Scientifically, the daylighted artificial sky would need to deliver the CIE standard luminance for an overcast sky—three times brighter at the zenith than at the horizon. The level of illumination could vary (as it does in the natural sky) as long as the distribution of light was consistent under any outdoor sky condition.

Four teams of five students each were assigned to one of the four proposed prototypes. It was immediately clear to the students that none of the prototypes were adequate to the task. Undaunted, the students developed their own proposals testing them with digital and physical models—the latter proved more useful. Each team had to work collaboratively to develop scale models of artificial skies that met the performance criteria. Their solutions were of two types, mirror-box skies with a diffusing skylight-fed luminous ceiling similar to electrically lighted mirror boxes, and conical skies with matte white walls. The mirror-boxes tested to be virtually identical to the electrically lighted mirror-boxes, which are a somewhat crude approximation of an overcast sky. We choose to build a full-scale prototype of the conical artificial sky because it differed from the norm and provided a more even distribution of light. The outcomes from this seminar were used to secure an internal seed grant of US$12k to construct the prototype artificial sky.

2.2 *Lessons learned*

This episode highlighted inquiry through design. Students applied their problem solving and design thinking skills to translate theory to working models of the proposed artificial sky. They also greatly increased their knowledge of natural lighting design through the conduct of research related to a practical design challenge.

3 EPISODE TWO

3.1 *Demountable prototype sky construction*

This episode took three semesters to complete. During the first semester a handful of students from the fall seminar opted to design and build the full-scale prototype. First we gained support from the architecture faculty to locate the artificial sky in the upper level of the architecture studio building, which has a cathedral ceiling of sufficient height for a 4.88-meter (16-foot) tall conical structure, and is adjacent to the senior and graduate studios.

In the spirit of sustainability we wanted the artificial sky to be demountable and crafted from local materials—in our case timber. The students designed a ten-sided structure that approximates a cone on a cylindrical base, composed of 30 modular panels that can be bolted together (and unbolted). They used *SketchUp* (Figure 2) to create the construction drawings and to calculate the compound angles required to fit the modules together. The students' work also was used to secure the donation of an industrial 53.34 cm (21 in) diameter tubular skylight to the project. University permission was sought to allow the skylight to be installed in the historic architecture building, and was amazingly granted.

Luckily the students were able to continue the project into the next academic year. During fall semester the materials were purchased and outside contractors were hired to install the skylight, which they finally accomplished as the term ended. Because we were quite uncertain about the exact placement

Figure 2. Sketch-Up model of the proposed daylighted artificial sky in the studio context.

Figure 3. Three phase construction sequence.

and height of the installed skylight until it was actually installed, we held off construction until spring semester. It took the entire semester to fabricate the panels, bolt them together in three stages from base to apex (Figure 3), and paint the interior matte white in the cone and 50% gray in the base (below the artificial sky's horizon).

3.2 *Lessons learned*

This episode presented lessons in hands-on design/build of a small architectural project including obtaining permissions and dealing with subcontractors. The amount of time needed to accomplish this phase was a revelation to the students. They also gained skill and confidence in translating construction documents for the artificial sky into a materials list, modular components, and the fabricated structure. The students were also inspired to write a technical paper and present it as a poster at PLEA 2012 in Lima, Peru (Haglund, 2012).

Figure 4. Image from our fish-eye lens before and after correction for vignetting. It's a subtle difference seen at the images' edges.

This trip also afforded them the opportunity to venture beyond Lima to Cuzco and Manchu Picchu, certainly on the bucket list for all architecture students.

4 EPISODE THREE

4.1 *Creating techniques for vignette correction and data collection*

We wanted to use our 180° fish-eye lens and digital SLR camera as a pixel by pixel luminance meter to verify the luminance distribution in the artificial sky (Inanici, 2004 & 2006). In gray-scale RAW file format each pixel of the image is given a brightness value on a linear scale from 0 to 255. However, fish-eye lenses have the tendency to undervalue luminance near the edge of the lens. This tendency is called vignetting and can be corrected for each specific lens and aperture/exposure setting. During the next fall term one of the students took on the task of correcting for the vignetting. In the end, a correcting mask was created that can be combined with fish-eye images in *Photoshop* to produce composite images with accurate luminance values. When this technique was used to analyze the luminance distribution of the artificial sky, it proved to conform well to the CIE standard. The mask is useful with all images taken by our camera (in manual mode, aperture set at F4 with a 1/6 second exposure) with the fish-eye lens attached—very valuable in obtaining accurate visualizations of daylighting scenarios (Figure 4).

Another student took on the task of setting up the data acquisition system that could calculate and give daylight factors for four points in a model being tested under the artificial or natural sky. This task seemed to be simple, but the coordination of the sensors' output with the data acquisition system was not easy. The sensors and the data acquisition system have different manufacturers, so technical representatives from the two companies gave incomplete/conflicting information and the process took the entire semester to accomplish.

4.2 *Lessons learned*

Tasks performed in this episode represented excellent applied research. Problem solving skills for specific

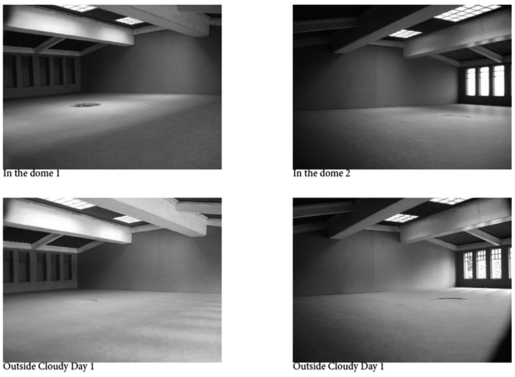

Figure 5. Images of daylighting model taken in the artifi cial sky (above) and outdoors under a perfectly cloudy natural sky (below). In the artifi cial sky, light from the skylight is brighter than that seen under the natural cloudy sky.

situations were invoked and used to find useful solutions. The students had the opportunity to write a technical paper on their work and present it at ARCC/EAAE 2014 in Honolulu (Haglund, 2014). Subsequent to data acquisition system investigation, the sensor manufacturer introduced a new data acquisition device that proved to be easy to use with the sensors and thus, user-friendly for architecture students. We've purchased the new system, well-informed that it is an improvement over the older technology.

5 EPISODE FOUR

5.1 *Diffuser prototyping and luminance distribution plotting*

During fall semester 2014 the graduate seminar in natural lighting was assigned to analyze and model a space that was both top- and side-lighted. They were encouraged to test their physical model with both the artificial sky and a naturally occurring completely overcast sky (similar to the CIE standard).

When they made their end-of-term presentations it became obvious that the light distribution in the models tested under the artificial sky differed from those tested under the natural overcast sky (Figure 5). The difference was caused by the brightness of the skylight's diffuser, acting as a spot source in the otherwise diffuse artificial sky—like a weak sun. So skylights under the artificial sky gave relatively more illumination than those under the natural sky.

Consequently, our next task was to create a diffuser for the top of the skylight to harvest the light and distribute it more evenly. So during spring semester a student continued on the project to create a roughly constructed prototype diffuser and to test its effects on light distribution in the sky. The prototype was constructed and installed. Testing with the fish-eye lens and digital camera proved it to be effective, reducing

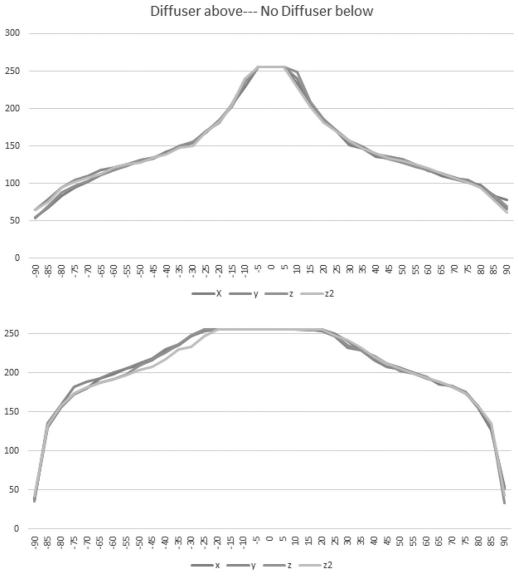

Figure 6. Luminance plots on four diameters of the walls of the artificial sky before (bottom) and after (top) installing the prototype diffuser.

the breadth of zenith brightness and in more evenly lighting the walls (Figure 6). Both before and after plots confirm that light is uniformly distributed on each of the four axises tested—the plots are virtually identical for all axises.

5.2 *Lessons learned*

Comparing model findings from the artificial sky and the natural sky side-by-side showed lighting characteristics that were not obvious in the parametric testing of the luminance of the artificial sky. This field testing is a valuable step in ascertaining the performance of the artificial sky. Even though the parametric testing of the prototype diffuser were promising, another round of field testing of physical models under the artificial sky and the natural sky is needed.

6 EPISODE FIVE

Our experience with the artificial sky has led to two further efforts to improve its performance—to design, fabricate, install and test a diffuser to permanently solve the over-bright zenith problem and to design a device to prevent loss of daylight at the gap between the bottom of the skylight and the top of the artificial sky structure while still allowing stack ventilation. The permanent diffuser requires testing to confirm its performance and the device (a shroud) to prevent daylight loss requires testing to confirm adequate stack ventilation and continued appropriate light diffusion.

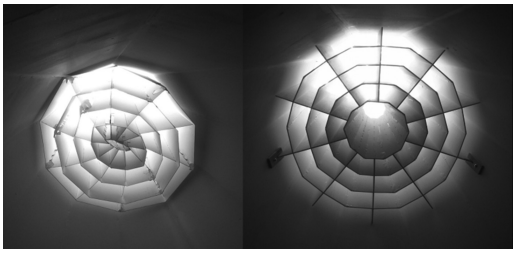

Figure 7. The draft prototype diffuser (left) vs. the initial version of the improved diffuser as described above.

Figure 8. Apex of the artifiicial sky without and with the shroud, which reduces light loss yet allows stack ventilation to occur.

6.1 *Diffuser testing*

The spring 2016 research class was charged to improve the lighting conditions in the artificial sky by designing, fabricating, installing, and testing a permanent diffuser.

Initial findings showed that the naturally daylighted artificial sky was successful at providing the desired lighting distribution without the need for introducing electrical lighting, even on overcast days; however, it became apparent that the tubular skylight created effects more closely related to directly overhead sun than to a completely overcast sky. Our prototype diffuser did provide relief from the direct sun effects: however, it limited the quality and intensity of overall natural light in the artificial sky which darkened the sky, making it difficult to use the sky effectively during all daylight hours of winter overcast days.

An improved light diffuser was needed to increase the amount of light penetration into the artificial sky while still offering the diffusing effects needed to simulate completely overcast sky conditions. Since the prototype diffuser reduced the amount of overall light into the artificial sky, the second-generation diffuser was designed just to be half as tall, allowing for it to absorb less light. The new diffuser has the same number of sides (10) and conical shape as the artificial sky and attaches directly inside the top of the cone (Figure 7). The diffuser's 5 fins are evenly spaced and radiate outward at the same angle as the edge of the sky's cone. The fins are designed to diffuse light from the tubular skylight toward the walls of the artificial sky, eliminating the appearance of a direct light source. The diffuser was painted white to match the inside of the sky's cone matte white surfaces so it would not absorb too much light.

6.2 *Daylight maximization*

Since a naturally lighted artificial sky depends solely on the amount of light brought in from the outside via the tubular skylight, it's critical to bounce all of the possible light entering the skylight down into the artificial sky in order to maximize the time frame for natural lighting model testing. We found that during cloudy winter days at our far northern latitude the time frame for adequate illumination for model testing was reduced to a few hours around midday—and that we were losing significant light through the gap at the top of the sky cone. A highly reflective shroud was designed to capture light escaping through the 20.32 cm (8 inch) gap between the skylight and artificial sky structure to maximize daylighting in the artificial sky (Figure 8).

We designed and installed the shroud during the spring semester of 2016. The shroud was placed on top of the sky structure and exterior to the skylight. The material used is aluminum flashing 25.4 cm (10 in) tall and 203.2 cm (80 in) long. Aluminum flashing was easily molded into a cylindrical shape with a highly reflective interior wrapped around both the skylight and artificial sky. The flashing wrap around the skylight was cinched tight to attach it to the skylight. Because the artificial sky creates the stack effect, it is important for the top of the artificial sky to exhaust heat. To combat heat being trapped in the artificial sky, seven 32.77 cm^3 (2 in^3) cubes of open cell foam were screwed into place at the top of the shroud as spacers to protect the skylight from damage and to allow exhaust heat to escape the artificial sky. The cubes are spaced at 25.4 cm (10 in) intervals. The air gap between the skylight and the shroud minus the area of the foam leaves a gap of 893.55 cm^2 (138.5 in^2) for air to escape. We are testing the artificial sky for heat stratification to ascertain that the stack ventilation scheme is still effective. Our test will compare stratification characteristics of the artificial sky in four stages of modification—with the temporary diffuser, with no diffuser or shroud, with the shroud, and with both shroud and new diffuser.

6.3 *Epilogue*

This semester's research assistants will continue to test the artificial sky performance under a wide variety of natural sky conditions during the spring term. Moreover, they will advise students in a upper division studio who will be using the artificial sky for field testing toplighting precedents. These testing activities may uncover further issues to study. The researchers will report the results from this semester's efforts when they present this paper at the 2016 ARCC/EAAE research conference in Lisbon.

7 CONCLUSION

At the onset this project seemed to be fairly straightforward and easily accomplished in a short time-frame. As can been gleaned from the foregoing text, it proved to be more complex and time consuming than envisioned. The pursuit of the naturally lighted artificial sky has proven to be a rich learning experience and a journey of discovery for all involved, for both faculty and student researchers. During the process we encountered unforeseen problems, difficulties, and opportunities. Our view of the practice of daylight modeling was tested and expanded.

The true value of doing research is not in the results, but in the discoveries along the way—and those that will follow. Students involved in this project have come to value not only daylighting design, but the research skills inherent in architectural design and the writing skills needed to present their work. These values will translate to their future architectural practice. The completed artificial sky will also serve as a facility for future students to hone their model building and daylighting design skills.

A solar Decathlon House intentionally designed to increase teaching opportunities

V.Y. Blouin, D. Albright, D. Harding, U. Heine & D. Pastre
School of Architecture, Clemson University, Clemson, South Carolina, USA

ABSTRACT: Clemson University participated in the U.S. Solar Decathlon competition in Irvine, California, in October 2015. The Solar Decathlon is a student competition that aims at educating the next generation of architects and engineers in the fields of solar technologies, housing design, and construction. This competition provides opportunities to push innovation through collaboration between students from various disciplines, faculty, and industrial partners. Architectural education encompasses two equally important aspects: (1) the study of existing knowledge in building design and construction, and (2) the investigation of innovative ideas and concepts. The solar decathlon competition is an ideal venue for experiencing both. However, the successful implementation of the latter (i.e., innovation) is not as trivial. This paper discusses the teaching and educational intentions set forth by the faculty from the beginning of the project to achieve the desired educational experience and how these intentions significantly influenced Clemson University's Solar Decathlon house design.

1 INTRODUCTION

The Solar Decathlon competition is an award-winning program that challenges twenty selected collegiate teams to design, build, and operate solar-powered houses that are cost-effective, energy efficient, and attractive. Open to the public free of charge, the ten-day competition gives visitors the opportunity to tour solar-powered houses, gather ideas to use in their own homes, and learn how energy-saving features can help them save money today.

The Solar Decathlon is also a student competition that aims at educating the next generation of architects and engineers in the fields of solar technologies, housing design, construction, and high performance buildings. This competition provides opportunities to push innovation through collaboration between students from various disciplines, faculty, and industrial partners.

It is recognized that architectural education encompasses two equally important aspects (Rothkopf 2010, Berlinguer 2012, Hunt 2015): (1) the study of existing knowledge in building design and construction, and (2) the investigation of innovative ideas and concepts. The solar decathlon competition is an ideal venue for experiencing both. However, the successful implementation of the latter (i.e., innovation) is not as trivial. This paper discusses the teaching and educational intentions set forth by the faculty from the beginning of the project to achieve the desired educational experience and how these intentions significantly influenced Clemson University's Solar Decathlon house design. The rationale for these intentions was to circumvent the inherent risk of innovation in educational settings. Innovation driven by students is risky and therefore needs time for development. A new idea must be materialized and go through multiple iterations of redesign, prototyping and testing. The time needed to go through this process takes months and sometimes years. As a result, the design of the Clemson's Solar Decathlon house had to accommodate these constraints if innovation was to be incorporated. Timing and design flexibility were the key aspects that led to the development of an innovative floor plan, materials, building techniques, and systems.

Many collegiate teams who participated in previous solar decathlon competitions have been able to incorporate significant innovations (Zaretsky 2009) such as new materials for exterior cladding, a semi-automated shading control strategy based on the climate forecast, and blinds passively actuated by a shape memory alloy spring mechanism. Even though it is difficult to estimate the impact of these innovations on competition scores, these teams have been able to integrate them in their respective designs in a timely manner and present them in meaningful ways during the competition, which should not be underestimated.

This paper includes seven sections. In section 2, the schedule of the competition is described. The Clemson University project and its objectives are discussed in section 3. The benefits of innovation, how innovation impacted the design of the house, and how the risk of innovation was reduced are presented in sections 4, 5, and 6, respectively. Finally, section 7 concludes the paper.

2 THE SOLAR DECATHLON COMPETITION SCHEDULE

The solar decathlon competition takes place every two years. The participation is a competitive process based on a proposal submitted to the U.S. Department of Energy organizers two years before the competition. The selected teams design and build a solar-powered house between 600 and 1000 square feet to compete in ten categories: architecture, market appeal, engineering, communications, affordability, comfort zone (i.e., maintain temperature and relative humidity within a specified range), appliances (i.e., operate appliances for specific tasks), home-life (i.e., operate the house for specific tasks), commuting (i.e., recharge and drive an electric car under specific constraints), and energy balance (i.e., generate more electricity than consumed).

Once selected as one of the twenty participating teams, students have 18 months to design, prototype, test and construct the competitive house. The teams that participate multiple consecutive times have the advantage of recycling their acquired knowledge over the years and develop innovative ideas over multiple years, which is a beneficial strategy. Clemson University (referred to as Team Clemson), like many other teams, intended to participate only once and therefore limited the bulk of its effort to the two-year period prior to the competition.

The competition takes place over a three-week period with a nine-day assembly of the house on the competition site, a ten-day competition, and a five-day disassembly of the house and clean-up.

3 TEAM CLEMSON'S SOLAR DECATHLON PROJECT

3.1 *Educational opportunities*

Clemson University assembled a committed team of students, faculty and professionals to design and build a solar powered house. The reasons for participating in the Solar Decathlon were primarily educational. During the two-year period, Clemson University's undergraduate and graduate educational programs integrated this project into the curriculum with the participation of about 80 architecture students in five dedicated studios and 30 students from other disciplines. Students were involved as decision makers in all aspects of the project, including building the house under faculty and professional supervision, fund raising, communication, and media relations. The educational opportunities provided by the project included, in order of importance and educational impact:

- *Real-life experience*. It is recognized that the quest for knowledge and productivity of the students increases tremendously when their design is actually built and utilized. In this project, it generally pushed the students to reach a higher level of professionalism and maturity that allowed them to deliver a finished product on time, ready to compete against other highly professional and motivated teams.
- *Collaboration with industry*. Most materials, components and systems used to build the house were either donated by or purchased from manufacturers and distributers from the building industry based on a rigorous selective process that required the students to be sufficiently familiar with each product through research. In addition, the students had to collaborate closely with representatives and engineers of each company in order to innovate and integrate new ideas.
- *Multidisciplinary collaboration*. As part of their training, architectural students must deal with a plethora of disciplines including engineering (mechanical, electrical, civil, etc.), communication, marketing, psychology, and sociology, which are all part of this competition.
- *Research activities*. As mentioned earlier, research and innovation is an important driver of a well-rounded and strong education. This project provided many research opportunities for all students involved. This topic is extensively discussed in the subsequent sections of this paper.
- *Exciting student experience*. This type of project can sometimes be stressful and may lack excitement and enthusiasm at the point of becoming a negative experience. Many factors can lead to a negative outcome, such as inappropriate management and scheduling, lack of organization, unrealistic expectations, and sometimes the unavoidable ramping damages from the bad attitude of one or more team members. However, when these factors are properly mitigated, this competition can positively drive the students and provide an extremely rewarding learning experience.
- *National and international exposure*. In order to be competitive, the students must study the previous competitions. A delegation from Team Clemson travelled to California to visit the 2013 Solar Decathlon and to France to visit the 2014 European Solar Decathlon where teams from all over the world exhibited their projects. These visits provided many opportunities for cross-cultural exchange of design ideas and construction practices.
- *Community outreach and involvement.* Clemson University's participation in this international competition triggered the interest of many residents of South Carolina and the surrounding states. It provided the intellectual capital and contributed to the training of the work force for a green economy. It also educated consumers on the potential of solar energy within residential markets, especially in South Carolina where the solar industry currently sees its highest rate of development.
- *Faculty education and training*. Even though all of the above outcomes primarily targeted the students, all faculty members who participated in this project highly benefited from this experience. A tremendous amount of knowledge related to

residential building design and construction, solar technology, and project management was acquired by the faculty. This knowledge will most likely be diffused and incorporated in subsequent courses and studio projects and will ultimately benefits many additional students.

3.2 *Core mission adopted by team Clemson*

The core mission of team Clemson's project was defined as follows:

> *"To design, build, and promote a prototypical, three-bedroom, 1000-sqft, low environmental impact, net-zero, solar house that is cost-effective in today's market and comfortable in South Carolina's hot and humid climate."*

The key objective was to develop an integrated design of the solar house based on the constraints of architecture, mechanical-plumbing-electrical (MPE), construction, transportation, user acceptance and usability while considering affordability constraints.

3.3 *Architectural concept*

The house was designed and built to respond to three significant characteristics of the state of South Carolina: its subtropical climate, its indigenous wood industry, and its domestic patterns. As can be seen in the traditional houses of the southeast region of the United States, the subtropical climate allows for the extension of the enclosed living space to a semi-open breathing space in dialogue with its surrounding context. Following this proven passive design strategy, the goal was to provide comfort while lowering energy consumption. Also, lowering the energy embedded in the construction process and in the materials themselves was a critical step in providing sustainable housing prototypes. The selection of wood as the basic material represented a significant reduction in embodied energy. In addition to it being a renewable natural resource, wood has the lowest embodied energy of any structural material (Wujek & Dagostino 2010). Additionally, the use of wood in South Carolina where it is indigenous and sustainably harvested, not only reduces the energy consumption in logistics but also supports the growing sustainable forest industry in the state. The third local characteristic responds to contemporary domestic patterns as evident in the program of the solar house. Different from the majority of the prototypes in preceding Solar Decathlon competitions, which mostly had a single bedroom and sometimes two at the most, the house includes three bedrooms. The idea of a three-bedroom house was based on South Carolina's housing demographics, which show that the majority of the houses in the state (39.8%) include three bedrooms and the average of persons per household is 2.52. In these circumstances, increasing the number of bedrooms enlarges the range of users and puts forward a more realistic and marketable housing option. Finally, the housing prototype was designed to be flexible enough to adapt to different user profiles and sites.

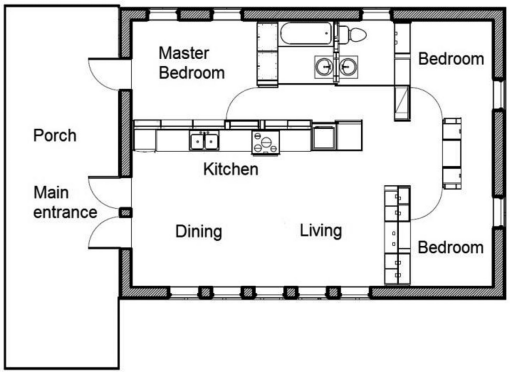

Figure 1. Floor plan of Indigo Pine, 936 square feet.

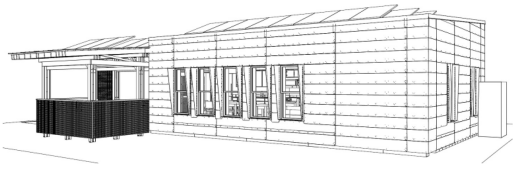

Figure 2. Exterior perspective.

The conceptual story grew from the history and culture of South Carolina. The name of this house, *Indigo Pine*, comes from two important South Carolina crops. The indigo plant was cultivated during the last two hundred years and produced as a dye with great success, thanks to the rich blue color it produces. Like indigo, the pine has also played an important role in South Carolina's development. Pine is a versatile, fast-growing timber used for innumerable functions. The Clemson Solar Decathlon Team is using these crops as representations of its values.

In order to create a home fit for South Carolina, as well as meeting all the competition criteria, team Clemson identified all of the aspects of a traditional Southern home which needed to be preserved to maintain the integrity of a Southern vernacular. The architectural design team attempted to integrate all aspects of a southern home in a contemporary way.

3.4 *Architectural implementation*

Since one of the main goals of this project was to design an affordable home in today's market, the approach used to select and design the engineering systems was based on an incremental improvement of systems currently used and accepted in today's market. The climate of South Carolina is hot and humid with mild winters. Most regions of the state require both heating and cooling, which means that the main goal of the design was to minimize solar heat gain during the summer and maximize heat gain during the winter. These conflicting requirements made the engineering design particularly challenging. Team Clemson

addressed this challenge by quantifying the energy performance of the home as accurately as possible; allowing a precise comparison of alternative design solutions.

Team Clemson used several methods for improving the energy performance of the home while maintaining affordability and marketability. Passive strategies based on natural ventilation and appropriate shading were implemented in order to minimize the use of active systems and maximize the duration of the fall and spring seasons. Another method was to use passive techniques to increase the efficiency of the active systems under extreme conditions.

The design of the electrical systems was based on the idea that the users are energy conscious and are willing to adapt their energy needs to the limits of the electrical production of the house. Under this assumption, the two main strategies were to minimize the unnecessary electrical demands and shift the use of electrical devices to periods of production of electricity from the PV system. While many solar projects consist of producing more electricity than consumed, the PV system of the house was designed as small as possible to produce only what is needed.

The rules of the Solar Decathlon competition often challenges the concepts of housing styles. With height restrictions, ramps, and alternative energy sources, incorporating traditional southern designs was not trivial. Indigo Pine still remained focused on the ideas of these traditional elements that are quintessential to the development of a southern home, yet reworked them to create the same expression through nontraditional solutions. The overall design was focused on the connection of exterior and interior space as well as daylighting that is received by the home and how it interacts with the inhabitants.

Structurally, the home was designed to be a smart wood system with much of the technology embedded into the pieces. For interior materials both wood and cultural colors and finishes were considered.

3.5 *List of innovations*

In order to be competitive in the Solar Decathlon, several innovations must be proposed and incorporated. They can relate to any technical and non-technical field of study. Team Clemson considered a series of interesting innovations listed below.

- *Sim[PLY]: a new structural framing system*. Made from Computer Numerically Controlled (CNC) cut sheets of structural plywood and held in place using predominantly metal zip-ties. This innovation is the center piece of Indigo Pine as it directly impacts the residential manufacturing and construction process.

  Overall, Sim[PLY] leads to reduced material costs, labor costs, and construction time. The advantages of Sim[PLY] can be concisely listed as follows: (1) local fabrication with local materials sources using an existing network of CNC fabricators; (2) quick and easy manufacturing of structural and finishing components including structure, exterior and interior cladding, and cabinetry; (3) set of digital cut files that can be transferred over the internet for easy replication of the house anywhere in the World; (4) accurate components that do not require additional on-site measurement or cutting to alleviate the need of skilled labor and reduce on-site waste; (5) components are designed to seamlessly interlock to adjacent parts based on a set of easy-to-understand drawings and held in place with manually installed metal zip-ties thereby reducing the need of power tools and heavy machinery.

  Historically, most teams pre-assemble the house months before the competition and truck-in prefinished modules that are ready to assemble. Alternatively, team Clemson decided to demonstrate the ease of construction of the Sim[PLY] system during the Solar Decathlon competition by successfully assembling the entire house from scratch in nine days and disassembling it in five days before and after the competition.

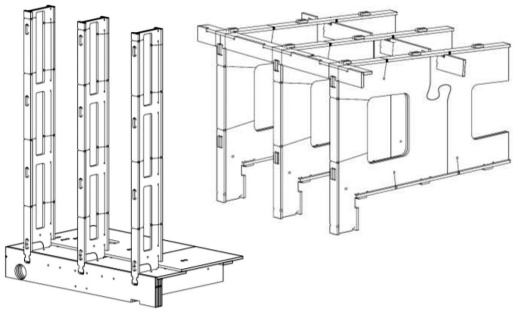

Figure 3. Wall and roof framing details.

- *New exterior cladding system made of CNC-cut polymetal panels.* The panels are made of a polymeric material sandwiched between two thin layers of aluminum for a total thickness of 0.25 inch. Each siding panel (roughly 1.5ft by 4ft) is CNC-cut and folded following origami rules to create a cavity for natural ventilation between the wood sheathing and the exterior siding. All siding panels are stacked, overlapped, and secured by screws and rivets in predrilled holes for easy and quick installation.
- *Enhanced air-source heat pump system*: An air-source heat pump for heating and cooling consists of an exterior fan-coil unit (i.e., also called outdoor unit) that produces the heat exchange between the refrigerant and the outside air. Air-source heat pumps are known for their high efficiency but also for their drastic loss of efficiency when the air temperature drops below the freezing point in the winter and climbs above 95°F (35°C) in the summer. In order to circumvent this issue and increase the temperature operating range, the air can be pre-heated in the winter and pre-cooled in the summer by drawing air under the house (i.e., crawl space) before passing it through the outdoor unit heat exchanger. A set of CMU concrete block was installed under the house as the foundation system but also as added thermal mass for pre-cooling and pre-heating the

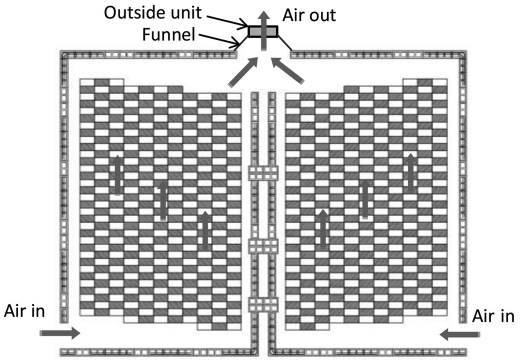

Figure 4. Plan view of foundation system to increase heat pump efficiency.

air. As depicted in Figure 4, the air enters the foundation system through vents at the south-east and south-west corners of the house, passes through the maze of CMU blocks, exits at the north of the house and is then funneled through the outdoor unit. During the competition, the fan of the outdoor unit was sufficient to draw the air through the foundation system.

- *A DC-powered water heater*: The most common water heaters used in the competition are heat-pump water heaters and solar collector water heaters. Both systems generally use alternating current (AC). Team Clemson selected a DC-powered water heater in order to use the electrical current directly generated from the photovoltaic (PV) modules (i.e., DC current, also called continuous current) instead of inverting it to AC current before use, which generally wastes 5 to 10 percent of the energy produced. Another reason was to avoid using solar collectors, which are notorious for their expensive maintenance. Also, DC water heaters are known to have the lowest life-cycle cost of all water heaters due to non-moving parts and low scale buildup on heating elements.
- *A manually controlled air-diverter system*: The ductwork shown in Figure 5 includes three tee's (called diverter tee-boxes) that distribute the conditioned air to four independently controlled zones, i.e., the three bedroom at each corner of the house and the dining room. The diverter tee-boxes include a flapper that controls the percentage of air distribution to each side of the tee. When the flapper is in the middle, each side receives 50% of the incoming air. When the flapper is rotated 45 degrees, 90% of the air is diverted to a single side and the other side receives only 10%. The distribution is symmetric with 100% of the air distributed at all times. The positions of the three flappers are controlled manually using Bowden cables (i.e., 50-foot bicycle cables) connected to three manual levers accessible in a centralized location of the house. Each diverter tee-box and its flapper were made from a CNC-cut polymetal sheet (i.e., same material used for the exterior cladding), folded and riveted together.

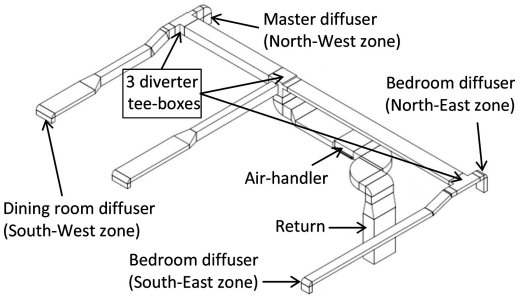

Figure 5. Ductwork showing the three divider tee-boxes.

The purpose of the air-diverter system is not to reduce the energy consumption of heating and cooling the house but mainly to provide additional control to the user and increase thermal comfort. In particular, it allows the user to adapt the supply of conditioned air to the zones based on user occupancy, hourly solar heat gain, and/or specific internal heat generation. As a result, the user is able to specifically define a more uniform temperature through the house or, inversely, a more non-uniform temperature distribution according to his/her desire. Compared to the traditional dampers available on the market, the diverter tee-boxes do not turn on or off the air distribution to a single duct, it only diverts the air flow between two ducts. As a result, the air handler is always able to circulate 100% of its air throughout the house and four zones can be independently controlled using only three diverter tee-boxes.

4 BENEFITS OF INNOVATION

4.1 *Impact on education*

It is recognized that creativity, research and the quest for innovation play a key role in education (Korobaniová 2015, Kuc 2015, Killen 2015). In the field of architecture, students are generally enthusiastic about creative design and innovation. Taping into this energy is a very effective way to motivate students and allow them to reach a high level of involvement. The ability to innovate requires generally the knowledge of current practices, designs, and theories. Unmistakably, most students who had the opportunity to follow their own path through design innovation went well beyond acquiring the basic education. They acquired it rapidly in order to give themselves enough time for developing new ideas, conduct research and ultimately innovate. They usually had a high level of productivity. It does not mean, however, that each quest for innovation was successfully integrated into the design of the house for various reasons.

4.2 *Impact on the building industry*

The need of innovation skills in education is fueled by the interrelated global challenges that we are

facing in terms of energy, food, water, and human health. Solving these daunting challenges will require global systems thinking and proactive local actions (Berlinguer 2012, Hunt 2015, Rothkopf 2010). Even though the building Industry is a very slowly evolving sector, the activities of research institutions such as the universities and colleges that participated in the Solar Decathlon competitions have contributed over the years to the evolution of the industry. Even if each innovation had a small impact, it made people think about the reasons for this innovation, its pros and cons, and it pushed the professional to constantly reevaluate their products and services in order to remain competitive themselves. Ultimately, each student involved today in the development of an innovation will become a professional decision maker at some point and will potentially use his/her knowledge acquired through the research process as a student to change practices as a professional.

5 HOW THE DESIGN ALLOWED FOR INNOVATION

Many researchers studied and reported on how to educate for innovation (Hanifin & Lee 2015, Luft et al. 2013, Ozaltin 2015, Puthoff et al. 2013, Rothkopf 2010). These techniques were considered by the faculty. In parallel, the group of faculty advisers selected the directions that the students should follow from the very beginning of the project. Two main aspects were specifically selected: (1) the use of as many off-the-shelf products as possible, and (2) the use of CNC-cut sheet goods for custom parts. Interestingly, these two aspects were not initially related to the purpose of allowing for innovation. However, in retrospect, it is now apparent that the innovations that were successfully integrated into the design followed these two aspects, i.e., they either used off-the-shelf products or were produced from CNC-cut sheet goods. All other innovations considered at some point during the project that did not make it to reality were based on a custom-made design (i.e., not off-the-shelf) that could not be produced from a CNC-cut sheet good.

The main reason for this trend is that any innovation requires an iterative process that involves, at each iteration: design, prototyping, testing, analysis and redesign. Using either off-the-shelf products or CNC-cut custom part allows multiple iterations to be conducted relatively easily as long as the off-the-shelf products are readily available from any building construction supplier and as long as the team had easily access to a CNC machine and sheet goods (i.e., plywood and polymetal panels), which was the case at Clemson University.

The most significant innovation of this project is the Sim[PLY] structural system. Many prototypes of all scales were constructed and tested using the in-house CNC machine that was easily accessible to the team. The students were able to perform a single iteration in a few hours for simple assemblies and a few days for more complicated wall sections. Without using a CNC machine, testing custom parts and assemblies would have certainly taken weeks and months, which would have been prohibitively long.

Similarly, the development of the polymetal exterior cladding required dozens of prototypes in order to identify the optimum CNC-cutting and folding techniques that lead to a successful design. The ductwork diverter tee-boxes were CNC-cut from polymetal sheets and had to be prototyped a few times before identifying the optimum design. They also incorporated off-the-shelf couplings and connectors for securing the ductwork sections to the boxes. Finally, the enhanced air-source heat pump system used off-the-shelf CMU blocks and spacers.

Innovations that were considered but did not make it because they were not off-the-shelf or CNC-cut include the following examples. The DC-powered water heater receives its electricity directly from five dedicated PV modules. Once the water stored in the 50-gallon tank is sufficiently hot, the five PV modules still continue producing electricity until the sun goes down for the night. This energy is therefore wasted and not using it is a missed opportunity. During the project, the students considered developing a custom-made switch that would divert the electricity generated by these five PV modules to other appliances or feed it back to the electrical power grid for credit (since all houses of the competition were connected to the electrical power grid using a bidirectional netmetering system). However, this valuable innovation required a custom-made electronic component with a specific safety rating and an alteration of the PV system. Several electrical engineering students worked on this topic until they realized that it would require significantly more time and effort in research and development. As a result, the innovation was not included in the design.

A second example is the use of a wraparound heat pipe around the air-handler in order to increase the energy efficiency of the HVAC system and reduce the air relative humidity. A wraparound heat pipe is a custom piece of equipment that cannot be built from off-the-shelf parts and cannot be CNC-cut. The reasons for failing to integrate this innovation are described in detail in the following section as they also relate to risk management.

6 RISK MANAGEMENT

6.1 *Faculty supervision*

As mentioned earlier, students go beyond expectations when driven by the opportunity to innovate. This is generally beneficial for their education. The flipside, however, which is also the greatest risk, is the potentially excessive enthusiasm of the students. In this case, they tend to spend excessive time on their research and neglect other less rewarding but necessary activities. It is therefore the role of the faculty and student project managers to anticipate and take the necessary steps to prevent this issue. This can be achieved by defining,

in collaboration with the students, a realistic and precise time schedule with milestones and deliverables. In theory, as soon as a significant drift occurs, the activity should be cancelled. Unfortunately, the progress of research is intrinsically difficult to anticipate, if not impossible.

As an example, one particular innovative idea had to be cancelled early on. It consisted of integrating a wraparound heat pipe, mentioned in the previous section, for dehumidification and efficiency increase of the heat pump air-handler in cooling mode. A wraparound heat pipe is a sealed tube filled with refrigerant. The pipe is wrapped around the outside of the air-handler and is exposed to the air return (hot) on one side and is exposed to the air supply (cold) on the other side. On the hot side, the refrigerant evaporates and moves passively by buoyancy to the cold side where it condensates and then flows back by gravity to the hot side. The advantage of this passive cycling system is that some of the energy carried by the air by-passes the air-handler, thereby increasing the temperature difference inside the air-handler and increasing its efficiency while dehumidifying the air. This innovative idea had not been used in residential HVAC systems in the past. If successfully integrated, the reward from using a wraparound heat pipe was going to be significant in the energy balance, comfort zone, and engineering contests. Two mechanical engineering students investigated its feasibility for several months. Unfortunately, the rules of the competitions restricted the use of the most efficient refrigerants because of their adverse environmental impact. The research for a valuable refrigerant lead to the use of either carbon dioxide, which would have required an excessively high and potentially dangerous operating pressure, or water. The latter was obviously selected. After a few weeks of further investigation, calculations, prototyping and testing, it became clear that the design needed several more months of research. In the meantime, the two mechanical engineers were not able to work on sizing the HVAC system, which was a more basic endeavor, but of higher priority. As a result, the team decided to discontinue the project. Interestingly, the humidity levels measured in the house during the competition were excessively high due to an unexpected heat wave. In retrospect, a wraparound heat pipe would have turned out to be highly beneficial and rewarding.

6.2 *A back-up plan comes first*

During the entire project, the group of faculty advisers emphasized the constant need of a back-up plan for any potential innovation. This required the team to develop a standard and successful design of each part of the house that was subject to innovation before attempting to innovate. The benefit of this practice was to alleviate any stress due to the risk of not having a successful design in case the innovation did not work out. As a result, the team was able to relax and work under less pressure to perform. Similarly, a recommendation was to avoid non-incremental innovations, which are usually highly rewarding but also extremely risky.

6.3 *Time management and organization*

The faculty guided the enthusiasm for innovation of the students by teaching them the importance of investing judiciously their time and resources in ideas and opportunities that lead to successful design decisions. In other words, the students were encouraged to constantly evaluate as objectively as possible the value of their activities and make sure that each hour spent on an activity was contributing directly and immediately to making progress towards the goal of the project.

During the entire design process of the house, all decisions were made in accordance to the core mission of the project (See section 3.2). When two or more design alternatives presented themselves, the selected alternative was the one that helped the most in achieving the core mission. This was very successful since it helped the design team save valuable time that would have been otherwise wasted on long deliberations among groups of undecided students. This is why the core mission was the first thing that the entire team developed and agreed upon. Each word of the mission statement was selected very carefully in order to provide guidance during the entire project. Interestingly, the core mission was never altered or even questioned during the two-year period. In retrospect, it is clear that the core mission was in fact a pillar of the project that people relied upon for guidance and building confidence in decision making.

7 CONCLUSION

The paper presents learning benefits associated with seeking residential innovations. The readily available construction method (i.e., CNC) and off-the-shelf materials were specifically selected rules to allow multiple iterations of redesign, prototyping, and testing of innovative ideas. The paper discusses the learning outcomes established at the beginning of the project in relation to the design process and how the faculty guided the enthusiasm for innovation of the students by teaching them the importance of investing judiciously their time and resources in ideas and opportunities that lead to successful design decisions.

Like many teams, the goal was to participate in the competition but also to win it, or at least compete at the highest level possible. In parallel to this competitive endeavor, team Clemson conscientiously decided to use the participation in the Solar Decathlon as one step towards developing a long-term education and research program focused on residential sustainability through architectural design innovation.

The educational intentions and the rules for research and innovation set forth by the entire team of faculty and students from the beginning of the project were key in achieving the desired educational experience and are the reasons that lead to a successful project.

ACKNOWLEDGEMENTS

This project was partially supported by the U.S. Department of Energy. The views presented here do not necessarily reflect the views of the U.S. Department of Energy. The authors thank Gene Wilson for his technical contribution to this project.

A contemplative pause on the integration of digital computational thinking into architectural education

R. Ajlouni
The University of Utah, Salt Lake City, USA

ABSTRACT: The use of computation and digital tools is actively shaping the way that designers approach design problems. The emergence of computational logic as a parallel design thinking approach is gradually redefining design reasoning patterns within architectural discourse. While computation offers a multitude of creative spheres for exploration and research, it also poses some unforeseen cognitive and technical challenges, which if not resolved can potentially drive the educational experience out of focus. Increasingly architecture students are required to learn and apply a vast host of digital and computational tools without a proper understanding of their internal algorithms or operating logic. Struggles arise when students depend on the tool's specific architecture and workflow to inform their design processes, without a conscious realization of such influences. These challenges are provoking critical pedagogical debates; raising many questions concerning the affect that this technological-driven shift has on architectural products and discourse. To contribute to this critical discussion, this paper explores the nature of computational logic, as the foundation for understanding the integration of computational thinking into architectural discourse. After looking analytically at the different digital computational models at a cognitive level, it is evident that computational-driven processes often follow a path of rational deductive reasoning, which is more suited for exploring a 'well-defined' design problem. However, when approaching an 'ill-defined' design problem, deductive reasoning can pose limitations on design thinking. Moreover, the type of knowledge-base and digital skills that are required to support advanced computational reasoning paths are often not provided by the architectural curriculums.

1 INTRODUCTION

Since the invention of the Sketchpad; the first interactive drafting computer program by Ivan Sutherland in 1963, computer graphics software has steadily evolved to become the standard means of production in design education and practice. The integration of digital technologies into the design process has enabled new ways of investigation; providing a range of tools for data structuring, visualization and analysis. Recently, the emergence of digital computational thinking models as an alternative design methodology is provoking critical pedagogical debates; challenging our conventional approach to design thinking (Lynn 1999, Knight & Stiny 2001, Oxman 2006, Oxman 2008, Ozkar 2007). While there is no doubt that the computer is actively shaping the way that we approach design problems, until today a robust and comprehensive theoretical framework underpinning the integration of computational thinking into architectural design pedagogy as it relates to cognitive theories is largely missing. There is, as yet, insufficient understanding of how the digital environment and its logic is affecting the design thinking process; often revealing a deep internal struggle within architectural pedagogy.

In architecture the computer as a machine is still seen as the 'black box'. Its operating logic and architecture remains a mystery to most users in the field. This can lead, in my opinion, to users underestimating its imbedded influence, as well as not fully grasping its limitations and potential in the design process. Unfortunately the architecture profession is rarely involved in designing the digital tools that it uses. It is therefore essential to take a deeper look behind the digital environment to understand the functionality of what is actively redefining the way we approach design investigations today. This paper takes an analytical look at the digital computational design thinking logic at a cognitive level, and hopes to clarify some important aspects related to the integration of computational logic into architectural education.

2 DESIGN COGNITION

The study of human information processing during design offers a theoretical foundation for understanding the issues of importance to design cognition, which should be considered essential for informing the integration of computational thinking into architectural design pedagogies. Since the emergence of cognitive psychology in the 1960s, design cognition as a paradigm has gone through many conceptual redefinitions moving away from the original static

conception of identifying design as an objective rational problem solving process (Newell 1969), towards a more dynamic realization that acknowledges the overwhelmingly subjective nature of design interpretations (Schön 1983). Within this new realization, a number of important issues to design cognition are highlighted focusing on the nature of the design problem, knowledge structure, and design representations (Eastman 2001). In this paper, these cognitive aspects are proposed as the theoretical platform for understanding the integrations of computational thinking into design education.

2.1 *The nature of the design problem*

Our understanding of design as a cognitive paradigm has evolved over time. The emergence of Artificial Intelligence, in the 1950, has sparked an interest into understanding the cognitive process of problem solving (Simon, 1968, Winograd & Flores 1987). Originally it was argued that cognitive mechanisms underlying both the processes of design and rational problem solving are identical (Simon & Newell 1958, Newell 1969, Newell & Simon 1972). The design process was seen as grounded in positivistic epistemology viewing the designer as a static being living in an objective world, in which, his/her interpretation of the world is constructed based on rational reasoning, objective data and explicit knowledge (Dorst 2004). This view was heavily influenced by cognitive research within the context of Artificial Intelligence, which views design as an advanced form of problem solving, similar to puzzle making . (Archea 1987). Design thinking was understood as a process of searching for solutions that satisfy a predefined problem space. However, this understanding was later challenged by the realization that design often operates within an undetermined problem sphere (Simon 1973). In cognitive science, there is substantial distinction between a 'well-defined' problem and an 'ill-defined' one. A 'well-defined' problem indicates that the information necessary to construct the problem is clearly specified at the outset. Such information is lacking when approaching an 'ill-defined' problem (Goel 1992). Thereafter, it was widely accepted that the design process overwhelmingly deals with problems that are 'ill-defined' (Eastman 1969, Simon 1987, Cross 1984, Eastman 2001, Dorst 2004). It is only through subjectively-driven exploration process that the problem space and its context can be defined (Schön 1983; Lawson 2005; Cross 2006). Schön (1983) stressed the implicit and subjective nature of design knowledge and activities identifying the design process as immersed in reflective practices. In this paradigm, attention shifts from the objective-rational view to highlight the subjectivity of the designer's conception of the design context. Such context is considered essential for understanding how design information is structured inside the designer's head; how it is recalled and manipulated during design processing (Schön 1983, Eastman 2001). This understanding is grounded in phenomenology, which views the designer as a dynamic, active and emotional social being with a unique view of the world, constructed based on his/her subjective interpretation of reality. Accordingly, the paradigm of reflective practice occupies the opposite end of the epistemology spectrum distancing itself from the paradigm of technical rationality. Mediating this distance a new understanding has emerged arguing for the dualistic nature of design, which involves both objective and subjective interpretations within its process (Gadamer 1986, Goel 1992, Dorst 2004). According to this understanding, defining the dominant interpretation depends heavily on the phase of design activity, the designer's level of expertise, and ultimately resides within the designer own discretion (Dorst 1997, Dorst 2004). Recent research has shown that a novice designer tends to consider the objective attributes of the problem, while an expert designer tends to cast his/her own subjective understanding of the problem under investigation allowing a wider creative sphere for innovation (Eastman 2001, Dorst 1997, Dorst 2004)

Rational	**What**	**+**	**How**	**=**	**Results**
Deduction	What	+	How	=	???
Induction	What	+	???	=	Results
Abduction	**What**	**+**	**How**	**=**	**Value**
Abduction-1	???	+	How	=	Value
Abduction-2	???	+	???	=	Value

Figure 1. Patterns of reasoning.

To understand the different design thinking approaches, it is beneficial to consider the different patterns of reasoning that are used for problem solving in different fields (Fig. 1). For predicting a phenomena that already exists in the world, scientists depend mainly on deductive reasoning (a.k.a. necessary inferences), and inductive reasoning (a.k.a. probable inferences) for seeking truth. It is also common, in the scientific method, to initiate the research by employing an abduction reasoning for hypothesizing the puzzling phenomenon, as explained by Charles Peirce (1839–1914). However, for most design fields the reasoning patterns often follow a non-deductive or inductive path. In engineering, design thinking process is heavily influenced by the logical reasoning of abduction-1, in which the designer knows '*how to*' achieve a '*value*' but the search is focused on finding the '*what*' (i.e. a service, an object, a system, etc.) (Dorset 2010). While the problem space is perceived as too wide, a rational solution to the structured problem is considered attainable. Architecture, on the other hand, deals mostly with an 'ill-defined' design context, which requires the designer to, simultaneously, define the problem space and the criteria applied to finding probable solutions (Akin 1986, Akin & Akin 1998, Eastman 2001, Dorst 2004). Therefore, this design process is better explored by employing an Abduction-2 reasoning logic, in which, the end '*value*' is the only known parameter allowing wider interpretation space

for the designer to figure out '*what*' to create and '*how*'? (Dorst 2004). In the architectural design process, the preliminary phases are seen as 'ill-defined', explorative in nature, and with a low degree of commitment. Design activities at this level are immersed in subjective interpretations (Eastman 2001). Therefore strategies for enhancing lateral transformations are seen as essential for widening of the problem space in search for multiple ideas and to facilitate the lateral movement between them (Goel 1992). At later stages, the focus shifts to a more defined and structured refinement and detailing, in which, attention shifts to vertical transformations moving in the depth of the problem space toward a more detailed version of the same idea. Therefore, the later stages of the architectural design process are seen as immersed in objective interpretations, which respond well to rational design logic (Goel 1992, Eastman 2001, Dorst 2004).

2.2 *Knowledge structure*

In design cognition, attention is shifting towards understanding the designer's conception of the design world and its context. Such conception is constructed by drawing upon multiple sources of information including the designer's sensory experiences, external sources of encoded information and the internal recollection of previous experiences and stored knowledge (i.e. factual, informal, procedural experiential, representational, etc.). Accordingly new questions have been emphasized focusing on how design information is carried in students' heads, how it is linked to other knowledge, and how it is structured, recalled, and manipulated during design reasoning (Eastman 2001). In this context, design is perceived as a knowledge driven process (Davis 2013).

One of the most important aspects of creative design has to do with domain knowledge (Akin & Akin 1998). As different design fields depend on discipline-specific knowledge, it is essential to recognize that designers rely heavily on the internal recollection of stored previous knowledge and experiences to inform design thinking (Eastman 2001). During design reasoning, relevant encoded information is recalled and used to structure the design context, which enables creative connections to happen. A command of domain knowledge is therefore essential for the creative process, and must be present during design reasoning (Akin & Akin 1998).

Depending on the nature of the design problem, designers draw upon different sources of relevant knowledge types. A 'well-defined' problem relies heavily on objective sources of information, such as formal, factual and procedural, while an 'ill-defined' problem relies heavily on the subjective interpretations by drawing upon a combination of experiential, social, cultural, etc. Once again, the subjective interpretation of the design problem and its context is highlighted as an important vehicle for achieving creative design. Therefore, architectural design education should focus on building an experience-based knowledge structure, mixing perceptual, historical, belief, cultural, social, formal, etc., which is brought to bear during design reasoning (Eastman 2001).

2.3 *Design representations*

In design fields, the ability to manipulate symbolic representations is considered essential for stimulating different aspects of information processing during design. Recently, new issues of significance have been introduced focusing on how different design representations are learned, internalized and integrated with other knowledge (Eastman 2001). Different representational mediums facilitate different aspects of design thinking. Cognitive studies have established a strong connection between internal representations (i.e. mental imagery, language processing, mathematical processing, etc.) and creativity. In the creative mind, internal representations play a substantial role in connecting conceptual ideas from different domains, during which mental constructs help to generate new concepts, while external representations act as support structures for the student's own knowledge base (Akin & Akin 1998, Eastman 2001). While there is enough evidence to suggest that imagination can be enhanced with practice (Wallace & Hofelich 1992), relying solely on internal representations can be limiting. Instead, design occurs as a result of a rigorous dialogue between both internal and external representations. (Reisberg & Logie 1993). To stimulate this creative dialogue, architecture education should bring forward a host of qualitatively different mediums, which engage both internal and external representations.

In design cognition, important distinctions between two modes of external representations are highlighted: 'ill-structured' representations (i.e. freehand sketching, diagramming, etc.) and 'well-structured' representations, (i.e. digital representations, computation, etc.). Each of these serves as an important stimulus agent during design processing. It has been argued that the use of 'ill-structured' diagrammatic representations in early design stages helps facilitate important cognitive processes; while 'well-structured' representations are helpful during the refinement and detail phases (Goel 1992). Freehand sketching offers a unique design thinking tool that can abstractly capture some of the structural properties during design processing, which helps to bridge the gap between the mental cognitive process and the physical world (Herbert 1988, Gross et al. 1988, Goel 1992, Goel 1995, Eastman, 2001). Moreover sketching and diagramming encourage lateral design thinking processes, which can be invaluable to concept generation and problem definition at the beginning of the architectural design process. While considerable progress has been made in understanding the role of 'ill-structured' representations during design, a deeper understanding of the role of 'well-structured' representations, such as computation and digital models, remains unclear. However, there is enough evidence to suggest that employing 'well-structured' representations in early

design phases can hinder the lateral exploration of alternative solutions forcing a premature crystallization of the design (Goel 1992). Moreover, Eastman (2000), argued that any learned external representation needs to be internalized in order to become part of the intrinsic cognitive mental reasoning ability of the designer, similar to reading, writing, sketching or math skills. Therefore the effective use of computation, as a design thinking medium, is closely linked to the designer's skill level and his/her ability to automate its use at a cognitive level (Eastman 2001, Peterson, Alexander & Webster 2001), which is necessary for facilitating the creative process during design (Akin & Akin 1998).

Building on this theoretical platform, the next few sections explore the nature of computational logic focusing on understanding the different reasoining patterns that are associated with the integration of computational thinking into the architectural design process.

3 COMPUTATIONAL THINKING

The concept of rule-based intelligence did not start with humans, as it occurs intuitively in many natural processes; including how cells process encoded information in the DNA. Within human history the first mathematical instrument used for calculation appeared in Mesopotamia (2700–2300 BC), with the invention of the Sumerian abacus (Ifrah 2001). In modern times, computational thinking was first introduced in 1980° (Papert 1980). Originally known (1950s–1960s) as '*algorithmic thinking*', computation is defined as the *"mental orientation to formulating problems as conversions of some input to an output and looking for algorithms to perform the conversions*" (Denning 2009, pp 28). The invention of the modern digital electronic systems allowed for the automation of complicated problems, which previously were seen as challenging. The design concepts behind the digital computing systems are mostly attributed to John von Neumann architecture, published in 1945. Neumann (1945 pp1) proposed a device that "*can carry out instructions to perform calculations…. The instructions which govern this operation must be given to the device in absolutely exhaustive detail. They include all numerical information which is required to solve the problem under consideration*". Accordingly, the digital system accepts numerical data '*input*', processes data arithmetically and/or logically, and then produces numerical information '*output*' following a linear '*fetch-execute*' cycle, in which instructions are laid out in consecutive order in memory. Digital computational power allowed for the organization of complex problems through well-defined procedures, which was proven to be instrumental for describing, simulating and modeling natural systems. At its core, computation involves abstraction and rational reasoning about the methods of investigation.

A central premise of using the digital computing systems as design tools, is understanding the "*necessary limitation on computable functions as mediator between input and output*" (Kotnik 2010, pp 6). Therefore, the question of '*computability*' of a relationship or a process becomes essential to its execution. In order to apply computation, it is necessary to describe the problem with "*absolutely exhaustive detail"*(Neuman 194, pp 1), using precise arithmetic and/or logical expressions, which requires the designer to provide a detailed definition of the design problem under investigation before initiating the search for probable solutions. Such definition clearly fits within the 'well-defined' problem sphere. The use of computation mandates that the design problem be mathematically expressed, has an algorithmic solution and that its functionality can be measured quantitatively.

Computational design thinking logic involves the decomposition of the entire decision making process into smaller controllable and quantifiable entities through, pattern recognition, abstraction, algorithm design, rational reasoning, deduction, etc. In this process, a close-fitted association, exists between the degree of '*computability'* of the design intent and the computational modeling logic that is used to derive design alternatives. This association serves as the foundation for understanding the integration of computational thinking into architectural design discourse. This paper identifies three levels of computational modeling logic: an output-driven computational modeling, relationship-driven computational modeling, and process-driven computational modeling. In this context, the designer's command of domain knowledge and level of digital craftsmanship are seen as necessary tools for enabling the integration of digital computational thinking into architectural discourse.

3.1 *Output-driven computational modeling*

The output-driven computational modeling logic, also referred to as '*the direct modeling*' (Davis 2013) equips designers with a computational strategy to quickly capture and manipulate geometry exploring design ideas by focusing on the desired output rather than on the deriving computational logic. Such computational models are descriptive in nature and are characterized by the lack of engagement at the algorithmic levels (Oxman 2006, Kotnik 2010). The output-driven computational logic denotes the utilization of a digital geometric environment that facilitates the representation of the desired geometry.

The range of digital environments, used for descriptive modeling, is wide and extends from the basic CAD modeling software to include high-level programming languages for writing independent algorithmic representations. However, the use of available graphics software environments implies the use of a set of predefined computable functions, or equations that explicitly define the governing rules between cause and effect following a deductive reasoning logic, '*output = function(s)* (*input*)'. The dependent '*output'*

is given in terms of the precise known quantities of the independent parameter(s) '*input'*. Relying on existing software means accepting the limitations imbedded within its code, workflow and user interface, which confines the geometric manipulations to specific tool pallets. Therefore programming skills are seen as providing a wider sphere of exploration not limited by a predefined set of computable functions. In recent years the use of programming has allowed architects to break free from these limitations enabling the exploration of new methods of organization and form-generation, often derived from nature (Weinstock 2010). In this context transferring existing mathematical or physical models into an architectural context, is still seen as operating within the same descriptive explicit modeling sphere. The digital environment in this case, provides the geometric language that facilitates the representation of the complex geometry, which can be challenging to represent using manual tools (Kotnik 2010). Hence, the output-driven digital computational modeling logic is seen as an extension to the traditional geometric environments and, if internalized, is isomorphic to the sketch-driven thinking models.

3.2 *Relationship-driven computational modeling*

The relationship-driven computational modeling, also referred to as *'parametric modeling'*, denotes the design and use of a fixed field of explicit relationships for generating design alternatives. In this context, computational logic shifts from being a tool for descriptive representations towards encoding design intentions at the algorithmic level. This process involves the design of "*a set of equations that express a geometric model as explicit functions of a number of parameters*" (Davis 2013, pp 31). This is achieved through explicitly defining the governing rules between the '*input'* and '*output*' following a deductive reasoning logic: '*output = equation(s)* (*input*)'. Variations of the dependent '*output'* are generated in terms of testing ranges of variations across the independent '*input'* parameter(s) space. The value of the relationship-driven exploration lies in the way that the computational algorithms is created; requiring the designer to anticipate design output by defining the logical sequence of formulas, constraints, explicit relationships, parameters and dependencies, to derive design outcomes (Davis 2013). Such logic denotes the existence of a hierarchical structure with direct cascading and causal relationships, often moving from the global to the local. In this context, design computability becomes a method for exploration, confined within the predefined relationships operating at the level of parametric manipulation (Burry & Murray 1997, Kotnik 2010). While such logic is suited for addressing 'well-defined' design problems with strict performance, aesthetics, or structuring criteria, etc. (Davis 2013). By confining the 'problem space' to a predefined set of relationships and parameters, this process risks narrowing the 'solution space' to a limited range of possibilities. Relationship-driven computational modeling often informs design decisions that are derived by a numerical formula as a measure of testing formative or performative output. This quantitative perspective on design thinking can steer the process towards optimization; potentially limiting the creative design sphere (Kotnik 2010). Moreover, learning to think parametrically requires the designer to express design process and outcome with explicit computational functions, which is a "*hard-won skill*" (Burry 2011, pp 38). Smith (2007) summarized some major technical challenges associated with crafting and implementing parametric schemes including the substantial front-loading investment for building the model, limited flexibility, the instability of the parametric model in relation to substantial variation, the difficulty in visualizing changes, and the difficulty of sharing or reusing parametric models.

Today a range of computational environments are available for crafting parametric models, including, history-based modelers, visual scripts, physical modelling, scripting, high-level programming, etc. However, Most available 2D and 3D graphic software (i.e. AutoCAD, Sketchup, 3D Max, Rhino, Grasshopper, etc.), are not readily designed to facilitate parametric explorations at the algorithmic level. However most of these tools allow for programming languages (i.e. C++, C#, Python, VB, etc.) to extend their functionality enabling better control over programing algorithms. In this context, digital programing skills are considered essential for employing relationship-driven computational logic into the design process.

3.3 *Process-driven computational modeling*

A process-driven computational modeling is a generative design approach, in which, design intent is algorithmically encoded in a system that is structured to evolve independently beyond the designer's initial input. In this model, attention shifts from the parametric manipulation of the explicit filed of relationships, towards the development of sequences of operations that encode the design intent. Process-driven models are characterized by the use of computational mechanism for formalized generation processes (Oxman 2006) operating at the level of algorithmic computability (Kotnik 2010). The use of process-driven generative logic denotes a bottom-up approach, in which, design hierarchy emerges as a result of the self-governing processes (Snook 2012). By defining the local entities, relationships, transformations, constants, constrains, degrees of freedom, parameters, etc., the designer sets the initial rules for the system to self-organize and to independently evolve to generate the design output. This involves building a dynamic model for encoding the behavior of the local values in response to their local environment focusing on the process as a design driver rather on the artifact (Snook 2012). In this case design thinking logic is not geared toward calculating the optimal output, similar to parametric design logic, but rather towards a self-emergent output; evolving beyond the control of the designer's initial input and

derived from the decision-making process of the local entities.

In this context, design solutions are seen as an emergent global outcome of an intensive local processes, in which the interaction among individual entities give rise to the collective emergent behavior at the global scale. It is worthy to note that this concept is not completely new to design, as similar design concepts were applied throughout history. One of the unique examples of a process-emergent design output, can be found in the way that traditional and vernacular cities have emerged over time. By allowing a degree of freedom within the initial set of local ordinance, a dynamic design emerges that is responsive to individual needs as well as bound by the collective global values that safe guard the collective behavior. In principle, the generative design process is a powerful design tool, if allowed to operate intuitively within a complex social, collaborative, bottom up design approach that is intended to evolve in real time. However generative computational design logic, operating within the digital confines, is seen as an experimental method for exploring 'form intelligence' or 'behavioral-driven formations' at an abstract level. The use of digital computation implies a limitation on defining local entities from available digital geometric primitives (i.e. point, line, body, etc.), and are expressed numerically through physical attributes, (i.e. materiality, location, etc.). At the same time, the behavior of such geometric entities can only be manipulated through digital geometric transformations (i.e. translation, rotation, scaling, etc.). While such vocabulary can be effective in expressing the organization of abstract systems of quantified complexity, it is yet to be seen how such systems can encode complex social, economic behavioral patterns when approaching real-life design situations.

Recent explorations of using generative computational logic as a design generator is more about phenomena recognition than formal design method. So far these explorations are focused on extracting complex systems from nature such as genetic algorithms, flocking, and cellular automaton, etc. (Davis 2013) and deploying them as design generators. However, applying such schemes into design process requires the designer to have a higher level of programming skills and deeper formal knowledge of mathematics, biology, physics, chemistry, etc., most of which are rarely provided by architectural curriculums.

4 CONCLUSION

This paper is set to explore some cognitive aspects, associated with the integration of digital computational thinking into architectural education. After looking analytically at the three main modes of computational logic (output-driven, relationship-driven and process-driven) at a cognitive level, this paper argues that the shift towards digital computational thinking as an alternative design methodology has deep pedagogical consequences on design education, as it relates to design reasoning patterns, domain knowledge and technical skill level.

Architectural design discourse is widely recognized as immersed in subjective interpretations as designers respond to the overwhelmingly 'ill-defined' nature of the design problem. The creative design process is enabled by the subjective context of the designer's experience-based knowledge structure mixing perceptual, historical, belief, cultural, social, and formal, etc. However the rationalization of design thinking by means of computable functions is grounded in positivistic epistemology, which views design exploration as operating within an objective sphere, and based on deductive logical reasoning, objective data and explicit knowledge. While this view provides a viable framework for the systematic exploration of a 'well-defined' design problem, it poses unforeseen limitations on design thinking when approaching an 'ill-defined' problem; acting as a thinking barrier by limiting the exploration of wider design sphere. In this context, the computational framework is seen as providing a specialized design strategy; enhancing but not replacing the intuitive nature of the creative subjectively-driven design process.

Moreover the integration of advanced computational thinking logic into architectural discourse, requires pedagogical shifts at multiple levels. A high-level command of formal knowledge structure and programming skills are considered essential for supporting the computational path. While this direction might present an opportunity for offering a specialized graduate interdisciplinary educational path, it encompasses multitudes of challenges at the undergraduate professional level. It is therefore critical to examine the value of shifting architectural pedagogy toward computational thinking.

Decode: Reverse engineering abstract art a method for teaching computer programming to architects

I. Vukorep
Brandenburgische Technische Universität Cottbus – Senftenberg (BTU C-S), Germany

ABSTRACT: This article describes why modern art can help architects and designers learn computer programming languages—it is a very suitable medium for reverse engineering new forms. From 1955 until now, a number of artists have experimented with generating fine art in a coded manner. Some of them explicitly use machine code, whereas others use analogue drawing machines or simply code-like descriptive methods for their art. Some of the works, created from the 1950s to the 1980s, are re-purposed in this course as their main formal methods are repetition, recursivity and iteration. After an analysis and 'reengineering' of existing artwork, students develop their own designs using the methods learned and, furthermore, go on to produce/draw these on a table-sized CNC mill or 3D-printer. The goal of this research is to assemble a database of reference samples and create a series of programming handbooks aimed at assisting architecture students to surmount technological barriers. This paper describes the current research stage of this teaching method and provides examples that signal directions for further research.

1 INTRODUCTION

Art and technology have developed concurrently throughout history. Soon after computers were installed in major institutes worldwide in the mid-1960s, we observe a surge of artists eager to create computer-generated art. Shortly thereafter, the first computer aided design (CAD) systems for architects were developed (Weisberg 2008). This was the beginning of coding; that is, the ability to develop a set of rules in computer language and to convert that code into another representation. In this work, we are dealing with codes representing 2D and 3D forms. Typefont, typesize and spacing.

The term 'decode' describes the interpretation and conversion of symbols from their coded to their original form. Decoding is a process mainly used in information technology for communication or visualisation tasks. In the context of this course, we consider artwork as coded work. That is, the process of formal dissection is done by analysing the principles of the formal structure of the original work. With the help of computer languages, the observed works of art are rebuilt experimentally.

When we observe the average architectural work environment, we find that programming skills are not essential for doing the job. For normal designing, technical or communication tasks, an architect will not need any scripting/programming knowledge since most tasks can be achieved using commercially available or free software tools.

Until a few years ago, the barriers to developing an independently programmable tool were quite high in terms of platforms, program language and incorporation into a working system. This is changing and these barriers have been reduced, with a shift towards software development in design and techniques programmed not by software engineers, but by architects. There are several reasons for this: (1) new innovative software instruments are simplifying the act of coding; (2) online learning and exchanging platforms are increasing the speed of getting 'how to' information; and (3) the transition from big universal programs to small custom applications for specific needs.

As this ongoing process is inevitable, the professional development of programming skills for architects is an important step towards better functioning architectural or office applications (efficiency, usability, maintainability, dependability and reusability) (Sommerville 2004; Daniel 2013). Furthermore, architects with programming skills are better informed and motivated in their areas of expertise than software engineers. Considering this, there is a need for an alternative teaching method more suitable for the needs of architectural professionals.

This teaching method is build upon the idea to encourage architects to develop programs, work on complex, procedural and generative design, get into computer-controlled production and be able to communicate with software programmers. For this demands they need to get in touch with programming what the Decode lessons are providing.

The curriculum exists in two parts: Decode 1 and Decode 2, together with a printed/builded output. Whereas Decode 1 focuses on programming language processing and painted art, Decode 2 concentrates on

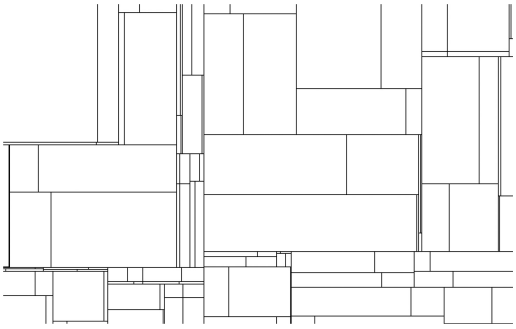

Figure 1. Decoded version of Ohne Titel (Palast des Midas), Georg Nees, ca. 1970.

sculpted artwork and decoding with Rhino-scripting tools.

The computer languages Processing and Python are used because they are simple in use and far spread. In comparison with the graphical algorithmic editor Grasshopper for Rhino, which is been widely used in offices and universities, these programming languages can give a basic understanding how software-programming concepts work.

2 RELATED WORK

Both this article and the course are based on artwork from the 1950s to the 1980s. Some art references come from traditional abstracts while others come from the experimental computer art era. The generic and parametric structures of minimalism, conceptual and op-art provide a sound basis for digital decoding. Conceptual and formal similarities are found between these different art movements despite their artistic deviations (Watz 2010).

The code-like abstract art of Sol Le Witt's Wall Drawings are the best examples of how explicit written instructions can produce form in a conceptual manner. Coding experiments to reconstruct his text-instructions are still very popular in current computer-art and interdisciplinary design courses. Casey Reas, one of the developers of the programming language Processing, describes that his main motivation for the development of a new programming language was the work of Sol Le Witt and the lack of programming instruments available for making intuitive formal solutions (Casey n.d.). Processing is now a widespread programming tool that is predominantly used by artists and those in other graphics-oriented disciplines. With a wide library of additional software add-ons, it can be used as a tool for any kind of media art.

The main collection of computer art is organised through the 'recode project', with a platform for a community-organised collection of mainly computer art from the 1960s to the 1980s. This collection contains a large library of artwork, where some of the work is decoded in programming language. It also holds a link collection for the magazine, Computer Graphics and Art, which was published quarterly between 1976 and 1978 by Berkeley Enterprises Inc. and focused on art experimentation around computer graphics, including essays on electronic art. Although the recode project does not contain a significant code collection, it still provides a good overview of computer art during that period.

Translab in the 'Burundi Datalab Project', in Slovakia, assembles a significant collection of articles and examples of computer art. This is an interdisciplinary research project to study the history of new media and contains a commented list and articles of artists and artwork from the second half of the 20th century.

3 GOALS AND CONTRIBUTIONS

3.1 *New method of teaching programming for architectural students*

The main motivation for the course is the development of a fresh approach to teaching architecture students about computer programming. One question is how these students, with no coding experience, solve design problems using basic programming techniques.

3.2 *Resolving abstract art through code as a driving force for learning programming*

Architects commonly work with visual elements, particularly when they explain their designs or try to describe complex content. Abstract art seems an appropriate graphic equivalent to common coding examples, where programming basics are explained step-by-step.

3.3 *New code solutions for several art works from the minimalism, op-art and conceptual art periods*

The course examines existing codes for art pieces, which are further developed and optimised. Since students are also working with art that has never been decoded, new code is produced. These codes will be published on the 'decode project' webpage to share this knowledge (www.b-tu.de).

4 HISTORICAL OVERVIEW

Art is always connected to its embodied code. When we look at art, we tend to find the 'deeper meaning' of the studied object. With the surge in abstract art 100 years ago, we can observe a switch from figurative narration to non-story-telling geometry and colour compositions. Even if the large part of abstract painted art is two dimensional, we can still often see the spatial components in most of them; for example, Malewitsch's main work, where objects float and overlap in space. Although the intuitive working process of some artists from the first part of the 20th century makes decoding a bit more difficult, this has been replaced by

more calculative art. Abstract expressionism, as a non-geometrical art movement, emerges from the intuitive movement of the artist's arm. It seems that the intuitive working process in abstract art fades away towards the 1960s, especially with the new conceptualist and minimalist art thinking. Conceptualism as an art movement, contrary to the digital art of the 60s and 70s, focuses on concept rather than output; that is, its own code. Similar to digital art, where the terms 'original' and 'copy' are being questioned, conceptualism supports the paradigm shift in the way that the original materialised work is set to background: this is the only similarity to digital art. Digital art, which has evolved from form-finding experiments with new computational methods and is still very heterogeneous, but lacks an overall conceptual foundation; however, digital art prepared the groundwork for the impending media art movement.

5 DIDACTICAL APPROACH

This course comprises four parts:

5.1 *Weekly lectures in programming*

Programming lectures in the first two months with exercises and homework. As most of the students do not have any previous programming experience, a simple programming platform will be used for the first part (Decode 1). Processing, developed by Ben Fry and Casey Reas at MIT in 2001, is considered a perfect platform that unifies a simple IDE (integrated design environment), with a simple command structure based on java and C++, has good graphical output abilities and is capable of most programming routines. For the second course (Decode 2), the Python programming environment of the 3D-modelling program Rhino 3D (from McNeel) is used as it supports a wide range of preconfigured modelling commands. Python is a language that is used for a variety of purposes and a knowledge of Python can assist in further programming development.

Most examples used in the lectures are art examples that deals with common programming problems. The processing lectures encompass the following learning points:

- setup, draw, lines, basic shapes, coordinates, variables, loops 1
- conditionals 1/if then else, loops 2, comments, colors 1, expressions/statements
- export to JS, interaction / mouse, keyboard, colors 2, transparencies
- conditionals 2, classes 1, arithmetic
- harmonic functions, curves, random, translation, transformation
- iteration / recursion, l-systems
- classes 2, importing libraries
- interaction web, sensors, kinect

The Python for Rhino lectures concentrate more on the possibilities inside Rhino 3D, 3D-modelling

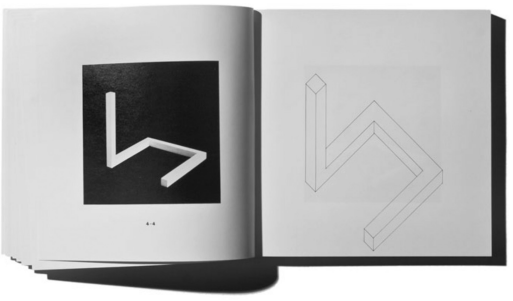

Figure 2. Open incomplete cubes, Sol le Witt, 1974 (Gross 2012).

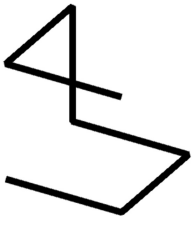

Figure 3. Decoded version, one from a series, open incomplete cubes.

aspects and simple algorithms dealing with balancing an object. The balancing procedures for single-material objects are purely based on geometry and are achieved by:

- finding the mass-centre of a volume;
- defining the footprint of an object (this can be tricky if the object is standing on several supports);
- checking if the vertical projected mass-centre is inside the footprint;
- if yes, object is balanced;
- if no, redefine object or let it fall (and repeating the balance procedure).

5.2 *Decoding exercise of an existing art work*

Parallel to the intensive input at the beginning of the course, students choose their work from a list of artists (Mohr, Nees, LeWitt, Molnar, Vasarely, Malewitsch, Lisitsky, Andrade, Riley, Zajec, Bangert, Basset, Aranda/Lasch, Silvermann, Perry, Hild, Clar, Carrajal, Bill, Serra). The goal is to decode the artwork as well as to explore the chosen artist's context and summarise the structural principles. The produced code gives a formal twin that should follow these principles without making an exact copy of the original work (Figs. 2 and 3).

Hand-schemes are essential for finding out the main principles of the observed art piece. After discovering programmable regularities in the observed work, an appropriate programming principle is suggested. In addition to the individual working with code concepts, this part of reverse engineering art work is crucial to understanding how complex systems can be reduced to simpler ones (Fig. 4.). The degree of difficulty varies

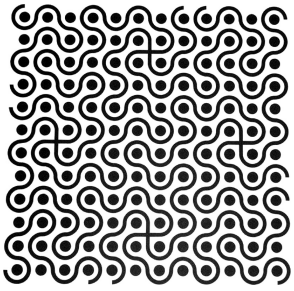

Figure 4. Black Dragons, Edna Andrade.

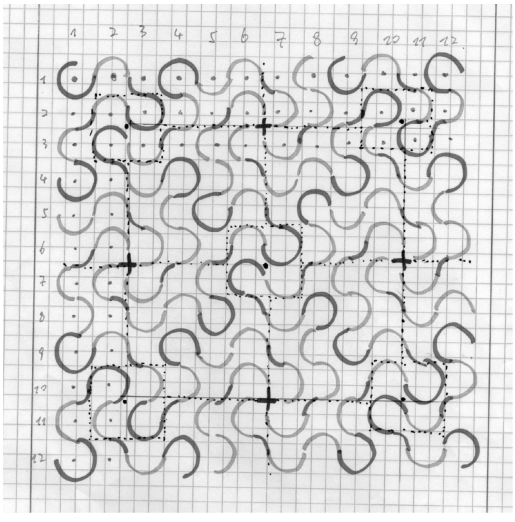

Figure 5. Hand-sketch, student Bing Ding, 2015.

among art pieces. Artwork with an obviously digital background (Nees) is more easily comprehensible in reengineering. Abstract art without an explicit digital context is particularly hard to decode (Vasarely).

5.3 *Individual work – coding*

Applying knowledge gained from the earlier course parts, students develop their own digital art codes. Their individual work is based mainly on code and principles from the decoding process. As the drawings are further processed with digital prototyping machines (CNC-mill and 3D-printer) it is important to consider the output format and its constraints. When exporting an image to a CNC-mill, two parameters are important for processing: (1) the drawing contains only lines. Filled areas should be minimised and pen-behaviour examined (jittering); and (2) inaccuracy of the pen attached to the CNC-machine is to be considered. Uncertain output can be part of the work (error and uncertainty).

If the code is 3D-printed, then all objects have to be closed, without any holes in their geometry; otherwise, only inferior 3D prints will be produced. This is a part of the coding requirements.

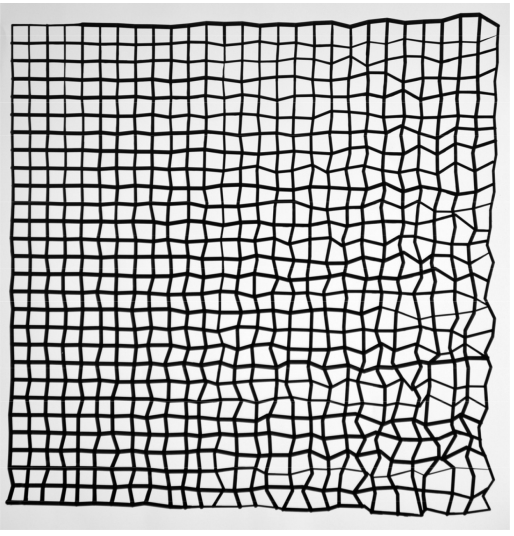

Figure 6. Individual work of the student Maria Fuchs based on a work of Georg Nees, Pen on paper, 2015.

5.4 *Individual work – materialising the code*

Prior to CNC-drawing and 3D printing, each participant learns the basics of exporting art work as a pdf file (Processing) or as a clean model (Rhino 3D) on a separate layer that can then be saved as an stl file. The procedure for using the CNC-mill is as follows: import the pdf file to Rhino-CAM, making the machine-paths, exporting the nc-file to the CNC controlling unit and, finally, controlling the machine-drawing process. Since all work is completed at an individual level, all participants go through the whole production process.

6 OUTCOME

Besides decoding significant art work and individual coded work, the long-term output of the work are the books, Decode 1 & Decode 2 (Decoded Art – a Programming Handbook for Architects and Designers). These handbooks contain code examples for two different programming languages: Processing and Python for Rhino 3D. Most examples come from the programming part of the course and the programming outcomes of the students (Processing and Python) that are then optimised for handbook.

It makes sense to build the lectures/courses in a sequential manner so new knowledge can be built on a sound foundation. Focusing on only one programming language can limit one's view when working with complex formal systems, particularly if they are interactive. To demonstrate alternative approaches in task dependency, it is important to recognise programming language differences. With the rising popularity of Grasshopper, a graphics algorithm editor, it is also important to demonstrate the weaknesses and strengths of graphical- and script-oriented methods.

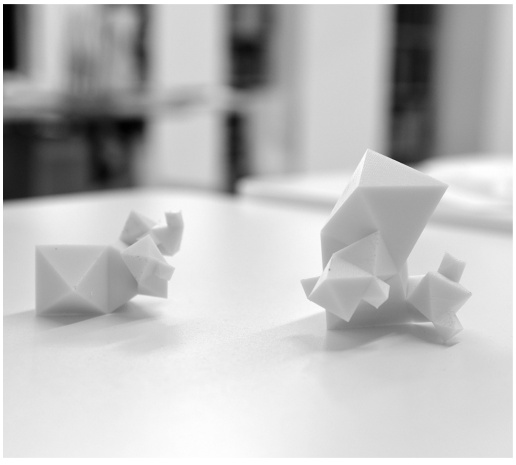

Figure 7. Decode Art: Sculpture – 3D-printed decoded work (student Robert Schwitzky), art by Aranda Lasch.

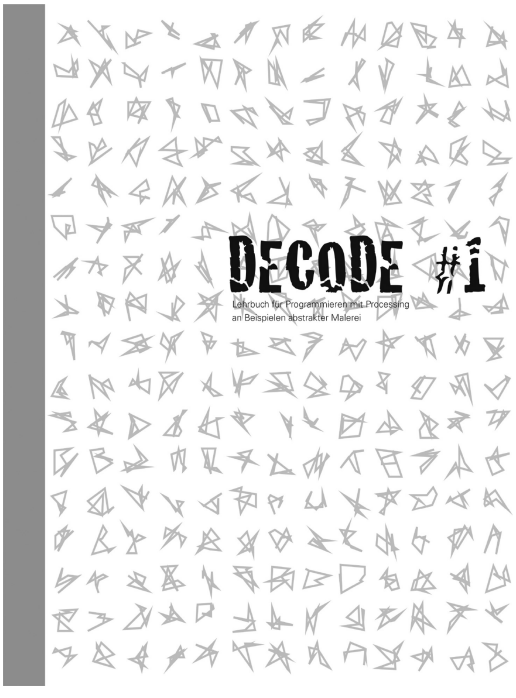

Figure 8. Decode Art: Painting – Programming Handbook.

The main goal of the books is to provide the reader with basic knowledge in programming techniques that will help them solve tasks independently of the programming/modelling surrounding. The code from the book is available on www.b-tu.de, with some additional code examples.

7 NEXT STEPS AND CONCLUSION

Post-course evaluations show that the decoding part of the course was the most demanding (75% of the students declared that it was difficult). Over 40% of the participants are interested in continuing the course towards programming 3D objects. Considering the evaluations, some improvements must be made in upcoming courses; for example, simplifying the examples, and reducing and concentrating on basic scripting principles.

With the upcoming third part of the course, 'Decode Art: Nature', and focusing on regular or irregular forms in nature, the course will emphasis programming 3D-meshes with a graphical scripting tool, e.g. *Grasshopper for Rhino 3D*. This is an entry course to give Master's students basic knowledge in parametric and rule-based design.

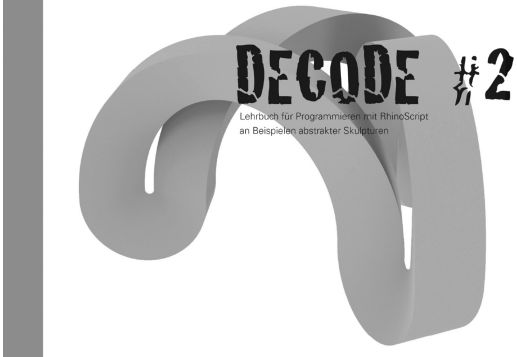

Figure 9. Decode Art: Sculpture – Programming Handbook.

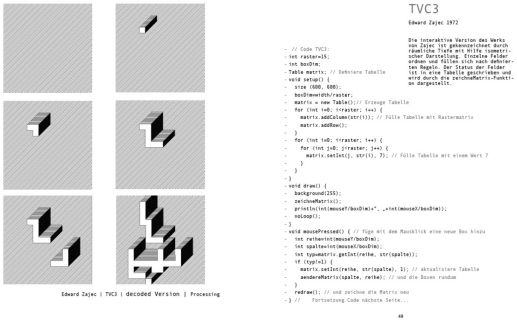

Figure 10. Decode Art: Painting – decoded work (student Martin Lederer), art by Edward Zajec.

Working with art analogies can be a push method for delivering programming abilities to students with no programming experience. The goal is not to make software developers out of architects but to encourage architects to develop programs, work on complex, procedural and generative design, get into computer-controlled production and be able to communicate with software programmers. Quick visualisation results as programming output gives a much better non-abstract approach to this complex topic. Combined with formal decomposition and reengineering of existing artwork in a descriptive and rule-based manner, it is a demanding course, but can provide participants with a basic understanding of how software systems are structured and motivate them towards further investigations in computational methods in architecture and design.

Exploring learning objectives for digital design in architectural education

Shelby E. Doyle & Nick Senske
Iowa State University, USA

ABSTRACT: What are the objectives of teaching digital design in architecture? While this seems a rather primitive inquiry it in fact is loaded with misunderstanding and disagreement. This paper aims to bring accepted educational research about learning objectives into the discussion of digital design's relationship to architecture. In particular, Bloom's Taxonomy is introduced and referenced as a tool for creating clarity, transparency, and accountability among educators. The purpose of reflecting upon learning objectives for digital design in architecture is not to produce a definitive list of what students ought to learn. Learning objectives are written for specific curricula, student needs, and faculty interests. They are useful because they provide a clear definition of expected outcomes and which becomes a point of dialogue. In order to evaluate something, it first must be named. Through evaluation and discussion, a discipline develops. When Bloom created the learning taxonomy, this was the goal. Not to explain or lay claim to how students must learn, but to provide a shared structure so educators could compare their approaches. In a similar manner, creating and sharing learning objectives for digital design instruction, using established tools like Bloom's Taxonomy, can produce a more organized dialogue about how to align the use of digital tools with the core values of architectural education and the development of the discipline itself.

1 INTRODUCTION

1.1 *Introduction*

During the past 25 years, the introduction of computing and other digital machines into architecture led many schools to consider and make changes to their curricula and courses. However, there is little agreement within architecture departments, much less between schools, on what it means to design digitally, what it means to teach it well, and how this integrates with more traditional methods and understandings of architectural design.

This problem is aggravated because much of architectural education today is what Bruner calls "folk pedagogy", guided by implicit assumptions but not connected with educational theory or evidence beyond one's experiences. (1996) As such, there have been few attempts to to apply peer-reviewed curriculum design strategies and instructional methodologies to the challenge of digital design instruction in architectural education.

In response to this challenge, this paper proposes that defining learning objectives for digital design in architectural education, in connection with established educational and learning theories, can create a productive dialogue and a starting point for evaluating and addressing the challenges of integrating digital design.

1.2 *Pedagogical alignment and the value of digital design*

The lack of agreement and clarity among schools regarding digital design creates problems for the discipline. How can a skillset be taught without a clear definition? And how can the field evolve when there is such contention over education in a critical area? Dialog and common ground are needed.

A key reason for the confusion surrounding digital design instruction in the university setting is a misunderstanding of its educational value as a set of skills beyond technical skilling. In architecture schools, there tends to be a cultural hierarchy that places significant importance upon studio courses as sites where skills are integrated and practiced, and less importance upon supportive technology courses (such as a digital representation course) where those skills are first learned. However, this hierarchy ignores much about how learning functions and how effective learning takes place. A more nuanced understanding of the relationships between digital skills and design processes is needed.

One of the most significant effects of educational research has been to redefine the scope and goals of learning. Decades ago, before the development of contemporary learning theories, schools emphasized developing core skills such as reading and memorizing information such as dates and facts in a history

class. The implicit assumption was that this level of learning was sufficient for students to write reports, solve problems, and produce other sophisticated applications of literacy. However, while many students could demonstrate ability at, for instance, providing the correct solution for a specific type of word problem, educational researchers found that students rarely understood what they had learned, nor could they easily apply their skills and strategies to new contexts. (Clement, 1982) The students knew their lessons by rote and adapted to succeed at their instructor's tests, but they had a superficial understanding of the material. Today though educational models and expectations have evolved, digital technology is often relegated to this type of learning.

While skills and facts remain important to learn, the goal of education today has been restated: to provide students with a foundation of deep learning and the intellectual tools to ask and address meaningful questions. (Bransford, Brown, and Cocking, 1999) In contrast to superficial learning of facts and procedures, deep learning entails knowledge of the underlying principles, domain structure, and strategies to activate skills and knowledge and apply them flexibly in a variety of conditions – particularly conditions which are different from the ones where learning originally occurred. Such as the translation of design thinking from an academic to professional context. Deep learning is what most instructors would recognize as productive and transferable learning yet few courses actually achieve. Architectural studios are examples of a deep learning environment.

In contrast to architectural studios, the current state of digital design instruction in architecture tends to follow an educational model which does not support deep learning. Presently, much of what students learn in technology skills courses is by rote: sequences of commands and procedures intended to produce reliable results. While students can operate software and other tools with what appears to be great fluency, the vast majority do not have a deep understanding of computing or digital media principles (Senske, 2014). As a result, their work tends to be inefficient and derivative. Like the school teachers in the earlier example, digital design instructors emphasize core skills for using digital tools and then expect students to apply them towards design projects. This is the reason a learning gap exists. First, students do not learn the tools with significant guidance to develop depth and rigor; second, they are not taught explicit strategies for applying digital methods to design tasks. Students often fail to develop an understanding of digital design methods because the pedagogy is not aligned with the goal of deep learning. This leads to a frequently cited criticism of digital design: work which is repetitive or uninventive because students are grappling with technology rather than controlling it. The technology does not make it this way – it is how it is used.

This assumes that such a goal is recognized in the first place. Learning digital tools is often seen – by students and faculty alike – as mere technical skilling rather than a way of thinking about design. Professional architectural accreditation (NAAB) in American schools uses a set of learning criteria which specify Ability and Understanding (NAAB, 2014). However, this set of criteria does not address digital design with any specificity. There is no agreement upon the value or content of a digital design education, and so student abilities can vary widely from school to school, and within academic units. Students are less inclined to develop a thorough knowledge of digital design because it is not universally considered a meaningful intellectual and creative pursuit. This not only hinders progress within the discipline, but, in practical terms, it affects the profession. Failure to recognize the principles of digital tools and structures of problems they address makes it more difficult for students to learn and retrain themselves in response to changing technology.

The educational model of the design studio is unique its approach because it has many elements which contribute to the production of deep learning, such as opportunities for synthetic learning, active learning, complex problem solving, and self-reflection and critique. This is precisely the kind of approach that would benefit specialized digital design courses. Unfortunately, the architectural design studio is often seen as one type of learning, while digital design, which is thought of as mere technology, is seen as another. This disconnection is due to a misunderstanding about digital design due to a lack of clearly-defined and shared pedagogical goals. The present situation in education has come about because the implied goal of digital design education is mere tool operation (which does not require deep learning) when the expected outcome should be increased agency and sophistication of design ability.

One way to address the problem of pedagogical misalignment is to develop learning objectives for digital design. Learning objectives have the benefit of being a structured, well-understood, and research-based approach to curricular development. This method informs clarity and represents an explicit way to connect the goal of deep learning with pedagogical execution.

2 LEARNING OBJECTIVES

2.1 *Learning objectives for digital design*

The idea of a learning objective is straightforward, but often misunderstood and misapplied. A learning objective is a specific statement which describes what a student will know (knowledge) be able to do (skills) as a result of engaging in a learning activity. A learning objective must have three parts: a measurable verb associated with the intended cognitive process, the necessary condition (if any) under which the performance is to occur, and the criteria for measuring acceptable performance (this is often implied). A simplistic example of a learning objective that fits this pattern is: "Given a set of contours the student will

be able to generate a topographic model." The condition is having a set of contours and the implied measurement is an acceptable model. Learning objectives are focused solely on student outcomes and do not specify methods or other expectations for the teacher. They are not an attempt to create uniform classroom procedures or hinder instructor creativity through standardization. The teacher has flexibility in their approach, so long as the performance criteria are met. Learning objectives are useful because they help instructors with course planning and the creation of content. Furthermore, the explicitness of properly-constructed learning objectives establishes a basis for student assessment as well as the evaluation of teaching and curricula (Anderson, 2002). A primary challenge of digital architecture evaluation is the lack of criteria and therefore a lack of agreed upon traits for which to evaluate whether digitally produced code, drawings or images are successful.

In this manner, learning objectives support better learning and provide a common framework for schools to organize their efforts at improving education. For this reason, many Universities have standardized their syllabus policies to address learning objectives [see (Vanderbilt, 2016) and (Carnegie Mellon, 2016) for example]. The use of learning objectives may seem obvious or unnecessary if one is only considering their use in one's own syllabi, but in terms of disciplinary alignment, digital design instruction could benefit from the additional clarity offered.

2.2 *Bloom's taxonomy*

A useful tool for developing better learning objectives is Bloom's taxonomy. The taxonomy is a hierarchical framework intended to help instructors coordinate their planning and assessment using a common language (Krathwhol, 2002). It represents the process of learning from acquiring simpler to more sophisticated thinking skills. The general idea of Bloom's taxonomy is that lower levels of cognition support higher levels. For instance, one must understand the difference between different methods of constructing a surface (comprehending) before choosing which surface to use (applying).

In its revised form, Bloom's taxonomy lists six levels of cognitive processes:

1 Knowing: memorization and factual recall
2 Comprehending: understanding the meaning of facts and information
3 Applying: selection and correct use of facts, rules, or ideas
4 Analyzing: breaking down information into component parts
5 Evaluating: judging or forming an opinion about the information
6 Creating: combination of facts, ideas, or information to make a new whole

A more recent addition to the discussion of the taxonomy is the inclusion of types of knowledge. Anderson and Krathwohl addressed criticisms of the taxonomy by recognizing that not all knowledge is equal in complexity and that knowledge tends to be developed from concrete (facts and concepts) to abstract (procedural) and finally to knowledge of one's own cognition (metacognitive). (2001) In concert with cognitive processes, the knowledge dimension of the revised taxonomy enables a more nuanced discussion of learning objectives. For instance, under the newer version, the taxonomy does not progress and stop with creating, but also includes thinking about one's learning progress and how one creates.

Bloom's taxonomy has been criticized because it does not represent the complex and interconnected nature of cognition (Furst, 1981), but the taxonomy was never conceived of as a model or theory. Nor is it a prescription for every course to follow. One could design a course with at least one learning objective at each level. Depending upon the skills required, some levels may need additional objectives. Students with different abilities may be able to begin learning at higher levels. The value of the taxonomy is less that it represents exactly how learning works or that it tells instructors how to teach, but rather in how it helps to organize and align pedagogical thinking.

Educational frameworks like Bloom's taxonomy are not in common use in architectural education. The reason for this is unclear but may derive from a disciplinary resistance to self-articulation. However, for those developing or revising architectural curricula, having access to a set of learning objectives that uses the taxonomy can enable a dialog within the discipline, with other disciplines and educational researchers.

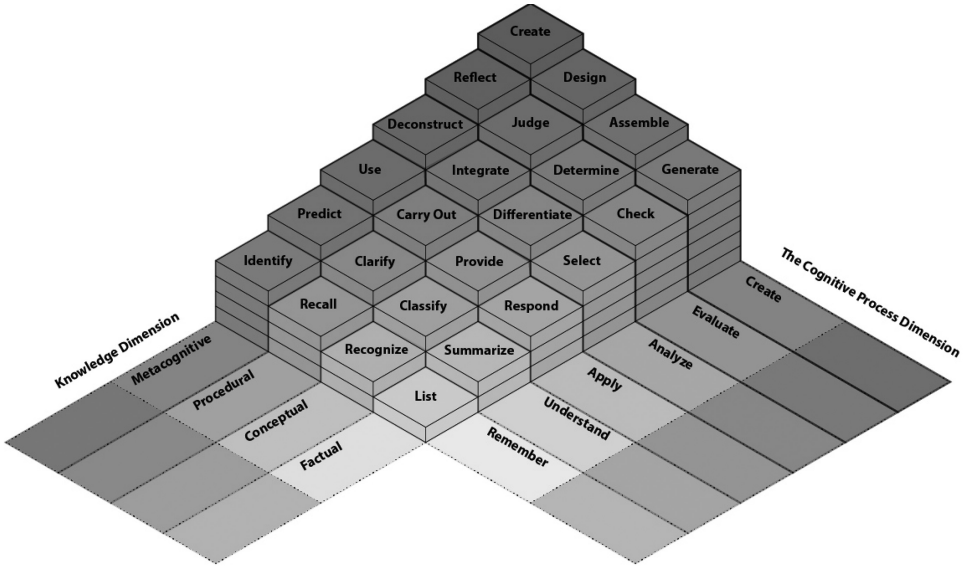
Bloom's taxonomy helps support the goal of developing deep understanding in digital design instruction. One way it accomplishes this is by establishing the basic cognitive processes involved in learning to design thoughtfully. To see all of these steps organized and consider them with respect to digital design is to shed light on what is often an opaque practice. The taxonomy makes it clear that one does not just use or not use various tools, but one must understand them, choose from them, and evaluate those choices as part of a design process. In this manner, an advantage of learning objectives developed through Bloom's taxonomy is that they can elevate student outcomes towards higher-order thinking. (Biggs, 1999) For example, without the proper outcomes articulated, a student might submit a design, but was merely applying a procedure. Bloom's taxonomy makes it clear that creation depends as much on understanding one's decisions (the "why") as knowing the correct commands (the "how" – which is often students' focus). For teachers and students alike, Bloom's taxonomy helps clarify that the goal of digital design instruction is not only to learn how to use digital tools, but to apply them towards better designs and more sophisticated design thinking.

With regards to teaching methodology, the clarity of learning objectives derived from Bloom's taxonomy can help motivate qualities of student performance which are often lacking in digital design courses, such as innovative solutions and well-crafted, thoughtful

representation. As mentioned in the previous section, many learning objectives are not specific enough, sufficiently measurable, or targeted to student's learning level. Bloom's taxonomy can help ensure that students are practicing the skills that they should be learning in their activities and at an appropriate level of cognition. This enables the pedagogical gap between learning digital methods and creating designs to be filled with deliberate (or mindful) practice.

Deliberate practice is a recognized process through which individuals train themselves to high levels of performance. Research has shown that learning of complex skills is most effective when students engage with tasks that are appropriately challenging, with clear performance goals and feedback, and sufficiently frequent opportunities for practice. (Ericsson, K.A., Krampe, R.T. and Tesch-Römer, 1993) The difference between merely making and deliberate practice is that a student monitors their progress towards a specific goal and changes their performance in response to feedback. The student continues to do so while increasing the challenge of the activity to further improve. Learning objectives assist students in deliberate practice by creating specific and appropriate performance goals which they can use to monitor their progress. This guidance directly supports the development of abilities on the highest (metacognitive) level of the taxonomy, which are crucial for sophisticated work and achieving transfer of skills and knowledge to other domains. (Perkins and Salomon, 1992) Thus, the notion of deliberate practice stands in contrast to the disengaged ways that many students learn and use digital tools, which is often oriented towards production for its own sake rather than for quality or thoughtfulness. Introducing deliberate practice is one way for schools to motivate deep understanding and to bring craft back into discussions about digital representation.

2.3 *Creating and teaching with learning objectives*



While many digital design courses have learning objectives listed in their syllabi, these are not often used correctly, in response to the findings of educational research. In this section, we propose several ways to make learning objectives for digital design more appropriate and effective.

First, many stated learning objectives do not take into account the learning process for developing complex skills and thinking. As mentioned earlier, traditional digital design pedagogy tends to emphasize learning through design tasks. The tacit learning objective of most activities, ostensibly, is to design something via digital methods. However, this does not acknowledge the steps involved to prepare students for design, such as learning about the tools, practicing methods, comparing and selecting methods, etc. These skills and knowledge are implied by the goal of designing, but by not stating this explicitly, the instructor might neglect teaching and assessing the constituent skills and knowledge that students need, but might not manage to learn on their own.

When developing learning objectives, it is important for digital design instructors to acknowledge how learning occurs as a developmental process. Creativity and autonomy, abilities exercised in design work, are higher order thinking skills. Higher order thinking is dependent upon requisite technical skills and other cognitive resources (Weiss, 2003). As such, these activities may not be beneficial learning experiences for beginner and intermediate students. Research shows the importance of matching learning objectives to student level (Klahr and Nigram, 2004). Novices benefit from direct guidance in basic skills and knowledge, while objectives for advanced students should emphasize synthesis and independence.

Second, many learning objectives for digital design instruction conflate activities and goals with learning outcomes. A goal is a statement of the overall intended outcome of a learning activity or course. Learning objectives are specific achievements which contribute to the goal (Ferguson, 1998). For example, a course description that says "students will be exposed to digital fabrication technologies" has presented a goal, but not stated a specific, measurable outcome. Likewise, a statement such as "students will fabricate a small-scale physical model" describes an activity, but does not provide enough information to discern what students are supposed to learn from the activity. A learning objective that addresses these issues would be: "students will use GIS data to generate a small-scale physical model using appropriate digital fabrication techniques." This objective presents a condition (GIS data), an outcome (the model), and assessment criteria (are the techniques appropriate? / is the model is correct?). Understanding the learning objective helps define the cognitive skill level of the activity and the appropriate assessment. For instance, if the objective was to learn about computing concepts, issuing a quiz with questions about procedures would not be a helpful measurement. To facilitate effective instruction, goals, activities, and learning objectives must be aligned with one another.

Last, many learning objectives as presented do not support a means of formative assessment. Most courses only assign grades for projects, which are typically creative or design work. Again, these are higher order thinking skills and may not be appropriate to assess from novices. Grading project submissions does not give the instructor or the student much opportunity to remediate skills or knowledge that were misunderstood or not acquired. Moreover, feedback on a design artifact may not help instructors and students achieve the goal of deep understanding because it makes conceptual and procedural knowledge indistinguishable from the outcome. Studies have shown that ability to perform procedural tasks does not mean students are able to explain what they are doing or why. (Schoenfeld, 1985) This is not to say that instructors should never grade projects. This is appropriate when the intent is to assess creative work and problem solving, particularly from an advanced class. Learning objectives should measure the correct student outcomes for

Bloom's Taxonomy 1956	Bloom's Modified Taxonomy 2001	Bloom's Digital Taxonomy 2007	Associated Skills	Digital Skills	Communication Spectrum

Higher Order Thinking Skills

Lower Order Thinking Skills

Figure 1. Bloom's taxonomy was first introduced in 1956 and since then has seen widespread use in instructional design. A revised version was issued in 2001, which changed the levels from nouns into active verbs, added the knowledge dimension, and placed creation (synthesis) at the top of the hierarchy of cognitive process (Krathwohl, 2002). More recently, Churches created a "digital" version of Bloom's taxonomy that updates many its application to computing activities (2004).

the level of the student and in a manner that allows students to respond with changes in their performance.

3 CONCLUSION

The value of learning objectives is not what they add to a syllabus, but rather how they prompt a larger conversation about educational and professional values and standards. Creating learning objectives for digital design in architecture exposes many implicit assumptions about what faculty believe about learning and the role of computing in the studio. At the same time, it raises the bar for architecture schools to consider digital design as more than merely learning to operate tools and software (activities which

are not themselves valid learning objectives) and to instead connect these practices to design thinking and the development of architectural designs.

Bloom's taxonomy assists in framing this discussion about learning to design digitally by offering a structure of cognitive accomplishments for students. This helps re-align architectural educators away from frameworks derived from folk pedagogy and towards established theories and research into educational psychology and learning cognition. Instead of teaching and learning digital skills and knowledge through a hierarchy of the tool's features or increasing complexity, Bloom's taxonomy foregrounds processes of remembering, thinking, and judgment. These objectives are more closely aligned with deeper understanding and integrative mastery. This type of learning is precisely the antidote to the kind of superficial engagement one often finds in architecture schools that prompts negativity towards the use of computing in design.

The purpose of reflecting upon learning objectives for digital design in architecture is not to produce a definitive list of what students ought to learn. Learning objectives are written for specific curricula, student needs, and faculty interests. They are useful because they provide a clear definition of expected outcomes and which becomes a point of dialogue. In order to evaluate something, it first must be named. Through evaluation and discussion, a discipline develops. When Bloom created the learning taxonomy, this was the goal. Not to explain or lay claim to how students must learn, but to provide a shared structure so educators could compare their approaches. In a similar manner, creating and sharing learning objectives for digital design instruction can produce a more organized dialogue about how to align the use of digital tools with the core values of architectural education and the development of the discipline itself. Learning objectives are not only for evaluating one's students or teaching. They help departments and educators understand whether they are teaching the right things. The question should always be: "how does this improve design?"

The vertical lateral: A model for social impact design education

F. Gandhi
New York Institute of Technology, New York, NY, USA

ABSTRACT: The Vertical Lateral is an integrated design education model specifically relevant for preparing the next generation of architects taking on multi-dimensional societal and environmental challenges, both locally and abroad. The proposed studio benefits from simultaneous specialist and generalist thinking to link disparate areas of focus both within architecture and also across disciplines external to it. This critical approach is as much about the design of the end product as it is about the interdependent systems and framework that surround it.

This method of design and teaching has been developed over several instances of an architecture course initiated and taught by the author at the New York Institute of Technology. This paper discusses its components, challenges, and outcomes, and positions it within relevant and comparable initiatives, historical and contemporary, alike. The classroom is used as rich testing grounds for these emerging dimensions of social impact practice within our increasingly connected world.

1 FROM 3D TO MULTI-D: A NEW TYPE OF DESIGN PROBLEM

Social impact design is an umbrella of many terms including public interest design, humanitarian design, design-build, bottom-up participatory design, and design for the social good. What all such endeavors have in common is an aspiration to positively affect meaningful change for the masses.

At the very minimum, it is now the responsibility of every architect to confront climate challenges and resource consumption. At the other end of the spectrum, socially-conscious architects are examining complex, multilayered issues ranging from disaster relief to mass migration. Impact design will soon move beyond a separate and distinct subset of the profession. Now more than ever, there is widespread public awareness for the value that architects can bring to everyday people and communities.

1.1 *The 3D design problem*

Social impact design is certainly not new and many design professionals have been committed to such challenges for decades. A typical example of a social impact project may include the design and construction of appropriate shelter in the aftermath of a catastrophic event. An NGO or non-profit might act as a client and the problem at hand comes with a desired architectural and "three-dimensional" physical result – that of temporary or permanent housing. A signed set of contracts between owner and architect as well as owner and contractor specifies a focused scope of work and anything extending beyond is billed as additional services or built into contingencies. The site is pre-determined and the solution is discrete.

1.2 *The Multi-D design problem*

The nature of the social impact design problem, however, has changed. Site and client are sometimes undefined and solutions, no longer local or so discrete. Although such work has always been fraught with challenges, a new "multi-dimensional" social impact design problem has emerged – one that is far less neatly packaged than its "three-dimensional," historical equivalent.

Globalization has fundamentally transformed the world and redefined relationships between nations, communities, and individuals. For example, mass migration is presenting problems both on an infrastructural as well as cultural assimilation level. Dependent on the youth and their ability to secure employment, the means required to sustain growing aging populations in most countries are proving insufficient. Globally linked economies and geopolitical tensions are increasing as food and resource scarcity become real in the face of climate change.

The overlapping and sometimes competing nature of simultaneous forces at play can make the very same problem of a disaster-relief housing scenario described above, far more complex. The now intricate and bureaucratic web of international and local organizations involved can make any immediate and large-scale architectural intervention close to impossible. Successful implementation and long-term impact are not just dependent on a nice design, committed team, and acquired funding. Countless additional challenges exist. How to physically move building materials and construction equipment to a disaster site in the context of failed infrastructure, for example, requires that the initial design problem extend to include these and other dimensions.

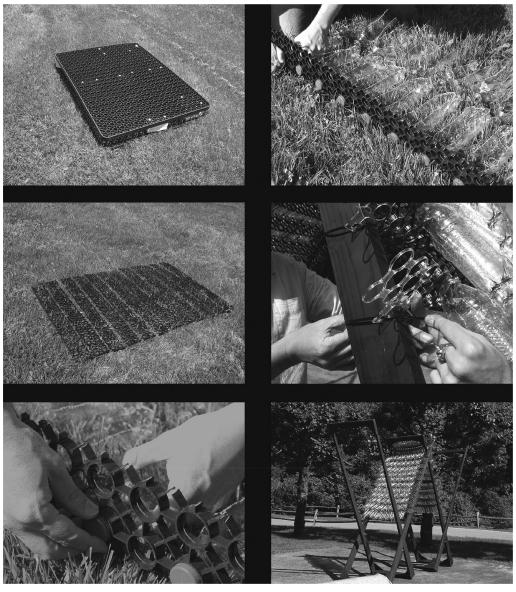

Figure 1. System assembly from shipping pallet to shelter.

2 THE ACADEMY MUST RESPOND

2.1 *The Multi-D at NYIT*

This is exactly what undergraduate architecture students at the New York Institute of Technology (NYIT) realized was necessary when taking on the design and physical prototyping of a kit-of-parts disaster-relief roofing system made of plastic waste. The now patented system takes advantage of the two things that appear naturally in aid delivery – water bottles and shipping pallets. The proposed shipping pallet delaminates and snaps apart into structural purlins. Its inherent offset geometry allows discarded water bottles to overlap and interlock as roofing tile (fig. 1). Hunt, founding director of Parsons' MFA in Transdisciplinary Design, argues that "the ambition is to pick out the feasible solution, the one that makes sense…to identify the inflection point where design will make the greatest change." (Hunt 2015). It was only after careful business planning alongside MBA students and thorough research of aid delivery mechanisms that the architecture students determined the shipping pallet as the point at which design could intervene.

Students at NYIT consider these"multi-dimensional" design problems in a social impact design elective course that the author has developed over several semesters. In another instance of the course, students intervened in an economically distressed community in Puerto Rico. Collaborating with local students at the University of Puerto Rico Rio Piedras, the group researched factors that had led to the area's economic decline and concluded that tourism had decreased substantially due to failing beach facilities. This led students to design and build a modest, prototypical pavilion that could be replicated across the length of the beach to instigate economic improvement and revitalization of the area.

This year, students enrolled in the course are working on a grant supported project for Dakar, Senegal. Although the mobile phone use is now widespread, lack of internet and app literacy keep the use of locally developed apps low. This is unfortunate since this technology can disseminate critical health and agriculture information. The proposed solution is one that complements digital media with a physical place and offers an outdoor classroom for workshop visibility, app feedback station, and charging/wireless hub as public infrastructure. The project aims to create a trustworthy, physical environment where the sampling of humanitarian-based apps increases their use and a direct interaction with local developers facilitates engagement and technology education.

Each of these design problems challenges students to dive deep and to allow appropriate scope, definition, and solution to emerge rather than being established at the onset. The research process undertaken to fully understand underlying and interconnected systems often leads to a redefinition of the problem itself. The right questions are sometimes not the ones we first ask.

2.2 *Social impact design education falls short*

The design problem is clearly expanding and the architectural academy must respond. Social impact design education in architecture has traditionally manifested as design-build studios. Given semester time and logistical constraints, these projects are specific and concise, organized with a real client, site, budget, and program. Students typically engage with full-scale realities by concluding the project with the actual construction of the proposal. While these experiences are, no doubt, tremendously rewarding and valuable, they represent a teaching model that proves inadequate when faced with the more "multi-dimensional" complexities of contemporary socio-economic and environmental problems.

As an alternative, the author offers the Vertical Lateral model for social impact design education. It continues to evolve in light of other challenges, but what is presented here is based on an elective design course she has taught several times in recent years. The very nature of the design problems demanded new ways of working. The model outlines several components as critical: [1] visualization of solutions across scales and within larger frameworks, [2] multidisciplinary collaboration, [3] vertical integration across levels and lateral integration across curricular content, and [4] field work that inspires relationships between local and global contexts.

Like traditional design-build courses at other institutions, students may still work through full-scale construction at the end, but this must be complemented with the detailing of other components that build a larger systemic solution. Learning to work with a client or community may, therefore, occur alongside collaborating with cultural anthropologists, social scientists, or economists.

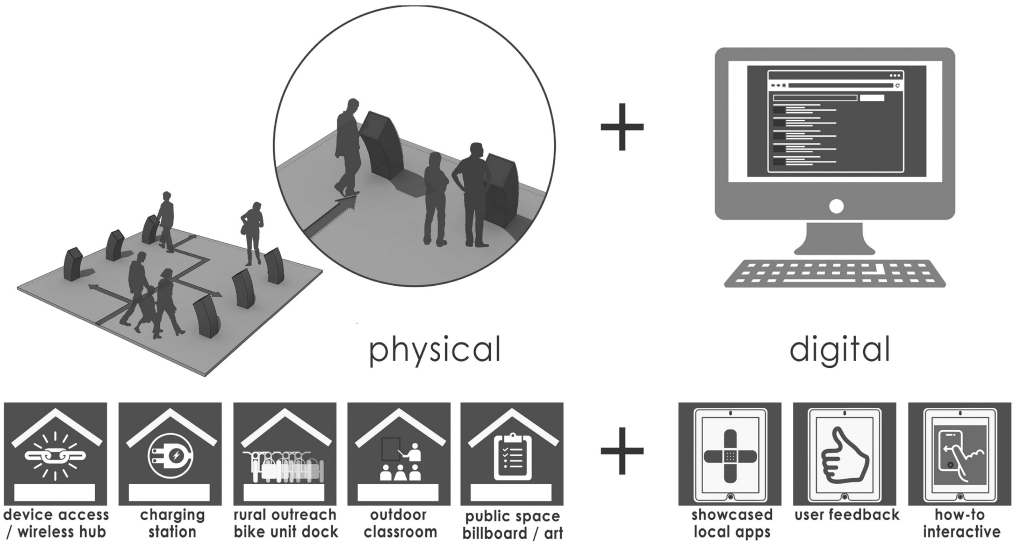

Figure 2. Designing both the means and the end by seamlessly complementing the physical with its digital counterpart.

3 THE VERTICAL LATERAL MODEL

3.1 *Larger frameworks*

In *Good Deeds, Good Design: Community Service Through Architecture*, an "operative practice" is defined as one whose end products of design positively transform the cultural and socio-economic frameworks within which they operate (Pearson 2004). What if this is *also* considered in reverse? Perhaps designing the framework can in turn, inform a better designed intervention. "Edison understood that (his invention) the lightbulb was little more than a parlor trick without a system of power generation and transmission to make it truly useful. So he created that, too." (Brown 2008).

Maybe, we, like Edison, should be designing the *means* and not (just) the *end*. The design of a disaster-relief roofing system made of upcycled plastic waste is only valuable if a system for its delivery is in place and also designed. The design of a public pavilion in an economically distressed area outside San Juan, Puerto Rico is only valuable if its community embraces it and allows it to cultivate urban-scaled change. The design of an outdoor classroom to promote smartphone technologies in rural Senegal, Africa (fig. 2) is only valuable if the digital content it offers can be seamlessly integrated with the physical structure, itself. In each case, students at the New York Institute of Technology realized that an architectural solution is only one piece of a larger scheme. By asking students to design the *means* in tandem with the *end*, new challenges associated with the larger framework emerge that frequently re-set the parameters of the architecture and vice versa. Reframing the problem across scales and beyond a singular client and singular site yields a richer, more comprehensive proposal.

The author believes that widespread social impact can only be achieved at the intersection of architecture and its framework. This framework includes not just a supporting infrastructure of water, sewage, energy, and transportation networks, but also local environmental, cultural, and socio-economic contexts. Studying the site goes beyond typical architectural considerations of adjacent built environs and target user groups. By strategically exploiting the loopholes of an existing framework or modifying one simply, a modest architectural intervention has the potential to act as a catalyst for systemic change.

3.2 *Multidisciplinary collaboration*

No single discipline's domain is sufficient to consider the interconnected layers of these multi-scaled, multi-dimensional problems at once.

At Temple University, students from various courses in architecture, landscape, urban geography, and fine arts work simultaneously, but separately and at different scales for different areas of concern within the design problem. It is at moments of "boundary-crossing" that the teams come together to negotiate implications of each other's work. These conversations "reveal economic, political, and cultural issues that are often excluded from dialogue framed by the studio or classroom situation," (Harrison 2007, 41).

At the New York Institute of Technology, the author is experimenting with a slightly messier form of multidisciplinary collaboration, where participating students are not necessarily limited to allied professions and where collaboration overlaps from the start and continues cohesively throughout. "As a way of working and thinking, design sits between the two poles of science (which observes the facts of the material world) and the humanities (which interprets the

Figure 3. NYIT architecture and Pace computer science students discuss design concepts, both physical and digital.

complexities of human experience)…Design is a culture that blends concerns…to search for outcomes that are balanced and opportunistic, grounded in the real world, but driven by human aspirations." (Boyer et al. 2011, 25). Hence, the dialogue in the author's courses at NYIT commonly bridges between architecture and industrial design; fine arts and applied arts; and infrastructural design and economics.

Most recently, her undergraduate architecture students worked hand in hand with graduate computer science students from Pace University to develop a holistic solution to promote mobile phone technology and app adoption in Senegal, Africa. To ensure long-term success, the project requires the design of a physical space (outdoor classroom, charging station, and wireless hub), but also the design of a digital space (how-to educational videos, sampling of apps, and user-developer feedback system). While these can be designed separately with parceled scopes of work and meetings at key scheduled points, the course examined the possibilities of working together throughout.

The students enjoyed shared brainstorming sessions and found the collaboration extremely helpful in developing a more seamless user experience. Discussions led students to confront issues of scale, dust, security, and even operational cost financing. This weekly dialogue (fig. 3) resulted in an innovative solution where a custom, lightweight, modular door and window system would securely house and display all the technology needed for the project. This system is designed to also detach from the masonry structure of the classrooms to act as a mobile bike-driven cart for additional rural outreach. What was most compelling about the collaboration was that students of each discipline were able to not only design within their scopes of work, but also participate and immerse within the design process of the other. For example, the architecture students mocked up branding/logo concepts and screenshots of potential website flows while the computer science students made full-scale physical mockups of the equipment and smart devices that would be integrated into the architecture. The aesthetics of the digital interface inspired the design of the physical building and vice versa. It was exciting to see the kind of meaningful design insight that can result through hybrid discussions in this grey space of discipline overlap.

3.3 *Integration*

The majority of architecture schools establish degree maps and prerequisites that require students to follow courses in sequence and per level. This structure separates courses into categories including design studios, visual media, history and theory, and technology. Given the credit weights assigned to these courses, a common distinction between studio and "support" courses results – these "other" courses somehow offering skills critical for design, but not necessarily participating at the onset of design. These academic divisions in both levels of students and areas of focus, of course, are false to the way we work in our profession. In practice, junior and senior designers commonly work together and "supporting" topics are not applied to, but rather are inherent to the very process of design and making. Any engagement with a real-world problem, then, must embrace a more synchronized approach.

The Vertical studio is a tried-and-true model in architectural education. It combines upper-level students with beginning students to create peer-to-peer learning and unexpected outcomes. In the proposed Vertical Lateral studio, this "vertical" component proves instrumental to its success given that tasks routinely range from the conceptual to the very technical. The NYIT elective course is open to upper level and beginning design students, alike. With an equal and shared level of investment and commitment, the group comes together and relies on individual strengths to participate in everything from setting up an infrastructure for social media marketing and crowdfunding to developing full-scale prototypes and construction details.

Laterally, the Vertical Lateral studio erases typical studio vs. non-studio separations to allow representation, technology, and construction research to drive design opportunities. In the case of the project in Senegal, students spent the semester researching local materials, traditional building construction methods, and passive environmental strategies to develop a solution appropriate for its site. They began with rigorous precedent studies and scaled wall section models and followed with interviews of project architects to learn firsthand about the challenges associated with building in West Africa. This research led to a series of 1:1 full-scale models of roof, wall, and foundation details.

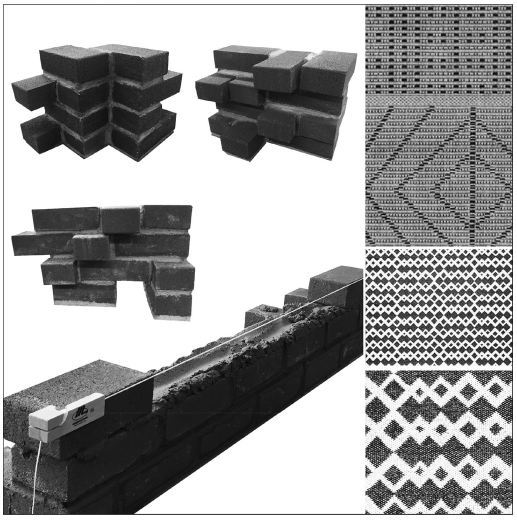

Figure 4. Full-scale brick wall mockups inspired by Senegalese woven mat patterns.

Students confronted the technical challenges of working with actual materials including wood, concrete, reinforced steel, bamboo, brick, concrete masonry unit block, and thatch. Details experimented with a number of passive environmental strategies including the use of breathable roof membranes, a double roof with vented cavity, and angled brick screens for cross ventilation. Historical and cultural research concurrently immersed students in local customs, colors, and forms of expression. To cite just one example of how these areas of focus overlapped in design, students chose to develop a series of brick wall patterns inspired by the geometries found in Senegalese woven mats. Building these as full-scale mockups, they also tested structural integrity and offered potential for cross ventilation (fig. 4). Such integrated thinking continued in developing the full project, where students relied not only on programmatic and site demands, but also on constructional logics from day one.

3.4 *Field work*

Finally, the Vertical Lateral model recognizes that our societal challenges inherently overlap in our increasingly connected world. In each instance of the social impact course taught at NYIT, students engaged in problems that while sited elsewhere (disaster site in subtropical climate, beach and camping grounds in Puerto Rico, and public space at the outskirts of Dakar), could certainly have implications for how we engage similar problems locally.

Miles away from the sites, students adapt with innovative digital methods and social media that demonstrate that meaningful work can be done across geographic boundaries while remaining specific to local needs, climate, and culture. Students use videoconferencing to hold meetings and workshops with the local end users so that community surveys can be distributed and design ideas can be presented for feedback. In some cases, students also travel to the intended sites for on-the-ground field work. For example, the NYIT students spent their Thanksgiving break building their proposed community pavilion in San Juan and current students intend to visit Dakar this summer to meet with local stakeholders and take on the next steps for design development.

Given that the architecture profession now routinely involves distant regions, these experiences prepare students for the kind of virtual client meetings and collaborative design practices they will, no doubt, encounter in their careers. Their solutions are relevant across borders and can also be easily rethought to work right at home.

4 ARCHITECTS MUST EMERGE AS LEADERS

4.1 *Non-designers adopt "design thinking"*

Despite the architecture profession's growing interest in service engagement, it is essential to note that the schools of *other* disciplines are the ones rapidly leading such efforts, surprisingly, often at the *exclusion* of architects.

What is most curious is that most such initiatives identify *design* as a critical component in confronting these global issues. Broadly labeled as "design thinking," non-linear and iterative problem solving strategies are infiltrating curriculums around the world in a wide range of disciplines, from biomedical engineering to social sciences. Both the MBA in Design strategy at California College of the Arts and the Masters in Design Management at the China Central Academy of Fine Arts, for example, offer design courses to augment analytical business and market tactics with creative thinking. At the Stanford D School, a step-by-step methodology to design thinking begins with questions of what, why and how, and follows with interviews, empathy maps, brainstorming post-it note sessions, and prototyping. These steps echo the kind of methods recommended in numerous how-to-manuals and community design toolkits that guide social impact processes at human-centered design consultant firms like IDEO and Frog.

While forms of such "ideation" are clearly becoming commonplace, any architect would agree that what these buzzwords represent do not come close to what it is that we, as designers do and how we do it. Alongside a very particular way of approaching problems, our creative processes are also rooted in the proper training and rigorous mindset of a formal design education, making us valuable contributors to any social impact design problem.

At the University of Virginia, Crisman had to work hard to convince her non-design colleagues to introduce architecture courses within a new interdisciplinary major in Global Studies. She questions, "Is architecture excluded because the physical world is often undervalued in the humanities disciplines that

typically form the core of global studies: politics, history and economics? Climate change, sea level rise, rapid urbanization, disaster relief and development, human health, sustainability and other supranational phenomena examined in global studies research are all connected to how we physically inhabit the planet. The way that architects approach problems using design thinking, speculative research and participatory design can greatly contribute…" (Crisman 2015, 615).

4.2 *Specialists vs. Generalists*

An architecture education *can be* very specialized. This may reinforce a perception by others that we are only relevant when it comes to the design of a building. "A closed loop is set up whereby the profession designates knowledge which architects must possess... students are taught according to set content – which in turn prescribes what architects do, design buildings, and the buildings in turn become constituents of the professional knowledge." (Awan et al. 2011, 43). At the same time, however, architects are great generalists. We have an ability to approach a problem from many different perspectives and can apply our skills to any given program, scale, and location, irrespective of complexity or intended physical result.

While the built environment is clearly central to the issues we face today, an architectural solution may not always be immediately apparent, nor appropriate. Regardless, architects are well poised to lead community-engaged and on-the-ground interventions that are otherwise often wrapped in bureaucracy, number crunching, and political debate. Consultancies taking on multidimensional problems have become known for seeking "T-shaped" people who have a deep core of technical abilities along with collaborative and managerial instincts (Hall 2011).

Arguably, architects are *best suited* to lead cross-fertile exchanges, given our ability to act as both specialist and generalist, at once. While we maintain a deep knowledge and craft within our discipline, we are unique in our generalist ability to shift between the disciplinary/autonomous to cultural/contextual and between parts (detail) to a whole (system). Architects can additionally use visual communication skills to invent common language between disciplines as varied as cultural anthropologists and climate engineers. An inability to speak to one another is often the greatest challenge when sharing in collective expertise.

Any such multifaceted collaboration is no different than an orchestra of specialized musical instruments. Each instrument must be in sync with its own kind, but also in harmony with its counterparts, regardless of whether their roles are in discord with one's own. The musical piece that results has common purpose and its impact is greater than any one individual part. While the architect may recede as a supporting instrument, he is equally able to rise as conductor of the entire production. It is important that we reaffirm the value we bring and capitalize on the growing interest in design within other disciplines to develop more meaningful forms of cross-disciplinary collaboration.

5 ACADEMIC CONTEXT: PRESENT AND FUTURE

5.1 *The structure of universities*

According to Georgetown University's Vice Provost, Randall Bass, "(future) schooling will become more interdisciplinary. Instead of a degree in biology, emerging fields will combine biology and global health, or neuroscience and entrepreneurship. The concept of the major will erode into something that looks like an overall portfolio with a bunch of microcredentials that speak to a whole range of strengths." (Hullinger 2015). In line with this thinking, MIT Prof. Christine Ortiz recently announced that she plans to create a new research university in Massachusetts that will "prioritize project-based learning, where students learn by working together on a challenge for an extended period of time…with no majors, lectures, or classrooms." (Mohdin 2016).

With the onset of massive open online classes (MOOCs), it is clear that education and its delivery will change drastically in the next ten to fifteen years. Able to access narrow subject area content on their own, students will look to face-to-face university settings predominantly for experiential and project based education. Interestingly, it is within architecture schools that structures for such opportunities are already in place.

5.2 *The structure of architecture schools*

Project based opportunities in architecture exist primarily within a single design-build studio or course. In 2008, faculty at the University of Minnesota experimented with a restructuring of their entire program. A traditional architecture curriculum of design studio and support courses in the fall was followed by a decentralized and vertically mixed set of project-based workshops in the spring. Each distinct form of instruction positively affected the other (Cheng 2014).

Although this model is exciting and should be explored further, it and any other such overhaul is not without many challenges. A real project comes with timelines that most often do not fit neatly within the constraints of semester schedules. Multidisciplinary collaborations with other schools or external professionals are difficult to coordinate given legal and monetary considerations. The rigid format of degree program requirements and a faculty compensation tied to contact hours make such project-based experiences far easier to logistically organize as extracurricular activities or within the context of a single course.

Additionally, for accredited university programs in the United States, the National Architectural Accrediting Board (NAAB) sets stringent criteria that would make the structure proposed in Minnesota unfeasible. On the other hand, in 2014, NAAB revised its conditions for accreditation to mandate that schools include evidence for "D.1 Stakeholder Roles in Architecture: *Understanding* of the relationships among key stakeholders in the design process—client, contractor,

architect, user groups, local community—and the architect's role to reconcile stakeholder needs" and for a new perspectives in "E. Community and Social Responsibility…A program's response to social responsibility must include nurturing a calling to civic engagement to positively influence the development, conservation or changes to the built and natural environment." (NAAB 2014). These requirements signal a need to invent new paradigms for architectural education in light of the global challenges that await our graduates in the workplace.

5.3 *Where does the vertical lateral approach fit in?*

Architectural education must not lag behind. *Can* and more importantly, *should* social impact design education fundamentally change the way we teach architecture? Or is it more appropriate to introduce this integrated approach and project-based curriculum on the sidelines?

Historically, architecture education has been shaped by a number of strong schools of thought – first, by the École des Beaux-Arts in France dating back to the mid-1600s which focused on representation, typology, and classical arts and later, by the Bauhaus in Germany in the early 1900s. Experiments in integrated design curriculums can be traced back to the Bauhaus at Weimar, where Walter Gropius first set up a dual teaching system of workshops co-taught by a Werkstattmeister (workshop master) and Formmeister (form master) in an attempt to remove the boundary between architecture and craft. In 1928, Hannes Meyer recognized the conflicts that came from having two directors within a single course. At Dessau, he replaced the system with teachers that had a double qualification as artist and artisan. While this was a stronger program, it resulted in what is most heavily criticized about Bauhaus pedagogy – a foregrounding of technical considerations of mass production and a marginalization of the arts (Wick 2000, 39). One might argue that a design curriculum driven by service learning or architecture-led multidisciplinary partnerships might also lose sight of core building design instruction. This exposure of many things can dilute the profession and result in students not knowing how to actually design.

Emphasizing any one set of skills over another has always been the cause of debate in architectural education, whether it is form in relationship to function, technology in relationship to design, or digital representation in relationship to analog. Rather than maintaining a dogmatic approach or replacing one methodology with another, it is far more productive to see the curriculum as a fully synchronized system, where techniques are considered simultaneously and comparatively to have a positive impact on design.

At the New York Institute of Technology, the author has introduced social impact topics specifically within the context of a single elective design course. Where appropriate, however, she underscores the components of her proposed Vertical Lateral approach (systemic, multidisciplinary, and integrated thinking) in the other courses she teaches and throughout the curriculum. Beginning with traditional groundings in form, proportion, and order, it is important that as projects increase in complexity, a more integrated dialogue be layered into courses rather than be thought of as add-ons or replacements for these foundations. Richer and more comprehensive solutions can result, preparing students for the kind of team-based collaborations they may encounter in practice.

Apparent in the work they pursue post-graduation, in their independent thesis topics, and in the commitment they show to community-based projects, architecture students are increasingly aware of the role that design can play in "real-world" issues. It is imperative that we offer our students lateral and comprehensive ways of thinking in our increasingly connected world. In this exciting time of change and promise, the way our students learn and become architects must radically adapt.

Designing education in the digitally preformatted age

Shai Yeshayahu & Phil Zawarus
University of Nevada Las Vegas, USA

ABSTRACT: Departing from the historical and contemporary references to social behavior that induce acts of creativity, the paper discusses the importance of using workflow and interactions between humans, software, and hardware to challenge conventional applications of technology while succumbing to social play—an act of learning fuelled by personal insight and collective thinking while exploring creativity via gaming tactics. All this with the intention of lacing analog and digital means of production to generate multiple outcomes. This pedagogical approach; where the learning sphere has become an interrogative platform for testing/playing with representational technique along with the how and why aspects of it, are discussed and ultimately suggest that we begin to address an educational model as inclusive of design+ing–making and thinking design.

1 INTRODUCTION

According to Google search stats and news media from the NY Times, the number of DIY spaces is, flourishing (Kurtz, 2013). Although, we recognized these types of places are not just situated in garages or basements of desolated towns; they are now spots for social interaction, located in urban spheres among bars, restaurants, and coffee shops. City hackers and tinkerers with knowledge or ability to resurrect equipment, favor these locales from which they intake a daily dose of social intoxication. Such emergence is also believed to parallel English coffeehouses of the 17th and 18th century, where customers would congregate in the hopes of gaining a first class education for the price of one caffeine shot (Johnson, 2011). Indeed, while these physical spaces where once considered incubators of knowledge, the expectation that such specific settings single-handedly promote innovation, is challenged, and one would even argue that this popularized trajectory has clearer understanding of DIY spaces may signal the sedation of ideas.

For this reason, within the pragmatism of these environments, we are attempting to recondition the places and methods of practices where the opposite of sedation is forged and where meditative processes are nurtured. Here, our initial focus was to engage in deep learning, in deciphering how adaptations of obsolete technologies interlace physical and virtual domains; of exploring how resourcing to systems capable of becoming flexible models can equally engage machine and humans; and of experimenting with how to develop new learning environments. The spaces, program, and equipment used challenged our current understandings of what constitutes creative working spheres: ateliers, workshops, coffee shops, design studios or maker-bars. It reinforces the contention that creativity is not reduced to a singular location; it happens anywhere, and in this digitalized era our work underscores that it happens at its best when social behaviors are capitalized on.

2 IN_ACTION

Our research differs from using tools as prescribed. Instead, we are constructing additives, [customized devices] to combine with obsolete equipment like CNC's, 3D Printers and Cameras. The intent behind our design approach is to uncover effective methods for repurposing machines and enable new productions of drawing mechanics. As such, this is a design approach with distinctly opposite agendas than the normative one currently exerted at maker-bars where pieces of equipment are regarded as a functional tool rather than a potential instrument for inquiry. Our concern, therefore, is in testing the grounds to ignite and visualize a new culture of making that stems from asking the following: How can we intervene in established sequences of existing machinery and how can we develop diversions that alter the prescriptive behavior of the equipment?

To start, we presupposed that equipment packaged to perfection is unsustainable. Foremost, because as we move design intentions forward, we regard the nature of standardized equipment as an open port that can receive additives, adaptable parts and newly design instructions formulated from social and digital interchanges. Accordingly, the significance of the work lies in the additives embedded in the machine and in recording imprecise/precise tactics while playing, futzing, hacking or tinkering with CNC machinery. Such actions might seem rebellious against digital standardizations but in actuality, they represent a quest for lacing analog and digital productions to achieve unique outcomes while succumbing to social play.

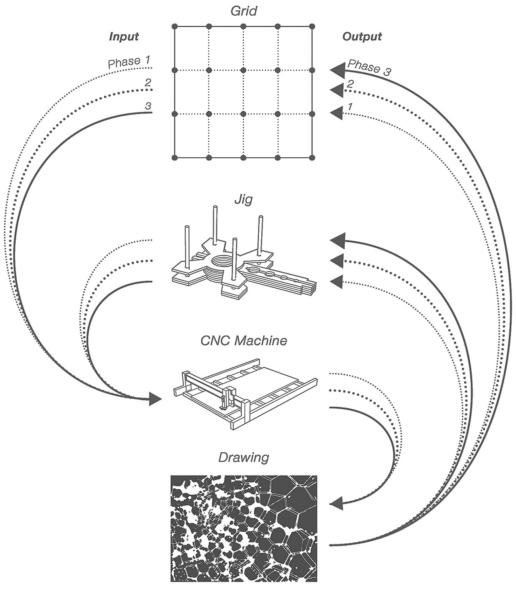

Figure 1. Grid, jig, machine; drawing loop.

This research, therefore, focuses on a problem-based approach that interferes with conventional formatives of studio-based design assignments. Here program based projects were suspended to underpin the initial shift from product-oriented thinking to design oriented objectives. It ignited the testing grounds for creating additives as extensions that interfaced with the axis of preformatted machinery like CNC routers. Subsequently, the work puts into question the deterministic behavior of digital receptors and its equipment. In this scenario, the additives undoubtedly re-conditioned the inherent qualities of both the machine as well as the design goals of human's. Together they afford a new form to examine performance-based studies resulting from tool design and its ability to generate iterations stem from productions and reproductions of combinatorial two & three-dimensional work.

From this inquiry, the work is based on a series of experiments aiming at creating a collective consensus within the studio. One that forges a new learning mandate, triggered by the realization that infinite series of interactive processes and decision-making opportunities could occur between what the machine was preformatted to do and what the human could intellectually, socially and actively alter. A true manifold of events that links information with the physicality of making drawings. In this approach, the customization and adaptability of designing a jig became a direct response to the production of a cyclical design process. (Fig.1)

3 METHOD

The mechanics of the work, like historical permutations of artist and architects, follows the understanding

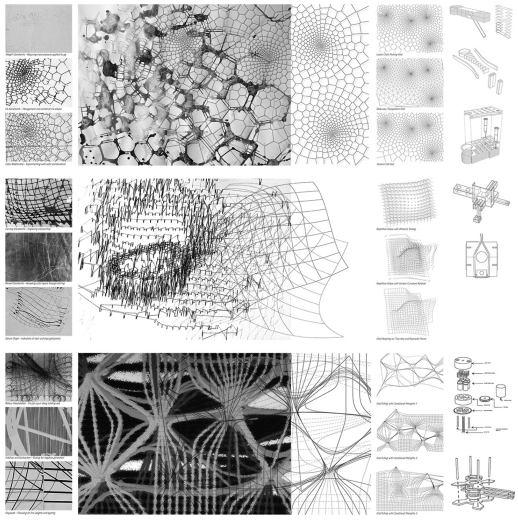

Figure 2. Matrix of Jig, grid, and drawing.

that technologies are often repurposed to alter predictable outcomes. Consequently, the work presented exemplifies the processes and functions we implemented with an interdisciplinary group of design students charged with the task of using a workflow of interactions between humans, software, and hardware.

The format for this undertaking was initially based on a series of challenges simulating a master chef competition that limits equipment and materials to its contestants. The intention for us was to formulate a gaming based agenda, introduce it and then allow it to stir a collaborative dynamic that would set the initial stage to heuristically forge the collective of players who would engage the school's fabrication lab in discovering how to produce unpredictable outcomes.

Beyond these initial task, the sequential exercises were formatted to encourage each team's engagement in communicating ideas and providing revisions interactively and in real-time. Such imposition allowed each team the flexibility of working at whim, anytime and from any place. This means that participants would be motivated to work from remote stations such as their home, the studio, lab, or other wifi arenas. The goal was not to diminish physical interaction but rather to afford all contributing members a richer understanding about interactive collaborations and about producing a series of digital drawings and models that would inform their making process in the absence of spatial confinements. (Fig.2)

4 THE ADDITIVE

The use of a three-axis Shopbot, where varying speeds and directions generated different moments of contact and legibility in the physical delivery of the digital coding to the surface, determined the legibility of the media on the drawing surface. In using diverse types of software to draw, model and build,

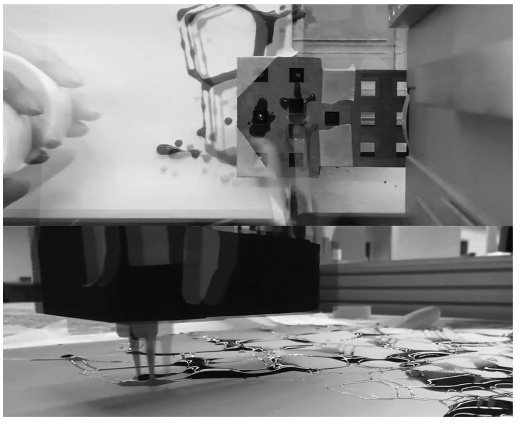

Figure 3. The act of machine drawing with customized jig.

the charge for each team was to imagine and compose unique additives as extensions of the CNC tool. In translation, all teams designed jigs, which needed extensive testing to ensure that they attach safely to the machine's tool head and that it could withstand the rigor of movement; speed and torque imposed by the new design condition—the repurposing of the toll head. Maintaining consistent results with various media types, dynamics of movement and rigidity of the jig, informed additional design decisions related to material strength, weight, and method of attachments. This also forwards attention to how the detailing of media receivers and the machine's tool head must be synchronized to work. After several design iterations, the customized jigs afforded us opportunities to test rapidly and prototype the performativity of the tools. Many of these jigs were reconfigurable and capable of additional rotations along specific XYZ axis and, as a result, these alternatives challenged our ability to control the behavior of the equipment. In time, these auxiliary axes augmented the prescriptive interpolations of non-linear directions and unveiled the manifold potentialities of the jig as an instrument and its latent potential to generate un-prescriptive outcomes. (Fig. 3)

5 THE ANALOG

The analog elements consisted of brushes, pens, blades, and custom dispensers for either liquid or sand. These are referred to as the inscribers, allowing for the passage and recording of information. They ultimately depict the characteristics of originality and uniqueness that each jig posed. However, together, the tool head, jig, and media behave as one synchronized operation against the medium (the drawing surface) and causing multiple diversions. Each gesture often resulted in the instruments inability to deliver marks on the surface. Admittedly, the inability to perform was due to the interlacing of tools and media, which required constant calibration. The most obvious derailment

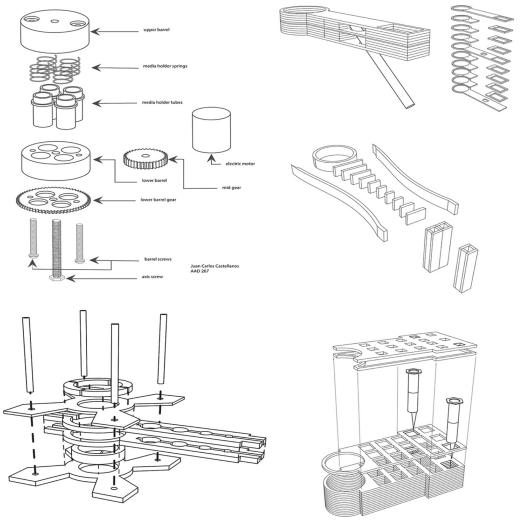

Figure 4. Jig as a media holder; from top clockwise; Spin, Crayon, Spider, and Drip-jigs.

among the variables and constraints erupted from their unpredictable performances and lack of durability, longevity, and dispersal, requiring refilling containers of either ink or sand to complete the drawing without interruption. As such that with each variation a reevaluation of the relationship between media and medium occurred as the parameters of pressure, legibility, or dispersal differ respectively from one jig to the other.

In this regard, testing the relationships between mixed media and medium did not solely rely on the machine interface or its capability for holding multiple drawing tools but in reconfiguring the CNC tool head. This process, in turn, produced unexpected abstractions from generated scripted dialogues between machine, code and surface. We were then able to test these interactions without the constraints of machine parameters and to experiment with the depiction of fundamental drawing methods. Ergo, combining precise tactics of machine coding with the organic delivery of drawing media has generated unexpected outcomes that we recorded, analyzed and refined through both changes in digital coding, jig enhancements, and media adjustment.

These productions are currently unreeling original outcomes that clearly demonstrate how intervening in established sequences of operations introduces new potentials to divert the original behavior of the machine in ways that every printed iteration can be understood as an authentic original drawing. (Fig. 4)

6 ITERATION

Our jig fabrications and their ability to add new drawing mechanics to the standardization of digital fabrications begins to mark a return to the concept of seeking originality as understood by Renaissance masters—artistic simulacrum, where painting

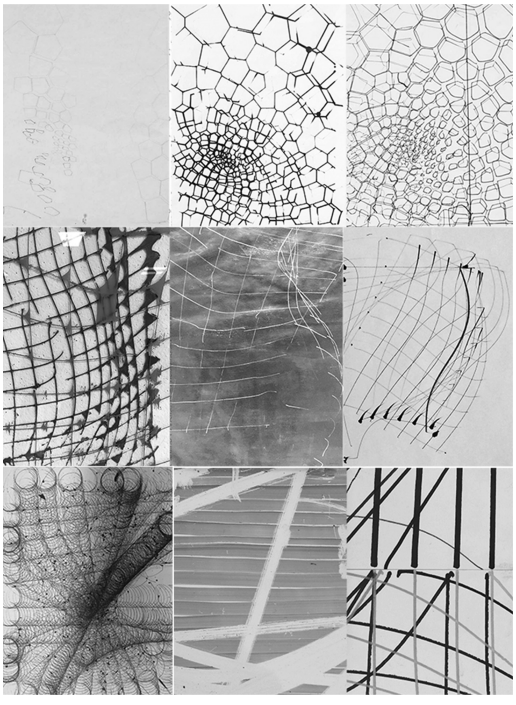

Figure 5. From top; drawing iterations with Drip-jig, Spider-jig, and Spin-jig.

are sometimes created by copying a photograph that is itself a copy of the real (Massumi, 2015). The uniqueness of this thought lies in the combination of the parts. Hence, each drawing unfolds new challenges and opportunities to refine and develop infinite outcomes using a process-based approach. The transition from traditional representations techniques—drawings, to mechanical performance demonstrates how the adaptability of feedback loops becomes repetitively iterative—a process enhanced through the assessment and interpolation of data. (Fig. 5)

7 DRAWING

From a digitized perspective, the procurement of these drawings is assumed to be simplistic yet, these series of exercises add manifold levels of re-understanding design processes. First, they are processed that are elemental to the potentials inherent in learning. In how to modify standardized computer-controlled equipment one is analytically looking at the parts and mentally configuring the steps require. Second, they are digital-analog explorations that are not to be confused with learning to customize robotic tools or with learning to script codes. Third, they are disruptions to predetermined rules. Additionally, noting these distinctions is important because our efforts seek to embed prefabricated tools with the possibilities to produce infinitely flexible and dynamic outcomes; even when the instructions stem from a single G-code file.

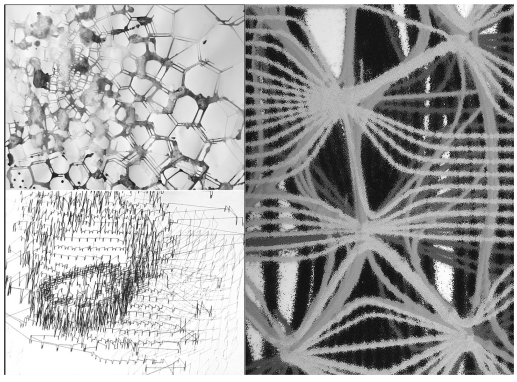

Figure 6. From top left clockwise; inscribing with ink, sand, and magic marker.

In part this body of work attempts to introduce designers to re-engage with drawings and making of ideas using workflows that allow for a cyclical feedback loop approach to help attune one's ability to see the benefits of design investigations.

It is through this experimentation and by repurposing standardized tools that a matrix of constraints and opportunities established by explorative drawing methods that designers might shift from automotive workflows towards new processes that re-explore the opportunities of conventional fabrications. Indeed, these are innovative and rational lessons allowing us the possibilities to reexamine the complexity of our built environment. (Fig. 6)

8 OUTCOME

The research work we have outlined in this presentation has yielded a twofold outcome; one that is about social interactions and the other of cognitive impact on design thinking. Important to note is that it could not have been possible to attain optimal results unless the technology around which play is orchestrated—the jig, become instrumental by its capacity to perform—make drawings. As such, the work rendered was made possible by connecting static and non-static elements to pre-programmed artifacts. This linking approach is not new but similar perhaps to how Jackson Pollock's paintings are said to be about __ technique, and where technique is just a means of arriving at a statement (Herschel, 1984). For us, however, the technique is a way to forge broader understandings about the interplay between humans, code, machine and that which will emerge out of social play. It is precisely in these repetitive moments that observing and documenting how reassembling occurs, that we have come to realize that intentional alterations become innate, and practice becomes strategic-a method to analyze strategically and calibrate previous implementations of interplay. That we believe is the basis of our experiment and that which separates any DIY place from our current studio environment as it is where manifold networks are

working together and collaborating in larger structural objectives.

How CAAD is changing society's role in architecture

T. Maver
Mackintosh School of Architecture, Glasgow School of Art, Glasgow, UK

ABSTRACT: It is a modest four decades since the potential for the application of computers to the design of buildings was first realized by a few academics who are still alive. The author is one such! This presentation provides an outline of these four decades but with an emphasis, not on how the technology facilitated the 'production' of the architectural process, more upon the 'product' i.e the *quality* of the designed artefact. Specifically, the relationship between *the objective* criteria – cost and performance - and the *subjective* criteria – aesthetics, cultural significance, etc and on the relationship between design decisions and their consequences.

1 CONTEXT

In October 2015, the ACADIA conference was held in Cincinnati, Ohio. Some one hundred plus mostly young people heavily committed to CAAD, attended. Dr Robert Ash presided over a panel discussion ' Pioneers of Design Computation' It featured Don Greenburg arguably the father of computer graphics, Chuck Eastman, arguably the father of BIM and the current author – Tom Maver, who in the mid sixties struggled to develop primitive computer software to predict how design decisions – the geometry and construction of the buildings – might impact on their capital cost, their recurring costs, their energy performance (heat, light sound), their efficiency in pedestrian movement, their evacuation in emergency and in every other aspect of their cost and performance. The one hundred plus people accorded the panel a standing ovation – some welcome recognition that early endeavours were both welcome and worthwhile.

Four decades earlier, the issues were alive yet problematic. Notwithstanding the intellectual aspirations, the computational competence was truly primitive. In order to communicate a 3-D built form to the computer one had, in the language Algol, to;

- Type in the X,Y,Z coordinates of every vertex.
- Identify those coordinates that terminated an edge.
- Identify those edges that constituted a surface.
- Identify those surfaces that constituted a volume.
- Identify those volumes that constituted a building.

Figure 1 shows an example of a punched paper card, one of many thousand, required to represent the simplest of buildings. One alternative, no less problematic, was hundreds of meters of punched paper tape.

Figure 2 shows how a simple built form had to be encoded and Figure 3 shows how a primitive teletype terminal was best able to output representations of plan forms.

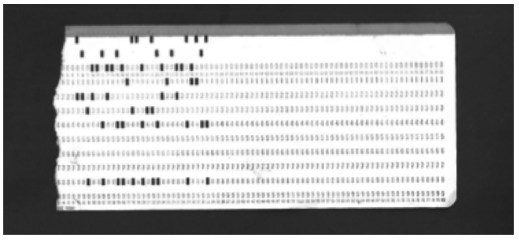

Figure 1. Punched paper card with part torn off to make a roach for a ciggy.

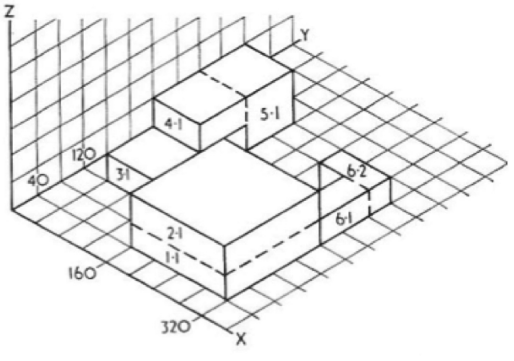

Figure 2. A preliminary drawing prior to inputting the vertices to the computer.

2 ISSUES

From the earliest and the most primitive steps in CAAD the issues were clear.

The architectural profession had its heart set against CAAD. Whereas architectural students would invite the few pioneers in the field to speak about the emerging techniques, quite frequently tutors would attend to revile the speaker.

Figure 3. A primitive output from the computer of a floor plan.

The worry was that computers, dealing solely with the measurable characteristics of buildings – capital costs, recurring costs, heat, light and sound, movement – failed to address the non – measurable characteristics – most importantly the aesthetics of the building and its cultural significance. The consequence, so the profession believed, would be soulless 'boxes'

Those struggling to develop the technology took a different view. The argument (one that was poorly articulated) was that the ability to predict the myriad *objective* characteristics provided a knowledge base that could inform judgements on the *subjective* characteristics. The degree to which this is the case is addressed in the concluding part of this paper.

3 EVOLUTION OF TECHNOLOGY.

The research group set up by the author at the University of Strathclyde in 1969 – the Architecture and Building Aids Computer Unit, Strathclyde (ABACUS) – was one of a handful in Europe and North America to wrestle with the primitive computer tools available at that time and progressively contribute to the development of the hardware and software that is now known within the broad field of Information and Communication Technology (ICT) as Computer Aided Architectural Design (CAAD).

In ABACUS the thrust of the software development was driven by a seemingly simple diagram (Figure 4) in which a design for the building – its geometry, construction and location- was described to the computer. A set of algorithms, based on the laws of physics and economics would then be applied to the design as it was subjected to the vagaries of yearly climate and functional usage. The output would be the histogram of the consequential cost and performance characteristics – capital costs, recurring costs (for heating, lighting, maintenance) energy consumption (heat and light) etc; ie all that could be measured with an acceptable degree of accuracy. This histogram and how it varied with changes to the design hypothesis, would (certainly could) inform the direction of the evolution of the design exploration.

The deceptive complexity of this view of the design activity is that the relationship (particularly the rate of change) between the wide set of cost/performance variables is highly dynamic. For example, changing the area of glazing, say, to the south façade of

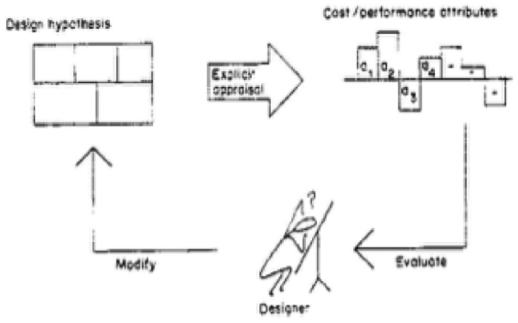

Figure 4. The early concept diagram of how a computer model might produce cost and performance output.

the building alters virtually *all* the cost/performance characteristics. This relationship is *a priori* unknown and can only be discovered as the explicit design investigation is explored.

Although the expression was not applied at the time (circa 1970), it is now clear that what was being created was a *virtual prototype* – as opposed to a *physical prototype* – on which design refinements could be applied.

The earliest publication of an account of the application of such a virtual prototype, deploying the most primitive computer technology (pre -graphics, pre online etc) was entitled PACE: a Package for Architectural Computer Evaluation (Maver 1972).

The difficult though rapid evolution from PACE to the current state of the art, over the exciting four decades, has yet to be properly recorded. However, at the ACADIA Conference in Cincinnati in October 2015, the panel session 'Pioneer of Design Computation' (Maver 2015) brought a standing ovation from the 100+audience of mostly young people and, more importantly a commitment to tell the story in order to extrapolate the future.

Nonetheless, the key development can be summarised as follows.

- The evaluation of 'back and white' (actually green and yellow) computer graphics introduced by the US company Tektronix in its iconic 4010 terminal; changes to a simple plan form requires the image to be erased and then redrawn.
- Encoding of the laws of perspective geometry to allow representation of 3D 'wireline' views of buildings and the subsequent development in BIBLE (Building with Invisible Back Lines Eliminated)
- Introduction of colour graphics to allow the first (embarrassingly crude) colour images of buildings.
- Visual Impact Analysis of constructions in the urban or rural landscape. The representation of alternative electricity transmission routes has moved from an innovative PhD thesis to software free on most PCs.
- The advancement in scale from the representation of individual buildings to the entire city scapes (Maver 1987)

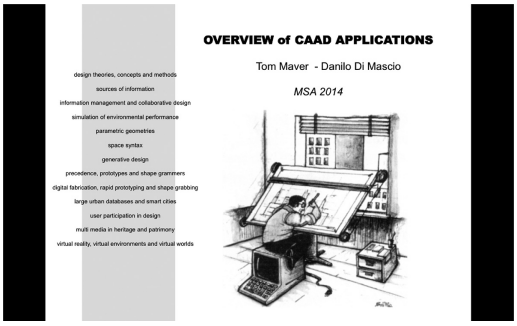

Figure 5. A summary of the current state of the art of CAAD.

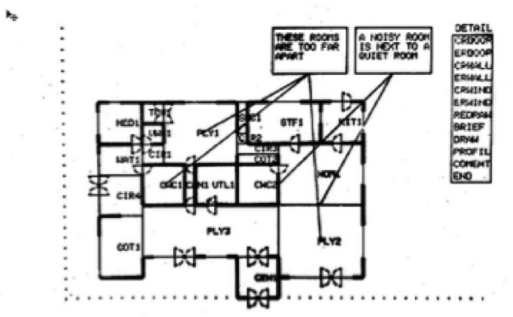

Figure 6. The work in progress for a nursery school teacher.

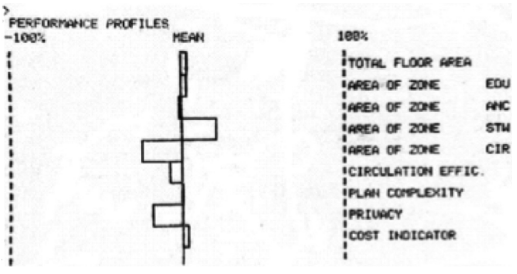

Figure 7. The simple feedback to nursery teacher.

- Animation: the change from stop – frame film-based technologies, set up to run all night, to real time dynamic inter – action.
- The huge increase in the sophistication of the modelling of the dynamic thermo-fluid behaviour of building as they respond hourly and annually to weather and climate (Clarke & Maver1991)
- The application of multimedia software that help to explain our built cultural patrimony
- The evolution of virtual reality and virtual worlds.

4 CURRENT STATE OF THE ART

The current state of the art of computer aided architectural design (CAAD) has been summarised, Figure 5, in the document authored by Maver and DiMascio (Maver & DiMascio, 2014). The areas of application, some well established and some still emerging, are:

- Design theories, concepts and methods
- Sources of information
- Information management and collaborative design
- Simulation of environmental performance
- Parametric geometries
- Space syntax
- Generative design
- Precedence, prototypes and shape grammars
- Digital fabrication, rapid prototyping and shape grabbing
- Large urban databases and smart citites
- User participation in design
- Multimedia in heritage and patrimony
- Virtual reality, virtual environments and virtual worlds

Given the increasing enthusiasm of our able undergraduate and postgraduate student cohort, we can anticipate an increase in the acceleration of the development of this area of architectural evolution. Yet – a central question remains.

5 DESIGN PARTICIPATION

Despite the thrilling advances in ICT and CAAD the fundament issue remains: how to deal with the value judgments that surround the subjective matters of aesthetics and cultural significance. After four decades of rapid development, the view of the author is unaltered: our ability to predict the *objective* characteristics provides the basis to inform the value judgements of the *subjective* characteristics. The question is *whose* value judgements?

Such was the confidence of at least one of the pioneers and a few far-sighted research fellows - that, in the longer term at least, the capability of the users of buildings, powered by increasingly intuitive CAAD software, would allow design participation.

The author persuaded the UK (then) Social Sciences Research Council (SSRC) to fund a study involving Nursery school Teachers in the design of a modestly sized school for which there are already was standard professionally designed and existing options. The ABACUS team developed the Partial (PARTicipation In Architectural Layout) suite of relatively simple computer programmes based on the Tektronix 4010 Graphics terminal. Partial 1 allowed the research team to define the design problem (the brief). Partial 2 allowed some 20 + teachers to create a single storey geometry and construction (with feedback) while Partial 3 recorded the design history of each participants design progression. Elaborate histories, both graphic and auditory, were catalogued (Smith & Watts 1979).

Figures 6&7 illustrate stages in the evolution (and feedback) of one participant's design exploration.

The research team was sufficiently encouraged by the fact that each and every nursery school teacher produced a feasible design within the pre-set constraint to go on to form teams of teachers who were then tasked with working towards a design that represented the best

possible compromise amongst the individual design options. Without exception, despite initially favouring their own design, the member of each design team found a composite scheme that all participants ranked above their own individual scheme.

The team then conducted two important controlled evaluations, with the following results.

i When presented with a number of design options, architectural tutors were unable to distinguish the design quality between those designs created by professional architects and those collaboratively created by nursery school teachers.

ii When (presented with the same set of options, nursery school teachers in another city wholly unaware of the background to the test, universally ranked all the scheme designed by the teacher above those of the professionals.

The final report to the SSRC captured the research team's thrill at these results. Regrettably, the SSRC review committee deemed the work to be too interventionist and declined to support if further.

6 CONCLUSIONS AND THE WAY FORWARD

It is undeniable that the rate and scale of development of ICT and CAAD specifically, over the last four decades has been quite extraordinary, but what of the issues?

Surely the concern that the application of computers would somehow result in all buildings ending up as boring boxes has well and truly been dispelled. Indeed, there is over-whelming evidence that our ability to 'test' design options, has promoted design innovation thereby increased variety in design solutions. A significant number of recently constructed and revered buildings could not have been designed and built without the application of computers.

This would suggest that the aesthetic and cultural characteristics, far from being neglected, are at the forefront of design thinking and that value judgements are, indeed, being given the attention they demand and deserve.

But *whose* value judgements? In section 5 of this paper, considerable evidence is presented to show that, in a relatively simple building type, the users can make seemingly positive contributions to the design evolution.

It is not suggested that this contribution in any sense supplants the expertise of the professional architect, but it is suggested that involvement in the design process, supported by the appropriate computer tools, allow the value judgments of user participation in building design is one of society's most important challenges.

7 ACKNOWLEDGEMENTS

The author gratefully acknowledges the contribution made by over 100 young people who came and went as research students and fellows, in the 40 years of the existence of ABACUS. He also thanks his current employee - The Mackintosh School of Architecture, Glasgow School of Art for its moral and financial support in presenting this work.

ABSTRACT: This paper presents research on the perception of three-dimensional space in two-dimensional media, and the methodology and results of a pilot study comparing the eye movements of architecture students when looking at different modalities of spatial representation. The results of this study show that student designers' physiological responses vary with different representation modalities.

1 INTRODUCTION

Architects design with varying modalities of representation, including sketches, drawings, physical models, and digital models. These representations may serve to assist architects in the development of design concepts (Schön 1992), or to communicate design intentions to the client and/or future users. The built work that results from a design process is a new configuration of spaces and forms that humans respond to both emotionally and physiologically. But how does the built work compare with its earlier representations? All modalities of spatial representation are abstractions of physical space and are therefore subject to interpretation. Since graphical representations are the most common form of representation of space during designing, it is important to know what the implications for the designer are when representing space in different graphical modalities. The research outlined in this paper is part of a project which aims to relate physiological responses in the embodied experience of the built space with the responses evoked when looking at architectural representations. This research could have substantial implications for our design process as architects and our pedagogical methods as architectural educators, in our challenge to bridge the divide between concept and built work.

Little empirical research has been done on the human physiological response to space and spatial representations. This project is a cross-disciplinary investigation involving researchers in architecture, computer science and psychology. Our research questions include: How veridical are these spatial representations? Do physiological responses to modalities across a participant group demonstrate consistencies? Are there cultural differences in physiological responses? Can physiological responses to space as represented in various modalities of architectural representation be correlated with physiological responses to physically inhabited space?

For the purposes of this pilot study, we narrowed our focus to pose the previously unexplored question: with the increasing application of computers in architectural design, what is the effect of different modes of digital representation on designers? With this pilot project we aim to produce evidence-based results about designers' physiological responses as they are exposed to two different modalities of spatial representation.

This pilot study utilized eye tracking to collect physiological data, comparing responses to different spatial representations. Through the collection of eye tracking data, our aim was to test our preliminary hypothesis: that physiological responses vary with representational modality. Building on the research paradigm of Scene Perception (Rensink 2000), researchers have been interested in how designers look at scenes. Experiments typically present the scene on a computer screen, allowing for a high level of control over variables of the scene (Holmqvist 2011). Our pilot study follows this methodology. From the analysis of the relationship between designers' eye tracking data and different modalities of representation – perspectival line drawing and photograph - designers' responses to spatial representation will be presented and compared.

The remainder of the paper presents a brief background to architectural representation, spatial perception and eye tracking. This is followed by the research

aim, significance and research design. From an analysis of the eye-tracking data, results are presented and analyzed, and broader impact discussed.

2 BACKGROUND

2.1 *Architectural representation*

Architectural drawings are understood as referential and non-autonomous; they are representations of architectural space and form. Plans, sections, and perspectival views typically follow discipline-specific conventions for representation. These drawings may specify the building, or they may depict it: defined as notational or imaginative drawings by Sonit Bafna (2008). This distinction accounts for the drawing-as-instruction, as well as the drawing-as-provocation. According to Bafna, "Richard Wollheim has argued that depictive seeing activates a special mechanism that he termed 'seeing-in'; faced with such pictures one cannot help but see figures within them despite knowing full well that they are just marks on the surface." Wollheim claims that we simultaneously perceive the drawing as an object, and the objects and spaces depicted within the drawing, with a "two-fold sense of perception" (Bafna 2008). While the intent of the imaginative drawing is not to evoke the experience of the building depicted, it is meant to provoke a "mode of attention," allowing for an engagement with the representation that allows for multiple readings (Bafna 2008).

With photography, however, there tends to be an assumption that it is an unbiased presentation of the space. Yet understanding the content and spatial implications of a photograph is a learned ability, and the photograph is, like a drawing, an abstraction of the architectural space. While studies comparing different cultures have shown no difference in perceptual organization, "the interpretation of perceptual material may differ considerably between two cultural groups" (Weber 1995). For example, African aborigines could not recognize anything in photographs they were shown. Two-dimensional representations of three-dimensional space requires interpretation which "relies on acquired visual conventions that may be as arbitrary as linguistic conventions" (Weber 1995). Photographs are authored and abstracted depictions of architectural space in the same manner as drawings.

2.2 *Spatial perception*

The ambiguity inherent in any architectural representation of space is a characteristic of spatial perception as well. Rudolf Arnheim emphasized the relative nature of perception, describing perceptual experience as being an aggregate of natural and manmade objects. This aggregation forms a "spatial framework" that causes visual percepts to "contain more than what is given in the physical stimulus pattern" (Arnheim 1977). In other words, our experience of an architectural space is influenced as much by the relationships and tension between architectural elements as by those elements themselves.

A related theory of spatial perception was developed by Michael Benedikt. Benedikt's isovist theory helps designers to evaluate visibility within or from a space from the vantage point of an occupant, considering the physically bound space in comparison with what can be visually perceived. An isovist is the volume of space visible from a given point (Benedikt 1979). Oliva et al. (2011) also studied the representation of the shape of visual space. In their study they critique the isovist theory of spatial perception for leaving out other characteristics of space such as texture, material and color that contribute to the human perception of space. They also propose a model called the "spatial-envelope representation," which describes qualitatively the character and mood of a physical or pictorial space, represented by its boundaries (e.g., walls, floor, ceiling, and lighting) stripped of movable elements (e.g., objects and furnishing). Then they proposed a formal, computational approach to the capture of the shape of space as it would be perceived from an observer's vantage point (Oliva & Torralba 2001, 2006, Oliva et al. 2011). The collection of properties describing a space in view is referred to by the authors as the spatial-envelope representation. This distinction in the characteristics that contribute to the human perception of space pertains to our research into representations of space that include or exclude some of those characteristics.

2.3 *Eye tracking*

Eye tracking data includes fixations and saccades, based on movement of the fovea. The fovea represents less than 2 degrees of the visual field, so the eye must move, or *foveate*, in order to take in detailed information (for example, in areas of an image with complexity). When the eye stops to take in information, this is called a *fixation*. The rapid movement of the eye from one fixation to another is called a *saccade*. During saccades, the eye is effectively blind: visual information obtained by the eye occurs during fixations, thus making fixations the most valuable data collected through eye tracking (Holmqvist 2011).

As early as the 1930s, psychologists were interested in how the eye moves and fixates when focused on a work of art. Guy Buswell (1935), a psychologist who invented the first non-intrusive eye tracker, found that the eyes do not follow edges, but tend to scan and focus on central concave areas. More recent studies confirm that fixations are likely to occur in concave and enclosed areas of a figure, rather than in what is perceived as negative space (Weber 2005).

Yarbus (1967) was another pioneer in eye tracking research, who found that the eyes move in different paths when looking at an image depending on the task the observer was asked to complete (Fig. 1).

Kaufman & Richard (1969) measured eye fixation times in several pre-defined parts of figures. The results show that the center of gravity is an attractor as are the edges and corners. Gould & Peeples (1970)

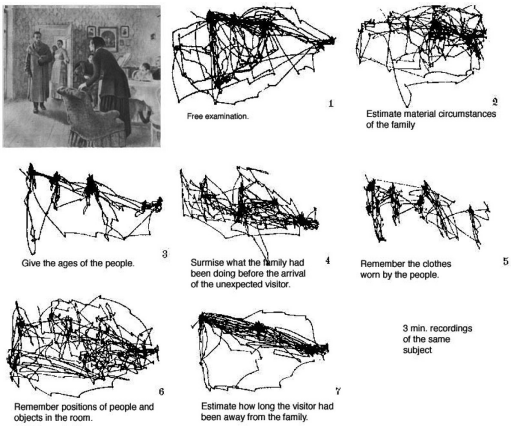

Figure 1. Eye tracking experiment by Alfred Yarbus in which participants were given a series of tasks while looking at Ilya Repin's painting 'An Unexpected Visitor' (Yarbus 1967).

suggest that a subject's interpretation of a figure does not affect eye movements, which means that only physical attributes have influence on the eye movements. Torralba et al. (2006) proposed visual attentional guidance through an experimental search task. Results of their study suggest that the context information plays an important role in object detection and observation. They also suggest some parts of the scene attract more attention than others.

While the relationship between eye movement and perception of artworks has been investigated, there has been very little study on the role of eye movement in the perception of three-dimensional architectural space. One of the few studies on this topic was conducted by Weber et al. (2002) in which they collected eye tracking data as participants were asked to look at three-dimensional models, or photographs of models, of architectural space. These models were constructed to collect data on the perception of the following architectural issues: empty space; symmetry vs. asymmetry; left and right reversed; obliquely-oriented elements; vista; and foreground. The research focused on comparing different arrangements of objects within a space, rather than different methods of representing the same spatial configuration. Their results showed that, with no priori model in a figure, the attention would fixate at the center; while the foreground was common for initial fixations, the eye did not typically scan the edges of interior space or rectilinearly-oriented contours; the objects on the left attract more attentions than the ones on the right. This confirmed the results by Arnheim (1985).

The study also concluded that fixations did not vary significantly when viewing the three-dimensional model compared with a photograph of the model, with the exception of the foreground, which attracted greater attention in the 3D model.

While these studies did not consider cultural background in their data analysis, a 2005 study by Chua et al. tested the hypothesis that those from Western cultures (in this case, American participants) have a tendency to look at focal objects, while those from Eastern cultures (in this case, Chinese participants) tend to look more at context and background. This hypothesis was confirmed by their study. The question of possible cultural differences in eye movement also arose in our study.

Figure 2. Eye tracking experiment setup by authors. This photo shows the setup at HIT in China; a similar setup was used in Charlotte.

3 PILOT STUDY

3.1 *Research design*

To test the preliminary hypothesis that physiological responses vary with representational modality, we set up an experiment that measured eye movement in response to spatial representations. In this experiment, 22 third and fourth year architecture students at UNC-Charlotte (UNCC) and 30 third and fourth year architecture students at Harbin Institute of Technology (HIT) in China participated in this pilot study.

During the experiment participants were asked to complete demographic questions regarding their gender, age, and first language. They were required to look at two images shown on a screen (Fig. 2).

The first image, labeled R1 (Fig. 3), is a computer generated perspective drawing. The second image, labeled R0 (Fig. 4), is a digitized photograph of the same space when built.

When participants looked at the images, their eye-tracking data were recorded by an eye-tracking system (Gazepoint in USA and Tobii studio in China).

Each of the images was shown for 20 seconds with a few seconds for recalibration in between them. Half of participants were first shown R1 then R0. The other half was first shown R0 then R1. After each image session there was a questionnaire session. Data collected included eye fixations and saccades.

3.2 *Results*

Four metrics of eye movement data were captured during the experiment: Time to First View (secs), Time

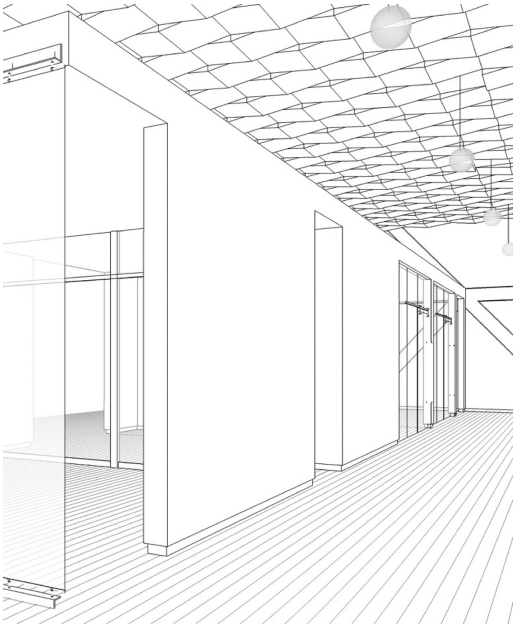

Figure 3. Computer generated perspective drawing (labeled R1 in the experiment).

Figure 4. Digitized photograph of the same space (labeled R0).

Viewed (%), Fixations, and Average Revisits. Time to First View measures how long it takes before a test participant fixates on an active AOI for the first time. Time Viewed (%) is the percentage of time viewed within

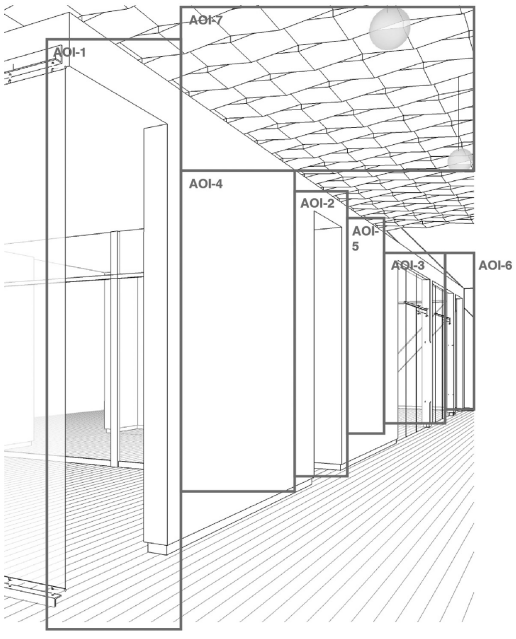

Figure 5. Seven Areas of Interest labeled AOI 1 through AOI 7 in R1; they occupy the same positions in R0.

an active AOI of the total viewing time – 20 seconds in this experiment. Fixations measure the number of times the participant fixates on an AOI. The Average Revisits measures the number of visits within an active AOI. A visit is defined as the time interval between the first fixation on the active AOI and the end of the last fixation within the same active AOI where there have been no fixations outside the AOI.

We identified 7 Areas of Interest (AOIs) in the visual scene presented (Fig. 5). Each AOI defines an area that we wanted to gather data about. AOIs defined the three doorways, the two wall surfaces between them, the terminus of the corridor and the ceiling.

Figure 6 gives a graphic example of the type of data collected: scan path and fixations for one participant are mapped to the images R1 and R0.

There were no significant differences in the results based on the order of viewing of the images.

Table 1 shows the averages of the four metrics for the data of the 7 AOIs in Image R1. Table 2 shows the average for each of the four metrics of eye movement data of the 7 AOIs in Image R0.

We next determine whether there are statistically significant differences between these two representation modalities. Table 3 presents the t-test results of comparing Image R1 to Image R0. Statistically significant differences are marked with an asterisk.

4 DISCUSSION AND CONCLUSIONS

4.1 *Analysis of results*

The results of eye-tracking measurements are discussed initially in terms of the architecture students'

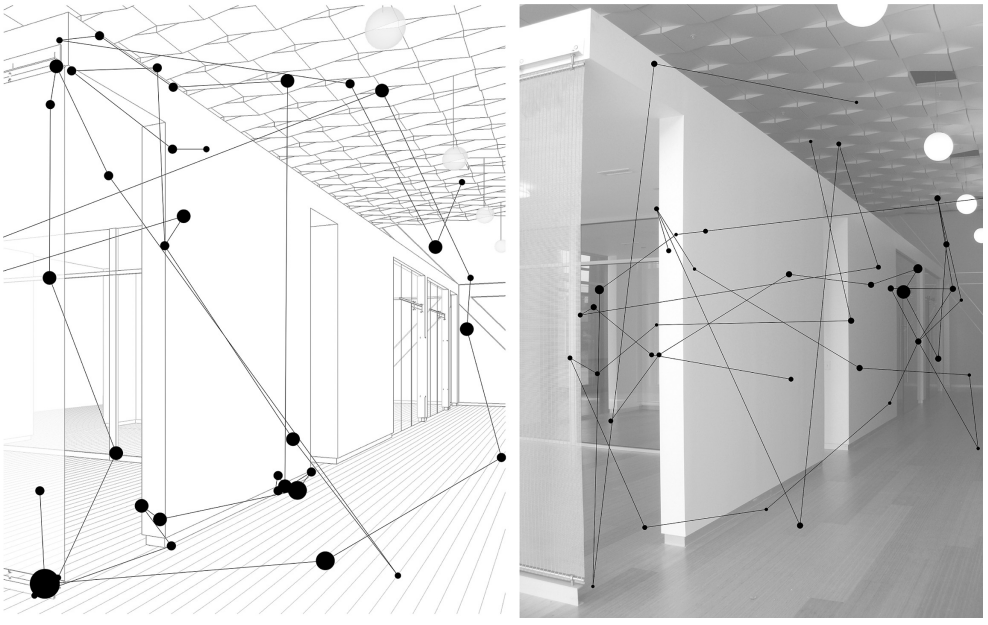

Figure 6. Example of scan path and fixations on R1 and R0.

behavior when viewing each image. This is followed by a discussion comparing the results of the eye-tracking measurements for both images to determine whether different modalities of digital representation produce different physiological behavior in the viewer.

The results in Tables 1 and 2 show how students allocated their cognitive effort. For example, from Table 1, we can see that the participants from both UNCC and HIT have the longest time viewed in AOI 1, largest average revisits in AOI 3 and the most fixations on

Table 3. t-test of Image R1 compared with Image R0.

*$p < 0.05$

AOI 7, AOI 1 and AOI 3. The least cognitive effort is allocated in AOI 2, AOI 5 and AOI 6.

There are two possible reasons for the longer time spent viewing and fixating on AOI 1. Firstly, participants may have been attracted by the relatively more complex spaces in a spatial figure: AOI 1 is an open door through which they could see a glass wall inside the room, as well as spaces behind the glass wall. When a designer is trying to understand the space, he/she will be attracted by this kind of complexity. Also, fixations tend to occur within a contained figure, rather than in the perceived negative space. While the white architectural volume sits as a figure in the larger space depicted, its two-dimensional representation causes the white wall to be perceived as negative space. (The contour becomes part of the figure it encloses, rendering the ground boundless.) Secondly, AOI 1 is located on the left hand side of the image, and according to study of Weber et al. (2002) and Arnheim (1985) the left side of a composition attracts more attention than the right. AOI 7 is the ceiling, which contains some complex structure, therefore it attracts the attention of the participants.

The most revisited is AOI 3. This may be because compared to AOI 1 it is relatively small and distant so that participants need to revisit to try to understand the space. The least attention is directed at AOIs 2, 5, and 6 possibly because they are relatively simple areas.

The results in Table 3 indicate differences in three of the four eye movement measurements. Time to first view, time viewed and fixations were all statistically significantly different when viewing the computer-generated line drawing perspective compared to viewing the digital color photograph for AOI 1, which is the first AOI to be viewed in the digital photograph but is only the third AOI to be viewed in the line drawing perspective. Interestingly, AOI 1 had the highest percentage of time viewed for both modalities, while there was a lack of congruence for the other three measures.

The results from this study additionally imply the following:

- Architectural students expend more cognitive effort on the relative complex spatial representation areas, as well as the structurally complex parts.

The complex spatial representation areas such as AOI 1 naturally attract more attention probably because it needs more exploration to understand the space. Certain features are more likely to attract eye focus, for example, in a face figure the eye focus is usually on "eye" and "mouth" (Gould & Peeples 1970). In architecture, past research suggest that architects pay more attention to the spatial arrangement of various architectural elements (Weber et al. 2002). The more complex spatial area such as AOI 1 contain multiple architectural elements: the extensive rooms behind the opening and the glass door. Also the complex structural parts in the ceiling attracted more attention.

- The left-hand side elements in an image are likely to attract more attention.

Research on eye movement of static images has shown that elements on the left-hand side attract more attention than the right (Arnheim 1985, Weber et al. 2002). The present research confirms this claim that human eyes tend to "rest" at the left hand side. This may be due to the visual pattern recognition and memory system of the brain. Further exploration of this phenomenon in spatial representations is needed.

- The edges of the interior space were not frequently scanned.

The most fixated areas are the complex spatial areas, rather than the edges or corners of the interior space. This result agrees with Weber et al. (2002)'s research on eye-tracking of interior space. However, in Kaufman & Richard (1969)'s study, they state that icons such as corners and edges are more likely to attract attention, while the current study does not confirm this claim.

- The center of gravity is not always the focus of eye movement.
- In the early eye tracking research, researchers found that the eye fixation is always focused on the center of gravity of a figure (Kaufman & Richard 1969), however in the current study, the center of the image is not the focus of eye fixation, instead it is the relatively complex space. This indicates that the semantics of the image plays a role. Cultural background of the student did not produce different results.

No significant difference was noted between the focal attention paid to AOIs by the American students as compared with the Chinese students. A previous study by Chua et al. (2005) confirmed the hypothesis that Americans fixated more on focal objects while Chinese participants spent more time looking at the context/background. This distinction was not noted in our pilot study.

This paper has presented the results of a pilot study comparing the physiological response of eye movement of architecture students when looking at different digital modalities of spatial representation. Results from the analysis of eye-tracking data suggest that designers' physiological responses vary with the changes of digital representation. In order to make a more comprehensive conclusion, a larger experiment is needed in a future study. Future studies would include a broader demographic (comparing trained designers with non-designers) and a wider range of representational modalities.

4.2 *Next steps*

Our goal is to integrate and expand on research conducted in a number of fields, including architecture, computer science, and psychology. Researchers in these fields have investigated the processes by which we perceive and understand space, by collecting and analyzing physiological data. We intend to further our research by conducting a larger-scale study with more participants, in which the sequence of modalities can be varied, and in which we can test the participants' physiological responses to real space in addition to representations.

The two key sources of relevant data for our next study are eye trackers and EEG. As a counterpoint to eye tracking as used in our pilot study, we are interested in additional physiological responses evoked by a space and its representations, which can be measured by EEG. Researchers have employed this tool to track brain activity and stimulation when viewing an image, as well as the emotional responses evoked by real-world spatial experiences.

Our methodology for the next experiment will focus on the emotional responses to these images as indicated by EEG data, as an additional layer to the eye tracking data. The Emotiv EPOC is a portable EEG headset that collects brain wave data to identify levels of cross-modal sensory processing, alertness/engagement, reflection, and engagement of memory in gamma, beta, alpha and theta waves respectively. As a portable device, we will be able to use it in subsequent studies in which the participants' physiological responses are measured in an embodied experience of a built space.

An anticipated outcome of a future large-scale study would be the identification of modalities of representation that most closely correlate with the embodied architectural experience to predict how spaces will affect the occupant's physiological state. As we improve our understanding of the relationship between our representations of architecture space in the design process and how that space as a built work will ultimately be experienced, architectural educators can work with students to represent their design work in a more authentic way.

Regenerative design – new role for the built environment

Bruno Duarte Dias
CITAD – Lusíada University, Lisbon, Portugal

ABSTRACT: According to the International Union of Geological Sciences we are in the Anthropocene, a new era caused by Human activity characterized by mass extinctions of plant and animal species, polluted oceans and altered atmosphere, among other long lasting impacts.

The building industry has one of the largest negatives impacts on natural systems, even if unintended. When buildings and infrastructures are raised they do not only change the landscape, but they also change the way the natural system works in those places.

To tackle these environmental problems caused by the building industry, several environmental design concepts have been emerging. But what are they really delivering, is energy efficiency, low impact solutions? Or do they have any positive contribution to the health of living systems, the systems that allow life to exist on earth as we know it? To really understand the way these several environmental design concepts perform it is necessary to compare and scale them, in a way in which it is easier to see the real outcome. With references from other environmental design concepts it becomes easier to understand what does the Regenerative Design concept aim to accomplish. This "new" design approach, can be applies to architecture, landscape and planning. It questions how natural systems function and how human activity can co-create alongside them in order to rebuild the web of life.

Instead of just aiming for high efficiency and reduced human impact, Regenerative Design sets a new role for the building environment, creating the idea that, if well design, the act of building and inhabiting a place can integrate human and natural activities, catalyzing a positive effect that will vitalize and benefit both sides. This is a holistic approach to design that spurs and integrates a new set of disciplines (systems thinking, geology, biology, ecology), as well as a new set of design concepts (sustainable, biophilic, and biomimicry design).

1 INTRODUCTION

There is a rising number of people committed to reducing the ecologic footprint, buying biologic food and products, living in more efficient buildings, "driving a Prius and put solar panels on the roof, but that isn't going to take us anywhere" (Moffat 2007). The real outcomes of our good intentions don't really have the impact that we think it could and should have, because most of those good intentions are just aiming to reduce human impacts. Reducing impact is important to slow-down the degenerative path that we are causing, but insufficient to reverse it, because we are still continuing to deteriorate the health of natural systems. Bill Reed, one of the leading researchers and practitioners on sustainable design, raised the question: "if the earth was covered with LEED platinum buildings (very efficient buildings) would the earth be in better shape?" The answer is no, it doesn't make the earth better. Because the problem is not about buildings, but about human activities in and around buildings that change the way natural systems work. Natural systems or natural ecosystems are here defined as communities of organisms (plants, animals, bacteria) that in a particular place provide ecosystem services – clean soil, clean water, clean air, food, natural resources, etc.

These services are essential to sustain life on earth as we know it (Daily 1997).

Building and development are necessary to provide habitat and substance for our society, but development inevitably alters natural systems. (Lyle 1994).

In the Cambridge dictionary, development is defined as "to improve a place or system, especially by making it more active or successful".

The quality of human and natural systems design is crucial to maintain healthy environments. Design is defined here as "conceiving and shaping complex systems", "environmental design is where the earth and its process join with human culture and behavior to create form." (Lyle 1994).

This paper is aimed at reviewing several environmental design concepts and attempt to assess what they are really delivering.

2 HUMAN BUILDING IMPACT

"*The major problems in the world are the result of the difference between how nature works and the way people think*" Gregory Bateson

It seems there is a lack of perception on how our world works and what the side effects of human actions

are. Humans are organisms classified as allogenic engineer's. Organisms that use tools and materials to change the environment, like beavers use trees to build ponds that modify water and nutrient cycle, which ultimately influence the distribution and diversity of plant and animal community (Jones 1994).

The major reason why humans have such adverse effects on the environment is because of the unintended consequences of our activities as engineers, from dam-building and skyscraper construction to forest clearance and the dredging and canalization of water courses, which alter the physical environment and module the flow of resources to other species (Jones 1994).

In the book Desert Meteorology, the author Thomas Warner argues that the Sumerian civilization agriculture and irrigation practices ruined the soil to such an extent that it has not yet recovered, because the system was destroyed to a point that it couldn't restore itself anymore.

We call "sustainable design" to several Environmental design concepts that aim to reduce human impact. Architect Bill Reed claims that "Sustainability is not deliverable. Sustainability is not a thing. Sustainability is not simply about efficient technologies and techniques. It is about life – a process by which living things such as forests, neighborhoods, people, businesses, mushrooms, and polar bears ensure their viability. It is a process of reciprocal relationship – a process by which living things support and are supported by a larger whole. That means a building can't simply be high performance and be considered sustainable." (Reed 2007).

3 EVOLUTION OF BUILDING DESIGN CONCEPTS

3.1 Vernacular – structures were made by empirical builders without the intervention of professional architects, using local natural and easy accessible materials like wood, straw, brick, stone and earth. Local materials combined with the local low-tech technologies allow people to adapt and live in certain places and climate. Buildings were characterized as low impact, low embedded energy and in some cases highly durable buildings/structures. From the example of Sumerian problems caused by irrigation systems we can question the knowledge and "quality" of ancient or vernacular interventions regarding the benefits and integration of natural systems.

3.2 Modern movement – Around the 1920s (in developed countries) modernist architects began to cast aside traditional or classical forms and experiment with sleek new designs that often use new materials such as glass, steel, and concrete. In the urban planning field, modernists moved away from the ecological holism to embrace social sciences and highly quantitative forms of analysis (Wheeler, 2004). Technologies like artificial light and air-conditioning systems allow buildings to have a freer form. This freedom indicates a slow disconnection from vernacular principles of passive design, use of local building materials, etc. Buildings start to have high embedded energy, very low efficiency, and bigger impact on resources and natural systems.

3.3 Turning point – around the 1960's and 70's the ecological movement emerged from the awareness that several notorious works, like "The Silent Spring", "The Limits to Growth" and "Design with Nature", spurred amongst the public. The economic and energetic crisis in the United States in the seventies was key to induce a shift in the way Western society looks at energy and environment. From this period two different approaches emerged to tackle environmental and energetic global problems, with different world views (Mang Reed, 2012).

4 OUTCOME OF DESIGN CONCEPTS

Graphic 1 was developed as the result of a reflection about what are this environmental design concepts delivering or at what level are they working, do they just aim to have low impact solutions, high efficiency, or do they have any positive impact on natural systems? Here three levels of action were defined. The ones on the top levels normally integrate some characteristics of the ones below.

Technological – in the bottom there are concepts that act according to a mechanistic world view, based on technical and engineering solutions (Mang Reed 2012), focusing on quantifiable efficiency and premises of low impact. In fact, this way to operate is just an upgrade of the modern movement in which technology is continually used, but in a more efficient way.

Ecological – In the Book Van der Ryn and Cowan (Ryn, Stuart 1996) ecologic design is defined as "any form of design that minimizes environmentally destructive impacts by integrating itself with living processes". Ecologic design or Eco-design is intended to conserve ecological integrity, while allowing ecosystems to provide sustainable flows of resources and to maintain critical services required by the human economy. Potentially, eco-design can contribute to the wise use of natural resources and the conservation of natural habitats, while still allowing people to engage in activities that provide manufactured products and economic services (Shu-Yang, Freedman 2004).

Hybrid – In my perspective, between these two opposite world views, emerged a way to operate that aim to benefit living systems, but still operate with a mechanistic mindset. Just because a building uses an interior living wall (a feature of biophilic design) doesn't mean that the building benefit local natural systems, its design just to benefit human needs of comfort and health.

4.1 Conventional buildings – Today, buildings are in fact getting more efficient. For example, in Portugal, the first thermal regulations for buildings were

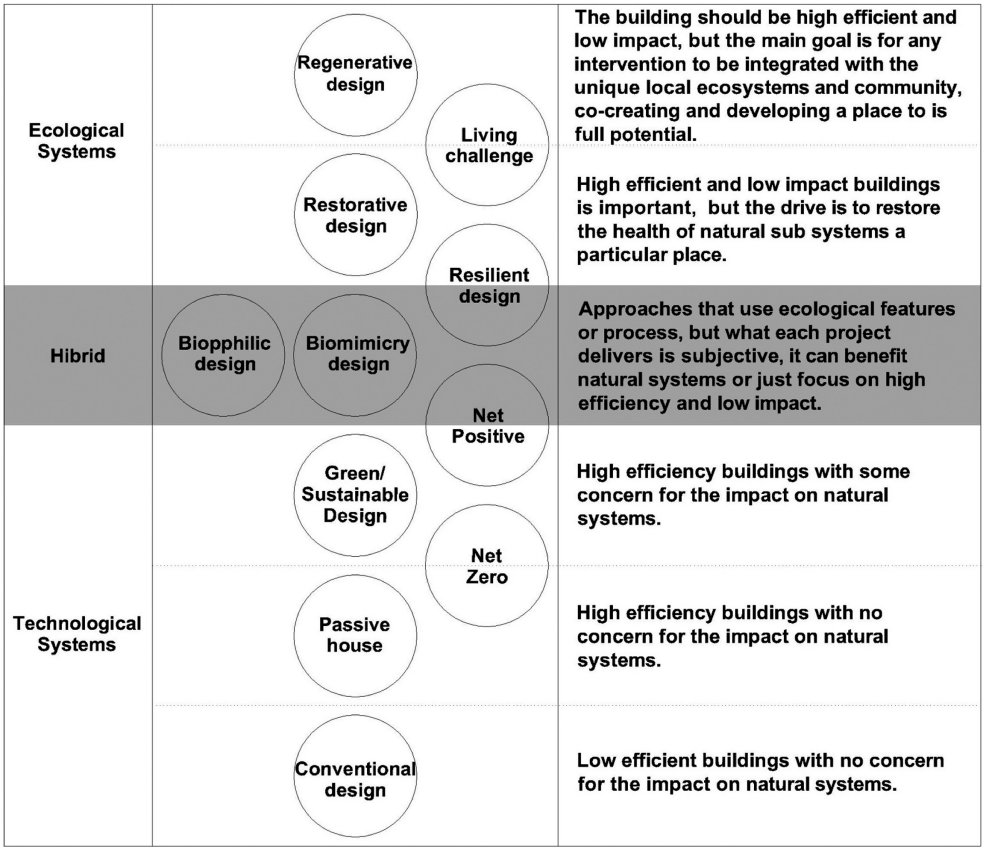

Figure 1. The outcome of environmental design concepts.

introduced in 1990, aimed at making our buildings more comfortable and efficient. Since 2006 we have the Energetic Certification program that has the goal to make buildings more efficient in terms of energy usage. However, this doesn't mean that the building industry is reducing, in any way, the degeneration of natural systems.

Today, comfort and efficiency levels of buildings are growing, but so is the embedded energy because buildings are getting more complex to build and operate.

4.2 Passive House – This program was launched in May 1988. Initially developed for houses, it is now also applied to non-residential buildings (commercial, schools, etc). The focus is on optimizing efficiency of building envelop (thermal insulation, window dimension and insolation, airtightness, absence of thermal bridges) with an efficient ventilation heat recovery system (Feist 2007). The focus is to make buildings as energy efficient as possible, with high comfort to users. It can be very efficient but it doesn't have any preoccupation about natural systems, making it as harmful as conventional buildings.

4.3 Green or Sustainable design – the US "Energy Independent and Security Act of 2007" establish that a green building should "integrate and optimize on a life cycle basis all major high performance attributes, including: energy conservation, environment, safety, security, durability, accessibility, cost-benefit, productivity, sustainability, functionality and operation considerations (EISA 2007). Green building is currently practiced within a mechanistic world view, using checklists systems like LEED. This can be compared to a health specialist's work on a heart, or intestinal system – healing the particular issue, but not addressing the overall systemic nature of the cause, whether it is diet, environment, stress, or genetics (Mclennan, Reed 2013).

Authors Michael Braungart and William McDonough argue that Sustainable design is a "less bad approach", although it is the first step in order to slow the damage, Van Ryn claims that "this kind of approach isn't going to take us anywhere" (Moffat 2007).

Green buildings have some measure of environmental conservation, but it still continues to degrade natural systems.

4.4 Net-Zero Building – has the goal to "generate enough renewable energy and water on site to equal or exceed its annual energy use". Net-zero is focused on the creation of new buildings and is largely technologically driven. "As currently framed, net-zero could be

seen as the endgame of green building design – doing less harm – or perhaps more symbolically, the vestiges of a reductive, mechanistic world- view." (Cole 2015).

Buildings are designed to mitigate human energy and water needs, but generally they don't aim at engaging with the health of ecosystems.

4.5 Net positive building – is considered as more than simply an extension of net-zero energy. It can foment the goal to produce, on site, more energy than is needed, supply water needs by storing rain water or recycling it. Net-positive approaches emphasize how buildings could work collectively within networks. A key issue, therefore, is how new buildings fit into and work with the existing building stock. Net-positive energy is put into practice by viewing the role of a building in terms of adding value to its context and systems in which it takes part. Rather than considering merely the generation of more exported energy versus its importation to individual buildings or the grid, the emphasis shifts to the maximization of energy performance in a system-based approach. Net-positive energy approaches open a host of new technical, behavioral, policy, and regulatory issues and opportunities not currently evident with net-zero energy buildings (Cole 2015).

These are very valid goals, but they have mainly high-tech aims and seem to be a paradigm change (from mechanistic to ecological) but, in my perspective, that is subjective, it depends on each project.

4.6 Biomimicry design – Janine Benyus defines this concept as "Innovation Inspired by Nature", a "new science that studies nature's models and then imitates or takes inspiration from these designs and processes to solve human problems". Benyus suggests looking at Nature as a "Model, Measure, and Mentor" and emphasizes sustainability (Benyus 1997) Biomimicry looks at nature in search for solutions. The Eastgate Center in south Zimbabwe has an air-conditioning system that mimics the way African termites regulate the temperature of their nests (Gunnell 2009) In this case, this design enables us to understand how nature makes the building more energy efficient, but that doesn't mean the building has any contribution to the health of the natural system where it was built.

4.7 Biophilic design – In the book Biophilic Design, co-author Stephen Kellert explores two dimensions. The first is an organic or naturalistic dimension, defined as shapes and forms in the built environment that directly, indirectly, or symbolically reflect the inherent human affinity for nature. The second is a place-based or vernacular dimension, defined as buildings and landscapes that connect to the culture and ecology of a locality or geographic area (Kellert et all 2008).

This is a concept that can be applied to several scales, with different outcomes. In object design and buildings (interior and exterior) it can have a positive impact in mental and physical health of people. When applied to landscape and city planning, depending on the project, it can have a restorative impact on natural systems and people. The real outcome depends on the way designers address the integration of natural systems in the project.

4.8 Resilient Design – Resilience does not imply a return to dysfunctional or unsustainable community conditions, but adaptation to dynamic social and ecological conditions in ways that protect and enhance quality of life, long term ecological productivity, and public and personal health (Beatley Newman 2011). The Urban Land Institute in Toronto argues that Resiliency thinking requires us to think not only about bouncing back from environmental, economic, and social crises, but adapting to changing circumstances by 'bouncing forward' through new paradigms, processes, and ways of working. A project design by the Resilient Design focuses on the concern it has about communities, not buildings. Buildings may endure or survive a disturbance, but it is communities that "come back".

In order to be able to design buildings and communities capable to resist and adapt to unexpected climate change conditions, designers must know in detail how local ecological systems work and use that knowledge to shape building design, finding effective and durable solutions to complex problems (Curtin 2014).

4.9 Restorative design – The aim of this design concept is for humans to restore an environment degraded by human presence. Bill Reed argues that we cannot restore something to the past state because nature is always in evolution. Restorative Design thinks about design in terms of using the activities of design and building in order to restore the capability of local natural systems to a healthy state of self-organization (Reed 2007).

4.10 Living Challenge design – It's a voluntary environmental building certification program with the highest requisites and ambitions, based on a measured outcome, instead of a modulated one.

The Living Building Challenge is, in many ways, a paradox, a reductionist tool to dismantle reductionist approaches. It is a program that is now on its third version. In 2006, the first version aimed at building neutral buildings or 100% sustainable. The second intended to have a restorative effect on the life and process of the site. In the third and last version, the aim is to help design and classify buildings that have the will/tendency to be regenerative (Mclennan, Reed 2013).

Living buildings can be almost self-sustainable buildings, designed to be have no negative impact on the health of the occupants and natural systems (Nugent et all 2011).

This design program as the highest ambitions, but does it have a real positive impact on the systems that sustain life, or can this regenerative goal be measured?

5 REGENERATIVE DESIGN

There are some approaches to Regenerative Design. In this paper we will look at Regenesis, which is referred by several authors to be the leading practitioners of regenerative design and development.

The term "regenerative" was used by Robert Rodale to reference the continuing organic renewal of complex life of the soil. The same principal of ongoing self-renewal can apply to all of the systems that support life (Lyle 1994).

Regenerative design is based on ecology and living systems principles (Mang, Reed 2012). Contrary to a technological world view, this is a concept with an ecologic world view, which looks at the world as a complex living system, interconnected at every level.

In the book Designing for Hope, Pamela Mang states that "we talk about living systems, rather than natural systems and human systems, because they are all living systems" (Hes, Plessi 2015).

There is plenty information about Regenerative buildings that can mislead the real goal of this approach. It is not about high performance building. In fact, a regenerative building only becomes meaningful and beneficial when understood as part of the living fabric of the place (Reed 2007). When properly designed, the act of building can give back more than it receives, building social and natural capital over time (Cole at all 2012).

Adopting one or two regenerative technologies or techniques into a green building practice without understanding the underlying premises and principles that make the approach distinctive, is frustrating at best and counterproductive, at worst.(Mang, Reed 2012).

Regenerative approaches place considerable emphasis on pre-design processes and, in particular, broad participant engagement that not only clarifies the design intent but also helps build collective commitment and capacity to ensure the building's long-term success (Cole et all, 2012).

The Regenesis design process to achieve regenerative design has three phases.

1 - Understanding the place – Instead of starting with the building and what surplus it can generate, a designer should start by asking what ecological services have been disabled in this place and what roles are missing that used to enable those services in the past. Instead of asking how to deploy any excess, in order to add value, a designer should ask what is the role of this particular project and that of the land it occupies in the larger systems of a particular place (Mang, Reed 2014).

Regenesis, defines Place as the unique, multilayered network of living systems within a geographic region that results from complex interactions, through time, of natural ecology (climate, mineral and other deposits, soil, vegetation, water and wildlife, etc.) and culture (distinctive customs, expressions of values, economic activities, forms of association, ideas for education, traditions, etc.) (Mang, Reed 2012).

Story of Place is a tool developed by Regenesis to discover the underline patterns of a place that serve to uncover the real potential of the project to enable regeneration. The site project goes beyond the physical limits of the building plot and can go up to the size of a watershed. After understanding this larger system and its core patterns, one has to develop an idea of the project role within the place (Hes, Duplessi 2014).

2 – Designing for harmony – is the second phase, where the potential of the place and the project aims to develop the regenerative design concept that reveals a greater potential for both (Mang, Reed, 2012). In the book Regenerative Design (Lyle 1994), the author describes design as a means to conceive and shape complex systems, where the earth and its process join human culture and behavior to create form.

After understanding the place and having in mind the potential of that project in that place the design team can start designing the new element that is going to restructure the system of that particular place and make it thrive.

3 – Co-evolution – A Regenerative project is not finished with the construction of a project. The real regenerative outcome can only be manifested if the people that inhabit the project and the land can continually unfold a source of inspiration and spirit to grow stakeholders that can have a role as regenerative agents or Regenerates in the larger system (Hes, Duplessi 2014).

5.1 *The project Aqua Viva*

This project in Loreto Bay, Mexico, is a private-public eco-resort development project with 6,000 units, divided in 6 phases of construction.

At first, the site appears to be a deserted beach. After Regenesis made a field assessment, they concluded that the site was in fact a severely degraded estuary that was landfilled with sand in order to extend the beach. After realizing that, the project team and the developers restructured the project because they found a purpose to this project: "To regenerate the health of the Sea of Cortez". This was a win-win situation. There would be more wildlife returning to the estuary, storm floods could be mitigated, the hydrology of the area would function better, while having a positive impact in nature would be excellent for the marketing of the resort.

The project Aqua Viva brought the promise that human building and development can reshape the way natural systems work and make them better than they were before the intervention. But this project can only became regenerative if the human community can continuously maintain the health and evolution of this living system through time.

6 CONCLUSION

The majority of the environmental design concepts applied to buildings presented in the bottom of graphic

1 are the first step to start making some change in the way people use energy and resources, design more efficient buildings and minimize impacts on natural systems. The concepts presented at the top are the ones that can really make some positive change, sustaining the life of natural systems that human activity have degenerated through time. To sustain life we should be working on both ecological and technological Systems. At the moment we are trying to fix problems that technology is causing on ecosystems with technology, so we creating more problems.

There aren't sustainable or regenerative buildings, the activities that people develop in and around the place and building they inhabit can have a regenerative or degenerative impact on the local ecosystems. When we make any change in a ecosystem, we change a system that took thousands of years to be shaped and work as it was before human intervention.

Regenerative Design is a complex and powerful design system that, in order to be successful, needs a multidisciplinary and integrative design team willing to consider each project as a unique opportunity to rebuild the web of life, not to build things in isolation.

The term Anthropocene remembers that man and its activities have a new role, the responsibility for the health of natural systems that support life on earth as we know it. Politicians, stakeholders, designers and others must be aware of what is the real outcome of the systems they design in a short and long time.

Building blocks: Abstraction and iteration

Bryan Shields & Jennifer A.E. Shields
California Polytechnic State University, San Luis Obispo, CA, USA

ABSTRACT: This paper describes an architecture studio project sequence in which the students were asked: How can the foundational educational concepts defined by Friedrich Froebel in the development of the first Kindergarten pedagogy, including the value of multi-sensory experience, flexibility, and abstraction, spawn a methodology for design?

1 PREMISE

How can the foundational educational concepts defined by Friedrich Froebel in the development of the first Kindergarten pedagogy, including the value of multi-sensory experience, flexibility, and abstraction, spawn a methodology for design? This was the question posed to a topical architectural design studio.

Norman Brosterman argues a link between Modernism, specifically the geometries of Cubism and the International Style, and a Kindergarten curriculum widely in use when Georges Braque, Piet Mondrian, Frank Lloyd Wright and others were children, which taught children to see the world as simple, repeating, geometric forms (Gabriel 1997).

"In abstract art," wrote Piet Mondrian in 1941, "we see … clearly there the elements of form are no longer veiled by the limited (the naturalistic) forms but appear as the expressive means." (Brosterman 1987) Mondrian's references to naturalistic, pictorial forms were always as "limited" or "limiting," and while that view of the pictorial vocabulary was not what Kindergarten teachers had in mind in their teaching, it may have been the emotional feeling conveyed to the creative children of many school generations (Logan 1950).

Friedrich Froebel, the father of the Kindergarten movement, created a series of 20 "Gifts" to foster a child's creativity. Each successive gift represented an instance in the sequencing of a child's development. Froebel believed that a child must first learn concepts through abstraction before engaging the physical reality. Froebel's "Gifts" and corresponding "Occupations" acted as a set of "graduated tasks that took the child on a quest for spiritual harmony with God, nature, and humanity." (Brosterman 1987)

The "Gifts" were not meant to be played with idly, but were expected to inspire the child, through direct manipulation and play, to form concepts of color, of texture, of size, of number, and of creative arrangements. The "Gifts" held a series of underlying objectives that privileged the sense of touch. The goals of each "Gift" were:

1. To aid the mind to abstract the essential qualities of objects by the representation of striking contrasts.
2. To lead to the classification of external objects by the presentation of typical forms.
3. To illustrate fundamental truths through simple applications.
4. To stimulate creative activity.

The corresponding "Occupations" further reinforced this approach, but could not be returned to their original form (ie. origami). All of this Kindergarten work was deliberately arranged to correspond to a child's inevitable and incessant activity (Logan 1950).

According to Jeanne S. Rubin, "All arrangements made with 'Gifts' and 'Occupations' were categorized into three types of forms: forms of life, geometric abstractions of familiar objects both natural and man-made; forms of knowledge, demonstrations of the principles of simple mathematics as well as plane and solid geometry, made possible by the graphed tabletop; and forms of beauty, a seemingly infinite variety of symmetrically and asymmetrically balanced forms." (Rubin 1989)

Although Kindergarten in its original manifestation by Froebel was lost, the ideals found their way into the teaching of the Bauhaus. Architecture became the keystone of the Bauhaus curriculum. Because it straddles an intersection of the environment, mathematics, and aesthetics (or nature, knowledge, and beauty), and is the sum of all the plastic arts, architecture, particularly after 1900 (and half a century of Kindergarten) ought to have displayed evidence of the impact of Froebel's unified training in any number of ways (Brosterman 1987).

Early modernist architecture was scarcely the simple embodiment of "truth to materials" or "form follows function" that some of its advocates claimed. With new technologies at the architect's disposal, but no tradition for their employment, much of what advanced into modern architecture was provided by

architects' involvement with the theories and practitioners of the allied discipline of abstract art. Cubism and geometric abstraction came just as architects were searching for new means of expression. Their concurrent adoption by architecture, which was recently unshackled from classical models, was assured. Kindergarten, which had become an important ingredient in art, was thus implanted into the architecture equation not only by the architects themselves (everyone of whom was born during the pedagogy's prime), but through contemporary art as well. Cubism, Futurism, and Neo-Plasticism found their way into architecture, bringing Kindergarten along for the ride (Brosterman 1987).

Even more direct connections can be made between Kindergarten and the distinct shift in architectural expression that occurred in the early twentieth century. Looking at the work and writings of Frank Lloyd Wright and Le Corbusier, there is substantial evidence that both were strongly influenced by the instruction of the original Kindergarten.

For Wright, the objective was unity, for Le Corbusier, harmony. A reliance on proportional systems and an almost religious devotion to the power of geometry linked the two, resulting in the creation of a substantial amount of what is definitive about modern architecture. "Wright transformed aspects of Froebel's system into the regulating grids upon which his plans were always organized and the interpenetrating rectangular solids that were their three-dimensional equivalent … Le Corbusier enlarged the Platonic solids to building size and ornamented them with nothing but their own shapes and shadows …" (Brosterman 1987).

2 OBJECTIVE

This paper describes an architecture studio project sequence in which the students were asked to reverse engineer a method of abstraction, using Froebel's "Gifts" as a foil for their analytical and interpretive process. This spatial interaction is inherent in Froebel's second gift, consisting of a sphere, a cube, and a cylinder. Learning is accomplished by way of comparison – the sphere with no flat planes, the cube with no curves and the cylinder being both flat and curved. This suggests a method for understanding the toy and its constraints before designing its classroom. How can the scale of the hand and the rules of play, affect the larger context it is located within? The position is that architecture does not have to be static, but can evolve and learn over time.

The objective was to explore the interactive potential of architecture, design that is responsive to both its context and the user. One of the advantages of working in abstraction is that objects can remain simultaneously scale-less and scalable. As conceptual depth is gained, the site and/or program constraints can be applied to situate and ground the formal logic and rules uncovered.

El Lissitzky, a Russian Constructivists, spoke of his Proun as the seminal object of abstraction (Fig. 1).

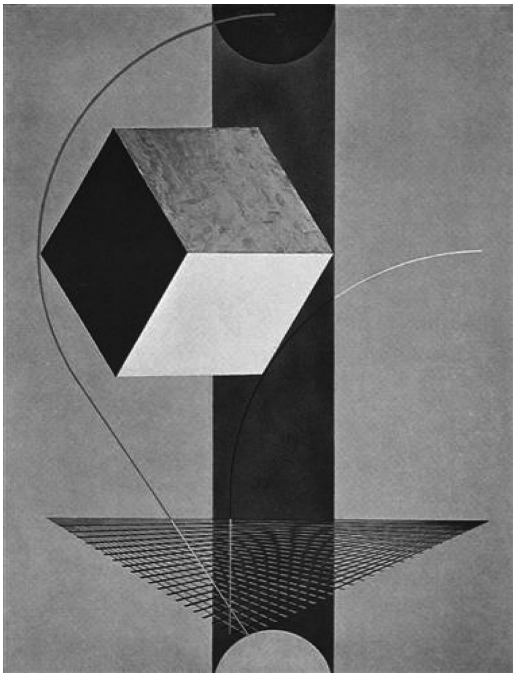

Figure 1. El Lissitzky, Proun 99, ca. 1923–25.

He said the "Proun begins as a flat plane, goes on to the construction of three-dimensional models, and beyond that to the construction of every object of our common life. Thus Proun supersedes painting and its artist on the one hand, the machine and its engineers on the other; proceeds to the construction of space, organizes its dimensions by means of its elements, and create a new, manifold yet unified, image of our nature." (Banham 1967).

This passionate quest for harmony bears striking resemblance to Froebel's premise for Kindergarten pedagogy: "All is unity, all springs from unity, strives for and leads up to unity, and returns to unity at last." (Hughes 1910).

3 METHODOLOGY

3.1 *Assignment sequence*

The studio utilized a design methodology that has exploration at its foundation, able to evolve in order to build on the unknown rather than be limited by it. The studio approached the site and program requirements with the same inventiveness and exploration as Froebel's Kindergarten.

The semester was broken into four assignments. The first three assignments graduate and influence the fourth and final assignment. The sequencing of the course followed the intent Froebel laid out in his gifts – mastering the first step before moving onto the next.

1. Assignment 1 focused on the analysis of the spatial complexities of abstract paintings.

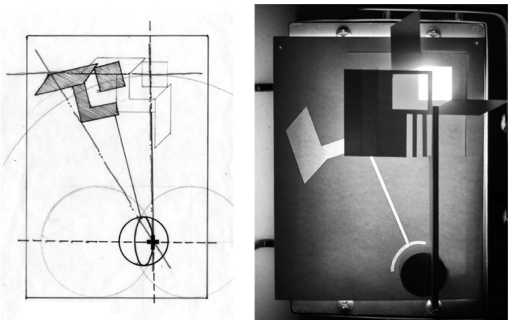

Figure 2. Student diagram and maquette of Proun 99.

2. Assignment 2 used the spatial analysis from the first assignment as the basis for the design of a toy.
3. Assignment 3 explored precedent; specifically, how the detail influences design as a whole.
4. Assignment 4 culminated in the design of a Kindergarten in Brooklyn, New York.

3.2 *Assignment 1: Abstract art analysis*

The students began by diagramming, in both plan and section, the influences of particular Froebel "Gifts" and "Occupations" in a work of Abstract Art. The diagrams demonstrated the concepts of color, shape, number, extent, symmetry, proportion, surface, lines, rings, and points. This exercise was based on Norman Brosterman's theory that the Abstract Art movement began in the "Child's Garden." (Brosterman 1987).

The students selected two paintings: one from the Cubist and one from the De Stijl or Constructivist movements. For each of the paintings they created a bibliography and wrote a short abstract on the intentions behind the artist's work and a theoretical criticism of the painting.

Based on their group research and in-class discussions of the abstract movements they created a series of diagrams, in both plan and section, that demonstrated the influences of particular Froebel "Gifts" in the work of art. The diagrams illustrated the concepts of color, shape, number, extent, symmetry, proportion, surface, lines, rings, and points. The goal of the diagram set was to isolate each layer of the painting in order to develop a spatial hierarchy.

The diagrams prompted the construction of a series of maquettes that described their interpretation of the three-dimensional space represented by the artist. The maquettes were given specific material constraints for their construction in order to explore particular aspects of form and space (Fig. 2).

3.3 *Assignment 2: The toy*

The students next constructed a toy to address one or more of the previous themes. The methods of abstraction discovered during Analysis were intended to provide a sense of order for the movement plays that the 1:1 object facilitates.

Figure 3. Student toy based on Proun 99 analysis.

Friedrich Froebel developed teaching objects as part of a particular, integrated curriculum. "Froebel's program of graduated tasks of arranging spheres, blocks, paper, and other materials was developed from the Enlightenment legacy of understanding the forces of nature through experimentation but was joined to a Romantic quest for spiritual harmony with God, nature, and humanity." (Ogata 2004) Frank Lloyd Wright said that: "The smooth shapely maple block with which to build, the sense of which never afterwards leaves the fingers: so form became feeling." (Rubin 1989).

From their analysis of Abstract Art in Assignment 1, students developed a vocabulary of "Gift" concepts. Assignment 2 asked them to elaborate on those concepts in the construction of a toy. Their toy was to address one or more of the following: color, shape, number, extent, symmetry, proportion, surface, lines, rings, and points (Brosterman 1987).

The students considered the following criteria in the design of their toy (Fig. 3):

- The toy can be adapted to many uses in construction.
- As the child's ability increases, the toy responds to the growing needs and the variety of form grows.
- The construction that suited yesterday can be improved upon today.
- The toy is governed by a set of rules that determine their use in construction.
- The toy allows for subconscious growth in the grasp of number, combination and partition. (Payne 1901).

The toy was required to fit within a $3 \times 3 \times 6''$ volume in its static or contained state. Students produced three diagrams of how they intended to manipulate this volume: one diagram that studied the concepts in a subtractive or solid form, one diagram that studied the concepts in planar form, and one diagram that studied a combination of solids and planes. The diagrams

were axonometric drawings at 1:1 scale showing all components of the volume.

3.4 *Assignment 3: Precedent analysis*

Taking the lessons learned and questions amassed during Assignments 1 and 2, the students were asked to analyze a building and its context. The same themes and methods of analysis from their abstract art exercises apply to the works of architecture described below.

In Cubism, geometry, as something both new and perennial, is comparable to the status of abstraction in de Stijl theory, and the two terms are almost interchangeable, particularly since their associated ideas borrow from the same vocabulary. The vertical and the horizontal are – among the sensorial manifestations of natural phenomena – verifications of one of the most directly apparent laws. The horizontal and the vertical determine two right angles, out of the infinity of possible angles, the right angle is the angle-type; the right angle is one of the symbols of perfection (Banham 1967).

Students were asked to research one of the following projects*:

- Maison de Verre by Pierre Cherault: Paris, France, 1932
- Casa Curutchet by le Corbusier: La Plata, Argentina, 1953

(*Notable precedents omitted: Villa Müller by Adolf Loos and Schröder House by Gerrit Rietveld.)

The students each produced both analog and digital orthographic diagrams. They were required to explore both plan and section, as well as to interrogate the project at the scales of the room, the building, and the urban block.

The diagrams created in the previous step were, as in Assignment 1, acting as drawings for the construction of a series of maquettes that describe their interpretation of the three-dimensional space created by the architecture. The maquettes were again constructed from a restrained material palette – studying the scale of the room, the building, and the urban block.

3.5 *Assignment 4: The 21st century kindergarten*

With the same concepts that guided the students through the Analysis and the Toy, students were asked to design a Montessori School within the ruins of the Tobacco Warehouse in Brooklyn, NY. The change in scale from Interpretation to Intervention was a provocation to test the movement plays (abstraction and discovery) in translation from object to site scale.

The design of the Kindergarten was to accommodate the following programmatic requirements:

- Gathering Space
- Reception and Admin Office
- Classrooms*
- Teacher Offices
- Play Space** (Outdoors)
- Restrooms

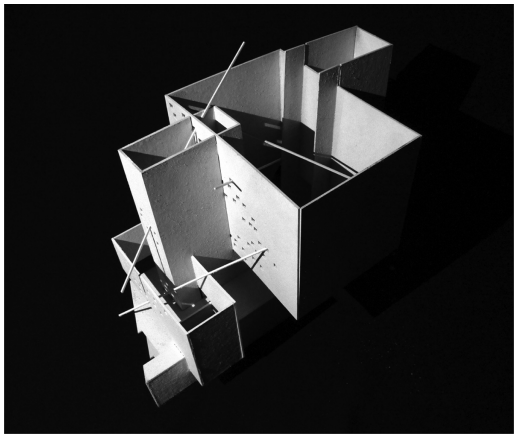

Figure 4. Student maquette analyzing Corb's Casa Curutchet.

Figure 5. Student design perspective.

*All classrooms were to have direct access to the exterior.

**Play Space was to accommodate both group and individual play.

The Tobacco Warehouse shell could not be altered but students could attach to any of the existing walls. The footprint of their project could not extend outside the South, East and West sides of the warehouse. Although there was more than enough square footage within the walls of the warehouse to accommodate the program, they could extend into Brooklyn Bridge Park to the North of the site.

The resulting projects nested within the given structure of the Tobacco Warehouse, facilitating a dialogue between given forms and new forms, in much the same way that Froebel's Gifts set up creative play between given components.

4 CONCLUSIONS

The design of a piece of architecture with a more normative program as the concluding assignment provided for an interesting dialog within the studio. There was an impetus to jump right to the details of the project, assuming that the earlier precedent exercises

served as the conceptual depth for the parti. The mid-review was a critical reminder that the relationship between the diagram and the detail had to be recursive. The reverse engineering assignments were not meant to be formal drivers but to encourage an understanding of the vectors of site and program – and to celebrate the geometry of the context.

Reflecting on the questions posed at the beginning of the project, the strongest projects fully embraced the premise of abstraction to gain a deeper conceptual clarity. The site and its contextual vectors were viewed as a game board where a series of what Froebel called "movement plays" could unfold using the programmatic needs as a foil to the rules of site. The process was itself an abstraction of how Froebel set up the "Gifts" to correspond to their "Occupations."

Subsequent iterations of this studio were given a much less normative program, challenging the students to more deeply analyze potential spatial relationships, rather than bringing deep-seated preconceptions to the project. In the words of Frank Lloyd Wright, "Children should not be allowed to draw from casual appearances of Nature until they have first mastered the basic forms lying behind appearances." (Rubin 1989).

Introducing digital soft skills: Bridging the gaps in architectural education

Shelby E. Doyle & Nick Senske
Iowa State University, Ames, Iowa, USA

ABSTRACT: Developing technologies, such as computational design and digital fabrication, are transforming the design and construction of contemporary architecture. However, the understanding of how to teach technology as an essential design skill has not kept pace with these rapid changes. Design education and technology education continue to be seen as separate loci of learning. In response, this paper argues that a set of complementary "soft" skills is missing from most discussions of digital design pedagogy in architecture and that these soft skills can bridge the current gap between digital education and design education in architecture. Soft skills are "soft" in contrast to more easily quantifiable "hard" skills such as operating a machine or knowledge of art history. Failure to acquire soft skills such as resourcefulness, good electronic communication, etc. negatively impacts how technology is introduced, practiced, and developed in architectural studio culture. Introducing soft skills will help bridge the gap between studio learning and technology learning. The first section of this paper describes a list of soft skills that support students as they learn digital design. In the second half of the paper, several methods for integrating soft skills into digital design instruction are proposed. Contemporary architecture schools are tasked with introducing digital technologies as they are changing, creating an opportunity to develop innovative curricula and democratize access to these skills. With the rapid pace of technological change, students need to be comfortable with and capable of learning, relearning, and integrating new programs and tools throughout their career. Therefore, this paper proposes that soft skills can and should be taught in architectural education and that teaching them will make digital instruction more effective in the design studio.

1 INTRODUCTION

1.1 *Introduction*

Computer-Aided Drafting and Design (CADD) technologies have become commonplace in architectural practice as tools of efficiency and production. For these very reasons the introduction of CADD in early architectural curricula has been fraught with anxieties along a continuum: from the undoing of creativity through positivist and reductionist logic (Pullasmaa, 1996) to a firm belief that these technologies will revolutionize the way architects practice and think about design. (Kieran and Timberlake, 2003) At the same time, there is a presumption that students who have grown up with digital technologies are "digital natives" who possess special aptitudes or insights which are disruptive to learning computing. The presence of these anxieties and biases often leads to gaps in architectural pedagogy, as digital tools are misunderstood and misappropriated by students and teachers alike.

Defining and using the term "digital design" is somewhat problematic, as there is very little architectural work today which does not use the computer in some capacity, and yet there are also designs which consciously engage in digital aesthetics and processes. For the purposes of this paper, *digital design* refers to the use of the computer and computer-driven tools (such as CNC machines, robots, etc.) when one designs architecture. The key is not what a person designs, rather whether that person employs the computer or not as a tool in architectural work.

Design is the verb in architectural education and in architecture; it is what architects do. It is necessary to distinguish between design and digital design – and to speak of teaching digital design – in this moment, because the introduction of the computer in architecture changes both what and how architects design. It introduces both new capabilities and new sources of bias and error. Therefore, architectural education must address and teach specific ways of designing with the computer – not how to use software or operate machines, but how to *design digitally*.

The very existence of the category of digital design is problematic because it implies two cultural silos in architecture: those who are digital and those who are not. This outlook potentially limits students' educational and professional development. To be clear, this paper interprets digital design as a broad skillset that should be available to all students, rather than a niche specialization.

The aim of this paper is to take control of the pedagogical agenda for digital design in architectural education by debunking the myth of the digital native and applying proven educational research to the pursuit

of digital design. This paper is a discussion of architecture, design, and education; not an argument for software and computer use in design. The relevance of this educational conversation extends only so far as it impacts the development of the profession's relationship to digital technologies as these technologies are changing. The goal of this, and any, educational proposal for architecture must be improving the state of architectural design in addition to advancing learning in both the academy and the profession.

1.2 *Myth of the digital native*

The common belief that students are self-regulating when it comes to learning and using technology may come from the notion of digital natives. The label "digital native" derives from a series of articles written by the technologist Marc Prensky during the early 2000s. Prensky describes the generation of young people born since 1980 as "digital natives" due to what he perceives as an innate confidence in using new technologies such as the internet, videogames, mobile telephones and "all the other toys and tools of the digital age." (Prensky, 2011) Enrique Dans counters Prensky's claims: "Simply being born into the internet age does not endow one with special powers. Learning how to use technology properly requires learning and training, regardless of one's age." Dans goes on to expand upon the issues of assuming students do not need to be taught to use technology thereby becoming "digital orphans", lacking in any model to copy or experiences that might have generated criteria for understanding. (Dans, 2014).

For this reason, beyond basic fluency, architectural instructors are uniquely positioned to model substantive content creation and healthy critical thinking about these technologies. By perpetuating the myth of the digital native, architectural education is missing the opportunity to establish strong pedagogical foundations from which future digital advancements will emerge.

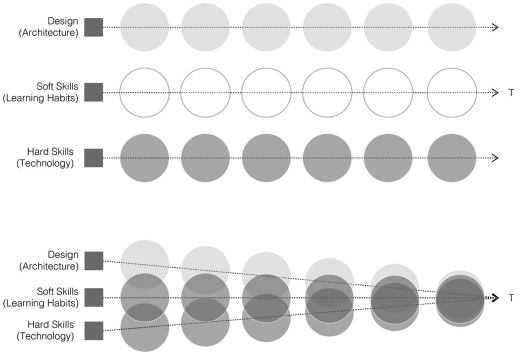
2 DIGITAL SOFT SKILLS

2.1 *Soft skills and fostering learning habits*

Computer use in architecture is often discussed and taught as a series of technical or "hard (as in absolute)" skills. In contrast, "soft" skills are related to emotional intelligence, attitudes, habits, and interpersonal relationships. An example of a soft skill is resourcefulness: being inclined and able to find alternate solutions to a problem, rather than giving up or deferring responsibility. In this manner, soft skills influence the ways that an individual applies technical skills to achieve goals, such as a design. Learning soft skills has been related to improved employment outlook and better job performance. (Andrews and Higson, 2008; Nealy, 2005) Professions such as business and information services have cited employees' lack of soft skills as one of the primary reasons why projects fail. (Bancino and Zevalkink, 2007) Thus, for students, developing soft skills is equally as important, if not more important, than learning technical skills.

Knowing how to operate a smartphone does not necessarily make one an effective computer user.

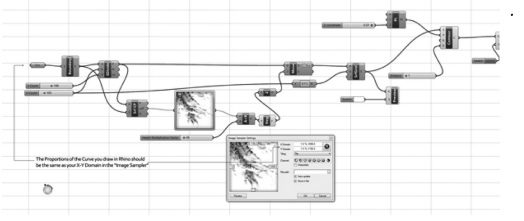
The influential Boyer report on architectural education concluded that: "[A]rchitectural education is really about fostering the learning habits needed for the discovery, integration, application, and sharing of knowledge over a lifetime." (Boyer, 1996) Soft skills are the learning habits Boyer references, and so are a critical element of architectural education in general. While this paper focuses on digital soft skills, this finding is not to be overlooked.



Soft skills must be taught rather assumed to be pre-existing skills. This especially applies to Soft skills which relate to digital design in architecture. Architectural education must recognize that university students are not comprehensively or consistently trained in digital technologies when they arrive on campus. This is exacerbated when less privileged students are potentially less digitally skilled than students from economically privileged backgrounds. By not addressing these inequalities, institutions, such as architecture schools, are perpetuating disparities through education and leaving students underprepared for the future. Soft skills can be reapplied to changing technology, whereas hard skills may fall away as technology changes.

2.2 *Traditional vs. digital soft skills*

The type of soft skills described in this paper are not entirely the same as soft skills introduced in the previous section. While traditional soft skills such as conscientiousness and empathy are helpful for architects, *digital* soft skills have a different purpose and apply specifically to the tools and processes used in digital design. Digital soft skills, such as asking clear questions, estimation, and planning skills, enable effective collaboration with other people while using digital tools and promoting effective workflows for collections of digital tools. Digital soft skills support students as they are learning digital design and, later, help students apply technical skills successfully and with sophistication and to adapt to a rapidly changing technologic landscape.



Digital soft skills also differ from traditional soft skills because they take into account the particular challenges of computing and digital machinery. The special attributes of digital tools that make them powerful, such as symbolic logic, abstraction, and automation, can invite cognitive biases when designers operate those tools simplistically, at face-value (i.e. using a computer like a cell phone, a pencil, or a typewriter). Humans must adapt their thinking, expectations, and habits, as their natural inclinations can interfere with working effectively with digital tools. (Sheil, 1983) Even those who work with digital tools frequently need to learn digital soft skills, as they may have developed bad habits and misconceptions over time. Merely using digital tools is not enough to cultivate mindfulness of the medium and one's responses to it.

To cite an example: digital tools are often "black boxes" with complex layers of interrelated procedures that make it difficult for users to be aware of what they are doing and how their software operates. Users expect simple cause-and-effect relationships between their operations and the results on a screen, when the reality is that many "hidden" processes are at work and can affect the outcome of an interaction. (Blackwell, 2002) This is also one reason why computers are not always dependable and why they tend to break down in obscure and obtuse ways. Working responsibly with digital tools requires a certain level of comfort and responsiveness with an opaque tool. Students who lack the digital soft skills to understand and respond to this condition often have a poor attitude when faced with computer problems and may spend their time in unproductive ways trying to "hack" solutions to technical problems. (Pea, 1987) This affects not only the quality of their final designs, but their outlook on technology in general. Digital soft skills are similar to traditional soft skills in the way they affect how students apply technical skills. They are the bridge across the gap that often exists between design skills and technical (hard) skills like digital methodologies. Unfortunately, very little time, if any, is given in architectural curricula to the explicit cultivation of digital soft skills.

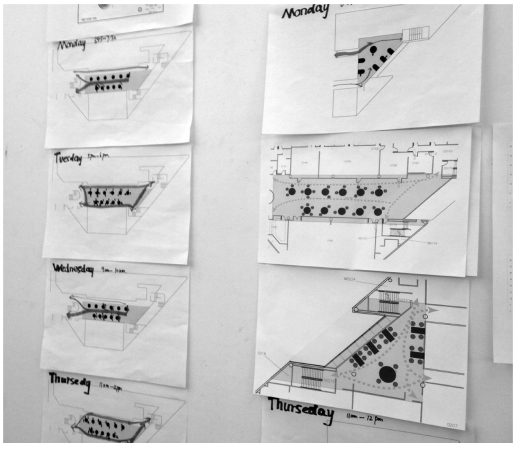
The top diagram demonstrates a curriculum where design (architecture) and hard skills (technology) are typically taught in parallel.

The bottom diagram demonstrates that soft skills (learning habits) create the bridge between design (architecture) and hard skills (technology). Over time these skills become mutually supportive.

Example of a downloaded Grasshopper definition. Working digitally demands questions of authorship and intellectual property be discussed with students.

2.3 *Samples of digital soft skills*

The following list is a representative sample of digital soft skills which could be taught in an architectural curriculum, organized according to four primary headings.



A) Communications Skills

Communication is an essential skill for architects. One could argue it is the majority of what a professional architect does. Whether it is through drawings, models, written, or oral, an architect must be able to clearly express their ideas and intent to an audience. Unfortunately, in architectural education, digital communications are often overlooked as a medium with unique challenges. For instance, many students have never been explicitly taught how to ask a question via email: to provide necessary information and files upfront, anticipate follow-up questions, and to communicate their expectations for resolution. This is important not only professionally, but especially when trying to learn or fix something like a new piece of software. Communicating well through digital media is critical, particularly as it has become a primary means of interacting with others.

Collaboration – The ability to work with others digitally, particularly at a distance. One aspect of this is organizing files and sharing them across computing platforms and software versions.

Authorship – This is the ability to understand digital intellectual property and to distinguish between resourcefulness and plagiarism. This notion of authorship becomes increasingly important when the line between programmer and architect is blurred by the use of digital tools. Of particular note is the downloading of code or Grasshopper definitions which are then deployed as design generators.

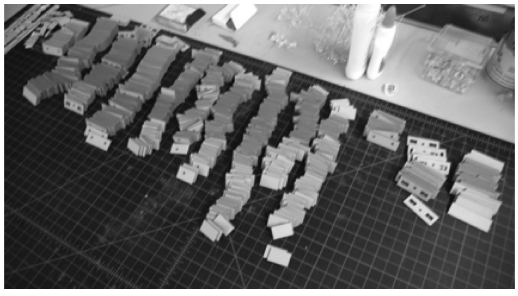
Support – Architects should be able to seek, locate, and pursue support for software and technical issues, many of which might exceed the abilities of the instructor or the support offered by an academic institution. These skills include asking fellow students, contacting

Example of a response to a large print which failed. Soft skills encourage students to anticipate such failures and to develop alternatives, such as printing on smaller paper, creating analog versions, and using a projector.

the software maker directly, and using the Internet as a resource.

B) Adaptability

Adaptability is resiliency in response to imperfect tools and a field constantly in change. Architects using digital tools should work with the understanding that failures are to be expected, while being empowered to seek alternatives. They must also update their skills and abilities often while remaining critical users of technology.



Autodidacticism – The ability and inclination to teach oneself (quickly) is a valuable skill for designers. This includes planning and scheduling regular time to learn and a recognition of common concepts and methods shared between tools, which can make learning more efficient.

Conversion – An effective strategy for error recovery is knowing how to share data several between types of files and programs. It is important to also note that many computer programs are able to convert various file formats and often have similar procedures.

C) Time Management

Digital design projects in architecture are often complex, involving many different programs and machines, as well as human team members. Some of these elements can be hands-off (such as rendering) or very hands-on (supervising CNC fabrication). Part of completing them successfully is knowing the workflows involved and having a sense of their coordination and time requirements.

Estimation – There is a common misconception that technology makes design faster and easier. It takes experience and skill to determine the full amount of time needed to complete a digital task or processes (e.g. milling, printing, rendering).

Example of a time management and workflow issue common in digital production. It must be reiterated that the computer is not automatic nor is digital production in and of itself 'fast.' A tedious laser file will become a tedious model to assemble.

Example of a back up protocol. Soft skills enable students to feel confident that computers will fail and that they are empowered to seek alternatives.

Sourcing – The ability to identify the most effective tool and process for the development of the idea and in relation to the time available for production. This requires understanding the different elements of digital production such as the difference between a raster and a vector.

Preparation – Plan for contingencies and alternatives. Assume some things will inevitably not go as expected and know the options available.

Scheduling – Develop internal deadlines, realistic calendars, and skills for planning and implementing a multi-step process. For instance: development of a digital file for fabrication, then fabrication, then post-production.

D) Digital hygiene

Digital hygiene refers to the good habits of caring for equipment, computer hardware and software as well as preventing and recovering from errors.

Organization – Maintain files in a structure which is both navigable and searchable by users.

Backups – Create a backup routine that is an embedded part of the digital process (cloud, physical media, & storage). This also includes knowledge

and use of software auto-backup and recovery. Keep at least one physical backup off-site.

Maintenance – Keep software up to date (but never upgrade before a deadline). Remove dust and other particles from sensitive equipment, such as laser lenses, after each use. Vacuum computer cases, power supplies, and hard disk enclosures often.

Clean-up – Regularly sort, store, and purge project files to manage storage and make important files easier to locate.

2.4 *Teaching digital soft skills*

Many of the examples listed under soft skills can be classified as character or personality traits. Successful students may already practice soft skills and therefore it is often assumed that these are character traits rather than teachable attributes. One might wonder, given the age of many college students, if such habits can be changed. However, the very notion of "soft skills" implies that these behaviors and habits can be taught to students. There is evidence to support the idea that, with training, young adult students can learn new traits and learning strategies. (Perkins, 1989).

Another common argument is that soft skills are best learned in the workplace. While the workplace presents an authentic context, it does not offer the same opportunities for focused learning as design school. Moreover, one of the reasons for learning soft skills is to make one more competitive in finding employment. Students should have a sense of how these skills translate into practice before they enter the market.

How can schools teach digital soft skills? Merely lecturing to students about them is not an effective strategy. While lectures can be helpful for delivering information or persuading an audience, changing and developing habits requires more engagement. The method of training varies depending upon the attribute and the audience, however, generally-speaking, habits of learning can be developed through a process of investment and practice.

Supporting a new habit which a student does not create themselves requires helping them understand its meaningfulness. It can be easy to dismiss soft skills out of hand because they might seem to be obvious or less interesting than learning technical skills. For this reason, it is important for the instructor to communicate why new strategies and habits are helpful. (McCombs, 1996) Investment begins by identifying the soft skills in question and explaining to students the value of the skills within design and production workflows. To be most effective, those values should be immediate and goal-oriented. Although it is true that developing soft skills can help a student get a job in the future, explaining to a student (for example) how organizing their files saves them time and reduces errors on their current project is less abstract and applies to their current situation. Helping students understand the usefulness of learning soft skills is the first step toward effective habituation.

In many architecture schools, there is a cultural separation between studio courses and technical courses. Students tend to think of studio as their most important course, because it is where they practice design and spend most of their time. For this reason, it is where most of their learning habits develop. This affects how they learn and integrate skills from their other courses. Introducing soft skills can help bridge the gap between studio learning and technology learning by explicitly connecting them through habits.

To be most effective, teaching soft skills should be integrated with hard skills teaching and preferably in the context of projects. (White and Frederickson, 1998) It is not necessary to revamp an entire course around soft skills. An instructor can introduce and reinforce them where they naturally occur within design and production processes. For example, using an error that students commonly encounter to introduce search, problem-solving, and communications skills. Relevant material like this helps focus student attention while a legitimate context helps them retain and access what they have learned later.

Demonstrations can be more effective when they are supported by teaching materials that help organize knowledge for students. (Bransford, Brown, and Cocking, 1999) A simple check-list, for example, can help students remember how to organize a digital group project. Once students have mastered the soft skills involved, the student will not need the scaffolding provided by the list. However, if the student makes a mistake or needs to refresh their learning later, the list provides a useful reference and a prompt for activating digital soft skills. Externalizing implicit practices and helping students focus on relevant information and methods improves the effectiveness of soft skills teaching.

Delivering soft skills in class benefits from a coaching approach. Because the goal is to change student attitudes over time, rather than delivering in formation or procedures, a "one and done" demonstration is not an appropriate teaching style. (Mistrell, 1989) (Bransford and Stein, 1984) With coaching, the instructor discusses the advantages of a skill (creating investment), then models the behavior while explaining to the student what they are doing and why. This last step is important because students need to understand when to apply a skill as much as they need to know the technical operations involved. (Scardamalia, Bereiter, and Steinbach,1984) (Simon, 1978)

Next, students demonstrate the skill and receive feedback from the instructor on their performance. This is followed by more practice and feedback over time and in concert with other skills to approximate holistic design activities. The goal of coaching is to cultivate not just practice but deliberate practice over time – making the student aware of their own actions and motivating retention and refinement. (Ericsson, Krampe, and Clemens,1993). This creates deep and lasting learning.

Adopting a coaching style of instruction requires a change in how students are graded and given other

feedback. Most assessment in studios and seminars is summative, meaning it measures the final outcome of a students' work. This is suboptimal for shaping behaviors, as it does not measure the process sufficiently and is often too late to influence a student's soft skills. Formative assessment techniques, which encourage personal reflection, timely feedback, and student response are useful support for the "coaching". (Vye et al., 1998) To supplement these techniques, instructors should not only observe student behaviors but review digital files, as well. Many courses emphasize the final artifact and never look at the files involved. Reviewing files is critical so the instructor can observe attributes such as organization, efficiency, and other procedural nuances.

Lastly, in order to properly cultivate habits, soft skills should be reinforced in the studio and lab even when they are not being formally taught. Instructors should be mindful and consistent in their own habits, demonstrating modeled behaviors in their personal actions. For example, an instructor's demonstration files should be well-organized to set a good example for the students. Student interactions should also emphasize consistent behavior. If a student asks for help with a tool, for instance, the instructor should evaluate how the student asks questions and replay the scenario with them while making explicit the strategies involved. Learning should be embedded in the classroom experience. It must be a continuous practice, not merely an exercise.

3 DISCUSSION

The challenge of making claims about design pedagogy interventions is proving their success. In educational research the difficulties of empirical measurement in traditional subjects like math and reading are well-known (Black and Wiliam, 1998; Shepard, 2000) but the challenges of demonstrating the impact of an intervention upon design outcomes – which are not easily measured or quantified – make this task even more burdensome and its conclusions unreliable. As such, there is no accepted model for proving the effectiveness of design pedagogy. At the same time, articulating these soft skills and naming them allows a conversation to begin as to why there is such inconsistency in digital education across architectural curricula. Digital methodologies have roosted and flourished in elite institutions whereas other schools have been slow to change (particularly in the area of early design education) and to integrate digital and computational thinking.

What is more important and perhaps easier to 'prove' is that well-articulated digital soft skills create a framework and a platform where technology can be used expansively and in unique ways rather than reductively and repetitively. The value of digital soft skills is to suggest a replicable model which remains relevant and useful for students as technology changes, improves, and adapts.

4 CONCLUSION

While digital design skills are critical for 21st century architects, architectural education must also recognize and deliver more than technical proficiency. Working creatively and effectively with computers, digital fabrication machines, and other devices requires a new set of workflows and adaptations to professional behaviors. Boyer's report makes it clear that one of the key values of an architectural education is developing learning habits. A present gap in student learning is that traditional learning habits have not been updated in response to changes in technology. (Boyer, 1996) Digital soft skills can help to bridge this gap.

Soft skills can and should be taught in architectural education. Soft skills support the goal of not only working well with technology, but together with other people in technologically-supported ways. They help support students who may not have had access to technology or formal training prior to college. Knowledge, abilities, attitudes, and habits not only shape one's process, but one's design goals and outcomes, as well. Soft-skills impact design and so they extend beyond pedagogical or semantic arguments. They should be of interest to anyone who values good design.

Architectural synergies: Participatory design and construction of a pavilion prototype

A. Michael, O. Kontovourkis & M.C. Phocas
Department of Architecture, University of Cyprus, Nicosia, Cyprus

ABSTRACT: An integrated approach to design and construction may be achieved through architectural workshops of specific educational context and aims that may serve as complementary modules within the architectural curriculum. The pavilion prototype presented herein was realized in a six-week design and construction phase. The primary structure consists of non-symmetrical frames, arranged in parallel and in sequential rotation. The frames rotation defines the building morphology of the pavilion and, at the same time, shapes the interior. The objectives of the research program in question involve the investigation of terms and conditions for the development and implementation of an architectural idea. In addition, the particular workshop aims at investigating and promoting the role of the structure and construction elements in the creation of the built form. An important outcome, in terms of the participatory design conducted, has been the actual cooperation of primary school pupils with architecture students.

1 INTRODUCTION

Contemporary architectural design and practice is characterized by an ever increasing complexity. The direct correlation between the architectural design and the potential of realization, construction methods and detailing with contemporary aesthetic expressions, highlights the integrated architectural design approach in contemporary architecture production (Michael & Phocas 2008). Integration may be achieved through architectural workshops of specific educational context and aims. At the same time, workshops may serve as complementary modules within the architectural curriculum at University level (Michael & Kontovourkis 2013; Michael & Phocas 2010; Michael et al, 2008).

Setting the involvement of students in the real process of conception and implementation of an architectural concept as a primary objective, a funded research program entitled 'Synergetic Multi-Objective Design and Construction of Timber Pavilion Prototypes', was initiated at the Department of Architecture of the University of Cyprus in the academic year of 2014–15. The program involves the design and implementation of a number of timber pavilions in open spaces of primary schools.

The current paper presents a case study of a pavilion prototype construction and further elaborates on its individual development aspects and especially the participatory design process.

An important outcome, in terms of participatory design, has been the actual cooperation of primary school pupils with architecture students.

The pavilion case example, presented in this paper, was realized in a design and construction phase during the summer semester 2015, in six weeks. The primary structure consists of non-symmetrical frames, arranged in parallel, in sequential rotation. The frame rotation defines the building morphology of the pavilion and, at the same time, shapes the interior. Seven different types of frames are used, based on the rotational position of their non-rigid joints. In all cases, the frames maintain the same geometrical characteristics.

An essential principle of the design is the standardization of the structural members and the steel connection elements. The specific pavilion was designed to be used by the primary school pupils, both for educational, and leisure activities. The interior space is organized in two main levels; those containing inclined surfaces and a corridor, ensuring, in this way, the exploitation of the structure as a small open air theatre for educational activities. The design of the structure allows the possibility of exhibiting artworks, or other kinds of educational activities. It also provides possibilities of spontaneous activities, i.e. games, theatrical events, debates and others.

2 CONCEPT DEVELOPMENT THROUGH PARTICIPATORY DESIGN

The research project under the title 'Synergetic Multi-Objective Design and Construction of Timber Pavilion Prototypes' addresses the implementation of a creative course that is initiated by children themselves as quest for spatial experience through the concept of developing an installation in the school courtyard. The initial driving mode for the conception was the children's creative imagination, originality of thought, combined with imaginative and at the same time, innovative

Figure 1. Concept development through participatory design.

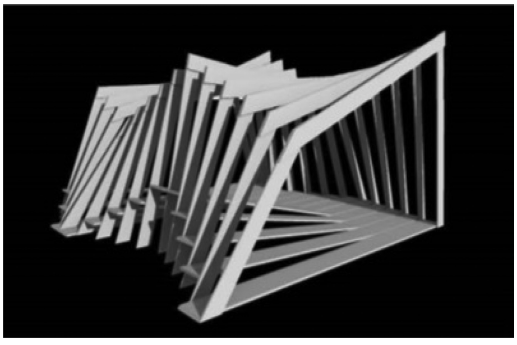

Figure 2. Photorealistic views of the preliminary design concept.

ideas. The result of the reflection was an original idea provided by pupils of the Kornesios Primary School, which referred to an installation in the outdoor space of the school. During this activity, the pupils worked with their teachers and external artists to develop ideas for their proposals. After putting the ideas and thoughts down on paper, the students of the Department of Architecture of the University of Cyprus were asked to shape and further develop the proposals into a real architectural product (Fig. 1). This came about after a parallel processing of functional requirements, architectural form and technological dimensions of the initial proposal.

In the initial phase of the preliminary study, the design was developed through sketches, drawings and three-dimensional models, both in real and digital environments. Specifically, during the academic year 2014–15, within the frame of the undergraduate courses on Timber Construction and Digital Media in Architecture, a series of parallel design proposals emerged. Through a series of participatory design workshops and creative dialogue between primary school pupils and University students, the proposals received further feedback. The process of designing and developing the proposals enhanced the architectural and structural dimension, as well as aspects of geometry, colour and texture.

Six respective architectural proposals were presented to the entire school community. In a special event, which was held in the presence of the Parents Association, the appropriate School Board and the Technical Services of the Cyprus Ministry of Education and Culture, the end users selected and approved a design proposal for further development and implementation.

The procedure for realisation of the pavilion followed by the University of Cyprus team was developed in two phases. The first phase lasted from the 15th until the 20th of June 2015, during which issues concerning the exact location within the open space of the elementary school, and the architectural expression in an integrative content of form, structure and construction, were thoroughly explored. Following the detailing of the structure, all the necessary construction approvals were acquired. The second phase lasted from the 6th until the 24th of July 2015, and involved the actual erection of the structure. The construction was built by a number of students of the Department of Architecture under the scientific supervision of the authors.

3 INTEGRATED ARCHITECTURAL DESIGN

The design and development of the pavilion prototype was based on an integrated architectural design process. The specific integrated design approach proposed enhances the role of the structure and construction elements in the architectural process influencing, at the same time, the aesthetic, technological and other criteria. More specifically, the design and construction process focused on the pavilion creation using timber as primary material, the design of the load-bearing and non load-bearing elements, as well as the design of the construction members and details. The ultimate goal was to highlight the role of the building construction in the architectural composition throughout the process of concept, development and realisation. In addition, the conceptual aspects of the design were explored, the forms, investigated through physical and digital design tools and environmental and construction aspects, were analysed with simulation programs (Fig. 2).

3.1 *Pavilion prototype design concept*

The design concept of the pavilion prototype is based on the development of a timber structure with variable configuration. The overall building morphology is achieved through successive rotation of planar frames. The structure is characterized by high construction standardization. It consists of a number of successive frames placed at fixed distances. The overall frames composition has the geometry of a hyperbolic paraboloid on the projected roof and side facades. On the inside, the space is divided into two main levels; namely, the inclined surfaces and the corridor. The space that is intended for viewer seats is divided in individual parts, with small altitudinal differences that result from the dynamic geometry of the construction.

The overall dimensions of the structure frames are $4.10 \times 5.12 \times 6.30$ m (height $\times$ width $\times$ length) and

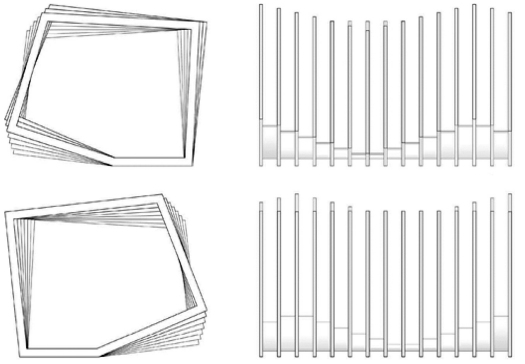

Figure 3. Elevations of pavilion prototype design concept.

the distance between the frames arranged in parallel is 0.45 m. The frames rest on a reinforced concrete slab of 30 cm depth and are strengthened by steel members at the base and at the connecting joints of the timber members. Each frame consists of two pairs of a number of members each, connected over moment resisting joints. The member pairs are interconnected at moment free joints and follow successive rotations, providing respective inclinations at the horizontal projection level. Each frame transforms and rotates at the corresponding joints by 2°. Due to the rotation of the joints, a single member in each frame obtains variable length, while all other members have the same dimensions. Overall, the structure consists of fifteen frames, whereas only seven different types of frames appear in the final rotation position of the joints (Fig. 3).

3.2 *Form investigation through parametric design*

At a further stage, the geometrical development and refinement of the form of the pavilion was realized and modelled in digital environment through parametric design logic and specifically through the use of the software Grasshopper (plug-in for Rhino). This enables the accurate calculation of the structural members of each frame, as well as their exact rotation according to predefined angles. Furthermore, this procedure allows the evaluation of the parametrically controlled morphology according to static and environmental criteria investigating, at the same time, alternative design solutions.

The morphology is achieved by defining fifteen structural frames in linear order, each of which controlled and rotated, based on four parametrically controlled arcs interconnected to formulate the five structural members of each frame. Important aspects that have been taken into consideration during the geometrical development stage included the standardization and fixation of the members according to their dimensions, as well as their length variability. The uniformly distributed difference in each angle of rotation has allowed, on the one hand, differentiation of the overall geometry of each frame and, on the other hand, mass-customization of each structural member, leading to the development of a

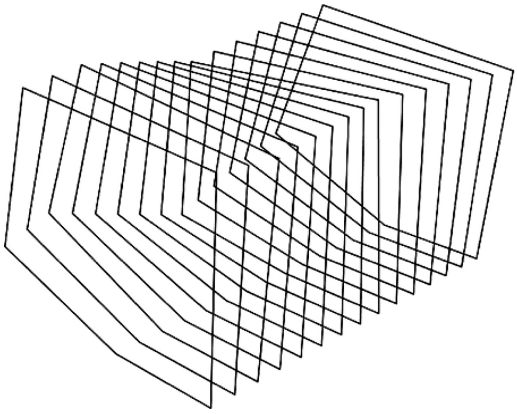

Figure 4. Axonometric parametric development of the proposed construction.

non-standard geometrical outcome. Figure 4 shows the three-dimensional arrangement of the overall system of frames, based on the uniformly distributed angle of rotation.

In addition, the parametric investigation has allowed the accurate realisation of the structure in actual scale, by extracting data related to the length of the structural members, as well as to the morphology of each joint. The design of joints was also standardized and simplified, in order to overcome possible obstacles during the construction stage, especially due to the non-standard nature of the final outcome. The application of CNC laser-cutting machine has allowed the accurate production of steel plates and position of bolts, initially using cardboard material, and then through the use of cut models during the construction and assembly stage.

The further exploration of the structural prototypes in question concerns more a system development rather than a materialized product. At the same time, the process of design and development followed offers opportunities for enriching the qualities of its specific components.

Consequently, its dimensions and shape could vary according to the performance criteria set in each case, based on parametric combinations that produce desired adaptations, required by particular functional or environmental conditions. Thus, a whole new range of possibilities and variations of the structure could emerge. Moreover, it is important to stress the multiple possibilities for architectural expression that the pavilion offers. The different potential variations of the structure may lead to a number of architectural design solutions. The different combinations might provide varying appearances, which may give the design product an added architectural value.

3.3 *Structural design*

The structure is founded on a reinforced concrete slab, 0.30 m thick, and consists of the self-supporting frames placed in parallel at a constant distance of

0.45 m. Each unit is supported on an anchoring base at two points. The timber members consist of two parallel sections, of dimensions of 35 × 195 mm, with an 8 mm gap in between. The connection of the timber members at the joints, as well as the cantilever members that extend to the inclined side of the structure, is achieved through steel plates of 8 × 190 mm. In the longitudinal direction of the structure, the frames are interconnected through steel members to form a secondary frame system, in order to increase the horizontal stiffness of the system. Moreover, the diaphragm created on the horizontal and inclined level of the structure allows the transfer of horizontal dynamic loads to the vertical load resisting elements of the structure within acceptable deformation range.

The permanent and variable loading actions taken into account in the design of the structure include a permanent vertical load of 0.10 kN/m^2, a temporary load of 4.00 kN/m^2 and an exhibits static load of 6.00 kN. The analysis considered safety factors as related to permanent loads, of 1.35, temporary loads, 1.50, structural timber, steel and concrete 1.30, 1.50 and 1.50 respectively. Timber strength grade of C24 applies to all timber members according to EN 338, S275 to the steel members, and C30/37 to the foundation slab. The load combinations for the permanent and temporary static, and dynamic actions (seismic loads) were derived according to EN 1990 and EN 1998-1 respectively. The maximum vertical deformation of the structure amounts to 1.1 cm at the ultimate limit state of the system and the corresponding horizontal one, 3 cm, in the longitudinal direction (Fig. 5).

3.4 *Construction and environmental design of the pavilion*

The materiality of the design proposal, as well as the construction design and process, form a significant part of an architect's education. The selection of the appropriate building materials, and the application of contemporary manufacturing technologies, directly affects the architectural expression of the product. The use of wood, as main structural material, ensures the minimization of the ecological footprint of the pavilion (low emission CO_2, low embodied energy) (Anink et al. 1996).

The aim of the construction and detailing design process is to standardize the timber frame members, as well as the steel components, in order to facilitate the construction process. All timber members have the same respective lengths in all frame types, with the exception of a single member with variable length. The fixed lengths of the members are 3.75, 3.45, 2.95 and 1.85 m while the 'transforming' member varies in the seven different frames between 2.55 and 2.85 m. The secondary steel frames, placed for the creation of the diaphragm, have standard dimensions of 1.12 × 0.37 m and 1.65 × 0.37 m. Steel connections of 0.37 × 0.95 m, 0.37 × 1.70 m and 1.80 × 0.37 m are positioned on the longitudinal sides of the structure (Fig. 6).

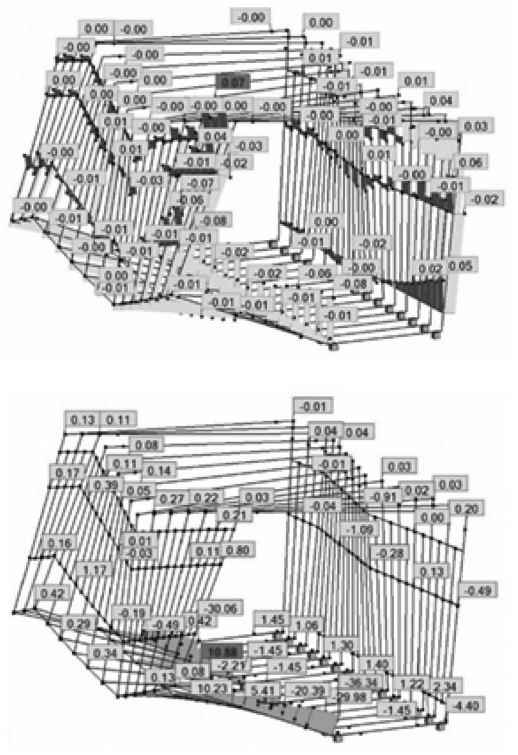

Figure 5. Diagrams of bending moments under vertical loading and horizontal loading.

The high degree of standardization and prefabrication of the construction units ensured the reduction of the individual frames realisation time, and consequently the required total construction time, as well as the embodied energy of the entire project (Anink et al. 1996). Moreover, the reduction of environmental damage involves the use of appropriate building techniques (drywall techniques, assembled constructions) (Fig. 7).

The assembled technique allows the re-use of all construction materials, which ensures recycling without downgrading their initial quality (Berge et al. 2003). The application of contemporary construction methods gives added value to the final construction product and increases the contribution of the construction design to the improvement of the structure's image (Baerlecken et al. 2012) (Fig. 8).

Finally, within the frame of investigating the environmental implications of the pavilion, shading and insolation issues of the construction were investigated. Specifically, a shading study of the pavilion and the impact of the built environment for the hours between 08:00, 10:00 and 12:00 for the periods of December 21 (Winter Solstice), March 21 (Spring Equinox), 21 June (Spring Solstice) and 21 September (Autumnal Equinox) were examined.

The shading study was performed using Autodesk Ecotect Analysis software. The analysis showed that during the winter period, the wider area of the

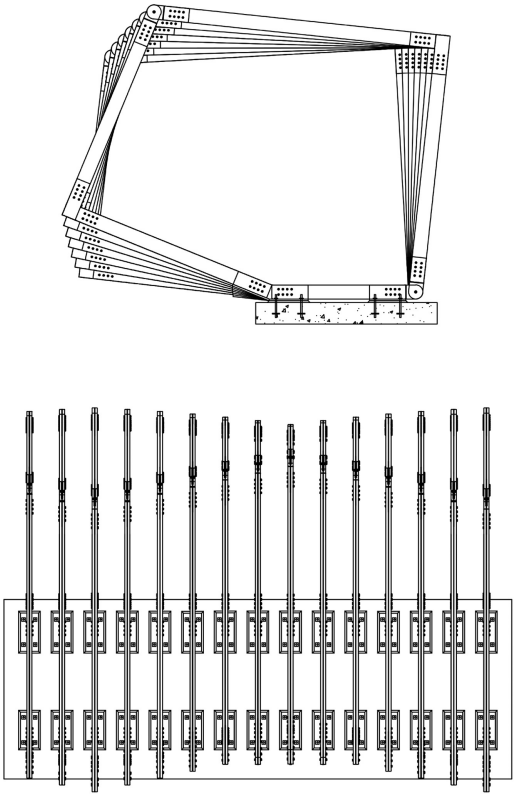

Figure 6. Construction drawings of pavilion prototype.

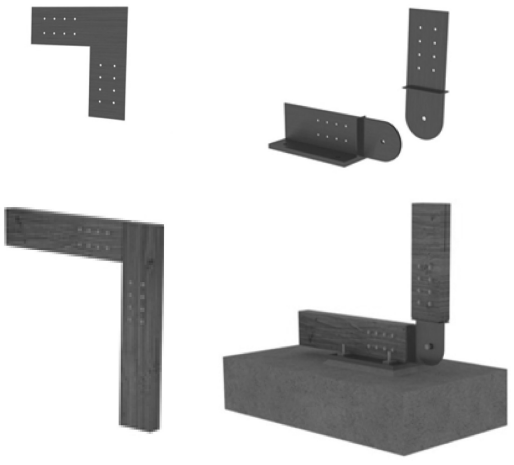

Figure 7. High degree of standardization and assembled construction techniques.

school courtyard is mostly shaded during school hours and the pavilion can be used during all working hours of the school, since solar insolation is desirable. During the interim periods, as well as during the summer, adequate shading is ensured until 10:00 in the morning (Fig. 9).

Figure 8. Parallel timber frames of pavilion prototype.

4 REALISATION STAGE

The realisation stage is considered an important outdoor activity that differs substantially from the typical design development process, which takes place in design studios or other design courses. Hence, the specific construction workshop aims to strengthen the students' experimentation and experience with regards to construction techniques (Figs 10, 11). In a pedagogical framework, students are introduced to the workflow, moving from the conceptual design and digital development of ideas to the actual materialization scale, forming an overall framework of construction development (Fig. 12).

In order to ensure adequate timber quality, a qualitative selection was carried out, taking into account parameters such as geometry, dimensions and material quality. The timber was then cut to predetermined lengths and planed by the timber supplier. The architecture students who participated in the workshop undertook the task of classifying, levelling properly and impregnating the timber with water-soluble varnish, with antifungal and insecticidal properties, suitable for outdoor use. The steel members were delivered, coated with a layer of primer, and were then run with two coats of paint.

While this work was conducted by the students, the reinforced concrete foundation and the anchoring steel plates for the structural supports were placed by an experienced workers crew. Preceding this, the existing reinforced concrete slab was demolished as it was deemed inappropriate to found the new structure. The removal of the frames steel base at the foundation was conducted by the steel construction crew that had

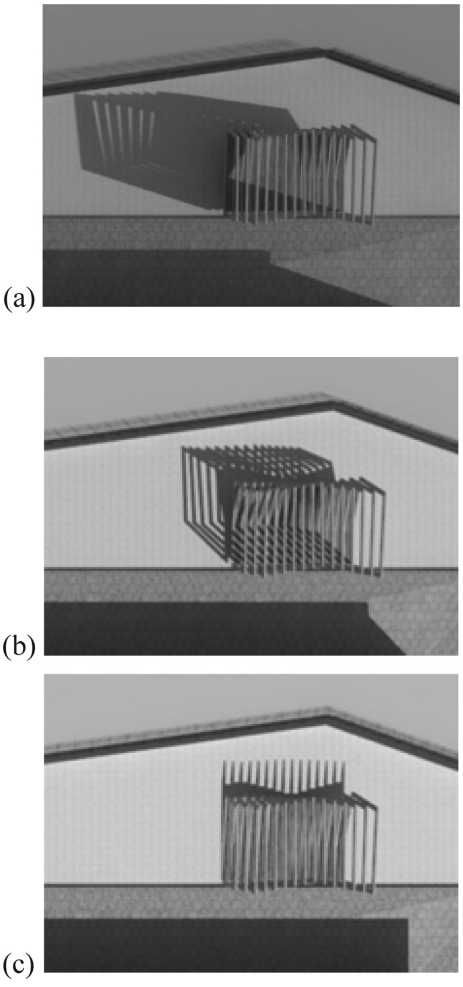

Figure 9. Shading rate for the immediate period i.e. March 21st at (a) 8:00 a.m., (b) 10:00 a.m. and (c) 12:00 m.m.

Figure 10. Construction process.

supplied the steel members of the structure. The connection of the timber members to the steel plates was performed by students using boltings.

Additional effort was made to ensure the best technical quality in the connections. To mitigate possible

Figure 11. Construction process and assembly.

Figure 12. Construction development.

negative effects on bolting positions, rings were used in the screw and nut positions.

4.1 *Usage*

The installation in the outdoor area of the school attempts to answer the initial question on conceptual level; that of investigating concepts of exposing and being exposed; notions which triggered the design development and realisation of the structure. The main functional use of the pavilion refers to the creation of an exhibition space that can accommodate thoughts, ideas and feelings of the pupils. Panels with drawings can be placed on the art posting system located on both sides, or at the deck of the construction. An artwork designed by the school students, which occupied the entire face of the structure, was the first artistic creation. It presents the children's perspective around issues concerning the student community and the school space. The placement of a fabric ribbon on the timber elements of the structure was a spontaneous artistic intervention by the pupils. The ribbon was placed on the first day, pupils returned to school after the summer holidays, and it was inscribed with wishes and goals for the new school year (Fig. 13).

Apart from exhibiting artworks, the geometry of the structure allows the organization of artistic events therein. The pavilion can be used for theatrical performances, children's book presentations and musical events. In addition, the structure can be used as an outdoor teaching area during sunny mornings in autumn

Figure 13. Artworks exhibitions and artistic intervention by the pupils.

and spring. The slopping part of the structure can accommodate pupils of one or two classes, thus providing an alternative teaching space and learning experience (Figs 14a, b). Moreover, beyond any artistic or teaching activity, the structure is intended for spontaneous and creative activities by the children. The structure could become, in the untamed imagination of children, another opportunity for creative play during recess.

The implementation of the architectural concept has been validated in several aspects: the pavilion has influenced reuse of the schoolyard area through intense flows of activities around and within the pavilion; the permeability boundaries of the pavilion enhance, or support, mixed activities to take place by the pupils at the interface of leisure and learning conditions (learning by playing); the different levels of the pavilion, with the varying inclination, support the development of diverse activities, experiences and visual connections by the pupils.

5 EDUCATIONAL OUTCOMES

The objective of the research program in question is to investigate the initiation, design and construction realisation of an architectural concept and to promote the role of integrated architectural design in the creation of the built form. Such workshops offer the participants the opportunity of learning the properties of the materials and the specific requirements of the construction techniques, as well as the basic structural design principles. Through the development of the designs and the implementation process, construction and manufacture are experienced in real terms, while these individual thematic sections are interdependent with no clear boundaries and with substantial overlaps between them (Michael, et al, 2007).

Finally, an important outcome in terms of participatory design has been the actual cooperation of primary school pupils with architecture students. At the same time, the Pavilion is the result of a shared vision and effort of primary school pupils and students

Figure 14. a,b Theatrical performances, children's book presentations and musical events at the pavilion.

of architecture. Through a collaborative process of designing, the initial thoughts and ideas of the pupils were first articulated at the design level and finally as a real architectural product through the process of the workshop. The end product forms a reference point of the school and a symbol of cooperation and optimism for a better future achieved through a collaborative process. This could have further implications on the way actual buildings, in larger scale, are designed and especially educational and public premises.

6 CONCLUSIONS

The present paper examines the introduction of construction workshops in architectural education at University level, with regards to the building component and its interrelation with the architectural design. Following the process of design, development and realization, which form parameters equally important and undoubtedly interactive and interdependent, the structure aims at bringing together and inter-connecting the space with the users. Through its materiality, the structure creates spatial conditions that allow the transformation of experiences, interacting with the natural and built-up environment, as well as with the final users. The development of the structural prototype, presented as case example in this paper, addresses the

stages of conceptual design, construction, and realization. In relevant courses of technology, the objectives should also aim at the integration and practice of basic principles of architectural design, development and realization. Furthermore, the integration of a series of thematic axes, such as construction, materiality and standardization, parametric experimentation, structural analysis and environmental awareness, in a conceptual and construction design process, within an architectural education framework, aims to develop a comprehensive approach of built-up spaces. To achieve this and capitalize on the educational benefits, the authors propose that, in addition to studio-based courses, such practical outdoor activities are taken up on a regular basis, as complementary methods to the design research conducted in studios.

ACKNOWLEDGMENTS

Many thanks are due to those who funded the research program entitled 'Synergetic Multi-Objective Design and Construction of Timber Pavilion Prototypes', to the Charalambides Christis Company and to the University of Cyprus.

We give thanks to the Technical Services of the Ministry of Education and Culture, the School Board, the Association of Parents and the Management of the Kornesios Primary School for their contribution to the project.

The authors express their special thanks to Chryso Heracleous, Panagiota Konatzii, Ioanna Dimitriou, Ph.D. students and researchers; and to the post-doctoral researcher Rogiros Illambas, consulting civil engineer for their contribution to the scientific supervision of the program. Finally, warm thanks are due to the architecture students who participated in the design and implementation work of the structure and to the primary school pupils for their valuable contribution and enthusiasm shown during our creative cooperation.

FAjúnior – Architectural games

M. Louro, F. Oliveira & M. Baptista-Bastos
CIAUD Faculdade de Arquitectura, Universidade de Lisboa, Lisboa, Portugal

ABSTRACT: The research project "FAJúnior" is a pedagogical project, based on two distinct components: a scientific and experimental view, which includes different teachers and researchers of the Faculty of Architecture of the University of Lisbon. It is the first and unique project of this kind, which is being developed at a Portuguese university. The project seeks to interact with children and young people of different ages, natures and realities. The purpose is to bring the thematic of architecture, urbanism and design to the younger layers of formation, which still unaware the academic world, towards an early awakening of a consciousness centered in the valences and interests of the educational universe of the Faculty. These values present multiple scientific and cultural approaches, where the teaching of practical and artistic heritage, aesthetic and ethical trials promote sensitivity in understanding the faculty and its various public and private dimensions.

1 INTRODUCTION

The work presented here derives from a research project (Fig. 1) in course at the Faculty of Architecture of the University of Lisbon, since 2014. The project is being developed within the Research Center of Architecture, Urbanism and Design of the Faculty of Architecture of the University of Lisbon in close relation with FAjúnior, the recent office created as promoter of the activities planned with the outsider communities.

(website: fajunior.fa.ulisboa.pt).

The presented approach makes part of a vast and complex theme of the awareness of architectural, urban planning and design issues, as an effective teaching strategy in youth training and in the awakening of intellectual sensitivities and creative predispositions that may or may not have subsequent academic developments. It is actually the thinking of "teaching" these themes in pre-university contexts of young age as stimuli-sensitive on the critical and creative reading of the surrounding environment. From the environmental study of the built structures, in close and familiar surroundings, students realize that they can intervene significantly, changing and improving these spaces. Effectively from an embryonic awareness that all it involves is drawn: the objects we use, the houses we live in, the books we read, the streets we walk on, until the cities where we live, all leads to an operative awareness in order to empower the children and the youth to greater fitness and critical intervention.

These logics carried out in various parts of the world, have usually as the underlying the playful dimension and are inserted on cultural programs extended to the family. These various examples are evidenced by the following references that illustrate various logics and assumptions: the thematic programs of the Bauhaus-Archiv in cooperation with the Jugend im Museum (JIM) in Berlin; the Archikidz programs organized in various parts of the world and finally the mediatic events of the Barbie Architect.

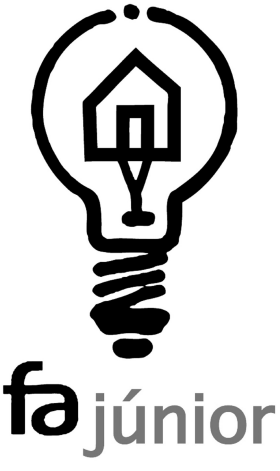

Figure 1. FAjúnior logo.

The thematic programs of the Bauhaus-Archiv in cooperation with the Jugend im Museum (JIM) in Berlin, advocate the ancestral logic, related to pedagogy and teaching of architecture. Perhaps with a most particular and selective character have the aim of stimulating creativity through various multiple expeditions in various museums of Berlin, enhanced with artistic work in workshops. In the background a stimulus to productivity, where children and young people can paint, draw, make pottery works, wood, photography, fashion, etc … A pedagogy that inserted in a basilar education, as is effectively the heritage of Bauhaus reinvents this proximity to children and youth paving the way for an intrinsically architectural

cultural education. These programs have effectively expression in several countries including Portugal, and are carried out in different museum spaces with diverse and comprehensive themes like nature, technology, science and art …

A second example are the Archikidz programs, that support a broader and cooperative attitude of this civic consciousness through concerted actions in several countries that lead the problems of architecture, urbanism and design to the young generation. From the motto: Inspiring Tomorrow's Thinkers and City-Makers, the Archikidz is a not for profit organization, providing a dynamic platform for inspiring and educating kids, probably future city-makers to create better communities and a more sustainable future. Archikidz Began in Amsterdam, in 1998 with an architectural workshop for kids. Events are now held annually in Amsterdam, Rotterdam, Bergen, Barcelona, Buenos Aries, Lisbon and Santiago. These events present a strong social mission that seeks to bring the themes of architecture to an event scale with a very performative character in the cities where they occur.

The third example focuses on the imagery of the global trend of the children, from the emblematic character of the Barbie Architect. The Barbie doll, created in 1959 in the US by Mattel won a new cast in 2011 when it launched the Barbie Architect. This Barbie, of the Barbie collection, I Can Be, called for the imaginary of the architecture through the personification of thisjob, its status and social function. This doll launched through a partnership with the American Institute of Architects, promoted also associated workshops. These were primarily intended to disseminate knowledge of the profession job and the fundamental role of the architect in the built environment, focusing on historical background aspects of the role of women architects over time. Guided between a more informative and ludic contenta and a more playful, the event was implemented freely in schools, educational centers, institutions, etc … and promoted since then a spatial approach asking the participating children to draw sketches of the Architect Barbie's Dream House. A concerted action that expressed, without doubt, the media coverage of these issues and how they can be disclosed and approximate the child's imagination.

These three examples focus, in different areas, scales and purposes, a common concern to bring awareness of the surroundings and its formalization to the younger generation through playful concerted, interactive and innovative actions. "The game of truth and error, is not played on empirical verification and logical coherence of theories. It also plays deep into the invisible area of paradigms". (Morin 1999).

2 SPECIFIC ACTIONS ACTIVITIES

It was effectively in this context that this innovative research project has been developed, both in the University, as at the national context, which seeks to understand the potential of this educational interaction

Figure 2. Open Day event.

with the youth, by promoting several specific actions in complementary themes. The dissemination of these activities are based on: Open Days and monitoring visits to the institution/college; coordination of summer programs; and organization of various recreational events, to which underlies a research content applied on the various actions undertaken.

The Open Days (Fig. 2) and the college visits are organized by the college or requested by secondary educational institutions. They are generally intended for a public that already have an interest or willingness to eventually attend college. They are effectively a pre-university public seeking contact with the college in order to understand the education courses of the institution and to establish criteria for a future selection. These visits beyond the presentation in the format of lecture about the contents taught and entry criteria are complemented with visits to areas where potential future students take contact with workplaces, classrooms, workshops and recreational areas. These approaches beyond to open the college to abroad, enhances livings within the academic environment where young people "experiment" classroom ambiences, contexts of examinations and academic gatherings.

The summer programs (Fig. 3), take place during the school holidays period, usually in the first two weeks of July and are organized by the University of Lisbon that through its 18 schools promotes outreach activities of its various areas of training to young people aged between 13 and 18 years. These activities are workshops, divided in two weeks, a first aimed to older students (secondary school – 10th, 11th and 12th grade) and a second for younger students (basic school – 7th, 8th and 9th grade). The workshops organized during these two weeks are distributed by three research areas: Architecture, Urban Planning and Design, and atr coordinated by professors and researchers from the School of Architecture,

Figure 3. Summer programs.

Figure 4. European Researchers' Night.

which provide practical experiences to the students. In a playful way, these students are faced with specific situations covering the various areas of the surrounding context (since the hand scale object to the scale of the city), as well as various fields of knowledge, addressing conceptually and by an embryonic form themes of history of architecture and urbanism, theory, design and representation. "It is therefore necessary to do well: start by judge. This is mainly a case of personal experience, it is through experience that all young people should learn, challenge the passions and provide them with these rules of conduct." (Bosch 2001).

The participation in events, target public, children, youth and their families (Fig. 4), are activities aimed at a broader public, where by an affordable way, fun and educational some researches on the built environment are promoted. In this regard we highlight

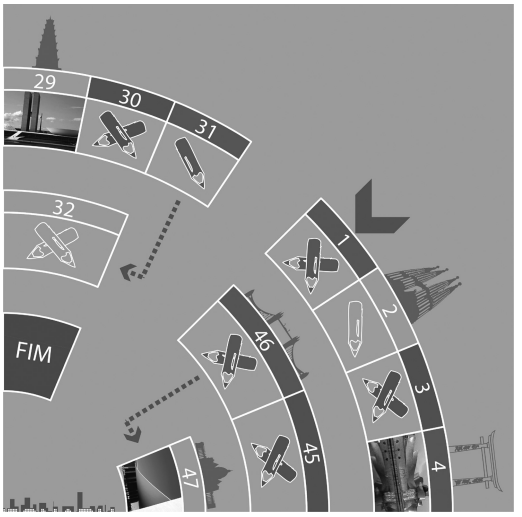

Figure 5. Architionary game.

the participation in events linked to the European Researchers' Night, which linked to the very general theme of the event that is to connect research and civil society, to promote activities where the themes of architecture, urbanism and design, "enter" so direct into the imagination of the participants. Other investments bind with humanitarian actions of solidarity with related events to support social causes such as disasters in cities, destruction of buildings or support to refugees.

3 APLLIED RESEARCH

Framed in this panorama of activity it has been developed an applied research tonseveral architecture games that are released, promoted and experienced in these various actions. Three methodological experiences can be highlighted: the Architionary game, the three-dimensional constructions ArquiBe and the thematic competitions for ideas.

Architionary (Fig. 5) is a game applied in the workshop of the same name integrated in the summer courses offered by the Faculty of Architecture to students of primary and secondary level of education. The theme of the game is inspired in the classic game Pictionary, where the players are conducted on guessing concepts through drawings. In this sense beyond the stimulus to the representation by design it is also promoted the contact with conceptual contents related with the themes of architecture, urbanism and design in all aspects, historical, theory, construction, etc … Organized by three levels of difficulty, easy, medium and difficult the concepts explore various thematic approaches, always accompanied by definitions transcribed of dictionaries or technical vocabularies architecture. Complementing this conceptual approach there are still references to architectural pieces that illustrate "houses" of the game

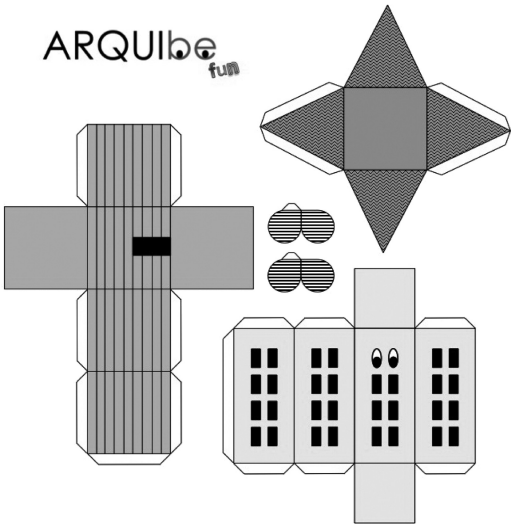

Figure 6. ArquiBe activity.

board that animate the challenge leading players to guess the author, location, or building name to reach closer to the target house.

ArquiBe (Fig. 6), is a playful experience to children and their families, where from sheets of paper printed with volumetric flat patterns organized int three types: base, body and top, the children are taken to cut, paste and assemble the three objects creating an architectural "being". An ArquiBe, which is basically a model, and a puppet that derives from the combination of three modules, which have different configurations, colors and textures and thus the ability to generate multiple appropriations and formalizations. Being an activity mainly developed with children, the objects produced are generally purchased by the authors, a kind of trophy and reward of the task performed by themselves. These objects/models, in addition to the plastic indentation practice, assembly, glue, raise a critical insight into the strategy of choosing shapes and patterns that will result in the final object. It is a sort of critical essay and value judgment, embryonic in the design process and on the way to read, think and conceive the surrounding space.

Finally the contests of ideas, establish themselves as challenges proposed to school communities, involving students at all levels, from pre-school to pre-university. These challenges are related to critical and creative conception of themes related with architecture, urbanism and design. In this sense it was framed the first contest launched by FAJúnior in November 2015: the contest of ideas – The House of the Future. (Fig. 7). This approach addressed students of the 1st, 2nd and 3rd cycle, had as main aim to take students from their creative imaginary to draw a house for the twenty-second century. It was proposed the exploration of various two-dimensional techniques such as drawing, painting, collage, etc … However, the drawing pencil and the pen havebeen the most used technique.

Figure 7. The house of the future competition.

From this experience there was the participation of 129 students from eight schools in different regions of the country. From a very broad and creative approach that explored various plastic, constructive and environment questions for setting up a home for the twenty-second century. In this sense it was achieved the main objective of the action that was to take the theme of the architecture to different school environments, where from the pretext of the House of the Future, several spatial experiences and ideas were developed.

4 FINAL CONSIDERATIONS

In terms of final considerations it is sets out a summary on the three approaches referenced (experiences of the Bauhaus, Archikidz and Barbie); initiatives undertaken by FAJúnior office (open and visiting days, summer schools, thematic events) and the research field formalized in three "architecture of games": the Architionary, the ArquiBe and the House of the Future. In this regard and in accordance with nature, the target public, the methodologies and the objectives achieved are defined as follows considerations.

About nature, the various references determine various perspectives nuanced by one hand by the educational and cultural approaches carried out by the initiatives of the Bauhaus, the summer courses and especially by the playful approach developed by the Archtionary game. By the social approaches taken in Archikidz events, in the themed events carried out by FAJúnior and especially by the event The House of the Future and the broad extension of this initiative to all schools in the country covering the school community and their families. Finally a perspective more commercial and in some way sectorial, evidenced in the events associated with the Barbie architect, the summer courses developed at the Faculty of Architecture and in some way in the patenting logic provided in the Archtionary experience, and in the future intention to take this experience as an educational and commercial product.

On the target audiences are also differentiated diverse perspectives in the three fields statements: references, activities and research. The specialized public and in some way directed to the subjects, for the teaching and the learning issues, related with architecture, urbanism and design stands out in the leisure experiences of museums, but especially in the summer courses developed in the faculty of architecture and in some way established for future students of architecture. A more academic approach stands out in approaches triggered by contests of ideas developed by various school groups, many of them in the classroom environment and guided by their teachers' holders. Finally, the initiatives aimed to families, are naturally extended to broader audiences including children, young people and adults. In this perspective, the themed events are specially highlighted, and by association the logics of the activity ArquiBe. Due to different levels of difficulty on the integrated execution, there is a different adult and child participation in the implementation of the various associated tasks.

On the methodologies applied stand out in this logic varied interactions between individual/group; school/family; community/faculty. This diversification at various scales, highlight the extension of the different actions and their complementary nature.

Finally and framing the final disposition of raids fall into the different objectives achieved, based on taking the theme of architecture, urbanism and design to the younger layers of society, their children and families through differentiated and specific actions, ludic dimensions, educational, and also scientific. Actions that beginning from different principles, such as, solidarity, industry and trade, converge in the joint action for the dissemination strategy as a game, an architectural game as playful way, directly, accessible to propose a research on the surrounding built environment and above all, on its assessment criticizes and its qualitative evaluation.

Community-driven design aspects of architecture education in Hungary

S. Portschy
Department of Design, Budapest University of Technology and Economics, Budapest, Hungary
Marcel Breuer Doctoral School, University of Pécs, Pécs, Hungary

ABSTRACT: While community design has enjoyed a more than 50 years long tradition in the Western world, in the post-communist countries of Eastern Europe, the notion of participatory architecture had not taken root until the early 2000's. Since then however, a great number of design practitioners have embraced the idea of a more democratic approach to their profession, and as a result, community design has slowly been finding its path to the mainstream. Architecture education was anticipated to reflect on the trends in a timely fashion, in case of a special program of the Budapest University of Technology and Economics, it even played a catalyst role in the process. This paper intends to recapitulate the various strategies, forms and structures of university-community design partnerships, to examine the particularities of community involvement in the Hungarian social, economic, political and academic milieu and to deduce conclusions through the experiences of a series of university-based community design workshop projects.

1 COMMUNITY DESIGN – OVERVIEW

The idea of community participation in architecture design dates back to the democratic renewal movements of the Western world in the early 1960's. Emerging social consciousness and a crisis of confidence in professional competence revealed the inequity in decision-making on several areas of the public sector (Comerio 1984, Pearson 2002). These symptoms were equivalently existent in the building industry. Government managed affordable housing programs and urban renewal projects that failed due to the lack of social sensitivity, exposed the need of a different approach (Turner 1977). Based on models of self-help community initiatives in the developing countries, where professionals joined the people to improve their environment, architects became the promoters of new, more equitable ways to address numerous issues of concern emerging in the changed socio-cultural environment. Community design was born.

Community design is based on the active involvement of stakeholders, a wide range of affected citizens, in the planning process of the shaping of their built environment. In the second half of the 1960s, a host of new federal and municipal programs focused on underserved urban population, and committed design professionals, who took the role of advocates in the process lead to the creation of community design centers in the United States (Pearson 2002). These community design centers – architecture studios dedicated to inclusive design – have proved to be a unique vehicle through which a crucial array of services in community development has been made available (ACD 2016). Due to the quick success of the model, the number of community design centers increased rapidly during the 1970s (Pearson 2002).

In parallel with the emergence of community design centers in the USA, a number of initiatives embraced similar citizen participation oriented vocation in the rest of the western world, often bringing alternative solutions, at times even contrasting the American advocacy practice. The Byker Wall regeneration project (1968–82) in Britain was among the pioneers, where architects opened an on-site office to develop communication and trust between existing residents (Jones & Canniffe 2007). The new medical campus development project of the Université Catholique de Louvain in Brussels (1969) offered architect Lucien Kroll a great opportunity to implement his methods of user participation (Sennott 2004). Dutch architect N. John Habraken proposed the separation of 'Supports' or base buildings from 'In-fills' in residential construction and design as a means of giving inhabitants a meaningful participative role in the design process (Habraken 1972). In the Saal process in Portugal (1974–76), technical teams, led by architects collaborated with local communities to address the housing shortage and design homes with the direct input of the residents. These are only a few of the various early community design initiatives in Europe.

Political climate however changed in the 1980s. The coming-to-power of more conservative governments on both sides of the Atlantic serially undermined local authority power, while seeking to reduce government roles in economy and promoting private sector and individual initiative. Funding possibilities for consolidating movements were changed in a radical way and over time – while stimulating some community-based activity initially, longer-term and development funding became focused on specific perceived problems (Jenkins & Forsyth 2010). The reduction of governmental support for social programs in the USA resulted

in a sharp decline in the number of community design centers (Pearson 2002).

The downturn of community participation in architecture design, however, proved only momentary. The following decade brought new economic, environmental and socio-cultural urban challenges and a new trend of sustainable regeneration policy highlighted the necessity of social inclusion and community participation in decision-making once again. Livable, human-oriented, sustainable and socially sensitive design of the built environment relies heavily on the comprehensive knowledge of needs and preferences of the local communities.

While several newly developed community powered design philosophy and methodology branches have diverged from the traditional advocacy role of architecture toward more pragmatist approaches (Toker & Toker 2006, Bezdek 2013), the core concept, the importance of community involvement in the design process, has remained largely unchanged.

2 COMMUNITY PARTICIPATION IN HUNGARY

Hungary is one of the post-communist Eastern European countries, where genuine democratic community development was regarded as politically undesirable; community participation in architecture design was therefore virtually non-existent before the democratic transitions. Whereas social sensitivity was officially promoted as a cornerstone of the communist ideal – and it must be acknowledged that there was no shortage of different community-purpose and social facilities – the actual design decisions for these facilities, public spaces and other urban development projects were based more on a curious and often incidental mixture of political ideology, top-down planning and theoretical professional concerns, rather than on the actual needs of the users.

Transition in this regard, however, did not happen as an immediate consequence of the political changes. Potential reasons for the delay are at least threefold. The fall of communism and the subsequent spread of democratic institutions happened to coincide in time with the global downturn of community-engaged design. Furthermore, in spite of the enthusiasm for Western administrative and governance models, the temporary economic recession that followed the transition in former Eastern-bloc countries seems to have diverted attention from the more abstract strands of democratic engagement and citizen responsibility.

In a democratically inexperienced society, which lacked the decades of tradition of community participation in decision-making, the initial disinterest in citizen empowerment may not strike as surprising. In addition, role players in local development projects (e.g. municipalities, private investors, NGOs) are still often unfamiliar, or cannot identify with the values of the local communities, and thus, these values are not reflected in the decision-making processes (Sain 2010). As a result, a number of developments become associated with negative impacts on their surroundings, draw unfavorable public sentiment and fail to catalyze further developments in the area (Sain 2010). As project details are often not shared with the local communities, citizens do not feel ownership and responsibility over new public and private investments even if these were intended to improve their neighborhood.

Meanwhile however, the practice of community involvement in the design process is becoming more common in Hungary. Affected community members are often invited to participate, even from the earliest stages of the design. People are asked for their input or even delegated to certain tasks in several development projects. Community development services are also becoming more readily available.

3 ROLE OF DESIGN PRACTITIONERS

The general attitude of design practitioners towards the idea of inclusion, as well as their competence in participatory design, is determinant in the success of community architecture. Public acceptance of architecture design has proved to depend more on communication and complying with the local socio-cultural identity than on aesthetic values (Lozano 1990). According to the traditional paradigm of strategic planning practice 'design tasks' should be assigned exclusively to highly skilled and properly licensed professionals (AIA 2015). Design activity, however, is not circumscribed as a clear definition. In a wider sense, people make a series of design decisions during their everyday life. While similar in fashion, most of these decisions do not require the technical assistance of qualified professionals.

Hence, it can be appreciated that non-professionals, such as the future users of a building, or an entire community affected by an urban development, could provide valuable input to the design criteria, if sufficiently enabled and capacitated to express that input. Especially, when it comes to strategic design questions derivable from the quality of life, living conditions and value priorities of the people the designed is intended for. Acknowledging the importance of the local knowledge, community participation is regularly set as a condition of funding for several urban rehabilitation and renewal programs and integrated urban development programs (Swyngedouw et al. 2002).

In some cases however, often as an attempt to bypass the labor-intensive and time-consuming but otherwise obligatory community participation process, or to legitimate the imposed proposals of political decision-makers, inclusion is confined to receiving information and a few consultations (Swyngedouw et al. 2002, Sain 2010). Participants, selected upon the judgment and preference of the decision-makers, do not represent the entire range of affected people. They also do not get to interact with each other, therefore, deprived of reasoning and negotiation, the collected

information articulate only a series of competing personal opinions rather than a collective consensus. Based on the gathered information it is the architect, who then makes the design decisions. The wider audience meets the basically finalized plans only at hearings and consultations, where they are often exposed to abstract technical drawings and terminology they do not understand. If, at the end, the concept fails to win the audience, conflict is guaranteed. These forms of *pseudo participation* (Sanoff 2000), or *outsider participation* (Hofman 1998) – even if carried out without any ulterior motive – are largely seen as destructive practice, since they can easily undermine the trust and engagement of community members to future participation.

As opposed to pseudo-participation, in *genuine* (Sanoff 2000) or *insider participation* (Hofman 1998), members of the community would meet already at the earliest stages of problem mapping. They get to know each other's interests, intentions, ideas and concepts. All essential information becomes public domain. Design professionals provide the technical assistance and maintain high design quality. Since design criteria are a result of consensus through interaction, there is no need for subsequent public confirmation. Every interested party has the opportunity to give their input and opinion during the design process. It is needless to emphasize that both the acceptance and the sense of ownership among community members are substantially higher.

As pointed out in this paper before, design practitioners play a vital role in the process. Therefore, it is important that they shall be equipped with the right skills. Beyond the traditional roles as highly qualified artist, technician and social engineer (Lipman 1969), architects engaged in community design also need to prevail as facilitator of the inclusive planning process (Burgess 1983). This requires the ability to listen and to correctly interpret the input – needs and priorities – given by the participants, and the ability to collaborate.

4 PARTICIPATORY DESIGN PROGRAMS AT UNIVERSITIES

Universities have proved to be an opportune host for the long-term provision of community engaged design services (Pitera 2014, Pearson 2002). As academic centers, universities are in a unique position to support access to and effective use of design knowledge (Feldman 2004). Several of the community design centers operating today are in some ways affiliated with universities or academic programs. The cooperation is beneficial for both parties; it provides exquisite opportunities for sustained design excellence and, at the same time, students of architecture and planning get exclusive first-hand experience in working with communities.

Whereas the model and structure of cooperation are usually unique for each partnership, most share certain common characteristics. Pearson (2002) examined the length of the programs, and the shift of focus among educational, community service and aesthetic objectives. Along this line, he classified partnership programs into three main categories. The first he calls university-based design and build programs. Partnership is usually facilitated by a local non-profit organization, which represent the community. They are responsible for the coordination of the program and communication between the participants. The university department provides the expertise and the academic administrative frame for the work. Students usually design and build small-scale, experimental projects as part of their coursework. The cooperation might be occasional or ongoing, but the projects are usually short term, a few days or weeks long. Emphasis is evenly distributed among the three objectives. Success is evaluated on the quality of the completed work and its contribution to the community. The second category encompasses university-based community design centers. It is found very common in the US academic system. These on-campus design centers operate with their own staff, most of which are teachers or students of the university. They provide technical assistance and design services to local communities and NGOs, however these projects are less integrated in the academic curricula. The design centers establish independent relationships to university departments and students get involved in the work as interns. Studios are equipped for longer-term community design projects. Emphasis is less on the completion of the built project, but rather on the help to communities (assessment of needs, developing clear objectives and program requirements) and the educational benefits through student engagement. The third type of partnership model is described between university departments and independent community design centers. The main aspect in which independent community design centers differ from for-profit design studios is that they focus their services primarily to underserved communities, and work at affordable rates. The involvement of the academic institute is mostly informal and occasional. Their ability to maintain high design quality depends on the project scale and the political context in which they work.

The community design center, whose work was selected for evaluation in this paper, has been regarded as an experimental initiative since the time of its creation in 2005. First of its kind in Hungary, the St. Joseph Studio Collegium (*Szent József Stúdió Kollégium*) shares similarities with all three cooperation models detailed in the above chapter. In this unique partnership between Budapest University of Technology and Economics and the Jesuit-founded independent studio, registered architecture students of the university take some of their advanced level design courses working on community participatory design projects. American Jesuit architect, Terrence Curry, AIA, the founding director of the studio, had had created two similar profile design centers in the USA, Fordham University Center for Community and Environmental Development and Detroit Collaborative

Design Center at University of Detroit Mercy, before arriving to Hungary as visiting lecturer of architecture at Budapest University of Technology and Economics. Since 2008, the author of this paper has been directing the operation and the design activities at the studio. Participatory design projects at the St. Joseph Studio Collegium are based on commissions directly from local NGOs, or through community development agencies. Design programs are usually based on bottom-up initiatives, without clear programmatic concept, or working with a group, whose individuals may have developed ideas, but a collective consensus is yet to be reached. The workshop process is one or maximum two semesters long, complying with the academic coursework of the students.

5 WORKSHOP PROCESS

Over the past decades, a great number of well-established inclusive design practices and methodologies have been developed. This paper does not intend to provide a comprehensive description of the different techniques; limiting its focus on those alone that have been applied – and further refined – at the St. Joseph Studio Collegium.

Design cooperation with the participants is structured into a multi-step workshop process. Depending on the availability of the client group program would include five 3-hours long up to eight 2-hours long exercises. The first half of the meetings walks participants through a process of establishing a range of design criteria. These include the programmatic requirements, building character, spatial experience, building quality, and project budget.

The program starts with community building exercises, where the individual participants introduce their vision of the outcome of the cooperation as well as their projected role in the process. Collected aims are then formed into a project statement that can be referred back at different later phases of the process.

Next step is the *program mapping*. Participants compile a list of activities they would welcome to see at the planned building or facility. Once the activities are arranged in the order of priority and sorted into corresponding categories, the list becomes the basis for developing a detailed needs assessment.

The following workshop is dedicated to the establishment of *visual criteria*. Students select a series of quality examples with varying reference and connection to the function, scale, or geographical setting of the design program. Participants then evaluate the examples based on specific aspects (style, spatial experience, character, form, applied materials, etc.). The goal of the exercise is to define a design vocabulary that reflects participants' preference for the visual character, but at the same time, allows enough room for artistic liberty.

Workshops continue with the development of the *quality model* that includes considerations and priorities based on the costs of operation, potential income and resources, applied technologies and the overall image. In order to equip participants with the necessary economical and financial context, the essential terms shall be pre-defined. After negotiation, participants make a prioritized list of the building's physical and operating qualities.

The collected data of the previous exercises form the base of the final scope of the project. Needs assessment is translated into square meters and room or space types, and the quality model helps setting an acceptable budget goal.

With these in possession, the first layout of the building can be started. Students prepare a kit of to-scale room/space cutouts; together with flexibly cut approaching and service areas. During the laying out, students provide design assistance, clarifying the concepts of circulation, proximity, connections, axis, building codes and zoning regulations, lighting, parking and sanitary requirements, geographical conditions, etc. Participants consider the various types of connections between the different functions and premises, spatial and structural conditions and requirements, special circumstances, and take note of all relevant comments. The resulted layouts are then used to confirm spatial relationships, based on which the architecture design can finally be started.

Students present the first conceptual plans to the community at the next meeting. Participants are welcome to comment or make remarks referring back to the established criteria. However, in order to avoid endless redesign and to keep the schedule, changes in the criteria cannot be made at this point anymore. Refined plans based on the input of the consultations get a final approval from the client group at the last meeting.

6 CONDITIONS OF THE EVALUATION

The objective of the evaluation was to reveal the efficiency and the particularities of the community design workshop model in the Hungarian socio-cultural and academic context.

Evaluation was based on the general experience of the operation of St. Joseph Studio Collegium and, in particular, five of the workshop processes conducted between 2005 and 2015. The selected projects share similar characteristics. In each case, the client was a Hungarian NGO or informal organization of the civil society. The number of participants of the client group varied between 10 and 25, while the number of students was between three and six. Programs which would require the inclusion of a wider group of affected citizens and which would involve previous community development process were not considered viable, due to the set timeframe and strict schedule of the students, however in two cases, where the planned intervention potentially affected a wider circle of residents than those represented by the workgroup, students conducted preparatory interviews and surveys.

Emphasis was divided between educational purposes, design excellence and community service,

in that order of priority. The final product of the participatory design process was a set of conceptual plans, specifications and renderings, which the client group then could potentially use for fund-raising purposes.

The projects were officially assigned to the fourth year design studio courses (Comprehensive Design Studio 1 and 2) in the five year combined Master of Architecture program of the university. Therefore, in order to receive course credits, the delivered plans also had to comply with the formal and content requirements set for regular students of the same course.

Evaluation encompassed the judgment of the overall efficiency, based on student recruitment and engagement, acquired skills, the conduct of the workshops, and the feedback from the client groups.

7 FINDINGS AND IMPRESSIONS

Many of the findings and conclusions of the evaluation of the workshop process can be attributed as specific to the general socio-cultural-political context in Hungary, the particular group of participants in the project, the unique relationship with the university and its administrative and academic requirements. Results however can help draw more general inferences with the prospect of further developing the efficiency of the workshop model.

Student recruitment has proved to be challenging. In spite of the advertising, oversubscription for the course has been somewhat lower than expected. This can be attributed to various reasons. Most capable students are already committed to a particular department or design supervisor by the beginning of the fourth year. At the start of St. Joseph Studio Collegium, advanced proficiency in English was a compulsory requirement, due to the English-speaking lecturer. Also, the studio space was originally located at an off-campus facility. While these conditions seemed to be attractive for some students, they may have been dissuasive for a wider crowd.

In spite of the substantial extra workload that complying with both the university course requirements and the community design workshop process meant for participating students, engagement could be assessed as more than satisfactory. After the course, majority of the students would go on to choose design projects with community impacts for their Master's degree thesis. During the entire time of the examined period, only a few students quit the course, those who did, identified scheduling problems or the excessive workload as main reasons.

Activity among the client group members was sometimes less steady. Ensuring all participants to attend every meeting proved to be the most challenging task. While those present tended to give enthusiastic feedbacks at the end of each workshop, some did not manage to fully acknowledge the importance of the continuous participation.

Client groups received both the collaborative workshop process and the finalized conceptual plans very well, in general. In the aftermath of at least two of the five partnerships, the community would continue developing the projects, and took further steps toward the realization of the concepts. A couple of projects gained recognition in the architect society as well (Bardóczi 2009). In some of the early cases, it proved to be difficult to clearly communicate, at what point the partnership and the joint work would end, or what the exact scope and level of the delivered plans would be. Participants would often want to continue the collaboration after the end of the workshop process.

8 CONCLUSIONS

The findings of the evaluation and the overall impressions of the workshop process showed that there is potential in the integration of community design aspects into the university level architecture education in Hungary and in other post-communist countries with similar socio-cultural, demographic and political background. Since the start of the St. Joseph Studio Collegium several other workshops and design programs in both the graduate and doctoral programs of the Budapest University of Technology and Economics as well as other schools of architecture in Hungary, were committed to the idea of community-driven design. While still not widespread, there has been ongoing interest from students in the technique. In light of the results, the first experimental university – community design partnership can be regarded as successful. Experiences can serve as positive inducement for similar future partnerships.

ACKNOWLEDGMENT

This research was made possible by financial support from the Budapest University of Technology and Economics, Faculty of Architecture and the St. Joseph Studio Collegium.

Applying a blended learning methodology to the study of housing

Leandro Madrazo
School of Architecture La Salle, Ramon Llull University, Barcelona, Spain

Carla Sentieri
School of Architecture, Polytechnic University of Valencia, Spain

Nadia Charalambous
Department of Architecture, University of Cyprus, Nicosia, Cyprus

ABSTRACT: A blended-learning approach was adopted to create a learning space to introduce architecture students to be basics of architectural design through the study of housing. Components of different courses from three European schools of architecture, in Spain, Cyprus and Serbia, were combined in a joint learning structure. The learning activities were structured as sequences which were carried out synchronously or asyn-chronously by students from the three schools. The main supporting technology was OIKODOMOS Work-spaces, an on-line learning environment specifically created to support the design and implementation of learning activities in collaboration based on a constructivist philosophy of learning.

1 INNOVATING HOUSING LEARNING

Since the academic year 2003/04, we have been steadily developing innovative pedagogic programs co-funded by the European Union to innovate learning and teaching on the field of housing studies. We started with HOUSING@21.EU, supported by an Erasmus Intensive Program (2003–2006) which counted with the participation of five European schools (Madrazo & Massey 2005). It followed the OIKODOMOS Virtual Campus (www.oikodomos.org) carried out under the auspices of the Lifelong Learning Program in two stages, from 2007 to 2009 and from 2009 to 2011. The purpose of OIKODOMOS was to integrate subject matters (housing design, urban planning, energy efficiency, sustainability), academic levels (bachelor, master), courses (design studios, seminars) and learners (students, citizens) to make a joint Virtual Campus dedicated to the study of contemporary housing. A learning platform was created to support the methodology of the OIKODOMOS Virtual Campus (Madrazo et al. 2012).

The last step in this line of work dedicated to innovate learning and teaching about contemporary housing has been "OIKONET: A Global multidisciplinary network on housing research and learning" (www.oikonet.org). Thirty-four institutions representing twenty-five countries in and outside Europe are part of this network. Partners are higher education institutions–architecture, urban planning, engineering, social and economic studies–research groups, local administrations and professional organizations. The goal of OIKONET is to enhance the previous OIKODOMOS Virtual Campus to transform it into a network dedicated to study contemporary housing from a multidisciplinary and global perspective. A distinctive feature of OIKONET, which distinguishes it from the previous two programs, is the interweaving of three areas: pedagogy, research and community participation.

2 A BLENDED PEDAGOGY

A common denominator through all of the three programs carried out from 2003 to date – HOUSING21.EU, OIKODOMOS and OIKONET–has been the aim to create innovative learning spaces following a blended-learning approach. Blended-learning is an ambiguous term which is endowed with multiple meanings. Generally speaking, the term "blended learning" refers to any combination of face-to-face instruction with computer-mediated instruction. More generally, it is also used to refer to any combination of media, pedagogic methods, and theoretical and practical work. Heinze & Procter (2004) have described blended learning as "the effective combination of different modes of delivery, models of teaching and styles of learning". The vagueness of these sort of definitions raises some doubts about the usefulness of the term to convey an identifiable model of education. Yet, much of the research on blended-learning have been concerned with describing the considerable variation of meanings across institutional contexts and charting the boundaries of the term (Moore & Anderson 2003).

One of the basic questions to address in a blended-learning environment is to identify what and how it is blended. Besides physical and digital delivery formats there are other components which might become blended: learners (e.g. students and teachers), learning styles, academic programs, subject-matters, disciplines, and institutional frameworks (e.g. formal and informal learning). Furthermore, there can be different modalities of blending. According to Hoic-Bozic et al. (2009), "Blended learning is learning based on various combinations of classical f2f lectures, learning over the Internet, and learning supported by other technologies, aimed at creating the most efficient learning environment"- whatever the term efficient might mean. The combination might involve using digital resources as *supplement* to traditional classroom education, as *replacement* of traditional classroom-based components by digital resources, or as a seamless *amalgamation* of distinct elements (active learning, collaborative learning, participation) to foster students' engagement (Beer et al. 2010). In this blending process, what is being blended might become diluted to emerge under a new form in a novel environment.

The value of blended-learning transcends the mere application of ICT for teaching and learning. For Garrison & Vaughan (2008), the real significance of blended learning lies in its potential to transform education, since "[it] questions conventional practices and the belief in the lecture as an effective approach to engage students in critical and creative thinking and learning." Furthermore, they contend that "Blended approaches to educational design recombine concepts that were previously considered contradictory, such as collaborative-reflection and asynchronous-community." Therefore, blended learning represents "a fundamental reconceptualisation and reorganization of the teaching and learning dynamic, starting with various specific contextual needs and contingencies (e.g., discipline, developmental level, and resources)" (Garrison & Kanuka 2004) which conveys "rethinking and redesigning the teaching and learning relationship." (Garrison & Kanuka 2004).

Expectations to bring innovation into education also rely on blended-learning approaches. However, blended-learning environments represent a challenge to learners, both students and teachers. Students are expected to adopt a more active role, interacting with "tutors, students, content interfaces, features, code, channels and environments and with other learners" (Donnelly 2010) and teachers need to develop their skills as learning designers, developing novel learning plans and strategies. Meeting these challenges requires from both types of learners skills that go beyond the mere use of the technology. In fact, pedagogic innovation occurs as learners are able to unfold new capacities in a blended-learning context.

The combined use of physical and digital delivery formats in a blended-learning environment can adopt two fundamental models (Bersin 2004): 1. The flow-model, based on well-defined successive steps. In each of the steps of this sequence, physical events can be replaced by e-learning activities 2. The core-and-spoke model, by which a program is designed in one media (physical or digital) and optional supplemental materials are provided by other means. In both cases, it is necessary to lay out a learning plan which assigns a place, a time and a purpose to each component through the learning process.

The unity of space-time-and-content which occurs in classroom-based learning is replaced by a network of distributed spaces-times-and-contents in a blended-learning context. The possibility to combine learning activities in synchronous and asynchronous ways is a distinctive characteristic of blended environments. Learning activities can be carried out at different times and in different places (on-line, in the classroom) combined in interaction with other learning resources. To effectively exploit these capacities, blended-learning environments require specific pedagogic methodologies which take advantage of their potential. Even though we can find examples of intertwining a specific learning style with blended-learning there still is not much investigation about the relationships between both, particularly in higher education. Shannon et al. (2013) have transposed the design studio model prevalent in architecture schools to a blended-learning context. Problem-based learning has been implemented by Donnelly (2010) in a blended-learning environment. Blended-learning is expected to create a sense of community among learners as a result of their solving a particular problem in collaboration following a constructivist approach to learning (Juvancic et al. 2012).

The combination of the all the different components – delivery formats, subject-matters, learners, learner styles following a blended-learning approach results in learning spaces which transcend existing boundaries – physical, disciplinary, institutional.

2.1 *Learning spaces*

Before the advent of ICT in education, the term "learning space" has been used to refer to the physical environment where education takes place. The interest for educators was to know how physical settings influence education, enabling or hindering specific forms of teaching delivery and innovation (Temple 2008). Punie used the term "learning space" to describe ICT-enabled educational spaces which transcend existing limits, physical, conceptual and institutional. In these new learning spaces students would be at the center of the learning, becoming co-producers of contents, and the role of teacher would change or disappear. The learning spaces Punie (2006) proposes would make possible social interaction at different scales (from learning individuals and communities to learning cities and regions), enable the personalization of learning (a personal space adapted to the needs of each learner), be a source of reliable quality contents; help to connect people emotionally and not only through the contents; detach learning from controlling (which in the traditional school system are amalgamated); foster

creativity rather than simply transmit knowledge; be flexible enough to integrate various learning styles, teachers' skills, and curriculums; help to evaluate the learning outcomes solely on the base of the individual's performance; be open and inclusive so that new contents and resources could be added at any pace; and become informal platforms to share expertise and knowledge across organizations.

In the OIKONET project, we use the term learning space to pursue goals which are in line with those described by Punie. In our case, a learning space refers to:

- A space which brings into relationship schools from different countries which include housing studies in their curriculum.
- A space which puts into relationship subject-matters (regular courses, seminars, design studios) from different academic programs addressing housing from multiple perspectives (architectural design, urban planning, representation, architectural theory).
- A space to support the exchange of knowledge among learners from different cultural background and academic levels.
- A space to design and implement learning activities in collaboration, with the participation of teachers and students from various schools.
- A space of collaboration which coexists with the regular academic activities that take place in each institution.

The creation of such spaces requires a pedagogical model strongly intertwined with ICT. In the previous OIKODOMOS Virtual Campus, an on-line platform was created specifically with this aim: to closely interweave a pedagogical model based on a constructivist philosophy and the digital tools to support it.

2.2 *Intertwining tools and learning processes*

There is a variety of tools which can be used alone or in combination to implement blended-learning environments. They range from learning management systems such as Moodle, Blackboard and WebCT to shared repositories of information (Google docs, Dropbox), social media (Facebook) as well as any other ICT tool which can be used to support a pedagogical strategy (Neto et al. 2012).

However, a more challenging way to integrate ICT in blended-learning is to create ad-hoc environments to support a specific pedagogic approach. Within the OIKODOMOS project, we created a full-fledged learning platform to support the collaborative design and implementation of learning activities in the virtual campus. It consisted of three environments: Workspaces – to design and implement sequences of learning activities –; Case Repository – a digital library of housing buildings documented and commented by students and teachers – and OIKOPEDIA – a Wikipedia containing entries about the main topics and issues addressed in the learning activities (Madrazo et al. 2010). This platform is being used to carry out the learning activities in the OIKONET project, together with some social web tools like Facebook and Twitter.

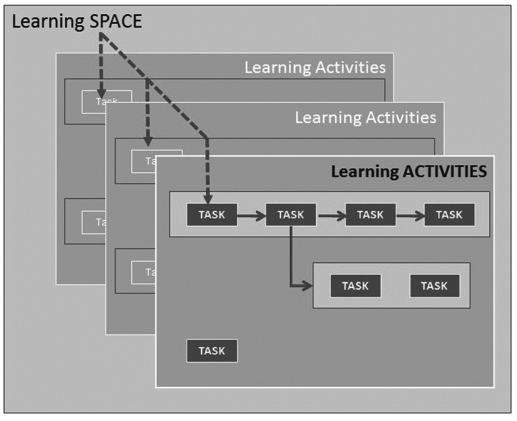

Figure 1. Learning structure of OIKODOMOS Workspaces.

OIKODOMOS Workspaces is a web-based learning environment which facilitates the design and implementation of learning spaces which interlink with other activities carried out at various institutions in design studios, workshops, seminars and courses. A learning space is designed and implemented by a group of tutors who decide to collaborate in the design and implementation of some shared learning activities around a particular theme over a specific period of time. These learning activities are made up of tasks which can be either single or grouped in sequences. A sequence of tasks can be constrained to a single learning activity, or they may cut across different ones (Fig. 1). This learning structure is sufficiently flexible and neutral as to support different kinds of activities – from the collaborative development of an architectural or urban project to course assignments – which can be done by students working individually or in groups, as well as by schools working independently (the platform can be used to support a course limited to the school program) or in collaboration with other institutions.

The theme of a learning space, and the activities and tasks that it encompasses, are put forward by the teachers from the participating institutions. In the OIKONET project, we have developed a procedure for faculty members to design a learning plan in collaboration which will then be implemented in various ways, adapting it to the conditions of the academic programs at each school. Basically, the procedure is abridged in one document which teachers need to jointly complete responding to the following issues:

- *Theme*. This is the general topic which teachers propose to address collaboratively. The theme is chosen as to facilitate different subject-matters taught at different schools to contribute to it.
- *Description*. The purpose and relevance of the theme.

– *Participating institutions*. The partner institutions committed to implementing the learning activities during the time the learning space is active.
– *Courses involved*. A short description of the courses at each institution which will be participating, and the level of the students involved.
– *Partners' contributions*. The expertise and resources that each institution will bring to the learning space.
– *Learning objectives*. The learning outcomes that participating students would achieve. A list and description of the learning outcomes needs to be agreed by teachers.
– *Learning activities*. The structure of activities and tasks which will be implemented in OIKODOMOS Workspaces.
– *Time plan*. A tentative plan of the activities that will be carried out to assure they suit to the time-tables of the course at the participating schools.
– *Forms of collaboration*. The forms of collaboration that will be implemented (team works with students from different institutions, peer reviewing, tutoring from teachers from other school, etc.)
– *Tools*. ICT that will be employed together with OIKODOMOS Workspaces (Facebook, Twitter, Moodle, etc.).

A learning plan described in this way becomes a roadmap for teachers to implement the activities. It also enables them to assess if the results achieved at the end meet the objectives of the plan, as well as to identify any deviations. The lessons learned are taken into account in the design of the next learning plan and in the subsequent editions of the learning space.

As a learning space is implemented, learning becomes a process by which some inputs – study themes, assignments, references and readings – give rise to some outputs – student work, comments on others' work, peer and teacher evaluations. Activities and tasks can evolve in an open-ended manner as the learning process progresses. In fact, they can have an existence of their own: they become more or less active as more tasks are defined and work submitted; they move from the virtual to the physical spaces, depending on the intertwining of sequence of on-site courses with on-line activities; they come to an end as learners stop to interact (between them, or with the learning resources). Furthermore, learning activities can be carried out in a synchronous or asynchronous ways during the time the learning space is active. Thus the temporal structure of the activities will have meeting points with that of an academic program (e.g. semester, quarter) at a particular school but does not necessarily have to coincide with it (Madrazo & Riddy 2011).

2.3 *Implementing learning spaces*

During the first eighteen months of the OIKONET project, from October 2013 to April 2015, six learning spaces were collaboratively designed and implemented with the participation of the 15 European schools of architecture and urban planning and 2 schools outside Europe. Each learning space was dedicated to a theme related to housing:

– Introduction to Housing . An introduction to some fundamentals of architecture and housing design, led by the School of Architecture of Valencia, Spain.
– Habitat Regeneration Strategies. It focuses on the redevelopment of deprived areas at various scales (housing, neighborhood, city, metropolitan area) encompassing multiple aspects of city life: physical, social, economic and environmental. It was led by the University of Belgrade and by the Faculty of Architecture, Slovak University of Technology, Slovakia.
– Threshold Matters. It was dedicated to study the intersection of public and domestic spaces and it was led by KU Leuven, Belgium.
– Housing Systems. Exploring the concept of housing system, from design to construction, which has been led the School of Architecture La Salle, Barcelona, Spain.
– Contemporary Living Patterns. It was dedicated to the preparatory activities for the first OIKONET international workshop in Lisbon, Portugal.
– Civic housing. Fostering the dialogue between professionals and non-professionals in the design of domestic space, led by the School of Architecture La Salle, Barcelona, Spain.

To exemplify these learning spaces, from design to implementation, in the following sections we describe "Introduction to housing", which started in the academic year 2013/2014 and has undergone two subsequent editions since then (Fig. 2).

3 INTRODUCTION TO HOUSING

The pedagogic purpose of the learning space "Introduction to Housing" is to initiate students in the basic principles of designing (and understanding) what a house might represent in our contemporary culture (or cultures).

At its first phase of implementation in the academic year 2013/14, the structure and contents of "Introduction to housing", drew on the curriculum of the first year design studio of the School of Architecture of Valencia, Spain, the housing design studio at the University of Cyprus and the 3D Visual Communication course at the University of Belgrade, Serbia. Around 200 students from the three schools have participated in the learning space.

Each participating school has a particular curriculum and schedule to carry out their study programs which run in parallel to the collaborative activities carried out distantly. Therefore, an important challenge faced in the design of this learning space was to agree on a common plan which embraces the pedagogic objectives of the participating institutions. A joint learning program was collaboratively created applying the OIKODOMOS Virtual Campus methodology. This program enabled the participant architecture educators

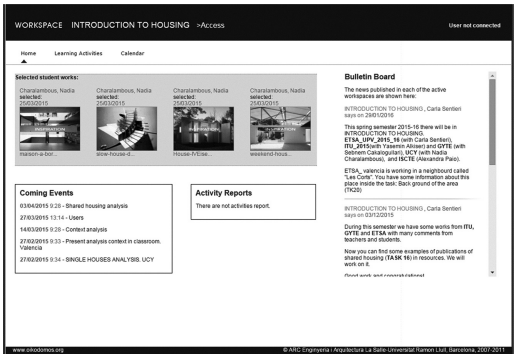

Figure 2. Entry page of "Introduction to Housing" in OIKODOMOS Workspaces.

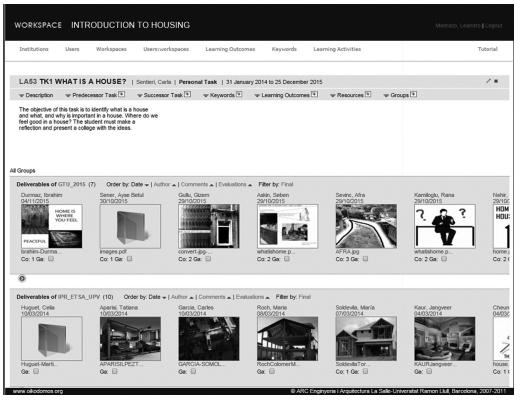

Figure 3. Outcomes of a task submitted by students to OIKODOMOS Workspaces.

to design a joint learning structure made up of learning activities and tasks, aligned with the common pedagogic goals which are reflected in the learning outcomes set by their respective institutions.

Learning activities included precedents analysis, understanding of the concepts of home and house, context analysis and analysis of users' profiles. Learning tasks carried out by students in the OIKODOMOS Workspaces environment were dedicated to apply knowledge derived from the theoretical background, to develop a coherent design process, to make appropriate use of different representation techniques (verbal, textual, and visual, both digital and analogue) in order to communicate ideas and design proposals in an effective manner, to develop team working skills through and the ability to criticize their own work and that of others. These tasks were organized in sequences and were carried out synchronous and asynchronously by the students from the participating institutions (Figure 3).

The learning space "Introduction to Housing" critically questions the conventional face-to-face (f2f) lecture as the most effective approach to engage students in critical and creative thinking. It transcends a simplistic combination of f2f instruction with computer-mediated instruction through a combination of both f2f and digital modes of delivery, teaching methods and styles of learning. Learners have shared comments about their design projects both in classroom and on line and have been exposed to different types of teaching and learning resources (f2f lectures and video-lectures, on line resources). Teachers have incorporated new methods and styles, resources and subject matters in their teaching with direct implications on their respective academic curriculum.

3.1 *Learning space implementation*

In this section an overview is presented of the Learning Activities and Tasks which make the learning space in an attempt to highlight the pedagogic structure devised by teachers of the three schools with the purpose to introduce students to some fundamental issues about contemporary housing.

- Learning Activity RECOGNIZING SPACE. Architects create spaces. Therefore, it makes sense that the first step in an introduction to architecture is to learn, perceive and represent space. The purpose of this activity is to learn to recognize the places we inhabit. Students can develop this capacity by analyzing designs or by observing the spaces we live in. All the tasks included in this learning activity focus on the analysis of the spaces we encounter in a house: rooms and space-defining elements, furniture and other objects, dimensions and particularities.
- Task What is a house? The goal of this task is to distinguish the concepts of house and home. Students are expected to address issues such as: what makes you feel good at home? These reflections are summarized in an A3 document combining different materials and techniques (texts, drawings, photographs).
- This task was done by ETSA-UPV students. The outcomes were commented by teachers from other schools and by students from UCY.
- Task Collective Housing. Examples of collective housing projects are presented and discussed in the classroom. Then, students are asked to reflect on collective housing issues through their own presentations.

Learning Activity DERIVING IDEAS FROM TEXTS. Argumentation is very important for architects, it is the way to explain ideas to people who are not familiar with drawings. An interpretation of a text is never unique. The purpose of this activity is to explore the transformation of the ideas described in a text- or, more precisely, the interpretation of those ideas- into drawings-that will become inhabited spaces.

- Task Interpreting a text. This task aims to provide the students with the graphic skills which enable them to translate a text into drawings. The tutor reads a text from the book "Invisible cities" by Italo

Calvino, which describes cities and places. Then, students draw the spaces described in the reading.

Learning Activty PRECEDENT ANALYSIS. The purpose of this activity is to learn from precedents, to understand the factors that influence residential architecture, to identify solutions provided from previous projects and to transform them into new ones.

– Task Analysis of residential architecture. Analysis of international examples of residential architecture (context, users, social, economic, environmental variables).

This task was done by students from UCY. The outcomes of this task were commented by teachers from other schools and by students from ETSA-UPV. They formulated questions to students, to make them continue thinking about the issues they have identified.

Learning Activity IDENTIFYING USERS' NEEDS. Houses are complex expressions of the social and individual worlds of their occupants. Social structures and patterns of behavior seem to be closely intertwined with domestic spaces. Students are encouraged to understand that the design of a "home" needs to address the practicalities of everyday life while responding at the same time to the owner's idiosyncrasy, personality and dreams. Therefore, it is important to be able to analyze and understand the needs of people.

– Task Analysis of potential users. Students are randomly given existing user types and are asked to describe their daily activities, hobbies, personalities, and needs.

The task was done by students from ETSA-UPV and UCY. Their work was commented by teachers also from Valencia. The revision of this task by the teacher was done on-line in the OIKODOMOS Workspaces platform, giving references to other learning spaces.

Learning Activity CONTEXT ANALYSIS. Homes often reflect differences between ethnic, cultural and social groups, including gender divisions between men and women or differences between adults and children. Also, homes reflect differences in environmental conditions (climate, light, air, topography) of a particular place and culture. Through this activity, students are expected to understand that domestic space is site/context specific.

– Task Visual mapping of context. Students analyze sites employing visual ethnography methods. They represent context specific characteristics (cultural, social, and environmental) through both digital and printed "visual" essays.

This task has been done by ETSA-UPV and UCY students. The outcomes of this task were commented by teachers and students from these schools.

Learning Activity AT HOME. DESIGN PROPOSALS. Taking into consideration all the work done through the preceding tasks, students are asked to design a "home" in a specific context that addresses local conditions and culture, the practicalities of everyday living and the user profiles, personality and dreams. Understanding the relationships between the spatial structure of the domestic space and the social milieu is one of the central challenges of this learning activity. The purpose is to explore the ways in which a home responds to social, cultural, and individual requirements, in the context of an increasingly divided, complex and differentiated experiences of contemporary life.

– Task Initial design proposals. Students develop initial design proposals for collective housing schemes.
– Task Collective housing project. Students develop design proposals of collective housing in a given context and for specific user types.

This tasks were done by ETSA-UPV (Figure 9) and UCY students (Figure 10). The outcomes of this task were commented by teachers and students from these schools.

3.2 *Evaluation of results*

An evaluation of the learning activities was conducted through an on-line questionnaire given to the students at the end of the spring semester 2013–14. The main objective of the evaluation was to assess the effectiveness of the learning activities, the achievement of the learning outcomes, and the acceptance level of the on-line platform into the students' learning experience.

Students had strong expectations regarding networking and sharing knowledge in a collaborative and international context. Their answers revealed that their participation in the joint learning space had changed or refined their approach to design and was particularly useful for getting in contact and communicating with others, as well as for sharing projects, ideas, learning resources, skills and feedback.

The participation in the learning space gave students the opportunity to be exposed to the work of fellow students but also to present their work to both students and colleagues of the participating schools, to comment the work of other students and to participate in peer evaluations, to attend video lectures, to access and to share learning resources through the web-based environment. It also gave tutors the opportunity to work in collaboration, to get to know diverse teaching methods as well as the work done by students from other schools, to attend but also deliver video lectures and to share learning resources through a number of platforms (such as OIKODO-MOS Workspaces, Blogs, Skype, Google+).

However, the first implementation of the learning space in the academic year 2013/14 proved that more time and better planning was required in order to make full use of the collaboration potential. A persistent problem has been the difficulty to reconcile partners' regular learning activities at their institutions with the collaborative learning activities carried

out in the learning space. Differences in schedules, learning approaches and tasks many times resulted in difficulties with harmonization of collaborative activities.

4 CONCLUSIONS

Designing and implementing the learning spaces in collaboration has contributed to forge links among the partners in the OIKONET network, to exchange knowledge about various matters related to housing studies, as well to share pedagogical methods and experiences. As a result of this collaborative work, it was possible to devise new strategies and procedures – which have not been developed in the previous OIKODOMOS Virtual Campus projects– to improve the process of designing the learning and also the implementation of the planned activities. The template used to describe collaboratively a learning plan before starting with the implementation of the learning activities constitutes an example of this. With regard to the technological platform to support the learning spaces, the experiences have shown that is recommendable to combine OIKODOMOS Work-spaces with social web tools which enable a more informal, personal communication between learners.

Concerning the design of a learning space, identifying the learning outcomes right at the start of the learning design process continues being difficult for most teachers in architecture schools. However, learning outcomes should be a constituent part of the learning design process. Besides, the joint evaluation of the students' works by teachers from different institutions can only be done after agreeing on a common rubric.

The implementation of the different learning spaces has demonstrated that it is necessary for the teachers involved in a collaborative learning process to maintain a fluent and constant communication during the whole period of implementation. It is fundamental to agree first on the communication channels to use (email, Twitter, Facebook groups, news board of the Workspaces environment) in order to keep the conversation alive during the whole process. These channels can be manifold. In this regard, the role of the learning space coordinator is fundamental for the success of the shared learning activities. The coordinator should undertake the task of maintaining the consistency of the common work, to keep all participants – teachers and students – informed throughout the whole process, and to highlight the value of what is being achieved.

With regard to the flow of activities being executed by multiple partners in a distributed manner, it is necessary to keep track of their progress summarizing at specific points during the learning process what has been achieved so far, in a way that it can be easily understandable to the learners involved and also to other interested partners – inside and outside the OIKONET network. This can be achieved by releasing regular reports, describing the stages of the learning process, illustrated with works of the students. Such summaries are useful to get a quick overview of what is being done in a learning space.

The work done in a learning space – the learning structure of activities and tasks, the resources collected and the works done by students – is a valuable learning resource which can be exploited later by other schools participating in the OIKONET network. On the other hand, a continuous aggregation of new learning activities and tasks can eventually undermine the coherence of a learning structure to the point the overall work might become unintelligible to later users. To avoid this, it is recommended to create subsequent editions of learning spaces in OIKODOMOS Workspaces, creating each time a new learning structure adapted to the needs of the new user.

ACKNOWLEDGEMENTS

OIKONET is an Erasmus Networks project cofinanced by the Executive Agency Education, Audiovisual and Culture Executive of the European Union with the project number 539369-LLP-1-2013-ES-ERASMUS-ENW. We would like to thank our project partners who have contributed to the work reported in this paper.

Trouble in Happy Valley.
The documentation of a research through design collaborative project between a postgraduate Atelier at the Manchester School of Architecture and the local community of a small town

S. Stone & L. Sanderson
Manchester School of Architecture, Manchester, UK

ABSTRACT: Places are defined by the people who live within them. As individuals and communities, deep significance is attached to familiar places, and complex relationships can develop between the residents and the place that they inhabit. This quality is present in the nature of the buildings and the streets, It is often generated by the ordinary actions of local people, many of who believe that their identity is essentially tied to the place that they occupy. This local distinctiveness is characterized by the activities that occur within the specific environment. Thus significant markers are formed, in both the present and in the past, which will allow a society to relate to a particular environment. Events that hold value in a community are often manifested in physical form, and therefore allow a population to trace back meanings and connections with their past. This organisation of the past seems to stimulate social cohesion and the feeling of being part of a community, and so, physical links with the past are often important elements within the cohesion of a community.

1 INTRODUCTION

Neighbourhood planning is a highly controversial policy. It was part of the Localism Bill introduced by the British Government in 2011. The policy shifted the responsibility for the decisions about the size, shape and location of neighbourhood development from central to local government. Communities are now asked to decide upon the nature and character of their particular district and actively participate in decisions about future developments. In theory this should be a positive move and quite straightforward; the UK has a housing shortage and rather than a top-down imposition of new properties, the bill allows local people to decide upon their own development strategy. However, well-meaning residents who have little or no training in planning, or skills in urban and rural development are making decisions too quickly without sufficient consultation or knowledge. This means that residential developers have been able to buy up packages of land and develop areas of the greenbelt and other bits of countryside that had so far been unavailable to them. More appropriate brownfield sites are often overlooked in the need to act swiftly and decisively and developments are not always the ones that the community really needs.

Bollington, known locally as Happy Valley, is a small post-industrial town in Cheshire in the North West of England, just within commuter distance of Manchester. It is a town defined by its topography; with heroic remnants of the Industrial Revolution such as the canal and the railway, contrasting with a calmer and more picturesque local vernacular of cottage, terraces, garrets and greens. Despite the remnants and detritus of warehouses and factories, it is an attractive and desirable place to live. The town council has already approved a number of substantial new-home developments, despite the fact that their Neighbourhood Plan is not yet in place, indeed, the discussion has hardly even started.

Continuity in Architecture is a postgraduate atelier, which has been established at the Manchester School of Architecture for more than 20 years. The atelier runs programmes for the design of new buildings and public spaces within the existing urban environment. The emphasis is on the importance of place and the idea that design of architecture can be influenced by the experience and analysis of particular situations. This interpretation of place can provide a contemporary layer of built meaning within the continuity of the evolving town or city.

The Bollington Neighbourhood Planning committee approached Continuity in Architecture to jointly develop a plan for the town that would sustain the place for the foreseeable future, that would allow the town to grow without losing its inherent character and would facilitate a future for all of the residents, not just those who can afford to live there. This partnership will develop a masterplan for Bollington, it will identify areas that appropriate development can take

place, propose designs for new buildings, suggest the redevelopment of existing structures and recommend areas for public space.

2 COMMUNITY

One of the fundamental characteristics of our post-modern society is democratic modernism and the rise of individualism. A new form of interconnectedness has arisen, one which bypasses normal state control and therefore operates despite of, rather than because of existing regulations. Advances in communications, information and transport technologies have facilitated a revolution in the global flow of objects, information and people. This has led to a pluralism of world-view, expansion of individual choice and a liberation of lifestyle (Gallent and Robinson, 2013: 10). This suggests that the global diffusion of culture and identity is incompatible with the traditional structures of the post-war period, which has inevitably led to a more diverse and separated patterns of sociability. This has prompted a questioning of traditional forms of authority, and conventional ideas of citizenship, social contact and allegiance.

A consequence of this individualism is a substantial rise in the number of community and interest groups, each with their own agendas and priorities. Traditional government, in which policy is formed by experts and administered by state officials, is increasingly being challenged. Within the UK, this movement was recognised as early as the beginning of the 1980s, when the rightwing Conservative administration led by Margaret Thatcher sought to confine the role of central government to strategic direction, while public policy formation and implementation were delegated to autonomous agencies. Since then, this policy of reform that challenges the basic principle of top-down governance, and promotes the devolution of responsibility for decision making away from the centre, has been a key aspect of all UK governments, including the Leftwing (New) Labour government, middle ground Conservative-Liberal Coalition and the rightwing Conservative only administration. (It should be noted that this policy of devolution is not only restricted to the UK, it is an international movement, but this paper is particularly focussed upon the UK and will therefore not discuss the international aspects of devolution).

Over the last generation the structures of community representation have been actively promoted through a series of Local Government Acts, which advanced community representation, especially that of parish councils. National housing delivery targets had been set and the advocacy of the "small state" at the beginning of the second decade of the twenty-first century paved the way for the formation of Localism. The intention of the Localism agenda is to empower local people to control developments within their own neighbourhood. That is, for (unpaid) community groups to work with local government and trained planners upon a strategic plan for their immediate neighbourhood. The existing planning system helps decide what gets built, and where and when it happens, it is essential for supporting economic growth, improving people's quality of life, and protecting the natural environment. The purpose of the Localism Bill is to formulate effective planning, widen ownership of the process, create a broad agreement around development decisions, and ensure the avoidance or prevention of major conflict. The National Planning Policy Framework for England describe the Neighbourhood Plan thus:

> "Neighbourhood planning gives communities direct power to develop a shared vision for their neighbourhood and shape the development and growth of their local area. They are able to choose where they want new homes, shops and offices to be built, have their say on what those new buildings should look like and what infrastructure should be provided, and grant planning permission for the new buildings they want to see go ahead." (National Planning Policy, 2012: Online).

The Localism Act 2011, along with associated regulations, lays out all the processes for preparing and putting in place neighbourhood planning tools. This includes three separate tools; Neighbourhood Development Plans (NDPs), Neighbourhood Development Orders (NDOs) and Community Right to Build Orders. Neighbourhood Development Plans are policy documents (like local plans), which could include policies on where and what kind of development will be allowed in the parish or neighbourhood area. Neighbourhood Development Orders can grant planning permission for a particular type of development, for example housing, on a particular site. Community Right to Build Orders are a special type of Neighbourhood Development Order.

The Neighbourhood Plan is formulated by a number of different groups; each with their own different interests and concerns, but who have come together to forge a new future for their own immediate locality. The intention is to put power in the hands of local residents, employees and business, councils and civic leaders; that is those who know best the needs of their local areas. Neighbourhood planning is optional, not compulsory, and importantly the members are not elected; anyone who lives or works in the in the area can join, simply by turning up, although there is a minimum of 21 members. The community groups are generally self-selected, made up of interested and concerned individuals who genuinely feel that they need to protect or that they can make a contribution to a plan for their neighbourhood.

Neighbourhood planning is occasionally referred to a community-based planning, and although it may be a better description of the process, it is not generally used. Various community groups working together may develop the plan as a shared activity, however it is the location of the activity at a particular geographical scale that defines the title, however uncertain the actual parameters of the neighbourhood are.

There are strict guidelines for how the Neighbourhood planning forum must operate. These were laid out in: Neighbourhood Plans, a Blueprint for Devolution and Local Democracy (Jellinek, 2014: Online) as follows:

1. Each forum picks its own members, sets its own area and writes its own constitution. Membership has to represent the character of the area, for example, balancing business and resident representation and geographical spread.
2. The forum will engage with the local community, assemble relevant evidence and write a development plan.
3. The development plan must: align with European, national and local policy, it must plan for sustainable development, and importantly, it must not be excessively static
4. A national programme offers support from consultants such as highway engineers, health experts and planning officials who can help translate intentions into policy.

Neighbourhood Planning certainly enables communities to play a much stronger role in shaping the areas in which they live and work and in supporting new development proposals. It provides an opportunity for communities to set out a positive vision for how they want their community to develop over the next ten, fifteen, twenty years in ways that meet identified local need and make sense for local people. To encourage the community to engage with the project, they will receive 25% of the revenues from the Community Infrastructure Levy arising from the development that takes place in their area, and the use of these funds should reflect the priorities which were formally set out in the neighbourhood plan.

Of course there are many potential problems with this system and at every stage of the process. Untrained but enthusiastic people who want something specific, which may or may not benefit the whole community could be seen as a recipe for disaster, or it could be that they are so perfectly positioned to understand exactly what the needs of the neighbourhood are that a genuinely productive and responsive solution is created.

Problems that could occur and complex and unprecedented. Will sufficient local people actually engage with the project? The group may not agree upon a unified approach, or more than one group will emerge, each putting forward a proposal for a particular area. Somewhat self-interested business people could group together to bring forward some schemes for commercial development which may give rise to objections from residential occupiers of that part of the neighbourhood. Once the consultations with locals and with experts have taken place, and the proposals for the development of the neighbourhood developed, the plans still could be rejected, for instance, in Slaugham in Sussex, it was deemed not to have taken sufficient account of EU environmental rules, and had insufficient evidence that its housing targets could be met.

In legislative terms, Neighbourhood Planning is still in its infancy. There is very little research into its effectiveness and pitfalls are not being well evidenced, documented or mitigated against. Most importantly perhaps, there is a limited supply of assistance available. Funds (£50m) have been made accessible by the government for local planning authorities to help local groups through the process, but what happens when this is all gone? The local council may reject the proposals created by the group outright, would this undermine the whole process and of course, the biggest concern for any architect, planner or designer is how can such decisions about the future of the built environment be devolved to people with no training and possibly no aptitude for it?

3 CONTEXT

The Industrial Revolution established Bollington as one of the most prominent cotton manufacturing communities in the north of England. Until the late 18th century, the town activities were broadly rural with a focus on sheep farming, wood cutting, stone cutting and surface coal mining. However, the town was ideally positioned to become an important actor in the rapid industrial development that spread across the north-west of England. The town grew fast and was dramatically altered, beginning in about 1760 with the construction of the first of a series of cotton mills. These were powered by the River Dean and located at the lowest parts of the town.

> "Once someone decided to build a mill there was a need for stone with which to construct it, so quarries were opened up. Mills and quarries needed labour so cottages were built and roads laid out. Homes needed warmth so coal mining developed. All of these facets of urbanisation required trade skills - shopkeepers, butchers, brewers, publicans, liverymen, farriers, carters, churchmen, cordwainers, cloggers, dressmakers, hatters, and so on. Very soon an entirely urban community was developed being provisioned by the surrounding rural community." (Bollington Civic Society History Group, 2015: Online)

Advances in industrialisation meant that the river soon proved to be insufficient, and therefore in 1831 a canal was constructed in an elevated position above the expanding town. This necessitated the construction of a number of stone aqueducts which served the larger coal powered mills. This split topography of a town generated by the river and then above that the high level canal is one of the distinguishing features of Bollington; the drama of which was further enhanced in 1870 by the introduction of the Macclesfield, Bollington and Marple Railway. This runs from south to north on a series of high level viaducts.

Workers lived below this massive infrastructure in stone terraces often built with shared yard spaces to the rear. The mill owners and middle classes

occupied larger cottages and semi detached stone houses. Houses were modest but well built, benefitting from the close proximity of a number of quarries, mining Kerridge Stone from the nearby area.

In a story common to most of the Western World, in the 1950's the town began a long slow decline; the textile industry faded, work and commercial activity dwindled and the rise of private transport and out of town shopping centres attracted residents to other areas (Bollington Civic Society History Group, 2015: Online). The Beeching Cuts of 1963 which saw a notable reduction in rail provision in Great Britain, caused the closure of the Bollington railway in 1971, just 101 years after its arrival. Sometime later this high level viaduct was transformed into a recreational path, now called the Middlewood Way. The mill buildings slowly closed and although the majority are still empty, some were demolished and a few have been converted for such uses as apartments, independent retail and a gym.

> The aqueduct is man's design
> A tower of strength to Bollington
> A Herculean labour
> Completed eighteen thirty one
> The advent of the speedy train
> Soon replaced the silent waters
> Whose short life was terminated
> Like a lamb led to the slaughter
> (The Aqueduct 1831. Broster, 1973: 45)

The rapid expansion of the town caused it to grow in an unnatural manner, it contains no distinct centre and the axial road effectively divides the town in two. However, despite this uncomfortable urban organisation and the remnants and detritus of warehouses and factories, Bollington in the present day is seen as an attractive and desirable place to live. With this in mind, housing is almost certainly the biggest challenge to be faced by Bollington and as such has been the driving force behind the development of a Neighbourhood Plan.

4 CONTINUITY

The college of Continuity in Architecture (CiA) at the Manchester School of Architecture was established in 1994. It is a post-graduate studio for teaching and research. The attitude that CiA take towards architecture has its roots in Contextualism. This is an approach to the design of the urban environment that uses the process of analysing and understanding the nature and the qualities of place to develop new elements. CiA believe that it is the responsibility of the architect to work with the identity of a place, to create architecture that is appropriate to its location and does not destroy the character of an area.

Contextualism emerged as a reaction to Modernism and now, more than a generation old, t it is more relevant than ever. Our post-modern society has the need to embrace ideas of memory and experience and this means that Contextualism is at the forefront of theories about contemporary architecture, urban design and interior design. The use and re-use of an architectural site creates a direct connection with the past. It is a strategy that establishes an explicit relationship with history, not just with the site, the building and its immediate surroundings, but also with the society that constructed it. The reading of a building or site can uncover a layered and stratified narrative and the understanding of the inherent qualities and conditions of building or site can provide clues to the redesign of the place. It is through a thorough knowledge and understanding of the existing condition that the architect or designer can uncover the meaning within a place. This knowledge can be used to activate, liberate and instigate a new future for the building. And so the architect or designer who is to develop a new strategy for an urban environment, or design a collection of new structures or even modify, transform or change an existing building to accommodate a new use has to adhere not just of the agenda of the new users, but also the intentions of the original place. This act of modification is part of the evolution of the site, it as another layer in the archaeology of the situation.

For over twenty years, CiA has been promoting a particular approach to the development of architectural solutions, one with profound integrity and which is contextual, expressive, and environmentally appropriate. Modesty and cooperation are emphasised and as such, the atelier encourages a response that does not generate a gratuitously flamboyant or overtly iconcentric solution or attitude, but instead advocates an approach that embraces a close and sensitive contextual reading of place. Building during any period of history represents a significant commitment of human, material and financial resources. The most successful cities have adapted urban patterns and buildings to uses never imagined by their original creators. CiA are inspired by the efforts of architects working within existing structures and urban fabric to produce a responsive architecture of narrative, space, intervention, and detail. Through both theories and the example of architects engaged in critical practice, the aim is to show that the ideas and methods examined within the postgraduate studio have real applications.

5 COLLABORATION

In November 2014 Cheshire East Council agreed to support the production of a Neighbourhood Plan for Bollington thus providing the local community with more control over the future developments in the town. Headed up by Professor Michael Burdekin and Councillor Amanda Stott, the decision came in the wake of the National Housing Crisis with a series of houses allocated to each area of the UK. The committee included key residents: retired Conservation Officer Sandra Edwards, Councillor Ken Edwards and Town Clerk David Naylor.

A few months after the committee formed, recently qualified Architect and CiA Alumni, Peter Millburn-Brown moved to the area and saw an opportunity to

connect the process to architectural education, linking back to similar contextualised projects undertaken in his own postgraduate studies. This partnership were tasked with the development of a masterplan for Bollington, the identification of areas of appropriate development, propositions for new buildings, suggestions for the redevelopment of existing structures, and recommendations for areas of public space.

Over recent years the population in Bollington has been steadily rising (Bollington Civic Society History Group, 2015: Online) which created the need for a number of new developments in the area which have, to date, been designed in a disconnected and haphazard fashion without a wider plan of the area being considered. The loss of the mills and other large industrial buildings has provided the town with a number of notable building plots which have been bought by housing developers (e.g. Bellway Homes). These have been somewhat unsympathetically developed as semi detached family homes.

Interestingly there is some controversy around the number of new houses which have been designated to be constructed the local area; Cheshire East Council have stipulated a quota of 300 new houses (within the UK there is insufficient housing, and each local authority is tasked with making a contribution towards the 240,000 new houses per-year target set out by the 2007 Labour government). Since 2010 there have been 172 houses constructed in Bollington, including the 86 located in Clarence Mill, but it is unknown whether these are included within the original quota. A further 48 houses are awaiting Planning Approval, thus it appears that there is a shortfall of 80 units. However, no further clarification has been offered as to the date when the 300 houses were designated so the exact number, somewhere between 80 and 300, is unknown.

Numbers aside, there is an inherent question of type. Affordable housing is certainly a priority for Bollington, this will allow families to grow without having to move from the local area. Building houses affordably is a challenge to any potential developer on the complicated brownfield sites that are available, with drastic topography, flood risk zones, listed structures and conservation areas. Solutions need to be well considered and thoughtful to their surroundings. Conventional solutions of "cookie cutter housing" may not be the answer.

Until recently Bollington did not attract commuters – it does not have a train station and the journey by car is just too long to be comfortable, but this is changing as house prices in other areas rise. With this in mind it is very much a self-sustaining town with residents who are proactive and passionate about their home. Apart from the approval of two substantial housing developments in 2014, the majority of planning applications in recent years have been met with overwhelming numbers of objections.

However, the town cannot remain frozen as the demands for additional housing will cause an inevitable rise in population; new homes will be required, as possibly will new schools, shops, workplaces and recreational space.

To be successful, the Neighbourhood Plan for Bollington would need to address not only the parcels of land available for development but the type, design, layout and quality of the buildings themselves. One of the biggest difficulties is developing a plan which can act as a design guide without restricting the opportunities for the more unique or perhaps even heroic developments which have come to define the town.

The inclusion of live agendas, such as this one, within architectural education have been increasing in popularity in recent years and this is in contrast with the tendency since the early part of the twentieth century for architectural education to be 'product' orientated most commonly concerning a traditional design brief to create a given building on a given site (Bishop, 1997: 87). This adjustment reflects the changing nature of the profession. One of the key advantages of this Problem Based Leaning (PBL) approach is the development of employability and life long learning skills which begin to set the context for a lifetime of continued professional development both formal and informal. The job of an architect requires both architectural design skills alongside the ability to analyse, organise, collaborate and communicate ideas; that is to solve problems. Within architectural education there has been a inclination to create a simulated setting which allows a students to show off the full range of drafting and design skills but not necessarily the additional skills required to deal with a real life problem.

> "Much design education is very remote and esoteric and even where design work has a 'real life' context there is a tendency to 'tailor' the design brief, often for valid educational reasons, in order that the creativity of the student is not limited by the reality of the context of the design problem." (Bishop, 1997: 87).

CiA was determined that the students would have the opportunity to react to the live context of the Neighbourhood Plan, while also taking into consideration the wider context of the town. This had advantages to both the atelier and the committee. The atelier could look at the problem outside of the restrictive framework set by national legislation and test ideas more freely, meeting wider curricular objectives but also bringing a new way of looking at the situation. Experience has shown that Neighbourhood Planning is a lengthy process requiring a number of layers of consultation, while the committee were bound by these timeframes, the atelier could be more responsive and also more creative, using drawings, models and interventions to investigate the area in a different way.

Work began in September 2015, and the academic-year-long studio project was broadly split into four parts: Interrogating, Intervening, Planning and Realisation. Each project resulted in outputs that were exhibited in Bollington.

'Interrogating' saw the production of a book which collected together initial research and subsequent

analysis of Bollington. The cohort of students were divided into overlapping groups and each were to examine something specific; Town Evolution (historic maps, historic narrative, key figures), Buildings (typology studies, elevation studies, key building analysis), Topography (site sections, site models), and Geography (climate, population, flora, occupation, activities). When all information was collected, the groups saw patterns emerging and split all research into two distinct categories: Heroic Remnants (Geology, Mills, River, Canal, Railway, Cotton, White Nancy) and Slow Vernacular (Houses, Doors, Windows, Churches, Persistence, Growth, Population, Territories, Townscape). After a series of weeks a book emerged: Oddments and Epigrams: An Intimate Interrogation of Bollington.

The second project asked the students to create a temporary solution to a site-specific problem in Bollington. Misselwitz, Oswalt and Overmeyer, who looked specifically at ephemeral projects in Belin developed 'two main hypotheses: 1 – spontaneous, temporary uses can have positive long term effects; and 2 – the unplanned phenomena of temporary uses can be successfully incorporated into the planning and management of cities.' (2013: 273). In collaboration with the local community, students worked on six proposals for interventions which were then either built, modelled or tested in the town.

Each proposition was designed to connect to the earlier research of Bollington and acted as a method of engaging with the local community in the wider objectives of the Neighbourhood Plan. The ideas were diverse and bold; one student used mirrors to reflect the heroic elements of the town back to the everyday lives of its residents, another explored materiality by casting and installing a concave golden stone, a third student used light to redefine the ruin of Ingersley Vale Mill. Others used techniques local to the area, one creating a kinetic machine driven by the River Dean, and another using the process of engraving on velvet called devore to create a panel imprinted with the elevation of the Clarence Mill. Finally, there was a project to reinstate the interior lining of the monument White Nancy into an end terrace house. All ideas were collated in an exhibition in Bollington Arts Centre in January 2016 where the local community began to discuss and comment more broadly on the way they saw the town develop.

This was a precursor to a much more serious project entitled 'Planning'. The students worked with an urban planning specialist from Think Place and through a series of design workshops built upon the knowledge of the town and developed a series of strengths, weaknesses, opportunities and threats for six key areas of the town. These were: Movement, History and Heritage, Townscape, Sport and Culture, Landscape and Economy.

> "Designers don't create communities. Design, however, if done badly can fragment communities and isolate people. If done well, it can bring people together, allow neighbours to bump in to each other, children to play safely and for the gradual shaping of a place over time by its people." (Think Place, 2006: Online)

A proposal for the town was developed which highlighted a number of potential sites in Bollington. Looking beyond these sites as pockets of empty space, the workshop aimed to determine buildings, structures and landscapes which had the opportunity for development as well as traditionally conceived development plots. Working momentarily outside of the Neighbourhood Planning Legislation allowed students to make big marks in the town, to undo previous developments and consider the ideal situation. Through dialogue with the local community this plan will evolve further, it will question how the town might develop in the near future and what type of developments should be sought.

As the project reaches its final stage, the atelier is working in three groups on the 'Realisation' phase of works, one highlighting the Civic Centre of Bollington, one focussing on the Recreational Centre of Bollington and one looking at the Industrial Centre of Bollington. Each group are tasked with developing a series of sites to be used for a mixture of community, commercial and residential uses. A minimum of 80 houses are to designed across the town as part of the process, these will be supported with a series of car parking spaces in line with the objectives of the overarching Neighbourhood Plan. The buildings are to be presented in a further exhibition in Bollington in May 2016 alongside the Policy Documentation for the Neighbourhood Plan. This joint exhibition aims to provide residents with a collective vision for the future of the town.

6 CONCLUSION

> "Obviously some middle ground is needed. To retreat to a hopelessly artificial past is unrealistic, but to allow a brutalizing system to dominate and destroy traditional urbanism is irresponsible." (Schumacher, 1971: 79)

Places are defined by the people who live within them. As they grow and change to meet the new demands of the community that inhabits them, layers of meaning and memory must be 're-read, re-analysed, and re-worked' (Boyer, 1996: 322).

Neighbourhood Planning will continue to create controversy at both a local and a national level as the power to decide upon the future of places is transferred to the local community. This devolution has the very positive potential to engage local people in the decisions that are made about their homes, as they are the ones who know the location the best and they are the ones who will have to live with the consequences of any decisions made. However, this also has the danger of opening up large parcels of land to profit hungry developers in a bid meet the target number of new homes set by national government. Commercial players on Neighbourhood Planning Committees

often outnumber well-meaning residents, who with little or no training in planning, or skills in urban and rural development are at risk of making decisions too quickly without sufficient consultation or knowledge.

In Bollington, by thinking collaboratively, this project has helped empower local people to contribute towards the future of their own town. It has provided the settlement with a plan that is suited to their needs, because it is based upon a thorough examination of the place itself. The analysis and understanding of the existing situation plus the identification of suitable areas for development combined with the design of proposals for new buildings, all of which was generated by the by the students has provided the community of the town with the knowledge to act in an emboldened and informed manner.

Through engagement with the over arching curriculum within architectural education, the project bought together local residents and students from the Manchester School of Architecture with mutual benefit to both the future of the small town of Bollington and the educational objectives of the atelier Continuity in Architecture. It is in this context that the student becomes aware of their role in the 'public understanding of the process of design and construction which requires the student to step outside the protected environment of the school of architecture and communicate both orally and visually, in the context of peoples lives' (Bishop, 1997: 87).

The Neighbourhood Plan Collaboration for Bollington will be completed this academic year and will be documented in the production of a final plan and series of notional building designs. This project takes the Neighbourhood Plan beyond what is normally expected. The general public have been able to comment on ideas because they have been visualised through the generation of real proposals depicted by drawings and models, are therefore easily accessible. An exhibition scheduled for May 2016 and a series of public meetings will advance the dialogue and engagement, which will further enhance the plan for Bollington, this will hopefully provoke great discussion within the town. Although these buildings are entirely hypothetical, they open up a conversation with the local community about the type of architecture that might be fitting for Bollington. It will be an architecture based upon an informed opinion of the place. The project should be viewed as an example of best practice in Neighbourhood Planning and will disseminated further at both a local and national level.

Ethics in architecture: Introducing concepts of power and empowerment

Alexandra Staub
The Pennsylvania State University, USA

ABSTRACT: This article analyzes the results of a broad-scale process of teaching ethics in architecture to both professional and research-based master's students at a major U.S. university. Redefining ethics as a question of both power and empowerment (or agency), classical frameworks such as Immanuel Kant's categorical imperative or Jeremy Bentham's utilitarianism are re-cast as a framework of power discrepancies that can be addressed using negotiation strategies. Using examples taken from both professional practice and areas of current architectural research, students are asked to identify stakeholders and their values and interests, and then insert themselves into the framework as mediators in search of ethically responsive outcomes. This approach has allowed the perceived ethical neutrality of both design and research problem statements to be called into question, as students explore an enhanced role as professionals and researchers in relating problem statements to outcomes, and outcomes to broad stakeholder satisfaction.

1 ETHICS IN ARCHITECTURE

1.1 *The legal view of morality*

Little has been written specifically on architectural ethics, and what is available has generally taken one of three approaches. The first, and oldest, of these presents ethics through the lens of professional practice. From early times, architects and builders have been seen as upholders of human welfare, and social codes regulating their activities were an expression of moral values canonized through laws. The Mesopotamian Code of Hammurabi, written in 1754 B.C., laid out punishments for professional negligence or incompetence, stipulating for example that the builder of a structure that collapsed and killed its occupant would likewise be put to death (cited in Ching and Winkel 2012, 2).

Current laws governing architects' behavior are less drastic, as licensure has sought to insure professional competency, while building codes ensure a structure's safety. In the United States, professional ethics are now largely defined as normed behavior between individuals involved in or affected by the building process. Both the leading national professional association and the national licensure board have developed edicts to this effect: the American Institute of Architects (AIA) has published a *Code of Ethics* and the National Council of Architectural Registration Boards (NCARB) a *Rules of Conduct*. Both texts approach their subject largely from the point of view of contractual law and thus use a fairly limited scope in defining architectural ethics.

Going beyond these legal-based rules to examine social and moral issues such as discriminatory practices and the right of the community to determine what gets built in its midst, Thomas Fisher's book, *Ethics for Architects* (2010) presents a series of hypothetical case studies taken from the point of view of today's architectural practice. Fisher's book offers illustrative examples that go beyond what is covered by the AIA and NCARB documents, covering issues such as respect for community values or avoiding discrimination based on gender or disability. Barry Wasserman, Patrick Sullivan and Gregory Palermo's tripartite book *Ethics and the Practice of Architecture* offers a broader approach, introducing ethical "awareness", before moving to "understanding" and then presenting "choices". The first section introduces the ethical nature of architecture and defines philosophical contexts and theories; the second section more selectively applies these concepts to the architectural process, and the third supplies textbook cases to be used in the classroom. The goal is to help students develop their "ethical stance and reasoning processes" in their role as professional architects (Wasserman, Sullivan and Palermo 2000, 180).

Langdon Winner's 1980 article, "Do artifacts have politics," provides a critical voice, exploring ethics in terms of systems and decision-making processes, or rather, how technical systems have a political dimension. Examining how the creation of artifacts has effects and repercussions that an ethical analysis must take into account, Winner lists examples such as Robert Moses's decision in the 1930s to build overpass bridges spanning the Long Island Parkways, which connected the city of New York with Long Island towns and recreational areas, with such a low clearance that busses could not pass through (Figure 1). The bridges kept the working class, who did not own private automobiles and thus relied on busses, from accessing Long Island's acclaimed public beaches. The bridges themselves appeared as neutral objects of civil engineering, yet their low clearance allowed them to

Figure 1. Low overpass bridges on Long Island Parkways prevented low-income residents relying on bus transportation from accessing Long Island's recreational areas. Photo courtesy NYC Municipal Archives.

become political pawns. In another set of examples, Winner points out that technologies used to maintain public infrastructure – for example that of nuclear power plants – requires a corresponding hierarchical political system, in this case a set of industrial and scientific elites trained to run them.

1.2 *Ethics and aesthetics*

A second area of discussion regarding architectural ethics approaches the topic from the point of view of aesthetics. In this body of literature, the architect is seen as an upholder of social welfare in the broader sense, creating a built environment that is to bring greater social happiness through expressing deeper thinking regarding the condition of life itself. The tenets of material honesty and structural and spatial transparency at the heart of modernism, or the social commentary expressed by the postwar Brutalist movement, are two cases in point. Texts are often based in philosophy, such as Karsten Harries's 1997 book *The Ethical Function of Architecture,* which discusses the uncertain path of contemporary architecture as a reflection on Siegfried Gideon's classic treatise that architecture should express "a way of life valid for our period" (Gideon 1967, xxxiii). Discussions of ethics as related to aesthetics remain the most intensely theoretical of the three approaches to ethics and, as we shall see, the most open to controversy over what is "right" and proper for a given society made up of individuals with differing needs.

1.3 *Ethics and ecology*

A more current direction that has become part of the debate on architectural ethics involves the ecology of our planet, and the role of architecture in our plant's future. In the United States, buildings have been shown to account for almost 40% of carbon emissions as well as 70% of the nation's electrical consumption (Green Building Council 2016). Architects are reminded of the essential role they can play in reducing energy use both in the construction process and post occupancy phases, a role that focuses on efforts to increase the common good. Books such as Warwick Fox's edited volume on *Ethics and the Built Environment* (2012) have pushed such considerations to the forefront as they explore the ethical nature of sustainable design.

1.4 *Ethics and the greater good*

All three approaches – professional ethics, the ethics of aesthetics, and ethics linked to environmental stewardship – can be seen as derived from ethical principles as defined by philosophers, principles that have in common their ideals of justice as well as action for the greater good. While many philosophers have written on what we might call ethics, I focused on two concepts that I felt were most useful for the focus of the class: Immanuel Kant's idea of the *categorical imperative*, and Jeremy Bentham's universalism. Kant stipulates that one should, "act only according to that maxim whereby you can, at the same time, will that it should become a universal law," (Kant 1785/1993). With this phrase, Kant postulates that an action is only morally right for one if it is morally right for all. Jeremy Bentham frames the ideal of social justice a bit differently. In his theory of *universalism* he instructs us to maximize pleasure and happiness and minimize pain and unhappiness for the greatest number of people; the profit of a few may not outweigh the good of the many (Bentham 1789/1988). This theorem can be amended to consider the degree of unhappiness a minority group may suffer – if maximizing happiness for most would create a situation in which a minority is truly miserable, the rules of universalism must be adjusted. Both the categorical imperative and universalism can be seen in contrast to social contract theory (Jean-Jacques Rousseau and others), in which individuals forfeit some of their liberties to the state, or Aristotle's *virtue ethics*, which stresses the moral character of the decision maker. Here, universal principles governing decision-making are less important than a pedagogical approach leading to self-regulation: the training and instilling of a proper, or virtuous, set of values (Aristotle and Barnes 2004). Aristotle's concept of an internalized virtuousness is not unique of course; non-Western philosophies, such as Confucianism, follow similar ideals.

What philosophical ethics deals with in the abstract, and professional ethics largely ignores, is a broad set of ethical questions that architects and architectural researchers have become deeply enmeshed in but rarely discuss: the role of the practicing architect and the researcher in shaping architectural, and with it social, discourse.

In professional practice, building designs, building placement, landscape and infrastructure, building

materials, office organization and the construction process itself all involve both process and product decisions that involve the architect. In most cases, the ethical dimensions of such decisions remain unexamined.

For the architectural researcher, discussions of ethical considerations remain equally limited. Ethical questions are often covered through institutional review boards, which oversee research designs and guarantee that human or animal subjects suffer no physical or psychological harm. Research questions themselves are thus largely seen as ethically neutral. Unearthing new knowledge and developing new concepts has become the measure of success, with little regard to choosing one's questions based on some sort of ethical construct. A longer-range historical view shows the fallacy of such valuation, however, since what is *not* asked is often as telling as what is pursued, or put another way, questions, like artifacts, "have politics". This recognition has led to changes in the research landscape; for example, research of the past two decades has questioned earlier interpretations of architecture and urban planning and analysis as written from the point of view of white, middle-class males, and has countered existing theories with new ways to frame questions and offer theories of space (see for example Colomina 1992, Massey 1994, Sandercock 1998).

2 REFRAMING THE ETHICAL PARADIGM

In the course "Architectural Ethics" offered as part of Penn State University's graduate program in architecture, I propose a new framework for architectural ethics, approaching the topic as a question of both power and empowerment. Put another way, I propose that it is power imbalances that create ethical dilemmas, and as architects and researchers concerned with ethics, we must become aware of who holds the power to act in any given situation, and why others might not share this power.

Students were asked to think of decisions concerning the built environment in terms of stakeholders. Stakeholders have interests in the outcome of decisions, but do not always have the power to act to their own benefit. It is when stakeholder groups become disempowered that ethical dilemmas often occur – when the categorical imperative is cast aside or when definitions of the "greatest good" become skewed. Fueling this tendency is a commonly held view that decisions must involve a zero-sum outcome: that allowing one group to gain must mean a loss for another. Breaking through this pattern of thinking became one of the main course objectives.

2.1 *The course methodology*

In order to gain practice in framing ethical dimensions in terms of power discrepancies and to find solutions for identified problems, I presented students with a series of readings and case studies and asked them to determine the set of stakeholders in any given situation. I then asked students to list what interests those stakeholders might have, as opposed to the positions they were expressing, in order to uncover common ground between stakeholders. Using this analysis of stakeholder interests, students then worked to develop options for mutual gain for all stakeholders, keeping Kant's categorical imperative and Bentham's concept of utilitarianism as reference points.

Students in the course are assigned just one textbook: Roger Fisher, William Ury, and Bruce Patton's book *Getting to Yes: Negotiating Agreement Without Giving In* (2011), a how-to guide written by three members of the Harvard Negotiation Project. The book allowed students to perform ethics analyses based on a simple concept for negotiation strategy: 1) Separate the people from the problem, in this case by identifying the stakeholders involved, 2) Identify each stakeholder's interests instead of simply accepting their stated positions on an issue 3) Develop a set of options for mutual gain, and 4) Identify objective criteria by which such options could be assessed. Student used these principles to work through the readings and case studies assigned.

The course is arranged topically, and covers diverse areas such as contested terrains based on race, ethnicity, religion, social class or gender, expressions of power through the built environment, specifically through spatial arrangements and the use of monumentality; ethics and aesthetics, the role of ethics in green architecture, the role of ethics in technical advances, specifically in computational design, and case studies taken from professional practice. In each situation analyzed, I asked students to consider ethical dilemmas as power discrepancies that could be addressed through negotiation strategy as outlined above.

The first case they were presented with was a 1975 dispute carried out in the New York Times between sociologist Herbert Gans and architecture critic Ada Louise Huxtable on how the Landmarks Preservation Commission of New York City should choose which buildings to preserve. The case, described in Dolores Hayden's book *The Power of Place: Urban Landscapes as Public History* (1997), saw Huxtable arguing that the Commission should focus on preserving major architectural monuments, while Gans countered that this preserved the architecture of the rich and the elite, while the built history of the common people was allowed to disappear. Countering Huxtable's point that "great buildings" designed by "great architects" exemplified public culture, Gans pointed out that the Commission was funded through taxpayer money and warned that while, "[p]rivate citizens are of course entitled to save their own past, […] when preservation becomes a public act, supported with public funds, it must attend to everyone's past," (cited in Hayden 1997, 3). To underscore his point that the Commission was not acting according to these values, Gans presented a quantitative analysis of the buildings the Commission had acted to preserve, most of which were, in fact, created for the affluent.

The students rightly saw this exchange as a failed attempt at negotiation, with each side digging into positional thinking. Huxtable and Gans were using terms such as "architecture", "vernacular", and "neighborhood" very differently, a point they both failed to recognize. Their positions were based on different valuations of these concepts: Huxtable saw vernacular architecture as buildings created by anonymous builders, which meant the building became defined by its general historic style, while Gans saw vernacular architecture as buildings with a wide social use or public accessibility. While to Huxtable the term "vernacular" lessened the historical value of the building, for Gans the term heightened value.

The students saw several stakeholders in this exchange. Gans and Huxtable were identified as two stakeholders whose verbal sparring, evolving from two incompatible positional arguments, was designed to influence the future of the Landmark Commission's activities. Students saw a power imbalance between Huxtable and Gans, noting that, "Huxtable [has] more power because […] Gans is the one who is trying to make a change from the [status quo]," (McKenna 2015), while also noting that when Gans seemed to be winning the argument through pointing out the ethics of using taxpayer money, Huxtable's employer – the New York Times – censored his rebuttal by shortening it and relegating it to an obscure section of the paper.

Despite the strong positions Huxtable and Gans adopted, students found common interests between the two, chief among them the desire to preserve the history of both the city and its built artifacts. Students also recognized that both wished to spend the Commission's money wisely, while satisfying the public, another identified stakeholder. Students suggested options for mutual gain (some already mentioned by Hayden), such as highlighting the role of workers in the construction and upkeep of buildings for the wealthy, or of presenting architectural monuments within the context of adjoining working-class neighborhoods. Such measures, they argued, would give a fuller picture of both the architectural significance and ensuing symbolism of the stately architecture as well as the "back story" context of how earlier societies created and used the built environment. Students pointed out that in this way monumental architecture could be preserved without stripping it of its social context, creating opportunities for more fully recognizing an earlier society's achievements and way of life.

2.2 *The topics of ethical practice and research*

Further cases the students analyzed were socially more complex. Joe Feagin's *Racist America* (2014) traced how the consequences of American slavery of the 18th and 19th centuries resonate to the present day, as the unpaid labor of slaves and the unequal opportunities under the physical segregation that followed its abolition caused inequalities of economic and social capital that have been compounded over the course of twenty generations. Chad Friedrich's film *The Pruitt Igoe Myth* (2011) provided a poignant example of this inequality. Examining the background to one of the most notorious failed housing projects in the United States, Friedrichs pointed out how – contrary to the common narrative that the architecture was somehow to blame – the de-facto segregation of low-income African Americans into the complex, the ensuing lack of investment in the project's infrastructure, social agencies' paternalistic rules for project residents, and poorly conceived financial plans for maintaining the project, led to its assured demise. *The Pruitt Igoe Myth* introduced two ethical dilemmas: treatment of a group of stakeholders on the one hand, and correct representation of historical events on the other. Madhuri Desai's article "Mosques, Temples, and Orientalists: Hegemonic Imaginations in Banaras" (2003) illuminated another example of misrepresented history, as a dominant Hindu society in India claimed the city of Banaras as a "Hindu pilgrimage city", in the process erasing any references to the substantial Moslem population that has resided there for centuries. Barbara Hooper's "'Split at the Roots': A Critique of the Philosophical and Political Sources of Modern Planning Doctrine" (1992) presented the mechanisms of women's exclusion from modern planning doctrine from the late nineteenth century onwards, while Beatriz Colomina's article "The Split Wall" (1992) pointed out how women, as a group, were presented as exotic "others" in the spatial arrangements of iconic modernist architecture. In all of these scenarios, students analyzed not only the cases themselves and how a dominant group exerted power over space and other resources, but also how such cases had been researched and presented in the form of a narrative controlled by the dominant group.

The emphasis on examining both an architectural or urban problem and its portrayal in the literature became a useful tool for understanding how narratives – including those the researcher contributes to or controls– affect a power matrix. Analyzing the underlying questions of power and agency showed that neither the artifacts created through the architect's labor, nor the questions and narrative of the researcher's work are neutral.

The course examined a range of topics related to the built environment. Simon Guy and Graham Farmer's exploration of "Contested Constructions: The competing logics of green buildings and ethics" (2012) opened an avenue towards understanding the debate around how the concept of "sustainability" is interpreted by different groups of stakeholders. Daniel Cardoso's article "Inertia of an Automated Utopia: Design Commodities and Authorial Agency 40 Years After the Architecture Machine" (2011) shed light on the early hopes for how design computing would make the built environment more humane by allowing users direct input over the product, and Lilli Irani's article on Amazon's mechanical Turk (2015) led to a lively debate about the role of humans and machines in rote tasks, and the ethics of allowing humans to perform repetitive

and machine-like functions as part of a profit-making system.

2.3 *Ethics have politics*

As one of the students pointed out, the political angle of the course readings was largely liberal. This resulted quite simply from the way the assignments were constructed: in placing an emphasis on identifying stakeholders' interests – no matter their conventionally perceived level of social importance – and attempting to find areas of mutual gain, I was following a narrative based largely on the value of social egalitarianism, rather than one based on more conservative values, such as merit or in-group loyalty. I had also not introduced social contract theory as a working philosophical framework because, based on my experience with feminist, race- and class-based theory, I did not believe that a process by which persons negotiate among themselves to shape society would necessarily yield morally valid results. To introduce students to an example of conservative thinking on ethics, I assigned an article by the economist Milton Friedman from 1970: "The Social Responsibility of Business is to Increase Its Profits," in which Friedman argues that a corporate CEO may not take social actions that could lessen the corporation's profits, since doing so would represent a from of shareholder "taxation" to which the CEO is not entitled. In developing his argument, Friedman pointed to the government's role as initiator of social action through democratically voted demand (a form of utilitarianism), and pointed out that a CEO would be usurping the government's role if he initiated – and had his shareholders pay for – social programs. The discussion that this article provoked in class showed the importance of considering value systems when analyzing ethical questions. Friedman assumed that a free market system incorporates the checks and balances needed for ethical behavior to remain the norm (a form of social contract). This belief was the basis for his call to consider the needs of those stakeholders best capable of performing under the "open and free competition" of Friedman's lauded meritocracy. With other words, Friedman argued that a market system created inequalities, and that these inequalities were justified. Having by now performed a series of analyses to present stakeholder interests and win-win options as part of a non zero-sum game, the students quickly realized a pattern that allowed the wants and needs of the have-nots to simply be canceled out of Friedman's social equation.

3 APPLYING ETHICAL THINKING

The final assignment for the course required the students to develop a case study based on their thesis topic. Students in both the professional and the research-based programs choose their own thesis topics, which range from highly technical projects to exploration of social issues. In the related ethics assignment, students identified stakeholders, analyzed stakeholder interests, and developed options for mutual gain, based on their analysis of the background issues associated with their thesis topic.

Figure 2. A proposal for a disused London underground station reconfigured as a public bicycle path. Photo ©Gensler.

Of the eight students in the class who were pursuing a professional degree, six centered their analysis on the urban contexts of their proposed building designs. One used David Harvey's matrix presented in *Social Justice and the City* (1973) as a basis for developing scenarios for disused London underground stations in a way that would benefit as many diverse stakeholder groups as possible (Figure 2). One created an analogy between the urban gentrification process and natural ecosystems, analyzing that changes at too large a scale in the urban fabric can have results, good or bad, similar to natural disasters in the wild such as a forest fire or flood, and arguing that as a rule, change should be more controlled. Another student questioned the "modernization" plans for a thriving community in Mumbai, concluding that stakeholder interests could be satisfied with far less radical interventions than were being planned. One student took a different path, looking at the stakeholders involved in end-of-life scenarios, and concluding that new types of spaces that cater to the dying and their families would serve those stakeholder groups better, while saving patients, hospitals and the health care system millions of dollars annually.

The five students pursuing a research-based degree largely focused on the interplay between architecture or urban spaces and policy decisions, many examining who controls urban space and how such control is presented to the population. One student examined how political parties in a major city in India make use of a waterfront park to erect monuments that, while presented as public recreational spaces, in reality use public funds to showcase the parties' own political agenda. Another student traced how a major park in Bogota, Colombia failed because the municipality and the architects neglected to acknowledge the presence of a large homeless and drug-using community that quickly took over the park's spaces, making them unattractive for the intended users (Figure 3). A further project analyzed the commercialization of public space in global cities through the presence of lit billboards occluding the buildings they cover, and

Figure 3. Tercer Milenio Park in Bogotá, Colombia. The park remains underused, due to social problems unrecognized by the planners. Photo by Pedro Felipe.

questioned the architect's role in this arrangement. In all cases, students learned to understand the process of creating spaces as something that involves a variety of stakeholders. They also came to understand how analyzing the power structures between stakeholders, as well as stakeholder's interests, can lead to a better understanding of what is needed for a successful, and ethical, design.

3.1 *Negotiating power structures*

In framing ethical problems as an issue of power discrepancies and questions of agency, students began understanding design problems as more than just a question of function, structure, cost or aesthetics – considerations they are commonly taught as part of an architectural education. Instead, students began to systematically consider the broader implication of design and planning decisions and how such decisions affect the built environment and the people it serves. Identifying stakeholders affected by design and planning decisions became a first step in assessing stakeholders' relative degrees of empowerment and stakeholders' ethical treatment. Analyzing stakeholders' interests moved the design problem beyond the creation of space and form, allowing students to consider how their own actions ripple beyond the architect's immediate set of tasks to encompass ethical questions they can address. Most importantly, teaching students negotiation strategies to achieve win-win options, and helping them to identify values and criteria by which such options could be evaluated, helped students to address conflicting interests between stakeholder groups as a quest for ethical solutions to architectural and urban design problems.

For students engaged in architectural research, expanding the search for stakeholders beyond those immediately touched on by the research problem allowed students to consider how stakeholder groups sometimes remain invisible, how such groups, once identified, can be empowered through providing information or through reframing the research question, and how exploring research problems as a quest for mutual gain allows far more wide-reaching research results than if results were geared towards a more limited or immediately accessible set of stakeholders. In both cases, identifying power imbalances, naming stakeholders and their interests, developing options for mutual gain, and evaluating those options based on a set of agreed-upon values and criteria led to an understanding of architectural ethics as central to architectural decision-making.

In search of meaningful interdisciplinary work in architectural education

T.R. Rider
North Carolina State University, Raleigh, North Carolina, USA

ABSTRACT: This paper assesses one promising approach to establishing interdisciplinary work in architectural education in the form of an interdisciplinary LEED Lab course, led by a partnership between the North Carolina State University (NCSU) School of Architecture and the NCSU University Facilities Division. The overarching goal of this course is to establish a method for interdisciplinary teamwork structures within the architectural curriculum, but outside of the studio setting. Example exercises for increasing meaningful partnerships between students of different disciplines are shared, with a review of how this type of course can address accreditation requirements. Future possibilities for research are presented.

1 INTRODUCTION

The process of architectural education is simultaneously uniform and diverse. While countries have established standards for accreditation, the emphasis of that education can vary quite a bit and range from an emphasis on history, to urban planning, to building science, to theory, and more. One thing that is historically common among these veins, however, is the difficulty in providing meaningful interdisciplinary experiences to the architecture students.

Interdisciplinary teams are becoming increasingly emphasized in the architecture profession. While architects and designers have always had to work with other disciplines, both the depth and number of interactions with other fields is growing. The manner in which these different professions are interacting, and in which the students will soon need to participate, is different than it has been historically. As the architectural profession makes the transition, so must architectural education. Realistic engagement with interdisciplinary teams must be better accommodated in the education of future practitioners. This paper assesses one promising approach to address this burgeoning need in the form of an interdisciplinary LEED Lab course, led by a partnership between the North Carolina State University (NCSU) School of Architecture in the College of Design, the University Facilities Division, and the University Sustainability Office.

While reviewing possible strategies for building partnerships between diverse student backgrounds through intentional exercises, this approach seeks to establish a common framework for complex environmental issues for use in architectural education and aligned disciplines. One of the primary goals – and challenges – of this interdisciplinary approach is to help separate disciplines understand the value of each other, as is often understated and begrudgingly addressed in the professions. The different offerings, perspectives, worldviews, processes and work strategies of each discipline are valuable tools for the students to understand prior to entering the workforce.

1.1 *LEED Labs at NCSU*

The NCSU LEED Lab course is one of a growing number of similar courses being offered around the world, and one of the largest with twenty-five students from across three different colleges including the College of Design, the Poole College of Management, and the College of Natural Resources. The NCSU LEED Lab course addresses two fundamental goals: (1) supporting architecture and aligned-major students with skills, knowledge and expertise to be effective critical thinkers, engaged leaders, and team players; and (2) assisting the owner in achieving efficiency, savings, and sustainability in campus facilities. The first objective is the focus of this paper. The course structure, activities, partners, and possible next steps will be reviewed through a teamwork lens. Reflection on these initial courses results in a solid template for including meaningful integrated design experiences in architectural education, and provides a method for sharing the value of the architectural education across campus.

1.2 *The development of LEED Labs*

The NCSU LEED Lab course is based on a specific program established by the U.S. Green Building Council (USGBC) called Leadership in Energy and Environmental Design (LEED). While the United States is home to USGBC and most LEED certified projects, many countries are establishing like-minded organizations, such as the Indian Green Building Council (IGBC) and the Green Building Council of Australia (GBCA). An increasing number of countries are either adopting or adapting the LEED rating system to their particular needs.

More specifically, the NCSU LEED Lab course reviewed here was developed based on an additional education program out of USGBC's Center for Green Schools. As noted on the Center's website, "LEED Lab is a multidisciplinary immersion course that utilizes the built environment to educate and prepare students to become green building leaders and sustainability-focused citizens." (USGBC 2016) Using this provided framework, the goal of NCSU's LEED Lab course was not particularly to achieve LEED certification for the subject building, but simply to involve NCSU students across disparate disciplines in meaningful interdisciplinary work with a common goal.

2 BACKGROUND

2.1 *Interdisciplinary opportunities*

With the need for interdisciplinary teams and integrated processes growing in the built environment professions, practicing and future architects are finding it necessary to expand existing dialogues to better collaborate with other disciplines (Keeler 2009; Moe 2008; Yudelson 2009; Deutsch 2011; Reed 2009). Literature shows that courses facilitating teamwork through interdisciplinary groups better engage students in simulations of communications and projects in practice (Smit & Tremethick 2013; Fixson 2009; Rhee 2010). Because no built environment projects can be completed without interdisciplinary collaborations, these types of educational experiences can have lasting implications for students after graduation.

Unfortunately, the lynchpin of architectural education – the studio – is also what causes the most difficulty with interdisciplinary collaborations. Potential collaborators in disciplines outside the design fields, such as engineering, do not have the history, credit structure, or cultural understanding to easily, meaningfully participate in a studio course. The sheer amount of time allocated to the studio course, both in and outside of official class time, is difficult for other disciplines to comprehend. While studio is the preferred setting for interdisciplinary collaborations, where most meaningful connections are established between design concept and implementation during education (Kurt 2009; Schon 1984), interdisciplinary engagement is not easily accomplished in this venue due to logistics.

While some architecture programs have been making strides in establishing successful and repeatable methods for true interdisciplinary learning in a studio setting, other opportunities do exist for architecture students to engage meaningfully with other disciplines on campus in a classroom setting. This profiled course is one such opportunity.

2.2 *The local context and service learning*

The NCSU LEED Lab course is hosted out of the School of Architecture in partnership with the University Sustainability Office and the University Facilities Division. With co-instructors from both Architecture and Facilities, the course is structured to include meaningful learning objectives and experiences for the students, as well as conceivable benefits for operations of the campus. Logistically, the instructional partnership helped address the perception that an institutional commitment to service learning is a barrier to success (Bringle & Hatcher 2000; Morton & Troppe 1996). By not trying to force-fit the design education process into facility operations structure, or vice versa, the objectives and products of the course were enhanced.

By using the campus as the sample boundary for project selection and thereby enlisting the university as the "client", students were given the opportunity to participate in a real-world, environmentally-focused project with committed stakeholders. A self-selected participant population, the students were able to better develop their skills for future employment in a sustainability-focused field, which helped forward personal goals. The benefits of incorporating real-world and service learning projects in university courses and the significance of experience in interdisciplinary teams in a real-world setting (Bryson et al. 2006) are popularly recognized in literature. Encouraging students to focus on critical, reflective thinking while participating in service learning projects also supports the development of personal and civic responsibility (American Association of Community Colleges 2015). Billig et al. (2005) noted that using service-learning projects to clarify course content was one of the greatest predictors of all academic outcomes, while Astin & Sax (1998) claim that participating in service learning projects increases a student's growth in academics, life skills, and sense of civic responsibility.

By using a modified service learning approach, participating students were able to significantly contribute to an initial assessment of existing buildings on campus through an interdisciplinary lens. Through the strategic selection of a campus building, viewed as one of their own, the course instantly establishes a common foundation and value for the students. The students come to the course as unified stakeholders in the project, despite being from differing disciplines. Attitudes toward the project building, as well as the project processes, would have likely been different the project building was owned by a third-party, such as a standard office building or corporation. The integration of a real-world project in the local context is believed to be a significant element in the success of the course, specifically as it encourages goal-oriented teamwork. By selecting a project in the students' immediate context, the values of the project and its deliverables were effectively set early in the process.

3 COURSE DESCRIPTION

3.1 *Dual course goals*

Because this unique course was highly dependent on two discrete university departments, addressing both academics and facilities, distinct but complementary

goals were established. One set of goals addressed student learning objectives while the other goals addressed serviceable deliverables to Facilities to impact future standard operating procedures.

Learning objectives for the course primarily targets two areas: the development of student knowledge regarding green building tactics in practice, and the importance of interdisciplinary teamwork as addressed earlier. The overarching goal of this course, academically speaking, is to establish a method for interdisciplinary teamwork structures within the architectural curriculum, but outside of the studio setting.

The first academic goal for the course was to use the established framework of LEED to provide a structure for students to make sense of complex issues surrounding post-occupancy and sustainability issues in buildings. As substantially addressed in literature (Espinosa & Walker 2011; Kay et al. 1999; Waltner-Toews et al. 2008; Zellner 2008), sustainability is a tremendously complex issue that is too convoluted and meticulous for one field alone. However, grasping this innate complexity, including the primary components of green building projects and systems, is precisely what is being asked of design students and future practitioners. The intent was to establish a framework to help organize this knowledge.

With a different focus area in the university structure, the goals for the course were different from the perspective of the University Facilities partner. More focused on how course deliverables could impact the university's movement toward sustainability, their interest was in the product of the course, not necessarily the process. Because this article is more interested in the course process, these goals will not be elaborated on here.

3.2 *Course structure*

While some other university hosts of the LEED Lab course extend the project over multiple semesters, the NCSU course was contained within one semester. Interested in both expanding knowledge of the students beyond their fields, as well as providing detailed experience to support their current fields, provided a challenge in designing the course. This, cross-referenced with the sheer number of issues to address within the LEED structure, led to establishing two different modules linearly within the semester, both of which follow the same general process. This phased module structure provided the students two distinct opportunities to go address different credits and considerations during the course. Ideally, in one module students would research credits applicable to their discipline, while broadening their exposure to other considerations outside of their fields of study in the other module. These two opportunities were thought to better help facilitate building an expertise outside of their field.

Students were given one group for Module 1, and regrouped with other classmates for Module 2. An example of these groups is shown in Table 1.

Groups were arranged not only based on student preferences, but also with equal numbers of students in each group. Even more important was to balance the distribution of students from different disciplines within each group. There were three disciplines represented in the class each semester, including architecture, engineering, and environmental sciences. Working within the student populations of both semesters, each group was ensured to have at least one participant from each discipline, but no more than two from each. Using these established guidelines, the five groups for each of the modules were as well balanced as possible within the makeup of the course rosters.

Table 1. Examples of Module 1 groups.

Group 1 Sites/Location	Group 2 Water	Group 3 Materials
Site Management	Indoor Water Use	Purchasing Policy
Site Development	Water Metering	Maintenance/Reno
Rainwater Mgmt	Outdoor Water	Purchasing: Ongoing
Heat Island Reduction	Indoor Water Use	Lamps
Site Management	Cooling Tower	Purchasing: Reno
Site Improvement		Solid Waste Mgmt

3.3 *Delivering content*

Though groups were given particular credits and considerations to focus on during the course, it was important that all students received the basic information for all topics. While student teams worked on gathering data for the considerations assigned to their groups outside of class time, all major topics were covered in class and presented to all students. With these layers of hands-on (from independent work with their groups) and lecture-based (from class time) information gathering, all participants could become more knowledgeable about all green building considerations, including indoor air quality, energy consumption, waste management and recycling, and more. By using the LEED framework to establish a conceptual structure for the wealth of information needed, students possessed a tool to relate the content received in class back to the relevant credits addressed by their teamwork outside of class.

When structuring the course, representatives from the University Facilities Division were asked to participate as guest speakers whenever possible. For example, one class session reviews issues pertaining to indoor environmental quality. Instructors provided an overview of the larger concepts surrounding indoor air quality in the first half of the three-hour class. During the second half, staff members from the University's Environmental Health and Safety team presented to the students about their responsibilities in practice, including examples of typical issues seen on campus and in different building types.

These practitioners provided valuable background regarding real-world processes while also supplying students with information to facilitate productive teamwork and relevant deliverables. Representatives

from University Facilities departments including Building Maintenance and Operations, Repair and Renovation, University Housekeeping, Energy Management, Waste Reduction and Recycling, Environmental Health and Safety, Energy Solutions, Purchasing, Grounds Management, and the Building Maintenance and Operations' Commissioning Team participated in classes throughout the semester. Staff from each of these University departments addressed the class individually to share their daily processes with the students. When appropriate and feasible, staff facilitated in-class workshops for students to better explore issues.

These guest visits not only establish a basic level of knowledge for students, but also begin to create a unique partnership between the students and the University staff. These sessions allow students to ask questions of the staff and engage in meaningful discussions about concerns and perceptions of the different fields in the built environment. These sessions also had a secondary impact of energizing the staff themselves, providing additional kudos and energy to their roles and responsibilities on campus. These guest-speaking roles for staff helps to unify both sides of the university around the same common goal of green building, helping to further develop and extended the unique premise of a team consisting of both students and university staff. Though not the focus of this paper, this was found to be an important facet of the course.

4 CASE STUDY METHODOLOGY

This exploration was approached as an explanatory case study, which seeks to understand how or why something happens (Yin 2009). Rooted in a pragmatic approach, this study is interested in looking more closely at how meaningful interdisciplinary teamwork might be facilitated in a seminar format in design education. The case study methodology accepts that the context is important to the findings of the study (Yin 2009), and cannot necessarily be generalized to other settings or populations. The case study methodology explores interest areas in the natural context, collecting data within the real-world settings as opposed to contrived, laboratory settings.

The primary qualitative data to support this exploration was gathered through direct observations and unstructured interviews. Indirect secondary data was gathered through online pre- and post-surveys addressing perceptions on interdisciplinary teamwork, as well as through online assessment questionnaires focusing on the productivity of their teamwork and team members. All online surveys were hosted by the university survey service. The team assessment surveys included both Likert scale questions speaking to the perceived efficacy of teammates, as well as open-ended questions for further comment on teamwork processes. This data was gathered to establish insight on students' perception of how their teamwork progressed, as well as opinions on the need for teamwork in this type of interdisciplinary setting.

5 EFFORTS IN TEAM BUILDING

To address the primary goal of fostering interdisciplinary partnerships between on-campus disciplines that rarely intersect, the course design integrated a series of in-class exercises in an effort to build familiarity and fellowship between the students. The inclusion of team building exercises has been found to be a key to improving deliverables and process in student team projects (Hansen 2006). Similarly, a sense of solidarity, or investment in a group, is significant in establishing powerful teams (Albert et al. 2000). With an eye to teamwork development literature, a series of exercises were incorporated throughout the class to help establish a sense of teamwork, entity, and commonality. Two exercises included in each of the first two classes had the goal of establishing a "safe place" where participants would feel comfortable with others, as well as become more aware of other expertise and value in the room. Additional in-class exercises that addressed real-world issues of existing buildings were also included to give the same experience to students of different disciplines, helping to level the playing field.

5.1 *Identifying myths and stereotypes*

To kick off the first class and to set the stage for both cooperation and owning assumptions, a *Myths and Stereotypes* exercise was shared. Participants were asked to identify three myths and stereotypes about each of the collegiate groups, including their own. The resulting comments were both entertaining and illuminating. Stereotypes identified by other disciplines about Design students included, "They have a lot of free time, but are always stressed," and "Often forget to shower." Stereotypes relating to the Natural Resources students included, "They hate to wear shoes," and "They all work on grass and things …?" and "We don't really know WHAT they do …" Engineers were regarded as, "Detail oriented and snobby," and also "So stressed – ALL the time." (Rider & Bowen, in press)

Verbally reporting these myths and stereotypes to the entire class helped to highlight the silliness and absurdity of some of the statements. This exercise worked toward cultivating a level of comfort between students of different disciplines and academic structures. Through this activity, each student was given the opportunity to better appreciate multi-disciplinary perspectives on environmental challenges and opportunities. This was one of the best-received and most productive exercises focused on team building.

5.2 *Experiential exercises*

As stated, a primary objective of the course was to create a basic level of comfort regarding non-traditional partnerships for and with design students. Though teambuilding exercises help with this, as outlined in the previous section, the course also addresses this fundamental need through strategic in-class activities. These events are purposefully designed to form

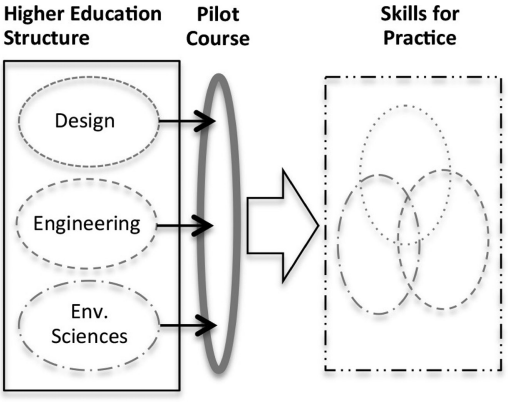

Figure 1. Conceptual diagram of the course addressing interdisciplinary design requirements in the building professions.

a collective understanding of in-field processes and terminology. These joint understandings then help to establish a common vocabulary for the participants, centered on existing building and operations. The precision and efficiency terms from the engineering and environmental science students are merged with the conceptual knowledge from the design students. This new (to the students) joint-rhetoric and experience also bridges the abstract and theoretical knowledge provided in the classroom into a context of application, and useful for future practice. This is shown conceptually in Figure 1. Three in-class exercises were completed, including an indoor air quality test, an energy audit, and a waste audit. The exercises were each planned and executed to build relationships and interactions between often disparate fields in academia, as well as with facilities departments that are rarely engaged.

Contribution of the proposed structure toward architectural eduction objectives

The course objectives, which emphasize collaborative skill development, enhanced understanding of complex issues, hands-on experience on a real-world project, and data gathering and analysis, are more suitably accomplished by using a collaborative teamwork approach. Meaningful interdisciplinary relationships were critical to complete the final course deliverables. In addition, these strategies also addressed larger goals for architectural education as outlined in the accreditation process in the United States.

The National Architectural Accrediting Board (NAAB) is the sole organization in the United States responsible for accrediting professional degree programs in architecture. As reviewed in the 2014 Conditions for Accreditations, a series of requirements are outlined for programs to show they are meeting established minimum standards. Within Part Two: Educational Outcomes and Curriculum, four Realms are identified as the pillars of a quality architectural education: (1) Critical Thinking and Representation; (2) Building Practices, Technical Skills, and Knowledge; (3) Integrated Architectural Solutions; and (4) Professional Practice. (NAAB 2014) This interdisciplinary seminar course as reviewed speaks to each of these pillars.

The design of the course addresses three of the eight points outlined under Realm A: Critical Thinking and Representation. Specifically, the participants' direct engagement with the stakeholder, including their final deliverables and presentations to the university staff, directly addresses the criteria pertaining to Professional and Communication Skills. The primary deliverables for the course are a culmination of weeks of gathering, assessing and recording data. This results in a gap analysis addressing both the current state of the building operations as well as the goal for building. With this, the course project squarely addresses the criteria for Investigative Skills.

Relating to Realm B: Building Practices, Technical Skills, and Knowledge, the course addresses seven of the ten criteria outlined. Because participants are exploring an existing building in-depth, most major building systems are addressed in the final analysis and documentation, including Environmental Systems, by way of daylighting, solar geometry, indoor air quality, lighting systems and acoustics; Building Envelope Systems and Assemblies, in terms of moisture transfer, durability, energy consumption and material resources; Building Materials and Assemblies, as participants explore the performance and environmental impact of construction materials, interior finishes, cleaning products, and assemblies; Building Service Systems, by exploring building systems through audits, measurements, data collection and staff interviews; and Financial Considerations, through cost estimates of repair and renovations, such as life cycle costing of retrofitting plumbing fixtures, equipment, or even adding solar panels. Other criteria in this Realm are also addressed, including Site Design and Technical Documentation.

The course activities and deliverables address all criteria as outlined in Realm C: Integrated Architectural Solutions. These criteria are actually somewhat innate in the course because the two primary issues in the course were (1) providing interdisciplinary approaches to (2) complex problems. Each of the considerations addressed individually were complex, and in total contributed to a more complex whole. Participants were tasked with assessing these complex projects with an eye to environmental stewardship, building systems, site conditions, user populations, and stakeholder goals and engagement, as outlined in the Integrative Design criteria. Skills developed in the course are addressed in the Integrated Evaluations and Decision-Making Design Process criteria. Embedded throughout the course was the requirement to implement applied research methodologies as they relate to the built environment.

Lastly, in Realm D: Professional Practice, the role of students as pseudo-consultants to the university enables them to step briefly into a real world scenario.

While they are not practicing in a firm, nor experiencing the business and legal practices of an architecture office, the participants do get an in-depth understanding of stakeholder roles in an existing building project, including owner, maintenance, users, community and consultants. While these roles are not those regularly seen in new construction or major renovation projects, the roles encountered are exceptionally valuable to understanding the goals of a building. These roles are addressed in the Stakeholder Roles in Architecture criteria.

Though this course was not structured to require individual execution of the final course deliverables, it is believed that the products delivered were more thorough and of higher quality than those that would have been delivered by individuals. One participant noted, "The biggest strength of the course is giving students access to knowledge and interdisciplinary experiences not typically available to students, making them more valuable in their future job-hunting endeavors." (Rider & Bowen, in press) Another stated that, "The interdisciplinary work between the three schools was beneficial and helped us all to grow as students and helped prepare us for working after school." The goals of the course would not have been achieved without a solid foundation in interdisciplinary work.

6 DISCUSSION OF FINDINGS

Feedback received from students via an online post-course survey indicate that participants had not been in such an interdisciplinary, collaborative, project-based academic setting prior to this class, and thoroughly appreciated the opportunity. One participant noted, "I also liked that there were other students from different majors in the class. I think having the variety of different majors in the class helped us learn from different perspectives." (Rider & Bowen, in press) By addressing complex built-environment issues through a multidisciplinary perspective, class participants would be better prepared for their future roles in their chosen professions, and were encouraged to begin to understand the importance of complexity (Johnson et al. 2010; Rapoport & Kantor 1967).

Similarly, emphasizing teamwork and investigative strategies in the course structure was undeniably valuable for the participants. As one graduate student notes, "Rather than being taught at us, which is usually the case, the students played an integral part in providing data and analysis. Having spent nearly half a decade in school, I have grown tired of teachers leading us down a winding road. One in which our skills are not tested and we are not challenged to excel and progress. This progression is not so for this course. We had the opportunity to learn from professionals outside of our fields. This challenged me to be comfortable communicating with my peers as well as the university faculty." (Rider & Bowen, in press) The common framework for analysis established and recognized early in the semester assisted teams in communicating more effectively, and working more efficiently toward a meaningful final deliverable. As such, the common knowledge framework presented in the course addressed the issues of challenging communication in interdisciplinary teams (Hall et al. 2004; Minssen 2006; Dayton & Henriksen 2007).

7 FUTURE RESEARCH

Future research on interdisciplinary efforts in architectural education could explicitly explore LEED Lab participant schools, beyond just NCSU, through pre- and post-tests to assess the different models, processes, structures and activities used the variety of courses (Rider & Bowen, in press).

Additional research is also needed on the topic of interdisciplinary teamwork as it relates to design education, investigating different methods for team building between design fields and other disciplines. Though design teams are often indiscriminately placed in working groups while in school, there is substantial literature on team development that could support future efforts of interdisciplinary teams of students (Dyer & Dyer 2013; Thompson 2009; Way & Bordass 2005), and benefit them both in school and later in the profession.

Still further studies could explore various ice-breaker activities, assessing which might provide the most opportunity for meaningfully engaging design students with those from other disciplines. There is also a need to assess varying approaches to interdisciplinary courses in different settings, such as comparing opportunities within a studio setting with those of a seminar. The differences between shorter and more transferrable opportunities compared with the intense setting of a studio could provide further clarification and insight into prospects for meaningful partnerships.

8 CONCLUSION

The NCSU LEED Lab structure is a practical model for significant, collaborative relationships between architecture students and non-design students using the LEED rating system as a both a conceptual and applied framework. The first two offerings of the NCSU LEED Lab course resulted in multiple positive outcomes, one of the most important of which was building rapport between previously disparate and seemingly distant student disciplines (Rider & Bowen, in press). Used as a model for student engagement, environmental stewardship, policy management, and interdisciplinary collaborations, NCSU's LEED Lab could be transferrable across all NCSU campus precincts and to similar institutions in the region.

The primary goal of the NCSU LEED Lab course was for all participants to obtain a well-rounded understanding of the considerations needed to operate and maintain a building after occupancy. This exploration indicates that interdisciplinary projects can be meaningful in a design-based seminar setting, illustrating that students from different disciplines can form significant, productive partnerships.

Spatial imagination and representation, a method for integrating the theory and practice of spatial analysis in architectural education

J.C.T. Voorthuis
Philosophy of Design in Architecture, Faculty of The Built Environment, TU Eindhoven, The Netherlands

H.M.T. Aarts
Faculty of The Built Environment, TU Eindhoven, The Netherlands

ABSTRACT: The course "Spatial Imagination and Representation" brought two rather unlikely subjects together: philosophy and drawing. They have become a promising couple, braiding the theoretical with the practical. Special about the new course is its methodological approach. We have made the philosophy of space into a tangible and concrete subject, explaining various conceptions of space and working out how these conceptions affect our way of responding to space. At the same time, the lessons in drawing explore these theoretical positions, giving the theory a foundation in practice. Both philosophy and drawing are concerned with processes of abstraction in the exploration of our environment. These abstractions express themselves in images and descriptions that can be explored through both disciplines, after all drawing is often defined as a kind of 'thinking of the hand'. Philosophy on the other hand thinks about the process of thinking itself, but also about the object of its thought.

Keywords: architectural education, models and concepts of space, philosophy & drawing, thinking & doing

1 INTRODUCTION

For the past three years we were given the opportunity to explore the setting up of a course in which cross-fertilization was a central goal. A teacher of drawing techniques and an art historian-philosopher working together to give students of the built environment the tools to study and conceptualize the idea of space and thereby to help them further their studies in design. The collaboration has proven very fruitful. This paper describes how we set up the course and discusses some of its results and concludes with an attempt to explain the success of the formula through the means and intensity of the integration of disciplines.

Nietzsche wrote in his notebooks for the years 1886-1887 that there are no facts only interpretations. Well, that fits in with current constructivist thinking. Henri Lefebvre (Lefebvre, 1991) developed a model of space in the 1960's whereby he distinguished three intimately braided activities: firstly, the actual behavior of bodies and things in space, secondly the perception of that behavior, and thirdly the conception of what is happening, that is, the generation of meaning. This triadic model in fact fits in very well with Wittgenstein's idea that the logic of relations is spatial and temporal and that therefore space is about the relations that obtain in a situation. These two models of space form the starting point and core of the course.

For students it comes as something of a surprise that the idea of space as a design tool for architects is relatively new. It was introduced by the art historian August Schmarsow in the 1880's (Mallgrave, 1993) and it is from that moment on that space gradually came to be a normative concept in the design of architecture. This instrumentalization of the idea of space as a design tool, and as a criterion by which designs and buildings could be judged, does not however mean that this was the beginning of spatial practice in the arts. The arts have, albeit implicitly, always worked with space in some way or another. Painting and film have always concerned themselves with the production of framed virtual spaces. Music and architecture are immersive arts; they make you undergo their spatial relations through movement. Music moves through time, while you perceive architecture by moving through it. Dance in fact confronts the two; it is an art that specializes in movement through space to express the movement of the music, which in turn expresses some or other emotive or narrative moment. Like sculpture, dance shows itself in space, thereby transforming it. These considerations formed the sketch version of our argument to combine the thinking about space with the creation of virtual and interpreted spaces through the practice of analytical and exploratory drawing.

The purpose of the course is to help students learn to observe analytically, critically and creatively, to make

them spatially aware and allow them to instrumentalise what they have learnt in confronting the philosophy and history of spatial representation with their own excursions in the analysis and creative or investigative exploration of space. At the end of the course students have learnt to describe and learnt to apply a specialist set of spatial concepts and tools of representation to the analysis and criticism of objects and spatial situations, and demonstrate a more refined understanding of the design process and in the qualitative evaluation of a design. In short students develop a critical apparatus tailored to practical skills of representation with reference to the production of space that will help them refine their professional interest in the design and production of the built environment.

2 EDUCATION AND METHODOLOGY

The subject is taught in the third year of the bachelor course of the built environment. In the charter of the faculty we are told that "The Department of the Built Environment is primarily oriented towards the technology of the building and technological solutions that contribute to the cultural dimension of the built environment." The signature indicates that the emphasis of the bachelor program is technological and that this technological bias is then applied to questions of culture and quality of life. Subjects like ours are serviced by the department of Architecture, Urbanism, Design and Engineering (AUDE) group which offers a carefully delimited part of the bachelor course. Our subject helps the large number of students who will, after the third year, go on to do a master in architectural design.

Design is both a technical as well as an artistic discipline. Our course "Spatial imagination and representation" is geared to exploring the possibilities of this attitude in tying theory and speculation to the development of practical skill, whereby we are careful to contest and explore the often problematic division between the technological and the artistic. We want students to realize that theory and speculation are inextricably connected in design and that the technological and the artistic both contribute to the design of the quality of life in equal measure and are in fact not so easy to separate. The word technology comes from the Greek Techné, which referred to the *art* of some discipline or craft. Moreover if technology refers to the technique of *how to do things* then art is itself serviced by technology. A last argument to contest their separation is that technology may be quantitative in its evaluation, but in its development and application it qualifies as an art. The reason we dwell on this is that, especially in our subject which concerns itself with the improvement of the spatial quality of life, however indirectly, it is very desirable that we do not see technology and art as enemies. Such an attitude, though common is restrictive and destructive to both.

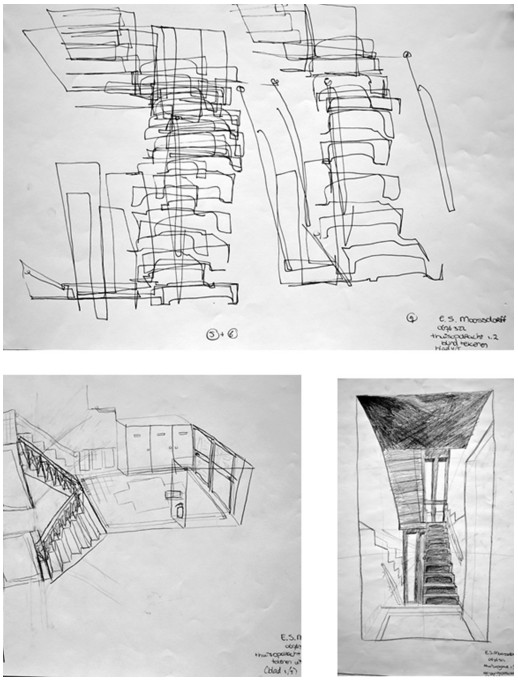
The course, which is given 5 ECTS, is built up of three equally important parts. A course of lectures on the history and philosophy of space, in which students are confronted with various models and conceptions of space and are given examples to see how these concepts can be used as instruments of analysis and critique (8×1.5 hours). The content of the lectures is carefully coordinated with the lessons in drawing (8×3 hours) where students are challenged to explore various means of representing space. The two parts of the course come together in the seminar, where the students are asked, in groups of three, to analyze, critique and artistically explore a particular instance of space or spatial representation. The weekly development of the students doing this assignment is discussed and given feedback by both teachers as well as the rest of the student group taking the course. The seminar culminates in an exhibition accompanied by a presentation to the whole group in which the result is described and explained with the help of arguments underpinning the decisions that the students made. Both the work and the exhibition are carefully documented in a report. The method helps students not just to make decisions, but requires them to argue them through.

During the first year of the course students were asked to analyze a work of art in 2 dimensions, depicting some form of virtual space. As it was the first time, we thought it wise to select the works ourselves and chose salient examples from the whole range of the history of world art. It was the task of the student to analyze and transform this two dimensional virtual space by adding a dimension, this could be the third dimension, but it could also be the dimension of time, or a dimension of meaning. During the second, and current academic year, students were asked to find a space in their daily surroundings, analyze it and transform the space by exploring their specified method of analysis and critique.

What we hope is special about our approach and method is that we are attempting to achieve a high level of integration between theory and practice, the thinking about space and the thinking about the representation of space as well as the integration of the technical and the artistic in the design of spaces. In this way all facets of spatial design are consciously confronted with each other to achieve a well-argued synthesis.

3 SPATIAL CONCEPTS

Apart from the ones already mentioned, such as Lefebvre and Wittgenstein, the lecture course investigates a number of specific models of the way space has been conceived and represented from the Pre-Socratic philosophers who were concerned with ideas such as chaos and cosmos, infinitude and emptiness to the Platonic ideas of Chora and Topos; from medieval ideas of godly space to early modern developments such as Brunelleschian Perspective and Cartesian space; from enlightenment ideas such as Kant's Copernican revolution, in which space and time became categories of mind rather than categories of the world to late modern and post-modern constructivist theories such as those of the phenomenologists, J.J. Gibson and Gilles Deleuze. Rather than just contextualizing and



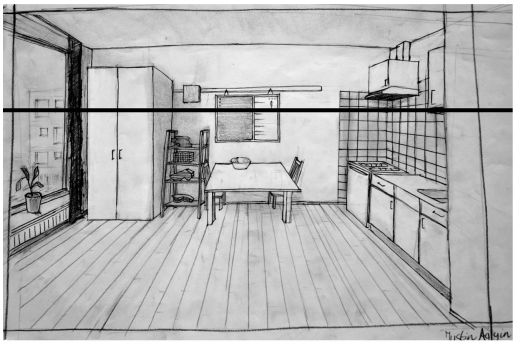
describing these models, we spend a lot of time making sure that the student is able to apply the concepts in the analysis and critique of concrete spatial situations and objects. Students are encouraged to don the glasses of a particular concept and approach specific examples in the other parts of the course. In this way students learn to free themselves from unhelpful habits and the mire of pre-conceived notions determining their outlook normatively.

4 THE DRAWING WORKSHOP

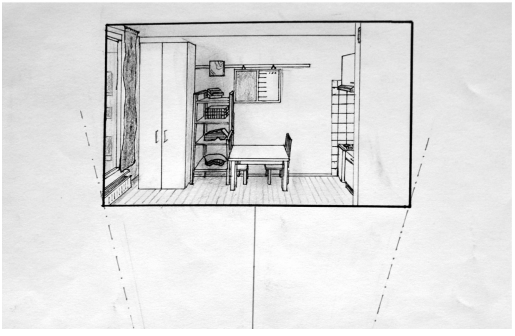
It is important, we believe that the student learns to look critically at his own perception of the environment he finds himself in by considering his own perceptions, the conceptual instruments he uses and the assumptions he makes. The course is about making students conscious of what they do. They are shown how our habits of perception and our thinking are both determined by silent assumptions that are descriptive, evaluative and prescriptive. They soon experience how difficult it is to distance themselves from such notions. However there are useful techniques that allow students to take a conscious position regarding their own perceptual habits and preconceptions. To help them decondition themselves, both the teacher and the student are required to leave their pictorial comfort zone by drawing from multiple points of view (Schaeverbeke, Aarts, Heylighen 2015). In what follows, we will illustrate some practice-based examples of drawing assignments, which aim to extend the language of drawing.

4.1 *Conceiving space – representing space*

The first assignment confronts the student with diverse ways of experiencing and imagining space. Their first confrontation with a space of their choice is devoted exclusively to observation for a period of 20 minutes. Afterwards they are asked to document their observations (picture 2). We purposefully do not tell them how to do this, it is up to them to explore the possibilities, after which the various approaches used are discussed and evaluated. A second exercise is to draw the same space 'blindly' (picture 1), with which we mean that the student is restricted from looking at the paper she is busy drawing on. In this way the eyes explore the space, but cannot control the hand to make it follow the acquired logic of a way of coding that space through, for example, the learnt tricks of spatial organization and perspective. Because they are not allowed to look at the paper they are forced to course exclusively on observation and an intuitive sense of relationships and their logic. The result is thus dependent on the realization that the draughtsman has to let go of preconceived aesthetic schemas and ideas of the correct. Normally when we draw, we are continually checking the actual drawing, to see whether it matches correctly the actual situation. However, correctness is very much determined by the visual schema's we learn from others, rather than from our own observation. When



Picture 1 & 2 & 3. From Lisa Moosdorff; resp. two "blind" drawings, drawing from memory after observation, drawing by observation.

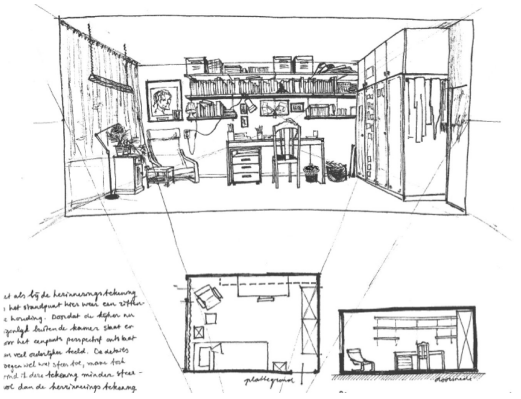


drawing blindly, preconceived order breaks down as the observing eye cannot correct the drawing hand. Order collapses and in the realization the focus of the draughtsman shifts to the pictorial exploration of the hand. One student testified that after a while her hand stopped drawing as soon as she stopped observing.

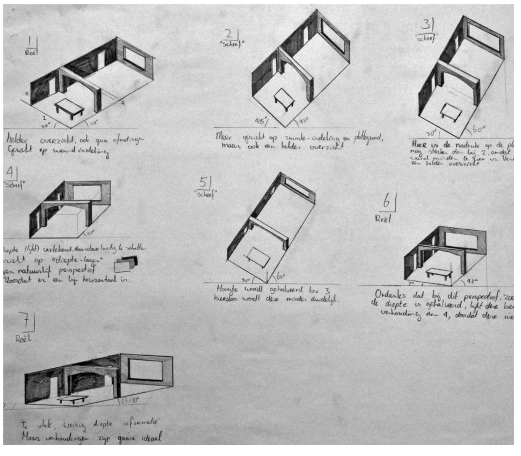
A third exercise requires the student to draw the space according to the laws of perspective and a fourth is to reconstruct a perspective representation using documentation such as plans, elevations and sections (pictures 4 & 5)

The drawings by Andrea Dolfsma (pictures 6 and 7) show, in her own judgement of them, that the construction in perspective gave her drawing a totally different expression and missed the untidy or messy character of her room, which is more visible in the drawing from memory.

The first assignment shows students that there are widely divergent approaches in the representation of space. This aspect is of course also explored in the later assignments, but the particular exercise, by separating the hand from the eye, dislocates the silent habits and continuities of perception and representation, thereby producing a very different image of the same space, containing very different information about the logic of relations. The phenomenological and Wittgensteinian approach in philosophy similarly look at meaning not in the things themselves, but in their active relations and their use. The 'I', the body and its environment are immersed in a continuous negotiative process in thinking about what to do.

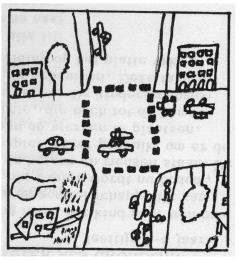


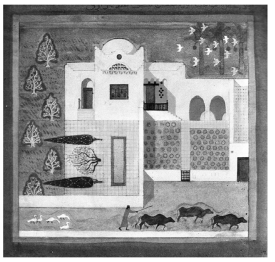
Picture 4 & 5. Justin Agyin; resp., drawing by observation, perspective construction.



Picture 6. Andrea Dolfsma: drawing from memory.

Once students have learnt to let go of preconceived notions of representation, blind drawings select and relate the information they show on the basis of different criteria, giving us a compelling view of how space is experienced and used. How for instance the staircase is walked (picture 1) by Lisa Moosdorff. In the perspectival drawings made by the same student we see a much more cerebral and constructed approach.

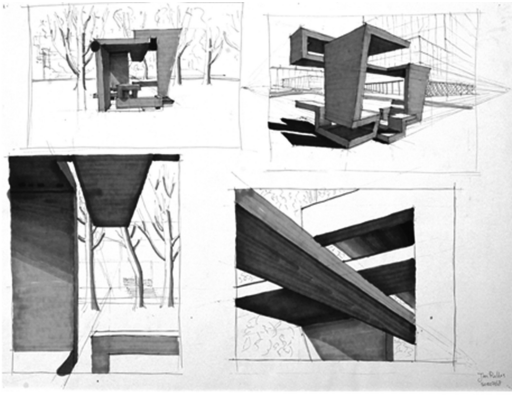


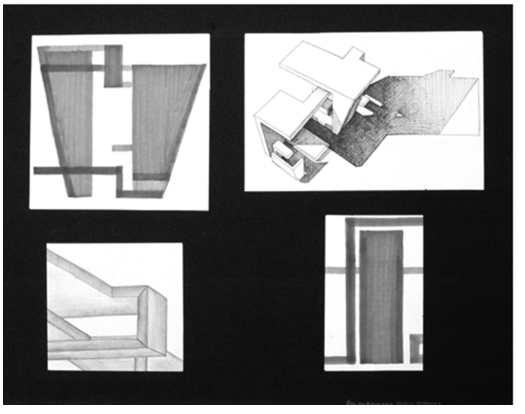


Picture 7. Andrea Dolfsma: drawing with perspective construction.

Picture 8. Student's work; drawing different kinds of (parallel) projections and perspectives.

The contrast between the "blind" drawings and the drawings that have been constructed on the basis of perspectival logic is enormous (pictures 1 & 3). However it is even more remarkable when comparing them to the constructions made from plans, sections and elevations, based as they are on Euclidian or rather Cartesian space (picture 5 & 8). Cartesian space in the work of the mathematician is a conceptual model in which the position of something can be expressed in coordinates using three numbers each representing a point along the X,Y and Z axes respectively, of a continuously calibrated space. In this way the relations between points are expressed in standardized distances, angles and vectors. Examples of representations of such spaces are flat projections, axonometries and converging projections such as perspectival constructions. During the drawing workshop students are introduced to various systems of representation and to get them to try them out and to discuss the way these systems achieve an effect on the beholder of the image (picture 8, 9 & 10).



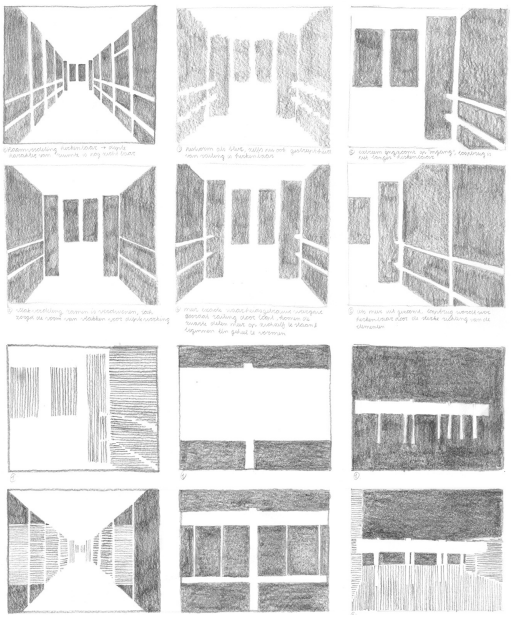


Picture 9 & 10. Resp. child's drawing and Hassan Fathy, Villa Hasan'Abd al-Razik, gouache exhibited in 1973.

Students are given examples of various types of projection, including various forms of perspective and how these systems have been used by artists. In this exercise students' work with a space of their own choice and experiment with as many different kinds of projection as possible, annotating each with a few remarks about the effect the projection has on the object represented.

At the start of the assignment and during the lecture course examples are used to show the many and diverse ways of translating a three-dimensional world to a two-dimensional surface. In each of these approaches the meaning emerges in the way that these various projections have been used. The child's drawing shows how various objects are assembled and represented in a way that makes them recognizable. It is important to strip our approach to such drawings from our educated, adult eyes which have learnt to see the world in a perspectival organizational scheme. Perspective creates a totalizing image in which the logical relations between things is exclusively approached from the point of view of the 'I'. When the perspective is only used as a system, blindly following its "rules" without any connection to the world around us, the outcome is a drawing that has little to do with any reality.

Wilson & Wilson (Wilson and Wilson, 1986) assume that any drawing is not so much a *representation* of reality but is itself a sign. A cloud is a sign and the drawing of a cloud as well as the word 'cloud' are also both signs *to us*. The drawing of the cloud is no more accurate as a representation of the cloud than the word 'cloud'. No language of representation, in word or image is isomorphic to the real world (Peckham, 1967). Wilson and Wilson see learning to draw as the learning of a sign-system, learnt not by observing reality itself, but by imitating the signs used and developed by others. Only after learning the sign-language themselves, do students begin to explore the reason why things are depicted in this or that way and to observe which situation demands certain shapes to be used. Apparently we need models to imitate. An Egyptian image seems comparable to a child's drawing in the way the objects are represented (figure 11 & 12). The objects are shown from the side from which the object can best be recognized as *that* object. The Egyptian image captures nature in a strict elementary way,



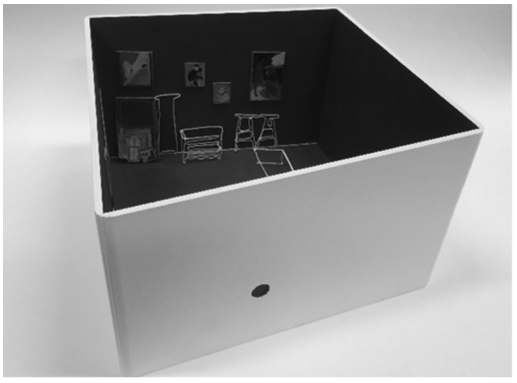
Picture 11 & 12. Student's work; drawing an object which is in front of them, using point of view and framing to manipulate the expression and spatiality of the image.

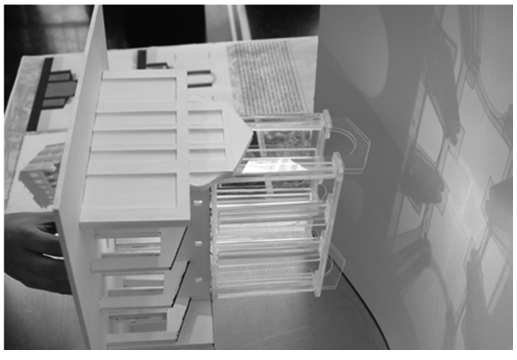
concentrating on essentials. In Egyptian culture it was important to represent completeness and give clarity as to the identity of the object. The Egyptian architect Hassan Fathy refers to this tradition using the rabattement, the geometry of rotating a plane to align it with another. After the exercise the drawings made by the students are discussed and compared with historical examples.

4.2 *Portraying and Framing*

In the workshops, parallel to one of the lectures on this subject, students investigate how "portraying and framing", one of the titles of the philosophical lectures, influences the atmosphere of the image. They make different studies while they are observing an (architectonic) object and try to analyze the outcome afterwards (pictures 11 & 12).

How does my point of view – a higher or lower point of view-, my angle of vision – close to the object or from a bigger distance and the way I frame the object, influence my image of that object? Those are questions that lead students in their research, making drawings that can be compared. How do we, the observers of the drawings, "read" the images? What





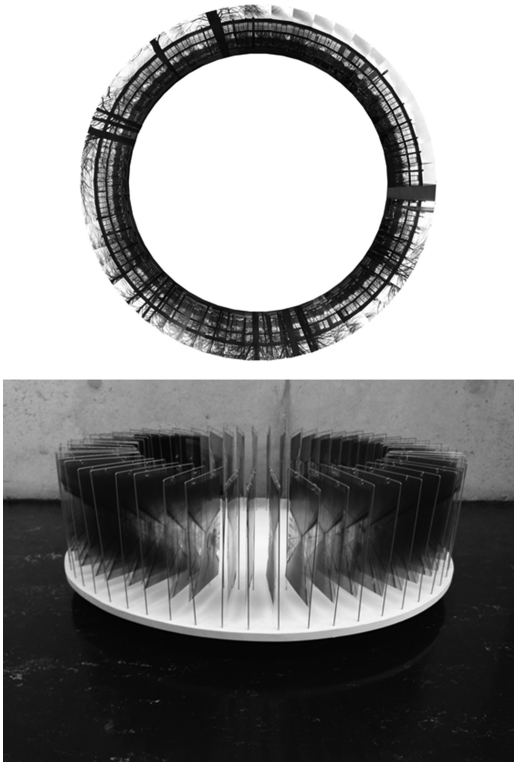
Picture 13. Simone Creemers, some of her studies exploring the spatial effect by not drawing the object, but only the surrounding space.

is it the other person observes? Here we enter the world of visual literacy. Glenda C. Rakes, professor of instructional design and technology, defines visual literacy as the ability to accurately assign meaning to visual images, combined with the ability to create and communicate with such images (Rakes, 1999). Visual literacy implies that images and drawings represent a language or a symbol system on their own. Visual literacy implies that pictures can be "read" and that meaning could be communicating through a process of reading them. (Kress, Van Leeuwen, 1996).

4.3 *Form and residual form*

Usually when a student is asked to make a drawing of an (architectural) object, he/she is focused on representing the object, very often without drawing the surrounding space, or framing the image, which itself creates a space around the object, be it undefined (picture 13). The intention of this assignment is to create awareness that the space surrounding an object is as important as the object itself. Students are asked to draw the object without drawing it, but rather concentrating on the surrounding space. Students thus learn to play with the role of hierarchy, questioning what determines a space, the object or the surrounding or negative space. Negative space is an established exercise within art drawing courses. It is often linked to a Buddhist's awareness for the non-material and negation (Maslen M. and Southern J. 2011, Edwards B. 1989). Negative space establishes a relation between a form and its background. The change of focus forces the draughtsman to study the interaction between form and space, between subject

Picture 14 & 15. Students work for the seminar 2015. Resp. Hein A., Hillenius T., de Rooij W & Meeuse M., Nuijten B., Wijers C.



and its surroundings. Within this exercise an object is studied not by drawing the thing in itself, but by building its contours from the surrounding space (figure 13). This exercise avoids our inclination to start drawing lines with the lines functioning as a boundary between objects and the space around them. Drawing negative space breaks with one's perceptual habits. (Schaeverbeke, Aarts, Heylighen, 2015).

5 THE SEMINAR

In the seminar the workshops and lecture courses link up explicitly. The students are asked to analyze, critique and creatively explore a particular instance of space or spatial representation. The first year it was a two-dimensional pictorial representation of space (an art work such as a painting, a print or a drawing), which needed to be transformed by adding a dimension (Pictures 14 & 15).

Picture 14 shows a 3 dimensional object made after The Red Studio from Henri Matisse, 1911 and picture 15 shows an extension of the Church San Ignacio made in Perspex and projected as a shadow on a rounded surface. This was made after Andrea del Pozzo's painting, the Triumph of St Ignatius on the ceiling of the San Ignacio Church in 1680.

This year students were asked to choose a specific space they wanted to investigate and which could at

Picture 16 & 17. Students work for the seminar 2016. Hemesath J., Creemers, S., Kromhout W. The 3 dimensional object (left) representing the 'He' perspective as seen from outside the bridge and the 2 dimensional work (right) representing the 'I' perspective, as seen from the inside of the bridge.

the same time be used for the drawing workshops. The experience they acquired here helped them investigate the meaning of the concepts of space dealt with during the lecture course and by transforming the space with the help of those concepts using an established work of art as a point of departure. One group of students chose one of the bridges connecting the first floors of each building on our campus. The group researched the historical background of these bridges, investigated descriptions of the space in words and in images, the function of the space and observed how people behave there while looking at the light and temperature and contingent circumstances. They noticed a difference between the strict organization of the space, with the strict rhythms of its mullions and vertical tie rods, and the movement of people through the space, shifting from moment to moment. The contrast illustrated the difference between Gilles Deleuze's "striated" and "smooth" space, a concept that featured during the lectures (Deleuze 1987). They also observed how the bridge changes from an 'I' perspective, walking through the bridge, to a 'he' perspective, observing someone walking through the bridge from afar. Seen from the inside the strict articulation of the structure and the windows gives a feeling of indeterminate infinity from a single point perspective. Seen from the outside, the bridge looks like a long horizontal beam hanging in the open air. Their inspiration was the work of the Dutch artist Jan Dibbets, who uses photographs of spatial elements to encourage people to think about our spatial observation. In the end the group made two objects, one was a set of photographs composed in a flat circle –representing the observation as seen from "he", the other object was a set of separate photographs hanging in vertical frames, arranged on a circle which could turn around, representing the observational position of the 'I' viewpoint (Pictures 16 & 17). Within those two models the students brought together all the aspects they mentioned as specific for this space.

6 CONCLUSIONS

One of the main questions for the educational part of this conference is: "Which didactic principles best prepare students to take a well-argued position to face future societal challenges?" Of course we don't have any idea what the future will bring, but perhaps one of the most important future societal challenges will be dealing with the globalization and increasing complexity of the world. This requires a multivariate point of view, based on a well-grounded understanding of our own ways of understanding spatial relationships and their representation. It is necessary to understand and become aware of what your own position is regarding the things about you and what determines those relationships: "What is my personal viewpoint from where I start observing the world, how does it work, where does it come from and what are the viewpoints of the people surrounding me?" In a global complex world students need to have the capacity to consciously and carefully analyse and transform their own point of view so as to make them at least compatible to those of other people they have to cooperate and collaborate with. We have to at least be able to consciously step out of the shadow of the 'I' perspective, developed during 15th century to see how a view of the world is a philosophical construction showing how theory and practice are in fact intimately and inextricably linked.

Displacements and notes on searching the architecture of the placeless

E. Komez Daglioglu & N. Sanaan Bensi
Delft University of Technology, Delft, The Netherlands

ABSTRACT: Today, we are witnessing an enormous number of people displaced worldwide ever recorded. From the vast migration of refugees to expulsions due to economic, political, and climatic reasons, from students to transnationalist capitalist class moving across territories constantly, we have become nomadic subjects living in the age of temporary or permanent displacements. This constant condition of displacements causes a state of placelessness, conceptually if not only physically. What is the architecture of placeless and how can it be addressed within the realm of architectural education? This paper does not aim to find solutions to the global phenomenon of displacements but rather demonstrates the necessity of framing new questions addressing the spatial dimensions of this immense condition. In this regard, it introduces three lenses as a background for new didactics in architectural education: the territorialization/de-territorialization of the nomadic human subject, site/non-site condition, and concurrences of temporalities and permanencies of (infra)structures.

1 INTRODUCTION

"By the end of 2014, 59,5 million individuals were forcibly displaced worldwide as a result of persecution, conflict, generalized violence, or human rights violations," reported the United Nations High Commission on Refugees (UNHCR) Mid Year Trends 2015 document. This amount perhaps exceeded 60 million so far, reaching the highest level of worldwide displacement ever recorded. This number in fact does not cover number of people displaced due to the large-scale land acquisitions, financial manipulation, catastrophic climate change, etc. as Saskia Sassen (2014) highlights. When all these causes are considered, number of forcibly displaced people worldwide shows the primacy of this global phenomenon. According to Sassen (2014), the issue can broadly be understood as a type of expulsion where "people, enterprises, and places [are] expelled from the core social and economic orders of our time." She argues that today's global capitalism triggers expulsions in contrast with Keynesian Welfare State, which was based on incorporating individuals within mass production and consumption cycle (Sassen, 2014). Globalization and its economic organization also provoke other forms of displacements where workers, students, transnationalist capitalist class – temporarily or permanently – move across territories. All these different forms of displacements of people, norms, and milieus resulted in a state of placelessness where home is neither the country of origin, nor the migrated land. According to urban sociologist Walter Siebel, we are anyway placeless since urban lifestyle or urbanity as a way of life is not tied to a particular place (Upmeyer, 2015).

Displacement of people has been for long an issue in many parts of the world, which, however, has become central to the debates in Europe within the last few years due to the direct effect of the consequences of the Syrian war. Unfortunately, the discussion on the recent "refugee crisis" is limited to providing temporary accommodation for the new comers. This is a very narrow point of view, not only because other modes of displacements are ignored but also due to the (un)conscious misreading of the refugees' legal, political, and social status. Designing refugee camps and temporary structures address a very small part of the "problem" when the overall picture is reviewed. For instance, there are now 2,5 million Syrian refugees registered in Turkey, among whom only around 280 thousand are leaving in the camps. In other words, more than 85 percent of the refugees are living in cities, mostly in the ones closer to the border or in the big cities like Istanbul. Hence, neither the refugees' situation can be considered temporary, nor the issue can be reduced to the problem of building temporary accommodation.

Against this background, the current modes of displacements and the state of placelessness have not yet fully been addressed in the field of architecture except some design studios and organizations (such as What Design Can Do Refugee Challenge), which problematize prefabricated shelters as the zero point of architecture. In fact, similar approaches were developed during the catastrophic World War II period. From Le Corbusier's "Flying Schools" proposals to Buckminster Fuller's "Dymaxion Deployment Unit", from Walter Gropius and Konrad Wachsmann's "The Packaged House System" to Ernö Goldfinger's "Holiday and Evacuation Camp for Families," many architects searched design strategies, structural systems, and materials for fast and easily built prefabricated constructions (Jean-Louis Cohen, 2011). The difference today is that developed countries see design as the ultimate way to deal with the "problem"

of displacements. Fortunately, new voices are rising regarding the limitations of these approaches within the field of architecture. Very recently, Ruben Pater (2016), the Netherlands based designer and researcher, criticized positioning design as the principal tool for solving the refugee problem – which is "political and socio-economic at heart" – and for legitimizing "a state of permanent temporary living" while the problem demands more permanent solutions. Similarly, Wouter Vanstiphout and Michelle Provoost (2016), in their article titled "A City of Comings and Goings", argue that instead of providing temporary shelters, cities have to be designed more flexibly to accommodate mobility of people.

Hence, the issue of displacements is also of importance not only in regard to the current intensity of migration patterns but also in addressing future migrations, which might be caused by many other reasons such as environmental and climatic changes. For instance, just recently the head of the task force in Iran published a report regarding a critical shortage of water source in Iran, announcing the fact that in forty years most part of the Iranian plateau might become with no possibility of habitation if the reduction in water source continues with the same speed. We are aware of the fact that architects do not hold powers to intervene in the mechanisms of these global phenomena. Moreover, many think that "the socially minded architecture is a choice not a moral responsibility" as also introduced by the Chilean architect Alejandro Aravena, the curator of the Venice Architecture Biennale of 2016.

However, we still do believe that architects are important social agents that could reflect on the spatial dimensions of these complex situations. In this regard, schools of architectures are the first places where critical insights towards displacements and the realm of placelessness have to be developed. To do so, the pedagogical models, which integrate research and design, should be emphasized. Thus, instead of approaching design pragmatically as a problem solving task and research as fact-finding and data analysis, current societal challenges should be addressed through a rigorous conceptualization of the phenomena. Architectural design education today still relies on conventional definitions of design problems where site, user, and program are considered as predefined fixed design entrees. However, the current mass displacements show that architectural design and research cannot get these dimensions as granted anymore and should re-examine their transient nature. This paper thematizes three entrée points – human subject, site of intervention, and time dimension – hoping to generate a debate for re-approaching the conventions of architectural design in relation to research.

2 PLACELESS STATE OF THE HUMAN SUBJECT

It has been posed several times by various philosophers, theorists, and critics that nomadism is a recurrent state of human subjects. Rejecting the modernist notion of a unified, homogeneous, rational, and expressive subject, postmodern philosophers such as Gilles Deleuze & Félix Guattari (1987) attempted to frame possible emergence of new decentralized subjects liberated from fixed identities. In this way, they anticipate new modes of existences emerged and shaped in the constant process of becoming and transformation as expressed through the concept of nomadology, or in the process of de-territorialization as Deleuze puts it. On the other hand, architectural theoretician Stephen Cairns (2004) claims that the status of migrants falls into a different sort of nomadism since their aspirations are oriented towards stability and settlement. In other words, it embodies both the processes of de-territorialization and re-territorialization. It is in this act of constant movement and displacements – this space in-between – that the state of human subjects is defined. For instance, pastoral nomads strengthen their status through displacements while refugees or asylum seekers lose their legal status due to migration, which sometimes even result in statelessness. According to United Nations (UN) there are more than ten million people in the world who fall into the category of statelessness, which means not having nationality or citizenship.

Through the processes of displacements, a discrepancy between human subjects and their politico-juridical status might occur, which can lead to a state of exception and exclusion. This is what the Italian philosopher Giorgio Agamben (1998) explains in the life of *Homo Sacer* (sacred man), a subject of Roman law who "presents the originary figure of life taken into the sovereign ban and preserves the memory of the originary exclusion through which the political dimension was first constituted." Under Roman law, *Homo Sacer* was someone who committed certain kind of crime and, as a punishment, excluded from the civil rights, which means "he may be killed but not scarified." And it is in this state of exception as the "no-man's-land between public law and political fact, and between the juridical order and life" where the human subjects become placeless, conceptually if not physically (Agamben, 2005). In short, placelessness might be a result of different mechanisms of nomadism, process of de-territorialization and re-territorialization, state of exclusion, etc. Hence, architecture of displacements should address the placeless state of its human subject. We ask then how architectural design can address placeless subject rather than a predetermined and fixed user?

3 SITE/NON-SITE

Placelessness is not only limited to the human subjects but also it is about elements of architecture transposed for place-making strategies elsewhere. Copying and imitating authentic places are some of the strategies used in architecture to deal with global phenomenon of displacements. For instance, Gaoqiao, a Holland Town

built in Pudong area in Shanghai shows how traditional Dutch buildings and cityscapes were imitated in China to establish a Dutch Village miles away. On the other hand, there are utopian architectural approaches, which abandon any reference to physical place. For instance, avant-garde architectural group Archigram developed hypothetical projects in the 1960s where buildings or even cities become machines moving along indeterminate places. In their Walking City project, city was interpreted as an insect like giant robotic object that could move wherever in the world with its nomadic citizens. In the Instant City, the project does not even touch the ground since an airship carries balloons containing educational and cultural facilities and drop them from air onto remote areas to cultivate a metropolitan life there. So, in addressing displacements of people and their living environments we see on the one hand an attempt of artificial place making and on the other hand complete abandoning of place as a reference.

Alternatively, there are approaches, which are addressing the transition between site and non-site. Artist Robert Smithson developed several non-site projects in 1968. He represented actual sites in New Jersey in indoor gallery spaces by moving the land into containers and transforming them into abstract artworks. In his "Provisional Theory of Non-Sites" Smithson (1996) stated, "…one site can represent another site which does not resemble it – this *The Non-Site.*" Hence, site is displaced without imitation. There is a space in between the actual site and its representation, which has a "metaphoric significance" that can be traveled. Smithson (1996) stated: "Everything between the two sites could become physical metaphorical material devoid of natural meanings and realistic assumptions. Let us say that one goes on a fictitious trip if one decides to go to the site of the *Non-Site*. The 'trip' becomes invented, devised, and artificial; therefore, one might call it a non-trip to a site from a Non-site." It is actually this space in between that nomadic human subject travels constantly and it is the non-site, the abstract representation of the site, where architectural intervention takes place. In this regard, the conventional understanding of site in architecture as an empty lot awaiting architectural intervention has to be questioned. Martin Hogue (2004), in his article "The Site as a Project" proposed an understanding of site not as an a priori given in architectural design but as a project constructed, invented, and made through architecture. The architecture of the placeless is therefore about a critical projection of non-sites on sites. How can then the non-sites be designed to address the displacements spatially?

4 TEMPORALITY AND PERMANENCE

Non-sites are used to be understood as temporary locations of inhabitation. In fact, an average stay even in a refugee camp, which is thought to be the most temporary place to host displaced people, is 17 years: almost one generation! In addition, repatriation can only be accomplished as a result of complex set of advancements in the place of origin in environmental, economic, social, and political terms. As stated in United Nations High Commission on Refugees' Global Appeal 2015 Report "UNHCR helps achieve durable solutions for refugees and internally displaced people (IDPs) around the world every year. But for several million refugees in protracted situations and a greater number of IDPs, durable solutions remain elusive." If more general condition of displacements is considered, constant movement of nomadic subjects – the spaces in-between – embody temporality, which lead to the establishment of normality or permanence constituted out of exception. This dichotomy of temporality versus permanency could be approached spatially in various ways. It's either been visited through the lens of infrastructure versus architecture. Infrastructures are often referring to a state of relative permanency, both concerning their territorial aspect and capital used for their constructions. For example, after the WWII, many German bunkers built during the war remained abandoned along the coast of France, which were beautifully illustrated later by cultural theorist Paul Virilio (1997) in his book *Bunker Archeology*. Losing their original context, these bunkers from the Atlantic Wall have become permanent objects in the landscape. Although ignored, these infrastructural elements continue to exist as the marker of permanencies.

Regarding the temporality of a camp, the permanency of infrastructure is often understood as being conflictual. In camps, infrastructures often operate as plug-in to the existing networks within their environments rather than constructing the space 'infra'. (i.e. the space beneath or below as an underlying layer supporting built environments) Furthermore, the binary of 'temporality versus permanency' can be looked through the lens of materiality. We can argue that in a camp, the architecture of which is almost absent, the presence of a certain material can rule the state of temporality or permanency. In an article titled "Assembling and Spilling-over," Nasser Anourahme (2015) raises an intricate discourse against this separation between the temporal and the permanent or as he calls it the contradiction between "symbolic-political" and "material-lived". By referring to a Palestinian camp, Anourahme (2015) argues that it has become extremely clear that the refugees would need to "negotiate an impasse between the political imperative to return (and thus remain temporary) and the material exigencies of life and the need, essentially, to build." (Fig. 1) Hence, what is negotiated is again this space in-between and in this case it is the material – cement – that mediates. Anourahme (2015) stated:

Cement, as both aesthetic and thing, mediates camp life in entirely unintended ways, breaching topological boundaries, spilling quotidian life–in all its uncategorized mess–into the political, and generating tension between the temporary and the permanent, return and

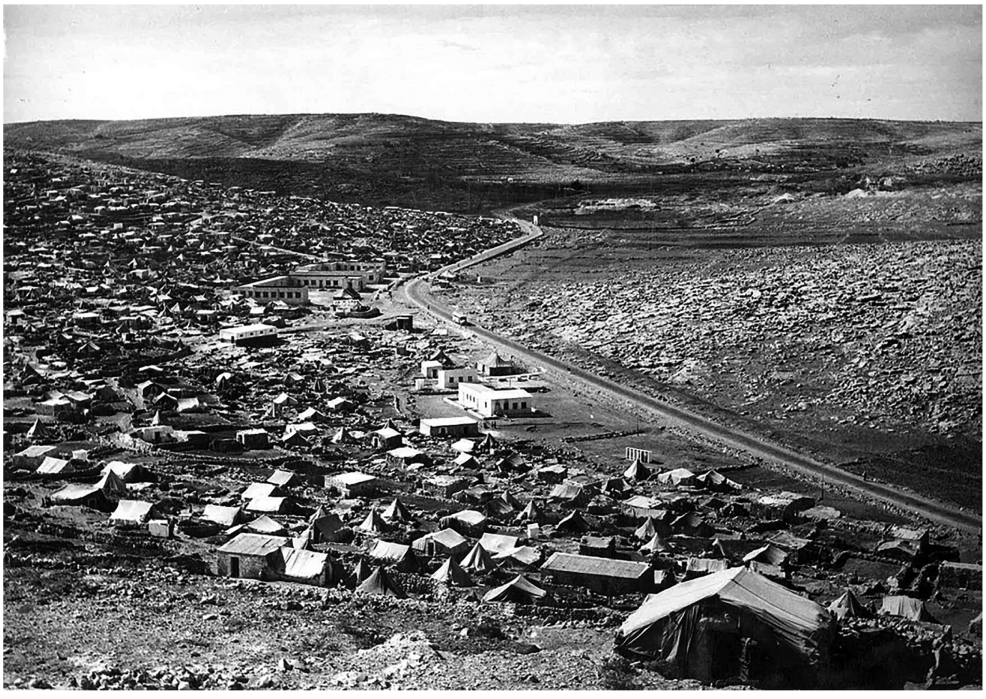

Figure 1. Deheishe Camp, Palestine, 1952. Courtesy of Ibdaa Cultural Center.

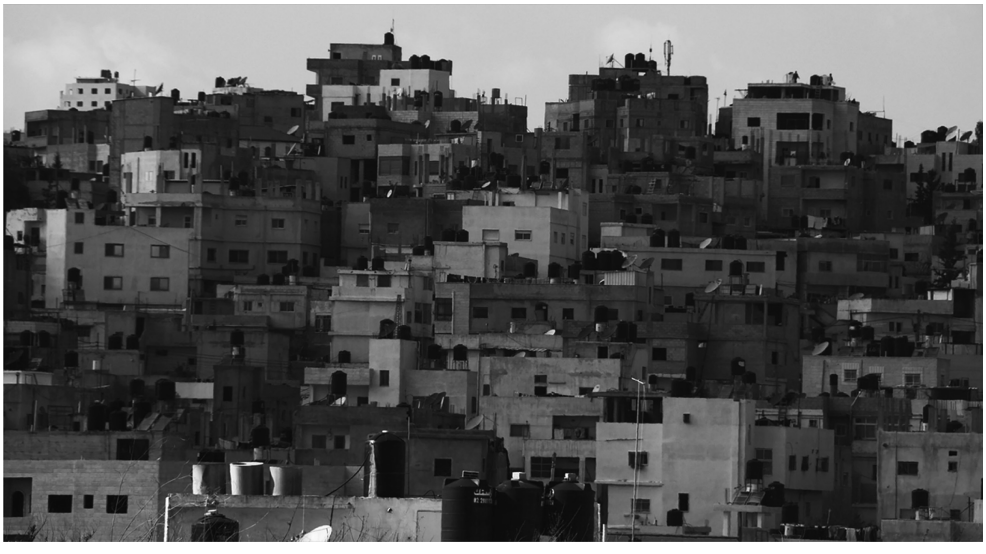

Figure 2. Deheishe Camp, Palestine, 2011. Photo by Nasser Abourahme.

the built. It is precisely in these tensions that refugee subjectivity takes shape; never simply as the directed actions of sovereign actors, but always as an everyday 'negotiation' of the in-between space of the spillover.

In the case of Deheishe Refugee Camp in Palestine (1949) located at the southern city of Bethlehem, the improved access to affordable cement in 1970 allowed for the expansion of housing and building beyond the boundary of the camp. (Fig. 2) The transition between changing materials is tightly related to the shift in political attitudes towards the idea of camp. As it is depicted beautifully in a passage of Khoury's novel, it is exactly this replacement between a zinc roof to a concrete one which constitutes this narrow space in-between temporality and permanency. Khoury wrote (quoted by Anourahme, 2015):

From the tent to the concrete room roofed with canvas, to the corrugated iron roof, to the 'roof of the

revolution'—-she had to wait twenty years until '68 to get a concrete roof. The concrete roof came with the revolution and the Fedayeen [freedom fighters].

Hence, it is the cement, which constitutes the relation between the political economy and power relations (as representation) and the built camp (as production), while the infrastructure operates as a posteriori, which plugs into the existing network. (i.e. the electricity network, sewage and clean water, roads and etc.) How the architecture of the placeless can be designed to embody the concurrences of both the temporalities and permanencies?

5 CONCLUSION

"What is the new role of an architect?" In fact, this question has never been posed as much as today within the scene of architectural debate concerning societal challenges. Besides lingering about the correctness of such a question, we might wonder if architects too have been partaking in the process of expulsion as argued by Sassen. In other words, the shift that has been occurring since the 1980s from Keynesian Welfare State to global capitalism also affected architects' role in relation to society. Does this mean that architects are disempowered actors within the mechanisms of globalization? Perhaps the call for the Architecture Venice Biennale 2016 by its curator Alejandro Aravena is an inviting alarm for a "battle field" in order to "improve the quality of life while working on the margins, under tough circumstances, facing pressing challenges." Therefore, for our concern, the question is how the architectural education not only participates but also engenders debates, questions, and interventions?

As it comes out from the paper, when the topic of displacements is considered, three main questions need to be examined carefully: How architectural design can serve to placeless subject rather than a predetermined and fixed user, how the non-sites can be designed to address the displacements spatially, and how the architecture of the placeless can be designed to embody the concurrences of both the temporalities and permanencies? In other words, to approach the architecture of displacements, it is not possible to be confined to the conventions of site, program and user as departure points of design intervention and research. Rather, there is this space in-between territorialization / de-territorialization of human subject, site/non-site, and permanence / temporality, when thematized critically, might provide new didactic tools for architectural design, education, and research.

We do think that *Chaharbagh* (The Persian Garden) is perhaps an intriguing promised space, which could work as a model with its capacity to negotiate with the space in-between territorialization / de-territorialization, site / non-site, and permanence / temporality. (Fig. 3) *Chaharbagh* is a place where the nomadic life meets the idea of inhabitation. Here the territorial movement of the nomad is folded within the architecture of the garden. The architecture of the garden becomes a tool for forming the life by delineating a piece of land. Eventually, it protects [the life] through separating the inhabited land from desert by means of a wall. It is interesting to note that in Farsi desert comes as *Biaban*, which literally means without water. Through the activation of infrastructures, the garden provides a permanent habitation where nomads can constantly move within its boundaries during the change of seasons. The garden reveals the hidden water resources by means of underground water infrastructures (*Qanat*). It manages the life through the organization of topography and plantations based on the grid of water channels and pools. In the end, *Chaharbagh* negotiates between the actual and virtual, the space of desert and paradise, and between architecture and territory.

Architecture as interface: A constructive method for spatial articulation in architectural education

A.P. Baltazar
School of Architecture, Universidade Federal de Minas Gerais, Brazil

ABSTRACT: This paper proposes a discussion of the problems with the conventional design process having representation as paradigm and argues for an alternative process based on architecture as interface. It then presents a design course proposed for twelve students at the School of Architecture, Universidade Federal de Minas Gerais, Brazil. The students were required to create a constructive method for spatial articulation to be used by different groups of people to produce spaces suitable for their wishes and contexts. The main discussion concerned the possibility of architecture as interface (process) instead of finished space (product), in which the role of architects is no longer that of controllers of a finished form but that of designers of interfaces with which people are able to engage in the production of their own spaces.

1 THE DESIGN PROCESS IN CONTEXT: FROM THE PARADIGM OF REPRESENTATION TO DESIGNING INTERFACES

Architecture students are socialised in their field by reproducing that which Pierre Bourdieu (1990) calls *habitus*. Architectural *habitus* might be described according to Reyner Banham (1999) as the reproduction of unsaid and unquestioned prescriptions, a black box that determines a *modo architectorum*. In the case of architectural education, Banham's critique applies to 'some secret value-system' that determines what architecture is, drawing it in 'the right style' (Banham, 1999). The main problem is that it is in schools that 'architects are socialised into the profession ... acquiring attitudes, work-habits and values that will stay with them for life' (Banham, 1999). In other words, architecture students reproduce the *modo architectorum*, which is nothing more than 'the making of drawings for buildings in the manner practised [sic] in Europe since the Renaissance' (Banham, 1999). This implies the division of labour, in which the architect is responsible for the conceived (abstract) space and builders and users responsible for the lived (concrete) space (Lefebvre, 1991). Architectural design is understood as merely conceived space and taught as a set of codes that aim to develop competences and skills to use drawings as means to represent and play with known solutions to problems. Bryan Lawson (2005) describes such a drawing practice as the puzzle trap, which reinforces the tradition of representation and formalism. Such a process praises the final appearance of buildings, separating design conception from building and use.

Looking back to a brief history of architectural representation it is no difficult to understand its main problems. Alberto Pérez-Gómez (1994) points out the importance of depth as the first dimension until perspective became a paradigm. With the perspectival paradigm length and width made depth become merely one among the three dimensions. The process of representation, then, reduces the three-dimensional object to a two-dimensional medium. In the case of representation of architecture, it is not just about presenting a three-dimensional object by means of a two-dimensional medium. The gap between architecture and its two-dimensional representation is not just of one dimension. We cannot take architecture as a three-dimensional object; we can be certain of at least two more dimensions – time and behavior – and, therefore, perspectival representation is three dimensions behind architecture (Baltazar, 2012).

Moreover, the problem of representation resides not only in its reductionist character but in its procedure. Olkowski says that 'the system of representation, whether in the realm of philosophy, psychology, social and political theory, ethics, or aesthetics, operates by establishing a fixed standard as the norm or the model' (Olkowski, 1999). Architectural drawings are no different. Although the devices used enable architects to freely draw whatever they wish, architectural drawings are not as free as the devices enable them to be. They reproduce the *modo architectorum*. On one hand there is a clear standard for technical drawings as the norm to be reproduced, which has not changed much. For instance, the plan drawings of Palladio or Durand are easily understood today as technical architectural drawings. On the other hand is a more inventive tradition of architectural drawings which, though not explicitly agreed, defines a sort of code. For instance, many architects today use collage in their drawings perhaps inspired by Archigram; others have as their models Zaha Hadid, Lebbeus Woods or other precursors of a certain kind of architectural drawing; a few

also try to establish their own style of architectural drawings. Because of the establishment of a standard to be followed, these drawings are recognised and accepted by the current *modo architectorum*.

The main problem with such modes is that they are not valid for minorities, as 'the very meaning of minority is associated with falling below the standard of that norm, failing to represent that standard in all its perfection and completeness' (Olkowski, 1999). Nevertheless, as de Certeau (1984) argues, contemporary society is made up of minorities, which he calls 'universal marginality'. He says that marginality is becoming universal, though the group or society composed by this universality is not homogeneous. In this view, what was before based on averages is now permeated by differences. Once the majority is composed of marginalities, it is no longer possible to represent the majority, as representation implies a homogeneous standard. So Olkowski's argument that the 'ruin of representation' is 'the ruin of hierarchically ordered time and space' (Olkowski, 1999) can be extended to most practices, including the design of buildings. A design process based on fixed norms of representation might therefore be replaced by a non-predictive, non-prefigurative, non-normative design process.

Olkowski (1999) links the ruin of representation to the practice of 'difference'. She stresses that difference is not the mere fact of being different, being part of a minority group, but a practice. She criticises the definition of 'individual' by generalisations in which any member of a minority is unrepresented and thus excluded. This definition presupposes equality rather than difference and fixes the nature of the individual. Even in a society that defines human beings primarily according to their sex, nobody would claim that all men or all women are the same. She draws from Gilles Deleuze's idea that representation, the dominant way of seeing and thinking in the west, 'has been constituted . . . in terms of the Aristotelian framework' (Olkowski, 1999) which implies the inscription of all difference in a general concept, as 'Aristotle is completely unwilling to count as differences those differences that . . . do not begin with something in common.' (Olkowski, 1999). This common ground of difference is similar to the standard of representation, based on the generalisation and crystallisation of what is otherwise particular and in movement.

The practice of difference proposed by Olkowski, brought about by difference itself, can be seen in a new inventive process which does not reproduce a fashionable standardised kind of drawing or even intend to establish a new standard. This new practice will have value not because it differs from others, but because it fits the intrinsic conditions of the project; it emerges from the project, and not from other drawings. We can think of difference in the architectural design process without attaching it to different styles of the same standard of representation, its current basis. As Olkowski states, difference is in fact a practice. Such a practice of difference presupposes the ruin of representation and points towards designing interfaces rather than finished spaces.

The ruin of representation, though, does not presupposes give up representation all together. Representation 'is a valuable tool and should not be excluded from the production of architecture as interface, but it should be seen as a tool, not a paradigm' (Baltazar, 2012). In other words, one needs to be careful not to conclude that representation is to be replaced by interfaces. The conventional representation-based process and the architecture-as-interface approach do not belong to the same logic and are not analogous. As I have written somewhere else:

> While the conventional design process is based on defining and solving problems, the architecture-as-interface approach aims at problematising situations, leaving it open for users to give continuity. There is no clear separation between design, construction and use, but the proposition of an interactive repertoire, which can either be a combination of physical, digital or hybrid parts, or a set of rules. The process of production of interfaces obviously uses drawings, but there is a shift in representation from its central, paradigmatic role and an emphasis on interactivity. (Baltazar, 2012)

The design of interfaces might be guided by that which Cedric Price (1996) calls 'value-free architecture', i.e., a structure with no meaning prior to users completing it temporarily. In other words, a structure which is carefully designed in order to enable users to decide the final spatial organisation. In this case representation is no longer inscribed in the building predefining its meanings. On the other hand, the design of interfaces might also let go of the European Renaissance manner of designing that gives continuity to the current *modo architectorum*. In this case representation is no longer that which Sérgio Ferro (2006) calls an instrument of domination, division of labour, and separation between design, building and use.

In order to develop further what is meant by architecture-as-interface, I draw from John Chris Jones, Vilém Flusser, Ivan Illich and Siegfried Zielinski (Baltazar, 2009). From Jones it is important to learn his proposal of designing designing (Jones, 1991), which started to be developed in his 1980s version of *Design Methods* (Jones, 1992). He proposed that modules, such as words, bricks and playing cards, 'is perhaps THE way of designing independently of any exact knowledge of aims, purposes, functions (the things which, in designing, as we've known it, get fixed at the start)' (Jones, 1992). In order to design the design process—designing designing—Jones emphasises process-orientated over product-orientated design, separating the logic of objects from the logic of use, focusing on the former. At first it might sound incoherent not to focus on use, as the aim is to enhance possibilities of use. However, if one is willing to open their designs for unanticipated uses one must not predict uses (design people's experience) but design objects for people experience.

So, one 'should look at the objects themselves and their intrinsic character in the context of open processes, designing modules as interfaces for people to keep on designing their worlds' (Baltazar, 2009). So, an interface, in the sense proposed here, must be object-orientated.

It is not enough to focus on the design of modules, which is a limited kind on interface, without making them dialogical and open to unanticipated uses. For Flusser (1999) every design is an object of use which is in itself an obstacle designed to remove a previous obstacle. 'And if this "object of use" is not to become a greater problem, it must be dialogical, intersubjective, proposing continuity and obstructing as little as possible those coming after us' (Baltazar, 2009). Flusser (1999) calls this 'responsible design', the one that responds to others. The main challenge is to escape from designing objects of use that obstacularises instead of opening possibilities for people. The concept of 'post-historical structure' (Flusser, 2002) is very useful to cope with this challenge. For him, we are now living in a post-historical world, 'in the midst of images that order concepts (in 'structure')' (Flusser, 2002). This is radically different from pre-history (the mythic world of images) and history (the world of linear conception). However, we are still designing our post-historical world with old tools: we base most of our designs on representation predicting their final appearances in a pre-historical manner (starting from the present towards a predictable future), or using representation to organise the uses of space in a historical manner (investigating past uses and crystallising a present possibility of use). We are not usually designing responsible 'structures' in a post-historical manner, open for those coming after us, as proposes Flusser (1999). The design of structures with open possibilities of organisation also defines interfaces as proposed here.

Illich (1973), on his side, adds to the discussion of object-orientated design and responsible structures, by proposing tools for conviviality. He is worried about how people will interact with each other and with the world considering that the tools used for that 'are never neutral but consistent with a certain mode of production and its corresponding social formation' (Kapp, Baltazar and Morado, 2008). The capitalist mode of production, which dominates Western culture, finds a prolific way to reproduce the social relations of production by means of the production of space (Lefebvre, 1976). Thus, the production of space is implicitly related to the reproduction of capitalism and its unfair distribution of wealth. In order to escape such a relation one should move beyond merely changing the ownership of the means of production (promoted by classical Marxism) and change its very constitution. For that Illich opposes industrial (manipulatory) tools with convivial tools.

> Convivial tools are those which give each person who uses them the greatest opportunity to enrich the environment with the fruits of his or her vision. Industrial [manipulatory] tools deny this possibility to those who use them and they allow their designers to determine the meaning and expectations of others. Most tools today cannot be used in a convivial fashion. (Illich, 1973)

Illich does not define how to design convivial tools, but indicates that one should avoid 'overprogramming' and should also 'simplify the tools' in order to 'enable the layman to shape his immediate environment to his taste' (Illich, 1973). So, the convivial constitution of the interface, as opposed to the manipulatory industrial constitution, is also a feature to bare in mind.

Moreover, for Zielinski (2000) 'an interface is something that separates and connects at the same time'. It works as a mediator without the presence of who designed it and without determining even the nature of the mediation it enables (separation or connection). It is a structure that depends on interaction to temporarily define spatial organisation. So, an interface in the sense proposed here is also a structure that mediates the organisation of spaces without determining them.

Drawing from such a discussion of interface and the design process that might give rise to it, a design course was proposed for twelve students at the School of Architecture, Universidade Federal de Minas Gerais, Brazil. The students were required to create a constructive method for spatial articulation to be used by different groups of people to produce spaces suitable for their wishes and contexts. The main drive for that was Segal Method (Mckean, 1989; Segal, n.d.), which is not a constructive system, but a method for self-production with which a single person or a couple of people are able to design and build a two stored house with materials found in a DIY shop. The main discussion concerned the possibility of architecture as interface (process) instead of finished space (product), in which the role of architects is no longer that of controllers of a finished form but that of designers of interfaces with which people are able to engage in the production of their own spaces.

2 EDUCATING ARCHITECTS AS INTERFACE DESIGNERS

2.1 *From didactics to mathetics*

Before discussing the structure proposed for the course I will introduce the pedagogical approach, based on mathetics (the art of learning), and also the students' motivation to engage in such a course. Seymour Papert (1980), a constructionist that defends mathetics instead of didactics (the art of teaching), was inspired by the Brazilian schools of samba. For him it was inspiring how people 'learned by doing' in the process of producing their costumes, their instruments and simultaneously prepared the carnival's big day by learning to sing, dance and play. There is no need for heteronomous teaching; Brazilian schools of samba set an example for autonomous learning (of course resorting to all kinds of information and material needed for that). In other words, there is a strong

structure supporting different possibilities of organisation, which encourages creativity and independence. Of course Papert romanticised the schools of samba's procedure, as it is in fact dominated by capitalism and not as free as it seems at first site. However, we might learn from Papert's insight regarding mathetics. Instead of working with didactics, teaching students predetermined contents, we can create a structure for students to develop and try by themselves their own critical perspectives on architecture. This is not an easy task, as the structure needs to be well designed to induce autonomous critical thinking and at the same time enable students to engage with contemporary historical and theoretical thinking (they are not supposed to invent the wheel). Moreover, the learning by doing approach, which is usually misunderstood with any sort of practical exercise, needs to be faced in the light of mathetics, in which the student 'learns how to learn' benefiting from a practical perspective, not only a discoursive one.

At our School of Architecture we have been running an introductory course based on mathetics for more than a decade. The students are required to learn by themselves having a carefully designed structure to orientate them in their learning process. In a cybernetic way, the pedagogical structure works as a meta-approach to be used in their design processes. After going through a range of information, they are required to propose and build an interactive intervention in an urban area, taking into account the current uses of the space, the shortages of the community and the features of the space. As this is their first exercise in architecture, they propose amazing interfaces with which people can play and modify the spaces temporarily. It must be said that representation only comes after the intervention is built and used, as their creativity must not to be limited by their initial lack of skills. After building their interventions, the students are required to develop their own language to represent them for future building without their presence. This is a clear learning of how to deal with representation as a tool, not as a paradigm.

However, this happens only in the introductory course. After that the students enter into the traditional design process mode, most times with a didactical demand, and are not able to formulate by themselves that the interfaces they produced in the first semestre might also inform other design processes. We came to realise that even if they experiment an alternative process which is usually quite successful, they are not able to oppose that to the traditional design process. First because they do not know such a tradition at the time; second because they are not encouraged to try it again in more advanced design projects; and third because architecture-as-interface is an attempt to move beyond normative conventional processes, which makes it non reproducible (each project needs to be invented from its own demands) and thus much more difficult to 'apply'. So, from this findings came the idea of proposing in the second semestre of 2015 an advanced design course based on designing interfaces rather than finished spaces, having as outcome a constructive method for spatial articulation in order to stimulate students to work with a practice of difference.

The twelve students who joined the course were already questioning, in different ways, the traditional design process. Eleven of them had already done our introductory course but were not able to discuss and overcome the conventional design process. They came from different years and all of them were enthusiastic to discuss and experiment a process that would not lead to a finished formal product. All of them were curious about participatory processes, as this word has been widely spread even if meaning anything but people's engagement in the whole process of production of space. In this context, the challenge of creating a constructive method for spatial articulation, treating architecture as an interface, was very well accepted.

2.2 *Deconstructing the brief of the design competition*

The course took as its theme the 'KYM Field Schools for Tropical Savanna Climate of Africa International Architectural Concept Project Competition' (kimfield-schools.com). It was proposed by the Turkish NGO *Kimse Yok Mu (KYM) Solidarity and Aid Association* to design a rural school to be placed in a variety of countries in Africa (they mentioned that it would be possible to build more than 1,000 schools in different countries in the tropical savanna climate). The brief of the competition was very conventional, presuposing a final product which would be also presented in a conventional manner. The architectural program predetermined that the school would occupy an area of 100 m2 (plus or minus 10%) with at least 200 m2 outdoor and semi-outdoor areas for surrounding landscape accommodating every outdoor activities and equipments needed (water well, sewerage, power supply, garden, playground, etc.). The brief also predicted indoor space for 60 students to be educated (divided in one, two or three rooms), a teacher room for two teachers (with toilet and shower), girl and boy student toilets and a small material storage. That is, the brief almost defined the pieces for the students to play with them in a puzzle (Lawson, 2005).

The aim of the design course was to depart from the brief of the competition and challenge the students to move beyond the puzzle making trap (which would possibly lead to amazing formalist results) towards questioning the design of a single project to be replicated in a variety of physical, cultural and social contexts. For that, the ideal would be a participatory process taking into account the physical features of the site as also the desires and constructive knowledge of local people. The challenge was then to join a replicable design with a participatory process accommodating local differences. In order to orientate the students the course was structured in an open way, but orientating their thoughts towards designing a constructive method for spatial articulation. This means, the students were not blind in their attempts

to overcome the conventional design process, but had a very open requirement to work with, proposing a practice of difference.

The course was set to work in two ways: seminars and design workshops. The seminars were very important in the beginning to make the students acquainted with different architectural alternatives to traditional design processes (ranging from Walter Segal, John Habraken, Yona Friedman, Cedric Price and many others) and also to understand the African diverse context (cultural, religious, climatic, geomorphological, etc.). In both cases, the students were induced to investigate by themselves, exchange information in small groups (up to three people) and present their finds in collective seminars to inform the design workshops.

3 ARCHITECTURE AS INTERFACE: DESIGNING A CONSTRUCTIVE METHOD FOR SPATIAL ARTICULATION

3.1 *Knowing the context*

Starting the course, the students were required to read a paper that synthesises a keynote lecture Silke Kapp and I gave in a conference on alternative practices in Sheffield in 2007 (Kapp, Baltazar and Morado, 2008). This paper presents critical exercise, design of interfaces and mediation as three alternatives to conventional architectural practices. Moreover, a range of participatory practices dealing with these alternatives were presented, both in the mentioned paper and in the site spatial agency (Awan, Schneider and Till, 2011) and the students were required to choose a practice to investigate further and present in a seminar for the whole group. The practices were chosen having in mind the main idea of the course, which was to propose a constructive method for spatial articulation. So, the students decided to investigate further the Segal Method (Mckean, 1989; Segal, n.d.), Habraken's support and infill (Habraken, 1972), the practice of Friedman (Friedman, 1986; Friedman, n.d.) and the practice of Price (Price, 2003; Obrist, 2003).

Segal Method was very inspiring, as already mentioned, because it is not a constructive system, but a method for self designing and building affordably. Segal developed a set of rules for people to decide on the design of a house and build it with materials found in DIY shops. Differently from the pillar and beam structure, Segal's method proposed a timber frame structure combining porches that worked independently, so anyone would be able to put it up with a simple foundation. One of the advantages of Segal Method might be seen in the self-built houses that are going through easy transformations over more than 30 years. The walls are not structural, so they are very easy to be displaced and assembled again, making it easy to expand the house or even rearranging its interior. As the porches work independently, it is also easy to give continuity to the structure, even with different materials, such as in one of the self-built houses that was expanded with metal porches. From that the students reinforced the idea that it is possible to design an interface, in this case having a sort of constructive method able to receive different materials and also enabling local people to decide on the spatial articulation.

Habraken was also an important contribution, as he deals with planning with future uncertainties enabling diversity in mass production. For that he separates support and infill, the support being not necessarily the structure of the building, but that which is of collective decision, and the infill being those parts that are left for individual decision. From Habraken the students learned the possibility of defining the support, which might be reproduced, and leave it open for local people to decide on the infill, which is specific for each space.

Friedman was also helpful for his general proposal of collective planning, even if it were more applied to the collective plan of the city and to his ideas of mobile architecture. The students investigating his works were more concerned, though, with his flatwriter, which proposed a machine programmed with parameters to enable users to define their own apartments and also check its placing in the urban environment. Such an interface was inspiring as it enabled the students to understand a structure, very carefully designed with a range of parameters, opening up possibilities for users to try by themselves their own spatial articulations and see the outcome of it.

The ideas of Price were also quite inspiring. For him architecture should not be faced as monument and should not be an instrument of power. He proposes that buildings be ordinary spaces to reconcile working and leisure with dwelling (a separation that was consecrated with Corbusian modernism). The students focused on analysing his 24 hour houses and the Fun Palace, designed together with the theatre director Joan Littlewood. The 24 hour houses are good examples of ordinary value-free architecture promoting a simple but carefully designed permanent structure enabling users to easily accommodate different activities in the spaces over the 24 hour period. The Fun Palace, a more complex structure, enables openness by means of cranes and mobile structures, with which the public might play and decide the configuration of the space for different days and performances. The students were very impressed by the concept of 'enabling', as it opens up a range of possibilities in architecture beyond foreseeing possibilities of use. They learned from him the possibility of proposing ordinary 'value-free' structures 'enabling' people to invent their own uses.

As the students had not gone through Christopher Alexander's patterns in the seminars, the Assistant Lecturer Guilherme Arruda has presented them with *The language of school design: design patterns for 21st century schools* (Nair, Fielding and Lackney, 2013), which is inspired by Alexander's patterns for school design. From that the students learned different patterns to enable a broader range of uses of school spaces, such as niches that work as intimate spaces or soft sitting areas inside rooms, which would also add to

inform the interface to be proposed opening possibilities for local people to engage in decisions regarding their local rural schools.

Giving continuity to the seminar series, the students were required to raise data on the African region subject to the competition. The brief only mentioned that the rural school to be designed was supposed to be reproduced in the tropical savanna climate, which encompasses ten countries from West to East of Africa (Senegal, Burkina Faso, Niger, Chad, CAR, Sudan, Ethiopia, Uganda, Kenya and Somalia). So the students divided themselves in groups to understand these countries diverse contexts (cultural, religious, climatic, geomorphological, etc.). From the point of view of objective features, even if considering the savanna climate, there is the dry and the wet tropical savanna, having different average rainfall. The wet tropical savanna rates 1,500 to 2,000 mm rainfall against a lesser rainfall in the dry tropical savanna. This is very relevant if one is required to propose a water supply system. Another important information raised by the students was the geomorphological map, showing the ground water table in different locations. Again, the variation was relevant, as in some places one can find water almost in the surface and in others they are very deep, needing a sophisticated harvesting system. The students also learned that people would build in very different ways in each place (even within the same country). They raised a range of types of spatial articulations and also the use of materials and constructive techniques. Apart from that, the students also found out that cultural habits are completely different. Sometimes in the same country they have identified more than ten languages being spoken and a variety of religions (ranging primarily from Muslim to Catholic). Moreover, the education is influenced by a range of issues. After colonisation an imported European system was implemented by missionaries, ignoring the local culture of the tribes in which the youngsters learn from the elders as they perform everyday tasks in a sort of 'learning by doing' natural pedagogy. In the urban areas the private system is nowadays based on Montessori and Feinet pedagogy, which even if reproduced in the rural schools is mixed with the missionary traditional system and with the poor conditions (it is said that a table supposed to accommodate two students in the formal educational European system, is sometimes used by four students, making it impossible for them to use the infrastructure as predicted in the educational system). Finally the distance from the house to the school (most children walk to school), seems to be responsible for the poor attendance and high rates of abandonment. From what the students have investigated, they were able to say that the diversity was so great that it would be impossible to replicate one single project in all contexts.

The findings of the seminars led to the discussions in design workshops. The students, then, were convinced that an interface was needed to articulate such a diversity and also to enable local people to engage with the design and building of their local schools. So, the design workshops served to trigger a process of discussion amongst the students under Guilherme Arruda's and my orientation. At first they thought of creating two or three groups and develop different proposals, as some of them were more inclined to emphasise locals's participation in the decision making (thinking of proposing a game and not an architectural project), as others were more inclined to propose structures that enabled a diversity of uses but were predefined by them (thinking of arriving at Habraken's idea of support and infill). As the ideas started to take shape, they realised that it would be possible and more fruitful to join their ideas in different stages of a single design proposal. The interface for a constructive method of spatial articulation started to take shape with the whole group (the twelve students) working on it.

3.2 *Proposing a constructive method for spatial articulation: a game-interface in three stages*

The students then agreed to design a game for local people to conceive and build their own school. Such a game starts by setting the plot and its context and then stimulates people to open their imagination about the future school with cards narrating different events for them to deal with articulating the spaces in plan and volume, internally and in its relation with the external space. It also proposes that people define the structure, openings and materials to be used, according to their constructive knowledge, traditions and climate. People are invited to experiment with a series of preset events proposed in a set of cards to finally be able to articulate their own school. At the end of the game, each community is expected to have one school designed specifically to meet its context and demands. The final outcome results from discussions arisen during the playing of the game as the players engage with the design of the school.

The first stage of the game was proposed as a quiz in which players are invited to acknowledge physical aspects of the site such as the size of the plot and climatic features that will determine water supply, sewerage, orientation of the openings of the building, etc. Players are then required to unfold the game board to fit the size of the plot and place the fixed elements, which range from water well, rain catchment system, septic tank, power supply system, garden and playground). The students defined that 'the sizes of the water well and rain catchment system will depend on groundwater storage and rainfall index. The definition of the septic tank depends on sewage, water access, geomorphology and possible reuse of water. It might be combined with a sinkhole, and/or an anaerobic filter, and/or an evapotranspiration system. The energy supply will depend on wind availability and solar incidence to locate pre-dimensioned residential wind turbine and solar panel' (Blind competition material, 2015). Moreover, players are also able to locate playground structures they wish (the quiz provides a set of structures inspired in Aldo van Eyck's structures designed for children's bodily engagement).

From that the board is ready to play with different spatial articulations.

The second stage of the game was set to open players imagination by trying out spatial articulations to accommodate different events that might happen in the school. This stage counts with five important instruments. First are the events' cards, presenting the players with fictitious situations that might happen in the school and inviting them to articulate spaces to accommodate such events in 2D, 3D and also thinking about materials to be used, structural system and openings. Second are a set of different modulated shape options for rooms supposed to match the competition brief and include circulation areas (that might also become meeting spaces between rooms), which combination is designed to sum between 90 and 110 m2. Third, directly related to the modulated shapes, is a spaces' catalog, presenting the main benefits of each shape to help players to decide on which to use. Such a catalog is based on patterns for school design (Nair, Fielding and Lackney, 2013). Fourth is the structure, which is an articulated 3D frame manipulable by players in angles of 30, 60 and 90 degrees in all of its articulations. This enables players to cover their plans with a flexible frame that can be thought of with different structural systems, use different materials to close and leave different openings, according to the event card. And fifth is a decisions's catalog, which is a *volvelle* (wheel chart) that presents tips for using different sorts of walls, roofs, openings and furniture. Such decisions are directed by the event cards concerned with spatial quality for shape articulation, its possible connections, thermal comfort and lighting and ventilation. At each event card taken, the player in charge needs to negotiate with previous players that had already set a design in the board to make changes according to the card's requirements.

After playing with the event cards players will have a final card, the third stage of the game, which asks them to design their own local school having in mind what hey have learned from the game. The main task is to define the main events that might happen in the school and respond to that having in mind the positive and negative aspects of the solutions they proposed during the game and also resorting to the same instruments used in the game (but the event cards).

4 CONCLUSION

The game-interface designed as a constructive method for spatial articulation of rural schools in Africa was an exercise that brought together a previous theoretical critique of the current design process and an inventive response from the students drawing from little pointers that appear in alternative practices. Such an interface started from Segal Method, having an articulated structure based on porches, but was developed further towards manipulating the modulated 2D room shapes and the 3D structure, inviting players to define collectively that which will become the support and the infill. Such a carefully designed interface is also inspired by Friedman's parameters programmed for collective decisions drawing from Price's 'value-free' and 'enabling' structure opening possibilities for different local organisations. The students have also orientated their design towards process (not product) observing the logic of the object not that of use (Jones, 1991). It also presented players not with industrial tools or preset decisions about techniques or materials but stimulated them to resort to their own constructive knowledge and materials in a convivial manner. As for Zielinski's definition of interface as that which separates and connects without defining the nature both, the game-interface is an attempt (not completely accomplished) as it is too much assertive regarding its aim to connect local people with its context.

The role of architects was certainly scrutinised by the students beyond the conventional design process and instead of producing a package of drawings representing the final appearance of buildings, they were able to propose a common interface to promote different outcomes. The feedback of the students after the end of the course was very positive, stating how secure they were with proposing interfaces, showing that 'learning by doing' worked properly. They said that before this course they already believed in a possible alternative to the conventional design process but were not able to put it in practice abandoning the formalist production of finished buildings. Now they are able to not only defend that architects might be interface designers but also to actually develop a practice of difference.

ACKNOWLEDGMENTS

I would like to thank the Assistant Lecturer Guilherme Ferreira de Arruda, who helped me running the course, and also the students who embraced the proposal making this educational experience possible: Alice Rennó Werner Soares, Ana Paula Pitzer Angelo, André Higino Bastos Inoue, Bárbara Madeira Antunes, Larissa Guimarães Reis, Luis Henrique Marques de Oliveira Silva, Maria Cecilia Rocha Couto Gomes, Maria Laura de Vilhena D. e Silva, Mariana Julia Souza Barbosa Lima, Marllon Luiz Oliveira Morais, Ricardo Yoiti Hanyu Junior, and Vinicius Augusto Bicalho Moreira. I would like to acknowledge the funding agencies Fapemig, CNPq, CAPES, FINEP and also UFMG (PROGRAD, PROEX, PRPQ and PRPG) which provided funds that made my theoretical and practical research on interface possible.

The role of representations in architectural design learning

A.Z. Aydemir
Istanbul Technical University, Istanbul, Turkey

B. Pak & K. Scheerlinck
KU Leuven, Ghent-Brussels, Belgium

ABSTRACT: In this study we aim to gain a better understanding of representations and reorganisation of the studio setting in design processes of the students in a studio context. To serve this purpose, we carried out a 15-week studio work in an urban architectural master design studio. We investigated how students use representations in relation with reorganisation of the setting. We analysed their design process by the development of representations, studio observations and a survey questionnaire. We found that reorganisation of the studio setting positively effect learning process and final proposals; whereas new ways of representation modes have a significant contribution.

Design process is comprehended as an interdependent combination of figural and visual reasoning (Goldschmidt, 2001, 12; Akin & Lin, 1995, 236). This duality is used for describing verbal-conceptual and visual-graphic representations. On the other hand, Schön's idea of reflection in the medium of representation included 'design reasoning', which is an explicit articulation of knowledge, as an essential part of reflection-in-action and reflection-on-action (Schön & Wiggins, 1992). This approach takes the complementary quality of design thinking further to an iterative and reflective understanding and in this paper, we specifically interested in this articulation.

Studio culture, as a principal focus of architectural design education, requires learning-by-doing (Schön, 1983) that is inherent in reflective practice of architecture. This culture coincides with the position against apprenticeship; and many pedagogical experiments advanced this position towards flexibility and interdisciplinarity. However, these open-ended approaches could not end the contradiction between liberation and discipline, autonomy and authority and they characterise regimes of transgression and resistance in higher education for art and design (Dodd, 2015). Therefore, established pedagogical aims and practices are found to be ineffective in promoting learning and social change (Froud & Harriss, 2015).

In literature, several references to representations and reorganisation of the studio setting can be found. In the following part of the paper (Section 1) these are elaborated in detail. However, there is not enough empirical research on how representations play a role in design studio learning.

Motivated with these observations, in this paper, we aim to develop a better understanding of this topic and address the following questions.

- *How can we collect and study representations proposed by students in an architectural design studio?*
- *What is the role of representations in architectural design learning processes?*
- *What are the implications for future practices and studies?*

In order to explore these questions, an urban architectural design master studio setting was used for an action research in Fall 2015. Self documentations of students' works were obtained through design diaries. They provided clues on their learning and design processes. Furthermore, the first author participated in the studio as an instructor and an observer for 15 weeks and made a survey with the students at the end of the design studio. We used a triangulation method which involves: 1) findings from the collected design diaries, 2) statistical analysis of the survey and 3) studio observations to address the research questions. In what follows, these will be reported in three sections.

Section 1 will introduce a background review of representations' role in architectural design. In the following section, (Section 2) research design regarding the learning process and the final proposals will be presented. Section 3 will reveal the studio work that was carried out and the obtained results. Finally, in Section 4, conclusion will be presented in which an overview of findings is provided and future research on the role of representations and reorganisation of

the studio setting in architectural design and design learning are suggested.

1 BACKGROUND

1.1 *The role of representations in design*

Design process is primarily associated with the creation of forms and visual imagery which are expressed by representations (Goldschmidt, 1994). In architectural design research, most studies about representation focus on the act of drawing. Design drawing, as an iterative and interactive act, involves recording ideas, recognising functions, and finding new forms and adapting them into the design. (Do & Gross, 2001, p. 136). This reflective action suggests conversations between ideas, functions, forms and interpretations. Representations also facilitate the examination and expression of architectural thought, filtered through the unique conventions that are embedded within each specific mode and technique of depiction (Simitch & Warke, 2014, p. 25).

Schon and Wiggins explains that the designer has a reflective conversation with the design (1992, p. 135); similarly, Lawson describes a conversation between the designer and the drawing (2006). We can say that all kinds of representations are included in this conversation. According to Do and Gross, this conversation does not merely communicate ideas to others but serve as a primary vehicle for thinking in design process (2001, p. 142). Thus, if the representation of final design is for communicating the ideas to others, drawing is certainly serve for thinking.

Representations are open to interpretations. Studies show that regrouping representations are associated with generating new interpretations (Suwa et al., 2001, p. 217). Furthermore, according to Gero and Kannengiesser, designers change their opinions about the design itself while generating and interpreting representations (2008). For instance, sketches serve as an external memory, a provider of visual cues for association of functional issues, and a physical setting in which functional thoughts are constructed (Suwa et al., 1998, p. 1047). Thus, construction of thoughts is associated with interpreting representations.

Architectural practitioners discuss the role of representations under a plethora of themes such as abstraction, function, urban scale, text and writings. They use the term 'diagram' for explaining these representation modes.

Anthony Vidler describes some of the key qualities of architecture as abstraction, reduction and geometrical simplicity (2000). He argues that both in history and in present, architects positioned their works with these qualities. He suggests that a new significance about the recent translation of the architectural vocabulary to production is almost simultaneous, so that processes between the representation and the architecture of itself disappears.

Representations' are also used for functional purposes and to redefine architectural design research and professional practice as having the technical authority (Pai, 2010, p. 64). In this context, Hyungmin Pai underlines weaknesses and limitations of representations and architectural diagrams that are developed as a problematic tool for control.

Diagrams in urban design scale are found especially useful and also dangerous. David Graham Shane argues that diagrammatic representations in urban design can reduce the complexity of the city which could create an illusion; whereas they can show individual paths, complex sections, and collective shared maps (2010, p. 87) to guide urban design processes.

Contemporary avant-gardes in architecture use diagrams dominantly. Somol argues that diagrammatic representations suggest an alternative mode of repetition and they are performative devices (2010, p. 89). He states that Koolhaas and Eisenman works diagrammatically instead of simply working with diagrams; displaying both social and disciplinary projects (p. 90).

According to Eisenman, diagrams can be traced and read in architecture. He explains this role within anteriority and interiority. Diagrams of anteriority traces the history of architecture in real buildings; whereas diagrams of interiority mediate other possible buildings within that buildings (2010).

1.2 *Representations in design learning*

Besides theoretical claims by quintessential design researchers, several empirical studies about implications of representations were carried out. Focus of these studies varies from thinking to manipulating during design processes. In this section, we will give examples of empirical studies on design learning processes.

In *Reflective Practitioner*, Schon draws a case study to explore the reflective conversation in an early phase of an architectural design studio with a studio tutor and his student. In this process verbal and non-verbal dimensions are closely connected. He names simultaneous drawing and talking as 'language of designing'; and he links it to a language for doing architecture. While the tutor and his student follow their conversation using the language of designing both verbally and graphically, the student reflects on her design. He claims that design actions can never be associated merely the effects intended for it; but materials are continually talking back to apprehend future potentials (1983). This study shows that there is a reflective conversation between representations and design process.

In another study, Oxman aims to study the way designers manipulate design drawings and to identify the knowledge and cognitive capability for re-describing design (1997, p. 330). She proposes a model for identifying and formalizing of re-representations in the interaction with graphical medium. She documented adaptation processes in graphic re-representation of an architectural design assignment. She claims that each new adaptation opens the possibility for further interactions. Study shows that manipulations of multiple re-representations is

crucial for design process and allows unexpected diversity and novelty in results (1997, p. 346).

Akin and Moustapha, in their study, aims to understand specific cognitive processes contributing to massing through strategies that facilitate a discourse between designer and graphic representation (2003, p. 31). They observed and collected protocol data of six design activities from early stages that lead to three-dimensional massing models. Their analysis shows that regulating elements are used for manipulating design process. These elements help them to understand and manage processes like part-whole relationships, design hierarchy, topology-geometry relationships, scaffolding the design process, structuring and restructuring parameters (2003, p. 34).

Bilda, Gero and Purcell conducts think-loud experiments to test if sketching is essential for conceptual designing (2006, p. 587). They compared two conditions of design activities including and excluding sketching. They defined sketching as a learned process including thinking with drawings, developing ideas, and solving complex design questions. However, their experiment shows that there are no differences between sketching and blindfolded design activity in terms of design outcome scores, total number of cognitive actions and overall density of idea production (2006, p. 604).

Figure 2. An alternative representation like a marketspace.

2 RESEARCH DESIGN

2.1 *Studio setting*

In order to respond to research questions, an action research was set up in an international urban architectural master design studio at KU Leuven Sint-Lucas Architecture Faculty in Brussels during 15 weeks of 2015/2016 Fall semester. Tutors of the studio were Bruno Peeters, Asiya Sadiq, Laurens Bekemans, Maria Cecilia Chiappini and Ayşe Zeynep Aydemir. The participants were 68 international architecture students (47 females and 21 males, 15 exchange and 53 regular, 27 nationalities) in their first year of master studies, who were not told the research questions or goals. The studio theme was '*Kokumi'* which is the sixth taste after Salt, Sweet, Bitter, Sour and Umami; and in English, it's described as 'mouth-fullness', 'mouth-coating thickness' or simply 'heartiness'. Students were expected develop a comprehensive urban-architectural proposal conjuring their own interpretation of infusing the idea of *'Kokumi'* within a complex urban environment in dialogue with their Peer Assisted Learning (PAL^{e}) teams.

2.2 *Action research*

The enquiry employed within the method of action research which includes four stages that work in tandem, namely, defining and framing, planning and acting, analysing and reflecting and reporting and reengaging (Figure 1). Action research cycles were used as a research methodology for an ongoing PhD research; in which the study of this paper represents one of the cycles. Each action cycle has a range of qualitative and quantitative data collection methods and analysis with an initial motive for supporting the learning process. In this cycle, 1) findings from the collected design diaries, 2) analysis of the survey, and 3) studio observations were used for this purpose.

2.3 *Kokumi experiment*

Reorganisation of Kokumi studio employed different than traditional architectural design studios in terms of process. This process included a first day experiment, collective group works, design teams, roundtable discussions, lectures, reviews, open-ended briefs and design diaries. Reorganised structure enabled alternative representation modes of proposals such as exhibitions, performances, and experiences (Figure 2).

Studio started with an introduction and Kokumi experiment that includes meeting at Musée Science Naturelle Bruxelles, walking to Maison Antoine in Place Jourdan, eating French fries with mayonnaise and walking back to Schaerbeek to have a 10-minutes observation on the site, Liedts-plein. During the first discussions students used following concepts for describing their first encounter: chaotic, nobody cares, joint, different point of view from just one place, multi-ethnicity, active, not-quite, fabric invaded by different nationalities, hard to get a mental map, hard to get oriented, mazy feeling, public island, tram lines/mesh,

square is separating people instead of gathering them, there is not much activity, everything is kept inside beside traffic, closed spaces(night shops), there is a difference of level (slope), it is exposed to the elements, whole square is full of parasites, it's like a mess, confusing.

Study site was a complex urban environment which cannot be easily identified within common architectural vocabulary. For the question "Is this a street or a square?", they answered as, "It's a mesh, it's very unshaped you don't know the limits". After discussions on the first impressions on Liedts-plein, we decided to prepare a profound research on site including physical, spatial, social and empirical aspects. Students formed four groups namely, Digital Model, Spatial Analysis, Humanities, and Case Studies. Groups worked together during the first four weeks of the semester until the first review of the studio.

2.4 *Collective group work and design teams*

Digital Model group prepared 3D models of terrain, buildings and façades in a common format. Humanities group discovered social aspects of the area through research questions and objectives. Spatial Analysis group produced urban analysis on transportation, walking routes, land use, density etc. Case Studies group researched relevant cases that could be useful for studio works. All four groups were expected to prepare a booklet and a presentation for the fourth week; all collected data would be a guide for all students during the rest of the semester.

During their research Digital Model group used modelling software, building laws, regulations and personal evaluations; Spatial Analysis group used mappings, sections, notes and sketches; Humanities group used notes, sketches, interviews and recordings; and finally Case Studies group used literature and case reviews.

All groups prepared a booklet for the first review. In addition to booklets, Digital Model group made a projected presentation; Spatial Analysis group prepared an exhibition setting for their analysis in three main titled of Non-Fixed, Fixed and Semi-Fixed; Humanities group made a projected presentation on their experiences, observations, interviews and literature research with diagrams and mappings; Case Studies group prepared a research in three main themes of Motion, Appropriation and Transformation.

After the presentations, they were all asked to decide for team leaders. There should have been 14 team leaders that would be responsible for the communication between the tutors and their teams. Volunteered team leaders were asked to form their groups concerning PAL^e (Peer Assisted Learning) Composition Instruction rules with an additional rule of including at least three different analysis group members for each team. These rules were referring groups of 5 students with a wide diversity of skills and background. For instance, the distance between any team members' university of origin must have been at least 400 km.

2.5 *Lectures and reviews*

In parallel with studio works, during the third, fifth and sixth weeks, students received a lecture from experts. Firstly, Leeke Reinders (TU Delft) gave a lecture on space-syntax, privacy, interior and social class, public front, private backs, parochial space, notations and mapping. Secondly, Meriç Demir Kahraman (ITU) gave a lecture about squares, public spaces and private spaces. And lastly, Burak Pak (KU Leuven) gave a lecture about Schaerbeek, super-diversity, Brusselisation, Brabantstraat and immigrants. Futhermore, on the seventh week, they had a workshop week coordinated by Lilet Breddels (Archis). Leeke Reinders and Meriç Demir Kahraman were invited also for the following review sessions.

During the semester four review sessions were realised. Projects were reviewed the 4th week for analyses, the 8th week for initial proposals, the 12th week for developed proposals and the 15th for final proposals. For each review, briefs were delivered to students to organise the sessions. For analyses, they were asked to prepare a booklet and a presentation. For initial proposals, each group had 20 minutes to present with a total use of space not exceeding 2 times 4 m^2 and they were asked to send a postcard featuring a slogan with an image summarising their project by surface mail individually to their respective design-studio tutor. For developed proposals, teams received the brief as an expression, which was *"Architecture has landed!"*. For final proposals, all outputs were evaluated on basis of submitted materials only, and no oral presentations were organised.

2.6 *Data collection*

Students were asked to record their own verbal and visual productions with design diaries for us to follow their design process as well as our studio observations. At the end of the semester, they were asked to participate an online survey for their insights about representations and reorganisation of the studio setting in the context of their design process and final proposals. In this way, design diaries, studio observations, and online survey questionnaire a triangulation method for data collection.

Survey was prepared as two sets of questions regarding design process and final proposals respectively. It includes an identification question, 7 scalar questions and two open-ended questions, which make 10 questions overall. 52 students out of 68 participated in the survey.

3 FINDINGS AND DISCUSSIONS

3.1 *Define & frame*

Discovering the role of representations and reorganisation of the studio setting in design learning process by developing a comprehensive urban-architectural proposal conjuring the own interpretation of the idea

Figure 3. First review presentation of team Taste.

Figure 4. Final review presentation of team Kokumi Attack.

of 'Kokumi' within a complex urban environment and a playful studio setting were main objectives of this action research. During first 4 weeks of the studio semester 4 research group; and during other 11 weeks 14 design teams worked collaboratively. Teams named themselves as F5, Makka, Codes, Average, Taste, Nozomi, Flex, Karami, (Mt2Ge)3OBr+Mn, Place Needs, Ki, Jupiter, Tea-m, and Kokumi Attack, respectively. Teams were asked to find 'Kokumi' of Liedts-plein and develop their proposals for this place.

3.2 *Plan & act*

During the semester, eight main actions were planned and employed. These were first-day experiment, PAL[e] groups formation, collective research within 4 main themes, working in teams and with team leaders, round table discussions, lectures, open-ended briefs for reviews, design diaries, and survey. These actions were related to representations and reorganisation of the studio setting. Some of the groups responded actions associated with their design proposals. For instance, team Taste, built their design strategy on eatscape of Liedts-plein and presented their proposal within a designed setting of an eating act (Figure 3), whereas team Tea-m presented their cinematographic proposal as a movie in a local setup. Furthermore, team Kokumi Attack presented their proposal in an exhibition setting.

3.3 *Analyse & reflect*

We observed that our plans and actions had reflections to design process. The first day experiment enabled a playful setting for understanding the studio theme and experiencing the place with a new set of mind. This experience transformed into another game while they were forming their research groups according to the restrictions announced. Predefined research objectives helped them to organise and work collectively. Forming teams according to the rules and determining a team leader helped them to understand their responsibilities and division of works within their teams. Round table discussions enabled to develop their ideas

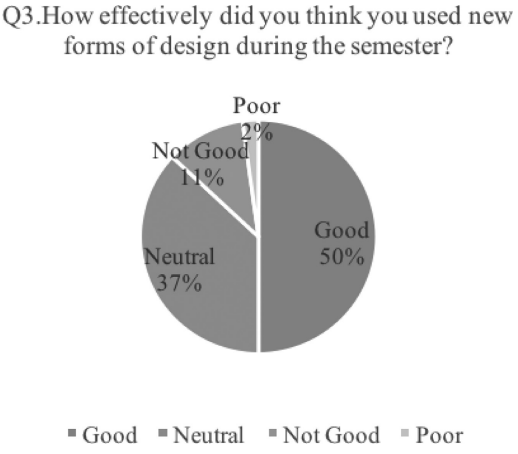

Figure 5. Use of alternative modes of representations.

with tutors collaboratively. Lectures elaborated the discussions. Open-ended briefs triggered new ways of representing their ideas. Design diaries helped us and them to follow their design process.

To support our observations, we needed opinions of students on these subjects. Therefore, we posed ten questions that evaluate design process and their final proposals regarding representations and reorganisations of the studio setting. Survey results show that 1) they used alternative modes of representations effectively (Figure 5), 2) reorganisation of the studio setting contributed design process positively (Figure 6), 3) alternative modes of representation contributed to final proposals (Figure 7), and 4) reorganisation of the studio setting contributed to final proposals (Figure 8).

3.4 *Report & reengage*

Based on students' comments to the open-ended survey questions related to representations and reorganisation of the studio setting, we realised that students find new ways of representation modes useful and beneficial during their design process and for their

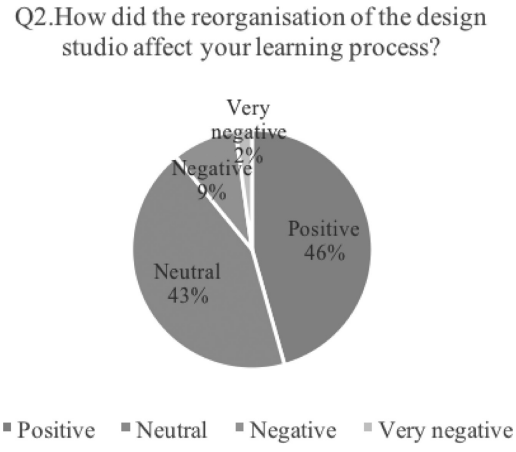

Figure 6. Contribution of reorganisation to studio setting.

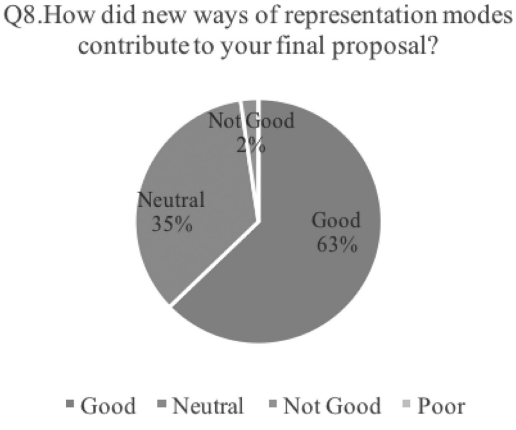

Figure 7. Contribution of alternative modes of representations to final proposals.

final proposals. They helped them to open up their minds for new ways of learning, to negotiate with others, to express their ideas freely, to discover new possibilities, to experiment, and to learn new skills. Nevertheless, they also remark that they needed more guidance and technical support. For this reason, they suggest that there could be more lectures, seminars and jury sessions.

4 CONCLUSIONS

The study presented here, considers the role of representations in design learning and how they relate with reorganisation of the studio setting. Studies on design learning are very crucial for understanding design process and it is suggested here that to develop a better understanding about design process, further studies on reorganisation of the studio setting should be followed.

Admittedly, representations in design and reorganisation of a studio setting can be approached and examined in a variety of way. However, this study

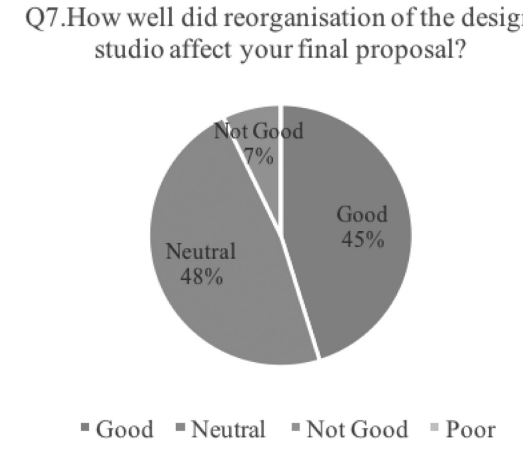

Figure 8. Contribution of reorganisation of studio setting to final proposals.

focuses on their effects on learning processes and final proposals in an architectural design studio setting. We used the setting of an urban architectural master design studio as a laboratory, design diaries for observations, and an online survey for collecting insights of students. In this study, the role of representations in relation with reorganisation of the studio setting in design learning are analysed based on an action research.

Even though majority of students found alternative modes of representation and reorganisation of the studio helpful for their design process; there were also opposite remarks. Some of the students indicated that they were not guided, they had problems with other team members, they needed more support on technical subjects and consult for a better process. These remarks should also be elaborated in further studies.

We believe that this study could be helpful to researchers on design education. We observe the role of representations and reorganisation of the studio setting intuitively but there is still a need to be ensure how they effect the process. Further research is needed for a discovery of their stimuli on different phases of design process.

ACKNOWLEDGEMENTS

This paper was written as a part of a PhD promoted by Prof.Dr. Arzu Erdem (ITU), Prof.Dr. Kris Scheerlinck (KU Leuven) and Dr. Burak Pak (KU Leuven) during a visiting PhD research in Sint-Lucas Faculty of Architecture at KU Leuven. Authors would like to thank to other Kokumi studio instructors, Bruno Peeters, Asiya Sadiq, Laurens Bekemans, and Maria Cecilia Chiappini; and the international master students of the studio. Authors gratefully acknowledges the receipt of an international research fellowship from TUBITAK (The Scientific and Technological Research Council of Turkey) part of which supported the writing of this paper.

Curating and exhibiting architecture: Pedagogy in the gallery context

Deirdre L.C. Hennebury
Lawrence Technological University, USA

ABSTRACT: MoMA's 2011 exhibition, *Small Scale, Big Change: New Architectures of Social Engagement*, featured eleven architectural projects located in underserved communities on five continents. The designs were not 20th century utopian gestures but instead represent "radically pragmatic" solutions that signal a deep reconsideration of the social responsibilities of architecture. A more recent exhibition, *City of 7 Billion: A Constructed World*, on display at Yale's School of Architecture during the fall of 2015, highlighted the worrisome implications of global development. The culmination of rigorous research, the findings were presented through the language of architectural representation – models, drawings, and digital renderings – to illuminate the roles of designers in confronting population growth and resource consumption. In both exhibitions, exigent subjects are addressed, critiqued, and evaluated within the space of the gallery.

Using a selection of socially-engaged architecture exhibitions as exemplar studies, this paper looks at the gallery and its potential value in architectural pedagogy. Intrinsic to the gallery experience is active questioning and enquiry. Playfulness and risk taking are also central when paired with reflection and critical thinking. Considering the various criteria and editorial choices that culminate in exhibitions addressing contested themes, specifically those shaping our understanding of societal challenges, the benefits of curation to the education of the architect are explored. With its immersion model of studio-based pedagogy and its emphasis on graphic and verbal presentations, architecture education finds a fruitful companion in the instructive tool of exhibition curation. When students actively curate their work – research and design – for public consumption, the capacity of architectural education is expanded. In the space of the gallery, architecture can be constructed effectively as a conceptual enquiry that embraces inspiration, critical thinking, and the building of meanings each of which is fundamental to the creative process.

1 INTRODUCTION

> *In socially engaged art … what is important is the process, and the process is inextricable from the experience*. (Helguera, 2012)

In her essay, "The Exhibitionary Complex of Architecture", Eszter Steierhoffer notes that in recent years architecture exhibitions featuring complex architectural themes linked to "questions of sociology, ecology, science, new technologies, cultural theory, or contemporary art" have emerged that connect architecture with a range of disciplines. (Steierhoffer, 5) Her observation of an "opening up" of the discipline and a re-examination of its social purpose is reflected in other commentary as well. There appears to be a growing consensus that while in the past the design process was "treated with the Hegelian legacy of genius and intuition … now the cultural and technological conditions have allied for architectural research to become less introverted. The opportunity exists for a new design culture, one rooted in research, openness, innovation and transferable knowledge …." (Adhya, Stevens, Plowright, 9) This new design culture would partner well with the architecture exhibition as a tool for teaching particularly when difficulty topics are addressed. Drawing from museology and a diverse selection of architecture exhibitions, this paper proposes that the curatorial and exhibition strategies used to confront difficult topics are valuable pedagogical tools that could more pointedly inform architectural education.

2 FROM MUSEOLOGY

The discourse emerging from Museum Studies and writings on museology support the use of the gallery space as a laboratory for exploration and experimentation, particularly when the exhibition addresses contested themes. In a keynote address to the International Council of Museums' annual conference in 2000, Barbara Kirshenblatt-Gimblett claimed, "a 'new honesty' has encouraged museums to 'open up for public interpretation the darker side of human society' and to do so more reflexively and self-critically." (Kirshenblatt-Gimblett, 1) Susan Pearce, another prolific scholar in the field, views exhibitions as performative structures composed of "objects in action"—that is, complex practices of language that attempt to communicate with those who engage them.

(Pearce, 19) Social anthropologists Sharon Macdonald and Paul Basu have characterized a similar approach in more recent practice as one of "exhibitionary experimentalism," noting that the exhibitionary apparatus is understood for its capacity to *generate* knowledge and information, rather than merely to provide the frame in which to represent knowledge. (Basu and MacDonald) According to these authors, the very processes of exhibition practice have become visible, resulting in "reflexive" creations.

The word curate derives from the Latin root *curare*, or "to arrange, attend to, undertake." While traditionally curators were tasked with delivering didactic content, there has been a shift in museum practice that emphasizes, instead, education in the gallery as an experience that fosters intellectual and sensorial engagement of many sorts. Graham Beal, former director of the Detroit Institute of Arts, noted that whereas the earlier curatorial approaches were technocratic, the current desire is to find ways to shift the voice of the exhibit to express different interpretations of the work. (Beal) Macdonald and Basu's observation identifies an epistemological change in our understanding of the exhibition space from one that is representational and didactic to one that is experimental and open-ended. Similarly, within the field of architecture, Eve Blau are argued that "by privileging forms of graphic documentation and representation produced in the process of imagining, designing, producing, recording, and thinking about architecture, the exhibition (perforce) shifts the focus of concern from finished object to process, from form to idea." (Blau, "Reviewing," 256) This shift from object to process is in keeping with a new approach to curatorship which sees the final exhibition as exploratory and experimental.

Looking at recent international architectural exhibitions in museums, galleries, and biennales, it is clear that the gallery or exhibitionary space is being used productively as an instrument for research that "forges links between architectural thinking and practice, addressing contemporary issues via historical perspectives and an engagement with social, environmental, and political themes." (CCA Exhibitions website) Retrospective and projective architecture exhibitions are expanding the field beyond mere representations of finished buildings to include materials produced during the design process. The biennales in Venice have focused recently on the wider social and political context of architectural practice. Linking these types of strategies more firmly to the education of the architect seems appropriate and timely. In Pablo Helguera's book, *Education for Socially Engaged Art*, he develops the term abstract education to distinguish between symbolic versus actual practice. According to Helguera, actual practice is where the designer and curator will get their hands dirty and make an authentic attempt at engagement. (Helguera, *Education*, introduction). He suggests that the academy can benefit from the curatorial process in terms of pedagogy because both realms have an "emphasis on the embodiment of the process, on the dialogue, on the exchange, on intersubjective communication, and on human relationships." (Helguera, "Bad").

The student curator must take a position, define an approach, create the materials, deal with the graphic design and formatting of the display, and consider the manner in which they position their ideas and representations for public consumption. The design of an encounter, requiring the consideration of audience, compels a student to consider points of view that are not familiar, challenging, and, perhaps, even uncomfortable. Since the exhibition "… is about an event and an experience; it is concerned with a way of looking at and constructing arguments about architectural subjects that is different from that of the book and the scholarly article." (Blau, "Reviewing," 366) Designing an exhibition enhances the skill set of the emerging designer by forcing the questions of audience and visual communication during their formative development. With the complex challenges facing the social-engaged designer, new strategies and methods are required "to cultivate an audience with the spatial sensitivity to engage with the built environment in a conscious and potentially more responsible way." (Chan) An examination of recent exemplar architecture exhibitions confronting social subjects reveals the benefits of *Curation and Exhibition as Research*. While these selections do not specifically feature student work, their diverse exhibition strategies provide an abundance of precedents for the student curator to consider. In these projects, several compelling and productive themes emerge: Experimentation, Advocacy, and Interdisciplinarity.

3 EXPERIMENTATION

> *Expositions and exhibitions have perhaps changed the character of American architecture of the last forty years more than any other factor … exhibitions are more effective than schools, newspapers, magazines … are more "public" than buildings.* (Colomina, 240)

Architects who curate typically have a specific research or design agenda. They are interested in using exhibitions as productive agents through which they can develop their architectural research and practice. "A museum or architectural center is not only a place for the classification, conservation, and presentation of objects and documents, but is also a place of production and a generator of activities." (Zardini, 82) As curators, these architects are charged with the task to make this knowledge constructive and generative for the field. "Exhibitions [have] become places of creative and intellectual production, of in-depth study and reflection, and of experimental design practice." (Van Gerrewey, Patteeuw, and Vandeputte, 1) The conception and surge of architecture and design biennales is also an effect of this desire to create potential

instruments for facilitating experimental and critical architecture production.

One way to look at the exhibition space is to perceive it as a laboratory, where it is not simply a place to display a finished product, but a place to produce new content as well. This concept allows curators and architects to overcome "the difficulty of all architecture exhibitions – the impossibility of showing what architecture is really like rather than merely elaborating the means of its representation." (Forster, 62) Installations provide architects with a way to express their designs physically and directly where they can experience the effect of the spaces that they are trying to create. These proposals can also advocate for particular causes or methods.

Home Delivery: Fabricating the Modern Dwelling mounted at MoMA in 2008 offered a survey of the history of the prefabricated houses in the Museum's Fifty-fourth Street lot. Overall, the exhibition attests to the diversity of procedural, formal, and technological innovation in prefabricated architecture, and illustrates that the prefabricated house is a critical agent in architectural invention, material and formal research, and sustainability. "[T]he challenge is to exhibit not simply the results but the very processes and the larger stakes-creative, social, economic, even ethical-of architectural practices in a world that demands radical change." (Bergdoll and Christensen, 9)

> *Exhibitionism looks at and thinks through the productive forces of display that go beyond mere knowledge production, although that remains an essential component. It proposes that the exhibition is a work of architecture and, as such, produces a disciplinarity tied to practice. Architecture – often publicly understood as merely built form – is expanded to include exhibitions as critical, spatial practice … Architecture, as a spatial apparatus, embodies an expanded praxis, articulated and performed through myriad mediums and the circulation of media – text, drawing, model, exhibition, building, film, video and so on. Its proliferation and circulation constitutes, and is constituted by, the spatial environment.* (DiCarlo, 39–40)

In this way, the space of the gallery is also an interactive field. "The exhibition represents a setup in which ideas can be tested in their purest form and on a 1:1 scale … as a research space, testing directly how spatial geometry can assist in the production of intersubjective encounters." (Mueller, 90) The exhibition space has become a quasi-laboratory that provides architects with opportunities to advance their research. As a research endeavor, installation design is integral to the practices of an increasing number of architectural firms because, like competition design, it presents an opportunity to explore ideas that can later be incorporated into built work. Furthermore, "many educators use installations to train future architects … to teach students about playing and building with materials, the collaborative nature of architectural practice, as well as the importance of social action and public engagement…and see installations as a form of creative expression situated within the discipline." (Bonnemaison and Eisenbach, 183).

At the 12th Venice Biennale of Architecture *People Meet in Architecture*, the principal agenda was to examine architectural agency in the creation of space and atmosphere. The emphasis of the Biennale was on experimentation and collaboration.

> *Many of the projects are collaborative and staged as controlled experiments – a cloud is generated, a working studio in Mumbai is airlifted to Venice, space is shaped with light, water vapor, sound, vegetation, fabric. Time is given substance through stop frame photography and stroboscopic light. The past takes its place with the present and reminds us of the dreams of different times and alternative futures. The interdependency of space and time are explored through projection, movement, and images (still and moving) that reveal both the complex subjectivity of perception and the intersubjectivity of experience that is shared-in the spaces of architecture as it is in the context of the exhibition itself. Throughout the exhibition the worlds of information and experience collide, intersect, and multiply their contradictions.* (Blau, "Agency," 40)

Experimentation is about discovery. The process of experimenting involves the investigation, reflection, and action. Whether describing a science, writing, or design project, the pedagogical process of experimentation intermeshes theory and practice in potentially fruitful ways. In architecture, drawings and models and full-scale elements "represent both developing thought processes and samples of parallel possibilities … all imagine actual structures, but their form differs depending on what (program, structure, message, etc.) is most central to the representation." (Hasegawa, 83). For the architecture student, "the architecture exhibition, in providing a spatial experience of architectural ideas, in fact produces architecture." (Chan).

4 ADVOCACY

Advocacy exhibitions address socio-cultural issues related to design practice. In these types of exhibitions, the curator – regardless of their status as an architect – plays a key role in the conception and execution of the exhibition because they set the theme and direct the course of discussion around the show. The student as curator is compelled to ask hard questions and, in so doing, develops an increased awareness of architecture and the social implications of design.

Exhibitions are also a significant medium for both expression and criticism in architecture, "suggesting renewed considerations on the work of major architects or bringing to light overlooked figures, pointing

to scenes or territories ignored by the main narrative, or signaling the emergence of innovative design strategies." (Cohen, 49) Beyond documenting history, exhibitions can be used to articulate a multitude of messages, from demonstrating noteworthy ideas on architectural design to advocating for environmental responsibility in building practices. (Lavin, 8).

MoMA's 2011 exhibition, *Small Scale, Big Change: New Architectures of Social Engagement*, featured eleven architectural projects located in underserved communities on five continents. The designs were not 20th century utopian gestures but instead represent "radically pragmatic" solutions that signal a deep reconsideration of the social responsibilities of architecture. With project ranging from vernacular-derived structures in Bangladesh to the transformation of a housing tower in France, "Small Scale/Big Change" is an attempt to reach backward in time, all the way back to the founding years of the modern movement in places such as the Bauhaus in the 1920s, to reconnect architecture with its early social idealism.

City of 7 Billion: A Constructed World, was displayed at Yale's School of Architecture during the fall of 2015, and highlighted the worrisome implications of global development. The culmination of rigorous research, the findings were presented through the language of architectural representation – models, drawings, and digital renderings – to illuminate the roles of designers in confronting population growth and resource consumption. Set within an academic institution, the exhibition used "shock and awe" display tactics to advocate for change and additional attention from the design fields for an increased sensitivity to population explosion and the dangers of excessive energy consumption.

The efforts of architectural curators are important because they are capable of producing developments that are aesthetically, politically, socially active and generative. These experiments are crucial not only because they are research tools, but they also respond directly to the societal issues at this moment, putting seminal topics on the table so that architects develop a critical understanding of these issues in relationship to what it means to build.

5 INTERDISCIPLINARITY

Interdisciplinary exhibitions are creative practices which feature cross-media perspectives. Often, where different disciplines and architecture converge, inquiries about new materials, technologies and media come into focus, making it fertile ground for discussions about design processes/techniques and discoveries of new generative networks. It is interesting to note that, as Kazuyo Sejima, curator of the 2010 Venice Architecture Biennale puts it, "space is no longer solely designed by architects and built forms are realized through collaborations with other professionals and also users of a building. So, curating here is a collective project involving the collaboration of design professionals as wells as exhibition visitors." (Blau, Curating, 21).

Exhibitions can be seen as a medium through which architecture can extend outside its disciplinary boundaries to explore wider territories. Anthony Vidler noted that "the foundations of the architectural discipline have been substantially redefined in relation to an 'expanded field' and a set of different disciplines." (Vidler quoted in Steierhoffer, 10) Vidler observes multiplicity and plurality in contemporary architecture and a widening interest in the 'non-architectural' to construct new answers for architecture's challenges.

> *In a milieu characterized by territorial and institutional deadlock, architects, urban researchers, and community activists increasingly must intervene in situations by questioning traditional architectural methods and "going beyond building." This does not mean dispensing with the value of architecture per se, but rather acknowledging each situation's unique complexity. Our exhibition explores the original ways that these actors are taking up the challenge of designing the conditions from which new architectures can emerge. They are becoming activists, developers, facilitators of a more inclusive urban policy, as well as producers of unique urban research.* (Menking, Levy, and Sturm)

As the official United States representation at the 2008 Venice Biennale, *Into the Open: Positioning Practice* highlights America's rich history of architectural experimentation and explores the original ways architects today are working collaboratively to invigorate community activism and environmental policy. "The curatorial logic behind this project highlights the ways that architects, urban researchers, and activists reclaim the ability to shape community and the built environment. It is our hope that this taxonomy produces a new understanding of American architectural practice and potential forms of social participation" (Menking, Levy, and Sturm). The sixteen, multidisciplinary practitioners in the exhibition include: The Center for Land Use Interpretation, the Center for Urban Pedagogy (CUP), Design Corps, Detroit Collaborative Design Center, Gans Studio, The Heidelberg Project, International Center for Urban Ecology, Jonathan Kirschenfeld Associates, Project Row Houses, Rebar, Rural Studio, Spatial Information Design Lab/Laura Kurgan, Studio 804, Smith and Others, The Edible Schoolyard/Yale Sustainable Food Project, and Estudio Teddy Cruz. The tremendous diversity of the exhibitors meant that the final exhibition was able to project many different interpretations of architectural practice and community engagement.

In recent years, the focus of the biennales in Venice have shifted clearly to the wider social, political and historical context of architectural practice. *Common Ground*, the 2012 Venice Architecture Biennale curated by David Chipperfield, "focused

on the expanded field of architecture, emphasizing its political, social, and public realms as well as the collaborative nature of architectural production." (Steirehoffer, 7). For this Biennale, the curator stressed the importance of including different working methods and the critical roles of other aspects of architectural culture. By working with methods used in allied fields, architects have gained insight into their own works as well as contributed to ideas in other disciplines, thereby creating fruitful relationships with different practices. For example, "emulating artistic practice has given architects a license to release themselves from the obligations of function, shelter, and permanence associated with architectural design. But, as architects adopted these practices from the art world, they also added expertise and perspective shaped by their own discipline, bringing architectural concerns to new audiences." (Bonnemaison and Ronit Eisenbach, 183).

6 CONCLUSION

> *The exhibition structures its arguments interactively with the viewer and is therefore also indeterminate, fluid, and constantly changing. This is a discursive structure that allows the curator to engage historical as well as theoretical questions in a way that is speculative and suggestive rather than conclusive. It also makes the exhibition an ideal format for tackling subject matter that is difficult, multifaceted, even risky*. (Blau, Reviewing, 366)

A new willingness to take on what has been described as "difficult subject matter"—narratives related to violence, loss, and conflict, among other themes—is increasingly evident in museum presentations. With this shift towards a design approach that fosters and encourages social engagement, a new pedagogical approach can be fostered within the academy to assist emerging designers in curating and communicating the many variables that make up our built environment. For the student, a "larger and less bounded conception of architecture as not primarily concerned with objects in the built environment but as a way of thinking about living in the world." (Blau, "Reviewing," 256) Exhibition development is collaborative, messy, and open-ended – a perfect complement to traditional instructional strategies.

In her book, *From Knowledge to Narrative: Educators and the Changing Museum*, Lisa C. Roberts presents the process of designing an exhibition at the Chicago Botanic Garden. Rejecting a simplistic view of pedagogy, Roberts defines education as entertainment, empowerment, experience, ethics, and narrative endeavor. (Roberts) Through these five lenses, each evident in the socially-driven exhibitions briefly explored in this paper, Roberts argues that the role of teaching and learning in the space of the gallery has changed. While her focus is on the role of curatorial and education staff, the emphasis on a multi-pronged pedagogical approach resonates with the interdisciplinarity of contemporary architectural education. The exhibition venue opens up many diverse possibilities for representation, and, consequently, for modes of reception and learning. (Carter, 47) When students actively curate their work – research and design – for public consumption, the capacity of architectural education is expanded. "New models of citizenship, changes in knowledge formations, and competing media environments have challenged museums to rethink both what they are as a medium and their role in society." (Kirshenblatt-Gimblett, 1) The benefits of curation to the student of architecture can, indeed, be empowering, by providing new immersive experiences, promoting critical, ethical thinking, and entertaining those who participate in the narrative endeavor.

An investigation of building systems education in architecture

R. Liu & P.V. Marks
Kent State University, Kent, OH, USA

ABSTRACT: A survey was created to evaluate the influence of building systems education on architects' career. 667 received responses indicate only 77% architects believed engineers communicate their requirements clearly and they understand engineers' requirements, and less than 60% architects agreed their education at school was sufficient to understand the technical design principles of building systems. Traditional "lecture – example – homework – exam" approach is widely used in teaching building systems. But many students have difficulties in demonstrating their understanding of design principles in their studio projects. This issue could be addressed though integrating experimental learning into building systems curriculums. Students will be motivated to actively participate in experimentation, reflectively experience and observe experimental phenomenon, and conceptualize the fundamental concepts. Experimental learning projects are integrated in structural system courses in the College of Architecture and Environmental Design at Kent State University. Assessment shows positive effect of experimental learning projects has had on students' knowledge.

1 BACKGROUND

Climate change, depletion of natural resources, environmental degradation, and other "buzz" words arose from the complex interactions between humanity and the natural environment. Architectural design must address these challenges to meet the Architecture 2030 Challenge (http://architecture2030.org/) as well as fulfill its purposes of commodity, resilience, aesthetics, and sustainability. This would require Architects to increase their knowledge in the areas of science, ecology, engineering, technology, sustainability and integrated building systems design. Historically, many architects' creative designs were "killed" by engineers for reasons of structural and financial realities. However, amazing architecture projects are made possible by mutual understanding, excellent communications, and collaborations between architects and engineers. To explore the relationship between architects and engineers, and to evaluate the influence of building systems education in the college on architects' career, a survey was created by the authors in order to improve the teaching approach on building systems in the College of Architecture and Environmental Design at Kent State University, which is located in the State of Ohio, United States. Traditional "lecture-example-homework-exam" teaching model, originated in civil engineering programs, is widely used in building systems courses in the Colleges of Architecture in the United States. But it is observed that many architecture students have difficulties in applying basic design criteria and demonstrating their understanding of design principles in their studio projects. An innovative approach to integrate experimental learning into building systems curriculums is proposed and discussed in this paper. Motivated Architecture students will actively participate in experimentation, reflectively experience and observe experimental phenomenon, and conceptualize the fundamental concepts as well as building design principles.

Experiential learning techniques are already commonly accepted in various aspects of architecture education as well as the profession (Archnet, 2014). Many institutions use experiential learning models in their design studio, and the U.S. National Council of Architecture Registration Board model for professional development is fundamentally an experiential learning model. Perhaps, the most famous example of an experiential learning model is Samuel Mockabee's Rural Studio (MackIntosh, 2014). Not all experiential learning models need to be as immersive as the Rural Studio; there are examples in almost every institution of experiential learning practices many of them taking the form of community involved design studios and research projects. The key to experiential learning is creating an environment where the student is an active participant in the learning process, whereby the student's context and understanding of the material is built around their experience exploring the content area. This method of learning is common in the studio environment and is recognized by the American Institute of Architects (AIA) through its internship program. However, it is uncommon to see experiential learning methods employed in the technical courses that makeup the engineered building systems curriculum.

In late 2013 and early 2014, a survey was administered to practicing Architects and Architectural interns, mainly in the State of Ohio. The intent of this survey

was to gauge how architecture practitioners feel about their architectural education in engineered building systems. The information gained in this survey was used to better understand teaching methods and teaching priorities as it pertains to engineered building systems at the university level. The four engineered building systems surveyed were:

- Structural
- Mechanical
- Electrical
- Plumbing

The survey was disseminated using a variety of social and professional networks. The vast majority of respondents received the survey via an invite from the AIA Ohio chapter. AIA Ohio sent the survey to every registered Architect in the state.

2 SURVEY DEMOGRAPHICS

All respondents to this survey were either registered architects or architectural interns. The survey produced 667 valid responses, which were used for analysis in this paper. Respondents were asked a variety of demographic questions. Of these respondents, 537 self-identified as being 16+ years practicing in the industry, this represents 80.9% of the total responses. 24 respondents (3.6%) identified themselves as being 1–5 years in the industry and 103 respondents (15.5%) self-identified as having 6–15 years of experience.

Architects and engineers engage in a variety of contractual relationships that help frame the working environment and expectations. Respondents' were asked to identify the typical contractual relationship that they engage in with engineers. Respondents were asked to select one of the three following contractual relationships with their engineers either: subcontractor, in-house, or partnership. In a subcontract relationship, the engineer is hired by the architect to perform engineering services on a project. An in-house relationship refers to design firms where the engineer and the architect are both employed by the same entity; these entities are commonly referred to as A/E (Architecture and Engineering) firms. The final option for the respondents is partnership. A partnership refers to when the engineer and architect pursue a project together either as contractual equals. As shown in Figure 2, 71.0% of the survey recipients indicated that the engineer is typically a subcontractor of the Architect. 17.7% have contractors in-house and 11.3% are typically engaged in a partnership with the engineers. This means in the building industry in the United States, architectural design and engineering design are two critical interdependent professions especially in this age in need of resilient and sustainable design and development, which requires mutual understanding and excellent communications between architects and engineers.

Respondents were also asked to identify the project types that they have engaged in over the last 24 months. Commercial had the greatest number of responses at 514, followed by public works at 307, Educational at 263, single family residential at 247, Industrial at 224, and multifamily at 189 (Figure 3).

These numbers indicate the architectural design industry in the United States relies on condition of the economy, and it is most influenced by private and

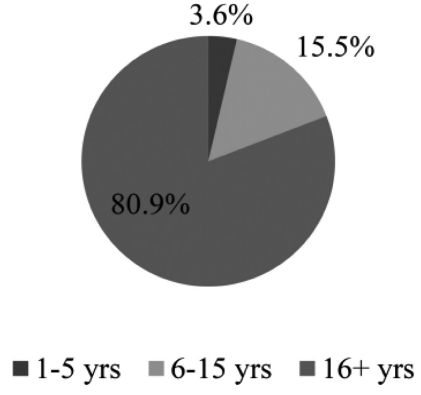

Figure 1. Survey demographics.

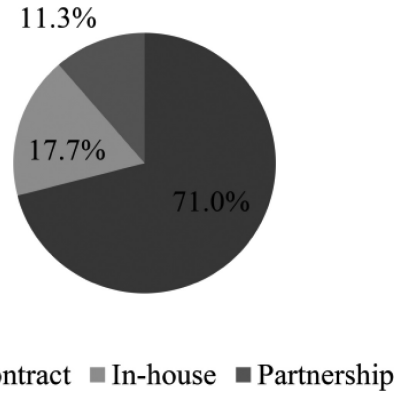

Figure 2. Typical project relationship between the Architect and engineers.

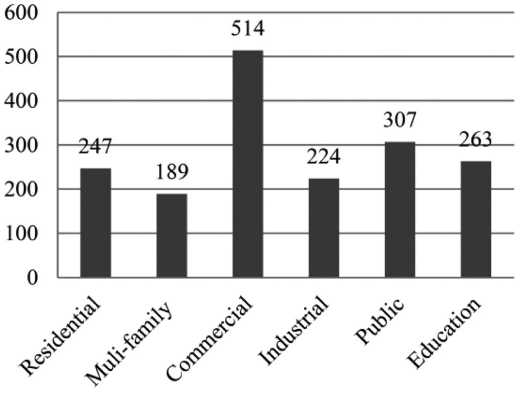

Figure 3. Over the past twenty-four (24) months, what types of buildings have you been involved with.

public investments. In the recent economic recession in the United States, the profession of architects was affected a lot. But the building industry is one of the most important driving forces to turn the economy around in the United States. Architectural design is a profession with both challenges and opportunities. Architecture students need to be ready through training at school and in practice to grasp opportunities and address challenges.

3 SURVEY RESULTS

There were three main objectives of this survey. The first was to identify how Architects self-identify their working relationship with engineers. The second was to determine if architects feel that they are sufficiently competent in the subject matter, and the third was to determine if Architects believe that additional university education (during college) on engineered building systems is desired.

3.1 *Relationships between architects and engineers*

In order to understand how architects feel about integrated building systems design, and how architects communicate and collaborate with engineers, respondents were asked to respond to the following three true/false statements:

- Engineers and I collaborate well together
- Engineers generally appreciate architectural requirements
- Engineers communicate their requirements clearly, and I understand their requirements

97% of the respondents indicated that the engineers and architects collaborate well (Figure 4). This response was consistent regardless of the respondents' years of experience (varying from 95.5% to 97.1%), contract type (varying from 95.9% to 98.3%), or project-type (varying from 94.7% to 99.4%). These results illustrate the strong professional and working relationship that exists between architect and engineers within the building industry in the United States.

Despite Architects identifying that they work well with engineers, only 77% believe that engineers appreciate architectural requirements and engineers communicate those requirements clearly. The discrepancy between collaboration and understanding may indicate that despite a strong professional working relationship (which might be compromised), there are still communication issues between architects and engineers, which may be caused by structural and/or financial realities.

The collaborative environment between architects and engineers can be further understood when the contractual relationships were examined in conjunction with the collaboration questions. Here it is indicated that the professional relationship may influence the collaborative environment. 80.3% of architects who typically partner with engineers believe that engineers communicate their requirements clearly, with only 76.8% and 76.9% for subcontract and in-house respectively (Figure 5). The architects and engineers in partnership relationship have a much better mutual understanding than the other two contractual relationships. This may be because of their equal positions in the project contracts, which requires more frequent open and honest communications between the architects and engineers.

Similarly, 71.8% of architects with in-house engineers claim that engineers appreciate architectural requirements while 78.8% and 76.7% of architects with subcontract engineers and in a partnership with engineers respectively feel engineers appreciate architectural requirements (Figure 6). It is a little surprising the see the architects with in-house engineers have the lowest percentages to feel their work effort is appreciated by engineers. This is may be caused by the potential conflicts of personal interests in the same entity.

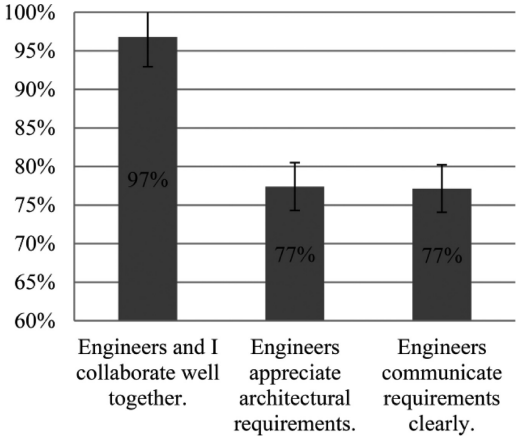

Figure 4. Relationships between architects and engineers.

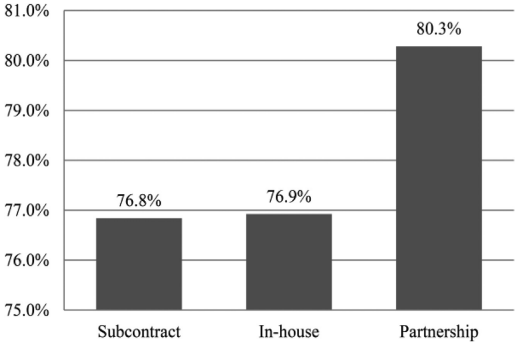

Figure 5. Engineers communicate their requirements clearly.

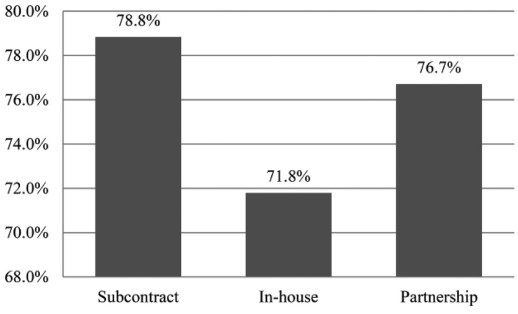

Figure 6. Engineers generally appreciate architectural requirements.

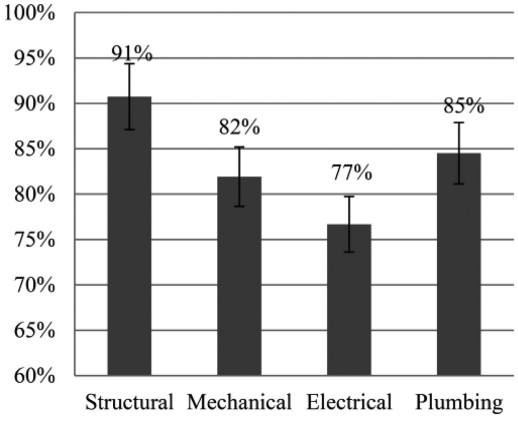

Figure 7. I understand the technical design criteria for the given engineering field.

3.2 *Architects comfort with technical criteria*

The second objective of this survey was to gauge the architects' comfort with the technical criteria for each engineering discipline. When asked whether architects understand the technical criteria for more about a particular discipline, it is shown in Figure 7 that there is a spectrum of architects' comfort with each discipline. Structural: 91%, Plumbing 85%, Mechanical 82%, Electrical 77%. The results above indicate that the majority of architects are comfortable with technical criteria for engineered building systems. However, when asked if they wanted to understand more about the technical criteria, 57.4% of respondents wish they learned more about structural, followed by Mechanical at 64.1%, Electrical 62.9%, and Plumbing 54.0% (Figure 8). This indicated that even respondents that are comfortable with the technical criteria have a desire to learn more. Comfort with technical criteria does not indicate if the professional is content with what they know.

3.3 *Architects learning objectives*

The architecture profession is one with constant learning and growth. The expectation of the university is to prepare young architectural professionals for the

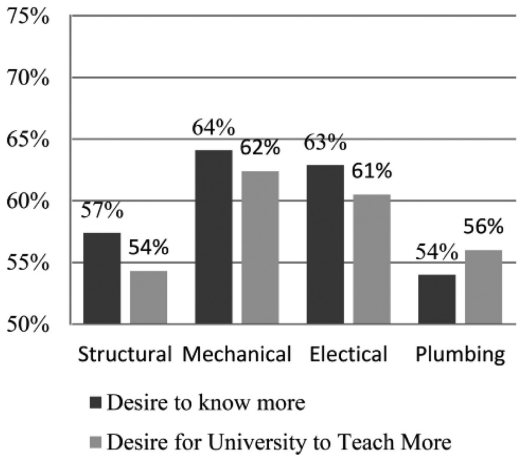

Figure 8. Architects learning objectives.

building industry. Once engaged in the building industry, there is an intern requirement followed by yearly continued education. It is not uncommon for architecture students to make statements similar to the following:

"While it would have been good to learn more in school, there are other aspects of Architecture are best learned in school. The engineering focus may be best during internship."

The above statement may be true if the fundamental engineering design principles are well understood in school. Having identified that the majority of architects have a desire to know more about engineered building systems, the final question was to establish if that learning should take place in the university environment. When respondents were asked whether they wish they understood more about engineered building systems, the majority answered yes, and the majority also believes that the university is the appropriate place for that learning as shown in Figure 8. Based on the survey results, it is important to emphasize students' understanding of the fundamental design principles of engineered building systems at school and make sure students acquire life-long learning skills.

4 EXPERIMENTAL LEARNING – CASE STUDY

The Architecture program in the College of Architecture and Environmental Design, Kent State University balances art and science, and humanity and technology. Like the majority of Architecture Schools, design studios are the central pillars of the program, and other humanistic and technological courses support the design studios. The teaching method for architectural technologies and building systems was traditional "lecture – example – homework – exam" approach, which originated in civil engineering programs. However, based on authors' observation, many students were not able to demonstrate their understanding of

fundamental design principles in their design studios. One reason might be the traditional engineering teaching method does not trigger their curiosities and interests in learning architectural technologies considering design studios take most of their times and efforts. To address this issue, experimental learning is proposed to be integrated into the curriculums of building systems. It is expected that architecture students enrolled in these architectural technology courses will actively participate in experimentation, reflectively experience and observe experimental phenomenon, and conceptualize the fundamental concepts, and fundamental design principles. Taking structural system as an example, this paper introduces the experimental learning projects developed to enhance structural courses in the College of Architecture and Environmental Design at Kent State University.

4.1 *Case study – architectural structures*

The basic goals of structural education for Architecture students should include but not limited to:

- Understanding of form synergy and building structures
- Understanding selection criteria for appropriate structural systems
- Conceptual design of structures for gravity and lateral loads and integration of structural design with architectural objectives
- Basic hand and computer-aided structural analysis
- Understanding of structural design principles, and capability of seeking practical design solutions for building structures
- Effective communication with structural engineers

There are three required structural system courses for architecture students at Kent State University. *Introduction to Building Structures* emphasizes fundamental concepts of building structures. *Structural Systems I* and *Structural Systems II* discuss structural design principles for steel, timber, concrete, and masonry structures. However, many architecture students struggle to apply basic structural design principles and demonstrate their understanding of these principles in their studio projects. The authors concur with Professors R. Gary Black and Stephen Duff from University of California, Berkeley that *"a higher aim (of architectural structures education) is to enable (architecture) students to use structure as a creative design force throughout all phases of design,……. To do this, students must understand buildings at the level of their detailed structural behavior."* (Black, R. G. and Duff, S., 1994).

4.2 *Experimental learning projects*

Experimental learning projects were developed to enhance the lectures of the three structure courses. These projects include:

- Hands-on lab experience to learn fundamental concepts
- Computer modeling using free educational programs RISA 2D and 3D
- Constructing structural models using the 3D printing and/or laser cut technologies

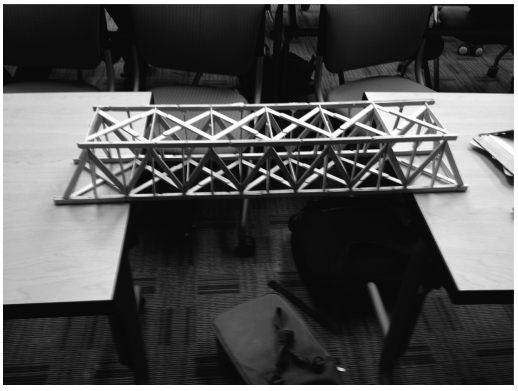

Figure 9. Truss structure.

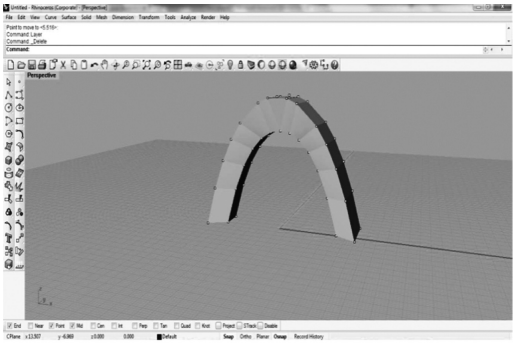
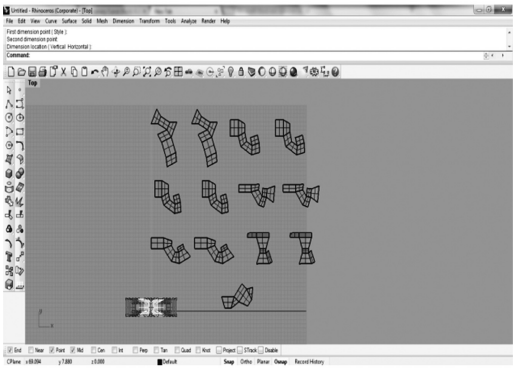
Integrating these experimental learning projects into structure curriculum requires changes of students and instructor's roles. Students are the center of the classroom, and they must be willing to actively get involved in the experimentations, capable of using analytical skills to reflect on and conceptualize what they see, and apply what they learned from structure courses in their design studios. The instructor must motivate students or get them self-motivated, and assist them in conceptualizing new knowledge.



The following experimental learning projects have been developed:

- Truss structure
- Building catenary arch structure
- Concrete frisbee
- Summation of forces
- Measurement of strains of a cantilever beam
- Stable vs. unstable, redundant vs. non-redundant truss structures
- Buckling of columns
- Axial, shear, and moment diagrams developed using computer modeling
- "Zero reactions" using computer modeling
- Deformation of frames with various boundary conditions under lateral force
- Analysis and construction of building structures



The following contents were included in the write-ups of the developed experimental learning projects:

- Overview
- Objectives
- Materials
- Preparation
- Classroom Activity
- Questions
- Answers
- Note

Three projects i.e. truss structure (Figure 9), building catenary arch structure (Figure 10), and concrete

(a)

(b)

Figure 10. Cantenary arch.

Figure 11. Concrete frisbee.

frisbee (Figure 11), have been implemented in *Introduction to Building Structures*, *Structural Systems I*, *Structural Systems II* respectively. Students enrolled in my classes started to learn fundamental concepts, behaviors of structures, and design principles through reflections on participating in these projects. It took approximately 15 minutes for the instructor to explain each project and perform a classroom demonstration after the new fundamental concepts are introduced in the class. Instructions are provided for students to work on their own during the class and after class

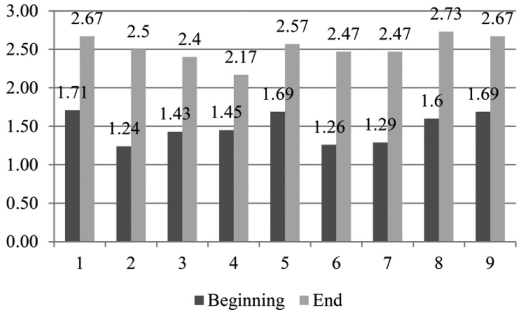


Figure 12. Course outcome assessment.

to continue learning structural design concepts and principles through reflections.

Course outcome assessment was created to evaluate how the experimental learning projects help improve students' overall understanding of structural form selection and structural behaviors in the long term. Students are encouraged but it's not a mandate for them to participate in the evaluations. The purpose of the "course outcome assessment" is to evaluate the effect this course has had on students' knowledge. The survey is given twice, one at the beginning of the semester and the other on the last day of the class.

The following discussion took *Structural Systems II – Design of Reinforced and Masonry Structures* as an example to explain to the evaluation process. Figure 12 shows the results of course outcome assessment of this course. Forty-two surveys were returned at the beginning of the semester and thirty were returned at the end of the semester. Students ranked 9 questions using the following criteria:

- 1 = I cannot solve this problem at this time
- 2 = I can (moderately/50%) solve this type of problem if given adequate time and supporting material
- 3 = I can solve this type of problem with EASE if given proper supporting materials

The lowest rating at the beginning of the semester is 1.24 for the second problem, which is to draw the stress and strain distributions for the rectangular reinforced concrete beams when the section is cracked. It is important for students to understand the basic assumptions made for the reinforced concrete design. The highest 1.71 is for the first problem, which includes questions about the material properties of reinforced concrete. The survey indicates students generally were not capable of solving the problems at the beginning of the semester. With the concrete frisbee project implemented, students had a better understanding of properties of concrete materials and performance of the reinforcing in the concrete. In addition, the project triggers their interests in learning reinforced concrete design. At the end of the semester, the survey indicates all problems can be solved by the students with adequate time and supporting materials. The improvements of ratings range between 0.71 and 1.26. Problem 4 is the one with the lowest rating 2.17 and least

improvement 0.71. This is the question to define the three steel reinforcement ratio conditions: balanced, under-reinforced, and over-reinforced. The students were also asked which condition should be considered to design reinforced concrete beams. The three conditions were discussed at the beginning of the semester. Some students might not have very good understanding of these concepts when they learned the topic. This helps instructor identify the problem and this may be a potential experimental learning project to develop in order to help students gain a better understanding in the future.

5 CONCLUSIONS

A survey was created in this study to identify how Architects self-identify their working relationship with engineers, gauge how architecture practitioners feel about their architectural education in engineered building systems, and determine if Architects believe that additional education on engineered building systems during college is desired.

The survey concluded that although a strong professional and working relationship exists between architect and engineers, there are still communication issues between them. Majority architects are comfortable with the technical criteria, but they have a desire to learn more. University is the appropriate place to facilitate that learning.

Based on the information gained in this survey, teaching method was adjusted by integrating experimental learning in architectural structure curriculums at the Kent State University.

A series of experimental learning projects and a course outcome assessment have been developed to be implemented in the architectural structures curriculum at the Kent State University. Students' active participations, self-reflections, and conceptualization of structural behaviors have been observed in the successfully implemented experimental learning projects. The developed evaluation indicates these projects have played important roles in improving students' understanding of architectural structures. Due to lack of data, there is no information on how the experimental learning enhanced lectures perform compare to the a traditional "lecture-example-homework-exam" approach. But according to several studio professors, students who participated in the experimental learning projects start to demonstrate their better understanding on structural design criteria and principles in studio projects. It has been planned to collect data to confirm it. The course outcome evaluation will be used to monitor the long-term effect of these experimental learning projects on students' performance in structure courses. The successfully implemented experimental learning projects have inspired the authors to develop more projects to be implemented in other engineered building systems courses.

Structure in architecture – A definition in the poetic tectonic age

F.X. Oliveira
FAUL/CIAUD, Lisbon, Portugal

ABSTRACT: Praising structure in architecture reveals its importance as a physical, symbolical and metaphorical expression of its most basic formal syntagma, the minimum architectural significant unit. The present article seeks to determine the meaning and value of structure as a conceptual determinant of architecture. What is *structure in architecture* in the poetic tectonic discourse? The methodology of analysis is based on *Complexity theory* (Morin, 1991); on architecture as a *Pattern Language* (Alexander et al., 1977); and on the *Structure of scientific revolutions* (Kuhn, 1962) in order to detect paradigms and paradigm changes. This cumulative reconstruction of data, in a global and structuring concept, possesses a four-dimensional meaning, understood as universal invariants: space, technique, thinking, and time. The (re)construction of the concept as an open map of patterns searches for order, acting as a theoretical/practical mnemonic for knowledge. It allows its operability as an auxiliary of divergent thinking by raising consciousness.

1 STRUCTURAL SYNOPSIS

1.1 *State of the art*

Rizzuto (2010) concluded that the discourse on tectonics is presented as a Historical invariant, a philosophical pattern of architecture as a discipline. Architecture as a physical reality depends on the *techne* because structure is part of architectural truth in its essential condition of support. Tectonics is the intellectualization of thought about the technique. Tectonic symbolizes the connection between chaos and order which requires a process of know-how for the technical construction. Putting into order is the mythological connection associated with the concept, from which arises architectural meaning.

The critical discourse on tectonics reveals a cumulative and interconnected thought from antiquity to actuality, which can be praised. The tectonic arises as a critical vision of History, emerging in this context as a strategy of know-how linked to architectural form. The tectonic epistemology in Rizzuto analyses detects three key periods in 2500 years of construction: Classical, Rational and Poetic.

Classical tectonics corresponds to the Classical period and it is related to its philosophy. The tectonic philosophy has its origins in ancient Greece mainly in the dialectic between art (*techne*) and *phronesis.* The *phronesis* with its origins from Aristotle is associated with a sense of practical wisdom understood as an intellectual virtue: “common sense”. The etymology

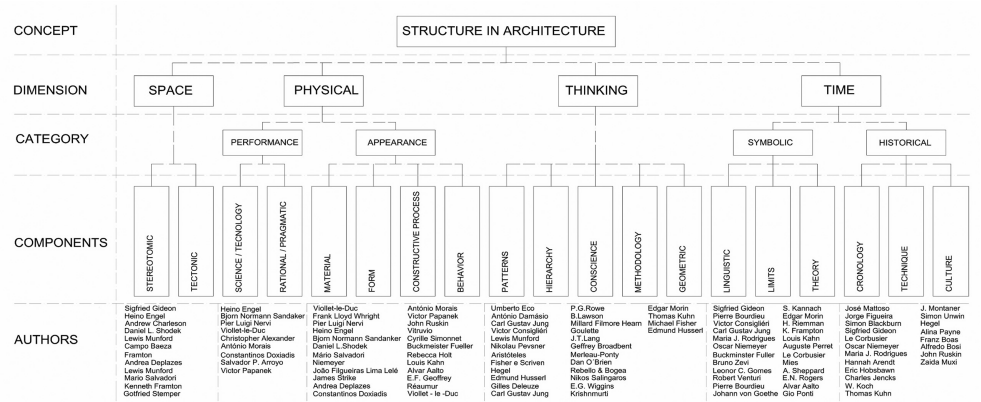

Figure 1. Structure in architecture.

of the word *architekton* symbolizes a network of interconnections between theory and practice used in the design, assumed as a prior idea of what we want to build (Rizutto, 2010).

Rational tectonics has correspondence with the early-modern period and receives influences of epistemology of science while maintaining the general principles of classical tectonics. Renaissance is analyzed in this context with a structural epistemology linked to science and metaphysics. The Baroque is an epistemological change of Vitruvian concepts through the critique of mimesis. The Cartesian thought is changed between mind and body, between artistic subjectivity and technical objectivity (Rizutto, 2010).

Poetic tectonic arises in the late modern period and incorporates the rational enlightenment thought along with poetic Romanticism via a dual conception. The poetic tectonic presents itself as a new epistemological framework that links to the notion of structure concepts such as "nature" and "truth", allowing new scientific conceptions of tectonic analyses in architecture. The poetic tectonic does not reject the rational tectonics but rejects the notion of mimesis. Architecture is understood in this "deep structure" as an individual artistic expression. Freedom of action is enhanced by developments in technology associated with new materials (Rizutto, 2010).

The Vitruvian principle of *structure as architecture* related to the nature of materials in the search of savings and constructive rationality is one of the oldest and long-lasting theoretical/practical traditions of an ideal architecture that still persists. Within the poetic tectonic age different authors have spoken critically on this topic. The historical and global understanding of different perspectives of the concept of "structure" in its relationship between theory and practice, allows an understanding of what is structuring in architecture and how it has changed over time.

Ruskin (1849) discusses the logic of materials within the concept of structure, while adornment is linked to the symbolic and artistic expression of architecture. Viollet-le-Duc (1877) refers to *truth* and *nature* of structure as a ruler component of architecture. Le Corbusier (1927) argues for structural truth interconnected to nature of new materials and the aesthetics of the engineer. There is in Le Corbusier a clear distinction between art and technique as a result of complexity of specific knowledge associated with new building materials. Kahn (1955) develops the idea of a metaphysical school of architecture around the concept of *Order*. Nervi (1956) argues about truth in construction associated with the constructive process. Heino Engel (1967) defines *Structural System* and presents a compendium of organized structural models based on properties materials. Venturi (1977) incorporates structuralism in his philosophical discourse of architecture and demonstrates how structure in architecture has a double meaning: symbolic and functional. The "deep architectural structure" is associated with the symbolic expression that seeks to communicate through language patterns. Alexander (1977) incorporates complexity theory into theory of systems and defines architecture as a pattern language. Patterns are seen as archetypes, primary principles that are comprehensive enough to enable different perspectives. There is a need for obtaining the natural order of things, understanding their internal logic, related to "nature." Eisenman (1984) shifts the concept of deep structure towards linguistic away from the classic concept associated with nature and truth in architecture. Structure in this perspective is understood as a tool for control of architectural discourse. It is the autonomous theoretical discourse that validates the architectural form, into a deliberate distance between art and technique. Prix (1991) considers structure as a *metaphor for forces that* are independent of gravity but depend on energies. The architectural form is designed independent of material because it depends on the logical response of technological tools: the computer. Tschumi (1994) considers that in a project there are three different logics: the logic of words associated with the concept; the logic of design into creating space; and *logic of materials*. The logic of materials depends on the decision of software, independent of architectural design.

2 PROBLEMATIC

By being *structure in architecture* the object of study it is important to define structure and architecture. The starting question is simple and yet complex: What is structure in architecture in the poetic tectonic discourse?

Structure in a broad sense defines a system. A system is a set of cross elements connected to form an organized whole. Accordingly, Structure is a set of items, a collection of interrelated components or services. Structure implies a logical thinking (convergent) through hierarchy, a cascade relationship of one-to-many, or an analog thinking (divergent) in which there is a relationship between various entities via a network. Structure is by definition a system, understood as a set of connected elements according to logical thinking (hierarchy – one too many) or analog interconnections (network) that seeks to form an organized whole (Encyclopedia *Luso-Brasileira da Cultura*, 1970, Vol. 7, p. 1655).

Architecture, in its first and broader sense, refers to the art and technique of arranging and configuring spaces. For Vitruvius, the architectural practice was related to experience, which resulted from consciousness of architectural own structural grammar that sought construction put into order. He added that practice without theoretical sustain of work, did not give moral authority to the author. As a social art and principle of human condition (dwelling space), it is an extremely complex activity because it is a multidisciplinary field covering areas as diverse as: mathematics, art, science, social sciences, technology, history, philosophy, among others. Producing architecture results of a process of synthesis of all these aspects

interpreted accordingly the spirit of its time and place (*Genius Loci*).

A holistic view is essential for understanding the concept of *structure in architecture*, because architecture is an indivisible practice (fig. 1). Therefore, it cannot be understood from a separate analysis of its parts: Art and Technique. Their understanding requires the application of system theory, an open system in continuous interaction, in order to understand its complexity. Complexity realizes that the whole is greater than the sum of its parts and that focusing on particular, can cause blindness (Morin, 1991). Eunice and Carlos Abascal (2010) in an article in the Vitruvius magazine refer the need "(. . .) *to reveal a specific scientific condition of Architecture, within the framework of so-called human sciences"*

3 METHODOLOGY

The supporting theoretical framework is based on the Complexity Theory (Morin, 1991). A global understanding as opposed to specific knowledge can create a wider perception of how architectural theory relates to practice. It allows a holistic vision of architectural knowledge in the search for multidisciplinary analyses.

The theoretical framework is what sustains the perspective to analyze the problem. According to Quivy & Campenhout (1988) the: *"Conceptualization is more than a simple definition or terminology convention. It is an abstract construction that aims to account the real. It does not retain all aspects of a certain reality, but only those that expresses the essence of that reality (. . .) it is, therefore, a construction – selection".*

4 STRUCTURE IN ARCHITECTURE

The concept of Structure in architecture seeks to define the underlying structural lexicon that leads to architectural design, from which it is possible to study language in architecture, by being a *pattern language* (Alexander, 1977).

This cumulative reconstruction of useful data, in a global and structuring concept, possesses a four-dimensional meaning, understood as universal invariants: space, technique, thinking, and time (fig. 1). The dimensions make up the totality of views on this reality intertwined with architect's fundamental knowledges. The clarification of the four distinctive dimensions with its specific categories and components allows their operability as a theoretical/practical mnemonic, extoling their useful value.

Know how to be is the ontological perspective of the object. Ontology is the science of being. Anything that exists and it is seen as something that it is. Knowing how to be architecture refers to spatiality, therefore, within the concept, this leads to the space dimension, the way it is structured, organized and composed.

Know how to do are the abilities and skills applied to solve a characteristic problem of specialization. Knowing how to do architecture refers to its technical dimension linked to practice. Therefore within the concept this corresponds to physical structure, what sustains form. This dimension is divided into two different categories: physical performance and physical appearance.

Know how to think is the theoretical perspective within the global knowledge. This has correspondence with the thinking dimension, the way we reason and structure thinking when producing an object.

Know how to communicate is inherent to the architect's condition of being creative throughout a dynamic learning process. In architecture this is linked to time. Time dimension is divided into two different categories: the symbolic, representing how physical structure carries meaning, and how that meaning has changed; and another related to the historical perspective of physical structure, throughout history, understood as a compendium of evolutions and revolutions (Kuhn, 1962).

5 SPACE DIMENSION

The ontological dimension of *structure in architecture* is spatiality, the set of predicates and qualities attributed to the being. Spatiality is inherent to physical structure as a reality, because it evidences from the very first moment its essential existence. Without structural support there can be no materiality.

Structure as a physical reality can be regarded as a primary form of organization of space due to placement of structural elements (fig. 1). This relationship between elements, arranged in a logical (calculation) and intentional (idea) way attributes a relational and rational nature to the conceived space. Munford (1952) and Engel (1967) concluded that structure and architecture belong to the domain of art because they refer to human spirit as intentional decisions.

Frampton (2002) defines two different categories of structure regarding to its spatial and existential genesis: stereotomic and tectonic. About structure Framton defines "(. . .) *structural unit as irreducible essence of architectural form".*

5.1 *Stereotomic*

Alexander (1977) refers to stereotomic architecture as an example of an efficient structural design defined by a supporting structure that runs continuously and through compression. There is a continuity of material and form, applied in repetition according to a three-dimensional system.

This category of spatial construction defines the space limits with a clear indoor/outdoor separation, understood as a spatial and structural unit. The concept of spatial cells provides outdoor addition to architecture with additive or inner subdivision growth, based on the subdivision of a large initial volume. According to its nature there is no structural hierarchy, because

all structural elements (bearing wall, for ex.) booth support and define spaces. The materials applied are mainly- masonry, brick, adobe and concrete (Deplazes, 2005).

5.2 *Tectonic*

Tectonic architecture is based on a space reticulum due to a structural skeleton. In architecture the structural elements are parts of a bigger whole associated with lightness. In terms of structural performance it is defined by possessing moments due to tension stresses to which it is subjected.

Deplazes (2005) stated that the lightweight construction composed by horizontally and vertically arranged bars, when exploited in their aesthetic sense, provides to space: movement, metrics, rhythm, simplicity, randomness, complexity, proportion and scale. The structural elements are arranged hierarchically according to their behavior in an open system that searches for light in architecture. In terms of openings, it allows the void as a part of the structural reticulum, as we can see in curtain façades, independent of structural plot. The materials applied are mainly- brick, concrete, wood and steel.

6 PHYSICAL DIMENSION

The physical dimension linked to technique is associated with practice, the know-how in terms of building knowledge. This dimension is divided into two separate but interrelated categories with their respective components and indicators: Physical Performance and Physical Appearance (fig. 1).

6.1 *Physical performance*

Physical performance is the set of characteristics achieved through structure that are linked to optimization. It is essentially the field of engineering made from a strictly rational analysis of structure, followed by an approach which makes use of mathematical models for comparative analysis. This category is divided into two components: a scientific approach applied to technology and rationality connected to pragmatic.

Science and Technology covers mathematics applied in calculus, chemistry associated with materials and ultimately, physics related to structural behavior (Engel, 1967). As a manifestation of technology within structural performance we can find software applied to structural calculus and cost.

The rationality and pragmatic components are linked to economy achieved through structural syntheses of functional and aesthetic capacity. The mechanical efficiency emerges as a compromise between the lowest expenditure materials facing a higher yield (Sandaker, 2008). Structural maintenance, durability and ecology are rational and pragmatic concerns. Constructive efficiency and speed (economy of scale) which gives rise to a business plan, also belongs to the act of planning.

6.2 *Physical appearance*

The physical appearance emerges as a category associated with the know-how, the physical structure as an architectural and constructive reality that contributes to the cause of architecture from the perspective of its appearance. This category is subdivided into four interconnected components that affect its physicality: material, form, construction process, and structural behavior.

6.2.1 *Material*

The material has a decisive role in physical appearance of structure for its interconnection with form, the construction process and the behavior. Each material has a constructive logic inherent to its nature that affects structural endurance, its mechanical behavior and durability. There is an intrinsic poetic linked to materials that provides expression to architecture understood as a whole. This is achieved through material application in which values such as: image, identity, plasticity, texture, color and stereotomy take a decisive role (Deplazes, 2005).

6.2.2 *Form*

Structural form belongs to the category of physical appearance by being a real and visible phenomenon that establishes an interactive relationship with Man.

Engel (1967) stated that: "*structure is the first and only tool for generating form and space in architecture*". Structure is an essential mean to model man's building space. Engel's structural systems constitute a set of structural principles in the form of diagrams arranged in structural families. This analysis provided five families of structural systems arranged as a structural genealogical tree: active – Form; active-Vector; active-Section; active-Surface; and lastly, active-Height.

Morais (1997) argues that, conceptually, there are two types of structure: structural forms and structural skeletons. Structural forms have an inherent plastic potential because they depend on specific shapes that optimize force behavior through matter. In this sense, architectural form is also structure.

Charleson (2008) contributes with a third distinction in the relationship between architectural form and the structural form. Structural shapes are *syntheses* (shell structures; textiles; catenary; ribbed; pleated; arches, porches; and supporting walls). *Skeleton structures* have a relationship of agreement with architectural form. Finally, a *contrast form* refers to a hybrid relationship between structural form and architecture, by using the unexpected in order to achieve plasticity.

6.2.3 *Constructive process*

Viollet-le-Duc (1877) suggested that the various elements that made up architecture were related and prioritized according to a logical system. He connected this idea with the notion of truth. The author concluded that builders should be faithful to architectural program and constructive process.

Kahn (1955) refers to the constructive process as a connection between the developments of an idea that gives rise to syntheses in the form of a plan.

Papanek (1995) by analyzing vernacular architecture concluded that a building has an empirical nature, in the sense that knowledge, also plays through experience, trial and error. The author defended a methodological explanation, in which "(. . .) *the method is a combination of material, tool and process*".

Architectural expression varies for the same material once revealed from different constructive processes. Architecture has evolved and perfected from the domain of construction process, from which also draws its own expression. James Strike (1991) detects a breakthrough in terms of building processes within each material, having in common, the inevitable notion of prefabrication, normalizations of measures associated with standardization.

The construction process is the management of tasks in order to achieve a goal with maximum efficiency, throughout a dynamic and evolving process. This notion of construction planning has to do with the know-how by the awareness of strategic options in a given context, such as the material-tool-process.

6.2.4 *Structural behavior*

Engel (1967) defines architecture as the "total" depending on three factors: function, form and technique. The structure for Engel acts as a technical determinant. Structure is the result of another triad, consisting of forces – geometry – material. The concept of structural system is defined as a model projecting structural principles focusing on the flow of forces and geometry. Engel's structural system is based on the fundamental principles of theory of structures: the balance of forces. In order to achieve balance of forces, architects must be aware of structural behavior through concepts, such as: strength; own weight; moment; tension; stiffness; and balance.

Schodek (1992) considers that a structure functions as a whole whenever the parts work together to influence each other, in which the qualities and properties of a system are checked. Verification of the system is demonstrated by structural behavior.

Morais (1997) argues that basic balance of forces is crucial to understand the need for the existence of a reaction force (internal forces) contrary to external forces exerted on a given structure, allowing it to stabilize. In order to decrease the moment, decomposition of forces is needed, usually related with the plastic capacity of structure. This basic equilibrium of forces can be achieved through three types of equilibriums: direct; indirect and nonlinear. Direct equilibrium can be achieved throughout two principles: form and triangle.

7 THINKING DIMENSION

The architectural structure of thought is a dynamic process involving organization of knowledge, in order to achieve synthesis. Although there exists multiple approaches to architectural design (epistemology, praxis, axioms, and hermeneutics), the emphasis is based on the epistemological study of *structure in architecture*. In order to understand the relationship between architecture and structure, it is necessary to underline what's common: the structural lexicon. The architectural vocabulary is the result of a choice from the existing structural lexicon.

The knowledge of structural lexicon allows its subsequent applicability in architecture, understood as a technical useful value, since structural elements assume themselves as syntagms of architectural language. The separation between art and technique is harmful to architecture because it reduces the architectural vocabulary. It's conscience allows sustained evolution of architecture, understood as a language.

The meaning of creation in architecture contains uncertainty in the discovery process, in the search for synthesis. In this perspective architects are by definition voyagers of uncertainty. As Umberto Eco points (1968), this sense of discovery, of mental structure, comes from the capacity to absorb information through memory, subsequently applied into new ideas, when facing new problems. Memory does not come as a source of knowledge, but rather as a faculty that allows us to remember experiences gained through perception, witness and a priori reasoning (Damásio, 2010).

Accordingly to Damásio (2010) thought is considered the most tangible expression of human spirit, because through images and ideas it reveals precisely the conscious will. The author describes human mind as a unique fingerprint, since each one of us has different ways of doing brain connections. Philosophically, thought depends on language because this determines the concepts, judgments and reasoning (Rodrigues, 2000).

Architecture is a universal language that communicates ideas through agreed archetypes (door, window, beam, podium, etc.). It is through architecture that concepts, judgments and reasoning underlying architectural thought, materialize and physically manifest. Although it is an axiom that there is no architecture without structure (principle of sufficient reason), the diachronic mechanisms associated with the creative process go beyond pure logic.

Structural lexicon understood as an architectural technical language depends on the conceptualization of thinking as a form of mental organization, with two distinct approaches: the analog and logic. Divergent thinking and convergent thinking. The way thought is structured comprises: patterns, hierarchy, conscious, methodology and geometry, the invariants detected in different types of thought associated with architectural design (fig. 1).

8 TIME DIMENSION

The time dimension associated with the concept attempts to understand how architectural system evolves. Giedion (1941) considers that the useful

character of architecture can be considered as a factor of communication. The relationship between time and construction, time and ways of thought, time and space, demonstrates that architecture as a discipline is inseparable from communication. It is divided into two categories: the symbolic, associated with the way architectural structure as part of a system of values, carries meaning and how that meaning changes; and finally, the historical perspective of physical structure as a time tool in the evolution of architecture (fig. 1).

8.1 *Symbolic*

The category associated with the symbolic is studied by semiotics. Semiotics seeks to understand the signs as cultural phenomenon's that allow communication. Signs express a sense of belonging to a particular culture and its use revitalizes architectural own culture.

The "architecture of spirit" developed by Levi-Strauss (1962), seeks an understanding of human structural spirit, perceiving that communication is linked to the social domain. The foundation of the symbolic category is the structure of unconscious mind, articulating unconsciously, symbolic and social. Man is a symbolic being that manifests symbolically through language (E. Cassirer, 1944).

The symbolic dimension of structure in architecture explores the duality of the concept. Structure is presented as a constituent of architecture understood as a language. In this sense the structural form has a dual function: the constructive logic (logos) and the symbolic capacity expressed through signs. As Venturi stated: "*There is no way to separate form from meaning".* Architecture, understood as an art of representation, has this symbolic capacity of communicating the ruling power, usually political, religious or economic. The symbolic category comprises the following components: theory; linguistics; and limits.

Whereas theory explores the evolution of meaning associated with the concept of structure, linguistics analyzes the tectonic understanding of "architecture as petrified music" (Goethe, 1839), a discursive pattern. Music and architecture are considered performing arts, whose meaning varies according to culture and time. However, both grow out of immutable and independent internal structures of their own culture and time. This apparent contradiction reveals sensitivity to an implicit order (language), which guarantees universality, independent of communication analyses (speech).

Finally, *limits* as a component of structure represents the overcoming of man against of laws nature, which can be seen through structural spams, high and thickness, as symbolical representations of *sublime.* Economic constraints can also be considered as a *limit* depending on common sense and technical cunning, the Greek "phronesis".

8.2 *Historical*

The historical method applied to the analysis of data has three distinct operations: heuristic related to source collection; critique related to evaluation of pertinent data; and, hermeneutics, the theory of interpretation which seeks the validity of the first issues raised. The category of history encompasses: chronology, technique and culture.

Chronology is a time structure in which different time "scales" might coexist, allowing order into historical events, assuring its scientificity and working as a "*reading machine"*. Therefore, it is essential to rank chronologically, architectural history in terms styles, the aesthetic patterns detected by other historians. It is important to understand alongside communication means in terms of dissemination of knowledge and evolution of transport in order to understand the relationship between space and time. It is also essential to understand: the means and modes of production; military conflicts while epitomes of crisis; evolution of social structures; philosophical ages; and finally, the most influential literature through thematic areas, that can be defined as cultural and civilizational manifestations (Architecture, Politics/Philosophy, Science, Religion, Novels, Economics/History).

Technique is the perspective focused on structural paradigm shifts, its development according to building materials. A perspective on technical developments (structural lexicon) interconnected with materials allows the understanding that architectural evolution and technical evolution are distinct. In architectural history the (r) evolutionary leaps, comes whenever there is a new paradigm associated with technique. Changing to new materials can be considered as a scientific "revolution" because it leads to a new constructive process connected to empiricism. The further development of technique according to a new materiality that becomes recurrent is part of the same paradigm and it is based on evolutionary logic (Strike, 1991).It is possible to find patterns in history from a selection of works that represent the best know-how of their time, the constructive limits of each period focused on technique. In order to analyze technical evolution according to materiality it is necessary to focus on structural paradigms, historical invariants, such as: domes, arc bridges, and height structures.

Culture emerges as a component of structure in architecture because architecture and structure are inseparable entities. Both fields are product of their social, economic and political context. Using historical materialism, focusing on the means and modes of production, it is possible to understand the interrelationships between architecture and its historical time. There are two distinct but intercrossed approaches to the concept: scientific culture linked to *techne* and architectural culture. One is dedicated to the development of constructive solutions in a cumulative process of knowledge, usually related to the field of engineering. The other, of social nature, is related to the set of solutions adopted through history according to specific context (zeitgeist and volksgeist), translated into works or projects that are part of architectural culture.

9 CONCLUSION

The original contribution to knowledge of this manuscript is based on the (re)definition of the concept *structure in architecture* as a theoretical/practical invariant. The concept of *structure in architecture* is achieved after a holistic analysis using the complexity theory (Morin, 1991) as a way to achieve a multidisciplinary approach. By applying the complexity theory it is possible to detect pattern detection (Alexander, 1977) associated with tectonic discourse. Resorting Kuhn's notion of *Structure of Scientific Revolutions* (1962) it is possible to detect paradigms and paradigmatic changes. Paradigms are important because they reveal knowledge patterns. Paradigmatic changes reveal displacements of the concept. The tectonic discourse is interconnected with the architectural philosophy in terms of design.

Different perspectives were then (re) grouped into dimensions creating a wider perception of the concept, understood as a rational gear. By defining structural multiplicity understood as patterns, it allows us to comprehend a particular complex world, anticipating actions and reactions. Establishing a parallel with automotive design, Porsche stands out with a strategy: evolution instead of disruption. In the tectonic discourse it is possible to evolve by having the same structural DNA off all its antecessors.

This cumulative (re)construction of useful data, in a global and structuring concept possesses a four-dimensional meaning, understood as universal invariants of architectural knowledge: space, technique, thinking and time. The clarification of the four distinct dimensions with their specific categories and components allows their operability as a theoretical/practical mnemonic, extoling their useful value.

This (re)construction is an exercise of order linked to cumulative knowledge in its distinctive dimensions, treated at the same level, in a non-hierarchical logic (fig 1). The construction of a mental map allows its operability as an auxiliary of divergent thinking associated with the creative process. The expanding of tectonic consciousness in the act of project extolls the useful value of theory, in its relationship with practice.

Accordingly to Michel de Montaigne (1580) it is preferable to have a well-made head over a well-filled head. This paper contributes to research on architectural education because it works as a compendium of different structural perspectives, organized as a global concept. The whole is bigger than the sum of its parts, by clarifying traditions and putting into order architectural knowledge. The advantage of categorization facing pluralism is related to the expansion of consciousness in the act of designing and top clarification of theoretical/practical ideals (Jencks, 1973). The use of theoretical diagrams as syntheses of complex though allows a deeper understanding of architectural practice extolling the useful value of structure for the continuous evolution of architectural field. By raising conscious that architecture cannot exist without structure this diagram will reinforce a basic, but out of fashion, critical tradition – Tectonics discourse.

Structure in Architecture must constitute a physical syntagma in which space, thought and communication are mingled and together reinforce architectural form, the way of living and economy. Praising structure in architecture is also extoling the rationality linked to architectural intentionality as a useful art, markedly social. Vitruvius already stated that the proper use of the structure was a compliment to architecture.

Architectural responses to societal challenges via design-build programs in architectural education

A. Şahin
Graduate School of Science Engineering and Technology, Istanbul Technical University, Istanbul, Turkey

ABSTRACT: The aim of this paper is to introduce public interest focused design-build programs in architectural education. The architectural education programs that embrace both designing and building/constructing of a project are commonly called 'design-build programs' in literature. Design-build programs have the potential to make architecture students think and play an active role to overcome societal challenges. In this study, nine different public interest focused design-build programs that are both curricular, and extracurricular are studied by reviewing the literature to comprehend what design-build programs are, how they emerged, the elements and organizations of these programs, their content, their application formats in architectural education, their goals and contributions in architectural education. When it comes to understand the process of design-build programs, the author of the paper participated in the workshop called Design-Build for Public Interest, which is organized by Yestermorrow Design/Build School in the state of Vermont in the USA in August 2012, making good use of the observations and experience gained there besides comments of the participants who joined different design-build programs. The paper presents findings of above mentioned studies.

1 INTRODUCTION

1.1 *Design-build programs*

The architectural education programs that embrace both designing and building/constructing of a project are commonly called 'design-build programs' in literature. Design-build programs present an educational atmosphere in which students are offered not only the chance of designing but also the opportunity of learning about construction site, structure, building construction, material and material processing within practice. In these programs, building is an essential part of design process. The primary purposes of these programs are learning how to build a construction and experiencing the things exposed during building by participating in the building process actively. The main learning methods of design-build programs are as follows: experiential learning, experience based learning, hands-on learning, learning by doing, learning by making, learning by building, 1:1(full size) learning, learning by serving (service-learning) and cooperative learning.

'With their emphasis on experiential education, collective effort, and community service, design-build studios have some resonance with the educational theories of the American Pragmatist philosopher John Dewey (1859–1952), who placed experience at the center of learning' (Hayes, 2012: 287).

Design-build programs offer a process in which building is inseparable from designing. In design-build projects building is a learning tool and students use building as a catalyst for design decisions (Carpenter, 1997). Thinking and building feed each other constantly and the decision-making process always continues (Fig. 1).

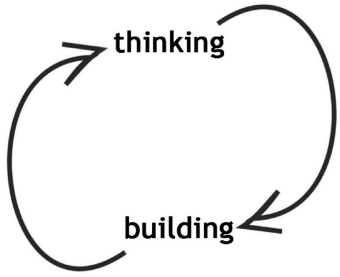

Figure 1. Cyclical process of thinking and building.

The process of design-build approach consists of communication with users, programming, designing, budget allocation, documentation and building. However these processes feed and affect one another continuously rather than a linear process in which one finishes and another begins (Fig. 2).

Tanju (2013) expresses this subject as follows 'Design process cannot be concluded. Despite of the standard practice in which design and its implementation is separated sharply every decision in each step is examined continually and a door is always left open for change.'

Figure 2. Process at design-build programs.

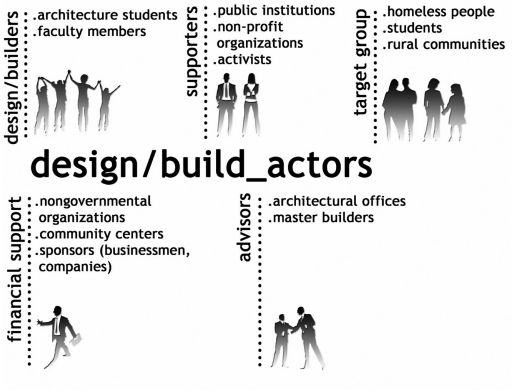

Figure 3. Actors of design-build programs.

In design- build programs, many actors take place such as students, project coordinators, project requirers (activists, civil society organizations, non-profit organizations etc.) professional architects, public institutions, and sponsors. As it is seen in the Figure 3, these partners are classified into five titles, which are design builders, supporters, target group, financial supporters and advisors.

According to Carpenter (1997), design-build approach is a combination of following four points: 'Thinking and making, collaboration, giving back to community and communication skills.' Besides that, design-build programs have the potential to make architecture students think about societal challenges. This makes it possible for architecture students to produce projects that promote the public interest by participating in design-build programs. From this aspect design-build is a hybrid approach in which design and its implementation is integrated by fulfilling a social aspect as well. Hereby in design-build programs, the ethic of giving back to society can be encouraged (Fig. 4).

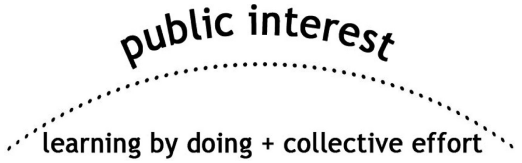

Figure 4. Objectives of design-build programs.

1.2 *Design-build programs from past to today*

The idea of 'design-build' emerged early 20th century and was championed by architects like Walter Gropious at the Bauhaus in 1919, as well as Frank Lloyd Wright with his Taliesin West School in 1938 and followed by Paolo Soleri's Arcosanti in the 1960s.

If we take a glance at the history of design-build programs in Turkey, the Summer Construction Practice at the Middle East Technical University (METU) having designed by the department of Architecture in 1958 has a great importance, being the first design-build study of Turkey. This program got involved in curriculum of the department of Architecture in METU as a mandatory internship. While the first year-internship was practiced at school between the years 1961 and 1968 after that the internship practice, which was funded by the Provincial Bank with governmental support, was based on students' hands-on experience with building in different parts of the Anatolia. Here, the significant point is that students both learned how to build a construction literally, which is also compatible with the principles of Bauhaus, and they achieve a social goal by contributing to the mission of improvement of Anatolia. With regard to this, the schools, guest houses, government offices, and dorms that are constructed in different villages in every summer term have the quality of a community-oriented education (Artun & Aliçavuşoğlu, 2009: 385). METU Summer Practice Program continued without interruption during the period 1958–1974 including the time between 1999 and 2007, but this program is no longer going on.

'First Year Building Project at Yale School of Architecture, the oldest continuous design-build course in North America. Founded during the 1966–1967 academic year, Yale's program originated in a context of student activism and volunteerism during the 1960s and reflected the idealism of President Lyndon Johnson's Great Society program' (Hayes, 2012: 286).

Yestermorrow Design/Build School was founded in 1980 as a summer camp for non-architects who wanted to design and build their own house by Yale University graduate John Connell in the state of Vermont, USA (Carpenter, 1997: 30).

Student activism and volunteerism in 1960s following the World War II, the social politics of the era and improvement projects had an effect on the outbreak of the design-build initiatives.

'In the 1990s, design-build programs expanded. Steve Badanes program at the University of Washington along with the now iconic Rural Studio under the

direction of Samuel Mockbee emerged at this time. Both are still in operation and continue to influence programs. The themes of alterity, community service, and experimentation that define this history remain and provide a sketch of the activity overall' (Canizaro, 2012: 21).

According to Gjertson (2011) there are approximately 100 design/build programs throughout the 123 NAAB accredited architecture schools.

Today it is impossible to assume the number of design-build programs in the world. There are both continuous programs such as Rural Studio and intermittent initiatives by faculty members or students.

1.3 *Methodology*

Within the scope of this study nine different public interest focused design-build programs that are both curricular, and extracurricular, that is to say, the ones which are disincluded in architectural education and carried out in the forms of workshop and, summer school are studied by reviewing the literature to comprehend the content, the elements and organizations of these programs, their application formats in architectural education, their goals and contributions in architectural education.

When it comes to understand the process of design-build programs, the author of the paper participated in the workshop called Design-Build for Public Interest, which is conducted by Yestermorrow Design/Build School in the state of Vermont in the USA in August 2012, making good use of the observations and experience gained there besides comments of the participants who joined different design-build programs.

2 ARCHITECTURAL RESPONSES TO SOCIETAL CHALLENGES VIA DESIGN-BUILD PROGRAMS

2.1 *Public interest focused design-build programs*

According to Canizaro (2012: 23) the most prevalent characteristic of design-build programs is their organization around and intention to provide service to local communities. This is done for both pragmatic and aspirational reasons. In pragmatic terms, it is more reasonable for institutions to support and offer services to those in need when using the labor and talents of students. This keeps them out of competition with local professionals as they tend to work on projects with no potential for profit and it sidesteps the conflict between students paying fees so that they can in turn provide services to others. Virtually every program designs and builds as a public service and as such, engages in service-learning.

Thomas Dutton, who runs Miami University's Center for Community Engagement, and focuses on supporting the Over-the-Rhine neighborhood, sees a further role. 'We're not just trying to help a community, but we're trying to deconstruct students' privilege. We're trying to get them to be better citizens, better community advocates, and to understand the complexity of urban areas' (Sokol, 2008: 125). The six-week Over-The-Rhine Design Build Program creates a well-rounded experience where students engage with the community on many levels—as designers, advocates, and neighbors.

Samuel Mockbee who was a co-founder of the Auburn University Rural Studio program in Hale Country, Alabama, calls Rural Studio as 'classroom of the community' (Dean, 2002: 3) and states that 'Architectural profession has an ethical responsibility to help improve living conditions for the poor and it should also challenge the status quo into making responsible environmental and social changes. Hence architectural education should expand its curriculum from paper architecture to creation of real buildings and to sowing a moral sense of service to the community' (Dean, 2002: 1).

Design Bridge is a multi-disciplinary student organization and states its mission as: 'The focus is to bring the resources and energy of students to communities and organizations that don't have access or resources to acquire professional design services. We focus on projects that have a mutual benefit to us as design students and to the community.' (Url-1).

In this study to be able to understand the content of public interest focused design-build programs a table is designed (Table 1). At the table nine different design-build programs are examined under the heads of affiliation, project types, project's target group, project duration, materials and classroom size.

When we analyze the position of design-build programs in architectural education we observe that each program is constituted in a different shape both in the architectural curriculum and as an extracurricular activity. These programs can be involved in almost every stage of architectural education which includes curricular subjects, which are in the forms of compulsory and selective courses or summer internship for undergraduate and graduate students, and extracurricular activities such as workshops and studies generated through students activism and volunteerism.

In design-build programs projects are mostly prepared for low-income communities living in rural and urban districts, majorities deprived of architectural service and the societies affected by the political and natural disasters. In these projects, with an average class size of 20, the subject of sustainability, which is among the aims of architecture is emphasized by utilizing local products, sustainable and recyclable products easy and cheap-derived products and salvaged materials. Within design-build programs, in addition to indoor and outdoor restoration and extension projects, which can be concluded in a short time, more complex projects that continue for a long time and necessitate infrastructure are also designed. However the primary objective of design-build program is not the size or dimension of the project. Actualized projects are the tools to reach the targeted pedagogical and social goals.

Table 1. Public-interest focused design-build program examples.

Program name	Affiliation	Project types	Project's target group	Project duration	Materials	Classroom size
Rural Studio	Auburn University	Affordable housing	Rural communities in Alabama, USA	1 year	Timber, Steel	4 to 20 Students
Design Bridge	University of Oregon	Sustainable and green building practices	Non-profit organizations	1 year	Wood, Stone, Concrete, Metal	8 to 10 Students
Basic Initiative	Portland State University & University of Texas	Elementary schools, clinics, libraries, houses etc.	Rural communities in the world	15 days to 4 years	Locally-sourced materials	11 to 45 Students
Urban Build	Tulane University	Affordable housing	Deteriorating neighborhoods of urban New Orleans	1 semester	Timber, prefabricated materials	11 to 20 Students
Over-The-Rhine Design Build	Miami University	Redesign & renovation of historic buildings	Non-profit organizations	1 semester	Timber, steel, concrete	12 to 16 Students
Learning by Making A	University of Tasmania	Playgrounds, compost toilets, bus stops, mud-brick domes etc.	Community groups in Tasmania, Australia	1 to 2 semesters	Sawn timber, plywood, concrete, steel, mud-brick	9 Students
Summer Construction Practice	Middle East Technical University	Small scale houses, dispensary, computer workshop etc.	Rural communities in Turkey	2 months	Timber, stone, concrete	1st month: 30 Students 2nd month: 30 Students
Architecture for All (AfA)	AfA is Istanbul based nonprofit organization	Redesign and renovation of old school buildings.	Rural communities in Turkey	10 days to 8 weeks	Timber, stone, concrete	10 to 40 Students
Design-Build for Public Interest Workshop	Yestermorrow Design/Build School	Bus stop, pedestrian bridge, compost toilet etc.	Non-profit organizations	2 weeks	Timber	6 to 12 Students

According to Schuman (2012: 256) 'Interest in humanitarian work in recent years has been quickened by a series of political and environmental disasters starting with the attacks of September 11, 2001, and continuing with the Indian Ocean tsunami in 2004, Hurricane Katrina in New Orleans in 2005, and earthquake in Haiti in 2010. After the attacks in 2001 Architecture for Humanity, founded by Cameron Sinclair and Kate Stohr in 1999 and promotes architectural solutions to humanitarian crises, reported a fourfold increase in membership, with upticks following each of the succeeding catastrophes. These events constituted a call to conscience, prompting people in all fields to reevaluate their priorities in the face of human suffering. Because the reconstruction needs so directly involved architectural skills, however, many architects felt a special sense of urgency to respond. Professionals and students volunteered in rebuilding efforts, from weeklong stints cleaning debris in New Orleans to design-build projects in affected areas.'

Urban Build Program organized by Tulane University was founded in 2005 after Hurricane Katrina and within the scope of this project; low-cost housing projects were conducted for hurricane victim New Orleans Region in cooperation with a nonprofit organization called 'Make It Right'. Another example is that Portland State University organized a summer school in 2011 in Haiti to design and do the projects such as solar kitchen, clinic, canteen, agricultural production gardens for earthquake-victim communities.

Urgent architectural solutions are needed for societies influenced by the 21st century wars in today's world such as 2011 Syrian Civil War, besides political and natural disasters. Design-build programs can be potential to meet such immediate architectural need.

Design-build programs depend on the willingness of the actors such as executives, participants, taskmasters and users. Executives' taking the responsibility of the conduct of design-build programs, students' designing and doing a project by laboring and devoting time for love, taskmaster's supporting the project in progress financially, users' requesting the project willingly are all based on the principles of volunteerism and in the meantime the communication that have an important place in architecture is also put into practice.

In design-build programs in the form of a workshop and the programs working in the form of associations based on volunteerism and activism, the participant profile has variety, for such programs are open to participation of national and international volunteers. In this case, people having different perspectives, who don't have acquaintance before, come together and so an environment of rich communication and information exchange is provided.

2.2 *Yestermorrow experience and student comments*

'Yestermorrow Design/Build School in Waitsfield, Vermont trains students in the arts of design and craftsmanship as a single integrated process. Through experiential learning in the design studio and workshop and with an emphasis on designing in partnership with the natural world, students develop critical thinking skills and technical know-how, expand perception and perspective, and deepen their creative assets for living and building resourcefully through the work of their own hands.' (Yestermorrow Design/Build School, 2012/2013 Catalog: 4).

Within the scope of the study the author of the paper participated in the Design-Build for Public Interest Workshop at Yestermorrow Design/Build School in Vermont. With guidance from Steve Badanes, Jim Adamson and Bill Bialosky. a group of six students, including myself, designed and built a composting toilet for Shelburne Farms, a century old educational farm outside Burlington, Vermont. Utilizing consensus design and natural building principles, we built our structure with materials sourced from the farms property. The first week of two-week Design-Build for Public Interest Workshop was devoted to investigation of the land on which the construction was going to build, creation of the budget and requirement list by meeting the client, improvement of the project, presenting the project to the client and time planning; the second week was left for the construction of the project.

The experience gained during the design and implementation of the project in question will be attempted to be expressed under the titles given below. Additionally, comments of the students who participated in other design-build programs are going to be given in terms of providing insight about design-build process.

2.2.1 *Learning by doing*

During the study of Design-Build for Public Interest Workshop organized by Yestermorrow School of Design/Build, the state of acting simultaneously, the formation process, and the inversion process always continued. Design and practice's feeding one another is experienced with this workshop.

Regarding this issue, Rural Studio participant Josh Cooper expresses 'Rather than drawing a window and not having a clue what I was drawing, there was now a client standing there and that window had to work for him. On a different level, I gained a lot of confidence knowing I could make that window work' (Dean, 2002: 3).

Likewise a student from University of Tasmania states 'We all learnt things that can only be realized through experience, no amount of lectures could have taught us as much' (Wallis, 2005: 182).

2.2.2 *Details*

The workshop was also very useful to get the grips of joint details. I realized that I used to draw some details rotely, without understanding completely in my construction sciences and construction project courses at university. To sum up, drawings in construction sciences course, which was blurry for me most of the time, formed in my mind better.

Concerning this issue a student from University of Tasmania expresses, 'Gave good knowledge of basic detailing which enhanced understanding of construction in general' (Wallis, 2005: 125).

Similarly Rural Studio participant Andrew Olds states, 'Samuel Mockbee had made me understand that where things come together provides a detail opportunity. He taught me about economy of materials, to compose a building without excess' (Dean, 2002: 157).

2.2.3 *Team-working skills*

A lorry full of timber, which was going to be used in the implementation of project during the workshop, was brought to campus. We experienced the power of teamwork by piling the timbers in materials area in a short time like forty minutes with six participants and three executives together.

Regarding this issue, Rural Studio participant Jen Stanton states 'The fact is, architecture is teamwork, and this is the first time most students have worked with someone else. We do everything as a group and learn to compromise. Sometimes we yell at each other, but we learn to figure things out together' (Dean, 2002: 3).

2.2.4 *Realization of scale*

In the course of workshop while working on compost toilet project, one of the striking points was the difference of scale. We used a full size scale in this project, so the mistakes we made in the previous steps had an effect on the next steps. Although it is unrealistic to expect everything to be perfect, a more careful study was required. Because of the fact that spaces widened, we needed scaffolding materials to support construction elements continuously. We could feel how much the construction would be heavy. We weren't able to

carry alone some construction elements. Therefore we asked for help.

Similarly Rural Studio participant Jen Stanton expresses that working construction has taught her that a built design often feels different and functions otherwise than she imagines in a drawing and continues, 'A five-foot space isn't the same in your mind as in reality; your mind can play tricks' (Dean, 2002: 155).

A student from University of Tasmania states that with the participation of design-build program he becomes more aware of the materiality of building elements, their physicality and realization, that it is far more than lines on paper. Making offers possibilities that may be unknown in a drawing (Wallis, 2005: 120).

Another student from University of Tasmania states 'Looking at the design models and drawings, then exploring the finished building, my sense of scale changed' (Wallis, 2005: 181).

Likewise another student from University of Tasmania expresses 'Experiencing design-build process enables you to realize any errors whereas drawings tend to allow more mistakes go unseen' (Wallis, 2005: 182).

2.2.5 *Social responsibility*

Shelburne Farms is a century old educational farm and works as a nonprofit organization outside Burlington, Vermont. Designing and building a composting toilet for such an organization and, to know that our design will be used by community, provides us, the participants, with the senses of social responsibility and working ethics.

Similarly Rural Studio student Jen Stanton was attracted to the studio, she says by 'the opportunity to design something and actually see it come to life, be used, and be part of a community' (Dean, 2002: 155).

2.2.6 *Learning from each other*

I suppose arising from inexperience, the feelings of fear and doubts stood out about how it could be to experience constructing a building, which I had never tried. In this step, I grasped the drill for the first time in my life and with the help of my group friends I learned how to use it smoothly in a very short time like ten minutes. Some participants in group who had construction experience before eased the burdens' of executives about helping the inexperienced ones, as they had an idea about how to use the tools.

Regarding this issue, Rural Studio participant Jen Stanton states 'The assigned task was to help fifth-year thesis students build a little cottage. We got to interact with the thesis students and create a family atmosphere. They shared what they'd learned. I think of them as models for us architecturally and socially' (Dean, 2002: 155).

Another Rural Studio student Andrew Olds says considerable learning happens through doing and from other students' mistakes (Dean, 2002: 158).

2.2.7 *Lifestyle*

In design-build programs by going out of the studio in spatial terms, that is to say, working in different places during construction process apart from the offices or university campus, the opportunities of learning in the open air at the same time building relationships with local people and knowing about different cultures are provided. In design-build programs in the case of doing a project out of the campus area students and executives lives together in construction site by this means, close relationships feeding both student-student and executive-student rapport are built. This intimacy gives way to asking questions without fear and learning freely. The culture of living in learning community contributes to build close relationships to a great extent.

Concerning this issue Rural Studio student Jen Stanton expresses 'We lived, breathed, slept, and ate architectural school there. We didn't have a break from it. At the studio home is school and school is home. It's a lifestyle; it's not just education' (Dean, 2002: 156).

2.2.8 *Lifelong learning*

About lifelong learning subject, Madeleine Claire Hahn, who was a participant of Design-Build for Public Interest workshop expresses 'I did learn some basic construction rules that are important in the design process. Knowing the basics of construction will also help inform my future designs.' (Şahin, 2013: 167).

2.2.9 *Time exceeding*

About timing issue Rural Studio participant Jen Stanton states that her team accomplished less than she had hoped because everything took longer to build than she had expected (Dean, 2002: 156).

Regarding to this subject one of the hardest things for Steve Hoffman, who was a participant at Rural Studio, is accepting the slowness of the building process (Dean, 2002: 159).

2.2.10 *Limited kind of material*

With regard to usage of limited kind of material a student from University of Tasmania states 'The level of understanding construction/structure in this school of architecture is very limited to only one material – timber' (Wallis, 2005: 120).

Similarly, at Yestermorrow Design/Build School's Design-Build for Public Interest Workshop, the material we used while building a compost toilet was also timber like the material used in previous studies of the same workshop. The reasons why wooden elements are utilized predominantly in projects are the ease of working with wood, enabling carrying out small size projects and its easy transportation.

3 RESULTS AND DISCUSSION

The building, which is a part of design process, is a creative action, at the same time a learning tool

that plays an important role in improving the design idea. The experience gained in design-build program causes the participants to think the designing activity again. As a result of this rethinking, participants figure out that designing and building are processes feeding one another rather than being apart from each other, because in the learning environment of design-build programs it is possible to trying full size scale, to head for a different idea when you feel your mistake and to experience by doing.

Construction's taking a long time, but academic calendar's comprising a short time, design-build program's need for budget on the other hand funds' being limited, perceiving the implementation of design-build projects as a vocational training rather than an academic and intellectual education can cause design-build programs not to be supported by the university administration. Inexperienced participants and limited time can cause the executives to take the role of master and lead the students to take an inactive role in design-build process. All of these are the leading obstacles preventing design-build programs from being a part of the architectural education, its foundation and sustainability.

Although working in design-build programs bring certain limitations such as budget, time, and lack of knowledge of construction it is very important in pedagogical terms to experience a process in which design and build feed each other, to touch what you design, to deal together with certain subjects such as structure, material and details from the very early phases of design.

The faculties of architecture have to enrich their programs, make them flexible and personalize them according to their students. For this reason, in the curriculum of architectural education there should be enough variation in terms of courses. There should also be courses that give importance to teamwork, material, touching the design, understanding the details, enabling communication and dealing with abstract and concrete, imaginative and the real together. Even if these courses are not compulsory in the curriculum they should take place in the form of selective courses.

4 CONCLUSIONS

In the design-build programs, students can gain awareness about topics such as research, environment-friendly designs, salvaged construction materials, building construction methods, passive building techniques, public relations and communication with people by doing projects for people in need. In design-build studios the necessities of projects' implementation, utilization and delivery in due time provide the participants with the senses of responsibility and working ethics. In addition to this, the practice of projects for people in need contributes the growth of awareness of social responsibility in participants. Public interest focused design-build programs see architectural practice as based in an ethical commitment to others. Because of the fact that the projects are designed and built labor intensively for a specific aim they help the participants to understand how important the team work is in architecture. The participants of design-build programs comment that the knowledge they obtained in the process of design-build is going to affect their future designs, too. From this perspective, the fact that the knowledge and experience gained through design-build programs is going to be adapted to architectural situations encountered in professional life which makes a contribution to lifelong learning.

According to Gjertson (2011: 24) 'design/build projects directly address the National Architectural Accrediting Board (NAAB) criteria of collaboration, project management, leadership, legal responsibilities, ethical and professional judgment, and community and social responsibility.' Besides that participants of design-build programs become skillful at communication skills, sustainable design, financial consideration, client role in architecture, building materials and assemblies integration which are also included in NAAB criteria.

Architecture is a discipline in which theory and practice go hand in hand. Therefore, in architectural education, application should also find its place besides theoretical teaching. As design-build programs are a hybrid approach in which design and its implementation is integrated by fulfilling a social aspect as well, covering these programs in curriculum will enrich the architectural education.

Modeling architecture design studio on practice-based integrated "ways of working"

T. Collins
Ball State University, Muncie, Indiana, USA

T. Hegli
Snøhetta, Oslo, Norway

ABSTRACT: This paper focuses on an architecture design studio aimed at preparing students for their transition to a professional context and encouraging them to explore and embrace the complexity inherent in contemporary design problems. The studio used five pedagogical methods to simulate professional practice-based integrated "ways of working:" workshops at regular intervals; design teams to promote collaboration and enable individuals to assume "expert roles;" tools and technologies to inform and guide design decisions; the use of a detailed precedent that illustrated how another design team made design decisions; and performance targets used as ways of evaluating the effectiveness of design concepts and ideas. These methods were successful in stimulating the student teams to think holistically about the design process and may serve as an effective model for future design studios at other design schools. A number of recommendations are offered as ways of improving upon the methods discussed.

1 INTRODUCTION

1.1 *Background*

Contemporary buildings are more complex and technically sophisticated than ever before. Addressing code requirements, performance targets, sustainability goals, and user needs during the architectural design process now necessitates the involvement of a wide range of specialists. Gone are the days of the "hand-off" where architectural teams worked sequentially in silos passing information and changes back and forth. Emerging integrated design processes (IDPs) demand early, active, continuous, and collaborative involvement of all design team members to achieve a consistent integration of myriad project components into a unified, holistic design outcome that meets increasingly stringent client expectations and goals (Elvin, 2007; NIBS, 2015). Yet most students in design schools still complete projects independently, a "sole practitioner" model that is increasingly rare in professional contexts (Nicholson, 2005). Such a model is antiquated in an era of emerging integrated design practices. Some schools have responded by moving design studios off-campus to professional contexts (Crosbie, 2012).

Buildings now account for approximately 40% of total primary energy use in the US and the EU and 40% of carbon dioxide emissions in the US and 36% of carbon dioxide emissions in the EU (DOE, 2015; European Commission, 2015). These staggering figures demonstrate the critical role of buildings in addressing broad-scale global climate change issues and have spurred tremendous interest in sustainable design practices and standards (e.g. LEED, BREEAM, and Passive House) as well as building performance targets (e.g. net-zero energy, carbon neutral buildings, etc.) aimed at reducing overall building environmental impact. The 2010 Imperative advocated for, among other things, instructors at design schools to include language in design studio projects requiring students to dramatically reduce or eliminate the use of fossils fuels in their design solutions (Mazria, 2007). Clearly, the goal was to prepare students in school for addressing the kinds of complex environmental issues, targets, and requirements they will face in professional practice, but few design studios at schools of architecture appear to be meeting the goals of the 2010 Imperative.

The ways in which building designers work together in professional practice settings are rapidly changing and differ significantly from the ways in which architecture students are accustomed to working on design projects in school. If we wish to get students excited about emerging trends in professional design processes and to prepare them for future professional work once they leave the academy, a critical question emerges: how can we align the design curriculum with emerging models of design practice to provide our students with stimulating and useful design experiences that address real-world conditions and problems? This paper presents one approach to addressing this discrepancy through the design and implementation of an architecture design studio course.

1.2 *Goals*

The four goals for the ZEB House design studio were: (1) to simulate innovative professional design processes on a smaller scale with architecture students and select visiting experts in lieu of a large and diverse assortment of building design professionals (e.g. landscape architects, sustainability consultants, engineers, and many more); (2) to train design students to handle integrated "ways of working" through the complexity and apparent chaos inherent in real-world design problems and to use the expressive power of design to address a range scales from regional-level considerations to building performance to fine-grained (and often "softer") end-user experiences; (3) to focus on site-specific qualities (e.g. view, macro/micro climate, local material resources, walkability, and transportation) and client-specific considerations (e.g. user needs and lifestyle) prevalent in professional practice that are critical to market acceptance, adoption, and success of sustainable design; and (4) to help students feel comfortable working with the types of numbers, calculations, and metrics common in high-performance building design as a way of informing and guiding their design explorations.

This paper describes a series of pedagogical methods employed in an intermediate-level design studio with undergraduate and graduate students at the University of Oregon in the United States in Spring Term 2015. The design studio was co-taught by a PhD candidate with teaching and professional practice experience and a visiting instructor working in international professional practice.

Five primary pedagogical methods were used in the course: workshops, design teams; tools and technologies; the use of a precedent; and performance targets. For each method, we describe the connections or links with practice-based integrated "ways of working;" how the method was adapted to suit the design studio course curriculum and format; and specific examples of outcomes from the ZEB House studio project, which focused on the design of a zero emissions single-family house in Oregon. In addition, we will address the challenges, practical implications, and recommendations resulting from our pilot test with this specific design studio course.

1.3 *Ambitions*

The studio project example relied on the ZEB (zero emission buildings) sustainable design concept and procedure developed in Norway, which is arguably the most ambitious sustainability standard or target being used in the building design industry today. We chose to have students focus on a zero emission building: to introduce them to ZEB as an emerging research and design mindset, to encourage them to deal with sustainability issues on an advanced level, and to get them to consider/rethink the standards and methods required to fuel innovation in the design professions.

This paper is not concerned with the ZEB concept per se, but rather with how a ZEB-focused project can illustrate specific pedagogical methods employed in the studio. A number of excellent papers already describe the ZEB concept and outcomes in detail (Houlihan et al, 2015; Good et al, 2015; Goia et al, 2015; Kristjansdottir et al, 2014). A ZEB-focused project is not a prerequisite for adopting or applying the methods we describe in this paper. However, for us, ZEB represented one of the most complex types of integrated design processes we know of and, as such, it served as a useful target or ambition for student design explorations.

2 PEDEGOGICAL METHODS

2.1 *Workshops*

Workshops are a cornerstone of integrated design processes. Sometimes called by other names such as "eco-charrettes, team meetings, planning sessions, etc., the basic premise of workshops are to get the design team members in the same room at the same time to work through concepts or problems collaboratively. Workshops are not so much about designing something together or by consensus, but rather about talking through the range of ideas and/or issues that can inform the way specialist team members approach their specific design task. Designing happens in between the workshops. Also, workshops are less about *how many* people are present and more about *who* is present. All voices are heard. Diversity of representation is a key element to the success of the process. Finally, workshops happen at intervals, which helps provide structure to specific design phases and are often successfully used to launch the next design phase and to plan ahead.

In this studio, we used three workshops as a way of dividing the 10-week project into phases with the workshop acting as the kick-off event for the next phase of design development. We addressed the lack specialists among the architecture students by assigning roles (or "hats") and by inviting visiting experts to join-in on the discussions to help fill in the gaps in student knowledge or experience. Each workshop was one 4-hour studio class period and entailed a combination of different kinds of activities: breakout groups, all-class discussions/presentations, and feedback from visiting critics. (See Figure 1).

A goal for the ZEB House project in particular was a strong connection between indoor and outdoor space as a way of connecting occupants with local climate, extending occupant comfort during cold/warm times of year, and reducing primary energy demands for heating and air-conditioning. The first workshop addressed this goal by asking the students to role-play different perspectives on the design of outdoor living space and to develop a set of design criteria and ideas. Visiting experts from NUTU in Trondheim, Norway, a visiting practitioner from San Francisco,

Figure 1. A Workshop where invited experts provided feedback to facilitate activities in which students played a specific role on a design team and work through concepts and ideas collaboratively.

Figure 2. Students worked in 3–4 person design teams for the entire project. Here students work collaboratively on their ZEB House design during studio class time.

and the instructors provided feedback on specific architectural responses to climate considerations and the emerging student design ideas. The role-play activity was organized such that one-hour role-play activities were separated by all-studio check-in meetings, where the groups presented ideas and received feedback before moving on to the next workshop activity. The workshop initiated the first phase of the design project and helped to emphasize the importance of the outdoor space as a key programmatic component early in the conceptual design process. The workshop allowed students to focus on one type of space in some detail and the final projects at the end of the term, perhaps unsurprisingly, had strong and developed outdoor spaces represented in their design concepts and schemes.

2.2 *Design team*

Professionals most often work in teams, not alone. Design team composition reflects the skills and competencies needed to address the project scope, goals, and ambitions of particular design projects. The more sophisticated or elaborate the aims of the design project, the greater the need for specialty expertise on the design team. For example, a ZEB project addressing embodied material emissions, life-cycle of material assemblies, and carbon pay-back strategies using renewable energy will likely include team members with expertise in life-cycle analysis (LCA) and renewable energy system design and production, roles that may be absent in standard design projects with no stated carbon emissions or renewable energy goals. Of course, these specialties are *added* to the design team (making it larger) and the traditional design team members remain and their role in the design process is in no way diminished.

For large, elaborate integrated design teams, it is crucial to identify, define, and agree upon a project goal at the very first team meeting. Since large teams often have overlapping competencies, it is also critical that team members know their role on the team and which deliverables they are expected to furnish at each phase. A design process leader will coordinate the work in the early stages and plan the team workshops where architectural concepts will be evaluated with respect to the project goals.

The traditional model of design studio in many schools of architecture is predicated on the idea of the student as the singular designer who deals with a variety of project considerations from a "generalist" perspective. Rarely do students truly work collaboratively on teams composed of "specialists." The Solar Decathlon design teams may be one notable exception to this rule, where architecture students may work with students in marketing, engineering etc. We wanted to give students the experience of working in teams of experts to address design challenges collaboratively (DOE, 2016).

In this studio, students worked in small teams of 3–4 people. Since all team members were architecture students, we introduced expertise roles into the teams in two ways. First, we had had students interview each other prior to creating their design teams to discuss individual skills, interests, and strengths to ensure that the group composition would include members that could fill specific roles (e.g. concept development, 3D modeling software, sustainable design strategies, etc.). The team member selection process was modeled on the idea of speed dating where each student in the studio interviewed his or her classmates for 2–5 minutes each. Second, where skills or expertise were lacking in all team members (e.g. use of energy modeling software), we asked someone from each group to become the de facto expert in that area based on their level of comfort and previous skills. This "expert" could then share their new skills and knowledge with the teammates as needed to satisfy the workload.

A goal for the ZEB House project was to assemble strong design teams that could endure and succeed throughout the course of the 10-week term. The speed dating-style interview exercise resulted in groups with shared interests, good group work dynamics, and a variety of skills needed to complete a complex design project. Only one of the five groups struggled with poor group dynamics, but this situation gradually improved over time. We were impressed with the level of collaboration among the design teams. (See Figure 2) In effect, the teams self-organized their

own collaborative workshops between the all-studio workshops described above.

The "expert" roles on the teams also worked surprisingly well with those students having previous interests/skills in various technical aspects of design filling those roles. For example, one student used Multiframe structural design software—a program she was learning in a structures class she was taking that term—to refine the structural system design for the project and to demonstrate the viability of reducing the quantity of materials to address embodied material emissions issues.

2.3 *Tools & technologies*

Contemporary building design relies heavily on digital tools and technologies to facilitate the design process and negotiate the complexity inherent in design problems. These tools are many and include software applications for building information modeling (BIM), 3D parametric modeling, energy simulations, daylight analysis, structural design/analysis, computational fluid dynamics modeling (CFD), climate analysis, and more. Specialists use tools to analyze and explore conditions, synthesize the results, and report the information back to the project team. No single project team member is fluent in all of the digital tools and technologies necessary to produce a modern building—it is a team-effort that relies on skills and competencies that specialists bring to the table.

Digital tools are an integral part design education and most architecture curricula teach basic software skills to students early in their education. However, architecture students are routinely exposed to a small number of basic tools comparatively speaking and they have varying proficiencies using these tools.

To address this difference in tool exposure and skill-levels between students and professionals, this studio asked students to ensure minimum levels of software proficiency and skills learning new applications on each design team. This arrangement helped to compensate for the fact that some students had less developed skills or confidence using certain tools or technologies. A student, who was not as confident with software, would be paired with others who were. This equalized the groups and facilitated peer teaching among the team members. In addition, students with more developed skills using digital tools assumed an "expert" role on the team. We also paired analog and digital tools (e.g. building physical daylight models tested using digital photometer sensors) to enhance the learning experience. Thus, the goal was to have students use a wider range of tools in their design process than they ordinarily would use in a typical design studio.

The ZEB House project was specifically designed to necessitate the use of myriad technologies and tools to address the complexity inherent in contemporary high-performance building design. Rather than taking a "use what you know" or "use what you like to use" approach, the studio employed a set of basic digital design tools that students all had

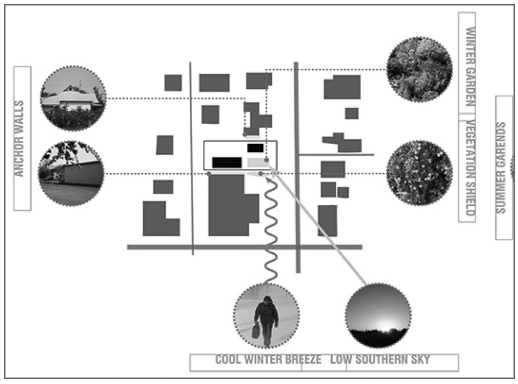

Figure 3. Students analyzed climate data using Climate Consultant software, synthesized specific climate attributes, and illustrated how the climate conditions relate to their project site.

preexisting experience with (e.g Adobe Creative Cloud, Rhinoceros, Revit, Sketch-up, etc.) as well as new tools that built-upon their previous skills (e.g. Sefaira for energy modeling, Climate Consultant, PV Watts calculator, etc.). At each stage of the project, we introduced select new tools necessary to inform the design process and assist the student teams in satisfying stated building performance goals and ambitions.

The new tools acted as specialty consultants in the design process. Whereas an integrated design team would likely have an engineer developing a sophisticated energy model, members of the studio teams acted in that role using digital tools (e.g. Sefaira) to provide basic level analysis. In this way, the studio used tools in concert with team member roles to simulate what would, in real life, be a more sophisticated expert perspective in a practice-based design process.

Climate Consultant—a free online application that translates standard TMY weather data for thousands of locations worldwide—was used to analyze site climate conditions and to explore potential passive and low-energy strategies suitable for the Pacific NW region of the US where the ZEB House project site was located. Information from this tool was then synthesized, illustrated graphically, and incorporated into design processes or considerations through other tools. For example, Climate Consultant helped the students understand prevailing wind conditions and opportunities for natural ventilation. These patterns were then documented using graphic site plans and the prevailing wind information was used to influence building orientation, aperture sizing/placement, etc. (See Figure 3).

2.4 *Using a precedent*

Although each design project is unique, professional practitioners often have the benefit of precedent projects that they worked on previously to help guide and inform a current design challenge.

Figure 4. ZEB Multicomfort House pilot-project in Larvik Norway as a precedent for a way of working through a complex design process. Photo courtesy of Snøhetta.

Precedent studies are common in design studio projects. However, the information available on most completed design projects is typically limited to a few overall drawings describing plan layouts, program distribution, design concept, sectional properties, and facades and sometimes basic descriptions of how the completed building is being used or satisfies user needs. While useful, such information lacks the detail and specificity to effectively inform other designers of how to solve technical or fine-grained issues in their designs.

In this studio, students had access to very detailed information related to a precedent project similar to their project—the ZEB Multicomfort House pilot project in Larvik, Norway—that one of the instructors recently completed in professional practice. (See Figure 4).

The ZEB pilot house was completed in 2014 as a demonstration project showcasing innovative approaches to the design and construction of zero-emission buildings and was a collaboration between the design firm Snøhetta, the ZEB research center at the Norwegian University of Science and Technology (NUTU), and other industry partners. The project relied on a unique, iterative, and integrated design process with a large and highly specialized design team. Since the project was part of a ZEB research initiative, there was copious documentation of the design process and the technical solutions. The pilot was intended to be a model for residential construction and to catalyze market transformation toward zero emissions residential design in Norway and abroad. As such, design and aesthetics were as critical to achieving market acceptance of the concept, as were the performance goals.

Having the pilot house as a precedent allowed the students to see how specific design challenges were addressed in a completed building. However, the students were not asked to duplicate the pilot house on a different site in a different climate. The student projects had different overall areas, program elements, orientations, material choices, and aesthetic sensibilities from the pilot house that responded to how each team understood the project goals and the unique characteristics of their sites. However, the pilot house was a useful litmus test for students to ask questions such as "how did the team fit enough PV panels on the roof to achieve a net-positive energy performance target" and "what was the overall embodied carbon of materials per unit area for the house." In some cases teams chose to make different decisions than were made in the pilot house, but in other cases the decisions made in the pilot house served as a useful tool to help the student teams move forward or take a shortcut where time was limited.

2.5 *Performance targets*

In high performance buildings, design teams set specific performance targets at the outset that guide and inform the design process. These targets are based on a host of real-word requirements and/or project goals including: health, safety, and well-being; energy and resource use; accessibility, costs, durability, environmental impact, and sustainability considerations, etc. These targets are not satisfied at the end of the design process, but are introduced at the beginning and serve as benchmarks or goals that the design ideas, concept, and solutions must satisfy. In some cases targets are based on user needs, client expectations, or design team ambitions. In other cases, targets are based on code requirements or voluntary standards. In either case, project success depends on the extent to which a design meets the established performance goals.

Design studio curricula tend to address real-world dimensions of design projects—like performance targets—in a piecemeal fashion. For example, the 3rd year undergraduate studio may incorporate accessibility requirements that students must meet through more detailed restroom layouts or stairway designs or a design-build studio may incorporate material cost considerations. Higher-level performance criteria are often too complex for students to tackle during a single semester project. However, as mentioned previously, initiatives such as the 2010 Imperative (Mazria, 2007) have advocated for stronger, clearer performance targets even in hypothetical design studio projects.

The design team arrangement of this studio allowed the students to tackle multiple performance targets together in one 10-week design project—many hands makes lighter work. In addition we leveraged data and information from the ZEB Multicomfort House precedent when time was limited or specific information for our project site/location was difficult to find.

The primary performance target for the ZEB House studio project was that it was to be a zero emissions building—zero emissions from annual primary energy demand for operations and zero emissions from materials to be offset over a 60 year life cycle period—through the use of site-sourced renewable energy systems. These performance targets allowed students to better understand that energy and emissions impact their design just as much as end-user needs and behaviors do and that design must account for durability and maintenance concerns over a building's

Table 1. An example of the types calculations the student teams performed to determine embodied carbon profile of a window assembly and how to off-set this carbon through sizing an appropriate amount of renewable energy (Solar PV) on the roof.

1	Window volume = 0.3419 m^3
2	Window mass: 0.3419 m^3 × 2,579 kg/m^3 = 881.8 kg
3	Window embodied carbon: 881.8 kg × 700 g CO_2/kg = 617,260 g CO_2/1000 = 617.26 kg CO_2
4	Utility emissions: 0.0272 kg CO_2/kWh electricity
5	Total payback: 617.26 kg CO_2/0.0272 kg CO_2 per kWh = 22,693 kWh
6	Annual payback: 22,693 kWh/60 yrs = 378 kWh/year
7	Replacements over 60 yrs: 2 = 378 kWh/yr × 2 = 756 kWh/yr
8	A 0.75 kW PV array at 15% efficiency with a 38° tilt angle will generate 897 kWh/yr on the site
9	0.75 kW/1 kW/m^2/0.15 panel efficiency = 5 m^2 roof area

lifespan—considerations that design students rarely have the time or opportunity to think about in their projects. See Table 1 below for an illustration of the kinds of simple calculations that students performed to validate that their designs could meet or exceed the zero emissions performance targets set for the project.

3 COURSE OUTCOMES

3.1 *Challenges*

There were several challenges we faced in simulating an integrated design process for a project with complex performance objectives.

Time was a significant limitation for the studio. Less than 10-weeks were available for small groups of 3–4 students to work through a design process that took a much larger ZEB pilot house project team many months of design and development. What this meant for the studio was that we were unable to get anywhere near the same level of detail with certain design considerations. Additional time would have allowed for a greater number of exercises focused on isolated topics and related tools/strategies.

Instructors and students do not have the same access to resources as professional practitioners. For example, we asked students to perform basic calculations on embodied material emissions, but environmental product declarations (EPDs) are still hard to find for most products. In the absence of good information, teams had to scramble to find rules of thumb or placeholder information. Having additional resources and research on topics including materials, technologies, and user behavior would have improved the accuracy of the student responses to the project requirements and goals.

When time and resources are limited, precedents can be useful tools to help inform the design process. However, our precedent was quite different from our studio project in a number of ways: location, culture, climate, units of measurement, etc. It was not always easy use the precedent to directly inform the design studio project for all project considerations, which meant that we were in the position of having to tell the student teams which information from the precedent was applicable and which was not. For example, the carbon content of local electric generation varies considerably and we lacked a baseline or methodology for estimating the impact for our specific project site. Thus, having necessary information at the beginning of the term would have saved time and energy once the student projects were underway.

Workshops benefit from visiting experts. There were a number of other faculty that could fill this role for our studio. However, bringing outside guests to campus is costly and most design studios do not have a budget to support these expenses.

3.2 *Practical implications*

The ZEB House design studio demonstrated that it is, indeed, possible to simulate aspects of complex integrated design team processes in an academic design studio setting. The hallmarks of integrated design are team collaboration, iterative design thinking, and evaluating design ideas against project goals. The attributes may look different in a design studio context than they do in professional practice, but they effectively approximate the important elements of emerging practice-based "ways of working." The process gets students excited about design possibilities and prepares them for the kinds of team design experiences they will face when they leave the design school. In this way, the design studio becomes a vehicle for building stronger connections between the practice and the academy.

The focus of our studio project was a zero emission building—perhaps one way of introducing a high-level and ambitious design challenge. However, the methods employed in the studio are not specific to ZEB-focused studio topics by any means. The studio serves as a flexible model that can accommodate a variety of design projects, team sizes, and academic calendars. In fact, a 16-week semester may provide an ideal fit for this studio model, a time span that we did not have available to us.

3.3 *Recommendations*

The ZEB House studio may serve as an effective model for future design studios. As such, we offer a number of recommendations for instructors considering adopting our methods and approach:

– Design students feel empowered when they work through the numbers and determine that their designs meet or exceed targets or goals for performance or use. All design students are capable of doing basic mathematical calculations (e.g. sizing a PV array, converting between SI and IP

Figure 5. We observed strong camaraderie and impressive levels of productive collaboration among the carefully composed student design teams.

units, etc.). The idea that consultants do these calculations for architects in unhealthy and interferes with the learning process.

- It is easy for design students to lose motivation over the course of the academic term. Using workshops as a "kick-off" event for the next phase of the design process helps to re-energize students. Likewise, working in groups can help students stay involved and motivated. The design student as an isolated island can be overcome with activities that get students to work together collaboratively.
- We learned in this studio that, if you set the bar high, students could meet incredibly ambitious expectations. It is not impossible for students to design a building that produces more energy than it uses annually or pays back embodied carbon from materials while working on a design studio project—these are not concepts or processes that only professionals or experts can achieve.
- Precedents are useful, but can be especially valuable when they provide detailed information such that students can understand how the designers intended the building to work, how it is actually working, etc. Finding such a precedent or access to information for such a precedent is a worthwhile activity for an instructor preparing to teach a studio following our model. However, be aware that differences between projects and precedents can make comparisons challenging.
- Design students are fairly adept at learning new tools and using them in basic ways. However, limited knowledge, experience, or competence with these tools can result in primitive or under-informed design responses. For example, energy analysis tools can lead students to eliminate or resize apertures in simplistic ways that improve performance at the expense of other design considerations. It is important to use tools, but to use them cautiously.
- Make the end-user part of the design process. In practice, architects often have the benefit of working with the future users of the building or, at the very least, knowing something about the user needs. In the absence of defined users, design students make decisions that can have a significant influence on the user experience. Finding creative ways to bring hypothetical "users" into design studio projects adds a realistic dimension to the process. For example, we may have to discuss comfort and the possible lifestyle changes at the same time as we are calculating energy use and carbon emissions, which introduces complexity that challenges students and allow them to see a multiplicity of possible solutions or design responses.
- It is important not to lose track of the larger-scale implications of specific design responses at the project site scale. Again, this adds a level of complexity to the design process. For example, our students understood that there task was more than simply satisfying program requirements such as net-zero energy and zero emissions for materials in their designs—holistic issues related to climate response, sustainability, life-cycle implications, etc. were always hovering in the background.

4 CONCLUSION

The design professions are moving away from traditional modes of project design and delivery and toward integrated design processes that emphasize diverse design teams that meet early and often to collaborate and evaluate ideas against performance goals and project ambitions. The ZEB House studio aimed to introduce design students to this emerging practice-based "way of working" in a 10-week intermediate design studio project.

The studio employed five pedagogical methods or innovations to simulate the integrated design process in an academic setting: workshops, design teams, tools/technologies, use of a precedent, and performance targets. Overall, the methods were quite successful in stimulating students to think more deeply and holistically about their design processes, and this assisted them in generating compelling design solutions by the end of the 10-week term.

Our experience teaching this studio demonstrates that the pedagogical innovations employed in the ZEB House studio may be an effective model for future design studio instructors and can accommodate a variety of different types of design projects aimed at better preparing design students for future experiences addressing real-world design challenges.

Quest for "openness" in architectural pedagogy from 60's onwards

S. Türkkan
Faculty of Architecture, Istanbul Technical University, Istanbul, Turkey

ABSTRACT: In the last century of creative culture, the notion of "openness" came into prominence in particular thresholds such as: "open work" discourse charged by 1960's radical socio-cultural paradigm shifts, and "open source" debate, enabled by 1990's emergent digital modes of co-production and sharing. Although spatial practices are pluralistic by nature, open culture implied a number of challenges against the long-lasting conventions of architectural discipline, yet inspired a number of architectural design studios to tackle this challenge. This paper focuses on architectural pedagogy's response towards open culture via design studio experiments that were stirred by these motives to explore openness in their peculiar design methodologies, processes and outcomes. By critical examination of selected design studios, it is aimed to survey and compare various conceptualizations of openness in architectural pedagogy, discuss their reflections on architectural knowledge, and speculate on design studio's potentials in provoking an open architectural culture.

1 ON ARCHITECTURE AND OPENNESS

1.1 *Open culture vs. architectural culture*

In the past decades, a number of revolutionarily instances were staged against the rigidity of authorial power and control mechanisms that has been dominating creative cultural production for the last few centuries. Emerging philosophic and socio-technological paradigms, such as 60's open work discourse and 90's digital revolution fueled the spurring of an open culture of production and sharing. In various disciplines including architecture, number of practices started to challenge the ossified rules, control mechanisms, structures, roles and relationships assigned to the creator, his means of control over the production, role of the recipients (or the users) and the value system these cultural practices dwell in.

Changes in the discourse brought in a new vocabulary aiming towards the rigid disciplinary norms and mark new potentials in creative cultural modes of production. During this paradigmatic transition, the notion of "openness" appeared as a critical discourse with implications on a number of practices including architecture and pedagogy, with respective influences on architectural design studio education.

Hereby, this paper aims to focus on architectural pedagogy's response towards open culture via a selection of design studio experiments from 60's onwards, exploring notions of openness through peculiar design methodologies, processes and design outcomes, and finally to critically reflect on future potentials for an open architectural culture.

1.2 *Thresholds of "open" 60's onwards*

Openness being a highly interpretable concept, its antonymous qualities such as rigid, fixed, suppressed, over-controlled, pre-determined, linear, authoritarian, nonnegotiable, etc. render more helpful in grasping it. In certain intervals, a range of creative cultural fields embarked on critical explorations on various conceptualizations "openness" and its unfolding into various theories and practices.

Notably Eco's seminal book "Open Work" brought the notion of "openness" into prominence in late 1960's, emanating concepts from literature, art, music, language and semantics. Eco explained that a work of art is: "a complete and closed form in its uniqueness as a balanced organic whole, while at the same time constituting an open product on account of its susceptibility to countless different interpretations which do not impinge on its unadulterable specificity"(Eco, 1962). He asserted that openness is not necessarily an intrinsic quality of the work but driven mainly by interpretation and performance. In the introduction of 1989 edition of the book, Robey states that "Open Work" remained significant for its "insistence on the element of multiplicity, plurality, or polysemy in art, and emphasis on the role of the reader, on literary interpretation and response as an interactive process between reader and text".

During the 60's, rebellious and optimistic spirit of free culture blended with contemporary discourses regarding the birth of the reader, the "open culture" shed reflection upon various architectural ideas and experiments. Possibilities of open-endedness,

open-work, open-form, open-city, open university, etc. inspired architectural explorations on self-generated, bottom-up, participatory design modes in architecture, which examples like Fun Palace, New Babylon, Rural Studio and some others broadly epitomize.

1990's digital turn bought "openness" into a novel ontological framework. Possibilities, which before were only theoretically possible, or limited to the mediums at hand, earned new grounds of exploration. Mainly in fields like software design, music and digital arts, new strategies of production, ownership and sharing emerged, such as: open source, open data, open knowledge, open educational resources, leading to practices such as distributed intelligence, crowdsourcing, peer-to-peer production and open licenses like copy-left by Creative Commons. The essay "The Cathedral and the Bazaar" (Raymond, 2001) originally presented in 1997, epitomized the era's discussions on emerging notions of ownership, distribution and intellectual property with the spatial analogy that contrast two design models in software engineering: the bazaar (open-source software model) and the Cathedral (closed-source model employed by commercial software vendors).

Architecture's interest in commons discourse as well as collective data sharing and processing, network practices, digital co-design platforms like BIM(Building Information Modeling) and alternative licensing are expanding fields of research with experimental qualities to be explored.

Despite of the multi-layered and pluralistic nature of spatial practices, implications of open culture have been and are still puzzling for the long-lasting conventions of architectural discipline, therefore are worth examining for what they have to offer to architectural practice and pedagogy.

2 ARCHITECTURAL DESIGN STUDIOS ON OPENNESS

2.1 *Three architectural design studio explorations on "openness"*

The architectural and pedagogical investigation on the idea of "open" has been translated into a number of diverse design studio practices during the last decades. However, because openness is a quality that is difficult to define and capture, this paper will only pay interest to some of those studios from 60's onwards that claim an "open" quality either in the studio's name, brief or discourse as a clear and visible statement.

Henceforth, in the scope of this paper, three cases of "open" architectural design studios are selected that apply a notion of "openness" through their design studio methodology, and are inspired by 60's and 90's openness discourses. The selection of "open" design studio cases are not considered as representatives of the total spectrum, but as epitomes of discernible and divergent efforts in architectural pedagogy that may allow further discussions on the topic.

Through the critical examination of selected studios' peculiar pedagogies built on "openness", it is aimed to compare and survey the various conceptualizations of open architecture and related design studio theories, methodologies and tools that intend to facilitate it.

Briefly, architectural design studios' inquiry into "openness" will be examined over three cases: open form, open city and open source.

2.1.1 *Open form*

"Open" notion in Hansens' design studio methodology is a manifestation of Open Form theory, formulated by Oskar Hansen in late 50's against Closed Form, which he characterized as "subordinated subjectivity" that is "dominant and hierarchical" in nature. Presented in 1959 CIAM congress in Otterlo, the theory was rooted in the conflicts particular to late modernist debates and standardized housing construction in postwar Poland, which neglected human individuality and uniqueness. It aimed to democratize the conventions of any scale or form of social-spatial practice to include the experience of individuality and explore new modes of subjectivity in design.

The architectural school for Hansen was both a fortress of Closed Form empowering the conventions through "education", and a great atmosphere for experimenting new possibilities. Together with Zofia Hansen, alongside their artistic, architectural and urban design practices, they applied the idea of "open form" in their studio teaching in Warsaw Academy of Fine Arts, Faculty of Sculpture from 1954 to 1981.

Hansen related Open Form to the interaction and connection between people, hence to social conditions, more than the technical openness regarding the transformation of the build environment. In this regard, a series of recurrent themes and concepts marked the infusion of Open Form theory into architectural education.

The "figure-background" narrative was one of those recurrent concepts that emphasized binary analogies such as individual-collective, public-private, natural-artificial. In this duality, architecture was sought to function as a backdrop for life to take place within its vicinity, and the architect as a background provider on which users will be included in the process of creating the build environment. Instead of imposing his/her subjective influence or aesthetic choices, the architect would act as a facilitator who's responsible for performing a dialogical mode of design, in collaboration with the recipient-co-authors. Hansen & Hansen (1961) rejected the Closed Form aesthetics with an urge to reveal the Open Form's -the art of events- own methods of study, means of expression and its own aesthetics. Notion of "scalability" was utilized through any given set of procedures or techniques that could be applied equally well to a piece of paper or to a fragment of the public space of a larger city, to provide an operational language that provokes experimentation and highly complex (trans-individual) collective projects. (Ronduda et al. 2007)

In 1973, Hansen proposed an "Adaptation Project" for the Sculpture Faculty building according to the Open Form conventions, in order to pressure the didactic process of the studio work and cause new spatial relations to develop. The project spurred from Hansen's interest in housing studies as 'a form of protest against the idea of "optimized" architecture for the "average" user. (Obrist & Parreno 2004) Students were given a large building block as a "backgrounds" for their design, and asked to design their own apartments in given frames, in collaboration with colleagues and teachers. By the individual authorization of students the housing projects were exercised as an exploration of subjective design adaptations for each housing, yet framed by the totality of the collective apartment block. Hansen's called this the expression of a group form, "the form of the sum of events -of the sum of individualities of a given group." (Hansen & Hansen, 1961)

The underlying design principles were paralleled in the organization of the studio space. Hansen's strong opposition to the "chapel" model of a professor "preaching" to the students (Hansen 2005) spur collective modes of learning particularly through active participation of students in the studio and collective games (mostly open-air) where students and teachers participated and performed collaboratively in the search for new design possibilities through different mediums in inter-changeable scales. Paralleling the figure-background narrative, a large white background was placed in the studio to exhibit student work and reorganize common (public) space for work and relaxation according to students' own will and participation.

2.1.2 *Open city*

"Open City" in Ritoque, the open-air laboratory of the Institute for Architecture of the Pontifical Catholic University of Valparaiso, Chile, is an ongoing radical field of experiment for architectural education since late 1960's. Guided by Alberto Cruz, the head of architectural school at the time, a group of poets, philosophers, sculptors, painters, architects and designers, also known as e[ad] community, came together to bring into fruition an alternative conception for architectural practice and teaching.

The e[ad] community was critical against contemporary architectural practice and education dominated by commercialism. In its place they proposed an architecture originating from, and understood as, a poetic act. (Cordua et al. 2015) The school's mission was manifested in the form of a poem called 'Amereida' that portrays a poetic vision of America, and is performed in a format what they considered to be the origin of architecture; Phalène, a group act of generating a collective poem by its participants. For e[ad] concretizing the poetic image of a 'Phalène' into buildings was an essential base for architectural thinking and performance.

For this purpose, the e[ad] group, who are also teachers from Catholic University of Valparaiso privately bought a site in 1970's, to be named as the "Open City". Spanning onto 270 hectares area and stretching 4.8 kilometers along the Pacific coast, the site was comprised of dune fields, wetlands, a river, pine forests and a diversity of flora and fauna.

The Open City became a site of thinking, research and experimentation for architecture that doesn't emanate from didacticism, but from the concept of discovery, improvisation, performative acts and constant negotiation between individuals on proposals for new works. "It is to become a town, collectively owned and governed, with no private property, constructed for, and by, 'hospitality and speech' and following Amereida's poetic vision of America." (Cordua et al. 2015) In the absence of a master plan or hierarchical infrastructure, the city was self-governed by "creative acts of discovery and its particular experience and perception of the site" (Pendleton-Jullian 1996) Characteristically, all projects initiate with a poem. Inspired by French modernist poetry, chiefly by Mallarmé, the belief was that the world's real torment lay in the human condition much more so than in the social condition. Therefore the poetic influence in architecture was demanded to be much more radical and extreme, but primarily transcendental in nature (Pendleton-Jullian 1996).

The Open City continues its experimental role in architectural education after many decades. Among various pedagogical experiments with hands-on, design-built projects, one commitment endures in the inauguration of each process: the use of poetry as a guide to design.

The pedagogical methods based on poetic acts can be seen as a replacement of conventional formal compositions that depend on stylistic concerns, historic precedents, drawing norms or academic discourse. In terms of teaching, the triggered design endeavor by ever-changing perceptions of the site and poetic improvisations is considered more important than the result itself. In this sense sketches and words became essential instruments to apprehend the relations between space and phenomena: "We find [in these sketches] the sensual dimension of the habitable space which has been captured at that moment, as well as the dimensions of knowledge that presented themselves on that occasion." (Jolly 2012).

Pendleton-Jullian (1996) describes how poetic acts guide a design process, stating they are not only applied to discover sites of construction, but also to determine strategies for the making of space. There may be a series of poetic acts that occur simultaneously, or at different stages of the conception and design of the project. Accordingly, in some cases the work is done by a complex collaboration between professors and students, whereas in others, individuals may lead portions of the work. Constructions proceed in their own pace, sometimes depending on the availability of scavenged material from demolished buildings, with no outside time pressures, since the only funding is by the Faculty of Architecture. Chance and improvisation are welcomed in the

process, with no dependence on construction documents or no clear definition of a "finish" for the structure, opening the buildings to endless addition and transformation.

2.1.3 *Open source*

Columbia Building Intelligence Project (C-BIP) & The Integrated Design Studio (IDS) was carried out in New York, Columbia University GSAPP in 2010, as part of an experimental three-year pilot project that explores "new forms of technology-enabled collaboration within and between the various sectors of the architecture, engineering, and construction industry." (http://www.arch.columbia.edu/files/gsapp/imceshared/tct2003/CBIP-Studio.pdf, p.3)

Neglecting architectural education's conventional "single critic, single student, single project" model, the studio's research interest leaned on embracing new modes of collectivity and design collaboration in education, for its increasing potentials in architecture's role in the total process of realizing a project.

With this concern, besides other research interests, the studio attended to "open source" as a critical and operational field of exploration, in search for cumulative and communicational platforms that might better embrace the design potentials embedded in the complexity of projects. The studio brief launched following questions on "open source" potentials in architectural design: "Can open source design method pioneered for software development be applied to or reformulated for architectural design? Could modules of buildings and 3D files be "checked out," revised, and "checked in" by different architects, fabricators, and contractors over time durations that exceed a single project? If complex building components could be designed, documented, and released into a broad architectural community, how would authorship and intellectual property be handled? Might an open source model start to change the one-off nature of buildings and reduce inefficiencies in the construction industry?" (http://www.arch.columbia.edu/files/gsapp/imceshared/tct2003/CBIP-Studio.pdf, pg.20)

The studio developed by Laura Kurgan, Scott Marble and David Benjamin was entitled "Energy + Adaptation", and proposed to design adaptation strategies to enhance the quality of urban life while reducing energy consumption in existing buildings in New York City by %30, as the city authorities envisioned for 2030.

To embrace the potentials of "open source" in the studio's workflow, "design-and-release" model was located at the core of the organizational scheme, in coordination with the studio's research progress into energy mitigation in existing buildings. In a highly integrated model, 36 students worked interactively on specific parts of a larger problem in collaboration with peers, critics, consultants and experts through an array of integrative, simulative, digital and physical design and communication tools.

Each student was responsible for designing a generic building component to reduce energy consumption in existing buildings, using CATIA software and document it with an instruction manual, and then release it to the open source library to make it available as "a tangible research product that others can download, re-configure, and utilize". In the next step, students were asked to form teams to collectively develop a "Building Strategy" for specific buildings in NYC. To achieve that, teams were requested to pick, use, adjust, test and re-use the available components in the open source library. Meanwhile, if they had any feedbacks or modification requests they would send them to the original author who is solely authorized to make changes to the component. The suggested changes would be considered by the author of the component, refined, re-documented and released back to the library in its updated version, available for future use. (http://www.arch.columbia.edu/files/gsapp/imceshared/tct2003/CBIP-Studio.pdf,p.19)

Along the progress, collectivity and interaction was enabled by the use of design and communication platforms such as Building Information Modeling (BIM), Integrated Project Delivery (IPD) for legal structure, CATIA for the design, parametric modeling and fabrication, and other software for managing complex information, environmental data, simulating building performance etc.

In the process, components and building adaptation strategies were rigorously tested through digital building simulations or physically fabricated mock-ups, presented, discussed and revised in above mentioned platforms as well as face-to-face dialogues and studio reviews. "By the end of the semester, the IDS offered dozens of individual design components, as well as several more comprehensive design strategies, that were both flexible and re-usable." (http://www.arch.columbia.edu/files/gsapp/imceshared/tct2003/CBIP-Studio.pdf, p.14)

The "design-and-release" model endorsed a critical break from the typical studio in which students produce their designs in spatial and mental isolation. With the help of sample building elements, wireframe BIM models and complementary open source software, all students become capable of experimenting with and suggesting specific updates to each component, allowing each author to continuously improve her components' design without refraining it from the use of others.

Concurrent and common use of design elements, allowed the development of complex architectural ideas with variation and feedbacks in a progressive rather than competitive environment, which added up to increase the total quality of the design library for such a purpose. However, the sophisticated use of open source didn't completely remove the conflicts over the ownership and rights on the designed elements. Because the protocol only authorized individual authors whether or not to apply the feedback or allow suggested changes in the use of their elements, it was observed that harsh negotiations took place between the authors and groups

who suggest changes, and not all ended up with agreements.

2.2 *Critical review on "open" architectural design studios*

Although the selection of 1960's on architectural design studios in this paper only represents a small portion in the wider spectrum of inquiry into open culture, they are insightful in displaying the diversity in the conception of architectural "openness" and its respective translations into pedagogical methods, tools and modes of organizations in design studio. In common they share an experimental effort to incorporate open culture into the disciplinary confines of architectural education, and abandon the idea of closed, finite, fixed, singular work or processes, through a range of counter possibilities made available in a design studio setting.

The aforementioned design studio cases operate through a number of openness strategies, not only rhetorically, but also directly, provoking non-conventional design performances by digitalized or physical platforms of co-designing, individually or collectively, simultaneously or successively. The scope of design tools that urge "openness" range from performative games, to poems, graphic representations, parametric models or hands-on constructions. Despite of these variances among the strategies, there appear certain tendencies in affording "openness" in architectural design studio.

In order to understand these tendencies, a relational chart has been devised to trace recurrent motives, themes, concepts or tools that are explicitly stated in the studio manifestations. (See Figure 1.)

This brief diagrammatic chart displays that some motives appear to be more frequently addressed than others. Among them, performativity, collectivity, collaboration and subjectivity emerge as common notions that mark all three studios and broadly define a framework for how "open" is commonly preconceived in architectural design studio.

However looking deeper into how these motives unfold in each studio's specific context, divergences and peculiarities become more visible.

Hansenian "openness" is formulated as a structured philosophy, encompassing a set of instructions and tools for a more democratic and pluralistic design behavior. Using the language of "open form", one is encouraged to take a position towards a reality through the given theoretical framework, and apply open form principles in scales from elementary to urban design. It is an oppositional and universal worldview that celebrates performativity, subjectivity and collectivity in all designerly acts.

Yet both notions of subjectivity and collectivity in "Open Form" are mostly performed in the confines of the suggested framework; a stack of subjectively designed elements collected in parallel compartments, side-by-side, composing what is called as the "group form". In other words, by emphasizing subjectivity and

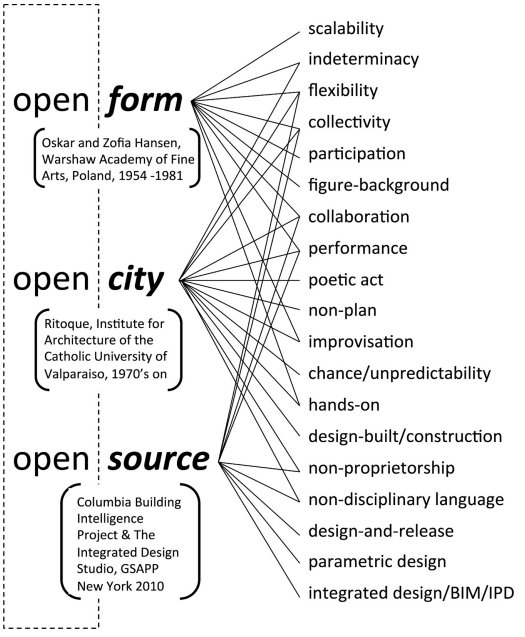

Figure 1. Relational chart representing recurrent openness motives in selected architectural design studios.

user's right for adaptation, what is advocated is a sense of individual and independent proprietorship under a larger scheme, with less emphasis on the designerly negotiation amongst concurrent, convergent or fluxional subjectivities.

The sense of "open" in Ritoque, Chile, giving its name to the actual site, is more concerned with celebrating the performative and poetic aspects of architectural thinking in education. Rather than restricting the design process into the overly controlled and rationalized relationships of the studio environment, the in-situ, poetry-guided design practice invited the impulsive dynamics into architectural learning, revealed from the material and immaterial realities such as geography, climate, material performances etc. as well as chance, improvisation, feelings, inspirations and dreams.

Compared to similar design-built educational programs of its time, such as Rural Studio, set to meet the needs of an impoverished user group in harsh socio-economic conditions, or Arcosanti implying a top-down design philosophy and aesthetics for a sustainable architectural vision, Open City is less occupied by a pre-set agenda, except for the commitment to poetry and material constraints of the land, equipment or human resources at hand. The agenda of the project is open to oscillations with changing moods of experimental wills in the service of architectural and artistic research.

In the following sense, the subjectivity notion in Open City differs from the one in Open Form, because the transcendental nature of poetic act doesn't necessitate the immersion of social concerns or collectivity as

in number of actors in a group. Subjectivity relies on the artistic liberation of individuals' minds, activated by poetic performances, which can also be collectivity performed in a group act such as "Phalène". Yet, the act of discovery lies beyond the inner dynamics of a structured collectivity. It is the immediacy of momentary, sensual impulses in a poetic performance that is anticipated to guide one's way in thinking about architecture.

Lastly, in CBIP&IDS, the idea of "openness" reveals itself as a platform for organizational and operational affordances, aiming to investigate highly integrated and trans-disciplinary pathways for architectural production. Exchange of design ideas, interactions and negotiations between numerous actors and actor groups were carried out via "open source" platforms, which perform in a directly operational level, rather than representational.

Different from Open Form's design games, or Open City's poetic acts, "performance" suggests a different connotation in the case of CBIP&IDS. In the exploration of open-source, the emphasis on "open" expands from the performance of the designer/architect/student person or group, towards the performative qualities of the design element itself. When the design element is translated into a fragment of digital information, its performance becomes much more tangible and accessible to a variety of users, simultaneously, without limitation. It can be received, processed and designed individually and collectively, by disciplinary and non-disciplinary parties, can be formulated, simulated, shared and tested via a combination of digital and analog design tools.

Hence, in the context of this studio, due to the setting of authorship protocols, groups and individual students were still responsible for making critical judgments and evaluations for their design action, even after they released an element into the library. The open source library was accessible by a combination of high-end software tools and parametric models, but particularly when designed elements from library were placed in a context, urgent architectural and urban issues still needed to be discussed and evaluated in person, face-to-face. Therefore, it can be said that this studio blended an array of performative actions that are both defined by parametric nature of the design item, as well as personal and subjective authorial judgments for design. This blend of simultaneous performative design modes and tools brought in an unconventionally layered, complex, entangled notion of collectivity in the design studio.

Questions on the compatibility of open-source for an open architectural culture bear its predicaments. The fact that, in order to be placed in an open-source database, an architectural idea needs to be seized in the scale of an element, decontextualized, formulated and parameterized, therefore cleared from any attached meaning, ideology or stylistic concern is a subject that has to be discussed in its equivocal consequences.

CBIP&IDS may have carried the investigation on open source at an experimental stage, via cutting edge design tools and software, but the foundation of the idea has been seeded long before the emergence of digital tools. Neufert's Architects' Data was also famously born from his teaching practice in Weimar, with a shared interest on the future of building industry and concerns on efficiency and speed in realization of design process in 1930's. Clearly today, the advancements in the open source debate and technologies offer much wider perspectives, yet its socio-cultural-economic consequences are yet to be born in the foreshadow of centuries old establishment of authorship norms and power mechanisms.

Compared to other pedagogical explorations of openness, "open-source" may bear concerns that are less oppositional or political, but more practical and pragmatic at first. However, the newly available authorship, ownership and sharing protocols brings into a whole new level of socio-political issues to explore with burning discussions on ethical, cultural and economic reflections into architecture and architectural pedagogy that are radical in nature.

3 PROJECTIONS ON OPEN ARCHITECTURAL EDUCATION

One being a *theoretical framework*, other referring to a *land shaped by poetry* and third constituting an *operational medium*, all three "open" architectural studios embark on radically various facets of the idea of openness in architecture and its education.

All three cases of "openness" represent a conscious refrain from stylistic concerns and elevate other aspects that are often suppressed by the established modes of architectural thinking and production, which lay the foundations of conventional design studio education.

They also showcase that in proportion to the angles to architectural production and thinking, there may be as many potential "openisms" in the pedagogy of architectural design studio, through the selection of design subject, location, assignment of roles, studio's physical or digital setting, relationships among the actors, use of design tools and targeted design outcomes, etc.

60's onwards transformations in the intellectual, technological and social paradigms have clearly been influential in architectural pedagogy and provoked experimental intentions to incorporate open culture into design studio education. Meanwhile the question of openness continues to puzzle the enduring conventions of architectural practice and pedagogy.

In this regard, new approaches may be vital in assessing what openness entails for architectural praxis and education.

Firstly, the typical dichotomy between openness and closedness, marked by the contrast of political poles, needs to be put into reconsideration. Instead of a blatant opposition, openness can also be argued as a continuum, which prompts evolution in any progressive praxis either by breaking the norms or creating

new ones. For example, instead of limiting the possibilities to binary dualities such as individual or collective, new design modes that blend individually in a collective manner may suggest a more comprehensive approach. Hence, "openness" discourses should be critically reviewed in the larger context of historical continuities, and acknowledged for the equivocal suggestions that may broaden the perspective over the notion of openness.

Another point can be made via Eco's reminder on openness not being an intrinsic value. This statement broadly implies a shift of focus from the architectural object into its immediate forces, that both are disciplinary and beyond. Architectural design education should esteem non-disciplinary, non-architectural aspects into central consideration, to incorporate the practices that dwell outside architecture's disciplinary limitations. Studio's communicatory and representational language could be reconsidered to increase chance encounters with the unbridled forces of open culture merging into architectural culture.

Till (2007) emphasizes that architecture is a contingent practice despite the discipline's persistent claim for autonomy and a self-referential historical account. Therefore it is critical to address the conditional circumstances that contextualize "openness" in regards to socio-economic, cultural, political and technological frameworks that shape the state of architectural production.

Technological advancements from 90's onwards undoubtedly enabled open culture possibilities into a whole new ontological level. Yet the orthodoxy regarding the dominance of power structures, ownership and control mechanisms, which have been challenged in late 60's are still issues that need to be thoroughly debated under emerging circumstances.

It can be said that the biggest barriers to openisms in architectural culture are neither legal nor technical ones, but mostly cultural, organizational, and psychological habits and admittances that endure trough the formation, primarily in architectural schools.

Quest for "openness" is a continuously growingly potential as well as a struggle for its ethical, cultural and pragmatic predicaments in architectural knowledge. Schools and architectural design studios in particular, are foundational environments that explore, facilitate and question both the dilemmas and opportunities in this field. Therefore, the crucial role of design studio education in stimulating and questioning openness for an ethically responsible and open architectural culture remains to be a critical ground for exploration.

Trading our ivory towers for ones made of wood: Models for solid timber research and education in the US

M.K. Donofrio
University of Oregon, Eugene, Oregon, USA

ABSTRACT: Advances in the development of cross-laminated timber panels and other engineered wood products have renewed interest in non-residential uses of wood as well as in the use of mass timber in mid- and high-rise residential buildings. Engineered wood is being successfully used for multi-story construction, large span structures and complex architectural forms. Architects and engineers are beginning to reconsider this very old material in new and exciting ways. Universities in the United States charged with the training of future design professionals have unfortunately not kept pace with ensuring that students are equipped with the skills to fully leverage the recent advancements in wood product innovations. This paper examines a sampling of wood research and education efforts currently underway by universities around the world in order to identify commonalities and indicators of success that can inform and help shape future wood research and education efforts in the US.

1 INTRODUCTION

According to Alex de Rijke, founding director of the London based architectural practice dRMM, the relationship between material technology and architectural expression can be summarized as follows: "the best 17th century work can be characterized by stonework, the 18th century to be the refinement of brickwork, the 19th century to be the heyday of the steel frame, and the 20th century as the era of concrete. This leaves the 21st century open for the successor to concrete. My prediction is timber" (de Rijke 2011). While some might consider de Rijke's assessment of the history of architectural technology to be slightly reductionist, it is hard to argue with his prediction of the 21st century being the century of timber in the face of growing number of mass timber buildings around the world pushing the limits of what was previously thought possible.

2 CLT AND THE RETURN OF MASS TIMBER

Advances in engineered wood manufacturing and products have resulted in the development of new wood buildings systems that have elevated wood from its use predominately in light-frame residential construction to rival the use of steel and concrete. Since the development of cross-laminated timber in Europe in the 1990's, worldwide interest in mass timber construction has been revitalized. Cross-laminated timber (CLT) panels are made by compressing alternating layers of boards, typically finger-jointed 2x6s, into panels to be used for large-scale construction. Panels are being produced that are as strong as concrete and steel, but more sustainable and efficient to use (Mayo 2015).

Advances in the development of CLTs and other engineered wood products have renewed interest in non-residential uses of wood as well as in the use of mass timber in mid- and high-rise residential buildings. Engineered wood is being successfully used for multi-story construction, large span structures and complex architectural forms. Architects and engineers are beginning to reconsider this very old material in new and exciting ways.

2.1 *The international year of forests*

The United Nations (UN) declared 2011 as the International Year of Forests. The goal being to create an important platform to educate the global community about the great value of forests as well as the extreme social, economic and environmental costs of losing them. This effort sparked new interest around the world about the inherent value of forests in their ability to help to reduce greenhouse gas emissions, serve as a carbon sink as well purify drinking water for humans and wildlife.

2.2 *The push in the United States*

As part of the UN's International Year of Forests, the Agriculture Secretary of the United Stated, Tom Vilsack, announced a strategy led by the United States Department of Agriculture (USDA) to promote the use of wood as a green building material. Vilsack directed the US Forest Service to favor wood in new building construction; maintain commitment to certified green

building standards; examine ways to enhance research and development projects using green building materials; and actively work to identify innovative nonresidential construction projects that use wood as a green building material.

An important part of the strategy laid out by Secretary Vilsack included a study published later that year titled "Science Supporting the Economic and Environmental Benefits of Using Wood and Wood Products in Green Building Construction" (Ritter et al. 2011). This study clearly summarizes the scientific findings that support potential economic and environmental opportunities of promoting the use of wood products in the building industry. The study also identifies the barriers currently in place that limit wood's widespread acceptance as a viable building material. The barriers outlined in the study include:

- A lack of information on the life-cycle environmental impacts of wood and alternative construction materials is incomplete.
- Research and development of wood product and building systems is significantly lagging behind that of other materials.
- Most codes and standards related to green building do not include adequate provisions to recognize the benefit of a life cycle environmental analysis to guide selections of building materials.
- Insufficient education, technology transfer, and demonstration projects are hindering wood as a green building material.

In September 2015 the USDA, along with the Softwood Lumber Board and Bi-national Softwood Lumber Council, awarded two projects a total of $3 million to help construct tall wood buildings to serve as demonstrations that wood can be the principal building material for multistory, nonresidential buildings. Also in 2015, CLT was incorporated in the International Building Code (IBC). The IBC recently also adopted ANSI/APA CLT Standard PRG 320, in order to provide an avenue for design teams to seek approval via an alternate material, design and methods (AMM). The ANSI/APA standard covers the manufacturing, qualification, and quality assurance requirements for cross-laminated timber and serves as a means for certification of material to be produced domestically in the United States. D.R. Johnson Laminators in Riddle, Oregon are the only producer of CLT in the US to have been certified by the APA to manufacture building-ready panels. While CLT panels imported form Canada have been used on a few building projects in the US in the past few years, these domestically produced panels have recently been installed in a project under construction in Portland, Oregon designed by one of the firms that recently won the USDA tall wood competition.

2.3 *A long way to go*

The rising awareness of the often-negative environmental impact of the building industry has motivated architects, engineers and clients about the need to be more thoughtful about the materials with which we build. In the light of increased governmental support it is clear that efforts will continue to be made to help facilitate the use of wood as a more sustainable building material. Much of the immediate efforts have been focused on revised building regulations and the education of current design professionals in order to spur short-term successes. While these short-term efforts are admirable, in order to ensure that wood becomes a viable competitor with more energy intensive materials such as steel and concrete, long term shifts to university research and education must be made. This is necessary to produce the next generation of design professionals that are better equipped to push the boundaries of what is possible with wood and seek further material innovations.

3 WOOD EDUCATION IN THE US

Schools charged with the training of future design professionals have unfortunately not kept pace with ensuring students are equipped with the necessary design skills to fully leverage the recent advancements in wood product innovations. In architectural programs, the use of wood as a structural material, other than light wood framing in residential projects of four stories or less, is not common. This can be traced to a limited understanding of engineered wood as a structural material and the perception that it lacks durability and flexibility in form and has low fire resistance qualities. However, recent conservation efforts and sustainability concerns have appropriately elevated wood as one of the most sustainable structural materials.

While there have not been exhaustive studies about wood education in architecture, and the information tends to be more anecdotal, the challenges facing wood engineering education have been well documented by Gupta and Gopu (2005) with the factors contributing to the current state of affairs being identified as follows:

- The decline in the number of credit hours required for graduation and mandated by accreditation criteria.
- Decline in research funding in the area of wood engineering
- Lack of coordinated industry support for training wood engineering educators and keeping them abreast of new developments, technologies and teaching tools.
- Lack of faculty qualified to offer wood design courses.

These issues outlined by Gupta and Gopu, as well as more general changes in the educational landscape as the generation raised in a digital world, poses difficult challenges for the future of wood education in the United States.

The lack of knowledge of a material can often cause reluctance to use it by the design professionals, or,

when used, result in improper use and subsequent disappointment with its performance. It is important that architects and engineers are well educated in the strength and weaknesses of materials and work collaboratively to ensure their proper and effective implementation. Most, if not all, of the learning related to collaboration between the two professions currently occurs in the workplace. It would be valuable to provide engineering and architecture students with an educational experience that will launch them on the path of mutually beneficial collaboration as they enter the professions.

4 INTERNATIONAL MODELS IN WOOD RESEARCH AND EDUCATION

European countries have had an almost twenty year head start compared to the US in finding a successful model of academic research and education that helps facilitate material innovation in wood products. Therefore, it is helpful to examine some of these models in an attempt to identify common themes and threads that might be beneficial in developing a framework for a successful model for the US. This study is a work-in-progress and is part of a larger, more thorough analysis being undertaken by the author. What follows are a few case studies of successful efforts at European universities that begin to highlight some of factors that lead to successful efforts in the balance between research and education focused on innovation in wood buildings.

4.1 *Swiss Federal Institute of Technology in Lausanne (EPFL), Switzerland*

One cannot discuss wood research and education without mention of Julius Natterer and The Laboratory of Timber Constructions (IBOIS). IBOIS is a laboratory that undertakes research and teaching within the civil engineering program at the Swiss Federal Institute of Technology in Lausanne (EPFL). The laboratory grew to prominence under the leadership of the prolific German timber engineer Julius Natterer. Natter headed up IBOIS for almost 30 years and during that time was involved in many advances that helped to shape the current timber industry both in Switzerland and globally.

Among several other advancements, Natterer was responsible for the invention of Brettstapel in the 1970s, a massive timber construction system, fabricated exclusively from softwood timber posts connected with hardwood timber dowels. It is a relatively simple method of construction that exploits low grade timber, not normally suitable for use in construction, to form load bearing solid timber wall, floor and roof panels (Haller 2008). Brettstapel is a glue-free solid wood panel that was a precursor to the developments that led to cross-laminated timber.

Natterer's research served as a vital link between his teaching and practice. He worked closely with both students of civil engineering and architecture instilling in them concepts of structural engineering and construction meant to inform their conceptual designs. He was very active in the design and construction of various demonstration projects, which served as vehicles for the new technologies he was developing at IBOIS. The Hannover Expo Roof, designed and constructed in collaboration with architect Thomas Herzog for the 2000 World Expo, is probably the project he is best know for.

In addition to his teaching and research, Natterer is one of the authors of the Timber Construction Manual (Holzbau Atlas), considered to be the definitive reference for wood design and engineering. Natterer has been retired from the IBOIS lab for several years, but he continues to practice and advocates for the environmental benefits of timber construction (Haller 2008).

4.1.1 *Hannover Expo Roof*

The centerpiece of the Hannover Expo 2000 was the Expo Roof designed to remain as a permanent marker. The structure consisted of ten roofs in the shape of umbrellas that hung from 26 meter tall timber towers. Each umbrella consists of four timber shells covering an area of 40 square meters. The shells are made up of crisscrossing glue-laminated ribs that form doubly curved shell surfaces. Four large cantilevered trusses support the shells of each umbrella. In the middle of each umbrella is a large steel cap that transfers the forces onto the towers. The umbrellas are connected at the outer edges of the shells and the ends of the cantilevers. The structural components were mostly manufactured in the plant and in an exhibition hall near the site. Large cranes were required to assemble the completely pre-manufactured construction parts (Berger et al. 2000).

The design and construction of the Expo Roof afforded Natterer the opportunity to test several technologies and types of construction that were unregulated by existing codes and standards at that time. A few of the innovations Natterer and the rest of the design team were able to explore included the design of the stacked-plank ribs, various glue and mechanical connectors, 3D computer-aided design (CAD) and computer-aided manufacturing (CAM), as well as the BVD system connector. German building authorities had only recently approved the BVD system connector, now fairly prevalent throughout Europe. Natterer worked closely with laboratories at the University of Technology in Munich to perform testing to verify that the connectors would perform as intended in their application in the roof (Herzog 2000).

4.1.2 *Chapel of Saint-Loup*

The IBOIS laboratory has been under the direction of Yves Weinand, engineer and architect, since Julius Natterer's retirement in 2004. Under Weinand's leadership, IBOIS has continued to push the boundaries of timber construction through research that challenges the perceived typologies possible in wood. A project that showcases the current direction of IBOIS, grew

out of research undertaken by an interdisciplinary team investigating new methods of designing folded plate structures built with cross-laminated timber panels (Weinard 2011).

The Deaconesses of St.-Loup needed a temporary structure for their community's religious activities during an extensive renovation of their motherhouse. A folded plate structure built in cross-laminated timber panels provided an ideal solution. The use of a form generation tool developed by IBOIS allowed integrating structural as well as production design right from the beginning into the planning process. Because of this, the entire project took less than six months from start to finish and the chapel was built in less than two months.

Interpreting the traditional layout of protestant churches with their variations in width and height between transept and nave, the design creates a space whose horizontal and vertical dimensions vary via a series of origami-like folds, which give rhythm to the interior and exterior of the building. Transparent plastic panels in the gable side facades, covered with fabric, allow natural light to enter the chapel and their framework evokes qualities of traditional stained glass.

4.2 *Aalto university, Finland*

The Department of Architecture at Aalto University offers a one-year intensive program focusing on wood and wooden architecture. The Wood Program, partly funded by the Finnish wood industry, explores the ecological, technical and architectural properties of wood, providing a thorough and complete view on the whole chain of wood construction, beginning with the tree in the forest and ending up with the construction of an experimental wooden building.

Architect Pekka Heikkinen runs the Wood Program with the help of additional tutors. The program includes lecture courses on topics including the ecological importance of forests and wood, technical properties of wood, as well as the study of traditional and contemporary wood architecture. These lecture courses are intended to provide students with a theoretical background in wooden architecture. Design projects are a critical part of the program as do field trips to connect with the local wood industry. Students also benefit from visits to various examples of Finnish wooden buildings. The success of the program relies on collaboration with the Department of Forest Products Technology's Wood Material Technology Laboratory as well as the Department of Civil Engineering. In addition to lectures and research in wood construction, the Wood Program culminates in the design and construction of an experimental structure in wood, often using digital design principles and tools.

4.2.1 *Liina transitional shelter, 2011*

The Liina transitional shelter is a temporary building to be used in cold climates during crisis situations anywhere around the world. Designed and built in 2011 by the students of the Wood Program, Liina is made of mostly Finnish wood and wood-based materials. As Liina is designed to be quickly and efficiently deployed, it utilizes a simple flatpack system of prefabricated timber panels. The panels are simple enough to be fabricated almost anywhere in the world, and all components for two complete Liina shelters fit within a standard International shipping container.

As a transitional shelter it is intended to be a secondary response after a crisis. Two adults in six hours with only common non-electric tools and a cartoon diagram can assemble the shelter. It is designed to house a family of five for up to five years during the post-disaster reconstruction phase and then can be upgraded, relocated, resold or recycled. The Liina concept is based on a series of prefabricated sandwich panels. Each panel is 600 mm wide (half the dimension of a piece of plywood) to cut down on waste and to be easily carried by one adult. The modularity of the design allows for the addition or subtraction of frames in order to increase or decrease the size of the shelter to accommodate the needs of the inhabitants.

The panels are comprised of a laminated veneer lumber (LVL) frame sandwiched between two sheets of plywood and filled with wood-fiber cellulose insulation pads. Six panels are joined together with simple, repeated wooden-dowelled joints to form a frame and tightened using nylon straps, 'liina' in Finnish, like those used for the transportation of cargo. The strap creates airtight joints without any metal fasteners or the use of electric-powered tools on-site.

The exterior and interior surfaces of the panels are identical in nature and make use of a plywood Birch solution for the prototype. A foldable waterproof canvas protects the shelter from rain, snow and UV damage and can be easily replaced if needed. The canvas is pulled taught over a series of battens affixed to the exterior of the panels, thus creating a ventilation gap between the two skins.

4.2.2 *Säie pavilion, 2015*

The Säie pavilion is an open-air covered space located in the plaza space between the Helsinki Design Museum and the Museum of Finnish Architecture. The structure is the most recent project designed and built by students of the Wood Program. It was created to be an event space where activities such as lectures and workshops could be held.

The inspiration behind the pavilions concept came from the covered canopy structures that are scattered throughout public parks and gardens in the area. An idea of creating a sense of a forest within the heart of the city influenced the tectonics of the form. The columns recall tree-like trunks that branch out to carry the translucent roof cover.

The form was achieved by using active-bending wood members that are twisted into shape. Each "branch" is made up of two planks of pine with plywood sandwiched intermittently between the two outer planks. The roof structure uses three planks that are sandwiched together. The engineering for this structure was quite complex and required that the

students worked closely with students in the Department of Civil Engineering to assist with the structural design.

The wood platform of the pavilion is constructed out of thermally modified spruce decking boards. A local company called Lunawood, which specializes in heat-modified wood, produces the product, Thermowood, used for the platform. The process involves compressing and heating the wood to an extremely high temperature. The end result is a very durable, dense wood material that has zero organic content or sugar, in order to eliminate the issue of rot. This process also serves as an alternative to using chemical laden wood sealers. The product is used mostly in cladding and decking, but has more recently used as a framing material for doors and window fenestrations.

4.3 *University of Stuttgart, Germany*

The Institute for Computational Design at the University of Stuttgart is dedicated to the teaching and research of computational design and computer-aided manufacturing processes in architecture. The Institute of Building Structures and Structural Design (ITKE) also based at the University of Stuttgart is a leading institute in the research of innovative structural systems and high performance materials.

Architect Achim Menges is the head of the Institute for Computational Design (ICD) and his research and practice focuses on the development of integrative design processes at the intersection of morphogenetic design computation, biomimetic engineering and digital fabrication. Structural Engineer Jan Knippers is head of the Institute of Building Structures and Structural Design (ITKE) as well as a partner at Knippers Helbig Advanced Engineering. Knippers teaching, research and practice focus on new materials and efficient structures for architecture. While the primary research focus of these two institutes is not exclusive to wood, the partnership they have developed over that past five years has yielded cutting edge research on the design and fabrication of demonstration pavilions that explore the new wood typologies.

4.3.1 *ICD/ITKE research pavilion, 2010*

In 2010, the ICD and the ITKE designed and constructed a temporary research pavilion. The innovative structure demonstrates the latest developments in material-oriented computational design, simulation, and production processes in architecture. The result is a bending-active structure made entirely of extremely thin, elastically-bent plywood strips.

The research pavilion demonstrates an alternative approach to computational design where the computational generation of form is directly driven and informed by physical behavior and material characteristics. The structure is entirely based on the elastic bending behavior of birch plywood strips. The strips are robotically manufactured as planar elements, and subsequently connected so that elastically bent and tensioned regions alternate along their length. The force that is locally stored in each bent region of the strip, and maintained by the corresponding tensioned region of the neighboring strip, greatly increases the structural capacity of the system. The work is contemporary while evoking qualities of traditional Mudhif houses of the Madan people of southern Iraq (Fleischmann et al. 2012).

4.3.2 *ICD/ITKE research pavilion, 2011*

In summer 2011 the ICD and the ITKE, together with students at the University of Stuttgart realized a temporary research pavilion made of wood. The project explored the architectural transfer of biological principles of the sea urchin's plate skeleton morphology by means of computer-based design and simulation methods, along with computer-controlled manufacturing methods for its building implementation. A particular innovation consists in the possibility of effectively extending the recognized bionic principles and related performance to a range of different geometries through computational processes, which is demonstrated by the fact that the complex morphology of the pavilion could be built exclusively with extremely thin sheets of plywood (Menges and Schwinn 2012).

4.3.3 *Landesgartenschau exhibition hall, 2014*

Through work on the 2011 pavilion as well as additional research in robotic fabrication in timber construction), the ICD and ITKE institutes developed a robotically fabricated lightweight timber construction system sourced from regional wood products. The building system and its computational design methodology were successfully tested through the design and construction of a large-scale prototype building for the horticultural exhibition of Baden-Württemberg in 2014. The Landesgartenschau Exhibition Hall uses a digital chain from design to fabrication of both structural and non-structural building parts resulting in a geometrically highly differentiated and efficient construction system. Its flexibility allows for adapting to diverse and complex boundary conditions while ensuring high structural performance and resource efficiency. Additionally, the developed system expands the application of regional timber products in accordance with future foresting strategies in Baden-Württemberg (Schwinn and Menges 2015).

5 OPPORTUNITIES IN THE US

The case studies highlighted in this paper are part of a larger effort by the author to examine more thoroughly wood research and education occurring outside of the United States, where advances in the use of mass timber have been more rapidly developing over the past several decades. A few insights that can be drawn from this study include:

- Beyond just building big, new systems and typologies must be explored through the use of computational design and advanced manufacturing.

– Developing a holistic view from forest to building is necessary to understand and appreciate the full potential of the material innovation.
– Experimental demonstrations projects serve as ideal test beds for implementing research ideas with minimal financial burden. These projects also serve as an effective means for dissemination of new knowledge.
– Success in these efforts relies heavily on interdisciplinary teams working with close industry partnerships and support.

The recently formed National Center for Advanced Wood Products Manufacturing and Design is an ideal location where these types of activities might occur in the US. The center was created in 2015 as a partnership between the College of Forestry and the College of Engineering at Oregon State University (OSU) as well as the School of Architecture and Allied Arts at the University of Oregon. It aims to feature research and educational programs focused on the unique intersection of design, engineering, and construction using innovative wood products. One of the primary goals of the center is the development of research and education programs targeted to strategically support and grow the competitiveness of the US wood manufacturing sector and building design profession.

6 CONCLUSION

Advances in the development of CLTs and other engineered wood products have renewed interest in non-residential uses of wood. Architects and engineers are beginning to reconsider this very old material in new and exciting ways. Universities in the US are unfortunately not properly equipped to prepare students with the design skills to fully leverage the recent advancements in wood product innovations. By examining institutions in Europe, where innovation in advanced wood products have been more widely adopted for the past few decades, US universities can base future efforts in wood research and education on successful models adopted from abroad and adapted to the unique conditions of the US buildings industry and economy.

Intermediate landscape regeneration. Implications on architectural education

P. Vall-Casas, M. Benages-Albert & A. Cuéllar
Universitat Internacional de Catalunya, Barcelona, Spain

P. Elinbaum
Centro de Estudios Urbanos y Regionales, Buenos Aires, Argentina

ABSTRACT: Architects in urban planning and design are mainly devoted to providing piecemeal, instant, expert-driven solutions rather than systemic, long-term, co-produced ones. Such reductive approach compromises architect's capacity to guide the transformation of the suburban landscape towards a sustainable city. Against this backdrop, techniques geared towards taking advantage of the inner capacities of the suburban landscape for incrementally increasing urban life should find their place in architects' curriculums. In this regard, the Regenerating Intermediate Landscape studio of the UIC Barcelona School of Architecture deploys three complementary approaches with significant implications on architectural education: (1) systemic analysis focused on the identification of networks of places with collective meaning; (2) evolutionary analysis addressed to the discernment of regenerative tendencies such as unplanned development of systems of public open spaces; and (3) participatory analysis aimed at propelling communities' involvement in the definition, materialization and maintenance of civic spaces.

1 INTRODUCTION

The environmental, social and economic impacts of sprawl are well known, and the need to alleviate such negative effects is widely accepted. In the USA, this field has gained momentum since the 1980s and a wealth of proposals to repair sprawl at a regional and community scale have been implemented (Calthorpe, 1993, Dunham-Jones & Williamson, 2009, Tachieva, 2010). In Europe, retrofitting suburbs has also appeared on the agenda of national and supranational institutions as an important issue (Bruegman, 2005, EEA, 2006, Indovina, 2009). Against this backdrop, landscape-based approaches are essential for reframing contemporary urban regions (Shannon, 2006) and have to consider the "intermediate nature" of the suburban landscape (Rowe, 1991, Sieverts, 2000): 1) the middle position, between city cores and greenfields; 2) the hybrid morphology, between urban and rural; 3) the inter-scalar scope, between regions and communities; and 4) the ongoing transition, ranging from initial single-functional subdivisions to sustainable urban fabrics. According to these characteristics, the technical and political agendas of the 21st century should undertake the incremental dissemination of urban life in large-scale suburban areas, conceived as dynamic physical and social organisms.

However, this challenge may be compromised by a reductive interpretation of the role of architects in urban planning devoted to providing piecemeal, instant and top-down urban design solutions (Dunham-Jones & Williamson, 2009) rather than systemic, long-term and co-produced ones (Magnaghi, 2000). In this respect, major efforts to update academic programs in architecture schools are required, mainly in Europe, where the tradition of compact cities might explain the lack of undergraduate courses on retrofitting suburbs. A response to this is the Regenerating Intermediate Landscape (RIL) studio of the UIC Barcelona School of Architecture, which contributes conceptual and technical grounds for intermediate landscape regeneration covering every level of design practice, including: landscape architecture, urban design, and architecture. Below, we introduce the RIL studio with the aim of highlighting its educational implications.

2 REGENERATING INTERMEDIATE LANDSCAPE STUDIO

For the last fifteen years, the Regenerating Intermediate Landscape studio has required students to undertake the field research needed to comprehend the urbanization processes of a large-scale suburban area, and then propose planning and design solutions for its retrofitting from regional to community scale. The studio combines landscape architecture and urban design, involving an analysis of the intermediate landscape, a

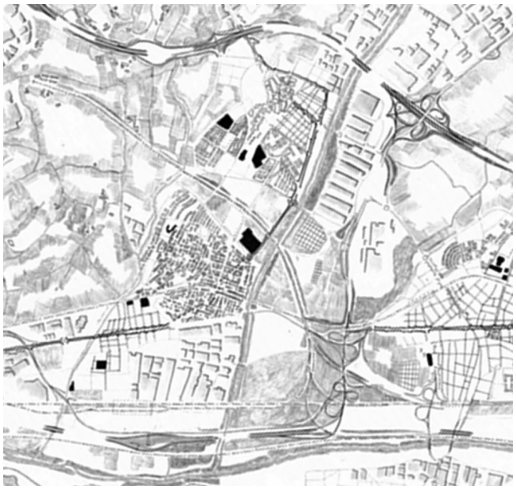

Figure 1. Student map of the built-up areas, main mobility networks and ecological matrix of the Caldes Stream South Sector. Map by Cristina Coll, Domènec Massuet and Anna Perramon (Course 2013–14).

proposal for a physical structure for landscape regeneration, and a proposal for intervention in a specific retrofitting site, developed in both text and graphic format. Students must grapple with the physical components of the intermediate landscape such as urban agriculture, rural-urban interface, activity corridors, sprawl types (commercial strips, industrial parks, residential subdivisions), infill and redevelopment sites, and public transport systems. The analysis of these materials requires not only standard cartography for understanding the current technical conditions (aerial photographs, topographic and zoning maps), but also historical cartography for illustrating the complexity of the urbanization processes over time; and qualitative data collection in order to capture public landscape perception. Because intermediate landscape regeneration encompasses so many issues and requires an interdisciplinary approach, the studio has focused on repairing the suburbs of the Metropolitan Region of Barcelona (MRB) close to the UIC Barcelona campus where expert and lay knowledge is available. We select areas whose scales can be grasped by teams of three to four students and are suitable for data collecting and analysis (typically river corridors approximately 5–10 km long with surrounding suburban areas covering 10–50 km^2). Urban rivers are compelling sites for studio projects that have been identified by current metropolitan planning as strategic areas for MRB's sustainable development, and have increasingly attracted public attention, as demonstrated by the large number of local organizations involved in their protection.

The course is organized into three distinct phases: inventory/analysis, regional planning, and urban design. First, students conduct urban transects and map distribution of built-up areas and potential infill and redevelopment sites, document traces of heritage,

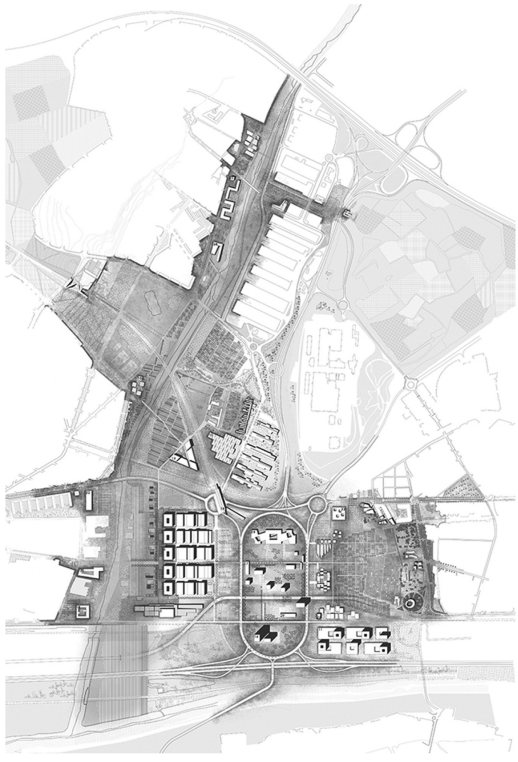

Figure 2. Final Master Plan for the Caldes Stream South Sector. Map by RIL studio students 2014–15.

and map the mobility networks, including arterial and local roads, pedestrian trails and public transport systems. Students also analyze the ecological matrix of the landscape, drawing upon green infrastructure maps including riverbanks, forests, agricultural land and local features such as public open spaces and facilities (Fig. 1). For this purpose, students take field trips to the project area and learn about ongoing issues from public agency staff and nonprofit groups.

Next, in the master plan phase, teams of three to four students work at the scale of the entire study area (10–50 km^2) for designing civic networks, i.e. cohesive and meaningful systems of significant collective places aimed at contributing to the visual understanding of the intermediate landscape and making it more livable. With this aim, the teams tackle issues of particular interest to them, such as enhancing open space systems along the length of the stream, reprogramming surrounding obsolete residential and productive areas, generating new urban centralities and improving public access from them to the riverbanks. Next, a final course proposal which includes the best contributions of all the teams is developed jointly by the students (Fig. 2).

In the third phase, students develop individual retrofitting projects for specific sites consistent with their master plans, making tangible the overall concepts. For example, to develop a new urban center, students have designed hybrid typologies of buildings

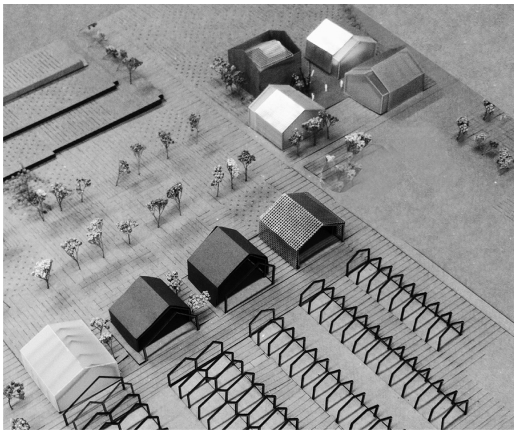

Figure 3. Student proposal for R&D Urban Allotments in the urban fringes of the town of Mollet del Vallès. The project is set in a rural environment and is based on the existing geometry of the agrarian plots. Made by Cristina Coll (Course 2013–14).

and public spaces that reconcile urban intensity and the rural environment (Fig. 3). To retrofit a commercial strip, students have developed conceptual designs to progressively replace large containers by small-scale, dense and mixed-use urban blocks. Students have also proposed new designs for urban parks and riverbanks to remove obstacles blocking public access and enhance the civic network.

Early on in the class, students are provided with conceptual frameworks, models, tools and methods for intervening in the intermediate landscape. Students make presentations to panels of professionals, government agency staff and community groups, who raise real-world concerns. After refining their work, the students present to the final jury with an external referee. The students' analyses and projects are assembled into reports which are then presented to city councils and non-profit advocacy groups.

3 CASE STUDY

In the Regenerating Intermediate Landscape studio, students are challenged to develop innovative design solutions for the transformation of urban rivers into legible civic corridors (Lynch, 1960). Beyond their high ecological value as "bio-highways", urban rivers deserve special attention due to their growing social use after decades of intense degradation closely associated with urban pressure (Warner et al. 2013). In fact, urban rivers are essential infrastructures for the sustainability of suburbs (Vall-Casas et al. in press), and for this reason they are a fundamental issue for the RIL studio. The Besòs River, which is one of Barcelona's two connections with inland Catalonia, has been studied for several courses. Six main watercourses with over a million inhabitants living around its flood plains flow down the slopes of the Coastal Mountains north of the city of Barcelona. The Mediterranean climate results in highly seasonal precipitation, with occasional flash floods and very little flow during much of the year.

Here we present a representative case study of the Besòs River Basin streams, formerly devoted to providing irrigation, energy and raw materials in a rich agrarian landscape. All of them, in the 1960s and 1970s, were subject to overexploitation of water resources, contamination of ecosystems and flooding due to the uncontrolled development of riverbanks. Natural cross sections have been highly modified and flood plains have become areas of growth; spaces for road and railway communications; and channels for drainage, waste, and energy supply. In the process, major stretches of the riverbanks were neglected and left to decline, leading to the dwindling of local riverside residents' feeling of belonging that had been characteristic of the first half of the twentieth century. However, this condition underwent a reverse in the 1980s as a result of significant efforts to reappraise social and environmental assets (Benages-Albert & Vall-Casas, 2013).

In this context, the goal of the RIL design studio is to recover the civic, ecological and economic value of the River Besòs space, combining effective urbanism and healthy ecological systems. In particular, the studio advocates alleviating the impact of mobility infrastructures, relocating polluting activities such as cement factories, stimulating connections between the existing residential fabric and the mosaic of riverside farmlands and woods, enhancing the river's urban embankments and facilitating public access. For this purpose, students design a system of selective repair scenarios interconnected by public open spaces such as avenues, plazas, allotments and parks, the objective being to reinforce the physical and social cohesion of suburban river stretches and contribute to their legibility. To achieve this, students are asked to consider the intermediate condition of the landscape, as regards: 1) the scale of work involving simultaneous local and regional decisions, 2) its hybrid urban-rural nature which questions the traditional concept of public space and suggests the incorporation of new functional programs such as urban agriculture, and 3) the ongoing urbanization process.

3.1 *The case of the Caldes stream*

The concept for "re-envisioning" the Caldes stream resulted from the agreement signed by the Catalan government and the UIC Barcelona with the aim of offering technical advice to the Department of Territory and Sustainability (DTS) for planning supramunicipal areas that have a role to play in boosting the Catalan economy and need new methodological bases in order to be developed. Specifically, the students' work supported the Master Plan for the Caldes Stream South Sector, directed at transforming currently expectant spaces around the 7 km lower stretch of the Caldes

stream in a metropolitan sector that constitutes a point of reference for its economic, ecological and social potential. This contribution took the form of an integral project comprising collective proposals for urban and territorial structures and individual proposals for urban design (Fig. 4).

The Caldes Stream South Sector covers the urban cores of Mollet del Vallès, Santa Perpètua de Mogoda, Martorelles, Sant Fost de Campsentelles and La Llagosta, set in large extensions of peri-urban open space that is often residual with limited accessibility. The transformation of this sector into a new metropolitan center involved three main issues: (1) structuring and re-assessing the peri-urban open space fragmented by the forceful footprint of road and railway infrastructures; (2) the environmental and social recovery of the lower stretch of the Caldes stream as a full-blown river park to contribute to the improvement of adjacent residential and industrial fabrics in Santa Perpètua de Mogoda and La Llagosta; and (3) reassessing the urban outskirts of Mollet del Vallès South and the adjacent peri-urban open space by means of facilities and public spaces with added value.

With this aim, students dealt with: (1) the recovery of the ecological and cultural values of the existing agricultural substratum by means of the civic consolidation of historic roads connecting Mollet del Vallès, Santa Perpètua de Mogoda and La Llagosta, strengthening links along the embankments of the Caldes stream, and the preservation and respectful recycling of agricultural heritage; and (2) the reinterpretation of metropolitan road junctions by means of projects that combine infrastructure and landscape, incorporating innovative economic activities with high added value. Students presented their results to the Catalan Government in an exhibition held in Barcelona's Museum of Modern Art. The resulting model of the master plan was exhibited in the DTS offices, helping to influence the urban planning of cities along the Caldes stream.

4 IMPLICATIONS ON ARCHITECTURAL EDUCATION

From our experience of teaching regeneration of intermediate landscapes on a number of river corridors in the MRB, and in light of the relevant literature, we propose three complementary techniques that deserve special attention due to their implications on architectural education: (1) systemic analysis oriented to the design of civic networks ; (2) evolutionary analysis addressed at identifying regenerative tendencies such as the incremental development of systems of public open spaces; and (3) participatory analysis aimed at propelling communities' involvement in the definition, materialization and maintenance of daily life spaces. These techniques will provide methodological support to identify and take advantage of the inner capacities of suburban landscapes for building civic networks while increasing citizens' involvement in them.

4.1 *Systemic analysis*

The systemic analysis is essential to transcend intermediate landscape complexity and build operational narratives for understanding and designing its shape. In particular, the systemic analysis supports the design of the civic network through three stages (Cuéllar & Carracedo, 2011, Elinbaum et al. 2013) (Fig. 5).

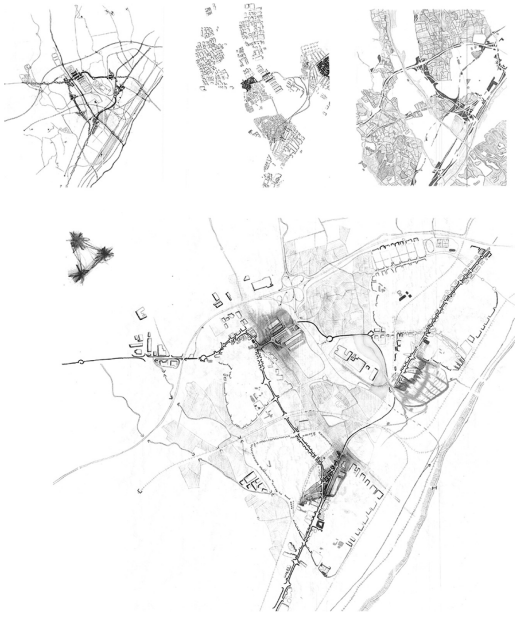

Figure 5. Example of systemic reading. At the top, morphological layer analysis maps. At the bottom, from left to right, landscape model scheme and landscape structure map. Made by: Cristina Coll, Domènec Massuet and Anna Perramon (Course 2013–14).

4.1.1 *Morphological analysis of layers*

The first stage makes a morphological analysis of the Caldes Stream South Sector landscape, following the methodology of Ian McHarg (1969) for assessing landscape capacities. Specifically, the students map several thematic layers such as green and grey infrastructures and built-up areas. In addition, each working group suggests new complementary thematic approaches according to their particular interests, such as: cultural heritage, ecological values, current planning regulations, etc. Once students become familiar with the morphological analysis of layers, they develop two types of synthetic vision, a specific one (landscape structure) and another abstract one (landscape model).

4.1.2 *Landscape structure*

Designing the landscape structure implies an inductive operation based on the selection of the most important elements of each thematic layer and their articulation in a synthetic representation. Among other results, students determine: the consistency and diversity of the system of open spaces, the fluent interconnection of the arterial road system and local road system, and the appropriate interface between built-up areas and green areas. At the same time, the design of the landscape structure is a deductive operation aimed at assigning a new regional role to the Caldes Stream South Sector, and thus giving a new meaning to its urban fabrics, open spaces and infrastructures.

4.1.3 *Landscape model*

The landscape model is an abstract expression of the landscape structure that allows us to clarify and communicate its basic principles. Unlike the landscape structure, which is directly related to one specific case study, the landscape model consists of an abstract diagram that might fit with multiple cases. Thus both analysis and design converge in the model, reflecting the duality between reality and utopia, or reasoning and intuition, characteristic of the practice of urbanism. At this stage, the students de-construct the landscape structure, identify a number of linked parts, and rebuild the whole forming a new, more efficient, clear and communicable entity (the model).

The three phases of systemic analysis do not follow a linear development but rather an iterative path. The identification and comprehension of new layers, the redesign of the landscape structure according to these layers, and the subsequent reworking of the landscape model build a complex back-and-forth design process, along which a number of sprawl repair opportunities emerge. Students then select the most strategic ones and determine guidelines for their development consistent with the landscape structure and model.

4.2 *Evolutionary analysis*

An improved understanding of how historical layers contributed to the evolution of the intermediate landscape provides better opportunities for effective regeneration strategies (Secchi, 1994, Corboz, 2001). In this sense, there are a number of relevant experiences of urban stratigraphy addressed at uncovering the genesis of metropolitan regions with deep historical roots such as Barcelona (Font et al. 1999) and Milan (Boeri et al. 1993). According to this background, the present educational proposal seeks to incorporate a comparative analysis of historical cartography as a standard tool for designing historic-based civic networks by identifying pre-urban patterns that undergo processes of cumulative collective meaning.

4.2.1 *Identifying pre-urban patterns with civic potential*

Pre-urban patterns are spatial structures with the capacity to prevail in the face of the pressures of the urbanization process and to determine the form of the intermediate landscape. Roads and paths, agricultural plots, old villages, farms and churches, and irrigation and drainage infrastructures built traditional networks that structured the productive and social activity of farming communities. These types of historic materials embedded in suburban areas help to improve functional diversity, connectivity and pedestrian accessibility, while promoting citizen participation in retrofitting suburbs (Vall-Casas et al. 2011). Within this conceptual framework, students select individual elements from different historical layers and reconnect them in specific sets. The resultant conjunctions of historic roads, main streets, abandoned rail tracks and paths, farms, parks and urban centers, watercourses and canals, create cohesive and meaningful civic networks. In particular, entities such as old roads and streams are redesigned, taking advantage of their intermediate scale, with the goal of reorganizing the fragmented metropolitan puzzle, and interconnecting a broad spectrum of isolated retrofitting projects (Fig. 6). We believe that rather than imposing an ahistoric design, helping students to find a plan that builds on historic patterns is preferable.

4.2.2 *Analyzing processes of cumulative civic value in pre-urban patterns*

Watercourses and historic roadways of contemporary urban regions are becoming channels of collective significance (Vall-Casas et al. in press). For this reason long-term processes of the transformation of roads and rivers into civic corridors, which have increased the sense of belonging of local residents and improved the legibility of large suburban areas, must be considered carefully. In our case study, the accumulation of public open spaces along the riverbanks of the Caldes stream and the intensification of their social use is an important issue that deserves to be acknowledged. For this purpose, students deploy chronological assessments of the urban river corridor aimed at verifying the incremental development of a supra-municipal open space system. This evolutionary approach provides an enhanced understanding of the significance of the present moment and allows us to align past and future strategies for regenerating the intermediate landscape.

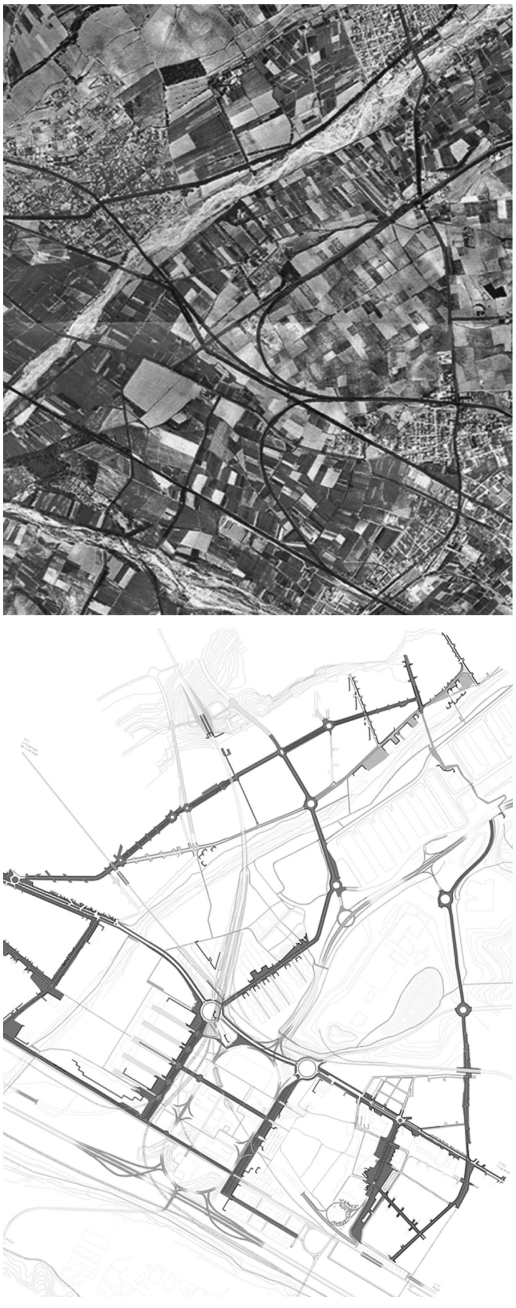

Figure 6. Design methodology of a historic-based civic network. At the top: mobility infrastructure of the pre-existing rural landscape drawn on a 1956 aerial photograph of the Caldes stream. At the bottom: historic connectors transformed into boulevards or main streets of the Master Plan for the Caldes Stream South Sector. Map by RIL studio students 2014–15.

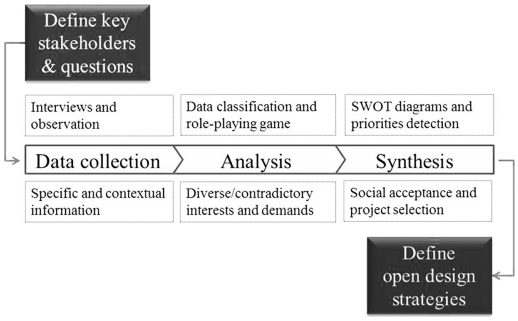

Figure 7. Participatory analysis. Conceptual framework.

4.3 *Participatory analysis*

The move from the design of a landscape structure towards the design of a civic network calls for the integration of experiential knowledge in spatial design, with the aim of transforming abstract systems with civic potential, developed in previous expert analyses, into socio-physical structures. To access the experiential knowledge of local stakeholders and integrate it in the design process, qualitative techniques are developed following three main phases (Benages-Albert & Elinbaum, 2014) (Fig. 7).

4.3.1 *Data collection*

The first phase consists of identifying key stakeholders related to the case study and interviewing them to access the social component of places (*civitas*) (Delgado, 2004). This process of qualitative data collection provides *hic et nunc* knowledge of places based on the stakeholders' experiences, requests and interests that students incorporate as a complement to the morphological approach. In particular, each group of students defines an interview guideline with specific questions depending on the previous spatial analysis and the interlocutor expertise to recognize places with special value and tackle sprawl repair projects from the perspective of real needs and expectations. All the information gathered is analyzed and synthesized in the following phases to obtain a balanced socio-physical structure in which the systemic, evolutionary and participatory readings complement each other.

4.3.2 *Analysis*

The analysis of all the qualitative data provided by different actors allows the emergence of diverse and sometimes contradictory perceptions and demands that the designer need to study and prioritize in an on-going dialogue with the other actors involved in the design process. After examining and classifying the data obtained in the previous phase, students participate in a role-playing game with the whole class to discuss the perception and conception of reality according to the different stakeholders interviewed. During this phase of collaborative learning, students understand the complexity of the project beyond its morphological dimension and feel encouraged to continue with the design process when discovering new project ideas linked with the local stakeholders' needs.

4.3.3 *Synthesis*

The synthesis of the stakeholders' demands by means of open design directives (Binnekamp et al. 2006) allows the definition of a socio-physical structure attuned to public landscape perception. To do so, based on *in situ* knowledge the students validate or refute the project hypotheses that have emerged from the morphological analysis, adding any new opportunities provided by the stakeholders and calibrating the social response in terms of the specific projects identified. A SWOT analysis (Strengths, Weaknesses, Opportunities, Threats) then facilitates the proposal of flexible guidelines for the design of the civic network and its particular components. In this way, rather than general proposals arising from an independent process of the architect/urban planner, a much more profound practice-based reflection is the result of a wide variety of intellectual approaches commensurate with the singularity of the different contexts and situations (Innes, 1995).

The use of this methodological tool provides three key elements for defining a participatory project which facilitate its materialization, social acceptance and maintenance: (1) knowledge of the place as a social space of life and interaction, which is impossible to achieve by studying maps; (2) a better understanding of the complexity of urban planning in relation to the conflicts of interest of the different stakeholders involved; and (3) the identification of specific ideas for the urban design and landscaping with a more solid social basis. This approach introduces a new way of understanding urbanism as an open process – an imperfect, contentious, contradictory and ambiguous process, if you like – but one which also embraces the complexity of opinions and processes to allow more realistic, robust and operational designs in the long term.

5 CONCLUSIONS

The regeneration of intermediate landscapes will always be challenging. It requires systemic, evolutionary and participatory analysis to know how to activate smart regeneration processes committed to the incremental production of local networks of public infrastructure with civic value. In teaching students how to approach the design of such socio-physical structures, we try to instill a respect for citizens' attachment to their daily life environment as a powerful force for sustainable development. Similarly, we encourage students to learn from pre-urban patterns to build a solid foundation for evidence-based design. This approach questions the traditional problem-solving structure of most design studios based on individual, instant, and expert-driven solutions, proposing instead the co-evolution of the intermediate landscape as a question-driven approach that emphasizes an understanding of the collective processes of transformation.

Typo-morphology: From research to architectural education

J. Leite & R. Justo
Forma Urbis Lab, Ciaud, Faculty of Architecture, University of Lisbon, Lisbon, Portugal

ABSTRACT: The contemporary city presents itself as an urban organism of great complexity, consisting of an increasingly number of elements, systems, dynamics and extracts, which makes their reading an equally complex task. The method of typo-morphological analysis, it is assumed in this context, as an important reading tool of the city, giving order to what is naturally disordered through a classification process of the different elements that structure it – streets, squares, urban blocks, buildings, plots, among others. It is precisely from the reading of two structural elements of the city urban fabric, the urban block and the street, that we seek to illustrate the applicability of the methodology and its usefulness in the academic education and as a tool in the (re) design process of the city.

1 INTRODUCTION

The urban fabric, both in its public and private component, reveals in the diversity of its shape the tension between transformation and resistance. This is the result of constant need for man to reinvent the place where he lives. The systematization of knowledge relating to this process of change and to interventions that have occurred in the built fabric is the key in decoding the physical and spatial structure of the city and in its own consolidation/design process.

The complexity of this process makes the articulation of the architectural education with research activities increasingly significant and even directly with the architectural practice. The method of typo-morphological analysis, as a classic reading tool of the city, can contribute to strengthen the link between these different fields of action. It presents itself as an important tool for the apprehension of the urban phenomena, to stabilize and consolidate ideas but also to check the adaptability and consolidation of some concepts, in periods of disciplinary uncertainty.

The article aims to show that this articulation is a reality and it offers added value in the moment of thinking and designing the contemporary city, mainly in the academic context. Its therefore important to explain that this study is related to the development of two parallel researches – "The Lisbon Urban Block: from Shape to Type" and "Emergent Streets. A morphological interpretation in Portuguese urban context" –, whose methodological basis is strongly influenced by the research laboratory FORMA URBIS Lab. This lab to which we belong is composed by professors of the University of Lisbon – Faculty of Architecture, research fellows, masters and Phd students developing studies related to the thematic of city urban form. The presence of a productive research environment with a common focus – the city – understood from tested and stabilized methodologies – the typo-morphology – makes available both to academics and students useful tools for the process of reading, interpretation and design of the city.

The article shows, at first, the developments of both researches by using the method of typo-morphological analysis, applied to two structural urban elements of the city public and private component, the street and the urban block, analyzed in different urban contexts of Lisbon. Secondly, it tries to show through the work done by university students the utility of this methodology in the understanding and design process of the city.

2 THE TYPO-MORPHOLOGICAL READING

2.1 *Studies and approaches*

The typo-morphological studies have assumed since the mid-twentieth century an important role to understand the dynamic of the urban fabric. They reveal their physical and spatial structure based on detailed classification by types of the elements that shape its urban form – open spaces, buildings or streets (Moudon, 1998).

It's composed by an analytical and a classification process that is important to explore according to the studies and approaches of the different urban morphology schools with particular focus on Italian, Anglo-Saxon/German and French.

The morphological analysis is framed within the analytical process of reading, being realized from a common procedure in this field – the morphological decomposition. Reading the city from the decomposition of the urban system in morphological elements – streets, squares, buildings, plots, topography, etc. – connecting them to each other and relating them to the context, can be seen in the work of authors

such as Lynch (1960) and Cullen (1961) as a way of perception the built environment. If the morphological elements compose and organize the urban fabric, study their mutual relations contribute to the explanation of the city.

The typological analysis as a classification process aims to differentiate the Types, recognizing and systematizing its characteristics, differences and their relationship with the urban context, historical period and the society that originated it. This allows us to build a typological framework that makes easier the interpretation of the different elements that shape the city. The construction of the Type, and its corresponding typology, should not be seen only as a systematic act of classification, but also as an important design tool, as advocated by Carlo Aymonimo (1966).

The initial studies of typological analysis, linked to urban morphology were conducted by the Italian school, which is characterized by understanding the city as an "architectural organism" (Muratori, 1959). Taking the present as a starting point, the study begins with an interpretation of the urban fabric as a result of an evolutionary process shaped by the changes of the architectural typologies.

The work of Muratori (1959) is an important reflection about the physical component of the Italian city, especially for the definition of analytical tools based on the concepts of urban fabric, type and typology. In this study, Muratori stabilizes the concept of typo-morphology, based on the reading of physical form as a result of an evolutionary process. The concept of Type (Building-type) is understood as a theoretical and abstract exercise, a kind of interface between the real object and the man mind. This is an exercise that allows us read, but also conceive. The Type is a starting point for the creative and design process. These settings were at the genesis of several works in Italy and Europe.

On the other hand, the Anglo-Saxon and Germanic school is based on the analytical characterization of a particular space in a certain time or over several times. M.R.G Conzen is probably the main reference with several morphological studies of small towns or British urban areas, especially the analytical reading of Alnwick in 1960. In this study, Conzen mainly uses the plots structure, but also the street and the buildings, as basic elements for understanding the urban form. This methodology would have a significant impact on the Anglo-Saxon world, on authors such as Jeremy Whitehand or Ivor Samuels, Micheal Conzen and Anne Vernez Moudon in the North American continent.

The French school as the Italian arises in the 70s in response to the modernist principles and models, with important methodological contributions. Issues such as the evolution of the urban fabric and the organization of the plots structure (Castex; Celeste; Panerai, 1980); the fragmentation process of the closed urban block to the modern building (Castex; Depaule; Panerai, 1997), and the relationship between the built element, plot structure and public space; or the urban form classification by different deformation processes (Borie; Micheloni; Pinon, 1978), are all issues worked by a large group of authors who belong to this school.

In this context, it is important to refer two essential and complementary studies for understanding the city. The first – "Analyse Urbaine" – reveals the city form through its decomposition by extracts, fragments or samples. The second one – "Projet Urbain" – Panerai and Mangin indicate a more operational sense. The analysis of the different urban elements, and its diversity and classifying processes, reveals indirectly some projectual suggestions that can generate new systems of urban production.

The French school introduced a new methodological dimension, a more refined critical sense, differentiating the design theory "as an ideal" from the design theory "as a practice". Thus, the French school studies provide essentially working tools to guide the project design (Panerai, 1999b). It makes more valuable the role of typo-morphological method in the city understanding and project.

3 URBAN BLOCK

3.1 *From shape to type*

A reading that addresses the issue of the urban block, through a typo-morphological study, allows us to stabilize in a ordained way the knowledge about the processes, rules and models that build the private city. More than that, it is relevant for the understanding of the multiple design possibilities that this element offers to the contemporary urbanism, a result of its different evolutions and changes over time and space.

The city of Lisbon presents itself as an exemplary space of practice and manipulation of the urban block design. It is evident the tension between diversity and unity; urban fabrics that have suffered long processes of sedimentation (Alfama) and others designed as an integral unit (Baixa Pombalina); operations who reject the idea of urban block (Olivais); others more recent representing the recovery of urban block as an element of urban composition (Parque das Nações); between different development phases of the city; and even between different natural supports (hills, valleys, river front). It is in the actual city shape and its evolutionary process that we recognize their different dynamics of urban production.

The aim of this topic is not to find the types of Lisbon urban blocks, being that the purpose of one of the PhD thesis in development, but rather to reveal the methodological framework that will contribute to its identification.

The typo-morphological study of the urban blocks unfolds in two different phases, complementary and essential to read this element: the morphological analysis – individual approach to the subject of study; and the typological analysis – comparative approach. It's the aim of this topic to explain with more detail each of these stages, using some representative examples of Lisbon urban blocks.

3.2 *Morphological approach*

Two types of readings – the Decomposition and the Evolution, will support the morphological characterization of each urban block selected as representative of Lisbon urban fabric.

The first reading seeks to decompose the urban block through the study of the different elements that gives it shape and the relationships established between them: the building relationship with the plot; the plots structure with the shape of the urban block; the relationship of the dwelling organization with the built fabric; the relationship of the built fabric with the urban block shape; the urban block relationship with the shape of the city.

Assuming these relationships, six elements were considered as able to reveal their complexity – the Topography, the Perimeter, the Plot structure, the Built Fabric, the Courtyard and the Building.

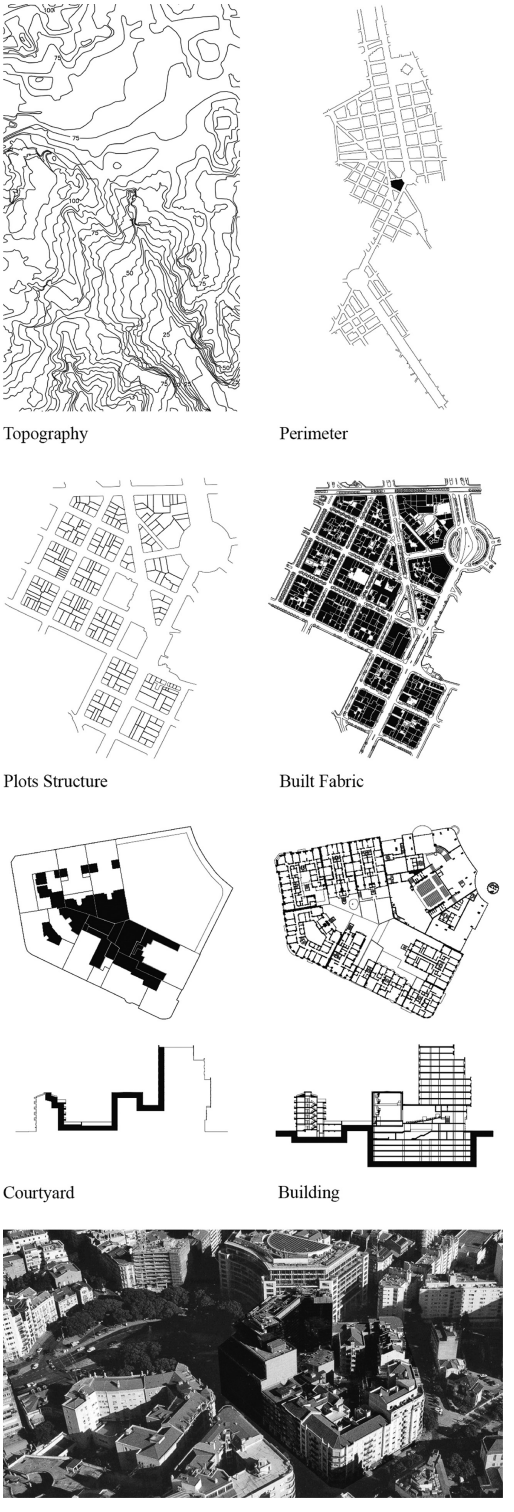
The Topography, because it is repeatedly the constraint and generator of the urban block design and the urban fabric diversity, established in the combination of different natural supports – hills, valleys, river fronts, among others. The Perimeter, by the definition of the urban block boundary and the physical form of public and private city, organizing the buildings from the street and articulating built and empty spaces, public and private domains. The Plot Structure, because it is one of the main supports of the urban block dynamic and organization. It is shaped from different plot aggregation types– regular or irregular – regulating the form and density of occupation. The Built Fabric as a result of the buildings aggregation that defines the built shape of the urban block and at the same time the nature of its interior space – Courtyard – which can be public or private, built or empty. Finally, the Building – singular or common -, by the relation between the interior organization of the architectural typologies and the shape of the urban block built fabric.

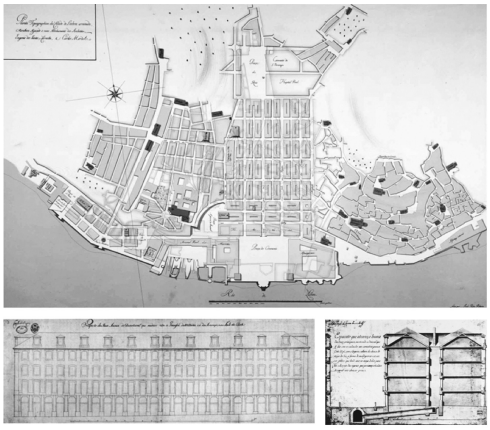
For each of these elements we will find the rules that define their own shape, size, that explain their location within the urban structure and, above all, the rules that influence the shape of the urban block.

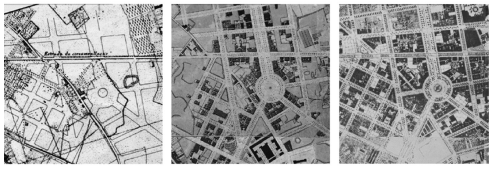
The second reading – the Evolution – is related to the action of time on the urban block, understood as the result of a dynamic and continuous process of urban production, a space where the elements that give it shape, move in time at different velocities. Therefore, the urban block will be analyzed and interpreted not only in the actual crystallized state but also over time through the reconstitution of its evolutionary process. It can have a very variable time cut, depending on the period of the urban block production.

In this regard, four main phases were identified in the urban block evolution process – the Production, the Sedimentation, the Transformation and the Resistance.

The Production refers to the first moment of the urban object, the moment of its creation. This process can start from very different principles, for example,







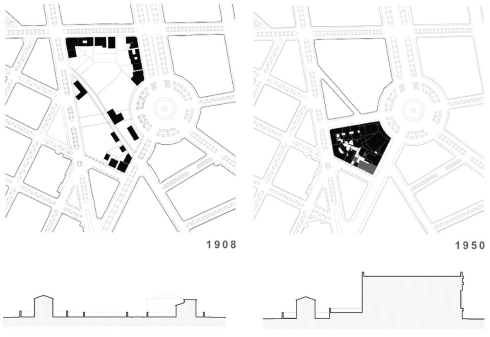


Figure 1. The six urban block elements. The urban block decomposition in Avenidas Novas.

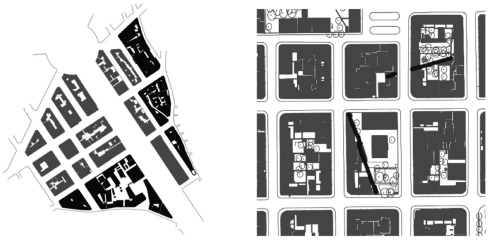

Production . Baixa Pombalina

Sedimentation . Avenidas Novas

Transformation . Monumental urban block in Avenidas Novas

Resistance . Avenidas Novas Campo de Ourique

Figure 2. The urban block evolution phases.

the Baixa Pombalina plan in Lisbon, drawn up following the 1755 earthquake, was created with a clear idea of urban production based on a compositional logic of urban layout, plots structure and building. The Sedimentation, in turn, is connected with the urban block development processes that follow the original principles of composition. The densification process is an example of it, because there is no structural change in the shape and organization of the urban block, only an integration of new buildings within a consolidated structure. The Transformation, however, has to do precisely with changes that are structural and are easily recognizable in the reconstruction of urban fabric evolutionary process. The urban block of Monumental, in Avenidas Novas, reproduces clearly this process, taking into account that between the late nineteenth/early twentieth century and the mid-twentieth century suffered a significant change in its morphological structure. This it was driven by a reorganization of the road system that included the removal of a street and the opening of another. Finally, the Resistance refers to elements that survive the urban block transformation process. In the examples, we recognize clearly the influence of pre-existing structure had, in the case of the Avenidas Novas urban blocks, in the definition of their perimeter and, in the case of Campo de Ourique, in their plots structure.

Therefore, for each of the evolution development phases we will identify the processes that are representative of the urban block dynamic in Lisbon.

These two types of reading – the Decomposition and the Evolution – that support the morphological analysis of the urban block in Lisbon, will produce a set of essential results for the type identification.

3.3 *Typological approach*

The typological analysis gives meaning to these results through a comparative reading of the worked urban blocks. Knowing the specificities of the study objects we can compare them and aggregate them to common morphological matrices that show particular characteristics of their nature.

In this sense, the Types are established according to the morphological reading, allowing the support of a comparative study between urban blocks that are very different from each other. However, they can be understood together when reduced to their essential elements, making the understanding of particular characteristics of the urban object clear and objective. This means that after defining the Types, you can explore relationships of different nature between them, an ordering procedure of isolated types that reveals the urban block typology.

This methodological construction based on a typo-morphological reading of the urban blocks does not end in a typology definition, because it is supposed to develop an interpretative and conceptual framework that gives it a more operational sense. This is useful to the actual discussion about the urban production, allowing us to inform the emerging issues about the intervention on the urban fabric. In this (re)design process of the city, the urban block may have an important position, because it assumes an extraordinary versatility and allows increasing the existence of new models, new spatial concepts and new production

processes. It assumes an essential role in the urban fabric restructuration or even as a conceptual support on the sedimentation process.

4 STREET

4.1 *The emergence of others configurations*

The consolidation of the major mobility axis as essential elements for the structuration and aggregation of the urban fabric causes big changes in actual urban paradigms.

One of the issues it takes, in recent times, has to do with the (re) interpretation of some linear urban systems as emerging forms of streets. The existing accessibility and the strategic positioning within a network, enables the urbanization development along certain infrastructure mobility axis, reconfiguring your identity. The established dynamics between this marginal urban fabric and its own formal characteristics generate transformation processes on the previous infrastructure, modifying and creating another urban element.

The characteristics of these linear urban elements that emerge, brings us to some features normally associated with the urban element Street, for example: the urban fabric support; the connection between at least two locations (Panerai, 1999b) and the regular compactness of a building fronts (Bohigas, 2004).

In this sense the use of the typifying process in these elements allows us to decode them, identifying their main characteristics and thus allow a deeper understanding of these emerging urban settings that assume an increasingly and an ever greater importance in the structuring and referencing of the contemporary urban territory (Mangin, 2004).

4.2 *The case of the Strip N117*

The case of the road N117, located in Lisbon Metropolitan Area illustrates a type of street configuration that emerges in the actual Portuguese urban context. This road initiated in the late 80th of the twentieth century an intense metamorphosis process, becoming during the following decades in a *Productive Strip*[1].

One of the urban components that most has changed over this evolution process was the urban layout. Starting from a filamentary base with some connections to the territory, it presents nowadays with a great complexity and composed by two systems: the primary

Figure 3. The road N117.

circulation channel and a roads complementary network. The symbiotic relationship that is established between these two systems enables the maintenance of high velocity, through the central corridor, and the support of the plots and building structure. The surrounding buildings, which colonized the margins of this infrastructure, produce this secondary network and through it connects with the central structure of the element.

4.3 *Composing the urban layout type*

In order to confirm the characteristics observed in the road N117 reading was used the methodological principle of typo-morphological analysis.

For this, it was made a comparative analysis between the N117 and other two elements of the same typological family, the A44 in Vila Nova de Gaia, and the A25 in Aveiro area. With this process we were able to identify the common features between the three urban layouts.

So, observing the urban layout of the three elements we could see that, despite the own deformation of each infrastructure, all shows a consistent network that intertwine the main axis. This network, not necessarily structured and rationally designed, serves as an access to the plots around the main axis and at the sometime introduce more complexity to the urban layout as a whole.

The central circulation axis is segregated, connecting specifically itself with the same type of roads, mobility infrastructures with higher territorial relevance. The connection nodes are configured avoiding the level crossing of driving lanes, preserving a more fluid movement. The conservation of car traffic as its main function in the central axis is the dominant concern. In all cases, N117, A44 and A25 can be seen on the major axis the use of different height levels. The strongest situation is in A25 where the main corridor is always develops at lower level than the adjacent margins apparently immune to what it happening in the surround area. In contrast, the A44 presents the infrastructural axis most of the time at the same topographic elevation, but using occasionally some barrier elements for separate the centre channel and the other roads.

The different complementary network present an irregular shape, result of different kind of urban processes but without compromise its main function, the supporting of the plots. In the N117 and A25 roads the

[1] The Productive concept it is associated to new principles and to some contemporary activities, which are able to generate economics values. In the actual pos-industrial period some urban paradigms changed and another urban condition appears. The industrial production move to other fields, related to high technology where robotics and electronics prevail. On the other hand, it is possible to identify in the actual productive spaces activities linked to commerce, finances, services, knowledge and technology.

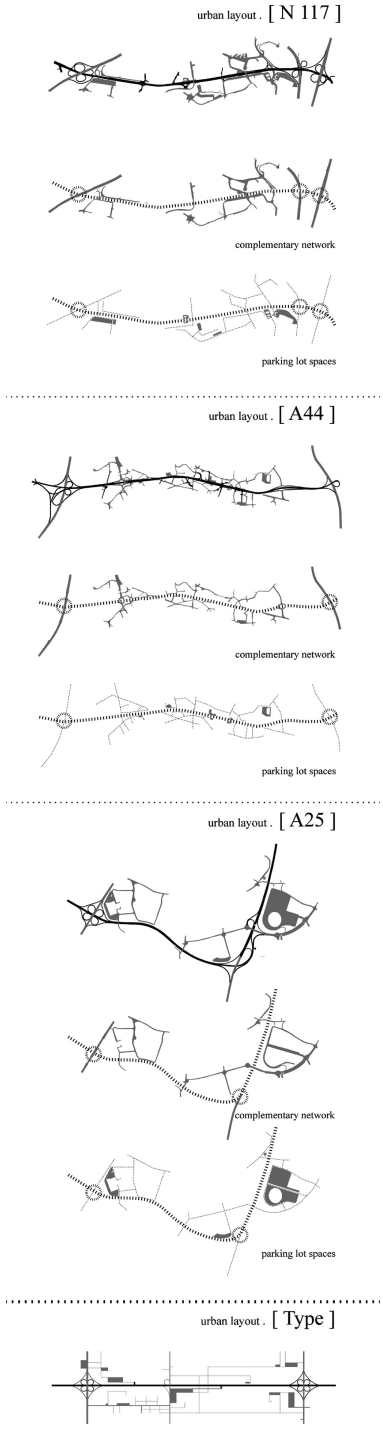

Figure 4. The urban layout type.

complementary network is a response to the access needs of big architectural objects and functions that are implanted nearby. This may be a consequence of an industrial or specialized plot subdivision or simply a result of a building construction that immediately create its own access to the infrastructure. The road A44 has a complementary network that is mainly formed by the pre-existing road structure with a rural nature, presenting some parallelism with the main channel. Over the pre-existing structure were being introduced new parts, with wider sections, seeking to serve as interlocutors between the two circulation scales. These added elements make cross-connections between the two sides as well as with the main infrastructure.

In a second moment of analysis we can see on the three case studies the presence of large open spaces, voids associated with parking lots, which supports different types of commercial spaces such as shopping centres; retails or mega-stores. These parking lot areas assume itself as a kind of plateaus showing the attractive power of each big architectural piece and functions, which are associated a long of these urban elements.

The urban layout type emphasizes the existence of two relevant extracts: the first, more basic and fundamental with a infrastructural nature and the second corresponding to the irregular network of roads that suture and link the several urban components, which confers a greater cohesion to the element.

5 TYPO-MORPHOLOGY: A TOOL FOR CITY EDUCATION AND DESIGN

5.1 *The experience of Campolide analysis*

The use of typological analysis is not confined to a decoding tool of the basic characteristics of urban elements and its formation processes. The understanding of this methodology, for one side, as a didactic tool to understand the urban and architectural form, and for other side as a tool generate new forms, is in our perspective something increasingly essential.

In this sense the inclusion of this analysis process in architectural education becomes more relevant, providing more tools to the students and with that improve its creative and design process.

As an example of this process we can use the work of 4th year students, from the Master course in Architecture with specialization in Urbanism at the Faculty of Architecture of the University of Lisbon. They were challenged to make on the first exercise a site analysis and on the second a design project, using as reference the typo-morphological analysis to identify types and urban changing process that were at the origin of a specific territory.

Therefore, taking as a case study the Campolide area in Lisbon, the students[2] were asked to look at the evolution of this territory in 4 periods: 1856; 1911; 1950; 2009. These times correspond to cartographic surveys produced by public services and design by

[2] The Campolide schemes presented in the article (figure 5) were made by the following students: Giada Spana, Inês Montes, João Mapão, Nuno Pereira, Tomás Nunes.

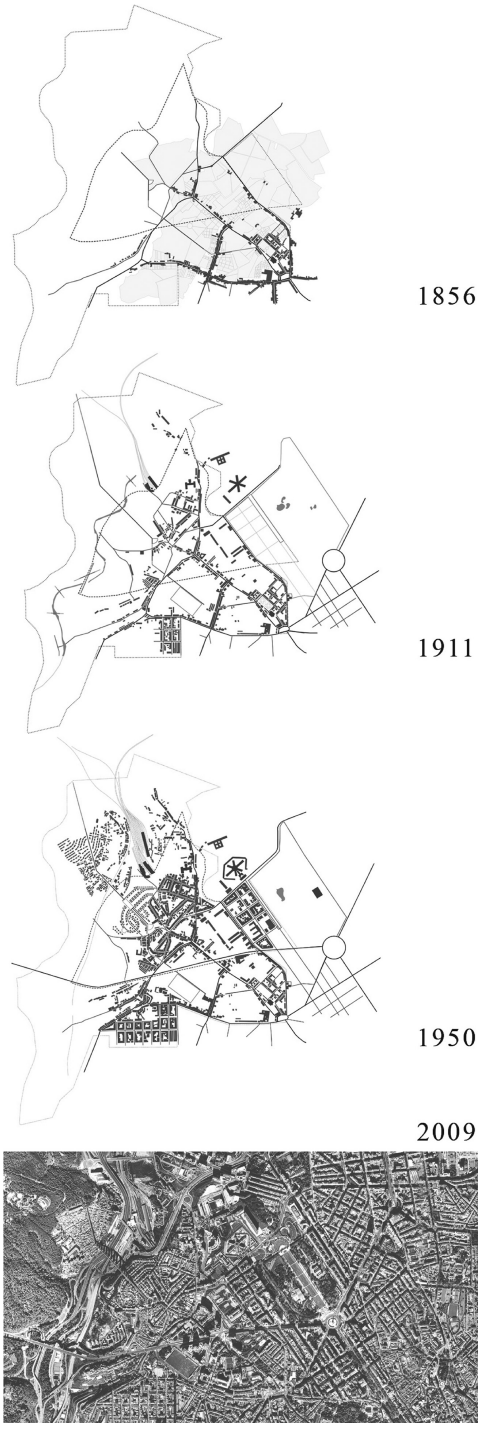

Figure 5. The urban structure evolution *[student schemes]*.

Filipe Folque (1856), Silva Pinto (1911) and Lisbon Municipality (1950 and 2009).

The exercise allowed students to become aware to the urban structure changes, particularly in the urban layout and the building fabric, but also the resilience of some elements over time. They also identified some morphological transformation processes such as: a street opening; integration of pre-existing elements in the urban design; development of architectural typologies and plots structure.

Thus, it became possible for the students understand the site, its history and its evolution process, building a more appropriate and adapted reference frame to the site. This information could be used for the next phase of the exercise – the design. Issues such as the preservation of certain elements or structures are now included in the propositional speech of students. However, it is significance mentioning that such concerns did not mean a copy or reproduction of pre-existing elements or an obstacle to creative and inventive process of an urban design able to dissipate weaknesses or some urban ruptures.

6 FINAL REMARKS

In times where the city and its physical space live moments of some formal and conceptual uncertainty, it is important to look at the typo-morphological reading process as a tool in the systematization of a set of elementary principles (urban and architectural) that could help in futures design processes.

The exercise of elementary decomposition, as well as the understanding of the formation process allows in a first moment to understand the genetic code of a particular object or urban system.

In a second moment, however, is essential to look for this exercise of typo-morphological analysis as a compose tool of new urban elements which are prepare to answer the needs of the contemporary city. The systematization of types, and it understanding, allows a deep knowledge of the main morphological characteristics of a particular urban system. They become, consequently, more evident certain structures and elements to preserve, as well as fundamental weaknesses to correct.

For this, the type generated cannot be seen as a model to repeat. The type should be an elementary abstraction that allows the development of other objects. These tend, on the one hand, to respect the characteristics and pre-existing compositional principles but, on the other, to work with the object's potential exploring new configurations that could connect different urban objects, or elements, with different kind of times and with that contributed for the urban fabric sedimentation process. It introduces a practical sense to the analytical and criticizes process of classification. In this sense, the urban production and its creative act, is grounded in a tested and stable methodology that makes safer and appropriate the design options.

We understand that is important to share this methodology and theoretical statements in the architectural and urbanism education as a support of a sustained creative process, able to answer the challenges

that the contemporary city puts us, as well as in consolidated and non consolidate areas.

The actual urban and architectural design should, in our view, be able to articulate different fragments or spaces, promoting the sedimentation of the urban fabric in all of its dimensions, public and private, while that build spatial references in order to create spaces more legible and usable by everyone.

This methodology is not intended to restrict innovative solutions, but show that the design process should combine new paradigms and configurations with typological/genetic characteristics of the site. In this sense is recovered the sediment city as educational object of conceptual and compositional reference.

Unveiling the city_the case of Aeolou street

Konstantina Karvountzi, Mattheos Papavasiliou & Elena Konstantinidou
School of Architecture, NTUA, Athens, Greece

ABSTRACT: The research addresses the understanding of the urban fabric in the center of a particular Mediterranean city like Athens, focusing on the analysis of the borderline of public and private space. Studying the properties of the boundaries between public and private is introducing the concept of *in-between*. Hence we have the opportunity to register typologies of great significance for the education of young students of architecture. The ongoing research in School of Architecture in Athens complements the introductory courses in Architectural Synthesis and simultaneously assists teachers and students to clarify the concepts describing the city and the social relationships that grow in it.

1 INTRODUCTION

This paper communicates a part of an ongoing research which addresses issues of analysis and identification for spatial qualities of the city centre which are critical in the process of architectural and urban design.

Furthermore our research focuses on certain characteristics of the Mediterranean city such as the interface between *private* and *public*, inner and outer space, as the field which engulfs and also generates a range of encounters between inhabitants and visitors, individuals and collectivities (groups), varying from informal – spontaneous to formal – deliberate ones.

Exploring the "key" question, on the role of Architectural Research addressing Societal Challenges, we will employ a range of analytic tools, as there are applied both in our research and educational activities, having Aeolou Street as our case study.

The research focuses on the importance of recognition and understanding of a place in its spatial and social context. Moreover in a case of this particular street bearing important spatial characteristics and a history entrenched in public consciousness, we propose methods for observation and transcription of the elements of space, related to geometry and configuration issues, by means of permeability and visibility. One primary issue emerging from the research is the existence of the transitional spaces between public and private, and their transformations.

For this reason, one could introduce the notion of *in-between* aiming to distinguish the common features of Mediterranean urban landscapes. This intermediate state is expressed primarily by the size, the openness and the mutation of spatial boundaries through time.

In conclusion, we argue that societal changes are being continuously imprinted in Mediterranean city centres, especially in the modes of interconnectivity between private and public sphere and they are affecting every-day life both spatially and temporally. By unveiling spatial relations of the Mediterranean city, research may contribute to the education of young architects and their awareness for the urban environment.

2 THE NOTION OF "*IN-BETWEEN*" IN MEDITERRANEAN CITIES.

Stavridis commenting on porosity of urban space argues: "Instead of thinking of social identities as bounded regions one can consider them as interdependent and communicating areas" (Stavridis, 2007: p. 1).

Since ancient times the Mediterranean cities constitute specific characteristics, as a result of favorable climatic conditions, that allow the development of outdoor life (individual and collective spontaneous daily activities).

This resulted in the evolution of building types and urban typologies that allowed the development of loose interior and exterior relations as mainly a variety of transitional spaces – *in-between – closed* and *open*.

Thus Urban everydayness is surrounded by a plexus of transitional spaces such as "stoas", galleries, atriums, courtyards, staircases and passageways, allowing both the infiltration of public space in the interior, as well as planned or unplanned expansion of private on open public space.

The building boundary of traditional Mediterranean cityscape and here in Athens has been characterized by openness and alterability. The introduction of the New Greek capital after the mid-19th century in neoclassical style, especially in emblem-atic public buildings gradually led to a change of the image of the old city center with an emphasis on rig-id impermeable boundaries.

The architectural movements of the 20th century, as modernism and the contemporary architectural trends

of the last decades, with the introduction of new materials and the increasing use of glass facades, brought several changes in the material expression of the building envelope, but largely the element of *in-between* space is maintained in its various forms.

3 RESEARCH SURVEY: AEOLOU STREET

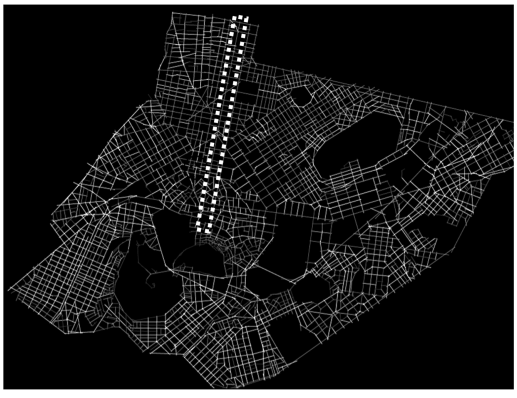
We were intrigued by the idea of investigating Aeolou Street as the oldest and perhaps one of the most important streets of Athens. The street is oriented to Parthenon, connecting Omonia square (second most central square of Athens) with the remnants of Roman Agora underneath Acropolis. Aeolou street was designed as one of the central axes in the first plan of contemporary Athens. Since 1833 it has been a part of the commercial and cultural centre of the modern city bearing important historical references, also connecting ancient monuments and sites, such as the Roman Agora, the Acharnean Gate, traces of ancient roads, walls and fortifications, important churches etc.

Until the beginning of the 20th century the area preserved characteristics similar to Oriental bazaars. After the Fifties the street gradually accommodated a mosaic of uses including central administration, retail, workshops, crafts, services and recreational uses. At present, most of it is pedestrianized, and is one of the most well known and crowded shopping streets which gathers a multitude of uses, such as administration, services, retail, street vending, recreation activities and various urban functions.

Through a sequence of socio – economic transformations in the late twentieth century the center of Athens, like most Mediterranean cities was emptied of its population. The model of the urban growth failed to address the emerging needs for spatial commodities and an upcoming life style, leading most of middle class strata to the suburbs.

In recent years the migration of the larger part of the population, previously located in the city center, towards the suburbs was intensified. The migrating in-habitants of the city center gave their place to immigrant and refugees seeking shelter in cheap apartments.

Most of the central uses (administration and services) retreated to the suburbs, leaving their empty edifices as grey scenery to a degrading city.



The deepening crisis that began in 2008 led many small companies and retail shops to extinction, while their position occupied large department stores, chain stores from abroad and recreation centers that cater to foreign tourists.

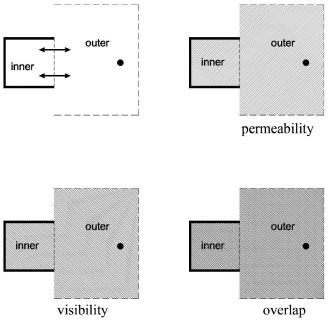
The importance of Aeolou Street lies in the variety of old and new interventions and in the range of different types of interstitial space. This research aims to highlight the most characteristic typologies of *in-between* space as the most significant area of human contacts.

4 METHODOLOGY OF UNVEILING THE "*INBETWEENESS*"

4.1 *Analysis from global to local level*

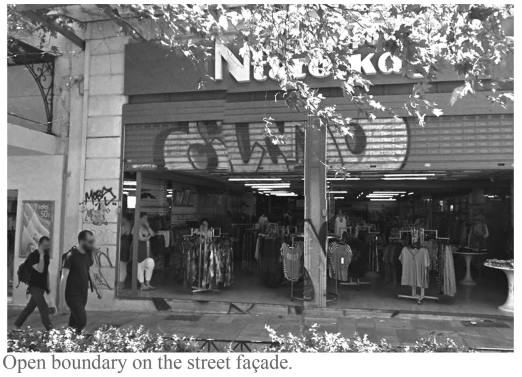
Primarily the analysis was intended to investigate the manner and the degree of integration of Aeolou Street in the wider urban fabric. The survey covered more specifically the analysis of the configuration of the urban grid, using syntactic tools developed at the University College London. (Hillier B, Hanson J, 1984). This topological analysis shows that in the entire Municipality of Athens Aeolou Street is the most integrated axis (see next figure).

Then we focus on the analysis of *boundary lines*. The map of *boundary lines* contains the lines of urban blocks, the transitional areas and internal passages which are perceived at the pedestrian level and incorporates geometrical characteristics of the urban layout. This new map focuses on the surrounding urban tissue of Aeolou Street and thus constitutes an intermediate level of analysis that we call *glocal*. We argue that the geometrical analysis of the *boundary lines* contributes to the awareness of scale, prioritize and set up the public space into a recognizable whole, designating the field for human encounters (See next figure).



4.2 *Spatial embodiments of the in-between*

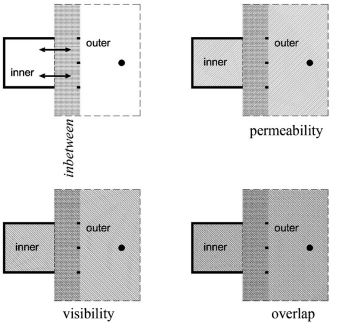
In order to proceed our investigation from *local to global level*, first of all we examined the interweaving of public and private sphere by employing conceptual diagrams of permeability, visibility and their overlap at the street level. What mostly intrigued us was how people move, stand and interact and how deep they can get in space. We classified boundaries regarding their material status (solid - transparent: walls, columns, colonnades, parapets, glass facades), their permeability status (openness – closeness) and their alterability (permanent – ephemeral). The existence of *in-between* spaces is indicated in each different diagram. In most cases we examined galleries, staircases, passages and recesses, but there are also identified *in-between* zones in the open space that form the transition between discrete areas.



Here are some indicative diagrams from the survey showing: the permeable areas, as well as those visible from an observation point frontally positioned towards the facade and finally their overlap.

Open boundary diagram.

Absence of in-between space
full visibility = permeability = overlap

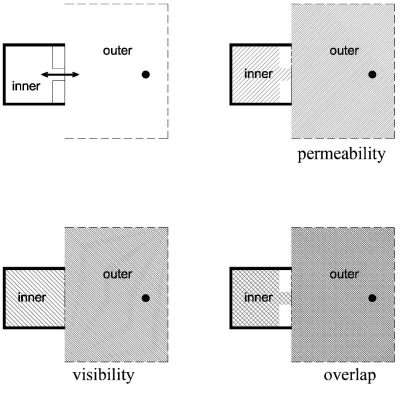


Absence of *in-between* space facilitates direct and spontaneous contacts. The public space penetrates deeply into private. This typology has references to traditional Greek flea markets.

Open boundary on the street façade.

The intermediate space acquires gravity attracting and gathering peoples contacts. In most cases an extension of private is using the intermediate space for stacking. This typology has references to the oriental markets.

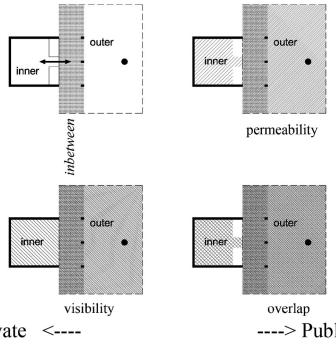
Open boundary with in-between space diagram.



Private <----- ---> Public fully
connected / In-between / fully connected
Full visibility = permeability = overlap

Open boundary with in-between space

Transparent boundary diagram.

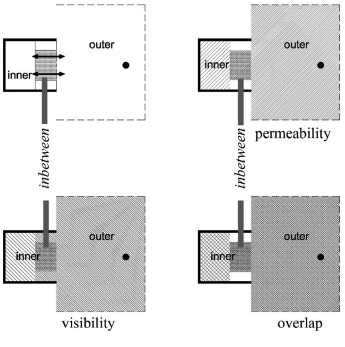


Absence of in-between space
permeability ≤ overlap < visibility

The transparent boundary with limited accessibility, e.g. the shopping windows, inserts between the interior

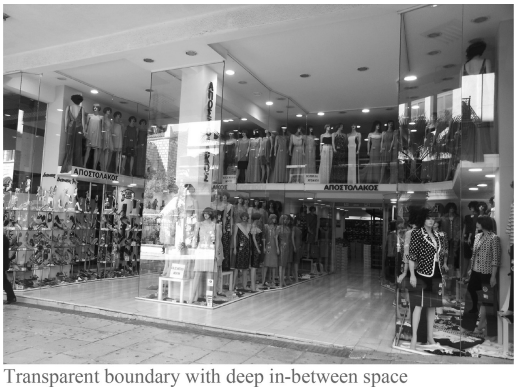
and public space a zone that ultimately prevents direct contact.

Transparent boundary / in-between space diagram



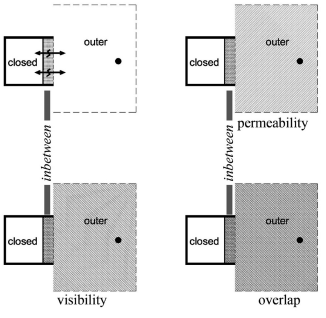
Private <---- ----> Public
fully connected / In-between / partially connected
permeability ≤ overlap < visibility

The intermediate space acts as a zone of observation towards the interior, creating a distance from public space and keeping away eventually inhabitants and visitors.



Transparent boundary with in-between space

Transparent boundary / Deep in-between space

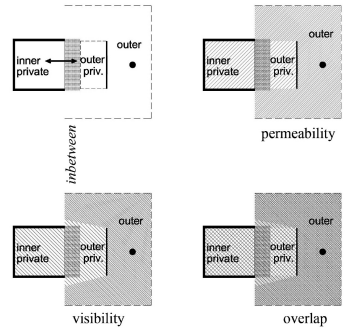


Private <---- ----> Public
connected / In-between / connected
permeability ≤ overlap < visibility

The deep penetration of public space to the private is mediated by the lengthening of shopping windows. The intermediate space acts as an extension of the public and also as a passage to the interior, attracting the observer deep inside. The *in-between* space acts as vestibule of the private, expanding the distance from public space and keeping away eventually inhabitants and visitors.

Transparent boundary with deep in-between space

Closed / abandoned inner space / in-between.



Private <---- ----> Public
connected / In-between / disconnected
permeability = overlap = visibility

Closed /abandoned inner space with in-between space

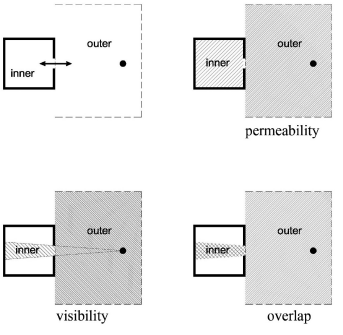
In between space in front of an abandoned interior, although privately owned is open to the public use, acting as a recess of the street. Due to the lack of care, space is either a homeless shelter or fills garbage.

Private perforating public diagram.

Private <---- ----> private
Connected / In-between / connected
Permeability = overlap = visibility

The expansion of the private space to the public is carried out either through the unorganized and spontaneous diffusion of objects and equipment, or the demarcation of space through temporary or permanent elements. In the first case, the area attracts a variety of contacts and assemblages of individuals or groups, while in the second case the contacts are limited within the certain area.

The penetration of the interior towards the inside is limited visually, while accessibility is fully controlled. Mainly public premises and banks endeavor to impose total control at the entrance of passers generating a hard borderline on the street level.



Evaluating the diagrams one can conclude that visibility and permeability overlap only in the case of open boundaries. The degree of the boundary openness is of particular importance to the interrelationship of public and private space and determines the function of the *in-between* space as an integral part of both regions.

In the case of transparencies visibility prevails, while accessibility is more significant in the case of more opaque boundaries.

Private use of public space

Solid boundary diagram
Restricted visibility/ permeability diagram

Absence of in-between space
visibility ≤ overlap < permeability

As Jan Gehl asserts “Visual opportunities are another important requirement for close encounters.

It is desirable to be able to see out of buildings – and preferably into them – so that the activities inside the buildings and outside in public space are connected visually and thus can enrich and in-spire each other” (J. Gehl et al, 2006, p. 30).

But although it seems that the existence of transparency is opening the interior to the gaze of passerby

Solid boundary facing public space at the street level

by creating a sense of visual integration, it doesn't necessarily ensure the creation of conditions for direct and spontaneous contact.

Further on our study focused on investigating the mutation in the relationship between public and private regarding the mutation of activities and uses. This revealed interesting patterns of expansion and contraction of space that people perceive.

4.3 *Mutations of the in-between*

The diagrams presented above make clear the relationship between closed and open space in relation to accessibility and permeability. But they exhibit a static aspect of the existence of public space. During the day the relations of public and private constantly are changing from morning hours till evening.

Through an extensive and systematic series of observations, that was carried out by our team in the context of a research laboratory in Aeolou Street during spring of 2015, we were able to detect the mutations of boundaries caused by the urban uses and activities during the daytime and their effect on space occupancy patterns. (Open/Closed/from 7.00 am to 10 pm).

When there is an interaction between public and private sphere, then we have an expanding perceptual space. This highlights the importance of *the in-between*, since it constitutes an extension of the public and in parallel an expansion of private space, becoming the field for stasis and continuous contact for individuals and groups.

We also discovered that when there is an interruption of permeability and accessibility (when the shops are closed and the shopping windows are shut), various marginal groups and homeless people are using in-between as their refuge.

This means that even in the absence of the space use in-between acquires a different but important role in the city's function.

Diagrammatic boundary of the overall mutation through the day.

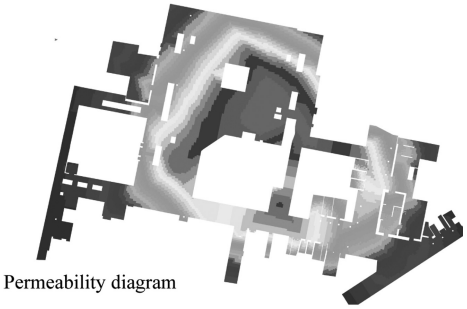
4.4 *Analysis from local to global level*

Our aim was to investigate, at a level in-between Global and Local (that we call *Glocal*), the relationship between the public and private by means of visibility and accessibility diagrams and their overlap in order to highlight centralities, integrated or isolated areas, spatial continuities and discontinuities.

Under the 9th semester in the School of Architecture in Athens we organize a special course for understanding the city using various digital tools. In this course we investigated a transformational technique that we employed to convey the importance of transparency enriching visibility fields than in turn advocate space syntax values influencing the probabilistic spatial patterning of movement.

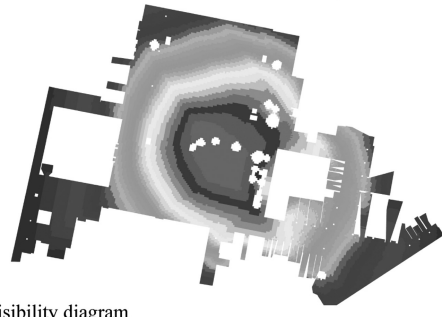
The technique is based on an idea found in Bill Hillier's book "Space Is The Machine". Hillier's idea is to introduce the architectural plan first as a shape. "[…] It is clear that any shape can be represented as a regularly constructed mesh of cellular elements, or tessellation, provided we can scale the mesh as finely as we need. This can then be treated as a graph, and thus expressed as a pattern of universal graph distances.[…]". (Hillier 2007 p. 80).

Hence Bill Hillier applies the syntactic analysis he introduced together with Julienne Hanson (Hillier, B. & Hanson, J., 1984) calculating "[…] the mean depth of each cell from all others, and express the results in a distribution of dot densities for the square elements in which the higher densities, or darker colours, stand for greater integration – that is, less depth – graded through to lightest colours for the least integration, or greatest depth." (Hillier 2007 p. 81).



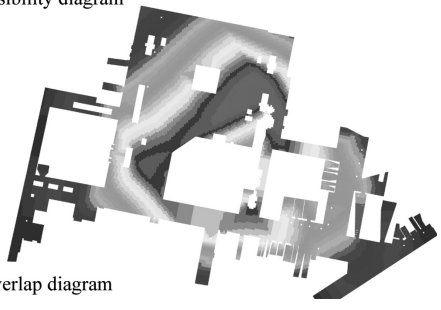
The following figures are some of the examples studied, showing the probabilistic importance of visibility fields overlapping on a syntactic permeability diagram. Top figure is based on calculations based on a permeability diagram of Kotzia square in Athens, which is the first prominent urban space along Aeolou Street; the figure in the middle is based on a visibility diagram alone and the bottom one is the overlapping contribution of visibility diagram to permeability.

It is important to stress out that through the comparison between the overlap diagrams with the observation data of space occupancy patterns, there is a strong relation of the integration core with the flows of pedestrian movement.

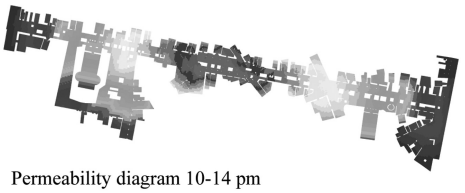


Below are some figures showing the diagrams of permeability/visibility and their overlap in a certain part of Aeolou Street during midday and evening hours.

As expected, in a system which analyzes a narrow zone (street – shops) without the surrounding urban fabric, the integration core lies in all cases in the geometric center. But nevertheless one can find very interesting and considerable differences between the diagrams in both periods.



There seems a clear expansion of the space, regarding permeability during the midday, when shops are



Permeability diagram

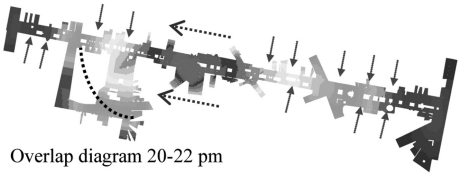
Visibility diagram 10-14 pm



Permeability diagram 20-22 pm

Visibility diagram 20-22 pm

Overlap diagram 10-14 pm

Overlap diagram 20-22 pm

open, whereas during late evening hours space is contracting. Through diagrams also it seems that a large part of the inner space remains visible during evening hours, since many of the closed stores retain their storefronts lit.

Observing the permeability – visibility overlap diagram, one can detect a shift in the integration core towards the area, where during the evening hours operate bars and restaurants.

Overall comparisons during daytime, among the overlap diagrams of the entire Aeolou region with the space occupancy observations data, revealed a strong correlation between the static co presence of individuals and groups (mostly preferring in-between areas), and the high degree of accessibility and visibility, as well as the *glocal* integration values (Boundary lines analysis).

Evening observations though revealed an inversion of the space occupancy patterns. Thus along highly integrated boundary lines, when permeability and visibility are absent, most of in-between spaces are occupied by destitutes and marginalized groups. On the contrary, regardless the degree of integration of the boundary lines, where a multitude of recreation uses exists, ensuring both visibility and permeability, the static co presence of various individuals and groups is multiplied. Spatial configurations, and more conclusively the views from spaces, are critical factors influencing the probabilistic spatial patterning of movement, *stasis* and, through this, of human interaction.

5 CONCLUSIONS

The city is the most appropriate context in order to comprehend space as the imprint of society through time. Unveiling the city's features is an important process in architectural education and presupposes both the understanding from global to local and local to global level.

Hence our research was based on a multi-faceted analysis tools to investigate the issues of urban space that is subject to constant transformations (some-times slow and sometimes rapid) through the social changes and challenges. It primarily focused on spatial issues in relation to everyday life patterns in the Mediterranean cities, through the case study of Aeolou Street in the center of Athens

Athens "[…] has been traditionally mixed and porose—a palimpsest where land uses and activities, as well as spaces of social groups and classes, have interpenetrated each other […]" (Leontidou 2012, p. 300).

In particular this paper has provided information about an ongoing research which investigates the various ways public and private, inner and outer space intertwined both spatially and temporally and also the different aspects of in-between spaces.

There is evidence that the degree of openness and the materiality of spatial boundaries define the level of visibility and permeability, contributing to either the expansion or the contraction of perceptual space.

Transitional spaces complement both private and public space and acquire different roles during daytime depending on the urban uses. In-betweenness becomes the determinant element of urban space for the variety and quality of encounters between inhabitants and visitors, individuals and groups.

As J. Gehl et al. argue "[…] It is precisely these edges and transition zones between buildings and city spaces that become the natural place for the wide variety of potential activities that link the functions inside the building with street life in general: recreation, play, seating, standing, exhibitions, trade, banking, smoking breaks and so on. The more irregular the facade, the more it invites and supports activities." (J. Gehl et al, 2006, p. 30).

The place of architectural design studios in Portugal in response to the Bologna agreement

Pedro Luz Pinto
Dinâmia-CET-IUL (ISCTE-IUL), Lisbon, Portugal

ABSTRACT: The curriculum harmonization of European university courses, converging for a *European Higher Education Area* by the so called *Bologna Process* (1999–2010), relocated the debate about the specificity of education in architecture, and its traditional methodology of learning by design, within the University environment. This paper approaches the structural, organizational and curricular developments of a group of Portuguese architectural schools, describing the changes driven by the *Bologna Process* and inquiring to what extent they present a change to the organization, the contents and the significance of traditional teaching of architectural design.

1 ARCHITECTURE AT THE UNIVERSITY

In Portugal architectural education achieved "higher education" status with the 1950–57 artistic education reform, leading the way for a new social and economic recognition, nevertheless still far from the status of "stronger" disciplines like engineering. Within the only two schools in the country, the fine-arts schools of Lisbon and Porto (ESBAL and ESBAP, since 1836), it was a moment of institutional transition, from the old "beaux-arts" system to a "modern" model of education, in which the vocational and artistic issues were mitigated in favour of social and exact sciences, more alike "modern" ideals of social, technological and economic progress.

Just before that, in 1948, the 1st *National Congress of Architecture* had criticized the concept of "architect-artist", demanding a change in education towards the principles of a "modern" conception of architecture: technical knowledge; the spirit of collaboration; the spirit of research and the cult of an autonomous discipline.

With the 1950 reform, the two schools experienced the "implementation of a method of analytical design in the pedagogical act" (Silva, 2011:30), developing an interest for design methodologies and "real context" exercises, introducing real local problems, in which the traditional conservative and formal culture could give way to a more experimental and methodological culture, advocating the need for research (Fig. 1) and for trans-disciplinary collaboration to ensure the assertiveness of the "why and how" (Le Corbusier, 1938).

In the sixties, pro-democracy movements increased and gained growing expression, mobilized by the post-war environment and the overall rejection of the Colonial War in Africa (1963–1974), but also by the consolidation of an expanding middle class and the rise of the consumer society. The students turmoil of the sixties since 1963 with the war in Africa lead to curricular autonomy, the so-called "Experimental Procedures" (1970), allowing a certain self-determination among both schools of Lisbon and Porto, both in curriculum composition and staff composition. Therefore the school of Porto proclaimed the objective of "development of the student's personality, their critical capacity, autonomy and responsibility through working groups, participation in school management and control over their own education" (Moniz 2011:10). It was also time for a distrust in all scientific and analytical contents separated from the disciplinary tradition, growing the need for an epistemological clarification of the "territory of the architecture", defending a disciplinary autonomy against any technocratic derive that would weaken the traditional humanistic dimension of architecture.

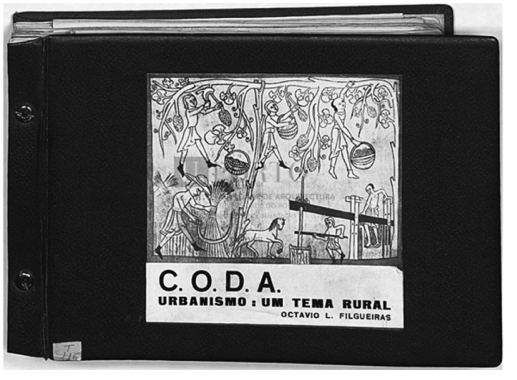

Figure 1. Octávio Lixa Filgueiras (1953). First mainly written research graduation thesis. Porto: ESBAP.

With the democratic revolution in 1974, Lisbon and Porto became independent schools (FAUTL and FAUP in 1979), losing their connection with fine-arts schools of both cities. These new institutions would go on to "teach the basic education leading to bachelor" and "conduct and stimulate scientific research" (statutes, 1979), but again, not without fear of losing identity, as the passage of the old "beaux-arts" regime to an "over-technical" context could "impose a technocratic logic over an educational heritage" (Silva 2011:43).

In the 1980s the Portuguese university system opened up, expanding the number of institutions and students. In Lisbon this was the decade of postmodern incursions and "didactic dispersion", while Porto confirmed its historical and methodological legacy, strongly instrumental, "without any theoretical losses" (Alves Costa, 2013, pers. comm.) and gathered around the work of Álvaro Siza (Silva 2011:74).

In the 1990s Architecture gained a new social recognition, as the country was transitioning into democracy, circumstances like the UE admission (1986) or an enormous investment in infrastructures, simultaneously regulated and expanded the profession. It was also time for international recognition (Alvaro Siza obtained the *Mies Van der Rohe Award* in 1988 and the *Pritzker* in 1992), leading architecture to a visible place in the social, economic and political agendas.

Therefore, in the 1990s, the number of architecture students rose from 1800 to about 9000 (*Jornal Arquitetos* n.º 201, 2001:8). New schools opened, both public and private, ending the exclusivity of the two "historical" schools of Lisbon and Porto. The vast majority of schools and courses was now university level, and the new framework for teaching career (ECDU, 1979) required a PhD to access the highest rungs of the career. Thus, university research arose slowly, and at Porto (FAUP) and in the new public school at Coimbra (d.ARQ-FCTUC, 1989) the final graduation evaluation switched to a theoretical work (1994), reinforcing the written component in the architect's basic training.

However, the massive expansion of architectural education raised a concern within the profession. Hence in 2000 a system of courses accreditation and graduates admission were implemented by the Portuguese Institute of Architects (*Ordem dos Arquitectos*, OA), therefore finishing the regime of direct access from the academia to the profession, and creating the first overall evaluation procedures.

With the Bologna process and *European Higher Education Area* (EHEA) adequacy beginning in 2006, the evaluation of all higher education would be congregated into a national *Assessment and Accreditation Agency* (A3ES), leaving to the OA the process of admissions into the profession, in the shape of a post-graduate internship and a few more pre-professional training through thematic seminars. Consequently, just a few years after finishing the direct admission to the profession, the mismatch between university education and the traditional professional training and practice was somehow institutionalized.

In parallel, the national legal framework of the Bologna adequacy confirmed the "binary" nature of the Portuguese higher education system, separated in universities and polytechnic institutes, where the first ensured a "solid scientific training, joining efforts and skills of teaching and research units," and the second focused in "vocational training and advanced technical training, professionally oriented" (RJIES 2007, Article 3). As for the faculty, universities required a minimum PhD / pupil ratio of 1/30, while the polytechnics would fill up to 35% of its faculty with professional "experts". Therefore the ECDU was reset (2009), with the PhD becoming the "basic-grade" for universities, and exclusive dedication became the "regime-rule", accompanied by a periodic compulsory evaluation of teaching, research and other academic activities. As the preamble of the ECDU states, the faculty devotes itself to "scientific research as a central element of the university career."

The development of research, required by the profession in the fifties in order to support the conversion from the "architect-artist" into "technical-architect", appeared now to gain autonomy in itself, mainly due to the professionalization of the teaching-research career.

The great economic crisis of 2008 further exacerbated the condition, dramatically reducing the practice among an overcrowded profession and exposing a scenario of two decades of built uselessness. Hence, there was an increasing attractiveness in the academic career and a new demand upon the necessity of the "how and why".

And yet again the debate: how can architecture be useful in a situation of crises? Can it survive without building? What to do with the disciplinary heritage? How to react to different expertises within the profession? Do the traditional design classes still maintain their pedagogical centrality? And, how can the project – design courses, as an empirical practice, representing architecture as material culture, be taught and investigated away from the material conditions of their own production? Given the productive imperative of research, within the "research-university" domain, architects questioned if "research in design means the passage of the field of architecture from a physical, real and pragmatic world, to an academic one, working on itself" (Jorge Figueira, 2013:205).

Back in 2004 the "architecture area" preparation report towards Bologna (Domingos Tavares, 2004), portrayed an architectural education focused on training to design practice. But, that was not totally reflected in the schools' adequacy (2006–2008), the circumstances of change were bigger. Underpinned by the curricular structures and design programs of five public schools of architecture in Portugal – Minho (EAUM); Porto (FAUP); Coimbra (d.ARQ-FCTUC) and two schools in Lisbon, FAUL and ISCTE-IUL (see Table 1) – we may perceive the changes operated by the schools facing the overall observed circumstances, trying to foresee the place of the design studio culture within these set of changes.

Table 1. 5 Portuguese schools of architecture – Structural data.

	University Students	School Since	Type	Students	Faculty	Products – Courses
EAUM	18.490	1997	School	374	53	3 Bachelors/1 Master/1 PhD
FAUP	31.352	1836	Faculty	990	100	1 Master/1 PhD
d.ARQ-FCTUC	22.741	1988	Department	548	39	2 Bachelors/3 Master/1 PhD
FAUL	48.147	1836	Faculty	2.700*	140	3 Bachelors/8 Master/3 PhD
ISCTE-IUL	8.600	1999	Department	330	34	1 Bachelors/1 Master/1 PhD

*The FAUL Integrated Master in Architecture has about 1167 students. There are different Bachelors, Masters and Integrated Masters, all data gather in subsequent tables relates only to courses in Architecture. In 2014–2015 there were 22 different schools of Architecture in Portugal (*Jornal Arquitectos* nº252:2014).

2 TRANSITION TO THE BOLOGNA AGREEMENT

2.1 *Curricular changes*

The "architecture knowledge area" report, coordinated by Domingos Tavares in 2004, proposed a double cycle reorganization for Bologna, articulated in a first 5 years cycle, giving access to the profession, and a second one of 2 to 4 semesters, intended "to strengthen the professional preparation and training, leading to the disciplinary investigation" (report, p. 2.3).

This division maintained the distinction between general professional training and expertise or research, according to the traditional progression of bachelor-master. It also viewed the profession as it was specified by the OA statutes of 1998, mainly divided into designers and public administration technicians. Also noteworthy, the report was silent about the concerning international debate, and although consistent with the EAAE 2001 Declaration of Chania, it was not related to the ACE Report/CEA of 15 October 2003 or the defined since 1996 by the UIA/UNESCO architectural education charters.

Nevertheless the profession was changing. It was recomposing and specializing at a rate apparently unaccompanied by its institutional representation. Maybe given its strong professional *ethos*, mainly focused on the material and symbolic resources around families and networks of traditional practitioners, making it hard to face the dynamics of transformation (Villaverde Cabral & Vera Borges, 2006). At the same time, recent graduates showed a relative satisfaction with the courses, enhancing their ability to present a cultural *ethos* but also criticizing the scant preparation for professional practice (idem, 2006). So, expressing a growing difficulty in deciding between a more professional training profile or a more general and cultural one, leaving the university unsure between the poles of teaching a pure science or professionalizing its teaching.

The Portuguese legal reform towards the Bologna Agreement acknowledged that training in architecture should be an "integrated cycle", accomplishing both two cycles in basic training, with an overall duration that could go through a six-year work course. But it persisted in determining a first cycle with six semesters, making it impossible to maintain the pre-Bologna models and the recommendations of the Domingos Tavares report (see Table 2).

The public schools of Minho, Porto, Coimbra and Lisbon (EAUM; FAUP, d.ARQ-FCTUC; FAUL) launched informal contacts between 2005 and 2006 to devise an integrated curriculum with 11 to 12 semesters (Pedro Pinto, 2014). At least FAUL (format $3+2+1$ years) and EAUM (format $4+2$ years) succeeded in producing documents for accreditation. Nevertheless this effort was rather fruitless, given the speed with which other schools advanced to the double cycle of $3+2$ years and given the apparent government unwillingness to accept any curricular arrangement longer than a total of 5 years. Therefore, rapidly between 2006 and 2008 all courses adopted the format of 10 semesters and 5 academic years, in $3+2$ years curricula, giving rise to a hegemonic model in Portugal.

2.2 *Architectural design teaching*

The Bologna Agreement adequacy also accompanied a crucial mutation in the mission of universities, as they refocused on the production of knowledge and in a growing financial autonomy (Neave & Amaral, 2012:2). Factors such as the knowledge fragmentation and specialization, the hyper-transformation of production conditions and the weakening of the political and social context, for the benefit of growing and expanding economic markets, provided a broad sense of indeterminacy, in which individuals perceive adaptability as a condition for survival. This instability pressed the traditional model of education, centred in the unitary transmission of a set of technical and professional knowledge, to a more differentiated and diversified offering, that could emphasize the development of individual and systemic skills.

In their curricular adequacy reports (2006–2008), the schools defined their ends in preparing the future architects for a profession that was spanning into a range of activities from planning, building design, construction and maintenance works, urban and real estate management, and, it should be noted, the ability to develop "disciplinary scientific studies" (FAUP adequacy report, 2008:8). Yet, despite the identification

Table 2. Courses and Learning Cycles in Lisbon (L) and Porto (P). 1837–2014.

	Admission	1st Cycle Designation	Years	2nd Cycle Designation	Years	Internship
1837–81	10 Years old	Drawing Course	4–5	Civil Architecture Course	5	–
1881–1911	12 Years old	Preparatory Course	3	Civil Architecture Course	5	2 Years
1911–31	12 Years old	Preparatory Course	3	Civil Architecture Course	5	2 Years
1931–39	7° Grade	Special Course	4	Superior Course	2	–
1957–69*	7° Grade	–	2 + 4	–	–	6 Months
1969–83 (P)**	High school	Bachelor	1 + 3 + 1	–	–	6 Months
1984–91 (P)	High school	Bachelor	1 + 3 + 1	–	–	1 Years
1968–75 (L)	High school	Bachelor	–	–	–	–
1975–90 (L)***	High school	Bachelor	5	–	–	–
1991–08 (P)	High school	Bachelor	5 + 1	–	–	–
1990–08 (L)	High school	Bachelor	5	–	–	–
2008–(…)	High school	Bachelor	3	Master	2	–

*In 1957 ceases the preparatory and special courses sequence, yet there was an implicit division inside de learning sequence (Silva, 2011), reflected in the format "n + n + n" years. ** The curricular differences between Porto (P) and Lisbon (L) increased from 1968, with both schools having curricular autonomy. *** From 1975–90 the Lisbon school had 9 curricular plans, but the overall 5 years formation without internship would persist.

Table 3. Curricular areas (2008).

Areas	Intervals	Average
Design	31,6% (FAUL)–37,8% (ISCTE)	35,1%
Urbanism	3,5% (FAUL)–12% (FAUP)	7,8%
Theory/History	8,6 (ISCTE)–24,6% (FAUP)	16,8%
Final Thesis	5,0% (FAUP)–14% (ISCTE)	8,58%
Representation	8,0% (FAUP)–13,1% (FAUL)	10,3%
Building Tech.	11,0% (FAUP)–22,6% (FAUL)	16,9%
Human Sciences	0,0% (FAUP)–6,8% (FAUL)	3,4%
Exact Sciences	–	–
Optative's	3,0% (FAUL)–6,6% (EAUM)	5,6%

Including both cycles (bachelor and master). The Final Thesis is diversely organized in different areas; therefore it could have further interpretation.

of expertise profiles and the explicit incorporation of research in the architect's basic training, teaching "by design" would remain central to many adapted curricula (see Table 3). This centrality reflected the methodological persistence of "learning by doing", but also the persistence of a seminal dialectic between the overall training finality and its main pedagogical tools, the architectural design courses. Although the mutation of both graduating profiles and institutional structural framework question the conditions of this centrality.

A major structural change was the compression of the academic rhythms: since one of the Bologna Agreement paradigms was of learning as an active self-driven construction, in which individuals were able to contextualize theoretical and expertized knowledge with practical work, therefore opening and breaking the vertical, one-way, curricular structures, benefitting individual choices and different interconnections. Thus, the direct teaching load was reduced for the benefit of individual work and research, forcing a compression of individual units and correspondent curricular time (see Table 4). There was consequently a double curricular compression: the total years of learning and the weekly hours load, transferring time of direct tutoring, often in design and drawing classes, to the overall student's independent work, with a much greater distribution by various units. This pressure can however be considered equivalent to the compression experienced in professional practice, reflecting a sign of the times, which influences both the conditions of the profession and its teaching.

Moreover there has been a change in the academic calendar. Even considering that in Portugal the Bologna Agreement adequacy framework did not explicitly determine a single temporal model, rather noting that the organization of different "units" could be annual, half-yearly, quarterly or other. However, the semester regime was widely implemented, allowing an increase of rhythms and enhancing the flexibility of curricular pathways. Not coincidentally, the semester regime was originally the standard unit for elective courses (see Table 5).

The schools have therefore semi-adapted the old curricular structures to a semester regime, adjusting themselves to the general academic calendars. While the design classes would be a bastion of annual temporality, either by maintaining the annuity or imposing curricular precedence between subsequent design units, unifying paths in double semesters, the "integrated master" dual-cycle would maintain a hierarchical curricular path. This "almost-annual" order would be pressured by the "half-yearly" pace of the academic calendar, which led to regular interruptions in the examination periods at the end of each semester, reducing the semesters from 12 to 14 weeks of classes, thus with 3 and 4 months of effective duration.

These conditions resulted in an accentuation of the pedagogical nature of the evaluation, either by the imposition of end-semester examination periods or through the generalization of public presentations at

Table 4. Curricular Weight – transition to Bologna.

	Pre-Bologna		Post-Bologna (2006–2008)	
	Units/Years	Hours/week	Units/Semesters	Hours/week
EAUM	6	32	5	26 (1°c), 20 (2°c)
FAUP	5,5,6,6,8	32, 36 (4°, 5°y)	6	26 (1°c), 23 (2°c)

FAUL	–	–	6	28 (1°c), 24 (2°c)
ISCTE-IUL	9,10,10,10,10	34, 36, 36, 34, 31	6 (1°c) – 5 (2°c)	26 (1°c), 23 (2°c)

(y) years; (c) cycle.

Table 5. Curricular rhythms and precedence after Bologna.

School	1st Cycle	2nd Cycle	Precedence
EAUM	ANNUAL Design, Drawing, SEMESTRAL	SEMESTRAL	Design I to Design V; Design II to Design VI Research Project to Research Lab (final thesis)
FAUP	ANNUAL, except electives	ANNUAL, except electives	All Design and Drawing courses. Need to complete all units from the previous year.
d.ARQ-FCTUC	Design, Drawing, Geometry, History, Theory, ANNUAL Others SEMESTRAL	Design, History, ANNUAL Others SEMESTRAL	There is no official precedence regime, although a hierarchical sequence is strongly advised in Design
FAUL	SEMESTRAL	SEMESTRAL	Design
ISCTE-IUL	SEMESTRAL	SEMESTRAL except Thesis	Design. 24 ECTS are needed to change year.

the end of each design unit. Some say that the appreciation of autonomous work by the Bologna learning paradigm matches the traditional teaching method of learning-by-design. However, facing the pressures of time compression and shorter academic rhythms, the Bologna Agreement adequacy triggered a debate about the need to change the pedagogical conditions and didactics of design classes (Spencer 2012:120; *Joelho n.º 4,* 2013).

This debate was extended to include the lecturer's competence for tuition in design classes, a debate which had been intensifying with the twofold effect of professionalization of the faculty and mass limitation of the teaching conditions (Graça Dias, 2001). This is a still an ongoing debate, which accompanies a rapid change in the faculty profiles (see Table 6). Yet, this change did not necessarily correspond to the abandonment of practitioners, having also given rise to a category of teachers that are both academic and practitioners, thus entangling this framework. At the same time, the centrifugal effect of the ECDU (teaching statutes) combined with unemployment in the profession increased the attractiveness of the academic career and created a momentum for academic production that is progressively encompassing the area of architectural design, encouraging multiple expertise in architectural design teaching: the practitioner, the theoretical and pedagogical specialist and the researcher.

With respect to the content of the design units, one can find a relationship between the curricular organizational structure variants and a range of pedagogical principles. Such a situation also reflects a certain position facing Bologna, i.e.: differences concerning the pedagogical structures: (a) Hierarchical and continuous programs, organized in a growing sequence of programs and scales, that one can entitle as a "canonical approach", whose most significant example is the school of Porto (FAUP); (b) Semi-flexible and two-cycle programs, organized either in a sequence of programs and scales or by different themes, which can be called an "experimental approach", whose main example is the school of Minho (EAUM).

Nevertheless, there are similarities between the courses, such as the weight, significance and centrality of the design studio, and the overall organization of the design classes, with regard to conditions like the ratio lecturer/students and the layout and material conditions of the working spaces.

As for the curriculum sequence, there is a common structure of learning as well as the general adoption of a final graduation thesis, with a strong theoretical nature, which recently tends to incorporate, or somehow relate to, the design classes, i.e.: (i) There is a common legacy in the design studio: (a) There is a general sequence that somehow all courses follow; (b) Emphasis on methodological aspects and housing programs in the 1st cycle; (c) Emphasis on complexity, equipment and urban design in the 2nd cycle. (ii) Design is being introduced in the final graduation thesis: (a) Testing a relationship between design and research.

The abovementioned "canonical approach" corresponded also to a vertical hierarchical sequence with an identical program for all design classes within the

Table 6. Architectural design teaching profiles (2008–2015).

History	Contemporary Theory and History	Antiquity and Modern times	Portugal	Seminars	

same curricular year or semester. This sequence started with introductory and conceptual issues and developed in a hierarchical sequence of progressively complex programs, scales and levels of achievement, gradually reaching the practice protocols.

Otherwise, the "experimental approach" admits some curricular fragmentation, including the possibility of different curricular paths and choices, as well as a more diverse organization of the design units around specific design, urban or technological subjects or questions, related to research issues followed by the faculty, rather than the traditional homogeneous sequence of design programs (see Tables 7–8).

In any case, there is an implicit specification of each learning cycle: the first being more instrumental, methodological and general; and the second being more professional or exploratory, introducing the subject of research related to architecture, even if it is mainly a pedagogical tool rather than an end in itself. This change is represented by the final thesis format and a set of preparatory units. Although there are more exploratory courses – like in Minho and Coimbra

(since 2015) –, the structure of the design units mostly remains cohesive and continuous between cycles, and there is not, nevertheless, a clear assumption of inter-cycle learning outcomes related to the design classes sequence.

As a whole, with the general compression of the curriculum there is a depuration of the core learning contents, which are interrelated more closely (theory-history-technology-representation-design). There is also an urge for methodological and theoretical contents inside the design units, enhancing pedagogical aspects of design practice, accelerating the learning outcomes (Spencer, 2012). Design classes therefore gain a dimension that is no longer a simple extension of ordinary practice. Also against a scenario of temporal compression the issues concerning the organization of the teaching space gain more expression. Concerns such as the average size of the design units and the equipment of the educational spaces arose. Altogether these issues are once more related to the type of lectures in the design classes, contributing somehow to a mosaic of relationships that would "tune" the schools identities.

3 CONCLUSIONS

In Portugal, the changes driven by the Bologna Agreement adequacy framework gave continuity to the continuous adjustment of architecture as a discipline within the "university", following a line of epistemological delimitation which arose from the transition from the "beaux-arts" system to a "modern" model of the architect as a professional, with a technical and researcher profile. These changes also followed the recent upgrade of the university's mission into research and "managerialism", which simultaneously recycles the discipline heritage, including its very own generalist and humanistic syncretism as a cultural act, as an artistic whole, in which the material culture and design as methodology are traditional references. Factors such as the curricular compression, the fragmentation of the academic calendar, the valuation of the teaching productivity and research, or even the drive into specialization within the profession, all exerted pressure on the traditional conditions of learning-by-design and increased the gap between academia and the material tradition of architecture and its practice. The response of the Portuguese schools of architecture to this scenario was somehow ambiguous, as epitomized by the format "integrated-master". The curricular changes introduced in the Bologna Agreement adequacy rehearsed (again) the reconciliation of vocational training and research, linking methodological, instrumental and general contents with more thematic and speculative contents, particularly at the 2nd cycle level.

A resistance against the fragmentation of learning cycles and curricular dispersion was observed, particularly in design courses. Struggling to maintain a core of generic education, the schools not only held out against the curricular dispersion but also maintained the design courses as connectors, bringing together different subjects, disciplines and individual interests, thus rebalancing the compressed and fragmented theoretical units around the design, still understood as an operative tool of knowledge application and recognition.

Therefore the design studio is simultaneously a learning tool and an expertise, as well as a sort of disciplinarian translator, which methodologically allows an architectural specificity (and disciplinary heritage). This leads us to the idea of architecture as being both autonomous and contingent. Autonomous in its own mechanisms and propositions, dependent on the set of knowledge areas that helps to give sense and evaluate the complexity of the real on which architecture intervenes as well as the impact of architecture on the built environment. Hence one condition of autonomy lies in the design as a methodological approach to architectural problems, a guarantee of syncretism, since the humanistic wholeness of the built architectural object can only be projected by the methodological totality of the design process.

Nevertheless, the basic requirements of the design studios faculty have also changed and the pedagogical and didactic issues have gained increased relevance, facing the abovementioned structural constraints. Teaching practices are somehow more academic and likewise the architectural design rehearses its own autonomy and relevance within the university.

The relationship with the practice became more complex, in keeping with the complexification of the profession in itself. The recent professionalization of the faculty is paradigmatic. Therefore, the very distinction between "theoretical practices", "critical practices", "architectural practices" and "material practices" is blurred by the advent of both "practical" and "academic" individuals. The balance between academic, practical and guests-scholars could be achieved according to different strategies and school cultures.

Inside the "research university", the traditional learning-by-doing is also a field of knowledge and research. Hence design could be a dual device of learning and research, whose methodologies and applicability are still to be explored and "tuned" (Providência, 2013). The breakup of the "integrated-master" format, which changed the pedagogical environment of design units between cycles, as well as the combination of theory and practice in the final graduation thesis are signs of change.

The drawing school in Christiania – architecture education into modern times

Mathilde Sprovin
The Oslo School of Architecture and Design, Oslo, Norway

ABSTRACT: Norway got independence from Denmark in 1814. The *Royal Drawing School in Christiania* was founded in 1818, in Norway's capital city, Oslo, then called Christiania. The school educates craftsmen, artists and architects. The author discusses the role of drawing schools and education of architects as a major factor in nation building in Europe in the 19th century. It also discusses the development of architecture education as a result of new requirements for the architecture profession raised by the industrial revolution and the changes into modern society.

The majority of European countries established their own art academies in the 18th century. The academies were closely connected to the King, and meant to promote knowledge, a purified taste and the country's economy (Pevsner 1940/1973, p. 140–159). The art academies also trained architects. In the 19th century the polytechnic schools occurred. This had implications for the education of architects.

Norway became a sovereign nation in 1814. This sparked the quest to found a national Norwegian art academy, which first emerged in the form of a drawing school in Christiania. The conditions in Norway can be used as an illustration of Europe, and how the ideals of the Enlightenment, the French Revolution and industrialism shaped the modern architect's profession and imposed new requirements in training of architects.

1.1 *The Royal Drawing School in Christiania*

The Royal Drawing School in Christiania was founded as the first public school for aesthetical education in Norway. The founders of The Drawing School were all part of the patriotic movement at the beginning of the 19th century, a group of intellectuals whose main aim was independence from Denmark, and to see Norway as an autonomous nation with its own constitution. When Norway gained its independence from Denmark in 1814, the country was facing big tasks with regards to reconstructing the nation. Important public buildings had mainly been located in Copenhagen, but now Norway had to build its own royal palace, university, parliament, prison and hospitals. The demand for craftsmen and architects was huge, and the Royal Drawing School in Christiania was founded in an effort to meet that demand.

The ambitions of The Drawing School in Christiania were to be a Norwegian art academy, similar to other national art academies established in Europe during the 18th century. The Drawing School never achieved an academy status, however, and the *Norwegian Art Academy* was founded nearly a hundred years later, in 1909. But in spite of this, The Drawing School in Christiania was the aesthetical centre in Norway throughout the 19th century.

1.2 *Art academies in Europe – towards the modern society*

Public schools for aesthetic education, art academies, were not exclusive for Norway and the crucial years around the independence in 1814. Norway, as a small country on Europe's fringe, was nearly a hundred years behind the rest of Europe. The majority of the European art academies were established in the 18th century. This was closely related to the development from the feudal social order to the modern society with the trade citizenship as a leading factor. It was advantageous for each country to be self-provided with craftsmen, artists and architects.

The word *academy* can be traced back to the Greek antiquity and the philosopher Plato's school, where he was teaching philosophy. The teaching took place in a park near an exercise track devoted to the mythical hero *Akademos*. Today the term signifies fellowships of intellectuals, scientists or artists, and schools for higher education in art. Academies as schools for training in art goes back to the Italian Renaissance, during which the *Accademia del Disegno* in Florence (1563) and *Accademia di S. Luka in Rome* (1577) were regarded as the leading and influential academies. These later became a model for the *Acadèmie Royal de Peinture et de Sculpture*, founded in Paris in 1648. Acadèmie Royal was crucial in establishing a modern academy tradition (Goldstein, 1996).

The art historian Nicolaus Pevsner published his book *Academies of art. Past and present* in 1940. This became a fundamental work on the European art academies. Pevsner analyzes the foundation and

development of European art academies and shows how the academies develop in near contact with social changes in the society. He outlines the development in three stages. From supplying the state with skilled artists and architects in the first stage, with Acadèmie Royal in Paris as a model, to educate good craftsmen as the main goal in stage two. Part of this was related to the growing trade, and the need for products of good quality, which do well in the increasing competition. In the third stage the education of craftsmen was phased out and handed over to specialized schools for craftsmanship. The art academies were thus mainly reserved for training of artists and architects (Pevsner, 1940/1973).

1.2.1 *The academy training*

From the first European art academies drawing was established as the basic ingredient in the academy teaching. The Renaissance artists and teachers used the term *disigno* for describing drawing and knowledge in drawing. The term has an abstract meaning, and includes a basic feature every artist needs, a form of visual awareness. This was a common knowledge for all of the three arts: painting, sculpture and architecture. This disigno (drawing) includes the art of sketching, an observation attached to paper, a "thought", or a part of the prosess as opposed to the completely finished artwork.

Lessons in drawing were an important component at the early academies. *Accademia di san Luca* (Academy in Rome) stated in the regulations from 1593 and 1596 that the students should get basic knowledge in drawing by copying patterns from what they called the "alphabet in art" – initially in the form of the human body's individual parts like head, foot and hands, before they could draw the entire human figure (Goldstein, 1996, p. 30). Acadèmie Royale in Paris developed and established this form of teaching, based on the teaching from the early Italian academies. This included training by copying patterns, in the next level the student should observe and copy plaster casts, before they in the highest level produced drawings based on observations of living models. Drawing lessons were mandatory for the architecture students teaching too. In the same way as the artists, they also had an alphabet, an architectural vocabulary they were schooled in. For the aspiring architects the human figure was replaced with architectural components like entablatures, pediments, columns, and not to forget: studies of the three orders *Doric*, *Ionic* and *Corinthian*.

The rediscovery of the classical architecture during the Renaissance was based on studies of European antiquity through two main types of sources: Written sources, with Vitruvius' ten books of architecture being the most important, and studies of ancient ruins. The Renaissance architects studied the ruins by drawing them. In that way they managed to harvest detailed knowledge about the architectural expression, the material and the architectural details. The discovery of the printing technique in the 15th century gave the Renaissance architects and theoreticians opportunity to publish their work, both in text and illustrated books. Alberti's ten books of architecture is a well-known example, but it was Sebastian Serlio, Vignola and Andrea Palladio which published illustrated books with drawings and a set of rules that architects could transformed and use in their work. These illustrated books were also the beginning of a significant tradition with architectural drawings being utilized in the education of architects.

In Paris, King Louis XIV (1638–1715) founded *Acadèmie Royale d'Architecture* (Academy of architecture) in 1671 for educating French architects. The Acadèmie d'Architecture was in 1816 part of the art academy, *Acadèmie Royale*. As part of this process the academy changed its name to *Acadèmie des beaux-arts*. The teaching provided here evolved into a distinct direction in architecture education known as *beaux-arts*. This denotes architecture based on the classical vocabulary with rich ornaments (Kostof, 2000). The architect and theorist Jacques-François Blondel (1705–1774) taught at Acadèmie d'Architecture. He also founded the private architecture school *Ècole des Arts* in 1742. Blondel wrote the capture about French architecture to *Encyclopédie, ou Dictionnaire raisonné des sciences, des arts et des métiers* (*The French encyclopèdie*), a work which was a prerequisite for Enlightenment, and in the years towards the revolution in 1789. Blondel also wrote the book *Architecture françoise* (about French architecture), and he published his lectures in his *Cours d'architecture* in 1771 and 1774. In his book about French architecture he explains how he incorporated elements from Vitruvius, Alberti, Vignola and Serlio into his own theories (Struges, 1952). For Blondel the architecture was based on the classical principles, on geometry and harmony, and of studies on the classical orders (Picon, 1992). Around 1750 Blondel reorganized the education at Ècole des Arts, and he also brought with him this organizational structure to Acadèmie d'Architecture. This meant that the training was split into three stages: Stage one was elementary course were the student practiced drawing and basic principles of architecture. This stage was for all students. Stage two was for those who aspired to become architects, painters or sculptors. Stage three was more geared towards the science of engineering (Picon, 1992, p. 122–129).

Blondel's theoretical approach, and studies of classical architecture, was soon challenged by contemporaries and teachers from the next generation at the Acadèmie Royale, and soon at Ècole Polytechnique. Julien-David Leroy (1724–1830) was member of Acadèmie Royale in 1758, the same year as he published his book *Ruines des plus beaux monuments de la Grèce*. The book is important because it moved the discussion on classical architecture from an abstract form to concrete studies of the ancient monuments and their dimensions, and how this could be used in contemporary architecture (Villari, 1990, p. 9–11). Jean-Nicolas-Louis Durand (1760–1834), professor at Ècole Polytechnique from 1795, followed Leroy, and Durand was even more concrete. In 1799 he published the book *Recueil et parallèle des edifices de tout*

genre, anciens et modernes. Here he presents architectural components and principles of construction of the building volumes, based on the doctrine of proportions and symmetry (Villari, 1990).

The change, from an abstract approach to the classic architecture to concrete studies, had consequences for the teaching material used in the education of architects. Both Leroy and Durand's books consisted of architectural drawings collected in a large-format hardcover book. As already mentioned, the training of architects, particularly at art academies, was drawing after patterns. This type of training would also dominate the drawing lessons at the polytechnic schools. Books like Leroy and Durand's were soon used in the training, supplemented by a large number of similar books published in France and Germany in the 19th century.

1.3 *The polytechnic schools – France*

Modern European society, with the industrial revolution as an important factor, created a need for specialized knowledge to solve new tasks for modern agriculture and factories, to establish roads, canals, bridges and preparing maps for the regions. In addition, the emergence of railroads meant that someone had to provide rails and adjacent buildings. As a result of these technical inventions and social changes the polytechnic schools occurred in the 19th century, and thereby offered an alternative form for training of architects.

Ècole Polytechnique was founded in Paris in 1794 and is considered as the first polytechnic school. The foundation of this school came as a result of the French revolution and the ensuing societal conditions. The French republic was supposed to be a modern society, which took a greater social responsibility than previous governments. There were need for technical expertise to solve public tasks related to infrastructure as roads and railway. In addition to this there were also building projects such as roofed halls for markets, railway buildings, factories, modern housebuilding, schools, hospitals and prisons (Pfammatter, 2000, p. 51). Ècole Polytechnique was built upon the Enlightenments ideals with an expressed desire for a school separated from the traditional university education. At Ècole Polytechnique the philosophical studies, which had precedence in the universities, were reduced, and studies of science and techniques were instead given priority. The study program from 1794 reflects this with lessons in subjects such as mathematics, physics, geometry, drawing, chemistry, mechanics and architecture. At the school the architectural teaching was also split in two – civil architecture and fortification architecture.

Despite the focus on civil tasks in the French society after the revolution, Ècole Polytechnique become a school for the military with production of army arsenal and fortifications as its main tasks. When Napoleon Bonaparte came to power in 1804 he strengthened the military aspect of the school's curriculum, and in the years 1806–1813 85 % of the students went directly to military assemblies (Saint, 2007, p. 438). Despite the military aspect, Ècole Polytechnique become important for the development of education of the modern architect in the 19th century. The school's teaching based on practical assignments adapted to the modern society, represents an alternative to the art academies studies of architecture history. Central teachers at Ècole Polytechnique were important for this teaching, and here they developed new working methods for the modern engineer and architects like descriptive geometry and technical drawing.

The situation, where Ècole Polytechnique was a school mainly for the military, persisted also after Napoleon. Civil engineers and architects were therefore needed. Consequently, *Ècole Central des Arts et Manufactures* was founded in 1829 (Ahlstrøm, 1978). Here the teaching in architecture was influenced by the interaction with engineering sciences, and lessons were given in topics like turbine technology, steam engines and railway technology (Pfammatter, 2000, p. 118). This combination of engineering science and architecture grew to become important for the development of the modern architecture towards the twentieth century. The American architect and engineer William Le Baron Jenney (1832–1907) is an example of this trend. He was a student at Ècole Central in the years 1853–1856. This education brought him knowledge of construction systems that involved an internal iron skeleton in the buildings, thereby enabling him to design some of the earliest skyscrapers – what would later be called the *Chicago-Frame*. These principles were developed further by his assistant, Louis Sullivan – construction principles that had an enormous impact on twentieth century architecture (Pfammatter, 2000, p. 170).

1.4 *The polytechnic schools – Germany*

Despite the fact that the foundation was laid in France, Germany became in the 19th century important for the polytechnic training. Germany is also particularly important for Norway and the Norwegian architects for two reasons: 1) many of the Norwegian architects were trained at the German polytechnic schools, 2) teaching material used in the training of architects at The Royal Drawing School in Christiania were imported from Germany.

For most part of the 19th century Germany was not a properly united nation. Rather, it consisted of a loose confederation of 39 independent states. The national territory currently known as Germany did not appear until 1871. The industrial revolution happened early in this area, and the first polytechnic schools were founded as early as the 1820'ies: The polytechnic schools in Karlsruhe (1825), Darmstadt (1826), München (1827), Dresden (1828), Stuttgart (1829) and Hannover (1831). In Berlin the art academy, *Die Königliche Akademie der Künste zu Berlin*, had been founded back in 1699 for training of artists, sculptors and architects. Similar to the situation in France new social tasks from the end of the 18th

century gave new challenges for the architects. These tasks were more closely related to the engineering profession than traditional architectural training. In 1799 *Die Berliner Bauakademie* was founded, for teaching building technology with lessons in subjects like mechanics, hydraulics, machine learning and design principles for the construction of roads, bridges and canals (Mislin, 1999). The education of architects in Berlin was then divided between the Academy for training in drawing and studies of architecture history, and for the technology teaching at the Bauakademie. The separation between the Academy and Bauacademie seems however to be less successful and soon the Bauakademie took responsibility for all aspects of the education. Bauakademie was in 1879 part of *Königliche Technische Hochschule in Berlin*.

The two polytechnic schools in Karlsruhe and Hannover were both among the early polytechnic schools, and they serve to demonstrate how the emergence of the modern society laid the foundation for the creation of polytechnic schools, in Germany as well as the rest of Europe in the 19th century. *Karlsruhe Polytechnische Schule* was founded in 1825 in Karlsruhe, a city near Rhine and the border to France. At the beginning of the century the city had a drawing school led by the architect Friedrich Weinbrenner (1766–1826), as an academic sort of training (Brownlee, 1986). In 1808 Johann Gottfried Tulla (1770–1828), who worked as an engineer connected to locks on the Rhine, started a private engineering school in Karlsruhe inspired by Ècole Polytechnique. The city council decided in 1820 to establish a public polytechnic school. This assignment was then given to Tulla (Pfammatter, 2000, p. 376–378). At Karlsruhe polytechnic school basic training in mathematics and crafts were given over three years. After this the students could go to engineering studies lead by Tulla, or study architecture at Weinbrenner's drawing school. Ulrich Pfammatter, (professor at *Hochschule für Technik und Wirtschaft* in Switzerland), defined the training at Karlsruhe polytechnic schools as the *Karlsruhe-model*. In his doctoral thesis he shows how these principles for polytechnic education were continued at the other German polytechnic schools in the 19th century (Pfammatter, 1995).

I Hannover the polytechnic school, *Hannover Polytechnische Schule*, was founded in 1831 as a school for teaching craftsmanship. The railway came to Hannover in the 1840'ies, and a need for skilled work force for the railway soon became a necessity. Therefore, in 1847, the teaching at Hannover polytechnic school was reformed. A report from the school in 1856 shows that the craftsmanship subjects were replaced by lessons in mathematics, geometry, machine learning, chemistry, technology and architecture (Die Polytechnische Schule zu Hannover, 1856). In 1863 the training of architects was organized over five years and included higher mathematics, technology, geometry, mechanics, architectural ornaments and machine learning (Program der Polytechnischen Schule zu Hannover, 1863–64).

1.5 *Summary – two ways for architecture education*

The education of modern architects emanated from the French society in close connection to the revolution in 1789, the Enlightenment era and the technical development that came along with the industrialization from the end of the 18th century. It was also in this country that two different forms of architecture education occurred – the Beaux-aux tradition and the polytechnic schools. The industrial revolution and the technological innovations were however not reserved to France. The rest of Europe also underwent these changes, and after France, Germany soon became the leading country for polytechnic schools.

The two forms of architecture education differed both in the content and the form of the training. Both educations taught drawing based on the classical architecture. The academic tradition combined this training with extended teaching in perspective and extensive studies of architectural masterpieces of the past. Jacques-François Blondel was an important figure in the academic tradition both as a professor at *Acadèmie Royale d'Architecture* in Paris and as the founder for *Ècole des Arts*. He structured the training into different levels where the elementary courses, mainly training in drawing, were for every student, both architects and craftsmen. At the higher levels there were lessons in architecture history and theory. This level was only for those who aspired to become architects. The teaching at the polytechnic schools was, in addition to drawing, increasingly reserved for technical topics. The subjects changed in parallel with technological development, and included topics like railway knowledge, steam machinery, mechanics, hydraulics, machine learning and principles for construction of roads, bridges, canals, ports and buildings (Picon, 1992, p. 130–133).

1.6 *The Royal Drawing School in Christiania – building the nation*

When The Royal Drawing School in Christiania was founded in 1818 the main goal was to educate craftsmen. This appears in the school's first regulations adopted in 1822 (Kongeligt Reglement 1822). Most of the students were apprentices in craft, who attended the school in order to get lessons in drawing. When the Ministry chose to prioritize craft, this must be seen in relation to the development of the art academies varying focus on craftsmanship versus art (more below), but also as a conscious choice with national interests in mind. Norway was a young nation that wanted to mark its independency from Denmark and the Danish culture, which had influenced Norway's sense of identity for more than 400 years. In addition to this came the increased focus on Norwegian language and identity, its history and national traditions in craft. Skilled craftsmen were therefore in demand. Another aspect was the many public building projects, which meant that there was a need for architects.

The regulations from 1822 stated that those who wanted to become artists and architects should be

offered lessons in drawing at The Drawing School. My research on the school shows that despite the Ministry's decision to give crafts priority, The Drawing School also provided high quality lessons in architecture. As a matter of fact, many of the Norwegian architects in the 19th century were educated at the school. That the school actually educated architect does not however necessarily means that it was a full architecture education on a full European scale, but it was good enough for the Norwegian conditions – a small country with many building tasks to be solved in order to recreate the nation.

The Royal Palace was the first public building raised in the independent Norway. Thereafter followed the University, the Observatory, the Bank Building, Hospital and Theater. All of those buildings were in classical style. Except from the palace, they were also all tribute to one architect, Christian Heinrich Grosch (1801–65), who became the city architect in Christiania in 1828. His background and education is however symptomatic for the early architects in Norway. Grosch started his training at The Drawing School in Christiana. After finishing Drawing School he went to the *Academy of Art in Copenhagen* and the academy's school of architecture. In Copenhagen the German classicism dominated, and this architecture also influenced the Norwegian architecture in the first half of the 19th century.

Around 1870 there was a change in the architectural landscape in Norway – both in the building tasks, architectural expression and the Norwegian architecture profession. The main public buildings were already completed at this stage. But while the public buildings were few in numbers, the 1870's marked a major change in the amount of building projects. The industrialism has established and the populations of civil and working class in the main Norwegian cities grow extraordinary. These sparked a marked for building speculations and a demand for architects, who were need in order to create residential buildings and commercial buildings. A large part of Oslo (Christiania) as we know it today, was built in the period 1870–1900, in form of 3–4 level buildings in block structure. The architecture had developed from classicism to historicism. Part of those blocks were also commercial buildings, and like the architect Jenney used the iron skeleton to design the early skyscrapers, the Norwegian architects used it to create large display windows on two floors to promote the shop's goods.

The building tasks changed toward the end of the 19th century, as well as the development of the architecture and it's style. But also the Norwegian architect profession changed at this epoch. The task of creating the official buildings erected in the first half of the century was solved by limited group of architects. Toward the end of the century the number of architects increased considerably. This must of course be seen as a result of the increasing building projects, but also in conjunction with a national education for architects, erected in the mileu at The Drawing School in Christiania.

1.7 *The Royal Drawing School in Christiania – in a European context*

There was an explicit wish among the founders and early teachers at The Drawing School in Christiania that the school soon ought to take form as a national Norwegian art academy. Back in 1818 the school's founders had delivered a draft provision for The Drawing School to the Ministry of education. Here it emerges that one of the school's tasks was to educate Norwegian architects, similar to the academic tradition (Forslag angaaende en offentlig Kunstskoles, 26. April 1818). Because of the poor economic conditions in Norway at the beginning of the 19th century, there was only money to establish a drawing school. But despite the economic realities and its implications for the school's teaching program, we could also relate The Drawing School to the European context when it comes to the development of art academies.

If we use Nicolaus Pevsner's analysis as a template: The Drawing School gave priority to craftsmen from the beginning, as warranted in the regulations from 1822. This placed the school in the second stage of the development of the art academies. At this time most of the other academies had reached stage three, and the craftsmen were taken out of the academies and transferred to specialized schools for craftsmanship. Norway was lagging behind in general development, and this applied to several aspects of the Norwegian society. First with our independency in 1814 followed the need for public buildings, raised by Norwegian craftsmen, but also for national architects. In a review of the teachers who gave lessons in architecture at the school, it emerges that they all were leading architects in Norway through the 19th century. These architects saw the need for a national architecture education, located at The Drawing School.

If we follow The Drawing School's history throughout the 19th century it transpires that the regulations were geared towards technical education when the industrial revolution came to Norway around 1840, and the first factories were establish in Christiania around 1850 (Plan for den Kongelige Tegneskole i Christiania, 1869). The dream of The Drawing School as a Norwegian art academy was however alive, and in the 1870's a new regulation for the school was adopted, with increased focus on artists, sculptors and architects. One can thus say that The Drawing School developed in accordance to the last stages of the art academy tradition (Forslag og Plan for den Kongelige Kunstog Haandværks-Skole i Kristiania, 1875). This regulation was however short-lived and another reform in the 1880'ies again gave crafts priority. But still, in conflict with the regulations, the school continued the training of architects. A question therefore emerges: what kind of architectural education was offered?

1.8 *The Royal Drawing School in Christiania – training of architects*

The Drawing Schools regulation stated that the school was supposed to teach drawing. The training of

architects consisted mainly of drawing lessons in the architectural vocabulary, like the classical orders, and studies in architecture history. The students drew according to patterns, in the first decades after classical architecture. These principles of teaching architecture could, as well known, been traced back to the art academies in the Italian Renaissance, and thereafter developed at the French schools of architecture erected in the Enlightenment era.

The preserved teaching material after The Drawing School is mainly French or German. Most of the French material is published around 1800, and sustain prints, engravings, of classical architecture. The German material marked a change, both in the architectural style, and in content. With the publications of classical architecture were presentations of the antiquity and had detailed engravings of architecture components like the columns and entablature. The material shipped in from Germany was published around 1850 and onwards. The classical vocabulary was here replaced by the historicism style, and the engravings were also concentrated on technical solutions in the architecture, like construction of the cornice, gutter and arched walls to name a few.

1.9 *Summary and conclusion*

The teaching material and The Drawing School's training of architects, based on drawing after patterns, place the school in the academic tradition of architect training. The use of the large format hard-cover books as patterns for the architect students, confirms the academic approach to the education. Most of the teaching material was shipped in from France and Germany. While the French material mainly was concentrated on the antiquity, the German teaching material focused increasingly on technical solutions. This reflects an influence from the German polytechnic schools and there priorities of techniques.

The large collection of preserved teaching material after The Drawing School, tells us that the teachers were well updated on European architectural currents, and it confirms their ambitions for the school's architecture education – to create a Norwegian school built on the ideals from the European art academies.

Transforming architectural education at the cross roads of the world

Ahmed K. Ali
Texas A&M University, Texas, USA

ABSTRACT: Located at the intersection of Europe and Asia, Turkey is constantly facing both societal changes and challenges. Major cities like Istanbul and Ankara are booming with construction of modern high-rise buildings, while historic Ottoman architecture often seems to stand in the background, observing the race to modernity. While architectural education is at the core of this evolving transition, concerns similar to that of Rafael Viñoly about people coming to the profession without knowledge of construction are being raised. Schools of architecture, particularly in the United States and Europe, are re-evaluating their curriculums and discussing the reinvention of the role of the architect as a master builder. In this paper, we discuss our efforts to transform Turkish architectural education through the establishment of the first design/build lab at one of the leading universities in the country. We describe our built project and compare it to both traditional and contemporary precedents. We develop our argument through an experimental and qualitative method.

1 INTRODUCTION

> *"It's a crisis for the profession. In the last 20 years, people have come into the field without knowing what construction is. In architecture, construction is the medium."*
>
> – Rafael Viñoly in an interview with Fred Bernstein. *Architectural Record*, Feb. 26, 2014.

Despite criticism, design/build academic programs around the world have become a prevalent model for architectural education. The many facets of the hands-on experience gained from such activities could potentially address not only Viñoly's concerns, but also other issues related to the role of today's architect, the role of architecture schools in their communities, and the increasing gap between design and making. The exact number of design/build programs in the United States is not known, but according to Gjertson, there are approximately 100 design/build programs throughout the 123 National Architectural Accrediting Board accredited schools (Gjertson, 2011). The Association of Collegiate Schools of Architecture underscored the recent increase in design/build programs in North America with the introduction of a design/build award in 2012, noting that design/build is now included in over 70% of its curriculums. On the other side of the world, and based on the model of American endowed private universities, Bilkent University in Ankara, Turkey, has distinguished itself as one of the top 100 universities in the world under 50 years of age. The Department of Architecture, which was founded in 2012, is the newest addition to the university. In its recent evaluation report, the university defined itself as follows: *"Since its beginnings in the early 1980s, Bilkent University has defined its core mission and portfolio in relation to its national and international context, wanting to help instill the highest international standards in Turkish higher education and offer teaching and research areas which 'were not yet offered in the country"'* (IEP, 2010).

1.1 *Architectural education culture in Turkey*

According to the Turkish Ministry of Higher Education, there are currently at least 25 universities in Turkey that offers architectural degrees in various specializations. Building technology, building assembly, and building materials and construction are, by default, required courses in the curriculum of most of the undergraduate programs. At Bilkent University, a two-semester sequence in building assembly/building materials and construction is required for undergraduate students, along with an additional laboratory component. Architectural education in Turkey, as is the case with many higher education institutions in the Middle East and the Gulf region, suffers from the absence of the culture of 'making' and has long overlooked the importance of understanding 'how buildings are put together'. This educational approach reduced architecture to flat representation of manipulated images and construction drawings that do not convey the depth of understanding building assemblies including structure, construction and tectonics (Sekler, 1965). In his book, *Architecture Depends*, Jeremy Till argues that traditional architectural studios failed to provide any tangible outcomes beyond simulation of preconceived exercises (Till, 2009). According to Bilkent University curriculum, the objective of the 'lab' component in the required building materials course was to offer students a computer lab where they

could produce construction drawings for two hours per week. The introduction of our design/build lab was a paradigm shift for the department and its students, many of whom expressed both enthusiasm and also anxiety in not knowing exactly the nature of the pedagogical experience awaiting them.

1.2 *Challenges and opportunities*

Design/build programs all across architectural education are having a significant impact on a large number of areas: by developing experience and skills in future architects, by contributing to local communities through their efforts, and by exploring the integral relationship between architectural design and building construction, to name but a few examples. Establishing a design/build program at any school of architecture is indeed a daunting task, especially when the architecture department itself is relatively new and the unknowns are many. It is further compounded by the absence of a culture of 'making' and the existence of an undefined fear of offering direct contact between students and machinery. The case study presented in this paper was part of a required two-semester undergraduate course sequence in architectural building systems and building materials and construction. The lab was the first of its kind in the university and perhaps in the country. The lab focused on issues of pre-fabrication, prototyping, and construction, as well as subsequent testing and analysis of fabricated assemblies and materials. An important goal was to demonstrate building assembly, process innovation, and multidisciplinary research while emphasizing the importance of collaboration with other disciplines, especially structural engineering. The lack of a dedicated indoor fabricating facility and a start-up fund required minimizing onsite building time. Three important principles were valued: pre-fabrication, optimization, and sustainability. The built project incorporated ideas of flexibility, disassembly, and reconfiguration and utilized a zero-materials waste strategy by adhering to standardized off-shelf building materials. Framing and skin systems highlighted stability, lightness, and simplicity.

While there is no 'one model fits all' for design/build programs, every architecture school must develop its own program based on its resources, students and faculty interests and, most importantly, according to its curriculum, which is the biggest obstacle when it comes to introducing time-consuming, labor intensive, and beyond classroom activities to an existing oversaturated program of study and overworked students of architecture. In our post-project opinion solicitation, our students were split over preferring the design/build lab as a required versus elective course. Students reported in the post-project survey that the main challenges and obstacles to the success of the lab included time, arriving to decisions, labor, and fundraising. Almost a quarter of the students emphasized that arriving to decisions as a group was the biggest challenge, while others confirmed that "less devoted members to the project," "lack of interest," and "doubts from university administrators and other faculty members on students' abilities" were also major obstacles.

Figure 1. Typical traditional Turkish Kilim.

1.3 *Historical, traditional and cultural precedents*

Cultural and historical precedents from Turkish traditional arts influenced the first built project of the lab. Two traditional works of art were studied and greatly informed the design of the project. The first inspiration was the art of weaving, which has a history that spans as far back as the earliest human settlements (Barber, 1995). Turkish textile arts have won the admiration of the world with their motifs, colors and materials. The traditional Turkish "Kilim" (Fig. 1) is well known to the world for its distinctive motives and colors. The first built project of the lab incorporated principles similar to those employed in weaving, especially in aspects of form, structure, joinery and furnishings.

The second source of inspiration was the vernacular architecture of the Eastern Black Sea region. A visit by the authors to the *Pervane Köyü Araklı* (Pervane Village in Trabzon, Turkey) resulted in the discovery of the wooden structure of the Black Sea area called "Serander", also known as "*Paska Karadeniz,*" which is used for drying and storing grain. The 3.90 × 3.30 m structure stands on six or eight wooden pillars and is made of chestnut wood joined without using nails to allow for future disassembly and relocation to other villages (Eruzun, 1977), as seen in Figure 2. On top of the pillars, just before they meet the main body of the structure, are round discs to prevent rats from reaching the stored grains; these discs may be wood or stone (Karpuz, 2003). The decorations on three sides of the entrance door replicate other examples of its kind. These decorations commonly consist of plain geometric carvings (Batur and Öymen Gür, 2005).

2 THE 'KILIM' PROJECT

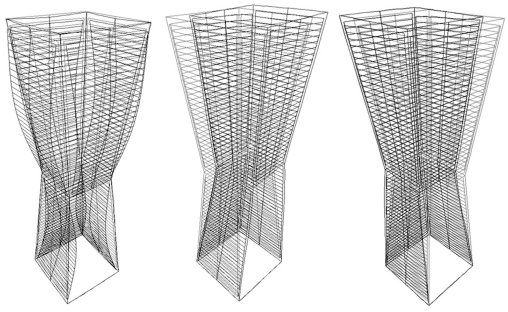
Our first design/build lab project was conceived as two-8-meter tall towers built from wood. The Kilim project used motifs and forms that symbolize the sacredness of the male/female figures. The design

Figure 2. Details of the Black Sea Serander in Trabzon, Turkey.

Figure 3. Bench Seats constructed from short lumber $2'' \times 4''$.

utilized principles of weaving by using wood dismantled from shipping pallets in order to foster an awareness of materials reuse and concern for sustainability. The design allowed for a high flexibility of disassembly and reconfiguration of different structures and utilized a zero-materials waste strategy. The design of the two wooden towers was based on developing a 2×4 meter wall module of a light wood-framing that could be assembled from horizontal and vertical members enveloped with a layer of wooden boards disassembled from shipping pallets that works as exterior "skin". The wall module would then be reproduced 16 times to create all components of the project. This optimized method allowed for shorter construction time, less materials waste and greater efficiency.

2.1 *Dissecting the shipping pallet*



Shipping pallets are typically recycled and reused all over the world. It is very common to see huge stacks of pallets in the backyards of most big box stores and supermarkets. According to a recent report produced as part of the Value to Wood Program, 95% of all shipping pallets are made of wood. In the European Union, 60% of fiber-based packing is required to be recycled, and in the United States, 70% of pallets are repaired and reused (Baumeister, 2009). There are mainly two types of wooden pallets, called block and stringer, that differ in structural integrity and size. The "block" type is mostly used in Europe and is made of soft wood. In our project, and since we requested in-kind donation of pallets from vendors, we received approximately 120 pallets with a mix of types and sizes, but the majority were of the European type. The size of the acquired European pallets was 1200×1000 mm, which is similar to the USA size of $48'' \times 40,''$ which are made from solid Spruce wood. When dismantling one pallet, it yielded approximately the following inventory: 12–15 "boards" sized ($15 \times 90 \times 1200$ mm), 9 "blocks" sized ($90 \times 90 \times 90$ mm), and short dimensional lumber sized ($50 \times 100 \times 750$ mm). Through several design iterations, students developed a strategy of incorporating the exact sizes and dimensions of the inventory into the Kilim towers in order to minimize waste and the need to refurbish and recut materials. Boards were used as the "skin"; blocks were used as the "floor," and short dimensional lumber were used in furnishing as "bench seats" see Figure 3.

2.2 *Multidisciplinary collaboration with engineers*

Collaboration between architects and engineers resulting in iconic masterpieces of architecture in the 20th century dates back at least to the 1950s, according to Don Watson, who noted that Louis Kahn would often refer to his colleague, the structural engineer August Komendant, as an "equal partner" (Watson, 1997). Theirs was an exemplary relationship that began in 1956 and lasted for almost 18 years, at that time, Komendant was known for his outstanding pre-stressed concrete work, which Kahn found a good fit for his architectural forms and ideas. In his book, Komendant reproduced a letter that Kahn had written to the American Institute of Architects (AIA) in 1973, recommending that Komendant be honored with the AIA's Allied Professions Medal for "*inspiring or influencing the architectural profession*" (letter from Louis Kahn to Eero Saarinen, March 23, 1959 (Komendant, 1975). That relationship is one example of how closely architects and engineers work, and how the design process can be inspired by both disciplines.

Catherine Wetzel also has recently argued that when architecture schools integrate design and structures, they increase the working vocabulary and expertise of students, as well as the potential for innovative collaborations in the academy and the profession (Wetzel, 2012). Similarly, in our project, concerns were raised by university officials regarding the structural integrity of the towers and required that we test the proposed design before the actual construction began. Computer simulated structural analyses were performed at the design development phase of the project in order to determine the stability of the proposed structure and to understand its performance under its own weight and wind loads.

While the proposed framing and skin systems were initially found to be acceptable, the connections between the upper and lower modules, and the whole

Self-weight deformation Δz-max=0.023 mm | Wind load deformation (X axis) Δxmax=142.38mm | Wind load deformation (Y axis) Δzmax=089.79mm

Figure 4. Displacement Analysis for the Kilim Tower.

structure to the ground, were critical. A permanent foundation was not suitable since the installation needed to be dismantled and relocated to different locations. A temporary foundation base larger than the tower's footprint was required to overcome the overturning effect of the structure. The exterior wooden skin attached to the structural frame could only carry its own weight. The wooden frame was subject to deformation, and steel connectors were needed to ensure stability. In addition, a cross bracing steel wire measuring 2 mm in diameter was determined to be sufficient for establishing rigidity, and only the sides of the structure subject to torsion needed additional bracing. Knee bracing for the modules would also help in providing rigid connections. Continuous frame members were required but the use of spliced short members salvaged from the shipping pallets were not suitable.

The structural analysis of the "Kilim Tower" was performed using SAP2000 software that considered the closest real dimensions and material characteristics. There was two load conditions: the self-weight of the frame and wind forces (considered according Turkish Structural Analysis Codes). According to the initial results, no critical conditions were found in relation to the preliminary decided dimensions. Two overlapping timber members (50 × 100 mm) were suitable for the main frame, but they had to be held firmly by steel connectors). The simulation models showed deformation of the shape of the frame due to gravity and wind forces respectively as seen in Figure 4.

3 METHODOLOGY

The first design/build lab project was conceived as an experimental case study, utilizing careful observation and recording, followed by a qualitative opinion solicitation of the project participants to document their lived experiences and reactions. Finally, the results were compared to both historical and modern precedents. The project followed a traditional design process, starting with programing, schematic design, refinement and modification, and finally construction. Emphases on collaborating with engineers were implemented throughout the process.

Figure 5. Group decision making and presentation sessions.

3.1 *Group decision-making process*

Following the presentations of design proposals from individual students, a design was consensually agreed on for further development and students were asked to break into six teams of 3–4 individuals. Each team assumed responsibility of one important aspect of realizing the project and these responsibilities ranged from design development to materials sourcing and construction means and methods. Teams were asked to appoint a team leader who was responsible for managing the tasks of the individuals, coordinating with other team leaders, and providing a weekly progress report to the course instructor and other team members. As the project progressed to its construction phase, the design team, in collaboration with the lab instructor, developed the final design and was asked to present their weekly progress to the entire class. Afterwards, informal discussions addressed concerns and suggestions from all the students, during which decisions were made and action agendas were developed. In addition, the other five teams were asked to present their findings and share the progress of their work with others. A group decision-making process was implemented to ensure efficiency and healthy progress of the project (Fig. 5).

3.2 *Four elements of architecture*

There were four elements of architecture that constituted the Kilim Tower project: wall framing, skin, flooring, and furnishings. All were the result of the integration of the available resources, the design concept, and the construction methods within a framework of sustainability measures (Fig. 6).

The decision to purchase new dimensional lumber sized 50 × 100 × 4000 mm for the wall framing was based on the structural analysis that required "continuous" members versus spliced short members. The 15 × 90 × 1200 mm boards salvaged from shipping pallets were surfaced and applied to the exterior of the frame as a perforated skin to allow for shading,

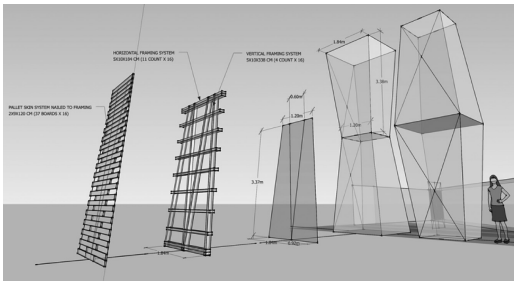


Figure 6. Framing and skin components of the Kilim tower.

Figure 7. View upward inside the Kilim tower.

breathing, visual connection with outside. They also reduced the total weight and wind load effect. The $90 \times 90 \times 90$ mm-salvaged blocks were used for flooring. The $50 \times 100 \times 750$ mm salvaged short dimensional lumbers were assembled to construct four bench seats, which were held together using galvanized steel bolts. All connections of the wall modules and furniture were designed for future disassembly and reconfigurations. Similar to the vernacular precedent of the Black Sea Serander, the corners of the wall modules were overlapped and connected from the outside, leaving a clean joint from the inside and allowing the temporary assembly of modules during construction to be secured (Fig. 7).

Construction Phase: The setting of the lab was a hybrid of a design studio environment, an indoor fabricating facility (wood-shop), and an outdoor assembly/testing yard. Although the workload was generally divided between teams, team leaders and project managers, everyone was involved in every aspect of the project at some point. The project started with zero funding. Students were therefore asked to seek sponsorships and to raise funds and in-kind donations of discarded materials from vendors. Wooden shipping pallets were the only donated materials and a strategy for disassembling and sourcing structural members were developed. After consulting with the structural engineer, however, it became apparent that continuous framing members were essential to the structural stability and integrity of the project. At this point, the university provided a fixed amount of funding (TL 1000) to purchase the structural framing members. After the completion of the project, a reflection phase consisted of two stages. First the students participated in a study abroad program in Italy where they visited the Venice Biennale in 2014. Second a post-project survey/questionnaire was administered to collect their lived experience.

3.3 *Finnish pavilion at the 2014 Venice Biennale*

The Finish pavilion at the 2014 Venice Biennale consisted of a two-part installation based on a concept by Anssi Lassila. With two "primitive huts" that the visitor could enjoy from within, the installation provided two examples of space and shelter at their purest. The pavilion embraced an appreciation for tradition as a source of identity combined with an openness and curiosity toward international influences. Finnish modernism have been inspired by local tradition and by exposure to the world beyond one's immediate sphere of experience (MFA, 2014).

It was a surprise to both students and instructors to observe the similarities of ideas and assembly in both the Finnish pavilion and our Kilim project. The fundamental difference between the two is related to their construction methods: stacking versus assembling. Since earliest times, human beings have constructed their dwellings and shelters by stacking materials, such as stone, to form elements of architecture (e.g., walls), but recently, modern architecture is mostly conceived as planar elements. Eladio Dieste argued that the construction tradition had lost the vitality of its great creative movements due to the enormous effect of the planar framework on today's structures (Anderson and Dieste, 2004). This distinction was clearly evident in both the Kilim project and the Finish pavilion, where one is conceived as planar framework and the other as traditional construction method. Our students were confronted with the two methods of construction and were able to reflect on their own work in light of the Finish pavilion installation.

4 RESULTS AND DISCUSSIONS

Following the completion of the Kilim project, an online survey was conducted to solicit students' opinions. The survey was sent to two groups of students; those who participated in the project from inception to completion, and those who would take part in future design/build labs. The total population sample was 37 students, which consisted of 23 third year students (project participants) and 14 second year students (future participants). The response rate was close to 60% (22 total responses), consisting of 29% second year students (4 responses) and 78% third year students (18 responses).

77% of the respondents had also completed the required two semesters course-sequence of Building Assembly/Building Materials and Construction. 85% of the respondents reported that the design/build lab

was critically integrated into the curriculum of building technology courses, while 15% reported that the lab was not integrated in the curriculum.

According to the university schedule, only two hours were allocated for the lab per week. However, 68% of the respondents reported that they actually spent more than 6 hours working on the lab per week, and 32% reported that they spent between 2–6 hours per week. As a result, 30% reported that they couldn't achieve a balance between their other course workload and the lab, another 30% achieved "some" balance, while 40% achieved "quite a bit" balanced workload. In regard to the size of the lab project in relation to the semester-long activity, half of the respondents reported that the size and scale of the project was 'appropriate', 25% reported 'neutral', and 25% reported that the project scale was 'inappropriate' for one-semester schedule. More than half of the students saw that the distribution of workload was respectively "rarely" and "never" balanced among teams and individuals, the other 35% saw the workload was "sometimes" and "often" balanced, and carefully distributed. The majority of respondents (89%) reported that safety measures were implemented during construction, and that safety information and training were offered during class prior to the beginning of construction. Surprisingly 44% reported that coordination and collaboration with the engineer were 'effective' in understanding the structural issues of the project, while 39% reported that is was 'neither effective nor ineffective' and 17% reported it was 'ineffective'. We assume this is due to the limited interaction and lack of interest of all students during the collaboration sessions and only few interested students, mostly from the design team, attended these sessions. The majority of students (65%) reported that 'major learning outcomes' from the lab included the following:

– Applying knowledge learned from the building technology courses.
– Exploring light wood construction framing techniques.
– Assembly of tilt up wall construction systems.
– Design for disassembly and reconfiguration.
– Resources reuse, optimization and sustainability.

The majority of students (90%) stated that the lab was a necessary part of their education. One summarized his experience as follows (edited for clarity):

> *"Applications should be a large part of our architectural education; it is not common to build a full-scale model during my education years. We improved our skills on working collaboratively and the design/build project played a crucial role in understanding real construction and design problems. Otherwise, we couldn't understand the problems with computers or hand drawings only."*

In addition, some added that their "real-life experience" included collaboration/communication with

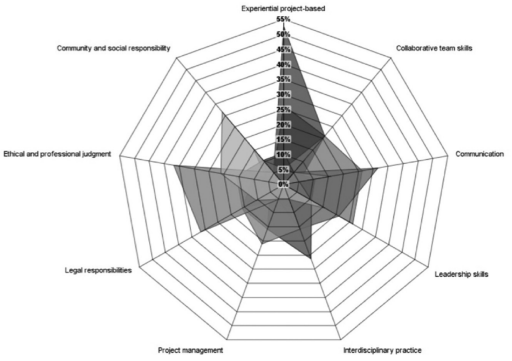

Figure 8. Distribution of personal & professional skills gained.

classmates and instructors, fundraising and sourcing/procurement of materials. 68% agreed that some personal development opportunities that emerged from the lab experience included understanding the relationship between design and construction, having built work on one's portfolio before graduation, solving real construction and onsite problems and learning how to work and collaborate in teams. Students ranked personal and professional skills gained from the lab as follows (Fig. 8):

– Experiential project-based
– Collaborative team skills
– Communication
– Leadership skills
– Interdisciplinary practice
– Project management
– Legal responsibilities
– Ethical and professional judgment
– Community and social responsibility

4.1 *Findings and lessons learned*

Our observation of the Turkish culture indicates that Turkish people generally prefer working and socializing in groups. Our hypothesis was based on the assumption that this attitude would ease the group decision-making process. However, in our post-project survey, only a little over half (53%) thought that "collaborative work culture" distinguishes Turkish students from others, while 47% don't think so. This split could work against a healthy progress of a design/build project, however the end result changed the preconceived mindset of the majority of participants. In general the majority of students reported that the lab garnered very positive attention for the university (79%) while 21% thought a little to none attention was gained. 65% reported that they definitely were willing to participate in any future elective or extracurricular labs. 74% reported that the lab experience succeeded in eliminating the preconceived fear of working directly with real materials and machinery. A little under half of the students (45%) viewed the lab instructor as a "collaborator" and 25% viewed the instructor role as an

Figure 9. Students during construction of the Kilim project.

"advisor". Other roles included "designer", "architect of record" and "leader". As for the project decision-making process, the majority of respondents (75%) viewed that design and construction decisions were made equally by students and instructor. Almost a quarter of the students viewed that collaborative work, realizing design ideas, and the lab instructor were the main factors in motivating them to build their first project. Another quarter viewed the instructor as the main motivator while a third quarter viewed learning onsite, building a project with monumental value and grades, as among their motivations to participate on the project (Fig. 9).

Although respondents were split in half regarding the question of including the lab as a required course versus an elective one, they continued to surprise us. When asked if they were given the opportunity to choose between spending the 2 hours/week of the lab time in front of a computer drafting construction documents, or working on a design/build project, the majority of them (86%) selected working on a design/build project, while only 14% preferred a computer lab. This is very much confirmed our hypothesis that the majority of students favor a real-life experience over a computer drafting one. Justifications for favoring the lab was explained by one students as follows (edited for clarity):

> *"We have many theoretical courses in the curriculum, yet we don't find an opportunity to apply the things we learn in theory to practice. With the design/build lab we had the opportunity to apply what we learned. It's always difficult to visualize joints and details in drawing. I didn't understand them until I actually constructed them by my hands. Now, I have self-confidence about my architecture."*

Students who favored the lab as an elective course stated that their lack of interest halted a smooth progress of the project and created negative arguments among students. In addition, the nature of "labor work" is not suitable for some students, especially females due to cultural constraints. Also the extra time required for the lab beyond the two hours created a burden on some students who couldn't manage a balance for other course workload. The majority of students (84%) agreed that the construction experience gained from the lab could potentially distinguish them from their peers in other Turkish institutions at the time of graduation. Some students stated that they now know more about construction, management and processes than their peers. Others suggested that most of their peers have not experienced this kind of material applications, teamwork and group decision-making and that the experience would most likely be an advantage in their professional life. One student reflected on her design/build experience as the following:

> *"We have done something we couldn't imagine doing before, like what we see in books and magazines. One who didn't experience something like that would never know how it feels like; that proudness and self-confidence. We really built it with manpower, collaboration and belief; we gained courage that certainly will distinguish us from our peers who are unaware of this kind of architectural education."*

5 CONCLUSION

Our design/build project brought a pedagogical evolution to the Turkish architectural education, which was favored by 63% of our participated students. According to some, Turkish higher educational system generally does not pay much attention to applicatory teaching, and we suggest that Turkish architectural education, in particular, could certainly benefit from design/build initiatives. Our design/build lab was developed from the ground up with zero funding, no facility, and a pessimistic view from some faculty members, yet it proved that vision, dedication and hard work pays off and that changing students' perception is applicable through collaborative work. 95% of our survey population agreed that the experience formed an important ingredient in their architectural education for several reasons, and that it provided them with essential skills such as a better understanding of architectural tectonics, assembly and joining of materials, solving construction problems onsite and efficient management, realizing the difference between theory and practice through application, incorporating lesson learned from real life problem back into the regular design studio projects, and finally developing collaborative skills and iterative design process. The three guiding principles for this inaugural project – pre-fabrication, optimization and sustainability – were thoroughly investigated in the context of the available resources and time constraints. Collaboration with a structural engineer at the early stages of the project was essential to the realization of the project within the framework of these principals. Exercising a group decision-making process was challenging, but ultimately yielded a successful experience. We strongly believe that architectural education in Turkey could benefit from integrating design/build initiatives to its existing curriculum and distinguish itself from that

of other countries in the region. Turkish culture, in general, holds quality education in high regards and design/build initiatives such as the one we presented will critically help reposition the role of the architect to the ever-constant societal challenges and changes in the region.

ACKNOWLEDGMENT

The author wishes to thank Bilkent University architecture students' class of ARCH 252 Spring 2014 for their dedication and persistence to design and build their first project. Also, sincere gratitude extended to Dr. Meltem Gurel, Dr. Ali Ihsan Unay, Dr. Giorgio Gasco and the woodshop technicians, Erol Bey, Lutfi Koç. The project was dedicated to the victims of Soma mine disaster in 2014.

The EAAE and the Lisbon School of Architecture—A common history between 1976 and 1986

L. Matos Silva
Instituto Universitário de Lisboa (ISCTE-IUL), DINÂMIA'CET-IUL, Lisboa, Portugal

ABSTRACT: On April 25, 1974, Portugal underwent a political revolution that put an end to a 40-year-old dictatorship. Since 1976, and in the ten years following, when the country entered the European Economic Community (1986), only two institutions were providing architecture education: the Superior School of Fine-Arts of Oporto and its namesake in Lisbon. The revolution transformed the whole country, including both schools and their architecture courses.

This article analyses the post-revolutionary period within the Lisbon School, taking into account the history it shares with EAAE. Thus, the use of the expression "common history" will firstly here have a sense of sharing; secondly, it will underscore the importance of the recollection of architecture schools' histories for deepening the debate and thus facing present and future societal challenges in architectural education.

The major theme for this conference—Architectural Research Addressing Societal Challenges—is a basic pursuit and a pedagogical quest for two of its hosts: the Faculty of Architecture of the University of Lisbon (FAUL) and the European Association for Architectural Education (EAAE). This article addresses the common history of the Faculty of Architecture of the Technical University of Lisbon (FAUTL, previously to FAUL) and the EAAE in the years 1976 to 1986, a period in which the first was called upon to respond to striking societal challenges and the latter had just been created to "enable teachers and students of Architecture throughout Europe to collaborate towards a fuller communication of ideas, methods and philosophies" (EAAE, 1978).

This article will overview and question architectural education having for basis an historical analysis of architectural education itself, i.e., it will describe institutions and mechanisms that promote teaching, discussion and dissemination of architecture. Thus, it will strive to address a complex and potentially diffuse issue by a narrowing its field of analysis.

The importance of the development of historiography on the most recent decades of the twentieth century—the 1970s, 1980s and 1990s—is widely debated. We find that many of the case studies of this period, even the most complex, are missing pieces of the current history of architecture and culture and have not yet been studied due to the multifaceted and contradictory features that they present. Architectural culture within the Lisbon school of architecture is one of these unexplored and yet revealing themes; it specifically justifies an in-depth study for a Ph.D. that describes Lisbon's architectural culture in the 1970s and 1980s through analytical observation of its architecture course.

To overrun the difficulty of being an unexplored object of study, overall research relies heavily on primary sources. This specific essay is documented by the FAUL's own registries—administrative (paper) and videographic. In addition, personal collections were consulted and re-assessed, and numerous taped interviews and written testimonies were reviewed.

A significant number of secondary sources support the major research; for this paper, the EAAE historical archive should be pointed out, namely its News Sheets, available online (Archive EAAE).

1 THE LISBON SCHOOL OF ARCHITECTURE—HISTORICAL FRAMEWORK

The history of the Portuguese democratic revolution is widely acknowledged, studied and celebrated. Images of the historical streets of Lisbon filled with people show both the physical and social grounds of revolutionary ambience. Lisbon's institutional architectural education participates in this engagement because teaching takes place in Saint Francis Convent, a preserved XIII century building in historical Chiado area (Calado, M. & Ferrão, H. 1996), and because politics, in 1974, were a general concern.

Before 1974, architecture was officially taught in Lisbon as post-secondary education at the Superior School of Fine-Arts. During the 1974 revolution, inner turmoil led to the course of architecture's suspension until 1976, when it was re-established for, among other goals, the purpose of distinguishing the department as an autonomous university faculty from the other fine arts (George, 1987).

The decade that followed the reopening of architecture classes within the school—which was, in 1979,

formalized as Faculty of Architecture of the Technical University of Lisbon (FAUTL)—was characterized by social instability, political struggle and prolific extra-curricular activity.

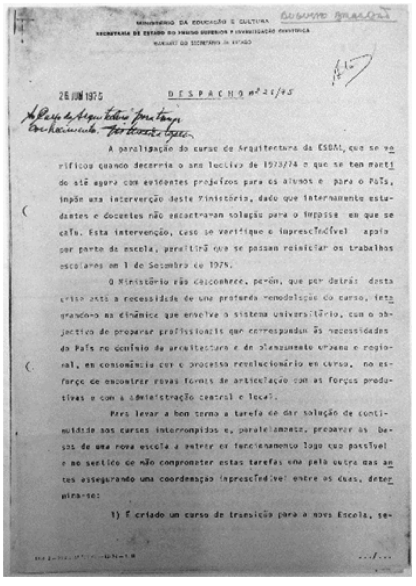
1.1 *Architecture and revolution*

The years from 1976 to 1986 are critical for understanding contemporary architectural education in Lisbon. They will testify to an extreme transition between two systems: a collegiate *beaux arts* structure to a university system linked to a wider and substantively more complex academic field (Silva, 2012). Although this process was not immediate, Portuguese schools were instantly 'democratized' under military governance that lasted about two years. Lisbon's Architecture Department embarked on a virtual internal revolution just a few days after April 25, 1974 (FAUL, 1975a).

At first glance, the suspension of architecture classes and the closing of the working spaces were the practical result of the expulsion of many docents for political arguments, supported by groups of students (Silva, 2011); a second examination adds that this closing is naturally caused by a sense of opportunity given what Lisbon architects and students had regarded as a social and cultural depreciation of their discipline and careers in the previous decades. Therefore, an immediate proposal for the separation of architecture from plastic arts to integrate the university system was made. The option of disciplinary autonomy and specialization and the urgent need for architecture's ethical and technical refinement were generally agreed upon among those who ended up intervening in the school's reform. The Lisbon Superior School of Fine-Arts' previous division into two sections—architecture and painting and sculpture—was thus reinforced by the conception of two new post-revolutionary departments: architecture and arts and design (FAUTL, 1981a).

It was clear at this point that the school's population believed in its own self-awareness and in acting on behalf of architectural practice rather than for strict academic values. However, this implicit assertion in times of such turmoil does not mean a disregard for teaching methods or a lesser concern for architectural education; on the contrary, the political crisis intensified the disciplinary discussion. The debate within the school revisited theoretical inquiries that utterly questioned pedagogical methods, specifically the reasonableness of the *beaux arts* system. The Lisbon School's students wanted to be prepared for the 'real world'. The academy stood face to face with a territorial reform expressed in actions like self-construction and in many cases supported by the state. Architecture discourse revolved around primary questions like the *utility* of architecture, taking into account a country with deplorable housing conditions (RTP, 1975). The idealism of the conjecture 'Architecture or Revolution', put by Le Corbusier years before, is illustrative of how architectural education would have profoundly marked a societal transformation if only the extreme and programmed makeover that was being planned had taken place—in other words, if the shift had been portrayed as an heroic, modernist-like act. However, some architecture students of the Lisbon School as well as some teachers who gathered in successive general assemblies after April 1974, expressed not only their views on the political and social circumstances but, most incisively, on their academic and personal expectations, uncertainties and frustrations (ESBAL-Arquitectura, 1974). In sum, despite having prompted an educational blackout for political and ideological motives, these students and teachers were admitting during the revolutionary years that the conjecture *'Architecture or Revolution'* should, in fact, be more of a conjunction of words— like in Architecture *and* Revolution—anticipating that architectural education would in fact at the Lisbon School, overcome instability and engage in societal transformation within a mild everyday transitory manner, as we will see.

1.2 *The post-revolutionary first study plan proposals*



1.2.1 *Architecture, regional and urban planning school, by N. Portas*

In June 1975, more than a year after the April 25, 1974 revolution, the dead end in which architecture students and teachers found themselves motivated A. Avelãs Nunes, the Secretary of State for Superior Education and Scientific Research, to write a legal resolution (Fig. 1) (FAUTL, 1975b) that created a three-headed installation committee for the conception of a new school to be called *Architecture, Regional and Urban Planning School*. To do this, Nunes appointed architect N. Portas, a former professor at the Lisbon School and a dedicated researcher at National Civil Engineering Laboratory (LNEC).

As a member of the installation committee for the creation of a new school of architecture, Portas wrote out its program in detail (FAUL, 1975c), conceiving a fresh start supported by his convictions on the matter.

He carefully planned the integration of the students from the current suspended architecture course—which should be eliminated, according to his proposal—and the complete change of the faculty composition. As to its substance, the new structure Portas planned summarized most of what he had been advocating in his classes at the school, in the years prior to the revolution, and, moreover, on his experience at LNEC: In this proposal, Portas intended to join urban planning and architecture, giving urbanism a prominent place, in a straight relationship to social sciences.

MINISTÉRIO DA EDUCAÇÃO E CULTURA
SECRETARIA DE ESTADO DO ENSINO SUPERIOR E INVESTIGAÇÃO CIENTÍFICA
GABINETE DO SECRETÁRIO DE ESTADO

26 JUN 1975 DESPACHO nº 25/75

A paralisação do curso de Arquitectura da ESBAL, que se verificou quando decorria o ano lectivo de 1973/74 e que se tem mantido até agora com evidentes prejuízos para os alunos e para o País, impõe uma intervenção deste Ministério, dado que internamente estudantes e docentes não encontraram solução para o impasse em que se caiu. Esta intervenção, cedo se verifique e imprescindível apoio por parte da escola, permitirá que se possam reiniciar os trabalhos escolares em 1 de Setembro de 1975.

O Ministério não ignora, porém, que por detrás desta crise está a necessidade de uma profunda remodelação do curso, tendo em conta a dinâmica que envolve o sistema universitário, com o objectivo de preparar profissionais que correspondam às necessidades do País no âmbito da arquitectura e de planeamento urbano e regional, em consonância com o processo revolucionário em curso, no esforço de encontrar novas formas de articulação com as forças produtivas e com a administração central e local.

Para levar a bom termo a tarefa de dar solução de continuidade aos cursos interrompidos e, paralelamente, preparar as bases de uma nova escola a reter o funcionamento logo que possível e no sentido de não comprometer estas tarefas uma pela outra das antes assegurando uma coordenação imprescindível entre os dois, determina-se:

1) É criado um curso de transição para a nova Escola, se-

to his proposal—and the complete change of the faculty composition. As to its substance, the new structure Portas planned summarized most of what he had been advocating in his classes at the school, in the years prior to the revolution, and, moreover, on his experience at LNEC: In this proposal, Portas intended to join urban planning and architecture, giving urbanism a prominent place, in a straight relationship to social sciences.

This process was elaborated upon and roughly debated (at a distance) between Portas himself and the school's population from October to December 1975 (ESBAL, 1976a). Students and teachers would then present a myriad counteract proposals to the same level decision-makers therefore Portas did not succeed in providing Lisbon with a new architecture school.

1.2.2 *Architecture and planning superior institute – estrutura 76*

The Lisbon School's architecture course reopened in April 1976, two years past the political shift, under a new resolution (Dispatch 7/76 and 7A/76), signed by A. Brotas, the Secretary of State after Nunes. This legal statement was based on a work document titled *ESBAL-Arquitectura*, presented by six professors, that had made its way through earlier disputes (FAUTL, 1976b). This document included a study plan called *Estrutura 76* [Structure 76], supposedly named after the year 1976 (Fig. 2) (Estrutura 76, 1976), that had no single authorship, being the result of an agreement among students and teachers under the guardianship of F. George, a dedicated professor and a renowned cultural figure who enabled a smooth transitory process thereafter. In fact, the myriad of ideas contained in *Estrutura 76* confirms a harmonious relationship

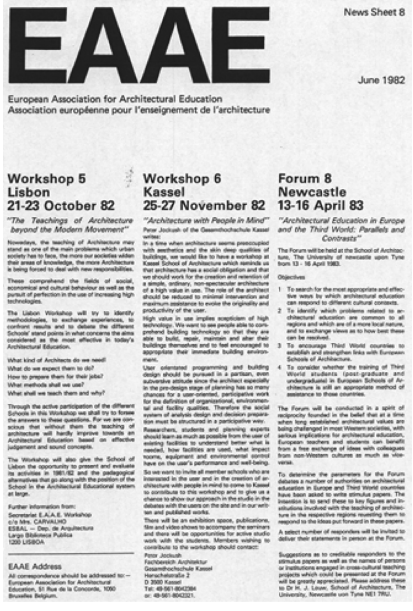

Figure 3. EAAE News Sheet n. 8, June 1982. Announcement of the Fifth Workshop in Lisbon (EAAE, 1982).

between multiple worldviews; on the one hand, the text alludes to George's pedagogical artistic charisma:

> "It is difficult to establish the borders for an architect's intervention; the range of materials include the positive sciences, and the humanistic and social sciences, ever combined with

a spirit of permanent creativity" (Estrutura 76, 1976).

On the other hand, the written words of *Estrutura 76* are clear political sound bites:

> "The architect will have to question some of his concepts, using, for that matter, idealistic and materialistic philosophies, and should give prominence to an analysis of society, from the perspective of historical and dialectical materialism (. . .)" (Estrutura 76, 1976).

This drafted study plan diverges from Portas' proposal in other aspects, all reflecting the multiple contributions from the school's population. Overall, it is a less demanding and more flexible proposal for both students and teachers engaged in the former system, reinforcing the counteraction thesis.

Specifically, it suggests a four-year curriculum for a diploma in architecture that is sufficient for registration in a professional association. In addition, students could then engage in a specialization of 18 months in architecture or planning, but also in theory and architectural history, a specialization disregarded by Portas, and aimed for developing skills for specific "public agencies devoted to the Portuguese architecture heritage conservation and protection" (Estrutura 76, 1976).

Estrutura 76 narratively reflected the students' idealism, whereas, in practice, it proposed a simplistic and pragmatic learning process. In this aspect, the collective study plan was extremely different from Portas' line of intentions, since the latter believed that a highly demanding course was the only way to "avoid social disqualification in a certain "batch" [meaning a group of students who would graduate in the same year] of architects" (ESBAL, 1976a).

Besides cutting the course from six to four years, this study plan included for evaluation methodology a "continuous assessment" and the passing of the year dependent on a "general consensus between students and teachers" (Estrutura 76, 1976). This plan included the abolition of classes with precedency—which meant, if necessary, the passing over of students with a "poor knowledge on the subjects". All this was in favour of "collective work", "group spirit", and elimination of exams, an "evaluation act" that promoted "individualism, creating undesirable competitive situations, moreover the infallibility and injustice thereafter raised" (Estrutura 76, 1976).

As for the students from the fourth to the sixth year from the former curricula who had to line up in a transitory scheme, it was planned that they would not have to meet the requirements of the new study plan to graduate. The same benevolence was here applied—that is to say, these students were implied victims of the previous system (idealist view), or a 'complicated business' for the new one (practical view).

As for teachers, this study plan most of all acknowledged the interests of the interim school's population; specifically, the professor's 'acquired rights' should be acknowledged in a clear statement against the extinction of the course and their contracts, as proposed a year before by Portas through the former Secretary of State.

This study plan enforced the creation of a new school, to be called Architecture and Planning Superior Institute. However, this school was not mentioned by Brotas when the document *ESBAL-Arquitectura* was submitted for legal support. Brotas would only support *Estrutura 76* as the basis for an experimental period for the reopening of the architecture course, thus recognizing the architecture department within the fine arts school, from April 1976 to December 1976.

Estrutura 76 was then accepted with some ecpections like the evaluation methods, which would have to be exclusively individual, and of the full docent responsibility. In addition, Brotas required the course to have a four year curricula for a bachelor's degree, starting at year one to four, and two more years for a master's.

Brotas' appreciation and subsequent legal resolution and reopening of the architecture course in the spring of 1976 did not mean that classes in the years followed achieved *Estrutura 76* or any other stable and rigorous plan. In fact, until the mid-1980s, study plans were altered yearly (FAUL, 1977) to contend with multiple deficiencies—an increase in the number of students and scarce resources of financial, administrative and spatial natures. Pedagogically, absence was severe among both students and teachers. As to educational contents, exploratory architecture contents like drawing and experimenting with models were scarce. It was difficult, especially for students who wanted to be engaged at school, not to devote most of their energy in bringing to classes their concerns about everyday post-revolutionary outdoor life. Classes were, therefore, the natural ground for debating architecture education (Planeamento, 1976).

2 THE EAAE AND THE LISBON SCHOOL OF ARCHITECTURE

In that same year of 1976, when the architecture department reopened in Lisbon, the EAAE was founded for the promotion of "a wider understanding of the theory and process of Architectural Education" (EAAE, 1978).

The EAAE is an important entity in this essay since the relationship between the EAAE and FAUTL is symbolic of the interest that FAUTL revealed about both architectural education and external worldwide affairs in the decade in question. On this matter, Professor A. Brandão stands out in his role as president of the architecture department's governing board from 1978 on. Working alongside the installation committee designated by the 1979 law to conduct the entry of architecture course in university, and eventually as its member, Brandão enforced a stable internal structure and promoted a connection of the department to the rest of the world.

The promotion of a qualified pedagogical offer, internationally referred, as an agency for a personalized

Figure 4. Fifth EAAE Workshop. FAUTL, Lisbon, 1982. Lecture by T. Dejksdtra. (Faul, 1982d).

Figure 5. Third EASA Workshop, The *Lisbon Ateliers*. FAUTL, Lisbon, 1983. (Faul, 1983h).

and credible renewed school, was particularly important for Brandão. His endeavour meant, in practical terms, a particular insistence on requesting financial aid from various entities and for particular needs like travelling (Silva, 2011). In his tenure, Brandão also encouraged more disciplined conduct among the school's population, enforcing, for instance, new pedagogic and docent structures with pre-determined objectives (FAUL, 1977). Although he was not always successful in his quests, the interaction with outer academic realities, in which the EAAE played a special part, are significant outcomes.

From as early as 1980, Brandão established a relationship with EAAE, sending Professor S. Sanches to the First EAAE Workshop titled *The Teaching of Architectural Technology* (Fig. 6) (FAUL, 1980). The First EAAE Workshop took place at ETH Zürich, academic home for H. Kramel, who had become EAAE's president in 1979 (EAAE, 1980). In the firs visit to Libon, Kramel delivered a seminar on *The Teaching of Architectural Technology* (FAUTL, 1982a). His lecture focused on the environment, energy conservation and how a university education should be able to articulate research related to both rudimentary and contemporary technologies (FAUL, 1982b).

In his visit, Kramel encouraged the Lisbon School of Architecture to innovate in technological research, stating his conviction about the importance of pedagogical evaluation. These two aspects—experimentalism and self-evaluation, within technological research—might seem reasonable at a distance; however, in the early years, they meant unsettling the pedagogical ground on which the architecture course had been raised, thus potentially triggering political distress. This episode hence illustrates the risks that Brandão had to face when trying to develop a school based on a set of external references, instead of promoting internal debate and participation. In this context, a series of post-graduate courses, namely on building energy conservation, were made, rather than bringing the know-how and spirit of initiative into everyday architecture classes (Silva, 2014). On a specific point of Kramel's statement, he affirms it is "advisable to consider as academic work all the school activity". Brandão handwrites on the subsequent report report the word "fundamental" (Faul, 1982b), valuing the globalized path the university system was undertaking and the potential of the institution within this line of inquiry.

This is the context in which the Fifth EAAE Workshop took place in Lisbon between 21 and 23 October 1982, having for theme *The Teaching of Architecture* (Fig. 4) (Faul, 1982c). A few months later, Kramel reported his impressions, noting what he believed were the two most identifying characteristics of the FAUTL in the early 1980s: a desire for affirmation and a particular geographical status—peripheral in relationship to Europe, central to the rest of the world:

> "The same feeling of being on the edge of Europe was recreated in Lisbon [in comparison to Ankara]. (. . .) South America and Africa seemed closer than at any other place of the continent.
>
> (. . .) While Portugal, in the past, has been very strongly orientated toward colonies, today it seeks stronger alliances with Europe. The Workshop was one of the many attempts made to re-establish ties through relationships with other schools of architecture.
>
> Brazil, Mozambique and Macao are reference points even today. The role of Portugal in these countries has been considerably different from the one England played *vis à vis* with its colonies. (. . .) The Portuguese, more than any other former colonial power, have the potential to mediate between Europe and the other continents.
>
> (. . .) The motivation, energy and vision of Professor A. Brandão, (. . .), together with the support of an enthusiastic staff, made this EAAE event possible." (EAAE, 1983)

The Fifth EAAE Workshop stood out for its quality: The participants were all suggested by Kramel

and debated teaching methods in a genuinely scholarly environment, which is directly observable from the videographic records, one of the features that adds to the school's efforts to enrol in a technological dynamic (Figs. 4 and 5). As for the contents of the debate, it is in line with 'turning the page' from the idea of a *utilitarian* school— an issue that had been strongly articulated in the revolutionary years. In his Fifth EAAE Workshop's lecture, T. Dejksdtra, on the contrary, defended the development of academicism, foreseeing the coming times:

> "A massive class, as opposed to the studio method, is based on the assumption that architecture can be taught. This approach is based on the idea that architectural problems are teachable, i.e. accessible to a rational treatment and to a rational argument. Any didactic strategy in class, at school, is then not basically different from the process of office practice. (. . .) The virtue of a school is not to be practical, like the office practices. The virtue of the academy is to be academic" (Faul, 1982d)

Having once been very close to extinction, the Lisbon School of Architecture was then welcoming numerous foreigner academics who had persisted in the architectural education debate in their own contexts. Along with Kramel and Dejksdtra came A. V. Randen, from the Delft University of Technology; N. Segvic, from the Architektonsky Fakultet in Zagreb; B. Hoelsi, from ETH Zürich; R. Schweitzer, from Paris; P. Jockusch, from Kassel; P. Rich, from London; and N. O. Lund, from Aarhus, Denmark.

3 A BRIEF HISTORY OF OTHER EDUCATIONAL DEBATE AT THE LISBON SCHOOL

Since the late 1970s, the teaching of architecture had been the subject of numerous conferences that the Lisbon School of Architecture had promoted and in which it had participated. For instance, its representatives had been present at the First Congress of the newly founded Association of Portuguese Architects (AAP) in 1979, which had for theme the *Education of the Architect* (Fig. 6) (FAUL, 1979). At this gathering, the architects had debated the "creation of the architecture Faculties of Lisbon and Oporto", which were to be formalized that year (Decree-Law 498-E/79). The two primary topics for debate were the "educational programme for architecture and urban planning in the European context" given the "impact of the EEC", but also "educational degrees and postgraduate courses" (FAUL, 1979).

In 1982, FAUTL had planned the creation of an association of schools between developing countries (FAUL, 1982f), a theme that was undertaken by the 1983 EAAE Forum, planned for Newcastle upon Tyne, titled *Architectural Education in Europe and The Third World: Parallels and Contrasts*.

The FAUTL again made its presence known, this time with professors J. Real and J. Calado, who had asked for travel funds from the Gulbenkian Foundation, having for fundament the presentation of a "thesis" with the title *Teaching of Architecture in the 3rd World. The Basin of the Mediterranean and Africa* (FAUL, 1983b). The interest some teachers had about developing countries, together with the FAUTL's self-proven capacity of promoting its own events, had motivated the idea of uniting some architecture schools from the Mediterranean to debate architecture, society and teaching methods, in particular, at an event titled *Réunion D'Écoles D'Architecture Méditerranéennes: Architectures, Societés et Enseignements* (Fig. 6) (FAUL, 1983e). This reunion also had the contribution of Mello, who presented *Knowledge in Architecture and Its Transmission* (FAUL, 2006).

At this time, Brandão had already invested in designing abundant extra-curricular pedagogical training for FAUTL (Fig. 6). In 1982, a post-graduate course was begun, titled *Monument and Building Rehabilitation and Conservation* (PG1). Its study plan consisted of an eight-month period of late afternoon classes two times a week.

In 1983, a new edition of PG1 was administered, along with two new post-graduate courses that won especially positive feedback from the participants, titled *Environmental Architecture. Energy Conservation in Building* (PG2) and *Architecture for Tropical Areas* (PG3).

In 1984, a new seminar focused on the *City Outskirts Housing*, and in 1985, PG1 was at its third iteration (FAUL, s.d.).

As for undergraduates' school work, the conviction of a "qualitative jump" (N/A 1982) within a school path for internationalization had led Brandão to ask the Royal Institute of British Architects for recognition of the course of architecture (RIBA, 1983d). The schoolwork was then formally presented at an exhibition that was visited by Kramel during his 1982 visit and by members of the AAP—an attempt to gain formal recognition of the pedagogical progress.

The year 1983 was the most culturally active year in the school's life. Debate on architectural education gave way to an overall post-modern tendency for 'seizing the moment'; many events then assumed other themes rather than architectural education, but most either had for basis the invitation of foreigner personalities or imported artistic expressions. Many of these occurrences were recorded on home-video technology (VHS and others), a symbol of the abandonment of any bias against consumerism that signalized a rapid mentality turnaround or new political detachment (Silva, 2016; Silva, 2017).

The Faculty of Architecture Students Association (AEFA) itself played a fundamental role in the school's engagement with architectural education debate and external liaisons by participating in events organized by the European Architecture Students Assembly (EASA). First, AEFA promoted the presence of FAUTL by sending students and teachers to the first

two EASA workshops in Liverpool (1981) (FAUL, 1983a) and the Delft (1982) (AEFA, 1982e); secondly, and most importantly, AEFA organized, in an almost freelance manner, the Third EASA Workshop in the FAUTL's ground, with the title *Lisbon Ateliers* (see Fig. 6) (EASA, 1984). This workshop gathered students of three nationalities outside the European continent, a total of 520 participants from 26 countries—an impressive demonstration of an effective internationalization of a Saint Francis Convent's improvised campus (FAUL, 1983h).

In 1985, the Architectural Association School of Architecture in London promoted an early visiting school programme to the FAUTL, enrolling 15 of its students (FAUL, 1985).

In 1986, the FAUTL and its concerns on architectural education reached a turning point, prompted by Portugal's entrance into the European Economic Community. From then on, Portuguese architectural education became liberalized, and the three major concerns of the very First Congress of the AAP back in 1979—architectural education, university and Europe—adapted to a different prospective future. In 1989, one of FAUTL's assistant professors was sent to the 20th EAAE Workshop in Helsinki, reporting that "FAUTL continues to be in debt as to its participation towards the AEEA, since 1986" (FAUL, 1989). The same year, AEFA promoted an introspective debate titled *What Architecture Is Taught Here?* (Mello, 2006).

4 CONCLUSION

This paper's primary objective was to trace a common history between the EAAE and the FAUTL in the 1980s. Secondly, it proposed to demonstrate the importance of developing historical research on the common histories of contemporary institutions.

Bearing the conference's theme in mind, what we can observe from this joint analysis is an overall educational crisis and deep societal challenges from the 1960s on. Particularly in Lisbon, a 1974 political revolution induced student takeover within the architecture school. Great political narratives are still present in the Lisbon School of Architecture in the first post-revolutionary years; however, a proposal for the old architecture course's elimination, meaning a school's actual radical reform, was rejected. The succeeding experimental years, within a convened transitional manner, much less connected to 'the real world', as proposed by the students' initial idealisms, will then reveal the first true identity for the new democratized FAUTL.

Even so, the first sequence of events that link FAUTL and EAAE unfold a general concern over qualifying and invigorating the school by connecting to other revered institutions as well as other accountable aspects like didactic offers or extracurricular events.

The agency of promoting the school and referring to external and visible actions implies a reflection over didactic problems like the precarious pedagogical structures, the lack of human and material resources, and the growth of the student population.

It is true that the school's agency, in the years 1976 to 1986, was to turn outwards to a globalized system, i.e., to invite foreigners, to record and publicize a specific self-image, to invest in specialized collaborative research rather than in this interim observation. If the new university-levelled Faculty of Architecture was to abandon its collegiate nature, with the disadvantage of being disqualified from its former familiar scale,

this was accorded to this premature susceptibility and for the sake of some advantages, namely the ability to seek out a wider field of educational options and realities. Whether this opportunity was embraced and hat kind of work and teaching resulted from this option are subjects for another study.

ACKNOWLEDGEMENTS

The author would like to acknowledge the collaboration of the Faculty of Architecture of the University of Lisbon and the Portuguese Foundation for Science and Technology (FCT) for the individual doctoral grant (SFRH/BD/80535/2011) funded by the State Budget of the Ministry of Education and Science.

The author expresses her gratitude towards J.M. Fernandes, L. Sousa Pinto and N. Portas, for their most generous contributes to the background research, and particularly to this essay.

This essay is dedicated to today's FAUL's students.

A changing academic community: The faculty of architecture of the University of Lisbon

F. Roseta & J. Sousa Morais
CIAUD-FAUL, Faculdade de Arquitectura da Universidade de Lisboa, Lisbon, Portugal

ABSTRACT: Throughout the period of two academic years, the Faculty of Architecture of the University of Lisbon (FAUL) underwent a revision of its five-year study plan for Architecture. In 2013, the final version of the syllabus was approved and it has already been implemented. The previous syllabus had already been conceived to respond to Article 46 of European Directive 2005/36/EC, set to guarantee the basic knowledge and skills required for training architects within the European Union. The challenge addressed in the revision of FAUL's study plan was to find a better balance between research and practice. This paper aims to identify the current challenges faced by the Faculty of Architecture of the University of Lisbon in the midst of a changing academic community, which is evermore international and research-based. Framing the debate within the historical evolution of the Faculty from its sixteenth-century origin to today aims to contextualise the nature of the present day challenges.

1 INTRODUCTION

This paper aims to present the current challenges faced by architectural education at the present day Faculty of Architecture of the University of Lisbon (FAUL), by framing the current debate within a five-century old tradition. The early beginnings of the present day FAUL can be traced back to the sixteenth-century. Despite its long history, the detailed evolution of FAUL has not yet been fully addressed. The literature reviewed for this paper mainly includes research produced within FAUL, namely by Frederico George (1964), who presents a broad historical framework with some statistical information; Maria Calado (2003), who refers briefly in her PhD research to the early beginnings of architectural education in Portugal. Furthermore, the review included legal decrees and regulations, which legally record the rules and ideas defining architectural education in Portugal throughout changing times.

2 HISTORICAL OVERVIEW

2.1 *Education through practice*

Architectural training in Portugal had its early origins in the 'Aula do Risco', which roughly translates as 'classroom of tracing'. Aula do Risco was created by the Italian Filipe Terzi, at the end of the sixteenth-century, under the rule of Filipe II. At the time, there were three students per tutor, and education was mostly based on classical treatises. As described in George (1964, p. 21) 'There were four hours per day of classes and the Professor of Architecture had to, in the first two hours, teach the fundamentals of arithmetic and geometry, and in the next two hours, show his disciples the main proportions of the five orders of architecture – Tuscan, Doric, Ionic Corinthian. Then move onto the layout of a simple house, and, from then on to a palace. He had to provide the exact notions of the solidity of construction, and then introduce ornament and the use of perspective'. Aula do Risco was a small studio, with its principal location at Paços da Ribeira, in the centre of the city; however, it can be nowadays be characterised as a mobile classroom, as it was created to operate mainly on construction sites of royal commissions, as was the case with Mafra (Calado, 2003, pp. 93–95).

In 1755, Lisbon had its central core destroyed by a devastating earthquake. The reconstruction of the city, that succeeded the earthquake, became the means for the Casa do Risco to improve both its techniques and theoretical support. At this time, there was a merger between the studio and the engineers dedicated to building fortifications. Manuel da Maia, an engineer responsible for overseeing the reconstruction of the Baixa Pombalina after the earthquake, himself became the architect of Casa do Risco, overseeing, onsite, the reconstruction works of the city (Calado, 2003, p. 95).

This early tradition traces the roots of architectural education in Portugal to practical training, as architects were instructed through the practice of architecture directed towards ongoing construction works. This tradition would change with the influence of Liberal ideals and French culture in the nineteenth century.

2.2 *Academy of the arts*

In Lisbon, architectural education framed within an Academy emerged in 1835, with a national-decree

that provided a general revision of education. At this time, all courses in Sala do Risco were discontinued, transferring existing human and physical resources to Lisbon's Academy of the Arts (Calado, 2003, pp. 96–99).

Lisbon's Academy of the Arts was created on the 25th of October of 1836, stating its purpose as being 'uniting all arts within one institution' (Calado, 2003, p. 99). While the education provided at Sala do Risco was mostly practical and onsite, at the Academy, the education of the Fine Arts was considered more important. The main tutor was no longer the supervisor of construction works, but the Drawing tutor. Architectural education was then guided by the academic education of the Beaux-Arts, inspired by the French tradition of classical treatises. The minimum age to enrol in the Academy was 10. Students had to be able to read, write and know basic mathematics (Calado, pp. 99–101).

It was only in 1881 that architectural education in Portugal, received a more specific syllabus, different from the general education of the arts; however, architecture only earned its place in higher education, along with the arts of Painting and Sculpture, in 1957.

2.3 *Escola de Belas Artes, the Beaux-Arts school*

In the early twentieth-century, architectural education was taught as a course, alongside Painting and Sculpture, to selected groups of around 10 students per year (Tainha, 2005).

In 1957, there was a decree (Decreto-Lei,1957) changing the status of the Beaux-Arts education from a general course to a higher education level. Universities did not offer this course. It was today's equivalent of an undergraduate course; thus, in the 1950s, it did not include scientific training. The decree of 1957 included the possibility of creating "centres of study", which were to cooperate with museums and workshops.

The Architectural diploma was obtained after six years of study and a mandatory six-month internship onsite. The Faculty included a mix of lecturers and professors from the Instituto Superior Técnico, an engineering university (Decreto-Lei, 1957).

At this time, Portugal was under a dictatorship, which lasted until 1974; hence, the decree did not fail to include, in the preamble, that schools of Architecture must take into account the 'the natural and ethnical diversity of conditions (…) the popular and erudite references of the metropolis and the overseas empire (…) without losing sight of the fundamental unity of the nation and its traditional mission' (Regulamento das Escolas Superiores de Belas-Artes). The school was framed by the decree of 1957 until 1974, the year of the democratic revolution, which overthrew the dictatorship. The school was then closed for one academic year (1974–1975) and, when it reopened, it started on its path towards technical training, moving away from the arts.

2.4 *Faculdade de Arquitectura da Universidade Técnica de Lisboa, from Beaux-Arts to Technical University*

It was only in 1979, five years after the revolution, that the present-day Faculty of Architecture of the University of Lisbon evolved from being a course taught by Lisbon's Faculty of Beaux-Arts (Escola de Belas Artes de Lisboa) to becoming an autonomous Faculty of Architecture (Decreto-Lei nª498-E/79 de 21 de Dezembro).

The new institution moved away from its beaux-arts tradition to become part of the Technical University of Lisbon. The preamble of the decree, in 1979, underlined the need for an architectural education of a scientific nature given the 'evolution and development of society and the pressure arising from both demographic growth and the concentration of the population in urban areas'. According to the preamble these societal changes demanded constant research seeking 'new solutions' which required 'high scientific training'. This training should 'cooperate with other scientific and technical areas (…) safeguarding the artistic elements' of architectural training.

In 1979, the Faculty offered two five-year graduate degrees, Architecture and Urban Planning, and, for the first time, PhD courses in these areas; however, the clear specification of the curriculum, the system of credits and the abolition of the architecture course from the Beaux-Arts were only stated definitively in 1984. (Portaria n°448 de 9 de Julho). In this Administrative Order, architectural education emerged with a syllabus of 5 years. The first four years were dedicated to generalist training in architecture, and the final year included three specializations: Architecture, Urbanistic Planning, and Renovation and Conservation of Architecture and Urban Areas.

In 1995 (Despacho Reitoral, 1996), there was a Senate decision within the university, introducing new areas within the Faculty of Architecture, namely Design, Fashion Design and Interior Design. The existing specialization in Planning was divided into two areas, Urban Planning and Urban Management.

2.5 *The European Union: the master degree and the rise of scientific training*

In 1999, ministers of education from 29 European countries signed a treaty, the Bologna Declaration, which held as its main goal the establishment of common rules for higher education in the European Union. The aim was to implement these rules by 2010. One of the fundamental tools established was a common European Credit Transfer System (ECTS), promoting the interchangeability of students between member states. (Decreto-Lei n°42/2005).

One of the most important decisions for architecture, in the Bologna process, was the decision to keep training with 4 to 6 years of study; thus, placing mandatory education of architecture at the second cycle level, with an integrated master's curriculum. As defined by Decreto-Lei n°42/2005, first cycle education, today,

refers to undergraduate courses consisting of three years of mandatory enrolment, second cycle to master degrees and third cycle to PhD degrees.

The European Directive of 2005, related to the recognition of professional qualifications in member states, further declared the fundamental contents of architectural training, which must, in all European Universities, be upheld to the present day: 'That training, which must be of university level, and of which architecture is the principal component, must maintain a balance between theoretical and practical aspects of architectural training and guarantee the acquisition of the following knowledge and skills: (a) the ability to create architectural designs that satisfy both aesthetic and technical requirements; (b) adequate knowledge of the history and theories of architecture and the related arts, technologies and human sciences; (c) knowledge of the fine arts as an influence on the quality of architectural design; (d) adequate knowledge of urban design, planning and the skills involved in the planning process; (e) an understanding of the relationship between people and buildings, and between buildings and their environment, and of the need to relate buildings and the spaces between them to human needs and scale; (f) an understanding of the profession of architecture and the role of the architect in society, in particular in preparing briefs that take into account social factors; (g) an understanding of the methods of investigation and preparation of the brief for a design project; (h) an understanding of the structural design and of constructional and engineering problems associated with building design; (i) adequate knowledge of physical problems and technologies and of the function of buildings, so as to provide them with internal conditions of comfort and protection against the climate; (j) the necessary design skills to meet building users' requirements within the constraints imposed by cost factors and building regulations; (k) adequate knowledge of the industries, organizations, regulations and procedures involved in translating design concepts into buildings and integrating plans into overall planning.'

At FAUL, the first syllabus framed by the Bologna Declaration, with a five-year curriculum leading to a master degree, was approved in 2008 (Despacho n°22848/2008) and, since then until the current curriculum of 2013, changes have been made in 2009, 2011, and 2012. These changes focused on fulfilling the requirements laid out by the European Directive, specifically for the specializations in Urban Planning and Urban Management, which were initially not recognized as architectural training by the Directive, due to too many ECTS being dedicated to planning and not enough to architecture. The changes implemented in 2013 focused on providing a common first cycle of study to all courses, followed by two years of three possible specializations: architecture, urbanism and interior design and rehabilitation.

In 2013, the Technical University of Lisbon merged with the University of Lisbon becoming not only the oldest, but also the largest university in Portugal. The Faculty of Architecture is one of the eighteen faculties included in the University of Lisbon. Today, the Faculty of Architecture is no longer framed by the Technical institution created in the 1970s; thus, is free to find its place in between the sciences and the arts.

2.6 *Today's heritage: practice, arts or science?*

This historical development of Lisbon's architectural education, at present day FAUL, gave rise to an ingrained heritage, which can be divided into three components: practice, arts and science. The practice-based education is the heir of the sixteenth-century origin of architectural education in Lisbon. Training through knowledge of the Arts dominated in the nineteenth century with the rise of Liberalism and the influence of French culture. Scientific training emerged at the end of the twentieth century.

The challenges of the present mirror these three poles (practice, arts and science) proving that institutions have a memory which can be forgotten but never erased.

3 CHALLENGES OF THE PRESENT

3.1 *The final project*

One of the main questions, which remains as a source of conflict and debate, is the content of the Final Project. In 1957 (Decreto-Lei 1957, Art. 28), to get the architectural diploma students were required to present a report of the mandatory six-months internship taken within a construction site to a jury of three architects. Today, the internship is no longer a possibility, due to the school's current second cycle regulation.

Those who uphold the practice-based tradition defend that students should end their diploma with a project-based architectural design, or even an internship, as was the case in 1957. The Drawing Department, which makes up a large part of the ECTS credits in the first two years of the syllabus, claims it should be more involved in this final process, reclaiming the school's Beaux-Arts tradition. Professors who are focused on scientific output and research-based work argue that a dissertation abiding by scientific methods and tools is the only possible conclusion to a Master degree.

The most debated change in the current syllabus was the introduction of the possibility of choice for the student. Today, the student can chose to end the diploma with either a dissertation, or an architectural design project. Research-based professors believe progress has been made. Practice-based defenders are currently preparing a proposal, which aims to end this possibility of choice, imposing the mandatory presentation of both an architectural project and a dissertation.

3.2 *A changing academic community*

Long gone are the sixteenth-century days, when one architect was made responsible for the architectural training of groups of three students. Table 1, presenting an evolution in the numbers of students and teachers throughout the past four decades, best shows how

Table 1. Teachers and Students at FAUL.

**** Data provided by the Repartição Académica (Registry) FAUL, as of March 2016.

the architectural community involved in architectural education has changed.

3.2.1 *The teacher: practitioner or researcher?*
The total number of teachers hired by the institution has increased 18 times from the 1970s to today. Two clarifications need to be made regarding the data from the 1970s. The first is that, in the 1970s, the students took some courses in the Faculty of Engineering; hence, the ratio of 1/90 cannot be compared to today's, when students study only at the FAUL faculty. The second is that, in the 1970s, both school and country were in turmoil after the revolution of 1974. The school was closed for one academic year (1974–1975); hence, it is not safe to determine any valid ratio for the 1970s.

In 1979, the Faculty included 38 people: one full professor, 36 assistants, and one intern assistant. Of the 38 members of Faculty, only 5 held a PhD. Given the very few people with a degree, regulations allowed the Dean to choose personalities who might be 'qualified for any of the positions in the Academic structure' (Decretolei, 1979).

One verifiable conclusion is that the academic community hired by the institution, from the 1970s to today, increased and changed its profile from mostly practitioners (7 out of 9) to mostly Doctors of Philosophy (130 out of 163). Most of the Doctors of Philosophy who are architects either practice architecture or have practiced in the past; however, a considerable portion of their time has been devoted to research. The Faculty further includes painters, historians, economists, social scientists, engineers and geographers, providing a diverse faculty that meets the European Directive's 11-point requirement.

The reality of today is that architects, with a thriving practice, are a minority within the permanent members of the Faculty, as most of the practicing architects invited to be professors make a valuable contribution, but have little say on the scientific council's decisions; hence, little influence on the future of training and research in architecture.

This has been a fundamental change that has had both positive and negative aspects. On the one hand, losing experienced practitioners carries the risk of having an academic body out-of-touch with the reality of architectural practice; on the other hand, having a strong research component in diverse fields, such as computing or sustainable design, can open new fields of specialization, which might lead to emerging possibilities within the practice of architecture. These emerging fields within research are particularly important in the current times of economic recession that potentially shrink an architects' career possibility.

FAUL's current policy has been to keep hiring, as invited professors, architects with a thriving practice, recognized both nationally and internationally; thus including, within its community, the best of both worlds, practice and research.

3.2.2 *A changing community of students*
The number of students, from the 1970s to the present, has increased by threefold, and the tendency of the past couple of years has been an increase, despite the shrinking demand for architects due to the economic crisis of the past years.

One of the main reasons is an increase in the community of international students, as can be seen in Figure 1, showing the countries of origin of incoming students, from the 1980s to the present. The present-day community of students has little to do with the 10 students enrolled in the early 1930s in architectural training and it raises many challenges, the most important of which is the ability to provide a common ground to train a community of students with not only different languages, but also diverse cultural and technical backgrounds.

The PhD student body has also increased, from 0 students in the 1990s to 156 students enrolled today. The growing research community, along with the growing internationalization of the institution, are the most important changes in this academic community, creating challenges, forcing the institution to adapt, and at the same time providing opportunities, through widening the scope of the research and of cultural diversity.

4 CONCLUSIONS

This paper aimed to identify the challenges today's Faculty of Architecture of the University of Lisbon faces in the midst of a changing academic community, which is evermore international and research-based. Answers to these challenges are not simple, as they have not been met before.

The historical development of Lisbon's architectural education gave rise to an ingrained heritage, which, we believe, can be divided into three components: practice, arts and science. The practice-based education is the heir of the sixteenth-century origin of architectural education in Lisbon. Training through knowledge of the Arts dominated in the nineteenth century with the rise of Liberalism and the influence of French culture. Scientific training emerged at the end of the twentieth century. Today, most of the conflicting debates still revolve around these three different perspectives.

The one conclusion, which can be drawn, is that architectural education will not move forward if the academic community ignores the changes of the present, but it will certainly fail if it chooses to forget the changes of the past.

Renaturalizing urban campus case study: integrated-design, placemaking, and ecology

A. Kamal
The University of Texas at San Antonio, San Antonio, Texas, USA

ABSTRACT: Pollutants from nonpoint sources increase with urbanization and urban sprawl due to the intensification of the amount of land covered with impervious surfaces (e.g. roofs, roads, and parking lots). Research confirms that when chemical pollutants accumulate on these surfaces and transmit to the groundwater during rain events, they could cause different types of chronic and acute illnesses to people through drinking water. With funding from two agencies, this paper introduces Low Impact Development (LID), an intertwined ecological landscape and site design technique, for stormwater management practices developed as a crucial tool to mitigate these impacts of urbanization. Utilizing the principles of contemporary urbanism, placemaking, and multilayered landscaping, multidisciplinary teams of Architecture and Civil and Environmental Engineering students applied an integrated-design framework to renaturalize an urban campus's open spaces through a series of LID techniques, and to provide a prototype system for adoption by local and state regulatory agencies.

1 DESIGN FOR ECOLOGICAL URBANISM

1.1 *Green infrastructure*

Contamination of surface water and groundwater is caused by two sources of pollution known as point and nonpoint. The United States Environmental Protection Agency (USEPA) defines point source as those from which pollutants are discharged, such as a pipe, ditch, ship or factory smokestack. On the other hand, nonpoint sources of water contamination are the most significant, particularly as pollution from these sources increases with urbanization and urban sprawl (USEPA, 2015a). This increase is due to impervious surfaces such as roofs, roads, and parking lots. With the expansion of the amount of land covers, the likelihood of accumulation of chemical pollutants on these surfaces and the transmission of pollutants to groundwater during rain events enhance (Gaffield et al., 2003). As a result, symptoms of different types of chronic and acute illnesses are developed among the people who drink from the water. In order to reduce the negative impacts of nonpoint sources on water contamination, Green infrastructure (GI) site configuration that mimics pre-developed land characteristics has successfully been implemented in emerging urbanized areas. GI is a set of an intertwined ecological landscape and site design practices for stormwater management. Within urban and city territories, this approach utilizes tools known as Low Impact Development (LID) practices.

LID eliminates or reduces pollutant loadings through filtering the pollutants and reducing the quantity of storwater runoff in the areas adjacent to contamination sources. LID techniques, see figure 1, include rain gardens, vegetated swales, pervious pavement, and green roofs. Each is restricted by a set of landscaping and site characteristics to efficiently manage rainfall through reiterating the natural process (USEPA, 2015b and USEPA, 2015c). When properly designed, LID practices capture water on site, filter it through vegetation, and penetrate it into the soil layers and recharge groundwater reservoir.

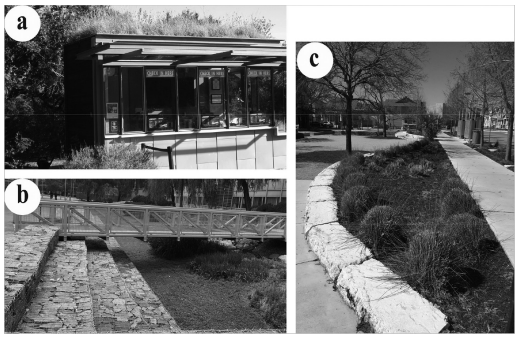

Figure 1. Examples of LID practices: a) green roof of ticket booth at LBJ Wildflower Center, Austin, TX; b) vegetated swale at MIT campus, Cambridge, MA; and c) rain garden at Mueller community, Austin, TX.

1.2 *Sustainability and water management*

Through multi-complex and diverse layers, our ecologies collectively inform the design of our urban and urbanizing landscapes. According to Waldheim

(2006), landscape design is a synthetic phenomenon that offers more than just the manipulation of a physical surface. It also serves as a medium of construction and interaction. Dealing with sites and their context goes beyond their physical components of the ground plane, and extends to embrace socio-cultural, political, and economic dynamics of landscape, as well as new infrastructure typologies. Multilayered landscape is also evident due to the complexity of physical and non-physical issues it responds to, and therefore it requires a multifocal perspective that entails both culture and nature to intertwine throughout the metropolitan landscape.

The emerging need for sustainable landscape and resilient design not only maintains the performance and condition of infrastructure systems, but allows them to recover from disturbance and to tolerate climate change, all of which are factors contributing to the complexity of landscape and contemporary urbanism. Therefore, resilient, adaptive, and thus sustainable site designs that mix economic, ecological, health, and cultural vitality needs to be further examined. Agencies concerned with sustainable sites and resilient infrastructure have developed various programs to assess sites and/or communities based on sustainability credit systems. This paper focuses on one program, known as STARS.

1.3 *STARS plan*

Throughout North American higher education campuses, administrators are rethinking their resources use to reduce costs and -at the same time- improve the environmental performance and campus resiliency through various policies including water conservation programs (Mascarelli, 2009; and Jackson-Smith et al., 2009). These policies aim to raise awareness about sustainability, as well as promote and advance the institution's role as exemplar in the society (Creighton, 1999; Leal Filho, 2009).

The Higher Education Associations Sustainability Consortium (HEASC) organized the policies into a plan for a campus sustainability rating system in 2006. The program, a Sustainability Tracking, Assessment & Rating System (STARS), encompasses benchmark comparisons provided –via collaborative efforts- by all participating departments. STARS materializes through a track, measure, and self-report framework for both long-term sustainability goals in already high-achieving institutions, and for institutions that are taking first steps toward sustainability, eager to secure entry points of recognition.

STARS covers all facets of campus sustainability including health, social, economic, and ecological issues. It expands to all functions of the campus including curriculum, facilities, operations, and engagement with communities. To increase the credit attained in the STARS academic category, the author developed various metrics for the research and curriculum components.

2 INTELLECTUAL OUTREACH MODEL

2.1 *Research-centered studios*

The format of the research-centered studio combines scholarship with learning outcomes, which is adopted by different schools of architecture in North America (Chodikoff, 2004, Hinson, 2007, and Douvlou, 2006). The studio vividly integrates structured methodology for attaining specific research goals with a foundation of practice. Diamond (2002) explained the distinction between regular studio and research studio as the way the latter is likely to focus on activities for organizing and documenting all studio stages. The studio procedures control over various variables, and maintain a reliable method of inquiry. It also entails a systematic review and an assessment of the work produced by several discipline-based experts (Diamond, 2002). The research-centered studio supplements orthodox components of the studio (i.e. design decisions, reviews of best practices, and regular critiques) with intensive research of publications examining similar design problems, reliable data, and avenues of dissemination of outcomes in research professional venues. In his article in the National Academy for Academic Leadership, Diamond (2002) also argued that rigorous scholarly research can be conducted in the studio setting (i.e. classroom, laboratory, and community).

Research that looked at the results of different models of research-studio teaching (Symes and Seidel, 2001) found that the young architects who graduated with this learning experience continue to benefit from the knowledge they acquired and the skills they developed through this focus on research and pragmatic thinking. The author argued that studio curriculum should be centered on developing the imagination and creativity, unlike in practice where the emphasis is on the application of knowledge to serve the client.

Short's (2008) study, nevertheless, discussed the limitations of research-studio models as a result of lacking the capacity to manage design research and the shortage of academic resources including research-trained professors. The structured and intensively controlled setting for research-studio curriculum encompass working with various organizations and partners within and outside the academic institution. As a case study, this paper is based on a studio that supports state policy and promotes Low Impact Development techniques as a public interest issue. The author taught the studio in fall 2015.

2.2 *Public interest and policy*

State, regional and local regulations in Texas' Edwards Aquifer Region deal primarily with allocating water use. Water quality standards are managed by two agencies: San Antonio Water System (SAWS) and Texas Commission on Environmental Quality (TCEQ). Both agencies offer two separate records of locations of structured engineering systems designed for treating pollution from nonpoint sources. According to SAWS' 2015 records, there are 141 noncompliant structures

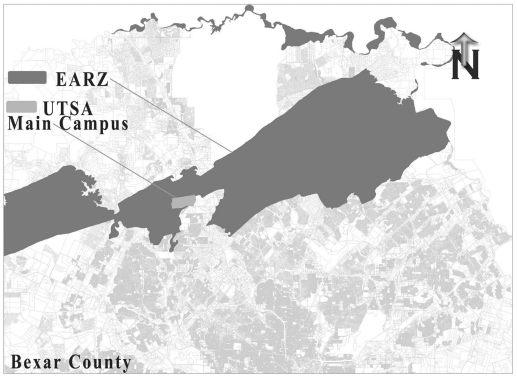

Figure 2. Campus location on the Edwards Aquifer Recharge Zone (EARZ), and Bexar County, Texas.

over the Edwards Aquifer Recharge Zone (EARZ) in Bexar County alone, shown in figure 2. Noncompliance is due to existing problems of clogging, unsustainable maintenance, and accumulated debris and litter. A County-wide public interest in changing the design, maintenance, and operation regulations created pressure on various local and regional agencies. Collaborative efforts resulted in a tendency to adopt LID techniques (GEAA, 2014) and to fund the exploratory designs in the author-led research-intensive studio.

The studio integrated a multidisciplinary framework of research, design, and community outreach and was structured around individual and teamwork expectations discussed in the orthodox models of (Diamond, 2002; Douvlou, 2006; and Hinson, 2007). The studio developed students' skills in dealing with real-world complex design problems, and focused on understanding LID practices, implementing ecological landscape, and manipulating different water management scenarios. Existing engineered-structures for water treatment located on the main campus of the University of Texas at San Antonio on the EARZ were the proposed sites that the agencies have been exploring for a pilot project. The sites were identified for exploring potential implementation of a series of LID practices to replace the dysfunctional, poorly engineered structures, known as San Filters. All developments in that area are sensitive and are potential causes of water contamination due to their location on the EARZ. Rain gardens, swales, pervious pavements, and green roofs are some of the proposed components of LID practices for the campus site.

2.3 *Multidisciplinary framework*

Building on Waldheim's (2006) premise of multilayered landscape and utilizing green infrastructure benefits discussed in the Center for Neighborhood Technology's report (CNT, 2010), three teams of architecture (ARC) seniors and juniors collaborated with three graduate and undergraduate Civil and Environmental Engineering students (CEE) in ARC 4156 studio. The goal of this collaboration was to exchange expertise among the team members to advance the research foundation for this studio. The teams therefore aimed to evaluate site characteristics of five existing, dysfunctional and poorly engineered, systems build a digital simulation model for hydrology and environmental performance, assess the number and location of LID sites, and design these sites according to standardized LID criteria. An overarching goal of the project was to identify locations where outdoor event places would complement LID practices and enhance the STARS sustainability score. The pedagogy was structured to reach these goals. It was designed around a framework that includes benchmarks for different tasks in addition to a set of developed skills through engaging students in various formats of work configurations and expectations. Tasks transitioned between research, creative inquiry, and design. Consequently, the acquired skills and development were intended to build preliminary skills such as basic literature review and best practices analyses. Gradually, students would develop advanced skills at the final studio delivery in a learning curve with incremental levels of increased complexity. Acquired skills were independently measured using different metrics (see Table 2) and based in how the teams responded to the following tasks:

1) Identifying the university campus as a pilot study for future regional replication;
2) Selecting different typologies for incorporation into LID series;
3) Analyzing natural hydrology and terrain;
4) Reviewing possible credits for campus Sustainability Tracking, Assessment & Rating System (STARS), developed by the Higher Education Associations Sustainability Consortium (HEASC, 2006);
5) Developing the program and integrated-design of LID proxies;
6) Quantifying the total ecological, economic and social benefits of a selected proposal; and
7) Proposed enhanced visual representations of the framework to advance campus and community awareness about the practices and benefits of LID in the regions with endangered sources of water supply.

3 INTEGRATED DESIGN APPROACH

3.1 *Pedagogical structure*

This upper level –vertical– studio that focused on examining LID techniques for the University's main campus included 13 senior students. Students enrolled in this studio with them technical skills attained through pre-requisite courses such as structure and building technology. The process of intervention in the existing sites focused on exploring available open spaces within the central campus zone; developing data-driven and measurable section criteria, including site characteristics and pollutants loading. Sites

were shortlisted, and two final sites were advanced for design iterations of a series of LID practices. In each of the two proposed sites, individual students were also responsible for designing a light-structure that would host various events to promote social and cultural sustainability. The following phases, see also figure 3, explains further details about the study:

Phase I (LID Design Research), stimulated students critical thinking through working in small research teams -four to five students each- to explore GI typologies, create a catalog for native plants, conduct intensive site analysis, and develop a preliminary LID proposal. This phase triggered students' curiosity, challenged their understanding of ecological urbanism, and created a work environment for collaboration and exchange of ideas.

Phase II (Sustainable Edifice), focused on measuring individual design skills, independent problem-solving challenge through integrating technology and innovation in tectonic and design concepts of eco-friendly edifice for outdoor activities.

Phase III (Assessment and Performance) entailed environmental, social, community, health, and aesthetic benefits to the campus and users. Students also developed a list of possible STARS credit using HEASC, v2 (2006) metrics that could be attained upon implementation of LID techniques.

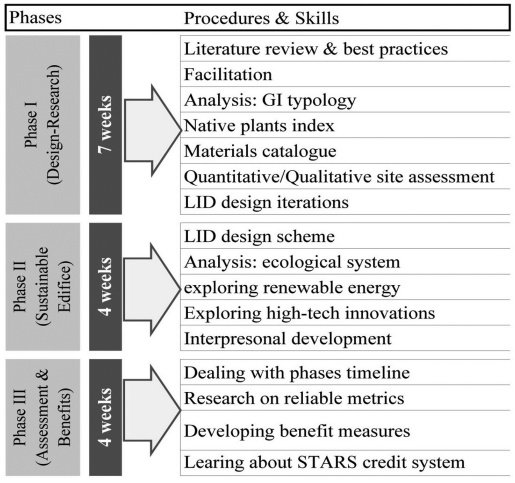

Figure 3. Pedagogical Structure and skills set.

3.2 *Design negotiation & collaboration*

The 13 students chose their teammates, forming three teams. After a thorough review of literature on LID specification, and site requirements, each team conducted a comprehensive site assessment for the UTSA main campus, and identified one of the five existing water treatment basins to be re-designed. Scholarly evidence backed their analysis of hydrology, topography, catchment area, social, environmental, economic, and built environment attributes (LaGro, 2001, and McElvaney, 20112). Two basins -Water Quality Basin B (WQB-B), and Water Quality Basin D (WQB-D) – met the selection criteria, and therefore were selected by the teams (see figure 4).

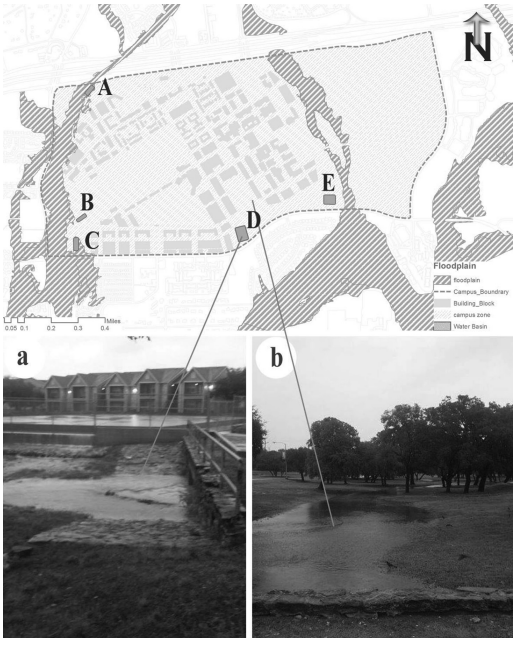

Figure 4. Water quality basins (A, B, C, D, and E) in the UTSA campus, and views of a) WQB-D after intensive rain event, and b) flooded swale near WQB-D.

The teams proposed three design iterations, one for WQB-B and two for WQB-D and their adjacent open spaces. ARC and CEE students negotiated between themselves to develop design concepts, programming, water conservation estimates, and hydrology/ infiltration models for each basin.

Members from each discipline (ARC and CEE) highlighted the following as design goals and worked together to achieve them: site sustainability, project feasibility, and maximized campus benefits, water treatment and conservation, and design aesthetic.

A multidisciplinary approach for design, through organized meetings between ARC and CEE students and faculty advisors from the two departments developed confidence and furnished a trajectory for negotiating design iterations for edifices for events and placemaking, green components, renewable energy, tectonics, water conservation, xeriscaping, plant selection, materials selection, LID series, treatment train (TT) technique, and site terracing (Barret, 2005 and GEAA, 2014). In phase I, the teams developed design concepts according to strict site requirements identified from reviewing best practices. They based their designs on the following criteria: 1) achieving high water quality through infiltrating 80% of stormwater into the EARZ without jeopardizing aesthetics and other design goals; 2) a maximum of five-acres for a catchment area; 3) a proximity to academic core and

high-traffic nodes and routes; 3) a maximum slope of 15% for LID feature, and 1:3 (vertical: horizontal) for riparian land; 4) spatial distribution of multiple cisterns for water harvesting; 5) reuse of 300,000 gallons of air conditioning condensate -reclaimed from existing Engineering and Science building- for irrigation.

As part of the protocol assigned to students, the instructor of this studio imposed professional role play. Each team was required to elect a coordinator who would manage everyday work, facilitate tasks overlapping with the CEE team, and discuss major procedural updates with the instructor. The process helped the teams build interpersonal skills, accountability, and control over time management.

Instruction methods and the nature of student involvement varied throughout the semester. A collaborative work environment furnished a milieu for reflection on students' own perspectives on the facts retrieved from research, and improved innovative skills and creativity when linking facts with real-world best practices analyses as well as site constraints in Phase I (see figure 3). Developing individual accountability was a transformative experience that prepared students for the job market. This was measured by assigning parts of the analysis to each team member, observing each student while discussing research and assessment tools with teammates, and consulting the overall goals and outcomes of the research among team members.

In Phase II, an autonomous design proposal was undertaken by each individual in the three teams. Students utilized data acquired from Phase I to define an event, for which discussions over placemaking were brought about during studio critique. Students focused the design work on exploring different sustainable light-structure for the edifices. Space functions and events programming was at students' discretion, yet an all-inclusive and coordinated program for the entire team was encouraged. Place definition was utilized to redesign outdoor spaces. The phenomenology of defining a place comprised a complex, scientific, and multidisciplinary approach that intersects various viewpoints. It also addresses the interrelationships between multiple disciplines (Castello, 2010). In these disciplines, place varies widely from a physical-territorial approach in which a place by itself is the gathering of separate elements, to a psychological interpretation where events could be encouraged, or discouraged. Place has also been described through architectural and urbanism interpretation, or anthropological interpretation (Castello, 2010; and Malpas, 2006). Events are largely manifested as happening and as gathering/belonging.

Places created by students incorporated interactive and high-tech events that support academic programs and extracurricular activities. Proposed events also expanded instruction activities to the outdoor environment, and enhanced engagement in campus life, student-led activities, and promoted interaction between campus and contiguous communities. Events varied by time of occurrence, duration, location, serenity, and involvement. Examples included: meditation, class instruction, group study, reading, eating, art performance, exhibits, walking, sitting, sports, recruiting, advertising, and selling fresh produce.

	Research	AC9: Academic Research
Operations (OP)	Grounds	OP10: Landscape management
	Water	OP27: Water management

Source: Based on HEASC (2006).

Phase III synthesized the knowledge developed in phases I and II through developing assessment tool for the performance and benefits of the design work produced. Scientific metrics from literature were used to assess water management and conservation, LID social and environmental benefits, sustainability credits attained through STARS plan, and plant selection benefits. A strong partnership with the funding agencies, the UTSA office of facility planning, and different organizations and the programs, strengthened the feasibility of the produced design as well as the reliability of the assessment metrics (see Figure 5). Partnering organizations encompassed a multidisciplinary team of experts including LID policy makers, practicing architects, and faculty members as well as landscape architect, environmental planner, water management professional, university administrators, and urban designer.

3.3 *Design quantification & data*

Data used in this studio comprised existing maps and reports on the university's master plan, and Geographic Information System (GIS) digitized features (i.e. trees, entrances, roads, transportation routes, etc.). Students created 3D data visualization models using existing data and maps, integrating 25-year growth projections for the campus.

Developed models were used to examine LID techniques and to eliminate floodplain areas. Building on the research of LID typologies and nationwide best practices, Phase III challenged the team to quantify the performance and benefits using scientific metrics. The students adopted two methods of quantification: first, an assessment of possible STARS credit that could be attained upon the implementation of LID features; second, a quantitative analysis of water management. STARS credits were estimated to increase in two categories: Academic (AC), including curriculum and research; and Operations (OP) including groundwater management (see table 1). Assessment of water management performance yielded 1) the count, location, and area of rain gardens, surfaces, and swales required to achieve an 80% water treatment during intensive rain events; 2) volume and count of water harvesting cisterns that would store stormwater and would enhance design quality and aesthetic; and 3) environmental benefits of the edifices around LID proposals for WQB-B and WQB-D.

Assessment of students' development and learning outcomes throughout the studio were quantified using metrics for review benchmarks throughout the three primary phases of the project. Metrics were developed using reliable rubrics associated with measures of deep-learning (Bain, 2004). Measures focused on evaluating students' progress, creativity, self-motivation, facilitation, accountability, and communication with teammates.

4 RESULTS AND CONCLUSION

This paper reviewed the procedures and challenges of a real-world design studio for the upper level undergraduate students taught by the author. The studio challenged students' traditional learning styles with a profession-based format that sought experiential and evidence-based design solutions to a multilayered design problem of dysfunctional water treatment sites. Approaches to tackle design problem were transformative for students through enhancing their technical, creative, quantitative, engagement and team-work skills. Design solutions for LID proposals, see figure 6, emerged by different configurations of team/individual mechanisms that forged facilitation, negotiation, and performance measures. Results of this collaboration produced three projects, each focused on improving water quality through LID techniques, embracing an ecological landscape through xeriscaping and natural plants, and enhancing placemaking for educational, extracurricular, and community event. Improvement of campus life was considered to be the most significant economic and social benefit for the university that would be achieved through a number of multi-purpose edifices designed around LID features for WQB-B and WQB-D. These edifices aimed to enhance instructional spaces and raise student awareness of sustainability and water management.

The two proposed LID designs (WQB-B and WQB-D) were redesigned by three multidisciplinary teams of ARC and CEE students. Design iterations, programming, and hydrology model for each basin were examined through virtual and simulated models. Proposed designs will advance water conservation on the UTSA campus, in addition to incorporate local and affordable materials. A series of rain gardens, bio swales, water harvesting systems; terracing, and pervious surfaces composed the proposed treatment train (TT) of the stormwater management system.

The research studio format channeled student work through a systematic development of the design framework. Through the process, students gained technical skills and learned about the benefits and efficiency of combining LID typologies. The results of this process addressed the challenges and policy barriers for higher education institutions in integrating LID techniques; and discussed the pedagogical and learning outcomes of the multidisciplinary learning. The process also revealed the need for creating metrics for LID benefits because of the lack of such metrics.

Proposed LID designs for existing water treatment sites (WQB-B and WQB-D) located in the UTSA main campus promote ecological and water-conservation landscape, enhance the quality of spaces for various redefined events; and support campus sustainability through increasing STARS scores. They also serve as an open outdoor learning laboratory for future multidisciplinary courses on sustainability and water conservation that the university campuses should implement, which would raise awareness of the benefits of using native and drought-tolerant plants

that conserve water and enhances water infiltration through various LID-design techniques. The proposed designs enhance the visual quality of the campus landscape, promote easy and frequent maintenance of stormwater infiltration structures, facilitate water collections for irrigation, and create a natural environment for social and educational events. The results inform future research and practices regarding necessary metrics as well as multidisciplinary collaboration in the study of urban sustainability, ecological landscape, and applications of LID practices. Funding agencies sponsoring this studio and the broader research aim to utilize the design schemes and metrics developed in this studio for site selection processes by local communities and neighborhoods, and to facilitate LID-design guidelines on the EARZ through state regulations.

The results of this paper raise the awareness of future professionals who will be engaged in projects related to sustainability through pollution prevention from nonpoint sources, and managing stormwater runoff in areas with groundwater and surface water streams. The paper paves the way for future professionals with methodological approaches for LID design tools, a commonly emerging practice in site design and water treatment policy across North America. It also provides educators, curriculum developers, and university administrators with tools to support the curriculum that could, in turn, be counted towards the academic credit for the university's STARS score.

ACKNOWLEDGEMENT

The author would like to thank the two funding agencies for sponsoring the studio and the broader research: Edwards Aquifer Authority (EAA), and San Antonio River Authority (SARA). The author would also like to thank the Greater Edwards Aquifer Alliance (GEAA) for supporting and facilitating the funds. Finally, the author acknowledges the remarkable effort and hard work, and dedication of all the students, from Architecture, and Civil and Environmental Engineering departments, who participated in this successful studio in fall 2015.
