Therefore, indoor environmental quality may vary significantly from one LEED building to the next. In designing this analysis the goal was to explore these variations in building design. The method developed here was used to correlate differences in academic performance with differences in building design.

There has been one study of human performance in Ohio's LEED certified schools. The preliminary results were presented as a poster at the 2013 USGBC Greenbuild International Expo & Conference. In their study, The Impact of Sustainable Design on Educational Outcomes in Ohio's K-12 Public Schools, Davis and MacGregor compared average student performance for LEED schools and non-LEED schools. They used the performance index (PI) as measured by the Ohio Department of Education to determine average student performance for a group of LEED schools and a group of non-LEED schools. The performance index measures the academic performance of every student in a school using standardized tests. Davis and MacGregor attempted to control for a variety of socioeconomic factors impacting student performance with standardized coefficients. The results were inconclusive but surprisingly suggested that non-LEED schools outperformed LEED schools (Davis, et al, 2013). No further analysis has been published.

It's possible that Davis and MacGregor's use of standardized coefficients to adjust for socioeconomic factors made comparisons of performance from school to school unreliable. Therefore the first step in developing the method for this analysis was to study the socioeconomics at play in Ohio schools districts. Demographic case studies were conducted across the state of Ohio. The demographic data was obtained from the Ohio Department of Education. The case studies included large urban school districts, suburban districts, smaller more rural districts, districts in mid-size cities, wealthy districts and poor districts. The case studies revealed significance variation in socioeconomic factors from school to school. Figures 4 through 6 compare some socioeconomic factors influencing student performance for two Ohio schools.

The example above is typical of results from case studies across the state. After confirming that schools performed differently when there were variations in socioeconomic factors the case studies sought out schools with similar socioeconomic profiles.

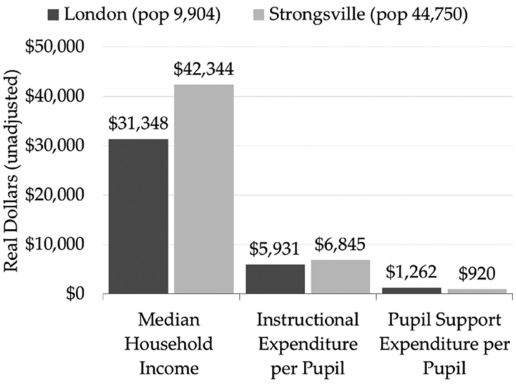

Figure 5. Comparing school district economic data 2011.

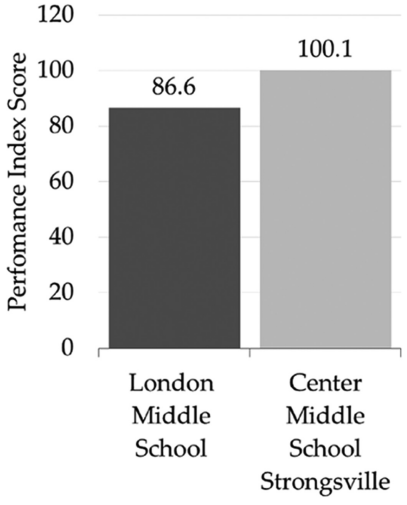

Figure 6. Student performance 2011.

The thought was perhaps schools with similar socioeconomic profiles performed similarly. However, it quickly became clear that groups of schools with similar socioeconomic profiles would be too small to make statistically significant conclusions.

The demographic case studies did reveal an opportunity. A pattern emerged among the case studies which shifted the focus from comparing different schools to studying changes in individual schools over time. In the demographic case studies socioeconomic factors influencing student performance remained fairly constant for an individual school over a short period of time. Figures 7 and 8 present an example to illustrate this point.

As shown in the example above, socioeconomic factors such as median family income, instructional expenditures, enrollment, race and other factors did not change significantly from 2011 to 2014. In other words, the socioeconomic makeup of communities did not change much over a period of only several years. Therefore, when a new school building replaced an

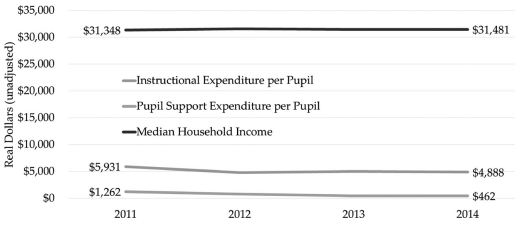

Figure 7. Change in economic data the case of London, Ohio.

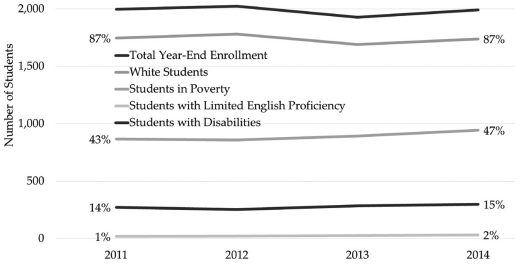

Figure 8. Change in student data the case of London, Ohio.

old building the subsequent short term change in academic performance correlated with the change in the built environment. The method described here controls for socioeconomic factors influencing student performance with boundaries. Instead of comparing academic performance between different schools across socioeconomic boundaries, an individual school was compared to itself.

LEED schools were selected for the study if an old traditional building was replaced with a new LEED certified building servicing the same age groups in the same community. The new buildings had to be certified under LEED for Schools 2007 or LEED for Schools 2009 which have nearly identical Indoor Environmental Quality standards. The resulting sample group included over 150 of Ohio's 250 plus LEED certified schools. Change in performance index was calculated using data from the Ohio Department of Education for each individual school over a period of 4 years (2011–2014). There was no change in the method used by the Ohio Department of Education to determine the performance index in these years. As shown in Figure 9, change was calculated using the slope of the line of best fit with performance index as the dependent variable and time as the independent variable.

The rate of change in performance index (PI points/year) was calculated for 115 of the 150 green schools which met the selection criteria. The schools that were eliminated were excluded due to availability of data from the Ohio Department of Education. Finally, the design data for each school was obtained from the USGBC and paired with the calculated change in academic performance. Table 1 presents the data collected for each school.

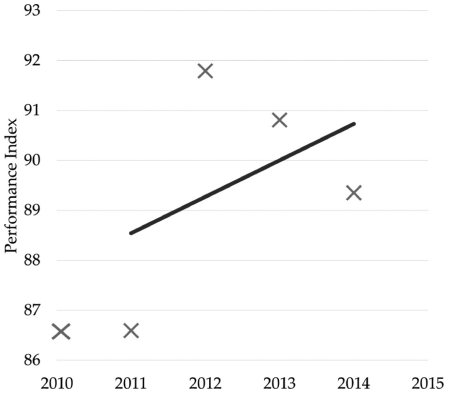

Figure 9. Change in student performance London, Ohio.

Table 1. Examples of data collected for statistical analysis.

School	Louisville elementary	London middle
New Building Type	LEED Gold	LEED Platinum
Occupied	2012	2011
Square Footage	128,778	74,823
Indoor Environmental Quality	12 credit(s)	14 credit(s)
Indoor Air Quality	3 credit(s)	7 credit(s)
Thermal Comfort	3 credit(s)	3 credit(s)
Daylighting	2 credit(s)	1 credit(s)
Performance Index 2011	103.3	86.6
Performance Index 2012	103.9	91.8
Performance Index 2013	104.5	90.8
Performance Index 2014	105.6	89.4
Rate of Change in Student Performance (PI points/yr)	(+) 0.8	(+) 0.7

The data shown in the examples above was available for 115 schools matching the selection criteria. After collecting the data a statistical analysis was completed.

2.2 *Applying the statistical model*

Two primary indoor environmental design typologies emerged from the sample of 115 green schools.

The first design typology (Green Schools Type I) included nondaylit green schools designed to be both highly thermal comfortable and for high indoor air quality. Type I schools were awarded 2 or 3 credits for thermal comfort design and between 5 and 10 credits for indoor air quality design. There were 53 schools of this type. As shown in Figure 10, most of Ohio's green schools were designed to be highly thermally comfortable.

As shown in Figure 11, most of Ohio's green schools were also designed for high indoor air quality.

As shown in Figure 12, most of Ohio's green schools were not designed for daylighting. However, there

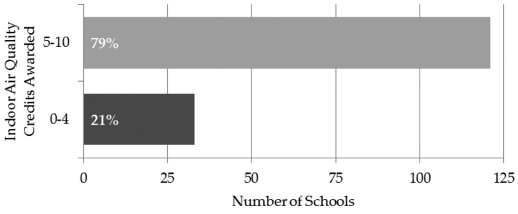

Figure 10. Thermal comfort design in Ohio's LEED schools.

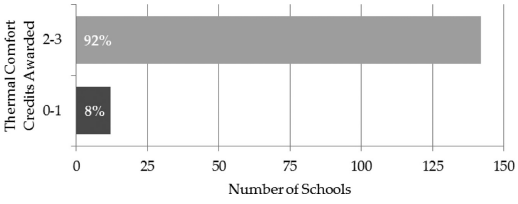

Figure 11. Indoor air quality design in Ohio's LEED schools.

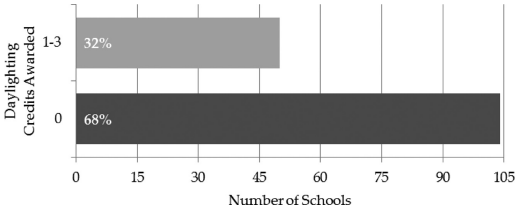

Figure 12. Daylighting design in Ohio's LEED schools.

were enough daylit schools to allow for a meaningful comparison between daylit schools and non-daylit schools.

Therefore, the second design typology (Green Schools Type II) included all daylit green schools. Type II schools were awarded 1 to 3 credits for daylighting design. There were 40 schools of this type. The unique nature of the design priorities at work in Ohio allowed for a statistical analysis focused on daylighting.

An independent sample T-test was used to analyze change in student performance for the two green school design typologies. One of the assumptions of this statistical test is the two groups are unrelated. Unrelated groups do not share defining characteristics. In this study both Type I and Type II schools were LEED certified. Also most of the Type II daylit schools were designed to be highly thermally comfortable and for high indoor air quality like the Type I schools. Therefore, a third group of schools was established as a baseline for comparison. This group included traditional Ohio schools that were not LEED certified. The traditional schools were not designed for daylighting and were not designed to be highly thermally comfortable or for high indoor air quality. Therefore the independent sample T-test could be applied when comparing Type I schools to traditional schools and when comparing Type II schools to traditional schools.

Table 2. T-test for equality of means for traditional schools and green schools type I.

		Equal Variances Assumed	Equal Variances Not Assumed
Levene's Test for Equality of Variances	F	12.711	
	Sig.	0.000	
	t	-0.120	-0.190
	df	3059	56.854
	Sig. (2-tailed)	0.904	0.850
	Mean Difference	-0.053390	-0.053390
	Std. Error Difference	0.443448	0.280737
95% Confidence Interval of the Difference	Lower	-0.922877	-0.615588
	Upper	0.816096	0.508808

Table 3. T-test for equality of means for traditional schools and green schools type II.

		Equal Variances Assumed	Equal Variances Not Assumed
Levene's Test for Equality of Variances	F	10.514	
	Sig.	0.001	
	t	1.042	2.038
	df	3046	43.278
	Sig. (2-tailed)	0.298	0.048
	Mean Difference	0.530781	0.530781
	Std. Error Difference	0.509573	0.260431
95% Confidence Interval of the Difference	Lower	-0.46836	0.00567
	Upper	1.529923	1.055893

The null hypothesis for the first independent T-test was the mean change in student performance for Type I schools was equal to the mean change in student performance for traditional schools. Table 2 presents the results of the test.

According to Levene's test for equality of variance equal variance should not be assumed for this data set. Therefore the significance ρ was 0.850. Since ρ was greater than the standard significance level α ($0.850 > 0.050$) there was not a statistically significant difference in the change in student performance between Type I schools and traditional schools. While the mean change in student performance for Type I schools was slightly higher than the mean change for traditional schools the difference was not great enough to be statistically significant. This means that indoor air quality and thermal comfort did not have a statistically significant impact on student performance over the study period.

The null hypothesis for the second independent T-test was the mean change in student performance for Type II schools was equal to the mean change in student performance for traditional schools. Table 3 presents the results of the test.

Again, according to Levene's test for equality of variance equal variance should not be assumed for this data set. Therefore the significance ρ was 0.048. Since ρ was less than the standard significance level α ($0.048 < 0.050$) there was a statistically significant difference in the change in student performance between Type II schools and traditional schools. This means that the addition of daylighting in Ohio's LEED schools had a statistically significant impact on student performance over the study period.

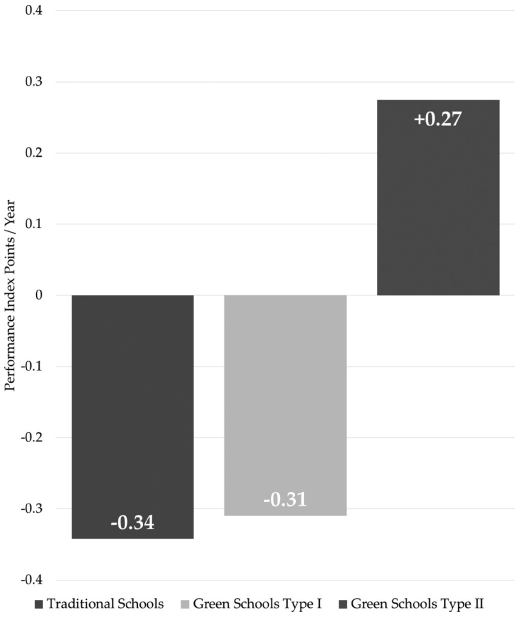

Figure 13. Median change in academic performance.

3 CONCLUSIONS

3.1 *The significance of daylighting*

Figure 13 presents the median change in academic performance for the two green school design typologies as compared to the baseline of change in traditional schools.

As shown in Figure 13, Type I green schools designed to be highly thermally comfortable and for high indoor air quality slightly outperformed traditional schools for the study period (2011–2014). However, this difference was not statistically significant. In other words, the rate of change in student performance between Type I schools and traditional schools was similar. Figure 13 also shows that Type II green schools designed for daylighting outperformed traditional schools for the study period. The difference between daylit schools and traditional schools was 0.61 performance index points per year. The analysis found that this difference was statistically significant. This means the addition of daylighting in Ohio schools has had a significant impact on academic performance. Additionally, daylit schools have outperformed all other green schools.

As shown in Figure 13, academic performance in Ohio's daylit schools improved while performance declined in all other schools. As previously discussed there are many socioeconomic factors that influence student performance. The socioeconomic climate in Ohio over the study period was such that most Ohio

schools were experiencing a decline in student performance. However, the influence of daylighting was significant enough to overcome the net negative influence of other socioeconomic factors.

These results indicate that over the short term daylighting was the leading influencer of academic performance in Ohio's green schools. The results also indicate that the impact of high indoor air quality and thermal comfort design was minimal over the short term. This does not mean that there is not value in high indoor air quality and thermal comfort design. It's possible that there are benefits to academic performance which only manifest over a longer term. It's also possible that high indoor air quality and thermal comfort design has other benefits in the short term, such as improved attendance, which were not addressed by this study. Additional research may answer these questions.

3.2 *Rethinking design priorities*

The results of this study challenge the design priorities at work in Ohio's green schools and beyond. The analysis showed that among indoor environmental quality elements known to impact human performance, daylighting was the leading influencer of academic performance. This is a unique contribution to the growing body of evidence linking improved indoor environmental quality and human performance.

Given the significance of daylighting established in this study it is unfortunate that nearly 70% of Ohio's LEED schools are not daylit. However, the public, the government and the design community all stand to benefit from studying these schools. The lessons learned from studying the performance of existing green schools may inform the design of future schools.

For example, the results of this study may prompt green building programs like LEED to consider modifying indoor environmental quality guidelines. A shown in Figure 1, there are 19 indoor environmental quality credits in LEED for Schools 2009. Of the 19 credits available, 13 are for indoor air quality and thermal comfort, 3 are for daylighting and 3 are for other items (USGBC, 2008). Currently, there are no prerequisite items in any version of LEED related to daylighting. Restructuring design guidelines may help decision makers understand the significance of daylighting.

More importantly, studies like this one prompt further research and discussion of green design priorities in schools. This is especially important in the United States right now where educational infrastructure has a D+ rating (ASCE, 2013). The American Society of Civil Engineers (ASCE) estimates that $3.6 trillion dollars is needed to overhaul educational infrastructure before 2020 (ASCE, 2013). Figure 14 presents the investment needed state by state in relation to Ohio.

There will be thousands of new schools constructed across the United States over the next decade. How many of these school buildings will be designed to improve student performance? How many will perform as designed? Coherent design priorities will help maximize America's return on future investments in green schools.

S. Song
Korea Institute of Civil Engineering and Building Technology, Gyunggi-Do, Republic of Korea

ABSTRACT: Building practitioners work diligently to develop more energy efficient buildings while not compromising human comfort. Building Automation System (BAS) has gained popularity as one of the key information sources for building Commissioning (Cx) and Performance measurement and verification (PM&V), which are typical practices for energy efficiency improvements. However, the BAS installed in buildings itself cannot estimate performance level relative to the design intent. It does not inform the building manager of how much energy could be saved from implementing Energy Efficiency Measures (EEMs) after the Cx processes either. This paper presents a framework of integrating Cx and PM&V with BAS and Energy Management & Control System (EMCS) in existing commercial buildings. This framework has been conceptualized based on the Cx and International Performance Measurement & Verification Protocol (IPMVP) Option-C and D. The framework was tested in a case study using a building located in the Research Triangle Park (RTP), North Carolina. The proposed framework takes advantage of both simulation modeling and regression analysis in its process to provide the information about potential energy savings and energy efficiency improvements in buildings.

1 INTRODUCTION

1.1 *Background*

The topic of high performance buildings has gained popularity along with energy efficiency, green buildings, and sustainable buildings. In this regard, building practitioners are persistently trying to develop more energy efficient buildings while maintaining and/or improving the human comfort to achieve the Architecture 2030, 2025 Commercial Buildings Initiative, and the Net-Zero Commercial Building goals. However, building energy systems often represent more (about 20%) energy consumption than they were expected compared to the building design intent.

According to the Bailey et al. (2011), HVAC systems, mainly air distribution systems, and common control systems are the main sources of flaw in the building. Although identifying the specific sources and root causes of energy waste in particular buildings can be challenging, but it is possible to achieve more than 20% of energy savings by conducting existing building commissioning (Mills, 2010). Therefore, most of the buildings go through the commissioning processes during their life to maintain the high building performance level.

According to ASHRAE guideline for the commissioning process, Cx is a precise documentation process whose purpose is to ensure that building systems are designed, installed, and functionally tested, and that they are able to be maintained and operated for performance that is in line with design intent (ASHRAE 2005). Through a wide range of research in the scope of building commissioning, several different terms have been created to describe the time and process of commissioning such as Re-Cx, retro-Cx, existing building Cx, new building Cx, continuous Cx, ongoing Cx, and persistence Cx. After and during the Cx process, some building owners or managers invest in implementing the suggested EEMs in the building, and they want to know how much they have saved and how long their savings will last. The determination of energy savings requires both accurate measurement and replicable methodology, known as Measurement and Verification (M&V) protocol (IPMVP 2001).

Nowadays, traditional PM&V approaches can also be too complicated or expensive. Building managers desire to reduce time, cost, and complexity of PM&V. Moreover, access to data via smart meters, devices, and analytics tools has been increased and building managers are showing more interests in multi-measure whole-building programs that can generate deeper savings (Granderson et al. 2015).

In general, the Cx and PM&V process requires hiring Cx engineers and takes a long time and hard work to achieve, verify, and document the performance of facilities, systems, and assemblies in buildings.

It is also an expensive process which should be repeated several times during the building life cycle. A critical obstacle in the Cx process is the lack of data or information at sufficient detail due to lack of measurement systems or difficulty in acquiring such data in most of the small and medium size existing commercial buildings. Most of them have not been equipped with required sensors and BAS to isolate abnormal changes in load conditions or irregular operations (Bailey et al. 2011).

Although, a systematic building management system has the potential to save energy by estimated range of 5% to 30% (Pérez-Lombard e al. 2008), but these systems cannot estimate performance reduction relative to the design intent and are not able to inform the building manager of how much energy has been saved by implementing the EEMs in the building after the Cx process (Bailey et al. 2011). Therefore, it is not sufficient to just rely on the BAS in the building.

To avoid the costly Cx process and facilitate the PM&V process after installing the EEMs in the building, a standardized framework, both cost- and time-effective, is required to help building managers identify any change in building performance, recognize type of that fault and make decision how to fix that problem. This framework (Cx and PM&V) integrates the data from existing BASs or installed meters.

This research aims to develop a new Cx and PM&V framework, which can maintain or improve the energy performance level of buildings. This new advanced framework utilizes the building data (BAS database, utility bills, and installed meters data) to detect and recommend ways to fix the problems with minimal human interventions. This framework is intended to significantly improve the efficiency of both Cx and PM&V processes for continuous energy savings through the life of small and medium size existing commercial buildings with minimal costs. The previously mentioned framework uses some key parameters (among thousands of data points in BAS) which affects the building energy performance the most to achieve higher energy savings.

This conceptual framework is intended to serve as a support or guide for the development of Mini-Building Energy Management System (Mini-BEMS) that expands this framework into something useful. Mini-BEMS is the name of the tool that will be developed over the Cx and PM&V framework. The tool is called Mini-BEMS since some key factors have been selected among a pool of parameter and building data to analyze and control the building performance.

The framework integrates the Cx process and IPMVP Option C and D. It uses building simulation and machine learning techniques to calculate and predict the building energy consumption and savings after implementing EEMs. This framework uses the EnergyPlus reference model (calibrated building model) which is built based on the building description, geometry and materials, internal heat gains, schedules, and characteristics of building's HVAC system. This framework enables building energy managers to compare alternative corrective actions using whole building metrics after detecting the faults, and finally to validate enhanced performance when corrective actions and required Energy Efficiency Measures (EEMs) have been implemented.

The anomaly detection, building energy savings, and performance will be visualized in a graphical user interface to facilitate the building management process.

1.2 *Precedence*

There are several researches conducted in the scope of automated and real-time commissioning to develop tools and methodologies to address the complex problem of building energy performance management and to help reduce the energy waste in buildings with various approaches.

A new integrated toolkit which is using building performance objectives has been developed by Costa et al. (2013). This tool allows building manager defines new key factors such as temperature set points or lighting level set points for any different operation strategy and runs the simulation again. The comparison between previous results of the calibrated base case building with the results of the building with different key factors enables the manager to evaluate the thermal comfort and energy consumption of the building. One more tool has been introduced by Bynum et al. (2012), in the study conducted by Energy System Laboratory (ESL) at Texas A&M. The Automated Building Commissioning Analysis Tool (ABCAT) is a prototype fault detection and diagnostic tool which is tailored for Cx services in order to extend the benefits of Cx and to aid in reducing excess energy consumption in buildings. Two of the previous Fault Detection and Diagnosis (FDD) tools are Performance and Continuous Re-Commissioning Analysis Tool (PACRAT) by Facility Dynamic Engineering, and The Whole Building Diagnostician (WBD) which is guided by Pacific Northwest National Laboratory (PNNL).

Similar to previous literatures, Automated Building Commissioning Analysis Tool (ABCAT) also utilizes a calibrated mathematical model to predict energy consumption for given weather conditions. ABCAT is a Microsoft Excel based tool that uses three different sensors to get its required data, whole building electricity, whole building heating, and whole building cooling. The predicted energy consumption is compared to the measured consumption, and faults are detected based on statistically significant deviations between the two data sets (Bynum et al. 2012).

Automated Measurement and Verification (M&V) 2.0 module, recently developed by LBNL is beginning to be introduced to the energy management and information systems. Baselines (building energy consumption profile) are atomically created using historic interval meter data (machine learning techniques) and weather data feeds. User enters the date of EEM implementation and savings will atomically be calculated (Granderson et al. 2015).

Some of these researches only focus on the Cx part, and some of them are concentrated on the measurement and verification part after adding EEMs to the building. Most of the tools mentioned above use a mathematical calibrated model (using machine learning techniques) as a baseline model to predict energy consumption and compare it to the measured consumption to detect the faults based on statistically significant deviations between the two data sets. This approach is similar to IPMVP Option C. According to IPMVP Vol. 1, Option C is using modeling technologies such as regression modeling and inverse modeling for the baseline development. The option-C process requires several steps such as pre-retrofit data process, post-retrofit data analysis, and data quality control procedure. IPMVP Option D is using computer simulation software to predict facility energy use for one or both of the energy use term(s). Simulation model must be "calibrated" so that it predicts an energy use and demands pattern that reasonably matches with the actual utility consumption and demand data from the real building. Option D is not considered a popular technique, since accurate computer modeling and calibration to measured data are the major challenges associated with option-D. To control the costs of this method while maintaining reasonable accuracy, the simulation analysis needs to be conducted by trained personnel who are experienced with the particular software and calibration techniques. Therefore, there is not many Cx and PM&V tools to use the IPMVP Option D approach.

The Cx and PM&V framework in this study (Mini-BEMS) has been conceptualized based on the Cx and IPMVP option C and D. This framework takes advantages of both approaches to facilitate the process of Cx and PM&V.

2 CX AND PM&V FRAMEWORK

2.1 *Framework structure*

Figure 1 illustrates the framework structure and data flow. The Cx and PM&V framework (Mini-BEMS) includes three main subdivisions.

- BEM development and calibration process using EnergyPlus (IPMVP Option D).
- Building energy consumption profile development (IPMVP Option C)
- Energy Savings calculation

These three phases are explained more in detail by using a case study building for better understanding.

The case study building is located at the Research Triangle Park (RTP) area in North Carolina. According to climatic analysis, this area is a humid subtropical climate.

Advanced metering at the facility, including submetering for electrical and water use helps building facility managers identify and fix any power drains and water leaks. This feature of case study building also facilitate the process of this research since the advance metering system installed in the building provide us with enough data to use for the calibration and commissioning purpose.

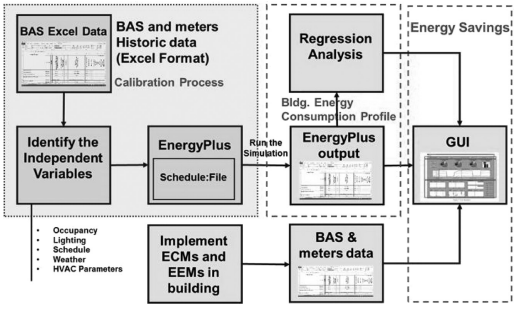

Figure 1. Cx and PM&V Framework (Mini-BEMS) data flow.

3 BEM DEVELOPMENT AND CALIBRATION PROCESS

3.1 *Geometry and HVAC modeling*

The case study building (Fig. 2) is an office building with varying types of office occupancy built in 2014. The building has three occupied floors and a floor space of 4,273 m^2 (46,000 ft^2). The building has rooms of many different purposes being served with two types of HVAC system. The heating and cooling are provided by Air Handling Units through VAV boxes for each zone. Three zones are being served by split systems for heating and cooling. This building also is equipped with an Energy Recovery Unit (ERU). The energy recovery process is the process of exchanging the energy contained in normally exhausted building or space air and using it to treat (precondition) the incoming outdoor ventilation air in residential and commercial HVAC systems.

The case study building has been modeled using SketchUp and OpenStudio plugin based on each floor's HVAC zoning diagram. In the next step, the geometry file has been imported into the EnergyPlus tool to add the internal heat gains (people, light, and equipment), and HVAC systems to the model and develop the base case model based on the ASHRAE Standard 90.1 2004.

The building is assumed to follow typical office occupancy patterns with peak occupancy occurring from 8 AM to 5 PM weekdays with limited occupancy beginning at 7 AM and extending until 6 PM for janitorial functions. For the medium office, Saturday, Sunday and holiday occupancy are modeled at 10–50% of peak. Schedules for lighting and miscellaneous equipment were matched to occupancy schedules with additional limited usage during unoccupied times. HVAC system schedules were matched to the occupancy schedules, and allowed for earlier startup times

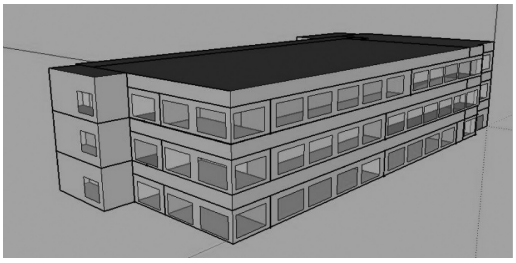

Figure 2. Case study building west Façade.

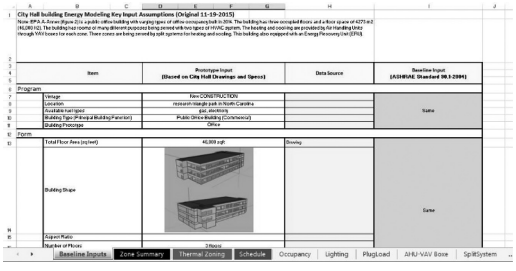

Figure 3. Cx and PM&V framework Excel interface. Geometry and HVAC modeling.

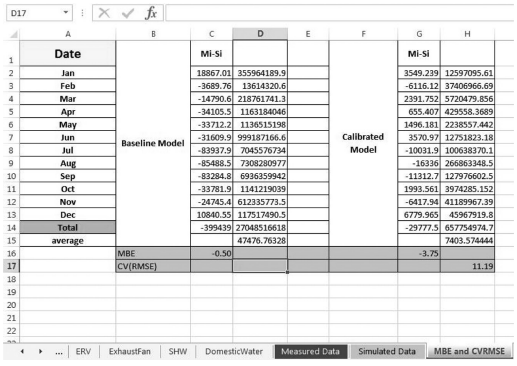

to bring the space to the desired temperature at the beginning of normal occupancy.

The Cx and PM&V framework (Mini-BEMS) is a Microsoft Excel based framework that collects all building information such as baseline inputs, zone summary, thermal zoning, schedule, internal loads, and HVAC systems characteristics in different tabs. Figure 3 shows a screenshot from the first page of the Excel file.

3.2 *Calibration*

Calibration process is divided into two parts. In the first step, the main independent variables have to be identified and modified in the baseline model. For this building, the main independent variables are weather data, envelope characteristics, Lighting/Equipment Power Density (LPD/EPD), lighting/equipment schedule, occupancy schedule and HVAC operation hours.

A manual and iterative calibration approach has been used to calibrate the building model based on the independent variables collected from the case study building. After several iteration between the baseline and calibrated model, the measured data (building energy consumption) obtained from BAS or extra meters are used to calculate the calibration acceptance criterion which are MBE<5% and CVRMSE<15% for monthly data calibration, and MBE<10% and CVRMSE<30% for hourly data calibration, respectively (Lam et al. 2014). This process has been shown in the second sets of tabs in the Cx and PM&V framework Excel file. Figure 4 shows the Excel interface for this phase.

Figure 4. Cx and PM&V framework Excel interface, calibration process.

4 BUILDING ENERGY CONSUMPTION PROFILE

The evaluation of building energy consumption during a specific time interval usually requires building energy profiles (baseline model) on an hourly basis. Building energy profiles can be developed by using the historical monthly electricity bills in buildings without BAS (similar to most of the automated Cx tools that were mentioned before) or by using the BAS data stored in an Excel file in buildings with advanced BASs. However, a serious challenge is the lack of sufficient data due to lack of measurement systems or difficulty in acquiring such data in small or medium size office buildings. Most of the buildings have not been equipped with required sensors and BAS to observe the hourly key factors to develop the building energy profile (Bailey et al. 2011).

Now this question may come up that why has calibrated building energy model been added to this framework to obtain the building energy profile. The Cx and PM&V framework has to be applicable among general building types rather than buildings with unique function. This feature enhances the applicability and popularity of the framework among building owners/managers in the future. Among different commercial building types, office buildings in different sizes make up the major building stock. According to Commercial Building Energy Consumption Survey (CBECS), the majority of office buildings consist of small and medium size offices (1,000 to 5,000 sq-ft for a small size office, 5,000 to 50,000 sq-ft) that are rarely equipped with BAS. Using this framework in such buildings will be more cost effective and appropriate for the building owner than an expensive complete package of BAS.

Therefore, after calculating the MBE and CVRMSE for monthly data calibration, now it is time to use the calibrated model to develop the building energy consumption profile on an hourly basis. The calibrated EnergyPlus model has this ability to provide the hourly required outputs or key factors that may affect the building energy consumption the most, to generate the

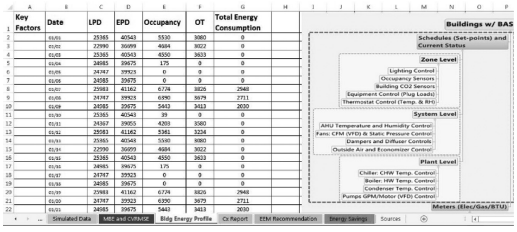

Figure 5. Cx and PM&V framework Excel interface. Key factors and building energy profile.

building energy profile without using and installing extra sensors and meters in the building.

According to Fumo et al. (2010) weather data can play an important role on predicting energy consumption in buildings. Parameters such as solar radiation, air velocity, and dry-bulb temperature are the most important factors on energy consumption since they have the most deviation during the day. However, there are other key factors that may affect the building energy consumption profile. Those key factors can be different for each case study building based on its location, type, and characteristics.

Therefore, the building energy profile in Cx and PM&V framework (Mini-BEMS) is a multivariable regression model based on the outputs from the calibrated EnergyPlus model. In this study, the number of occupants and LPD/EPD are selected as the main key factors. Weather parameters already are considered in the calibrated model for the specific interval (year 2015).

5 ENERGY SAVINGS CALCULATION

5.1 *Cx report*

As mentioned before, the Cx process requires hiring Cx engineers and takes a long time and hard work to achieve, verify, and document the performance of facilities, systems, and assemblies in the building. Existing building Cx is an expensive process which has to be repeated several time during the building life cycle and may or may not bring the building to its original design intent (Hensen & Lamberts 2012). The Cx and PM&V framework aims to turn the traditional Cx process to an ongoing process which optimizes energy use. This framework (Mini-BEMS) will be embedded in the existing Energy Management and Control System (EMCS). In case of small and medium size office buildings which are not equipped with advanced EMCSs or several meters, this framework will be added to the building management interface and serves as an alarm any time consumption deviates beyond the limits.

This framework utilizes the building energy consumption profiles (linear regression or multivariate regression model) for each specified key factor (outdoor air temperature, LPD/EPD) to compare the predicted building energy consumption with the measured building energy consumption (utility bills data) for a specific time interval. If the comparison shows a deviation in building energy consumption which is beyond the limit, it indicates an anomalous event. Based on the owner's determination, several meters can be installed in the building rather than using utility bills to repeat this process for the HVAC components such as AHU, chillers and hot water system.

The building energy consumption deviation from the design intent is evaluated based on the statistical methods which rely on the assumption that the characteristics of the data variations are relatively unchanged unless a fault occurs in the system. This implies that the mean and variance, at a particular operating point are repeatable, even though the individual values may show significant fluctuations. This repeatability allows thresholds for certain measures that indicate anomalous operation to be determined automatically. This is the core of the fundamental standard used in the Cx phase of this framework.

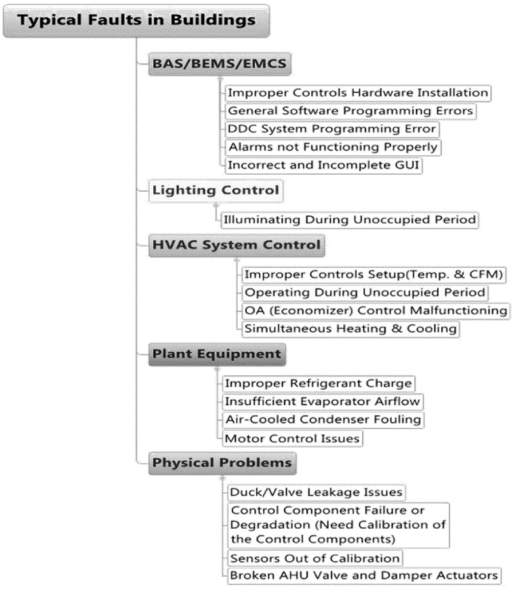
The anomaly score is computed when the system is in operation and building manager requests to observe the building performance for a specific time interval.

In case of having several meters in the building, this process will be completed for each component. Therefore, it is easier to assess each component in order to detect the fault's origin. But if there is just utility bills or whole building electricity meter available, this framework will provide building manager with several common problems/faults in commercial buildings which being summarized of a rigorous literature review and interviews with Cx engineers at NCSU campus. Figure 6 shows the main typical faults in commercial buildings. However, there are two groups, BAS problems and physical problems which are different than other groups. The physical problems are not related to the data points extracted from the BAS. Also, the BAS systems have their own issues such as improper installations and the program itself malfunctioning.

5.2 *EEM recommendation*

This framework integrates Cx and IPMVP Option C and D processes. It uses the calibrated building simulation model to calculate and predict the intended building energy consumption (design intent) and savings. The Cx and PM&V framework enables building energy managers to compare alternative corrective actions after detecting the faults, and finally to validate enhanced performance when corrective actions and required EEMs have been implemented.

In the last phase of this framework, building energy manager is being provided with a list of different EEMs which can be used in the existing office building after the Cx process. The EEMs list which is added to this framework has previously gathered from different sources such as AEDG-2004-2006-2008, ASHRAE 90.1–2010, and High performance building database (HPBD). Building manager selects a proper EEM from



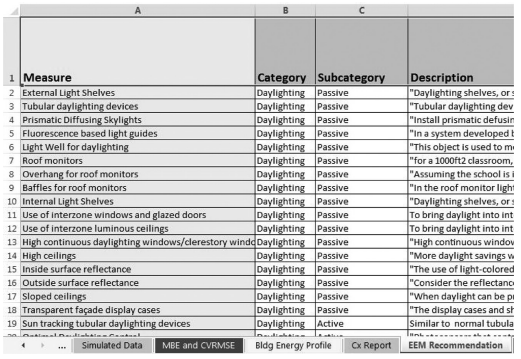


Figure 6. Typical faults in commercial buildings.

the list of EEMs to implement in the existing building according to building size, shape, age and the owner' budget. The future research will focus on the techniques (partly atomization methods by categorizing the EEMs) to facilitate the decision making process for the building manager. Figure 7 shows the Cx and PM&V framework Excel interface for the Cx report and EEMs Recommendation section.

5.3 *Final energy savings results*

According to IPMVP, Option C uses the utility meters or whole building sub-meters to assess the energy performance of a total building. Option C assesses the impact of any type of EEM, but not individually if more than one is applied to an energy meter (IPMVP, 2001). Based on this explanation, the savings are calculated from the subtraction of predicted building energy consumption (using the building energy consumption profile) from measured building energy consumption (using utility bills or meter data) after Cx process and implementing the desired EEMs to the building for a specific time interval (it may be a week or a month).

The Cx and PM&V framework has this ability to develop and use the building energy consumption profile (Baseline) by using IPMVP Option D techniques such as simulation modeling and calibration process, and regression methods. Therefore, it is the building manager's role to collect the measured data for a specific time interval after Cx and implementing EEMs, insert them to the framework' Excel interface and let the framework to calculate the final amount of energy savings.

Figure 7. Cx and PM&V framework Excel interface. Cx report and EEMs Recommendation.

6 RESULTS AND DISCUSSION

The Cx and PM&V framework can be used for new and existing buildings. In case of using it for a newly constructed building, the result may not show a significant deviation from the design intent. The case study building was built in 2014 and the measured building electricity consumption for 2015 show a relatively good match with the building energy profile. In this situation, this framework is very useful in predicting the heating and cooling performance of the building. Moreover, this framework can be used to test any new control code in the building and its energy impact before implementation.

It is always a challenging task to develop an acceptable and reasonable building energy profile (baseline model) for the energy savings calculation. However, the Cx and PM&V framework facilitates the process by decomposing it to several sections. Adding this framework (Mini-BEMS) to the EMCS will be able to enhance the building management role and bring the ongoing commissioning to the field. This framework can also be improved or manipulated based on the owner's need and applied as an advanced tool by having the capability of assessing the real-time data points from BAS and weather data.

7 CONCLUSION

This paper introduced a new Cx and PM&V framework, which has capabilities to continuously maintain and/or improve the energy performance level of buildings during the entire building life with minimal costs associated with operation and maintenance. A systematic approach for the development of the framework and its application was presented. The ultimate goal of this research was to achieve energy savings in buildings through smart building management system.

The framework consists of key parameters and key data points from BAS and EMCS that mainly affect the building energy performance the most. As a result, it focuses on energy related issues for maximum energy

savings in the buildings. The Mini-BEMS concept was introduced to include the intended functions of Cx and PM&V. The potential benefits of Mini-BEMS were also addressed.

ACKNOWLEDGMENT

This study was funded both by the key R&D project (No. 20160116-001) of Korea Institute of Civil Engineering and Building Technology (KICT) and the project No. (1202) 2016-2650 of North Carolina State University.

ABSTRACT: Like similar revolutions transpiring in science, engineering, and industry, the future of building design will be driven by the power of structured data and the development of new computational tools, frameworks, and methodologies capable of bringing heterogeneous design data and information together in order to make it more accessible, reliable, and effective in modern practice. And like these associated disciplines, leveraging the full body of data, knowledge, and expertise in our discipline – including that which is already embedded in the built environment – will require new structures to propagate critical cross-disciplinary virtual communities and collaborative networks, new tools to facilitate the use, reuse, and sharing of knowledge, and new platforms to grow and sustain new networks of information. Authors will describe current research efforts to advance building design in the Post-Digital Era, specifically: multi-criteria decision support tools and web-based strategies to streamline the creation and discovery of building information and design data.

1 INTRODUCTION

1.1 *Motivations and background*

The advent of ubiquitous information catalyzed by the development of the World Wide Web (WWW) and by extension the Semantic Web (Hendler & Berners-Lee 2010) has transformed the way humans work, socialize, and interpret the world. As a consequence, humans are becoming increasingly dependent on data in nearly every aspect of life. Practically speaking, this immense influx of data and information, coupled with the rapid rate of change in all disciplines, means that it is getting more and more difficult to synthesize and apply the state-of-the-art knowledge in one's own field, in closely allied fields, and even in one's own sub-disciplines. Indeed, Design Knowledge and Practice are more distributed now than ever, due in large part to vast amounts of heterogeneous data related to the design, construction, and ecological impact of the built environment that span the currently incompatible levels of open access, proprietary, and other types of special interest databases.

Meanwhile, new knowledge in allied fields and disciplines is influencing architecture in major and conceivably unprecedented ways, i.e., in digital technology and material science; in energy production and consumption by buildings; and systems innovation.

Consistent with past revolutions in discovery (Hey Tansley, & Tolle 2009), technology is once again transforming the way disciplines observe and describe the world, generate new knowledge, communicate with one another, and ultimately make impactful decisions. The instruments that are used to support design-learning and advance both the scholarship of design and the physical execution of design have evolved far beyond traditional modes. Society, at large, produces and digests information by vastly different mechanisms than just 50 years ago.

1.2 *What does this mean for architecture?*

Whereas the greatest shifts in general discovery were previously achieved by innovation in empirical and theoretical models and later, by harnessing the power of advanced computational modelling (Hey Tansley, & Tolle 2009), the new paradigm for discovery in this era – that is the post-digital era and the era of "Big Data" – will be marked by newfound abilities to access and consider large amounts of disassociated data in order to make discoveries that would not be possible in a single view of the data or from a single data set. The future of discovery in our discipline, as in others, is in the development of new tools, frameworks, and methodologies capable of bringing design data and information currently compartmentalized across areas of expertise, databases, and sources back together, in order to make the data and information more accessible, reliable, and useful in building design, construction, and operation.

Gaining access to building design data and related information presents new challenges as well as a myriad of timely opportunities that will influence the future conception and execution of the built environment, particularly as concern over the impact of the

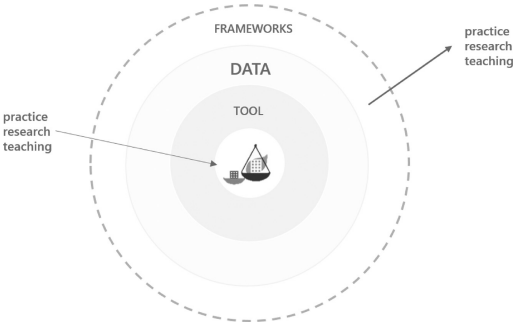

Figure 1. Integrating data into the design process.

built environment on the natural environment continues to grow. When up to 90% of a building's lifetime energy use potential can be determined in the earliest stages of the design process (Keolien, Menery & Curran 1993), expanded access to reliable and useful data is essential.

The first step is to add structure to the data with formal, machine readable, conceptual models (Janowicz, Harmelen, Hendler, & Hitzler 2014), capable of facilitating more complex decision-support (Ishizaka & Nemery 2013) for architects. In order to guide the design of impact-aware buildings, methods and tools must, at minimum, be capable of assessing up-front energy costs alongside operating energy costs, repair and replacement life-cycle costs, and potential repair or replacement costs related to hazard mitigation or loss. However, current tools are not yet capable of generating this full picture – or rather, the data that is needed to achieve this type of robust, holistic analysis is not in a format that is well structured, reliable, or readily accessible.

These circumstances are changing, in light of the sheer quantity of building-related information that exists in digitally fabricated design documents, material and manufacturer databases, and even the "experiential data" in the minds of the design professionals. These developments mean that distinctly new tools and methods are needed to facilitate the use, reuse, and sharing of design data and knowledge (Gruber 1995) over distributed localities and processing components. However, in order for data to effectively influence – or inform – the design process, mechanisms that are capable of harnessing data effectively must be developed and then overlaid by frameworks capable of integrating data into the design process (Fig. 1).

2 METHODOLOGY

2.1 *Background*

Recognizing the need for enhanced tools and methods capable of weighing the broader ecological impacts of building design decisions from the outset of design is essential if the goal is to achieve the greatest possible influence over design outcome. Enhanced decision-support by these computational tools will be enabled by harnessing building design data and information in new and powerful ways. The GreenScale Research Project (The Green Scale 2014), an interdisciplinary team with expertise in architecture, computer science, and knowledge engineering, has been working along three related workflows: the development of a new multi-criteria design tool called the GreenScale Tool, theory plus use-case based approaches for Linked Open Data (LOD) methodologies that are beneficial for generating the data structures and translations required, and the creation of modern computational architecture infrastructures capable of intelligent processing in our world of distributed data processing for Decision Support System consumption.

Simultaneously, our work considers other non-trivial challenges surrounding ubiquitous data in the age of data-driven design. For example, we strive to answer questions including:

- Beyond harnessing the data itself in a structured manner, what are the threats to authorship and intellectual property?
- What are the barriers to reliable, validated data, both computational and psychological?
- What are the opportunities within these same challenges?
- How might the built world adapt to reflect our data-driven society?
- And how might unprecedented – or unfettered – access to building information and design data change the process of design, the practice of architecture, & pedagogy?

Our research commenced with a study and rigorous testing of existing analysis methods and tools in 2009. This study revealed the short-comings of many current design analysis and support tools in the face of a Big Data driven world, and meanwhile inspired the development of a novel tool and analytical data models that we discovered to be essential for advancing the testing and validation of existing tools (discussed in detail in the following section). Development of the novel tool also enabled the research of methods for expanded data discovery by tools and the development of novel strategies for achieving enhanced decision-support beyond what is currently possible with the tools tested and most-widely used in AEC (Ferguson, Buccellato, Vardeman II 2015). The tool we created, the GreenScale Tool (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016), underwent thorough testing and validation, which led to the realization and subsequent hypothesis: prevailing tools and methods are only one part of a much larger set of challenges for our built environment. We believe that data is, in fact, the more critical – and non-trivial – barrier to achieving higher resolution and reliability in building performance and impact analysis simulations.

In response, in 2013, the research team launched the Sustainability Data Initiative which brought together experts across the academic, industrial, governmental,

and technology research domains to discuss the challenge of data and information related to the construction of buildings and cities, and to find opportunities to leverage existing knowledge, tools, technologies, and data to overcome the status quo. These conversations led to a series of workshop events (Geospatial Semantics Workshop and GeoVoCampDC, 2013 and GeoVoCamp, 2014) sponsored by the Spatial Ontology Community of Practice – or SOCoP (SOCoP 2013) – a community of spatial knowledge experts who develop spatial ontologies (Ontology Design Patterns.org 2010) or data pattern languages for use on the semantic web (Berners-Lee, Hendler, & Lassila 2001). The initial workshop (GeoVoCamp, 2013) was held at the National Science Foundation and lead to sustained collaborations with experts in semantic web frameworks and decision theory focused on finding practical ways to structure building design information and data and advance frameworks capable of bringing the data back to the user in new and more meaningful ways.

2.2 *A study of tools and methods*

Prevailing computational tools available to and used by architecture and engineering professionals purport to gather and present thorough and accurate perspectives of the environmental impacts associated with their contributions to the built environment. Research of building modeling and analysis software used by the Architecture, Engineering, Construction, and Operations (AECO) industry reveals that many of the most heavily relied-upon industry tools are isolated in functionality, utilize incomplete models and data, and are, in fact, disruptive to normative design and building optimization workflows (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016).

At the outset of this research and as mentioned above, a study of current architectural design tools revealed large gaps in the capabilities to advance the design and execution of both data-aware and impact-intelligent buildings. A review of primary functions and limitations of prevailing tools (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016) led to a series of case studies to further evaluate the current state-of-the-art in tools and building energy analysis, followed by the development of more advanced models (Ferguson, Vardeman II, Buccellato 2015) to assess, among various factors, lifetime building energy consumption alongside operating energy use. The novel GreenScale Tool was developed in response to the functional comparison of tools and the need for this specific functionality. The fundamental goals of this particular effort, as well as some of the goals of our research, in general, are to a) better understand the efficacy of tools used by architects and engineers to influence the design process and b) to increase the use and efficacy of building impact studies conducted during the building design process.

An analysis of the current state of AECO modeling and analysis platforms (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016) revealed a number of tools that endeavor to process one type of energy analysis or another, whereas they either have limited – or no – capacity to evaluate material variations against overall building energy impact, including pre-construction material energy costs. Additionally, many of the tools are not able to operate beyond a narrow set of functions within each application, and are almost always limited to single-metric calculations, meaning that no comparative analysis can be completed without extensive manual intervention. For example, there are individual tools that are able to produce an embodied energy simulation that categorizes total energy summations into specific categories, such as transportation impacts, construction processes, and manufacturing impacts; however, if only one type of analysis is possible, separate analysis is required to anticipate lifetime building energy impact, including operating energy.

Other, distinct tools used frequently in industry can consider isolated metrics like daylighting potential, carbon emission totals, water usage, and ventilation capabilities, conduct performed carbon emission analysis and thermal calculations that include daylight and shadow. However, many of these tools function in a non-iterative manner, making it difficult to meaningfully analyze – or respond to – how changes made during the design process might ultimately influence a building's overall performance. There are also tools, such as SuAT ®, that will separate analyses into distinct categories, such as thermal flux, zoning, and climatology, and while these calculations are important, all are based on thermal calculations, which is what we refer to as single-metric. The multi-metric comparative analysis that we are referring to exists where broader and more disparate types of simulation comparisons can be made and enhanced by decision support. For example, the multi-metric analysis required by the modern industry would be able to take these thermal results and dynamically compare them to embodied energy data types, material shipping information, market costs for parts, and other data sets that are currently not compatible – but need to be.

In addition to these function-based comparisons, several experiments were conducted to gain an understanding of prevailing industry tools' relative strengths and weaknesses, focused in two key areas: capacity for estimating key metrics of building energy use in operation and initial (embodied) energy consumption. To accomplish this, simulations were conducted with a consistent set of architectural models using a select set of prevailing, commercially-available analysis tools (Fig. 2) and a control model, the GreenScale Tool (GST) (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016).

The results of the experiments revealed large differences in calculated results for the same architectural building models. This was due, in part, to differing levels of precision and accuracy in the settings and calculation methods between the tools. Further investigation, including verification by manual calculation methods, revealed that the majority of the numerical

Figure 3. Industry standard tool experiment results.

differences (Fig. 3) resulted from discrepancies originating in the raw data values and the associated material properties that the commercial tools were using to tabulate the results. For example, prevailing analysis tools may use significantly different density values for the same material, yielding significantly different results when aggregated over an entire building. Furthermore, observations of the outputs of these tools (i.e. aggregated energy use totals, for example) demonstrate that building simulation programs used by architects today lack uniform data and processes to facilitate the consistent and reliable evaluation of both customary and novel building practices, meaning that there is a high degree of uncertainty behind the critical decisions that architects are making using these tools. At minimum, this suggests that the decision-support tools that are currently available in the marketplace may vary widely in accuracy.

Specifically, there are differences in numerical values due to rounding and approximation techniques as well as issues with the semantics of the naming system for materials, among other properties, leading to comparisons being a best guess in a lot of cases. For example, certain databases will record material data (assume for pine), but the values can also differ for the exact same pine because of unit translation precision or because they are referring to two different types of the same pine but from different geographical regions that yield slightly different wood due to different soil, rainfall, or mineral availability. As expected, the potential propagation of these differing values can make building simulations vary drastically to say the least.

The study of the existing tools, the results of the experiments conducted with them, and industry case studies allied with these concerns (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016) reveal the following:

- Single-metric analysis tools are not capable of evaluating the full energy impact of a building over its lifespan; a single view of data, or a series of independent views, is less efficient – and potentially less effective – than multi-metric analysis tied to consistent, uniform data sources.
- Whether single or parametric utilities, data and processes that are utilized by prevailing analysis tools are currently non-standard and embody too much uncertainty (in the data sourcing and thus in the outputs). Uncertainty is also not adequately considered in the decision-making process.
- Regardless of the capability of a tool (GST or otherwise), data reliability and consistency is critical to achieve a complete picture of environmental impacts, and ultimately, data is the central factor for advancing the use of simulation in architecture.

3 DATA

3.1 *Confronting the data challenge in architecture*

Gaps in data – whether in provenance, reliability, accuracy, etc. – increase uncertainty in the results handed to the user by the tool and meanwhile contribute to widening gap between intended, simulated, and achieved building performance. In the data-rich disciplines, like the life sciences, or even in more closely-allied disciplines, like engineering, gaps in data are mitigated as these disciplines turn to current computational and Big Data analytics technologies to enable broader access to and reliability of their data. When compared to other disciplines, like automotive and aerospace design, or even closely allied industries, like civil engineering, architecture is currently underutilizing these potentially very powerful technologies; our data remains largely siloed, fragmented across areas of expertise, allied in sub-disciplines, or tied up in proprietary databases.

Our discipline's relatively restricted use of advanced computational models in conjunction with limitations of the data it is currently using, means that decisions are being made by humans considering a smaller, and often skewed, scope of parameters and criteria than could be possible by utilizing Big Data practices and

modern computing power applied to that data. If such methodologies could be harnessed by the building professions – by the architects and engineers who will determine the future of the built environment – we could achieve a much greater understanding and practical ability to affect the way that the built environment is conceived, how resources are consumed or conserved, and the effect of design choices today on the future.

3.2 *Here's how: LOD principles for architecture*

The WWW with which we are all familiar – and dependent upon – has evolved from a network of documents into a Semantic Web of intelligent data that enables access to a volume of information previously unimaginable. However, in order for humans to make sense and proper use of the vast amount of data available on the web, strategies that have been developed to support data interoperability and contextualization need to be fully implemented. Machine-readable data formats based on the web standard Resource Description Framework (RDF) (Resource Description Framework 2014) computationally appropriate data structures (Ontology Design Patterns 2010) can all be enlisted for use in modern Decision Support Systems. However, for this to be successful, we must be able to correctly describe, classify, and relate cross-domain data. The aforementioned formalizations of data enable computations to "understand" human conceptualizations and link – or connect – the data that matters to that conceptualization or specific human effort (like design).

Because ontologies have the capability to capture complex logical relationships, frameworks for promoting data sharing, discovery, and interoperability via the semantic web are being widely adopted, from the scientific research community (Kandil, Hastak, Bridges 2014) to the US government (DATA.GOV 2016) to the private sector (Samwald, Coulet, Huerga & others 2012).

There is significant ongoing research aimed at developing tools and techniques to lower the barrier to adopting semantic technologies, including several on-going efforts in architecture and allied professions to create extensive controlled vocabularies, like the Industry Foundation Classes (IFC) (Building Smart 2014), a commonly-used data model designed to facilitate interoperability within the AEC communities.

In fact, the origin of pattern languages is not remote from architecture. It was Christopher Alexander who first introduced the concept of pattern languages to describe problems and specify potential solutions in his A Pattern Language (Alexander, Ishikawa, & Silverstein), which describes design patterns for architectural design, building, and planning. The goal of Alexander's patterns for architecture is to enable people to describe their own conceptualization of design at different scales: for houses, streets, and cities. Inspired by this work, the software engineering community began to adopt software design patterns that

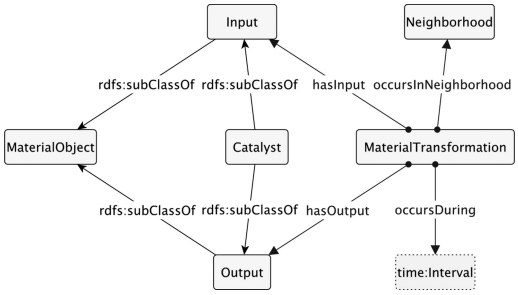

Figure 4. Material transformation pattern data model.

created reusable, successful solutions to commonly-occurring programming problems. (Gamma, Helm, Johnson, Vlissides 1995). Ontology Design Patterns (ODPs) share a similar goal: to enable communities to describe their domain and domain-specific data using (their) natural vocabularies and meanwhile provide additional guidance to the data and formalization of the process.

To this end, our research group recognizes the data challenge in architecture and also the capability of ontology design patterns to tie together these data schema with varying degrees of formal specification in conjunction with existing controlled vocabularies used by the AECO community. Our research team, in collaboration with experts in ontology, developed a formal Material Transformation Pattern (MTP) (Vardeman, Krisnadhi, Cheatham & others 2014) to contextualize necessary data and provide automated reasoning support for Life Cycle Inventory analysis related to construction materials (Janowicz, Krisnadhi, HU & others 2015).

Briefly, the MTP (Fig. 4) "tells" a computer there exists a class of things in the world called a MaterialTransformation that has inputs (hasInput) and has outputs (hasOutput) that these both refer to MaterialObjects. It also tells the computer that a MaterialTransformation has some spatial extent, a Neighborhood, in which the transformation must occur and some specific time interval associated with the transformation. Lastly, we specify a class of MaterialObjects that are necessary for the transformation (manufacturing equipment, tools, etc) and that are necessary for the process to proceed, but are not part of the transformation. These we call Catalyst. Behind these logic classes are a set of machine readable axioms in formal logic, the most interesting of which expresses that a MaterialTransformation has at least one input that is not part of the output and at least one output that is not part of the input, which is the crux of the notion of transformation.

The MTP is designed to work in conjunction with other ontology design patterns, such as the semantic trajectory pattern (Hu, Janowicz, Carral & others 2013) that defines "a path through space on which a moving object travels over time". An example of the most basic use case would be to GPS tag an object as

it traverses some path through space and time resulting in a GPS data output that is a Semantic Trajectory. Such a pattern might also be applied to material supply chains to describe the path that objects take during their life cycle. MTP lets us then describe the situation in the data where one object may stop, be transformed, and continue its journey with a new identity. When a computer detects this situation in the data, it may "infer" that a transformation has occurred.

Other patterns such as "a Minimal Ontology Pattern for Life Cycle Assessment Data" provide a conceptual model for Life Cycle Assessment and Life Cycle Inventory at a higher domain specific level. This pattern can be formally "aligned" against lower level patterns, such as the trajectory and transformation patterns, to give domain practitioners a natural conceptual "view" to consume the data and ask questions of the data.

Assuming that material and material supply chain data were published as Linked Open Data using these design patterns, it is conceivable that machines could automatically discover relationships in data atoms using probabilistic machine learning algorithms, such as the multiway neural network approach that Google (Dong, Gabrilovich, Heitz & others 2014) has developed as part of its Knowledge Vault effort. Methods such as these add new information to a knowledge graph along with the probability that the relationship represented in the graph is a true relationship. This form of algorithm may hold advantages over traditional reasoning algorithms which are strictly coupled to the definitions expressed in mathematical logic.

4 FRAMEWORKS: ALIGNING DATA & TOOLS

4.1 *Rules engine layer*

As indicated by our initial study, many simulation tools in use today perform data analysis on a single design metric, but in the era of Big Data, tools will need the capacity to run efficiently through several metrics simultaneously and over a large quantity of design choices. To reach an optimal level of usefulness and efficacy, modern multi-criteria decision tools must be capable of performing routine calculations efficiently, considering a much broader range of data and information, including, as we propose, data harvested from heterogeneous sources linked to all aspects architectural material manufacturing, construction, and usage.

In response, Green Scale Research aims to discover more efficient methods to both aggregate and process data. This work is further motivated by our understanding that within certain existing simulation tool databases, there is syntactical and semantic ambiguity that is not adequately addressed by the application of regular expressions or even in generating the correct nominal values for material data. By extension, adjustments in energy calculations are often overlooked due to these misinterpretations because of the structural nature of Open Green Building XML-based (gbXML) (Green Building XML 2016) schemas, which are commonly implemented in architectural design tools. Additionally, the capacity of current tools to interpret XML tag-structured data is limited. However, by using the PyKE (Python Knowledge Engine 2016) rules engine, rules can be adaptively constructed to fix these discrepancies and can be extrapolated for use across other rules engines and applications.

PyKE is a knowledge-based inference engine inspired by Prolog11 (Logic Programming 2016) but implemented completely in a programming language, called Python. It is a type of logic programming allowing customized, domain-specific system rules. Incorporating rule sets with existing simulation processes means that there is an extra set of knowledge: in addition to a set of instructions, the model now has an additional set of information describing what those pieces of information mean as well as how to proceed in special cases. It also means that originally missing schema data, imperfections in schema layout, and capturing human-implicit "rules of thumb" can all be resolved computationally instead of manually.

In our own Tool study, we specifically focus on the incorporation of construction material data into a multi-metric application and develop ways to access additional data without harming the performance of a multi-metric application. Next, studies were completed to explore how these methods could communicate beneficially with the larger Semantic Web. One of the avenues of research included developing a PyKE Rules Engine (Ferguson, Vardeman, Buccellato 2015). A rules engine is a part of a computing infrastructure that captures categories of scenarios and the associated set of actions or computations that need to happen when a certain schema instance is encountered.

For example, a rule might be to use the T-by-2T "rule of thumb" for describing spread footings. This piece of knowledge about a building structure is translated into computer code and stored electronically in what is called a Knowledge Base, so that the machine knows how to process something of this category each time certain types of building footings are encountered in computational representations. Layers of computations, such as these, lead to more accurate results than would be generated without knowing the rule(s). The ultimate goal is to seek machine-assisted solutions that will positively impact the way that the built environment is conceived and executed.

For this portion of the study, we implemented the previously developed GS Tool (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016) with sets of rules as they were needed to fill in information that is not explicit in the schema file that is handed to the tool itself. To explore experimental methods of rules communication used for handling the types and quantities of data that we anticipate means that we will need to collectively work toward bridging the gap between our tools, the larger semantic web, and decision support, all

using linked open data principles (Janowicz, Hitzler, Adams & others 2012). The Green Scale (GS) Tool (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016) itself was built to seamlessly integrate with the normative workflow of the architect and to provide a broader perspective of the potential ecological impacts of design decision-making through a multi-criteria, comparative analysis including BEAM thermal heat flux model and Embodied Energy life cycle inventory model (Ferguson, Buccellato, Paolucci, Yu, & Vardeman II 2016).

4.2 *What does the horizon look like*

This above instance of a PyKE implementation builds on the GS Tool by adding a flexible framework for mapping regular expressions to normative conditions and by linking regular expressions to an associated action for several types of architectural design decisions (material choice, geometry discrepancies, and architectural best-practice rules).

However effective, this is only one set of solutions to a much larger problem. These rule sets and tools need to become more accessible and eventually need to be part of a larger cyberinfrastructure that can handle distributed processing. Currently the efforts of the research still function within a closed computational environment often a single machine. Some organizations are beginning to move data stores to cloud-based locations and are providing their tools as a service via the internet. Similarly, the computational components we are researching and developing need to have access to many other elements, such as reasoners, triple stores, and other computational models (The Digital Manufacturing and Design Innovation Institute 2016). Upon further development of a Linked Data Platform (W3C: Linked Data Platform 2015) used for distributed computing, the rules layers we develop, the tools we create, and the resulting knowledge bases generated can all be moved to the Cloud and subsequently enhanced and improved upon by Machine Learning [10]. Additionally, light weight (W3C: SPIN 2015) rules can be integrated with query mechanisms like the web standard (W3C: SPARQL 2015) for generating inference based connections with relevant methods in the expanding knowledge base. Additionally, SPIN could provide mechanisms for data consistency and integrity checks within the knowledge base.

Using a framework such as this, varying architectural perspectives and experience can be leveraged to generate a broader set of accessible and reliable data. Using specific types of interfacing and web services such as REST APIs (Fielding 2000), the accessibility of our data can be expanded and the framework can be made effective for cloud-computing environments. This means that advanced implementations of our research could enable wireless and web-based applications to communicate with other applications and more usefully connect a series of elements, tools, sensors, etc., within the same system or for the same simulation purposes.

5 CONCLUSION

By virtue of the mechanisms that we use to observe and describe the world, generate new knowledge, and communicate with one another, we arguably "know" more than has ever been known to civilization, but consequently – due to this proliferation of information – there is that much more to know. Yet, in many disciplines, like architecture, this abundance of information has made the design and execution of the built world more complicated – not less – and the utilization of design related data and information more challenging, due to the sheer quantity of data, the myriad places where the data "lives", and the limitations of the tools that we depend on to use the data effectively. And this is just the data that already exists. What about the future, and the data that is generated daily, in BIM, in simulations, and by our buildings?

Given the predominant use of digital design and analysis tools in building design today, a building's lifespan now begins in computer simulation. Therefore, the consequences of consistency and reliability – of both the tools and the data – impact the environment from the commencement of the design process throughout each iterative step thereafter, including the selection of materials, the methods of their assembly, and the myriad long-term implications of a building's design on the environment. And yet, without a more efficient way to discover data, we will never become more effective in harnessing it, understanding it, or, perhaps most importantly, in applying the data.

While concerns about the proprietary nature of building design – and by extension, the data "created" in the process of design – will persist, by recognizing the opportunity of utilizing existing Big Data practices along with modern computing power applied to that data, it would be possible, in this post-digital era, to advance beyond the status quo, in tools and in data, to achieve greater understanding about the impact of our design decisions and enhanced practical ability to affect the way that the built environment is conceived and how resources are consumed or conserved.

Refund Brunelleschi: The redefined role of representation for an integrated building process

M. Lo Turco
Department of Architecture and Design (DAD), Politecnico di Torino, Italy

ABSTRACT: A design architect working today may have access to a range of software applications designed for a number of different sectors: this may bring them into contact with the disciplines to which the programmes belong; what at first glance appears to be a technological opportunity fast becomes a professional challenge. But to what degree is it possible to expect architects to step outside their comfort zone and address questions that come from other disciplines? To answer the question, we look at the broader construction process, in particular the separation between the conception stage and design development. At the regard, it is very close to Brunelleschi's design process and the manner of his research, connected with the act of making in concert with others. The thinking will be developed by addressing to topic issues such as the role of the use of digital technologies, arguing about theoretical knowledge and some examples of teaching experiences.

1 INTRODUCTION

"What is really disturbing is not that world could turn into a complete kingdom of technology. Much more disturbing is that men are not prepared at all for such a radical change. Much more disturbing is that we are not capable yet – through mediative thinking- to an adequate deal with what we are really facing in our time"
(Heidegger, 1959)

A design architect working today may have at his disposal a wide range of different software each one designed for a specific sector and this may, as a consequence, may bring into contact with the disciplines to which the software are addressed – e.g. structural analysis, environmental analysis, cost estimating, services installations, structural engineering etc. Young designers in particular may use a whole host of software tools which eases to achieve photorealistic representations with a degree of precision taken from the world of cinema and together encourage the construction of digital models for technical simulation needed to construct a building. So what at first glance appears to be a technological opportunity fast becomes a professional challenge. Architecture, though, if it is to survive, must react to the constraints imposed on it, since the penalty for not doing so is flimsy, insubstantial design and the banal symmetry of pure construction.

But to what degree is it fair or even possible to expect architects to step outside their comfort zone and address questions that, while influencing and interacting with design, come from other disciplines? The recent scenario has shown the development of systems to produce design strictly related to the possibilities offered by digital instruments. They do support the formal expression developing new design paradigms but the proposed organic forms are far from a traditional conception of space.

The major potential of digital instruments lies where technology becomes "transparent" to its own aims. A goal that is sometimes blurred by other kinds of digital simulation, that have very little relationship with the real aim of every project, that is its final construction. Guadet stated: "*Architecture conceives, then studies, then builds. But construction is the final aim of conception and study: we conceive, we study, only to be allowed to build. Construction must be the constant thinking of the architect. It gives him his arsenal of resources and bounds his field of action. Every attempt for architecture that's not built makes no sense; and every form in architecture that breaks or fakes the rules of construction is vicious*" (Guadet, 1984).

2 THE COMPARISON WITH THE MASTER OF THE PAST

In order to better understand the issue, a broader look at the construction process and the actors involved is due, focusing in particular on the separation between the design conception phase and the design development stage, on the relationship between small architectural firms and large multidisciplinary engineering companies, on the role that consultants and specialists employed in the building process have and on their relationship with the figure of the designer which seems to be gradually relegated to a concept designer role.

Referring to the Masters of the past it is interesting to compare the added value provided by new

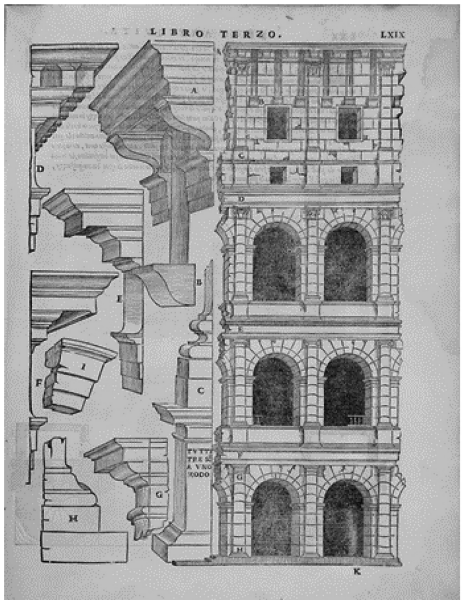

Figure 1. Sebastiano Serlio Bolognese: the cover of the Third Book, which is part of his treatise in Seven Books, seems to be the manifesto of the method used to represent and describe the antiquities of Rome. The method of decomposing and recomposing is completed by particular three-dimensional details related with the assembly drawings. Cover and Table LXIX, on Colosseo orders, drawn by the Venetian edition of 1544.

digital tools (that consent a multidisciplinary design knowledge) and the design process conceived by Filippo Brunelleschi, born of a mind firmly engaged in the totality of building, and Leon Battista Alberti's delight in a more two-dimensional and façade-based architecture deeply rooted in conceptual thinking and writing about beauty, proportion and composition. Brunelleschi's design process and the manner of his research were fundamentally and inextricably connected with the act of making in concert with others. He had technical discourse with tradesmen, held their contracts, sketched with stone masons, had complementary collaborators in Arnolfo di Cambio and Antonio Manetti, and understood that it was not enough to dream something up: the dream itself had to include the methods for its own realization; in his opinion, design and making were indistinguishable. In the same years, Alberti fathered a new lineage of architect –heroic, elevated from the primacy of making, focused on conceptual thinking and concerned with architecture as a system unto itself and with the refinement of its own terms as the central purpose and pursuit of the individual genius of the architectural mind.

It is interesting to compare what nowadays graphical representation is and how it was in the past. It's evident its role of interpreter, and often of protagonist, in activities of analysis, investigation and design of architectural and landscape heritage. It is considered a language aimed to describe, expose thesis, and demonstrate hypotheses.

As known, the three-dimensional space described in the Italian architectural treaties of the fifteenth and sixteenth century[1] is firstly revealed through analytical descriptions, but soon enriched with graphical interpretations that become more and more used by the authors of the texts (not always the same authors of the illustrations) with expressive qualities and very different outcomes depending on the author and the production techniques.

In the various Renaissance treaties, drawings and graphical representations, either more or less sophisticated in the treatment of surfaces and volumes (plans, elevations, sections, perspectives, pseudo axonometries) are the visual means through which static, functional and aesthetic needs are illustrated, issues that are then widely explained in the texts.

3 BRUNELLESCHI'S UPDATED APPROACH

Comparing the past graphical representation processes with the current digital modeling procedures, used today within the design phase, it's evident that behind

[1] Leon Battista Alberti printed his *De re aedificatoria* in 1452 (in 1550, the vernacular version of Cosimo Bartoli), Filarete was the first to draw up a vernacular architectural Treatise, between 1461 and 1464; Francesco di Giorgio Martini in 1480 wrote the *Trattato di architettura civile e militare* Sebastiano Serlio published since 1537 the *I Sette libri dell'architettura*. In 1562 Giacomo Barozzi da Vignola published the *Regola delli cinque ordini dell'architettura*, in 1570 were printed *I quattro libri di architettura* by Andrea Palladio. The lack of illustrations in the original version of the *De re aedificatoria* in ten books of Leon Battista Alberti, written between 1443 and 1452 and printed in 1485, joins this treatise to the *De Architectura* of Vitruvius, but there are more or less over fourteen centuries between these two authors. The Alberti's vision, entrusted to only textual description, will soon be overcome, thanks also to developments in printing techniques.

similar images there is a complete different graphical approach. In the past the three-dimensional representation were considered as the complementarily part of several representations; in recent digital environment, the 3D model is the source from which new drawings are generated.

In the past, as well as today, the architect has been considered an all-round professional, with good design, craft and management skills all together. Thus within the construction process the architect is the person that leads the design, deals with the digital models, manages the administrative issues and follows the construction phase. Nowadays, within this scenario, software applications have not a "linking role" though: each actor have specific software to address its specific purpose and most of the software have their own proprietary formats tending not to facilitate dialogue with other software.

Thus now new professionals, experts in producing rigorous rule-based digital models, are becoming crucial within design and engineering firms in order to introduce process innovations supported by complex software. Such innovations are for the most part deployed on projects with complex forms or architectural configurations and that require dedicated systems of representation and analysis or, at the very least, customizations based on existing standard platforms.

The innovations in question are for the most part deployed on projects involving complex forms or configurations that require dedicated systems of representation and analysis or, at the very least, customizations based on existing standard platforms. In these cases, dialogue between disciplines is a requisite if standard solutions are not being used. A common terrain is required in which interrelation and conflict can take place between the ideal solutions and configurations of each of the various disciplines involved in the construction process. Exchange and conflict always occur and generally lead to unwelcome cost increases or the scaling down and simplification of solutions, but in the case of complex forms they are often absolutely indispensable.

This is what led to the emergence of new professional forms such as the first computational geometry groups created to handle and optimize geometry using high-precision digital modelling, which include the Specialist Modelling Group at Foster & Partners and the Advanced Geometry Unit created at Arup by Cecil Balmond, an engineer famous for his collaborations with architects (including Rem Koolhaas and Toyo Ito to name but a few) in which the engineering aspect is always closely connected to the architectural conception.

In Italy, where authoritative endorsements of the adoption of the new technologies are few and far between, their impact has simply been postponed for a few years. We must therefore wait for a process of emulation to emerge and generate a rapid growth in parametric design products and the requisite shared parametric design culture, which in turn will facilitate the adoption of new forms of work management, employing the sort of collaborative working environments still rarely seen in this country.

At present, in Italy, the acquisition of know-how is still strongly disregarded and having a software it doesn't mean to be able to use it effectively. Time, resources and energy: all need to be invested in training.

In this current period of transition are precious and crucial professional figures that in addition to their specific professional skills are also capable of acting as a point of reference for the adoption of new teamwork organization procedures and strategies.

There is, therefore, an increasingly high demand for new professional figures capable of providing support for short periods of time at design and architectural firms, and delivering advanced level training through the development of one or more pilot projects. This approach enable to transfer the needed know-how through training activities designed to teach how to manage the complexity defining efficient controls over the working methods.

This is the area in which the distinction between professional practice and research is blurred almost unrecognizably: the architects and engineers working for the software houses need to possess technical skills and an understanding of professional practices in order to be able to correctly coordinate the production of new functions. They may also work as consultants, because the software houses provide resources and services to design firms, who advise on the adoption of procedures and technologies.

At a very advanced level, these procedures enable the customization of certain functionalities and the creation of others, meaning that there is a shift in the role of the professional from mere software user to full-blown software developer and into a role which is an embodiment of the work that up until now was done within the computational geometry groups set up in large design and engineering companies.

Because of their interoperability, digital models have the capacity to act as recipients for information related to geometry, the physical characteristics of materials, construction cost estimates, material and component performance evaluations, energy performance analyses, structural behavior, information regarding contracts and tender procedures, and much more besides. The question is therefore what know-how and exercises to present to students and how to present them within the learning environment, that will translate into an improvement in their skills and into the abilities they will need in the professional world of the future.

4 OPEN ITEMS: THE IMPORTANCE OF TRAINING OPPORTUNITIES

It is therefore clear the active role of the academic teaching staff: they must keep themselves abreast of the continuous technological and procedural developments, with particular regard both of the progress in

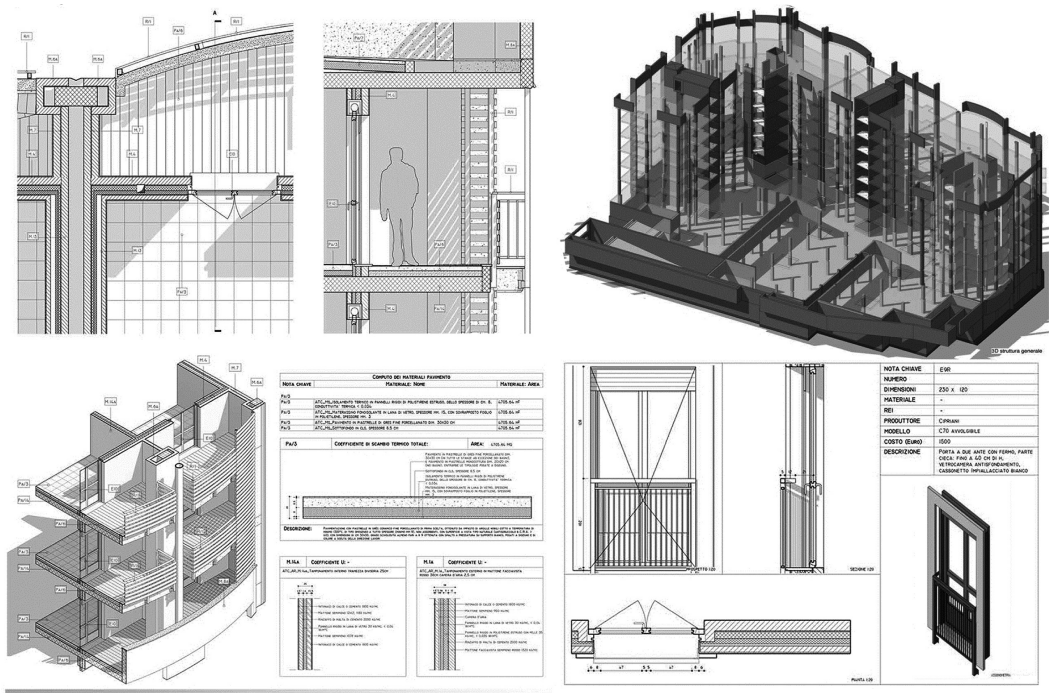

Figure 2. Orthogonal projections, space views, thematic views and details of the same building. 78 residential apartments for ATC in Spina 4, Turin. Source: Alberti, A. (2014). *L'evoluzione infografica del processo edilizio: dalla progettazione integrata in ambiente BIM alla gestione del cantiere 4D e 5D*. Master Degree in Architecture-Construction and City, supervisor: Prof. eng. M. Lo Turco, Department of Architecture and Design, Politecnico di Torino.

the various sectors of the construction industry and of the implementation of such improvements by professionals. The constant updating of the teaching content as an immediate by-product of experimentation in research is therefore crucial in a sector that is constantly evolving, as is the case of all fields of digital technology.

So, what represents an opportunity in terms of digital technology needs to be turned into a professional challenge within the world of architecture (both in the theory and in practice) in order to break down the barriers between design and technology, or at the very least to help bringing together two disciplines which are currently too far apart. Thus a network of teaching courses are being created for establishing closer links between disciplines, for introducing a greater degree of continuity in work with students and for implementing a semi-professional approach.

The educational intent is to show to the students the operating tools, exploring the potential of the new tools in terms of their capacity to provide access to an information system for supporting the construction process, including management and maintenance, in a scenario in which time is the determining factor in the various decision-making processes and operating phases.

Particular attention is paid on the role of the BIM Manager, who has the delicate task of coordinating and optimising those procedures which constitute the core of a multidisciplinary approach, such as:

- the creation of templates for different three dimensional parametric models according to the purpose;
- the definition of standards for the design phase and for the inbound and outbound data exchange;
- the implementation of graphical representation standards for models (architectural, structural, systems, building site, etc.) compliant with the applicable laws;
- the setting of modelling procedures and strategies geared towards achieving interoperable workflows;
- the management and the use of multidisciplinary information contained in relational databases.

The Master of Science degree program in Architecture Construction and City of the Politecnico di Torino is structured into Design units, Subject laboratories and courses. In the course of Building Information Modeling students are first of all asked to create a model of a modern or contemporary architecture and to study different collaborative working approaches in order to provide students with the necessary tools for the further design activity. In fact the students will measure the level of learning achieved through the Design Unit, a multidisciplinary activity that requires the involvement of different disciplines,

Figure 3. Proposals to help students to manage unusual forms and complex interventions. such as technology, structural engineering, building physics, economics and design organization.

We see great hope in the design schools refocused on maker culture and cultivating collaborative modes of teaching, learning and designing. Here we find inspiration and look for our future collaborators. We also notice that in University design units, individual leadership is essential to move forward a critical design culture only if it is based on collaboration. Individual vision is necessary, but it may be most productive when

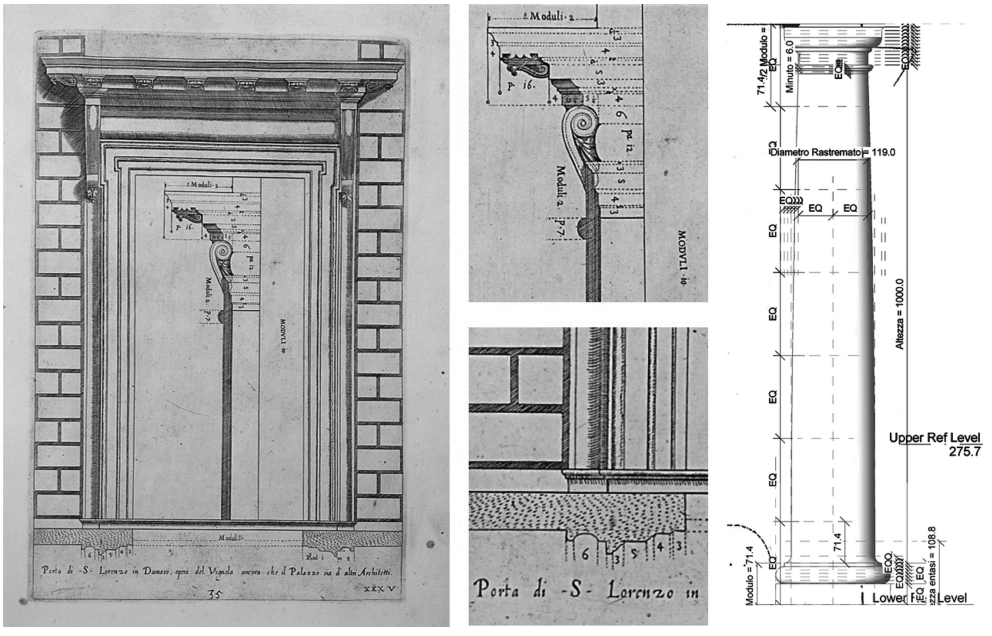

Figure 4. Jacopo Barozzi da Vignola, in the drawing for the *Porta di San Lorenzo in Damaso* in Rome, uses the spatial shadow to render his architectural idea for the elevation view; then, he associates the horizontal section, treated with modules, a side view, overlapping elements belonging to different plans, using hidden lines and hatches. Table XXXV published in the Roman edition of Fausto Amidei (1754). On the right, the Tuscan order of Vignola updated in a parametric environment, according to the rule of successive partitions through a control of rules and constraints between the parties.

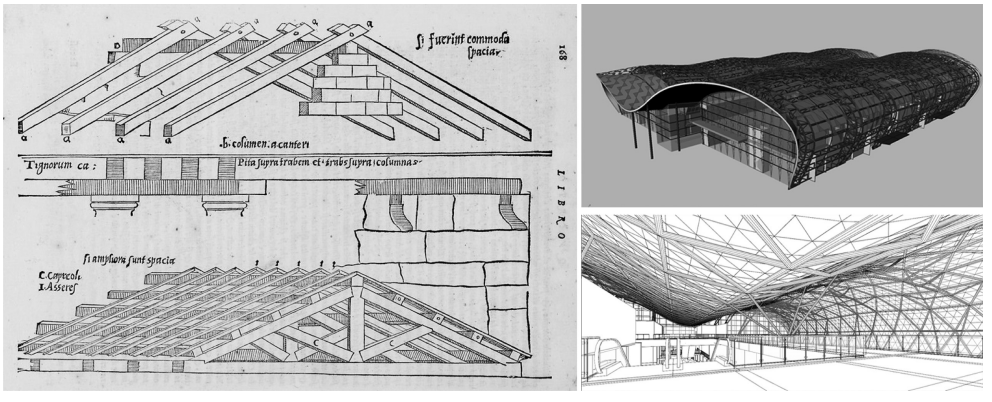

Figure 5. The solutions of wooden structures supporting roofing of small and large areas are outlined in a spatial representation, reproduced not to alter the geometry of the principal beams; in order to keep the visibility of the whole, the other parts are only hinted at and drawing is suspended. Figure taken on page 168 of *Libro Quarto*, Venetian edition of 1567 of the translation of the *Dieci libri dell'architettura* by Vitruvius M., commented and with addition of some illustrations by Daniele Barbaro, (on the left). On the right, spatial perspective representation resulting from the virtual model, not in true form, but essential to simulate complex shapes, such as organic forms and double-curved surfaces. Taiwan Exhibition Center, Cox Architects (2010).

it is altered and nuanced by dialogue within a collective culture.

In the not-too-distant future, information flows will become increasingly like the process employed by parametric software applications. This is why teachers are required to prepare students for a new cultural revolution in which they will be the heirs and standard bearers of a new methodology that that soon will become firmly established within the construction industry. Traditional teaching methods linked to construction need to be updated, to evolve and to adapt to the new information systems. If we understand innovation as the act of introducing new ideas, new technologies products or processes to solve problems,

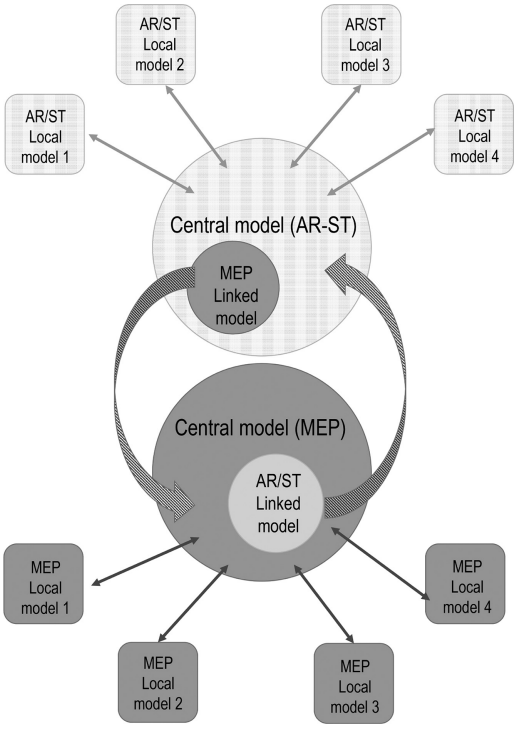

Figure 6. Work organization chart sample for the complex projects developed using a BIM approach: two central models, divided based on disciplines, constantly related to each other and each one divided into several local-models.

employing differentiated approaches, then it is clearly fundamental to ensure a close relationship between research and teaching.

At this regard, the representation plays a dynamic role; it stimulates actions and collects instances; it works to produce ideas that must be responsibly evaluated and verified through a series of checks that, to better operate, need more and more information, in terms of quality and quantity, upon which achievement of performance and successful service life of the implemented work rely: it therefore claims an increasingly strong cognitive value as an active medium throughout the whole investigation process, since its inception, according to the modus operandi advanced by Brunelleschi. So, the term "representation" is referred to a selected recording of the elements that constitute the essence of the object identity and the importance of the relations between the system and its components.

A change in professional practice will not probably have a strong impact on the average structure of offices or in common workflows but it will make the awareness and appropriateness of technology use – so distracted today- an increasingly crucial topic, in a society based on cultural inhomogeneity, fragmentation of material culture, and great availability of technology and highlight, therefore, the need for a "mediative thinking" (Converso, 2009).

Model as machine/machine as model: Emerging representational devices in stereotomic practice

S. Fernando & M. Mindrup
University of Sydney, Sydney, Australia

ABSTRACT: This paper will discuss the origins of the architectural model as a representational device in the design and construction of vaulted structures. Through the study of historic precedents exploring shell structures, techniques in modelling will be investigated based on the relationship to scale and material properties. Assessing the need for physical models in contemporary practice and whether advances in emerging technologies are influenced by material properties and scale. Situated within the art of cutting solids (stereotomy) and the evolution of machine tools; this paper will examine stereotomic based practices, their modelling techniques and how they are fundamentally shifting the role of the architect. It will explore the relationships between the architects, the models, the machines and the design outcomes.

1 INTRODUCTION

Since antiquity, the architectural model has enjoyed a great popularity amongst architects as a source of inspiration and tool for designing buildings. In its earliest form, history tells us that the first humans used nature as a didactic model for imagining the spatial and tectonic attributes of the first architecture — the primitive hut. Despite a handful of examples for the fabrication of proportionally accurate three-dimensional representations of proposed structures in ancient Mediterranean cultures (Egypt, Greece and Rome), it was not until the 15th century that the model received its theoretical framework in Leon Battista Alberti's architectural treatise *De aedificatoria*. However, in Alberti's proposal the model was not something found or constructed as a mechanism for imagining new designs but a tool to visualize preconceived architectural ideas in three-dimensions. By relieving the model of its role as a thinking mechanism, Alberti initiated a major change in the use of materials for modelling architectural form. It was not until the 17th century that the role of the model was revived as a mechanical device for projecting architecture in three dimensions.

Our contemporary understanding of a machine is inherited from ancient philosophers such as Archimedes who also created complex devices — a water screw — to complete difficult tasks. Certainly architects were involved in the design and fabrication of tools and machinery to construct architecture. The sublimation of this mechanistic imagination into architectural design practice finds its beginning during the end of the 17th century with, most famously, Giovani Poleni and later Antoni Gaudi who both employed hanging chain models to study the effects of gravity on arched, vaulted and dome structures. More recent explorations with this approach towards form finding include architect Jorn Utzon's Sydney Opera House based on shell structures and emerging researchers such as the Block Research Group in Zurich and New Fundamentals Research Group in Italy who are investigating various modelling methods towards the construction of freeform masonry structures. Compared to an emphasis on architectural form, what these examples demonstrate is a use of the physical model for analogical simulation that invites material and mechanistic speculation.

Today, the use of digital simulation as a modelling method for constructing freeform masonry structures is confounding our traditional concepts of model and machine. With the development of increasingly complex computer programs the architect is now free to simulate the effects of forces on different constructive materials in absentia. Without any recourse to material as a medium for design, the machine is now the model. Nevertheless, despite its advantages, one factor still remains — the need for a thinking mind to make analogical associations between the model and the projected structure it represents. This paper seeks to explore the changing role of model as a machine by challenging our assumptions about material, model and machine as interchangeable and exchangeable factors in design.

2 THE MODEL

2.1 *Model, paradigm and prototype*

The word 'model' is derived from the Latin term '*modus*' meaning 'basic measure' in early Greek and

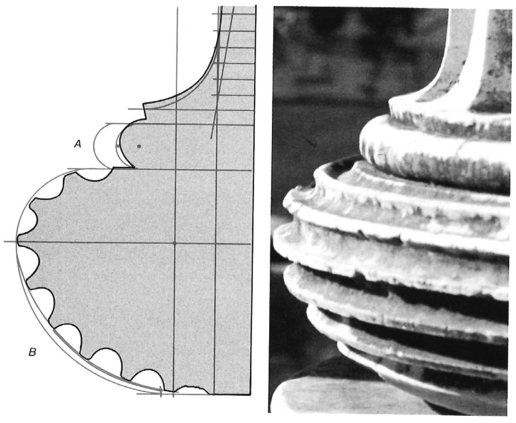

Figure 1. Lothar Haselberger, Planned and Actual Column Base. The inscribed lines on the inner wall are reconstructed by extending visible lines.

Roman Temple designs. With the exception of an often-cited story about the presentation of miniature scale military models in Vitruvius first century BCE treatise on architecture there are very few examples for the use of three dimensional representations of architecture as a design tool before the Renaissance. Rather ancient architects relied upon simple drawings to describe the distribution of the modus in different architectural elements. It was the meaning and purpose of these early architectural drawings that gave the model its name and define its role of the design practices of digital architects today.

Until recently, it was believed that little design work was involved in planning Greek temples that instead relied on specifications for directing the work of others. Indeed, at the Temple of Apollo at Didyma Lothar Haselberger discovered that the construction of large temples concerned the use of not only chalk but also the inscription of construction lines or drawings onto the actual building material. Inscribed on the smooth lower walls of the adytum (inner sanctum) Haselberger found full- scale plans for the components of the temple that dictated their precise and strict geometric relations. For example, the construction and layout of the column bases were established upon 'perfect' torus profiles in a process involving inscribing circular centres on a horizontal axis and projecting them vertically (Figure 1).

What Haselberger's discovery suggests is the presence of a 'master builder' who would be involved in making decisions about the application of geometry and selection of material. As Haselberger explains:

> Geometrically pure paradigms were drawn first, but the architects did not hesitate to alter them to suit their refined sensibilities. . .. The construction plans must have been drawn before the individual components pictured were fashioned but after the stone "drawing boards" were smoothed. (Haselberger, p. 119)

Haselberger's diagrammatic paradigms should not be confused with the Greek *paradigma* – full-scale examples of architectural elements to be copied. By contrast, the drawings at Didyma are prototypes in the sense of Greek *protopon*, (primitive form), the neutral form of *protopos* (original, primitive), from *protos* (first, foremost) and *typos*, (impression). In contemporary practice, prototypes usually involve the extra factors of consideration such as materialisation. They are systems of modules that describe an object or larger system in material form. Although a prototype is similar to a paradigm (pattern or model), by visualising an idea or thought process the architectural *paradigma* is an evolved scale paradigm to be imitated or copied. This is the meaning typically ascribed to an architectural model today.

The familiar image of an architect constructing scale three-dimensional models to study or workout their designs only came into practice during the second half of the 14th century. One finds the earliest records of the use of models by architects in the practice of building around the construction of the Florence cathedral. In 1366 there is a modelling explosion when the Opera del Duomo ordered designs for the completion of the cathedral to be presented in drawings and models. The drawings ran under "*desingum seu modellum*" and a large brick model of Neri di Fioravanti's design referred to as "*chiesa piccola*" had to meet a double similarity: on the one hand it had to be similar to the drawings, on the other hand the church had to be built similar to the model (Guasti, p. 192ff, Doc. 175 & 214). However, the construction of Neri's ambitious dome project, a double shell using no buttressing and only wooden or stone chains to prevent buckling was never realized for the lack of technical skill and knowledge how to accomplish it (Grote, p. 229). The discussion to solve these difficulties began 50 years later in 1417 when another model competition was offered in 1418 and won by Fillipo Brunelleschi (Guasti, p. 15ff, Doc. 11-14; Fabriczy, p. 67). Here, one can find in the payment receipts for the 11 other competition models that they are referred to for the first time as '*modello*' (Guasti, p. 22–25; Saalman, p. 250).

In 1485 a friend of Brunelleschi, Leon Battista Alberti became one of the first individuals since Vitruvius to define the importance of models for the development of architectural ideas. Herein architects are encouraged to follow a time-honoured custom to not only prepare drawings but also '*modello*' to study and develop their ideas in order to avoid making faults. Alberti argues this point by suggesting in Book I of his treatise on architecture that architects have immaterial architectural ideas called lineaments to define the surfaces of the enclosure:

> All the intent and purpose of lineaments lies in finding the correct, infallible way of joining and fitting together those lines and angles which define and enclose the surfaces of the building. (Alberti, p. 7)

As Alberti suggests, it is quite possible to project these lineaments in the mind without any recourse

to material, by designating and determining a fixed orientation and conjunction for the various lines and angles (Alberti, p. 7). However, in Book II Alberti observes how the lineament as formed in the mind was imperfect and could only be given its consequent form through the examination, exercise of judgment, and modification of it through drawings (Alberti, p. 34).

The model, then, for Alberti, was not a vehicle to present an idea to a client, but a means to study and realize their ideas in three dimensions. Because lewdly dressed or painted models can distract from the study and appreciation of these lineaments, Alberti argued that architects should construct plain and simple three-dimensional forms. These models whose lines and angles had a scale and measure embodying the proportions and distribution of a modulus are likened to the diagrammatic paradigms Hasselberger discovered at Didyma.

2.2 *Analogue and digital prototypes*

The development of architectural science in the 16th and 17th century was made possible because of a growing number of technical innovations and the dissemination of scientific ideas to the construction workforce. These developments gave craftsmen and model makers access to up to date knowledge. Scientific achievements from the publication of 'thought experiments' from across the industries of manufacturing to astronomy "raised people's confidence that all subjects would benefit from such methodical study, both intellectual and practical" (Addis, 2007, p. 191). This included the study of the strength of materials.

Physicist Galileo Galilei (1564–1642) was perhaps the earliest to propose non-linear scaling based on what is currently known as the Square Cubed law (Addis, 2007, pp. 191–192). This is based on the area increase with the square of the scale factor, volume and mass that will increase as the cube of the scale. As shown in Figure 2,

> [h]e used this observation to explain that the finite strength of bone material means the size of animals cannot be scaled up indefinitely. (Addis, 2014, p. 35)

Ancient builders in this case would perhaps not have known the distinction between the two categories of models, where one is independent of the structural properties of a material and the other is dependent on them.

Because of his observations with material performance, Galileo was very critical of Alberti's proposed use of models he believed could only provide visual information, regardless of scale (Di Pasquale, p. 665).

Those models based on proportional forces and vector systems verses material qualities are scale independent. For example hanging chain models based on Hooke's Law were both physically modelled and digitally re-interpreted. Giovanni Poleni (1683–1761) made use of Hooke's Law in the 1740s to

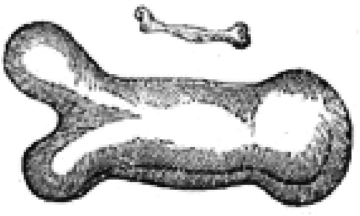

Figure 2. Drawings of Galileo's representation using bone strength of the square cube law.

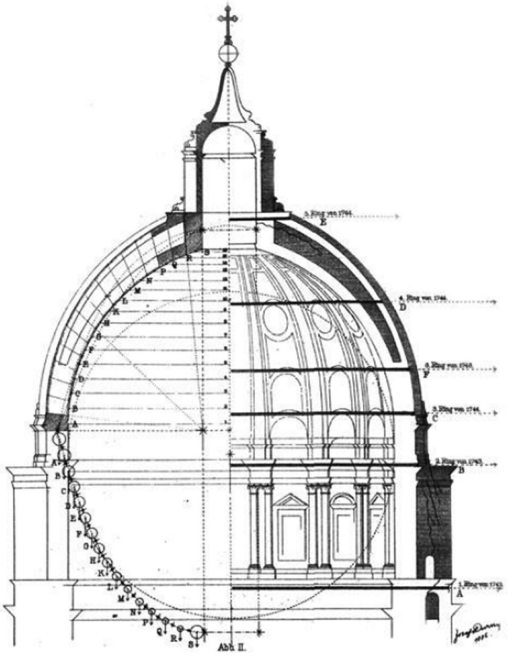

Figure 3. Giovanni Poleni St Peter's Cathedral, Rome, 1506–1626 Superimposed sketch showing Poleni's hanging model on the section of the dome.

> [a]ssess the safety of the hundred-year-old 41.9 m diameter dome of St Peter's Cathedral in Rome, which had developed a number of alarming radial cracks. (Addis, 2014, p. 36)

According to Poleni's report of 1748

> [h]e knew of Hooke's hanging chain, and he has an astonishing preperception of the safe theorem by his explicit statement that stability of a structure is assured if it can be established that the line of thrust lies completely within the masonry. (Heyman, p. 751)

As illustrated by Poleni's drawing of a catenary arch over the section of Michelangelo's dome of St Peter's Cathedral, the paradigm, in this case a mathematical principle is used as the basis for the creation of a modelling system or prototype to assess the safety of domed masonry structures (Figure 3). These mathematical principles based on forces are directly

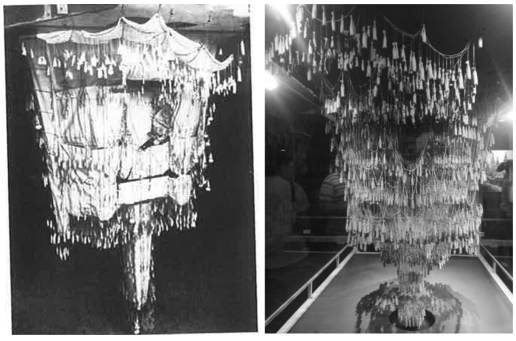

Figure 4. Left: Funicular model by for the chapel of Santa Coloma near Colonia Guell, Barcelona 1898 (Sardo, 2004) Right: Hanging chain model currently exhibited inside the Bascilica La Sagrada Familiar (Fernando, 2015).

Figure 5. Variety of historic models and machines on display at the Sagrada Familiar workshop museum, Barcelona, Spain (Fernando, 2015).

applied to contemporary computational models that can simulate and analyse forces in more than two dimensions.

Antoni Gaudi (1852–1899) used Poleni's chains as a design tool for modelling the shape that the Sagrada Familiar structure would take in response to the loads and thrusts acting on it (Figure 4). To this end, Gaudi hung chains upside down adding weights to distort the parabolic catenary arches into funicular polygons by attaching weights where sculptural elements would be placed. Using these chain models as a tool to investigate structural integrity of arched and vaulted spaces was an effective modelling method for form finding.

A more recent example of a scale dependant model was the 1:60 scale thin shell test version of Danish architect Jørn Utzon's (1918–2008) design for the Sydney Opera House (Addis, 2014, p. 39). Ove Arup & Partners' were appointed as consulting engineer in 1957 and utilized a team of researchers at Southampton University. Due to the complex initial geometry they adopted a solution based on using thin parabolic concrete shells. The complexity of concrete shell structures make the use of material model tests

Figure 6. Left: timber scaled model of roof of Sydney Opera House for wind tunnel testing. Right 1:60 scaled model of a thin shell version of the Sydney Opera House roof being tested at the University of Southampton in 1958 Source: (Morice, 1958).

at various scales useful for many designers to analyse the performance of a structure.

What began as understanding of elasticity and stiffness in the eighteenth century became a paradigm for design in the 1:60 scaled model of the Sydney Opera House (Figure 6). Similarly the chain models used by Gaudi to test structural forces can be seen as machines because they employ a series of mechanisms which are responsible for the transfer for forces and energy.

3 THE MACHINE

A machine is a tool that uses a series of parts to transfer energy in order to perform an action. The word machine is derived from the Latin word '*machina*' derived from the Greek word *makhana*, and *mekhane* meaning (machine). The contemporary definition of a machine implies the use of electricity as a generator to complete complex tasks. However, with the printing of three-dimensional models, the machine becomes a generator of the tool itself, confounding our traditional assumptions about the definition of a machine as a tool.

Historically craftsman in Western culture controlled the skills necessary for creating the devices that greatly affected the daily rituals of humankind. Already during the fourth century BCE the philosopher Plato was concerned that craftsman sustained the skill to create illusions of reality. His student Aristotle however states that mechanical skills were necessary for overcoming problems caused by nature. Vitruvius devotes his entire final chapter to the discussion of the machine. He believed the method of creating improved architecture was with educated craftsman who understood both the theory and practice of mechanisms (Vitruvius, p. 5–6).

Herein, Vitruvius defines a machine as "a combination of timbers fastened together, chiefly efficacious in moving great weights" (Vitruvius, p. 283). This definition implies that a machine uses mechanisms in order to achieve a function or effect. The relationship between the two mechanisms is what differentiates the desired outcome thus making the machine a tool.

For the construction of the Florence Duomo Filippo Brunelleschi solved the issue of lifting and manoeuvring heavy materials such as blocks of stone

by inventing lifting mechanisms. His sketches of machines for lifting heavy loads including hoists, castellos and cranes, were published in manuscripts as drawings of machines (Addis, 2007, p. 131) Another example is Leonardo da Vinci (1452–1519) who employed and communicated structural analysis tools through sketches of mathematical forces in order to solve practical problems such as cracks in masonry structures (Addis, 2007, p. 143).

Today there are more various types of tools and desired outcomes for which machines are employed. The advent of a 'machine age,' which was formed through the industrial revolution in mid to late 19th century, saw the rise of new building techniques. With the development of early twentieth century Modernism, architects began to explore new materials and methods for creating models of architecture as machines for generating and imagining architecture (Mindrup, *The Merz Mill* 2013). Today, increasingly complex computer modelling software and fabrication tools, are beginning to blur our traditional concepts of the model and machine.

4 THE DIGITAL MODEL AS THINKING MACHINE

A tool for architects and designers the machine has been widely accepted as a generator of design outcome regardless of its type. Mario Carpo makes the distinction between "a mechanical machine (for example, a press) that makes objects and a digital machine (for example a computer) that makes a sequence of numbers- a digital file" (Carpo, p. 5). However the content of this digital file and the resultant outcome is dependant on the initial setup and whether it is a 'performative' device meaning that it relies on its execution of instructions. For example, in the case of a structural model that can be further distinguished as a 'behavioural model' which is "designed to demonstrate clearly some particular structural behaviour or principle" (H.J. Cowan, 1968, p. 66). This structural model is ideal as a teaching device as it demonstrates concepts and feasibility of various scenarios. In this case the model is a thinking machine.

Advances in computational power make visualisation, analysis and simulation more accessible to a wider audience have redefined the process and outcome of the 'model' and 'prototype.' Parametric models which are set up to define certain relationships between elements of the scheme have enabled designers to quickly generate and iterate various scenarios and possible outcomes. In this way the parametric model is not only a tool but a thinking machine. It is made up of parts that can be modified, regenerated and replicated based on the code provided by a reflective modeller. Machines such as 3D printers now have the ability to re-produce parts for themselves based on the program defined by humans further distorting the boundaries between the use of the machine and model as a thinking machine.

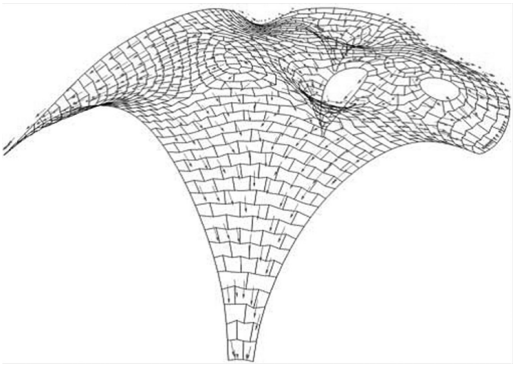

Figure 7. The Digital Model showing magnitude and direction of forces on each module Source: (Philippe Block, 2013).

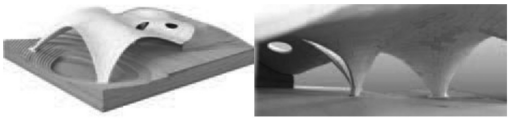
5 EMERGING STEREOTOMIC PRACTICE

Contemporary architectural practice and research is often subject to emerging trends and advances in technology. As these technologies have developed the capabilities of modelling complex geometry, this has caused a revival of historic methods of modelling and crafting. Stereotomy or the art of cutting solids emerged in the 1500s as a process of calculating the geometry of complex:

> [n]on-uniform stones and making drawings of them so the masons could work on many stones simultaneously, and the stones can be placed in situ as soon as they were needed (Addis, 2007, p. 153).



This highly mathematical process emerged due to advances in computational power which speeds up the process and makes the model more accessible to a wider audience.

5.1 *Structural analysis and form finding tools*

The use of the model as a machine can be seen in the work of practices engaging with structural analysis models. A contemporary example of stereotomic practice using structural models is from the Block Research Group in Zurich. Here a digital structural model is produced and is used as a behavioural model to analysis various structural issues as it simulates load conditions of a masonry vaulted form (Figure 7).

The form finding which occurs as a result of the optimization of the structural model is 'machine' generated. Smaller scale test models are produced of the vaulted surface to test connections between each of the modules and overall relationship to the context.

Another example created by the New Fundamentals Research Group in Bari, Italy as shown in Figure 9 is the Osteomorphing Catenary Marble vault in which a model prototype was recently produced at full scale working directly with the material properties. Here a combination of computational and traditional stereotomic techniques was adopted to test and manufacture the structure. The final model outcome is also

Source: http://www.atelierfallacara.it/prototipi.html.

a prototype which can be used to base further iterations of various materials. Here the model produced is a thinking machine similar to a 'behavioural' model to demonstrate and test a particular concept or idea.

5.2 *Robotic technologies in stereotomic practice*

The utilization of industrial robotics originally developed in the automotive industry as a method for cutting complex stone modules expands the concept of the machine as model. This development is due in part to the combination of the instructional properties provided by software with precision of a robotic arm (Fernando et al 2015 p. 395). In these instances, the use of sensors to create a feedback loop between code and manufacture elevates the digital model to the level of a thinking machine enabling the provision of direct feedback from material outcomes.

A recent project adopting stereotomic practices using robotic crafting tools is the Stereotomy of Wave Jointed Blocks (Weir et al 2016 p284) project, exploring the 6 axis wire cutting of interlocking blocks. A custom hot wire cutter end effector was developed as part of the fabrication system utilizing an industrial robot arm to cut foam blocks to prototype a construction method. This single tool cutting system maximises the proficiency of the cutting process and returns the once technical factors of robotic construction back to the designer. This research explores a variety of outcomes and engages the architect with the machine as a thinking tool in the early stages of the design process. Here it is important that the architect has an understanding of structural and material properties which are investigated through structural analysis tools as well as experimentation with the material itself.

6 CONCLUSION

As a thinking tool the use of a model for generating and imagining new architecture has begun to blur. The recent rapid rise of 3D modelling software and sophisticated digitally controlled tooling permits more complex structural investigation and modelling techniques. The use of manufacturing machines can enhance the precision and accuracy of cutting materials such as stone. Because the model has now become a thinking machine, it can be optimized specifically to the type of material used. This changes the way an architect uses the model contributing to a shift in the manufacturing and use of the architectural scale model as thinking machine.

Additive architecture: 3D printed architecture

Brian Peters
Kent State University, USA

ABSTRACT: 3D printed architecture is rapidly developing globally, with new projects and techniques promising to revolutionize the building industry. This emerging movement within digital fabrication, called additive architecture, will no doubt play a role in how architecture is built in the future, and therefore it is important to provide a comprehensive study and documentation of this quickly-evolving topic. The paper will provide an overview of 3D printed architecture projects around the world, identifying the emerging means and methods of this movement by categorizing the different approaches and trajectories.

1 INTRODUCTION

The idea of 3D printing a building seemed like a futurist's dream until engineer Behrokh Khoshnevi introduced the Contour Crafting project in 2006 (Khoshnevi et al. 2006); demonstrating the possibility of 3D printing at a large scale and taking this dream into reality. Since then, the number of projects pursuing this goal has expanded exponentially, leading to several architects simultaneously racing to 3D print a full-scale building. These projects, and others, are located worldwide and utilize various printing processes, materials, scales, and machines. They are also promising to revolutionize the building industry, with complex components that are materially efficient, tailored for specific structural applications, and fabricated on-site using local, bio-based or recycled materials. While there are many questions and broad implications to consider with 3D printing, the focus of this paper is on the many approaches people are taking to additive architecture.

2 BACKGROUND

3D printing is a fabrication process that stacks thin, two-dimensional layers (x, and y-dimensions) on top of each other vertically (z-dimension) to create a three-dimensional object. Historically, this technique was used by architects as a prototyping tool to produce scale models of building or details. However, this small-scale prototyping tool has quickly evolved into a full-scale production tool for architectural building components and structures. There are several widely accepted benefits of 3D printing in comparison to traditional manufacturing, which are outlined in the book Fabricate (Lipson 2005). From this list there are four principles that highlight these benefits, or new opportunities. They are the reduction of material waste, increase in geometric complexity, portability of manufacturing, and custom material blends.

3D printed architecture uses an additive manufacturing method, which is relatively new to the field of digital fabrication in architecture. Therefore it is important to understand where this technique fits within the digital fabrication movement, and compare it to the standard tools, techniques, and machines that have traditionally been used.

Since its inception, digital fabrication or CAM (computer aided manufacturing) has revolved around a given set of standards that have been widely adopted and utilized. First, the primary machines are three-axis CNC (computer numerically controlled) tables or gantry systems. Secondly, the tools or end effectors are most often based on standard, industrial, hand tools, such as routers, welders and plasma cutters, which are simply attached to the 3-axis CNC milling machine. Third, the production has relied on off-the-shelf or stock materials, which are prefabricated and sold in standard sizes, densities, and finishes, such as wood, foam, plastic, and metal. The typical machine is built to accommodate the most common building material size, a 1220 mm by 2440 mm sheet. Lastly, and most importantly, the fabrication techniques have relied on subtractive methods, where the machine and end effectors are used to remove or subtract material, such as milling, routing, cutting operations.

However, over the past few years, many of these widely held standards are being challenged. With the recent proliferation of multi-axis machines, or robot arms, into professional and academic research labs, as well as open source hardware and software platforms that have made these machines more accessible to architects and designers, there has been greater experimentation. Architects and designers have also begun building and customizing their own machines that perform specific functions, which has helped the development of additive architecture projects.

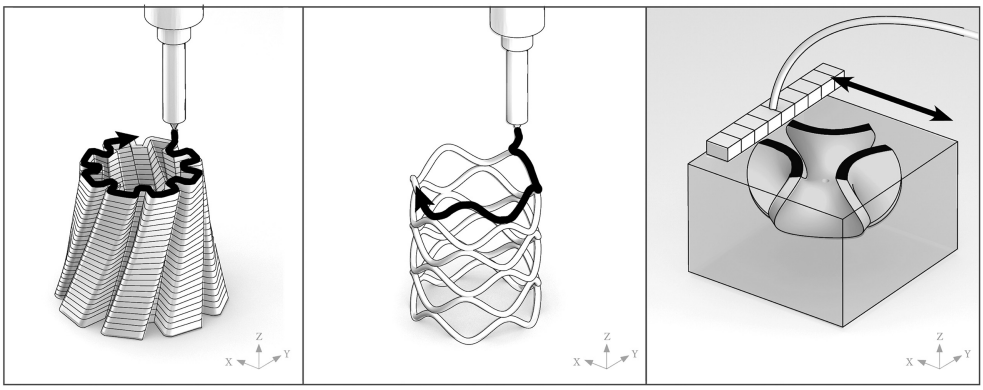

Figure 1. 3D Printing techniques: (*a*) fused deposition modeling (*b*) anti-gravity printing (*c*) stereoligraphy.

3 ANALYSIS

The data set analyzed consists of current and past projects that have pursued 3D printing at the scale of architecture. The project list was compiled by Erno Langenberg (2015) and provides the project name, location and material used for approximately the first forty additive architecture projects in the world. Using this list as starting point, we created a more comprehensive comparison between the projects by also categorizing their printing techniques, mechanics, extruders or print heads, and fabrication approaches. The intent is to use this data to identify the emerging methods of this movement.

3.1 *Materials*

There are a wide variety of materials being used to 3D print building components. They range from traditional building materials, such as concrete and ceramics, to experimental materials such as bio-based polymers or composites. One of the most popular materials currently being researched and used for 3D printing in architecture is concrete, (Buswell 2006, Rael et al. 2011, Stampler 2015) with over a third of the projects pursing it as the main printing material. It is typically printed using a FDM style printer with either a gantry system or multi-axis machine. There are several projects that have used large machines to 3D print large sections of buildings or walls in concrete, however the industry still has concerns about how structural reinforcing, such as rebar, is included during the printing process. Ceramics is another popular material being explored (Peters 2013); however one of the limitations of the material is that it needs to be fired. This is simple to accomplish at a small scale, however at a large scale, the size of kilns becomes a barrier to printing large components. There have also been experiments with the use of local materials, such as adobe, however the results of their structural tests have not been released. To date, there have been no large-scale, 3D printed architecture projects that use wood, which is otherwise a typical building material. Other traditional building materials that are harder to 3D print and were not included in the project list, such as glass (Klein et al. 2015) and metal (Crolla et al. 2014) have been proven to work at small scales.

Less traditional building materials being used include plastic (Peters 2016, Wainwright 2014) and artificial stone (Fixsen 2015), which have their advantages. For example, plastics can easily be recycled by grinding 3D prints into pellets, re-extruding filament and then reprinted the material again. There have also been experiments with a bio-based plastic material, which alleviates some environmental concerns. Artificial stone has been used in one project and promises the durability and strength of the natural stone, while being able to use recycled or local material.

It is important to note that all the projects listed are mono-material systems, where only one material is printed at a time. One of the largest hurdles in advancing the use of 3D printing in architecture is multi-material printing, where metal, concrete, and glass can be combined simultaneously. This opens up many possibilities in terms of environmental and structural performance.

3.2 *Printing techniques*

There are three main types of 3D printing techniques being utilized at the scale of architecture (Figure 1). The first, and most popular (60% of the projects surveyed use this technique) is fused deposition modeling (FDM) printing. This style involves extruding a liquid-based material on top of the layer below, typically without a support material. The FDM style is easy to visually identify, since the prints always reveal the printing process and the layers that were used to fabricate the system. The resulting ribbed texture can be minimized by reducing the layer height, however this will greatly increase the overall print time. Since this style of printing relies on the layer below, it is problematic to stop and start the printing process and print failures may occur when layers don't properly adhere to one another.

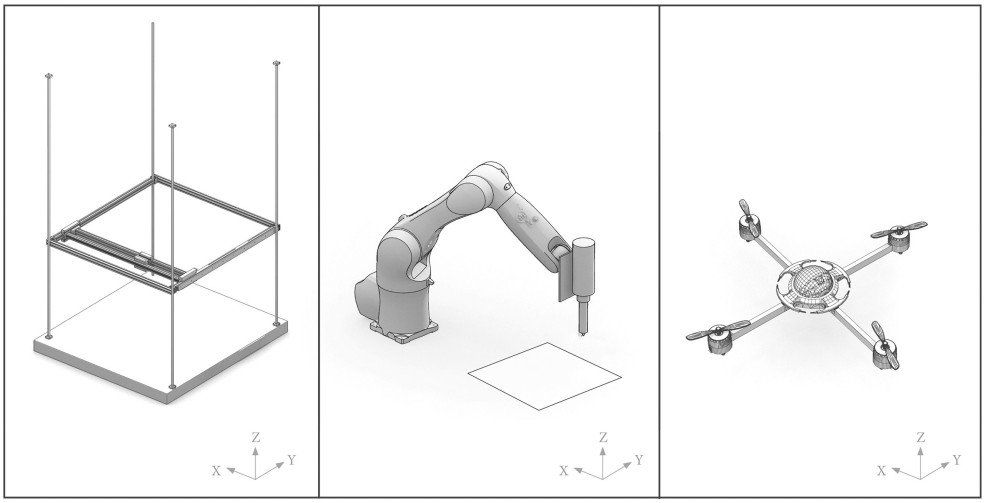

Figure 2. Machine typologies: (*a*) gantry (*b*) multi-axis (*c*) mobile.

The second most-often used technique in additive architecture is stereoligraphy (SLA). This involves printing objects in a bed of material (powder or liquid), thereby having the objects suspended in that surrounding material during the printing process. After the print is complete, the support material is meticulously removed. The projects using this technique have shown greater geometric flexibility because there is a support material; however the process is more time intensive and usually requires manual labor to remove the print after it is complete.

The third technique that is being utilized is an approach called anti-gravity printing, which is a version of FDM style printing that is done in midair. There are a small, but quickly growing, number of projects that have experimented with this technique (Hack et al. 2014, Laarman et al. 2014). The printing material does not rely on the layer below for stability, but rather dries immediately upon exiting the print head. This technique provides exciting geometric possibilities and can be highly material efficient, however it can only be achieved with materials that dry and harden almost instantaneously, such as composites, polymers, and metal. The applications currently experimented with include lightweight lattice structures and support material for a secondary process, such as reinforcing for concrete casting.

3.3 *Mechanics*

There are a wide range of machines being used to fabricate architectural components, however they can grouped into three typologies (Figure 2). The first and most commonly used typology is the gantry style, which is typically a three-axis machine. It is widely utilized because the system can be constructed out of off-the-shelf components, such as extrusions, rails, motors and electronics, allowing the system to be easily customized for various scales or applications. Of the thirty gantry projects, the largest is 12 m^3 and the smallest is 200 cm^3.

The ten most recent projects have utilized the second typology: a multi-axis machine, such as a 6-axis robot arm. These machines allow for more geometric freedom compared to a three-axis gantry system, but are less accessible in terms of modifying the mechanics. They may also be popular because there are a variety of robot arm sizes that can carry a wide array of loads and stresses.

The final typology is a mobile machine, such as an unmanned aerial vehicle (UAV) or quadcopter. These machines are far less prevalent and suffer from limitations relating to weight loads and precision. Their inclusion is based on speculative projects and their application in additive architecture is still yet to be seen.

3.4 *Extruders or print heads*

There are two primary types of extruders being utilized for FDM style 3D printing of additive architecture. The first is an auger or screw-type mechanism that takes material from an input and slowly feeds the material through the system. The second type of extruder is a piston-based mechanism, which uses a mechanical device or air pressure to force a plunger down a cylinder, pushing the material out of the extruder. The benefit of using an auger-based extruder is that the material can be continuously fed into a hopper, however it is difficult to cleanly stop and start the extruder during the printing process. The benefit of piston-based extruder is that the operator has more control over the speed of the extrusion. The limitation is that the cartridge needs to be refilled, which hampers the printing of large components.

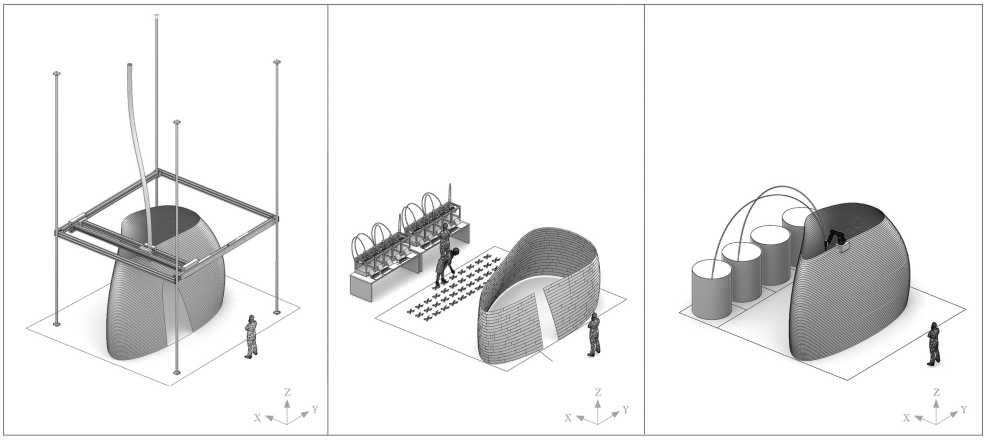

Figure 3. Fabrication approaches: (*a*) large scale machine on-site (*b*) small scale machines on-site (*c*) small mobile machine in-situ.

3.5 *Fabrication approaches*

While there are several fabrication approaches to additive architecture projects (Figure 3), including pre-fabricating components, one of the exciting advantages of 3D printing is the potential to fabricate on site, utilizing a mobile printing lab. To date nearly half of the projects have used on-site 3D printers to fabricate building components, though there are two different approaches. The first is printing on site, or even in-situ, with very large-scale machines. At the other end of the spectrum, there are several projects that have utilized small desktop 3D printers to fabricate small components that come together to form a larger structure. This approach uses small, easily transportable printers that are relatively inexpensive. While they can offer a high resolution of detail compared to larger printing machines, the number of components required to be printed in order to assemble a full scale structure can take much longer to fabricate. The final approach is to use a series of small mobile machines to print a large structure on site (Jokic et al. 2014).

3.6 *Mold printing*

While the majority of the excitement and energy of the architectural community is focused on directly 3D printing building components, there are a growing number of projects investigating instead 3D printing molds and formwork for casting building components (Gardiner 2014, Peters 2014, Sun et al. 2014). While 3D printing molds does not take advantage of all the design benefits of 3D printing, it does alleviate some of the problems associated with traditional casting by reducing fabrication steps, which in turn reduces the material waste and fabrication time. 3D printing molds can also sometimes produce more high definition and geometrically intricate designs then large-scale FDM style 3D printers because of the resolution of the printing process. These projects are utilizing a typical molding material (flexible, wax, etc.) to either recycle and reuse the material from each subsequent mold, or reuse and reconfigure the molds repeatedly.

3.7 *Custom machine fabrication*

With the recent proliferation of 3D printing projects into professional and academic research labs, there has been an increase in the development of custom attachments (end effectors) for these machines. This has been aided by open source hardware and software platforms that have made these machines more accessible to architects and designers. For example, through projects such as the RepRap (Gershenfeld 2005), which is an open source 3D printer kit, the knowledge for how to assemble, modify, and customize a 3D printer has greatly increased. Additionally, in combination with other open source hardware projects, such as Arduino, it has become relatively easy to learn how to program and prototype small electronic projects. This new knowledge is empowering those who would typically not able to do so, such as architects or designers, to build new digital fabrication devices, tools and end effectors. The results range from custom additive fabrication processes, such as 3D printing, to hybrid systems that combine various techniques, such as a carbon fiber spinning attachments to stacking devices.

Of the projects researched, a majority (almost two-thirds) used off the shelf machines, such as multi-axis robot arms, and built custom extruders or print heads that were attached to the robot arm. The rest actually built custom machines and extruders for their projects. How are architects developing custom machines, and not simply accepting or relying on machines that are given? While architects may not feel they have the expertise for such work, collaboration with various experts, such as mechanical and electrical engineers, is the solution for these complex problems. Those that are currently exploring these possibilities are producing new and exciting design ideas for architecture and

demonstrating how architects can be directly involved in the fabrication process.

4 CASE STUDIES

The following two case studies demonstrate how the role of architects in fabrication is evolving and adapting; highlighting architects' involvement in the development of fabrication tools and machines.

4.1 *3D print canal house*

An example of a professional project where architects are leading a team in the development of a large-scale, custom-built, 3D printer for architectural production is the 3D Print Canal House by DUS Architects. The project, located in Amsterdam, Netherlands, was started in 2012 and continues today. The concept was to build a large 3D printer that could easily be transported from site to site, and therefore it was built inside of an existing shipping container. The complex project necessitated collaborating with several companies, including a desktop 3D printing manufacturer, extrusion system manufacturer, and material engineers; however architects were at the helm. Since being built, the custom 3D printer, which prints with pellets of bio-plastic, is being used to 3D print a full-scale house on a public site in Amsterdam. The project was innovative due to its scale of FDM style printing, its use of bio-based materials, as well as its portability.

4.2 *Building bytes*

A personal project that highlights this growing trend of architects building their own small-scale, custom 3D printers is Building Bytes (Figure 4). This project combines a traditional building material (ceramics) with a new fabrication technique (3D printing) to re-think an ancient building component (bricks) and demonstrate how 3D printers will become portable brick factories for large-scale construction. Bricks have been a standard building material for centuries, and while their manufacturing has undergone changes, this project seeks to update this building component to suit architects' needs using this new fabrication tool. The intent is for architects to be able to design each individual brick in their projects, bringing them into the fabrication process. The project was realized by customizing an existing 3D printer to print in ceramics and focuses on producing bricks quickly, efficiently and within a limited budget.

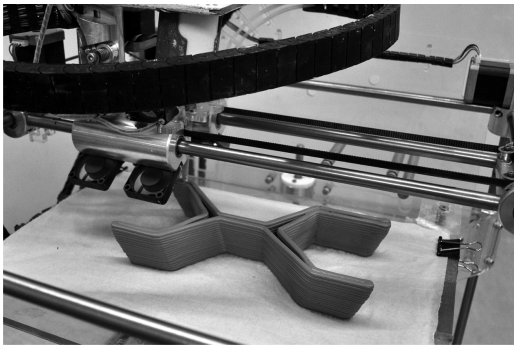

Figure 4. 3D printing ceramic brick.

5 CONCLUSION

3D printing in architecture is driving architects to become more involved in building fabrication. As a result, they are customizing machines, developing new approaches to fabrication and using new materials. Additive architecture is therefore taking many forms, but its full impact on the building industry is yet to be seen.

Laser scanning: The transformation of architectural practice through 3D imaging

S. Kim & M. Hylton III
The University of Florida, Gainesville, Florida, USA

ABSTRACT: 3D imaging technologies like laser scanning are shaping architectural practice, especially when projects involve the existing built environment. Laser scanning helps rapidly produce highly accurate digital representations of existing buildings, spaces, and details. Architects are increasingly utilizing the technology to quickly capture places and spaces. The resultant large sets of data can then be easily accessed from remote locations. The research presented in this paper investigates how laser scanning can advance the field of architecture and allied disciplines, especially in respect to extant buildings and sites. First, the paper explores the growing trend towards reusing existing buildings and the growing use of laser scanning for architecture. Second, through case study analyses, this paper examines what products can be generated from laser scan data and how they can help with distinct issues at varying scales ranging from the recording of existing interior details to the mapping of topographic information. Case studies include Steinway Hall, New York City, United States and Shwe-Nandaw Kyaung, Mandalay, Myanmar.

1 INTRODUCTION

Laser scanning and other 3D imaging technologies are changing how architects and allied professionals document, perceive, and interact with existing buildings and the built environment. With ongoing improvements in hardware and software, laser scanning and 3D imaging will become an integral part of the documentation and design process. Rapid and highly accurate, terrestrial laser scanning captures large quantities of 3D data that result in digital models of spaces, buildings, entire neighborhoods, and cities. These digital models–referred to as point clouds for laser scanning–can be accessed by architects and others from their office or elsewhere to aid in continually studying the building or environment.

The purpose of this study is to investigate how 3D digital imaging and laser scanning help change and advance the field of architecture. Therefore, this paper explores laser scanning for existing and historic structures and the built environment through the review of architectural projects and literature and examines case studies where 3D imaging was used to document the context and details of building. To be specific, this paper discusses what products can be generated from laser scan data and how they help with a variety of architectural practice.

2 ARCHITECTURAL PROJECTS REUSING EXISTING BUILDINGS

Today, demands for reusing existing buildings are increasing as a part of global efforts for preserving cultural heritage and reducing energy consumption caused by new construction and demolition (Bennett 2009). Further, architects have increasingly retained and incorporated existing building elements and features as part of a design strategy. *ArchDaily*, a popular online architecture newspaper, has annually announced the *Building of the Year Award* voted by the public based on 14 categories, one of which is "refurbishment" (Stott 2016). A 2016 winner House in Guimarães, Portugal, designed by Elisabete de Oliveira Saldanha, has modern additions simultaneously preserving, restoring, and sometimes replicating historic elements of the existing building (ArchDaily 2015).

The utilization of existing buildings and sites often requires careful historical and physical analysis. Depending on cultural significance or deformation of existing buildings, architects collaborate with heritage specialists. For instance, Musée Unterlinden Extension in Colmar, France, designed by Herzog & de Meuron, involved a close collaboration with architects of the French national heritage department to adaptively reuse a medieval convent complex (ArchDaily 2016). However, in many cases, architects themselves make decisions when encountering challenges. One example is the interior intervention project for Stedelijk Museum Schiedam that adaptively reused a listed building–the 1787 Neoclassical chapel in Schiedam, The Netherlands. With this project, architects had to cope with substantial deformation of the floors and ceilings, according to Nathalie de Vries of MVRDV (Dezeen 2015). Thus, accurate as-built data is critical for designers and engineers to deal with existing conditions as well as new interventions.

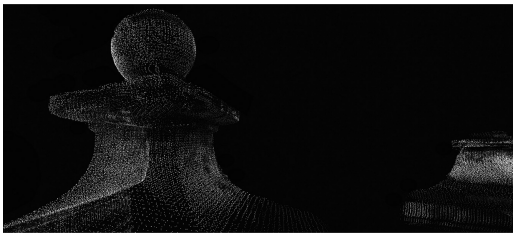

Figure 1. Point cloud. Parapet detail of Shwe-Nandaw Kyaung, Mandalay, Myanmar. Laser scanning by the authors, 2014.

However, many old buildings and sites have no digital design records or have never been inspected after construction (Bennett 2009).

3D digital models from laser scanning can provide accurate information of complex existing buildings and sites and their conditions. This information can help with design and construction for restoration, retrofit, interior renovation, architectural expansion, landscape addition, and urban rehabilitation. For instance, a construction firm Beck Group employed laser scanning to repurpose 1939 Hinman Research Building at Georgia Institute of Technology, Atlanta, USA. Not only did this provide an accurate digital model of the existing space but also reduced time and cost required to go back to the field and undertake onsite work (Turner 2011).

3 LASER SCANNING

English Heritage defines 3D scanning (often referred to as laser scanning) as "the act of using a laser device that collects 3D coordinates of a given region of a surface automatically and in a systematic pattern at a high rate [as much as a million points per second] achieving the results in (near) real time" (Jones 2011, 19). There are numerous systems and types of scanners for recording a variety of object scales, range, and accuracy (Boehler & Marbs 2004). The principal product of laser scanning is a point cloud. Point clouds are generated through the registration and alignment of individual scans (Jones 2011). Depending on size and density, point clouds can contain millions to billions of points establishing the xyz coordinates of the surface of a building including its details and context (Fig. 1). Products that can be generated from point clouds include, among others, two-dimensional, black-and-white line drawings in AutoCAD or another program, surface or solid models, and video animations (Boehler & Marbs 2004).

4 APPLICATION OF LASER SCANNING IN LITERATURE

4.1 *Use of point clouds for monitoring*

Some research addresses the use of point clouds generated from laser scanning for monitoring of not only existing structures but also new constructions. Point clouds can be used for mapping historic masonry building walls to inspect overall surface changes, cracks, and structural issues (Pesci et al. 2011, 2012). For the maintenance of concrete structures, the point clouds can help detect and measure spalling by calculating the depth of sectional changes on a wall surface (Mizoguchi et al. 2013). In addition, the progress of building construction can be estimated by matching a point cloud of a construction site with a designed CAD model (Zhang & Arditi 2013). This concept can also be applied to monitoring MEP projects by matching circular cross sections of pipes' point clouds to determine how accurately a structure was built as designed (Bosché et al. 2015). Monitoring elevational change of a 3D laser scanning model can help with seismic damage testing for structural engineering (Takhirov 2010).

4.2 *Surface or solid modeling from points*

A point cloud is literally composed of points, and this unique format may limit its architectural use by many architects and engineers who do not typically use it despite highly accurate information. The usability of point data can increase when it is converted to 3D digital models with surfaces or parametric components, which are more widely used. Using modeling software capable of housing a point cloud, a surface or solid model can be built directly over a point cloud by using sectional profiles traced on the point model (Leonov et al. 2015). If a historic building has a repeated classical language, knowledge from archival sources, like pattern books or historic drawings, can be added to develop a library of building components for a parametric model (Murphy et al. 2013). For other irregular or non-classical buildings, however, starting from point clouds by laser scanning can generate more accurate results than modeling upon two-dimensional information (Quattrini et al. 2015). Furthermore, laser scanning attic spaces can significantly enhance understanding of complex structures inside historic vaults and domes, which are often hard to measure by hands and different from original drawings (Balletti et al. 2014, Herráez 2014).

4.3 *Development of HBIM*

As Building Information Modeling (BIM) has become an important part of architectural practice, recent research examines developing so called Historic Building Information Modeling (HBIM) using geometric information from point clouds by laser scanning. Most research discusses modeling strategies and appropriate levels of detail, since standardized BIM assemblies and objects are hard to use for many historic buildings with complex shapes and variations (Fai & Rafeiro 2014). Challenges are the representation of historic elements avoiding excessive simplification and at the same time, development of a model that different experts can use together (Oreni et al. 2014).

Although existing buildings with relatively simple shapes can be modeled using original or surveyed 2D drawings (Fai et al. 2013), most research on HBIM development shows the use of spatial data from laser scanning or other 3D imaging (Quattrini et al. 2015). While literature mostly focuses on modeling, some recent projects, like the 3D documentation of George Washington's Mount Vernon, Virginia, USA, show a more comprehensive approach in terms of integrating survey and archival data into a 3D digital model and 3D GIS application (Benson et al. 2015, Fink 2015).

4.4 *Lack of research on architectural practice*

There is a limited amount of research and examples of architects' active use of point clouds by laser scanning. HBIM projects often require time-consuming modeling work, and in previous literature, the direct use of point clouds is mostly for surveyors' monitoring such things as cracks and deformation. Professional architects and engineers, however, often have a limited amount of time and budget, and a point cloud by laser scanning itself can convey a substantial amount of information of existing architecture. Therefore, designers who plan interventions for existing buildings and sites need to directly use a point cloud. This practice can be aided by recent improvement of software, such as Autodesk products and ArchiCAD, in capability of handling large point data. Designers can combine and render their new design components with the as-built virtual space without additional modeling.

An important benefit of laser scan data is that designers and engineers can virtually visit the site whenever they want from their offices and collect specific, detailed information for documentation, analysis, and creative design. Another advantage of laser scanning, distinguished from typical manual modeling, is that one-time scanning can capture not only buildings but also contexts. When dealing with existing buildings, the surrounding environment is often an important part to study, but most research on 3D imaging focuses on buildings and structures as single objects. Therefore, this study incorporates a comparative case study of laser scanning for historic interiors and a monastery complex representing some products and information from scan data for consideration in architectural practice.

5 COMPARATIVE CASE STUDY

5.1 *Steinway Hall, New York City, USA*

The Steinway Hall on 57th Street, New York City, is a sixteen-story masonry building constructed in 1925 by the Steinway & Sons piano company. The building had recital rooms on the ground floor where professional and amateur pianists tested new pianos before purchase. The building also had its own recording studio to broadcast music on the radio. Recently, a developer purchased the building and an adjacent property and is building what will be, for a while, the tallest residential

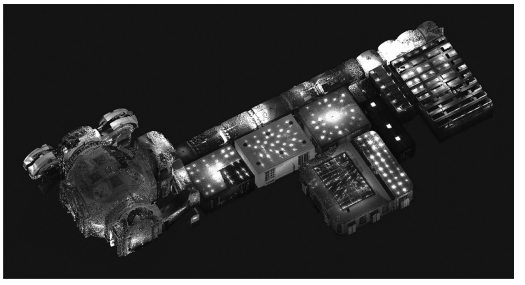

Figure 2. Point cloud. Interiors of Steinway Hall, New York City, USA. Laser scanning by the authors, 2014.

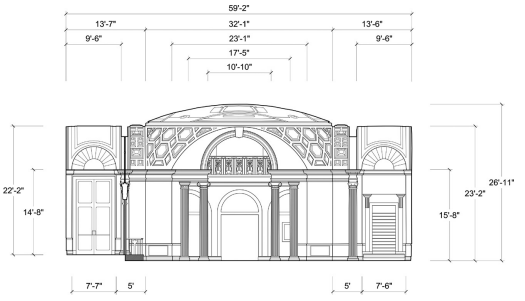

Figure 3. Interior elevation. Steinway Hall, New York City, USA. Drawing by the authors, 2015.

tower in New York City. SHoP Architects (2016) plan to adaptively reuse the historic building for an entry hall and community space for the new adjacent tower. Although the Steinway Hall's exterior and its grand hall are listed as landmarks and protected, other interior spaces, including the recital rooms with ornate plaster ceilings, were demolished in 2014. Before the selective demolition, the interiors were digitally recorded using laser scanning (Fig. 2).

The initial purpose of laser scanning was to document the historic interiors that were selectively demolished. Only a few hours were allowed for scanning due to urgency of the construction, thus medium resolution scanning, which took shorter time, was undertaken. 29 scans were taken to cover the approximately 9500 ft^2 (883 m^2) ground floor interior with one grand rotunda, five recital rooms, and one hallway. A point cloud of the 29 scans helped with creating detailed interior elevation drawings for each individual space and a simple mass model of the area to be renovated. For potential replication for design purposes, partial surface models of the ornate plaster ceilings were created from the point cloud. In collaboration with the University of Florida Envision Heritage, American College of the Building Arts created rubber molds based on measurements taken from the 3D digital models to recreate the lost plaster ceilings.

Highly accurate two-dimensional drawings of the historic interior elevations were created by tracing over scalable orthographic images of walls, floors, and ceilings taken from the point cloud (Fig. 3). These black and white line drawings, including spaces remaining

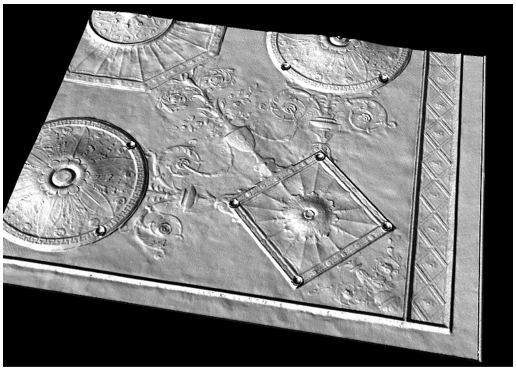

Figure 4. Mesh surface model. Interior ceiling of Steinway Hall, New York City, USA. Modeling by the authors, 2015.

and gone, are critical records of what existed. According to Dodsworth (2009), if creating interiors within an existing building, the designer should understand what formed the character of the building. At the same time, a simple 3D mass model was quickly created by putting and trimming flat surfaces on planes of the walls, floors, and ceilings. Despite lack of details, this simple model provided designers with the sense of proportions, volumes, circulations, and opening positions of the existing spaces. Both products are basic, but fundamental resources for any interior rehabilitation project, and no extensive hand measurement is required if laser scanning, which guarantees quick, accurate 3D documentation, is conducted.

Surface models of the decorative historic plaster ceilings were created to examine the possibility of using the scan data for recreating historic elements for new design or potential later restoration (Fig. 4). Partial mesh models composed of triangle surfaces, smaller than a quarter inch (6 mm), were built by automatically connecting individual points of the scan data. These rough mesh polygons were smoothened for better representation. The software Rhinoceros 5 and its plugin RhinoResurf helped with modeling. The surface models increased the visibility of small details that were hard to look closely on the point cloud because points disappeared when zooming in. The mesh models exactly trace the point cloud and make computer-aided fabrication, like 3D printing or CNC routing, possible. Moreover, high quality handcraft was experimented by artisans taking measurements from both point cloud and mesh models. While computer fabrication physically copies a digital model whether it is good or not, hand fabrication allows artisans to make the decisions for parts weathered or lacking sufficient scan data.

5.2 *Shwe-Nandaw Kyaung, Mandalay, Myanmar*

Shwe-Nandaw Kyaung is a nineteenth-century Buddhist monastery in Mandalay, Myanmar. The main building, constructed in the traditional Burmese style with ornately carved teak wood, has two connected

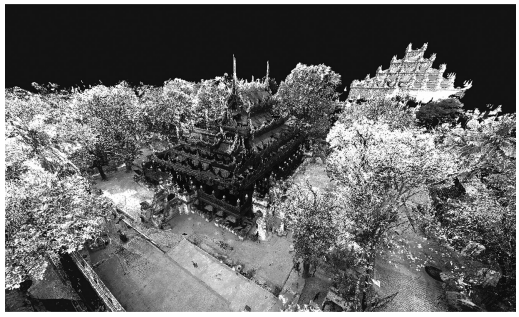

Figure 5. Point cloud. Shwe-Nandaw Kyaung, Mandalay, Myanmar. Laser scanning by the authors, 2014.

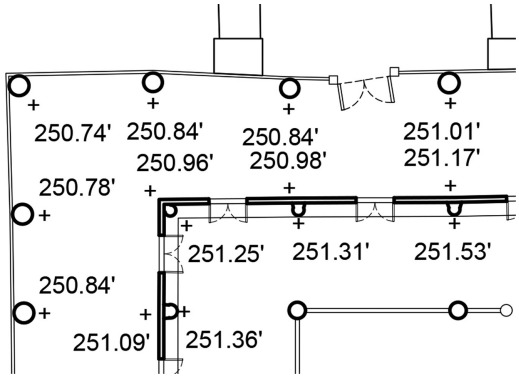

Figure 6. Floor elevation mapping. Shwe-Nandaw Kyaung, Mandalay, Myanmar. Drawing by the authors, 2016.

interiors surrounded by a veranda and stands in a garden with other smaller structures. This historic place has been threatened by seasonal flooding that is exacerbated by the lack of appropriate drainage maintenance in the site and surrounding urban context.

To help with rehabilitation of this place, a total of 217 scans recorded the main building's exterior and interior, garden, neighboring properties, adjacent canal, and surroundings (Fig. 5). It was challenging to secure scanner stations and complete field work in a busy tourist place and changing weather conditions.

The point cloud covers an about 5.2 acre (21,000 m^2) area, including the 1.7 acre (6900 m^2) monastery site. The point cloud helped with creating a complete drawing set of the building and site and some mappings with specific information, such as floor elevations and ground topography. Using these products, a water management plan, as a part of a comprehensive rehabilitation effort, is being prepared including redesigning the existing garden and improving the drainage system of the building.

After two-dimensional drawings were created by tracing over orthographic images from the point cloud, accurate three-dimensional information was added. For instance, a floor plan with detailed spot elevations of the floors of the veranda and interior helped with renovation planning for the 336-foot-long (102 m) veranda to improve drainage of the building (Fig. 6).

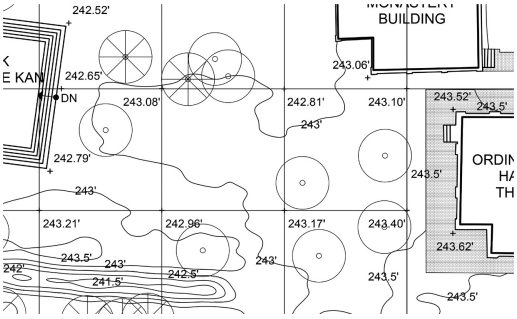

Figure 7. Topographic mapping. Shwe-Nandaw Kyaung, Mandalay, Myanmar. Drawing by the authors, 2015.

This information helped figure out irregular inclination of the historic structure. After defining GPS information of a fixed benchmark that was in place during scanning, spot elevations were documented by measuring vertical differences between the floors and benchmark. Since the point cloud virtually represents reality with millions to billions of xyz coordinates, highly accurate elevation information can be collected from the laser scan data. This is a significant advantage of laser scanning, and the benefit increases when the point cloud is used for landscape mapping.

For the landscape design intervention incorporating a water management strategy, a two-dimensional base map of the site was integrated with accurate topographic contour lines with 6 inch (0.15 m) interval, elevation grids for every 30 feet (9 m), and spot levels at the corners of buildings (Fig. 7). These are crucial survey resources for landscape design especially for a site with water issues (DesignWorkshop 2016). The contours were created from NURBS (Non-Uniform Rational Basis Spline) surfaces that were draped over the point cloud using the software Rhinoceros 5 and its plugin RhinoResurf. NURBS surfaces are often used for modeling organic-shaped architecture due to their smooth curves. The nature of this mathematical structure can benefit landscape modeling. Like a thin cloth covering an object, NURBS surfaces that were draped over the point cloud accurately depicted the topography of the ground. Once the surface model is done, it is possible to automatically create sectional contours with any benchmark and interval. The grid and spot elevations were added in the same way that the floor elevations were collected.

6 CONCLUSION

Steinway Hall and Shwe-Nandaw Kyaung represent different types of architectural heritage from western and eastern cultures and demonstrate two varying approaches to the treatment of existing and historic architecture. Due to the unique form and features of each structure, the challenges of each site context, and the time and other limitations placed on field work, accurate documentation and analyses of both properties proved difficult. Despite these difficulties, the two cases demonstrate that a laser scanning survey can create an accurate as-built digital model (a point cloud) of a building and its context. The three-dimensional data serves as a powerful repository of information that designers and engineers can refer to and use remotely as they continually assess and understand existing and historic buildings and their sites.

The Steinway Hall and Shwe-Nandaw Kyaung demonstrate that a point cloud produced by one-time laser scanning can generate a variety of information for different experts and purposes without physically revisiting the site. The Steinway Hall case shows that a point cloud helps with not only drawings and digital models for the new design intervention, but can also inform the reconstruction of lost elements and even whole resources. The Shwe-Nandaw Kyaung demonstrates that the same type of digital data gathered to record the architecture and built environment can also provide a highly accurate topographic mapping for water management planning, as a part of a comprehensive rehabilitation effort. Both projects also relay the ability to collect and analyze information from the point cloud, significantly reducing time for surveying and field work. For example, the Shwe-Nandaw Kyaung topographic mapping was continually updated using the digital documentation and information provided by the project manager and other experts working from varying locations. Architectural practice, especially focused on the built and historic environment, will continue to transform as laser scanning and 3D imaging technologies advance and become more common place.

Keio University, Tokyo, Japan

ABSTRACT: After The Second World War, Japan has built many public facilities, including art museums. To nowadays, museum buildings have been characterized for having freer shape due to the program exhibition requirements, so architects are encourage testing how far they can push the limits of their abilities in architectural design. In this investigation, art museums are taken as an effective sample of architectonical design processes of the last 65 years. First, through the analysis of the architectural elements' cases and compositions, a typology classification had been made. This study tries not only to identify some of the elements and characteristics of the Contemporary Japanese Architecture, but also to establish the relationships between the formal composition and the interior organization that define them. The goal is to establish a classification of Japanese Contemporary Museum, describing the characteristics of the new types that have emerged over the past years.

1 INTRODUCTION

1.1 *Background and research question*

Since the beginnings of the Architecture there have been authors who tried to summarize architectural principles and theorized about them. In architectural composition, the classification of buildings attending to their intrinsic characteristics is one way of summarizing concepts as types. This study aims to continue previous studies classifications and adapt them to a contemporary way of thinking architecture.

As for Contemporary Japanese Architecture, at the beginning of the 1930s, at the same time when Japan adopted Western modernism in architecture, an identification of Japan-ness (Isozaki, 2011) to an external gaze began. Since then, the debate of the "Japanese taste" in architectural design reminds when studying Japanese conformed architecture. In that sense, it is relevant to talk about Japanese architecture as an example of a particular way of thinking architecture because the social and historical context in which is formed.

After The Second World War Japan has built many public facilities, including art museums. During the bubble-era (1989-1995) (Daniel, 2008), many buildings were demolished and replaced with new ones. Because of the economic and social circumstances of Japan at that time, buildings started to acquire new roles. In some cases, various projects, particularly museums and cultural centers, "were completed mainly for reasons of rapid investment, prestige, their image value, or even political pressure or rivalry" (Bognar, 2008). To nowadays, museum buildings have been characterized for having freer shape due to the program exhibition requirements, and most of them have a larger budget than other public buildings, so architects are encourage testing how far they can push the limits of their abilities in architectural design.

This investigation takes art museums as an effective sample of architectonical design processes of the last 65 years in Japan. This study tries to identify some of the elements and characteristics of the Contemporary Japanese Architecture, and also to establish the relationships between the formal composition and the interior organization that define it. The goal is to establish a classification of Japanese Contemporary Museums, describing the characteristics of the new types that have emerged over the past years.

1.2 *Methodology and sources*

Due to the complexity of architecture, graphic analysis is a method used to express architectural form, concepts and systems in a reduced way. Many architects theorized about architectural concepts by using this analytical method. Alexander Klein (1980) established a graphic method to study typology classification and make comparison and validations between different buildings. Another architects such as Peter Eisenman (1982), John Hejduk (1984) or Christopher Alexander (1977) used graphic analysis and architectural diagrams to express concepts and architectural systems.

In order to a better understanding of the study cases and their design concepts, this study is focused on museums form analysis for being more objective than intangible qualities. The investigation method is based on form analysis to provide an appropriate model to describe architectural concept formation. The analysis of the geometry of the building plan, and the creation

of conceptual diagrams, is one way to show how new architectural concepts can be derived.

In most of the cases the plan conveys the central organizing strategy of a building. It is full of clues about the designer's values and attitudes toward theories of order, methods of construction and so on. The idea is not to use the plan just as a set of data, but also of values, ideas and analogies that had shaped the building in a particular way.

The conceptual diagrams are created from every case like a parti diagram, in order to delineate the dominant organizational and formal concepts governing an architectural scheme for the subsequent analysis. The purpose of this study in plan is not to demonstrate the abstract perfection of ideal form itself but a schematic design process through which the creative intention can embody the complex relation between concept and form, and the internal organization.

1.3 *Object of study*

102 samples (Table 1) had been selected from the period after the Second World War. These buildings are published in the periodical Shinkenchiku Nenmatsu from 1950 to 1990, and in Japanese Architecture Yearbooks and GA Publication from 1990 to 2015. This study uses these sources because their consistent review-oriented approach and the precision of its data. The information is based on architectural drawings and pictures found in those sources.

The purpose of the buildings is art museum, dismissing other purpose museums such as natural museums or science museums. Small pavilions and galleries annexed to other buildings different from art museum are not considered. Renovations and temporary buildings are also excluded. In the cases that museum program is mixed with other uses such as library or auditorium, only the examples where the main public access area is intended for exhibition use are considered.

1.4 *Previous studies*

After the Second World War, the socio-economical context where Japan was immersed allowed architects to develop new ways of experimentation in architectural concepts. In this way, museums are able to show the architectural thinking evolution, and very often they are open to public debate. There are several studies on Japanese Contemporary Architecture and museum typology that show a relation with this paper. The studies of Nakai, Moriyama and Sakamoto (2006) show an approach to museum elements composition. In the case of Koike and Nakagawa (2011), they focus their research on public museums' spatial configuration.

This paper aims to identify issues that could be of broader relevance in architectural design analysis, the study of museum architecture, and research about Japanese Contemporary Architecture.

2 CONCEPTS' DEFINITIONS

Two descriptive levels are defined. On one hand, cases are analyzed in terms of boundary conditions. On the other, the relationship between internal elements is defined.

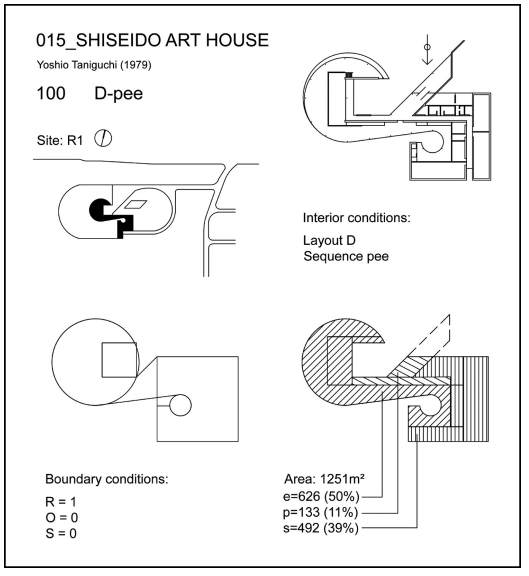

Figure 1. Analysis example.

Table 2. Concepts for boundary conditions.

REGULARITY = 1				REGULARITY = 0	
ORTHOGONALITY = 1		ORTHOGONALITY = 0		MIX	PURE
AXIALITY = 1	AXIALITY = 0	STRAIGHTNESS=1	STRAIGTNESS=0		

The entire samples are diagrammed according to these levels of study, and defined by a code (Table 1). For example, the analysis of Example 1 (Fig. 1) is defined by "100 D-pee" code. The first part of the code defines the case in terms of boundary conditions; the second part describes the layout and the sequence pattern. There is also an approach to the surrounding conditions and the usage areas of the program.

2.1 *Boundary conditions*

For the boundary conditions the interior space information is systematically dismissed in order to emphasize the idea of the shape, as a figure-ground diagram. For the creation of these diagrams, secondary elements such as exterior open galleries or small walkways are not considered.

The selection of the concepts is made with cautious consideration: Regularity, orthogonality, axiality and straightness (Table 2). These concepts have representativeness mainly in the description of the shape of the boundary diagrams and are applicable to architecture as an object, enabling to explain some issues of museum's architecture in terms of space composition.

A system for Boolean analysis is used, where data type has only two possible values: true (1) or false (0).

Regularity

"Regular forms (R = 1) refer to those whose parts relate to each other in a consistent and orderly manner. They are generally stable in nature and symmetrical about one or more axes. (…) From our experiences with similar forms, we can construct a mental model of the original whole even when fragment is missing or another part is added.

Irregular forms (R = 0) are those whose parts are dissimilar in nature and related to one another in an inconsistent manner." (Ching, 2007) They are usually form by organic shapes and more dynamic than the regular forms. They are called "mix irregular forms" if they are composed of a regular form with some irregular element or organic shape part. On the other hand, the ones that are totally irregular are called "pure irregular forms".

Orthogonality

Two types of regular forms can be distinguished: The cases where the reconstruction of the whole form is made of combination of rectangular shapes (O = 1) are defined as orthogonal examples. Non-orthogonal examples (O = 0) are defined for being regular forms with subtracted items, forms created from a regular shape irregular composition, such as trapeziums, and regular curve forms as made with circles or ovals.

Axiality

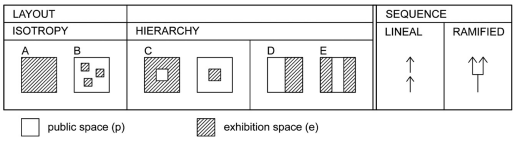
Regularity and orthogonality are two important concepts to understand the shape of the elements in a plan, but there's still one more concept needed to define the relation between the pieces. In this way, axiality defines the turns of elements and a main axial direction. For the group of cases which elements are defined as regular and orthogonal there are some of them where axiality value is true (A = 1) and others where the elements interact with turns, and then the value is false (A = 0).

Straightness

For non-orthogonal forms, there's still one more characteristic to be consider and that it's especially important for architecture: The presence of curved elements. When talking about boundary configuration, straightness is related to the geometry of the whole regarding to the segments taken one by one. The construction methods and most common structural systems nowadays consist of geometrical and rectilinear elements. However, there are many attempts to find new ways of architectonic expression by using curved shapes in their buildings. In this way, it is interesting to subdivide this group into two categories: The forms witch boundary is composed by straight sections (S = 1) against the ones that include curved parts (S = 0).

2.2 *Interior conditions*

For the interior conditions, not only the shape and size of the spaces is relevant, but also the program and the connections between them. In the programmatic diagrams, three different areas are distinguished: areas for



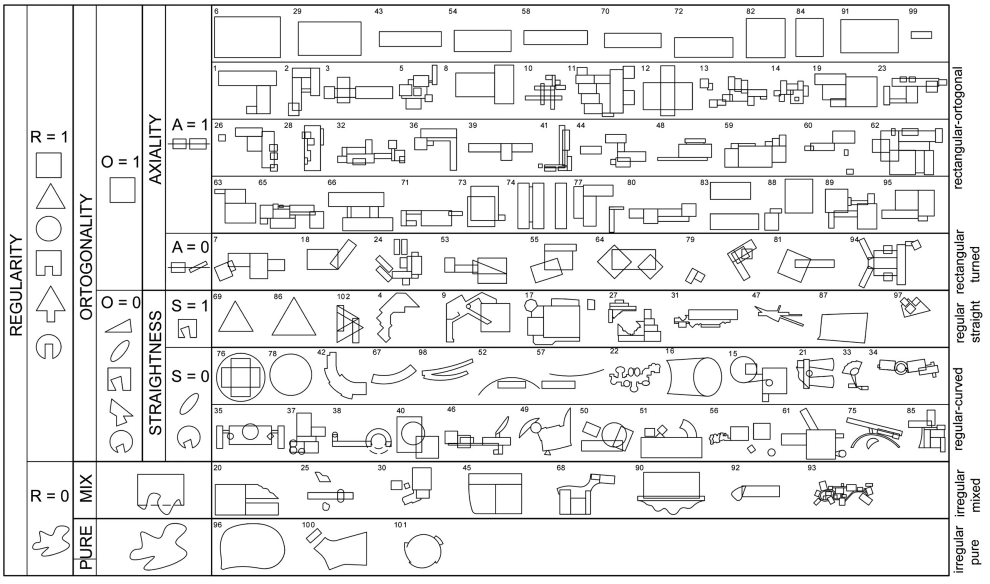
private use restricted to public access, such as office or storage (r); areas for public services, such as cafeteria, auditorium or library (p); and areas for exhibition spaces or expositive galleries (e) (Table 3).

In terms of sequence, the space is diagrammed according to the layout and the circulation. Comparing the layout, five different groups are defined. The fist two ones (A and B) are differentiated for been isotropic spaces. Isotropy is uniformity in all orientations. When talking about architecture, isotropy is related to the perception of space and it's connections. In this case, the parameter of isotropy wants to qualify the connections between spaces through the sequence of the visitor.

So isotropic cases (A and B) are related to non-delimitated exhibition spaces and non-hierarchical space connections. By contrast, anisotropy cases (C, D and E) are those in which space properties are directionally dependent. Layout C has a central distribution. D and E have a hierarchical distribution for the areas depending on the use. In D cases the distribution attends to the program separating exhibition spaces from public spaces. For E cases, the public space act as a link between exhibition spaces.

Interior conditions in terms of shape and position is defined by the terms above. But there's still one more parameter to consider, the connections between spaces. Besides the sequence of the building depends basically on the layout, the circulations order through the building it's also needed. In this way, cases are also classified attending to the circulation sequence from the main entrance to the exhibition space. The building sequence is diagrammed base on the analysis of the space divided in phases, attending to the use of the areas and it relative position, dismissing shape and size.

Table 3. Concepts for interior conditions.



3 ARRANGEMENT

3.1 *Compositional diagrams. Typologies based on boundary conditions*

In order to understand the external boundary, cases are divided according to their specific qualities and similar arrangement in terms of formal composition. In Table 4, concepts are shown in the left column and the result of the classification in the right column, distinguishing the following six different types:

- Rectangular-orthogonal type (code 111) is defined by their regularity, orthogonality and axiality and it represents the simplest shape boundary condition. The rectangular shapes are combined to create the whole composition of the plan (46 cases out of 102). Sometimes (11 out of 46) just one shape is enough to conform the whole building plan.
- Rectangular-rotated type (code 110) whose composition in plan is also based in rectangular forms, but the axiality is lost (9 cases out of 102).
- Regular-straight type (code 101) is formed by regular but non-orthogonal cases formed with rectilinear boundary composition (11 cases out of 102).
- Regular-curved type (code 100) is formed by regular but non-orthogonal cases including curved boundary elements (25 cases out of 102).

Table 4. Boundary conditions types.

- Irregular-mixed type (code 0M) present cases formed by irregular forms, including some organic-shaped elements combined with regular parts (8 cases out of 102).
- Irregular-pure type (code 0P) is composed by cases with organic form along the entire boundary (3 cases out of 11).

3.2 *Sequence diagrams. Typologies based on interior conditions*

As for the internal organization of the museums, cases are divided according to their specific qualities and similar arrangement in terms of interior layout and sequence. Concepts are shown in the left column of the Table 5 distinguishing two main groups:

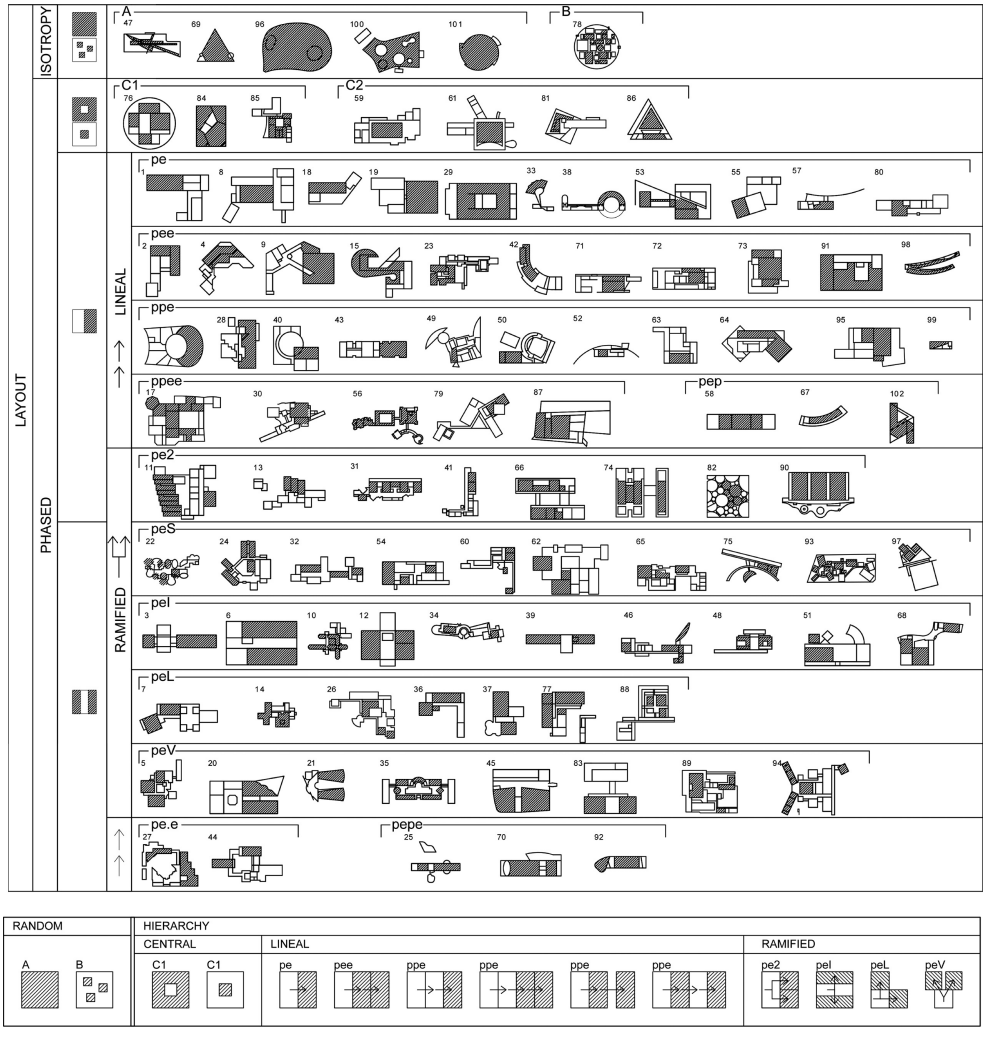
Isotropy group (6 cases out of 102) is formed by cases where the layout presents an isotropy space configuration. Two different types are consider in this group:

- Type A (5 cases out of 102) is formed by unitary small spaces.
- Type B (1 out of 102) is formed by multiple exhibition spaces connected in a non-hierarchical way.

Phased group (96 cases out of 102) includes cases related to phased architecture sequence with a hierarchical formation layout. Three types are included in this group (C, D, E). In D and E layout types, the classification in terms of sequence is specified within two subgroups: Lineal sequence and ramified sequence.

- Type C (7 cases out of 102) is formed by central layout cases. In this type, the direction of the movement is described when talking about sequence. In this way, there are centrifugal cases (C1, 3 cases out of 7) and centripetal cases (C2, 4 cases out of 7).
- Type D (49 cases out of 102) is formed by cases with hierarchical layout, where the use of the areas is divided clearly in exhibition space and public space.

Table 5. Interior conditions types.



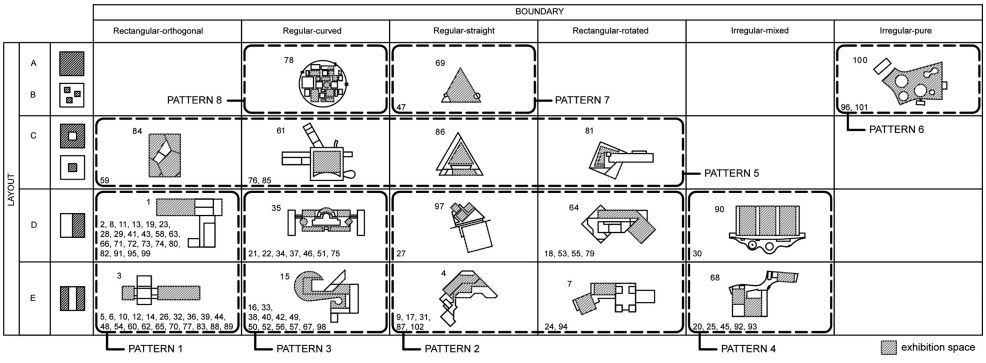


Table 6. Boundary-Interior connections patterns.

- Type E (40 cases out of 102) is formed by cases with hierarchical layout, where the exhibition space areas are divided in two or more areas and connected by public space areas.

3.3 *Boundary-interior connections*

Once cases have been analyzed and classified based on their external boundary and interior conditions, the resulting typologies are combined and eight patterns are created and defined as shown on Table 6.

- Pattern 1 (44 cases out of 102) is formed by cases with a rectangular-orthogonal external boundary and D or E layout.
- Pattern 2 (16 cases out of 102) 2 is formed according cases regularity and straightness (regular-rotated and regular-straight boundary types). This group presents D or E layout.
- Pattern 3 (21 cases out of 102) is formed by cases with a regular-curved external boundary and D or E layout.
- Pattern 4 (8 cases out of 102) is formed by cases that present an irregular-mixed external boundary type. This group also presents D or E layout.
- Pattern 5 (7 cases out of 102) is formed by central layout cases. The clarity of the central space organization and the regular shape of the boundary characterize this pattern, so the group is classified according to the interior distribution, presenting several different external boundary type compositions (rectangular-orthogonal, regular-curved, regular-straight and rectangular-rotated).
- Pattern 6 (3 cases out of 102) is formed by irregular-pure cases. They present a non-hierarchical layout organization type A, composed by a single exhibition space.
- Pattern 7 (2 cases out of 102) is formed by regular-straight cases. They also present a non-hierarchical layout organization type A, and composed by a unitary space.
- Pattern 8 (1 case out of 102) is formed by a single case (case 78, 21st Century Museum of Contemporary Art) and is consider an exception for been composed by multiple exhibition spaces. This case has regular-curved external boundary type.

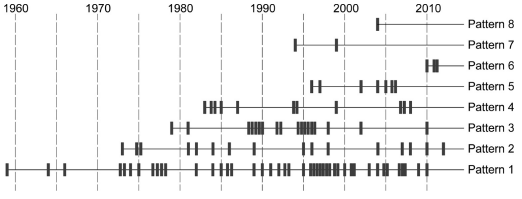

Figure 2. Timeline groups distribution.

3.4 *Timeline*

Finally, groups are analyzed in terms of time (Fig. 2). Cases are plotted along their group timeline according to the year when they where built. A progression in the timeline from pattern1 to pattern 7 can be noted, giving some clues about concepts evolution. As an overview, results suggest a tendency for the use of organic shapes in the boundary conditions and the preference for non-hierarchical plan layouts, allowing museums design became more dynamic.

The comparison between patterns 1 to 4 indicates that, within the same static and phased layout (D or E), an evolution through time from regular to irregular shapes can be noted. Whereas pattern 1 rectangular-orthogonal boundary type characteristics continues over time, cases with irregular boundary conditions are appearing during the last analysis years. This means that some cases, even if they follow the tendency on external boundary for including organic shapes, the layout configuration remains static according to the previous years patterns. For example, case 20 (The Museum of Modern Art of Saitama, 1983) presents a irregular-mixed external boundary and E type layout (code 0M-ERpeV). By contrast, some of the regular boundary type museums that had been built in the last two decades (Patterns 5, 6 and 7) show a significant change with regard to the layout configuration, having more dynamic compositions (A, B and C layout types). For example, case 84 (Kanno Museum, 2005)

has a regular-orthogonal external boundary and a C1 layout type.

4 DISCUSSION

From the typology viewpoint, a clear grouping is shown: Cases related to classical architecture understanding are characterized for having a regular boundary and hierarchical formation layout (Patterns 1, 2 and 3). Pattern 4 also shows a hierarchical layout (D or E), but with different external boundary (irregular-mixed). Central layout (Pattern 5) is related to changes at the external boundary composition, but with a strong involvement with the interior conditions. For patterns 6, 7 and 8, cases have an isotropic layout, but the big differences in their external boundary conditions give us the need of split them in tree different groups. Patterns 6 and 7 cases have a common characteristic: To be formed by a unitary exhibition space. Pattern 8 composed by case 78 (21st Century Museum of Contemporary Art) must be underline for being a singular case formed by several exhibition spaces, presenting a regular-curved plan boundary and, at the same time, having a layout composition that suggest the release of hierarchical order.

From the timeline viewpoint, the result show that regular-orthogonal boundary type with static phased layout type (Pattern 1) prevails over time. For the next groups (Patterns 2, 3 and 4), the changes in the external boundary had been included gradually through time. There are also some regular boundary type museums that have been built in the last two decades (Patterns 5, 6 and 7) showing a significant change with regard to the layout configuration, having more dynamic compositions (A, B and C layout types). The timeline analysis suggests some tendencies with special emphasis on the use of organic shapes in formal design and the intention of finding non-hierarchical plan layouts, so architects are trying to develop new ways of designing compared with the previous years conception of art museum. This can be interpreted as an attempt to design according to the new social reality where art is observed according to the user mood and freedom of movement.

5 CONCLUSIONS

The characteristics of contemporary Japanese art museums in terms of external boundary and interior layout have been examined. First, cases plan configuration was defined as parti diagrams, as a way to find formative ideas and architects intention. Second, diagrams where analyzed according to the different concepts definitions. Third, classification in terms of external boundary and interior conditions was made. Finally, applying comparisons and connections of these typologies, patterns had been clarified and some tendencies outcome from the timeline analysis.

As an interpretation, we can find there's a change from more regular to more irregular forms in the external boundary analysis of Japanese art museums. There's also a tendency from more stable to more dynamic interior plan layout, attending to the new way of enjoying art.

Additionally, the results show some possibilities for plan design and program distribution, and also give a clue for establishing connections between them. This study provides a basis for further work to deepen on other architectural Japanese art museums elements and concepts, such as daylight, materials or environmental analysis.

ACKNOWLEDGMENT

Japanese spirituality, flexibility and design: Influences and impacts on agile architecture + open building

B.R. Sinclair
University of Calgary, Calgary, Canada
Sinclairstudio Inc., Calgary, Canada

ABSTRACT: Contemporary times can be characterized as turbulent, shifting and uncertain. Rapid urbanization and dramatic intensification are coupled with technological leaps and a call for sustainability. Conventional architecture was typically purpose-built with limited concerns about adapting downstream to new users, different purposes and altering conditions. Today however, with climate change, different demographics, resource depletion and affordability challenges, it is argued that building plasticity is urgently needed (Sinclair, 2015a). Rather than having people adjust to static spaces and places, next generation architecture must be dynamic, responsive and adaptive to needs, circumstances, culture and context.

Japan is a country that has historically approached extreme demands on space in unique, innovative and successful ways (Sinclair, 2015b). In this island nation with inadequate resources, large population and limited legroom, environmental design has assumed directions that explore and overlap inside with outside, pragmatics and poetics, and the sacred with the profane. Spirituality is pervasive in many dimensions of everyday living, including in the design, construction and occupation of architecture. Powerful Buddhist concepts such as emphemerality, impermanence and non-attachment have had demonstrable consequences on the theories and practices of design. Traditional Japanese housing, for example, deploys tatami mats and shoji screens to afford infinite degrees of mutability, plasticity and change. Spaces shift in size and function. Borders blur between interiors and landscapes. Proportions swing, walls move and movement becomes fluid. The architecture accommodates fluctuations in need, intention and experience.

For a wealth of reasons it is argued that architecture of the 21st century must approach similar levels of flexibility and adaptability. Rather than demolishing buildings to bulk up landfills, our architecture should be developed for disassembly, redesign, reassembly and reuse. The present research, following from focused literature reviews in Architecture and Spirituality realms, examines housing & commercial (both historic and modern) case studies from Japan. Included in the methodology is a critical examination of Japan's open building movement, undeniably a leading edge strategy for introducing greater choice and freedom in design, delivery and dwelling. A series of qualities, variables and approaches are delineated that hold relevance, and provide lessons, for agile architecture more broadly considered. Building upon the analytical aspects of the present research, a model is then synthesized and presented, suggesting a novel path for next-generation architecture.

At the present juncture architectural theory, education and practice needs to grapple with unprecedented demands, unforeseen complexity and a call for much greater responsibility. Within this milieu agile architecture stands as one viable route to meeting such charges. The author contends that Japan's proven methods for environmental flexibility hold tremendous value beyond Japan as we struggle to make our cities, blocks, buildings and interiors more mutable, adaptable, responsive and responsible. The present paper draws unique connections between agility (e.g., Open Building) and spirituality (especially Buddhism), while concurrently expressing the need for other nations to learn from the design accomplishments of Japan. Emphemerality, impermanence and non-attachment prove highly pertinent notions in the new millennium as we strive to reposition architecture from static to dynamic and from fixed to flexible.

Keywords: open building, agility, architecture, Japan, Buddhism, change, society, sustainability, design

1 INTRODUCTION

> *"The spaces of the contemporary city are characterized by fluidity, multiple layers and phenomenality; these also happen to be the characteristics of microchips.*
>
> *(Toyo Ito, 1994)*

Modern society is intensely complex, both at the local level and on the global stage. Rules and regulations, while often established for safety and security reasons, commonly spin out of control as one face of daunting bureaucracy. Depletion of resources, rapid urbanization and a collective call for greater environmental accountability introduce wicked problems into realms

of design and planning. Technology proves a blessing and a bane, with many contemporary crises fueled by state-of-the-art products and processes yet frequently solvable only via deployment of these same systems. While a century ago many problems were comprehensible and localized, today many problems are incomprehensible and universal. Without question the facets to be considered, and the variables to be managed, have exponentially cascaded to the point where we often are uncertain how best to begin and confused regarding where best to intervene.

Within this milieu architecture is routinely viewed as progressive and leading. While there are undeniably moments of innovation and edginess, the author argues that in general the profession is more conservative than it could, should and must be, especially considering the high stakes presented in today's ethos. A major concern of the present paper is the static nature of design and planning outcomes, and in particular the general inability of our products to shift, morph and mutate based on quickly changing requirements and demands (e.g., human needs, environmental conditions, financial forces, etc.). Today's buildings, for example, deploy approaches (e.g., development, organization, production, operation, etc.) that are in many ways similar to those utilized over the past century. Despite remarkable advancements in material science, information technology, and systems performance, many projects are designed and constructed in old-fashioned ways, with antiquated means and with permanence in mind.

The rigid nature of design and construction translates into architecture that is not easy to change, into interiors that can't readily adapt, and to the burden of responsibility for accommodation placed on users of environments rather than the environments themselves. Such conventional posturing is especially seen in North America where the design, development and construction industries are intensely fragmented, fractured and arguably less than optimized. However, in some global jurisdictions, such as the Netherlands and Japan, great strides have been made in both theory and practice concerning models for more flexible and mutable interiors, buildings, blocks and cities. Falling under a series of monikers, most notably Open Building (OB), such approaches consider building systems that cooperate (interoperability) together yet which retain separate identity and component integrity. The sub-systems or components differentially respond to such factors as anticipated life-span, ease of change, levels of complexity and shifting use.

Japan is the main focus of the present paper, which looks at how spiritual and philosophical tenets have informed and influenced a societal embrace and a move to more flexible design and agile architecture. In particular the presence and principles of Buddhism are critically examined in light of Open Building strategies. Qualities of spiritual practice, such as the illusory nature of reality and our perceptions of solidity versus fluidity, have shaped both Japanese designers and the consumers/end-users of the resultant designs.

Figure 1. Modern 'Traditional' Room in Japan.

There are many lessons to be learned by Western architects, developers and builders, and especially so given the dramatic pressures to be more responsible, more accountable and more sustainable. Design needs to respond to the ever-changing needs of users and communities, versus having these users adjust to arguably inappropriate and ineffective static and staid environments. Interiors, buildings, blocks and cities need to be far more dynamic and accommodating, in many ways responding sensitively and sensibly to the volatile, uncertain and constantly fluctuating features of modern societies.

2 JAPAN + DESIGN

> *"If there is to be any order of beauty in the age of life principle, it will be in a dynamic balance that maintains its order, while always moving, roaming and changing."*
>
> *(Kisho Kurokawa, 1995)*

Space in Japanese culture is fundamental to design, dwelling, working and living – the nation assumes very different ways of understanding and approaching space compared to the West. As an island society with limited resources and large population, space is particularly precious and valued. Many families in Tokyo live in a fraction of the residential space that counterparts in North America might enjoy. Japanese society lives with high density and crowding as a simple fact of coping with a significant population on a less significant land base. The metropolitan area of Tokyo is home to more residents than the entire country of Canada. In Japan psychological, cultural and social norms have developed that permit so many people to live in such close proximity. Personal space is tight and crowding is commonplace. Expectations for resources are relatively low while conservation and reuse is unquestionably high. Architecture and design support the need to live in confined spaces and tight places, and mechanisms of design work hard to make the tight feel more expansive and the small seem larger. Vehicles such as choreography of path and control of view (including the so-called 'Zen view') are vital in the quest for promoting comfort, pursuing beauty and seeking harmony (e.g., between people and environment; between the built and the natural, etc.).

Form and materials are important in Japanese design, interplaying in balance with the significance and meaning of space. On the material side, Japan is known as a 'wood' culture due to the historical access to timber as a primary building material. The structural qualities of wood, with its limited spans, gave way to a post and beam construction system. The manner of building homes and temples, with complex joinery and regular grid layouts, fostered the rectilinear geometry that is so prevalent in historic Japanese architecture. From this building approach arose many aspects of Japanese design that are now well known in the West, including perhaps most significantly the interconnection and mutability of spaces, the use of infill panels (most notably the shoji screens), and the creative control of perspective to shape perceptions. Nishi and Hozumi (1983) describe qualities of architecture arising through reliance on post and beam construction: "There is, moreover, a fluidity in Japanese architecture between inside and out. Though fixed walls are frequently used, the distinction between wall and door is very elastic, and whole facades in both temples and residences can be opened to the elements at will by folding open or swinging up the panels between posts or by sliding open, or even removing entirely, the wooden or paper screens." Such historically embedded understanding of space has had demonstrable impacts on modern architecture in Japan, including on designers' willingness to pursue agility.

In Japan there is an important concept known as *shibumi*, which in essence translates as an unassuming elegance and conscious reserve. When shibumi is elevated it invokes what is called the beauty of *wabi sabi*. *Wabi* is about the wretched, forgotten and forlorn while *Sabi* is about the 'rust' of age. It is arguably in the union of *wabi* and *sabi* where Japanese design becomes most compelling and aesthetics most remarkable – where the simple, the unaffected and the elegant coexist. We find this search for beauty, and the invocation of *wabi sabi*, deeply rooted in the traditional Japanese arts of *ikebana* (flower arranging), *bushido* (the way of the sword), and perhaps most notably *sado* (also referred to as *chado* or the way of tea). For the purposes of this paper, each of these 'arts' include strong temporal, and ephemeral, qualities. While preparations and reflections are inherent and valuable, it is the moment that proves especially critical. Certainly such concepts loom large in the efforts of Japanese architects and landscape architects, especially in their search to impart beauty, tranquility, mutability and meaning in an ever-escalating modern milieu of technology, urbanity and uncertainty.

One critical aspect of Japan, that informs and inspires design, is the deeply rooted spiritual history that underpins the culture. Shintoism and Buddhism are inextricably intertwined in the society, with ramifications witnessed over a spectrum of endeavours from business and the arts, to education and politics. The Zen notion of *mushin*, or 'no mind', is a good example. Without a mind one is rendered without a self. Without a self one is afforded great freedom from the many trappings and seductions of common existence – inching ever closer to escape from the vicious cycle of suffering Buddhists call *samsara*. Ideas around and implications of 'non-attachment' loom large. Japanese design and architecture often seeks such release from trappings and clutter, electing instead for the simple, the austere and the unadorned. The Japanese term *kanso* acknowledges the importance of simplicity of design, akin perhaps to German modernist architect Mies van der Rohe's famous dictum "less is more".

Modern Japanese architecture, perhaps most notably in the work of the Metabolists and inspired by deeply-rooted philosophies (Kurokawa, 1995), pursued ideas of reconfigurable form and space in a new era of technological, material and societal revolution. Coupling simplicity of design and economy of means with the need for fluidity and mutability in environments, Japanese architecture has historically, and continues to, acknowledge and respond to the need for users and their built realm to exist synergistically, to transform as conditions shift, and to be less about solidity and more about fitness.

3 FUNDAMENTAL CONSIDERATIONS

> *"People are very open-minded about new things – as long as they're exactly like the old ones."*
>
> *(Charles Kettering)*

The central topic that this research paper explores is the connections and relationships between the tenets, philosophies and features of Buddhism in Japan and their influences and impacts on flexible architecture and planning. To address the central curiosities of this paper, the author critically reviewed the literature on both Buddhism & Open Building (OB), and visited/studied numerous agile projects (e.g., Kikou Skeleton Infill [KSI], Next 21, Muji, Sekisui & Toyota housing, prefabricated housing + others) with a view to establish some links and connections.

While previous studies have explored the role of Buddhism in shaping Japanese design more broadly, the present paper is particularly concerned with implications on more mutable (i.e., agile) contemporary architecture. Without question historical design approaches have been influenced by spiritual and philosophical views of humankind's place in the cosmos, including the illusory nature and transitory character of existence. We see in the traditional Japanese dwellings many connections to such viewpoints, including for example, the blurring of boundaries of realms (e.g., inside versus outside) and the infinite permutations (e.g., a meeting room transforms to a bedroom). Limited study has been focused on the role of the spiritual underpinning of Japanese culture on the development of agile approaches to modern buildings.

Present research underscores that such design is undeniably an outcome of prevailing world and self

views. It is important to stress that while designers and architects have pioneered this agility in buildings, the broader societal acceptance of the approach has permitted it to grow and flourish. It is quite difficult for architects in the West to easily understand the motivations and forces shaping this agile architecture, especially given the West's subscription to science and technology at the expense of other ways of seeing, thinking and acting. However, the author contends that being open to this approach, and grasping some of the drivers behind greater agility, could translate into more responsible, responsive and sustainable projects beyond Japan. Some serious shifts in mindsets and methods are, of course, fundamental in this regard.

4 OPEN BUILDING

Modern architecture can arguably be seen as conventionally generating buildings of rigidity, and inflexibility, with designs unable to adapt to changing needs and with limited integration of inherent systems. Such buildings, unable to be effectively retrofitted and easily renovated, have all too often seen demolition only to become one of the most significant contributors to our landfills. Open Building, as an evolving architectural methodology, allows our buildings, similar to ecological systems, to shift and adjust over time. Embedded flexibility enables such buildings to adapt to different circumstances and be mutable in terms of systems upgrades and ongoing maintenance (Kendall & Teicher, 2000) – hence, in the larger picture, they prove more resilient and less wasteful.

The adaptability in OB has become possible through separating the structure or 'support' from the interior or 'infill' – in essence ensuring that the systems in a building are independent yet inter-related (Habraken, 1999). This innovative approach challenges the typical 'entangled' systems in conventional buildings and provides much greater degrees of flexibility. John Habraken (1994) introduced 'support' and 'infill' as new categories among existing levels in his theory of "decision-making levels in the built field". In this theory, Habraken divides the built environment into different aspects that have varying lifespans and across which the decision-making and control is delegated to different parties. In these various 'environmental' levels, users have the ultimate control over the 'flexible' interior or infill level to adapt it to their own needs and desires. In this system, 'support' is the continuation of urban fabric in the third dimension (Habraken, 2008) – its longer life-span and relative permanence supports stability with respect to long term community interests while 'infill' accommodates change in respect to individual preferences in the shorter, more immediate, term.

Debatably Open Building's century-old history has been more dedicated to the technical development of 'support and infill'; while the discussion over the design, character and aesthetics of these buildings have been largely overlooked. In a previous paper,

Figure 2. Next 21 Open Building Project, Osaka Japan.

the current researcher introduced the notion of 'aesthetic flexibility' (Safarzadeh, Mousazadeh & Sinclair, 2011) as a complementary concept to already established notions of 'spatial flexibility' and 'functional flexibility'. The notion of 'aesthetic flexibility', as a novel dimension in OB theory, holds promise to celebrate 'identity', foster 'customization' within the OB design equation, and strengthen built outcomes. The idea of 'aesthetic flexibility', in the author's sense, applies to two different levels in the theory of "decision-making levels". First, it applies to the 'infill', which allows the users to adjust their interior environment according to their changing spatial needs but also modify it to reflect their personal character, culture and aesthetic preferences. Second, it applies to the façade of the building, which interestingly lies between the domain of community interest and individual preference. Consideration of such duality is arguably a crucial and innovative step in the evolution of Open Building. The concept of 'aesthetic flexibility' further positions itself within a broader understanding of the design & construction milieu, including a significant resonance with the notions of and frameworks for Agile Architecture and Holistic Design + Planning (Sinclair 2009, 2010, 2012).

5 BUDDHISM

In Buddhism there is strong awareness of the illusion of permanence – that is, we construct and perceive our lives in a manner that suggests solidity, stability and predictability. All of this understanding of permanence however is mere folly, for the world and our lives are in constant change. What we accept now as reality is merely our best interpretation based on available knowledge, stimuli, past experiences and guesswork. Japanese culture accepts that life is ever-changing, and that a path that acknowledges the frailty & vulnerability of our journey, and the uncertainty of our path, is wise and reasonable. Zen teaches that in the midst of unpredictability, disorder and delusion one is well

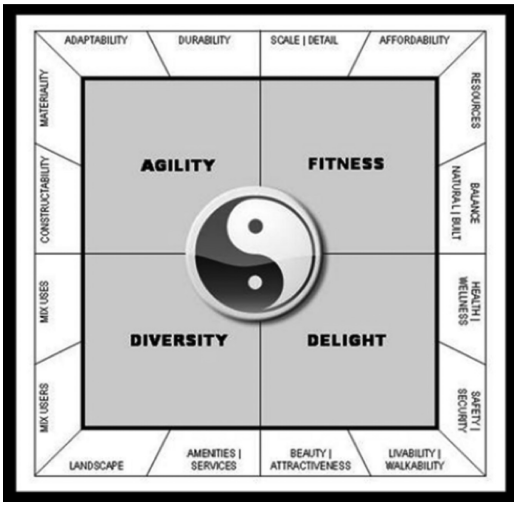

Figure 3. Sinclair Holistic Framework for Design + Planning.

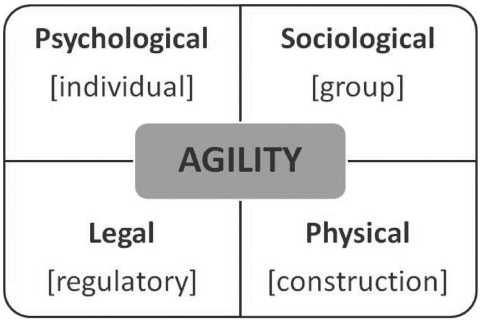

Figure 4. Sinclair Agility Framework.

advised to make things as simple as possible. The goal of reducing one's environment down to its basics, to limit exuberance and seek the most minimal essence, is indeed noble.

While we see this search for simplicity, austerity and restraint in contemporary Japanese design, from Tadao Ando's awe-inspiring concrete churches to Kengo Kuma's masterful collages of glass, steel and wood, it is also clearly evident in far more modest fabrications, including the constructions of the homeless. The author has previously written about Japan's informal sector, delineating the 'temporary' housing of the day-labor class. Such 'architecture' is unquestionably accepting of uncertainty, mutable in nature, light on the land, efficient in operations, and effective in the provision of shelter that protects, nurtures and provides a rightful sense of dignity.

Japanese architecture, from both historical and contemporary perspectives, has encountered strong inspiration & influence from Buddhist thought. Spiritual notions of impermanence & ephemerality (*mujo*) impart a sensibility into design. Such impact is seen in the employment of cardboard and paper as building materials in the projects of contemporary architect Shigeru Ban. Concepts of layering, lightness, change, transience and the transitory can also been seen in the work of Arata Isozaki, Rei Kawakubo, and Metabolist master Kisho Kurokawa (notably his Nakagin Capsule Tower in Ginza). Taro Igarashi (2005), in his article "Kisho Kurokawa: Buddhism and Metabolism", noted that the architect's "…global view that creation and destruction run fluidly into one another has its roots in Buddhist doctrine." He adds that, "In the original language of Buddhism, *samsara* means 'to flow', and also means the combination of various states, expressed through the process of reincarnation." It is clear that the work of numerous modern Japanese architects celebrates many dimensions of Buddhist thought, including demonstrably the inevitability of change, a lightness of being, and the cycle of suffering common to all sentient beings.

6 CONNECTIONS + RELATIONSHIPS

> *"An empty space is marked off with plain wood and plain walls, so that the light drawn into it forms dim shadows within emptiness. There is nothing more. And yet, when we gaze into the darkness that gathers behind the crossbeam, around the flower vase, beneath the shelves, though we know perfectly well it is mere shadow, we are overcome with the feeling that in this small corner of the atmosphere there reigns complete and utter silence; that here in the darkness immutable tranquility holds sway."*
>
> *(Junichiro Tanizaki, 1933)*

Architectural and urban design in our modern ethos is ever more complex, driven in part through remarkable advancements in technology, in part through escalating regulatory demands, and in part by dramatic shifts in demographics, expectations and needs. Designers and developers of projects, across a range of scales, struggle to ensure relevancy, viability, potency and sustainability. To achieve such ends the exploration and application of Open Building theories and practices proves increasingly important. In reaction to static and immutable conventional environments (e.g., interiors, buildings, landscapes, etc.) Open Building and Agile Architecture methods foster a milieu of flexibility, modularity, adaptability and change. This vital notion of change has numerous dimensions, including key qualities that take account of the technical and the social. While the vast majority of research efforts have focused on scientific, technical and quantitative characteristics of Open Building, the present paper argues that the human, social and spiritual attributes are equally critical. Included in this latter set of pursuits is Buddhist philosophy that is richly infused and subconsciously pervasive in daily life in Japan.

In our quest for heightened mutability and adaptability of environments it is essential to consider

change in a broader fashion. While the technical capabilities of change in an environment can be developed and realized, such possibilities prove moot if the users of the resultant space(s) are resistant to adjustment, unwilling to take action, and reluctant to transform. In other words, the provision of flexibility in environments does not, de facto, translate into environments that will be modified by users. Key to the equation of greater mutability is not merely the ability of a user to effect change, but more importantly the willingness and desire to effect change. In the West change has not been a common part of many design equations nor of many constructed environments. In this way an embrace and adoption of more flexible and agile architecture in North America is an uphill climb. There are many fundamental ways of operating that need massaging and transforming if the design and development sectors in North America are to move towards greater mutability of our spaces and places.

The following Buddhist principles are worth considering in more detail when exploring agile architecture and open building:

6.1 *Ephemerality*

Ephemerality is in some ways the opposite of being concrete, being fixed and being set. It implies a lightness of existence and an ethereal quality. In the West our architecture often aims at being grounded, at conveying stability and communicating certainty. In Architecture schools we often witness the intense pursuit of iconic, monumental and over-bearing structures. Seldom in such settings do we see students encouraged to include changeability, to foster user-driven design roles, and to relinquish the architect's 'divine authority' to create and control. In contrast Open Building, in the eyes of the author, strives to address all of these qualities. Hence, especially in the West, the movement towards Open Building and Agile Architecture is viewed with suspicion, concern or even outright denial/dismissal.

6.2 *Impermanence*

Impermanence is a core principle of Buddhism, which holds that all of reality is in constant flux. To assume that any circumstance, object or being is truly fixed is truly folly. Life is a journey of constant motion and ever-changing situations. Each moment is distinct from those preceding and those proceeding. Uncertainty is a certainty. In Western approaches to design and architecture we are most comfortable, on many counts, with total predictability. Financing models, for example, are aimed at costing out projects at a fixed moment in time based on a set bill of materials. In many cases project capital costs exclude less rigid components such as moveable walls and furniture. Such narrow views then serve to limit any embrace of uncertainty and tend to preclude more agile, flexible models of development (including, for example, modularity and sometimes prefabrication). With skepticism abundant, and the role of architects and architecture rather entrenched in notions of permanence, it is easy to understand how the environment in North America has proven hostile to more mutable buildings. The author argues, in light of an urgent call for greater sustainability, that a deeper understanding of impermanence is important. Approaches aimed at a design for disassembly, deployment of modular building systems, and empowering users to modify their spaces and places, seems timely and worthwhile.

6.3 *Non-attachment*

Non-attachment involves our ability to distance ourselves from the material world in an effort to more fully understand ourselves and our reality. In the West our obsession with consumption and consumerism (albeit now growing rapidly in the East) make non-attachment an ellusive concept. North American marketing efforts tell us that "We are what we own". In design this translates into the role of buildings as status symbols, of products as instruments of power, and of Architecture as object. Non-attachment, as a concept of Buddhism in Japan, serves to weaken the link between the object as precious, as unchangeable and as primary. With space seen as ultimately changeable and the material world viewed as transient and detached (or detachable), architects and end-users are far more willing to accept buildings that might morph, shift, subside, reform and resurface.

7 SUSTAINABLE RESPONSIBLE DESIGN

> *Sustainability is a term commonplace in contemporary culture. The idea that we do no harm, and even that we might leave the world in better condition than when we found it, seems reasonable in principle yet incredibly difficult in practice. Globally, our populations are growing, our cities expanding, our technologies developing, our environments decaying, and our cultures destabilizing. Buildings are placed everywhere yet belong nowhere. Literacy increases. Yet crime spreads. Indifference grows. While compassion dissolves, internationalization advances. However, fragmentation proliferates.*
>
> *(Brian R. Sinclair, 2015)*

While few would question the environmental challenges confronting designers and facing civilization more broadly, it is remarkable that contemporary architecture and urban design remains so entrenched in conventional practices. Our landfills are ripe with construction waste, primarily with products of demolition. As cities change and grow, the built environments struggle to keep pace. The need for more and better space frequently translates into renewal, revitalization and redevelopment, which usually involves removing the old and building the new. Given the dynamic

Figure 5. Nakagin Capsule Tower Unit.

character of our cities it seems logical, and imperative, to conceive of and construct spaces and places that can twist and turn, adapt and adjust to shifting needs. Rather than building environments that are glued, wired and welded into single aggregations it seems wiser to assemble worlds that can readily be dismantled, reconsidered and reconfigured. We need a next generation of walls that morph as needed, floors that travel as required, ceilings that alter as called for, facades that flex, and systems that exist independently while operating collectively. If environmental design professions are serious about responsibility, accountability and sustainability, the author argues a dramatic change in design strategy is needed. If educators are to prepare graduates for more effective contributions, then studio pedagogy needs to jump from an obsession with the creator and his/her iconic creations to models that focus on the users of buildings and on environments that are quick to respond. If governments are keen to see optimization of resources and better management of finances then far greater attention must be paid to the way that environments age, accommodate, amend and repurpose. Agile Architecture, Open Building and Resilient Environments seem prudent directions to pursue given the tremendous pressures at play and the certainty of uncertainty in our complex, turbulent and often unstable world.

8 CONCLUSION

"What is called the spirit of the void is where there is nothing. It is not included in man's knowledge. Of course the void is nothingness. By knowing things that exist, you can know that which does not exist. That is the void."

(Miyamoto Musashi, 1645)

The present paper has considered the largely unknown intersection of, and relationships between, aspects of Japanese spirituality with key traits of Open Building. While previous research has exposed connections between Buddhism and traditional design in Japan, little consideration has been afforded to links between the country's leadership in agile architecture and Buddhist principles. The author argues that a number of over-arching tenets of Buddhism have played roles in facilitating and catalyzing such dramatic innovation in the design and development of spaces and places.

Fundamental spiritual principles, including ephemerality, impermanence and non-attachment influence daily life in Japan, albeit in often subdued and unconscious ways. Over many centuries a rich mix of Shinto and Buddhist practices have inspired and shaped culture. The conduct, and indeed the consumption, of design in Japan have likewise seen significant influence and impacts via such deeply embedded spiritual guide posts. With dramatic advancements of Japan after the Second World War, and given pressures to accommodate growth while addressing intense change, it is understandable how innovations in design were so aggressively pursued. With a bright yet unknown future in mind, many emerging architects in the 1960s and 1970s pioneered novel ways of crafting space, meeting needs, and addressing uncertainty. Subsequent designers pushed notions of flexibility even further, beginning to consider (e.g., Next 21) how the full development, including facades, might mutate to tackle shifting needs and emerging demands. Over recent years many efforts by Japanese practitioners, researchers, and government agencies have actively explored Open Building and experimented with agile architecture. Throughout this post-WW2 period it is argued that the intertwining of the spiritual and secular realms has had demonstrable influences upon architecture and design, including most notably on the ingenious and brave approaches of Open Building. The author contends that while the West has operated under very different circumstances, there are valuable lessons to be learned that could make architecture more responsive, responsible, accountable and sustainable. Spiritual notions of ephemerality, impermanence and non-attachment can be reconsidered and applied, in a secular manner, within design principles, pedagogy and practice beyond Japan. In an era and ethos of environmental urgency, the design world has much to learn and much to gain by migrating from the static to the mobile, from the fixed to the flexible, and from the rigid to the dynamic.

The urban persistences and social traditions in the (re)creation of the Japanese urban modernity

J.M. Silva
Forma Urbis LAB, CIAUD, Faculty of Architecture, University of Lisbon, Portugal

ABSTRACT: In a time of a constant urban and cultural transformation is imperative that traditions remain in use by society as a link between the past and the present. The problem is that the continuity of the traditions it isn't always a fluid and authentic process. But still it's possible to find in the present city values and routines that persist form the previous social layers.

So, the main goal of the study its to identify traditional scenarios and rituals that persist from Edo era to the present social experiences of Tokyo, her successor. The idea is to show different forms of appropriation of the public and private spaces that continue to be used as before in the local beliefs and culture of today. This hypothesis integrated in urban traditions can be shown, for example, in the relationship between the Shrines and Temples with the local communities through religious rituals, festivals and ceremonies.

1 TRANSITIONS AND PERSISTENCES FROM EDO TO TOKYO ERA

Since the late nineteenth century that Japan is in the process of building a new identity with the production of hybrid forms of heritage, based on precise values of the past that are adapted and reproduced in building a "Japanese Cultural and National Identity". In this context, spaces are lived in the image of an "authentic" identity of the past, returning to an origin that is intended to value and lived by today society.

The profound changes occurred in the Meiji period (1868–1912) and after the 2nd World War (1945–1952) have introduced in Japan new ideas and concepts that imposed a forced redefinition of a culture that defines itself according to traditional values. That is, Japan lives since then the dichotomy between modernization and the preservation of his past, or between the innovation and the safeguard of the traditions. The sequent Japanese societies over time have created and idealized the past traditions, "as an ideological for present conceptions" of a Japanese way of life (Scheiner, 1998).

In Tokyo, the complexity between the old and the new it's a constant characteristic that determines the diversity in a very homogeneous urban texture. The previous layer of the city appears in small spaces between the current urban fabrics. In this confrontation, lies sometimes the construction and reproduction of elements that redefined the relationship between society and their history. This interaction allows the invention of traditional spaces that society embraces as heritage in our days (Hobsbawn, 1983).

For Eric Hobsbawm the "historical continuity" results from the invention of the traditions as a creative process of adaptation to a new cultural environment. The creation, the invention of traditions, emerges in time in fast social transformations that destroy the patterns of the traditions, producing automatically new ways to adjust the inadaptability of the society to its previous meaning and use.

The creative process of remaking the traditions may involve: the break with the past to claim new a tradition; the construction of a new element fully copied from a past shape, creating a "false historic"; or through the repetition of past characteristics and shapes in a new environment.

The "invented traditions" are imposed formally in the present as rituals of a lived past. A past adapted to current uses or that serve as examples to new identity and cultural perspectives (Hobsbawm, 1983).

The reuse of the traditions that haven't been "relived" or "invented", if they aren't deliberately adapted may represent a resistance to innovation. Traditions are often (re)invented from a "routine" or a "convention" of the common sense and not from an ideological meaning. Hobsbawm points them as a social resistance to the transformation of the cultural habitat by new concepts and rules. But, in practice when an object "symbolic" or "ritual" reaches its uselessness by saturation, it can't be re-used or transformed.

For example the invention of the "traditional" Japanese castles in the 80s representing architectural models of a feudal period from the seventeenth and nineteenth centuries; or the gardens that are no more than reinventions that copy different forms like places, artefacts and buildings to sustained the Japanese memory and history.

So, how does the Japanese society adapts to the evolution and modernization of the city, especially in a period of globalization, keeping intact its cultural and architectural traditions and identity? How does the "traditional" city adapt to the twenty-first century keeping the past intact?

The urban landscape of the contemporary city can be considered as a scenario of close relations between the monuments and the people, a urban framing made from the reciprocal relationship between the history built and society.

The urban landscape is understood here as a process of contextualization of collective memory, relationship of the observer with the built environment (buildings, public spaces and monuments), which affirm concepts corresponding to the identity of the place time.

The cities of Edo and Tokyo were made between hills and rivers, urban spaces created in communion with nature. The first was build as a castle town, extremely ruled by a hierarchical system, organized in different districts: the "upper town" created as a "green city" for the high samurai class and the "down Town" in a relation with the water front, populated by a lower-class samurai and common people.

Tokyo, in turn, grew on top of the urban fabric produced by the old system, keeping it largely intact. What have changed in this new city were the political systems, the war destructions and the cultural external influences that affected the social experiences, the design and the materiality of urban space.

Beyond the urban structure, hills, rivers and green landscape it's still possible to find a few reinterpretations of the old social habits like the yokocho-streets in Shinjuku or Ueno district areas (Fig. 1–2). The streets are filled with markets, "Sake" drinking establishments, yakitori restaurants and karaoke bars that transform Tokyo social behaviour from a day business life to a human city by night. But some times this is seen, as a "stain in the grime of history" as Hidenobu Jinnai says in is work "Ethnic Tokyo" (Jinnai, 1991).

The vernacular traditions have been used to provide the present with traditional images, long after the transformation caused by the modernization of the nineteenth century, including wooden-houses and spiritual buildings, even clothing and social identity (Sorensen, 2002).

2 INFLUENCES AND URBAN REFORMS: OUTLINE OF JAPANESE HISTORY

The multiple influences of the West cultural societies allowed the establishment of architectural and urban values that are recognized as identities of the historical image of Japan. Among others it can be highlighted the influences of the Chinese culture between centuries VI and XII in the production of urban and local arts as well as in the definition of spiritual values, for example the introduction of the Buddhism in the Japanese religious culture.

Figure 1. Shinjuku Omoide Yokocho. Surrounded by a big cosmopolitan city exists within the urban blocks narrow and winding old streets, part of a network of alleyways with small bars and restaurants.

According to Hideto Kishida[1] the inclusion of the "foreign arts" in the Japanese society allowed the improvement of what he entitles as "beauty of proportion" and exemplifies with the Buddhist temples Shitenno-ji, Hōryū-ji and Hoko-ji (Kishida, 1935). Another example of this influence are the cities of Nara (Heijō-Kyō) and Kyoto (Heian-kyō), two old imperial capitals that were planned according to a Chinese urban system characterized by a regular orthogonal

[1] Hideto Kishida in his book "Japanese Architecture" makes a characterization of the Japanese architecture organised in a "chronological classification of architecture in Japan". The chronology is divided into three major periods: the first period (660 BC – 551 AD) is the introduction of Buddhism in Japan by the Chinese. According to the author there was no specific style that features buildings or urban ensembles; the second period (552 AD – 1867 AD) extends from the introduction of Buddhism to the Tokugawa Shogunate, corresponding to the "Buddhist style" period; and the third and final period (1868 –... AD) extends to the present the one corresponding to a period of profound influence of the West in the production of the arts and the city itself in Japan. Simultaneously he makes a characterization of the different architectural typologies of the Shinto Shrines, Buddhist Temples and Japanese architecture in general.

Figure 2. The Ameyokocho Market was built after the Second World War and was used by the American soldiers as a black-market. The market is located under and beside the Yamanote rail line at Ueno.

mesh structured from the Imperial Palace in the centre.[2] On the other hand, comparing with this strait Chinese system, the Japanese "Castle-town" demonstrates an asymmetric and irregular urban growth.

The "Castle-Towns" are a typical Japanese urban settlement, originated in the Tokugawa period and its major examples are the cities of Edo (Tokyo), Osaka and Nagoya. This method is the result of the establishment and affirmation of the Samurai class from the twelfth century to the beginning of the seventeenth century.

The organization of these type of urban layout, corresponded to a extremely hierarchical and military system organized into three segments: the "Inner Castle" represents the power with the houses of the feudal lord (Daimyo or Shogunate) and the most important Samurais in the society; the "Outer Castle" for the second-class samurai surrounded by areas of common people (peasants, artisans, merchants); and, the third, in the peripheral areas existed the monks with the Temples and Shrines.

While the interior it was highly organized its urban and peripherical context grew without planning, with an asymmetric growth. During the XVII century the "Castle Towns" overlapped existing fortified structures, taking advantage of easy defence sites that already contained some business functions, population, agriculture and communica-tion areas such as rivers and roads (Jinnai, 1995).

In this sense, it was in the Tokugawa period (1603–1867) that were made the firsts urban reforms of Edo. In the year 1600, with the Shōgun Tokugawa Ie-yasu (1543–1616), were changed river courses, built new communication routes between the center and the outline prefectures, urban expansion to north with the earthmoving of the Mount Kanda and to south with landfills in the city's bay, and the reconstruction of the castle using part of the existing functional structure.

A second renovation took place in 1657, after Meireki fire, involving the rebuilding and the displacement of shrines and temples from the downtown area for the uptown of the city. This process permitted the constructions of "major highways" that connect the center of the city with the peripheral areas. The approach streets to temples and shrines began to be built between the houses (Jinnai, 1995).

With the end of the hierarchical feudal system in the Meiji period (1868-1912) it happened a new reform of urban space. The new "Imperial restorations" were the beginning of a deep restructuring of the political, social and territorial system. The physical process of modernization of this "new" imperial city, Tokyo, was designed based on western guidelines but with the necessary adaptation to the Japanese culture. For example the downtown was reorganized as a Central Business District according to projects developed by German architects, English and Japanese. This reorganization involved the dismantling of parts of the castle fortifications to use stone in the construction of bridges, the occupation of the south land that were before in daimyo control for installation of government infrastructure and the construction of the first public park in western style Kasumigaseki, Hibya Park (Cybriwsky, 1991).

Between 1872 and 1923 the city is marked by a series of catastrophic events, fires and earthquakes, imposing a new transformation of the urban image of the city. However, these events and changings also represent the addition of new architectural and urban concepts that allowed a gradual modernization of the city's infrastructure.[3] During this period was developed the "Archi of Japanese Taste" joining a certain revivalism influenced by the Renaissance and Gothic architecture in Europe and the symmetric clearance of the modern movement. Among other examples was built the Nihon-Ginko (Bank of Japan) in 1896 and the Tokyo Station in 1914, both designed by the architect Kingo Tatsuno, and The Imperial Hotel, design by Frank Lloyd Wright in 1915.

In the city's reconstruction process after the 2nd World War (1939-1945) was introduced the memory as a mark of the recent past, a symbolic idea of the national commitment to the reconstruction of their own identity. For example, were built new memorials, valued the ruins as physical memories of an past

[2] With the ascension of the capital Nara in the VII century the influence of the Chinese arts resulted in the development of the Japanese "arts and crafts" and the in the introduction of a new urban system by coping the Imperial style of the "Changan Palace" in China. In the sequential dynasties the Chinese arts influence the architecture and landscape of the temples, especially in the Heian period, like the Kongō-Buji and Enryakuji on the Hiyei Mount; in the Kamakura period it was introduce the Zen Buddhism as a spirit and concept to the conception of architecture, the Shari-den of the Engaku-ji temple its an example; or the temples built in the Momoyama period as a Kamakura revivalism, rich in colour and carved decorations, as exemplified by the Zuigan-ji near Sendai.

[3] Among other events, the 1872 fire preceded the urban plan "the Tokyo city ordinance improvement" and the construction of the "Ginza Brick Quarter" designed by the architect Thomas Waters.

event and built new cultural symbols, as exemplified in the memorial A-Bomb Dome[4] in Hiroshima and, in a sense, the 1964 Olympic Games.

From the 80s was reintroduced the "revival" style in the architecture with the construction of neo-classical elements or neo-mannerist such as the Tsukuba Civ-ic Center, designed by Japanese architect, Arata Isozaki. The project is a reproduction of Michelangelo's Piazza del Campidoglio in Rome and shows somehow the appetite for the past forms rejected by the modern movement.

Currently the transformation processes of the city are related with the active super real-estate market that keeps the urban spaces in constant revolution. The curiosity of this process is the ability of the urban fabric to blend in a rhythm of advances and retreats between the public and private space.

Despite the approach and influences of the West in the production of the Japanese heritage or in the continuous globalization and transformation of the cities today, some culture practices still prevail in a local level. These events are connected in many cases with their spiritual believes that keep alive the culture identity in the relationship between the society with the shrines and temples.

3 SHRINES AND TEMPLES IN THEIR URBAN AND SOCIAL CONTEXT

The cultural significance of the shrines and temples and their importance in the organization of the urban space and local life experiences imposes a brief morphological analysis to their relationship with the urban and social context.

In the Edo period these spiritual spaces were located in the peripheral areas and along the main axes of the city's output, mixing the urban space between religion and the profane, promoting urban expansions and, above all, military defence. These areas were organized in a close relationship with their neighbourhood, according to their nature and usefulness. They were build in wood, some times in a agriculture environments, placed outside of the settlement and on top of small hills surrounded by forests as costume of the "Japan's ancient community structure (Fig. 3–4). The mountain shrine, plain shrine, village and field shrine, as models of developing farm villages spaces, were transferred to the structure of the shrine grounds, formal approach, gate and surrounding neighbourhood in the urban context" (Jinnai, 1991:61).

Before the opening of Japan to the West culture these sacred spaces were also consider as "green parks" in a near concept to the public space of a Western garden. But, none of them corresponds to a true concept of public space because they are private and without influence of uses and public administration. In the Meiji period some private gardens belonging to daimyo residences or sanctuaries were transformed into public spaces. Unfortunately, some of these areas have been reduced with the urban growth since then.

The particularity of these spiritual spaces before the Meiji period is that as the city grew they were successively displaced to the new areas of expansion. However the action is not synonymous with a physical displacement of the original building but the change of the religious community from the old building to the new one (Jinnai, 1995).

Despite the continue transformation of the urban fabric and landscape of Tokyo, the structure and organization of the shrines in the Edo period are still preserved in the present days. Despite being integrated within the urban blocks they are still evolved in the mythical relation between man and nature (mountain/forest), symbolic representation of the ancient sacred spaces. But, in many cases this relation it was produce or fabricated by man him self, as demonstrate by the inner-precinct forest of the Meiji Shrine in Tokyo built in 1920 to emphasize a political symbol with an idea of a national, traditional and sacred space (Imazumi, 2013).

Their relationship with the urban environment is in many cases made through a long and thin avenue that connects the city to the religious complex, passing the main entry (Torii) in the direction of the deity building. This element is the sandō. These walking paths are sacred spaces to prepare people before they reach the shrines and main temples, symbolize the way to achieve divinity. In the case of shrines the sandō is preceded and punctuated by a *Torii* or the *Tōrō* (stone, wood or metal lanterns) as demonstrated by the approach in side of the Meiji Jingu (Fig.5) and the Omotesando in Tokyo (Fig.6). And, in the case of the temples, the way can be started, or not, by a Temple Gate (Monzen-machi) as exemplified by the Senso-ji Temple in Tokyo (Fig. 7).

The days of festivity around the Shinto religion mark the space and social livings in the local context of the shrines, surviving from the Edo era to the present (Fig. 8). The inner-precincts and the surrounding streets of the shrines are absorbed by people who seeks to participate both in the ambience created by the food stalls (Fig. 9), located in the sandō, as well with the shrine deity's palaquin, the mikoshi[5] (Fig.10).

[4] The A-Bomb Dome (Genbaku Dome) it is located in the Hiroshima Peace Memorial Park, in Hiroshima, and was one of the few standing structures after the explosion of the atomic bomb in 1945. The preservation of the remaining's of the Hiroshima Prefectural Industrial Promotional Hall constructed in 1914 symbolises the war destruction and is an expresses of the hope for world permanent peace. The ruin had three conservation projects (1967, 1990 and 2003) and received a structural reinforcement to secured its integrity but lost part of its autentecity with the replacement of the steel structure of the dome (the original is in the Peace Memorial Park).

[5] The most traditional and important *mikoshi* event was held in a annual festival around the Edo Castle, connecting him to the Kanda Myojin Shrine at north and the Hie Shrine in the south of the city.

These social and cultural events are a very similar to the religious Catholic processions. The mikoshi symbolizes the deity, attempts to approximate the shrine to the community and delimit the neighbourhood area with the path created, a method to define his influence by affection to a specific sanctuary[6].

On the other hand, the temples are built integrated into the urban fabric and are mostly surrounded by cemeteries[7], may also include periodic fairs that encourage the habits and memories of the inhabitants of that community, give meaning to the locus. After the political transition the relocation or construction of new temples in consolidated urban areas were made in the public patios (Kaishi), interstitial areas of the urban blocks that served in Edo era as open spaces for deposit of wastes (Kochi, 2013).

Over time many areas with temples were developed in popular centres (Sakariba) joining the economic aspect to the religious celebrations. These leisure areas could contain theatres, teahouses, food stalls, and located along the Temple Gates (Monzen-machi). The urban context was developed in a similar system to the current Senso-ji and Gokoku-ji in Tokyo or Zenko-ji in Nagano, becoming an important part of the urban sprawl of Edo and partly of Tokyo (Cybriwsky, 1991).

4 FINAL REMARKS

The traditional persistences are forms of culture that result from the will of the society to return to their origins, at least to understand their utility in the production of social and historic identity.

These processes of cultural affirmation trough cultural traditions are in both western and Japanese culture a condition of the modern society; both of them are being transformed by a global point of view. The difference is that in Europe the traditions born, in part, from the sedimentation of time. So, it is to believe they will continue to be produced and created as before. In the Japanese case, traditions were kept for centuries almost intact in a closed society. Now the new traditions are the result of the influence of other cultures, and the old traditions just reflexes of actions reproduced or reinvented trying to keep unspoiled the "Japanese way" of the past in the present.

Thus, the continuity of the traditions is only possible with the peculiar relationship between modernity and time. In the Japanese case, as elsewhere, the residues of traditions are taken by nostalgic feelings of actions vanished from time, "fetishized" many times as functions of special events, religious practices or in the rebuilding of heritage scenarios. "We have seen, for example, how Japanese nativist ethnology, in its attempts to rescue disappearing words of narrative and practice from oblivion, rehabilitated them in the guise of the folkloric" (Ivy, 1995:242).

The places and acts of worship have tried to keep the old representations and habits of the traditional way. Even realizing that the processes of conservation or entrepreneurship sometimes loses some feature in

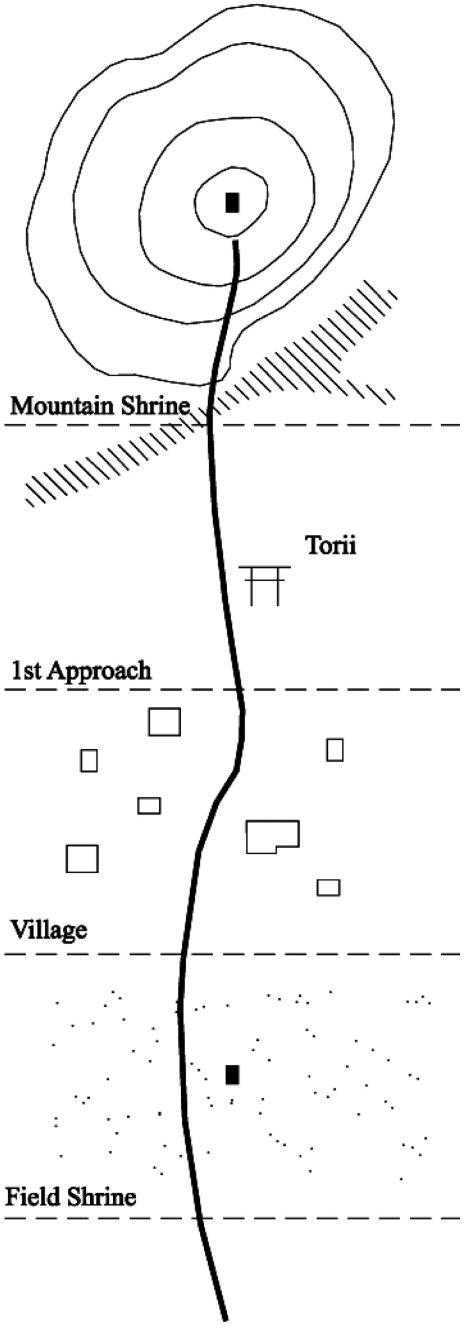

Figure 3. Hypothesis of a shrine approach (sandō) in his primitive urban settlement form.

[6] A special event is the festival that takes place in the Asakusa Sanja Gongen Shrine, where the mikoshi route simultaneously integrates a path by land and another by water, aboard a boat along the Sumida River.

[7] In some case it's possible to find temples fully integrated in a forest like the Eiheiji Temple in Fukui.

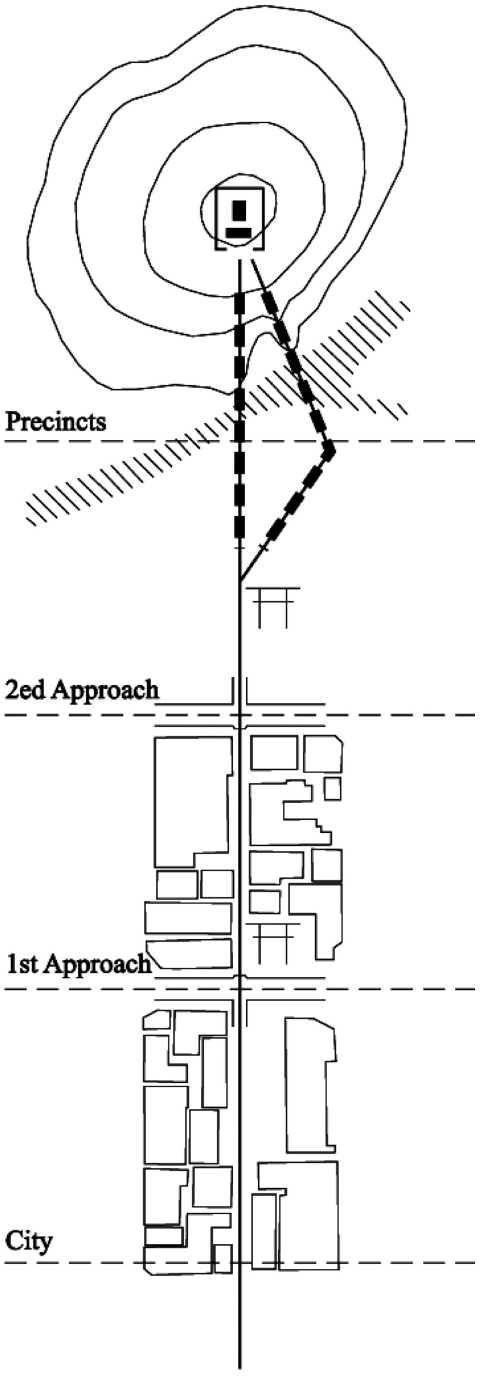

Figure 4. Hypothesis of a shrine approach (sandō) in its current urban form.

the translation of time, it's still possible to see an old lady wearing the traditional kimono on a Noh play, a traditional wedding procession in a shrine, an almost extinct tea ceremony or the rituals of purification and prayers performed over the deity in a shrine or temple.

Figure 5. The Sandō of the Meiji Shrine is an example of a path completely surrounded by a man made forest and marked by two Torii.

Figure 6. The Omotesandō is considered as the first approach to the Meiji Shrine and it's fully integrated in the urban fabric. The beginning of path it's marked by two stone lanterns (tōrō), decorative Shinto symbols that represent the sun and the moon.

Figure 7. The Senso-ji Temple, Asakusa, is fully integrated in the urban block and the Sandō exemplifies the commercial use that some times they have.

For example these expressions of the traditions can also be found in the Senso-ji Temple in Asakusa area. The temple was a popular and worship space even before the emperor Tokugawa establish the capital in Edo at the beginning of the seventeenth century, and remains as a important place for the spirituality of the Japanese people. As evidenced by the large attendance every day or in special celebrations, such as the

Figure 8. Spring Grand Festival ceremony at Meiji Shrine, Harajuku.

Figure 9. Food stalls aligned with the Benten-do Temple and the Kiyomizu Kannon-do Temple at Ueno Park.

Figure 10. Mikoshi at the Namiyoke Inari Shrine, Tsukiji.

Asakusa Sanja Matsuri, a spring festival in May, and the New Year's Day when thousands of Japanese traditionally pay their first prayers to the several deities inside of the temple precinct.

Another peculiarity of this temple is the market located along the Nakamise-dori and next to the temple gate remembering the relationship of these worship sites had in Edo era to the local religious and economic dynamics. The street-market is aligned axially

Figure 11. The Harajuku Girls is a youth phenomenon started at the beginning of the XXI century that quickly gained fame and tradition in Japan. The costumes differ from the cartoon characters to rock idols.

with the Kannon Hall, the main building of the religious ensemble reconstructed in concrete in 1925 and 1950.

So, it's recognizable that the Japan of today contains a vast cultural tradition, present in the vernacular and spiritual buildings and spaces, even in the way of life, as shown by this reconstruction forms and images of a sense of historical authenticity.

But, social traditions are a heterogeneous facts and layers that resist or are recovered, even reinvented, to delight and connect the modern society to there historical identity. The problem is that the modern and postmodern societies are producing new traditions in a blinding speed that imposes a wedge between the present and past traditions, in Japan as elsewhere (Fig. 11). "Perhaps his not quite obsolete vision of modernity is taking its place as one more instance of the vanishing, along with its [traditional and new] objects" (Ivy, 1995:246).

Top-down and bottom-up approaches in Tokyo's recent urban re-development projects

L. Alessio
Politecnico di Torino, Turin, Italy

ABSTRACT: In the last thirty years, Tokyo went through consistent re-development projects. In big top-down plans, new visions were explored and created. But, nothing was done in order to keep or to enhance local identity and lifestyle. Case studies, such as Roppongi Hills, Tokyo MidTown and OMY analyze the top-down approach for the creation of high-dense urban settlements, with mix-use of functions in "vertical cities". In Tokyo, some other areas have been testifying a slower re-development, which happened piece-by-piece in fragmented and traditional urban fabrics, where a strong sense of identity is felt by citizen. Areas such as Komagome, Ura-Harajuku, Shimokitazawa show up the strength and characteristics of the bottom-up approach. Nevertheless, in order to avoid banal building speculation in gentrified areas new models for re-developments are needed. Otherwise, the lost is enormous: from the identity of place to the social encounters and structures, to the traditional liveliness and vitality in different parts of the city.

1 TOKYO AS GLOBALISED METROPOLIS

1.1 *Urban policies to revitalize the economy*

In recent years Tokyo has undergone huge urban transformations. Different areas in the metropolis have completely changed their image and identity. By doing it the original urban fabric has been altered. This is specifically evident when huge top-down developments are compared with the existing urban fabric surrounding them. Nevertheless each development was pursued based on a specific vision, much connected with notions of Tokyo' s attractiveness to the globalised world.

Following the bursting of so-called "economic bubble" in the 1980s, Tokyo and Japan suffered a decade of economic recession, now seen as the lost decade for the failure to take positive action against the economic downturn.

The recession in the 1990s brought to question the Tokyo status as global city of virtual command post in the networks of twenty first century capitalism (Sassen 1991). In fact, Tokyo was challenged by other Asian cities emerged at global level, such as Shanghai, Hong Kong, and Singapore (Saito and Thornley 2003).

Several issues in the economy were pushing for a change: depressed property market, banking sector in crisis, non performing loans (Katz 2002) and lack of money flow. Companies in the corporate sector could not recover from the investments they made in the 1980s in Tokyo's property market. (Kantor 2012).

Starting in 1986 Nakasone launched the Urban Renaissance Policy, which implemented projects and ideas of large scale redevelopment projects. But, due to the big economic crisis, it was not consistently applied.

In 2002 the government led by Junichiro Koizumi set up a committee called "Headquarters for the Urban Renaissance of Cities" chaired by Koizumi himself, with the aim of promoting 21st century urban and environmental re-vitalization projects and internationalization while at the same time ensuring disaster prevention measures. The Act was aiming to enhance the attraction of the cities and their international competitiveness; to stimulate economic recovery and reinvigorate the land market. (Urban Renaissance Special Measure Law, 2002).

A clear indication on the creation of more compact, dense and unified urban structure was given, willing to limit the urban sprawl and expansion of cities; defining a safer urban life in regards of earthquakes, traffic congestion; promoting a higher quality of urban life in beautiful, secure cities realizing a sustainable society; and the evaluation of accumulated assets in urban areas making use of them in conjunction with a new arrangement of facilities. (Basic Policies for Urban Renaissance, URHQs).

The urban regeneration strategy presented three main programs: urban regeneration project by state initiative, urban development by private investment, and urban regeneration project in nationwide to be carried out by local government and NPO or voluntary sector, being the private sector the key element of regeneration.

The Special Law on Urban Renaissance designates the priority urban redevelopment areas, relaxing the existing planning regulations, giving private developers the opportunity to propose projects, and providing various incentives, such as financial aid, tax relief, and a simplified approval process. Controls and

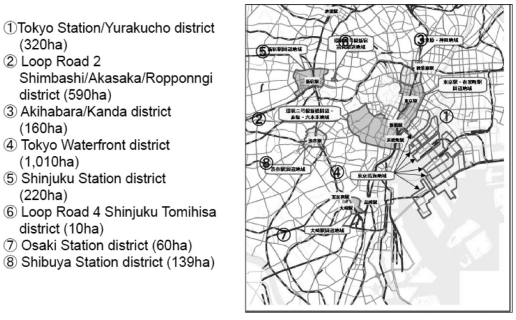

Figure 1. Priority Urban Development Areas.
(source: Prime Minister of Japan and His Cabinet).

restrictions have been further loosened, with a series of measures that have significantly increased Floor Area Ratios (FARs) (Sorensen 2003, Waley 2007). Thus, by giving cabinet authority to designate regeneration areas, the central government made much easier and faster the projects' approval for redevelopments of inner city sites.

Among the first targeted areas for urgent improvements, on a total of 3,515 hectares, 2,370 hectares where in Tokyo.

Until 1990s Tokyo was characterized by a vast and fast growing sprawl thanks to private companies developing along new rail way lines the urban residential settlements. Political and economic interests created those strong centripetal forces (Cybriwsky 1998). In fact, until then Tokyo's vast infrastructure had been constantly enhanced to allow decentralization and urban development in outlying districts beyond the Yamanote inner ring. As a result, the metropolis spread inexorably west and east.

But not only the Urban Renassaince Headquarters were looking for a strong re-development of some central areas in Tokyo, but also the Tokyo Metropolitan Government. In 2000 TMG in the White Paper recognized that Tokyo was losing its role at global level as the main Asian metropolis of attractiveness level. TMG's urban policies proposed an important turning point abolishing the sub centers policies in favor of centre of Tokyo. Specifically, it came up with the decision to create a "central business district", the CBD, covering the centre of Tokyo and neighbouring areas. Moreover, thanks to the fact that the usual height of 31 meters could be overcome, TMG encourage the realization of high-rise buildings to maximize the density in the city, and offering FAR bonus when creating at the high-rises bases open public areas. The aim was to encourage international companies, financial institutions and media companies to set up in an area that also offered medium to top-end residential accommodation. The main focus now became centralization, bringing people back into the centre to work but also for living. Central areas underwent radical new development. Several small plots were combined to create large development areas, and large state-owned properties were reallocated in compliance with the government's new urban plan to drive economic recovery.

1.2 *Re-conceptualization of urban condition. A prototypes for top-down approach. Roppongi Hills*

Roppongi Hills developed by Mori Corporation is one of the first mixed use re-developments. It proved to be successful in term of uses and property investment.

It is needed to affirm that the previous Ark Hills project provided to Mori Corporation the needed know-how that brought Roppongi Hills into realization. In fact, Ark Hills was characterized by an area of 5.6 ha, with a main property owned by Mori, but other parts owned by many people living in the area. The involvement of all the residents into the project required several years of negotiations. It was a process of development that started in 1967 and ended in 1986. One of the critic that followed the realization was the fact that almost all the previous owners changed areas for living.

In 1986 Tokyo Metropolitan Government designated Roppongi 6-chome as a Redevelopment Inducement Area, where redevelopment should be induced through cooperation between the public and the private sector. In Roppongi 6-chome more than 500 residents were living, on an area of re-development of 11,6 ha.

Being interested in the development, Mori Building with TV Asahi started to involve the residents setting up councils to create an agreement for the re-development.

The latter was reached only in 1998 with 94% of the residents' participation. The Union was founded and between 2000 and 2003 the mixed-use development was constructed.

The development included a main office tower, residential towers, hotels, a high-end commercial gallery, a cinema complex and restaurants. It combined culture into a private re-development with the realization of a contemporary art museum.

The development allowed the insertion of large floor areas for offices. It stimulated people to live in the center offering a new life-style in apartments, where people could be close to the central areas of Tokyo, and close to work. Roppongi Hills became also a prototype for the creation of public spaces managed by the private sector: plazas, park, incorporating contemporary art.

Roppongi Hills urban development completely altered the urban frame of the area, enhancing the process of gentrification of the area. Looking up at map in Figure 2, it is clear the difference of scale between the new project and the surrounding urban fabric.

Which was the vision to re-conceptualize the urban condition? The inspiration was taken from European cities, where mixed use facilities keep cities alive 24 hours a day, as "Artelligent City". And, attention to creation of public spaces were given, recalling Western approach to the making of the city. "66 Plaza" with its "Maman" by Louise Bourgeois immediately became

a place for gathering and moving to restaurants, contemporary art museum, cinema complex, events.

Because of the development's high density, public spaces can be found at different levels.

66 Plaza itself is located at the entrance of Roppongi Tower but not at the street level, while at street level we can find an arena and a garden.

Roppongi Hills is one of the first cases in which a street was characterized by interventions of urban design with contemporary art pieces.

Clearly, Roppongi Hills constitutes the model that inspired others developers willing to revitalize huge central areas in Tokyo. Thus, each new project needs to get a new unique vision, able to compete and attract people during different moment of the day and for various activities.

2 PRIORITY URBAN DESIGN AREAS – TWO CASES

Among the Priority Urban Development Areas established by the Urban Renaissance Act, we find Tokyo Midtown and the area of OMY. The two sites have been developed respectively by Mitsui Fudosan and Mitsubishi, based on different concepts and approaches.

2.1 *Tokyo midtown*

In order to re-develop central unused or under-used settlements TMG promoted the so-called Land Use Transition District Plan, aiming to revitalize the city

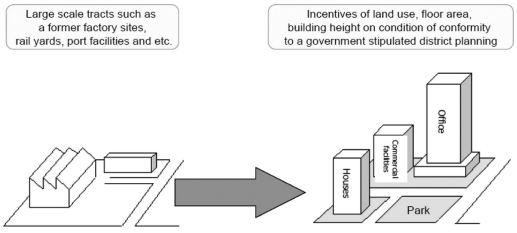

Figure 11. TMG – District Planning.
(source: http://www.asianhumannet.org/db/datas/9_transport/udt_reference_en.pdf).

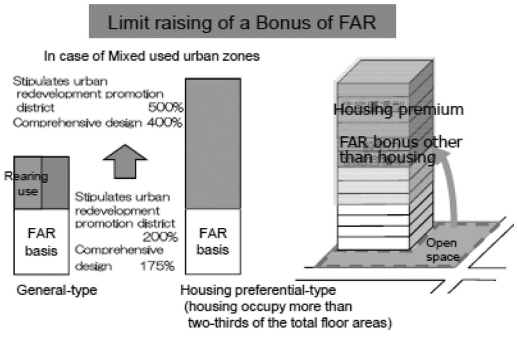

Figure 12. TMG – Mixed used urban zones – Bonus FAR.
(source: http://www.asianhumannet.org/db/datas/9_transport/udt_reference_en.pdf).

with an effective use of land providing urban functions, houses and offices.Tokyo Midtown was developed as a transition district plan on a vacant area owned by Defense Agency. It is a consistent site of 7.8 ha. The project promoted by Mitsui Fudosan defined a mixed use facilities plan, which was realized from 1988 to 2007. It was based on a vision that expressly wanted to be something “new”. Still nowadays, the area is branded as a place where people could find a new part of city expressing a new vision and unique image. A place where people could work, dwell, play and relax. The intention was to define new values and lifestyle that could be share at international level. Compared to Roppongi Hills, Tokyo Midtown is composed by a compact group of buildings surrounded by public open spaces. Those spaces are all located at ground floor, isolating the new development from the existing surrounding buildings through a garden, a park and a plaza. The park is a historical landmark of a previous feudal villa. All the development is a very high-end settlement, comprising a very elegant commercial gallery, museum, hotel, offices, residences. While in Roppongi Hills the museum is located at the top floor of the office tower and it became a very important facility in the contemporary art field, here the museum in inside the main shopping gallery and offers small refined exhibition on traditional Japanese arts. Temporary exhibitions find place in another structure connected to the open garden.

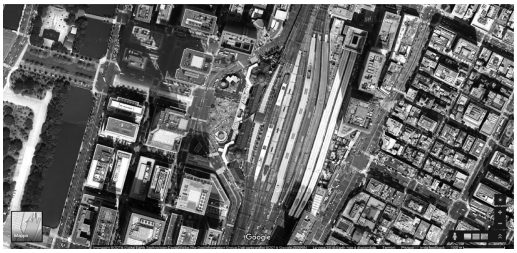

Figure 13. OMY Area.
(source: Google map).

2.2 *OMY*

Otemachi-Marunouchi-Yurakucho (OMY) is the district situated in Chiyoda city and is the hearth of metropolitan Tokyo. It has always been known as the center of international business in Japan. Its redevelopment has been considered essential to reinforce globally its centrality. The Otemachi-Marunouchi-Yurakucho District Redevelopment Project Council was founded by landowners of the area in 1988. Only in 1996 Tokyo Metropolitan Government (TMG) set up an Advisory Committee on OMY Area Development and few years later defined the Central (Ward) Area Development Guidelines, and the Landowners' Council was organized "as a forum for discussing specific city renewal plans for the 21st century" (OMY District Redevelopment Project Council, April 2008).

The Council is composed by 70 landowners, 17 observers, 9 special members with a totality of 96 members.

The Council defined the vision for re-development as "ABLE CITY: A City of New Opportunities. Amenity, Business, Life, Environment". The Council proposed to plan an urban landscape based on three-layers. The one, with the existing 31-meter building heights, to create human scale and pedestrian comfort at Hibiya street (dori) and Marunouchi Station Plaza. The second height up to approximately 150-meter in the city center, with the possibility of achieving 200-meter buildings around major railway and subway stations, in spite of the legal limit up to 260 meters. The height could be reached thanks to FAR bonus system, as in Figure 13 and 17. Public spaces are part of a comprehensive urban design strategy characterized by an unprecedented public-private cooperation. Today, thanks to the different activities it offers, the area attracts the contemporary *flaneur* (Dinner 2012).

The development started in 2000, and it is still going on.

3 BOTTOM-UP APPROACH

In other areas of Tokyo, we assist to very interesting processes of small scale development. The three chosen sites present a very strong identity and sense of community felt by its residents and users. They present different characters and targets, but they share a common issues for future developments.

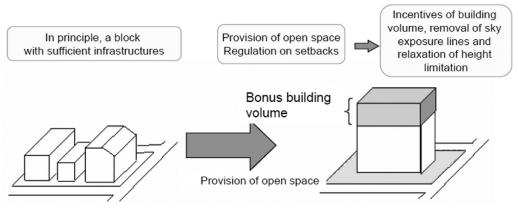

Figure 16. TMG – FAR – Bonus System.
(source: http://www.asianhumannet.org/db/datas/9_transport/udt_reference_en.pdf).

3.1 *Komagome*

Situated in the north-west part of Tokyo, still inside the central JR line-system, in Komagome is possible to find the ancient urban structure. Komagome is a neighborhood counting around 10,000 inhabitants in its central core. Strolling around the district of Komagome, the sensation in entering in this neighborhood is to enter in a sort of village. Houses are single detached houses of one or two stories high, generally in wood; every dwellings is differently decorated by a small independent entrance or a narrow private street of entrance shared by four or five houses. The actual situation of Komagome is very charming from the point of view of external visitors, but instead very critical for the community living. First, some dwellings

Figure 17. Komagome Area.
(source: Google map).

Figure 18. Komagome Plan.
(source: http://www.arigalab.arch.waseda.ac.jp/you_he_long_yan_jiu_shi/212ju_purojekuto.html).

are obsolete facing tiny streets which make very difficult to prevent a natural disaster or fire explosion. Therefore, new building standards define the maximum buildable in an area of 60% of the GFA (gross floor area), however, for the actual situation, one plot is almost built for the 100%, leaving just a small passage for entering in a house in the one besides. Second the aging population in Komagome area requires new public facilities. Third, being the area very central it is very valuable and investors try to buy plot of land from the elderly for building speculation.

How to solve problems of disaster prevention, growing elderly population and urban redevelopment keeping an identity of space? The City of Toshima, helped by Waseda University, is trying to collaborate with the community by means of participative workshop, in order to reclaim the most critical areas. The University in synergy with the community is trying to progress is the reconstruction and the restoration of Komagome, keeping the special human scale dimension of the building, the everyday activities and the familiar connotation of outdoor spaces.

3.2 *Ura-Harajuku*

Ura-Harajuku has a very distinctive character. It keeps the feeling of human scale. Being located at the back of Omotesando and its high-end fashion shops, it developed as one of the best place for unusual attractive shops. It is place known for subculture and very popular among young people.

Figure 19. Komagome Street Views, playground and garden.
(source: Photograph by the Author).

Figure 21. Ura-Harajuku – Street View.
(source: left- http://www.travelience.com/blog/top-10-places-to-shop-in-shibuya-area-tokyo/
right- Photograph by the Author).

Visually, facades are continuously changing and adapting themselves to the small commercial business that buildings host.

The area is recognized as an area of creativity and originality both for the shops and for the people strolling in it, that define their personality by creating a personal mode of consumption. Smallness and fragmentation of urban fabrics and buildings match with the peculiarity of the shops characterized by individual contributions and creativity in reusing existing buildings.

Places of meanders and surprise are welcome. Thus, urban fragmentation and irregularity, small mainly pedestrian streets are preserved as a value.

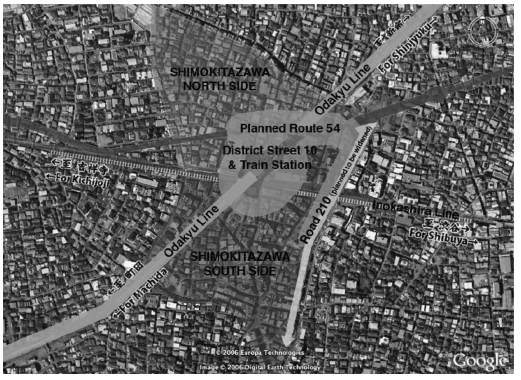

Figure 22. Shimokitazawa Plan. (www.koba-lab.com/masami/research/Shimokitazawa_Icomos.pdf).

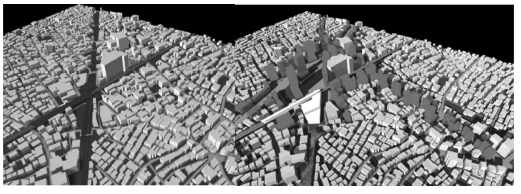

Figure 23. CG Simulation of the Future image of Shimokitazawa with Government's Plan – left: Existing condition; right: In 30 years. (www.koba-lab.com/masami/research/Shimokitazawa_Icomos.pdf).

3.3 *Shimokitazawa*

Shimokitazawa is located at around 2–3 km from Shinjuku and Shibuya, West side of Tokyo. Historically, it is not very old, but it is a friendly pedestrian compact city with narrow streets. This is due to the fact that it grew as depending on rail system, more than cars. It is a neighborhood very much loved by young people, a vital area with many theaters and music clubs. It is also considered a comfortable are where to live with its 20,000 residents.

Almost 60 years ago, Tokyo Metropolitan Government planned the realization of Route 54, to become 26 meters wide crossing Shimokitazawa. And, the actual station of Odakyu Line is now under re-construction with an underground station.

Those two big infrastructures' interventions are going to completely modify the actual urban fabric in Shimokitawaza. Moreover, according to Japanese building regulations the height of buildings depends on street's wideness. Therefore streetscape of the neighborhood is going to change in the near future close to the wider street. Building relaxation rules would even make the case worse. Until then, the urban redevelopment of the area worked out through small interventions, operated by local owners. The urban fabric has been kept using existing building or inserting new ones in the original context, enhancing the atmosphere and the identity of the neighborhood. When the two over mentioned projects became public, the reaction of local residents, shopkeepers, professionals and young visitors was strong. Several movements to protest against the project started. Three major citizens' groups were risen. "Save Shimokitazawa", volunteer group of young people spending their time in the area. They spread up news and awareness about Shimokitazawa and in 2003 started a signature campaign. A second group, the "Shimokitazawa Forum" is composed by local professionals, architects and urban planners, journalists represented by Prof. Masami Kobayashi from Meiji University. They have developed inquires, workshops, comparative studies, lectures and symposiums. The Forum proposed alternative plans.

The third group is "Shimokitazawa Shopkeeper's Council" which consists of 500 shopkeepers, mostly tenants. They made many petitions against the Government's plan. Nevertheless, TMG progressed with the plans and Shimokitazawa will be changing in the next five to ten years.

4 BIGNESS AND SMALLNESS

4.1 *Tokyo and identity of place*

Tokyo has always had many identities. Being a multinodal city, it is composed by towns with different insights. While differences among some nodes tend to disappear, Tokyo has accepted and created new identities with the aim to open the metropolis to the world. "Gaijin (foreigner) friendly" I would say. TMG is always looking for new visions which could bring Tokyo to become the world's best city (Masuzoe 2015). Until now, top-down approaches to urban development in Tokyo defined new visions for the city. While doing it, local identities were substituted by new ones, more homogenous, organized and controlled. Visions which took inspirations from the Western cities and lifestyle. They defined new ways of the making of the city. These are cases in which big stakeholders through agreements with public sector develop big areas with high rising building offering to the market new type of mixed use facilities with big floor areas of office buildings, commercial areas and central apartments. The new mixed use developments brought people back to the center for living. Life in apartments was enhanced as a new type of lifestyle, matching with the new trend of female entering and staying in the labor market. While defining new urban models, the concept of public space also changed. Plazas, arenas and open public spaces were created, while traditionally not existing in Japanese cities, characterized by completely different urban settlements.

On the other hand, other areas of Tokyo still present highly fragmented urban fabrics, due to a vast number of ownerships and small building types. Those areas host a socially strong environment and specific atmosphere. Many times the urban fabric is particularly dense and characterized by small streets (roji) turning

around small buildings. In some ways, Tokyo presents the big size and the small–very small size, but not a medium one.

Nowadays, small size is brought into question both by standard building regulation for disaster's prevention. For instance, actual building regulations do not allow to re-built single building in front of small streets, because of risk prevention issues. Setbacks rules have been defined, reducing plots land already very small. Moreover, many areas are suffering building speculation. The risk of banal gentrification still exists (Boontharm 2012). Models of reuse and development proposed by the public are lacking of creativity. On the other hand, participatory projects see citizen working with university's labs on town-planning and urban design to clarify approaches and methodologies to solve local issues of future developments without losing the specificity of the places. Bottom up approaches recall for uniqueness and intimacy of space. Some developers are looking for new ways to approach urban development incorporating those local needs. But, in order to avoid empty stylish exercises, an interdisciplinary approach is needed. It is about having experienced and analyzed the city from many view points, studying the existing situations. It is important to look for the importance of keeping variety and flexibility to assure users' personalization through life and time.

New schools of thought – an investigation on tendencies in architectural education

ABSTRACT: This paper elaborates on the first findings of the ongoing research project NeST (New Schools of Thought), which investigates reactions to academic homogenisation within European architectural education. NeST defines a New School of Thought as a set of ideas and new approaches on methods of knowledge creation and forms of knowledge transfer, which a group of people who are dedicated to architectural design and spatial planning share about architectural education. Schools are no longer the only privileged place for thinking. New sites of knowledge production and reflection have arisen, giving way to new types of schools of thought. Through a multiple case study situated at the level of secondary education, higher education, and public mediation, this paper analyses the inherent concepts of new schools of thought and reveals their alternative routes as responses to tendencies in architectural education. This framework gives indications of potential impacts on models of architectural education.

1 INTRODUCTION

Architecture reflects, shapes, and enriches society and its culture. At the same time, it seems increasingly incapable to be influential in determining 'the course of things in space' (Eisinger 2008). At the most, it can be considered as 'a singular way of thinking about anything', being 'a diagram of everything' (Koolhaas & McGetrick, in: Eisinger 2008). It is exactly in this encompassing and indecisive way of 'being in the world' that architecture 'manifests itself as an instrument for exploring the world' (Eisinger 2008). Latour values architecture as a unique practical and visualizing tool that political language does not have (Ghosn *et al.* 2008). In its "singular way of thinking about anything", architecture – as a tool and an instrument – provides a unique lens which "preserves a view of the total" (Eisinger 2008).

Architecture is embedded in culture. With its traditions, it is inseparable from education. In architectural education, architecture is the pathway for self-formation. Teaching architecture is not solely teaching *about* the role of architecture in society. Its pedagogy consists mainly of *learning from* architecture and *educating via* architecture. In essence, it is teaching *in* and *through* the moment in which society manifests itself through architecture. What then is it that is taught? Or – as formulated by the Swiss architect and teacher Andrea Deplazes with an exhibition in the Schweizerisches Architekturmuseum in Basel in 2006 – "was studieren sie wenn sie Architektur studieren?" Indeed, architectural education cannot be considered as mere vocational training towards professional proficiency. Given architecture's inherent responsiveness and sensitivity to societal change, its capacity to critically conceive new futures as creative responses to current conditions, and since architecture acts as a unique *practical and visualizing tool* and as an *instrument* for *exploring the world*, *preserving a view of the total*, architectural education provides rich grounds both for self-formation of the individual student and for critical reflection and transformation of society as a whole. In times of rapid changes and societal challenges which lead to uncertainty and complexity, one could argue that architectural education is providing society with schools which feature a certain "cunning of uncertainty" (Nowotny 2015) while embracing contingency and complexity.

Architectural education has many roots. Apprenticeship on the building site, pupillage in the office, Beaux-Arts training in the academy, engineering lessons in the polytechnic school, and – more recently, owing to the ascent of cultural studies and critical theory – a master's degree at the university. Each of these approaches has been challenged. Europe's recent higher education reform has tended to advocate

the university as the ultimate place for higher education. But is the university the optimal biotope for architectural education to flourish?

1.1 *The university as a place for architectural education*

The university is a particular institution in that it hosts both research and education. Its legitimation to provide academic higher education consists of this proximity to research. This idea originates from the beginning of the nineteenth century, with the foundation of the University of Berlin as an icon for the modern European university. Since then, the public role of the university has been fundamentally questioned several times. Two centuries after the founding of the first university, at the turn of the twenty-first century, there is a widespread consensus in academia and society that the mutual relationships between science and society (including economy and politics) have drastically changed (see e.g. among many others Delanty 2003, Simons et al. 2007). The evolution towards mass higher education and the rise of the knowledge society, accompanied by the emergence of a knowledge economy, have transformed the relationship between science and society, the role of research, and the identity of the university as a place where research and teaching coexist. Higher education no longer addresses an intellectual elite. Since the university is *democratised*, it has not only delivered many cohorts of graduates, it also has delivered cohorts of knowledge producers, generating and exchanging knowledge in a variety of sites and contexts. The university has lost its privileged position as knowledge producer. The university gradually becomes acknowledged as a place typified by its limitations and restrictions in the conduct of research – narrowed to emphatic interpretations of scientific research – rather than pictured as the place par excellence where teaching is embedded in the most thriving and intensive research environments available. This is particularly the case for architecture and architectural education.

Architecture is connected to many disciplines and knowledge fields – it is "boundary work" (Kurath 2015). This boundary condition manifests itself at least in three ways. (1) Being in a margin of the scientific environment of the university, merely contributing to the academic body of scientific knowledge, architectural education takes a defensive stance. Academisation makes architectural education operate in a climate of confusion and pressure (Gisler and Kurath 2015). (2) In this boundary condition, architecture acts as a connector. It connects many disciplines, and it gets many actors involved (both human and non-human) (Yaneva 2012). (3) Given the fact that new knowledge is created at many sites and in many contexts, given that architecture is connected to many fields and many types of knowledge, and given the specificities of the type of research conduct actually fostered by the university, it is hard to assert that the university – as it operates today – would provide the most appropriate conditions for architectural education.

1.2 *Architectural education in times of homogenisation*

In 1988 the *Magna Charta Universitatum* was proclaimed by the rectors of European universities. It referred to the coming abolition of boundaries within the European Community in the next four years. In 1999 the European Union's Bologna Declaration was defined "in order to enhance the employability and mobility of citizens and to increase the international competitiveness of European higher education" (European Ministers of Education 1999). Together with both European qualifications frameworks – the QF-EHEA, or *Bologna Qualifications Framework*, and the EQF-LLL, or *European Qualifications Framework for Lifelong Learning* – and European Directive 2013/55/EU, it was a milestone towards comparability of European education. However, it is also seen as the starting point for academic standardisation which, from an academic point of view, could potentially result in "Verschulung" and "didatticizzazione", "rigid and compressed curricula", "with less space for creativity and innovation", less time for "independent research or study, critical reflection, fostering of an independent mind" but instead "greater efficiency and delivery" (Froment *et al.* 2006).

Reichert & Tauch (2005) designate the added value of the Bologna reforms as the "internationalisation of study programmes", "increased mobility", and the "improvement of international communication. This reform takes place in circumstances of increased competitiveness, contributing to it at the same time. Academic institutions are required to become more self-sufficient and thus entrepreneurial, raising more third party money, particularly for research (Smith 2010). As a result, private academic institutions and excellence clusters within public academic institutions develop as an alternative and open up "the economic discourse about the value of education" (Verwoert 2007,Hochmuth and Mangold 2012).

Architectural education in Europe has been a kaleidoscopic landscape, reflecting differing roots and cultures. The higher education reform, which started in the 1980s, contained strong preconditions for homogenisation. These processes have reached their full development and maturity today. Learning outcomes, subject-specific competences, institutional evaluations, professional accreditations/ regulations, research assessments, etc. have developed a strong grip on all higher education, including architectural education.

1.3 *New schools of thought*

The Bologna process is not to be seen only as an educational reform. It has to be understood as a response to a changing world. Delanty (2003) concludes that the post-industrial knowledge society – consisting of

services rather than of production – is increasingly driven by communication and information technology. The post-industrial knowledge society is not a European but a global society, in which the separation between knowledge and economy has blurred, giving way to the "scientisation" of society (Delanty 2003). Facilitated by the Bologna process, knowledge production and education are turned into globally marketable products (Kurath 2015). Since the late twentieth century, architectural education in Europe has been reshaped by these conditions of digitalisation and internationalisation, which have brought forth tendencies of *scientification* and *commercialisation*. Within these circumstances, architectural institutions have undergone changes in content and in methods of knowledge creation and transfer, as well as shifts in organisational structure.

How much these processes have effectively homogenised architectural education and to what extent formal adaptations to superimposed structures are simply masking submersed resilience of pedagogical traditions is not clear. It can be observed, however, that several initiatives have emerged as alternative routes of education, all of which comply with what we identified as *New Schools of Thought* – a set of ideas and new approaches on methods of knowledge creation and on forms of knowledge transfer, which a group of people who are dedicated to architectural design and spatial planning share about architectural education. These initiatives illustrate that there is an urge to expand the current scope of architectural education. They operate under a diversity of circumstances, address other audiences, involve other disciplines, and adopt a variety of methods for sharing insights and disseminating knowledge.

The research project NeST investigates these alternative routes, which – like Derrida's (2001) "university without condition" operate as battlefields of theoretical discourse with academic and unconditional freedom, sovereignty, democracy, and resistance.

2 RESEARCH INTEREST

Jenson (2014) criticises "the conventional educational structure of design and architecture schools" and suggest that "the global changes to education demand the necessity for the emergence of a new type of reflexive educational space" apart from the mind-bordering classroom. In accordance with Jenson's argumentation, NeST will investigate such new types of *reflexive educational space*. Studies on architectural education focus mostly on formal higher education at the university or at a school of architecture. This focus does not allow for grasping the many initiatives which emerge elsewhere, and which – deliberately and with great enthusiasm and conviction – present architecture as a means to explore the world, for the personal development of their audience and as an "offer being made to society" (Eisinger 2008). Therefore, NeST takes a comprehensive stance, open to include a diversity of initiatives which address architecture as a medium for learning (about the world). It widens the term "school of thought" in terms of scope, place, and audience. In addition to universities and schools of architecture, it includes institutional think tanks, networks, and platforms (both physical and digital), etc.; it includes *formal* as well as *non-formal* learning, and it includes all stages of learning, from childhood education to lifelong learning. The research project NeST views these schools as possible social and cultural innovators. It aims at uncovering the motivations, goals, innovative approaches, and ranges of these schools of thought. By including these schools of thought, NeST aims at broadening the debate on architectural education by expanding the scope of approaches taken to address the challenges of societal and environmental change – through architecture.

3 RESEARCH DESIGN

This paper reports the first findings of an early stage of the project, which rely on an empirical study consisting of the analysis of multiple cases (Yin 1994).

The study concentrates on the European context. Within this limitation, cases were selected based on three parameters: (1) the chosen case had to be understood under the definition of a *new school of thought*, (2) the initiative must have arisen after the educational turn in Europe in the 1980s, and (3) the initiative has to provide new approaches for knowledge creation and for sharing insights to a public audience, in and through the field of architecture and spatial planning.

Cases were found, either through their prominent appearance in the media, or through the networks of the partners of the NeST-consortium. Twenty-one initiatives have been designated for further investigation, of which eleven have responded. After a concise screening of the documentation available online, a qualitative online survey has formed the study's most substantial body of information to date. The aim of this survey is ideosynchratic: it is not looking for generalisations, but aims to reveal a rich pallet of diverse characteristics, approaches, and stances of innovative and thought-provoking approaches with regard to architectural education. Representatives of the chosen initiatives have responded to three thematic clusters, which were based on a review of the literature. The first set of questions asks about the reasons behind the creation of the initiative, its main characteristics and the challenges faced in running it. The second part of the survey maps the target audience and the scope of disciplines which are involved, as well as the methods and techniques used for knowledge creation and mediating the work to the public. The third and last section explores how and to what extent the school of thought positions itself towards the tendencies of *commercialisation* and *scientification* – tendencies which emerged from the literature review as determinants of the current educational landscape. The aim of this third part was not so much to confirm or estimate the

significance of the tendency, but to map the diversity of routes that have been taken in relation to this tendency as a factual condition, identifying the particularity of each approach while giving special attention to the context in which the initiative operates and to which it responds (Mortelmans 2011).

Responses have been received for the following eleven cases, which have been designated for further investigation: Architecture Workroom Brussels (AWB); ADAPT-r; aut. Architektur und Tirol (aut); bink; Bundesstiftung Baukultur (BB); Estonian Academy of Arts, Faculty of Architecture (EAA); Spacespot; TRANSark; University of Sheffield, School of Architecture (UoS); University of Reading, School of Architecture (UoR); Vorarlberger Architektur Institut (vai).

4 FINDINGS

The following section will firstly explain the mind-sets within the typological framework of the cases in order to then elaborate on their responses and alternative routes set out in response to tendencies in architectural education. When examining the aims rooted in the mind-sets of the different cases, it becomes obvious that within architectural education, certain types have evolved which can be clustered by their target groups: secondary education, higher education, and public mediation. Within those three types, one can clearly identify coherent (meaning homogeneous and logical in its system of thought) and at the same time distinctive (when comparing with other traditions or entities of thought) mind-sets. It is important to note that individual cases are not necessarily bound to one typology; they may be comprised of a mix. For instance, vai operates in the realms of secondary education and public mediation. The aim of this section is to present the inherent concepts of the three different typologies. This will form the basis for understanding their reactions to the multiple tendencies within architectural education, which are presented afterwards.

4.1 *Mind-set within the topological framework of architectural education*

Within secondary education, the NeSTs participating in the survey intend to create a network which links architects and schools. Another aim is to implement architecture as a subject in the school's curriculum. This shows that architecture is not yet established as a teaching subject. Hence, the initiatives have to fight for their existence. Nevertheless, they emphasise the positive feedback they get from architects, teachers, and children for their approaches. They are aware of the importance of their work: "young people are the decision-makers of the future. They will contribute to our built environment as politicians, clients, or the like" (Spacespot). Therefore they emphasise the importance of increasing sensitivity for the built environment among students, teachers, and parents.

Within higher education, the NeSTs participating in the survey have aims which vary in *content*, *method*, and *attitude*. Concerning content, issues such as climatic change, economic crises, and large-scale environmental crises all challenge our planet and "call for a rethink in architectural education" (TRANSark). Concerning methods, there is a desire to "close the gap between academia and practice while creating space for reflection on both" (UoS). One can identify the intention to bring back "critical thinking, reflection, and an evolutionary approach" (UoS). Furthermore, the University of Reading intends to "make it a multi- and interdisciplinary environment around understanding, designing, and managing the process of buildings". However, the applied methods of knowledge creation and forms of knowledge transfer vary significantly among the different schools of thought and will be elaborated upon further. Concerning attitude, one can make out a strong social ethos that links the initiatives within higher education.

Within initiatives of public mediation of the NeSTs participating in the survey, the general assumption is that sufficient discussion and action is lacking on the built environment, building culture, and the building process. Hence, the general aims within this typology are (1) to raise political and interdisciplinary discussion about the built environment, building culture, and the building process, (2) to create a broad network, and (3) to develop pertinent and meaningful responses to crucial societal challenges.

The different approaches are nevertheless distinct when looking at their point of departure. Aut intends "to develop a societal and legal basis in order to improve the living environment". In contrast, Bundesstiftung Baukultur already fought for their political influence: In October 2014, the German Federal Cabinet dealt with the first Building Culture Report 2014/15 developed by the Bundesstiftung Baukultur (2015). This report had then been forwarded to the German Parliament and Bundesrat as basis for legislative draft.

Through literature and the answers given to the survey, certain tendencies in architectural education have been identified. The following paragrpahs will elaborate on the NeSTs' responses and the alternative routes they have set out in response to those tendencies outlined here as sub-chapters.

4.2 *Responses to tendencies within architectural education*

4.2.1 *Several gaps in architectural education*

There is a common need to close several gaps between (1) academia and practice, (2) public awareness and financial support for the initiatives, and (3) architecture and pedagogy.

In order to close the gap between academia and practice, the situation calls for, on the one hand, "the development of a new level of pedagogical practice which requires dual-role professionals, that is, professionals who are as skilled in their discipline as

they are with academic teaching abilities" in order to confront societal challenges (TRANSark). On the other hand, new forms of knowledge creation and transfer have been tested by the initiatives. University of Sheffield School of Architecture, who is the initiator of the Live Projects programme and the Live Works initiative in the UK, emphasises collaboration and participation between the civic community and students: "The motivation behind setting up Live Projects was to give students an opportunity to learn through doing – to actively experience the connection between theory, practice and community engagement. We were aware of the disconnection between our teaching, via studio work and lectures, and the socially-engaged ethos we promote. Live Projects close the gap between academia and practice while creating space for reflection on both" (UoS).

This approach can also help in closing the gap between public awareness and financial support for the initiatives. By simply including sponsors in the creative process and at the same time widening their audience, the new schools of thought achieve acceptance and financial support.

In order to close the gap between architecture and pedagogy, pedagogues (being professionals in mediation) and pedagogical theories and methodology should inform educational programmes for architecture (Spacespot, bink, TRANSark). Additionally, TRANSark uses a limited set of courses as "testbeds for didactic experimentation" which are later being internally discussed through seminars and evaluation.

4.2.2 *Inability to find a language for architecture*

There is an inability to communicate design strategies and to find a language for architecture in spoken words, images, and spaces in order to mediate to people outside the discipline and to support the profession. "The 'architect' has contributed to her own marginalisation for many years by allowing other disciplines to take over large and vital parts of the processes producing architecture. Even for core aspects of our profession, such as creativity, other disciplines such as design have developed a much stronger rhetoric and narrative, placing designers in a more potent position with *design thinking* than architects with *XXXX*. There is a strong need for research, development and formulation of our contribution in society" (TRANSark).

As a reaction to this tendency, the initiatives increasingly make their work public in order to mediate to a wider audience outside the discipline and to support the profession. Their methods of inquiry vary widely. They establish a constructive dialogue through internal and public "dialectic debates" (aut), a public "atelier" (AWB), or "excursions" (vai, bink). Bundesstiftung Baukultur conducts polls to find out what public authorities and private persons think about building and planning. This is incorporated into a bi-annual report about the state of building culture in Germany (Bundesstiftung Baukultur 2015). Vorarlberger Architektur Institut emphasises "communication at eye level" as a general means of architectural mediation. Certainly, many of the initiatives also conduct marketing in various media, such as journals, magazines, or radio, yet aut uses *space* as a common language to mediate to the public. The institute designs exhibitions "developed as specially conceived architectural projects synaesthetically designed so as to directly convey what is involved in the work of the exhibiting artists". This reaction can also be understood as an alternative route to counteract the following tendency.

4.2.3 *Scientification and digitalisation weakening the quality of architecture as physical and embodied matter*

Scientification and "increased digitalisation may influence the understanding and quality of architecture as a physical and embodied matter" (TRANSark) leading towards a shift in the content studied and the tools used.

As a reaction, aut implemented the project "bilding" (bilding 2016), an art and architecture school for children built by 27 architecture students over two semesters. Through this hands-on project, students got insights into "dirty reality" (aut) and craftsmanly topics. Furthermore, the initiatives recommend to promote interdisciplinary dialogue, providing building and planning as a culture of general interest (BB), and to introduce the socio-political focus of basic architectural themes in the debate against "digital formalisation and pseudo-sciences" (aut).

4.2.4 *Scientification*

Scientification of architectural education has led to (1) an ongoing discussion about knowledge production in architectural research, (2) the demand for appropriate evaluation and validation techniques for architectural research, and (3) competition in regard to research outputs. Controversies regarding these issues have impacted education.

The increasing emphasis on research in higher education has provoked architectural education to stimulate more staff to do research, and to put a greater focus on knowledge production. The ADAPT-r project can be understood as a result of such a process. This tendency has also led to an increasing variety of teaching and learning formats. In order to inform architectural education with "good quality research" (UoR), new methods such as research-led studios (EAA, TRANSark, ADAPT-r, UoR) were introduced, which combine the techniques and content of research and studio designs. This potentially develops into architecture-specific research methods like research by design. In the long term, this can lead to "a consistent theoretical and methodological framework for pushing our didactic development further" (TRANSark), and hence it can help overcome the necessity of boundary work (Kurath 2014). The Faculty of Architecture at the Estonian Academy of Arts, however, warns that design-based research models need to be accepted by the responsible

institutions and not be subordinated to pure academic writing.

Consequently, there is a demand for useful evaluation and validation techniques in architectural research and teaching. Since "architectural research is still a young research field and has provisionally to lean on other disciplines for methodology and funding" (TRANSark), the initiatives use synergies coming from the cooperation and discussions with other disciplines: "Architectural production has become increasingly regulated from the side of legislation and demanding from the expectations of both the technological and financial performance as well as the cultural and intellectual adaptability to the changing needs of the society. These increasing demands cannot be faced by one professional nor addressed by one single curriculum, but signal a need for a wider interdisciplinary collaboration" (EAA).

In order to keep pace with the competition in regard to research outputs, the initiatives increase credibility by mediating to an academic audience (through papers, conferences, etc.) as well as to a practice-based one (through lectures, exhibitions, journals, and magazines). Additionally, they aim to gain resonance through discussions with invited practitioners and others (UoS, UoR). As a result, the initiatives become interesting for young, experimental practitioners (EAA).

4.2.5 *Commercialisation*

Commercialisation in architectural education has led to (1) a shift from the qualitative value of creativity to an economic one, (2) greater dependency on financial supporters, (3) pressure on the organisational and administrative management of institutions, and (4) a decrease of critical thinking, reflection, and innovation.

Marketing is used as an answer not only to increasing competition in regard to research outputs but also to commercialisation leading to a shift from the qualitative value of creativity to an economic one. The initiatives need to be understandable for and communicative to a wider public, and hence they are challenged by an "increasing pressure for simple messages and nice pictures for the media" (EAA). In order "to highlight the creative role that universities can play in the development of their home cities", the University of Sheffield School of Architecture created the Live Projects programme. Naturally, this has led to increased collaboration with and hence funding by external partners, and turned their dependency on financial supporters into an interrelationship with external partners. Real live projects have the potential to turn commercialisation from a pressure and a threat into an opportunity for learning: "In our education we approach commercialisation by involving the students in real live projects in the framework of 'live pedagogies', allowing the student to 'learn the game' in small scaled 1:1 deliveries. We are also developing platforms for entrepreneurship competences enabling the students to engage with stakeholders in society" (TRANSark).

As a reaction to commercialisation leading to pressure on the organisational and administrative management of institutions, the initiatives within higher education are pushed to decrease student contact in order to create more time for research, to cut back on space and resources allocated to teaching, and to increase fee incomes and student numbers.

"The core values of architectural education as a generator of innovation and critique of the discipline and profession are being eroded. Design skills cannot thrive within an environment of commercialisation where efficiencies of space and resourcing are prioritised over quality of the creative environment. It is very difficult for students and staff to make time and space for risk-taking, experimentation and reflection in the design process. Outputs are becoming more homogenous and predictable because of this – innovation is being squeezed" (UoS). As a reaction to this tendency, the initiatives foster different methods of learning. University of Sheffield School of Architecture introduces mutual learning between students and an interdisciplinary community (clients and the public) in order to offer "an opportunity for critical thinking, reflection and an evolutionary approach to project and design development" (UoS). TRANSark "investigates the transformative aspects of the learning experience when students, exposed to extreme complexity of aesthetical, ethical, technical, economical, and functional challenges as they become architects." (TRANSark 2016). Additionally, the initiatives stress interdisciplinarity as a source for complex, lateral, and creative thinking: "This can't be replicated within the institution – students need a public audience to be able to gain feedback and critically reflect upon their skills, their role and how they can make a difference to society in meaningful ways" (UoS).

5 CONCLUSIONS

5.1 *Tendencies*

This first approach to identify tendencies within NeSTs has been done in a heuristic way. The study of the cases served to expose their main driving forces, objectives, attitudes, and target groups in architectural education. These have been explored further within five tendencies and ways of handling them. (1) There seems to be a breach between architectural academia and practice as well as a mismatch between financial support and public awareness. These circumstances which ask for new instructional approaches and skills. (2) The lack of a common architectural language (spoken words, images, and spaces) makes communication with a wider public difficult and leads to misunderstandings about the architecture profession. In response to this lack, work results are increasingly expected to be formatted and mediated to an audience outside the discipline of architecture. (3) Moreover, the value of architecture as physical presence

appears to be repressed by an augmented scientification and digitalisation. This has a direct impact on the topics studied and the tools used. (4) Scientification of architectural education has further led to ongoing discussions about knowledge production, demanding appropriate evaluation and validation procedures for architectural research. It also has contributed to a growing competiveness in regard to research outputs. (5) Commercialisation is increasingly leaving aside the qualitative and formative value of architectural education, focusing instead on the economic one. Academic institutions compete against each other through the amount of research they produce. The quantity of research done by the universities is also used to recruit students. Frankly speaking: the better the research and the higher the ranking of the university, the more students enrol (UoR). This provokes ongoing pressure on the organisational and administrative management of institutions, leading to financial dependencies and decreasing the possibility of critical thinking, reflection, and innovation. Responses to these challenges include decreased student contact time, cutbacks on spaces and resources allocated to teaching, higher fee incomes and student numbers, and an emphasis on different methods of learning, including an interdisciplinary community. Hence, the initiatives do not only include other sciences, such as the social sciences (architecture and planning, media and communication, economics and business, geography, sociology, psychology etc.), the humanities (arts, cultural studies, literature, archaeology, philosophy, religion, etc.), and the technical sciences (engineering, software and hardware developers), but also medical and health sciences (medicine, neurosciences etc.) in order to provide deeper insight into the interrelations between perception, thinking, and action.

Although the findings of the tendencies contribute to a first understanding of NeSTs, additional in-depth studies of the correlations between the tendencies are planned.

5.2 *Research in architectural education*

As a consequence of the Bologna reform, and the academisation process which it induced, architectural education was expected to strengthen its research orientation. An ongoing tension has arisen between research in architecture, drawing on methods and ontologies borrowed from other disciplines – research into architecture – and attempts to develop design research and practice-based research up to the levels of a recognised academic methodology – architectural research (Crysler *et al.* 2012). Architectural research is a contested concept. In order to give exposure to its existence and to advocate its potentials, the European Association for Architectural Education [EAAE], felt a need to write a Charter on Architectural Research (EAAE 2012). Our future investigations will expand the scope of typologies to include research-oriented NeSTs and focus on tendencies within research in architectural education.

5.3 *The role of space in architectural education*

Finally, the spatial component of NeSTs will be a subject of future research. The sprawl of knowledge sites makes teaching through and learning from architecture now appear in a variety of places, ranging from the typical classroom over exhibition floor, discussion platforms, think-tanks and transdisciplinary networks, to virtual spaces as blogs and websites.

In times of digitalisation, an educational space may no longer be confined to physical walls but may expand into digital space, where a set of rules for the regulation of pedagogical interactions and communications forms an alternative learning environment. As Latour (1983) explains, the whole society is turned into a laboratory, "there is no outside of science but there are long, narrow networks that make possible the circulation of scientific facts."

NeST is a research project conducted in collaboration with the following research partners: the Institute for Architecture and Planning at the University of Liechtenstein, the Architectural Association School of Architecture in London (AA), the Institute for Art and Architecture of the Academy of Fine Arts Vienna, the Faculty of Design Sciences of the University of Antwerp, and Umeå University School of Architecture.

Ancient architecture and new meaning in the New World. Current tendencies in the USA

C. Giannattasio & A. Pinna
Department of Civil-Environmental Engineering and Architecture – DICAAR – University of Cagliari, Italy

ABSTRACT: The question concerning the relationship between ancient and new in architecture is still relevant, even though it has been debated for over sixty years. The research starts with an analysis of some words, such as restoration, preservation and conservation, in the USA, compared with their European meanings. On this basis, theoretical approaches and practical outcomes are illustrated with reference to the United States of America. Specifically, the aim is to understand how design/restoration/conservation/adaptive reuse projects of historical buildings are oriented.

Through the analysis of some projects, it was possible to evaluate whether the compatibility and reversibility criteria were observed and if and how they were able to create a dialogue between the past and the present, enhancing cultural/material values and at the same time giving relevant answers to contemporary necessities.

1 THE MEANING OF WORDS AND CULTURAL POSITIONS

This study aims to focus on the way interventions on historical architecture are carried out in the United States. The project began because of the awareness that internationally, also in terms of terminology, there are substantial differences due to varied cultural habits. For example, leaving aside the technical literature and referring to the meanings described in dictionaries, we realize how true this is, and how it reflects the history and culture of each country.

The word "restoration" in the English-speaking world means "the act of restoring or state of being restored, as to a former or original condition, place". It is, moreover, interpreted in a negative sense by the academia, certainly influenced by Ruskin thought. Furthermore, "The action of building up again or reconstructing; the process of carrying out alterations and repairs with the idea of restoring a building to something like its original form; a general renovation" (Oxford English Dictionary).

In its place we more commonly use the term "conservation", i.e. "the act or an instance of conserving or keeping from change, loss, injury, etc." (Collins English Dictionary); "the preservation or restoration of archaeological artifacts, historical sites, works of art, etc., by means of specialized techniques" (Oxford English Dictionary).

In France "restauration" means "restitution", translated as "Ensemble des actions visant à interrompre le processus de destruction d'une œuvre d'art ou d'un objet quelconque témoignant de l'histoire humaine, à consolider cette œuvre, cet objet afin de le conserver et, éventuellement, à le rétablir plus ou moins dans son aspect originel" (Dictionnaire Larousse de Français). In other words, it is an act of stylistic restoration, evidently influenced by Viollet-le-Duc's approach since the second half of the 19th century.

In Italy the term "restauro" has followed the criteria of the critical restoration theory since the end of the Second World War. Therefore, it has little to do with re-establishing the former shape of a building. The Treccani dictionary, for instance, explains the lemma as "qualsiasi intervento volto a rimettere in buono stato e in condizioni di funzionalità (...) un edificio o alcune sue parti, oppure altro manufatto", that is "any operation to put in good functional condition (...) a building or some parts of it, or another artifact"). On the contrary the term "ripristino", is "l'operazione di restituire l'aspetto e la consistenza che [un monumento, un edificio] aveva a una data epoca, per lo più fra le più antiche della sua storia, e che aveva perduto in seguito a opere successive di trasformazione e adattamento", that is to say the task of restoring the appearance and texture that a monument or a building had in a specific previous moment of its existence – most commonly the oldest one – and which it lost because of transformation and adaptive reuse. Thus, from place to place the terms listed above assume very different meanings. Matero remarks: "It should be mentioned that translations of the Italian *restauro* as "restoration" are an inaccurate use of the English word. At least from the time of the late nineteenth century debates to the present, the word 'restoration' has come to mean "the process of returning the artifact to the physical condition in which it would have been at some previous stage of its morphological development"

Figure 1. Chicago, downtown landscape (Photo: C. Giannattasio 2015).

(Matero 2007: 55). In Brandi's opinion, "restauro" is "any operation that aims to put back into effective order a product of human activity" as opposed to "preservation" which is "preventive restoration". In this regard, a better translation of "restauro" would be "conservation" which "describes any physical intervention in the actual fabric (...) to ensure its continued integrity" (Fitch 1990: 46).

Another difference is the American context, where "restoration" means "reinstatement in a former position, rank, etc.; restitution for loss, damage, etc; a putting or bringing back into a former, normal, or unimpaired state or condition, a representation or reconstruction of the original form or structure, as of a building, fossil animal, etc.". "Conservation" means "1. the act or practice of conserving; 2. protection from loss, waste, etc.; preservation; 3. the official care, protection, or management of natural resources; 4. the preservation, reconditioning, and restoration of works of art" (Collins American English Dictionary). "Preservation" is often used as a synonym of the term.

Referring to the United States (Fig. 1), the issues of preservation of historical heritage, debated for over two centuries in Europe, have been addressed over time in different ways. In a country characterized by a strong spirit of innovation and given the dominant position of economics in public and private choices, the transformation of the building heritage had less to do with scrupulous attitudes than in the Old World. Nevertheless recently we can notice a growing awareness, demonstrated by greater integration between environmental protection and urban planning (Mugayar Kühl 2007: 139), also in terms of sustainable development (Stubbs & Makaš 2011: 473–74). We can clearly see that the results of preservation are strongly conditioned by the intense connection between the private and public sectors (Rosina & Corbin Murphy 2002: 55).

Reflections on architectural history and on historical heritage preservation were at a crucial point in the 1960's and 1970's, also illustrated by the birth of the National Historic Preservation Act in 1966 and the successive territorial conservation registers and commissions (Longstreth 1999: 326). During this period scholars and American professionals looked at the European experiences (Figs. 2–3), as demonstrated by the Getty Conservation Institute's effort to publicize European ideas in the USA (Mugayar Kühl 2007: 139).

With regards to the different context and architecture, attitudes differ: in America, aspects like national identification, symbolism and historical narration, as well as economic interest are more important than the authenticity or the historical value of the building. In American culture a restored and preserved building has no intrinsic value as layering of history, and it is 'disconnected' from the flow of time. Architecture is seen "as a tool for illustrating history" (Fiorani 2013: 17); at the same time, a historical building which does not have a symbolic and patriotic value, is susceptible to transformation, replacement or demolition.

American thought has long been influenced by a rigid idea of preservation, basing the classification and evaluation of cultural heritage only on style, function and symbolism. Nevertheless, it should be pointed out that recently a new focus on the issue of preservation of existing buildings is emerging. Indeed, "today increasing numbers of high-caliber students in doctoral as well as master's programs are giving serious consideration to the field" (Longstreth 1999: 332). The recent awareness in dealing with the theme of preservation and restoration is indeed evident in the university programs of the main American schools of architecture, analysis of which highlights how students are faced with the issues of authenticity and testimonial value of historical heritage, with a more critical attitude towards preserving historical buildings than in the past.

Figure 2. Boston, Berkeley Building, listed by the Boston Landmarks Commission as Boston's City Landmark in 1975 (Photo: C. Giannattasio 2015).

The sensitiveness towards the past can be seen by the active participation in international conventions (such as UNESCO's World Heritage Convention in 1991), the commitment of many research centers (such as the Getty Conservation Institute in Los Angeles) and the growing number of cultural associations and charities supporting the preservation of heritage.

2 THE PRACTICE OF PRESERVATION

In the United States the practice of restoration and conservation has recently been strongly linked to the themes of patriotism and national identity, as well as to economic and marketing issues. The approach towards the historical and architectural heritage varies, depending on the subject of the project. It ranges from restoration projects to partial or total replacements of the pre-existing building. Some emblematic cases highlight this attitude.

The restoration act to reinstate a former or original condition represents the first approach – also in chronological terms – to the theme of the commemoration of a past to remember and maintain. This theme is often present in the history of architecture. It influences projects and preserves the architecture which is the expression of national identity. What we are talking about is not an exclusive attitude, but rather a direction followed over and over again in the American experience. A classic example concerns the sites and cities where the main historical events took place,

Figure 3. Boston, Old State House (1713). In 1776, from the balcony of the city's oldest building, the Declaration of Independence was read to the citizens (Photo: C. Giannattasio 2015).

Figure 4. Chicago, Crown Hall, IIT, Mies Van Der Rohe (1952–56). An iconic building of the Modern Movement (Photo: C. Giannattasio 2015).

such as the American War of Independence (1775–83) and the American Civil War (1861–65). In this sense Williamsburg is a typical case. In fact from the early years of the 20th century it was decided to 'reconstruct' a precise moment of the city's history. Consequently, all the structures built after the War of Independence were demolished, and a stylistic reconstruction of the destroyed Capitol and Government Houses was created, based on written descriptions and illustrations. The commemorative framework was completed with the staging of the period events, introducing costumed characters that simulate the lifestyle of the second half of the 18th century (Fiorani 2013: 16). Similar projects

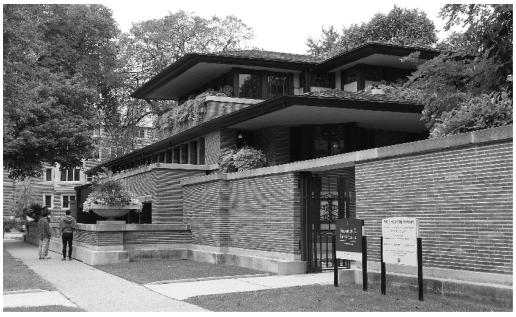

Figure 5. Chicago, Robie House, Frank Lloyd Wright (1908–1909). At the beginning of the 21st century it was restored to its former state (Photo: C. Giannattasio 2015).

Figure 6. Chicago, Art Institute, the Modern Wing opened in 2009, designed by the Renzo Piano Building Workshop (Photo: C. Giannattasio 2015).

are carried out today: an effective example is the demolition of the Visitor Center at Gettysburg National Military Park, designed by Richard Neutra and Robert Alexander between 1959 and 1962. This important example of architecture from the post-war period was intended to serve as a bridge between past and present, introducing visitors to the site of the bloodiest conflict of the Civil War, and where Abraham Lincoln proclaimed his famous speech. Despite the significant value of this modernist work and the opinion of preservationists, the Visitor Center was demolished by order of the Park Superintendent, the National Trust and the Advisory Council on Historical Preservation, in order to restore the landscape skyline of the Civil War period. The operation was completed in 2009.

Therefore, the tendency is to treat architecture and its history as a tool of communication and storytelling: unbound by time, it is considered to represent an elective period or the identity values of the nation. The great respect shown to other modernist buildings, in contrast to that manifested by the last example, confirms this position, leading to operations of reinstatement of the original condition (Docomomo 1991). This is especially true regarding architects enhanced by contemporary American historiography, such as the architects of the School of Chicago and of the Modern Movement, like Frank Lloyd Wright, Walter Gropius, Mies Van der Rohe and Louis Kahn (Figs. 4–5); that is American architects, native or naturalized, who have been able to produce architecture representative of the national identity. An effective example of this approach, certainly not respectful of the modern principles of authenticity and minimal intervention, is the restoration of the Monadnock Block in Chicago, started in 1979 after the acquisition by a partnership headed by William S. Donnell (Miller 1991: 140). Designed by the famous architects Daniel Burnham and John Wellborn Root, School of Chicago, and begun in 1891, this skyscraper is one of the most interesting examples of the pre-modernist movement. It was the subject of several renewal projects carried out in the 20th century, which had compromised its former design. Therefore, Donnell restored the building to its original condition, taking care of every detail and reproducing furnishings, doors and the lighting system (Miller 1991: 145).

Following a similar approach, some of Frank Lloyd Wright's masterpieces such as the Fallingwater House in Bear Run, Pennsylvania (1936–39) and the Robie House in Chicago (1908–10) have been restored.

The latter was adapted to a student center for the university in the 1970's, with consequent modifications and replacement of furnishings. Recently, it was restored and transformed into a museum. It is considered representative of the national architectural identity and so it must be preserved and transmitted to the future, not simply for its historical and material values, but mainly for its intrinsic identity meanings. In accordance with this point of view, at the beginning of the 21st century the Frank Lloyd Wright Preservation Trust undertook the restoration project, both re-establishing the original architectural configuration of the house and reproducing the furnishings, decorations, etc.

Another current and common tendency in the US, in contrast to those described above, regards historic architecture which is not considered representative of the aforementioned symbolic or identity values. Even though they are listed in the National Registers or in Preservation Lists, usually economic and marketing factors prevail on conservation or restoration issues. Consequently the design project focuses on the creation of invasive contemporary structures in order to extend or renovate pre-existing architecture, without considering its peculiarities and meanings. In this sense, many adaptive reuse projects are carried out, recently influencing also the European context, where this practice is becoming more and more widespread. Therefore, the delicate relationship between old and new, which has been widely debated in Europe since the end of the Second World War, is not really considered in the US. The recent demolition of the Takashimaya Department Store façade in New York, designed by Philip Johnson and John Burgee, is a clear demonstration of the loss of attention shown towards some buildings. In 1993 David Chipperfield was asked to design a new façade. The English architect justified his invasive project saying that it was an attempt to

reproduce architecture like that created by Mies Van Der Rohe, specifically inspired by the famous Seagram Building. Chipperfield's work, even though it is of high quality, reflects the American innovative spirit, distant from European, and especially Italian, culture.

In extreme cases, the economic and functional needs lead to the complete demolition or replacement of the pre-existing building, a fact accepted even by preservationists. These actions are done "irrespective of their intrinsic physical qualities or their role in the development of the community" (Longstreth 1999: 330). Façadism seems to be the compromise widely used in the United States, and in Europe as well. Following this kind of practice, the structure and material of the architecture are considered as separate entities, giving more importance to the former. A representative example is the Penn Mutual Building in Philadelphia (1971–75), reinforced concrete and glass skyscraper built to replace the Pennsylvania Fire Insurance Company Building, by the neoclassical architect John Haviland in 1838. Nowadays only a portion of the former marble façade survives, conserved as a reminder of the past.

When the design project is conceived by architects deeply involved in the cultural debate concerning the union between old and new, sensitive to the conservation and valorization of historical buildings, the outcomes are highly remarkable. For example, Renzo Piano's works in the United States, often consisting of the extension and renovation of existing buildings, are strongly marked by respect for the relationship between old and new (Fig. 6). Some significant examples are his plans for museums and libraries in Atlanta, Chicago and Boston. A very notable case is the renewal and extension of the Morgan Library & Museum in Manhattan, New York, designed by the Renzo Piano Building Workshop. He describes the project as "three new pavilions connected to the historic buildings, leaving a large open 'plaza' at the center of the Morgan complex that could be used for public functions and as a metaphorical breathing space for visitors. The three historic buildings, the plaza and the new pavilions meet under a transparent steel and glass roof" (http://www.rpbw.com/).

Regarding adaptive reuse, cases of transformation of existing buildings are numerous and often interesting, although it appears that functional motives could prevail over conservation aims. In other words, contrary to modern principles of preservation, the function becomes the 'aim' and not the 'tool' of the project.

One of the first large scale urban rehabilitation and reuse projects was the preservation of the Quincy Market-Faneuil Hall Marketplace in Boston and its three-year conversion into a contemporary shopping center in 1976, through which the revitalization of the area was achieved (Stubbs & Makaš 2011: 452–53). Inspired by Anglo-Saxon urban strategies, this operation was later reproduced in several other cities in the United States (Fig. 7).

A more recent project, on the architectural scale, again in Boston, involved the Liberty Hotel (Fig. 8).

Figure 7. Boston, Quincy Market-Faneuil Hall Market-place. Converted into a shopping centre in the 1970's (Photo: C. Giannattasio 2015).

Figure 8. Boston, Liberty Hotel. An example of adaptive reuse designed by the Cambridge Seven Associates & Ann Beha Architects in 2007 (Photo: C. Giannattasio 2015).

Inaugurated in 1851, the building was originally the Charles Street Jail, designed by John Fox Grigley Briant, exponent of the so-called Boston Granite Style. When it opened, this prison was considered exemplary, but the lack of investment and increasing overcrowding lead to its closure in 1990. Recognized as a National Historical Landmark building, it was acquired and used for a while by the Massachusetts General Hospital; after it was transformed into a luxury hotel, redesigned by the Cambridge Seven Associates and by Ann Beha Architects. The *rotunda* was transformed into the hotel lobby, and balconies once used by guards and prisoners now connect guest rooms to conference spaces. At the same time many significant historic features were restored.

Reuse also involves structures and infrastructures that have completely lost their function, in the presence of which transformation can obviously be more audacious. For instance, the New York High Line (Fig. 9) is an example of urban regeneration through the reuse of an abandoned railway. It successfully renovated the entire area which it crosses, from a social and economic point of view. Furthermore, even though it is too early to make an efficient evaluation, the High Line seems to be a good example of participatory planning

Figure 9. New York, High Line, designed by James Corner Field Operations and architects Diller Scofidio + Renfro in 2002 (Photo: C. Giannattasio 2012).

and of a new gentrification process: "A neighborhood that had already been greatly impacted by sweeping gentrification since the late 80s may have experienced an increase in gentrification since the installment of the High Line, as the area is over-run by new real-estate developments of high-end condominiums, hotels, and loft conversions in expensive new residential spaces" (Alvarez 2012: 10). Thus, in New York the High Line is a significant project in terms of urban regeneration, which seems to reflect the usual American approach linked to the need to have economic benefits.

Another interesting example, connected to a much rarer operational tendency, which reflects a coherence with the critical restoration approach, is the Franklin Court in Philadelphia. Former home of Benjamin Franklin, situated in the Independence National Historical Park, in 1976 it was the subject of a significant redevelopment project: "a team of designers, engineers, and archaeologists offered a revolutionary solution by revealing the site's historical and aesthetic authenticities through real and exaggerated elements" (Matero 2010: 1). The team, including Robert Venturi, elaborated a project which allowed visitors to rediscover archaeological spaces and reinterpreted the original space of the former house, by means of a ghost structure made of white-painted metal frame reproducing the outline of the demolished main residence of Benjamin Franklin. The concept of Venturi's project is close to European culture and to the principles of the 1964 Venice Charter, although this document has never really been taken into consideration in the United States (Fiorani 2013: 29). Actually, in the American, and in the Anglo-Saxon world in general, "Brandi's words and concepts have been largely absent, due to the lack of an English version of his 1963 Teoria del Restauro until the first excerpts were published in 1996" (Matero 2007: 45; Brandi 1996).

3 TEACHING PRESERVATION

After seeing the projects carried out in America, it is useful to examine ongoing university research and educational programs there. The aim is to identify and emphasize the relationship between the cultural/academic world and the professional world. The tendency among preservationists to prefer typological reinstatement (which considers historical architecture from a stylistic point of view, combined with other factors, such as function, symbolism and structure) is no longer prevalent in the academia. Actually other factors are considered in preservation projects, such as revitalization and sustainability and giving architectural heritage new purpose and vitality (Longstreth 1999: 332). This new way of thinking can be seen by analyzing a few educational programs of the main American universities.

Even though history and culture are the basic topics for preservation courses as well as for design and architecture teaching, one can see that these two subjects are studied in depth in some specialized courses specifically dedicated to heritage. For instance, if, on the one hand, important institutions like MIT in Boston or Yale University in New Haven provide a few specific courses on heritage preservation within the architecture programs, on the other hand, more and more universities offer graduate programs in Historic Preservation. This is the case with the George Washington University in Washington, the University of Pennsylvania in Philadelphia, Columbia University in New York, the University of Southern California in Los Angeles, just to mention a few. In these courses the study of history and culture is not limited only to the US territory, but expands its interest overseas. The course "Urban Conservation Seminar: Heritage and Urbanism in China", held by Randall Mason at the University of Pennsylvania, is an interesting example of this trend. Manson compares the slow evolution of the European cities with the explosion of Asian ones. Moreover, many aspects of American architectural history are explored in greater depth, including issues such as vernacular architecture, rural systems, etc. This connects the American and European cultures as they both move towards a more wide-ranging knowledge of historic buildings.

Similarly, preservation theory and history are taught, for example, "Historic Preservation Principles and Methods" at the George Washington University, "Theories of Historic Preservation" at the Pennsylvania University, "Architectural and Social History" at the School of the Art Institute of Chicago and "Preservation theory and history" at the Pratt Institute in New York. Also in this case the American teaching moves towards the European one: the evolution of the concept of preservation over time is at the base of the Historic Preservation courses, and increasingly in conservation design projects the typological tendencies are giving way to critical design positions.

Even the technical aspects do not differ particularly from the European school, ranging from the study of the properties of materials and construction techniques to the diagnosis of degradation and conservation of buildings. For example, "Conservation Methods and Materials" at the University of Southern California, "Physical Conservation" at the School of

Art Institute of Chicago and "Building Technology" at Pratt Institute look more closely at the themes regarding historical building materials, building pathologies affecting materials and construction elements, as well as actions and methodologies used to preserve and protect the architectural heritage.

An interesting point to be highlighted, and which characterizes the American school, not only academically, but also in the practice of conservation and reuse, is the importance acquired by one of the fields, which has significantly impacted on the preservation of buildings in American culture, namely economics. It exercised a considerable influence even before the enactment of a specific law on heritage preservation (1966) and the birth of the first educational program concerning historic preservation. Currently, schools are planning more and more classes in economics and management applied to the field of conservation and cultural heritage. At the George Washington University "Economics of Preservation" is taught, where, in addition to economic techniques, costs and benefits in the practice of preservation are considered. "Managing Heritage Sites" concerns the management of cultural sites and how to make them more pleasing to the public as well as how to manage budgets, staff and resources.

The Historic Preservation programs of the University of Pennsylvania include "Historic Site Management", "with topics like conservation policy, interpretation, tourism or economic development strategies", and "Preservation Economics" which, as described in the Donovan Rypkema's course program (Spring 2016: 2), "prepare the student, as a practicing preservationist, to understand the language of the development community, why a preservation project should be undertaken, and to be able to quantify the need for public/non-profit intervention in the development process, and also to acquaint the student with measurements of the economic impact of historic preservation".

In summary, in the universities examined the academic teaching of themes closer to the conservation and protection of historical and cultural heritage is frequently overlooked. The specialized educational programs mentioned above represent an exception, particularly those in Historic Preservation at George Washington University, at the University of Pennsylvania and at Columbia University. In these universities all areas are investigated that positively and negatively affect the conservation of cultural heritage at the same time as focusing on related topics such as "the legal framework, the nature and dynamics of preservation organizations, economic factors in rehabilitation, long-range planning and management techniques, the role of community activism, the opportunities of adaptive use and community revitalization, the management of historic sites, and the theoretical bases for current practices". The aim is to seize "the opportunity to deepen one's understanding of the richness and complexity of the built environment as a cultural landscape and the historical significance of its varied parts and relationships; to develop skills in documenting, assessing, and protecting this legacy; and to recognizing the design and planning issues that are central to managing the forces of growth and change within a historic context" (Graduate Program in Historic Preservation at George Washington University).

4 CONCLUSIONS

Ultimately, in the US, as often happens in other international contexts, both European and non-European, we currently have two parallel tendencies. On the one hand, projects are not really sensitive to the historical and material values of a building, and priority is given to economic factors, which justify the reconstruction or replacement of entire old sections. On the other hand, projects are linked to commemorative issues and their aim is to reinstate the original aspect of a building, erasing the signs attesting the passage of time.

This trend comes both from a critical analysis of the main projects, and also from examination of the teaching programs of the leading US universities focusing on historic preservation. First of all, we have to highlight that only some universities in the US include these kinds of courses. When this happens, the cultural reference is the Anglo-Saxon environment, that is to say, preservation is taught paying great attention to technological and conservation topics, as well as to marketing and the economic feasibility of the project.

It consistently emerged that the "critical restoration" principles do not succeed here.

Nevertheless, reflection on cultural heritage as a material sign of the past, also of the recent past, is nowadays more and more the focus of some American conservation specialists. Unlike some professionals and preservationists, they do not look at historical architecture as something to associate with typological building categories, representative of a particular historical period, and selected according to comparable processes of the classification of biological species. Despite the fact that typological conservation is still the main *modus operandi*, there is a certain optimism among those specialists who approach the preservation of cultural heritage with more vitality and a critical spirit.

Finally, we think that a dialogue between Europe and the US, from an academic and professional point of view, could be very useful for the growth of the conservation and restoration sector. If we do this, we will manage to create a common way of thinking and working which at the same time respects each country's differences. Specifically, this will allow us to enhance conservation and design projects based on a careful balance of old and new, once and for all stopping false "in style" projects.

Future studio: Preparing students for practice in the global context

M. Simon
School of Architecture, Planning and Preservation, University of Maryland, USA

ABSTRACT: How is the institution of the architectural design studio evolving in the twenty-first century in response to external pressures from the profession and society? How might current professional trends and societal challenges further transform the design studio? The architectural design studio is an educational setting that has evolved in North America from the late nineteenth century to the present day. Originally modeled on architectural practice, early studios grew in a variety of supporting institutions including architectural clubs, firms, schools, and universities. Through a process akin to natural selection, the university emerged, in the early twentieth century, as the predominant locus for design education. Henceforward the design studio developed into its present form as a result of influences from both academia and the profession. As with biological evolution, the development of the studio is an ongoing process with variations emerging in response to practice trends. The present research, part of a study of the evolution of architectural design education in North America, examines one particular practice trend, increasing globalization of society and professional services, and the various responses of architecture schools and allied institutions in the design of studio experiences preparing students for their future roles in globalized practice.

1 INTRODUCTION

The architectural design studio is an educational setting that has evolved in North America from the late nineteenth century to the present day. Originally modeled on architectural practice, early studios grew in a variety of supporting institutions including architectural clubs, firms, schools, and universities. Through a process akin to natural selection, the university emerged, in the early twentieth century, as the predominant locus for design education. Henceforward the design studio developed into its present form as a result of influences from both academia and the profession. As with biological evolution, the development of the studio is an ongoing process. Variations have emerged in response to emerging trends in practice. The present research, part of a study of the evolution of architectural design education in North America, examines one particular practice trend, increasing globalization of professional services, and the various responses of architecture schools in the design of studio experiences to prepare students for their future roles in globalized practice.

Studio experiences that bring architecture students into contact with international cultures have their intellectual roots in the Grand Tour. Beginning in the late 16th century, young aristocratic men traveled to France and Italy to learn about art and architecture (Sorabella, 2003). Aspiring American architects who traveled to Paris to study at the Ecole des Beaux Arts followed this intellectual tradition. As American architectural education developed largely based upon the educational model of the Ecole brought back by those early students, the value of international experience was fundamental to the system.

In the early days of American architectural education, the purpose of the international experience was to prepare American architects for domestic practice by giving them educational opportunities unavailable at home. It was not until the late twentieth century that international practice became an important factor in the development of the American architectural profession. International clients began to seek out American architects and firms for their expertise and American practices came to depend upon international markets for services to maintain their profitability through the vicissitudes of the United States economy. With time, international practice evolved into global practice, as American firms with commissions in other countries evolved into multi-national firms with worldwide strategic plans. Travel improvements enabled international practice to develop, and advances in communications technologies continue to spur the evolution of global practice.

This study first examines variations on the spectrum of international to global practice. Next, it identifies a set of models for architectural education preparing students for engagement in increasingly global architectural practice. Finally, it concludes with speculation about the future of studio in the preparation of students for practice in an increasingly interdisciplinary,

multi-cultural, global setting. professional models for globalized practice.

2 PROFESSIONAL MODELS FOR GLOBALIZED PRACTICE

Although the globalization process has its roots in early travel, key turning points have been identified as 1) the separation of communication from transportation with the invention of the electric telegraph in 1830-1850, and 2) the invention of the micro-processor, leading to the establishment of the first global networks in 1971. Economic, political, technological, cultural, and environmental factors all influence the process of globalization (Rennen and Martens 2003). Innovations in transportation and communications have spurred the globalization of architectural practice. American architecture firms have adopted several models for practicing internationally and for engaging in truly global practice. Major models include: 1) the traveling architect model, 2) the strategic alliances model, 3) the outsourcing model, 4) the field office model, and 5) the virtual team model.

2.1 *Traveling architects model*

In the traveling architects model, key project personnel fly to an international site for meetings and information-gathering, then return back to the firm's US office and inform the team that executes the work.

An example of the traveling architects model was the way Skidmore, Owings & Merrill organized to execute the Hajj Terminal at the King Abdulaziz International Airport in Jeddah, Saudi Arabia, completed in 1981. The airport work was executed in the New York and Chicago offices of SOM, with firm principals traveling for project meetings and bringing information back to the project team executing the work in the US offices. (Simon, 1979–1983)

An innovation in air travel at the beginning of the fourth quarter of the twentieth century, supersonic flight, ushered in with the beginning of Concorde service in 1976, cut flight times dramatically. Concorde service, although short-lived, launched faster air travel and an accompanying sense that international destinations were closer. In the late twentieth century, documents traveled by airplane as well. FedEx, a pioneer of air delivery, was founded in 1971, and by 1977 was delivering around the world, enabling next-day transfer of project documents. These innovations in travel for people and documents facilitated international practice. (Simon)

2.2 *Strategic alliances model*

In the strategic alliance model, the US firm forms an association or joint venture with a local firm. The terms of the association or joint venture agreement set forth the respective roles of the two firms. While the association model preserves the separate legal status of the two firms, the joint venture model unites the two firms into a single legal entity for the duration of the relationship. (McNeill 2009) In a simple strategic alliance, the US firm might execute the design, while the local firm, familiar with local construction methods and materials and constructors, might prepare construction documents and perform contract administration.

An example of a strategic alliance is the 2010 formation of a joint venture between Callison and HAYA Architects, uniting Callison's "global design expertise and experience" with HAYA's "local insight and strong delivery systems." (Callison, 2010)

2.3 *Outsourcing model*

The US firm outsources the preparation of construction documents to an overseas firm in a labor market, such as India, where the cost of services is substantially lower than in the United States. The international education of Indian architects in the United States facilitated their founding of architecture firms back in their home country prepared to interface with American practices. Another key factor enabling outsourcing is improvements in the technology of documents transfer. The ftp protocol came online in the 1980's, providing secure document sharing over the internet.

2.4 *Field office model*

In the field office model, US firm sends key personnel to establish an office at the location of an international project. The field office principal maintains communications with the firm's US office(s). The field office may be temporary for the course of a single project or may establish a long-term relationship, serving to develop new clients for the firm as well as executing local projects.

Developments in communications technology, such as email, becoming prevalent in the 1990's, facilitated the growth of international offices of US firms and the development of multi-national firms.

2.5 *Virtual team model*

In the virtual team model, the firm maintains offices in international locations, staffing the offices with local personnel, and manages projects as collaborative efforts among members of the geographically dispersed team.

An example of the virtual team practice model is the master plan and selected buildings for New Songdo City in South Korea, designed by KPF in their New York and Seoul offices at the beginning of the twenty-first century. Personnel in the New York office relied upon their counterparts in Seoul for information about urban culture in Korea (Nemeth, 2014).

A version of the virtual team model is the round-the-clock practice model, where a firm realizes economies of time by passing projects back and forth across time zones to team members in two or more geographic locations.

Virtual practice was enabled by the development of communications technologies and collaborative tools. Not only do architects pass documents back and forth among geographically dispersed team members by ftp protocol, but since the beginning of the twenty first century, they can collaborate in real time on an intelligent three-dimensional model with building information modeling (BIM). Whereas in the early days of international practice, architects and consultants would work separately, meet physically, and exchange physical documents, integrated project delivery now creates an interactive environment where virtual teams collaborate through the building information model. A rapidly expanding array of project management and communication tools facilitates easy exchange among team members.

3 EDUCATIONAL MODELS FOR LEARNING TO PRACTICE GLOBALLY

The American tradition of well-to-do young men (and one woman, Julia Morgan) traveling to France for study at the Ecole des Beaux Arts continued into the second half of the twentieth century. And, for those who could not afford to study abroad, a group of alumni of the Ecole banded together to form the Society of Beaux-Arts Architects, later becoming the Beaux-Arts Institute of Design (BAID), which promulgated a system of design education spurring the creation of American ateliers that emulated the Parisian ateliers of the Ecole. (Simon, 2012) In these ateliers associated with clubs, firms, schools, and universities, aspiring American architects were steeped in the French culture of architectural education, even learning the French vocabulary of architectural practice. (Simon, 2002) Of course, these experiences were not intended to prepare American architects to practice in France; instead they were intended to prepare American architects to practice in the United States as if they had studied in France. These were not study abroad studios, but rather studios that transferred a foreign culture to the United States.

The opportunity to study abroad in Paris, long a custom of the wealthy elite, was extended to all students in the American ateliers when in 1904 the Beaux-Arts Institute of Design (BAID) began offering a competition, the Paris Prize, which funded one American student each year for study at the Ecole. The BAID, renamed National Institute for Architectural Education (NIAE) continued the Paris Prize until 1963 (Schwartzman, 1964).

Another important American institution, the Rotch Traveling Scholarship, grew out of one family's experiences with the tradition of studying abroad in Paris. The scholarship, initially offering funding to an individual for two years of travel and study abroad, was founded in 1883.

These early opportunities for aspiring American architects to study abroad – or to study at home as if they were abroad – laid the foundation for the development of a variety of educational models introducing architecture studies to international cultures. Initially inspired by the animating concept of the Grand Tour, self-improvement through exposure to the monuments of the past, the mission of many of these educational experiences broadened and evolved over time in response to changes in educational institutions, in society, and in architectural practice. The education of architects moved from a diversity of early settings into the universities. As increasing globalization of drove the development of study abroad programs in universities, additional international opportunities opened for architecture students at the university level. And, as the globalization of architectural practice accelerated from the late twentieth century onwards, architecture schools and allied institutions developed new models preparing students to become global practitioners.

Major models include: 1) individual travel/study grant (offered by a variety of organizations including architecture firms), 2) study abroad course, 3) studio abroad with US faculty, 4) studio abroad with international faculty, 5) studio abroad in an international firm, 6) joint studio abroad in partnership with local school of architecture, 7) community-engaged studio abroad, and 8) virtual studio. The following discussion will focus on the studio-based models, introducing each model and illustrating it with a case study example.

3.1 *Traveling studio with US faculty*

A group of American architecture students and faculty travels to an international destination for site visits and information-gathering, then executes the project on site or returns back to the US school to execute the project. An influential sponsor of traveling studios is the Rotch Traveling Studio Grant, established in 2002 by the Rotch trustees, expanding their funding for international travel from individuals to studio groups.

A case study example of a traveling studio funded by a Rotch Grant is MIT's Cycles traveling studio that brings twelve students to Iceland for one and a half weeks of site research under the direction of Assistant Professor William O'Brien Jr. Students prepare for their international travel by researching current development in Iceland, along with developing methods and techniques that they will deploy on site. During their time in Iceland, students visit sites that give them insight into the relationship between geology and the development of infrastructure and urbanism. Upon returning to the United States, students engage in analysis and design projects based upon their site research (O'Brien, 2010).

The basic model of a traveling studio that brings a group of American students to an international destination where they are guided to learn by an American instructor seems to offer the most minimal preparation for global practice. Students are certainly exposed to an unfamiliar place, where they view local places, people, and activities under the guidance of an American studio critic. At face value, this seems less valuable than some of the other models, which give students

opportunities to view their international destinations through the eyes of local faculty, practitioners, students, clients, and/or local residents. However, the case study examined demonstrates the potential value of this model. In this particular example, the deep local experience and expertise of the studio critic gives these students specific preparation for global practice by teaching them to develop techniques for site-based research and analysis of resulting data. And, the studio teaches students to design based upon this intensive site research and analysis.

3.2 *Studio abroad with international faculty*

American students study in an international location with faculty from that country as their studio instructors.

A case study example is the Architectural Design Studio at the Danish Institute for Study Abroad (DIS). American students studying at DIS enroll in a studio course taught by Danish faculty. The Spring 2016 Architectural Design Studio explores the notion that "there is such as thing as a 'common ground' that guides, inspires, or frames the way architects and designers work in a specific region or culture." The studio takes students traveling in Denmark and farther afield in northern Europe (DIS, 2016).

The studio abroad taught by international faculty prepares students for global practice by introducing them to sites and programs through a local or regional lens. The theme of the common ground embodies the concept that there is a shared understanding. The DIS studio explicitly directs students to seek this common ground.

3.3 *Studio abroad in an international firm*

American architecture students travel to an international destination to participate in an architectural design studio taught by noted practitioners in or near their professional offices.

Harvard University's Graduate School of Design offers a Studio Abroad that gives ten to twelve students the opportunity to each semester the opportunity to engage in a design studio experience with international practitioners. Since the program's inception in 2011, noted international architects leading the studio have included Rem Koolhaas, Toyo Ito, Jacques Herzog and Pierre deMeuron, Anne Lacaton, Frank Barkow, Arno Brandlhuber. In the Fall of 2015, the Studio Abroad was hosted by Toyo Ito in Tokyo, Japan (Harvard GSD).

Students engaged in a series of projects for Omishima Island, titled "Making Omishima the Best Place to Live on in Japan." In addition to Toyo Ito, studio critics included three teaching assistants and studio consultants included a structural engineer from ARUP and a researcher, who also taught accompanying seminars. The final jury gave the students a range of perspectives on their work, from critics including GSD faculty, local faculty from University of Tokyo, and local practitioners. Throughout the semester, the students interacted regularly with Japanese architects through a series of experiences including visits to buildings and a smart city, office visits, workshops, lectures, and critiques. Students also had the opportunity to meet with local residents of their project site, Omishima Island.

This studio abroad experience offers several benefits. First, the semester-long duration offers the opportunity for extensive immersion in host firm, the local professional community, and the local culture. Under the aegis of a highly respected local architect, students gained entrée to people, places, and practices. The seminars accompanying studio provided students opportunities with knowledge to foster their understanding of the various experiences of their study abroad semester. Seminars and workshops taught them local design processes and technologies. The marked politeness of the students' verbal expression in their studio blog suggests that they absorbed lessons of interpersonal communication embedded in Japanese culture (GSD Studio Abroad blog).

In this case study of the studio abroad in an international firm model, we see students prepared for global practice in several ways. The foreign becomes familiar as students spend an extended period of time in another country. They learn about the settings of architectural practice in their destination country. They engage with local architects, consultants, clients, and users in meetings guided by local hosts who serve as cultural interpreters, assisting students in understanding these interactions. Students learn local customs and etiquette through frequent contact. In addition to gaining a set of local knowledge, students likely also gain a generalizable set of competencies that will allow them to skillfully navigate other international places and cultures.

3.4 *Joint studio abroad in partnership with local school of architecture*

The joint studio abroad model engages students from two cultures in a shared studio experience. One or both groups travels to the other's location.

Georgia Tech offers a joint studio abroad experience in the International Urban Design Workshop. This studio brings the College of Architecture together with collaborating schools and other institutions abroad for collaborative teaching and research to develop shared intellectual interests. Sustainable urban design is a particular focus of the studio projects. The primary objective of the studio is to "engage graduate students in the College of Architecture in interdisciplinary, collaborative and real-world experiences in support of global professional practices in urban design, architecture and planning" (Yang, 2016) The first two-week-long studio took place in Shanghai, with fifteen Georgia Tech graduate students collaborating with fifteen Tongi University students in project teams in an urban design project (Georgia Tech).

In this case study example, students are prepared for international practice by learning to work

collaboratively in international teams with students from another country and culture. In order to work effectively, they must navigate differences in language and culture. They learn to see urban situations and identify problems and opportunities from the point of view of local students.

3.5 *Community-engaged studio abroad*

The community-engaged studio model gives student the opportunity to work with clients, users, and stakeholders. These studios model practice and offer opportunities for students to use their growing expertise for the public good.

A case study example is the Old Accra: Upcycling of Agrowaste studio, winner of the 2015 Rotch Traveling Studio grant. This studio is designed to bring twelve students and two faculty from Rensselaer Polytechnic Institute for a ten day travel study experience engaged with local industry in Accra, Ghana. Before departure, students are to prepare by researching context and precedents and engaging in preliminary design exercises. Their itinerary in Ghana includes visits to grass-roots recycling hubs in Accra, a design charrette and workshop with local participants in Old Accra, critical review and public presentation. Back in the United States, students are to revise their designs and construct a full-scale prototype. Design instructions and components to be sent back to Accra will enable Ghanaian partners to fabricate and install the prototype at the Chale Wote Street Art Festival in August 2016 (Crembil and Lokko, 2015).

The model of the community-engaged studio abroad prepares students for global practice by developing their cross-cultural communication skills as they interact with local participants in research, design, critique, and sometimes construction of a project. In addition to developing knowledge of a specific place and people, students learn a process for operating within an unfamiliar culture.

3.6 *Virtual studio*

The virtual studio model brings American students together virtually with international students, unifying the students into a geographically dispersed team.

A case study example of this model is the The Bridging the Gap studio, which brings eight University of Maryland graduate students together with twelve Al Nahrain University undergraduates in a dispersed team working together on a series of projects in Washington DC and Baghdad. Studio critics are Associate Professor Madlen Simon of the University of Maryland (the author), Assistant Professor Shaimaa Hameed Husseini of Al Nahrain University, architect Marlene Shade of Dewberry, and Zahraa Alwash, Ahmed Khalil, and John Rivers of Gensler. Iraqi students are preparing information about a Baghdad site for the American students, who, in turn, are preparing information about the Washington, DC site for their counterparts. Team members exchange project information on an ftp site, get to know one another via a Facebook group, taste each other's local cuisine through a recipe exchange, listen to each other's music, and meet for questions and critiques of each others' work through video-conferences. Team members serve as informants on the ground and interpreters of one another's cultures. This virtual studio offers a means to bridge a gap in knowledge and understanding where actual travel to Baghdad is impossible due to the threat of terrorist violence and actual travel to Washington is unlikely for most of the Iraqi students. Prior to the studio, most of the students had little knowledge of each others countries and cultures other than what they learned from the news media. The studio gives the students new, direct channels of communication over the Internet. And, at the conclusion of the studio, two Iraqi students and two American students will be selected through a design competition to meet in the real world in an internship at Gensler's Washington DC office.

In this case study example, students are prepared for global practice by learning to work in a virtual team. Their need for knowledge about the sites and users they are designing for creates an obligation to learn how to break down the barriers of language and culture to communicate with their counterparts around the world. This involves the development of soft skills as well as familiarity with some rudimentary team communication tools.

Students were asked to select a specific user, construct a narrative, and focus their design proposals on the lived experience of that person. Developing student work in the US and Iraqi studios indicates a high level of cultural understanding and empathy for the users of proposed projects. At the conclusion of the studio, a post-survey will be compared with a pre-survey to measure change in a set of indicators over the course of the semester. Results will be reported in a future paper.

4 CONCLUSIONS

The value of international experience is fundamental to American architectural education, due to the significant influence of American architects trained at the Ecole des Beaux Arts in Paris, carrying on the tradition of the Grand Tour that exposed young architects to the monuments of Europe. Traveling grants for young architects, such as the Rotch Traveling Scholarship, emerged out of this tradition beginning in the late nineteenth century. Architecture schools developed studio abroad programs to broaden opportunities for international experience beyond individuals to groups. The Rotch Foundation supported this effort with the Rotch Traveling Studio grant program founded at the beginning of the twenty-first century. By this time, the value of the studio abroad had already broadened from the original mission of self-improvement through exposure to the masterpieces of Europe to preparation for practice in an already international and increasingly globalized interdisciplinary profession.

While studio abroad opportunities are proliferating in a variety of new models, education is lagging significantly behind the profession in this area. One of the examples examined in this research, the author's virtual studio, has the potential to build students' soft skills necessary for collaboration among geographically dispersed teams, but operates at a level of technological sophistication well below professional standards. Soft skills are critically important to effective global practice, as one of the key benefits of a virtual team is the ability to bring insider insights into local conditions to the benefit of geographically remote team members. Research on the ongoing virtual studio will measure the development of this capacity in participants during the course of the semester.

The next evolution in this arena would be a virtual studio using BIM to create an integrated project delivery environment for the geographically dispersed team. And, an important further development would be the inclusion of multiple professional disciplines, making the virtual student team both cross-cultural and interdisciplinary.

Architectural studio education in the United States developed out of the atelier model that simulated the practice setting to a large extent. While firms have undergone radical changes in response to the globalization of society and practices, the typical architectural design studio has not kept pace. Architectural education is lagging, not leading, the profession as it evolves to meet the challenges of globalization. The experiments in studios abroad and virtual studio examined here offer models for further exploration and development, critically necessary for the evolution of the architectural design studio experience necessary to prepare students for current and future interdisciplinary, multicultural, globalized practice.

Architectural education circa 2030: Results of master planning research

M. Sattler
California Polytechnic State University, San Luis Obispo, USA

ABSTRACT: This paper analyzes exploratory research conducted by the California Polytechnic State University San Luis Obispo Architecture Department in the 2014–15 academic year as part of a larger university wide 15 year Master Plan academic program visioning process. Tasked with visioning the Department in 2030, the intensive Master Planning process included exploring "Future Academic Leadership Opportunities" specifically related to curriculum, pedagogy, and enrollment, in addition to the exploration of strategic interdisciplinary opportunities, and the deployment of "Learn by Doing" educational models. Seeded by global forecasts, regional demographic projections, and observations from the profession, the Architecture Department developed and utilized six future socio-technologically constructed scenarios, driven by dynamic environmental conditions which have significant potential to shape architectural curricula in the decades to come, to further their planning process. These future scenarios include: the impacts of *Megacities and Increasing Urbanization*, *Energy/Matter Resource Relationships*, *Disruptions to Ecosystem Service Provisioning*, *Big Data and Ubiquitous Physical Computing*, *Manufacturing in the Age of Makerbots and Nanotechnology*, and *Economy, Employment, and Means of Production*.

These scenarios initiated a mixed-methods study which sought to answer the question: Given dynamic change, how do we maintain our position as a leader in the field of Architectural Education in 2030? Through a series of anonymous surveys and focus groups, this paper details the research methods, results, and ensuing conversations surrounding the development of educational responses that suggest the following: transitioning to pedagogical models of breadth linked to focus area(s) of specialized depth within Architecture, a targeted investment in representation, communication, and fabrication skills, and an increasingly sophisticated technologically based curriculum that is more seamlessly integrated with traditional studio design practices and formal pedagogies.

1 INTRODUCTION

1.1 *The master planning process at Cal Poly, 2014–15*

In the 2014–15 academic year, the California Polytechnic State University engaged a comprehensive Master Planning initiative that spanned all sectors. Lead by Linda Dalton, P.hD, AICP and the Vice Provost for Institutional Planning, the process was framed by theories of "Disruptive Change… [which] challenges the very role and value of higher education now and in the future" (SCUP 2014). The process was in part driven by a significantly shifting demographic in the State of California which is expected to impact the University's enrollment. As the State's University systems are attracting an increasingly ethnically and culturally diverse population, it is also forecast that it will see fewer California natives, increasing percentages of international students and non-traditional transfer students, and an increase in different languages spoken on campus (Pitkin et. al. 2012).

In the fall of 2014, each unit was tasked with the development of their own program narrative and a set of recommendations to their larger College committee which would compile and ultimately frame the recommendations. Each unit had less than a month to complete this process. This paper details the process the Architecture Department developed, and the results that were generated and shared with the College as driven by the research question: given dynamic change, how do we maintain our position as a leader in the field of Architectural Education in 2030?

1.2 *Research design*

Given the tight time frame, a mixed-method approach was selected to analyze data collected over three weeks. Six future socio-technologically constructed normative scenarios (Van der Merwe, L. 2008) were developed in advance of the first of three weekly focus groups by the author, who took the role of "participant observer" as she conducted the research on behalf of the Department. She also co-authored an anonymous survey with Department Head, Margot McDonald. These two mechanisms, in combination with constant comparison methods, were intended to facilitate the Department's development of its recommendations by focusing and legitimizing the work. After the second focus group, the survey was distributed to all forty-two of the faculty, who had five days to respond.

On October 23, 2014 the faculty of the Architecture Department convened their first of three hour-long focus groups to discuss possible departmental responses to evolving trends in the profession and discipline. All forty-two faculty were encouraged to participate. This initial group consisted of fourteen faculty. The discussion was initiated by a brief update on predicted California demographic trends (as reported in the University-wide meeting the week before) (Pitkin et al. 2012) and the introduction of the six future scenarios framework, developed from the resources made available through the University's Master Planning initiative, particularly the "2013 Forecasts from the Futurist Magazine" (The Futurist Editors 2013). The scenario planning format was chosen because it has emerged as "…a revolutionary alternative to traditional strategic planning because it [is non-linear and] recognizes the unpredictable nature of the future." (Chermack 2011). These scenarios were posited to seed focused discussions which highlighted disciplinary sectors that have significant potential to dramatically shift architectural curricula in the decades to come. Specifically designed to tap industry and academic trajectories observed from both within the academy and in practice, these future scenarios included: the impacts of *Megacities and Increasing Urbanization*, *Energy/Matter Resource Relationships*, *Disruptions to Ecosystem Service Provisioning*, *Big Data and Ubiquitous Physical Computing*, *Manufacturing in the Age of Makerbots and Nanotechnology*, and *Economy, Employment, and Means of Production*. The focus group was targeted to address three impact areas within the school (the 3 P's): *People*, *Programs*, and *Place* (visioned to roughly correspond to: space type, allocation, and adjacency).

The second focus group was held exactly one week after the first. Sixteen faculty attended (half of which also participated in the first group). This second group was focused specifically on issues related to fabrication, which emerged as a significant concern in the first group. Two of the faculty responsible for the fabrication lab and related curriculum spear-headed the group.

This second focus group was followed by an anonymous survey distributed to the faculty as a mechanism to collect a broader range of feedback and follow-up thoughts. The survey was made available to all forty-two faculty on October 27, 2014 at 7:00 pm and was administered via Survey Monkey. It consisted of five questions. Nine faculty completed the entire survey over the course of three days.

The third focus group was held exactly one week after the second. Eleven attended (five participated in both previous groups and two participated in the second group only). The full survey results (completed by nine faculty) were reported out. This third group summarized the data collected to date and focused on content and strategies for producing final outcomes and deliverables.

The process resulted in the production of two documents distributed to the College of Architecture and Environmental Design, one summarizing general recommendations, and the other focused on fabrication. These were then complied with reports from each of the other four departments in the College, and forwarded to the University Master Planning Committee.

1.3 *Six scenarios and survey questions posited*

1.3.1 *Megacities and increasing urbanization sectors*

"In 2025 the planet saw its 27th urban center attain megacity classification [population <10 million]. Globally, as urban areas continue to expand, issues related to their proximity to increasingly dynamic natural infrastructures (such as coastline adaptation to sea-level rise, food and energy sources, etc.) become more urgent issues for built environmental professionals as quantity and quality of resource generation, distribution, and allocation in megacities poses perpetual challenges. While the distinctions between developing and developed world urban contexts continue to blur, there are still critical differences in the relationships between their infrastructures and architectures. In the developed world, heavy footprint 20th century infrastructures continue to need significant maintenance, retrofitting, and upgrading as they slowly migrate toward their lighter/smarter siblings in the developing world. Architects work mainly on renovations and upgrades of existing building stock, and strategies to adapt existing structures and infrastructures to the impacts of changing economies, programs, densities, and climates. They are also struggling to deal with the long-term effects of the poorly conceived and coordinated "green housing boom" of the 2010's. In the developing world, new construction is still dominant and takes its design cues from lightweight/smart infrastructures and new resource savvy technological developments in material science and construction techniques. However, large percentages of their populations still do not have access to critical infrastructural services. Meanwhile, the developing world struggles to rapidly build new, climate and energy sensitive affordable projects."

1.3.2 *Energy/matter resource relationships*

Well into post-peak oil, the harvesting of energy continues to be a challenge as "alternative energy sources" have proven they cannot meet legacy electrical energy needs. "Next-generation" alternative energy sources, such as thermal energy mined from transportation, "junk" energy mined from ambient microwave and vibrational noise, and GMO modified energy producing algae are all harvested and distributed via highly localized systems facilitated by hybrid high-low tech bodies of buildings. Buildings increasingly capture, manufacture, and potentially distribute their own energy form a diverse portfolio of sources. Architects returned to low-tech, predominantly thermal active, high performance building materials and bioclimactic strategies to minimize carbon-based energy use. Nanotechnologies such as Buckypaper and Graphene

greatly improve structural, thermal, and other types of building component and material performance. Resource recovery [recycling] becomes increasingly efficient and ubiquitous as materials, and the energy they contain and manage, are increasingly recognized and valued through both global marketplaces and local economies. The transportation of goods and materials has decreased dramatically due to the cost of energy.

1.3.3 *Disruptions to ecosystem service provisioning*

Since 2010, humans have driven animals and plants to extinction faster than they could evolve due to the acceleration of anthropogenically driven climate change and concentrating levels of environmental toxicity. As critical ecosystem services oscillate between functionality and non-functionality [such as pollination, water filtration], architects, landscape architects, urban designers, ecologists, and engineers collaborate in the deployment of systems thinking to design and built habitat for critical species and services. Hybrid eco-technical interior habitats often prove more productive than their exterior equivalents, such as the aquaponic recycling systems now standard in most kitchens. More lay-individuals are participants in the regular maintenance of these systems. Continuous human management of the larger environment is aided by technology, and necessary to maintain and augment ecosystem service provisioning. Relationships between post peak-water and post-peak oil are widely understood as the energy costs of pumping, conveyance, and treatment of water, and the environmental cost of the resulting carbon emissions, renders access to clean water dubious.

1.3.4 *Big data and ubiquitous physical computing*

As the cloud shifted from being primarily a storehouse to an intelligent data clearinghouse which communicates seamlessly with sensors and actuators, we have abandoned discreet desktops, laptops, tablets, thermostats, etc. for computational devices embedded everywhere within our environment. Architecture and products are designed and built to physically sense our needs utilizing smart materials and environmental sensors [in some cases, through advances in neuroimaging, select sensors actually "see" our thoughts] to deliver both virtual and physical resources on demand. Robots increasingly provide services as they become more sensitive caregivers, and communication has become predominantly image driven, resulting in losses of verbal eloquence and precision. We struggle to manage the complicated energy footprint, the large quantities of data, and the implications of data talking to itself.

1.3.5 *Manufacturing in the age of makerbots and nanotechnology*

In May of 2013 the Department of Defense required "Defense Distributed" to remove 10 downloadable CAD files of their 3-D printable "Liberator" handgun and other firearm components from their public server [100,000 downloads in 2 days], a watershed moment in the history of 3-D print manufacturing. MakerBot 3-D printers cost just a few hundred dollars, free 3-D scanning software for mobile devices is readily downloadable, and print mediums are made from a variety of materials, artificial and natural, recycled and recyclable. Objects are regularly replicated by laypeople, International Space Station replacement parts are manufactured on-site, and 3-D printed eye-glasses have become accessible to thousands of people living in remote developing world conditions. With the variety of 3-D printer scales and materials, architects are printing buildings and building components from concrete, polymers, and recycled materials. Traditional manufacturers are struggling to keep from shutting their doors while nanotechnology manufacturing is booming. The design professions are struggling to redefine their value, market, disciplinary skills, and pedagogy in the face of ubiquitous mass, unskilled replication.

1.3.6 *Economy, employment, and means of production*

Since the global economic shift to "post-growth," steady employment has become increasingly rare. It's been replaced by a project-based economy driven by "service oriented design." Material goods are less and less in demand, in part because their value has inflated exponentially, along with energy, water, and food. As firms can no longer support their own overhead, architects are increasingly working as freelancers, hired into larger, interdisciplinary teams assembled for specific projects, or R&D consortiums. Liability has become an increasingly complex challenge. Architects are designing much more than buildings, the scope of services has expanded to include environmental products, materials, construction technologies/ tools and methodologies, supply chains, logistics, policy, habitats for other species, and whole environments [actual and virtual]. Because site conditions have become so complex, architects are valued for their deep understandings of specific geographies and contexts. Individual architects have become increasingly multi-disciplinary and networked as more of their work engages "wicked" interdisciplinary problems (Rittel & Webber. 1973) and revolves around securing paid work.

1.3.7 *Anonymous survey questions*

1. What are the most dramatic shifts that you anticipate the architectural profession will undergo in the next 15 years?
2. Who will our students be in the next 5, 10, 15 years? Please consider demographic, pre-architecture preparedness, interests, disposition.
3. Students typically experience at least a 10 year time-lag between the start of their architectural education and the point in their career when they have the experience and authority to substantially impact the projects they work on. Given this lag, and the shifts in the profession identified above, what

knowledge/methods/skills are critical to deliver during their education today? In 5 years?
4. What would our program need to look like [people, programs, place] to deliver that knowledge, those methods/skills? In 5 years? In 10 years? In 15 years? Please consider teaching, research, and service.
5. Is there anything else you'd like to add related to the long term vision for the architecture department program offerings?

2 RESULTS

2.1 *Analysis of focus group*

2.1.1 *Summary of responses to megacities and increasing urbanization sectors scenario*

Integration and interdisciplinarity will prove increasingly necessary as we continue to further our understandings of the inseparability between energy and matter related to urban scales. Examples of this include ways that buildings, transportation, food provisioning, and energy/water relationships are increasingly forming a nexus, and how this influences settlement patterns in relationship to climate change. This calls for more interdisciplinary integration, particularly at the program level. It would be possible to contribute to a larger university rebranding based on the development of transdisciplinary programs that merge units such as Kinesiology and Epidemiology with Environmental Studies, City and Regional Planning, and Architecture. The development of other degree program types such as blended degrees or multiple minor options would also facilitate this exchange. Expanded studies in Environmental Control Systems pedagogies will also become increasingly critical.

2.1.2 *Summary of responses to energy/matter resource relationships scenario*

At the building scale, because of the State of California's "Residential NZE Action Plan" (Craig 2015) which includes modifications to the 2019 State Building Code, all new residential construction will transition to Net-Zero by 2020. We must quickly further our students' preparation to fill this knowledge gap in the marketplace. At the environmental scale, resource relationships such as the energy/water nexus are becoming increasingly dynamic as their implications expand exponentially creating environments of increasing risk which is intimately linked to the built environment. Our program has opportunities to leverage this larger scale and complexity, building on our already robust sustainability and resiliency offerings.

2.1.3 *Summary of responses to disruptions to ecosystem service provisioning scenario*

Once again, the need for expanded studies in Environmental Control Systems pedagogies was highlighted. This was posited in relationship to the need for more rigorous pedagogy related to the creation of microclimates and habitats that leverage intersections between architecture, landscape architecture, and civil engineering. The spatial implications of this nexus is significant and worthy of study within the architectural discipline.

2.1.4 *Summary of responses to big data and ubiquitous physical computing scenario*

Increasingly we are seeing "smarthomes" and other spatial products that blur boundaries between the virtual and the physical worlds. There are significant additional arenas of spatial design that are currently not being addressed within the discipline of Architecture such as: smartobjects, augmented realty, virtual space (delivered through physical goods as well as digital), immersive physical/digital space, and even implants. All aspects of these novel spatial situations must be designed, and their spatial configuration would likely be better designed by architects than any other discipline. Data driven design is emerging with increasing force within our discipline. There are significant future employment opportunities for our students in this sector, particularly in the spatial reconciliation of the virtual and its physical interface.

2.1.5 *Summary of responses to manufacturing in the age of makerbots and nanotechnology scenario*

This scenario most directly impacts our students during their education as it is most accessible, immediate, and is a pedagogical focus in our program which is heavily informed by Cal Poly's motto: "learn by doing." In fact, it is so central to our pedagogy and brand that we need to convene a separate meeting to focus exclusively on this topic, and its implications for the Master Planning process.

In addition to this new wave of manufacturing, more traditional models are still prevalent in the marketplace, especially in the building industry, and are critical components of architectural production, so we need to continue to engage these in our pedagogy. The role of craft is necessary in both digital and analog production of products and materials that define space and its use. More targeted conversations about the role of tolerances are necessary for our students as they gain sophistication in their ability to understand and actualize fabrication.

2.1.6 *Summary of responses to economy, employment, and means of production scenario*

NAAB and licensure are increasingly acting as barriers for the profession as they add layers of liability that are prohibitive to many smaller scale firms that are pursuing a significant portion of the professions' technical and social innovation.

As a School, we must do a better job of creating culture and community, not just within our student population, but with our larger constituency which includes: alums, high school and other potential students, professionals, firms, and potential sponsors. This will greatly assist in training our students to work

within the increasing climate of generational barriers that exist within academia and firms today.

2.2 *Summary of responses to the anonymous survey*

As could be expected given such open-ended questions, the responses covered a wide range of topics and viewpoints. Based on quantitative counts, trends emerged in relationship to increasing interdisciplinarity, extradisciplinary knowledge within the disciplinary framework, collaboration, coordination, and visual literacy. There were a significant number of comments related to a desire for simultaneously broadening and deepening the curriculum such that students have a common core in their first two years dovetailed with more General Education coursework, then self-select into one of a range of deep tracks for their advanced study.

The responses revealed significant concern about shifting demographics: among practitioners, among clients, between large corporate and small agile design firms, and within higher education, and what appropriate responses might be to preparing students for these shifts. These shifts extended into socio-economic and eco-technical environmental concerns and emerged in questioning the relevance of design in larger societal issues, ethics, and environmental concerns (many of these were addressed in relationship to the topics of sustainability and resiliency). In order to address these shifts, several respondents referenced the increased use of systems thinking as an integral component of design process.

Responses also revealed significant concern related to the future roles and responsibilities of the profession including being held to higher standards, more interdisciplinary and team work, and increasingly moving away from direct design roles into consultation and coordination. There was discussion of pros and cons, slanted toward cons, related to new Licensure Upon Graduation programs and pedagogies. Generally, these comments were paired with recommendations related to increasing the amount of problem solving, critical thinking, research, and team-building skills which could be addressed through both professional practice topics and studio.

The respondents commented on the need for increasingly project driven research that leverages the "teacher-scholar" model (accompanied by appropriate levels of support) and the importance of "learn by doing" approaches.

Finally, there were a significant number of comments related to the role of technology in architectural design process and pedagogy. These responses addressed the need for more space, equipment and the need for facility reconfiguration to facilitate more integrated usage.

Though the survey sample size of nine was smaller than the Department had hoped, it was offset to some extent by the mixed-method approach and the constant comparison analysis (Given. 2008) (Bamberger et. al. 2006).

3 CONCLUSIONS

3.1 *Emergent issues*

Emergent themes from these conversations were predominantly forced around increased emphasis on systemic pedagogical and design approaches. These manifest through the lenses of health and energy/matter exchanges linked from human scale through building and urban scale to environmental scale. Architecturally, these explorations would likely emerge from an expanded Environmental Control Systems pedagogy augmented with some discussion of policy and regulatory control (emerging architects need training specifically in the design of Net-Zero).

Also emerging from these conversations is an emphasis on relationships between analogue and digital methods, interfaces, and products. Within schools of Architecture, these explorations might grow out of Digital Fabrication curriculum and expanded Structures and Environmental Control Systems pedagogies intentionally embedded within more traditional studio practices. Strategic employment of modeling and simulation, both physical and digital, in concert with Science, Technology, and Society coursework, and other inputs from external disciplines that facilitate an unpacking of ethical, social, technological, and environmental implications is necessary for a balanced understanding of the critical partnership between digital and analogue processes and products.

And finally, the multiplicity of Architectural Practices and Business Models today require that we develop pedagogies to unpack this complexity with our students. Critical issues to be addressed include: the evolution of interdisciplinary and collaborative modes of practice, the fact that architects are held to increasingly high standards with less time to actualize those standards, that architects are designing less and consulting more, the riff between large corporate and small agile design firms, breaking generational barriers, and ultimately, how Architecture can more adeptly position itself as a discipline with increasing agency to innovate constructed responses to diverse and dynamic circumstances.

3.2 *Discussion*

The faculty expressed concern over the tight time frame and limited resources available for the study. Several members expressed frustration that the scenarios and conversations couldn't be conducted in a more focused and structured way, over a longer period of time. Bowman et. al. identify two types of scenario processes: Inductive, in which the scenarios are developed collectively "…begin[ning] with the granularity of available data and allow[ing] the scenario to emerge incrementally." versus Deductive where scenarios are developed by a select few in management positions and posited to a larger group to play out (Bowman et. al. 2013). Their findings conclude that Inductive processes are significantly more successful than Deductive approaches. It's quite possible that

the study's Deductive approach limited the types of responses and conclusions, despite the fact that several of the faculty commented that the scenarios posited seemed correct and in alignment with current and immediately future trends.

3.3 *Recommendations*

Based on the research question, the faculty put forth a series of recommendations to the College and University Master Planning Committees. The basis of which related to transitioning to a scope that expands beyond the traditional scope of buildings, in ways that serve and support the design of the built environment through the studio pedagogical model. Linking breadth (informing studio design studies with required Minors or interdisciplinary General Education Pathway knowledges) with specific and deep focus areas of specialization within Architecture (potentially linked to original faculty partnered research which dovetails with the University's "Teacher-Scholar" research model) as a pedagogical strategy. Increasingly targeted investment in representation and communication skills, and increasing a sophisticated "hands-on learning" fabrication culture that emphasizes fluid transition between digital fabrication and analogue making tools and processes. This could be supported by increasing industry-academic partnerships which would provide first-had professional experience, while enabling students and faculty to design and develop innovative solutions grounded by real world parameters. Ultimately, this would titrate with "design thinking" studio pedagogy tooled to more fluidly integrate architectural technological content with formally based studio design practices.

The spatial implications of these recommendations include consolidating studio spaces currently spread across multiple campus buildings while reinforcing a primary focal space for the school's identity and community. It also includes restructuring studio spaces that are currently spatially isolated so that there can be more interaction between students both within the Architecture School and with outside disciplines. The ultimate goal being the facilitation of more exchange within and external to the studio environment through the creation of flexible collaboration spaces where 2-D and 3-D process work can be engaged in continuous dialogue. This physical restructuring would also include creating studios that are directly linked to shop or fabrication spaces. These, in turn, would be adjacent to a set of Integrated Research Labs, organized by tooling/material type, and an exterior Test Site, that would facilitate "Teacher-Scholar" research (Cabrinha et. al. 2014).

At the College level, the Architecture Department's recommendations, along with those from the other four disciplines within the College: City and Regional Planning, Landscape Architecture, Architectural Engineering, and Construction Management, resulted in proposals for the development of two new interdisciplinary undergraduate majors related to sustainability/resiliency and product design, a General Education core related to Society, Ecology, and Technology, and an interdisciplinary Masters degree.

ACKNOWLEDGEMENTS

The author gratefully acknowledges the support of the Cal Poly San Luis Obispo College of Architecture and Environmental Design, the Department of Architecture, and the Center for Teaching, Learning, and Technology. In particular, the author wishes to thank Robin Parent and Architecture Department faculty members: Robert Arens, Richard Beller, Angela Bracco, Kelle Brooks, Mark Cabrinha, Don Choi, Dale Clifford, Meghan Dorrian, Jonathan Foote, Thomas Fowler, Bruno Giberti, Andrew Goodwin, Doug Jackson, Thomas Jones, John Lange, Karen Lange, Steve Lee, Michael Lucas, Kent Macdonald, Margot McDonald, Margaret Pedone, Stephen Phillips, Jeff Ponitz, Jonathan Reich, Tom Di Santo, Sandy Stannard, Christine Theodoropoulos, Umut Toker, Stacey White, Barry Williams, Greg Wynn, and Christopher Yip. This paper was presented at the 2016 EAAE/ARCC "Architectural Research Addressing Societal Challenges" conference. The contribution of the current and previous ARCC conference organizers and committees is hereby gratefully acknowledged.

Teaching architecture in the 21st century: The role of research and extension in a transdisciplinary view

Maria Cecilia Pereira Tavares
PHD Architecture and Urbanism (Instituto de Arquitetura e Urbanismo, Universidade de São Paulo (IAU-USP) and Architecture Professor in Universidade Federal de Sergipe

Marcio da Costa Pereira
PHD Architecture and Urbanism (Faculdade de Arquitetura e Urbanismo, Universidade de São Paulo (FAU – USP) and Architecture Professor in Universidade Federal de Sergipe

ABSTRACT: This work highlights the need for an analysis and a revision of how architecture is taught in the 21st Century. It takes as its premise the idea that increasing urbanization has brought about changes which demand a reassessment of the professional profile of architects. It takes as its basis the notion of Transdisciplinarity and the Complexity Theory and develops a theme considered relevant in this context: the social awareness, interculturalism, design process renewed in the face of digital thinking and ecology with urban ecosystem and biotechnology in the production design. A set of strategies built on concepts and experience reports is proposed here with the intention of promoting a review in architectural education. Social consciousness is especially focused in this paper through the report of two examples of work done at the Federal University of Sergipe, located in the historic city of Laranjeiras (Sergipe/ Brazil). The first, an extension research involving the inhabitants of the historic center of Laranjeiras (SE), kept by the National Historic and Artistic Heritage Institute (IPHAN), in an assessment of their houses' living conditions. The second, the guidance of graduate work that developed a collaborative work with a disadvantaged community in the same municipality. The thesis proposed organizing the community in the search for an architectural solution that could be executed through a participatory process. These two examples aim at forwarding the idea that architectural education should involve both practical work and social consciousness in order to form professionals committed to improving the quality of life and reducing inequality. Extension research and collaborative work that involve inhabitants are part of the way to improve Architecture Education in the 21st Century.

Keywords: 21st Century, Architecture, Education, Transdisciplinarity, Social consciousness, extension

1 INTRODUCTION

The need for a revision of architecture courses in the twenty-first century has been a recurring theme. The international call was given by the charter of UIA (International Union of Architects)/UNESCO for architectural education published in 1996 and revised in 2011.

The document aims at providing an educational structure to train professional architects in order "to enable them to meet the expectations of XXIst Century societies worldwide for sustainable human settlements in every cultural heritage …"(UIA/UNESCO, 2011, p. 1). The justification for the publication of the document is the concern about the future of architecture development in the face of rapid changes in the world. It emphasizes in its text the social problems resulting from the growing population in urban settlements and the need to develop projects with a social focus. An explicit recommendation that these issues are worked on projects and research in the academic world to develop solutions to inequality and social exclusion in urban areas is made.

We can cite other documents that despite having different objectives contributed to the perceived expectation of architectural education in our context.

The first 'Towards a skills training-based architecture: convergence of educational structures in Europe [1] (ENHSA, 2007) is the result of work of the European Network Architecture School Principals (ENHSA) in order to create a parameter in the training of architects in terms of educational changes generated from the Bologna Declaration. It is one of the projects to ensure the consolidation of the educational process based on the Bologna Declaration. The development of professional profiles that can be compared and are compatible with learning outcomes is one of the objectives of this project to ensure the quality of training. The trend in this process is to change the focus to the students and their workload through an academic training less specialized in the first cycle and the possibility of flexibility during the two periods. The

ENHSA document seeks to establish an educational framework and to set parameters in the area of architecture. The ENHSA focuses on curriculum in a more specific way as it believes its structure involves the content of the subjects and the quality of the course. It also defines the professional profile and the possibilities for mobility. A skills platform has been adopted as a parameter basis for comparison of curricula. This platform allows the graduate profile of the European Schools to be equivalent, but allows that they have their own interpretation of the competencies avoiding a rigid posture that could enforce curricula or homogenize the courses.

The second document 'Criteria and Indicators for Regional Accreditation Training in Architecture' is part of the MERCOSUR agreements (Southern Common Market) Education that in the area of higher education is divided into three thematic areas: accreditation, mobility and inter-institutional cooperation (SYSTEM ARCUSUR, 2008).

Accreditation is a recognition system of undergraduate courses to facilitate mobility and ensure the academic quality among partner countries.

The third document 'National Guidelines of 2010 and a proposal revision made by ABEA (Brazilian Association of Architecture Schools)' (2013). The 2010 document is a resolution of the National Education Council (CNE) and the Council of Higher Education (CES) which regulates the architecture of education in Brazil. The Brazilian Association of Architectural Education published a review of the law in 2013. According to the document the ABEA revision of the Curriculum Guidelines is the result of a previous partial modification, from 2006, which in turn was based on a public discussion on the content of these resolutions made in 1998 (ABEA, 2013). The resolution was published eight years later which means that those modifications to the new resolution of 2010 were made without public debate and, unfortunately after a total of fifteen years without a public discussion. Due to the dynamic nature of the profession that is a sufficient period of time for rendering the resolutions out of date.

From this reading, four issues have been highlighted that must be addressed and included in the current reflections on the profile of architecture: social and environmental issues related to the urban life improvement and with the presence and use of both information and interculturalism theory, as knowledge production tools. Interculturalism is the main concept in the development of UIA documents, the ENHSA and ARCUSUL, to facilitate, encourage and orchestrate student and teacher mobility, and especially in the case of ARCUSUR, professionals. These four documents are based on the global context of the 21st century.

The social aspect is referenced in all documents, without any exception. Usually, this issue is associated with social responsibility and in this case we call it "social conscience" to distinguish it from the modernist connotation.

The UIA's document presents a differential outlook when it recommends working with new social segments and emphasizing the skills of graduates:

> "There is no doubt that the architect's capacity to solve problems, can greatly contribute to tasks such as community development, self-help programs, educational facilities, etc., and thus make a significant contribution to the improvement of the quality of life of those who are not accepted as citizens in their full right and who cannot be counted among the architect's usual clients" (UIA, 2011, pag. 1).

Emphasizes among the skills of graduates:

> "Ability to act with knowledge of society and work with users that represent the needs of society." And yet: "Ability to develop a project brief through definition of the needs of society, users and clients" (UIA, 2011, p. 12).

For ENHSA (2007, pag.15), it is the

> "Understanding of the profession of architecture and the role of architects in society, in particular in preparing briefs that account for social factors."

In ARCUSUL:

> "The ability to interpret individual and collective needs of society in its cultural and environmental aspects."

In the ABEA document a reference to the graduate's profile differs in words, but contains the same sense of ARCUSUL's recommendation and skills, as well as it reiterates the need for

> "knowledge of anthropological, sociological and economic aspects relevant and the whole spectrum of needs, aspirations and individual and collective expectations about the built environment."

Note that the document UIA is the clearest in the sense of working with the demand of the population that is really lacking of professional architects and urban services.

Transdisciplinarity was a theme in the documents of UIA (1996; 2011) and ENHSA (2007, p. 13), while the latter is presented as a general competence in the second cycle (master): "ability to develop a transdisciplinary understanding".

This article aims to present ways to engage this issue of social consciousness in the training of architects with the transdisciplinary understanding.

Transdisciplinarity is a term that derives from the complexity theory. Complexity theory works with the concept of the living being unstable and unpredictable, more open and creative, an innovative image of nature and society, which is contained in the concept of transdisciplinarity (MORIN, 2005).

The work of the philosopher Edgar Morin is fundamental for the consolidation of transdisciplinary

concept as well as its dissemination and application. Three principles developed by Morin in complexity theory collaborate to understand the transdisciplinary: recursion, hologramatic, dialogical. Warns the author that the way is linking the three principles (MORIN, 2005). However this time we will focus on the third principle for transdisciplinary understanding.

The dialogic term was found in other texts such as Richard Sennett (2012, p. 26) and Paulo Freire (1996, p. 130). It was also used by Gregory Bateson in their learning process theory (BALE, 1992).

According to the sociologist Sennett the term has to do about what is meant by two types of talk: the dialectic and dialogical. The dialectic is a "verbal game of opposites that should gradually lead to synthesis" (SENNET, 2012, p. 30), the goal is to reach a common understanding. In the second type conversation, dialogical, does not come to an agreement, but there is an exchange process towards to clarify the views of each other and the mutual understanding. Sennett calls the talk of the good listener, which includes silence and attention to gestures and facial expressions that carry on the discussion.

The educator Paulo Freire uses the term "dialogic communication" to address the educational evaluation that in our view is in accordance with Sennett. Freire made critics to evaluation systems as being a way to talk to students and not with students. For the author the evaluation should stimulate "the talk as a way to talk to" (Freire, 1996, p. 131). And it continues:

> "In the process of talking and listening to the silence of discipline to be made accurately and in time by the subjects who speak and listen is a" sine qua "dialogic communication" (Freire, 1996).

That is, as Sennett, Freire emphasizes that without dialogue and without the ability to listen to the other, there is no communication The dialogical speech allows the knowledge of the other, and perhaps the correct way to say the necessary without it being irrefutable. The knowledge should enable a joint construction and not a simple transfer of content.

Complex thinking accepts the uncertainty and conceives the organization.

> "The piecemeal intelligence, compartmentalized, mechanical, disjunctive, reductionist, breaking the world's complex, produces fragments, breaks up problems, separates what is joint, make single dimension what is multidimensional" (Morin, 1999, p. 25).

For Morin, the key challenge is to complement the specialized and fragmented thinking with knowledge from different fields. The author makes a comparison with the tapestry:

> "Let's take a contemporary tapestry. It is made up of threads of linen, cotton, and wool, in various colors. To really know this tapestry it would be interesting to know the laws and the principles concerning each type of thread. However, the sum of knowledge of these types of thread used in the tapestry is insufficient for knowing the new reality that is the fabric, with the qualities and properties that are proper to this texture. It is also incapable of helping us know its form and its configuration" (Morin, 2005, p. 85).

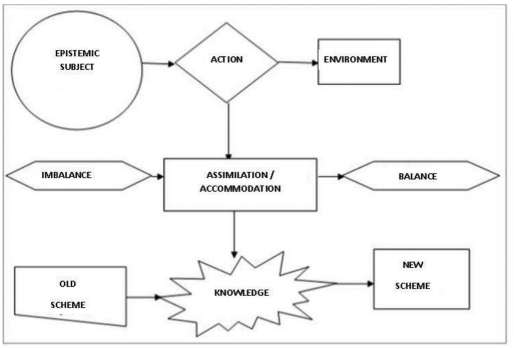

Figure 1. Construction of Knowledge representation according to Piaget. Source: Claudio Drews (2008,online, own translation).

The University is, to the author, where this thought reform should be encouraged, because it is the place of questioning.

How to contextualize knowledge?

Constructivism is the pedagogical theory that connects the concerns of Morin and the understanding of the theory of knowledge. In parallel to the development of complex thinking, and from the same sources as systems thinking and cybernetics, constructivism works with the assimilation of knowledge in education.

Constructivism had its development from the cognitive theories of Jean Piaget. Figure 1 illustrates the construction of knowledge that according to Piaget can be perceived constructivism connection with the Complexity Theory, because both Piaget and Morin believe that the imbalance or disorder is necessary to allow innovation and creation.

What is observed in the constructivist theory is the change of perspective it introduces in the learning process as it highlights personal experience, even if subjective, and that encourages the individual to challenge reality. The learning environment is organized as a system that allows the individual to be highlighted as a scientist.

Transdisciplinarity, according to Casilli (2011), aims to enable an integration of all disciplines in a unique knowledge and to reconfigure, as well, the formation of multi-skilled professionals. It is a collaborative practice and that takes into account the temporal dimension of research. His observation about collaborative practice is, because in this case the notion of hierarchy dissipates.

The methodology of transdisciplinarity, as we saw, considers practice as one of the leading knowledge-building means. And this line of thought leads us to consider the importance of practice in architect's training.

> "[...] 'Knowing it' depends not only on the acquisition of complex formal skills but also on experience and on a culture of practice, both of which impart tacit knowledge through personal interaction and performances, in particular contexts and social networks." (Larson, 2015, p. 21).

The two reports presented aim at introducing social awareness and practice in the learning environment adopting a transdisciplinary approach.

1.1 *First report*

In this first report we will focus on an extension and junior science scholarship project developed by students of architecture and urbanism at the Federal University of Sergipe (Brazil) under Professor Dr. Márcio da Costa Pereira (co-author of this article). The project proposes to identify the houses, as well as the residents, found within the historical heritage city perimeter of Laranjeiras, SE (Brazil) and raise their awareness as to the relationship there is between housing and health.

Following the recommendations of the UIA (International Union of Architects) the extension project emphasizes the architect's social conscience in relation to settlements "sustainable in each cultural context" (UIA/UNESCO, 2011). In the same document there is the recommendation that in developing countries the professionals should include assistance to disadvantaged communities with an attitude of "facilitators" instead of "providers". This suggestion demonstrates a direction for the profession that goes beyond the technicalities to embrace a commitment to society with less inequality in the global context. Therefore, we see the extension as a key tool in the formation of the architects of the 21st century.

The story of Laranjeiras (SE) has its beginning when the Portuguese reached the river Cotinguiba region (1530s) and installed a small river port that gave prominence to the village (IPHAN, 1970). The bases of the local economy dependent on sugar production, slave labor and trade flourished until the mid-nineteenth century and we can say that the architectural wealth of the city was accumulated during this period, when Laranjeiras was considered as the cultural and artistic center of the state. Throughout the twentieth century, the city of Laranjeiras experienced a period of economic decline that led to its condition of a dormitory town of the capital, Aracaju (SE). In this process, the historic site also deteriorated.

According to the IBGE 2013, Laranjeiras has a population of 28,533 inhabitants, 79% living in urban areas and 21% in rural areas. As for the HDI (IBGE, 2015), the municipality has an index equal to 0.642, considered average, putting the city in tenth place in the state ranking. While in the state of Sergipe the HDI is 0.665, in the capital, Aracaju, the HDI is 0.770.As concerns the gross domestic product, the highest value is that of the industrial and service sector. The municipal GDP per capita is R$35,710.09 (US $ 8,881.00), while the Aracaju is R$ 15,328.30 (US $ 3,825.00). It is noteworthy, however, that this figure does not represent a homogeneous distribution of the income of the local population. Laranjeiras has 67.7% of households by type of monthly returns between zero and a minimum wage. In the range between 2 and 5 minimum wages, this figure drops to 24.77% of households. Above 5 minimum wages fall further and reaches 7.53% of households.

Being Laranjeiras a historical city with a strong cultural heritage the county seat was listed by the National Historical and Artistic Heritage Institute (IPHAN) in the category of "architectural and landscape site" (Process IPHAN: 1288-T-89 18/06 / 1996).

According to the IBGE (Brazilian Institute of Geography and Statistics, 2010) there are approximately 7,000 households in urban areas, of which only 500 are located within the perimeter of architectural heritage and harboring a population of about 2,500 residents. It is noteworthy that 70% of houses are busy and have shortcomings with regards to habitability.

> "The houses of Laranjeiras are simple, although the houses and churches are imposing, forming a representative architectural ensemble of the lifestyle of the time of economic boom. Many homeowners are abandoned and the general condition is precarious. The high cost of property maintenance is sometimes inconsistent with the income of the residents." Diogo (2009).

It is observed in the city, the degradation of the surfaces of the residences by the incidence of rain, sun and pollution that cause cracks and cause the proliferation of fungi, mold and mildew, causing stains, deterioration of coatings and consequent unsanitary dwellings.

Self-building in this context is a recurring practice, calling attention to the lack of quality of the houses renovated by the residents themselves.

Through first conversations with residents we identified the high degree of unsoundness of housing, as well as recurrent health problems.

The extension project Technical Assistance to residents of the historic center of Laranjeiras was developed in stages, as follows:

1. Preparation: tour of Laranjeiras (walk through the field and collecting images and initial impressions);
2. Data collection: Live in Laranjeiras Center (primary sources: interviews with residents, architectural surveys of households and secondary sources: books, web and records);
3. Sensitization: Approaching with the population (Mini courses: Preparation and Action)
4. Organization and final systematization: (preparation, review and finalization of graphic designs and images to the final report)
5. Results Release

This led the team to relate the degree of habitability of housing with health problems reported by residents.

Our hypothesis is that the neglect of legal regulations for intervention in protect buildings, and the lack of technology as well as the principles for the preparation of projects to ensure the habitability of housing, can be considered an important factor in the deterioration of living spaces in Laranjeiras.

We define the objective to raise awareness about the relationship between the poor (constructive and architectural design) of housing (health of the housing) and the health of residents.

We define a strategy of providing minicourses on the topic of housing and construction technologies (paint and ceramic coating). Also define the target audience would be composed of elementary school students of public schools in Laranjeiras as replicators of the topics discussed at the family and community.

Minicourses have been organized into four workshops: two addressing the housing (housing and health of the residents and interventions) and two addressing technologies (painting and ceramic coating).

Taking as the theoretical basis the literature review on the topic of habitability, the booklet "LIVING WELL IN LARANJEIRAS" was prepared and distributed to students enrolled in the minicourses.

With reference to the article "Playing and learning to build" [1] the group involved in the project facilitated learning by creating dynamics/games for a better understanding of the proposed concepts.

We also had talks by medical school professors from the University who showed the possible causes of respiratory diseases related to poor quality built environments, and by IPHAN technicians who spoke of the importance of heritage conservation and its implications for the residents of Laranjeiras.

The community received with enthusiasm this activity paving the way for a next step which aims to provide technical assistance to residents of Laranjeiras through new Extension projects.

The research provided the development of skills related to the course of architecture and urbanism and provided an opportunity for direct contact of students and teachers involved in the survey with the local population, thus embodying the principle of social consciousness identified as one of the cornerstones in the formation the 21st century architect.

1.2 *Second report*

The second report focuses on a graduate thesis which had Professor Dr. Maria Cecilia Tavares (author of this article) as advisor. It is about 'collaborative architecture'. The student had a first experience in this approach with the Elos Institute. This Institute was created by architects who had their first collaborative work during the years of graduation in 1995 when they were responsible for the XIX Encontro Nacional de Estudantes (National Meeting of Architecture Students) with the theme "Outside architecture". This event proposed that students get in touch with disadvantaged communities and work with the residents in a few quick solutions to improve their quality of life. Work went on as usual by the group formed by students from the University of Santos. They founded the Elos Institute according to the same philosophy and developed social technologies and activities to mobilize communities.

This experience encouraged the student to carry out collaborative work at Barro Vermelho, a Laranjeiras's neighborhood. Laranjeiras has been previously presented in this article.

The first step was the production of a theoretical work to understand the concept of a collaborative work based on the precepts of Cedric Price. The architect defended that a building is not necessarily the best solution to a space problem. And that the architect should move the hero figure to take a more collaborative approach in which agents work with, and on behalf of another (Spatial Agency, online). Both professor and student believe on these precepts and for the first, it was an opportunity to prepare a future professional for working with new social segments, according to the UIA recommendations.

Thus a work project was designed following Elos methodology. A manual of procedures is provided by the group called Elos Phylosophy of Transformation. Following the guidelines, the first step is the 'look', i.e., the contact with the community seeking the potential contribution of each person and unprejudiced knowledge of space. The second step is the affection based on connections to gain the community trust, followed by the third step called 'dream', where you discover people's dreams and thus implementation possibilities. We are in search of stage resources and contact with employees to carry out the project.

The student has earned the trust and the affection of residents, created a bond and identified partners. The community is organized and prepared for the day of 'miracle', the terminology used by Elos group featuring the day of realization of the project prepared by the working group (teachers, students and residents). During our meetings we identified the need for action to improve access to housing with the reform of the local stairway which currently does not meet the technical standards of accessibility, which creates concern and discomfort for everyone. The latest step performed consisted in an "informal" conversation and presentation of the current situation of the stairway through a model used as a strategy to define the work plan. There were incorporated into the project a new student-team and a course on Technology, and an architecture and urbanism professor as co-counselor. For the professor, supervising this work has been a fulfilling experience as it meets the expectations raised on a survey conducted by her on the need for a review of the training of architects, oriented to practice and social consciousness approach.

2 FINAL CONSIDERATIONS

Following the guidelines of the UIA (2011), the two reports have in common the intention of creating an

educational environment close to reality, thus contributing positively to the challenges faced by society in the new century and being able to work toward a sustainable development taking into account the different cultural heritages. In this educational environment teachers transform their roles and begin to live with uncertainty accepting complex thinking.

The results of these extension projects were extremely important both for the locals as for students and teachers, because while that promoted empowerment, approached the city with the academic community in the search for quality of life of the local population. These actions refer to social issues that must be addressed and included in the current reflections on the profile and architectural education as outlined in the documents presented in this article that address the challenges in architectural education in the 21st century context.

We can also identify in these two experiences transdisciplinary concepts that seek to complement the specialized and fragmented thinking with thoughts from different fields. According to Morin,

> "The piecemeal intelligence, compartmentalized, mechanical, disjunctive, reductionist, breaking the world's complex, produces fragments, breaks up problems, separates what is joint, make single dimension what is multidimensional" (Morin, 1999, p. 25).

Finally, they highlight the need for action in promoting theoretical understanding that according to constructivism, will result in knowledge.

Case study strategies for designers: Teaching integrative data evaluation

Marja Sarvimäki
Abedian School of Architecture, Bond University, Gold Coast, QLD, Australia

ABSTRACT: Teaching research methodology and conducting architectural research for years has revealed to the author of this paper that there is noticeable lack of globally established depictions of methods in design research, also called evidence-based design or practice-based research. Partially this is caused by the fact that research carried out by architects and other designers is a somewhat new phenomenon, when compared to many other disciplines, partially by the wide range of subject matters and paradigms in architectural and environmental research. The lack of defined methodology applies particularly to case studies, although those are most commonly employed by designers. In professional jargon, however, the term case study itself seems to refer to anything from a simple 'precedent study' to a 'project description,' sometimes used even as a synonym for an 'example.' Hence, this paper sheds light into the pros and cons of both quantitative and qualitative paradigm from a transdisciplinary perspective, including ontological and epistemological premises of case studies. Special attention is paid to the characteristics of embedded case studies and holistic case studies in terms of their data collection and analysis methods, including conventional surveys, interviews, fieldwork, participatory design, and post occupancy evaluations, but also such novel strategies as memory sketching and phenomenological thick descriptions. These strategies are, then, examined from the perspective of integrative data evaluation with theoretical sampling, triangulation, pattern-matching logic, and analytical generalization. In other words, the focus is on deep understanding of a case within its complex context, in order to provide means of holistic interpretations of empirical inquiries in real-life contexts. The objective and future contribution of the proposition is to promote the value of research as the basis of design excellence among students and professional practitioners alike, with the mastery of case study method informing their design decisions.

1 INTRODUCTION

As case studies, when conducted properly, can be among the most valuable research strategies in many design disciplines, this paper focuses on the many facets of the case study research method as well as the best practices of evaluating, analyzing, and interpreting data coming out of the process. We investigate these procedures from an inter- and/or transdisciplinary perspective by applying the principles of integrative data evaluation, or the 'Four Pillars and the Roof', like Pauwels and Matthyssens call it. This is one of the significant ways in both ensuring the reliability of a case study and educating the proper means of conducting case studies.

According to Scholz and Tietje, most skepticism about case studies is caused by nontransparent knowledge integration, especially in case studies with multiple methods of qualitative data generation. They argue that this is why "integrative evaluation – an evaluation that integrates viewpoints from such diverse disciplines as ecology, economics, and sociology – is crucial component of case studies" (Scholz & Tietje 2002). For this process, they suggest a synthesis of knowledge integration that can be divided into four categories: integration of disciplines, systems, interests, and modes of thought. Correspondingly, in any design research case study, triangulation between methods, not just between sources of data and evidence, is crucial. It also allows great potential for creativity regarding the research design, with opportunities to develop novel data collection and analysis methodologies.

An additional reason for skepticism about case studies is, no doubt, the conventional call for scientific objectivity. In the context of multiple case study research in international business and the 'architecture' of such research design, Pauwels and Matthyssens discuss the ontological and epistemological premises of qualitative research "that departs from a time- and human-free objective reality towards a more context-bound intersubjective reality […], in which the social world is to be understood from the point of view of the individuals who are directly involved in the events that are investigated" (Pauwels & Matthyssens 2004). They go on arguing that "Multiple case study research aims at closing the gap between the objective of the study and the object of the study. In this respect, we explicitly aim at capturing the subjectivity that is embedded in the object" (Ibid). In evidence based design, this can be seen as an invaluable approach in interpreting the interrelationship

between the built environment and its users, from the perspective of the latter.

However, Pauwels and Matthyssens also point out the significance of reducing the researcher's impact on the validation and evaluation process. For this, they suggest the aforementioned principles of 'Four Pillars and a Roof' – an appealing simile for architects. Pillar 1, theoretical sampling, is based on selecting both typical and atypical cases, as opposing to a number of analogous cases. In this process, the analyses of atypical cases produce contrasting results, though for predictable reasons, and create theory-driven variance and divergence of data. Pillar 2, triangulation, is naturally one of the basic 'pillars' in any research project. For Pauwels and Matthyssens, it serves two purposes: it reduces random errors and increases internal validity of a study. Pillar 3, pattern-matching logic, is based on the fundamental scientific pattern model according to which, for instance, events can be explained in relation to sub-elements so that together they constitute a unified system. Pillar 4, then, deals with analytical generalization by testing the validity of research outcome and/or theory development against extant theories. Finally, the roof encompasses validation by juxtaposition and iteration of the pillars that support it, which we examine below.

2 FOUR PILLARS AND A ROOF

2.1 *Theoretical sampling*

In his 'classic' publication with regard to the topic of this paper, titled *Case Study Research: Design and Methods*, Robert K. Yin covers the issue of theoretical sampling extensively, pointing out that replication logic is different from sampling logic. In short, this means that in multiple-case studies in particular the former is analogous to multiple experiments, as opposing to random sampling (Yin 2013), which is further discussed below in the context of pattern-making logic. This kind of analysis process often is performed in two or more rounds in order to validate the outcome. In the first round, the goal is typically production of theory-driven data in order to build theoretical foundation on the divergence of evidence. In the next stage or stages, the abstracted process may require more practical considerations based on typical and/or atypical cases (Pauwels & Matthyssens 2004); in design research, this often means normative theory development with focus on a distinct design problem and its solutions.

The process is somewhat similar to the cross-case analyses Yin describes, though it is important to note that 'the more cases, the better' attitude does not itself provide validity. The cross-analyses can be literal replications producing similar results from multiple cases or units of analysis that are chosen as part of the analytic strategy – if the results are similar, they support the initial theoretical stance, if contrasting, they reject it. Theoretical replications, in turn, produce contrasting results for predictable reasons, thereby testing the theoretical framework, often contrasting it with rival explanations (Yin 2014). Even a two-case study can, hence, serve as the basis of theoretical sampling, while in a single-case study it can be provided by variety of units of analysis in one setting which strengthens the internal validity of an emerging theory. In multiple-case studies, with at least two cases, cross-case synthesis is naturally am essential means of analysis both in terms of theoretical sampling and evaluating research outcome.

In addition to pattern matching (see above), Yin lists four other analytic techniques: explanation building, time-series analysis, logic models, and cross-case synthesis. The three first ones are, in fact, specific types of pattern matching, while the last can be regarded as the 'roof' of Pauwels and Matthyssens. Cross-case comparisons are naturally possible only in multiple-case studies, whether those are performed separately by independent researchers or are part of a larger study by one investigator or a research team. As the goal is to generalize the research outcome, the above-discussed replication logic is the central part of analyses in this method. Explanation building, time-series analyses, and logic models, in turn, can be applied to both single- and multiple-case studies. For Yin, "[t]o 'explain' a phenomenon is to stipulate a presumed set of causal links about it, or 'how' and 'why' something happened" (Yin 2013). That is, obviously, relevant in explanatory case studies and usually involves creation of a narrative explaining the causalities, whereas in exploratory case studies it is primarily a process to generate hypotheses, not to analyze evidence.

However, the aim of this iterative process is not just to find patterns that support the hypotheses, but to test them against rival explanations. In time-series analyses, one also looks for patterns between observed phenomena that are usually empirical, though by tracing changes over a certain period of time; or the so-called time data points. One could, for instance, conduct a single-case study of a certain neighborhood and observe how changes in building code impact changes in the built environment and property values before and after each data point. Finally, logic models allow one to analyze evidence by "matching empirically observed events to theoretically predicted events", as Yin (2013) puts it.

2.2 *Triangulation*

Like theoretical sampling, triangulation should take place throughout the case study process: from the research design, through data collection, to its analysis and evaluation. The simple reason is to maximize the strengths of included data gathering strategies, whether multiple sources of evidence, measurements, methods, references, cases, or units of analysis, and the kind, while minimizing the weaknesses of each. This process convincingly confirms findings and reduces random errors which increases the internal validity of a case study. Originally triangulation is a navigation strategy with which you can determine your position

by the relative fixed locations and distances of two points, such as a landmark or a star, and that is what triangulation does in research as well; in other words, it determines the position of an investigator in relation to various measurements, methods, levels of analysis, or other 'points'.

Triangulation is usually associated with research as a means of avoiding bias or other undesirable impact in the substantiation of empirical phenomena through multiple sources and methods of data collection to improve the convergent validity of a study. Convergent validity is a common concept in sociology, psychology, and other behavioral sciences, including environmental psychology, as part of constructing validity of a study by confirming that the two measures of constructs that are theoretically related (e.g., by the theoretical sampling above) actually are related in reality as well. In the *Encyclopedia of Case Study Research*, Julie Wolfram Cox and John Hassard describe triangulation as a way of "developing a more effective method for the capturing and fixing of social phenomena in order to realize a more accurate analysis and explanation" (Mills & Durepos & Wiebe 2010).

According to Norman Denzin, there are four types of triangulation: (1) data triangulation, as the term implies, deals with corroborating data collected in different times from different sources; (2) investigator triangulation necessitates that different investigators collect data independently on the same phenomenon and compare the results; (3) methodological triangulation entails data collected by different methods, meaning that it requires a multiple method research design; while (4) in theory triangulation different theories are used to interpret the data (Denzin 1978). This kind of meta-triangulation can, then, include various subtypes, such as quantitative and qualitative data played against each other in order to examine various interrelationships within a setting.

However, as the said approach to triangulation is largely based on positivist paradigm according to which singular reality can be understood objectively, it has faced criticism within the postmodern theoretical framework that questions the dualistic subject-object distinction. Hence, Wolfram Cox and Hassard give a few examples of studies in which "new forms of triangulation can be used to analyze supposedly contradictory information and to show how positivist and interpretivist research may be mutually informative" and "can be understood as strategies of convergence and divergence" (Ibid), whether the data comes from quantitative or qualitative research. By convergence they refer to findings that provide a study with reliability and/or validity, while divergence allows its theoretical elaboration. Moreover, they point out that reflexive awareness includes sensitivity toward the relationship between the investigator and the investigation.

Accordingly, one should also look at dilemmas, inclusions, and exclusions within the research strategies which Wolfram Cox and Hassard call "their associated impossibilities". Particularly interesting is their description on how convergence can be found through "holographic typical cases" as a representation of layers of variables or data that helps you to see the whole picture. Without going into the details of this strategy, it is sufficient to note that the metaphor of holograph denotes a three-dimensional, virtual image which is only a re-presentation of reality; thereby it recounts the above-mentioned impossibilities. This is to say that the kind of triangulation, characterized by the involvement of investigators and participants as well as classifications derived not merely from literature reviews, multidimensional scaling, and other conventional tactics, but also qualitative strategies (e.g., metaphors) and other means beyond the status quo, aims to find partial views or new angles and perspectives. In this respect, it is important to bear in mind that in the subjectivist/ constructivist paradigm the investigator is only a tentative interpreter of a particular context with multiple realities.

There are innumerable ways to achieve triangulation in design research case studies and this also is an area in which there still is plenty of potential for creativity. Besides the multiple data collection techniques – varying from conventional observations, interviews, surveys, mapping, sorting, and such, to more novel means, like memory sketching and role playing – the analysis, evaluation, and interpretation, too, can include triangulations of less conformist nature. For instance, interviews or role playing can be followed by posing the initial tasks to a new group of people (for the purposes of theory sampling, preferably people with contrasting views), or conducting open-ended interviews with the same people on a particular new topic; in other words, the first round would be for theoretical sampling, whereas the next provides qualitative evidence for triangulation. Or, as another example, one can return to the field for feedback to check with the previous informants whether they agree with the interpretations, which would be a significant act in qualitative research.

Also, visual communication with both the informants and, subsequently the audience, is critical, which can take such forms as correlational charts, syntax diagrams, composite and/or gamma maps, concept matrixes, and the kind, or even story boards, Japanese *manga* cartoons or *anime* videos (Sarvimäki 2013), as visual interpretations of the phenomena in built environment.

2.3 *Pattern-matching logic*

According to Yin, pattern-matching logic is one of the most desirable techniques for case study analyses. In short, a pattern model explains events or settings in terms of related elements and subsystems so that together they constitute a unified system; in other words, this 'pillar' is linked to logical argumentation in which interrelated 'building blocks' form a conceptual system (see Groat & Wang 2013). As Pauwels and Matthyssens point out, however, this well-known analytical *strategy* has a limited number of established analytical *techniques*.

To overcome this shortcoming, they applied the Inferential Pattern Coding (IPC) of Miles and Huberman (Miles & Huberman 1994) in their study "The Architecture of Multiple Case Study Research in International Business". The research design included both literal and theoretical replications, as well as the following four analytic steps: (1) Pattern coding was based on the list of guiding constructs derived from the initial research questions. The coded patterns, constantly upgraded as the study went on, formed abstracted chains of events and attached meanings, which were visualized in a matrix of interrelated patterns of a particular case. (2) In the next step, the causal relationships that begun to emerge by integrating relevant patterns from different units of analysis were highlighted and further triangulated by the existing literature. Non-causal patterns were, by no means, disregarded either because they supported the delineation of interrelated causal patterns. (3) Through this iterative process of cross-case comparisons, a causal meta-pattern logic was constructed across all 12 cases, which led to an intermediate model of four cases. Although not all causal patterns were identified in all cases, even the contradictory patterns were potential material for cross-case analyses; in Yin's terminology, the rival explanations, or Wolfram Cox and Hassard's impossibilities. (4) Finally, Pauwels and Matthyssens grouped the dominating patterns found in step 3 in seven groups of non-overlapping process propositions that "accommodated both a causal pattern as well as non-causal yet conditioning patterns" (Pauwels & Matthyssens 2004).

Relevant to design research, Yin sheds more light into this process of pattern matching. He points out that while similarities between empirical and predicted patterns can help in strengthening the internal validity of a case study, especially in explanatory studies, in descriptive studies, too, "pattern matching is still relevant, as long as the predicted pattern of important descriptive conditions was defined prior to data collection" (Yin 2013). He also discusses the nonequivalent dependent variables derived from quasi-experimental research designs and warns us about certain threats to the validity of this logic, regarding single-case studies in particular. In those, it is crucial to identify a subset of the initial dependent variables and, using the same data, to show how the patterns could be different in different circumstances: "In essence, your goal is to identify all reasonable threats to validity and to conduct repeated comparisons, showing how such threats cannot account for the dual patterns" (Ibid), he says. In addition to rival theoretical propositions overall, articulated in operational terms (e.g., what are the mutually exclusive variables as opposing to inclusive variables of your initial position), literal replication can successfully match a proposition of a single-case study with evidence supporting the initial hypothesis, whereas similar cross-case results confirm it even more assertively. Likewise, theoretical replication can confirm the pattern-matching logic for rival explanations across multiple cases in which predictable, different results support your initial position.

One of my doctorate supervisees, with Yin as the prime reference in preparing and conducting her case studies, applied the idea of a matrix, at first, in developing the research question and, then, using it as pattern-matching model for the interpretations. This was an embedded multiple-case study, in which she combined quantitative and qualitative data to answer the initial topic of inquiry whether the impact of a building, in this study a house, on its users is actually the same as the architect claims or wishes. The research design included such quantitative strategies as performance analyses, census information of the neighborhoods, correlational questionnaires among the occupants, historical analysis of the settings, and visual scrutiny of pre- and post-occupancy floor plans, supplemented by qualitative data from critical analyses of these buildings, participant observations in the target buildings, open-ended interviews among the occupants (e.g., why they had modified the house design) as well as with the architects; as two comparison groups, the investigator had analogous developer-designed 'cookie-cutter houses' and user-designed-and-built homes (i.e., the atypical cases). In a significant role of knowledge generation was the POE with an open-ended survey with which the researcher was seeking to understand the occupants' own perception of their real-life setting.

Based on and updated by a literature review which focused on reveling why and how the disconnect between the user and the architect may have taken place, this doctorate candidate formulated her theoretical framework in a matrix with three horizontal lines of houses designed by a developer (D), an architect (A), or the user (U), whereas each had two vertical classifications of generic design (G) or that for a specific user (S). This created six categories: DG (developer generic), DS (developer specific), AG (architect-designed generic), AS (architect-designed for a specific client), UG (user-designed generic), and US (user-designed for him/herself). As UG is the least common category, the investigator acquired the role of a 'user-designer' in her design research for a flexible family home, in which design solutions were justified by the patterns found in the five other categories; this established the analytical generalizations for an ideal user-designed generic house (UG) by pattern-matching logic (Trimble 2014).

2.4 *Analytical generalization*

When an investigator has generated a pattern model that consists of related events and subsystems, which explains the workings (and usually causal relationships) of an unified system, s/he should ask oneself whether these relationships are generalizable beyond the setting of the case study, or settings of a multiple-case study. There are two options: statistical or analytical generalization, of which only the latter works in qualitative research. In the above example of an

embedded case study, statistically generalizable census records and some other quantitative data (e.g., median house values, floor areas, number and cost of alterations, etc.) was part of the collected evidence, but in order to answer how does a house design effect the inhabitants, and how to interpret the outcome by comparing developer-designed, architect-designed and user-designed-and-built houses, qualitative findings were of most importance in the validation process. Hence, the investigator tested the research outcome and the evolving theory against the existing theoretical framework on the topic through analytical generalization. This is naturally crucial in multiple-case studies, in which generalizability is the goal, allowing the juxtaposition of an emerging theory and the extant literature, including competing theories.

Pauwels and Matthyssens applied the so-called Degrees of Freedom Analysis (DFA), developed to serve qualitative research, as the means for analytical generalization by validating their "process theory of international market withdrawal […] against two established process theories of organisational and strategic change" (Pauwels & Matthyssens 2004). Although this study on international business, at the first glance, appears quite distant from design research, their method of using DFA in analytical generalization is useful for us, too. Overall, it was based on listing parameters (e.g., motive of initiation) and related questions (e.g., Which stimuli cause a decision process to start or not to start? How and by whom is the decision process initiated? Where is the decision process initiated?), and comparing their emergent explanatory theory to the two theoretical benchmarks.

In design research, just to think about the aforementioned topic of inquiry, the DFA questions could include such parameters as the reasons to buy a particular house/ plot, to hire the chosen architect, to not hire a professional designer, to make changes after occupying the house, etc., while the related questions would be: Why and by whom was the decision made? What were the other options? Which mechanisms prevented choosing the ideal options?, and so on among the myriad of possibilities.

Yin, too, addresses the difference between statistical and analytical generalizations by stating that "in doing case study research, your goal will be to expand and generalize theories (analytic generalization) and not to extrapolate probabilities (statistical generalizations)" (Yin 2013). This distinction cannot be overemphasized, since the characteristics and benefits of case studies are in-depth explanations, descriptions, explorations, even predictions of a setting by using data derived from multiple sources and methods which defines causal links, develops or tests a theory, and/or generalizes to theory. Subsequently, the ultimate objective is to integrate all this in a meaningful way.

2.5 *Validation by juxtaposition*

The four methodological pillars discussed above are essential 'structural' elements in the 'architecture' of multiple-case studies, but without balancing them – or providing lateral forcing, to use structural engineers' vocabulary – the construction would collapse. The 'roof' is what connects the pillars, and while doing so it also stabilizes the whole construct of the research it spans. This validation of data is an ongoing and deliberate process in which the investigator examines and creates possible explanations of both validity and invalidity from the perspective of various sources. The creation of invalidity is similar to the rival theories mentioned above. In other words, juxtaposing data by analyzing, interpreting and validating findings and extant theories, the emergent theory might upgrade, complement, or correct an extant theoretical stance. This, consecutively, provides opportunities for further theoretical sampling. In this process, the goal is not only to search for information that supports the hypothesis, but, most importantly, that which does not support it. Pauwels and Matthyssens, referring to Kvale (1989) go as far as stating that "[t]he researcher plays the devil's advocate by critically assessing the possible impact of sources of misfit or invalidity" and that "juxtaposition and iteration are two highly complementary validation strategies both aiming at the identification of possible sources of invalidity" (Pauwels & Matthyssens 2004).

Somewhat similarly, Yin categorizes the test for judging case study research design in four sub-tactics: (1) In constructing validity, the aim is to identify operational definitions and measures of the study, which takes place particularly in the data collection phase, and is concluded in composing a research report. (2) Ensuring internal validity is a process in which the investigator seeks to establish causal relationships in explanatory or causal case studies; this does not apply to descriptive of exploratory studies, as those focus on thick descriptions of one setting, not cause-effect analyses. The internal validation process occurs almost exclusively within the data collection and analysis stage, although it of course must be planned in the research design. (3) External validity also is considered in this context, as it deals with the generalizability of the research outcome; by using theoretical approach in single-case studies, and replication logic in multiple-case studies. (4) Reliability, then, is ensured by a rigorous case study protocol and database, for which space does not allow discussion here (for more, see Yin 2013).

One example of an embedded single-case study employing the 'four pillars and a roof' I was involved with as a supervisor investigated a relatively broad topic looking at Chinese geomancy (*fengshui*), environmental psychology, and biophilic design. In this instance, too, the topic of inquiry was the user's perception of a house and her own setting, though the primary objective was the architect-client relationship and communication during the design process; in other words, this was a pre-occupancy evaluation focusing on the impending user. In addition to a very comprehensive literature review on these three separate schools of thought with examples of their design

principles (pillar 1), the thesis went on identifying differences and similarities of these principles (pillar 2), pattern models underlying the logic of all three (pillar 3), and then tested the conclusions against extant phenomenological views on the perception of place (pillar 4). The 'roof' was a design project on a real site for a real family (though hypothetical as client) testing and validating the research results attained by the four 'pillars'. Thus, this design research case study highlighted feedback from the client and the impact of that on the design. The goal was to validate the research results and design solutions based on – or perhaps better with this metaphor, resting on – the theoretical framework by juxtaposing them with the extant theories on *fengshui*, environmental psychology, and biophilic design, as well as general theories on architecture and perception (Hudson 2013). In terms of evidence, the challenges were considerable in not only crossing many disciplinary and cultural boundaries, but also in integrative data evaluation deriving from these diverse fields.

In short, integrative data evaluation in design research case studies, like in any research project, amounts to deliberate, ongoing checks of validity or invalidity through concurrence of data and findings, both existing and emerging theories, case selection, data collection, definition of terms, and other internal and external reference points. These principles are reminiscent of Scholz and Tietje's integrative evaluation with emphasis on multiple sources of data and evidence, of the case study doctrines laid out by Yin, as well as of the 'four pillars and the roof' discussed above. As pointed out by Pauwels and Matthyssens:

> The omission of one of these pillars has a baleful influence in the methodological quality of the study and causes the roof – the ongoing validation process – to collapse. Yet, these pillars are only qualifiers: relying upon them is necessary though not sufficient. Each of the pillars should be operationalised and interwoven in a way that best fits the research questions and gives an optimal answer to the operational challenges of the study (Pauwels & Matthyssens 2004).

3 CONCLUSION

In closing, it is my wish that bringing together the aforementioned interdisciplinary views on case studies helps in defining this methodology in architecture and related disciplines, to the extent those could be discussed in the limited framework of this paper, Accordingly, it appears that the curricula in architecture and other design schools could apply much more rigorous interdisciplinary approach with regard to the education of research methods in order to ensure genuine integrative data evaluation in general. This might be stating the obvious, but it does deserve attention because, like in any academic field, design research education is based on determining one's position based on extant 'fixed points', in a similar way than triangulation does in navigation.

Yet, although the case study methodologies discussed above do demonstrate new approaches to design research, one definite challenge in teaching design research methods, as well as in conducting case studies, is over-emphasis on established methodology (as rules to follow) and under-emphasis on the role of creativity and intuition in research. Hence, an appropriate ending is Scholz and Tietje's statement with which I fully agree: "It should be mentioned that, as in architecture, developing projects in the field of the environmental sciences is an art […] in many such cases, the artistic design is a determining factor for success" (Scholz & Tietje 2002).

From design to research by design: Experimenting pedagogies to face territorial issues

J.-P. De Visscher & N. Willemet
Université Catholique de Louvain, Brussels, Belgium

ABSTRACT: This paper discusses the need to shift from a « design » to a « research by design » methodology when facing territorial issues in the architecture studio. The reasons and nature of this shift are brought to light through a case-study: a third year studio taught at Université catholique de Louvain over a complex but highly potential suburban territory of Brussels. This territory is made of layers erratically added through time, with no global vision. A traditional "design" studio where students individually develop their ability to answer a predefined question is inappropriate to face such complexity. The lack of a clear request requires a different methodology: « research by design ». From this point of view, the morphological structure of the territory is seen as a resource for programs, visions or ambitions. Design becomes a tool for exploring them, while the studio becomes a place where to build collective knowledge of these latent potentialities.

1 INTRODUCTION

The first semester 2015–2016 of the 3rd year at Université Catholique de Louvain (UCL), LOCI faculty is dedicated to the introduction to the territorial scale. The theme of the studio (with about a hundred students) is the study of the south suburban area of Brussels. This site offers great opportunities for the urban and housing development of the Brussels region. However it is a very complex territory, where different layers of transformation have been added over time without any global vision.

A classical « design » approach analyses the context through a specific brief and the project is designed as an answer to that brief. In such studios, the skills of the students are measured through the quality of the correlation between their design and the brief. In this case, the complexity of the project site is such that it is difficult to know what is suited to do or not in that territory. No brief or program can *a priori* be defined. Consequently, students have to elaborate the question as much as the answer. In order to face such indetermination, an individual approach to the brief is not sufficient and the studio has to become a place where an extended knowledge of the potentialities of the territory is collectively set up. Design becomes a tool of exploration, and knowledge results from the systematic multiplication and comparison of the different explorations. In other words, « design » studio as to become a « research by design » studio.

The argument of this article is developed in three steps. Firstly, the context of territory planning and its education is quickly synthesized. Secondly, the difference between « design » and « research by design » teaching methodologies is defined by comparing two types of training programs. Thirdly, the studio led at UCL in 2015 is discussed as both an experiment of « research by design », and an attempt to prepare the students to face the crisis of urban development.

2 THE AMBITION OF THE TERRITORY

2.1 *Planning sub-urban territories*

During the last century, territory was mainly produced through a collection of independent answers to specific conditions. The territory resulting from such processes is hard to describe. Is it a collection of dense cities and open countryside, an urban sprawl, a space in-between, a *Zwischenstadt* (Sieverts, 1997)?

As consequence, the inherited tools of urban planning are inappropriate to manage its development. As André Corboz pointed out: « *Territory as a surface is an inheritance of the 19th century (…). It's useless to underline the fact that this conception has become impracticable (…). A surface has a perimeter, though a web has only terminal points; surfaces don't really mix among each others, while webs, can surimpose and combine; furthermore, webs don't abolish surfaces, which requires to invent a dialectic capable of defining these relations. Such an argument means that most of the descriptive tools must be invented ex novo, the one we have being conceived for surface problematics* ». (A. Corboz, 2001).

Furthermore, most of te time, the service provided by architects tends to be reduced to a « commercial service ». They aren't asked to directly face these territorial issues in their practice. Indeed, within a professional order, a public or private authority who owns a piece of land produces a brief and one or more architects' answer is embodied in the form of a project. The one designated as the « best » answer is the one that reconciles the various given constraints: program, regulations, technical requirement, cost effectiveness, etc. These standards to be respected are the result of political decisions, implemented by instruments codified by engineers or surveyors. They determine the way in which the territory is made and thought. The architectural project is not much more than an answer to theses standards. It is an outcome, not a tool to design territories. These particular « answers » are rarely seen as innovative contribution facing territorial issues.

2.2 *Teaching about territory*

Territory Planning must be more than ever in the centre of debates and long-term visions. In that sense, education can prepare the future citizens for these challenges and has the ability to change society. Yet, what importance is given to territory in civic education? Particularly, in architecture schools, how are the future architects prepared for these problems? What are the methodologies used for teaching about territory? Why can architects bring a specific perspective?

In that regard, one must first look at what is specific about architecture teaching. Firstly, education is based on the « design » study and practice. Secondly, teaching is made through drawings and representations, which are used to represent the world physically, but also as a design production tool. They have this particular ability to makes inner structures readable and bear the potential of wider (and sometimes unexpected) transformations. As such, architects manipulate drawings as « morphological representations », based on construction of latent potentialities of spatial structures.

In order to highlight the shift from « design » to « research by design » as an opportunity to face territorial issues, let's compare two important moment in the history of architectural training: the Bauhaus school program in the 30's and the end of the Beaux-Art architecture education in France in the 60's.

3 TEACHING BY « DESIGN »: TWO METHODOLOGIES

3.1 *Teaching « design » as a development of individual skills: the Bauhaus program as paradigm*

The Bauhaus School, under the direction of Walter Gropius, intended to have a pragmatic approach to design, aimed at construction. The architecture studio was the central part of this training program. The adjunct courses were a complementary support to the studio. The project had to reflect the reality of professional practice.

In the book « Scope of Total architecture » (Gropius, 1955), Walter Gropius gives 12 recommendations on how teaching architecture in design studio could be. Let's consider some of them.

- Design is a work of coordination. Even tough group work is encouraged, the student is to be trained as a « *coordinator whose business is to unify the many social, technical, economic and artistic problems which arise in connection with building* » (point 1 and 8)
- Design is about construction. Education should totally be related to a professional design experience. Construction and design are seen as interdependent, and therefore taught by professional with relevant building experiences (point 7 and 10)
- Design is based on personal experience. Education should be based on an individual experience of matters, and therefore surface, volume and spaces. Students acquire basic convictions through a creative attitude and independence of conception, not by accepting ready-made formulas. « *Knowledge will come to life only by individual experience. Therefore, designing and building – the drafting board and the job – should be related on all levels.* » (point 2, 3 and 4).

According to Gropius, development of individual skills through the studio, based on the reality of construction and practice is the core of the architect education.

At UCL, as in many other universities, this method is still a dominant paradigm. Studio is seen as the place where to learn the reality of a professional order. A specific brief is asked to the students and their aim is to produce one project which best synthesizes the given options. The studio jury evaluates the student's ability to correlate at best the brief and the design through one proposition.

Little collective knowledge is built through this process. The students projects are criticized as individual entities, not as a part of a collection of different projects. Moreover, feedback between the individual experiences of the projects and the question asked by the brief is rarely established. The knowledge gained by all the projects is not used as a rereading of the initial brief. A studio jury has the potential of being a catalog of different project possibilities in relation to the initial request. It could also be a tool to check back the pertinence of the brief asked. However, it is never explicitly used as such.

3.2 *Teaching "research by design" as a production of collective knowledge: « L'atelier collégial » as paradigm*

The teaching experiment lead by Bernard Huet and his students part of the « atelier collegial », during the academic year 1967–68 represents a total rupture with the Beaux-Arts teaching of the 60's, and created a shift in the architecture design studio education.

At the time, architecture education in France was part of the Beaux-Arts School. Teaching was closely related to a « master » who was responsible for the studio and a wide group of students (450). Program was a fact not to be questioned, and often with few or no context at all. The main asset was to produce and compose a final presentation of the project drawings (A0 size) with a « *striking organisation* » (Pommier, 2011).

Bernard Huet, altogether with a group of students (38), thought this sort of teaching was too distant from the issues raised by the « trente glorieuses ». They stepped out from the traditional methodologies and suggested another studio model.

- Design is a collective research. Different teams of students led different researches through the same studio. Each student has an active role in the knowledge of the whole studio. Communication is done through talks or information sheets (A4 size). The studio is a place for collective knowledge and experimentation.
- Design is inter-disciplinary. Education is not only related to construction, but as well as to other disciplines: sociology, economics, … . Students are led to collect data on sites or to make interviews. Inside the studio, teachers and « taught » students are placed on the same level of equality.
- Design results from perspectives. Programmation should result from the preliminary analyses. Each aspect is controlled, documented and checked before designing the project. Its form comes from the analyses. Diagnostics and perspectives are made regarding the potential evolution of the sites.

Through this methodologies based on collective knowledge, Huet wants the studio to be a place of research. Teacher is more a guide than a master, and the student is seen as « *a latent autonomous designer* » (Pommier, 2011). He wants the students to acquire knowledge but especially to raise questions among themselves: what is the meaning of architecture? To whom do we build? A strong link between architecture and society is suggested. Architecture education should be more about a way of thinking than an actual know-how.

This experiment only lasted for one year but is still very relevant. As example, these few studios can be mentioned as experiments on similar pedagogies: O. Ungers with the first summer academy in Berlin (Ungers, 2013), P. Vigano in the Venetto region (Vigano, 2012), R. Diener, J. Herzog, M. Meili, P. de Meuron and C. Schmid with Studio Basel (Diener, 2006).

4 RESEARCH BY DESIGN(S): RE-QUESTIONING THE PLACE OF THE ARCHITECTS IN SOCIETY

A studio based on individual skills give the students the technical tools to design, such as representation. A studio based on collective knowledge put more importance to the process of designing, by raising questions and analyses. How to implement these programmes when facing complex territories such as sub-urban areas?

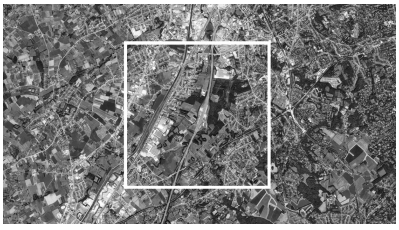

Figure 1. The studied territory.

Design and thinking should result from the territory itself. Its structure and form could be the condition to its own mutation. The territory becomes a project resource. A « design » would therefore no longer be a simple answer, but an exploration of the inner potentialities of the morphology of a territory.

As a result, a single answer to a given brief is no longer appropriate: all the different possible projects are gathered as a series that can be compared and objectivized. Where a jury usually studio fails, this methodology takes that opportunity as a basis.

5 TEACHING BY « RESEARCH BY DESIGN »

Territorial issues are an important challenge of our time and must be placed at the centre of education in architecture schools. A traditional design approach, based on individual skills, mirrors the reality of a professional order, but is not appropriate to the complexity of the territory. Teaching territorial issues could be nourished by « research by design » and methodologies based on collective knowledge, where the territory itself is considered as a resource for programs, visions and ambitions. The architectural project becomes a process initiator instead of an answer to a specific request.

In view of this, different education experiences are used in the studio. A « research by design » methodology is applied through a territory studio with one hundred 3rd year students. The site chosen is a south urban area of Brussels, which has a lot of potential for the future development of the city. It is made of complex layers added through times.

The studio is led and organized so that students express a long term « vision » of what could become of this particular territory and identify a first « action », a pilot project capable of initiating a mutation process. The semester is divided into different phases following methods of « research by design »: a first physical account of the site, a thematic representation of the territory structures, big-scale and micro-scales scenarios, the definition of a vision and a first action, the jury and an exhibition as a feedback. A strong accent is put on collective work and crossover approaches: students coordinate their different hypotheses throughout

Figure 2. First physical encounter with the site.

the semester. A panel of teaching methods are used: group critiques, collective crits, debate, weekly presentations, lectures, public exhibitions, … .

5.1 *The site account*

As an architect, it's the first and natural way to get into a place. To pace up and down, visit, set eyes on. « *Urbanism is done with feet* » (B. Secchi, 2006).

Traditionally, dealing with a project context becomes something nearly reverential, and design is made to be inscribed in its continuity. Here context becomes the tool. It's the matter. It's what the students will manipulate through the studio.

Students are therefore invited on a bike journey through the territory, to physically get into that landscape: to stop, look upon, draw, photograph, film, measure, interview the inhabitants and themselves.

5.2 *Morphological representation*

The territory itself is able to generate questions and ambitions. Therefore, representation of its hidden morphological structures is the key to manipulate it. Big scale drawings can make things appear. Drawing is more than a tool of representation or communication, it's a design tool. It's the root to interpretations. Without it, territory cannot be read.

Groups of students, following their on-site visit, are asked to choose a thematic approach to the territory. Each group is asked to produce one drawing representative of that theme. Different representations are made following the themes: flooded zones as spatial structures, vegetation as landscape definition, historical marks and old byroads as latent traces, housing typologies, night lighting, as traces of post-war planning,…The themes serve as keys to the interpretation and a gate to the reading of the site's complexity. Each theme leads to specific graphic representation choices. As an example, one group of students made a cut-section model of topography as morphological representation (see figure 3).

Within the studio, themes are discussed with the students. The idea is not that each group undertakes its own research alone, but that every theme meets the others. Through collective displays, specific representations are put together in perspective so that the territory is finally described in all of its complexity. A substantial cartography of the territory is established.

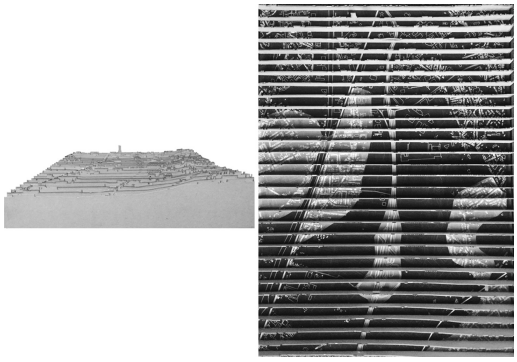

Figure 3. Topography as morphological representation.

Figure 4. Bottom-up scenario: mental representation maps and notion of neighborhood.

5.3 *Scenarios*

In order to improve the thematic and morphological approach, points of view are multiplied. Different approaches can activate the understanding of the latent structures, and can open them to new questioning.

They fall into two categories. Firstly, « Bottom-up » questioning. What can be learned from « below » and a micro-scale level? E.g. encounters with the inhabitants, sociological interviews and analyses, mental maps, local investigation,… .

Secondly, « Top-down » questioning. What are the bigger-scale territory issues? E.g. analysis of the administrative borders, agricultural policies, water management, urban regulations,… .

These are « levers of activation » of the morphological representations. It's in the resulting tension between these two scales that scenarios of transformation progressively emerge.

Students attend two lectures that introduce these new methods and approaches. They simultaneously undertake investigations at both scales. The goal is to teach the students to multiply their observations and point of view about the design they suggest. Their theme therefore becomes stronger, influenced by very

Figure 5. Top-down scenario: territory as an agricultural infrastructure.

Figure 6. Action on the canal as a potential leisure facility.

local request, to bigger scale realities. They are also encouraged to test specific representation of these investigations. Results are presented, criticized while students are asked to carefully step back.

5.4 *Vision/Action*

A themed cartography of the territory is built. It is reactivated by a careful reading of the site from below, with a local input, but also from above, on a larger scale vision of the area and its nearby region. What could the territory be or become? In what way could its hidden potentialities lead to its reevaluation? Far from considering a closed and finished idea of urban planning, an open model is suggested. « Speculation » on physical elements is the starting point of its shift.

The project is the result of an evolutive « scenarisation » (TVK, 2015). The interest is in the process itself instead of the finished product. A series of simple actions can lead to drastic transformation dynamics, by successive chains of events. All the urban planifications foreseen will maybe not happen at the same time, nor the same intensity. Sometimes it won't even occur at all. Territory undergoes a « metamorphosis »: it is transformed without losing its original inner qualities. It's the notion of a « slow » urbanism, latent but more anchored; just like the territory itself.

Through a series of project references, student are introduced to these concepts of evolution and long-term vision from small or radical actions. They now have the potential to build a speculative vision of the territory. A collective pin-up for the whole studio is organized with each group as the start of a critique and debate session. « Design » of the territory is placed into perspective and students are encouraged to « radicalize » their propositions.

Different visions and actions are designed by the students, connected with the different themes: promenade along the limits of the flooded zones, new multimodal transportation station on a wasteland area, public leisure facilities alongside the canal, …These actions are able to generate longterm mutations, but

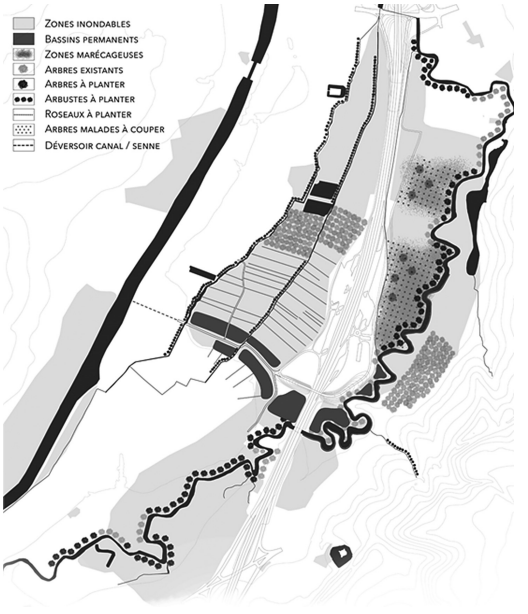

Figure 7. Vision of the flooded zone border as a promenade.

always with the sense of what the territory could handle. Specific forms of representation (e.g. collages) are also tested to achieve this representation of vision and action.

5.5 *Studio Jury and feedback*

The evaluation by the studio jury comes traditionally as the end of the semester. What collective knowledge of the territory has been produced by the different students projects? In a traditional studio based on individual skills, the studio jury is a critic on the different projects with few comparisons from one to another. Few time is usually given for a transversal thematic reading. Here the jury finally reveals its whole potential: it shows all the diversity of design that the brief – the territory – is capable of. All the different visions and projects present a wide catalogue or exploration

Figure 8. Expert critic as feedback.

of the different possible designs: *a field of possibilities* (R. Pleitnix, 2012).

Students present the evolution of their work through the whole semester. It's the total experience that matters, not only the vison and action proposition. They show in what way their proposition is pertinent to the territory. The jury becomes a panel of different hypotheses on the territory. As such, a comparison of the several designs can lead to a more objective knowledge of the potential of the territory.

The studio is concluded with an exhibition built by the students. A conference, on a real case study led on the same territory is also given by an outside expert. The students' work is put in parallel to economic and politic reality.

A transversal thematic reading of all the projects is done with the expert. If the jury is the time for the student to argue their own visions, feedback is the time for experts to bring an overall view and critic on the designs. It is done in a more casual way, without the pressure of the marks. It also invites the students to continue their reflexion after the studio.

6 TERRITORY AS A TEACHING RESSOURCE

Territory and its teaching are essential in term of future challenges and social crises of our time. A design studio based on individual skills focuses the students' attention on producing an answer to a specific question. This mirrors the process of a professional order. By contrast, « research by design » interrogates these models to offer methodologies which enlarge the student's point of view.

An experience of these methodologies based on collective knowledge was led through a territory studio, following different phases inspired by « research by design » methodologies. Students were invited to physically experience the territory, to produce a big scale drawing of its inner structures, to investigate the site from « above » and « below », to define a radical action which would allow a long-term vision mutation and finally, to present their work and objectivize it through an exhibition.

In terms of pedagogy, this method allows to achieve several assets of major importance in architectural education, considering graphic representation, speculation, clarification of hypothesis and collective dimension of the studio.

Placing morphological representation at the heart of the workshop process makes the students realize the opportunity of drawings as an interpretation device and not only as tool of communication. Representation is a design in itself. Each situation requires a specific representation. The latent potential of territorial structures can be revealed and their interpretation is capable of leading to a design.

Speculation on the potentialities of physical elements is taught as a starting point of the project, as the ability to think about the different scenarios without formalizing a finished product. Students are led to direct their own work by themselves and not entirely rely on the teacher's opinion. This forms the basis of a research oriented training.

Students are encouraged to clarify the different possible hypotheses. The studio becomes a place to objectivize several designs instead of being an iterative process on a particular design.

By comparing themes and drawings, students are confronted with each other's work. This helps clarify their own work with the other hypothesis feeding into and nourishing their own. It provokes debate inside the studio. The students learn to be critical not only with their own work but also with the other students work. Collective experience matters more than individual work.

However, this methodology faces several limits. Firstly, students must investigate and speculate on open questions, while having in the same time to position themselves within the studio with a particular design. Some could see this as difficult situations to deal with. Secondly, time is generally running too short for a real dialogue with local actors. To this end, a cycle of studios would be more appropriate.

All these particular skills take a decisive turn in the students' education. Their vision on design acquires new perspectives. Students are made aware of the realities of professional briefs on an urban scale, and learn that architecture has the potential of creating reflections on a political level. Design can also initiate change. To that end, teaching about territory through « research by design » represents a very important resource in terms of architectural education.

The European Quarter of Brussels: From district to neighbourhood The difference between study and research by design

G. Ledent & J.-P. De Visscher
Université Catholique de Louvain, Brussels, Belgium

ABSTRACT: Two kinds of investigations are usually carried out in the discipline of architecture: research by design and study. They are often mistaken for one another and the current trend is to call the latter research by design even though it does not technically qualify for it.

In order to illustrate the differences between the two kinds of investigations, a similar question is addressed by means of the two notions. This question relates to the issue of the residential attractiveness of the European District of Brussels for which a genuine study was carried out in 2015.

This analysis demonstrates major discrepancies between study and research by design in terms of framework, generalization, reproducibility and falsification. Yet, beyond those differences, both investigations could be valuable for one another if they were recognized for what they are.

1 INTRODUCTION

Research by design is a new phenomenon in the scientific field of many architecture schools. Evidence of this can be seen in the large number of conferences, publications on research by design but also in the general use of the concept in public and private commissions (e.g. investigations commissioned by various Belgian Bouwmeesters). Yet, if the concept is very popular, it is often used very loosely, as if all assumptions around its meaning and its methods were commonly shared.

There tend to be two main confusions regarding the definition of research by design. On one hand, many scholars are prone to declare that ordinary architectural design is research in itself. Yet, there are major differences between a regular architectural project and research by design in terms of produced knowledge, method, systematics, validation by peer-reviewing, or reproducibility (Archer, 1979). On the other hand, studies commissioned by public or private sponsors are also often stamped under the label research by design. Yet again, most of the time, those studies do not qualify for such a definition for the reasons stated above in the case of architectural projects.

In order to clarify matters, this paper tries to shed light on the major differences between study and research by design. To this end, a recent study on the European Quarter of Brussels will be used as a pretext for questioning the relationship between the two concepts.

This paper is organized into four sub-sections. Firstly, the scope of a study carried out in the European Quarter of Brussels is exposed in terms of mission statement, stakeholders and findings. Secondly, the general definition of the concepts of research by design and study are considered. Thirdly, the differences between the concepts are brought to light through the example of the European Quarter study. Finally, the differences, as well as the commonalities, are summarized in a general conclusion.

2 PRETEXT: A REGULAR STUDY

2.1 *Mission statement*

The work that serves as a pretext for bringing to light the differences between research by design and study is a regular study that was carried out in Brussels. The aim of this investigation was to apprehend the residential attractiveness of a particular district, the European Quarter, and its possible levers for improvement. This ambition could be summarized as an attempt to transform the district into a neighbourhood.

2.2 *Stakeholders*

The investigation was commissioned in 2015 by a semi-public organization, the King Baudouin Foundation. The goal of this independent foundation is to improve living conditions for the population in Belgium.

In order to meet the mission statement, a multidisciplinary team was formed. The team comprised experts in architecture and sociologists. It brings together university researchers in architecture (UCL) and an urban studies office (CityTools).

2.3 *Findings*

The study was divided in three major parts (De Visscher et al., 2015). The first part is a sociological survey of the European Quarter. This work demonstrates a great disparity in the assessment of the neighbourhood between its users and the resident population. Moreover, the quarter is commonly perceived as a Eurocrat ghetto with little social life. This stigmatization attached to the neighbourhood is demonstrated to be largely a question of perception rather than a matter of real data.

The second part is a spatial study. Carried out by a team of architects, this investigation analyses the physical constituents of the area. It explores the strengths and weaknesses of the European Quarter in terms of built and unbuilt spaces. In addition, it brings to light the possible levers for potential action to transform the district.

Finally, through the pooling of the sociological and architectural diagnoses, a series of intervention scenarios are developed. Due to the scope of the study as well as the nature of the commissioner, those scenarios are mainly "soft interventions" oriented.

3 DEFINITIONS

The comprehensive framework of the case study is thereby established. Yet, the purpose of this paper is not to expose the results of this particular study about the European Quarter but rather to use this investigation as an opportunity to highlight the differences between research by design and study.

In order to achieve this, it is important from the outset to define precisely both of the concepts that guide this paper.

3.1 *Research by design*

According to the Charter of the European Association for Architectural Education (EAAE), architectural research can be defined as an "*original investigation undertaken in order to generate knowledge, insights and understanding based on competences, methods and tools proper to the discipline of architecture. It has its own particular knowledge base, mode, scope, tactics and strategies."* (Ellefsen et al., 2015).

In the same charter the EAAE stresses the essential role of design for the architectural discipline. Hence, in turn, research by design is defined as *"any kind of inquiry in which design is the substantial constituent of the research process. In research by design, the architectural design process forms the pathway through which new insights, knowledge, practices or products come into being. It generates critical inquiry through design work."* (Ellefsen et al., 2015).

On this basis, there are three different ways to comprehend research by design. In an attempt to understand practice-based research in The Humanities, Bruce Archer lists those categories as: research about design, for design or through design (Archer, 1995).

In the first case – research about design -, the inquiries are carried out about the work of a practitioner or a specific architecture office. As such, it can be considered as a monographic investigation. Hence, design is considered in this case as a subject matter rather than a means. The investigation works carried out by the designed based research Royal Melbourne Institute of Technology (RMIT) reside essentially in this category.

In the second case – research for design -, the investigation can be considered as a preliminary work prior to the implementation of a project. It is the analysis phase of the process. Here again, design is regarded as a goal rather than a means.

Finally, research through design exploits architectural design as a means to an end. In some circumstances, knowledge can be unveiled through the *medium of practical action* (Archer, 1995). In this last case, knowledge is produced through the use of methods specific to the architectural discipline.

The latter approach has been elected by the Laboratoire d'Architectures Potentielles (LAPs) to conduct research by design. This research unit seeks to ground the foundations of research by design but also to develop its own methods (Pleitinx, 2012). The LAPs operates in an academic framework, ensuring the critical distance required to formulate scientific evidence.

The LAPs promotes research by design through a combination of two complementary operations. On the one hand, it makes use of the architectural project, whose role is to reveal potential habitats. In this context, habitat is understood as any *artefact* devoted to dwelling, including notions such as territory, city, building, means of transportation and furniture. On the other hand, once those potential habitats are revealed, the method suggested by the LAPs focuses on a classification of those habitats according to their characteristics as well as the conditions in which they can occur. In terms of outcome, this method offers an objective overall picture of the possible habitats in a given context.

3.2 *Study*

On the other hand, a study can be understood as a *"detailed investigation and analysis of a subject or situation" (Stevenson, 2010)*. Hence, a study is defined as a substantial amount of work accomplished for a specific purpose within a precise framework.

Based on this definition, an analogy can be drawn between the notion of study and architectural design. In addition to a similar *modus operandi*, both develop singular investigations based on personal methods in order to work on a specific assignment. Those methods

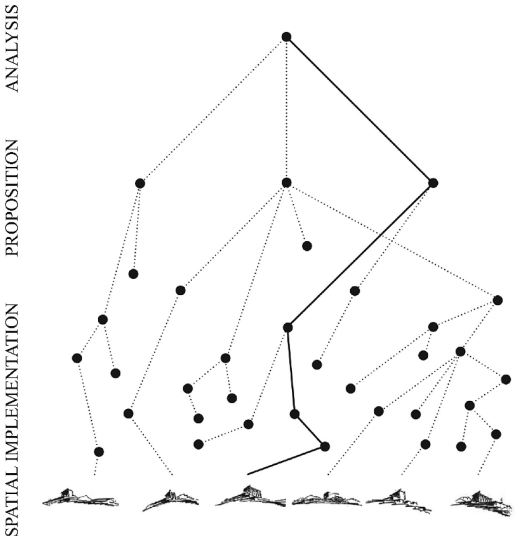

Figure 1. The result of a study.

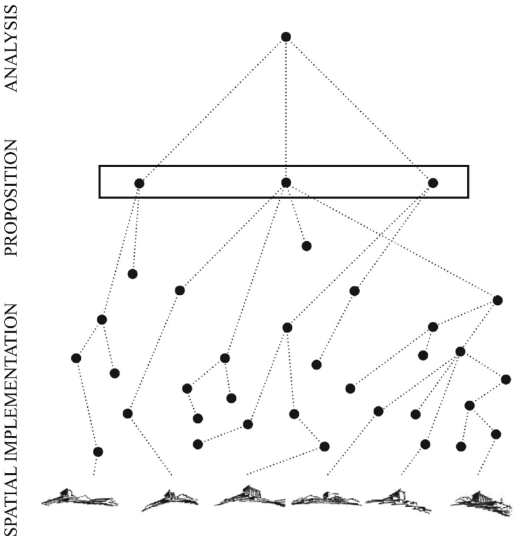

Figure 2. The result of research by design.

are largely tacit since their communication is not relevant to the findings of the project or the study.

3.3 *Comparison*

The process of an architectural project could be summarized in four iterative stages: analysis, proposition, spatial implementation and communication. On the basis of the above, a study process could be summed up according to the exact same scheme.

Firstly, the role of the analysis is to understand thoroughly the question and the aim of the study and its various implications. On the basis of this analysis, a series of hypotheses or propositions can be set forth. This suggests a particular direction – or logic – for the study. Thirdly, this logic is implemented, giving consistency to the study. Yet, it is quite clear that this process is far from being linear. On the contrary, in this process, some investigations will lead nowhere and steps backwards are often necessary. Hence, the role of the last phase – communication – is to trace back a linear and coherent path to communicate the study from its original question to its ultimate findings.

Therefore, the result of a study, similarly to that of an architectural project, is a vertical development where steps follow each other in a coherent order from initial question to the outcomes.

Inversely, research by design yields different results. From a given question, it undertakes a systematic exploration of the possible propositions. Its goal is to provide a general overview of the situation. Hence, instead of a vertical sequence, research by design can be described as producing a horizontal scope.

4 DIFFERENCES

This reasoning will be made more explicit here with the case of the study carried out in the European Quarter of Brussels.

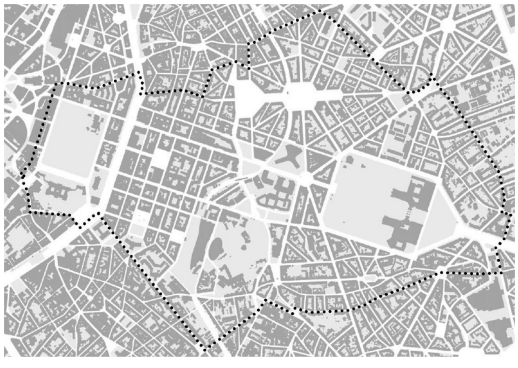

Figure 3. The European Quarter of Brussels.

The European Quarter is a district set east of the historic centre between two major parks, the park Royal and the park Cinquantenaire. This territory represents the perimeter on which the question of the residential attractiveness is investigated.

The differences between research by design and study are explored in the dissimilar outputs they deliver when treating the question of residential attractiveness. This comparison was made possible thanks to the disinterested environment provided by the university. Hence, coupled with the actual study commissioned on the European Quarter, the team of architects pursued the issue of residential attractiveness from the academic standpoint of research by design.

4.1 *Research by design*

As stated above, the LAPs lists two complementary operations in order to carry out research by design: revealing possible logics of habitat and ordering those logics according to their inherent attributes.

4.1.1 *Revealing possible logics of habitat*

On the basis of this strategy, various logics of habitat can be brought to light

The first underlying logic would be to build on the existing major networks of the district. Those are the institutional road axis of the city. Hence this logic could be called "the city as a program". And effectively, the main buildings attached to this logic are essentially institutional ones (e.g. the European and the Belgian parliament, the European Commission and the European Council buildings, the royal palace …). Furthermore, the parks that are articulated to this logic are very formal and give an impression of carefully orchestrated order, once again referring to an institutional character.

The second logic that could be built on is a series of features prior to the erection of the city such as topography and natural elements. As was the case with the first logic, a sequence of networks in the neighbourhood are organised according to this logic. A number of buildings and parks are also fabricated in relation to this particular logic. They develop in a more organic manner along the Maelbeek valley, a small river that once ran through the area. According to the nature of those elements, this logic could be entitled "the city as a natural framework".

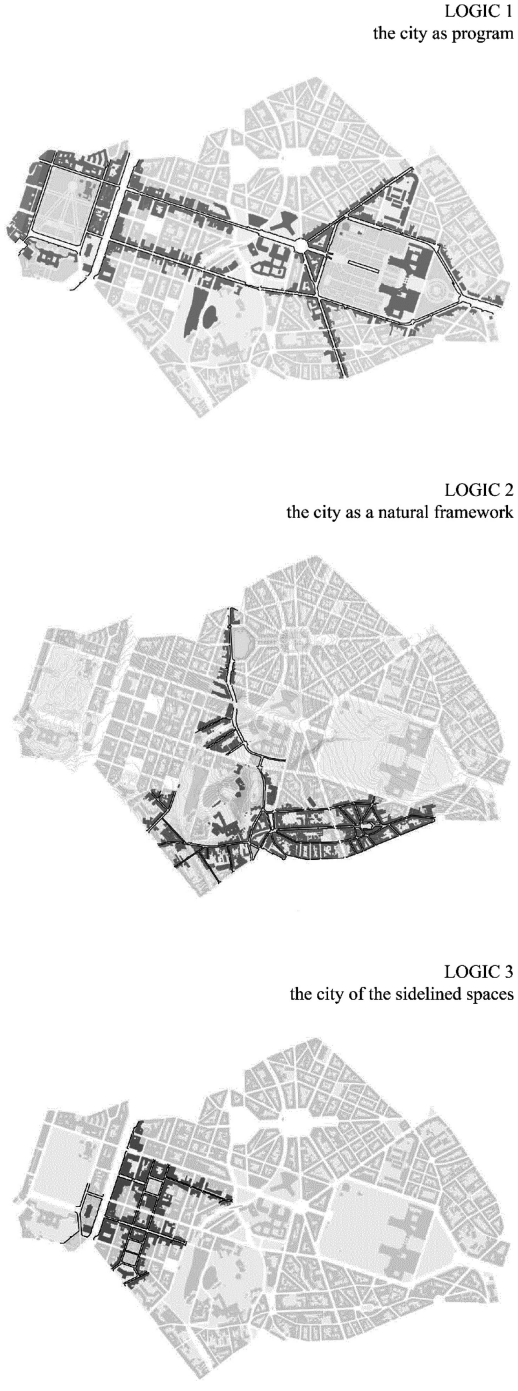
Finally, a third logic organizing habitat in the neighbourhood would be the one arranged around the leftovers, the side-lined spaces of the city. A logic that would fit in the cracks of the two preceding structures. In that regard, the ancient Quartier Léopold is very interesting since it assembles numerous spatial bodies responding to this logic. Once again those can be categorized in road networks, buildings and green spaces.

As stated before, there might be other possible logics organizing habitat in the neighbourhood. Research by design should challenge those three logics in order to uncover them all. For the sake of this paper, this array will be regarded as complete.

4.1.2 *Ordering the unveiled logics*

Once the array of logics has been revealed, the second operation of research by design would be to order them according to their attributes in terms of character as well as their implementation conditions. In order to do this, each logic is tested according to the kind of interventions it produces. Hence, within each logic, a series of fictitious projects are drawn. In addition to this, the real projects in the area are listed and analysed. Together, those two types of projects help understanding the nature of the possible logics of habitat in the European District.

The first logic – the city as program – generates larger-scale projects of a highly institutional nature. It is the case among fictitious projects. Those include the covering of the inner ring road of Brussels with a market hall bridging the district to the old city centre, the creation of a gigantic winter garden on the mail running in front of the European parliament to enhance some kind of public life in a usually deserted space …



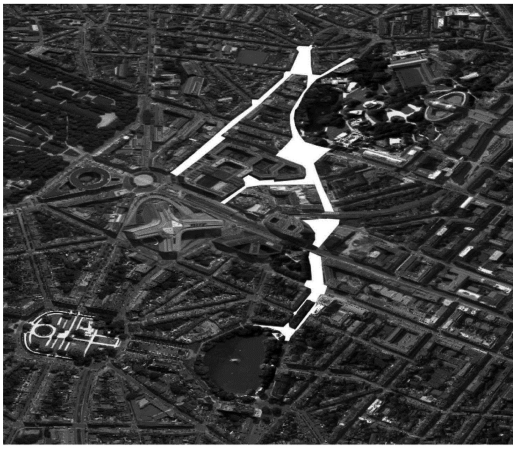


Figure 4. Logics of habitat.

The same nature of interventions can be found in the actual projects carried out in some parts of the district. It is the case for instance with the PUL (*Projet Urbain Loi*) led by Christian de Portzamparc, or the development project for the Schuman roundabout by Xaveer

LOGIC 2
a network of parks along the Maelbeek valley

LOGIC 3
soft strategies for the Montoyer street

Figure 5. Illustrations of the logics of habitat.

De Geyter facing the Park Cinquantenaire. All of those institutional projects require large amounts of funding, extended political support, and a considerable period of time.

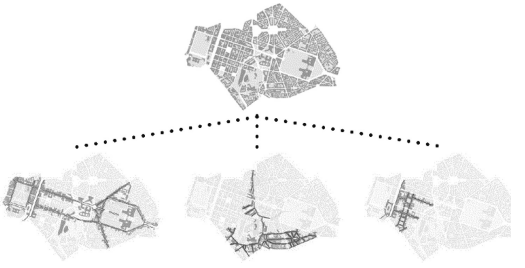

Figure 6. An array of possible logics of habitat.

The second logic – the city as a natural framework – relies on the pre-existing natural infrastructures of the city. Among fictitious projects, a new park system could be imagined, running along the ancient Maelbeek river bed. Not only would such an intervention create an overall structure for the district but it would also set forth a series of opportunities for local projects. Those projects are built on the natural structure of the valley. Once again, real-life projects can also be identified as referring directly to this logic. It is the case with numerous small to medium-scale housing projects as well as the redevelopment of the general accesses to park Léopold, an ancient landscape park set in the heart of the district, in the shadow of the European parliament. By analysing those various designs, the second logic can be qualified as more organic since it refers in the first place to what existed prior to the city. In terms of implementation, the necessary resources are less considerable both in terms of means and stakeholders.

The third logic – the city of the side-lined spaces – is based on scattered opportunities and specific local circumstances of the district. A series of fictitious projects were designed for various neglected public spaces (streets and squares) as well as buildings. Once again, an investigation into real cases provides information about the nature of this third logic. In this case, the interventional means and stakeholders are more flexible and the timeframes are reduced. Most projects are conducted by local associations.

4.1.3 *Overall picture of the possible habitats*

As illustrated above, the research by design process carries out two kinds of operations: identifying the possible logics of habitat and classifying those logics according to the intervention they produce.

Those two operations generate a comprehensive overview of a specific situation. Hence, in our particular case, the knowledge of the built and unbuilt structures of the European Quarter and its conditions for future evolutions has been brought to light by architectural design's specific means.

4.2 *Study*

The study, on the other hand, adopted a very different position. While research by design produces an array of potential logics of habitat, a regular study pursues a particular logic in order to produce a specific

Figure 7. Communicating the findings through a set of coloured postcards .

intervention. This choice is directed by several factors: the commissioner and the nature of the study (global, local, prospective vision …), the practical and financial feasibility, the personality and the expertise of the author…

4.2.1 *The European Quarter study*

In the case of the European Quarter study, the nature of the commissioner as well as the available means led the team to work on design schemes relating to the third logic.

As previously stated in the introduction, a sociological as well as a spatial analysis of the district was carried out prior to the design phase. Based on this in-depth analysis of the district, a series of neglected spaces and buildings were selected to be worked on. For each one, a drawn proposal was produced by the means of architectural design. Then, in order to evaluate and communicate the implementation of the designs, each scheme was summarized on a project sheet listing the location of the intervention, its socio-demographic dynamics as well as the potential stakeholders and the means to implement the design. Finally, in order to communicate the findings of the study, a set of postcards was produced representing each of the interventions. These are treated as ancient coloured postcards as if the future of the district would somehow reflect the bright past of the neighbourhood.

4.2.2 *A specific strategy*

As the foregoing clearly shows in the case of the European Quarter, the principles of the commissioned study differ significantly from those of the research by design carried out in the University.

The study produces its own *modus operandi* in terms of method and communication in order to generate findings. Similarly to an architectural project, it is a subjective investigation taken from the initial demand. Ultimately, the study tries to answer a specific request and its value can only be judged by the satisfaction of the commissioner. Hence, whereas research by design was trying to probe the potential of a specific situation, producing an array of possible logics, the study provides the commissioner with a specific solution for a particular situation.

5 CONCLUSION

The analysis of this particular case study helps underlining the main differences between research by (through) design and study. To conclude, those differences can be summarized as follows.

Firstly, the two notions differ in terms of framework. On one hand, to be conducted properly, research by design should not be affected by the contingencies of the commission. It is preferably carried out in the disinterested environment usually provided in universities. On the other hand, the study is accomplished within the limits of a specific assignment. Such studies are usually carried out in the framework of a "studies office".

Secondly, the concepts diverge in terms of generalization. Indeed, research by design proffers a holistic approach of a specific situation which can hence be helpful for orienting strategic visions of development. On the contrary, a study focuses on a specific and pragmatic proposal. It can thus serve as a lever for implementing particular projects. As unambiguously stated by Jeremy Till, research needs to be systematic while study (or project) needs to be thorough (Till, 2008).

Thirdly, research by design and study are different regarding reproducibility and communicability. Indeed, by definition, two operations are required in the case of research by design: unveiling a series of potential habitats and cataloguing them. Those operations try to be as exhaustive as possible. Henceforth, not only does it permit, but it requires a critical peer-reviewing to be as complete as possible. On the other hand, the search for reproducibility is important in the case of a study in order to communicate the findings in the most coherent fashion.

Fourthly, while the cumulative nature of the process is a fundamental feature of research by design in order to produce a critical array of potential habitats, this feature does not seem necessary for a study.

Finally, the two notions diverge in terms of falsification. By their very nature, the findings as well as the method of research need to be tested rigorously in order to verify the consistency of the knowledge brought to light. In the case of a regular study, no subsequent verification is needed when the findings meet the initial request as well as the satisfaction of the commissioner.

In view of the discrepancies highlighted above, the two notions should be adopted for very different purposes. They afford the opportunity to formulate innovative groups of stakeholders to address issues at various scales. Therefore, a careful distinction should be made between research by design and study since a lot of work labelled as research by design should

probably go under the name study. Once the two notions can clearly be distinguished, their benefits will be more acute and hence of greater value for one another. To this end, architecture academics and practitioner should find some common ground instead of ignoring or using improperly each other's work.

Design as research: A new trend in architectural design in the United States

F. Lian
Harbin Institute of Technology, Harbin, Heilongjiang Province, China

Y. Song
Texas A&M University, College Station, Texas, USA

ABSTRACT: This paper introduces "Design as Research," a new trend in architectural design in the United States. With this concept, the design procedure can be perceived as a research project, and design strategies are made based on the evidence of research results. It has been applied broadly and developed fast in architectural practice.

The authors conduct a literature review on the history and development of *Design as Research* and its application. The key events include the rising of Caudill, Rowlett, and Scott which started the architectural programming in the 1960s, the empirical study *View through a window may influence recovery from surgery* by Roger Ulrich published on Science in 1984, and the formalization of Evidence-Based Design in 2003. The application of the concept in practice can be categorized into three ways: (1) scholars providing supports to design firms; (2) devoted research center/department of design firms; and (3) collaborative projects between design firms and research institutes. For each category, examples with details are provided.

The authors discuss the possible misunderstandings of the concept and discuss the challenges for future development. *Design as Research* requires the transition of relationship between design and research, which is a substantial change with design mode. It emphasizes the uniqueness of each project; therefore design should adjust to different needs accordingly. Also with the new trends, architects do not have to be specialized in a certain area but with strong ability of finding problems, solving problems, and collaborating with multi-disciplinary teams.

With rapid development, the pros and cons of an architectural design project may depend on the degree of mastering and controlling the design-related knowledge in some extent. This paper suggests the significance of the approach of *Design as Research* which could be potentially wide used in both developed and developing countries.

1 INTRODUCTION

Making design decisions through the evidence from research have been used in architectural practices. In recent years, some design theories clarified the definition and collaboration method of "Design as Research", which broadly applied in healthcare, education, and office architecture. This paper will introduce the concept and development of Design as Research with practical examples in the United States, then discuss both pros and cons of this new trend on architectural design industry, and provide the guidance to future development and reference to other regions, especially where the architectural industry in transition to scientific and research oriented.

2 LITERATURE REVIEW

The authors conduct a literature review on the history of *Design as Research* and find three key events during its development: (1) Rising of architectural programming; (2) Beginning of the empirical study; and (3) Formalization of Evidence-Based Design.

2.1 *Rising of architectural programming*

It was not rare to analyze the site, resources, user group during an architectural design process, and such analysis involved certain research methodologies. The Caudill, Rowlett, and Scott (CRS) was the first firm to accentuate the importance of research work during the design process and independence the architectural programming from other types of work in the mid 20th century. The firm was famous for providing functional solutions, including the project budget, schedule, and analysis, rather than innovative architectural styles (Kliment, 1994).

2.2 *Empirical study of the impact of window view*

The study *View through a window may influence recovery from surgery* by Roger Ulrich published on *Science* in 1984 established a new era for architectural design

method. This paper was the first empirical study in the field of architecture to scientifically prove the impact of built environment on human health and build the real connection between research and design as well.

2.3 *Formalization of Evidence-Based Design*

Based on Ulrich's study (Ulrich, 1994) and borrowed the concept from medicine, the concept of *evidence-based design (EBD)* was formalized by architect Kirk Hamilton in 2003 (The Center for Health Design, 2008). The EBD inquires designers to make decisions "based on the best available information from credible research and evaluations of projects" (Hamilton, 2003, pp.18). In less than 13 years, which can hardly be counted long but definitely with fast development, many practitioners have designed healthcare projects with such principles and accumulated the new evidences.

3 EXAMPLES OF PRACTICES

The model of design as research have received attention from architectural design industry in the United States during the last decade, which impact on multiple building types such as the healthcare, education, office and commerce. The idea of acquiring the new architectural design evidences through research promotes the revolution of design process and then change the whole architectural industry. Currently, the trend of design as research in the United States can be found from: (1) more and more individuals and institutions with research background directly participating in or collaborating with design practices; and (2) design firms setting up specialized research groups to support design projects. We category the design firms involving research into the following three categories:

3.1 *Experts or research institutions provide research support to design firms*

Since architects may lack of the opportunity to access to the literatures and experience of using research methods, evaluating research results, and composing research papers, a number of design firms need to accomplish research work with the help from scholars or research institutes. For instance, Health System and Design Center (CHSD) in Texas A&M University (Texas, USA) is the largest research center which is constituted by architecture and medical professionals in the world. In addition to the regular teaching and research works, CHSD provides research support to health-related design project.

Sometimes the research for a certain design project is related to other disciplines besides architecture, so design firms would like to hire experts and scholars from other fields which are involved in projects, or develop cooperation with some independent or college research institutes to seek support for research. NBBJ Architectural Design Company cooperated with John Medina, a developmental molecular biologist and visiting professor at University of Washington, in a research project in 2014. John Medina joined design and leadership team of NBBJ and use his own research achievement in the field of information reaction and organization of brain, to explore the design thought and environmental experience. The research achievement is mainly used to guide the design of medical and office buildings.

3.2 *Design firms set up internal research departments*

Some large design firms of the United States, including HKS, Perkins+Will, Erdman, CannonDesign, and WHR, perceive research as an important part of the design process and include it into the core philosophy. They conduct research and train specialized researchers by establishing research departments and providing dedicated research funds. Table 1 listed rankings of design firms by different institutions and whether or not these firms involving in research activities. For example, in 2014 American architectural design firm rankings according to the magazine of *Architectural Record*, 6 out of the top 20 firms set up internal research departments, and 8 of them had cooperated with other institutions or individuals to launch research project.

HKS Architects, Inc. is a leading design firm in sustainable and healthcare design. It set up a non-profit research department named CADRE and a team called LINE composed by researchers and design professionals from several departments, with the aim of improving designs by applying the latest technology and methods. The firm holds a design competition each year: architectural students and HKS designers from all over the world gather together to create new ideas, research, and design in the three days workshop and present to experts composed of professors and partners. HKS also established a one-year fellowship program to discover and encourage talented graduates to carry out researches on healthcare environment. Another outstanding sustainable design firm, Perkins and Will, positions itself to research-based architectural design firm directly and clearly. It set up the non-profit research department named Area Research as a platform to connect designers, scholars, and research institutions and carry out innovative research to improve the living environment.

Since more and more design firms begin to establish research departments and recruit research personnel, architectural doctorate graduates in the United States are no longer limited to looking for jobs in the increasingly saturated academia; research or collaborated design-research positions of design firms become another options. If continuously developing, this trend will change the connection relationship between architectural education and the industry; the education, especially the higher education, and the market and industry will be tightly connected.

Table 1. The application of design as research among top design firms in the United States.

■: Yes, □ : No, —: Not certain.

3.3 *Design firms and research institutes collaborate on research projects*

Another important form of design firms participating in research is to collaborate with research institutes from other study fields. The design firms can provide knowledge and technical support related to human and built environment research from the perspective of architectural design.

The research department of Perkins Eastman, Research Collaborative, collaborated with the Alzheimer's Foundation of America to develop interdisciplinary research of dementia care and pension residential design. They jointly published the white paper "Optimum design: To provide the best living space for Alzheimer's disease and other dementia groups" in 2014. This report lists design details and elements which should be considered for the residents with Alzheimer; can serve as a reference guide for improving physical environment design of this building type.

4 DISCUSSIONS

Although the importance of research in design have been paid more and more attentions in practices, design as research is mainly applied in the big firms or limited to the projects regarding healthcare or sustainability. Some design firms and architects may aware of the trend but be restrained by the budget, schedule, and lack of sufficient methods; others may still doubt or misunderstand the design as research. The common confusions are listed and discussed as followings:

4.1 *Whether the design as research is identically different with previous design models*

In the traditional design models, architects may look up professional journals and books, collect case studies of the same building type, and interview with clients or user groups to collect relevant design information. However, only using the existing resources is not a research supposed to be. To utilize research findings and to conduct a research are totally different concepts: Design as research not only requires the application of existing research outcomes, but more important, it asks for conceiving hypotheses of key design objectives based on literature review and evaluation, then selecting methods to conduct qualitative or quantitative studies accordingly to support the hypotheses or not, and finally forming the new knowledge from the results for future research and design. Therefore, the design as research is fundamentally different with previous design models, especially on the delivery of design process.

4.2 *Whether the design as research leads to strict standards*

New research emerges every day. Design as research emphasizes running live update among projects, which means every project should based on new research findings while the feedback and evaluation from a finished project being the next new research findings. So the design as research will provide the powerful reason to help correct the out-to-date standards rather than been restricted. The design as research also accentuates the uniqueness of each project; design should be always adjusted to meet various needs.

4.3 *Whether the design as research weakens designers' creativity*

Architecture is perceived as a combination of science and art. Design as research is looking for a rigorously scientific method to solve the problems during design process. The contemporary architectural design need react fast and correctly towards challenges by the times, which sets higher standards for creativity. The creativity of designers are reflected from the design solutions under the limits and challenges.

4.4 *Whether the design as research requires designers specializing on certain building types*

With the information globalization, ever-changing environmental and society issues, and fast development of technology, we can expect that the future architecture will face more complicated and delicated questions. Therefore the challenges for designers are not being specialized on certain building types; instead, they will require designers with the ability of finding problems and making decisions through research and multi-disciplinary collaboration.

It is worth mentioning that two books, *Design research in architecture: An overview* (Fraser, 2014) and *The Routledge companion to research in the arts* (Biggs and Karlsson, 2010) discussing the topic more theoretically and providing examples in practice globally, which could be good references for conceiving a framework of this topic.

5 SUMMARY

In this paper we discuss about the development of design as research and its practical models in the United States. Design as research connects designers, clients, and researchers tightly, and provide user/client oriented high-quality design services, which could be a good reference for the industry in other regions, especially where architectural industry being in transformation and upgrading.

Designing a life-world for designers: A phenomenological inquiry into Weiss/Manfredi's Center for Architecture and Environmental Design building

William T. Willoughby
Kent State University, Kent, Ohio, USA

ABSTRACT: The work of Weiss/Manfredi reveals essential indexical relationships to which architecture aspires to exemplify and amplify. Through phenomenological inquiry into the design, documentation and construction of Weiss/Manfredi's new Center for Architecture and Environmental Design (CAED) building, I exposit on a work designed for designers. Taken on the whole, Weiss/Manfredi's buildings respond to contextual circumstances that inform their designs by experienced relations set between occupant, building, and context. Some of these affective relations include: connecting inside and outside through light and views, visual contact between spaces, choreographing connections within and around the building, centering the building through an active communal "heart," unifying form and event in a performative relationship, braiding new circulatory flows to preexisting paths, mediating the gap between ground and roof, and applying new materials and tectonics to existing contexts. By targeting significant spaces within the new CAED building, this essay uses phenomenology to uncover and describe these overlapping relationships.

Overall, Weiss/Manfredi has created a relational configuration shaped through space, movement, light, and materials. The building is an arrangement of affective experiences that offer agency to environmental design education. Through perception and experience, *space constitutes an affective bridge* of contextual relationships. By virtue of this insight, Weiss/Manfredi's work is not reducible to forms or images. Instead, the new CAED building is composed of indexical relationships best described through lived-experience.

This essay uncovers the affect-relations that Weiss/Manfredi explore in their work. The new CAED building by Weiss/Manfredi propagates relational interstices that support openness and creative exchange. Their architecture emphasizes the interplay of social, spatial, and material affects. Phenomenology, coupled with affect theory, is employed as a method for uncovering these experienced relations.

1 INTRODUCTION

1.1 *Lived-experience*

"Rooms must suggest their use without name. To an architect, a school of architecture would be the most honored commission."—Louis Kahn (1971).

I do not find it questionable to describe a building before it is fully occupied, since every architect and designer must anticipate and apply techniques for appreciating their designs before they are realized. Designing a building is predicting the affect it will generate for the people experiencing it. The actual has always been imagined through design.

Archimedes—whose name will be forever remembered for his water-lifting helical screw—is also known for his famous "eureka" moment. Archimedes stepped into an overfull bath, as his body displaced the water, he experienced it spill over the basin's lip—a vivid moment of physical insight and movement that answered his king's puzzle over the volume and the density of a gold crown.

Through physical insight and movement, matter may disclose ideas about the world. Archimedes was open to the affective possibilities of taking a bath. Each time we encounter the world through the powerful guise of habit, we fail to notice something extraordinary. The world contacts our body and we apply our mind to the world through daily actions. Each experience affords us the opportunity to ideate upon, poeticize, and appreciate the vagaries of matter. Like Archimedes' entering his bath, a young environmental design student enters a building rich with experiences and speculates on answers to design problems therein. The new Center for Architecture and Environmental Design (CAED) building at Kent State University is designed to compel and inspire invention through interaction.

1.2 *Affect, theories of affect, and architecture*

"Being or relating, that is the whole question."—Michel Serres (2007).

I must respectfully disagree with Elizabeth Diller who began her talk at the EG2 Conference held in Los Angeles, by declaring that, "Aside from keeping the rain out, and producing some useable space, architecture is nothing but a special effects machine that

delights and disturbs the senses" (Diller, 2007). Being more than a special effects machine, a building is an arrangement of relations affecting each occupant differently. The definitional distinction between words 'effect' and 'affect' has plagued users of English for quite some time. But architecture is not about effects, or permanent physical change in people. Architecture is an affective bridge composed of spatial and physical relationships—an intentional arrangement of varied ambiances where people interact over time and in ways that go beyond the full control or expectations of the designer.

The philosophy of affect, or affect theory, derived from the writings of Baruch Spinoza, was outlined initially by Brian Massumi in *Parables of the Virtual* (2002), continuing in Melissa Gregg & Gregory Seigworth's *The Affect Theory Reader* (2010), and with ongoing research and discussion showcased in the recent Affect Theory Conference, *Worldings|Tensions|Futures*, held in October 2015 and hosted by Millersville University. *Effects* are typically nouns, and indicate a permanent change, like the damage done after an accident. *Affect* is normally used as a verb, and therefore happens in time and has a rate of change—just like the person immersed within and living-through a building. A building affects its occupants, who are in turn affected by enclosures and openings that form varying sequences of interstices experienced over time.

Michel Serres introduced the idea of the quasi-object to suggest the interplay of forces that make an object forfeit to its context. Like a macguffin plot in a story or a ball in a game where changes in possession cause the plot or game to advance, a quasi-object—much like indexicals in language—is never totally neutral in and of itself (Serres, 2007). It is redefined each time possession changes hands. A building cannot be grasped like a ball or a button; instead, a building grasps us. So architecture may be understood as a quasi-object, an affective space or a set of indexical relations that shape society—forming a knot derived from contextual forces that altogether produce dynamic interplay. In reality, no object or building is ever settled; each is a set of slows shifting affects experienced differently every moment of our lives.

Reconciling contexts is basic to Weiss/Manfredi's approach to architectural design. Weiss/Manfredi's method winnows the many circumstances that can influence a design down to a set of affective relations that form the context the project is immersed within. I arrived at this set of affective relations from multiple sources, including a careful study of a video from the January 17, 2013 competition presentation by Marion Weiss and Michael Manfredi at Kent State University, their design update on January 16, 2014, close analysis of earlier works, and various statements underpinning the firm's oeuvre. These experienced relations include: connecting inside and outside through light and views, visual contact between spaces, choreographing connections within and around the building, centering the building through an active communal "heart," unifying form and event in a performative relationship, braiding new circulatory flows to preexisting paths, mediating the gap between ground and roof, and applying new materials and tectonics to existing contexts. In the following pages, I employ phenomenology to uncover these overlapping affective relationships by describing significant spaces within the new CAED building.

1.3 *The Life-world and Designers*

"The rooms which one likes to inhabit are never those which the architect conceived with that intent, but the corridors, the stairs, the antechambers . . . Habitable space is relational space. Bridges. Where we cross, from where we see, where we dance."—Michel Serres (1975).

Derived from outward phenomena, perceptions are embodied and therefore personal; but perception is also social—perceived by many over time and in space—and therefore part of a larger phenomenological identity defining the intercourse of things, events, and involvements we call culture. It is within the complement of these levels—or overlaid plena of differing experiences—that we have what Edmund Husserl termed *life-world*. The life-world is a series of strata that coexist and intermingle in the realm of human perception. The life-world is within the filament of relations that any context endows upon us and taken as multidimensional and layered. So, the life-world encompasses our everyday sense of the world and the way it is structured. A life-world, in order to be rich, must be varied and shot through with possibilities that open us up to creative action—it must be inconclusive and open to discovery, spontaneity, and deep interpretation.

Space is social. Spaces are variably charged with social energies that remain inseparable from the experience of the space. A building is an active involvement, not an object to be admired distantly. Architecture, or buildings in general, exists as a stratum between the material aspects of the natural world and consciousness. Architecture is a performance of affects. It is only through our active participation within or around a building—to affect and be affected—that we can truly phenomenologize its worth. Our bodies, and therefore our buildings, are the sum of their affects.

The life-world of a designer inhabits a slightly different 'everyday' since the daily activities of the designer includes questioning the order behind the things with which humans participate. The designer's perceptions should go beyond the habituated and terse use of a given stratum of the life-world. The designer contemplates upon the very production of that stratum, including considerations of its relationship to all the other strata that define a human's life-world.

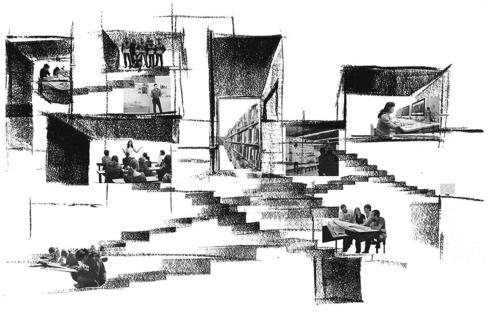
Designers work by breaking down the prescribed features of things, drawing the relation between things into question, connecting the unapparent together, and creating the potential for new things to emerge. So places endowed to fit with the designers purpose would

differ from the spaces for everyday use in certain ways. A space for designers should form variable bridges and break down the prescribed feature of things, challenging basic assumptions about space, social structure, and material things.

2 THE NEW CAED BUILDING

2.1 *Affective architecture*

"[R]elations that connect experiences must themselves be experienced relations, and any kind of relation experienced must be accounted as 'real' as anything else in the system."—William James (2006).



For Weiss/Manfredi architecture is an interplay of spatial, social, and material affects that change over time. The CAED building by Weiss/Manfredi produces and is produced by affects. The designers have created an overall configuration of affects shaped through space, movement, light, and materials. Affect is directly relational; affect implicates the affected as two sides of the same event (Massumi, 2015). Affect extends from the body's ability to act and constitutes *immediate experience as experienced* before reason or language. A building or an environment that inspires us to act aspires to become a universe of affections.

About 60 years ago, a group of vocal and ardent architects advocated that fellow practitioners should "articulate the in between" (van Eyck, 1962). Practitioners such as Herman Hertzberger, his mentor Aldo van Eyck, and other Team 10 members like Alison and Peter Smithson pointed toward a relational architecture of the "doorstep" (Smithson, 1968). Human interaction and innate patterns of association, if taken altogether and interacting through design, can multiply the qualities of a particular place. In other words, architecture should be approached with the same sensitivity and grace found in human culture. Just like societies, buildings are about qualities and affects, not quantities and facts.

The new CAED building can be understood best phenomenologically—as affective relations experienced in the spaces between its physical construction and the particulars of its social program. Architecture is forming a thoughtful space where two people can meet in purposeful exchange. But the new CAED building does more than reify structural anthropology through design. Weiss/Manfredi's work demonstrates that a building is a framework of affects operating within the larger context of human, material, and environmental associations. Their approach to design acknowledges that buildings are participatory experiences, acquired through the actions of the occupant, and inherently uncertain—both the happenstance of the encounter and the geometry of those encounters are arranged through architectural design. In the case of the new CAED building, the design uses the program to bridge between the Kent State University campus and the community of Kent, Ohio. The building's internal activities, displayed outward to the city and adjacent esplanade, connect two adjacent contexts laterally— binding the campus and city together at various scales.

Vertically, the floor levels interact by lofting the space between and stitching those levels together through variously configured stairways. Overall, first impressions of the scheme suggest a simple free-plan, reminiscent of Le Corbusier's century old proposal *Maison Dom-ino*, where structure blandly forms space and partitions distinguish and define the program. However, the CAED building stages the pretense of openness and flexibility, belied by the location of the systems and the tight fit of furniture systems that make reconfiguring spaces improbable.

Achieving an open flexibility between structure and program is not that simple. As Louis Kahn said in his 1971 AIA National Gold Medal acceptance speech, "A plan is a society of rooms. The rooms relate to each other to strengthen their own unique nature" (Kahn, 1971). In the CAED building, the designers adjusted each discrete space to accommodate its neighbor, while trying not to compromise the integrity of the overall space.

2.2 *A reconciliatory approach*

The building closest to the new CAED building in Weiss/Manfredi's repertoire is the Barnard College Diana Center, completed in 2010. The red enameled glass panels suggest the brick masonry of adjacent buildings. The Diana Center's variable facade, its urban alignments, its contribution to adjacent urban spaces, and its command of views both inside and outside are a manifold combination of strategic responses to cues taken from the campus and surrounding city.

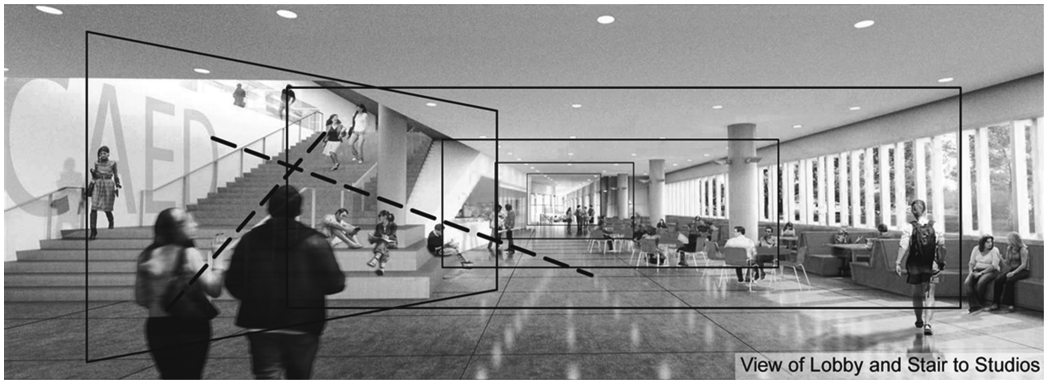
With a similar deference to context, Weiss/Manfredi's Women's Memorial and Education Center from 1997 retains the monumental semicircular exedra of the existing entry to Arlington National Cemetery. Their simple strategy preserves the original sculpted retaining wall, carves out programs spaces behind, and creates a transparent building that mediates between old and new. Their Seattle Art Museum & Olympic Sculpture Park completed in 2007 links the city to the shore of Elliot Bay while bridging above the existing road infrastructure. By yearning to span the gap, the building reshapes the two places it connects.

View from Northeast

In these three examples, we see prepositional strategies that accommodate new programs *between*, *behind*, and *above* their settings. Weiss/Manfredi's architectural strategy could be called an *art of prepositions*. In just about every example, their buildings reconcile themselves to contextual cues, fulfill a lack with new programmatic uses, or configure some social or material potential in a given context. By bridging city and campus, the new CAED building activates an interstices between the two—putting into play a set of prepositions that conjugate elements from the surrounding context together by forming a relational middle-ground. The building is not asserted on the land arbitrarily. Instead, the building is implicated, or folded, into its context—wheedling into the adjacent architecture, landscape, and preexisting paths surrounding the site. The new CAED building struggles to assert its own visual and programmatic identity while also seeking to support multiple associations within its given context.

2.3 *The landscape and the lobby*

The northern length of the building's ground level is public and parallels the shallow slope of the esplanade. The east entry opens onto the main stair seen across from, and cattycorner to, the main flow of the lobby. The stair ascends to the administrative offices and studio lofts above. Classrooms, a cafe with openly distributed seating, an adjacent gallery with adequate space beyond it to host receptions, a main lecture hall with a loosely defined lobby, and the library with various open study areas flank the ground level along an axial vista that widens toward downtown.



The rotund lecture hall centers the entire ensemble inside and out, forming an active and communal "heart" to the CAED building. The large lecture room's curving glass wall cradles the speaker and audience inside, and simultaneously curves outward, delving into the lobby with a graceful bulge. Curving space on both sides provides a lesson in reciprocity—offering the flexural experience of two curvatures in one element (centrifugal and centripetal)—and demonstrating how the curve of a wall can reverse affections between places—gathering and dispersing depending on which side you occupy.

The lobby increases in volume enough to accommodate a mezzanine. Like a solid ribbon, the masonry defiantly ascends along the north facade, flowing upward along the run of stairs, and connecting the studio lofts together. The technical logistics and the concealed tonnage of steel required to float a masonry facade contradicts the material choice—challenging our natural sensibilities regarding, weight, gravity, and groundedness. Custom masonry shapes protrude from the ribbon facade, forming fins that striate the facade with vertical highlights and shadows. The fins establish an alternating pattern, spaced out horizontally through a sliding sequence of 1, 1.5, 2, and 2.5 bricks in a course, laid out in a vertical stack bond pattern. The coursings shift and slide by one another in horizontal bands, composing a polyrhythm of alignments and misalignments.

At the west end, the facade continues to cut back along the same angle, raking up higher, and allowing daylight to enter the library, mezzanine, and faculty offices on the second floor. By standing at the triangular apex of the projecting light monitors, we can experience the masonry wall beyond its outer edge—making for an uncomfortable but revelatory experience that places the occupant simultaneously inside *and* outside, looking backwards at the building.

2.4 *The library and study spaces*

The layout of the library and study spaces follows the example of Aldo van Eyck's Municipal Orphanage near Amsterdam: make each inbetween space into a place, and design each place as if it were a bunch of places (van Eyck, 1962). The library acts as both terminus and hinge, allowing views outward to the city but also connecting spaces above and around the book

View of Lobby and Stair to Studios

shelves into an interrelated and varied whole. Adjacent study areas are both nestled and open, allowing for solitary, small, or large group study.

Situated above the book stacks, open to the lobby below, accessible long a flowing stair, and just below the faculty offices on the second floor, the mezzanine doubles as a materials library and small group meeting space. By being intimately separated but outwardly connected, the open mezzanine transgresses boundaries in ways attuned to enriching social interaction.

Similarly, the new CAED building will display its social interior outward to the esplanade. Like a *tableau vivant* depicting its narrative through silently related gestures, the library, lecture hall, gallery, cafe, and lobby blend and present together a larger center of action. Visible from the adjacent esplanade, students will be able to view in at night and see the building's inner story unfold. Like Hertzberger's "realm of the threshold" (Hertzberger, 1991), this relay of relations throughout the ground level presents a dance of agency and affect, with exchanges between its occupants choreographed through connections in space.

2.5 *Lateral learning*

In their public presentation during the 2013 design competition, Michael Manfredi spoke about "peripheral vision" in the studios. I take this to suggest that we learn out of the corners of our eyes. Manfredi's consideration of "peripheral vision" is a central feature of most studio-based education; but affordance for this kind of learning is not accidental. Instead, much of studio education happens when students turn their attention away from the professor and view the work of a classmate a year above or a year below.

The configuration of the "design loft" (Weiss/Manfredi's term) performs by doing more than stimulating the occupant's peripheral vision. The layered and vertically connected spaces turn a student's attention about laterally and without hierarchy. Especially from the third floor, the lofted spaces offer multiple views simultaneously—above, below, outward to the campus, and back inward to the columned space of the floor, and upward to the ceiling, cut and folded precariously overhead, tying all the levels together along a diagonal slope mirroring the angle of the sloping esplanade.

Once in conversation with art critic Christian Zervos, Picasso said, "Artists are receptacles for emotions that come from all over the place: the sky, a bit of earth, a piece of paper, a passing figure, a spider's web. That's why they can't discriminate between things. Because for true artists, there are no places of exclusion" (Zervos 1935). Weiss/Manfredi's three-level design loft, in conjunction with the array or spaces on the ground floor, form indiscriminate *places of inclusion*—a set of places where looking, learning, making, and collaborating are all part of an inclusive, permissive, and creative mix.

2.6 *Studio lofts*

Does this building flow despite being lofted and layered? In general, can floors be connected despite being pancaked? This has been a long-standing conundrum in architectural design. Mid-20th century architects recognized that structural and functional efficiencies were not enough to accommodate humans socially. I am thinking here of solutions like John Andrews' 1972 Gund Hall at Harvard, famous for its studio "trays" overlooking its ground level critique area all set beneath a sloping illuminated roof—notorious for its leakiness.

However, as I consider the new CAED building, another light-filled example comes to mind, Sir Evan Owens Williams' 1931 Beeston Boots D10 Building. Williams' wet pharmaceutical factory uses daylight and openness to facilitate flexibility and action. Boots D10 Building flows between floors and glows gloriously at night. Similarly, the new CAED building's structured openness and infiltration of daylight from three sides enlivens the interior during the day and provide views inward from the esplanade at night.

With studios making up roughly half of its useable space, the building's overall shape is determined by the sectional strategy of the "design loft." The spatial concept connects the three studio levels into one vertically layered space. The studio lofts and intervening critique spaces showcase research and design by affording visual and physical connections between

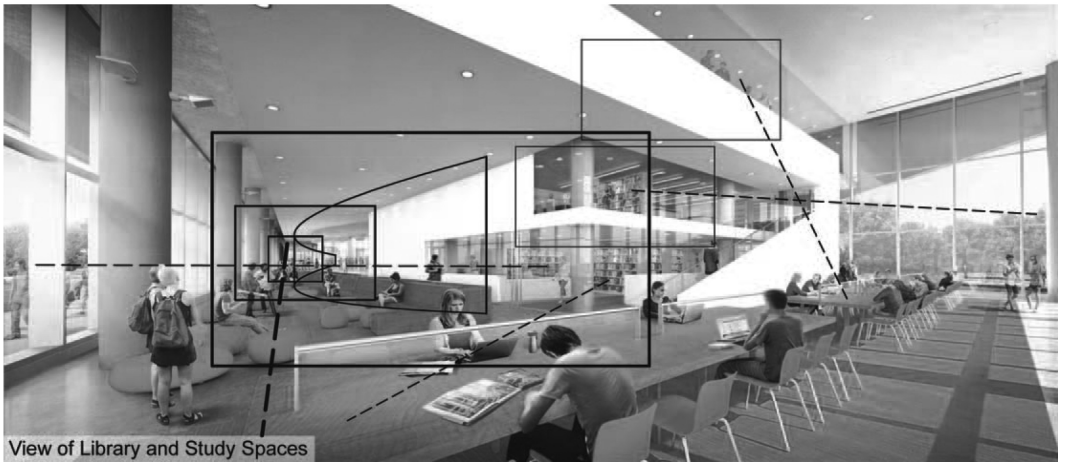
the lofted floors. The zig-zagging glazed stair that flows along the south façade—sloped and slanted with parallelogram-shaped glazing—connects all the floors together, jutting in-and-out jauntily from the stacked masonry facade. The design's three stair elements all transcend the perfunctory role of egress and combine to serve as vital connections, linkages, and circuits of flow.

The open stair skirting between the columns and the building's exterior envelope, the stacked fire stair which borrows light from outside, and the long cascading stair that dodges down the building's south facade link levels together in a manner reminiscent of the intertwining stairs in Hannes Meyer's 1926 Functionalist proposal for the Petersschule in Basel. The studio lofts, combined with the various stairs, form a powerful spatial concept whose performance derives from the potentiality, variability, relativity, and simultaneity of the relational experiences shared between floors.

2.7 *The roofscape and the sky*

Beneath the roof, the studio lofts will be suffused with light. Cut from a single sliced and bent plane, the canted monitors act like clearstories, gathering daylight from the north and east, illuminating the interior as they angle up along the lofted levels. By tilting outward in both plan and section, the monitors tie the campus to the city by opening the interior space outward. The space lifts instead of confines, stitching spaces together diagonally, encouraging occupants to move in one direction with eyes glancing in another. The person sitting down or passing through these spaces can look around variously—up or down, inside or out—always finding something new to look at.

3 DISCUSSION AND CONCLUSION



"What does it mean to create a college of architecture and environmental design? Well, it means many things. For us, I think that the spaces where we work in shape us and we are shaped by them . . . it is really a creative mess that shouldn't be so over designed as to not allow us to give it shape and measure that changes over time."—Marion Weiss (2013).

Space habituates society; so to change a society you should redefine its spaces. It is the nature of space to flow and present new encounters over time, forming an occasionally redistributed, adaptive, and memorable inbetween. When it comes to architecture, the elements from which we construct a building are sometimes static and stultifying. How to afford diverse involvements within a static container? If our buildings shape us, then how do we reshape ourselves if our building restricts us?

Weiss/Manfredi appears to dwell on this problem through their work. I believe that their architecture is no simple container of space but instead relates

View of Studio Lofts

View of Library and Study Spaces

experiences reciprocally, operating between interior and exterior, ground and sky, night and day, discrete and continuous—with open potential. This simple definition, that space constitutes an affective bridge, is their means of manifesting variable and articulate inbetween spaces. Weiss/Manfred; designed a building that compels the lazy hierarchies of tradition to split open, allowing occupants to pivot between varying choices. Their best works link an open interior of interconnected activities to an extended landscape of buildings, paths, lawns, and treescapes.

The new CAED building tangles together the varying ambiance of the day's light, students flowing in and out of the building, special events getting set up, looking at work on display, taking down exhibits, conversing in the hallways and on the stairs, eating and chatting at the cafe, designing frenetically at night, and studying silently. The place will grow in memory through lectures by celebrity designers and scholars, visits by alumni, faculty debates, tours by prospective students, shop equipment thrumming below, and people peering in while strolling along the esplanade. If taken altogether and arranged so that each activity correlates though various kinds of affective bridges, then the building will perform as a setting full of possibilities where personal meanings may be discovered but never fully defined.

The "design loft" concept is both obvious and cunning. The daylit drafting loft was an ancillary part of historic shipbuilding; its inspiration was to bring the act of drafting closer to the daylight and away from the dust and distraction of the workshop floor. By allowing overlooks between levels, Weiss/Manfredi connects students of varying year levels and majors into a single unified act of design—going from foundation design to the senior and graduate level. The space does more than demonstrate the upward lift of the loft spaces; it compels the occupant to look up and ascend the open stairs, embodying the very definition of 'aspirant' in studio education—a word pointing back to the beginning of architectural education in the Ecole des Beaux Arts.

Designers coordinate the affective energies that interact between people, things, climate, ecologies,

and material resources in a way where the dynamics of the composition equals something more than the sum of all parts. The new CAED building seeks to bridge between the designer and the world, act as a catalyst for environmental design education, and assist people entering it to appreciate each other, to appreciate building, to recognize their environmental context, and to depart and continue affecting the world.

Transition space and the image of contemporary city

P. Haupt
Faculty of Architecture, Cracow University of Technology, Poland

ABSTRACT: Once the sustainability became an important factor that had impact on surrounding architectural reality through deep changes in the building code requirements the ineluctable process of changing the cityscape began. After the initial phase, in which technology was used to improve building environmental performance the second phase emerged. Nature came back to light, and in variety of forms became a basic element of architectural composition, following its historical, utility path. Therefore there is a tendency observed to implement greenery, water, earth mass in the architectural design to support the building climatic behavior either adjacent to it, or combined in its structure, even in the interior. There are various composition relationships observed, but all of them have a common feature – they create a buffer of transition space between the building and its surroundings. This type of space on one hand interacts with the public space of the city, on the other with a building itself. It became an area for multilayer occurrences, interactions of users, nature and architecture, creating a changing image of the contemporary city. In the paper there are types of transition spaces classified and discussed along with their impact on the contemporary cityscape.

1 CONTEMPORARY CITY SPACE

1.1 *Urban space as multithread environment*

In his essay describing the nature of the city nowadays Jacek Gyurkovich states that urban space is "a natural habitat of contemporary man" (Gyurkovich, 2007). This thesis is based on Jan Turowski's opinion that man is by nature a social being, and his needs in that field are being satisfied within the city, the cradle of civilization and culture (Turowski, 2001) . Contemporary urban planning is focused not only on spatial qualities of the city layout, but also on its potentials to act as the scene of multithreaded events deriving from community's behavior patterns. The city in that case is a subject of socio-urban interdisciplinary research on both – spatial qualities of the space as well as its perception by inhabitants.

1.2 *Changes in perception of urban structure*

These changes in the perception of the city space, which can be described as the multi-threaded phenomena, not only are reflected in the spatial structure of the city, but also in the transformation of architectural forms that it is built of. Wacław Seruga observes these trends and describes them as an adequate point of reference for the research on contemporary anthropogenic environment. "The unity of architecture and urban planning as well as their mutual interdependence, studying the contemporary relationship between architecture and urban space causes the necessity of treating the issues of architecture in the urban context, and vice versa," out of which comes the belief that "there is no architecture without urban planning, equally as there is no architecture without urban planning." (Seruga, 2011) These words illustrate in practice the image of continuity and fluidity of the contemporary city and its architecture. Studying contemporary city space it is noticeable that urban structure acquires its new, hybrid form – an image created by the elements of urban composition, natural and anthropogenic – buildings and spaces. Research on the latest creations within the urban tissue shows that the buildings are no longer designed to form a figure against the background, where the external walls create a boundary to separate the internal space of the object from its surroundings. Contemporary buildings often create extended urban space by blurring the boundaries between interior and exterior space. The edge of the building becomes unclear, the city space penetrates through openings inside the interiors of the structure. Its function and spatial arrangement "flows" outward creating transition space, providing indirect contact with the environment. This is the field of most visible changes in the image of the city, as this zone is a place of interference between stable and unstable elements of composition – architecture and nature, the movement of human traffic... The area of interference described above, creates a buffer space between the city and the enclaves inside the buildings acting as extension of urban public space, making it difficult to define the limits between the building and the city.

2 TRANSITION SPACE

2.1 *Definition*

Transition space (interspace), describes the field of interaction between subject and object. This term originates in child psychology and was first used by D. Winnicott describing the area between the inner life and the objective reality, the sphere of experience. In art, site-specific, where "place" is in some way part of the creation or affects its perception – it refers to the realm of interaction between the work and its location. In architecture, it is defined as a space linking the two areas of different character, usually inside the given environment. In this context, the notion of the transition operates, among others, T. Ando. To understand the meaning of the transition space in the architectural and urban context, it is significant to identify the subject and object of the interactions, which in this case are the interior of the building and its surroundings. (Schoenholz Bee (ed.), 1999, *Tadao Ando*). J. Krenz described transition space as the area of relations between individual elements of a work of architecture, at the verge of the inside and outside world, at the junction forms and functions. He states that this is a place of the creation of messages with a strong emotional, formal and aesthetic dynamics that determine the clarity of meaning. In his opinion transition space is a hidden dimension of architecture, where the direct impact of the building on human emotion takes place. (Krenz, 2003) According to this idea the perception of architecture is not retaining on its external manifestations such as outer shell, but it allows to treat is as an integral part of the built environment.

2.2 *Factors*

New concepts of organizing urban space occurred after the public awareness of negative environmental changes have arisen. They included manifestos, principles and strategies describing how rational distribution of resources can improve the environment. The concepts also included new tasks for architecture and urban planning, with particular emphasis on urban areas. The basic idea, characterized by a very wide field of influence, which formed the basis for many followers was the doctrine of sustainable development. On its canvas, new, more targeted assumptions were created concerning sustainable design, green architecture and urban planning.

Legal requirements for modern buildings in terms of their environmental management of natural resources, led to the search for methods to reduce energy consumption and reduce carbon dioxide emissions in architecture. Initially, a remedy to improve the condition of the environment seemed to be technology – new insulation systems, maintaining comfort indoor air. However, with the growing awareness of the primary energy in the materials and ecological footprint generated during construction and the necessary transportation of materials led to the new direction of research – on the natural elements of composition. The utilitarian properties of soil mass, greenery, water and renewable as well as recycled materials was once more appreciated.

Changes in the finishing layers of the building contributed to the appearance of architecture: the characteristics of elevation, and indirectly also in its interiors. Common structural elements such as the wall and the roof or flat roof are being replaced by an integrated element of covering in the form of a green roof/wall. Traditional finishing materials are being replaced more and more by greenery, mitigating the effects of CO2 emissions or materials gaining solar energy.

At the same time there is a user-oriented tendency in the contemporary design observed, involving community in the investment process by social participation resulting in treating common areas, as a multifunctional space of a specific social importance. The consequences of these changes are visible by emerging a new type of public space – transition area. It can be described as the zone of direct contact of the building with its surroundings. This is an area of the greatest transformations and therefore it became a subject of interest for the designers and theorists.

The reinvented elements of nature have become the building substance for contemporary architectural form and compositional relationships as significant as traditional building materials. By the use of natural elements the extension of the building into its surroundings is possible. The zone of interaction between the structure and the environment is expanded especially by the use of terrain topography and green roofs. Public and semi-public space is extended onto the surface of the roofing providing a walking surface – the soft edge between architecture and nature. Green façades reach out to the city public spaces encouraging users to enter the building. On the other hand they define public space image by introducing greenery into urban environment. Urban space can also penetrate into the interior of the building in the form of open or closed courtyards, creating enclaves – an extension of the public space.

The contact zone between the building and its environment has gained importance as a place of social relations as well as interaction of man with nature in a place of residence, work or recreation.

2.3 *Tendencies*

The ambiguous distinction of interior and the exterior manifests itself in contemporary architecture, both in relationships between the building and the natural landscape, but above all, they allow the formation of a new kind of relationship with urban space. Berrizbeitia and Pollak describe and classify these relationships by studying the connections of the building with the adjacent landscape, natural or urbanized. (Berrizbeitia & Pollak, 2003) J. Rendell sees this interaction as one of the dominant features of the modern city – "the interior and exterior are intertwined together forming the fabric of the city and are again experienced as

a complementary aspect of everyday life." (Rendell, 2000) In many projects, modern buildings can be seen striving to seek liquidity in their relation with the environment. J. Gehl writes about the perception of soft and hard edges of the urban fabric. The first ones are extended transition spaces and they have ability to serve as a place of life and social contacts – the others, are lacking this capability. (Gehl, 2014).

The concept of the transition space, new to Western civilization was apparent in eastern societies. In these cultures, the man never objected to nature and did not intend to tame it. On the contrary, eastern civilizations tried to create an intimate relationship with nature. These beliefs manifest themselves in the form of traditional Japanese forms of residence lacking the separation zone between external and internal structures. Japanese architecture "pulls" the nature of the interior. There is no specific boundary between the spaces, the edge area is a place for penetration. These features can also be observed in contemporary architecture. The elements of nature are incorporated in the overlapping areas of buildings and their surroundings. They provide a composite substance for creating both – parts of buildings and the integrated urban design. They form a dynamic, variable over time, transition space constructed on the basis of the permeation layers of the architecture, nature, human traffic and communication media that results in new forms of urban area, and consequently, the anthropogenic landscape.

3 CONTEMPORARY CITYSCAPE

3.1 *Image of the city*

The pioneer theorist, author of theory of the image of the city. In his study Kevin Lynch who based his theory on the research on mental maps. This hypothesis is based on the observation that the long relationship between the inhabitant and the area of the city leads to substantial experiences, which are then stored in memory in the form of images. Lynch has separated the five basic elements of the imaginative maps – indicators (cues) of formal physical structure of the urban space. These are: landmarks, nodes, paths, edges and districts. (Lynch, 2011)

"Understanding the city and the building by the category of the landscape is a key consequence of the direction taken by the architecture of the early twentieth century (…)," says Lucyna Nyka. She adds that the changes taking place today are forming an increasingly strong and extensive trend, which identification is not easy, as it involves multi-faceted transformation taking place outside the visual language. The interpretation of urban space as a specific landscape finds its origins in the first decades of the twentieth century. Then, when the perception of the city was connected with the narration of the road, so far reserved for the nature of the term landscape, it began to refer also to the city. "Landscape of the city has all the essential features of the landscape. It is designed in such a small extent as nature (…) thus articulates in a way unconscious" writes Kracauer studying modernist Berlin. Lucyna Nyka stresses that this phenomenon coincides with the abolition of historical opposition between the object and the environment – architecture and nature. At the same time there are concepts of binding space with the community formed and indications of the role of direct experience in the creation of urban space.(Nyka, 2006) The current interpretations of the concept of the city are based on the perception of the urban space as environment. According to Lenartowicz, "the subject of architecture is the physical space of the human environment, specifically the built environment, and of which not all architects are aware, the very life of the human being is related to consciously shaped environment." (Lenartowicz 1992) One of the most important interactions of this kind is a mutual relationship between man and nature. In order to achieve and maintain physical and mental health providing a living environment that supports this relationship is crucial. Especially nowadays when more than 50% of world population are the inhabitants of the cities.

3.2 *Transition space and the image of the city*

The result of processes blurring the borders of the building and the city leads to a certain uniqueness resulting in creation of the new forms of public space, which lay in field of attention of contemporary sociologists and urban planners. Nowadays, the dynamic image of urban space, can be described as an active environment with the exposed factor of time. Most of the contemporary interpretations of the city are closely connected with the vision of their public spaces. Radical statements conclude that the buildings in urban space are one of the tools to shape the image of the city public space. It is possible by providing architectural structures with internal circulation routes and transitions spaces. They create a zone of ambiguous contact with the environment and the possibility for inhabitants to interact with the active context. They become an important component of the new image of the city. Buildings in this type of interpretation enhance urban spaces – participate in shaping their expansions and co-create their characteristics.

Such an approach to the problem makes the traditional concept of urban enclosure, as a basic element of the urban space insufficient to determine all the possible solutions in the context of the multilayered forms. Square, street, park – elementary definitions used in the characteristics of the city are supplemented by new forms of space – buildings, which provide circulation trails by creating a new topography, green spaces, vertical gardens and urban farms, intertwining with each other, creating new models of utility. Buildings may act as public spaces on surfaces of green roofs, as well as in the interiors according to their composition and methods of use. These spaces penetrate each other, and overlap with the spa the city public areas. Therefore the architectural form is created or influenced by both, the structure and urban space. This interpretation supports

the view of Jacek Gyurkovich who states that the elements of the public space of the city are an integral part of the ecological system of urban space. (Gyurkovich, 2010). Transition spaces combine elements of the variable layers, including nature – with the solid ones, such as city's spatial structure components, together acting as background for social contacts. Richard Sennett defines the city as a settlement, where it comes to meeting of strangers. (Sennet, 2009). Interaction between them occur in public spaces. Ray Oldenburg also stresses their importance. His theory of the third place, assumes the realization of human needs in terms of social contacts outside the home and work, just in the areas of accessible buildings and the city. (Oldenburg, 1989)

3.3 *Cityscape typology*

Cityscape can be described as a polymorphic structure. The dynamic image of the city seems to be the primary motive for many contemporary, even significantly different concepts. What they have in common is that they are based upon the ideas of pro-environmental doctrines including creating healthy living environment. The requirements related to the implementation of sustainable solutions in the buildings are one of the major factors of change in the contemporary built environment. They stem from the concept of protection of natural resources by placing its elements to the urban space as a tool for preventing negative phenomena. On the other hand they are the manifestation of the expanded concept of sustainable human environment, which is based on active participation in the community, and the sense of identity and belonging, as well as participation in its development. The determinants generate specific spatial forms that appear in the city in the form of pioneer images – showing contemporary trends in architectural and urban design, and thus the built environment. Nature becomes an integral part of the architectural composition. The consequence is creating forms of integrated urban landscape, built of stable and variable components. Their relationships are based upon both, the spatial and technological aspects. Transition spaces are places of connections that are created by the architectural form and the dynamic elements of the city: nature, human traffic, as well as layers of transferring meaning – events in space. Nature, understood as an element of both aesthetic and utilitarian significance, becomes the substance of composition for the fragments of the urban landscape. This happens through the introduction of elements of nature as an integral part of the building in the form of walls or roofs, and introducing them in the contact zone of the building with the environment. In this way they create technology system supporting the economy, energy and/or water management system of the building. In the big picture nature is inserted in the urban fabric as a green area associated spatially and technologically with the adjacent architecture in the form of: – utilitarian landscapes (fig.1), where the elements of nature in the area adjacent to the building

Figure 1. Utilitarian Landscapes. A. Jardin Charles Trénet, ZAC de Rungis, Paris, 2013.

are an integral part of the bioclimatic system of the building, – new topography (fig.2), where the green roof surface is used for creating an extension of the city recreational areas, – restored nature (fig.3), where degraded areas are converted into urban green spaces or in the form of "garden structures", where greenery is an inseparable part of the building, or – area for circulation (fig.4,5), where additional motion paths are created by introducing an architectural form into the city fabric, also – internal enclaves (fig. 6) where transition areas are located inside the buildings, providing natural elements in the interiors.

3.4 *Visions of the future city*

Awareness of adverse changes that results in a rapid economic boom of the last decades ushered interest in sustainable development, which gained the status of the contemporary paradigm. The answer to the problems of urbanization and metropolisation became a motive of search for a vision of the human environment. It is reflected in the form of the concept of cities of the future, often created from scratch, as means to the global improvement of the environment and the living conditions of the overcrowded areas. These projects are an attempt to answer climatic changes which are believed to be the effects of the greenhouse gas emissions. Their increased concentration in the atmosphere is credited to human activities of economic nature related to the combustion of fossil fuels, mainly coal and natural gas in particular, rising since the industrial revolution. Although the scientists' opinions on the effects of climate change are divided, it is undeniable that the growing global population, results in increasing the number of urban areas at the expense of others – used for agriculture and natural resources. This process disturbs the natural balance between the capacity of CO2 absorption, and its discharge to natural areas: the oceans and vegetation-covered parts of the land.

Scientists seek a solution to the problem of greenhouse gases in the use of alternative energy sources. An important element of this strategy is the introduction of built-up areas in the elements of nature that help maintain this balance. Looking at concepts of the cities of the future the continuous search for the solutions of the contemporary concerns is present. There designs are based on integrating natural elements into the city fabric that contributes to expansion of transition spaces as well as creating its new forms (eg. Lilypad by Vincent Callebaut Architectures or Gwanggyo by MVRDV). Visions of the future cities are presented as a form of integrated urban landscape, where architecture is unified with natural elements of the composition. (Serrats, 2011) Including them in the space of the city derives not only from the needs of aesthetic and the necessity of providing the residents with the contact with nature. Elements of nature are introduced for their reinvented utilitarian functions, among others, increasing insulation of buildings and improving the microclimate of urban space.

4 CONCLUSIONS

The appearance of the city as a dynamic environment introduces new threads to the understanding of urban space. Its physical components are the initiation stage for transformations and events. Both urban spaces and architectural objects – create a flexible environment complimented with events, traffic and media transfer layers. The transition area creates the soft edge of the city as a form of user accessible space in which elements of nature are introduced for their aesthetic as well as utilitarian properties. The buildings are shaped, as a sequence of spaces, directed by the architect. They provide the setting for the action taken by the user. Motion paths, uniting the interior of the structure with the surrounding environment are created by introducing natural elements at the level of the roof to create a new topography, either are integrated into the architectural composition. Nature can also penetrate the interior of spatial structure of the building turning it into a movement path linking interrelated spaces located on the outside and inside. The last type of relationship is to introduce natural elements to the interior of the building in the form of internal enclaves which form an extension of urban space located within the spatial structure of the building. Those tendencies observed in contemporary architecture and urban

space are also present in the future city concepts. In those designs the new forms of transition spaces occur and there is a tendency observed of softening the city edge by interfering interior space with the buildings surroundings. The city of the future therefore may be described as an organism of the multilayered, polymorphic structure.

Between research and teaching: Green infrastructure for dense urban areas

A. Magliocco & K. Perini
Department of Sciences for Architecture, University of Genoa, Genoa, Italy

ABSTRACT: The debate about climate change – aside of the question whether it is caused by human or natural factors – must become central for architects. The city of Genoa (where the author's institution, the University of Genoa, is located) has seen two floods in the last five years cause serious damage as streams, mostly channelled in tunnels, crossed the urban tissue. In this context, interesting opportunities arise to work with students to redesign of urban spaces in order to integrate green infrastructure strategies and reduce runoff. This work is particularly interesting because it addresses several fields, including the future of depopulating cities, urban structures' resilience, and the relationship between buildings and open spaces, among others. This paper shows some results of teaching activities on the integration of green infrastructure in cities, considering areas affected by minor floods due to rainfall causing rainwater sewers overflow.

1 INTRODUCTION

Often, architecture is identified as the work of a "genius", a professional characterised by both technical and artistic skills, able to realise his or her vision of the world through buildings of significant interest from several points of view. This way of viewing architecture is not new, but it has in recent years become dominant in the media and among the general public. In Italy, this type of architect is known as an "archistar;" elsewhere, the term is "starchitect" (The Oxford Dictionaries report that "starchitect" has origin in 1940s denoting a film star who designed a house).

Students often view the starchitect as a model, a kind of idol, and indeed, the work of architects is very important even when it doesn't qualify as work of artistic importance. Their role can be remarkable in our society, and is wider than simply that of "shapes generators".

There have long been more than seven billion inhabitants on this planet (The United Nations estimated seven billion people at the close of 2011). Environmental imbalances caused by human activities are now revealing long-feared dangers: cities are being transformed alternatively by overpopulation or abandonment dynamics causing patterns of both transformation growth and shrinkage (as stated in the ERA-NET Cofund Smart Urban Futures ENSUF research program).

Architects must be called upon to solve the problems of our civilization, to the extent of their competence. Sometimes the solution is designing a building, sometimes times not.

The educational project of the authors' group begins from this assumption. Many students understand that their professional future will be tied to the processes of urban space transformation that are dependent on demographic and socioeconomic dynamics and by the environmental management processes of sustainable development. Taking a practical approach when speaking about "urban resilience" (as much as possible in a teaching environment) is very important, especially in relation to the authors' backgrounds and roles in university education.

Two basic elements allow the identification of educational issues closely linked to research activities in progress, the need to adapt urban spaces and infrastructures to:

- the processes of economic change that are taking place, especially in post-industrial cities like Genoa; and
- climate change that (regardless of cause) impacts this article's study areas with increasingly sudden and intense weather events that result in property damage and even human injury and death.

So-called "blue and green" technologies (i.e., water cycle management and ecosystem services related to urban greening) are certainly not new but have been little studied in Italy outside of hydraulic engineering and urban planning research (and certainly not in Italian urban design, with urban green areas rarely designed to optimise environmental performance).

Interest in environmental quality and the tools for quality improvement must be encouraged, and it is by the authors, who have noted positive feedback from some students. This issue is highly multidisciplinary, or perhaps even "trans-disciplinary", according to the meaning given by Edgar Morin (1999) that holds that an economist who is only an economist is not a good economist. This issue is also really trans-scalar. This designation speaks to what is sometimes a problem

in the Italian academic environment, where educational practices are divided in "scientific fields" with each sector assigned to a specific scale: urban scale to planners; building to designers; and details to technologists, etc. Thus this "teaching transgression" becomes one step closer to professional practice, which is notably absent from the teaching of architecture in Italy.

2 BEFORE THE THESIS

The authors' research group's interest in green performance in the urban environment dates back several years (Katia Perini PhD thesis "The integration of vegetation in architecture. Innovative methods and tools. 2009–2012"). Educational activities have intensified in recent years as the construction of the first green façade on an office building in Genoa. In October and November 2014, a green facade was built on an office building owned by the National Institute of Social Insurance – Istituto Nazionale di Previdenza Sociale – in Genoa's Sestri Ponente district, an area characterised by relatively high population density. The first results of air quality, fine particle retention, and energy performance monitoring designed by the authors and implemented in collaboration with various research organisations (RSE SpA Research on Energy System for energy monitoring, Città Metropolitana di Genova for NOx monitoring) have stimulated students' interest in green technologies, which we consider both architectural elements and a means to improve air quality.

Four of five Europeans live in urban areas where quality of life is directly influenced by the state of the urban environment. Environmental problems within cities have significant consequences on human health, citizens' quality of life, and urban economic performance (COM/2005/0718). High levels of pollution in the atmosphere and excesses of "cementification" and low-albedo asphalted areas, relative to green areas, cause the urban heat island phenomenon. Temperature difference between cities and suburban or rural areas are between 2 and 5°C (Taha, 1997). Several studies show that this phenomenon causes damage to human health, especially during summer periods when air temperatures remain high at night (Taha, 1997;Tereshchenko and Filonov, 2001). High urban temperatures have caused in Europe drastic increases in the use of cooling systems and consequently fossil fuel sources. This is a particularly important field in the creation of a more sustainable environment because buildings, in Europe, consume about 40% of the energy used (IEA-ECBCS, International Energy Agency–Energy Conservation in Buildings and Community Systems, Annual report 2012).

To reduce this phenomenon, huge quantities of solar radiations have to be intercepted before reaching buildings and roads, or dissipated, possibly through the use of green systems. A study conducted in Florence, Italy, shows the impact of green areas on air temperatures inside the city, concluding that temperature distribution is related to distance from the city centre, the mean number of buildings per square metre, and their height, and that higher air temperatures were found in the city centre. Within green areas located in the city centre (such as parks and gardens), lower temperatures were recorded as compared to the street (a difference of 1.5 to 2°C, Petralli et al, 2006). This happens because greened surfaces have high concentration of water and different albedo values than artificial hard surfaces (Taha, 1997). Within urban areas, the impact of evapotranspiration and plant shading can significantly reduce the amount of heat that would be reradiated by façades and other hard surfaces (Scudo and Ochoa De LaTorre, 2003; Shashua-BarandHoffman, 2000).

The effects of vegetation on microclimate and comfort can be evaluated using environmental modelling conceived to understand many of the current environmental problems; it allows researchers to quantify the effects of zone changes (land coverage) on meteorological parameters and on quality of life consequences through microclimate models such as ENVI-met (Nardino and Georgiadis, 2011).

Students encounter green areas design, or green infrastructures, in a studio conducted by the authors with other teachers and professionals during the final year of their architecture Master's program as an alternative to courses focussing on issues of restoration or architectural composition.

The course is a studio of technological design for architecture called "Project Technology Environment" and dealing with themes of varied complexity where the design of green areas is complementary to the design of new buildings and/or renovation of existing buildings. These students mainly focus on environmental performance (quantitative evaluation of thermal comfort), and material choice, and use ENVI-met software to evaluate cities' effect on their microclimates (figure 1, figure 2). In fact, the results of a research conducted by Yang, et al. (2013), show that the ENVI-met model is capable of reasonably modelling the diurnal thermal behaviour of different ground surfaces and their effects on local air temperature and humidity. ENVI-met is a three-dimensional microclimate model designed to simulate the surface–plant–air interactions in urban environment with a typical resolution of 0.5 to 10 meters in space and 10 seconds in time. ENVI-met can be used to evaluate the effects of vegetation on outdoor comfort and urban heat island mitigation (Bruse and Fleer, 1998). Krüger, et al. (2011), observe and estimate the relationships between urban morphology and changes to microclimate and air quality within a city centre. Ali-Toudert and Mayer (2007) analyse the relation between outdoor thermal comfort and the design of an urban street by using ENVI-met, finding that vertical profiles and different orientations of street have a moderate impact on the air temperature and a strong effect on the heat gained by a human body; that is, the larger the opening of the canyon, the higher the heat stress.

Figure 1. Urban area students design.

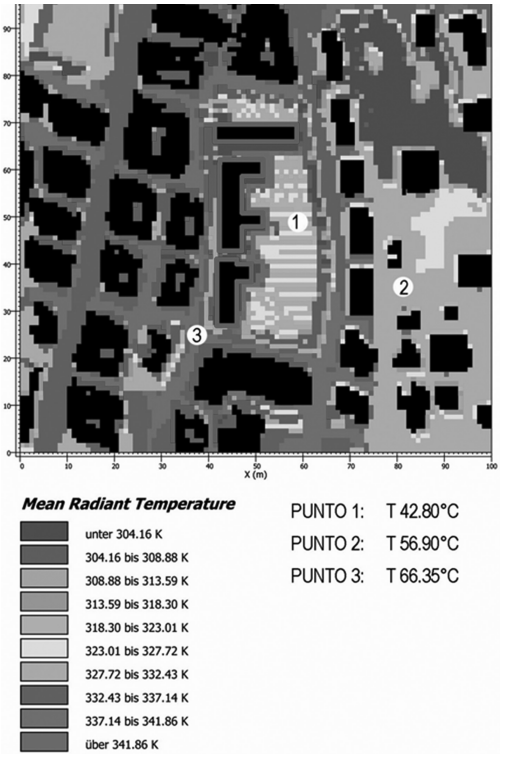

Figure 2. ENVI-met analysis of the above urban area (mean radiant temperature).

Students design green areas on the basis of aesthetic, or at least functional, criteria, but the functions considered are limited to the integration of artificial elements (paths, parking areas, etc.). They usually simply study vegetation's capacity to shadow, but in some cases use, for example, solar cards to correctly draw that capacity. The ENVI-met software allows a quantitative assessment and is useful, beyond the results, because it allows students to understand how physical phenomena can change the usability of an area and interact with the environmental performance of the buildings. Through the use of ENVI-met, students consider soil permeability and the evapotranspiration phenomenon of vegetation, essential elements of the water cycle in urban environment.

3 A NEW TOPIC FOR GRADUATE STUDENTS

The city of Genoa has seen two floods in the last five years cause serious damage as streams, mostly channelled in tunnels under the streets and buildings, crossed the urban tissue. Additionally, many areas are subject to frequent, minor floods due to the overflow from municipal sewer during heavy rainfall. While the municipality is planning structural interventions designed to prevent the flooding of urban streams, designers and citizens' associations are seeking solutions to prevent floods caused by atmospheric events. Interactions between urban tissue, services nets (energy, data, sewer, etc.) and weather (storms, rainfall, etc.) have to be analysed. At a first glance, this seems strictly an engineering issue, but due to its many consequences on the use of urban space, architects must also confront flooding and atmospheric events.

Soil sealing is one of the most pressing problems in urban management, and it is part of the threats identified by the European Commission in 2002. (COM 2002/179). Michal Kravčík argues that the key to global water problems (particularly pollution and scarcity) is to retain more rainwater in the ground to balance the water cycle. (Michal Kravčík is a Slovak hydrologist and environmentalist who won the 1999 Goldman Environmental Prize for his contribution to the environmental management of water in the Torysa River basin, running through the eastern Slovakia towns of Lipany, Sabinov, Vel'ký Šariš, and Presov.)

These educational activities are to verify the applicability of the technology integration of vegetation in the urban space to improve environmental quality and runoff control during intense rainstorms. In many cities, such as Genoa, high building density reduces the availability of open spaces useful for these green infrastructures. It is a difficult subject to address within

architectural instruction but it is a worthy research subject and an essential discipline for students.

Students, and especially graduate students, have learned and contributed much from participating, even at the analytical level, in this active research:

- analysis of the state of the art (including translations into Italian where there is no such field), and synthesis of book excerpts for instance: SUDS TEAM, (2011); Australian Government (2009). The only regions that have, so far, adopted guidelines to use green infrastructure to reduce the risks of soil sealing are Emilia-Romagna, Tuscany, Veneto, and Lombardy, and the autonomous province of Bolzano-South Tyrol. Some municipalities will also integrate their building code with guidelines for urban development (according to the principle of hydraulic invariance) for the creation of green infrastructure to control the runoff and to improve water quality before being discharged into the sewage system. Although many environmental engineers are researching performance in the Mediterranean climate (characterised by alternating regimes of drought and heavy rain), the knowledge of these systems in the design field is not very thorough and there remain risks that information and practices related to other weather systems' rainfall and plant species adaptability will spread;
- analysis of urban sites frequently affected by floods caused by sudden storm events (termed "water bombs" by the media) and the consequent damages to ground floor assets, either by water penetration from flooded roads or the infiltration of rising water from underground streams;
- analysis of the constraints due to the presence of underground utilities (water, sewer, electric, and data networks). Within dense urban areas, the space available for the installation of green areas suitable for filtering rainwater and slowing down time of concentration (from the ground to waste disposal system) is limited not only by the small size of open spaces but also by the presence of network services underground, which are very difficult to change;
- analysis of climate data, particularly related to rainfall, to provide a greater awareness of climate changes taking place and identify the scope of rainwater to be disposed of and the ability, on the part of green infrastructure, to contribute to this reduction in runoff.

These analyses oblige students to consult public authorities and professional employees with very different characteristics. Students, essentially, are accustomed to interact with teaching staffs comprising almost exclusively architects, albeit with different specialisations. Non-architects working in this area are generally engineers, usually specialising in structures design or technical physics. Students thus must learn to interact well with professionals such as hydraulic engineers, meteorologists, and botanists, among others. The tools and methodologies they are therefore using come from disciplines as divergent as sociology, hydraulic engineering, urban planning, or architectural technology.

Figure 3. Greening the city: an hypothesis of green covering of Genoa Sestri neighborhood.

Figure 4. Water square design for Piazza Martinez, Genoa.

Subsequent phases are focused on the design and construction of green areas engineered to filter and slow rainwater in order to reduce the load on sewer systems during heavy rains. These urban areas are thus equipped with green infrastructures that improve environmental quality.

There are graduation works, some complete and others in progress, that authors consider useful not only for students' cultural growth but even to improve

the awareness of professionals and public managers – through public presentation and papers for journals and local conference – of the possibility for rehabilitation the urban environment by implementing green infrastructures.

Giulia Pasqualini (2011–2012) analysed the forecasts for the Vado Ligure municipality in northwestern Italy for the area near Segno river, assuming a design solution enabling optimal use by transforming a former industrial areas within the residential fabric into an urban park – also through the use of ENVI-met software and with the collaboration of the meteorologist Dr. Marianna Nardino of the CNR of Bologna (Consiglio Nazionale delle Ricerche, the Italian national research office). This design hypothesis was shared with the municipal planning office as a possible urban area implementation scenario for the city.

Anna Ragosa and Carolina Queirolo (2014–2015) studied the neighbourhood of Genoa Sestri, an area near the aforementioned green façade, assuming a gradual greening over several years according to a plan adopting urban green solutions and green roofs solutions to change the water retention system and the release time and volume of rainwater bound for the sewer system, as well as improving the general environmental quality, especially of the air (figure 3).

Maria Mazzarello and Monica Raimondo (2015) investigated the state of the art of green infrastructures and identified possible constraints encountered in cities with very dense tissue, such as Genoa, where small sized roads and extensive underground utilities pose significant limits to the creation of green areas. Their project proposal for the area of the former Corso Sardegna market was subsequently shown to the Quarter President.

Ilaria Beghello (2016) is studying a long section of Corso Sardegna street, that is often affected by flooding during storms.

Giada Longo, Sara Moretti, Lidia Nario, and Irene Platania (2016) are studying a large area in the San Fruttuoso neighbourhood characterised by flooding during rainstorms; the area includes a square to be renovated and a former railway area to be allocated to other activities. In both theses in progress, in addition to verifying feasibility conditions for the introduction of green systems (e.g., rain gardens), students are carrying out quantitative analyses with the help of Professor Ilaria Gnecco, who is a hydraulic engineer (figure 4).

4 CONCLUSIONS

Completed and in-progress teaching activities aim to apply blue and green infrastructure (and verify their effectiveness) in a city with a Mediterranean climate and high building density. Sudden and intense weather events – occurring at higher frequency than in the past – cause flooding in some quarters, hurting the local economy. Furthermore, this type of city is subject to pollution due to intense traffic, especially on roads with the low width to height building ratios (known as urban canyons) that consequently accumulate air pollutants (gas and fine particles). Green infrastructures, the blue and green technologies, can simultaneously limit the effects of these events. The urban space quality depends not only on the architectural quality of its buildings but also on its environmental quality. The, the goal is to sensitise architecture students to climate change and socioeconomic changes of our city.

The students were able to understand how the project activity depends not only on the will and creativity of the architect but it is also strongly bound to context. The eminently multidisciplinary activities of the project are also multiscalar and cross-disciplinary, needing not only specialists capable of making quantitative assessments but also able to share knowledge and tools to better understand the project objectives and contribute to the best result. Another goal is to get the students in contact with municipal administrators, on a field of discussion on issues of common interest, showing urban regeneration solutions alternatives to those hitherto used. The teaching experience, thus, becomes an important moment of synthesis and a simulation of the type of collective design process necessary to address the complexity of today's problems.

A passive-first artificial sky: An educational tool

Bruce T. Haglund, Drew Gilbert & Malachi Payne
University of Idaho, Moscow, Idaho, USA

ABSTRACT: Architectural design that meets the goals of Architecture2030 or results in zero net-energy performance is most elegantly achieved when employing effective passive strategies before adding high-technology components. With this idea in mind, a research question was posed to a graduate seminar in natural lighting, "Can an artificial sky for testing daylighting models be designed that uses only daylight, rather than electric lamps, as its light source?" The threefold motivation for the question was: (1) matching—use a passive device to test a passive system (daylighting), (2) quality—use high-quality daylight to test daylighting systems, and (3) energy—use a low-energy system for model testing. Currently, all artificial skies use an array of fluorescent lamps to simulate sky conditions. These skies are solely mechanical systems, have color rendering capabilities far inferior to daylight, and consume thousands of kilowatt-hours of electricity. Developing our artificial sky has proven to be a six-year educational experience.

1 INTRODUCTION

1.1 *Project context*

This project has been accomplished in the context of a professional program in architecture by a faculty member and over 30 Master of Architecture student researchers. Since these students are not research-focused, they had to be integrated into the project strategically to compensate for their short (2 year max) tenure. This strategy was to involve students in the project through an elective seminar in natural lighting and to further their involvement via directed studies in non-thesis research. Furthermore, students were encouraged to contribute to the writing and presentation of technical papers about their research.

1.2 *Project history*

Teams of students have worked on this project over the last six years, accomplishing a series of explorations rich in learning experiences. First, teams presented with the theoretical basis for artificial skies (Haglund, 2011) in a graduate lighting seminar, were challenged to design and test a working scale model of an artificial sky that could simulate a standard overcast sky under any exterior daylight condition. They created successful models of two basic types—mirror-box and conical. Their research results helped to obtain university seed grant funding to design and build a full-scale prototype and to receive a donated high-efficiency tubular skylight. Second, the students chose to build the conical prototype because its geometry is unlike that of any artificial sky in existence and its light distribution more uniformly diminishing from zenith to horizon than the mirror-box. Architecture faculty supported the project by designating a space for the artificial sky proximate to the fourth-year and graduate studios—easily accessible for testing design studio projects' daylighting schemes. Third, students were asked to develop protocols for verifying the distribution pattern of light within the artificial sky. They developed a calibration technique to correct for the vignetting of our 180^o fish-eye lens as well as a testing methodology for recording the light distribution for various light levels and sky conditions. During the design and testing phase, students were encouraged to participate in writing about and disseminating their findings. Consequently two students presented a poster at PLEA 2012 in Lima, Peru, (Haglund, 2012) and two others presented a paper at ARCC/EAAE 2014 in Honolulu (Haglund, 2014). Fourth, while using the artificial sky to model a skylighted space, students discovered a slight flaw in the sky's performance—the brightness of the skylight diffuser that illuminates the artificial sky caused a significant difference in light distribution for a skylighted model when compared to the same model tested under the natural perfectly overcast sky. Consequently, a student researcher designed, constructed, and installed a rough prototype diffuser. He tested it for effective diffusion and illumination of the artificial sky's surfaces.

Students are now challenged to design and test a permanent diffuser that would reduce the brightness at the peak and maintain the prescribed distribution from zenith to horizon. They are also tasked with increasing the brightness of the sky by capturing the light that escapes via the gap between the top of the sky and the bottom of the skylight.

Table 1. Artificial Sky Model Assignments

Surfaces	Rectilinear	Cylindrical
Matte White	Model A	Model C
Mirrors	Model B	Model D

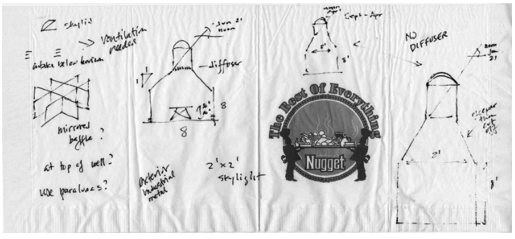

Figure 1. Daylighted Artificial Sky napkin sketch design circa 2009.

The project is focused on learning associated with the design, fabrication, and testing the artificial sky; on the change in mindset—valuing the efficient and elegant use of resources—required for a sustainable future; on problem solving; and on writing and presenting research papers.

2 EPISODE ONE

2.1 *Designing scale models to test sky design ideas*

In fall term 2011 the graduate seminar in natural lighting was introduced to the philosophic and scientific basis for a daylighted artificial sky (Haglund, 2011 & Tergenzer, 2011). They were also given four different scale models (Table 1) of proposed artificial skies built to the specs of a napkin-sketch design proposal (Figure 1) conceived at the Centre for Alternative Technology in 2009.

Philosophically, three points were stressed (1) matching—use a passive device to test a passive system (daylighting), (2) quality—use high-quality daylight to test daylighting systems, and (3) energy—use a low-energy system for model testing. Currently, all artificial skies use an array of fluorescent lamps to simulate sky conditions. These skies are solely mechanical systems, have color rendering capabilities far inferior to daylight, and consume thousands of kilowatt-hours of electricity—existing artificial skies are sized from 12.8 kw at Cardiff University to 1.3 kw at the University of Idaho IDL in Boise, ID.
