VOLUME 1

Changing society – In transit-global migration – Renaturalization of the city

Changing society

Urban transformation

Change agents in urban transformation: The case of Helsinki 3
M. Louekari

Urban regeneration of former industrial cities. A cure or a curse? The case of Ancoats conservation area in Manchester, England 11
T. Chatzi Rodopoulou & J. Hunt

Transporting transformations: A case study of built environment changed by transportation in rural China 19
X. Lin, B. Jia & M. Zhou

Emerging patterns of change for tomorrow's cities 27
D.P. Henriques

Transformation of Chinese traditional mountain village in contemporary era: The study case of Tangdu Village in Guizhou Province 33
Q. Du

Smart solutions in urban development: The medium-sized cities of Bydgoszcz and Rzeszow, Poland 41
O. Gazińska

Africa: The urban challenge 47
F. Ronco & A. Perino

Adaptable structures for emerging socio-cultural changes in Africa 55
D. Donath, B. Rudolf & A. Haile

Temporary commercial spaces: Celebrating the 'right to the city' 63
A. Allegri

South Africa's new challenges: Planning inclusive connection spaces 69
M. Bodino

Smartphone application for long-term urban lifestyle and mobility monitoring 77
L. Sobková & H.H. Achten

Neighborhood design and children's active travel to/from school 81
J.S. Lee, R. Moore & O. Demir

The experimental project of spread “social housing” of Real Estate Fund Ca’ Granda. Construction of a synthetic index for the implementation of the mobility plan 87
M. Borghi, G. Ferri & A.S. Pavesi

Public space and the contemporary city

Austerity, subverted 95
C. Chatzichristou & G. Makridis

The Guggenheim effect and failed public investment in architecture 101
M. Baptista-Bastos & A. Lau

The “Iron Curtain” as urban observatory of the contemporary social contradictions 107
C. Toscani

The social [il]logic of [sub]urban exodus: The rise and fall of Nasr City and the evolution of the Egyptian middle class 113
A. elBahrawy

Social and political agency of architecture: Performativity and the contemporary global city 121
J. Vela Castillo & M.O. del Santo Mora

Twin cities as urban laboratory of the contemporary social contradictions 129
C. Toscani

Lines, pipelines, and the contested space of transcontinental fossil fuel transport 135
E.E. Moore & I.M. Volynets

Unknown knowns of architecture: Reconstitution of vitality in Boston City Hall Plaza 141
E. Sheikholharam

Indian (public) spaces. Transitions and cycles 149
G. Setti

The squares in Portugal inventory and the creation of contemporary spaces 155
C.D. Coelho, S.B. Proença & S.P. Fernandes

Evaluating sense of community in the public spaces of residential neighborhoods in Tehran, Iran 161
H.H. Molana

The new roof spaces. The legacy of Le Corbusier in the contemporary city 169
A. Como & L. Smeragliuolo Perrotta

Sustainable habitat

NmeeTon: Self-sustainable habitat for new social challenges 179
E. Aparo, L. Soares & M. Ribeiro

Real estate, residency, design and sustainability: Reconsidering innovation and efficacy in development 187
S. Rajan & B.R. Sinclair

Shell performativity as a tool for urban action 195
S. Vyzoviti

Machinic approaches_new methodologies for responsive environments 201
B. Uçar

T.E.S.S. – An interactive sustainability lab 207
D.A. Kratzer

Rethinking heritage

Life-cycle assessment of historical building reuse: Is the existing building the greenest building? 217
M. Hu

Culture, context + environmental design: Reconsidering vernacular in modern Islamic urbanism 223
S. bin Zayyad & B.R. Sinclair

Beyond the passage: Analytical probe into the emancipatory potential of space 231
D. Ćorović & M. Milinković

Sustainability and design in heritage rehabilitation 239
A.P. Pinheiro

From monument to embodiment: A social case for a more expansive representational strategy for architectural heritage 247
S. Erdoğan Ford

Participation, social changes and inclusive design

Towards an adaptive urbanism beyond hard control: The theories of Johnson and Lefebvre 257
N. Abbasabadi & M. Ashayeri Jahan Khanemloo

IEP sites: Combining planning tools to address planning uncertainty 263
M. Bylemans, N. Vallet & M. Van Acker

Social challenges meet architecture – from participation to digital fabrication 271
S. Neves & A. Paio

Lifelong learning in the context of socialization and sustainable development 279
H. Melkonyan, O. Turchanina & A. Castelbranco

Measuring urban ageing. Città Giardino Torino: A resilient archipelago for the elderly 285
D. Vero & B. Giardino

Social sustainability in urban context: Concepts, definitions, and principles 293
A. Mehan & F. Soflaei

Mind the GAPs: Are urban planners defined by generational mindsets? 301
M. Del C. Vera

Red light at night to enhance cognitive functioning for society's special needs groups 307
E.V. Ellis, D.L. McEachron, E.W. Gonzalez & D.A. Kratzer

Classroom design for children on the autistic spectrum 315
A. Mokhov & E.H. Steinfeld

The impact of patient room design on airborne hospital-acquired infections 323
A. Copeland & A. Sharag-Eldin

Housing

Quality of life by design: Study of space usage for affordable housing in Harbin, China 331
M. Wang, H. Mei & X. Zhu

Permanence to allow change. The archetypal room: The persistence of the 4 × 4 room 339
G. Ledent

Versions of collectivity in housing architecture: From the modern to the post-human 345
C. Pantelidou

A more versatile and adaptable dwelling, for a changing society 353
H. Farias

Dutch experiment in co-creation in a collectively commissioned housing project 361
T.T. Veeger & S.J.E. Maussen

The sun for all: Social equity and the debate on best solar orientation of high modernist housing 367
U. Poerschke

Neighbourhoods with single-family houses growing old 375
H. Müller

Dwelling and family diversity: Analysis of housing units and households in Lisbon 383
A.S. Moreira & H. Farias

Equality of energy efficiency for low-income housing in the Mississippi Delta 389
E.M. McGlohn & E. Roush-Elliott

Housing of prime social need – Polish traditions of socially engaged architecture 397
N. Przesmycka

In transit-global migration

Vietnamese workforce housing research and design 405
D. Rockwood & T. Duc Quang

Knowledge management in post-disaster resettlement housing 413
B. Ballinger & K.D. Silva

Jewish neighbourhoods in prewar Poland – an attempt at typology 425
M. Hanzl

Refugee shelter: Cheap, fast, lightweight and sustainable 433
O. Chamel

"Hospitality now!" from meeting migrant needs to rethinking contemporary urban dwelling. A critical review of two studio experiments 439
J. Kent Fitzsimons

Integration of Turkish migrants in Germany: A case study in polarities 447
İ. Öz & A. Staub

Architecture "with the other 90%" – An African story 455
M.L. Khoury

Regeneration of barrack complexes as means to sustainable development 463
M.M. Rudnicka-Bogusz

Lisbon and Brasilia: Cities and cultural facilities in the face of globalization 471
S. Guimarães, R. de Castro Almeida & P. Pereira

Renaturalization of the city

Concepts

Toward a sustainable city-territory in a diffused context: The potential of internal limits 479
G. Vanneste

Imbricate ecologies: Rethinking the city-nature relational challenge 487
W. Mansour

Urban biophilic environments-a novel lexicon for trans-disciplinary practice 495
D.S. Nicholas, R. Truoncgao, W. Char & S. Anandan

Out in the open 501
S. Morgado

From structures to landscapes – towards re-conceptualization of the urban condition 509
L. Nyka

Sustainable environment

Transdisciplinary design framework and a NZE future for the city 519
C.C. Bodurow

Regenerative design for achieving net-zero energy commercial buildings in different climate types 527
A. Aksamija & Y. Wang

Tall buildings, high expectations, towering responsibilities: Critically considering skyscrapers, urbanism and sustainability 535
F. Alotaibi & B.R. Sinclair

Sustainable design and performance of architecture and landscape architecture in urban areas 543
C. Albrecht & U. Poerschke

An autopsy of an environmental tragedy: 1995 Chicago heat wave 551
A. Sharag-Eldin, K. Atchison, C.B. Heller, S. Gharehgozlou, H. Haji Molana & W. Lucak

Waterfront, urban and landscape design

The people's park: A study of the relationship between design and conviviality in Superkilen 561
M. Beltran-Rodriguez & M. Simon

Evidence-based design of outdoor learning spaces in winter: Behavioral mapping in a 'Forest School' 567
A. Rout & P. Galpern

Re-naturalization of post-war housing estates in Poland. The value of residential green space 575
E. Przesmycka & Z. Napieralska

Industrial ruins. A re-cycling approach in researches for dismissed areas 581
A. Massarente

The ripple effect: How saving Yamuna river will save Delhi 589
G.I.S. Keith

Bartram's bringing boating back: Reviving Philadelphia's Schuylkill River 597
E.V. Ellis

Learning from ancient Anatolia: Strategies of naturalization in metropolitan Istanbul 605
T. Frank

A city for the eyes of the future – children's visions of the city 613
R. Pelayo, P. Leal & I. Machado

A bio-socio integrative approach for future development of waterbodies in Alexandria 619
R.E. Abdel Galil

Bottom-up initiatives and urban acupuncture

Urban acupuncture as a tool for today's re-naturalization of the city: The non-constructible parcels of municipal Beirut through the case study of the Saifi district 629
D.R. Aouad

Neighborhood regeneration and vulnerable youth engagement through micro-level gardening interventions 637
L.M. Farah, C. Li & B. Tardif

Constructing urban habitats: Investigating the ecological potential of integrating natural environments into buildings and landscapes in urban areas 643
G. Mangone

Camouflage: Design innovation for "Grey Infrastructures" in the city of the future 651
O.E. Bellini

Green infrastructure in New York City: Top down and bottom up initiatives to improve environmental quality 659
K. Perini

Foreword

EAAE/ARCC International Conferences

The EAAE/ARCC International Conferences are held under the aegis of the EAAE (European Association for Architectural Education) and of the ARCC (Architectural Research Centers Consortium). The conferences are organized every other year, in collaboration with one of the member schools / universities of those associations, either in North America or in Europe.

The EAAE/ARCC Conferences began at the North Carolina State University College of Design, Raleigh / 1998 with a conference on Research in Design Education; followed by conferences in Paris / 2000, Montreal / 2002, Dublin / 2004, Philadelphia / 2006, Copenhagen / 2008, Washington / 2010, Milan / 2012, Honolulu / 2014 and Lisbon / 2016.

The conference discussions focus on research experiences in the field of architecture and architectural education, providing a critical forum for the dissemination and engagement of current ideas from around the world.

The issues are progressively refined and detailed, always open to general issues and the international dimension is expanding with a growing presence of researchers from other continents, what has been occurring since Copenhagen / 2008, with scholars and teachers from Australia, Africa or the Far East.

EAAE/ARCC International Conference – Lisbon 2016

Following an application process, the proposal of the FAUL (Faculty of Architecture of the University of Lisbon) for the hosting and organizing of the EAAE/ARCC International Conference 2016, in Lisbon, was accepted by the EAAE Council, during the Meeting in Prague (January 2014) and launched during the EAAE/ARCC International Conference – Honolulu 2014.

FAUL represents the newest link in an institutional chain, related to architectural teaching in Portugal, founded in the XVIth century with the "Paços da Ribeira Architecture Class". We regard 1881 as a critical year, when, through the creation of the "Civil Architecture Course of the Royal Academy of Fine Arts of Lisbon", the public teaching of architecture began, later followed by the establishment of the "Fine Arts High School of Lisbon".

In 1979, the Faculty of Architecture of the Technical University of Lisbon (FAUTL) was created, by the integration of the Department of Architecture of the Fine Arts High School of Lisbon, into the university. With the fusion of Technical University of Lisbon with the (classical) University of Lisbon, in 2012, renamed as FAUL, our faculty become an organic unit of the renewed University of Lisbon (∼45.000 students) – the aim is the construction of a powerful research university, engaged with education, innovation and technology transfer, focused on people, where the value of knowledge, merit and participation is raised and which is engaged with Portuguese society and the Lisbon region, but also with European dimension and open to the world.

According to the EAAE/ARCC International Conferences principles, the 10th edition/Lisbon 2016 whose theme was "Architectural Research Addressing Societal Challenges", was attended by architects, professors, researchers and students from all over the world. Overall there were about 280 participants and 182 accepted paper submissions, representing 107 universities, 33 countries and 5 continents, so enlarging the geographic reach and strengthening the potential of these conferences.

More than numbers, the scientific and social qualities of the event were also recognised, which was reflected in the many complimentary emails from the participants and now reinforced with the publication of the proceedings – we believe the quality of the conference is related to the evidence of a strong local identity together with broad global partnership.

By this we mean that representatives of EAAE, ARCC and FAUL, so from a large array of universities, were involved in every aspect of her conference including establishing the constitution of the conference committees (organizing and scientific committees), the boards of reviewers and moderators as well as participants.

Other partner organizations, related to the world of architecture, also contributed and were determining factors in that achievement, namely CIAUD (FAUL Architecture, Urbanism and Design Research Center), AEAULP (Academy of Architecture and Urbanism Schools of Portuguese Speaking Countries) and TRIENAL (Lisbon Architecture Triennial). As well as the organizations mentioned above, some individuals, the keynote speakers,

who came from different countries, China, USA, Belgium and Portugal, also presented high quality lectures related to the sub-themes of the conference.

Last but not least, we must acknowledge Lisbon, the city itself, including its people, history, culture, architectural patrimony, urban landscape, cuisine and climate, as a major contributor towards the success of the conference …

THEME

Since architectural research is at the core of EAAE/ARCC International Conferences, the scientific aspects to develop must be framed and specified.

Looking at the major issues of our era, we stressed (in 2014), the escalating interdependency of nations, that drives global geopolitics to shift ever more quickly and that societies seem unable to control any change that affects their cities, whether positive or negative. Challenges are global, but solutions need to be implemented locally. How can architectural research contribute to the future of our changing society? How has it contributed in the past? The chosen title "**Architectural Research Addressing Societal Challenges**", synthesizes all this, framing the call for papers. Papers were further divided into the following five sub-themes:

1. A changing society

Modernism and the quest for an industrialized welfare-society established a new standard of equality pursued by architects. Today, extreme wealth and urban poverty coexist, at times, within the same city. Worldwide, some nations are dealing with an ageing population, while others are concerned with overpopulation and birth control. Can architects find new standards for such extreme differences? How did the role of the architect evolve from the modernist period to today? We are looking for research that reflects the imprints of societal changes on architecture.

2. In transit – Global migration

A increasing number of people are on a global quest for work, knowledge, protection, adventure and a better life. The number of migrants worldwide reached 250 million in 2014. World Tourism is booming. How does this global mobility affect cities and cultures? How does the traveller from the past differ from the migrant today? We are looking for research on how architecture interacts with and deals with these questions. We are also looking for historical studies of situations that might mirror the present condition.

3. Renaturalization of the city

The urban areas are conceptualised in new ways. Urban and rural conditions overlap. Built areas merge with landscape and nature. How can research reconceptualize the urban condition? What will the city of the future look like? What was the presence of Nature in the urban fabric of the past? We are looking for research that focuses on this transformation process, past or present, and points to possible ideals for future urban development.

4. Emerging fields of architectural practice

The context within which architecture operates is drastically changing and new practices are emerging. The challenge of Climate Change sets a revised scientific and political agenda. Moreover, economic and socio-cultural changes challenge the role of both the architect and architectural practice. Furthermore, new conceptual methodologies, facilitated by emerging computer-aided technologies, expand the possibilities of the design and construction process. This leads us to question how the role of the architect will be affected by this changing context? What are the future possibilities suggested by new fields of development? What kind of new practices are emerging? There is a need for knowledge as to how architecture will answer, redefine or adapt.

5. Research on architectural education

Education in the discipline of Architecture has evolved, mirroring societal challenges and conditions. Architectural Education can also be considered as a multitude of traditions with different national flavours. New social challenges address architectural education. How can architectural education respond to the changing role of the architect? How should the ideal biotope for architectural education look like? How is it related to research or practice? Which didactics prepare students to take position and face future societal challenges? We are looking for contributions on the emerging field of research on Architectural Education.

Those were the questions.

In the next part of these proceedings we will present the papers, or in other words the answers, which were organized according to the sub-themes above. When we received the submissions, we found that it was possible to further sub-divide those sub-themes, which we did for a better understanding of the global approach towards Architectural Research Addressing Societal Challenges.

Hope to see you in the next EAAE/ARCC International Conference 2018, in the United States of America, in the city of Philadelphia.

Change agents in urban transformation: The case of Helsinki

M. Louekari
Aalto University, Espoo, Helsinki, Finland

ABSTRACT: We live in times of great change, and our cities are facing significant transformation. This paper is a study of change agency in an urban context. It explores different views of change agents, acting for formal and informal fields of the transformation of the urban environment. In the paper a fourfold classification model is created. It describes the field of change agency in urban transformation, in relation to the rate of centralization and scale. A case of Helsinki is studied through the fourfold classification model. Helsinki is currently facing major changes, both in the built environment and in the urban culture, as new self-initiated collective urban events are gaining popularity. Restaurant Day is one example of a local self-initiated event, which has grown rapidly and expanded in five years from Helsinki to 74 countries. New kind of activism is changing the scene and initiatives arising from the grass-roots levels are becoming recognized. This development offers new roles and emerging fields also for architects working in urban development. The aim of this paper is to explore how bottom-up and top-down dynamics of change can be reconciled and how the roles of the change agents are interconnected. Change agency is analyzed through themes of distributed leadership and co-creation.

1 INTRODUCTION

This paper aims to contribute to the discussion of societal challenges by examining change agency in the urban context. It explores the complex phenomena of the dynamic development process of a city through the viewpoints of change agents, both at formal and informal levels. Bottom-up and top-down dynamics are examined, to provide both traditional and alternative views on the process of the changing city. This study provides a framework for understanding the complex roles that contribute to constituting the urban environment. The aim is to clarify the understanding of the roles and dynamics of city development and offer a new point of view on the changing metropolis.

As power and leadership are increasingly distributed, there are more factors accounting for urban development. Cities have always naturally faced transformations, but nowadays possibilities for participation have increased, which has led to greater unpredictability. However, there is a growing need to increase the flexibility of the existing structures. Understanding the emergence of community-led and private initiatives in urban development is important for identifying potential ways of collaboration (van Meerkerk *et al* 2013, Zhang *et al* 2015). The processes of public engagement are generally gaining importance (Evans-Cowley & Hollander 2010, Monno & Khakee 2012). Informal urban development rising from ground up challenges mainstream planning theory (Porter *et al* 2011) and top-down perspectives are combined with bottom-up data to examine urban change (Lawless 2013).

1.1 *Change agency*

The development of cities is typically led by centrally managed city planning departments, which produce carefully studied general plans and detailed master plans. The city planners and the decision makers are the obvious actors of change in the development process. They are in the position to conduct externally driven episodic change. Karl E. Weick and Robert E. Quinn have researched change agency and the tempo of change. They see a distinction between episodic change and continuous change, based on the differences in the perspective of the observer. According to Weick and Quinn, the role of a change agent with macro perspective is "to be a prime mover who creates change. The perspective is distant and change linear, progressive and goal-seeking" (Weick & Quinn, 1999, p. 366). Interesting, authentic urban development often also arises from the grass-roots level. Contingency is typical of the processes of emergent and self-organizing change arising from the grass-roots level. "Change is constant, evolving, cumulative, a pattern of endless modifications. The role of a change agent is to be a sense maker, who redirects change in a process of recognizing and reframing current patterns, while showing how intentional change can be made at the margins. The perspective is local. The change is a redirection of what is already under way. It is cyclical, processional and without an end state." (Weick & Quinn, 1999, p. 366). Nowadays an expanding group of independent change agents operate in the field where the dynamics of top-down and bottom-up development meet. They function as mediators

and negotiators in the development process of a city, as well as culture-makers. Their work happens in cooperation and conversation, in creating a common understanding.

In his research Raymond Caldwell defines different discourses of change agency. Rational and dispersalist discourses seem to be relevant when considering change agency in today's cities: "Rational discourses identify intentional action and agency with rationality, expertise, autonomy and reflectivity" (Caldwell, 2006, p. 5). On the other hand, "Dispersalist discourses locate agency as a decentered or distributed team or group activity of self-organizing learning, operating outside conventional hierarchical structures or control systems" (Caldwell, 2006, p. 6). While the rational discourses offer a lens through which to observe the actions of well-structured expert organizations with power, the dispersalist discourses give space to the freely-formed organic development of change. Whereas rational discourses have traditionally prevailed, the significance of dispersialist discourses is currently clearly increasing. Spatial change agents are also described as "negotiators of existing conditions in order to partially reform them. Agents act with intent that is necessarily shaped and reshaped by the context within which the agent is working. An agent's action is guided by an initial transformative intent, but because of the dynamics of the structural context, that intent has to be responsive and flexible." (Awan *et al.* 2011, p. 32).

1.2 *Distributed leadership and co-creation*

According to Peter Gronn, the problem with the majority of leadership theory up until the 21st century has been the division into two parties: leaders and followers. He sees distributed leadership as an alternative for 'post heroic' leadership (Schedlitski & Edwards, 2014). The idea of distributed leadership suggests that "leadership is a widely dispersed activity throughout teams and organizations and that leadership capabilities and the development of these capabilities are needed at all levels within organizations." (Schedlitski & Edwards, 2014, p. 151). Distributed leadership represents a less formalized model of leadership where leadership responsibility is separated from the hierarchical models. Each individual can exert leadership and influence. According to Bennet *et al* (2003), the most remarkable attribute of distributed leadership is the division of leadership between various people. Three conclusions regarding distributed leadership can be made: (1) leadership is manifested in and arises from interaction, (2) the boundaries of leadership are open and various amounts of people and groups can participate in leadership, and (3) skills, abilities and expertise are widely dispersed (Buhanist 2008). Leadership may be considered as a regular, ordinary way in which to influence, in form of cooperation and coordination.

According to a study conducted by the London School of Economics, co-creation is a form of collaborative innovation, based on relationships. Emphasis is on the quality of the interactions. Co-creation is also a learning process. (LSE, 2009, p. 3). It has been acknowledged that co-creation can help to build value significantly. Cooperation can also prove to be a good source of results in urban development. The aim of co-creation is to strengthen knowledge processes by involving the user in the creation of meaning and future value. It transforms the consumer into an active partner and the users become change agents. The impact of co-creation can be seen in many levels: "1. Co-creation has a direct impact on traditional innovation practices and processes. 2. Co-creation can affect the quality and speed at which decisions are made in relation to the development and filtering of ideas. 3. Co-creation will enable creativity at individual and group level and potentially enable customer knowledge development and transfer across the organization. 4. Co-creation will increasingly be used as a way of creating strategy collaboratively" (LSE, 2009, p. 15).

2 MATERIALS AND METHODS

In this paper, the data collected for three cases of Helsinki is analyzed through themes of change agency, distributed leadership and co-creation. A mixed methods approach was adopted for this study. Data were collected through a combination of document analyses, observations and interviews. A fourfold classification model presenting different roles of urban development and the field in which the change agents of urban change act is introduced and tested by empirical analysis. Case studies were conducted in order to analyze change agency in urban development. The analysis is conducted to allow greater understanding of the complex field of urban change agency. Both centralized and decentralized viewpoints on the issue are examined, with an emphasis on how the different change agents understand transformation in a city and how their views are interrelated.

3 A FOURFOLD CLASSIFICATION MODEL

A fourfold classification model created in this study aims at describing change agency in urban development. It shows the fields in which the change agents operate. The classification model focuses on the individuals affecting the change in cities.

The official planning procedure with its stakeholders forms the background, in which these change actions operate. The background is the context of the operations. The political decision-making process as a standard procedure including its own roles and the official citizen participation included in the planning process are part of the context, and therefore they are not separately presented in the classification.

The fourfold classification model presented here describes the actions of change agents taking place in various phases in urban development. The model does not offer strict divisions, but shows the field

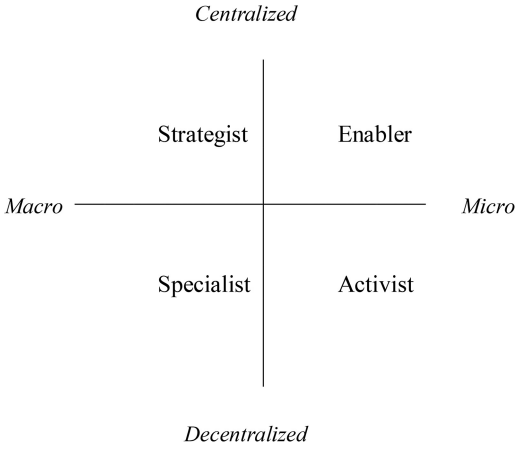

Figure 1. A fourfold classification model: change agency in urban development.

of operation. It is a flexible and adaptive system: individuals actively working on change in the urban environment can reciprocate in the field and take on different roles.

The change agents are categorized in relation to the rate of their centralization and in relation to their scale of activity. (Figure 1.) Each quarter describes the professional identities of a certain type of change agency. The level of centralization describes the location of a change agent in the networks in which they operate. Centralized actors typically belong to the public authorities, who use the legal power given to them based on their position. They conduct the change of cities and are typically explained by rational discourses. However, the significance of dispersialist discourses is increasing also in the public sector. The decentralized forces of change include private companies, including developers and architects, as well as organically organized teams, groups and individual actors operating in the urban environment with a goal of urban change. Explained by both rational and dispersal discourses, they are the agents arising from private initiatives.

The division between macro and micro scale of change agency describes the level they operate on. Whereas strategic planning deals with broad issues, it is characteristic to master planning to always have a close contact with the actual physical environment, with a certain site. Micro scale is characteristic of the urban events and temporary uses, typically arising from a potential of a place.

These dimensions clarify four roles of change agency in urban context. The roles that are defined are a strategist, an enabler, a specialist and an activist.

A strategist typically has a high position in the hierarchical centralized structure. They work at the strategic planning and master planning level of a city, covering complex issues with far-reaching impact. The view of development of a city is that of a macro perspective. An enabler also holds a position on the hierarchical power structure. They have the power to influence urban development on various scales from a single site to a district. They also have the position to affect the daily living environment in a rather short scope of time. The enabler has the resources and power to support or object to project-based development and therefore influence everyday circumstances. The processes of work of both the strategist and the enabler are based on rationality and systematicality.

A specialist is typically an expert working in a private company or on his own. They can contribute to urban change by offering alternative ideas, either under commission or voluntarily. A specialist can work e.g. as an architect, developer or researcher. They can have aspects of both rational and dispersal discourses.

An activist contributes to urban life by composing creative and innovative forms of using the urban environment. These can include events and temporary use. The processes of work are often self-initiated and cyclical and can be seen as a part of dispersal discourses. Both the specialist and activist use the media as a tool for influencing the course of urban development. They can be opinion leaders and media personalities and may have a remarkable impact on the course of urban development, as they possess the means to affect the values and attitudes of city dwellers.

The classification model helps to identify the different actors affecting urban change. It clarifies the roles while leaving room for adaptation and modification as the divisions are not strict separations. Individuals can move between the quarters, taking on different roles depending on the situation. Connecting to the other quarters is an important aspect of change agency. The classification model provides help and guidelines for commencing operations of co-creation. It defines some of the remarkably influential roles of the change agents, who could be involved in a co-creating process of urban development. As the model indicates how power is shared throughout the fields of various actors on different levels, it can be used as a framework when drafting an influential and innovative setup for collaboration and cooperation.

In the following sections the fourfold classification model is used in three cases in Helsinki: the different versions of strategic master plan, the Restaurant Day and the Helsinki Waterfront event concept.

4 CHANGE AGENTS IN URBAN DEVELOPMENT, CASE HELSINKI

4.1 *Strategic master plan case: strategists and activists operating separately*

In Helsinki a political committee and a city planning department operating under its supervision are responsible for city planning. The actual planning work is undertaken by professionals, mostly architects, planners and engineers. A participation procedure runs alongside the planning process, allowing city dwellers

to contribute their opinions and ideas. As former transportation and harbor areas are being transformed for new uses, seen from the macro level the city of Helsinki is facing a momentum of episodic change. In forthcoming decades, the city will have a major task of central importance for the urban structure as new areas are planned and built. Helsinki is expanding faster than ever before. The completion of the new cargo harbor in a new location has vacated the largest amount of space in a hundred years. This has provided the opportunity to develop the sites of the former port and railway yard areas for the construction of new housing and workplaces in the city. With the construction of new districts, the development projects will create approximately 100,000 residences and tens of thousands of jobs during the coming decades. A major land-owner in the former harbor areas, the city of Helsinki remains the most important actor of change in the new districts.

However, there is an even bigger change under way: the city of Helsinki is currently in the process of producing a new strategic city plan. The newly completed draft of the plan, designed by the strategic planning division of Helsinki City Planning Department, shows how the city can grow by 250,000 new residents by 2050. Directing the growth, the plan will have a major impact on how Helsinki will transform during the coming decades.

Besides the official strategic plan, alternative plans have been produced. Created by volunteering specialists and activists, the alternative strategic plans have gained wide media attention and triggered vivid discussion on the themes of future planning. The alternative city plans produced by voluntary groups of urban activists demonstrate one way in which contribution outside the official structure can have an impact on forming the future of the city by influencing public discussion. However, alternative plans do not always offer a realistic choice as they do not have to take into account all of the existing preconditions. More accessible methods of co-creation should be offered, to utilize the existing potential. Cooperation between the official and unofficial planning is currently on the level of discussion, but it is the wish of both parties that new ways of co-creation could be created.

4.2 *Restaurant Day case: activist driven*

Besides physical transformation, urban culture in Helsinki is currently turbulent – much has happened during the last years and it seems that the phenomenon has only started. The threshold for self-organized urban events used to be rather high, as the permission procedure was considered demanding and regulations were strict. The current upheaval is changing attitudes, as new self-initiated collective urban events are gaining enormous popularity. Restaurant Day is an example of a local self-initiated event, which has grown rapidly and expanded in five years from Helsinki to 74 countries. Restaurant Day is organized four times a year. During the event anyone can set up a restaurant for a day. It can take place anywhere: in private homes, on streets, in gardens and in parks. Collectivity is the key: anyone can participate and each organizer is responsible for their own contribution. The urban activists and founders of Restaurant Day have become the face of the currently escalating collective culture in Helsinki, arising from the grass-roots level. They see their role as being an advisor and mediator in linking people. Communality and having an impact on the society is a priority. Restaurant Day, with its open call for participation, is seen as a tool for democratization. According to the urban activists, the most significant change in the urban development of Helsinki is taking place in the values, thoughts and attitudes of the city dwellers. There is a clear change in the basic opinions and impressions of what can be done. When founding Restaurant Day, the activists simply announced that on a certain date anyone could establish a pop-up restaurant. The concept was clearly against various rules and regulations, but by the effective use of social media the organizers gained a following which could not be overlooked. Masses of city dwellers took the initiative to participate in the event and the phenomenon spread fast. The aim of the organizers is to change attitudes towards the use of the urban environment permanently, not just for a day.

In the case of the Restaurant Day change agency follows a model of a decentralized and distributed self-organizing group activity. The organizers of Restaurant Day operate outside traditional hierarchical structures. The network organization operates by horizontal coordination. The environments in which Restaurant Day operates are emergent and self-organizing. Change is a pattern of evolving adaptation. Change agents see the potentials of urban development and have the means to utilize them. The impact of their work shows the power of organic change, rising from the grass-roots level. Urban experiences arise from spatiality, but also from interaction. People, relationships between them, dynamics of urban life, incidents and encounters constitute the city. Communality and shared experiences affect the identity and image of a place and change the way in which the urban environment is seen and understood. The Restaurant Day event is a protest against existing circumstances and regulations, but it is a positive protest. Authentic change starts from within each city dweller. An influential way to change people is to offer an alternative: a positive vision including concrete actions. Considering the urban environment, the most effective change arises from the individuals, who constitute the city. Actions change along with values and attitudes. Participatory urban events can reveal new potentials of the daily living environment. As a result of the highly popular chain of collective events the city authorities up to the mayor have praised the phenomenon of the rise of a new culture of active participation and thinking in Helsinki. A major shift in attitudes and values took place as a marginal event arising from the grass-roots level, disregarding rules and regulations, became an accepted and encouraged part of the urban culture.

4.3 *Helsinki waterfront event concept case (enablers, specialists and activists in co-operation)*

In Helsinki, everyone lives within 10 kilometers from the shore. The downtown area is located on a peninsula and densely built, while the rest of the city is spread along shoreline. The city area also covers a vast sea area and over 300 islands. For a long time the inner city shores were mainly used as industrial areas and harbors, limiting the number of citizens living right by the shore. When the city's cargo and industrial harbors moved to a new location, vast areas were freed up for residential use. The construction of these new districts is set to continue until the 2030s, and the planning of further residential areas is already underway. The draft of Helsinki's new city plan proposes that the city structure be densified, which would free up space for further residential areas near the shores. The new districts under construction serve as testing grounds for new maritime housing solutions. (Helsinki City Planning Department). The seaside trail running along the city's shoreline is over 130 kilometers long and open to everyone. Opening the shoreline has long been one of the guiding principles of Helsinki's city planners, and in the future new maritime city districts will provide the city with more waterfront housing and leisure venues.

Helsinki's seaside trail offers magnificent and varied landscapes, and in the last few decades new maritime city districts have provided the city with even more open seaside trails. In order to enliven the waterfront during the summer and offer even more activities along the shoreline, the city of Helsinki developed an open shore event concept together with Yhteismaa for the summer 2015. The author of this paper was involved in the process. Yhteismaa – Finnish for Common Ground – is a non-profit organization, specialized in new participatory urban culture, co-creation, social movements and place making. In the concept, called Rantakesä in Finnish, fourteen places along the shoreline were offered for anyone to freely organize their own events. The different city departments agreed to give free access for non-commercial events on those pre-choosed locations. As a result the city dwellers willing to enliven their own hoods did not have to go through the usual path of applying for permissions. The requirement was that all the events had to be free of charge and open for everyone and there were certain restrictions considering the noise limits and night hours, but all in all the concept left it up to the citizens themselves to decide what kind of experiences the shoreline would offer. As a result a vast range of events took place along the waterline: for example yoga lessons, recycling workshops, music events, flea markets, an open dinner party, handicraft workshops, art projects, children's events and an open stage event for improvisation. Rantekesä will be organized again in the summer 2016.

In the Helsinki Waterfront event concept case the city authors had an enabling role in the process, which was based on cooperation and co-creation. The people of Yhteismaa had the roles of activists and specialists, bringing in their networks and expertise of urban culture. In the end it was the people on the city, who made the event happen and successful.

5 DISTRIBUTED LEADERSHIP AND CO-CREATION IN URBAN CONTEXT

In the big picture, major shifts of functions are taking place in cities. A view from closer in reveals constant modifications and adjustments at the level of daily lives in cities. Although these adjustments can be slight, it is even suggested, that "Small changes rather than comprehensive masterplans are more effective in steering urban development processes towards more desirable futures conditions" (Karvonen, 2014). There is significant change in the agency of urban culture. Continuous, adaptive change in cities can be seen in self-initiated projects and temporary uses of urban space. It may also rise from events, which can gain communal interest and importance and change the way in which people use their urban environment. Continuous change can rise from reactions to the possibilities and challenges of daily life. It might be inspired by a sudden window of opportunity or result from handling uncertainty. The perspective is local: continuous change often uses the momentum and the potential of the place. Nowadays, in Helsinki the many important actors in urban culture are private, independent groups and activists. The attitudes of the city administration are changing – and have to change. The course of development following the first Restaurant Day shows this: the city has seen the potential of the event and currently uses it in its official city marketing. Self-organized, loosely facilitated events have become powerful actors in urban change.

The phenomenon of distributed leadership is strongly evident in practice. Collaboration, co-creation and participation will continue to increase. Expertise will materialise through contribution and interaction. Today, leadership is examined through collaboration, interaction and multiple operators. The examination focuses on leadership in processes. It is important to be able to see the whole and its parts at the same time. Leadership develops through cooperation and discussion. An ability to see beyond what is familiar and adapt to change is key for success and even survival in a rapidly changing world. Various different forms of distributed leadership can be found in urban development processes. They can be seen in the operations of rapidly adaptive urban activism, arising from the grass-roots level, but they are also increasingly embedded in more formal urban development. The interesting future research topics include clarifying the understanding of the roles and dynamics of city development.

A variety of different views are needed for a changing metropolis. As the people make the city, co-creation is already embedded in the definition of a city. The question is how to bring together different actors and create forums for interaction. There is a need to

develop co-creation processes further. Tools for communication and conversation are developed both by the authorities and the urban activists. Cooperation is the key, not confrontation. The solution lies partly in the usage of new technologies, which become a valuable device for participation and co-creation. Identifying the different roles of change agency is essential for collaboration.

Many European cities aim at developing open processes of collaboration and participation, where bottom-up and top-down forces operate together. In Amsterdam 'Breeding Grounds', informal working places of cultural and manufacturing producers, provide spaces where independent organizations can collaborate, leading to the development of new initiatives. Berlin is known for spontaneous and unplanned use of open spaces and the redevelopment of the former Tempelhof airport is regarded as an opportunity to transform the area into a model location for participative urban development. The importance of informal tools has increased and as they contribute to spatial plans, the informal tools are nowadays accepted as an essential part of the planning process. "The tools available to the planning system are statutory plans and programmes and the legally permitted means of safeguarding and implementing them at all levels. In addition to statutory planning tools, supplementary, informal planning is possible" (Pahl-Weber & Henckel 2008, p. 43). Informal tools bring flexibility and can focus on certain aspects without the requirements linked to statutory plans.

In Berlin, agencies specializing in in-between use consultancy operate in the field where the dynamics of top-down and bottom-up development meet. The agencies work with a co-operative approach and bring together different actors involved in the city development process. These independent change agents function as mediators and negotiators in the development process of a city. Many of the individual, privately run projects of Tempelhofer Freiheit operate as networking channels. The Berlin Senate Department for Urban Development and the Environment still plays a guiding and coordinating role in the redevelopment of Tempelhof. (Berlin Tempelhof Project 2015).

Change in cities can hardly be managed only throughout as a rational and planned process. As a vast range of different factors affect the development of cities, both at the micro and macro levels, there are always unexpected twists and turns. However, a clear vision for the urban future is needed to guide development and lead transformation. For a comprehensive view of urban development, there must be room for both rational and dispersal discourses. As the different disciplines overlap, there is a need for new collaborative approaches to urban development.

6 CONCLUSIONS

This paper explores possibilities of combining collective urban development rising from grass-roots level with centralized city planning. Bottom-up and top-down dynamics do not have to be contradictory, and one way to enhance urban development could lie in finding possibilities to combine them. Postmodern societies are characterised by ambiguity, a low level of hierarchy, extensive participation, distributed leadership and uncertainty. The use of power is increasingly significant: more effective ways to exert influence are needed to get a message across in an environment of distributed leadership among a multitude of voices.

Co-creation is a form of collaborative innovation, based on relationships. It has been acknowledged that co-creation can help to build value significantly. Cooperation can also prove to be a great source of results in urban development. The aim of co-creation is to strengthen knowledge processes by involving the user in the creation of meaning and future value. It transforms the users into active partners as they become change agents. As seen from the examples of self-initiated collective urban events, individuals can take the initiative and have great influence on society. Phenomena may arise swiftly and people can cluster quickly. The actors of unofficial, organic urban culture can use significant power. Self-organizing and opinion sharing is easy and effective for the alternative forces of change. However, the urban activists often also believe that the main source of power is still found in politics, as the decision-making process remains political.

Identifying the different roles of change agency is essential for collaboration. A fourfold classification model created in this study defines and clarifies the roles. It shows the fields in which the change agents operate. The model does not offer strict divisions, rather it is a flexible and adaptive system: individuals actively working on change in the urban environment can reciprocate in the field and take on different roles. In the classification model change agency is categorized in relation to the rate of centralization and scale. Each quarter of the model describes the professional identity of certain type of change agency: a strategist, an enabler, a specialist and an activist. The classification model can offer help in organizing co-creation. As the model indicates how power is shared throughout the field of various actors on different levels, it can be used as a framework for collaboration and cooperation. The classification model also shows how leadership is distributed. Power can be based on authority, but collectivity can also be a significant source of power. Each view is important for formulating and constituting a comprehensive view of a changing metropolis. The dispersal discourses of urban change agency and the operation of the decentralized change agents offer an interesting topic for future research. Communality and sense making in urban development, as well as complex systems of self-organization are among the other rising themes in urban transformation.

Urban regeneration of former industrial cities. A cure or a curse? The case of Ancoats conservation area in Manchester, England

T. Chatzi Rodopoulou
TUDelft, Delft, The Netherlands

J. Hunt
UCL, London, UK

ABSTRACT: The anxiety to reverse the economic and socio-spatial degradation of deindustrialisation in Europe gave rise to a multitude of urban regeneration schemes. Urban regeneration practice has been at the centre of academic and political debate, characterised either as redemption or a chimera for the future of European cities. This paper revisits the topic, aiming to give an objective image of the nature of urban regeneration in the current socio-political system. Focusing on Ancoats in Manchester, we will explore the socio-spatial merits and pitfalls of urban regeneration schemes in the last three decades. We will argue that urban regeneration can have distinct implications on the social and spatial urban fabric, depending on the power balance of the stakeholders involved. The results of the research enrich the scientific discourse on the topic whilst offering lessons for future cases aiming at preserving a social, cultural and spatial balance.

1 INTRODUCTION

Since the 1980s European former industrial cities have been subjected to large scale transformations known as 'urban regeneration' practices. Intended to reverse physical, social and economic decline, urban regeneration has dominated academic and political discourse in recent decades.

On the one hand, politicians, property developers and some academics advocate urban regeneration projects, presenting them as the only opportunity to solve chronic urban problems (Florida, 2002). Conversely, opposition voices condemn them as vehicles of immaterial neoliberalism and gentrification (Hatherley, 2010). A limited number of researchers have tried to examine the topic objectively, acknowledging both the advantages and the disadvantages of urban regeneration (Porter & Shaw, 2010).

This research aims to complement the latter approach, challenging established assumptions that polarise the positive and negative implications of urban regeneration.

In this paper we will try to explore the social and physical impact of urban regeneration, using the example of Ancoats in Manchester, a city which has been described as *"the capital of regeneration"* (Hatherley. 2010: p. 119) Our particular focus is how urban regeneration impacts the tangible and intangible dimensions of industrial heritage, a key characteristic of the area under investigation.

The first part of this paper considers the urban and social development of Manchester and Ancoats in the eras of industrialisation and deindustrialisation. The second part focuses on the analysis of Ancoats' conservation area regeneration schemes. The paper will conclude by identifying the positive and negative implications of historic industrial areas' regeneration schemes.

Our research, positioned at the crossroads of urban regeneration and heritage preservation discourses, aspires to contribute to the current broad debate for a future social-inclusive, sustainable development of our historic cities.

1.1 *Methodology*

A multimethod research approach has been adopted to achieve the research aims outlined above. First, a literature review on the issue of urban regeneration was conducted resulting in the problem definition.

Second, the existing research base on Manchester's development was reviewed focusing on Ancoats; this involved an analysis of primary and secondary sources on the city's regeneration policy, followed by an analysis of selected literature focused on its industrial heritage. Further research covered relevant articles from local and national newspapers, as well as an on-line review of the main stakeholders' websites and publications.

Third, qualitative research was conducted, consisting of eleven face to face interviews with a wide range of stakeholders involved with the regeneration of Ancoats district. These included representatives from: the Homes & Communities Agency (HCA), the Ancoats Buildings Preservation Trust (ABPT) and

Historic England; four professionals who work in the converted industrial mills and five residents of the redeveloped Ice Plant and Royal Mills complex.

Finally, we undertook a field trip in June 2015, enabling us to experience the location first hand and establish a 'sense of place'. This research also provided us with photographic material and updated evidence for the creation of the map (Fig. 1) presented on this paper.

2 FROM INDUSTRIALISATION TO DEINDUSTRIALISATION

2.1 *Manchester's development*

In the late 20th century Manchester acquired the epithets, Madchester and briefly Gunchester, both of which were at least partly connected to the deindustrialisation that began during the post war years. Manchester's original nickname 'Cottonopolis' acknowledged its role as the globe's preeminent producer of cotton during the industrial revolution.

Established in the late 15th century, Manchester became the world's first industrial city growing at an incredible rate throughout the 18th and 19th centuries. The impetus for this unprecedented growth was the development of a number of technological processes, most importantly the evolution of steam power applications in industry. Simultaneously Britain's position as head of a global empire enabled it to source raw materials from around the world. The resultant economic, technological and trade boom had a profound impact on Manchester's urban tissue. Large textile mills and warehouses were erected to enable production on an 'industrial scale' whilst the city's growing population, attracted by increased employment opportunities, needed homes.

With industrial levels of production came industrial levels of grime and dirt and the city's influx of new workers experienced slum conditions in the hastily constructed residential dwellings. Ancoats, a district north of the city centre, epitomised this phenomenon and was one of the areas visited by Engels during his research for The Conditions of the Working Class in England in 1844. There he witnessed *"the defiance of cleanliness, ventilation and health"* which mill hands were subjected to both at work and home. Briefly, Ancoats was the heart of the *"world's most futuristic city"*, its *"repetition, inhuman scale and industrial materials of its mills*" offering a *"prophecy of the architecture of the future"* (Hatherley, 2010: p. 115). Manchester gave birth to the industrial age and soon cities across the globe were replicating its growth in productivity, population and poverty.

Ancoats' ensuing decline, discussed in more detail below, was replicated throughout Britain as manufacturing shifted across the globe in search of cheaper labour. As early as 1901, Reynolds Weekly Newspaper was predicting "*the first year of the new century will prove to have been the last year of good trade and we must look forward to a period of lean years and to decline in trade with our two great rivals, America and Germany"* (cited in Joyce, 2007: p. 9). That the *"lean years"* would last so long and that Manchester and other cities like it would be so slow to respond was perhaps harder to predict.

In the latter half of the 20th century Britain was economically stagnant, caught in the structural breakdown of industrialism but yet to be subjected to the violent jolt of Thatcherism and the deregulating forces of neoliberalism. Manchester ushered in the industrial and Capitalist age but was to become one of the most notable victims of the cyclical processes of Capitalism. Manchester's mills and warehouses represented outmoded structures that emerging technologies and cheaper labour in developing countries quickly replaced. As a result, Cottonopolis became a hollowed out city. By the 1970s the city centre was home to fewer than 400 residents (Hatherley, 2010: p. 116) yet its industrial origins cast a long shadow over its contemporary deindustrialised simulacra: *"The final disfigured, sighing remnants of the mighty industrial past had yet to be completely demolished, the statuesque warehouses and factories that had survived yet to be postmodernised as part of a glossy revitalisation of Manchester's historical enterprise."* (Morley, 2009: p. 9).

2.2 *Ancoats' rise and fall*

As the world's first industrial suburb, Ancoats is a district of huge historic significance (Hartwell et al. 2005: p. 106). Ancoats evolved as a result of increased housing demand from the area's growing population and the need to construct new modern textile mills. (Ancoats Buildings Preservation Trust. 2004) From its inception it was a mixed use district, with worker's housing extending on its north-west side and industrial sites covering its south side. Although the area's roots can be traced to the latter decades of the 18th century, its development gained real momentum in the 19th century. Ancoats proximity to the Rochdale Canal (Fig. 1, No: 01), completed in 1804, combined with the development of land for the construction of new mills saw Ancoats cement its positon at the heart of the industrial revolution. In the first three decades of the 19th century its population tripled, reaching more than 56.000 by 1861. (Rose et al. 2011: p. 33).

This 'golden era' of Ancoats is defined by two contrasting physiognomies. The first revolves around the district's industrial wonders. Ancoats was the site of the urban factory system's inception (Hartwell et al. 2005) From 1797 until the mid-19th century revolutionary steam powered cotton mills were erected in the area including Murrays Mills (Fig. 1, No: 02), et al. In contrast, Ancoats' alternative physiognomy was defined by poverty, overcrowding and slum-living (Nevell, 2014).

In the second part of the 19th century, Ancoats was subjected to a prolonged process of housing renewal. The local authority, in response to the notorious social

profile of the district, established a set of new by-laws to address the problem. As described by Nevell (2014) a series of 'unhealthy' housing rehabilitation and demolitions took place, intended to improve the sanitation level of the district. In 1897 slum demolition enabled the construction of Manchester's first model tenement block in Victoria Square (Fig. 1, No: 08), as well as the adjacent worker's cottages (Fig. 1, No: 09). The new accommodation, was of much higher quality but came with a significantly higher rental value, making it inaccessible to the district's poorest residents. This first wave of demolition and renewal by Manchester City Council (MCC) set a precedent that was to be repeated in cities all over Britain.

Towards the end of the 19th century Ancoats' industries began a slow process of degeneration as a result of increasing competition from cheaper international manufacturers, which simultaneously caused a reduction in population. With the exception of the interwar period, the 20th century saw Ancoats fall in to terminal decline. During the 1930s the district was subjected to expansive demolition schemes; communities were broken and removed; factories razed to the ground, schools and churches closed and the mills – formerly symbols of prosperity – were left abandoned. By the early 1960s Ancoats ceased to be a residential area while the cotton spinning era came also to an end.

3 REBIRTH

The *coup de grâce* for Ancoats occurred in 1987. The closure of the Daily Express site (Fig. 1, No: 10) exacerbated the sense of abandonment in a city that was experiencing increased levels of crime and gang related violence, resulting in its Gunchester moniker. However, it simultaneously provided a wakeup call. The regeneration of Ancoats, which is still occurring today, has its roots in this moment. In what follows we examine this process, breaking it down to four periods which differ from one another in terms of regeneration vision, stakeholders' action and power and development pace and quality.

3.1 *Sowing the seed of rebirth (1989–1999)*

The turning point for Ancoats came in 1989, when MCC designated it a Conservation Area, recognising for the first time its historic significance (Manchester City Council, 2016). In the following years the work of the MCC in collaboration with English Heritage (now Historic England) along with the action of the Ancoats Buildings Preservation Trust (ABPT) laid the groundwork for the district's rebirth.

The listing of historic buildings and the small scale interventions on the scarred urban environment, made possible by the Conservation Area Partnership Grant (CAP) from English Heritage put an end to the district's decline. Arguably the greatest impact on Ancoats' fortune resulted from the work of the ABPT, established in 1995. The Trust in its early days helped MCC to acquire the CAP grant, raised public awareness of Ancoats and argued for a proactive approach to the preservation and restoration of historic buildings (Ancoats Buildings Preservation Trust, 2004a).

A year later the Ancoats Urban Village Company was created by MCC, named after its first vision for the revival of the district. The Urban Village concept was based on the idea of a mixed use area with a strong sense of community. The establishment of the company, that aimed to attract commercial development to Ancoats was a facet of MCC's readiness to support the private sector (Blakeley & Brendan, 2013).

A contrasting process that occurred alongside the increased acknowledgement of Ancoats' history was the struggle of MCC to redefine Manchester's global profile. As a result, MCC led the city's bids for the 1996 and 2000 Olympics, hoping the interest and finance generated by a global event would redress the image of Manchester as a grim post-industrial city. These aspirations took a toll on Ancoats, caused by speculative buying of property which was left abandoned after the announcement of the bids' failure.

3.2 *Development fever (2000–2007)*

The first period established the foundation as well as the limitations of Ancoats' regeneration. At the dawn of the century, new players such as the North-West Regional Development Agency (NRDA) appeared, as a result of State policies (Blakeley & Brendan, 2013: p. 24).

The decisive move of the NRDA to acquire large parts of Ancoats with Compulsory Purchase Orders paved the way for a frenetic period of redevelopment. As shown in Figure 1, between 2000 and 2007 a plethora of historic buildings' conversions and new-built projects was realised. Perhaps the most important and ambitious project that set the tone for the conversion of the historic mills of the area was the restoration of Grade 2* listed Murray's Mills, undertaken from 2003 to 2006 by the ABPT. *"Everybody who wanted to develop at Ancoats wanted to know what is happening to Murrays Mills. [. . .] It was critical to get the complex repaired because people did not want to try to develop a new flat that looks out over a derelict site while there was vandalism happening … It was the catalyst that made everything else happen"*, states Kate Dickson (2015), former Director of ABPT.

In addition to the conversion of historic buildings, new developments started appearing in Ancoats, beginning with the erection of the residential complex MMII in 2003. (Fig. 1, No: 04). Darren Ratcliffe (2015), Historic Places adviser for Historic England, describes the MMII development: *"Facing on to the main road and being the closest to the centre the developer felt able to deal with that and sell it without being affected by what was behind, because it was very difficult to develop something in a rundown area. [. . .] And also with it being new built, the developers were able to set a value to the land and the units which could then*

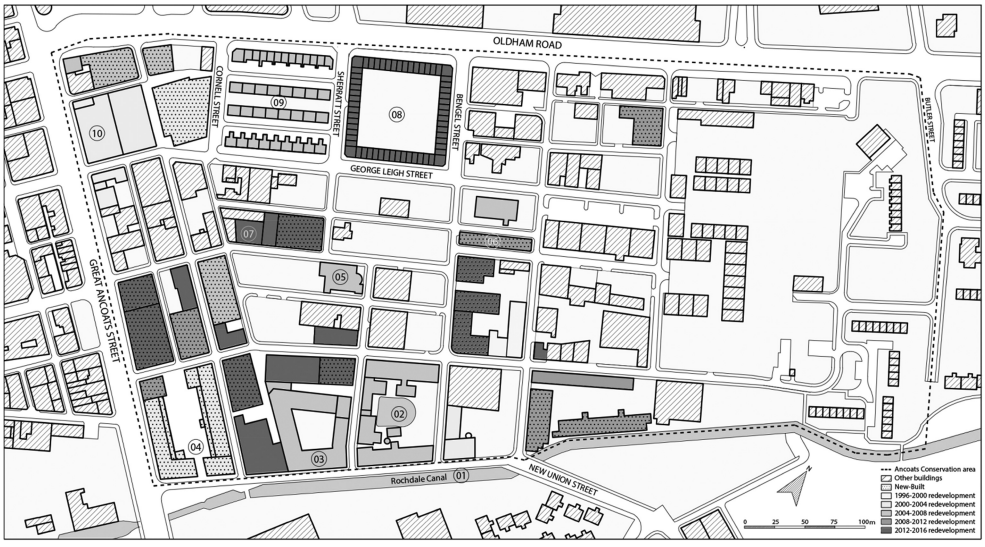

Figure 1. Ancoats' regeneration process, categorised into four distinctive periods which differ from one another in terms of regeneration vision, stakeholders' action and power and development pace and quality.

transfer into the mills. So they were setting a market rate with the new development."

After almost a century of decline, Ancoats appeared to be on the rise again. Once this process began however, the romanticism of the previous decade started to fade. MCC's desire to see the district's improvement resulted in too much trust being placed with developers. Ratcliffe (2015) recognises this tendency saying: "*The Council was prepared to accept an outline application on MMII with no design!"*

The concept of the Urban Village gradually gave way to a new idea, 'the Heart of Ancoats'. Even though the new concept was organised around a new public amenity – a square in front of the newly restored Saint Peter's Church – (Fig. 1, No: 05) it lacked the social qualitative characteristics of the previous scheme. In the years that followed, other less sympathetic schemes such as 41 Bengal Street (Fig. 1, No: 06) were built in Ancoats. An important characteristic of the development of the area at the time, common for both conversions and new-built projects, was the dominance of the residential function.

3.3 *Recession stagnation (2008–2012)*

The financial crisis that hit Britain in 2008 put a temporary halt to the rapid regeneration of the district. New development ceased; ongoing schemes were paused; conversions abandoned. With property developers withdrawing, folding or turning their attention to other parts of the UK, the willingness to favour a largely uncontrolled property development-led regeneration started to backfire.

Two cases highlight the essence of the period's stagnation and the impact of property development-led regeneration on the historic fabric. First, Murray's Mills; after a successful three-year restoration by ABPT and £10 million investment from the Heritage Lottery Fund and the NRDA (Ancoats Buildings Preservation Trust, 2004b), the complex was about to be sold to a developer, selected via competition. The Trust decided not to engage in the reuse of the Mills due to their limited financial means and the massive scale of the complex. Kate Dickson (2015) describing the events that followed the developer's selection, explains: *"The developer (once selected) wanted things changed and it was already too late to have that conversation . . . So it became a very acrimonious and difficult relationship. Finally, when the project came to an end the developer changed his mind and decided not to take it on. . ."*

The project remains uncompleted to this day.

Second, the Royal Mills complex scheme (Fig. 2, No: 03, 2), was left unfinished. ING development which realised the first stage of the scheme in 2006, withdrew from the UK during the crisis. Residents and professionals working in the Royal Mills complex interviewed for this research, commented on the developer's indifference. *"ING did not care. After 8 years there are still empty units on the ground floor"* (Royal Mills professional, 2015a). Another respondent adds: *"The atrium is lovely but it only works as a hallway. It is never used. They should have thought it through . . ."* (Royal Mills professional, 2015b). Such claims are bolstered by Phil Collings (2015), Senior Area Manager Greater Manchester HCA: *"ING transformed the building to put in office space, but they were not interested in fitting it out. They left the ground floor just a shell and it remained an unused space."*

3.4 *Towards a glossy Ancoats (2012–today)*

By 2012, Britain still reeling from the financial crisis began a slow process of recovery. The crash

Figure 2. The atrium of the Royal Mills' complex eight years after its conversion remains an attractive yet empty space.

caused major upheavals in Ancoats stakeholders' pool, redefining its former major players' roles. While the ABPT saw its influence wane and the NWCA was closed down by the Coalition Government (Blakeley & Brendan, 2013: p. 24) new actors such as the Homes and Communities Agency (HCA) entered the scene.

As highlighted in Figure 1, a new wave of development began. HCA, which acquired the assets of the NWCA, once again encouraged commercial investment in Ancoats. Important historic buildings such as the Ice Plant (Fig. 1, No: 07), were converted, while schemes halted by the crisis, like the Royal Mill complex, were completed.

A shared characteristic of this phase with the period prior to the crisis is the dominance of the residential function in the developments. Collings (2015) explains the reason for this mono-functional tendency and clarifies MCC' s position, *"In the Manchester market the residential uses are more valuable than the office uses. The local authority insisted in having a mixed use scheme."* Discussing the Royal Mills conversion, the same respondent also highlights another parameter of the residential development: *"The housing offered is not affordable. The average price is £200.000. The project is socially exclusive."* Collings' claim is confirmed by our comparative data analysis presented in Figure 3. The average rental price in Ancoats is considerably more expensive in relation to

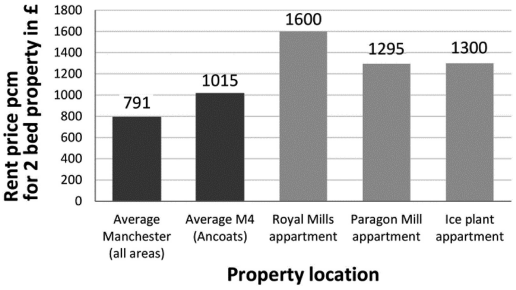

Figure 3. The comparison of the rent price in Ancoats and Manchester reflects the district's gentrification tendency.

Manchester's average. Of equal interest is the comparison of the converted historic complexes' rental value with Manchester's average figures. The results of this comparison clearly demonstrate the gentrification tendency of the current regeneration schemes. (home.co.uk. 2016, zoopla. 2016).

The analysis of the interviews conducted during this research provides an insight into the current state of Ancoats. It is notable that respondents recognised features of the regeneration involving Ancoats' intrinsic characteristics. The aesthetics and spatial qualities of the Victorian industrial complexes, boosted by their rehabilitation, were singled out as the most successful feature of the respective schemes. Most of the positive comments, also acknowledged the historic structures and their safeguarding (heritage preservation, reuse of historic buildings, successful blend of old & new, revival of a run-down area) whilst the majority of respondents referred to the advantageous location of the district in relation to Manchester's city centre, as one of its core qualities.

In contrast with the high evaluation of the regenerations' aesthetic result on a building level, many respondents appeared dissatisfied with the district's lack of amenities and its current social state. The scarcity of supplementary commercial and recreational amenities and the absence of green spaces were highlighted as shortcomings of the regeneration. Additionally, the lack of community spirit was a common criticism.

Closing the analysis of Ancoats regeneration, we need to refer to recent developments and future plans. The most important development predicted to have a decisive impact on the socio-spatial fabric of Ancoats, is the formation of Manchester Life Development Company (MLDC) in 2014. MLDC is a residential development joint venture company between MCC and Abu Dhabi United Group (Manchester Life, 2015).

The residential redevelopment of Ancoats and the neighbouring New Islington is the focus of the MLDC's agenda which has promised the development of more than 6.000 new homes by 2024. With the first phase of 'Manchester Life' underway, involving the process of planning applications for the reuse of three sites in Ancoats, including Murray's Mills, concerns have been expressed by the local community. The residents remain sceptical about the program of new

projects while highlighting a need for more amenities, claiming: "*The area is increasingly appealing to both young couples with children as well as older 'empty nesters'– it is no longer just about young professionals. Therefore, it is important to provide safe play spaces, recreational spaces and green spaces for the needs of a more diverse community."* (Tomlinson, 2015).

Reviewing current press coverage of Ancoats reveals there are plans for some modest development of small-scale supplementary uses around the Cutting Square and across Great Ancoats Street. The degraded state of the north-eastern part of the conservation area receives less attention.

4 CONCLUSIONS

In this paper we attempted to identify the impact of the regeneration practice on former industrial cities, examining the case of Ancoats. We discussed Ancoats' role and drew parallels with Manchester's development, demonstrating its spatial and social values and the problems it was facing. A detailed analysis of the full course of the district's regeneration and the stakeholders' action since the late 1980's as well as a division in periods with distinctive characteristics was sought, expanding the existing knowledge base. Finally, using data from our qualitative, desktop and field research we were able to evaluate the impact of the regeneration and highlight its merits and pitfalls.

The evaluation of our case can be summarised in three main conclusions.

First, throughout Ancoats' regeneration process considerably more focus was placed on the resolution of spatial rather than social problems. It was evident that, apart from the early vision of the Urban Village, all other concepts – driven mainly by partnerships with commercial developers – prioritised a development vision that sought to enhance only the built environment. It is worth highlighting that this spatial enhancement was indeed achieved, in a style sympathetic to the historic industrial structures that once defined Ancoats' character. However, it was achieved by using more piecemeal gestures rather than a comprehensive plan. Consequently, after almost two decades, there is still a lack of amenities and evident spatial discontinuities.

Second, Ancoats as a typical product of developer-led regeneration schemes, is gradually becoming a gentrified and socially exclusive area. The converted mills are sold or rented at extravagant values, limiting the potential residential clientele. The sleek new developments in conjunction with the lack of any type of interpretation of the history of the district place Ancoats in danger of becoming a sterilised English suburb with a few romantic Victorian features.

Third, the stakeholders' action has had an enormous impact, steering the direction of the regeneration. We suggest that even in a neo-liberal system, not everything is, nor should be, predetermined and left merely to market forces. The Ancoats example proves how actors from the voluntary sector such as the ABPT can exercise influence and achieve results for securing the district's historical and cultural sustainability. The case also demonstrates the considerable power of the local authority and illustrates the impact of its fluctuating priorities. As shown, the commercial developers' growing power is undeniable yet can be fortified or controlled depending on the political will of the local and national authority and the community engagement.

The growing power transfer from the public sector to commercial developers in the established neoliberal system, is expected to favour the described negative implications of urban regeneration more and more in the years to come. Thus, further studies need to be carried out to explore the potential and limitations of alternative development approaches.

Even though every case is *sui generis*, there is common ground in the regeneration of European former industrial cities, resulting from the influence of the established socio-political system they share. Therefore, the investigation of the regeneration history of Ancoats, a representative example that epitomises the problems of post-industrial cities, can inform future practice on similar cases, making this research highly relevant.

We suggest that the binary nature of debates on the positive or negative nature of regeneration practices of former European industrial cities is erroneous. Drawing from the Ancoats case, we recognise that urban regeneration in a neoliberal system can have both positive and negative implications for our historic cities. The positive ones concern mainly the physical enhancement and the preservation of tangible inherited assets whereas the negative revolve around the issue of social gentrification and the loss of intangible values of heritage. According to our research, the decisive factor that can influence the balance between the two is the stance of the actors, such as the local authority and the local community, involved in each project.

Transporting transformations: A case study of built environment changed by transportation in rural China

Xiaoyu Lin & Beisi Jia
The University of Hong Kong, Hong Kong

Miao Zhou
The Southeast University, Nanjing, China

ABSTRACT: The vast areas of the countryside in China undergo a series of radical changes, both socially and spatially. Changing transportation is one of the affecting factors. In this paper, an in-depth observation on a specific built environment in rural context, the Xiaqiao village, is conducted to illustrate how the changing system of transport triggers a chain reaction in architectural transformation. The methodology of settlement morphology is implemented in the research by examining the transformation process of a built environment from different spatial levels in order to study how the socio-spatial structure transforms and develops.

1 INTRODUCTION

Rural China has been experiencing a series of dramatic transformations spatially, physically, and socially. It is often regarded as an aftermath caused by urbanization that obtains less attention in the academic field. Thus, this paper conducts an in-depth case study of the Xiaqiao village to research the transformation of the socio-spatial structure.

A wide range of affecting factors relate to the radical changes that happen, including economics, geography, population size, technological innovations, social concerns, and so forth (Headicar et al., 2009, Mandal, 1979). For the Xiaqiao village, the changing transportation system imposes significant influence on the development of rural built environments. The means of transportation is an important indicator to measure economic development. It decides the accessibility of goods and resources and the size of a local's communication circle. The technological breakthroughs of transportation weaken the influence that distance imposes on goods trading, knowledge and technology exchange, and the accessibility for the mobility of people (Gugler, 1978).

Xiaqiao locates within the mountainous region of the southern part of the Zhejiang province. Seven field surveys have been conducted since 2013. They provided me sufficient first hand data to explore the transformation of the village through the past 300 years, including geographical mapping, architectural drawing, and interviews with locals. The morphology methodology is used to examine the development process in different spatial layers from the settlement pattern (Habraken, 1998), building fabric, inner space, structure, and infill, to further discover the socio-spatial structure in the village.

2 THE VILLAGE IN GEOGRAPHICAL AND HISTORICAL CONTEXTS

2.1 *The Xiaqiao village and its geographical environment*

The terrain of the mountainous region where the Xiaqiao village locates is so complex. It is full of steep hills, deep valleys, rivers and basins. It is descripted by locals accurately as "nine tenths of the land are mountains, half of one tenth are rivers, and the other half are farmlands." (Fig. 1) Geographical constraints by mountains operate on the availability of transportation for people and goods. Mountainous part cut off the world inside from the outside world to some extent. Compared to the crisscrossing circulation network by roads and water in plains, the complex terrain largely increases the cost of time and money, decreases the efficiency in transporting goods, shuttles people and circulates information. The difficulties of transportation obstruct regional development and make it to be the poorest region in the province for a long period (Wu and Liu, 2009).

The separation of geography makes this mountainous region a comparatively independent area socially, economically and culturally in the province. Also, the numerous mountains and valleys also restrict efficient communication inside. Thus, it forms several inter-independent sub-regions. The Xiaqiao village is the center of the southeast region serving as a regional traffic hub. It locates in a small basin that connects five adjacent townships and hundreds of villages within, taking up an area of one third of the whole county. The exploitation, formation, and continuous development of the community all benefited from the advantages of its location for centuries. However, conversely,

Figure 1. Historical Map of the Region (Lin and Lin, 1975).

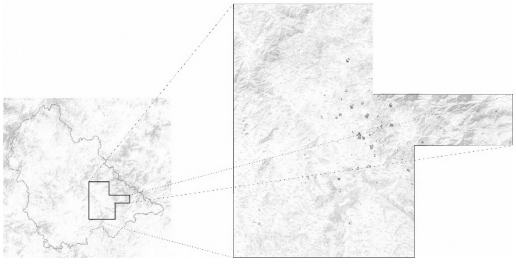

Figure 2. Geographical Distribution of Marriage Relations (Drawing by the Author Based on Google Maps, 2016).

the potential for the village's development is also restricted by the insular geographical environment and the undeveloped transportation system.

2.2 *The changing transportation system in the village*

Before the modern roads were well built, the traditional roads in the region were made of stone and mud allowing only a one meter width for horse rides and walking. It took a adult male half a day to arrive at Luoyang, the central town of the county, or Pingyang, the neighbour county, and three days to reach out at Wenzhou, the city to which the village belongs. The daily life and communication of the residents here are usually constrained inside a small geographical circle with a distance of half a day's walk. From the statistics of marriage and land reclamation counted from the family archives in the Qing dynasty, most of them are conducted inside the southeast part centered by the basin where the village locates (Fig. 2).

The first modern road going through the village was built from 1966 to 1971. Afterwards, more roads were planned, built and updated inside and around the village, and are still processing today (Fig. 3). The means of modern transportation changed the way people and goods travel. The time spent to move to other places has been drastically shortened. Nowadays, a resident only needs one and a half hours by car to reach the central Luoyang town or the neighboring Cangnan town, where a high speed railway station has been open for two years. It makes possible to transport villagers to places far away, such as Shenzhen or Shanghai, the two economic centers in China. To arrive at Wenzhou city, one only needs three hours via bus.

The improved transportation system is connecting the village with the whole world. Due to the advantage of the increased accessibility of transport, tourism has been developed tremendously, which changes the economic sector and lifestyle of the village. It is known that the village has received around 450,000 tourists in 2014, among which 60% are from Wenzhou and 40% percent from other places, including foreigners. It takes about 4.5 billion yuan in income from tourism and other relative industries. The gradually developed transportation system has been remodeling the rural landscape dramatically.

3 TRANSFORMATION OF SETTLEMENT PATTERNS

3.1 *Disappeared boundary*

The modern transport network dismantles the spatial separation between settlements. Traditional settlements are enclosed by geographical settings, such as mountain ridges, rivers, and farmlands as a result of adaptability to natural environments in the settling process, which always creates clear boundaries and can be defined clearly. The built area of Xiaqiao and that of its neighbor settlement Baifenqiang stood apart by the Dongxi River, farmlands and highlands between them. However, since modern construction, the Xinyang Road and the Sishui Road in the 1980s, both villages have grown along the line of traffic to maximize the usage of the roadside and finally merge together on space around the Dongxi river. Thus, the spatial boundary has disappeared through the connection of the roads (Fig. 4).

3.2 *Agglomerating settlements*

During the agrarian era, due to the limitation of capacity that a per area farmland can support, local peasants had to migrate to remote places to discover unexploited lands when the population increases continuously. Instead of concentrating, it is a process of settlement dispersing. However, the modern transportation system leads to a new round of population concentration. It reversed the movement of settlers existing in this

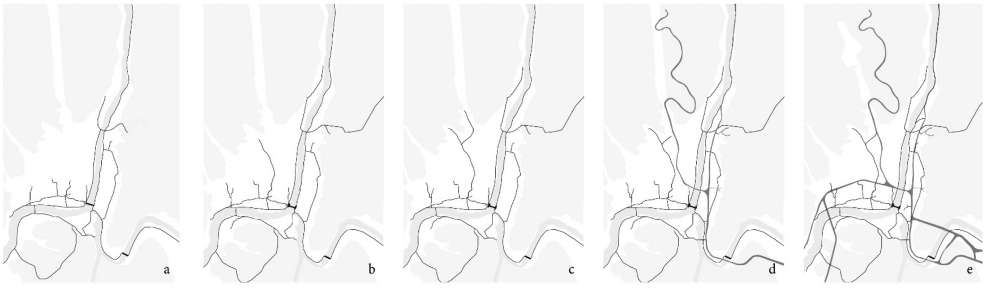

Figure 3. Construction of Roads along Temporal Sequence (a: The Early Stage of the Qing Dynasty; b: The Later Stage of the Qing Dynasty; c: The Republican Era; d: The Planned Economic Era; e: The Market Economic Era), (Drawing by the Author, 2016).

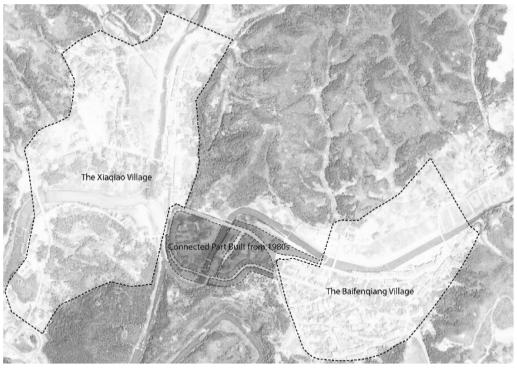

Figure 4. Connection of the Adjacent Two Villages (Drawing by the Author based on Google Maps, 2016).

mountain for centuries. Today, residents live in peripheral settlements moving toward a central one near the main road to increase the accessibility to reach more resources and opportunities for better life, education, and work. The advantages and economic interests can be seen on the roads via trade, and tourism stimulated the spatial agglomeration of settlements (Fig. 5). The new means of transport enable the mobility of people and their households sufficiently. Many families in Xiaqiao migrated from neighboring villages deep inside mountains in recent decades, and some of them are even from other cities and currently work here.

3.3 *Shifting value of land*

Houchi has been the best residential area with the highest built-up density, the longest history and the best Fengshui (Chinese Geomancy), which attracted the most influential families to compete for the right to live here until the 1970s. (Fig. 6) The area next to the Beijian bridge has been the primary trading field with several stores selling goods for passengers for a long time. The newly constructed road network reverses the spatial structure of the village. The original peripheral building groups around Nanshan Hill that are settled by the Chen family became more prosperous in the community because of its convenient location next to the new transport entrance from the province-leveled road into the village. New restaurants and hostels opened by renovating old dwellings. The first and also the busiest restaurants in Xiaqiao all belong to this area. In 2014, the first boutique hotel that can be booked via the internet in the small village operated by a couple living in Luoyang opened here as well. In contrast with the flourishing area of Nanshan, the west bank of Houchi contains two large traditional courtyard dwellings built by the elite from the wealthy Tang in Qing dynasty, but they have been desolated since the 1990s due to its location being away from the newly constructed roads.

The shift of land value also leads to the transfer of social structure. The previously powerless Chen family gained more power in the Xiaqiao village to compete with Tang and Lin. The convenient means of transportation brings in great income for the locals by tourists all around the world. Stimulated by the booming tourism, all space values are transferring. The wooden pavilion bridges and traditional dwellings lost their original function of traffic or accommodation and are now viewing spots for visitors. The area next to the Beijian bridge changed into a park where new construction is not allowed to protect the architectural remains and to attract tourists. Besides, a carpark, a spatial novelty that has never been seen in the village before, was built to fit the requirements of parking raised by new means of transportation.

4 TRANSFORMATION OF BUILDING FABRIC: NATURAL ENVIRONMENT ORIENTATION TO TRANSPORTATION ORIENTATION

The building fabric in Xiaqiao shows a clear shift from a natural environment orientation to a transport orientation (Fig. 7). During the pre-modern era, a close fit has been exhibited between an agrarian way of life and a domestic space. Conditions of a natural environment are always considered first for site selection. Thus, dwellings are built at the foot, or on the slow slope of a mountain, as a comprehensive measure for balancing the losses of farmlands by house occupation and Fengshui, the traditional evaluation system

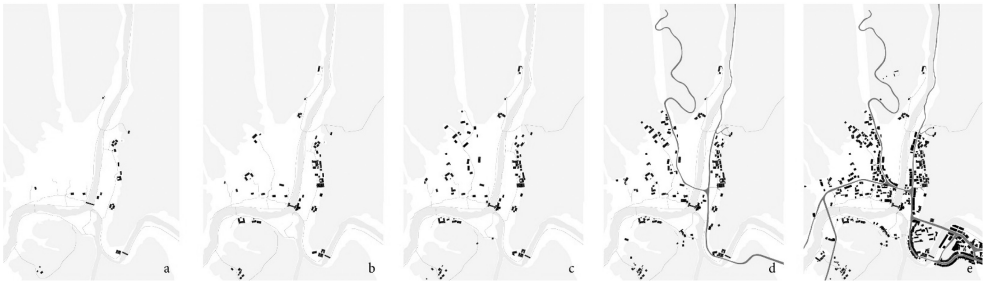

Figure 5. Growth of the Xiaqiao Village (a: The Early Stage of the Qing Dynasty; b: The Later Stage of the Qing Dynasty; c: The Republican Era; d: The Planned Economic Era; e: The Market Economic Era), (Drawing by the Author, 2016).

Figure 6. Function of Buildings in the Village (Drawing by the Author, 2016).

Figure 7. Co-existing Building Fabrics Built in Different Eras (Drawing by the Author, 2016).

of geographical environments in China. It is indeed a metaphor of environmental determinism (Fig. 8).

In addition, the direct relationship between the house and the traditional road has never been a necessary prerequisite in the site selection of new houses during the agrarian era. Essentially, house construction is often ahead of path construction. It is common that after the building was built, a pavement will be created spontaneously towards the new house. Besides, traditional houses always avoid facing main roads directly in pre-modern times both physically and mentally. They often are located on the secondary path deriving from the main road, with an enclosed courtyard wall or a receded space ahead as a transition so as to separate from the public.

However, the situation changes in the construction of modern road networks that a transportation-oriented approach to organize spaces is developed. Houses are emancipated from the restriction of farmland preservation and are lined up in a row trimly along the road. Houses are relocated next to new lines of transport, which substitutes the original group-shaped building fabric (Fig. 8). The line-rowed pattern fits the requirements of increasing mobility of rural populations as well as their accessibility for more resources. Meanwhile, transitional space has disappeared as well. The doors of new houses directly face the road and facilitate daily access. It fosters the spatial transformation from living spaces to small groceries next to the road where goods are sold to passengers and drivers.

Figure 8. Traditional Houses Built Next to Mountains (A, B, C); New Houses Built Along the Road (D, E, F), (Drawing and Photo by the Author, 2016).

5 TRANSFORMATION OF INNER SPACE AND ITS FUNCTION

Rural settlements only need to satisfy the requirements for a basic living during pre-modern times, like accommodation for shelter, cultivation for livelihood, and popular beliefs for spiritualism, with periodic fairs for exchange and other necessaries. With the all-directional transportation system spreading out, spaces with new functions are imported into houses. The tourists being transported through roads stimulates the renovation of common dwelling spaces into visitation spots, museums, stores, hotels, and restaurants entirely, or partially, by functional displacement of several selected rooms.

The new functions brought about cause a series of chain reactions in spaces. For example, the front space of the first floor in houses are always changed into small stores to sell snacks and groceries. It takes up the original space as the living room. Corresponding to the new situation, living rooms have to move backward and merge with the dining room and kitchen in the rear. In other cases, the front living room can be used as a temporary reception when the houses are partially changed into a hostel.

Figure 9. Envelops of New Houses (Photo by the Author, 2015).

6 TRANSITIONAL CONSTRUCTION SYSTEMS: MATERIALS, STRUCTURES, INFILL, AND FURNISHINGS

Rapid means of modern transportation improves the availability of transportation for goods and people. In this respect, new building materials and techniques are more accessible for local villagers, which in turn changes the form of vernacular dwellings immensely.

During the Qing dynasty, traditional dwellings were built by local builders and with local materials. Most of them used local wood while some poorer builders used mud-bricks. In the later Republic period, due to the rapidly expanding trade routes, newly imported material such as the steel used to construct window bars was being transported directly to the village. Right up until the 1970s houses were still being built by Xiagiao's villagers themselves, who used locally manufactured mud-bricks and quarried stone in response to the decreasing availability of wood. Both the architectural forms and construction methods are vernacular as a self-sufficient system with little reliance on the outside market.

The first batch of houses displaying modern architectural forms were built in the 1980s along the newly constructed East Sishui Road (Fig. 9). Since then,

Figure 10. Similar Organization of Inner Spaces in Traditional Houses (From Left to Right, A: The Central Hall of the Second Floor; B: The Central Hall of the First Floor; C: Kitchen in the Back; D: Private Domestic Space), (Photo by the Author, 2015).

Figure 11. Modern Furnishing in New Houses (Top: Kitchen; Bottom: Living Room), (Photo by the Author, 2015).

especially in the last two decades, the village has experienced unprecedented architectural transformation and modernisation. The transportation of new materials has been largely simplified by the use of trucks. Meanwhile, the outside world is more accessible to all villagers thanks to public buses and private cars and motorbikes. While still young nearly all residents leave the village for a larger city in search of a job or education. When they return home, they bring with them a modern domestic lifestyle along with new building techniques and novel architectural forms. The knowledge of modern architecture are then introduced to this remote village.

Instead of keeping to the traditional forms, the new houses are built totally in modern styles; with brick walls, larger windows, higher ceilings and bigger rooms. Fired bricks and steel reinforced concrete are the major materials used for the load bearing structures. Ornate tiles, colourful paint, clean glass, and aluminium alloy frames are used to clad the houses and decorate their facades. (Fig. 9)

Besides the decoration on the outside walls, inside the furnishing are different as well. The rooms in the traditional dwellings are sparsely decorated. Moreover, the type of furniture used and their arrangement in all traditional dwellings are so similar that there is hardly any variation. Chairs, tables, beds and cabinets are made of wood or bamboo and are allocated to rooms in keeping with conventional customs (Fig. 10). These days, however, a wide variety of appliances and furniture can easily be transported to every home which leads to a diversity of interiors. Instead of the completely self-operated construction method of vernacular dwellings, house construction takes full advantage of the newly found access to the wider world; as a part of the national market system or possibly even on the global level (Fig. 11).

7 CONCLUSION

Generally, under the influence of modern transportation that fastens and eases the circulation of goods and people whereby its all-directional roads' tentacles, spatial structures of rural landscapes are remodeled dramatically to fit the new needs created by increasing communication with the outside world. The Xiaqiao village transformed from a scattered pattern into a more compacted pattern. The whole system of construction transformed from traditional to modern including building form, techniques, and materials. All these changes are accelerated by economical interest and cultural globailiztion transported by new means of transportation. To respond to the new challenges raised

by the modern society, the village has to transform itself into the contexts of globalization gradually.

All the transformations happening in Xiaqiao is a small part of what is happening in rural China entirely. This analysis provided demonstrated the drastic changes that are now happening in every corner of rural China. It heralds a strengthening of ties between small villages and the whole world by this new means of connection.

Emerging patterns of change for tomorrow's cities

D.P. Henriques
Faculty of Engineering and Environment, Northumbria University, Newcastle Upon Tyne, UK

ABSTRACT: Today, climate and demographic changes are becoming the greatest challenges for cities and their multicultural populations. On the other hand, there is a growing societal acceptance of information and communication technologies around the globe. And this connectivity is influencing both design thinking and research methods, while generating large quantities and a wide variety of data. In this paper, emerging patterns of change for future cities are surveyed, and international networks for urban research are highlighted. As such, criteria to analyze and compare trends, shifts and hypes in urban studies and planning are searched. Moreover, interactions between open data and green infrastructures are foreseen, in order to promote public development for future cities. Finally, a need for common mind sets and methods is claimed, namely between computing and social sciences, to engage local communities and public organizations.

1 INTRODUCTION

According to Mortensen (2015) *change*, in its most general conception, can be seen as 'difference or non-identity in the features of things,' whilst another usage may be temporal change, exemplified by 'change in the properties of a body over time.' In his perspective, the change of temperature in distinct components of a body could be measured, the change in atmospheric pressure at different places might be recorded by isobars, and/or the change of parameters of a surface/body would be represented by numerical descriptions, contour lines or distinct colors. Nevertheless, '[c]hange is so pervasive in our lives that it almost defeats description and analysis' (Mortensen 2015).

At a recent TED Talk in Vancouver BC, Al Gore (2016) recalled our attention to a series of extreme weather events increasing around the world in recent years, which show dramatic *climate change* effects on cities, regions, countries and their multicultural populations, in past and present times, and for the future: Typhoon Haiyan in Philippines and Pacific Ocean, Storm Sandy in the west coast of the United States of America, particularly in New York City, and historic floods in Chile, Brazil, Serbia, Czech Republic, Mozambique, India, China, and Australia.

Since the turn of the 21st century, and for the first time in human history, the majority of the world's population is already living in metropolises, cities, towns, and other urban settlements. While the world's population by 2015 was estimated to be around 7.3 billion, of whom 60% are living in Asia, it is projected to reach 8.5 billion by 2030, and up to 9.7 billion people by the year 2050, of whom 66% will be living in cities. And this *demographic change* is not predicted to occur evenly in the entire globe, but also in extremes: whilst half of the global population growth between now and the year 2050 is anticipated to occur in Africa, a considerable decline is expected over the same period of time for the population in Europe (UN 2015).

This global and pervasive change in densification of urban populations, in developing and developed regions of the world, will certainly increase strains on the built environment, public spaces, buildings, infrastructures, transportation, energy, water, waste and other urban systems, and probably on the natural systems of the planet Earth as well.

On the other hand, there is a global acceptance of information and communication technologies (ICT) at all levels in societies, such as internet, static and mobile computing devices and wireless networks, clouds, GPS satellites, and so forth. As such, this *connectivity* between people, things, natural and built systems, is influencing design thinking and methods, while generating previously unforeseen quantities and variety of data.

What will cities look like in the future? How are networks of researchers generating and sharing data and knowledge on urban systems, in order to address these climate and societal challenges? In this paper, emerging patterns of change for tomorrow's cities are surveyed, while pointing out international *networks for urban research* that are tackling those challenges both in the lab, in the office, classroom, and at the auditorium, on headquarters and also on campus, in the field and increasingly online.

2 MODELS, FORESIGHT AND CHANGE

Whilst urbanization is already facing these complex and unprecedented challenges, such as climate and demographic changes, it is also influencing theorists, academics, researchers and planning practitioners to

understand cities as *complex systems* (Batty 2013, Jacobs 2001), through an interdisciplinary approach not only for real time sensing, visualizing, modeling, and managing processes for today's cities, but also for medium and long term strategic thinking and planning for the cities of tomorrow (Moir et al. 2014, Tewdwr-Jones & Goddard 2014, Ward 2004, Echenique & Saint 2001). Although several issues about knowledge transferability can be raised (e.g. a city is neither a tree nor a war), this understanding of complexity and uncertainty can have a considerable impact in urban studies and planning, since it has proven results in other fields during the 20th century, such as warfare and business operations, as it will be summarized in the following paragraphs.

2.1 *From warfare to business operations*

Mostly during second world war, researchers were mobilized into military operations and governments, to develop new fields, such as atomic and nuclear energy, radar, and computers: the results have been applied and known worldwide. In the 1950s and 1960s, many of these researchers were employed by private corporations and/or public institutes, to adopt the mathematical models and analysis to business operations, namely through foresight, trend reports, *scenarios* and other innovative processes that could alter past mental conceptions and enable unthinkable futures. Thus, corporate planning in such companies like General Electric (GE) and Royal Dutch/Shell Group (Shell) developed new standards for medium and long term strategic thinking and planning, which allowed these corporations to act quickly in crisis situations (e.g. Yom Kippur War in the Middle East and the following oil embargo), and to move into leading positions in the global markets, until today. Moreover, *systems thinking* was being developed by researchers, and applied to model interconnections and explore limits between key variables, such as population, natural resources, pollution, food and industrial production (Benn et al. 2014, Kosow & Gaßner 2008, Ringland & Young 2006, Wilson 1992).

2.2 *Complexity, computers and data*

Particularly since the 1970s, the initial acceptance of computers also started to change urban studies and planning, but they were available only to a limited number of theorists, researchers and practitioners. For example, Tobler (1970) and Batty (1976) developed models to analyze, visualize and understand urban complexity, through computing methods and collaborations with researchers from other fields, to enable innovative advances in urban research.

However, in the last decade static and mobile computing devices and wireless networks have been embedded in all aspects of our daily life, and societies in almost every location of the globe seem to accept this connectivity. These (new) digital possibilities are influencing both design thinking and research methods, and opening paths for novel sub-disciplines, for instance digital fabrication, generative and algorithmic design (Hanna 2013, Oxman & Oxman 2013, see also Hauschild & Karzel 2011).

At the moment, the possibilities of data to inform, model, manage and foresee complex urban systems and planning processes might be highly promising (if not overwhelming): more than 90% of all the data in the world has been generated since 2011, and this seems to be increasing non-linearly with more data being generated and released by people and/or things, groups and periods of time, which can be combined into larger groups and/or longer periods of time, shaping up what is presently named big data, and widening the range of advantages for research (Dragland 2013).

As such, between the utopian and dystopian urban visions imagined over the past centuries, and the best practice examples of urban planning around the world, there is the momentum to share *urban data* among public sector organizations, universities, transnational ICT corporations and local community groups involved and interested in urban research through international networks.

3 URBAN PATTERNS OF CHANGE

3.1 *Green, smart, refugee and collective*

In the past, several urban visions were proposed by historians, academic and practicing planners, novel writers and film directors, geographers, environmentalists and preservationists, local and neighborhood communities, public policy makers, and/or other stakeholders interested in urban processes, and some of these visions were planned, built and can be experienced today as best practice examples of resilient urbanism. In this section, emergent patterns of change in urban studies and planning will be surveyed: (a) the garden cities movement and its legacy for a green future; (b) the global smart cities trend, where governments and ICT corporations join forces; (c) the sudden increase of refugee camps, tent cities and shanty towns due to extreme weather events and man-made disasters; (d) the engagement policies and actions involving local communities; and (e) the open data initiatives.

3.2 *Garden, eco and green cities*

Initially proposed in *To-morrow: A Peaceful Path to Real Reform*, Howard's (1898) garden cities vision, i.e. a network of urban settlements combining city and country characteristics in order to manage social and economic change, has been claimed to be one of the most enduring and transferable of those visions, influencing urban planning in Europe and also worldwide, for more than one century (Ward 2016, Dunn et al. 2014, Hall & Ward 1998).

While addressing solutions to housing shortage and pollution issues in growing mega cities, such as London in the end of the 19th century (and in

many other locations still today), Howard developed an urban vision that combined both natural and built environment. Furthermore, the garden cities vision promotes a sense of community and considers limits of growth (e.g. the green belt strategy), while structuring a hierarchy of planning principles that allowed it to be reconfigurable and adapted in very different geographical, economic, cultural and even social contexts, and has ultimately also generated data and knowledge from scholars from distinct disciplines (Stern et al. 2013, Ward 1992, Hall 1988). And, to implement his urban vision, Howard also started the organization now known as the Town and Country Planning Association (TCPA), which laid ground for other similar groups in different countries, and for an international network that organized visits to the best practice case examples (e.g. Letchworth, Welwyn garden cities), meetings and conferences, even in some conturbated periods of world wars. Moreover, the garden cities movement (and the TCPA) helped to build the conceptual and methodological structure of a national planning policy in the United Kingdom, more concerned with environmental issues, and global policies for green cities which are still valid today, thus engaging through top-down and bottom up approaches, and promoting social and environmental values (Parsons & Schuyler 2002, Fishman 1977, see also Hein 2014, Jacobs 1961).

Considering the wide geographical application, the considerable timescale, the success of both top-down and bottom-up engagement, the promotion and adoption of social and environmental values, and how it laid ground for data and knowledge access through international networks and scholarly work, the garden cities movement can be considered the most meaningful (modern and) contemporary trend in urban studies and planning.

In fact, garden, eco and green labeled cities are spreading worldwide, though sometimes is not clear what ties together all these cities. Nevertheless, strong research in urban studies and planning with environmental motivations is still needed (Beatley 2012, Cohen 2011), to address these issues not only in higher education, but at all levels of society, for future generations and maybe even for the survival of humankind.

3.3 *Smart cities and ICT corporations*

ICT and Internet of Things (IoT) are currently being applied in experimental pilot initiatives across the globe to envision, monitor, and also manage urban systems (e.g. water, food, energy, green, waste, transport and communication), in order to generate and promote economic prosperity, social well-being, efficiency and sustainability.

On the one hand, recent examples from *tabula rasula* experiments with embedded ICT integrated in the earlier stages of the urban planning process (e.g. Songdo in South Korea, Masdar in the United Arab Emirates), developed by transnational corporations,

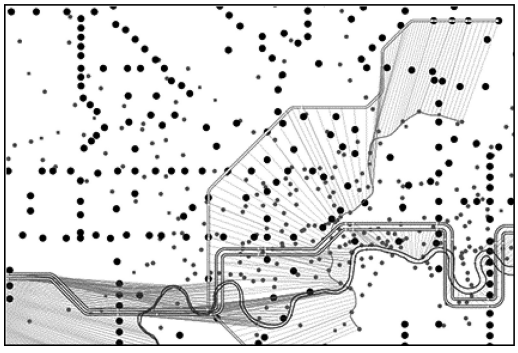

Figure 1. London's metrography, data visualization/ mapping processes, 2012. Authors: Benedikt Groß & Bertrand Clerc. (Courtesy of the authors). Available at: <http://benedikt-gross.de/log/2012/02/metrography-london-tube-map-to-large-scale-collective-mental-map/> [accessed 2016-2-21].

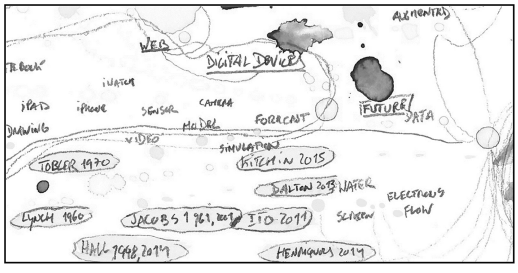

Figure 2. Timeline sketch, mapping technological processes and key researchers in urban studies and planning.

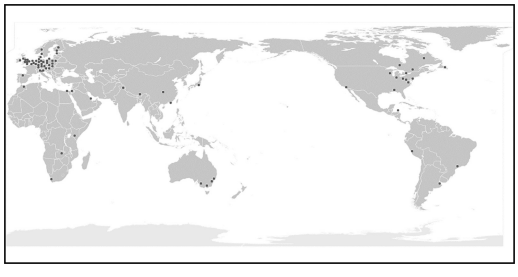

Figure 3. World map of garden cities.

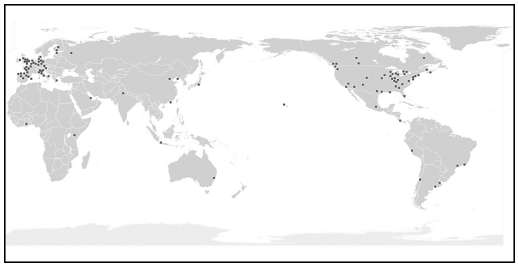

Figure 4. World map of open data initiatives, mostly distributed in Western Europe and North America regions.

seem to show evidence that successful cities thrive through a complex interaction of urban systems, whatever their classification relates to garden, eco, green, smart, or (gentrified) historic, with their local and neighborhood communities

On the other hand, and particularly through public developments in Europe, some degree of success is shown in overlapping new systems of ICT and IoT, which are adjusted to existing cities, alongside green infrastructure, tangible and intangible heritage, and so forth (Manville et al. 2014). And this seems to confirm that an interdisciplinary approach to cities is needed. While it could be argued that the association of both trends, i.e. urbanization and digitization, has indeed the potential to inform urban studies and planning, modeling, foresight, and also management processes in cities, there is still the need of evidence for civic and other cultural utilizations (Batty 2016, Kitchin 2016, 2015, Henriques 2014).

Particularly in smart cities, these transnational ICT corporations have been showing a deep interest in the generation of urban visions that seem to promote major changes in most urban lives, following such visionaries like Jane Jacobs or Le Corbusier (Greenfield 2016). This recent global smart trend (or is it only a hype?), promoted by corporations such as IBM, Cisco and Google, might raise ethical issues and other implications for the future of humanistic cities, since it implies opportunistic sensing and monitoring of its citizens through algorithms, sensors, cameras, crowdsourcing and other information extraction networks essentially from a top-down perspective. Nevertheless, more can be made through partnerships between some of these corporations, universities, local institutions and communities, to enable informal data collection and mapping efforts of bottom-up approaches, in order to augment our understanding of cities as complex systems.

3.4 *Refugee camps, tent cities and shanty towns*

Probably in every period of history, urbanization and temporary settlements such as refugee camps, tent cities, shanty towns and slums, have been associated (see also Lefebvre 2003). For example, between the 19th and the 20th century, slums were common in London (Yelling 2007), and Howard's invention of the garden cities vision was a response to those challenges. Nonetheless, refugee camps, tent cities and shanty towns continue to spread nowadays (Davis 2006, Neuwirth 2005), in particular caused by extreme weather events and other natural disasters, and also man-made disasters, for instance war, famine, social and economic inequality and/or pollution.

Although emergent research is being conducted in these areas (WHO 2016, Iosifova 2015, and also in forthcoming exhibitions at the Architecture Biennale in Venice and in the MoMA in New York), still much has to be done: their geographical location, timescale, the urgent necessity of both top-down and bottom-up engagement, and also the major social and environmental issues that these temporary cities are raising, make these temporary settlements one of the most underestimated trends in urban studies and planning for international networks. Available data and knowledge access could be a positive solution to promote research engagement, and perhaps even a meaningful shift for all humankind.

3.5 *Community engagement and open data cities*

Jacobs defended that '[n]o other expertise can substitute for locality knowledge in planning', thus arguing that '[t]he invention required is not a device for coordination at the generalized top, but rather an invention to make coordination possible where the need is most acute - in specific and unique localities' (1961), while laying the bases of a strong bottom-up reaction in the 1960s and following decades against the top-down approaches in urban studies.

Open data has been seen as a bottom-up approach to involve communities in the digitization of 'smart' urban systems and utilization of data sets, previously only available to researchers and institutions, in closed silos. Furthermore, the usability of transferable lessons between the smart and garden urban visions could allow a shift, in order to support new bottom-up perspectives on civic and social international networks to address climate and demographic change (Henriques 2016). This could promote community engagement in future cities, through interactions between environmental open data and green infrastructures, integrated in resilient urban systems to face extreme weather events. At the present stage, most of open data initiatives (either promoted by local institutions or by governments at a national level) are located in Europe and North America.

Moreover, hackathons and other collective events have been particularly successful in the last years, and these could be considered either a hype or a shift, within community engagement. These events can test, develop and show new methods and methodologies to conduct interdisciplinary research strategies and to involve public organizations, universities, corporations, and local communities.

While it seems that digital structures also follow geographical laws (Hecht & Moxley 2009), urban research concerning human factors (Walf et al. 2015, Henriques 2013, Zimring & Dalton) is needed. Perhaps, common(s) language(s) such as maths, sounds, images, visual and textual programming might represent possible links within international and multicultural networks.

4 CONCLUSION

In this paper, initial criteria to analyze and compare trends, shifts and hypes in urban research were searched: (a) geographical location; (b) timescale; (c) top-down and bottom-up engagement; (d) social

and/or environmental values; and most importantly (e) data and knowledge access.

As stated in the EAAE/ARCC 2016 call, '[a]lthough challenges are global, solutions need to be implemented locally.' And international networks for urban research, including universities, can thus contribute to imagine, discuss, develop and promote alternative futures for a changing society. For example, the principles that supported the global garden cities movement can lay ground for open data initiatives: data is the new soil. Thus, possible interactions between environmental open data and green infrastructures are foreseen, for public development in tomorrow's cities. Nonetheless, future research is still needed, in experimental urban data visualization alongside user experience studies, within urban planning processes.

Although interdisciplinary research strategies are essential between corporations, universities and local businesses to address these urban challenges, such as climate and demographic changes, it was claimed a need for common mind sets and methods, particularly connecting both computing and social sciences, to engage with local and neighborhood communities, and public organizations.

Transformation of Chinese traditional mountain village in contemporary era: The study case of Tangdu Village in Guizhou Province

Qian Du
Department of Dist, Politecnico di Torino, Torino, Italy,
Chinese Academy of Cultural Heritage, Beijing, China

ABSTRACT: This paper, from the aspect of architectural conservation and renovation, discusses the transformation of a Chinese traditional mountain village facing the modernization. Through the comparison between the traditional architectures and modern architectures, this paper tries to find the continuity and deformation of the local traditional architectural culture. Rather than criticizing the villager's spontaneous constructions, it is better to consider their demand of development and give appropriate suggestion.

1 INTRODUCTION

Protecting the traditional Chinese village culture and its vernacular architecture is a topic of general interest and concern in recent years. Modernization, urbanization, and accelerated economic activity are capable of affecting developmental shifts in the most remote areas in China. The accelerated and unpredictable course of such transition is always of great concern in developing countries – lest something of significant cultural value be permanently lost in transition.

Whereas the forces that drive this form of widespread change are unavoidable – infrastructure and industry grow in complexity – the effects are not always easily understood as intrinsically good or bad. In order to promote policies which safeguard the valuable qualities of traditional Chinese village culture, it must be discerned how progression serves to efface rustic or regional heritage. Understanding the nature of this phenomenon will provide a course of appropriate action.

The Chinese Academy of Cultural Heritage (CACH) initiated a case study of a traditional village in 2014[1]. By tracking data pertaining to the structures in the village, CACH has documented both traditional and modern structures. The information gleaned from the study provides many facets for detailed analysis.

2 BRIEF PRESENTATION OF THE STUDY CASE: TANGDU VILLAGE

The object of this case study is Tangdu Village, located in the Huangping County of Guizhou Province. (latitude N 26°50′01.5″, longitude E 107°59′21.6″). By elevation Tangdu is considered a mountain village situated at an altitude varying between 750–950 meters above sea level. It is of moderate size compared to surrounding villages, comprising 3.2 square kilometers of administrative area and 371 households (Fig. 1). The aborigine, Ethnic Ge, a minority without official recognition, practices the native crafts, such as silver jewelry making, batik, and embroidery.

The local economic paradigm is expressed as a predictable agrarian self-sufficiency, though encroaching modernization has changed the landscape of the village in recent years. This can be seen in the advent of modern concrete, brick, and multi-story buildings that have been gradually replaced existing structures.

Heretofore there has been little consideration of intrinsic value regarding the disappearance of traditional wooden structures in the village. On the other hand, the shift in building material preference is not motivated by any logical external force such as a desire to cultivate tourism or the intervention of outside interest in commercial exploitation.

The noticeable change in construction activity is entirely motivated by local internal interests. These circumstances make Tangdu village an ideal subject of inquiry. This case study clearly demonstrates an underlying evolutionary template at work on a societal level. Tangdu Village rests on the cusp of an imperceptible pivot of which pre-industrial standards of living give way to the modern.

3 RENOVATION OF TRADITIONAL HOUSE AND NEW CONSTRUCTION

In Tangdu village, the residential building can be understood to comprise the basic building block of life in the village. Its principle function is to

[1] The research was supported by Chinese Academy of Cultural Heritage research program 2015-JBKY-01.

Figure 1. The village structure, 371 residents, a primary school, two clinics, six retailers, a private brick making factory, and an-other two festival sites. (Drawn by author, source village survey map in 2012).

accommodate basic human needs that embody the comforts of home, be they social, economic, or bodily.

The residence found in the village is very distinct from a contemporary urban house meant to provide the same function. Whereas the villager may express the freedom to draft this building according to their idea of efficiency or personal taste, the urbanite must accept the widespread structural choice as they find it; as these archetypal choices were cemented in place by the sheer complexity of mass culture. In this light, any

Figure 2. House AE031 in Dec 2014 (Source CACH investigation in Dec 2104).

change in normative procedure within the village itself may pass without being perceived as significant by residents. The new approach evolves out of old thinking as a matter of progression.

Renovation, demolition and reconstruction of housing occur at a variable rate during the life of the average villager, especially in the case of the wooden buildings. This series of activities began with the founding of the village and continue as a matter of course. During this process the accepted cultural norms may change with the passing of each generation and in turn influence those to come.

Contemporary issues or particular needs in a given timeline may impact local opinion and result in evolutionary changes to the building. Rather than regard the traditional building as having inherent style, it would be more accurate to regard it as the sum total of a people's collective expression of the immediacy of their way of life. Small changes in longstanding practices in architecture lead to exponential re-ordering of the entire societal schema.

3.1 *Repair of old wooden house*

Although wood is a natural source of stability in structures, it is nevertheless subject to organic decay and gradual degradation. The house made of wood ergo requires periodic maintenance to prolong its utilitarian functionality. This method of repair may take the form of applying a coat of oil or the occasional replacement of the decayed component. Different levels of change in local structures accompanied this process. The following illustrates an example.

The first image (Fig. 2) shot in December 2014 shows the former condition of a traditional wooden house AE031[2]. House AE031 presents the typical vernacular architecture in Tangdu village. As seen from the photo, the house was a dark brown in colour, the upper wall made of bamboo weaving and earth, while the lower wall was comprised of wood panelling. There does not appear to be any damage to the wooden structure.

[2] All the houses in the village have been codified during the field investigation of CACH in Dec 2014.

Figure 3. House AE031 in May 2015 (Source author investigation).

Figure 4. House AE031 in Sep 2015 (Source CACH investigation in Sep 2105).

The second image (Fig. 3) shot in May 2015 illustrates the owner has acquired the wooden panels and modified them to suit.

In September 2015, the repair was completed (Fig. 4). There is no change to the former structure and the roof. Several brown panels over the door are preserved. New wooden panels replaced the bamboo weavings. The most noticeable change is the augmentation of the dimension of the window. Before restoration, the house had just four windows: two in the middle wall and two on the each side of the lateral wall. By contrast, the house after restoration added four windows, which altered the rhythm of architectural order, emphasizing the horizontal line.

We can define this case as "repair and restoration" because the house was not dismantled and the structure has been still preserved. However it is difficult to distinguish if the renovation of house AL014 (Fig. 5) and BC024 (Fig. 6) is still restoration activity. The preservation of the wooden structure and use of brick both appear on the same building. Without diachronic study, an argument could be made as to whether to describe this case as it "replacing the woods with brick" or "insertion of a formerly wooden structure into a newly constructed brick house". Furthermore, the length of the distance between the houses AE031, AL014, and BC013 (Fig. 7) is arguably indeterminate. Even through the basic layout of the house does not

Figure 5. House AL014 in Dec 2014 (Source CACH investigation in Dec 2014).

Figure 6. House BC024 in Dec 2014 (Source CACH investigation in Dec 2014).

Figure 7. House BC013 in Dec 2014 (Source author investigation in May 2105).

change in these cases, the demarcation dividing what is to be considered traditional maintenance and modern change becomes ambiguous.

3.2 *Construction new wooden house*

The continuing construction of new wooden houses remains in the village (Fig. 8). This is somewhat the result of the geographic condition of the region that results in limiting the depth of a traditional wooden house. New construction techniques and the use of

Figure 8. New wooden house AM010 in Dec 2014 (Source CACH investigation in Dec 2014).

Figure 9. House AG036 in Dec 2014 (Source CACH investigation in Dec 2014).

rivets for connecting pieces have contributed to the increase of building height.

According to the local records, 52 new wooden, two-story buildings, 51 of them present "|" form. The increase of volume does not change the traditional symmetric layout or the entrance space with a porch.

A notable innovation is the placement of stairs arranged inside the house, whereas traditionally the vertical connection afforded by ladder was the preference. Certain additions suggest changing sensibility about a home's relationship to society. Glass covering has been added to windowpanes suggesting preference to keep certain elements of nature from contact with the interior setting. Also of note is the addition of a sturdy metal plank used to bar the door against unlawful entry (Fig. 9). These changes are clearly motivated by a perceived need to offer a psychological reassurance of complete security at home – a physical and symbolic barrier against the world outside.

There is only one house among the 52 new wooden houses has changed the traditional layout: house AC011 (Fig. 10) uses "[" form. The new house contains elements of synthesis or combination of a classical symmetric floor plan with two perpendicular parts by each side.

According to interviews with locals, they are very satisfied with the improvements demonstrated in the

Figure 10. House AC011 in Sep 2015 (Source CACH investigation in Sep 2015).

new wooden house. The carpenters of the village are proud of the arrival of a new signature style, saying that "the old traditional house is backward, now the new wooden houses, with two-storey, are ideal". Not only are the residents assessing new directions for their buildings, but also creating a synthesis resulting in a pride of mastery over a new local style.

The significance of new wooden buildings in functional terms is the increase of average living space afforded to residents with a second story addition. Although the innovation that made a second story addition possible did not originate in the village itself, an "immigrant" from a nearby county brought the concept with him. As progression takes its course, the construction operations have been handed off to commercial building companies. The company gives the villagers a price including all the cost of material and manpower. Once the client accepts, the house can be completed within several months.

3.3 *Construction of modern concrete-brick house*

Since the enforcement of the "Rural Homestead Regulation" from 1986, it is a matter of law whereby villagers are restricted to a sole domicile for the purpose of a homestead. In practice this means in order to build new house, the current residence must be demolished to proceed. This law accelerates the disappearance of the older vernacular styles and is replaced with something nascent.

Fixtures and other aesthetic flourishes in the new brick housing show colour palettes unusual to this region (Fig. 11, Fig. 12). For example, the colour of the facade and ceramic tiling was not familiar. Seen from the photos, the modern buildings appear to seem out of place here that makes outsiders wonder how the local's rationale calculated the outcome.

In several cases, we also noticed the "citation" of occidental architectural elements (Fig. 13) at Tangdu village. It is supposed these elements were introduced by the villagers who possessed knowledge of cultural trends in larger cityscapes. The decorative elements introduced a sense of de-contextualization

Figure 11. House BE031 in Dec 2014 (Source CACH investigation in Dec 2014).

Figure 12. House CB031in Dec 2014 (Source CACH investigation in Dec 2014).

Figure 13. House CE008 in Dec 2014 (Source CACH investigation in Dec 2014).

within the village and suggest a wholesale assimilation into mainstream Chinese culture will follow.

Despite the symbolic gesture, the modernized residences remarkably demonstrate traditional features found in the village design. Comparing the 107 multi-floor buildings, the "|"-shape with symmetric layout accounts for 75%, "L"-shape accounts for 23% , the rest are of "[" shape. In regard to the "L" shape residences, the only added feature is the external stairs. The essential layout did not change. Minor aesthetic flourishes

aside, these buildings still exemplify the same design principles as the traditional structures with the village.

4 HOUSEHOLDS' CONSIDERATION

As outsiders of the village, we have no reason to criticize the choice of local habitants or laugh at their taste. If we look at it from the standpoint of the villagers, we can see what is desired in a new residence. The following lists the principle considerations of the local people according to the interview.

4.1 *Housing requirement*

4.1.1 *Augmentation using area*

The need to increase household living space is a principle need of the local habitants. The wooden house can support two storeys and remain structurally sound. Surpassing two stories would mean adopting new technology or new materials, which are still not feasible by local economic conditions. By contrast, the modern concrete-brick house can reach three stories without structural problems, which is real an advantage for local habitants. Since in the mountain area the flat space is limited, the addition of another story means augmenting usable living area, especially for the precious terrace on the top of the building. This space is ideal for the drying of grain and clothes, for example.

However, if the increase of volume surpasses the basic utilitarian need, it becomes cost-prohibitive for both for construction and maintenance concerns. As the average family unit is 4.5 people[3], it would be pragmatic to determine if a third story is needed at all. The answer to this question can be discerned by surveying the local people.

4.1.2 *Improvement of security: prevention of fire and burglar*

The problem with wooden structure is the increased incidence of fire. The density of residences is high in the centre of the village, meaning the likelihood of a single residence fire spreading from house to house is a high risk. For example, a nearby village named *Huangmao* was totally destroyed by fire. The traditional wooden housing was destroyed and then rebuilt using brick. In Tangdu village, a fire destroyed house AG017 and AG018 in September 2015, increasing the villagers' concerns about are the dangers of fire (Fig. 14).

Besides fire incident, other feedback from the interview is burglary has become of increasing concern. Several wooden houses are now installed with security doors or iron bars. Nevertheless, the safer way is rebuilding the entire house with solid material. The alteration of materials shows the instability of the community in general and growing suspicion between villagers.

[3] This information is given by the head of the Tangdu village.

Figure 14. the fire in September 2015 (Source author, date Sep 2015).

Figure 15. the factory of brick (Source author, date May 2015).

4.1.3 *Consideration of comfort*

Regarding the comfort, it is the irreplaceable advantage of wooden house according to the local habitants. Compared with the wooden house, the concrete-brick residence with flat roof leads usually to higher humidity.

Nevertheless, another deficiency of the wooden house is sound insulation performance. The noise is caused by people's movement, but exaggerated by wooden structure. This problem is not so serious for the family members but real troubles the guest.

4.2 *Materials and techniques*

4.2.1 *Availability of material*

If there were only demand for such residences but no access to the materials to build them, the popularity of brick residences would not have grown so quickly. These materials for the construction of modern house are available immediately in the village. A small brick factory opened in 2014 that makes it a matter of convenience for the locals and other nearby villagers (Fig. 15). Although wood can be found everywhere in the forests, it is seldom cut for building these days. Since the law has already regulated the preservation of forest, the habitants have to buy the wooden columns and panel from the construction firms.

Figure 16. the transportation of the material (Source CACH investigation in Dec 2014).

Figure 17. the construction activities in the village (Source CACH investigation in Dec 2014).

Nevertheless, there exists an uncertain factor: the cost of transportation. In the mountain area, the transportation of building materials is usually by human or horse (Fig. 16). The wood is relatively light, therefore saves money for transportation purposes, while brick is much heavier that increases this cost. That is the reason why the modern multi-floor buildings concentrates along the main route but the wooden houses remain in higher or lower altitude area where it is impossible to be reached by automobile.

4.2.2 *Convenience and efficiency of technology*

Constructing the modern concrete-brick house is not a complicated technique locally. Once the concrete pillar is formed, the masonry work begins. The entire family unit may participate in the construction process. Several structural components, the floor and beam, are prefabricated and accelerate the efficiency of construction (Fig. 17).

It is ultimately not a question of modernization, but rather it is a matter of financial concern. There is no significant difference between the cost of a wooden house and that of a concrete-brick house.[4] However, once one of them costs much less than the other, a decided prevalence of one over the other will take place.

4.3 *Personal experience and social cultural atmosphere*

If the above factors are the objective considerations of the villagers, the last one is relative and subjective, varying to individuals. As mentioned before, a lot of young people are working in towns, seasonally or temporarily. Inevitably, being influenced by urban contemporary culture, they are liable to bring the urban architectural style to their homeland.

In such atmosphere, the old traditional house is regarded as the "symbol of poverty". The people who live in the old wooden houses expressed frankly, "living in old house, you need not to worry about burglary, as there is nothing valuable in the house". In contrast to the sad situation of old house, the modern concrete-brick house becomes a demonstration of wealth. Driven by the community psychology, the construction of modern house is becoming a competition. The bigger the house and use of decorative flourish equate to the perceived value of the owner.

This perception creates an internal conflict within the villagers. Respect for one's ancestors is a central value with the region and extends to preserving the traditional family home. On one hand, the villager may be able to afford the new home, but on the other hand feels a cultural and family connection to the old house. It will be interesting to see how this conflict is resolved.

According to the interview with the local people about the style of old house, an interesting answer is "not in fashion". The definition of "fashion" is driven by the contemporary dominant culture. One of the local administers of cultural heritage made a metaphor for the houses in the village: "the house can be compare to the cloth of the people, when you need to look for a mate in marriage, will you dress the obsolete, worn-out cloth or the new cloth?"

5 CONCLUSION AND SUGGESTION

From the traditional wooden house in Tangdu village, we can notice the differences between east and west architectural culture. Unlike occidental historical masonry building, the wooden house needs periodic maintenance and replacement of decayed components. This process brings about the alteration of the house. By this mean, the traditional architecture can be seen as the accumulation of long-term renovation and local construction experience.

In contrast to urban construction activity, the village construction is characterized by the autonomy and spontaneity, usually without planning. The villager is the designer, the builder, and the occupant of the building. This autonomy has both an advantage and disadvantage: on one side, we should not overlook the villagers' creativity to improve the living conditions.

[4] According to the villagers, the cost of wooden house is around 100,000 rmb, which is the same or a litter expensive than the concrete-brick house.

On the other side, we should be aware of the impact the absence of city planning has on the totality of the village.

The choice between the traditional house and modern house is not easy to make because there are many aspects need to take into account: housing demand and financial comparison, as well as the cultural atmosphere. Influenced by popular cultural, the villagers are modernizing their homeland. The construction of modern housing is becoming a competition of the richer villagers, while the old traditional house is treated as the symbol of poverty.

However, when a community has enough cohesion and self-confidence about their original culture, such spirit can be expressed through architecture, instead of copying the modern style. This notion can be induced and stimulated. Political guidelines are one way, but if the policy propagandizes only a certain rigid style or emphasizes too much uniformity, ignoring local demand for development, the result may be cause resentment. Once their autonomy of changing the housing condition is removed and the living is without sufficient income, leaving the village and immigrating to the city maybe the most rational choice.

Smart solutions in urban development: The medium-sized cities of Bydgoszcz and Rzeszow, Poland

O. Gazińska
Faculty of Architecture, Wrocław University of Technology, Wrocław, Poland

ABSTRACT: Smart cities idea grows more and more popular in Poland and smart solutions are used by municipalities to make cities more competitive. Also smart congresses, where municipalities and companies launching smart technologies debate about cities future, are organized. Missing side in this discussions are architects and urban planners. This is the reason why the most frequently used solutions are technological systems connected with monitoring, information and others. In theory smart city model characterise in holistic approach towards city growth in six basic directions: economy, people, governance, mobility, environment and living. Technological systems are, in this case, tools that make reaching goals easier. Urban solutions used in smart city model do not differ from solutions used in other modern city development models.

In the case of polish cities primary goals in city growth are development and improvement of infrastructure and application of technological systems connected with it. Bydgoszcz and Rzeszow are examples of medium-sized cities in Poland, which base their development on elements of smart city model. Bydgoszcz is located in north part of Poland at the Brda River. Municipality actions are not only aimed at growth of technological systems, infrastructure or revitalization programs, but also on awakening ecological consciousness in citizens. Rzeszow is located in south-east part of the country. The most well-known sight, which, according to municipality, is based on smart city model, is circular pedestrian bridge (based on the one in Lujiazui, China). Going in that direction municipality bases city growth on innovation, infrastructure development and progressive technological systems.

Due to backwardness caused by events from newest history, polish cities are now on the beginning of development path. The most funds are prioritizing towards infrastructure growth that was neglected during 44 years of communists' governance. Therefore actions taken up nowadays are sectional and they do not have holistic approach to development. Only in the future it remains to be seen how these decisions will affect the growth of cities.

1 INTRODUCTION

1.1 *The smart city model in Poland*

The smart city is currently one of the most well-known models of urban development. In Poland, the idea of a smart city is also often used by municipalities: on the one hand a holistic development model, or, on the other hand, as the foundations for the one-off decisions. In Poland there is no single definition of a smart city. Consequently, every potential beneficiary of this model of development formed its own definition. For this reason, a lot of investments or ideas promoted as 'smart' actually have little to do with sustainable and holistic development of the city. It is also worth mentioning that cities of all sizes in Poland aspire to become a smart city, from Warsaw and other provincial cities, to small towns, with less than 100 000 inhabitants. Despite many differences and inconsistencies in perception of the smart city, in each case its concept is based on the six main directions of development, namely: economy, management, environment, quality of life, mobility and people. In the case of Polish cities development takes place mainly in the field of mobility and communication. The investments that are carried out extensively in most cities are related to the renovation of the streets, the development of public transport (the introduction of new lines, stops, dedicated lanes, increased number of vehicles), the introduction of bicycle lanes (mostly related to street repairs), the construction of parking lots, and information and monitoring systems.

1.2 *How the smart city model is perceived in Rzeszow and Bydgoszcz*

These cities, discussed later in the paper, were included in the European Smart Cities ranking, conducted by the University of Technology in Vienna. Both cities were present in all three rankings carried out for medium-sized cities in the European Union (in 2007, 2013 and 2014). Bydgoszcz also appeared in the ranking in 2015, carried out for big cities. Both Rzeszow and Bydgoszcz emphasized developing a model of a smart city. However, the approach of the two cities varies.

As the first city in Poland to promote itself as being a smart city, authorities in Rzeszow heavily emphasized the development of this model. Rzeszow also is one of the few cities seeking inspiration for projects in emerging Asian cities (such as Masdar City in the United Arab Emirates). Highly visible among city authorities, mainly the president, is the desire to transplant so-called smart solutions, which worked in other cities, to Rzeszow. Despite the lack of coordination of certain activities, some elements of the smart development have been preserved. This is particularly apparent in the ongoing investments in infrastructure, energy, and communication between the residents and the city authorities. An important element of urban development, not only promoted in Rzeszow, but also other Polish cities, is the protection of the environment.

The approach to the smart city model by the municipality of Bydgoszcz is more balanced. Inspirations and development models are searched for throughout Western Europe. A smart city, for Bydgoszcz, is a kind of platform of agreement between the city and other European cities and business partners. Just as in Rzeszow, heavy emphasis is placed on communication between the municipal office and residents, communications, infrastructure, the introduction of smart technology – especially information and monitoring and environmental protection. Each city also strives to create good economic conditions – centres of innovation and technological zones. Another crucial element of growth is the cooperation between cities and universities.

2 SMART SOLUTIONS IN URBAN PLANNING IN POLAND

Despite a broad approach to development, the smart city model does not propose solutions to urban or architectural growth. This leaves them as somewhat subordinate to the main fields of development, where architectural design and urban planning are treated as a tool for solving other problems, not problems themselves. Through this approach there is some danger enhances spatial chaos. Polish cities may serve as examples in this case. Cities in Poland are, in comparison to cities of Western Europe, in the early stages of modern development. They have historical baggage still visible in the city fabric and unresolved spatial problems. These are both rifts in the urban tissue caused by World War II, demolitions that subsequently occurred, and unfavourable spatial solutions implemented during the communist regime (mainly post soviet architecture). An additional obstruction to development is inconsistent spatial policy, manifested both in the absence of zoning plans, and, uncontrolled by urban planners and city architects, the issuing of building permits. The above-mentioned problems, combined with the lack of guidance in architecture and urban planning in the smart city model, mean that some cities are no longer harmoniously growing spatially. Instead, municipal offices often partake in unrelated, single investments, which do not always improve the quality of the space.

Polish cities not only need infrastructure development, but also construction, especially in areas neglected and abandoned, often found in city centres or in their vicinity. In such cases, municipalities need to visualize long-term development and steady financing. Thanks largely to financing from the European Union, Polish cities have begun to change. Not all investments, however, bring the desired results. Often, they are individual projects inconsistent with the environment; sometimes the city does not even have the resources to maintain them.

3 THE EXAMPLE OF RZESZOW

The most famous investment of Rzeszow in recent years is the circular pedestrian bridge, built in 2012. Designed by the architectural firm MWM Architects, it was inspired by the Lujiazui footbridge in China, and is located at the intersection of Pilsudski Avenue and Grunwaldzka Street. Pilsudzki Avenue is one of the main streets of Rzeszow that surrounds the old city from the north. Grunwaldzka Street is, however, secondary, and a poorly frequented street. In addition, pedestrian crossings were retained for Grunwaldzka Street. Entrances to the footbridge are stairs on all four sides, two elevators located diagonally from the north-east and south-west sides, and one ramp from the south-east side, with a grade of 8% (according to Polish building law exterior ramps of such height shall have a grade of 6%). On the catwalk there are benches, flower beds and litter bins. On the internal barriers posters have been put up containing information about the city's history. According to the municipality, the footbridge is an example of innovative architecture, part of the development of a smart city model. The footbridge is used daily, year round, mainly by residents, but also visitors travelling from the train station toward the old town. Besides the location of the bridge, on this route there is also the Provincial Office nearby, and a number of bus stops. Despite the good location of the bridge it is not the easiest to use. This is due to the limited amount of space, because of the existing buildings. The presence of only two elevators hinder its use by people with disabilities and the elderly. Only one of the ramps allows the use by cyclists, and there are no cycle paths reaching the footbridge. The footbridge as an object is strictly functional; however, it is not the best communication solution: 150 meters to the east and 250 meters to the west are marked crosswalks with traffic lights.

The only urban project run by the municipality is a project for a new administrative and legal center, called the district of justice, which is located in the eastern part of the city. The idea is to centralize all courts of Rzeszow, main police stations, the Faculty of Law of the University of Rzeszow and the national archive. One of the stages of the project is to transfer the court from historic Lubomirski's

Figure 1. Rzeszow, district of justice, fot. Olga Gazińska, 21/04/2015.

Figure 2. Rzeszow, circular pedestrian bridge, fot. Olga Gazińska, 20/04/2015.

Castle. The castle, in accordance with administrative functions, would be adapted to serve a cultural function. Currently, the project consists of an access road, originating from Rejtan Avenue (one of the city's main streets). The entrance is poorly marked and accessible from only one direction. The access road finishes with roundabout, where eventually all objects will be built. Currently, there is one building at the district court. Both the road and the roundabout were adorned with street utilities (benches, trash bins, green flower beds, lighting). However, both the new object and the whole premise are incompatible with the environment. In the vicinity of the district there are housing estates, schools, and local shopping centres. Access to the court is designed adversely: car parks for visitors and employees are located outside the zone, with completely separate, equally unmarked, access that leads to it. The project of the administrative and legal centre, on one hand is very homogeneous. On the other hand its neighbourhood offers a variety of functions, although unrelated. The justice district will operate only during the institution's work hours, and both at the main street and the driveway there are no designated cycling paths. However, the facility can be reached by public transport, and both the judicial building and its surroundings are accessible for disabled people.

Other investments in Rzeszow, regarded by the city as innovative and designed in the smart city model, are a multimedia fountain and two heated bus stops. A characteristic feature of Rzeszow investments is their inconsistency. Although the city government is very enthusiastic about the idea of a smart city there is a lack of vision for the whole proceedings. For this reason, the city seems more chaotic than it is. Rzeszow is not the only example of this approach to the smart city model, although it is especially visible because of the accumulation of such investments, and the way the city promotes itself.

4 THE EXAMPLE OF BYDGOSZCZ

In contrast to Rzeszow, the Bydgoszcz approach to the smart city model is more conservative. The city authorities are using smart solutions in the development of communication and mobility, and as a platform for establishing international cooperation. Urban projects, which are carried out in Bydgoszcz are presented as revitalizations based on sustainable development. The project at the forefront is the revitalization and development of the Brda River quays. It has been divided into five separate projects, the first two concerning the design of the water system and sewage (from 2002 to 2013). The next three are revitalization projects (since 2006), dealing with both the revitalization of the cultural and natural environment. Investments also include communication within the Brda River: the creation of boulevards, walking and cycling paths, reconstruction of the transport system, construction of pedestrian footbridges over the river, and the introduction of the water tram.

The biggest changes are visible within the old city. Walking boulevards were created on both sides of the river, and bicycle paths were introduced on the north shore. The quays were mostly excluded from traffic, but there are still parking grounds, partly undeveloped, in these areas. Most of the waterfronts have been developed for cultural functions. In 2006, construction of the Opera House was completed, which is a landmark for the whole project (the opera is located on the north bank). The northern quay, at the height of the Old Harbour, is the most neglected part of the downtown area. Facing the river there are neglected apartment buildings that require revitalization, banks, and the back of the post office building. Old Harbour Street is passable for cars with parking spaces located alongside. The boulevard there is rarely frequented by locals. One of the characteristic features of this area are richly decorated street lamps. Unfortunately, they do not provide sufficient illumination, which makes this part of the waterfront a very uninviting place by night. The separation of the boulevard from buildings, and a small diversity of functions, make this part of waterfront unattractive.

The northern quay, at the height of the Opera Nova, primarily serves this solitary function. In addition to the opera house and two above-ground car parks in the area, a green square and riverside boulevard with cycling lanes have been designed. Access to the

Figure 3. Bydgoszcz, Brda Riverside, Old Harbour Street on the left-hand side, fot. Olga Gazińska, 01/09/2015.

Figure 4. Bydgoszcz, Mill Island and view at Opera Nova, fot. Olga Gazińska, 31/08/2015.

opera is easy and clear, and it is also accessible by busses and trams. At the height of the opera, by the river, there is an amphitheatre-like staircase descending from the opera to the boulevard. This is the second place, beyond the green square, designed as a public space. Unfortunately both function mostly as part of the communication line, and at most as sitting areas. Small architecture (benches, litter bins, lighting) in this part of the waterfront is completely different than ones in the Old Harbour area. With that amphitheatre-like descent the view of Mill Island is spansive and stunning On the island there are branches of the national museum, located in converted granaries, a hotel with a marina for canoeing, and a big recreational green square. In addition to the facilities on the island there is still one decaying granary. The grounds of Mill Island, however, are unvaried functionally, and the green square, designed as a meeting place, is not very flexible, and it serves only a recreational function.

Other characteristic buildings of the city, located on the southern shore near the old town, at the height of the old harbour, are historical eighteenth-century granaries, now housing a branch of the national museum, and the so-called "glass granaries" bank building , completed in 1996. The last property located on this part of the waterfront is a hotel. This passage of the waterfront is the most inconsistent. The boulevard does not run through the entire waterfront, and surrounding buildings do not correspond (with the exception of the historic granaries) with the urban fabric of the old town.

The area of the Brda River quays, although planned as a coherent whole, impress chaos upon onlookers. In each section, buildings and spaces that require regeneration and function changes can be found. Thanks to the proximity of the old city and downtown, the riverfront seems to be functionally diverse. However, the riverside areas themselves are mainly pedestrian and bicycle routes, with the addition of recreational, mostly green, spaces and cultural sites. Another drawback in the implementation of waterfronts is their low accessibility for disabled people, via spatial barriers, in this case stairs and uneven surfaces. According to the organization Project for Public Spaces, a well-designed waterfront should have ten core values. Unfortunately the waterfronts of Bydgoszcz are not meeting these values. Buildings located along the quays are not open to them, and are functionally homogeneous. Likewise, the quays and public spaces are neither flexible nor easily adapted. Activities in which users can participate are also limited. Waterside spaces do not provide activities throughout the year or around the clock.

Compared to the implementation of Rzeszow, investments in Bydgoszcz are carried out more comprehensively. This approach fits with the holistic aspect of the smart city. Projects in Bydgoszcz are trying to meet the needs of both residents and visitors, taking into consideration communication, and the quality and welfare of residents. It is, despite its minor failures, one of the better examples of the vision of urban planning in Poland. It is important that although urban projects of the waterfronts in Bydgoszcz are not referred to as smart, by their more holistic approach, fit more into the model of a smart city than singular projects introduced in Rzeszow.

5 CONCLUSIONS

In the smart city model architectural and urban solutions are treated more as tools, used to solve other development problems. For this reason, the model does not have a separate category for architecture and urban planning. The approach to development and the chosen model proposed by the city, however, does not work in Poland, where the problem is the lack of, or poor quality of, architectural and urban planning. Smart solutions introduced in Polish cities mostly boil down to a kind of ornament, which often try to disguise bigger problems. It happens that some projects are called "smart" just to emphasize their high level of innovation, gain the support of residents, or present the city in a better light in the national arena. To take full advantage of growth opportunities, which the model of smart city provides, the city must undergo a high level of development. Therefore, in the case of the Polish model, smart city is not the best choice. Without a solid base of infrastructure, and well-developed urban

fabric, smart solutions do not meet their intentions. If a smart city is considered to be the next level of development, it is important not to skip any lower levels. In this case Polish cities, needing urban solutions, should still be using sustainable development models prior to other types of growth – especially when the sustainable model and smart city model have many similarities. The hype surrounding the smart city model in Poland is strong nowadays, and it is sometimes difficult for municipalities to think outside of the box. Fortunately many examples show that the smart city is not only a meaningless trend, but it is integrated into city development. The example of Bydgoszcz shows that a city doesn't need to use the newest technological systems to be perceived as smart, but it needs to know how to connect the best parts of different development models to establish its own creative growth.

Africa: The urban challenge

F. Ronco & A. Perino

ABSTRACT: Today more than 50% of the world population lives in cities, and in 2050 it will reach 75%. For this reason the issue of big cities is becoming more globally relevant. The big cities challenge concerns the control of large numbers of people, of pressure of migration from rural to urban areas, of poverty and of social stress linked to it. In particular the African continent is undergoing an unprecedented phase of urbanization. The short-sightedness about African big cities dynamics have consequences, not only for urban planning across the continent, but also for the understanding of twenty-first century urbanization. This paper explores main specific characteristics of African cities, their exceptionalism, past and present governance policies and future chances.

1 URBANIZATION PROCESS

Widespread urbanization is a recent phenomenon. In 1900 just 15 percent of the world's population lived in cities. The 20th century transformed this picture, as the pace of urban population growth accelerated very rapidly in about 1950. Sixty years later, it is estimated that half of the world's people lives in cities.

UN projections predict that urban populations in developing countries will be growing by more than 65 million people a year between 2000 and 2030 (UN 2006). It is projected that in around 2050, about 70% of the world's population will be urban (UN DESA 2011).

1.1 *Urbanization and growth*

Urbanization and growth go together: no country has ever reached middle-income status without a significant population shift into cities. Urbanization is necessary to sustain (though not necessarily to drive) growth in developing countries, and it yields other benefits as well. But it is not painless or always welcomed by policymakers or the general public. Managing urbanization is an important part of nurturing growth; neglecting cities – even in countries in where the level of urbanization is low – can impose heavy costs.

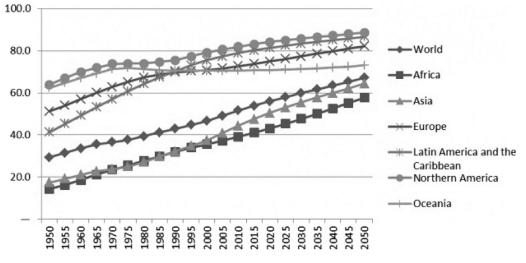

Figure 1. Percentage of urbanization by region, 1950–2050. Source: UN DESA/Population Division, 2011.

The relation between urbanization and income across countries is striking, but it is not necessarily accompanied by the rapid and steady growth that, for example, China and India experienced. Urbanization is far from being a sufficient condition for continued rapid growth.

In Africa there are a lot of countries that are experiencing urbanization without growth, in particular small African countries at low levels of urbanization or failed states. The World Development Report 1999/2000 (World Bank. 2000: p. 130) describes this phenomenon as follows: "National governments have often tried to influence the pace or location of urbanization. Often these efforts consisted of shifting resources from agriculture to finance the expansion of "modern" economic sectors – usually manufacturing – which were concentrated on cities. Urban workers in the formal sector benefited from food and housing subsidies and government-sponsored unemployment and pension schemes, while rural populations received low prices for their crops and had little access to government support. Such misplaced efforts are part of the reason Africa has seen urbanization with very little economic growth".

1.2 *From rural to urban economy*

In the African context, urbanization levels will also increase due to the reclassification of settlements from rural to urban. In some case is merely a bureaucratic task but, especially in Africa, cities do expand through encroachment, as former peri-urban areas are incorporated into the town or urban jurisdiction.

Africa with its tradition of return migration, oscillating migration and circular migration, is characterized by a not linear urbanization process, making very

difficult to detect or measure patterns of population settlement change over time (Parnell & Pieterse 2014).

The rapid growth of sub-Saharan African cities is caused less by rapid migration than by high rates of natural urban population growth, linked to poor education, inadequate healthcare plus the dominance of patriarchal values.

Africa has followed a specific path through the urbanization. There are some common themes regarding drivers of change on the continent. At the point of colonial independence, most of Africa was predominantly rural. Most urban centers were either small colonial towns, or traditional villages. Although the antecedents of Africa's urban revolution can be traced to the second half of the twentieth century, it is only now that the size and importance of urban Africa are becoming widely apparent. Increasing level of urbanization are probably inevitable and must be confronted.

In Africa this great urbanization process, accompanied by very low growth, is concentrating poor people in cities rather than the countryside.

1.3 *Urbanization benefits*

Two main reasons to explain the urbanization process are: efficiency gains and consumption benefits. Furthermore, agglomeration effects in cities affect knowledge sharing. By bringing together large numbers of people, cities facilitate the kinds of face to face interactions needed to generate, diffuse, and accumulate knowledge, especially in industries that experience rapid technological change. This aspect of urban agglomeration economies has received less theoretical and empirical attention, but it has promised to be one of the more significant drivers behind dynamic growth in developing country's cities.

Countries that are highly urbanized have higher incomes, more stable economies, stronger institutions. They are better able to withstand the volatility of global economy than those with less urbanized populations (UN-HABITAT).

Cities are so much more successful in promoting new forms of income generation, and it is so much cheaper to provide services in urban areas, that some experts have actually suggested that the only realistic poverty reduction strategy is to get as many as possible to move to the city (UN-HABITAT 2003).

1.4 *Urbanization criticality*

Urbanization, on the other hand, nearly always involves a multitude of chaotic problems – unsightly, unsafe, or unhealthy development; congestion; skyrocketing land prices; and highly questionable real estate practices – at least at the beginning.

Many of these problems are perceived as failures, although they often emerge in the face of economic success. To make modern cities work, a transformation in fiscal and administrative institutions is more needed than an incremental change, and it often comes in response to a crisis of some kind.

2 OVERVIEW OF AFRICAN CITIES TODAY

2.1 *African urban exceptionalism*

Though African cities are quite different from one another, there are main struggles, linked to previous features, that most African cities share: overcoming colonial inheritances of poverty, underdevelopment and socio-spatial inequality; dealing with informal sectors and settlements and governing justly.

Edgar Pieterse and Susan Parnell in their book *Africa's urban revolution* and Garth Andrew Mayers, in his book *African Cities. Alternative visions of Urban Theory and Practice* identify several distinctive features of African cities. First of all they are integrally connected to rural areas through the practice of circular migration, a strategy for maintaining multiple bases so as to optimize livelihoods and mitigate the risks of settling permanently in economically, environmentally, socially or politically precarious African towns. Second, there is the sponge of the urban fringe or peri-urban edge; this is often a porous settlement boundary which is neither urban nor rural in its character or governance. What is also distinctive in Africa is the phenomenon of urban primacy: one large capital city serves as the center point of national settlement system and is typically three to four times larger than the second largest city in the country. In many African countries this is a direct hangover from the colonial era. Colonial regimes attempted to restrict migration to cities from the countryside or even to exclude Africans from the legal right to live in cities. Under colonialism, rural-to-urban migration seems to have been fueled as much by the pull factor of perception as by actual opportunity, and by the push factors of rural landlessness, poverty and lack of employment. The end result in many countries was large numbers of the rural poor becoming the urban poor. This conundrum only became more extreme in the independence era in many countries.

Another distinctive feature of urban Africa is the predominance of informal modes of urbanization. African cities are characterized by overlapping and even competing system of power. Learning where power lies in the city can be as challenging as persuading those in power of the need of change.

Poverty, informality and the absence of a strong local state with a clear and unchallenged mandate to manage the city are arguably the leitmotifs of African urbanism today.

2.2 *The African urban legacy*

African cities inherited from European colonialism some material problems that demand urgent and clear solutions, first of all social and spatial inequalities.

Urban form thus reflected at least four ideological concerns: 1) separating out who could and could not be in the city; 2) devising a map for who belonged where among those allowed to be urban; 3) providing for and reinforcing spatial expressions of the hierarchy of colonial rule; 4) enabling the accumulation

of resources by the colonial regime, the metropolitan power and elites associated with both (Garth Myers 2011). South African apartheid represents perhaps the most extreme example of this on the continent.

Post-colonialism and geography are intimately linked. This meant that after independence, African countries had to come geographically "after" colonialism, in the sense of attacking or contesting its legacies.

The urban hierarchies of most former colonies remain highly imbalanced, and the political and economical dependence that characterizes many larger cities does not seem to be withering away.

In the contemporary city, formerly white or elite areas are increasingly full of exclusive and infrastructure-rich gated communities and fortress compounds, and the "dirt-poor habitats" at the other end of the segmented plan of the colonial order are even more overcrowded and destitute. Postcolonial regimes have often improved upon the strategies of colonial administrations, becoming even more exclusivist, authoritarian, and segmented.

2.3 *Informal city*

If we are looking for postcolonial urban thought, meaning truly attempts to move past colonialism, the places to look at are probably not necessarily in government planning offices or the posh campuses and gated compounds of expatriate donors. Instead, it may be found in the "ingenuity with which African urban residents have developed novel strategies" to face the "structural and social crisis confronting them" (Demissie 2007) in places like the crowded informal market.

Postcolonial regimes have struggled to subvert the internal urban form, segmentation and inequality inherited from colonialism. But truly postcolonial cityness seems to have more potential to emerge in informal settlements that increasingly dominate cities. Under current trajectories urbanization will see informality emerge as the definitive feature of life for urban Africans.

In the next 20 years, African cities will more than double in population, and their spatial extent could more than triple. What form will this growth take? The current planning regime in African cities focuses on Comprehensive Master Planning, a slow and costly methodology. Many of these plans are never built, but the cities continue to grow rapidly in the absence of a framework. Recent evidence indicates that this growth is highly informal and poorly laid out, lacking a network of arterial roads.

Already 61 per cent of urban Africans live in informal settlements and 60 per cent is engaged in informal work that precludes mortgage finance or progressive livelihood strategies (World Bank. 2014).

Africa had the fastest rate of urbanization of all regions in the world between 2005 and 2010. Since the majority of urban dwellers presently live in slum conditions, it is reasonable to assume that by 2030 the majority of them will still live in slums because most African cities and towns lack institutional, financial and political resources to deal with growing levels of urbanization.

Demographers talk about "push" and "pull" motivations driving the migration to cities. "Push feels like this: Life in your village is dull; backbreaking impoverished, restricted, exposed, dangerous, and static. You work like hell; then the weather changes, and you don't have crops to eat or sell. Visit your relative in town and you see what "pull" means. In the city life is exciting; work is less grueling; you're far better paid; you're free to move around and change jobs; you have some privacy; you're less vulnerable; and you have upward mobility. Will you put up with slum conditions for all that?" (Brand 2009).

Slum life represents a lack of access to a number of essential services and securities that make productive modern life possible.

Extreme richness exists beside extreme poverty, creating contradictory situations making cities sprawling and almost illegible places with a great diversity of experiences, activities and lifestyle.

This bifurcation of the economy finds its spatial equivalent for many observers in a neat separation of informal from formal residential settlement areas in cities. Between this two sectors however there are many connections. Some took this argument about connectivity to claim that the formal sector depended upon keeping certain facets of the informal sector going in order to further extracts profits from the majority economy.

Like Achille Mbembe and Sarah Nuttall say "we need a more complex anthropology of things, forms and signs in order to account for life of the city in Africa" and "the informal is not outside of the formal, […] processes of formalization and in-formalization work together". They argue that what ought to be the focus of the research is "how they work together and how this working together ends up producing city forms and urban economies" (Myers 2011).

We need to know much more about the interrelationships of informal settlements with formal visions of urban order if we are willing to develop an agenda of practical usefulness in order to improve African cities conditions. Some critics argue that informality is unproductive and raises the costs to the formal sector, crowding out agglomeration economies. In fact, the little evidence available on agglomeration economies in the informal sector suggests that it also benefits from agglomeration and that informal operators generally have a positive impact on their formal sector counterparts. The Challenge of Slums, 2003 UN-Habitat, report that 60% of urban employment in the developing world is in the informal sector and that the informal economy has essential links to the success of the formal sector.

The ideas of alternative planning generated from indigenous informality can be quite inspiring and stirring.

Let no one romanticize what the slum conditions are. Usually new squatter cities have no facilities at

all for sanitation, water, electricity, transportation. A typical squatter city, which may stretch for miles, has grown without a plan or government, in an area generally deemed uninhabitable. But the squatter cities are vibrant. The magic of squatter cities is that they are improved steadily and gradually, increment by increment, by the people living there. They look organic (Brand 2009).

According to urban researchers, squatters are now the predominant builders of cities in the world.

Maliq Simone (Simone 2006) – the most prolific and provocative urbanist working on Africa – speaks about "pirate towns", to describe those cities where order is essentially underfunded. Ordinary citizens turn to piracy as a mean to negotiate everyday urban life, in the absence of genuine state or formal private sector engagement. Informal sector is characterized by small, creative urban practices that are attempts by the poor to claim for "equal rights of membership" in a global urbanity that is not only "spectacularly unequal" but highly uneven in its capacity to acknowledge such requests.

The heart of the concerns with what informality means or what to do about informal settlements focuses on the land: uncertainties surrounding rights to occupy, control, and build on land are fundamental to understand why informal settlements are so often considered a problem for state and citizens.

Residents of informal settlements generally lack formal legal security of tenure.

In contrast to the logic of land reforms that aim to formalize the informal systems, in their daily struggle for survival urban dwellers develop their own rationality and logic of behavior, which often do not comply with externally imposed visions of the city or wouldn't be enforceable in modern courts of law, but they sustain people's livelihoods in a context of widening material poverty. The systems are often highly reliant on informal social networks which are themselves built from kinship and friendship.

Even if we assume that regularization of tenure is pro-poor, most states do not have the central or local government institutional capacity to facilitate the regularization in a fair and equitable manner. Some form of hybrid governance over urban land would appear to be the most viable option, but the route to it or capacity for it is bound to vary by city and context.

Informality, therefore, does not seem to inevitably disappear in the urban land development process under neoliberal reforms – the outcomes are highly variable. Generally, planners see informal or shack housing as unacceptable and in need of replacement by formal housing projects', with the goal of "extending the grid of formalized and regulated development" (Myers 2011). Crossroads case study showed that the splitting of extended families into individual, formal housing units is breaking social and family networks and destroying social capital built up in stretched households of shack settlements which connect rural and urban relatives.

Therefore, in order to plan and produce viable solutions to the problems, shack settlements represent for residents and planners a transformation of consciousness.

"The poor have time but no money, and the rich have money but no time; and so they deal. I find what needy people do with surplus time more interesting than what un-needy people do with surplus of money." (Brand 2009).

2.4 *Public and private actors*

In Africa the recent cities growth is linked to the development of infrastructures and economic activities that have been financed by the private sector.

Both foreign donors and local leaders have heavily emphasized strengthening the private sector, opening the door to transnational capital, enabling democratic, municipal governments, and empowering community groups by creating at the same time new networks and partnerships for urban development across the whole landscape of city management, from land and water to transport, electricity supply and solid waste services.

The Cities Alliance/Habitat/Western donor line of approach has involved making and remaking state institutions that can work in partnership with a new array of private sector and civil society entities in facilitating the delivery of urban services, but the evolution of implementation processes varies on the ground.

Unfortunately, often, the private investment, coupled with a shortage of coherent taxation and planning system, is superficially modernizing urban structures that are fractured. The resulting cities, planned through mega-scale power plants but with low levels of grid connectivity, are pre-disposed to long-term failure.

It seems that the new private sector actors have a real impact on the landscape policy, outstripping the influence of scholars, civil society pressure groups and the old-style development industry. It is not immediately clear why there has been such a noticeable shift with regards to who sets the intellectual agenda on African development, but it may be related to the growing volumes of highly targeted and partial foreign direct investment flowing into African countries, investment that is contributing to the further distortion of African urban landscapes.

3 AFRICAN URBAN GOVERNANCE

3.1 *The role of the state*

Today much of the debate in Africa centers on the degree and character of change in the role of the state, with the theorized shift from government to governance. There are plenty of professional place-makers among African urban planners and architects seeking to develop and implement imaginative, alternative, postcolonial urban visions.

3.2 *The failure of modernist planning*

Modernist legislation and urban standards, a system of management that was intended to protect elite colonial interests rather than provide for universal application in postcolonial African cities, continue to serve as a template for urban planning, land use regulation and public housing provision during the post-independence era.

The lack of transparency in urban management law and practice has not until recently, been challenged or reformed, possibly because of the lack of demand for effective, or transparent urban government from developers.

Concerted efforts continue to be made to govern cities through zoning, cadastre, property and administration. These efforts not only fall short, they also fail to eradicate the unruly yet dynamic intersections among differences of all kinds to which the city offers both setting and cause.

Real reform would require poorer groups having the power and voice to change their relationship with government agencies and other groups at the local level, like donors in urban Africa, making them invest money into pro-poor sustainable urban development via government agencies, that the vast majority of urban poor are alienated from and marginalized by.

Poverty cannot be tackled without addressing problems of power relation and the cultural and social interests that sustain unequal access to economic opportunity and social resources.

3.3 *Institutional problems*

The incapacity of African States to address the inevitable consequences of increased urbanization boils down to fundamental institutional problems, such as a lack of coherent urbanization policies and ineffective decentralization.

Most African governments continue to execute their functions without any explicit national urbanization strategy that can inform and guide strategic investments. This stems from a broader political sentiment that the economic future of Africa lies with improving its agricultural performance through a so called second green revolution that will allow the continent to take its rightful place in the globally connected international economy.

Agriculture is, of course, a vital component of a long-term development strategy, but it depends heavily on well-functioning towns and cities to get commodities to market and to absorb the produce. In other words, to plan for agricultural success without planning for effective connectivity and infrastructures and for the development of cities and towns is short-sighted.

In most Africa, urban local governments were unimportant during the colonial era (with a few exceptions), and generally became even weaker and more insignificant in the first few decades after independence.

Elected local councils had been put in place by the end of the colonial period, but their performance fell far short of their responsibilities and growing demands, and their political autonomy and physical base were progressively eroded during the 1960s and 1970s. Central governments generally failed to give local government adequate funds or revenue-raising powers to ensure that they had sufficient decision-making powers and trained staff to address the urban challenges they faced.

From the 1980s there was a shift towards decentralization in Africa. Decentralization is essentially any act with which central government formally cedes powers to actors and institutions at lower levels in a political-administrative and territorial hierarchy.

The key theoretical motivation behind the promotion of decentralization was to bring decision making closer to the people, helping ensure that programs and services better addressed local needs. Local governments were therefore established or re-established in many countries in an attempt to enhance local democracy and service delivery.

By 2000 it could be claimed that "There is not a single country in Africa in which some form of local government is not in operation" (Oyugi 2000). The implementation of decentralization in Africa has, however, been very uneven and partial.

In some case the aim of decentralization reforms was merely to reinforce vested interests in existing pattern of patronage and central-local linkage, thus having no impact on furthering a pro-poor development agenda. In addition, sometimes the motivations behind decentralization were driven by self-interest, for example to shift the responsibility for unpopular structural adjustment programs away from central government to urban local governments, which in many cases were controlled by opposition parties. Tension between national local governments and urban local governments controlled by opposition parties has continued to be a common characteristic of governance in Africa.

Currently, the status, power and functions of local government vary considerably across Africa. Only in a few countries local government is enshrined in the constitution and has at least some responsibility for important services such as water supply, roads and electricity.

Simultaneously with the increased decentralization of recent decades there has been a shift in the way in which local governments operate. In the "Anglo-Saxon" tradition, decentralization also includes the devolution of powers and resources to local non-state bodies, such as private companies and non-governmental organizations. In much Africa decentralization has been accompanied by a strong shift towards corporatization, privatization and partnerships. This has been linked to global shift to such institutional models in local government.

In addition, in many countries in Africa, most urban development and redevelopment projects are now structured as public-private partnerships.

4 NEW AFRICAN URBANISM: IS IT POSSIBLE?

4.1 *Africa in the global framework*

In the aftermath of the global financial crisis (2008-09), the rising awareness of the devastating impacts of climate variability, and a renewed commitment to systematically eradicate poverty, in the form of the Millennium Developments Goals (MDGs), the importance of sustainable urban development has attracted significant attention across the world. The emerging development consensus on the centrality of sustainable urban development is good news for Africa because it offers an opportunity to address the institutional failures discussed above.

Central to such national policy framework are two issues: sustainable development and clarity on the appropriate division of powers and functions across the various levels of government.

4.2 *Sustainable urban development*

It is a time in which there is a widespread recognition that the resource-extractive model of economic development is no longer viable. Cities are particularly important sites in responding to climate change, both in terms of mitigation and of adaptation.

The environmental crisis coincides with a profound social and economic crisis, and it is clear that mainstream economic activity and measurements need to be redefined. Again, cities and urban centers emerge as key sites of economic development because the dynamics of globalization reinforce agglomeration imperatives and because innovation, competitiveness and productivity all depend on the advantages offered by dense settlements. Lastly, following the realization that globalization dynamics had been accompanied by rising levels of poverty and inequality, the global community of states committed to significantly reduce physical poverty by improving access to basic services and political voice. Again, in the context of rising urban poverty, cities are seen as key to make significant progress in attaining the MDGS, although the profound challenges associated with rural poverty should not be neglected. In the wake of the sustainability critique and the worsening of urban inequalities, there is a growing consensus that the spatial form of cities and towns matters a great deal for the realization of more sustainable urban development outcomes. Specifically, greater density through compaction is encouraged along with much stronger emphasis on mixed land uses to facilitate greater efficiency and pluralism. In a context of limited resources and limited state capacity, it is vital that local governments work closely with civil society organizations and the private sector to co-produce development strategies and to ensure participation in various elements of the service delivery value chain. It is for this reason that institutional frameworks for decentralization are so central to how we redefine and activate urban development processes at the local level.

4.3 *Urban development strategy*

Very few African states have explicit policies to deal with urbanization and intra-urban development challenges.

System of planning law are necessary to provide a framework of rules to mediate and regulate competing pressures and interests.

Practical steps are required to institutionalize an effective policy agenda to deal with the complexities of uneven urban development in Africa. First step is to improve the quality of data, information and analysis about urban system and, in particular, settlements that play a major role in the national economy. A number of considerations should be taken into account. Most basic is the need for accurate and reliable data in the form of a periodic national census. It will be important for national statistical agencies to work closely with local government associations and urban development bodies to develop a shared approach to the collection and collation of data. A second dimension of the data agenda is local institutional data. It is vital to develop an overview of what data exist, their robustness and how they can be related to other data sources. Some recent technological advances in democratizing access to spatial data platforms, such as Google Earth, create substantive opportunities for data pooling and comparisons. In recent years, various grassroots organizations have adopted various enumeration processes to underpin their claims and strategies. This source of grassroots intelligence and information, typically from neighborhoods and contexts that are difficult to access for the state, is a vital component of an overall urban data system. It also offers promising opportunities for government officers to better understand, from a different angle, the contexts they are seeking to impact. Recent improvements in geospatial representation of various data sets have the potential to provide the glue to relate multiple categories of data. Moreover, geographic information system (GIS) representations can support administrative decision making processes to improve prioritizing and targeting, as well as potentially helping to facilitate the public's engagement with the data.

Another step to institutionalize this policy agenda is to build an infrastructure investment strategy and plan. The central role of infrastructure for economic, social and environmental development has become a focus of attention during the past few years. These investments aim to kick-start economies, create a new generation of green jobs and form the foundation stones for a much more wide-ranging transition to low-carbon economies. The world bank's authoritative Africa Infrastructure Report suggests that investment in infrastructure can both guarantee sustainable urbanization and social equity and improve productivity in the modern sector and connectivity with and across locations. It is simply not possible for African governments to leave infrastructure planning and management in the hands of sectoral interests that benefit from status quo. A strategic national policy framework on infrastructure is required. Traditional privatization

models tend to reinforce a sectoral approach and produce extremely negative social environmental consequences.

The last step is the decentralization policy and operational strategy. There is no single recipe or formula that can be applied to all African contexts. What is required is a strategic understanding of how limited resources can best be deployed to advance the national development project in the context of specific urban and rural settlements, correlated with local state capacity and the institutional modalities of service provision. A sensible approach to the division of powers and functions across different levels of government and across different institutional forms cannot be achieved without the awareness of the unique developmental roles of various local settlements. In developing decentralization policy framework is also important to have an explicit focus on democratic enhancement tools that foster state responsiveness, legitimacy, accountability and enrolment of civil society and citizens in development programs.

Genuine bottom-up interventions, appropriate division of powers and capacity across all levels of governance system are finally the ingredients for a good development strategy.

The imperative is to recast all of the conventional aspects of urban development – decentralization, infrastructure investment and local economic development – from the perspective of empowering the urban poor as an integral part of the urban development agenda.

4.4 *Obstacles to urban democratic development*

Modernist planning in Africa persists, as in many parts of the world, and particularly in developing countries where it was frequently inherited from colonial powers. Governments appear to be reluctant or unable to reform their planning systems that place a great deal of power in their hands. Modernist approaches are often land dependent, and authorities in many developing countries would not be willing to give up their control over land-related matters, as this would seriously weaken their position.

Furthermore urban areas are covered by rigid and outdated planning regulations that are only partially or intermittently enforced, and this opens the door to corruption. African political elites have systematically exploited their positions in order to line their own pockets. The political elites that took over African countries in the 1960s thus saw government as a source of power and personal enrichment, undermining the international perception of the continent.

In fact if on one hand African states are viewed as "more important than ever to the security and prosperity of the international community" (White House, 2012) and perceived as a major source of great natural and mineral wealth; on the other hand inner protests and strikes often reach the headlines in the international press, leading many to believe that the country is in consistent deadlock or economic paralysis. To make things worse, during 2015, several main African currencies have taken a significant hit, as economic growth slows, and falling prices for major export commodities reduce the flow of dollars into the continent.

Yet, despite substantial progress and even greater potential, various challenges remain, in terms of human development, inequality and poverty, economic diversification, productivity and infrastructure, institutional capacity, public management, and transparency.

5 CONCLUSION

In summary, Africa displays the fastest rate of urban growth in the world, albeit from low base level.

Optimists see a grand opportunity for reshaping the continent, envisioning vibrant, productive urban centers that can drive higher standards of living and create wealth. Pessimists look at the state of African cities today and they see failure, decline, collapse, and decay. However, at the moment most African countries are not able to capitalize on this demographic shift, because urban residents are structurally trapped in profoundly unhealthy conditions that impact negatively on productivity, economic efficiencies and market expansion.

Yet the global economy is shifting its axis to the emerging powers and, at the same time, there is a broader shift towards fundamentally different, much more resource-efficient economy. Technological opportunities are emerging to fuse citizenship and urban living. Within this context the African urban transition could be truly revolutionary. A new planning methodology is needed – one that is simple to prepare, cheap and easy to implement, and able to address the challenges of rapid urbanization. It must also be flexible enough to match the technical capacity of the local planning authorities, so that the people designing the plan will also be the ones implementing it.

It will allow governments to move beyond the confused and costly plans of today, toward a nimble, affordable, intuitive strategy.

In this framework there is a need to continue increasing participation of relevant actors at all level of urban development and specifically the marginalized and disadvantaged. Even as citizen participation is promoted, it is crucial to couple longer-term visionary planning with short-term upgrading of neighborhoods and to ensure that such processes are adequately anchored in appropriate planning institutions.

Further emphasis is required on inadequacies in the built environment professions, even though this demands a different scholarly agenda to what has been the norm for some time. The rise of Africa's cities shall not be ignored. How the revolution is navigated will depend on how well the forces of change are understood and taken up. In this regard the role of the continent's intellectuals in framing the debate about cities must be underscored.

Adaptable structures for emerging socio-cultural changes in Africa

Dirk Donath & Bernd Rudolf
Bauhaus University, Weimar, Germany

Asgedom Haile
Addis Ababa University, EiABC, Ethiopia

ABSTRACT: The developing countries are experiencing extremely fast and unique urbanization processes brought by a rapid increase in population (UN-Habitat, 2008), which in turn has produced a boom in the construction sector (Donath D., 2012). Currently, the situations that Africa is facing with regard to infrastructure provisions has also been in Europe decades ago. The article presents the individual and real built case studies and forwards series of recommendations to advocate new conceptual methodologies in the design and construction process for Africa as well as Europe. In response to the current situation, we needed to develop fundamentally new concepts that are socially responsive, spatially and functionally open and flexible structures which, in addition, employ innovative building techniques with a low maintenance requirements. Between 2012 and 2015, three different building prototypes were planned, built and tested as a potential model for flexible housing in emerging cities. The professional focus of the three different projects lay on different but intersecting areas in the field of architecture and construction innovations: the introduction of a new building material and corresponding working methods (SECU), the use of highly-prefabricated building elements to achieve short construction time (SICU) and the provocative use of state of the art production techniques using parametric planning systems (MACU). The design and implementation of all prototypes were carried out by the shared laboratory for emerging cities (ECL) which lays its foundation on a collaboration between the Institute of Experimental Architecture (ifex) at the Bauhaus University Weimar and the architectural institute (EiABC) at the Addis Ababa University. Various partners and parties have also been involved from the industry. Beside the research component, a strong educational objectives were hooked up throughout the project period. These real "design built" projects are a prelude to a whole series of full-scale experiments that the ECL has already constructed. They also paved the way for further and more holistic projects in the field of integrated infrastructure and industry based rural urbanization; projects that started in 2015 and 2016 consecutively.

Keywords: prototype, practical teaching, architecture, prefabrication, Africa

1 INTRODUCTION

1.1 *Background: 'Well Come Africa' Project: Academic research exchange through prototypes*

The "welcome Africa" project 2012–2015 at DAAD (German Academic Exchange Service) was an international academic research project between the Ethiopian, South Sudanese and German universities. Its objective was to strengthen the collaboration in research, practical experiences and competency to bring together contemporary building technologies with real circumstances. In a way, the program also aimed at introducing new method of teaching or interaction between teachers and students of architecture. The research program included the realization of three experimental prototypes in 1:1 scale between these years.

All the three prototypes had different theme and involved different batches of architecture students from the three countries. SECU – Sustainable Emerging City Unit was the first and material oriented prototype which was built in three months. SICU – Sustainable Incremental Construction Unit was the second prototype which took only 10 days to assemble. It was meant to enlighten students with the process of designing, manufacturing and assembly. The third and the last prototype which had the motive to provoke the existing design and construction industry with state of the art production process is called MACU – Mobile Automated Contemporary Unit. All the three projects are described and discussed with their added values in the teaching process of architecture and construction.

More than 40 students and teachers have participated in each project from the three countries.

1.2 *Teaching through experiment: architecture is a craft*

For every design problem, there exist always reasonable and possible options of solutions for design is not an exact science. In design studio classes, comprehensive problem is given to students who first analyze it and then reach a design scheme through synthetic process.

However, the way we have been teaching our students in the studios usually isolate the design problem from the context of a real design process. Numerous professionals with distinct background and different sets of values are involved in the design process to interpret and judge the design outcome (Y. J. Grobman, 2010). Therefore, it was believed that, creating serious of experimental 1:1 scale projects as part of the curriculum exposes students to more domain of knowledge if not to all. In addition, they learn effectively though making. This is because they are deeply involved in learning, if they construct something public and useful. The more they build structures, the more they are close to architectural realities (Beaumont, R., 2009).

There is no question about the importance of the introduction of experimental works into the educational stage. Experimental learning is necessary to transfer the theory into the practice and to get involved in the process. Experiments help to show up the difficulties, the details on site, to get prepared for all the stage of design and construction. Architects always need to '*be there'*. The involvement in the realization of prototypes leads to a new level which cannot be replaced by something else.

1.3 *Objectives of the research program*

Though all the three projects had specific objectives with regard to the technology and knowledge they have transferred, their collective objective in the teaching program was to combine theoretical architectural and construction knowledge with practical training for higher education, specifically at the EiABC (Ethiopian Institute of Architecture, Building Construction and City development). Therefore, the general objective of the program in addition to introducing new methods of planning, design and construction, is training students of architecture with real parameters of site situation, material and building construction systems.

2 THE PROTOTYPES

2.1 *SECU (Sustainable Emerging City Unit)*

SECU can be seen as the pioneer to introduce an alternative building material for the construction industry in Ethiopia, while the country is struggling to have

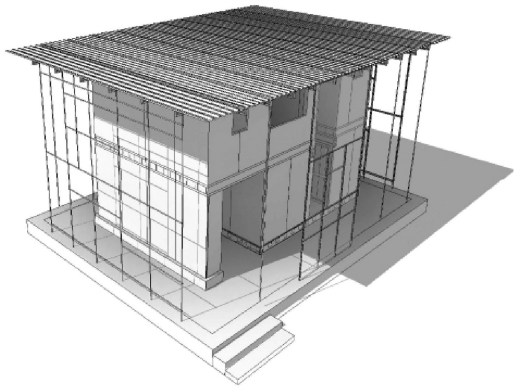

Figure 1. BIM model of SECU.

standards of its own for natural building materials. As the use of more sustainable and environmentally friendly building materials and techniques is increasing (Calkins, M., 2009), the research group felt that it is their task to experiment with new but pre-processed material and introduce it to the industry in line with the plan and wish of the government to do so.

Therefore, with the support of the STRAWTEC Company from Germany, the research team had the courage to further develop implementation methods for straw panels in load bearing applications. The research investigated construction elements and their necessary connection systems and details. Serious of architectural and engineering tests were done both by students and the team to identify possible challenges and qualify the material as a load bearing robust element ready for two story house.

The determining parameters influencing the design of SECU were the provided material properties, the systematic modular construction approach, and design principles coming out of the unique cultural and social settings in Ethiopia. In order to respect these settings, SECU proposed a balance between open, roofed and semi-private outdoor areas for economic activities and enclosed private spaces, which also functioned as structural core elements. This arrangement allows for further upgrading or extensions to be implemented by the inhabitants and gives them the opportunity to contribute in the creation process of their home (Fig. 4a & 4b).

All main building elements – walls, slabs and roof – are made of single or double layered compressed straw panels (6 or 12 cm thickness), joined by threaded rods and casein-based glue. A secondary structural system was not required. It is calculated to be earthquake resistant for two-story buildings (Donath, D., 2012). The individual panels are produced in a continuous prefabrication process where the straw is compressed under heat to form an end product resembling a material comparable to soft fibre board. The significant roof overhang and green screen of climbing plants give the unit its own character and protects the straw panels from rainwater.

Table 1. Parameters for SECU.

Building	
Location	Addis Ababa Ethiopia
Year	2012
Construction time	3 months
Total floor space	96.00 m^2
Floor dimensions	9.60 × 5.00 m
Height	5.20 m
Ground floor area	48.00 m^2
First floor area	48.00 m^2
Extension space	0.00 m^2
Max. no. of floors	Ground level + 01
Material	compressed straw panels (1200 × 2500 × 60 mm)
Foundation	Grid of natural stones bedded in gravel
Ground floor	Straw panels (double layer, 120 mm)
Slab	Hollow core sandwich plate, strawboard, prefabricated
First floor	Straw panels (double layer, 120 mm)
Roof	rib slab, strawboard
Cost	8,500 USD (as of late 2012) (includes sanitation, all finished first floors)

By introducing industrially manufactured strawboard panels as structural as well as infill material for the first time in Ethiopia, SECU rendered separated and usually expensive frame structures obsolete. For all vertical wall elements, a double layered, glued panel system proved to be the most adequate solution. The homogenous and compact material also allowed for a flexible location of openings such as windows and doors. A hollow core structure guaranteed the necessary load bearing capacity of the ceiling, considering the desirable double story application principle. One-sided ribbed panels were suitable for the roof structure, given the mild climate conditions in Ethiopia (no snow load).

Inspired by the results of SECU, the Strawtec Company has started to construct houses of a different model but with the same concept in Kigali, Rwanda since 2015 ranging from single story to three story residential as well as commercial buildings (Fig. 5).

2.2 *SICU (sustainable incremental construction unit)*

The second and process oriented experimental building prototype dealt with participatory design. It was constructed in one of the highly dense neighborhoods of Addis Ababa in 2013 as a show case where the team of students with their tutors researched and explored possibilities of designing and realization of an incremental housing unit in an urban context.

SICU had a very strong social strategy both at the design and construction phases. Because of which, maximum involvement of users and decision makers (authorities), was promoted started from the inception period. This brought a good solution in design and construction and created sense of ownership by the user.

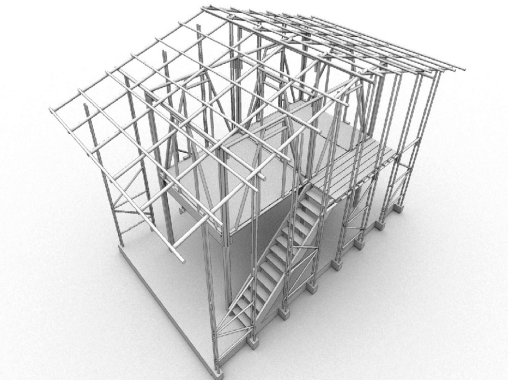

Figure 2. BIM model of SICU.

It also had to be affordable through the use of optimized and modular construction systems and locally produced prefabricated building elements with standardized dimensions. Therefore, its cost efficiency was checked at every level before construction using BIM technology (Karen M., 2014).

Because of its incremental concept, SICU has very open and conventional spaces that give room for further change and appropriation by users. There is an interface space (the shaded space at the ground level and the terrace at the top level), which is to accommodate future needs of the inhabitants as the public private transition is a very important aspect in traditional Ethiopian living domains (Fig. 4c).

The construction comprises of prefabricated concrete lower structure and lightweight eucalyptus frames for the upper floor inspired by few local cases in the countryside of Ethiopia. Close to 90% of the building parts of the house are prefabricated in a workshop.

The experiment will be far from over even after the construction of the main prototype building, as the structure needs to be appropriated and finalized by its prospective dweller. Therefore, further steps and scenarios concerning the incrementality and socio-economic questions have to be investigated and addressed before full evaluation and assessment can be done on the approach as well as the results and findings of the research. Additionally, an important observation will be provided by the adaptation of the house to different users and settings as well as continuous testing and monitoring of the proto-typology over a longer period of time.

2.3 *MACU (mobile automated contemporary unit)*

The research team wanted the last project to introduce a different but applicable construction system that allow the transfer of technology from developed countries to both Ethiopia and South Sudan, in a way

Table 2. Parameters for SICU.

Building	
Location	Addis Ababa Ethiopia
Year	Two units: 2013 and 2014
Construction time	ten days
Total floor space	86.00 m^2
Floor dimensions	9.40 × 6.40 m
Height	6.40 m
Ground floor area	28.00 m^2
First floor area	28.00 m^2
Extension space	30.00 m^2
Max. no. of floors	Ground level + 01
Materials	
Ground floor	Pre-fab elements from concrete foundations and column
Slab	Eucalyptus ribs with plywood sheets
First floor	Light timber frames and claddings, prefabricated
Roof	Eucalyptus frame, prefabricated
Cost	5,000 USD (as of late 2014) includes the finished first floor and an open ground floor

Table 3. Parameters for MACU.

Building	
Location	Addis Ababa Ethiopia
Year	2014
Construction time	ten hours
Total floor space	25.00 m^2
Floor dimensions	5.40 × 5.40 m
Height	3.60 m
Ground floor area	28.00 m^2
First floor area	28.00 m^2
Total floor space	56.00 m^2
Total floor space	2 × 35 m^2 + 25 m^2 extendable space
Max. no. of floors	G + 1
Material	Eucalyptus plywood, 18 mm, 1.20 × 2.40 m
Number of sheets	159
Number of individual parts	834 parts without wedges & connectors
Ground floor	Columns from customized eucalyptus plywood sheets
Slab	Waffle grid from customized eucalyptus plywood sheets
First floor	Columns from customized eucalyptus plywood sheets
Roof	Waffle grid from customized eucalyptus plywood sheets
Cost	10,000 USD (as of late 2014) (includes the full system and wall elements)

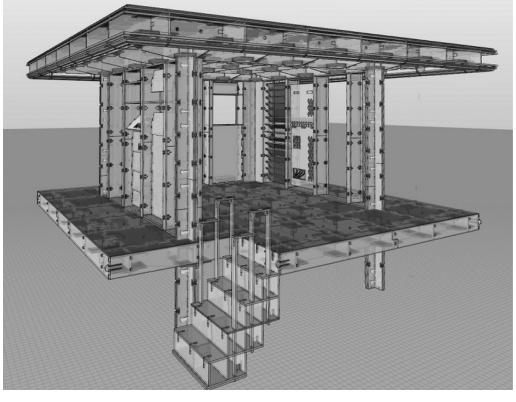

Figure 3. Parameterized model of MACU.

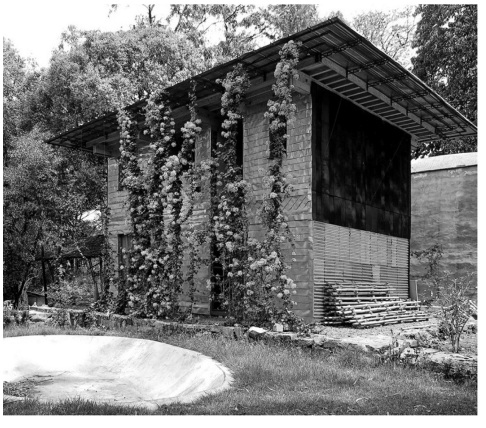
to Africa at large. Inspired by the potential of digital planning and manufacturing techniques of CNC (*computer numeric controlled)* machines, the project aimed at exploring their full potentials and acquainting students and practitioners with current state of the art.

The design of MACU was based on a parameterized computer model controlling a computer which again controls a milling machine for producing the individual building parts. This means a total flexibility can be achieved by changing the parameters of the individual building parts instantaneously. The result is a fully described building system which can be provided in various design layouts.

The prototype is fully made out of Plywood except the four small concrete pads on which the columns rest, as it is not logical to allow the connection between the plywood and the ground. The plywood has 18 mm thickness and is made out of eucalyptus wood by the company Heng Sen Lumber Manufacture PLC located in Addis Ababa and which also sponsored the project by providing us half of the plywood the project required.

The assembling of parts intentionally avoided the use of any other connecting materials including nails and glues due to the very fact that the project was meant to be mobile in addition to its automated features. Of course, this feature added a huge challenge in the overall design for involved students and research team until it looks impossible.



3 ADDED VALUES

3.1 *Give practical insight to students*

While the three experimental building where planned to be executed, parallel teaching courses were also designed mostly by the two universities (EiABC of Addis Ababa University and Bauhaus University) and more that 35 selected students had to work on each project for at least a semester. They have worked from inception up until assembly with almost seven involved teachers from both universities each year. There were also student excursions and exchanges which exposed students of different worlds to different culture and technology in addition to motivating them to conduct practical researches.

3.2 *Technology/knowledge exchange*

The exchange of technology/knowledge in addition to culture between students and teachers worked both directions. Ethiopian and South Sudanese students acquired some technological training from German teachers and students like the application of computer modelling systems and the usage of CNC machines. In the other direction, German students and teachers got the platform to work on different but real architectural challenges. They needed to be coached and guided by their counterparts from Ethiopia for the full understanding and analysis of living and spatial situations as well as construction material and other realities. These mutual benefits have initiated a sustainable cooperation between the universities and led them even to the creation of a new joint laboratory whereby students and researchers benefit from after the completion of the program.

3.3 *University industry linkages*

There have been many attempts recently by the country to resolve the problem of technological under development by creating a strong linkage between universities and industries. Undoubtedly, such activities and interactions would be of benefit to both industry and university by enabling them to:

- Establish multidisciplinary programs that are responsive to industrial needs,
- Carry out specific company-sponsored projects,
- Strengthen team-based, cross-disciplinary, problem-solving industry-university exchanges by placing faculty and students at industry sites and industry scientists/engineers at the university,
- Provide a real world and a high-caliber educational experience for graduate students.

4 CONCLUSION

These prototypes were not meant to replace any kind of existing construction system. They were supposed to provoke the industry to come out of its comfort zone by enlightening it with alternative approach to design and produce building elements. In this regard, the research program has met its objectives to a higher extent. However, a coordinated effort in publicizing the potential of it is required for making the maximum out of it.

The parallel but major academic objectives linked to all the three projects were successful example of learning by doing. It has given students and their mentors the confidence to do further academic but problem solving researches which can get recognition by Authorities and the industry than ever been done before in addition to its advantage of exposing students to practical knowledge. Enriching such courses in interdisciplinary way requires further polishing of the curriculum after careful study and analysis is done with the effect and impact of these newly designed practical courses on the overall teaching and learning process of architecture students.

ACKNOWLEDGMENTS

For helping to make this research project possible, we would like to thank the committed and involved

partners with whom we worked, shared ideas, and became especially well acquainted over long time working when our research was accomplished.

Dawit Kebede from AEE; Mr Eckardt Dauck from the STRAWTEC Rwanda Plc; Dr Gluth from the German Federal Institute for Material Research BAM; Mr Ackermann with his CNC workshop, and the owner from the Heng Sun Lumber Plc. For general assistance at every stage and moral support far beyond the call of duty, we would especially like to thank, the Scientific Directors Dirk Hebel and Joachim Dieter from the EiABC. The Addis Ababa University and the Ministry of Research and Education Germany funded this project.

Temporary commercial spaces: Celebrating the 'right to the city'

A. Allegri
Universidade de Lisboa, Faculdade de Arquitetura, CIAUD Centro de Investigação em Arquitetura Urbanismo e Design, Rua Sá Nogueira, Pólo Universitário da Ajuda, Lisbon, Portugal

ABSTRACT: Aware of the inseparable relationship between public space and commercial space, this paper aims at reading Lefebvre's concept of a "right to the city" through a survey of urban places for commerce.

Commerce and the city have always been complementing and constituting one other, generating spaces that are built up on the complex synergy between social practices, physical space and its modes of use. However, this centuries-long ability of commerce to contribute to the "making of the city" began to be questioned when commercial settlements started to close in upon themselves, turning into structures that are no longer open and permeable to urban life. Lately, though, we are witnessing different transient urban phenomena, such as "temporary" commercial occupancy of space: ordinary people producing space – not necessarily physically, sometimes just transfiguring its meaning and value – through the pursuit of their own needs, transgressing the formal spatial and temporal boundaries of the lived spaces of everyday life.

In some way, temporary commercial spaces celebrate Lefebvre's idea of a city that is accessible to everybody, making it possible for inhabitants to regain control of the city's decision-making and space creating processes.

1 ABOUT LEFEVBRE'S "SPACE"

City air makes you free
(Stadtluft macht frei)
Max Weber, Die Stadt, 1920[1]

Commerce and the city are both located in the deep core of the idea of an urban body, complementing and producing one another, in an inextricable bond. Open spaces and traditional commercial spaces are mutually enriching, they becoming more and more appealing and fascinating, together contributing to the production of an animated, colourful, perfumed, resonating and surprising urban texture, in which interchange is not limited to goods trading.

Retail spaces can be read as relational spaces by excellence. The act of exchanging goods implies building relationships, which is a step toward integration and social cohesion.

Integration and social cohesion generate "space of freedom" (Weber 1921).

Some commercial forms can then be read as spaces of freedom, built up on the complex synergy between social practices, physical space and its modes of use.

A space of freedom is far more than the individual liberty to access urban spaces or resources: it is, more likely, the same idea of a space of freedom which French sociologist and philosopher Henri Lefebvre introduced in his *Right to the City* (1968), with which he would challenge or replace current rights of all to the urban space.

The *Right to the City* has recently re-gained prominence in academic and political-activist debates on urban matters. In some ways, the "right to the city" has become something of a slogan that reshapes decision-making processes in the city, giving urban inhabitants a central role in any decision that contributes to the production of urban space. Instead of democratic deliberations made just by the state, Lefebvre imagines this right to apply to *all* decisions, fundamentally shifting control away from capital and the state toward urban inhabitants.

This idea comes from Lefebvre's notion of space, which contains what he calls *perceived* space, *conceived* space and *lived* space. Perceived space is the tangible or physical space people encounter in their daily environment. Conceived space is the mental construction of space, the representation of space. The combination of both, perceived and conceived space, results in the lived space: a person's actual experience of space in everyday life. And because, according to Lefebvre, social relations and lived space are inevitably related in everyday life, creating urban

[1] In 1920s, reflecting on the issue of the city, German sociologist Max Weber defined the character of the medieval town as being essentially free, thanks to the widespread presence of commerce. A city that welcomes commerce within its public spaces is a place of economic and social freedom. And granting space to economic and social freedom is the basis for social integration. At the end of his analysis, Weber quoted this writing seen on the door of a fortified town in Upper Rhineland: "City air makes you free".

space necessarily involves "reproducing the social relations that are bound up in it and therefore entails much more than just planning the material space of the city; it involves producing and reproducing all aspects of urban life" (Lefevre 1991). For Lefebvre, then, "the *right to the city* is like a cry and a demand for a transformed and renewed *right to urban life*" (Lefevre 1991).

In other words, it is a kind of re-appropriation of the decision process and of the city's production spaces and facilities by its inhabitants. This also implies the right of inhabitants to physically access, occupy, and use urban space so that it meets their needs. The use value aspect of urban space must therefore be the primary consideration in all decisions that produce urban space.

2 COMMERCIAL SPACES AND THEIR BOUNDARIES IN THE LIGHT OF LEFEBVRE'S THEORY

Good examples of spaces that are charged with a deep sense of all that Lefebvre states are those places which are dedicated to public traditional commercial activities: these are shifting and flexible settings which constitute a background to the complex network of relationships and social practices, as well as space and the way this is perceived, conceived and lived. Indeed, spaces of freedom where is celebrated the right to urban life.

Nevertheless, when tracing a brief history of trade, we realize that commercial spaces gradually lost their quality of being spaces of freedom. In a tangible way, this is proved, among other phenomena, by a clearer and clearer definition between the physical boundaries of open public spaces and those of commercial spaces. The progressive limitation of these boundaries results in concentration and commercial specialization, and, consequently, in a separation between the spaces for commerce and urban public life. Commerce gradually lost its ability to act as binder of urbanity, failing in its centuries-long tradition of contributing to the "making the city", while providing accommodation for everyone.

That was still true in the medieval town, which was heavily marked by the presence of spaces for trade. These were the result of an open and unlimited system created by the synergies between the different spaces that had been designated for living, socializing, representing, producing and exchanging. A system such as this did not seem to question the right for different kinds of activities (which might range from commercial activities to residential or administrative functions) to coexist in the same space, side by side. These manifold functions and activities, which were not necessarily all related to commerce, but did have some proximity to it, seemed to find the reason of their good functioning in the varied composition of the system itself: an articulated system which, at the same time, preserved the specific nature and character of the different activities it was made of. It was a network of inter-connected and inter-communicating spaces, which all belonged to the same urban public and commercial system.

In this case, public space coincides unmistakably with commercial space, in a situation where there are no definite boundaries. Commercial areas, like scattered points in a larger spatial system, are not formally defined or fixed (even though we might find a factory, or a specific architectural project), and do not appear as closed and definite units. We are referring, for example, to the simple result of the relationship between the workshop (or the small shop) and the empty space that is in front of it, or to the single architectural work, which hosts many more spaces on its inside, or – and that is a much more frequent occurrence – to a group of spaces, which have been built at different times and with different techniques, materials and styles, but which are organized in a coherent whole or path (Pevsner 1986). Anyway, it is the continuity or, we should say, the physical interference among the different urban spaces that constitutes the true identity of the communal and commercial aspects of the medieval town, together with the relationship between the various activities and the ever changing needs of its inhabitants/traders. Throughout many centuries, a busy multitude has been physically meeting and mixing up here, while carrying out their manifold activities. This multitude took possession of these spaces – which could be built upon or empty, with no clear boundaries, different in shape and function, separate but contiguous, connected but open – and thus actively participated in the actual building of the city.

Commerce and the areas in which it takes place also contribute to the shaping of the experience of urban life when middle classes begin to emerge. Open urban spaces become *Passages* (arcades): covered commercial streets with elegant settings, whose nature continues to evoke their original status. This is that of the street which, in close continuity with the network of the various blocks of buildings, appears as a natural extension of public space. Despite their reduced scale, as well as their complexity and multiplicity if compared with the market town, the arcades continue to encourage urbanity.

However, at this point, the physical boundary between open public spaces and the arcades begun to be less blurred, although remaining quite ambiguous. The arcade model eludes a fixed and univocal definition, it being, at the same time, an architectural work and an urban building typology, with the ability to sew together different parts of the fabric of the consolidated city. It is precisely this ambiguity – between solid and void, between open and close, between building and urban, public and private – which gives it the role of connective element and virtuous factor of urban vitality. More than the market hall or the department store, which are clearly defined and independent containers, the arcade creates a space which is constantly projected toward its outside, directing the flow of the intricate walkways of the dense fabric of the city center.

The ambiguity of the limits of the arcades contrasts with the clear definition of the department store, which, in the mid-Nineteenth Century, began to become a widespread model for commercial activities in established city centers. This is an accomplished urban unit, the value of which lies precisely and emphatically in the clarity of its limits, which are defined by monumental, compact and linear façades. Nevertheless, the department store continues to have a lively and direct relationship with the urban context, providing a gathering point for the flows of pedestrians, capturing them with fabulous displays and creating synergies with other types of functions.

The gradual loss of relationship between the public space and commercial space announced by the irremediable and increasing definition of physical limitations ends in the Twentieth Century, when the city turns into something radically different from the city of the middle and industrial classes. With the explosion of mass-society and the increase in peoples' mobility, as well as with the invention of new technologies and new media, the city begins a process of differentiation: a separation of the various urban organisms from one another and a specialization of functions that become more and more obvious. A new city is born. A sort of urban sprawl where the different urban functions are more and more separated – a separation encouraged by the growing use of private cars – and where, as a consequence, traditional forms of housing and buildings are abandoned in favor of a huge increase in the size and amount of infrastructures. The result of this process is an "erratic and scattered urban context, (…) atopic and discontinuous", where "squares and arcades, *avenidas*, plazas, and also the streets and roads themselves seem to have lost all identity and meaning" (Desideri 1997). Instead, commercial spaces, now trying to present themselves as ideal surrogates for all forms of traditional public space, acquire new status and meaning, as communal and social spaces. The department store, now "detached from the urban context and taken out of the city, sheds its osmotic architectural form, to become impermeable to the system of open spaces, choosing for itself a dimension that is more related to the definition of its interiors" (Gaglio 2007).

Today's big-box stores, retail parks, shopping malls, etc. all confirm this process.

Paradoxically, historical tissues are also victims of liberalism without rules. When faced with more and more aggressive competitors, traditional forms of local commerce and city organization seem to collapse. The only reactions to this process are, in many cases, projects of urban remodeling that, in the end, are not much more than *urban restyling*, focused on marketing purposes, often including renovation, communication and promotion strategies aimed at highlighting the "consumable" features of a specific place. This trend often results in a phenomenon of gentrification, which does not differ much from those processes of social and space segregation typically produced by extra-urban commercial systems (Rabbiosi 2013).

Figure 1. Typical car boot sale at Saint Augustine's Car Boot Sale in London. Source: A. Allegri.

3 TEMPORARY COMMERCIAL SPACES: POSSIBILITIES IN URBAN LIFE

But the changes do not end there.

Probably mostly due to the contemporary global financial crisis, we are now witnessing new and varied transient urban phenomena, such as "temporary" and "informal" commercial occupancy of space. As a matter of fact, side by side with the building of large premises for shopping or with the "marketing" of the old cities' centers, there is another notion of commerce and use of public space which is now spreading further and further: this includes things as diverse as leftover-stock market stalls in some disused warehouse, food tracks, pop-up stores and pop-up restaurants, sale of Panini stickers at subway exits, underground restaurants, sale of homemade products in some unusual itinerant stalls, and even poetry sold between the tables of a bar at dusk or *botellones* (street drinking).

If the food track is a vehicle equipped to cook and sell food in a quick and low cost way – even if a modern-day food track offers gourmet menus and can easily be a respectable venue for aspiring chefs to launch careers – a car boot, literally car selling items from the car's boot, is a form of market in which private individuals come together to sell any kind of goods, from household to books.

The popularity of car boot sales has grown enormously since their beginning in the UK in the early 1970s. Listings on websites suggest that hundreds of sales happen weekly in many countries, even if the larger number continues to take place in England, with over 25 in London alone (http://www.carbootsales.org/county/london.html; http://www.carbootjunction.com/complete-carboot-listings.php?qsearch=London&; accessed 24 January 2016). Car boot sales originally occurred on greenfield sites in the summer months. However, in a growing trend, they are now held all year in the grounds of schools, parking places (sometimes in the parking lot of a hypermarket), road junctions, and squares in the inner suburbs or even in the smaller interstitial public spaces of the compact historical city. Indoor boot sales are now appearing too (it is the case of car boots in some community building).

Figure 2. Street vendor at Palo Alto Market in Barcelona. Source: A. Allegri.

Figure 3. The farmers 'market at Principe Real in Lisbon. Source: A. Allegri.

Much more of a North American concept, the yard sale, also known as "garage sale", is an informal event for the sale of used goods by private individuals, in which sellers are not required to obtain any kind of business licenses or collect sales tax. The idea has moved beyond the individual front yard or garage and now includes neighbourhood sales. The Highway 127 Corridor Sale, promoted as "The World's Longest Yard Sale", encourages private individuals and professional vendors to conduct simultaneous yard sales along a 630-mile (1,010 km) corridor spanning five US states (http://www.127sale.com; accessed 24 January 2016).

Figure 4-5-6. 'Pop-up Stores TMN' in Praça Camões; Street vendor at Lx Factory; Flowers seller by bike, Lisbon. Source: A. Allegri.

In a similar vein, a new wave of street markets is emerging, although we must not forget that this is the most resilient and remarkable form of temporary commerce. Giving new life to many run-down urban

areas, a lot of declining markets have been able to reinvent themselves by introducing new and original variations such as car boots, yard sales, night markets and farmers' markets.

The recent interest in healthy food and more sustainable lifestyles, as well as the promotion of organic or homemade products, led to the rebirth of one of the oldest forms of exchange. Indeed, farmers' markets have existed since mankind has begun to produce a surplus from farming the land; since then they have been a vital factor for the economy of many cities. Nevertheless, with the growth of urbanization, intensive farming, the advent of supermarkets and a number of technical innovations, such as the refrigerator, farmers' markets had lost their strength. Apparently, however, the decline is over. In the US, for example, they grew from 1.755 in 1995 to 5.274 in 2009. In Los Angeles there are more than 100 farmers 'markets in operation (http://www.laweekly.com/restaurants/the-ultimate-la-farmers-market-guide-google-map-2895133; accessed 24 January 2016). The idea of fresh food produced locally seems to have caught up with Europeans too; in many European cities farmers' markets are a pivotal aspect of life. There, people shop for dinner, check in with farmers, taste some homemade product and grab a coffee or a fresh fruit juice with friends. Moreover, farmers' markets help farmers (normally small producers) stay in business, thus also helping to re-establish important social ties between rural and urban population.

Even if farmers' markets often offer relatively expensive products, which not everybody can afford to buy, they prove, as much as car boots or yard sales, that street vending is now widely accepted, and seen as a space for bustle, surprise, business opportunity and leisure pursuit. Likewise, temporary commerce is an interesting phenomenon not just for the sheer variety of its forms, but also for its power as a feature of urban life representing a consumer's world, where the limits between public space and commercial space are no longer clear-cut. History repeats itself, once again.

4 CONCLUSION

In the name of capitalistic freedom, the excessive power of the market has imposed its rules on the social relations and material organization of the city and territory. Freedom of economic initiative, which had contributed to making the city the area par excellence of tolerance and civil liberties, has become, with time, an element of social division and a primary factor of aggression to the body of the city itself.

"If the city has been enriched and made complex and fascinating by retail, now, in some parts, it is impoverished by it" (Consonni quoted in Gaglio 2007).

Yet, even if belatedly, the latest commercial models, with their temporary, "weak", spontaneous and unorganized quality, seem to stem the phenomenon of aggression to urban complexity and quality, giving new forms, new meaning and new value to places, some of which are often not expected to accommodate actions of trade.

Those who carry out this type of commerce, those who perform these actions – the traders –, are normally "ordinary" people, the inhabitants of these places. Sometimes, to even see these spaces, people, – the clients –, have, somehow, to participate in their dynamics.

Consequently, these are spaces that are directly created by people. As Lefebvre pointed out, here, people (the city's inhabitants) have the right to participate in first person, in collective ways, to the process of urban creation, as well as the right to have sufficient access to urban public spaces, which they should be able to make full use of. So, temporary commerce reflects the response of individuals in having to rethink established practices and consolidated spaces.

This new commercial dictionary, identifying a diversified geography of commerce, shapes alternative and important hubs of urbanity and becomes the engine of interesting spatial, social and economic dynamics. Urban space is no longer moulded through decisions originating from a few centres of power, but rather through a polyarchic and ever-changing model, where diverse uses and situations legitimately overlap, in opposition to the growing pressure for homogenisation of the city, understood as a place of consensus and consumption.

The phenomenon of temporary commerce represents a fundamental shift in the use of the city, impacting even on how public space is considered, with deeper implications for urban life, policy and practice. For this reason, we believe that any action that seeks to promote quality and equality in our cities should not ignore the issue of transient occupancy as a powerful emerging urban dynamic.

Therefore, research in this field is greatly needed, because a better understanding is essential in order to act and build urban strategies that ensure a reading and planning of the city through the prism of the individual, ensuring quality of life for all within the urban space.

In the specific case of the temporary commerce, if it is through consumption that people's activities and everyday lives and the physical and mental organization of the city are bound, then it is important that retailing is planned in accordance with the role it plays in the urban fabric and in people's everyday lives.

As Lefebvre puts it when he talks of a "right to the city", in this constellation of spaces, which are continually "lighting up" and "going dark" (La Varra 2007), every day public life in our cities seems to contribute to the production of urban spaces, transforming them in an even richer place for encounter and possibility.

This is why we should view these forms of temporary use of urban space as increasingly legitimate and important in their own right.

At the same time, different transient urban phenomena alert on the necessity of seriously thinking about what changes in society, culture, technology and economy are now driving urban processes, as

well as, inevitably, raising questions about the emergence of a new approach in urban planning and design. This is maybe a more dynamic or flexible one, where the city is becoming more responsive to the new needs and demands of its users, faced with economic uncertainty and rapidly changing possibilities.

South Africa's new challenges: Planning inclusive connection spaces

M. Bodino
Dipartimento di Architettura e Design, Politecnico di Torino, Torino, Italy

ABSTRACT: The purpose of this paper is to define whether and how it is possible to create inclusive connection spaces through planning, by analysing some of the most segregated cities in the world. The starting point is an overview of the current urban situation in South Africa, twenty years after the first democratic elections. Scholars argue that, due to a history of colonialism and apartheid, cities there are increasingly segregated and fragmented. At the same time the political agenda is struggling to address the process of transformation in order to mitigate spatial inequalities and promote urban integration, while on the other hand taking global interests into account. Through the examination of three examples this work attempts to identify some progress in the creation of inclusive spaces, while looking at the complexities involved in operating in a South African context.

1 INTRODUCTION

1.1 *African and South African context*

In Africa urbanization is becoming increasingly widespread. Since Africa has the fastest rate of urban growth in the world, it is constantly facing new challenges. The rapid urban growth in Africa is peculiar because it is not combined with a corresponding economic development (Parnell & Pieterse 2014, Albrecht 2014, Floris 2007, among others). This characteristic is straining the policies of most of the newly formed independent States. The rapid urbanization must be considered not only as a problem to face but also as a new chance to improve African cities. Indeed corruption, political instability, lack of economic resources, unemployment, growing poverty, crime, AIDS, segregation and inequality are common topics in the agenda of the last decades. All over the world, but specifically in the South American and African metropolis, inequality between the rich and the poor has increased dramatically. At the same time extreme wealth and poverty often coexist within the urban space. Conflicts may (and often) happen in these spaces. People concentrate in cities attracted by employment possibilities and global opportunities. Meanwhile cities become more and more divided within its boundary to limit or avoid crime generated by contrasting social and ethnic groups. Especially in South Africa, racial inequality requires specific attention in the fields of architecture and city planning. It is not only a social and economic problem; it also includes political and urban issues.

According to some authors, South African cities are the most segregated in the world, described as invariably twin cities, one white and the other black; one privileged the other marginalized (Bruyns & Graafland 2012, Noble 2011, among others). The segregation patterns and the inequitable environments have been inherited from colonialism and apartheid, and the new development patterns have not diverged significantly from them. The transformation of the fragmented urban reality has been the aim of government policies in the period after the first democratic election in 1994. Now twenty years on from this historic moment, it is time to reflect on what has been done and what future projections exist. South African cities' dual ambitions have been concentrated on the global competition while also looking at local problems (Bekker & Fourchard 2013, Lemasky 2007). "Whilst the pro-poor approach adopted in the early post-apartheid era proved to be fiscally unsustainable and unable to deal with macro-forces shaping the city, the urban efficiency and global city agendas for later years are likely to prove unsustainable in their inability to support social cohesion." (Harrison 2006). The result is one of the highest levels of income inequality, measured in terms of GINI coefficient as shown in the World Bank estimate (Bonaglia & Wegner 2014) and as stated in the African Progress Report, 2012. This growing gap is intertwining with the burgeoning urban transformations, where townships and informal settlements surround the city centres and the empty spaces between the formal settlements.

1.2 *Point of view*

Most studies are still built on theories utilizing US or European cities to stand as universal models, or measuring non-western settings by the models and metrics of the West (Myers 2011). While the theories of how cities function remain rooted in the developed world, the urban growth is happening in the developing world, where these rules are incompatible with the reality. Therefore, the role of the architect in these contexts needs to change.

It is essential to underline that a western approach has been imposed to the African territory since hundreds of years. This long-time domination does not

justify an approach that is not respectful of the identity of a place. Unfortunately nowadays defining identity in Africa is very complex because of the history of the continent. During a long period of time colonization, apartheid and globalization have modified profoundly Africa. In this paper the starting point is to realize the inadequacy of dualistic models, dividing the world between North and South, western countries and developing ones. If is accepted that planning tools based on developed western cities are inappropriate to the characteristic of the developing city (Roy 2005), then the expression city of the South needs to be abolished (Balbo, 2012). Therefore the approach must be analytic, without preconception. One possible approach is to learn from Third World cities, stressing the importance of acknowledging overlapping networks of interaction within the city, going beyond the geographical division of global cities and megacities (Robinson 2002). This is why the author decided to look at some case studies, learning from them.

There are different narratives about African reality, from afro-pessimism to afro-optimism (from "hopeless Africa" to "Africa rising" as defined by The Economist) that tend to generalize a complex and diverse reality throughout the continent. It is true that some recurring features occur when discussing urbanization in Africa, but the African continent is a set of specific realities and with differentiated histories. The challenge for researchers is to realize that it is possible to imagine a rebirth not linked or influenced by the spread of western models of development (Lucia 2007). In fact some opposite approaches are coming out, and they invert the vision, conceiving African development as an alternative to capitalism and globalization (Latouche 2009, Robert 2006).

1.3 *Data and boundaries*

The paucity of reliable data is one of the problems to be aware of dealing with urban Africa. Many times it can occur that the data available are out of date (Parnell & Pieterse 2014, Roy & Alsayyad 2004) or simply the reference source is unique, then is not possible to compare the results. When the area of interest is limited, it is easier to define the framework and the background of the research and it can be easier to find the needed information and a particular scientific production.

This paper defines the boundaries of the research within the Republic of South Africa. Some assumptions and conclusions may be also acceptable for other part of the continent, but the focus of this work is to understand a specific area, with specific history and geography. The City of Cape Town, where the author spent two months of fieldwork, is particularly significant for the topic of this paper. As a matter of fact the metropolitan area, also defined "Unicity", is a starkly polarized area where inclusion and integration are huge challenges to face.

Accepting, as some authors suggest, that some African cities are becoming or are aspiring to become global (Lemanski 2007; Crankshaw 2012), makes it possible to learn from the South African experience, and perhaps to generalize these ideas in a worldwide context, even if is not the main purpose of this work.

2 ANALYSIS

The aim of this research comes from the concept that contemporary fragmented cities need greater linkages to avoid the on-going division. Since the level of inequality in the South African cities is the highest in the world (Bruyns & Graafland 2012), an observation of the architectural and city-planning strategies to face these problems could be useful to build the framework in which architects and planners can operate.

The first assumption is the consideration of a society with peculiar characteristics in which people are in search of a local identity. As many other African states, the path toward the emancipation and specification of a new South African identity starts with the independence conquered in 1961. The first democratic election occurred in 1994 marked an historic shift for the state. The following twenty years are the focus of the analysis because they represent a crucial moment for the state, which can count on the ruling African National Congress (ANC), with unrivalled power and popularity since the outstanding political work of Nelson Mandela (Baarlaam & Nola 2010, Bonaglia 2014). Noble in his recent book tries to find the link between five South African public architectures and the search of an African identity, trying to answer to the irresolvable question of black identity described by Fanon (Noble 2011, Fanon 2008). The key question is for sure how to forget and overcome the stereotypes of the west applied to the "south". The role of the cities and of the urban landscape is essential, trying to define the African identity, as much as the consciousness of a non-uniform, but hybrid concept.

The wanted identity must ensure the coexistence between African ethnic groups and their community systems, a colonial past, an outdated apartheid system and the global influences. The common use of the prefix "post" in front of the words colonialism and apartheid implies a connection that is still current and not easy to go beyond. In fact all these factors have had a strong impact in the social structure and, further, in the organization of the spaces (especially in the city areas).

The apartheid city was carefully and minutely planned. In South Africa, the legislation criminalizes urban migration and through the Group Areas Act defined exclusively white areas, where black Africans, Coloureds and Indians were uprooted. Almost one million people of colour were evicted from properties in areas designated as "white only" and were forced to move into segregated townships, divided by race groups. Ultimately, however, this ideal of "white cities, black homelands" collided with the labour-market needs of big capital (Davis 2006), as demonstrated in the following example. Haller and Ngqulunga explained well the apartheid city structure describing

the pattern of segregation and the resulting disarticulation of Durban's spatial structure. Four concentric circles of racial segregation mark indeed the city: a first white core area of growth centres; a semi-periphery populated by Indians and Coloureds; a periphery of black townships; and a liminal zone of informal settlements (Bruyns & Graafland 2012). Such a strong division in the spatial level is attenuated by needed economic exchanges between different parts of the city. The centre needs the low-skill provision from the second area, while the third provides cheap wage labour for industry and domestic services for the white economy. The last area represents the recent immigrants, struggling to find their place in the economic circle. Socially the division are stronger and the connections are scarce, even if the informal economy processes cut across the whole social structure and not only the poor are involved (Castells et al. 1989).

Dealing with social problems is one of the main goals of the policies of the last twenty years. The segregated patterns that characterized Cape Town during the apartheid period have not been totally overtaken. Interracial income differences have remained almost unchanged; even if some deracialization has occurred in education, job opportunities and spatial redistribution. Even if the "desegregation is largely limited to formerly white-only or coloureds-only neighbourhoods" (Crankshaw 2012), it is still a promising signal. Despite policy and intention, most housing and service delivery has not been complemented with adequate social services. The social relations can not be simply deducted from spatial facts and common contribution of foreigner professional does not help to address the problem correctly. Architecture also exists for people only when they occupy a space. It belongs to people only when it is being used. Therefore, successful projects have to follow social movements, to respect community needs, rather than coerce people into new spatial patterns within the built envelope. Part of the challenge of contemporary social architecture is for its designers to become readers (Bruyns & Graafland 2012).

Globalization and capitalism influence the ongoing transformation process, often exacerbating already existing issues. Social and spatial polarization is a consequence of a dual ambition. On one hand, investments in city centres try to attract foreign and private interests, and focus on the international image of the city. On the other hand subsidised housing and pro-poor strategies take place in the townships and suburbs. Limited resources and overlapping of interests may inhibit the effectiveness of both actions (Lemansky 2007).

3 FORMAL AND INFORMAL

3.1 *Outdated dichotomy*

One of the most common definitions of informal settlement refers to the illegal occupation of a land. The land ownership is a big and unresolved issue in Africa. The reason is that in Sub-Saharan Africa land ownership was based on the concept of common property. The land belonged to the community and was administered and managed by the elders. Taking into account this fundamental point, it is easy to understand how big the impact of colonialism has been. The most radical shock has been in the city, where the "land ownership" was imposed and controlled by European models (Floris 2007) and exacerbated by segregation forms. For Soliman, in Egyptian context, the regularization of informal housing areas is the way to tackle the problem, thus formally integrated the informal settlements into the cities. For sure an implementation by stages that include the confirmation of land tenure should take place. At the same time the core question is instead the understanding of the squatting as a cultural and political construct (Roy & Alsayyad 2004).

Informality exists because formality concept has been conceived. Without the western definition of formality, it doesn't make sense to talk about informality. Of course differences exists between the two, but they work as counterparts. They need each other, especially if the term informal refers to the economic sector. A dichotomous approach refers to the polar extremities that separate "haves" from "have-nots", as a consequence of capitalism and the human desire for (individual) consumption and accumulation (Bruyns & Graafland 2012). The idea of the urban poor as responsible for their own poverty and failure to enter formal job and housing markets is outdated. The squatters are no more considered just as "other" and not part of the "normal" city. Therefore, the public policies of removal are no more justified a priori. On the contrary the government declaration states the opposite, affirming the clearance of all the informal settlement in South Africa would be abolished and replaced by formal settlements within 2014 (Slum Act, 2007), later modified to a strategy of upgrading. The marginality of the poor has the ideological-political function of preserving the social order which generated them (Perlman 1976); the myth of marginality, its passive and negative features has been dismantle looking closer to reality and learning from informality. The struggle of the poor to survive and the inefficiency of the formal sector to give an answer to a big part of the population force people to live, own property, and do business extra-legally. The informal entrepreneur is here considered has an economic hero who manages to survive despite the state's continuous controlling measures (De Soto 1989).

As Castells and Portes were claiming "there is no clear-cut duality between a formal and an informal sector, but a series of complex interactions that establish distinct relationships between the economy and the state" (Castells et al. 1989). The same thing is happening not only in the economic sector, but also in the housing one, where formal and informal are connected by a series of transactions and the physical border between them is not easy to identify. The provision of housing remains one of the biggest issues to solve in

relation to a South African "democracity". Alternative models are possible. Soliman specifies that informality represents a failure of official socio-economic and political programs to meet the basic needs and requirements of majority of people. When such programs fail to meet the requirements of society, informality takes place. Informality just allows people to obtain what they need at a lower cost. (Roy & Alsayyad 2004).

The challenge of this work is to investigate and outline the limit between formal and informal spaces, as a means of interpreting contemporary African cities where inequality and disparity are particularly evident. The edges are not only the areas of separation, but also spaces in which connection, integration and inclusion can happen.

3.2 *Gated communities*

In Africa the so-called gated communities are an answer to a fragmented and unequal environment that is perceived as dangerous and antagonistic. Somehow is a voluntary segregation, it is an extreme form of socio-spatial separation (Albrecht 2014). The perimeter is as close as possible with high walls and electric fences to reinforce security and to minimize contact with the exterior. Services, such as schools, library, markets, and pool may be designed within its boundaries. In South Africa gated communities are pretty common, probably because of the great inequality that distinguish the cities. The increasing form of urban gating is modifying new portion of the city into the sum of enclaves, more and more heterogeneous and fragmented.

Lemanski's analysis that compares a gated community in Cape Town to its poorer – but formal – neighbour is interesting. The spatial separation intertwined with social exclusion. The South Africa's post-apartheid urban planning has favoured compact city designs, using the city's empty spaces rather than expanding city edges. Policy focusing exclusively on preventing urban sprawl and spatial inequality at the city level increases the development of other urban phenomena (such as gated communities) that restrict micro-level desegregation. In this case the master plan development scheduled a requested secure place for a rich or middle-class community, answering to the common NIMBY attitude (Not In My BackYard). The Westlake village answers just to the request of housing for poorer people. Socially and functionally the areas are isolated (Lemanski 2006). Looking at this example, the formality or informality of the build environments is not relevant, even if it is a common to think that crime was confined to black townships during the apartheid years. Nowadays urban gating is one solution to avoid contacts with different groups (economically and socially different), it is a new form of segregation not directly connected to ethnicity or race. Gated communities are the best way to weaken the creation of a post-apartheid identity and integration in spatial terms.

3.3 *Contact space becoming connection space*

The dramatic and symbolic description of some African cities compares them to an archipelago of island cities, living in two different levels not communicating to each other except for economic reasons. The first one acts in a vertical way, linked through the network with the rest of the world. The second one is much more connected horizontally and is attached to the earth, occupied informally (Floris 2007, Bini & Ney 2012). Cities are becoming places of separation instead of places of exchange and integration. Here comes the need of research to concentrate the attention on the contact area of these two realities that coexist in the urban context.

This work aspires to examine some particular South African projects, which have tried (succeeding or failing) to address the challenging of a changing society. In South Africa where segregation and apartheid became more and more entrenched, interactions in the urban environments are even more complicated. The objects of analysis are spaces considered as "grey areas", places where different cultural and radical groups already live together. The multicultural feature represents a characteristic that is not typical in the apartheid segregationist plan, but it is closer to the concept of a cosmopolitan town. For this reason multiculturalism and the coexistence of different cultures can be determining to read existing connection spaces; and then to be able to design and replicate them, being respectful of socio-economic and geo-politic framework of the context.

3.3.1 *District Six Museum, Cape Town (Bennet et al. 2008, Minty 2006, Mceachern 1998)*

District Six is an inner-city suburb on the border of the historical centre. It was the last and sixth District of the city, formally recognized in the late 1800s. It was a heterogeneous, religiously and racially mixed area (white, Coloured and African working class people) with a vibrant cosmopolitan community. This unique multicultural quality made it a target for the apartheid policies applied by the National Party. The notorious Group Areas Act in 1966 defined the district as "white only", imposing its destruction. By 1982, the

Figure 1. Interior of the District Six Museum.

entire area where around 60,000 people were living was physically destroyed. Many were relocated in the townships out of the Cape Flats, divided by race. The consequence of this forced removals left the mark not only in previous inhabitants' lives, but also in the creativity and vital energy of the city centre. The area has become the symbol of the dislocation and harmed caused by the Group Areas Act.The government managed to build on Zonnebloem (new name of the neighbourhood), some houses for state employees and the Tecnikon, a controversial educational institution. "The rest is emptiness and ruin, in sharp contrast to the overcrowded, urban past". Despite the local struggle and the international mobilization, the return to the area is still complex and difficult. The Hand Off District Six campaign opposed strongly the suggested development plans, and became the only way to keep the contact with the past and to overcome the pain. Only a few churches and mosques remained and one of them, the Buitenkant Methodist Church, became the District Six Museum.

In 1994, this space was used the first time for a temporary exhibition called "Streets: retracing District Six", then it became a permanent museum thanks to the refusal of ex-resident community to close it. The space turned into a possible connection between past, present and future. Former inhabitants recognize in this space the possibility to remember their identity, asking the community to contribute tracing their physical destroyed past. The floor space is a huge map of the original District, where people wrote their addresses, notes and pieces of their histories. Participation and interactivity made the District Six Museum an award-winning model of a community museum, as much as powerful inclusive connection space. It provides a service to the city, working with children from schools, people interested in understanding the history of the city and common people. "A change of mindset is needed, people have been forced to live without connecting with other races for decades. A new approach is possible just if we will look each other as culturally different, understanding that we can learn from our differences" (interview with Joe Schaffers, worker at the museum as others ex-residents of the district). Despite the success of the museum the district area is still a contested zone and it has just been partially urbanized.

3.3.2 *Langa, Cape Town (Bruyns & Graafland 2012; Kjeldsen & Seeberg 2015; Contal & Revedin 2009)*

Langa is the oldest surviving former black township in South Africa and then is considered as a heritage site in the historic fight for freedom and democracy. As the first "model township" constructed in the country it can be regarded as one of the experiments in creating a segregated city. Between 1927 and 1959 Langa was the only formal housing area for black people in Cape Town and it was close to the Cape Town's Central Business District (CBD), making it an attractive location to live. Thanks to the economic growth of the city Langa was soon absorbed into the city limits and urban fabric, and the pressure on land has enforced a radical densification of settlement. Not only backyard shacks mushroomed, but also the so-called Joe Slovo informal settlement occupied the buffer strip between the suburb and the N2 highway, attracting more people. This is, as many of slums, rich in communal and social relationship, but poor in terms of the quality of its housing units, infrastructure and urban layout. It has become soon a conflict area between the inhabitants and the state. The site has been chosen for the N2 Gateway Project, occupying a portion of the Joe Slovo informal settlement. In 2004 the project was launched, aiming to build more than 200,000 units to replace shacks. In 2006 first occupants moved in, and the rent immediately jumped. In 2008 just 705 units have been completed and the Phase 2 (even less affordable for poor people) was about to start. In 2016 the process is still on going, without clear positive results and with a controversial political involvement. The concern with this project is about creating a neo-apartheid design, economically, politically and socially unsustainable. Some critics refer to an insufficient consultation and participation of the local population; as a result a portion of the residents have been forced to move further away from the city economy since the new flats were too expensive for them.

Figure 2. Guga S'Thebe Cultural Centre.

At the same time Langa has a positive example of an upgrading project inside its borders.

In fact in the corner of Washington and Church street is has been built the Guga S'Thebe Arts, Culture and Heritage Village by the architect Carin Smuts (CS Studio Architects based in Cape Town), considered a post-apartheid public building and an example of sustainable design. The realization of the project lasted from 1996 to 1999 and it has been built with a limited budget. The significance of the site and the community's need were taken into account during the design phase that investigated different schemes. The 820 square meters building is composed by various separate components around main circulation paths, generating a number of indoor and outdoor spaces. Ceramic artworks done by local artists decorate the forecourt, walls and floors.

Despite the fact that the Centre has become an attraction for researchers, students or interested people, the area around it remains a township, with all

Figure 3. Guga S'Thebe Theatre.

its prejudices. The creation of the adjacent Guga S'Thebe theatre, built between 2013 and 2015, is proof of the ongoing process of becoming an inclusive connection space for the neighbourhood and the city. The local community was involved together with CS Studio Architects, the University of Cape Town, other international faculties and companies (www.designdevelopbuild.com). The multipurpose centre is addressed particularly to children and young people of Langa, and answered to their need of a space for learning and performing, but it is open for external events too, bringing people from other parts of the city into Langa.

The design language is very different from the existing cultural centre: the construction method and materials (old shipping containers and panels made by recycled wooden crates or straw and clay) are responding to the need of affordable materials, but they are used in a contemporary way. This shift of language is deriving probably by the international team involved into the design process. The creation of new connection space around the cultural centre represents a success: a good architectural project aspires to generate an improvement in the surrounding context. It will take some time to understand if the Langa community is benefitting from the new theatre space both as a community space and as attraction for the Cape Town citizens in general.

3.3.3 *Red Location Museum, Port Elizabeth (Noero 2010, Msila 2013, interviews with architects)*

While the District Six Museum was created, supported and maintained by the local community, something different happened in the case of Red Location Cultural Precinct in Port Elisabeth. In this case the community occupied and closed the museum built by the government.

In 1994 The Nelson Mandela Bay Municipality decided to build in the Red Location Precinct some public facilities and a new museum with a liberatory function. The area has a long history starting from the First South African War when it was a Boer concentration camp with rusty huts. The new cultural precinct is planned in one of the oldest township in Port Elisabeth, in a place considered as a national site of struggle. Noero Wolff Architects won the competition in 1998, and was required to challenge conventional views of museum design. The project was organized in three phases. The first stage included the contemporary museum completed in 2005. The second (but last one) included the library, the city archives and the art gallery completed in 2011. The Museum comprises a series of 12 unmarked, rusted boxes offering a set of different memories of struggle in South Africa.

The project was conceived as a space of memory, and was an opportunity to trigger the transformation of the area, to change people's attitudes, building the cultural infrastructure of the township. Even if the community was involved in the design process and the project won international awards, the Cultural Precints is closed "due to community protest" since October 2013. The story soon became a political issue. Local communities transferred their housing problems to the Red Location Precinct, using the new buildings to extort the local government for their housing rights. "We are living in shacks which get flooded each time it rains . . . and yet the municipality spends millions of rands building a museum" (quotation from a News24's article dated 31.07.2014).

The decision to build such a modern attraction point in a poor black community is symbolic like many other similar interventions in South Africa, and its impasse situations show the great challenges and contrasting interests involved. Some improvement for the neighbourhood have been made through the construction of streets, sewage and lighting, but the unsolved problem of housing and the complex context involved contained the positive result of such an investment, limiting the potential upgrading for the community.

3.4 *Urban scale*

The awareness and the identity of the new South Africa, of the "rainbow nation" (De Readt 2012) are crucial in defining urban transformations. "Man both influences his environment and total man (physical, economic, cultural, social, psychological man) is influenced by that environment" (Dewar & Uytenbogaardt 1977). The two are strictly linked together; therefore the South African Constitution based on human dignity, equality and freedom is the goal to be achieved primary through urban transformations.

More has to be done at the urban scale. Cape Town urbanization is still exemplary, identified by a strong division between the rich tourist city centre, some intermediate neighbourhoods, and a huge quantity of townships and informal settlements surrounding it. As Crankshak confirms, the desegregation of many formerly-white areas in Cape Town is happening, creating some mixed neighbourhoods. Their strategic position between the city centre and the suburbs, the easy access to public transportation (trains, university shuttle, local and MyCity buses) and the vital economy is helping the transformation process of these areas. However the Reconstruction and Development Programme (RDP) started in 1994 did not change the planning rules and recreated dormitories and ghettos.

As an example, Du Noon settlement was built between 1996 and 2001 to answer to city's housing

Figure 4. Du Noon: example of an RDP house with a backyard shack in the front and brick extensions in the back.

needs and it should represent the vision of a multicultural Republic. Nevertheless the government subsidised houses are similar to the township's ones; the small space formally planned is surrounded by a spontaneous development: brick extensions and a great number of backyard shacks. Walking around Du Noon is considered dangerous as walking around Langa or Kayelitsha; and the spatial traits are comparable. The urban environment does not reflect the efforts in the implementation of policies illustrated by SACN 2014 ("from housing to sustainable human settlements").

4 CONCLUSIONS

If the South Africa government keeps building housing without considering the existing context, densification, job opportunities – both formal and informal – access to facilities, functional mix and community involvement, it will be difficult to include the urban poor and minorities sufficiently into the city's progress.

The examples described in this paper are significant for a starting process of transformation that needs to be strengthened and supported within a bigger network. If they are not connected in a bigger scale their impact will be minimal at the urban scale. Professor David Dewar states the importance of public transportation at the urban scale to help this process and the need for "street design" versus "road design". The street is a public space where people meet, work, pass, share . . .; while the road just provides basic services (water, sewage, electricity). It is a matter of understanding if it possible to accommodate and help the development of quality urban spaces or simply to provide services. This paper aims to demonstrate that some projects may be taken as good examples for connecting spaces, making them inclusive and equal. Single projects will not solve the entrenched segregation of South African cities, but can produce a shift toward a more inclusive, connected and less fragmented city for both physical and social points of view.

I believe that deeper research is needed to reaffirm and reconceptualise the importance of public spaces in South Africa, defining how and whether public spaces can become the backbone infrastructure for the rainbow nation. Only a network of public spaces – inclusive by definition – can create a greater urban integration and make the contribution of already existing connection spaces truly effective.

Smartphone application for long-term urban lifestyle and mobility monitoring

L. Sobková & H.H. Achten
Faculty of Architecture, Czech Technical University in Prague, Prague, Czech Republic

ABSTRACT: The mobility of people can be monitored using a simple smartphone application that maps their movement. Sensors in smartphones are a low-cost source of information which can be interpreted and subsequently used as a dynamic indicator of urban life. By using this wide spread and accessible tool, we can collect data about the lifestyle in urban structures. However, it is necessary to develop an appropriate marketing strategy for a successful acquisition of the data. We can gain access to the data through crowdsourcing or by offering attractive and gripping benefits. The data could be used for intelligent and smart urban planning, as well as for commercial and marketing strategies.

The proposed application "UrbanFit" for Android-based smartphones introduces an innovative technology, which monitors the daily exercise habits and caloric consumption of individuals through smartphone sensors. The UrbanFit is designed as a long-term source of mobility data for the Czech Republic.

1 INTRODUCTION

Cities continuously produce large amounts of information. The validity of some of the information is only very short. However, by using this volatile information, we can monitor and document the processes which are going on in a city. By combining these fragile and unstable "maps" and city plans, as we know them today, we can achieve a more comprehensive imaging and modelling of a city.

Information about on-going events and processes in the city is easier to obtain, but the full potential of the data from mobile technologies for spatial planning and crisis management has not yet been fully recognized in the field of city management [1], [2].

Currently we have technologies, which can acquire data very easily, because these technologies are already implemented in cities. In 2010 in the Czech Republic, 90.6% of people older than 16 years used mobile phones and 30 per cent of these people owned a smartphone [3]. Moreover, the marketability of these devices is showing a long-term upward trend [4]. Most smartphone devices have built-in sensors that continuously monitor and share different types of information [5]. Some of the information can be interpreted as dynamic indicators, which are useful for cities. Getting to know a city's dynamics better can provide better conditions for sustainable living in the city.

2 STATE OF THE ART

2.1 *Mobility sensing*

Two questions are crucial for the monitoring of life in urban spaces: How many people use the space and what they do there [6]. Worldwide mobile-phone penetration is increasingly turning the mobile network into a gigantic ubiquitous sensing platform [7], [8]. The quantitative question can be answered also by using mobile phone distribution analysis. The movement of citizens can hardly be tracked by this method, because it is difficult to recognize the exact path and way of movement due to the long period of registering of the devices and low location precision [9].

The potential of smartphone mobility sensing by using the location and acceleration data is already used by various applications. The CO2go project (http://senseable.mit.edu/co2go/) uses this method of analysing acceleration data in combination with GPS location to detect the trajectory and transportation mode, suggesting more eco-friendly routes and transport alternatives [10].

"A Crowdsourcing Urban Simulation Platform Using Mobile Devices and Social Sensing" uses data gained by the "CITYing" application (http://www.citying.ethz.ch/#). The application reveals CO_2 emissions produced by the user and shows how well the city is designed to meet the commuting requirements of its inhabitants. This application improves the location detection method – in order to reduce energy consumption, it uses network-based location sensors instead of GPS location [11].

2.2 *Impact of urban life on human health*

From beginning of the 20th century the incidence of lifestyle diseases has been on the rise [6]. Their causes include office work, stress, air-conditioning, inappropriate diet and a lack of physical movement on a daily basis [12]. The need to commute to work by car

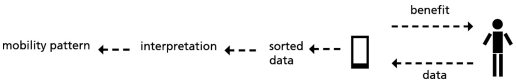

Figure 1. Scheme of data minig.

minimizes the natural opportunities for other forms of physical movement – walking, cycling etc. It has been proven that proximity of good-quality outdoor areas and possibilities for physical activities has a positive effect on your movement habits [13], [14]. Proven connection between health, social life and spatial structure [15] makes smartphone sensors – due to their ability to detect information about an individual's life and enviroment – powerful tool for both urban, sociological and medical research [16].

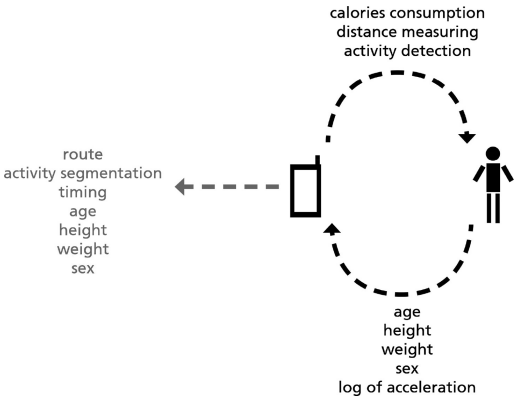

Figure 2. Applications benefits.

3 DATA MINING

3.1 *Aims of the application*

In relation to the collection of data from smartphones, the key element is the motivation of users to provide the data. It is essential to offer to them an attractive benefit which will turn the information they provide into a form they need.

UrbanFit focuses on gaining data from the broadest range of users possible, aiming at the collection of mobile data from urban units of different sizes and from different topographic profiles, while still maintaining a representative sample of the population. Unlike crowdsourcing-based data mining, which relies on a positive perception of the project goals, UrbanFit offers a benefit focusing on a broader range of users (Fig. 1).

The application will be collecting data on a long-term basis, enabling us to monitor changes in the-mobility patterns of the respective samples of the population.

3.2 *Data mining strategy – focus on health*

The type and duration of people's movements observed over a longer period of time reveal a lot about their physical condition and lifestyle [17]. The application monitors the type and routes of their movement including time data (i.e. the same kind of data which is monitored by sport testers). The data about the user's movement, combined with information about their age, sex, height and weight can be interpreted as their daily calorie consumption caused by their ordinary movement. The application is able to distinguish running, cycling and walking; however, it will not record other sports activities (see Fig. 2).

Apart from mobile data, the application will provide us with information about the user which will increase the informational value and data processing options. For example, it will be possible to compare the mobility habits of different age groups, men and women, or overweight individuals and those with an average BMI.

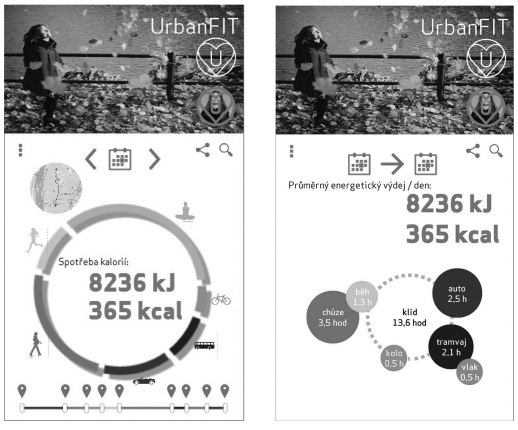

Figure 3. Interface of UrbanFit.

3.3 *Marketing strategy*

According to Google Play (https://play.google.com/store/apps/category/HEALTH_AND_FITNESS/collection/topselling_free), sport testers are popular and wide-spread software for smartphones in the field of health and fitness. This means that it will not only be necessary to provide marketing support for the application and to launch it in the Czech language, but that it will also be essential to offer another benefit which will be particular to the application.

Calorie consumption – as a piece of information gained through the application – becomes relevant for the analysis of lifestyle quality only when combined with the information about the individual's calorie intake. That is why the application will be compatible with the most downloaded smartphone application monitoring the calorie intake available on the Czech market – "Calorie Charts" (original Czech name "Kalorické tabulky", http://www. kalorictabulky.cz/). The "Calorie Charts" does not include a daily calorie consumption function; we therefore expect that UrbanFit could be a practical supplement to the "Calorie

Charts". The "Calorie Charts" enables the users to fill in their sports activities and it is therefore not necessary to add this function to UrbanFit.

Food and eating patterns significantly influence people's health and thus also the quality of their lives. At the same time, food and eating patterns are often specific for individual countries. "Calorie Charts" focuses on typical Czech dishes and that is why the combination of UrbanFit and "Calorie Charts" offers an advantage in comparison to commercial and international applications such as Strava (https://www.strava.com/), Endomondo (https://www.endomondo.com/), and others.

UrbanFit's user interface has been developed with an emphasis on a clear graphic structure and an easy design of the application (Fig. 3).

Appliaction UrbanFit will be advertised in professional environments as well as in the media dealing with nutrition, health, lifestyle, sports and medicine.

3.4 *Data mining method*

The method of collecting data from smartphone sensors is based on a mechanism which was described in "Lightweight Crowdsourcing: Monitoring Urban Travel Behavior Using Mobile-Based Sensing" [11].

The transportation mode detection will be based on data readings from smartphone acceleration sensors. Acceleration sensors show typical values when moving in different means of transport; these values are the basis for the distinction of the movement type (car, train/tram, bus, bicycle). Acceleration values enable primarily a very precise detection of walking and running. Walking is characterized by a very typical variable acceleration curve and it is always the linking element between other transportation modes [11].

The application will monitor the movement trajectories through the network-based location sensor. The precision of this method may be poor outside of urban areas with lower density of Wi-Fi networks. In longer time intervals, the movement will be logged through GPS as well, but only when this function is switched on and allowed.

4 RESULTS

The application aims at aggregating and storing mobile data. However, the main point is to provide the users the information about their daily physical activity.

4.1 *Classification of the application's outputs*

The database will store trajectories, divided into segments by transportation modes, as well as the starting and finishing time of the respective movements. The individual categories are: car, train/tram, bus, cycling, walking, running and the resting phase. The information will be stored with a specific ID generated and assigned to the individual application users. Information about the user's age, weight, sex and height, as

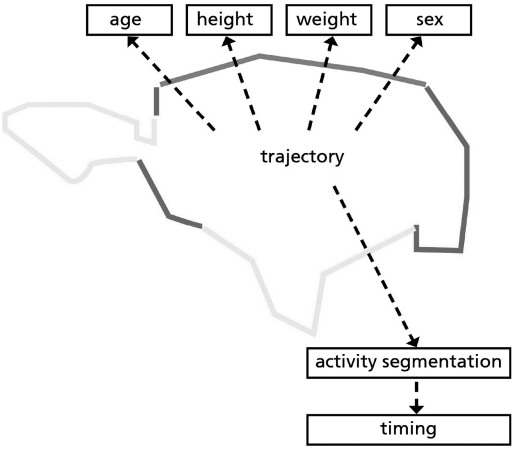

Figure 4. Scheme of sorting data.

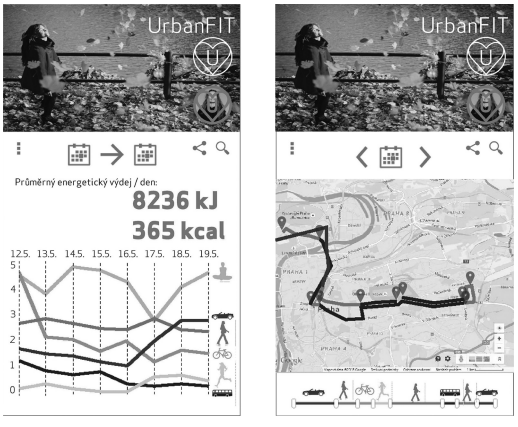

Figure 5. Users diary.

entered by the user into the system, will be attached to each ID (Fig. 4). Further information entered by the user will not be stored in the database.

UrbanFit will provide to the user a schematic visualisation of the trajectories travelled throughout the day, with the individual transportation modes graphically distinguished. The visual presentation of the daily statistics, including the numeric values measured and the actual energy consumption, will be available online. In the history section the user will also be able to look back at individual days from the past (Fig. 5).

By analysing the location of the ID at night, it is possible to determine which urban unit is most likely the user's place of permanent residence [1].

4.2 *Possibilities of data utilization*

Unlike data from mobile phone logs, data from mobile applications provides samples with only a limited quantitative informational value. This handicap is partly compensated by the informational density and precision of the data. Individual IDs are linked with the information about the users' age, weight and sex.

This information cannot be legally obtained from the big data of mobile network operators.

The possibilities to use and interpret aggregated data for the purposes of further research include:

- impact of urban structures and their infrastructure on the population's health;
- comparison of selected anti-stress factors (ASF = time spent walking/biking) in different types of urban structures;
- comparison of ASF in different topographies;
- comparison of ASF in connection with the time required for commuting and with the quality of public transport;
- comparison of mobility models according to the following indicators: age, weight, height, sex;
- monitoring of long-term mobility trends in selected user groups.

5 DISCUSSION

The big data of mobile network operators is not a publicly available source – the data is provided by the companies on a commercial basis which makes their availability for research difficult (interview with J. Novobilský, December 2015).

The application is currently at the stage of software development. A possible complication in the data collection can occur if the sample of inhabitants is not representative. Based on the application's focus, we expect that it will attract primarily people interested in healthy lifestyle. We assume that the oldest generation, i.e. people who use smartphones only rarely, will not be represented in the sample. An open point is also the possible connection with the commercial sector (cooperation with the "Calorie Charts" application).

The data will be accessible also for other research teams and thus remain available for further interpretation.

6 CONCLUSIONS

The data about people's everyday physical strain and mobility patterns obtained through the mobile application reveals how we behave in various urban areas. The data proves how our behaviour influences the environments in which we live. An evaluation of this data may give impetus to municipalities and, in consequence, help introduce measures which will foster diverse movement possibilities and support smart transport solutions.

Neighborhood design and children's active travel to/from school

Jong Seon Lee, Robin Moore & Ozlem Demir
North Carolina State University, NC, USA

ABSTRACT: Children's active travel (AT—i.e., walking, bicycling) has declined substantially especially for independent active travel (IAT). An increasing number of studies have examined walking behavior of adults to test the new urbanist hypothesis that design features support pedestrian activity. More neighborhood adult walking has been reported in new urbanist communities than in conventional suburban neighborhoods. However, study of children's AT in new urbanist settings is under represented. This study investigates the association between neighborhood design and children's active school travel (AST) in conventional and new urbanist neighborhoods. A group-administered survey was conducted with 4–5th grade children (N = 367). Built environment (BE) variables including distance to school, children's population density, mixed land use, street density, intersection and sidewalk density, and physical activity (PA) locations around home were measured within a quarter mile buffer of each participant's home in ArcGIS. Analyses of a further 254 students living within 2 miles from school with opportunities for walking were also conducted. T-test confirmed all BE variables were significantly different between conventional and new urbanist neighborhoods. New urbanist children engaged in twice the number of days of walking and 5–7 times more days of biking compared to children in conventional neighborhoods. Results suggest the need for further tests of new urbanist design principles in relation to children's AT to support development of neighborhood design policies and interventions that may provide health promotion benefits to children.

1 INTRODUCTION

Children's active travel (AT) (i.e., walking, bicycling) has declined substantially. Especially in the case of active school travel (AST), the decrease is significant for US children (McDonald, 2007), especially for independent active travel (IAT). Degrees of freedom for children to move around independently have diminished during the last decades (Gaster, 1992). In a similar vein, walking or bicycling to or from school has consistently declined (Sirard and Slater, 2008). Auto-centric environments have become one of the most important factors influencing children's daily, physical activity (PA). In 1969, approximately half of all U.S. school children walked or bicycled to or from school. Among children living within 1 mile of school, 87% of those walked or bicycled (DOT, 1972). In 2000, fewer than 15% of children and adolescents used active travel to or from school (EPA, 2003).

Recent policies and programs have targeted the built environment as a primary factor in discouraging children's AT. An increasing amount of literature examines how the built environment (BE) supports or restricts children's AT. In the domain of community design, studies have begun to examine walking behavior in association with new urbanist design principles that hypothetically provide supportive design features related to pedestrian activity (Rodriguez et al., 2006, Brown et al., 2008). These principles have been termed the 5D framework, including *Distance* of home to school, child *Density*, land use *Diversity*, pedestrian friendly *Design* and *Destination* of PA facilities such as parks. When homes are located on small lots near amenities, the resulting compact development and proximity make walking trips more feasible. Mixed use increases proximity (shorter trip distances), and thereby supports active travel. Streets with well-connected grid designs provide more direct and pleasant AT. Recent investigations comparing new urbanist neighborhood with conventional suburbs have focused on adult health outcomes, including BMI and walking behaviors (Rodriguez et al., 2006, Brown et al., 2008). To the authors' knowledge, only one study (Stevens and Brown, 2011) examined children's AT, in this case using accelerometer-measured PA to compare outcomes from a new urbanist community, a mixed community, and a less walkable community. The current study compares the BE and AST patterns by neighborhood type (conventional vs. new urbanist). Empirical evidence on neighborhood design is essential to inform design and policy interventions.

2 METHODS

2.1 *Research design and site selection*

North Carolina, Chapel Hill-Carrboro City Schools (CHCCS) elementary schools, local government, a national program, Go! Chapel Hill, and Active Living

Table 1. Participants by neighborhood type.

Schools	Neighborhoods near Schools	# of Children Participating Survey
School 1	Conventional	152
School 2	Conventional	10
School 3	New urbanist	10
School 4	New urbanist	195
Total		367

by Design collaborated to encourage the safe route to school (SRTS) program. Many Chapel Hill residents are health-conscious and proactive regarding health and physical activity, thus encouraging partnership for SRTS. Reflecting this background, Chapel Hill sites participating in the SRTS program had the advantage of community awareness of students engaged in walking programs and related activities.

Participants were recruited through four elementary schools participating in the SRTS program (Table 1). The neighborhoods around the four selected schools had similar 6-11 year old population and socio economic status (2010, U.S. Census block data). Schools 1 & 2 were located in conventional suburban neighborhoods, and schools 3 & 4 were located in new urbanist neighborhoods. The attendance school zones of schools 3 and 4 also include residences outside of new urbanist sites; thus, those participants were classified as conventional suburban residents. Each participant's neighborhood was defined as a quarter mile crow-fly buffer around each participant's home.

2.2 *Participants*

4th to 5th grades (9-11 year-old) children are at the stage of development of increasing independence and are relatively advanced in their spatial-cognitive skills. According to (Piaget et al., 1963) AT is crucial for the development of cognitive representations of the environment. Exploratory activities are especially important for children to learn to walk around the neighborhood with a coordinated system of reference. The period of approximately 10–12 years of age often marks a steep decline in physical activity and coincides with the transition from primary to secondary school. This is also a period when parental license for children to engage in physical activity without adult supervision increases (Jago et al., 2009).

2.3 *Children's survey*

4th and 5th grade elementary school children (N = 367) in four schools participated in a group-administered survey at the schools. During the information session, questionnaires were administered in group settings, and each respondent was asked to complete it while in the room. If the respondents were unclear about the meaning of a question they asked the researcher or teachers for clarification.

AST frequency and modes were developed from the "Active Where" parent children survey (Joe et al., 2008). Two sections include school travel mode and independent active school travel questions, as follows. First: "In a normal school week, how many days do you go to/from School in the following ways?" Options are walk, bike, go by car, and go by bus and participants are asked to circle one row for TO school and one FROM school. Second: "If you walk or bike to / from school, how many days do you walk or bike without an adult?"

2.4 *Built environment variables*

To account for the how neighborhoods' characteristics around homes are associated with children's AT behaviors, BE variables around each participant's home were measured within the quarter mile crow-fly buffer. In this study, BE variables were framed within a modified 5D model (Cervero and Kockelman, 1997). Except for the distance to school, all variables were measured within the home neighborhood BE, derived using ArcGIS 10.1 (Environmental Systems Research Institute Inc., Redlands CA).

The 5Ds were: *Distance* from each participant's home to school, estimated as the shortest route possible along a road network measured by Network Analyst 10.1 in ArcGIS. *Density* of child population measured as the number of 6–11 years old children (2010 U.S. census block data). When a buffer around a participant's home was not fully contained within a census block polygon, the data were assigned in direct proportion to the area of the polygon contained within the buffer. *Diversity* of mixed land uses within the neighborhood and was coded using a binary variable; equaling 1 if the neighborhood had at least one parcel (entirely or partially) with a retail, institutional or office land use code designation, and 0 otherwise. *Design*, included connectivity, which comprised length of road, number of intersections, and sidewalk density within the buffer. *Destination* measured PA facilities such as parks, greenway, trails, stream, pond, sports field, YMCA, school, shop, indoor sports facilities (martial arts, dance), cemetery, and bike lane within the quarter mile buffer.

2.5 *Analysis*

Descriptive statistics were calculated for days of walking/biking for the entire population. T-tests for BE was performed to examine the possible differences between neighborhood types. The sub-population of participants living in a 2 mile-buffer with the opportunity to walk was selected. T-tests for AST were performed to examine the possible differences between neighborhood types.

3 RESULTS

3.1 *Built environment and individual characteristics, and active school travel*

Table 2 presents descriptive statistics of BE, individual and household, and PA variables. One third of

Table 2. Descriptive statistics of built environment and individual characteristics.

BMI	367		19.11	3.79

participants (30.8%) lived in new urbanist neighborhoods. Mean distance to school from home was 1.71 miles. Mean population of children was 4.34 per quarter mile buffer. Only 27% of participants lived in mixed use neighborhoods.

Mean street length in quarter mile buffer was 16.3 mile. Mean number of intersections in quarter mile buffer was 34. Sidewalk density was defined to include not only sidewalk but also paved space from the sidewalk to the front porch; the ratio was 1.03, larger than one.

Almost 50% of participants were 10 years old (M = 10.16, SD = 0.71). Proportions of male and female students were similar. Proportions of white and non-white students were similar. Almost 50% of participants reported having two family motor vehicles (M = 2.05, SD = 0.76). The mean of BMI was 19.1 (SD = 3.79). Two thirds of the students (67.8%) reported having parental permission to go out on their own.

Table 3. T-test of BE variables by neighborhood type.

	Conventional M	New Urbanist M	t	p
Distance To School	2.16	0.72	**10.1**	.000
Population Children	4.52	3.92	**2.4**	.017
Diversity	0.15	0.52	**−7.0**	.000
Street length	7.02	37.28	**−22.6**	.000
Intersection	20.72	63.54	**−17.6**	.000

PA Location	0.94	1.97	**−13.7**	.000

3.2 *Difference of built environment variables by neighborhood type*

T-test indicated all BE variables (distance to school, children's population, mixed land use, street length, # of intersection, sidewalk length and PA locations) were confirmed to be significantly different between conventional suburban and new urbanist neighborhoods (Table 3). According to the design principles of new urbanist, new urbanist neighborhoods in the current study provided more walkable environments; distance to school was significantly shorter ($t = 10.1$, $df = 365$, $p = .000$); number of mixed use was higher ($t = -7.0$, $df = 166$, $p = .000$); street was longer ($t = -22.6$, $df = 134$, $p = .000$); number of intersections was higher ($t = -17.6$, $df = 135$, $p = .000$); sidewalk was longer ($t = -19.2$, $df = 114$, $p = .000$); the proportion of sidewalk to street was higher ($t = -18.6$, $df = 139$, $p = .000$); and there were more PA locations ($t = -13.7$, $df = 364$, $p = .017$). Against the new urbanist design principles, the children's population density was higher in conventional neighborhoods ($t = 2.4$, $df = 364$, $p = .017$). This may be attributed to the housing building types. Almost all new urbanist participants lived in single-family units (only 2 participants lived in multi-family units comprised of apartment or condominiums). Many conventional neighborhood participants lived in apartments, which results in higher population density.

3.3 *Differences in active school travel by neighborhood type*

Distribution of distance to school showed that after 1 mile from home, the number of students gradually decreased. Further analysis included only the students living within 2 miles from school who had opportunities for walking (n = 254).

For these 254 students, to understand association with the built environment, t-test of AST (days of walking/biking) was compared with conventional and new urbanist neighborhood types (Table 4). Since predicting variables were ratios, t-test was used. In days of walking and biking to/from school, new urbanist

Table 4. T-test of days of AST by destination, mode and neighborhood type.

		Conventional M	New Urbanist M	t	p
Days To School	Walk	1.10	1.78	−2.7	**.008**
	Bike	.25	1.49	−2.7	**.008**
Days From School	Walk	1.23	2.36	−4.3	**.000**
	Bike	.26	1.45	−5.7	**.000**
Days To School without an Adult	Walk	.71	1.52	−3.4	**.001**
	Bike	.31	1.33	−4.8	**.000**
Days From School without an Adult	Walk	.74	2.28	−6.0	**.000**
	Bike	.30	1.35	−5.0	**.000**

Note: Conventional: N = 144, New Urbanist: N = 110.

participants had a higher number of walking and biking days. New urbanist participants had approximately two times more days of walking, and approximately 5-7 times more days of biking.

In both conventional and new urbanist neighborhoods, the number of walking/biking days to school was lower than days from school. Generally, children and family had busier schedules in the morning, so fewer children walked in the morning than after school. It is noticeable that the difference between to and from school is larger in new urbanist neighborhood than conventional neighborhood types. This may indicate that more free time and increased walkable space affords conditions where children are more likely to be engaged in walking/ biking to/from school.

4 DISCUSSION

4.1 *Built environment characteristics*

Significant differences were discovered in neighborhood form and active school travel (AST) between conventional and new urbanist neighborhood types. Overall, the new urbanist neighborhood appears to better support a pedestrian friendly school travel environment with shorter distance, increased street connectivity, and positive sidewalk networks. Two previous studies reported higher PA of adults in new urbanist neighborhoods (Rodriguez et al., 2006, Brown et al., 2008). One study indicated that walkability of community related to more MVPA minutes of children during the half hour before and after school. (Stevens and Brown, 2011).

From school travel provided valuable opportunities for children's PA considering their busy schedule. The difference in the number of children between *to school* and *from school* was larger in the new urbanist neighborhood. This may indicate that with more free time and walkable space, children are more likely to be engaged in AST. One study of temporal active school travel patterns (Mitra et al., 2010) found that more BE variables were associated with walking in the morning than the afternoon. Due to parental/caregivers' schedules, working parents may not have time to pick up their children. This may lead to the mode shift from passive to active travel (Wong et al., 2011). For child pedestrians, routes to/from school using minor roads with less traffic volume and lower speed limits tend to be chosen (Duncan and Mummery, 2007).

4.2 *Comparison between walking and biking*

Neighborhood type was consistently associated with both walking and biking. For utilitarian travel, walking and biking are considered to require nearly identical BEs, indicating that short distances are better (Frank et al., 2003). However, beyond distance, other features influence pedestrian travel different to bicyclist travel. Pedestrians require good sidewalks and crosswalks, while bicyclists need either specialized bike paths or dedicated on-street bike lanes. Pedestrians desire interesting adjacent "eyeshot" spaces along the route (store fronts, building facades); bicyclists may not require them. For recreational bicycling and walking, these differences are more critical. While recreational bicycling is suited to low-traffic conditions with few stops, recreational walking is suited to either a social environment, where individuals can stroll, or an environment allowing fast walking (e.g., parks or neighborhoods with sidewalks). Thus, separate consideration of planning and design policy for walking and biking to/from school is necessary.

5 CONCLUSION

Neighborhoods exemplifying new urbanist design principles may support children's active school travel more than conventional neighborhood designs. Further examination of the association of these factors with *objectively* measured children's AST is required to improve understanding of correlates, mediators, and moderators to more confidently support policy development and design interventions to increase children's AST.

The experimental project of spread "social housing" of Real Estate Fund Ca' Granda. Construction of a synthetic index for the implementation of the mobility plan

M. Borghi
InvestiRE SGR, Milan, Italy

G. Ferri
Fondazione Housing Sociale, Milan, Italy

A.S. Pavesi
Politecnico di Milano, Milan, Italy

ABSTRACT: The "Real Estate Fund Ca' Granda" was born in Milan in 2014 with the objective of financing the construction of the new headquarters of the Ospedale Maggiore Policlinico of Milan, through the ethic enhancement of the real estate assets owned by the Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico. The financial instrument for the development is a social housing contribution fund. The Real Estate Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico in Milan consists of 1,390 residential units in 65 buildings, including 44 entirely owned, for a total of over 110,000 square meters, of which 53% were built between 1870 and 1900; 29% between 1901 and 1940; 18% after 1940. The construction of a new hospital pavilion through the establishment of a larger project of spread "social housing" in the city of Milan, provides an important connotation of social and ethical purpose of the project as a whole. Implementing the plan of valorization of the heritage requires the management of a mobility plan of the tenants, who currently occupy the property for various reasons, that could lead to redeployment, so as to be able to offer a housing service for those who cannot find an adequate response in the market, while enhancing a significant real estate heritage through the sale of some existing buildings. Specifically, the paper describes the case relating to the creation and the management of the Real Estate Fund Ca' Granda Hospital, with particular reference to the definition of a project for the operation of the mobility plan, the implementation of which is a necessary condition for the development of the real estate owned by the Fund. The study presents the construction of a synthetic index of characterization of the tenants, with the aim of providing, through a preliminary evaluation of the situation of each household, a useful tool to identify cases of social fragility, for the implementation of an experimental project of spread social housing, ever made in Italy.

1 INTRODUCTION

The Real Estate Fund Ca' Granda Hospital consists of 44 detached properties primarily for residential use for a total of 905 apartments (as well as offices, shops and outbuildings, for a total of 1,243 residential units) and 21 portions of buildings for a total of 81 apartments (as well as offices, shops and outbuildings for a total of 142 housing units). The heritage overall is largely decrepit, without elevators and appropriate facilities. About 53% of the total area, in fact, includes a built heritage that dates back to the last decades of the nineteenth century, while only 18% of the portfolio are buildings built after the '40s.

From the point of view of the rental, the residential contracts account for 63% of total fees, with a profile of maturities ranging from 2013 to over 2016, with a particular concentration of contracts expiring in 2015 and 2016 (respectively 45% and 12% of square meters leased).

It is therefore evident that the maturity profile, the amount of the already expired contracts for employment indennity and the presence of average rents lower than market rents, represent an opportunity for enhancement, but at the same time, if not properly managed, a potential problematic of social impact, political and media.

It is also true that the Real Estate Fund Ca' Granda is an ethical fund and represents the most significant Italian experience of valorization of public heritage, and for this it was awarded the Best Practice Public Heritage Award 2015. It differs from classic social housing projects primarily for two reasons. First of all from the technical point of view, because the Fund, large

sized, arises from the transfer of a real estate existing portfolio to be retrained.

While most of the social housing funds deal with interventions of real estate development called "Green Field", the Fund Ca' Granda involves the construction of social housing with no soil consumption, by regenerating existing buildings. The other peculiarity has got a social nature: the Fondazione IRCCS Ca' Granda has brought its owned buildings in the real estate fund to finance the construction of a new hospital pavilion with the revenues coming from the sale of part of the property in portfolio. Hence, therefore, the dual social purpose of the project: by strengthening the supply of social housing in the territory of the city of Milan, the construction of an asset to the service of all citizens is financed.

A key role in the realization of this unique project in Italy is covered by the management of the tenants whose main objective is to maintain the current tenants within the portfolio in social housing arrangements, subject to verification of possession of the access requirements, as well as the detailed analysis and evaluation of situations with particular discomfort. The management process includes the development of a mobility plan able both to carry out the plan to dismiss part of the buildings portfolio, and to implement the social housing project.

The paper describes the model of the mobility plan management, within which assumes the construction of a synthetic index of tenants characterization, with the aim of providing, through a preliminary assessment of the situation of each household, a useful tool for the identification of cases of social fragility for the realization of an experimental social housing project spread on built heritage.

2 THE MOBILITY PLAN

2.1 *The strategy for social management*

In the recent experiences of social housing in Italy (ABI, 2015) the financial structuring strategy of the entire real estate fund must be accompanied by an innovative management strategy that also considers aspects of social management already been tested. The design of correct social mix, creating sustainable communities, the selection criteria of tenants also based on motivational aspects, are all innovative responses on the basis of which it is possible to consolidate and maintain the long-term real estate value (Cassa Depositi & Prestiti, 2014).

The partnership with the third sector and housing cooperatives can ensure the most effective and innovative management of the community, with the identification of solutions that allow its management, mitigating shock and conflict. The great attention to the social impact generated by the sales process is also derived from the risk of generating a slowdown or a prejudice for the expected returns.

The management of rental properties, as either continuous relationship between the properties and tenants, is one of the sensitive issues of the administration of the constituting Fund. Therefore, the answer to two basic conditions has to be given: the good management of real estate assets spread with non-homogeneous characteristics; managing relationships with tenants through a coherent approach, with the aim to offer a housing service for those who cannot find an adequate response in the market.

The governance model foresees the cooperation of the SGR with Social Housing Foundation ("FHS"), in its role as technical and social advisor of the Fund, and it has decided to operate according to a model of social management of the property portfolio, based on the collaboration with the social manager and the involvement of tenants in the several stages of the process.

The implementation of the valorization plan of the Foundation's assets requires the proactive management of a mobility plan of tenants that allows the repositioning of the people and facilitates thus the enhancement of total volumes.

In implementing the social project, great care must be taken to families who, unable or unwilling to purchase housing where they live, they intend to stay in lease; it is expected that these households have priority in renting empty apartments of the portion of the inheritance for the long-term lease, and that in the process of mobility must be accompanied in all aspects of the transfer.

Through the detailed study of all the different personal and living situations, it proceeds with the preparation of a comprehensive plan that addresses the different needs and solutions, with the aim of optimizing the relationship between characteristics of housing and real needs of families, considering in such a scenario the presence of particular classes of tenants, such as the elderly and historians tenants who risk losing their personal network of relationships.

2.2 *The characterization plan for the existing tenants*

Understanding the composition of tenants is essential to the success of the operation and to enhance the buildings portfolio. It is therefore essential to set a characterization plan that takes into account the different phases of the operation and that it is structured to further investigations. During the "structuring of the plan", the analysis refers to the documented bases made available by the Foundation, only after the definition of the communication plan with tenants; during the "plan management" phase, it may be required to provide additional information, including questionnaires and interviews, only addressed to tenants set to remain renters or to those households interested in purchasing an apartment with different characteristics than that currently inhabited. The purpose of the "characterization plan" is to make an overall assessment of the situation of each family unit (dimensions, assessment of the new requirements, presence of young people or particular weaknesses) in order to identify

the housing needs and the requirements for particular services, which may also become a defining element of the social management project (Ferri & Pacucci, 2015).

Among the main activities for the analysis of the types of tenants, preparatory to the definition of the Mobility Plan, it is possible to identify a phase of analysis of the database provided by the Policlinico.

> with the main elements of the contract (nominee, contract type, application of special clauses, starting date, deadline, pending litigation, etc.) and a phase of analysis of procedures relating to the tenants.

From this analysis it emerged the following data macro areas that complete the picture obtained from the database:

- locative seniority (in view also of the contract transfers in favor of spouses or children living with, and lodging change, etc.);
- composition of the household residing in the accommodation;
- age of all of the family members;
- total household income (available for the year 2008/2009 only stated if that were asked for special treatment using the social clause or clause save-guard);
- interviews with the charge of the rental contract management to identify situations particularly fragile or critical (ie health issues, dependent persons that are followed by family members or neighbors, lack of family support networks, people followed by social services or people with disabilities);
- evaluation of the types of contracts and the requirements of access to housing defined by ac-territorial agreements;
- evaluation of the preliminary results of the technical due diligence.

The tenants' heterogeneity of this portfolio in relation to the income level, the sharing of the local roots in the reference district and the potential to find alternative solutions in the free market, are mainly factors due to the different ways of finding tenants that the Policlinico Foundation has adopted over the years; in the presence of both tenants historians who can say they live in the Policlinico homes since they were born and of tenants who have arrived in recent years; the different forms of protection of the most vulnerable families taken by the Foundation through specific clauses as defined by the territorial agreements.

3 THE DEFINITION OF A SYNTHETIC INDEX FOR THE MOBILITY PLAN

In the complexity of the above described scenario, it has been necessary to put forward a hypothesis that had the main objective to govern the complexity of the tenants in the management of the assets transformation process, without neglecting any aspect of social vulnerability.

For this purpose it has identified a numerical index, called synthetic index of inertia to mobility, able to allow a classification of the families of the real estate portfolio of Real Estate Ca' Granda Fund's, given in terms of social vulnerability and resistance to the displacement.

This is to measure a multidimensional phenomenon, not measurable in a linear way, whose valuation is still influenced by arbitrary choices. The methodology used for the synthetic index includes the following steps:

- definition of the phenomenon under study;
- selection of basic indicators;
- normalization of the primary indicators;
- weighting and aggregation of standardized indicators.

This analysis starts from the work of characterization and understanding of the current resident tenants' condition (hereinafter referred to as "tenants") achieved through the examination of the available documentation and the interviews with those responsible for the management of the real estate portfolio of the Fondazione IRCCS Ca' Granda.

The preliminary analysis, conducted during the phase of the structuring the initiative has allowed to collect a large amount of information about the general condition of households, as shown in the table (Table 1).

The great heterogeneity of this information must necessarily be related to synthesis, with the primary operational objective of identifying those specific situations that have to be taken into account in the preparation and implementation of the mobility plan.

3.1 *Selection of basic indicators*

During the selection of basic indicators it was considered appropriate to proceed with the identification of three different thematic areas corresponding to the main dimensions of the phenomenon under study:

- mental and physical health;
- socio-demographic vulnerability;
- displacement resistance.

3.1.1 *Mental and physical health*

The first thematic area has the aim of identifying within each family unit the number of individuals affected by both psychological and physical character discomfort. In particular, four basic indicators have been selected:

- psychic distress, is calculated by adding the number of family members with mental health problems;
- physical discomfort, is calculated by adding the number of family members with mobility difficulties, minor disability, walking problems, low autonomy;

Table 1. Information about the general condition of households.

Categories of information	Specific information
Personal data of the members of the households	– names, – age, – etc.
Household characteristics	– single-parent families, – number of minors in the household, – extended families, – families with familial network in another accommodation.
Contracts	– types, – clauses, – deadlines, – date of the first stipulation.
Income	– household income, – per capita income.
Factors economic difficulty	– loss of job or unemployment, – death of the only component with income, – subsistence through aid from third parties, – irregular employment.
Factors of psycho-physical discomfort and vulnerability of some tenants	– difficulty in movement, – psychic distress, – disease, – low autonomy, – people >75 and >65 years old.
Living story	– households from lodging change, – households from eviction, – households with other real estate properties, – households that have carried out restructuring, – households living in the accommodation for over 25 years.

– discomfort from serious illness, is calculated by adding the number of family members with serious illness, severe disability, diseases that cause bed rest;
– discomfort from other difficulties, is calculated by adding the number of family members with little other physical and psychological problems.

3.1.2 *Socio-demographic vulnerability*

The second area aims to identify families with "fragile" members, young and old, with special reference to situations of families made up with single parent and elderly people living alone. In the specific, four elementary indicators have been selected each of which is associated with an indicator:

– households with elderly, whose indicator is calculated by adding up the years of family members over the age of 65 years;
– elderly people living alone, each family composed of one component over the age of 65 years (binary variable);
– households with children, whose indicator is calculated by adding the number of household members under 15 years of age;
– single-parent families, each family composed of a single parent with dependent children (binary variable).

3.1.3 *Resistance to displacement*

The third and final topic area, however, is intended to identify potential families who, while not presenting any particular health conditions psychophysical or socio-demographic vulnerability, could make more difficult to move to another accommodation. To express this theme, four elementary indicators have been identified:

– attachment to the house, where the indicator is expressed through the number of years from which reside within the apartment;
– renovations, each household who performed renovations inside the apartment, these works of customization may be a deterrent to the movement, both for economic and affective reasons (binary variables);
– coming from lodging change, every household from a change of internal accommodation to the heritage of the Polyclinic and for this reason hardly willing to exchange for a new accommodation within the same assets (binary variable);
– coming from an eviction, each household that entered into the Polyclinic as a result of a procedure for eviction (binary variable portfolio).

3.2 *Normalization of the indicators*

The work of normalization of the indicators has the aim to make comparable the variables chosen to represent a specific phenomenon, bringing them to the same scale of measurement.

The normalization also allows to analyze the presence of any outliers, and to correct strongly skewed distributions. There are different procedures of data normalization and it is important to choose the most correct one with respect to the theoretical framework and data properties. One of the most used methods for this purpose consists in the transformation, within the same category, of the value of the individual observations in a new value compared to the maximum value expected by the series.

The positive aspect of this method is represented by the possibility of being able to bring back the values for each series to the range of variation (0; 1), thereby obtaining an amplitude of the same scale, and then the immediate comparability between different indicators considered. The inherent problem with this type of standardization process, however, is related to the strong influence of the presence of outliers in the sample, in fact these observations are not very useful to be compared because they are difficult to imitate.

To overcome the possible presence of outliers it was decided to compare the values of the individual observations to a benchmark, arbitrarily identified with the help of experts.

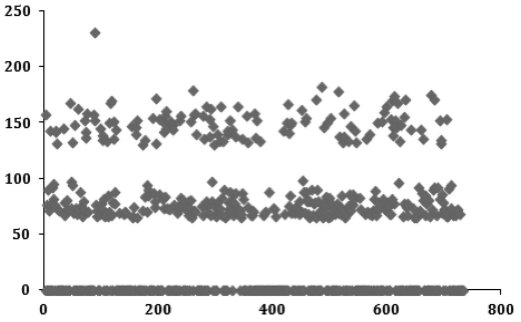

Figure 1. Indicator distribution: households with elderly.

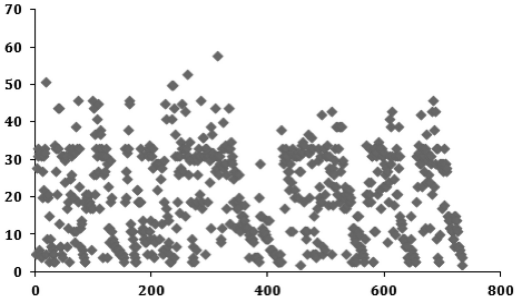

Figure 2. Indicator distribution: attachment to the house.

Given the matrix $X = \{x_{ij}\}$ $n = 733$ lines (families) and $m = 12$ columns (basic indicators), switch to the matrix $Y = \{y_{ij}\}$ where:

$$\mathbf{y_{ij}} = \frac{\mathbf{x_{ij}}}{z_j}$$

where z_j is the benchmark for each primary indicator. Finally, with the aim of maintaining the values within the same scale (0; 1), it has been decided to assign the value 1 to the indicators that are placed above the target value. It is therefore important to set a suitable benchmark so as not to incur a problem of information loss, since observations that are much above the target value or slightly higher will assume the same value.

For most of the basic indicators it has been decided to maintain as benchmark the maximum value reached by the reference sample, and only two indicators are excluded from this type.

3.2.1 *Benchmark indicator households with elderly*
Looking at the distribution of the basic indicator values it was decided to apply a value of 200 bench-mark.

3.2.2 *Benchmark indicator attachment to the house*
Looking at the distribution of the values of the basic indicator has been decided to apply a benchmark value of 50.

3.3 *Weighting and aggregation of indicators*

To get to the synthetic index, once normalized, basic indicators must be aggregated: the first step is the identification of a weighting system to assign a weight to each component, so as to reflect the characteristics that marks. The choice between different approaches to the definition of weights is not always easy to deal with and very often it is the result of subjective assessments, which become particularly complicated in case of the analysis of complex phenomena, where many variables interact. It is important to note that there is an established methodology for weighing the basic indicators.

Synthetic index of Inertia to mobility					
Synthetic index of Mental and physical health		Synthetic index of Socio-demographic vulnerability		Synthetic index of Resistance to displacement	
Psychic distress	0,20	Households with elderly	0,20	Attachment to the house	0,40
Physical discomfort	0,30	Elderly people living alone	0,30	Renovations	0,30
Discomfort from serious illness	0,40	Households with children	0,20	Coming from lodging change	0,15
Discomfort from other difficulties	0,10	Single-parent families	0,30	Coming from an eviction	0,15

Figure 3. Set of weights for synthetic indices.

The reasons on which is based the choice of a weighting system rather than another one are different. The underlying logic with which the weights are selected must be in accordance with the reference template on which the index is built, so as to obtain an overall structure as much as possible organic, transparent and conceptually consistent. The intent of the weights is to provide guidance relative importance of each elementary aggregate indicator in the indicator: in this way the weights represent the meaning and the basic indicator contribution to aggregation, and they are value judgments.

It has been therefore decided to use, as indicators weighting system, the method of weights allocation known as Budget Allocation Process (OECD, 2008). This method requires the intervention of experts in a given subject, who are asked to assign a "budget" of a hundred points for the set of basic indicators based on their experience and their own judgment.

You can then identify three distinct phases of the Budget Allocation Process:

– selection of experts for the evaluation;
– budget allocation to basic indicators;
– calculation of the weight of the basic indicators.

Specifically, it has been decided to involve, as experts for the evaluation of the phenomenon, the Social Housing Foundation team and the Fund Management team of the Real Estate Fund Ca' Granda.

The partial summary index for the h-th subject area will be calculated as a weighted average of the individual basic indicators:

$$\overline{\mathbf{y}}_{ih} = \frac{\sum_{j=1}^{4} \mathbf{y_{ij}} \cdot \mathbf{w_j}}{\sum_{j=1}^{4} \mathbf{w_j}}$$

Synthetic index of Inertia to mobility					
Synthetic index of Mental and physical health	0,40	Synthetic index of Socio-demographic vulnerability	0,35	Synthetic index of Resistance to displacement	0,25

Figure 4. Set of weights for synthetic index.

Similarly, it has been decided to allocate an additional budget for the balance of the synthetic indices of the subject areas.

The synthetic index of inertia to mobility will therefore be calculated as a weighted average of the synthetic indexes of the different thematic areas:

$$\mathbf{I}_{\bar{y}_i} = \frac{\sum_{h=1}^{3} \bar{y}_{ih} \cdot w_h}{\sum_{h=1}^{3} w_h}$$

4 CONCLUSIONS

Currently, the management phase of the mobility plan has started with the first cognitive interview made by the Social Manager with all the tenants of the property assets. During these first conversations it was not given information about the destination of the buildings and the tenants management.

The first cognitive interview has the purpose of:

- checking the information on the tenants in possession of the Social Manager derived from the database provided by the Policlinico and from the reports with the status of contracts;
- completing the missing information such as the number of family members living together, mode of use of the apartment, the apartment status, etc.;
- checking the situation of fragility or discomfort reported by the Policlinico during the interviews conducted by the Social Housing Foundation and possibly other existing warnings;
- reporting situations that might create conflicts with the Fund during the negotiations for the liberation of the apartment and/or tenants' displacement;
- assessing, as far as possible, the apartment suitability to the needs of the family unit in order to obtain useful information to its relocation, or to identify underutilized housing to be made available;
- assessing any predisposition of the tenant to buy housing;
- identifying the problems relating to functionality of the building and/or the apartments to provide useful guidance to the staff of designers and construction company.

The data are collected and summarized by the Social Manager in a special report that will be updated with future meetings or in case of additional information received by other means.

After the first interviews, the Social Manager, following the instructions provided by the Fund Manager and Social Housing Foundation, holds a second informative interview with the aim of:

- informing tenants about the destination (sale or lease) of the property where they reside;
- informing the tenants about the social housing project that will cover the portfolio of the Fund dedicated to the long-term lease, in order to verify the access possibility.

Those who find themselves in an apartment going for sale, can decide whether to purchase the apartment or to join the social project and move to an apartment intended for social housing.

Those who live in an apartment intended for social housing, will check the requirements to see if they will be entitled to continue the tenancy within the fund portfolio.

At present, the first interview has been carried out on approximately 70% of real estate and the second interview for approximately 10% of real estate.

The sample is thus not to be complete and therefore it is not possible to properly apply the index on the whole of the fund sample.

It is currently undergoing a working group for the mobility plan with the participation of:

- the Social Manager (which carries out the interviews)
- the Social Housing Foundation ("FHS");
- the Fund Manager.

During the working group (which is held every 15 days) the cases deemed critical by the social manager are discussed to find a solution to implement the mobility plan in the best way.

Austerity, subverted

Christakis Chatzichristou & Georgios Makridis
Department of Architecture, University of Cyprus, Nicosia, Cyprus

ABSTRACT: The possibility of a subversive version of the Lacanian enjoyment of the counter-action of joy, which is the equation of the regulation of pleasure with the pleasure of regulation, is assumed as a proposal for the adaptation of austerity as a counter-measure to the politically imposed austerity. Although intimately connected with the capital, architectural space can also constitute an alternative approach within extreme conditions. The research aims to trace upon the moments in architectural history that counter-culture developed a strong spatial dimension, investigate their reasoning as well as their manifestation and results, and draw the parallels between the era of the case studies and the current era. Architectural design can, in this way, inform and be informed in a reciprocal condition within which it can both survive itself and the people.

1 CRITICALLY AUSTERE

Austerity has made an appearance in the civic vocabulary as the politically imposed counter-measure to the recent collapse of the economic systems, briefly referred to as *crisis*. Consequently, the use of the term became more frequent, as it became intertwined with the negative sign of recession and lack of resources. Apart from a dictated series of rules, living within the limits of dwindling means can also be an adopted – either for reasons of preference, of necessity, or, of fashion – attitude, or, likewise, an inherited lifestyle. Therefore, to define austerity, one needs to spread the magnitude of its categories by tracing the associations of its occurrence. In so far as the interest of architectural design is not solely oriented toward matters of fact, but also involves matters of concern, as put by Latour (2007), the discourse of austerity is both timely and important. Otherwise the term will continue to suffer from unilateral and monochromatic interpretations, and will, subsequently, compromise architecture within the boundaries of the regime that initially conditioned it.

2 AUSTERITY

As a political framework, austerity is considered to be the outcome of the ideologies of neo-liberalism (Till, 2012), that acts as the mechanism for commodifying the non-commodified, or the semi-commodified (Goodbun et al, 2013). The very etymology of the word in its original language implies the maintenance of a set of rules without deviation. However, the meaning of the word fluctuates between positive, neutral and negative in different cultures (Suryawinata & Maas, 2012). The self-imposed austere lifestyle of the Zen Buddhists, for example, is definitely different in agency, expression and content to the austerity that a prisoner experiences in their cell. A house with an area of a hundred square metres is considered small in Greece and the USA, as it is considered average in Japan and Spain, at the same time that it is considered large in England and Hong Kong (Wilson, 2016). It becomes apparent that a mere number cannot be a criterion of austerity. Although a set of limitations, numerically expressed scarcities, or reductive acts can be inevitably connected with it, its occurrences and, subsequently, its contributions are the result of the performing of an extended list of actors, as dubbed in *Actor-Network Theory (A-NT)* (Latour, 2007), as a durable entity.

Society is the source and the recipient of the performances in discussion. The current situation the European Union (EU) is in has enabled a manifestation of austerity that is closely related with economic and political measures. These include a series of rules, dubbed as *memorandum* of understanding, which are agreed between a part that will go through a path that the other parts – the International Monetary Fund (IMF), the European Central Bank (ECB) and the EU – agree that will not quite conclude to the required results (Eliot et al, 2013).

The paradox concludes, or rather continues, with harsher measures of the same kind and with similar capacity for change. It becomes apparent that the final receiver of the failed policies is the society and its contents. A call for voluntary adaptation of spatial and personal austerity, i.e. the creation of a counter-culture, to resist the violence of political austerity may raise various objections, however it should not be completely rejected, as it has proven its resilience at the past

and appears to be gaining ground again at present. The latter is certainly not irrelevant with the timely coincidence of events.

3 LITERATURE REVIEW

The subscription of some, if not all, of the EU countries to the neoliberal policies of the 2000s and the subsequent burst of the mortgage bubble can be step-by-step understood as a legacy of the development decades that 'ritualised the end of necessity and reconstructed desires into needs' (Illich, 2010). Will for equality in the image and the likeness of the 1950s, 1960s and 1970s capitalist declarations and the 'economic catching-up' and 'narrowing the gap' slogans (Lummis, 2010) enabled similar conditions anew. The narrative of development might be well dead, but the 'propagators of need' are continuously reconceptualising their discovery, at the same time that they are redefining humanity (Illich, 2010). Neoliberalism is the living proof of this mutation. Žižek (2012) maintains that in such political systems new demands are continuously manufactured to replace the existing ones, in order to feed them back, expand and reproduce them. Therefore, the current mutation is probably not going to be the last one. An attack to capitalism per se appears as a rather painful solution to the matter, as the shock will probably re-appropriate it in its worst versions, i.e. authoritarian regimes, absolute control and the like. The gradual development of pockets of resistance to its violence within its urban boundaries, i.e. the coining or enabling of parasitic alternatives of dwelling or being together within the city, provides an option not widely applied, but definitely timely in its momentum and its precedents.

3.1 *Austerity shift*

One could argue that the 'less is more' doctrine is the core aesthetic and ethical principle of austerity in design. Indeed, it has been the frontispiece of the movement of Minimalism and its affiliations like Modernism, or Functionalism. The current shift of interest toward simplicity in architectural design, as a reaction to the blissful 'baubles' of the past decade (Till, 2012), has renewed the interest in collaborative living, communal spaces and the like, as it has renewed the interest in the 'less is more' design frame. A lot of architectural practices are criticised because of mere formal translation in an attempt to align their designs with the ethos of austerity (De Graaf, 2013). Aureli (2013) maintains that 'both the "less is more" attitude in design and the ethos of austerity politics seem to converge within the tradition of asceticism, which is commonly understood as a practice of abstinence from worldly pleasures.' A definition of austerity can therefore be looked for through the examination of asceticism and the subsequent subtraction of the elements that assign the 'less is more' attitude with capitalistic connotations. Put in form, or, rather, in equation: if *'less is more'* + *austerity* = *asceticism*, then *austerity* = *asceticism* − *'less is more'*. An attempt to define the contents in each of the factors of the subtraction would be an attempt to define austerity itself.

3.2 *Ascetic contemporary*

Aureli (2013) sees 'a means of oppression and form of resistance to the subjective power of capitalism' in asceticism. He combines asceticism in monasticism to reveal the virtues that the place of performance per se, i.e. the monastery, becomes the perfect coincidence of space and time, leaving behind nothing as a product but the performance itself (Aureli, 2013). The same principles can be found in spaces that are inspired by secular living, such as the hospital, the garrison, the prison, as well as the factory, the hall of residence, or housing estates. Immaterial labour (Dogma, 2014) and proliferation of technology added to these spaces renders the division between work environment and the living environment obsolete. Asceticism outside the religion is therefore possible, etymologically sound – its original meaning incorporates practice and exercise – and may still become a pocket of resistance against the oppressive forces of society. In the Genealogy of Morals, Nietzsche (1999) comments that withdrawal is yet another occurrence of a man's will to power, as it becomes self-preservation through self-negation. Žižek (2009) goes one step further in insisting that asceticism is the outcome of the demand for equality in pleasure, and names aspects of the lives of yuppies, i.e. exercising, healthy eating and the like, as ascetic. This culture of asceticism is no longer confined within the monastery, no longer refers to traditional religion, but it maintains its cause: self-improvement through self-limitation. Withdrawal might acquire a metaphoric quality, however the cell, the singular dwelling, the quintessential representation of interiority according to Barthes (2012) is still relevant as the space where the body can take care of itself.

3.3 *Less is more*

Aureli (2013) criticises the branding image of austerity and its reduction into fashion and formal language. In his book *Less is Enough* (Aureli, 2013) he renounces the 'perversion of austerity' and calls for art and design to play a fundamental role in defining a way of living that is beyond the promise of growth and the threatening rhetoric of scarcity. In the same manner, Till (2012) spots a number of architectural practices that are celebrated for their austere buildings that 'typically aspire to an aesthetic of minimalist decorum and tectonic rectitude' but are in no way financially, or otherwise, austere. It is precisely this sort of factor that the equation suggests to subtract from asceticism in order to define austerity.

3.4 *Visionary expressed austerity*

Theoretical proposals can be free of practical details, or application issues, however, perhaps it would be

a missed opportunity to consider certain visions as utopian and therefore unrealistic. Their suggestions and implications on issues of contemporaneity in relation with austerity are investigated in the five models of domestic space discussed next.

3.4.1 *Ito, Pao dwellings*

Access to the network of information within minimal shelter and the subsequent dissolving of the rest of the domestic functions in the metropolitan tissue are the main concerns of the projects *Pao I* and *Pao II*, 1985 and 1989 respectively, by Toyo Ito. The increasing price of homes in the urban metropolis and the simultaneous advancing of technology pushes the urban nomad to inhabit a light and ephemeral architecture, reduced to a series of objects.

3.4.2 *Meyer, Co-Op Zimmer*

Simplicity and cellular living within a communal environment are the ideas underlying a 1924 exhibition project by Meyer dubbed *Co-Op Zimmer*. It is intended to be the private part of a shared dwelling, aimed to provide the occupant with the opportunity of solitude and reflection. Contents are limited to a bed, two chairs, one of which hangs on the wall for when the visitor will arrive, a shelf and a small folding table with a gramophone on top. Aureli (2013) compares it with the monastic cell in the sense that it is the space that allows the person to live. 'The gramophone is important because it shows that the minimal living of *Co-Op Zimmer* is not only dictated by necessity, but is also a space to reclaim an element of "unproductive" time', he claims (Aureli, 2013).

3.4.3 *Absalon, living cells*

Ascetic and isolated existence, combined with a nomadic lifestyle and protection from an oppressive society are the underlying concepts of Absalon's *Living Cells*. Despite their deductive form and their white appearance, the cells – with a surface ranging from four to nine square metres – are conceived as fully functioning dwellings with electricity and running water. The artist was only able to complete the first out of six. Absalon is filmed to perform various functions in *Cell 1*, notably eat, drink and sleep with the use of minimum resources added to the ones existing in the space (Absalon, 1993). 'These homes will be a means of resistance to a society that keep me from becoming what I must become', he states in an interview for the exhibition of his cells in 1993 (Lucarelli, 2014).

3.4.4 *Antonas, the house for doing nothing*

Withdrawal from the burdens of contemporaneity and adaptive reuse of existing entities, i.e. buses, caves, or even buildings as dwellings is where Antonas focuses his writings and speculative projects. He maintains that networked screening, i.e. the inclusivity and the connectivity of the screen, has revolutionised the way of living to such extent that everything that is needed for contemporary living is a cave and a connection to the web (Wachtmeister, 2013). He even goes a step further by insisting that society is becoming simpler by the years. His *House for Doing Nothing* is a vision that exemplifies his approach on finding yourself by making new values inside a dwelling that may resemble a prison cell, but does not give you the idea of being somewhere small. It implies a space for temporary withdrawal on the premise of responsibility to discover the self, to make decisions and to finally be able to resist. The Internet connection is, in this case, the means to create dispersed interconnected agorae (Antonas, 2011). Co-habitation outside the virtual is also a possibility in this project.

3.4.5 *Malka, self defence*

In favour of the marginalised groups or individuals, architect Malka champions the utilisation of in-between spaces and parasitic architecture to create a new social scenario. *Self Defence* is a project that suggests a modular parasitic architecture installed within the void that the Ministry of Defence building in Paris prescribes. Although he admits that his proposal has issues of legitimacy, Malka (Wachtmeister, 2013) claims that building a city within the city creates a pocket of resistance against capitalism and an architectural hijacking. His vision takes the form of a modular scheme that uses existing modules, i.e. ship containers, to fill in the empty and the unclaimed spaces in the city.

3.5 *Subversive dwelling*

Simplicity and cellular living, ascetic and isolated existence combined with a nomadic lifestyle and protection from an oppressive society, withdrawal from the burdens of contemporaneity and adaptive reuse of existing entities, access to the network of information within minimal shelter and the subsequent dissolution of the rest of the domestic functions in the metropolitan tissue, and, the utilisation of in-between spaces and parasitic architecture to create a new social scenario, are the concepts in the works mentioned here. The possibility of a subversive version of the Lacanian enjoyment of the counter-action of joy, which is the equation of the regulation of pleasure with the pleasure of regulation, is assumed as a proposal for the adaptation of austerity as a counter-measure to the politically imposed austerity. This emergence invites for an alternative design-driven approach within extreme politically imposed conditions. The inclusion of historical, philosophical, sociological and political references certainly benefits the discussion around austerity, as the inclusion of visionary expressions of it does. The speculation that a misinterpretation, or rather, a 'perversion' of it endangers its possible salutary associations enabled an attempt to define its nature via a case study.

4 CASE STUDY: FLAT GEMK

Bought in the prime time of the bliss of the local economy *Flat GEMK* is an example of a small – for Cypriot standards – and expensive – for contemporary real

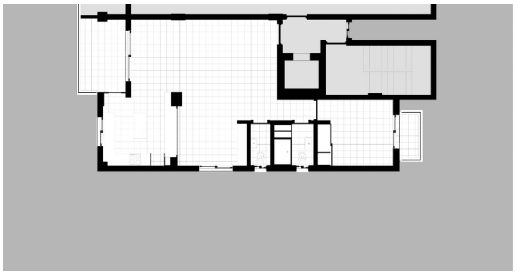

Figure 1. Flat GEMK. Plan. Lineal.

Figure 2. Flat GEMK. Plan. Montage on Lineal: Contents.

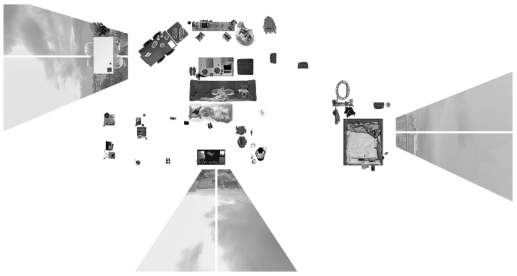

Figure 3. Flat GEMK. Plan. Montage: Contents.

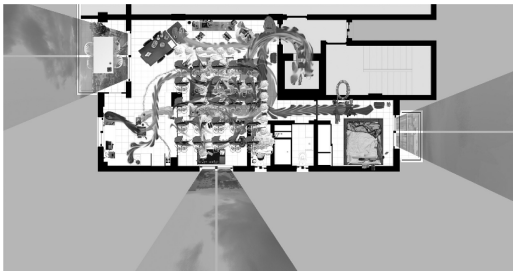

Figure 4. Flat GEMK. Plan. Montage on Lineal: Paths.

estate prices – home in the centre of Limassol (Figure 1). It is inhabited by a married heterosexual couple, both with demanding work and academic schedules. Although it is basically used only during night-time and a portion of the weekends and it was meant to become the permanent home for the dwellers, the couple is in the middle of a controversy at the moment, whereby one partner insists on moving out of the flat to prepare a space for a potential baby, whereas the other partner maintains that the existing space can accommodate such an addition while the time schedules and economic situation cannot (Figures 2, 3, 4).

The flat's use pattern reveals that only half of its area is used in the daily routines and an additional portion during crisis scenarios, i.e. the guest toilet doubles up as an isolation area during an argument (Figure 5), and the currently not in use office area doubles up as a guest bedroom. There are several indications that the couple is indeed undergoing a crisis which does not seem to necessarily be economic in nature, and that some forms of austerity are present which are not necessarily measurable in numbers or expressible in absolute terms. Perhaps the most obvious aspect of the co-habitation which reveals that the couple perceives their lives as going through a crisis is the way it deals with the tight time schedules and the allocation of jobs that need to be done around the flat such as grocery shopping, bill payment and the like.

Case study *Flat GEMK* findings do not necessarily justify an austerity condition, at least in the manner it is sought after. However, it has provided certain clarifications for future reference. A call for austerity in order to be aligned with the current flux is not applicable to everyone, and not everyone is willing to adapt to conditional counter-measures. In so far it is accepted that an austerity shift is evident in society, it needs to be understood that its acknowledgement will come from some, not from everybody. Furthermore, a phenomenal crisis, namely a family crisis and the like, might be partially associated to the subject matter, but, at the same time, it should not be assumed as a direct effect of it. The enablement of an actor-network (Latour, 2007) reveals more ties and mediators than previously assumed.

In the case of the *Flat GEMK* inhabitants, if being immersed in the situation, they can use means of communication sharable by both, a research examining the situation needs to develop the media of analysis more suitable to capture the nuances of the setup. This is where the present research has most felt the lack of appropriate means not only of representing but also of framing the concept of austerity in the first place. It seems that a closer investigation into the framing and representing not necessarily austerity but, perhaps firstly dwelling, is needed.

Another important part of this research is the one related with the observation of realised practice, be that case studies of already built spaces, that will be used to trace the nuances between the various austerities reported. These can include precedents of secular, or otherwise austere dwelling, such as a monk cell, a student hall room, the room of a prostitute, a prison cell, or more inclusive examples such as dwellings for larger groups of people, i.e. a family house and the like. The accumulation of entries describing the topic invites a reciprocal practice within which the device, i.e. the entry template, used for their inclusion is a work in progress that is being updated and re-appropriated by the very information that it contains. The acknowledgement of relevant information, its retrieval and the

Figure 5. Flat GEMK. Plan. Montage. Zoom. Guest Toilet.

subsequent appropriation in order to acquire a shareable form are the main targets for the future of this research. Keeping the entities, or rather, the tasks of taking into account and putting into form, separate is paramount for the public accessibility (Latour, 2007) of the research output.

5 CONCLUSION

Counter-cultures of resistance have been known to have managed to alter conditions of oppression in the past. Their spatial dimension is the living apparatus within which the catalysts of societal change can occur. Withdrawal and self-negation within the urban tissue are possible paths for the subversion of a systematic violence. Austerity can be central in this effort only outside the boundaries of the reasoning it has been reinvented. The process of subverting austerity toward a solution, rather than a condition, requires openness in means and methods, but, first and foremost, it requires the will to change. The latter is also the main ingredient of meaningful architectural design.

The Guggenheim effect and failed public investment in architecture

M. Baptista-Bastos & A. Lau
Faculty of Architecture, University of Lisbon, Portugal

ABSTRACT: During a long four decade period, from the 1970s until 2008, Spain went through a dramatic economic growth, in which the construction sector played a crucial role. Following the success of the Guggenheim Museum Bilbao, several City Halls embarked on enterprises investing in culture with projects designed by renowned architects, hoping it would attract visitors and promote the local economy. The 2008 global financial crisis was felt deeply by Spain, where years of austerity measures plunged the country into recession, causing stagnation in the construction sector. The purpose of this study is analyzing examples of failed public buildings in recent years, relating the motivations that encouraged ambitious programs with the causes of its incompleteness, for better understanding the underlying issues that caused high public debt. The political concern with popularity along with the dazzling effect of world-famous architects turned out to be a source of public expense in many cases. The expected result is a contribution for a greater social awareness, so that conclusions can be drawn and a lesson learned for the future. This study highlights the successful example of the Guggenheim Museum Bilbao, the years of the property bubble as a source of indebtedness, the consequences of the Great Recession and, last but not least, three cases that demonstrate the problem: the City of Culture of Galicia (in Santiago de Compostela) by Peter Eisenman (Eisenman Architects), the Alcorcón Centre for Creation of the Arts by Javier Camacho and Pedro Bustamante (cmA Arquitectos (Madrid metropolitan area), and Córdoba Congress Centre (for Córdoba, Andalusia) by Rem Koolhaas and Ellen van Loon (OMA).

1 THE GUGGENHEIM EFFECT

1.1 *An ambitious program*

In 1991, the Basque government took the initiative of proposing to the Solomon R. Guggenheim Foundation the creation of a Guggenheim museum in Bilbao, the largest city of the Basque Country (Fig. 1).

The government financed the construction and funded a substantial fee, ensuring that in return the Foundation would manage the institution, provide the annual budget, organize temporary exhibitions and rotate parts of its permanent collection. The chosen place to build the museum was previously occupied by a decrepit port and shuttered factories, remains of the former glory of Bilbao as a manufacturing centre.

Figure 1. Guggenheim Museum Bilbao ©MykReeve 2005.

This project was a part of an ambitious redevelopment program, made possible because of Spain's economic recovery after joining the European Union in 1986, that included also a new main terminal for the airport (designed by Santiago Calatrava and opened to public in 2000), a metro system (by Norman Foster, approved in 1988 and began operation in 1995), and a footbridge across the Nervión river (also by Calatrava, known as Zubizuri and opened to public in 1997) that links the hotels directly to the Guggenheim museum. According to this strategy of engaging expensive architects, the Solomon R. Guggenheim Foundation selected Frank Gehry and encouraged a daring design.

1.2 *The instant hit*

The political and economical strategy was disguised behind an apparent cultural phenomenon, by raising a museum for exhibiting works and installations by contemporary artists. In reality, culture played a secondary role, because the intention behind the building was, not its content, but attracting tourists and re-launching the local economy. It served its goal, with its colossal deconstructed shape that became a huge hit, and Guggenheim Museum Bilbao received international acclaim, now having a flow of over one million visitors every year. The building cost was recouped within three years and, because visitor spending in the city jumped, five years after construction its impact in the

local economy was an estimated €168 million, meaning an additional €27 million into Basque government tax coffers, the equivalent to adding over 4,000 jobs.

According to Iñaki Esteban, author of *El efecto Guggenheim* (Editorial Anagrama, 2007), the building can be considered an "ornament" in the sense that political institutions and business entered a new phase of an aesthetical and globalizing capitalism through the symbol of urban development. The cultural function is therefore an ornament for the political initiative to embellish an ugly city, and put it on the map. The futility associated with the ornament is replaced by "a strategic inversion to promote urban evolution", since the building is a resource that "creates urbanism, image and communication, economic activity and political loyalty". Its purpose is, therefore, communicating the city's new status as a touristic attraction.

1.3 *Generating resources*

The enthusiasm aroused by the international success originated an atmosphere of prosperity and economic growth that became expressed in an increase of consumption, which in turn legitimated the ornament, giving it an active role in generating resources. So, the main core of the museum is, undoubtedly, the capacity to project a strong identity through a powerful image, making the city more competitive and able to attract tourists at a large scale. From the economic point of view, Bilbao went from the manufacturing sector to the era of services and know-how, where leisure and culture are turned into business. Its cultural interest is relegated to a secondary role.

The museum's value is not mainly measured for its content but for its consequent urban, political and economical benefits. The ornament is legitimate and has prestige because it is, in one word, profitable. It is a business model, not reliant on government funding, able to promote commercial attractiveness and private investment, to publicize the support of companies, to attend the demands of politicians and to know how to preserve its image by using wisely the media (Esteban 2007).

1.4 *Illusion of luxury and merchandising*

The Guggenheim Museum Bilbao is, not only a work of art, but also a spectacle that creates an illusion of luxury, contributing to the image of a city open to novelties and in fashion. It is a setting that communicates prosperity, in which the content is less important than the appearance, because tourists desire distraction and amusement. The sensorial stimulus is carefully taken to the limit, provoking a wow factor, essential to capture attention in a society saturated with image and publicity. At the end, the impact of a strong ornament turns it into a resource generator, a profitable objet that ironically becomes useful by its apparent futility. Consequently, all activities associated with tourism increase and promote the local economy.

1.5 *Urban regeneration for political purposes*

The symbolism of a new era of prosperity and the luxury exhaled from the iconic building provides a positive sense of innovation, progress and trust in modernity, promoting cohesion and consensus among citizens. Politicians use that success in their own benefit, by associating themselves (and their political party) with the iconic ornament. The creation of an infrastructure that has such power gives prestige and appeals to citizen's loyalty. In exchange, the general public demanded more than the basic welfare; in a society of appearances and illusion, it required a luxury according to a society of abundance. And the answer to that appeal was Frank Gehry's astonishing Guggenheim.

The ornament is also a "machine of public relations", given that converges the political and economical interests, performing as a projection screen for the image and the message of political parties, institutions and private companies (Esteban 2007). As a museum, Guggenheim Bilbao is clearly one more branch of a Foundation headquartered in New York, focused on reducing costs. It doesn't have a permanent collection that provides identity to a proper museum, since the most profitable are temporary exhibitions that generate publicity and a sense of novelty. The art becomes openly merchandise and the visitor is considered a consumer.

1.6 *The Guggenheim effect*

The Guggenheim "effect" is an example of how architecture has the power to become a symbol and provide identity. The building is not so much relevant for its use but as a source of consensus among the citizens of Bilbao, a meeting place and scenery for illusions and dreams. The infrastructure goes beyond the regeneration of a decayed area of the city. It is an ornament controlled by politics and not by market; an example of urban innovation based on culture, claiming the involvement of citizens, that turn out to be the beneficiaries.

2 CONTEXT: THE BOOM YEARS

2.1 *The property bubble*

In the decade between 1996 and 2006, the property market in Spain increased at an astonishing rhythm of 8.3% per year. The purchase of housing (new and pre-existing) went from 400.000 units in 1995 to 955.000 in 2006, and the construction sector contribution to the GNP (gross national product) increased from 7% to 12.5%. The number of construction permits granted by City Halls for new housing reveals that same growth: from 270.000 in 1995 to 737.000 in 2006. As a result, house ownership in Spain is near 90%, a percentage superior to wealthier countries in Europe (Blanco Losada 2013).

If the housing market was growing, then also the construction sector was launched, starting a period of

great prosperity. The impact in the economy was huge: 14% of employees worked in the sector and 25% of the employment growth was due to this increase. The property boom had a decisive role in the Spanish economic growth of the twenty years preceding the Great Recession. The times were in high spirit: the growth seemed endless, the rise was taken for granted and prosperity allowed a frenzy of consumerism. Nothing predicted that the fall would be sudden and come to be sooner than expected.

2.2 *Rise of investment in housing*

The dramatic statistics of housing purchase and construction can be also explained by the fast rising of the price of housing. In 1995, the necessary investment to purchase a property was €671 per square meter and in 2001 the same effort required €1000, which corresponds to an increase of 5.8% per year in that period. Between 2001 and 2008 the value increased even faster at a rhythm of 13.3% per year (Sotelsek Salem, Zack & Senra Diáz 2013). Purchasers seized the opportunity to invest, causing an overbought of housing and consequently contributing to price rise.

This scenario was made possible by a predominant idea that markets and banks are able to self regulate, which lead to great facility in providing loans. The system turned out to be efficient and competent, but the risks became higher and the indebtedness of citizens and governments casted a shadow of a possible collapse. The government encouraged the purchase of housing through tax regulation that discourages renting and benefits buyers (mortgage payments are partly deductible from personal income taxes). Finally, when Spain became a member of the European Union in 1986, the government itself became provided with funding and able to have access to loans. With more investment, the economy growth was fast yet fragile. And in the case of Spain, the property bubble was a motor of the economic bubble.

2.3 *A sudden collapse*

During the decades of abundance, the Spanish government failed to collect reserves for challenging times to come, taking the stability of tax revenues for granted and allowing a major indebtedness. The increase in spending created a fiscal bubble that busted when the income from taxes over the construction sector decreased dramatically, since its contribution was reduced to 6% of the GNP. Consequently, the fiscal deficit became excessively high from 2009 onwards and the government was forced to withdraw fiscal stimulus. Between the years 2007 and 2012, the purchase of housing decreased 13.7% per year, from 955.000 to 361.000, of which new housing suffered the greater impact: 410.000 sold in 2006, 115.000 in 2012. The construction sector underwent a drastic slowdown and the number of unsold new housing reached 700.000 units in late 2011 (Blanco Losada 2013). With the slowdown in purchasing, the price of housing suffered a blow, decreasing 23.6% in the following five years, to 5.5% per year. The crash in the sector is responsible for half of the new unemployed (Sotelsek Salem & Zack & Senra Diáz 2013).

2.4 *The phenomenon of ghost-towns*

The 2008–15 financial crisis in Spain ended the property bubble of 1985–2008, causing a phenomenon of *ghost-towns*, large housing developments built during the boom years in the country that are now being abandoned and the houses offered for sale for almost half the original price. One of the most glaring cases is the town of Seseña, known as the Manhattan of Madrid (due to its proximity to the capital), with the capacity to accommodate at least 30,000 people in 13,000 dwellings already built, but of which only 5,100 are occupied. Most are uninhabited and the owners try to sell them with great loss.

Another example is Ciudad Valdeluz, in the town of Yebes (in the region of Guadalajara), an urban intervention program (*Programa de Actuación Urbanística*, PAU), promoted by the construction on site of a railway station for the high-speed train (AVE, *Alta Velocidad Española*). The location of the railway station would predictably be in the center of the city of Guadalajara, but the promoters seized an opportunity for real estate speculation and in 2004 begun the construction of 9,500 dwellings for an estimated 30,000 inhabitants. In late 2014, only 2113 people were residents and many signs for sale indicated that the migratory flow is back to Madrid. At a distance of a 30 minute travel between the two cities, the railway company charges unaffordable prices for a daily rhythm.

3 CASES OF FAILED PUBLIC INVESTMENT

3.1 *Córdoba Congress Centre*

The project for Córdoba Congress Centre (*Palacio del Sur de Córdoba*) begun in 2002, with an estimated cost of €80 million, and two years later escalated to €158 million, in a total of €171 million including taxes. An amount of €3 million were invested in the initial design by the famous architect Rem Koolhaas. It would include a Congress Centre, an auditorium, a luxury hotel, a commercial area and parking. But in 2008, the private construction company Ferrovial announced that it was not possible to gather more than €70 million in funding and the project had to be reformulated. Another €5 million were invested in a new design by Koolhaas. After ten years and €10 million spent, in 2012 it was canceled. Two years later, the City Hall had to pay €6 million, by returning a €5.5 million funding provided by the Government, aggravated by interests for late payment. In the end, the decision was to restore and expand an abandoned building, belonging to Cajasur.

3.2 *City of Culture of Galicia*

The Project for the City of Culture of Galicia (*Ciudad de la Cultura de Galicia*), in Santiago de Compostela, was launched in 1999 with the ambition of transforming the city into a cultural reference (Fig. 2).

The competition was won by the famous American architect Peter Eisenman, for a €108 million project. In the following phase, the budget increased to €475 million. The goal was attracting visitors and encouraging the local economy.

With the crisis, the project became unsustainable and, in 2013, was revised to cut costs. In consequence, two of the six buildings initially planned were embargoed. With €287 million already invested, it will cost another estimated €20 million in compensations for contract termination with construction companies. It is currently open to the public, but only half the annual budget is intended for cultural events. The other half is for administration departments that were transferred to two of the buildings. The annual budget in 2013 was €10 million, €3.6 million just for expenditure with electricity, gas, cleaning, security and maintenance of infrastructure. The project first announced as being profitable, became a heavy expenditure.

3.3 *Alcorcón Centre for Creation of the Arts*

The Alcorcón Centre for Creation of the Arts (*Centro de Creación de las Artes de Alcorcón*, CREAA) is a project launched in 2007 and today 70% completed (Fig. 3). Predicted to be inaugurated in 2011, the futuristic buildings are abandoned and have become a symbol of overspending.

Alcorcón is a city at a distance of 13 km (or 15 minutes by subway) from the center of Madrid. In 2007, the Mayor decided to transform the suburban residential area into a well-equipped and a pleasant place to live, with affordable housing, in hope to attract the younger population. The Centre for Creation of the Arts was intended to be the "Guggenheim of Alcorcón", a reference at European scale, putting Alcorcón on the map. The initial project, covered an area of 66,000 square meters over 9 buildings, including an auditorium (with over 1400 seats), a circus, 4 professional technical schools, a conference space and a restaurant. So far,

Figure 3. Alcorcón Centre for Creation of the Arts ©Zarateman/ 2013.

€94 million were invested and it would take another €40 million to complete but, in 2012, due to a €120 million indebtedness of the City Hall, the new Mayor decided to embargo the building, spending €5 million in compensations for contract termination with construction companies.

4 CONCLUSIONS

The high spirits lived in the 1980s, 1990s and until 2008 had a strong voice in society, through a generalized feeling of overconfidence in the economic recovery. The wealth of those years was assumed as a logical result of neo-liberalism working well. The *laissez-faire* nourished greed of companies, politicians and families, which saw an enrichment opportunity like never before. But the fast expansion of the economic welfare was based on a fragile system, soon proved to be particularly harmful for governments and families.

Economic liberalization policies were adopted with confidence and the immediate results seemed to confirm its efficiency. Free trade, privatization, fiscal austerity, and reductions in government spending were applied to strengthen the private sector in the economy, a strategy introduced by Margaret Thatcher in the United Kingdom and by Ronald Reagan in the United States. But in Spain, these policies were implemented in a recent democracy (after 1977) and, at the same time the society was trying to develop a previously non-existent welfare state, resulting in a contradiction.

The construction sector played an important role in the economic recovery of Spain and, as expected, also caused a heavy loss after the Great Recession of 2008. During that time, public investment in architecture was used as a political strategy by several local governments, some successfully, and others failed. The example of Guggenheim Museum Bilbao started a trend, but the unsuccessful cases show us that many different circumstances must be gathered in order to produce a positive outcome.

The first lesson to be learned is that a large-scale investment in a building, even when promoted by a City Hall, must have the capacity to sustain itself without being dependent on government funding. This means that Guggenheim Museum Bilbao is a success because it is an operating business: its annual budget is provided by an international institution, obtains funding from private companies and a well studied merchandising, and generates profit. The failed cases mentioned in this study demonstrate how fragile it is an enterprise that relies mainly on government funding: if the times are prosper, all goes well, but soon as austerity imposes its restrictions and costs are reduced, the consequent collapse is inevitable.

This conclusion leads to a second, which is the negative consequence of unclear motivation for investment in a public building: if it is a business, where users are consumers and services are for sale, or if it is public service, provided for benefits of citizens, regardless of profit. All the examples mentioned above demonstrate that, during the bubble years, both strategies were combined, even although it is a contradiction. The Guggenheim Museum was supported by a strong business strategy, camouflaged as a cultural phenomenon, but even being an ornament (rather than an actual cultural public service) it turned out to benefit local citizens through economic gain and a powerful image. The failed examples were ideologically ambiguous, in the sense that they were publicized as public service and as a profitable business as well, and came to be a great expense for the government, even when canceled, before beginning (like the Cordoba Congress Centre, because of the large amount already spent in the initial design and funding that had to be returned with interests), when partially embargoed and partially functioning (as in City of Culture of Galicia, where the income from the number of visitors is far from being sufficient to cover the building maintenance costs) or even canceled half way through construction (as Alcorcón Centre for Creation of the Arts, that even not open to the public is spending funds, in compensation claimed by the investors and indebted the local government for years to come). If the investment made was intended for public service, then profit should not have been expected as if it were a business, and so ambition had to be restrained.

A third conclusion is that, during the boom years, little attention was given to return on investment in the construction of a public building. The question if a building for cultural purposes should be a business, public service, or if it is possible to find a perfect balance was avoided during several decades, because tax revenue provided the amount necessary to endure large-scale buildings, its construction and its maintenance. But looking back, if those buildings are no longer sustainable in a less flourishing economy, then the return on investment was clearly overestimated and miscalculated, which reveals that the purposes were not financial, but political.

In the end, is possible to take a fourth conclusion, concerning the role of publicity in riding a wave of enthusiasm around, for which contributes hiring well-known architects. In comparison between the Guggenheim Museum Bilbao and the City of Culture of Galicia, the second can be considered to have fallen short of expectations. The main difference is that, in the first, Frank Gehry's project was another element in a well-structured plan, while in the second case the expectation was created around Peter Eisenman's project. But the architect's celebrity alone is not enough to generate other resources or even to ensure the maintenance of the building itself.

The charm of the well-known architects, during the prosperous decades, placed architecture in the spotlight, but also associated it with a business attitude, that has been ruthless. Guggenheim Museum in Bilbao is an example of how even a cultural experience, like visiting a museum, can be turned into a serious large-scale enterprise. Even being a success, it is a warning about the capacity that capitalism has to quantify, regardless of quality. The fact that the same few well-known architects are chosen based on their popularity tends to dehumanize architecture, community life and puts pressure on individuals to seek fame at any cost. The cases of failure of large-scale public investment in architecture are, not only financial, but also ideological and social, a symbol of ethical decadence.

The "Iron Curtain" as urban observatory of the contemporary social contradictions

C. Toscani
Politecnico di Milano, Milan, Italy

ABSTRACT: The expression "Iron Curtain" indicates the borders dividing Europe in two distinct areas – from Stettino in the Baltic to Trieste in the Adriatic.

Since the beginning of its dissolution, started on the border between Austria and Hungary, until the fall of Berlin Wall, several transformation of earlier militarized territories took place and led to the discovery of a new landscape, extended for kilometers in length and depth. The study of which therefore is a favourite and fruitful observatory regarding the different phenomenas of border areas transformation, as well as their context as the result of spatial effects of division or integration of European citizens. Studying these phenomenas can help us learn more about these kind of inbetween contexts and more about some possible strategies and actions for the conflicts resolution, so frequent, not only between the countries, but also within the city, and local comunities.

"(…) It is my duty however, for I am sure you would wish me to state the facts as I see them to you. It is my duty to place before you certain facts about the present position in Europe.

From Stettin in the Baltic to Trieste in the Adriatic an iron curtain has descended across the Continent. Behind that line lie all the capitals of the ancient states of Central and Eastern Europe. Warsaw, Berlin, Prague, Vienna, Budapest, Belgrade, Bucharest and Sofia, all these famous cities and the populations around them lie in what I must call the Soviet sphere, and all are subject in one form or another, not only to Soviet influence but to a very high and, in some cases, increasing measure of control from Moscow" (Churchill, 1946).

Churchill's speech is considered the ideological foundation of what we call Cold War. With his words, Churchill stated the end of the anti-fascist coalitions and decided de facto the new world alliance against the Russian enemy. The enormous influences deriving from WWII had had a drastic impact on the political and economical structure of each involved country, collapsing the great European powers. Germany had been defeated, France and England had been deeply weakened, USA were military and economically stronger than any other country, and Russia, despite being a winner, was also exhausted: still, these two countries were aiming to conquer the role of unique superpower in the world. In 1945, with the conference of Yalta, the Soviets accepted the limitations imposed on the superpowers in procedural terms; afterwords the representatives of 50 countries provided the 111 articles at the conference of the United Nations about the international organization to grant the world peace and promoting the economical and socio-political development of every people in the world. USA definitely aimed at re-establishing a stable order for the world, as they enjoyed the first place in terms of economy, the Soviet Union, instead, demanded the price of their victory in political and economical terms, especially since it had suffered serious loss because of the war.

Since 1946 it had become clearer and clearer that the tensions between the Soviet Union and USA were so high to start that world involving political phase later called "Cold War", a silent war, which was never fought by using weapons, but was carried on almost exclusively in diplomatic terms.

The clash counterposing their cultures had been rooted in the extremely different ideological grounds at the base of their two political-economical systems: capitalism and communism, as they were clearly inspired by opposed geopolitical interests. In 1947 Tuman Doctrine was affirmed, to control the Soviet dangers in defense of the rights of liberty and of the autonomy of peoples, thanks to which USA were concretely committed in sending economical and military aids to those nations that resulted internally fragile and particularly exposed to the communist propaganda and to the expansive aims of Russia, such as Greece and Turkey. In those countries, such as Poland, Hungary, Romany, Albania, Yugoslavia and East Germany, where the Soviet influence was prevailing, the political-economical structure was reorganized according to the Soviet model.

The birth of regimes controlled by the communists became more and more common, quite alarming the USA. Emblematic was the German Issue: since the end

of WWII, Germany had been divided in four zones of occupation forces, the French one in the South-West, the British one in the North-West, the American one in the South and the Soviet one in the East. The city of Berlin was split in two zones, belonging each to one of the two influence worlds, the American one and the Soviet.

The political tensions taking shape during the Cold War proved the impossibility of any agreement regarding the future of the country and what was supposed to be a temporary situation led to the constitution of a liberal-democratic government in the West side (occupied by the forces of USA, Great Britain and France) and of a communist regime in the Est (occupied by the Soviet forces). In 1949, the three Western zones of Germany united and the Federal German Republic, founded on a democratic and parlamentar Constitution in the capital of Bonn, was proclaimed; in the Eastern zone, with Pankov as the capital, the Democratic German Republic, supported by a regime of communist imprint. In 1961, to contain the continuous flows of Germans moving to the West side, the construction of a fortified concrete barrier was ordered, completely isolating the two sides of Berlin, the Wall.

The terms Iron Curtain, then, indicate the border line dividing Europe in two distinguished zones since the end of WWII in 1945, until the end of the Cold War in 1991. It represented the ideological and physical split and symbolized the Soviet efforts to stop the contacts with the Western world and those areas which weren't under Soviet control. This line used to cross Europe along the political borders among East and West Germany, Czechoslovakia, Austria, Hungary, Yugoslavia and Italy.

The Iron Curtain was built in order to defend the borders between West and East Europe: the closer areas to the line used to be highly militarized and were crossed by double enclosures, while in the urban areas the barrier constituted of a high concrete wall, like the one in Berlin. Many villages were destroyed because of their over-proximity to the border. Those people who lived within 15 kilometers from the line, in the so-called "border-zone", had to obtain a special permission to enter in the zone within 5 kilometers from the border. There were ground mines in the space between the two enclosures; the minefield was later substituted by an electric enclosure and by another barbed wire enclosure, with guard towers and a belt of sand in order to recognize eventual border violations. To prevent any escape attempt, the squads used guard-dogs and were allowed to shoot the runaways.

The dismantlement of the Iron Curtain began along the borders between Austria and Hungary on May 2nd 1989 and was carried on through several initiatives, such ad the Paneuropean Picnic and the exodus of thousands of citizens from DDR to West, which led to the fall of the Berlin Wall.

The abandonment of these highly militarized no man's lands has led, today, to the development of large natural reserves and has created the wildlife corridor through the entire Europe.

1 ACROSS THE LIMINAR LANDSCAPES OF THE IRON CURTAIN

Therefore the Iron Curtain was generated by a line which marked the territorial and ideological split between Eastern and Western European countries. An officially recognized border, a geo-political boundary, which counterposed two adjacent realities. Their modification cannot be restricted to the physical presence of an impassable border, but it is to find in many larger-scale geographical, morphological, economical and social adjustments, related to the surrounding territories. Adjustments that were necessary to shape a new balance for both the situation after the construction of the Wall and the situation after its removal.

The definition of border itself, indeed, refers to two Latin words, limes and limen. The first one is connected to the idea of limit, delimitation, demarcation of boundaries, frontier: limes indicates a horizontally traced line cross-cutting any surface or the ground, with the function of excluding, delimiting and marking the place of a difference. Limen, on the other side, means threshold.

Sergio Crotti defines the threshold as the outline of the shape between background and figure, but also between a subject and the set of objects constituting the physical world, and pushes its meaning up to several notions of architecture and urban design. In the multiple acts of building, the threshold appears quite fragile, uncertain, variable from case to case: it isn't something stable, instead it is a dynamic and variable element, both when intended in its spatial and in its temporal meaning.

Quoting C. Magris in Come i pesci il mare: "Borders die, revive, move, are deleted and unexpectedly re-appear. They mark the inhabiting space, politics and its often absurd cartography, the ego with the plurality of its fragments and their hard recompositions, society with its divisions, economy with its invasions and its retreats, the Thought with its maps of order" (Magris, 1991). Just the same way, during its formation and with its demolition, the Iron Curtain has transformed itself from impassable border to porous threshold that enables the territories to be crossed and used again, through new laws of appropriation of land, which are highly different from those readable before its construction. Once again, this reveals how the demarcation of a border, both in the intent of dividing and in the one of opening, generates an interesting process of change, which can be understood through the Entropy principle from Physics, if we take it as a measure to such variations. Entropy (from ancient Greek, $\dot{\varepsilon}\nu$, inside, and $\tau\rho o\pi\acute{\eta}$, transformation) is a physical quantity used in statistical mechanics as a measure of chaos in a physical system. To explain it, a typical example is the behaviour of two gases at first separated into two airtight chambers and then put in touch: the two gases mix up together and gain chaos, or increase disorder, entropy.

The entropy principle though is valid if we assume the universe as an isolated system, a system where

matter and energy are irreversible, so it's impossible to exchange them with an external environment. When referring to open systems instead, such as those concerning life and social science, we should rather appeal to Ilya Prigogine's studies about dissipative systems, structures which are far from order and open to the exterior, where the fluctuation of energy can produce "order from chaos". We shouldn't only take into account this type of phenomena: society itself can be defined a non-linear system; treating social phenomena means somehow to found a physics of people.

As it shows different orders before and after its construction and new ones even after its demolition, the case study of the Iron Curtain seems to come across this fascinating opportunity to find a new order to change. Order that is not only to distinguish on a temporal base, but also in relation to the considered territories and their morphological, social and economical characters. Thanks to the discovery of its liminar landscapes we can outline a few principles or mutation categories about the urban fabric and its inhabitants, which are particularly useful to understand the characters of resistance and resilience of a territory. Such characters are extremely important in establishing the new paradigms to define the evolutionary directions and the re-generational strategies which should support the urban and architectural design processes.

The etymological considerations concerning the meaning of border, the application of the Entropy theory in reference to the definition of the different categories of mutations represent the theoretical frame that this paper attempts to clarify, giving a background to several descriptions, especially to photographic descriptions from various surveys, such as the books Cortina Verde and La Linea inesistente, which appear to be the most incisive in telling the places, their atmospheres, and people, well depicting the complexity of these territories.

So today, along the ex Iron Curtain it's possible to find three different typologies of spaces: from the vast green areas, conserving the line through the Green Belt, inhabited zones, where the exploitation of land by man has taken place continuously, follow one another generating a greater status of chaos and indifferentiation. Analyzing those spaces, three main descriptive categories of their mutations arise: preserved spaces; abandoned spaces, re-generated spaces.

Some spaces are preserved because of their strong monumentality or their deep attachment to past, so that the border becomes a well-marked sign, especially for the collective memory, despite being crossable and permeable. Thus the substantial maintenance of the status of division preserves many of the morphological and cultural characters, reducing the interaction between the two sides. The exchange, in fact, is minimal and the territories present a rooted dishomogeneity despite the restored freedom of movement. A key example is represented by the little town of Modlareuth, on the border between Bavaria and Thuringia.

When Europe was split in two blocks during the Cold War, the Bavaria side re-joined West Germany, while the Thuringia side was annexed to East Germany. The border had crossed the country for forty-one years, at the end of which the two sides allowed all the inhabitants to cross from one side to the other, although without ever losing their own identity, which was either appeared or consolidated during the Cold War. The town, then, regardless the formal liberty of transit between the two sides, finds in its inhabitants the actual obstacle to reunification: the consolidation of the habits has always guaranteed people two distinct churches, two distinct schools, two ZIP Codes, two telephone prefixes and two typologies of license plates. A segment of the border has even stayed intact until today because of people's will: this highlights how the history of those years has greatly intensified the certainty of the separation and of the countless chances that could arise inside one unique urban centre.

A similar condition, or perhaps even more evident, concerns Gmünd and České Velenice, two cities divided by the border between Austria and Czech Republic. Their division during the Cold War has led to a strong differentiation in the two municipalities: Gmünd is a touristic town, thanks to its historical centre and its famous baths; České Velenice is a poor small city surviving because of low-profit activities. Gmünd counts 5.376 inhabitants in Lower Austria, while České Velenice is part of Jindřichův Hradec district, in the region of Southern Bohemia (Czech Republic). At the beginning, these two towns used to be joint as a unique urban centre in Southern Bohemia, but when the European cartography, after the WWI, was completely reshaped, the Northern part, Gmünd, passed to Czechoslovakia, modifying the name and the nationality of its inhabitants. The consequences of the split through the construction of the Iron Curtain have been affirming their division until today. The two urban centres, in fact, are characterized not only by morphological differences, but also by sharp political, cultural and social counterposed positions: if the image of Gmünd, with its baths, the historical centre and the natural park of Blockheide, is the one of a touristic city, České Velenice offers a mosaic of small casinos, blocks built during the years of Communism, red lights clubs and similar low-profit activities. The split at the two sides of the borders is severe and even violent, however both towns don't appear to be willing for their own regeneration, but are just strengthening the division imposed by the borders (Austria-Czech Republic).

The same preservative character, if considered through an ecological and naturalistic perspective, takes into account such a completely different background that we can even define it transformative. It is precisely thanks to the Iron Curtain that several extended parts of the territory could maintain their original natural condition intact, within each different country. Since 1989, indeed, after the demolition of the Berlin Wall, more than 300 environmentalists from the

German Democratic Republic and the German Federal Republic had activated the first projects for the protection of the curtain, which later became of European interest. This conservative plan turned into the European Green Belt, a political movement of people supporting nature maintenance and the sustainable development of the ex Iron Curtain, promoted by the International Union for the Conservation of Nature. This new green belt has defined a new buffer zone with a high capability of openness and integration of the two zones, both along its length and horizontally.

Nevertheless, it's worthwhile to consider the case of Lake Schaal, in the Northern part of Germany, between the Bundesländer of Schleswig-Holstein and Mecklenburg-Vorpommern, located in the middle of a wide triangular area among Hamburg, Lübeck and Schwerin. During the Cold War, those areas were almost abandoned and hardly populated; nature grew uncontrolled all along the territory. Until toady, it has developed a specific vegetation characterizing the bio-park (UNESCO site since 2000), which has represented an important attraction for tourists and has re-activated the surroundings of the lake, earlier abandoned because of the war.

The entire bio-park and the banks of Lake Schaal enjoy the presence of natural vegetation, as during the Cold War the routes via water and via land had been reduced, facilitating its little-controlled and dense growth, which today, instead, is well-protected and conserved in its beauty. Here, the Iron Curtain had been placed right in the middle of this basin to prevent the boats from crossing the lake bank-to-bank and from modifying the trade shipping routes of the zone. After the demolition of the curtain, the administrations decided not to return to the habits preceding the Cold War, but to maintain the newer routes, implementing them for the eventual lacking connections.

So the conservative character is evident here to describe both the conditions, on one side related to the preservation that redefines new landscapes for future scenarios, on the other side related to the maintenance of the structure of the shipping routes, leaving an invisible trace of the past. The will to remember as well derives from a preservative character, despite it has led to the re-conversion and the maintenance of the military equipments along the curtain for museum purposes.

Concerning this, Checkpoint Alpha is another interesting example: it's the largest passage of the German border, it's been preserved as it used to be and it has a museum host inside. Even if also in this case the exterior appearance has remained intact, with a precise intent to maintain these places as they used to be in order not to forget, this very action somehow turns division into integration and pacification.

On the other hand, in a degenerative way of preserving as lack of attention and lack of management by the administrations, we can find some abandoned places such a Priwall, in Germany, where the ex control-area of the beach and its control tower are today completely abandoned. Completely deprived of its military role, the construction appears almost out of place in such a natural context, but it still testifies the memory of the ex Iron Curtain.

When referring to the regeneration of these liminar landscapes, we certainly think about the symbol of this process, Berlin, with its important architectural, infrastructural and urban reconstructions, among which the project for the Museuminsel, Potsdamer Platz and the East Side Gallery are the most meaningful examples. The East Side Gallery in particular is considered the longest art gallery in the world, risen up towards the part of the Wall along river Sprea, in front of East Berlin. Potsdamer Platz, instead, Western to Friedrichstadt, one of the central places of the city, since the beginning of 1900s, has recovered its full value becoming the keystone of a meaningful wider operation of urban renewal.

Besides, there are also other smaller and less popular examples, such as Chvalovice (Czech Republic), Excalibur City, today turned into an amusement park near the border between Czech Republic and Austria. During the war, it used to be part of a military controlled area close to the Iron Curtain.

Or such as Gorizia, Italian city historically connecting the Latin world to the Slavic and German ones, where the construction of the curtain had as a consequence not only the division of the city in two parts, but also the foundation of a second city, Nova Gorica. This new city was supposed to be the symbol of the counterposition of progress according to the communist world against the one brought on by the capitalist world.

Nowadays, the two cities are part of two different countries and share only Piazza Transalpina, one of the most significant places of political and ideological separation between Western and Eastern Europe. It's interesting to notice how this place, which was born as destination point and railway station, crucial node of exchange and cultural connection for people, was re-invented after the end of the war as a square, a symbol of birth and new birth, of memory and cradle of civilization, a symbol of the new link between peoples, to emphasize how different cultures, separated by the Cold War, have now a new opportunity to reconnect and reshuffle themselves while maintaining their own particular identity.

2 CONCLUSION

This description seems to suggest how the social, economical, political and morphological context can change according to various directions and how it can offer different results despite, in the beginning, the conditions appeared similar. Since our objective is to use this type of analysis to understand deeper the changes that are occurring and to direct the future scenarios of the places where we live, it's clear that the idea of resilience needs to be the foundation to conceive strategies and tactics for the articulation of their renewals and later adjustments. This implies two main

Figure 1. Moudlareuth: diagram with the Iron Curtain.

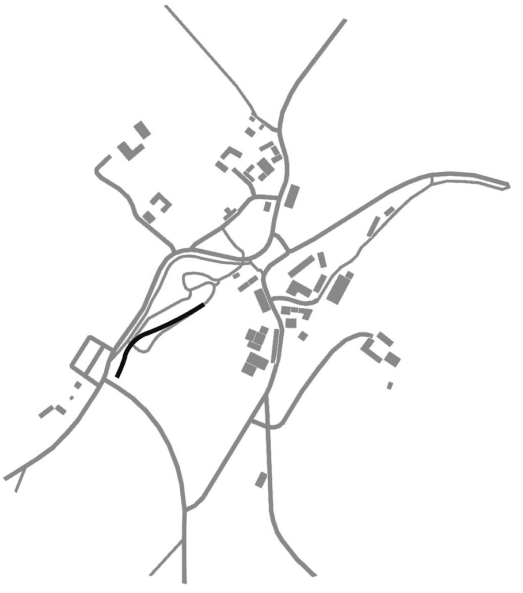

Figure 2. Moudlareuth: diagram after the Iron Curtain.

relations inside the architectural and urban design process, both of which are part of the notion of landscape: the relationship space/shape and time, as the necessary condition following eventual changes, and the relation to culture, or to cultures indeed. The notion of landscape contains both the interlocutors of this relationship, time and culture, as it differs from the idea of territory that was developed during the second half of the XX century as "a system to measure space". Just like the concept of architecture itself, the term territory relied on the idea of eternity, stability and of a unique culture. "The idea of landscape instead asks architecture for undefined time, it asks to have a chance to age together, to keep changing" (Ricci, 2013).

To design while taking the characteristics of time into account leads to activate strategies that are more connected to the idea of design as a process, either in the definition phase and in its actual development through a piece of architecture, and in the preset and eternally stable result.

There are three operating methods applicable to this relationship, and they can overlap and multiply the effects. The first one concerns the inclusion of time, determined by the idea of design as participatory process; the second one, instead, implies a more direct association of time and spatial solutions, including the variation of the project shape, of its use and of its material through time. This operating method refers to the particular concept of open work ("opera aperta"), defined by Umberto Eco: "The poetics of opera aperta tends to promote the performer through "acts of conscious liberty", placing him at the active centre of endless networks. (…) The opera aperta as a proposal for a range of interpretative opportunities, as the configuration of substantially undetermined impulses, so that the user is led to a serie of continuously variable interpretations; structure as constellation of elements

Figure 3. Gorizia: diagram with the Iron Curtain.

that arise according to different reciprocal relations" (Eco, 1967). The last operating method is more literal, since it purely refers to temporary projects, which, in some cases, are introducing interesting relationships between advanced technologies and architecture.

However, landscape isn't only a spatial condition, but it's also the cultural reflection of a place. Thus, this is something extremely important to wonder about in our historical period, as it is quite difficult to state which cultural reflection our landscapes should be made of. It's likely to be appropriate to address the panorama of the design process to those strategies involving cultural diversity, which can find the capability not to homologate nor dilute, but to usefully

Figure 4. Gorizia: diagram after the Iron Curtain.

interact and to imagine new possibilities for different worlds right in the structural resilience of the project's spatial character.

The frame we get is "an ethnic panorama (…) not only constituted by refugees and exiles, but by tourists, seasonal workers, and other crowds moving" (Appadurai, 1996).

The social and spatial processes that were born after demolishing the Iron Curtain show the capability of public space in taking the main role towards this direction. Both on a territorial scale, such as the project of the Iron Curtain Trail, which defines a cycle path from Scandinavia to Turkey, crossing 20 countries and extending the previous line of the wall further than its actual existence; and on an urban scale, recalling the square belonging to Nuova Goriza and Gorizia.

Both the projects are a landscape, despite the different scale, as they are both regenerating places as well as offering a new idea of citizenship, continuously changing. They serve as large containers, not only because they represent a compensation for a tragic past – if they had only such objective, they would only become monuments, useless for the future processes – on the contrary, because they are able to welcome diversity and mutations. With their spaces, they give a contribute in response to a functional condition and, more properly, they build common spaces, in their wider meaning.

This result can be only be reached by re-centering the actual needs of society and people, towards a new picture of what it means common good. Thus, common good doesn't rely only on material and economical aspects, but it has an immaterial side depending on the relational and emotional world: it is linked to the relationships between us and the others, just as well as to the places where these relationships are developed. Also the anthropologist A. Appadurai, in his studies about slums in Indian cities, explains how life in such places allows some important processes for the development of the planet – for the future of the Western world, too – to take place. Even in those places where the "traditional" public space isn't provided of any useful historical precedent, the presence of in-between spaces can be considered the image of a collective space. A collective space characterized by parallel and simultaneous activities, instead of the space of interconnected and common purposes. Dispelling any doubt about the capability of public space to be still useful for our cities, this truly confirms how addressing the perspective to these very principles is beneficial and fruitful.

The social [il]logic of [sub]urban exodus: The rise and fall of Nasr City and the evolution of the Egyptian middle class

A. elBahrawy
Canada

ABSTRACT: The main focus of this paper is Nasr City, one of Cairo's largest residential districts. It examines the forces behind its inception in the early 60s, its boom throughout the 80s and 90s as the hub of the Egyptian middle class; and its rapid decline as such since the mid 2000s. Through an encapsulated review of modern Egyptian socio-economic history, this paper aims to prove that each of the aforementioned instances in Nasr City's evolution directly corresponds to a major political and economic shift that resulted in significant social change. Such discourse would then be used to understand the psychological drive and sociological logic, or lack thereof, that fuel the rise and fall of urban attractors.

1 INTRODUCTION

Since its inception, the urban growth of Cairo has been largely a byproduct of major political and economic shifts that in turn prompted instances of significant social change. Such instances, which favored either an already existing social group or a newly introduced one altogether, typically manifested in a new urban attractor outside the city proper that served said favored social group. Eventually, that urban attractor would merge with the city proper either by virtue of the natural growth of the city, or – more often than not – due to the fast growth of the urban attractor itself as members of other social groups, who aspired to liken themselves to its inhabitants, gravitated towards it. Such fast growth usually happened on the cusp of one of the aforementioned instances of significant social change, which once it stabilized, a new urban attractor for its subject societal group would emerge, and the whole cycle would start again.

Cairo itself owes its existence to such dynamic. It started as an exclusive walled capital for the Fatimids – a foreign dynasty that had conquered Egypt, and which was rather ideologically different from the country's general population. As such, it was situated north of its precursor, alFustat, where Egyptian urbanites dwelled, and it was only after the fall of the Fatimid dynasty that Cairo exhibited significant growth as said native urbanite population started gravitating towards it. Since then, Cairo's thousand-year history has been dotted with many similar manifestations of such dynamic – from Khedive Cairo which marked the consolidation of the Muhammad Ali Dynasty that ruled Egypt from the early 1800s to the mid 20th century, to suburbs of Heliopolis and Ma'adi which marked the increasing European influence in Egypt since the late 19th century.

This paper, however, is primarily concerned with Nasr City – the latest, and arguably the clearest, manifestation of such dynamic, as it closely mirrors the evolution of the modern Egyptian middle class since the mid 20th century. It aims to examine the forces behind its inception in the early 1960s; its boom throughout the 80s and 90s; and its rapid decline since the mid 2000s. But most importantly, it aims to pose the argument that in numerous cases, the decline of Nasr City is at best premature, if not unwarranted altogether.

2 A BRIEF SOCIO-ECONOMIC HISTORY OF EGYPTIAN SOCIETY AND THE PROMISE OF NASR CITY AS A MIDDLE CLASS UTOPIA IN 1960S

For the first 160s years of its history, the modern Egyptian middle class remained a very homogeneous social group of well-educated professionals and bureaucrats. Its origins date back to the early 19th century when Muhammad Ali, a high-ranking Ottoman army officer who was actively establishing a feudal dynasty in Egypt at the time, elected to equip a small portion of the native Egyptian population with a modern education in order to run the various industries and administrative bodies of the country's agrarian economy which he had consolidate under his control. Due to its inherent feudal nature however, the socio-economic system established by Muhammad Ali was rather rigid and allowed for little to no social mobility. As a result, the budding Egyptian middle class remained a rather small social stratum throughout the 19th century and the early 20th century, as evident by the fact that, in 1914, the Egyptian middle class constituted a little under 10% of the country's population that was polarized between a lower class of peasants that amounted

to 90% and an upper class of aristocratic landowners that didn't exceed 1% (Amin, 2001).

However, thanks to the efforts of Egyptian middle class pioneers during the early 20th century, which aimed to make all education stages prior to university level free, and allow members of the peasant class to enroll in the Officers' Academy, the middle class exhibited a noticeable and steady growth starting in the 1940s while maintaining its longstanding homogeneous structure. Those reforms had allowed an increasing number of lower class individuals to get an education and subsequently become employed in the government or join the officer ranks in the Egyptian Army, which effectively helped them attain middle class status. As a result, by 1952, the Egyptian middle class had doubled to about 20% of the country's population (ibid).

In July of the same year, the Free Officers, a group of middle class Army officers who had attained such status during the 1940s as a result of the aforementioned reforms, staged a coup d'état within the Army, which then quickly developed into a fully fledged overthrow of the Muhammad Ali dynasty and the declaration of Egypt as a republic in 1953. Under the presidency of the Free Officers' key figure – Gamal Abd-alNaser, the regime that emerged in the aftermath of those events implemented a number of socialist-inclined policies which centralized all aspects of the economy under the control of the state in hopes of bringing about social equity. It stripped the aristocracy of its mass agrarian holdings and redistributed them in smaller parcels among the vast peasant lower class; it nationalized all large scale foreign and private companies and used their revenues to fund large scale national projects and the establishment of a national industrial sector; it embargoed all foreign investment and brought the private sector under extensive regulation, and at the same time, it augmented and expanded both the size and scope of public sector establishments, all of which effectively installed the public sector as virtually the sole economic agent in the country. The Nasserist regime also adopted a number of welfare policies that saw the state heavily subsidize the prices of goods and services offered through the public sector; it further extended the scope of free education to university level; and it put into effect employment policies which obligated the government to provide job opportunities for all university graduates.

In effect, the socialist reforms of the Nasserist regime resulted in a socio-economic system that not only championed and catered to members of the middle class, but also installed their characteristic hallmark of acquiring an education as the primary means of social advancement, and created the favorable circumstances to do so. Thanks to the extension of the scope of free education, and with the economic hardships of peasant farmer alleviated due to the agrarian reform laws, an exponential number of lower class individuals enrolled in the public education system to earn a professional degree, after which they were offered high paying jobs in the rapidly growing public sector, and henceforth enjoyed comfortable life styles thanks to the added convenience of government subsidies. As a result, the Egyptian middle class exhibited an unprecedented exponential rate of growth throughout the 50s and 60s while still maintaining its longstanding homogeneous makeup.

Arguably however, the greatest testament to the Nasserist regime's commitment to the middle class came in the late 1950s with the establishment of Nasr City, a suburban settlement on Cairo's eastern desert periphery. In many ways, Nasr city was the legitimate 'urban' child of the era. For one thing, it was Cairo's first ever high-end urban settlement to be purposefully dedicated to the middle class from the outset. The other four Cairene high-end residential neighborhoods at the time – Zamalek, Garden City, Ma'adi, and Heliopolis, which all predated the 52 revolution – originated as suburban settlements for the social elite and foreigners. They were also originally planned and developed by foreign entrepreneurs and private companies. Nasr City, on the other hand, was the first to be fully developed by a national public sector body. But it was Nasr City's modernist urban scheme that really set it apart. Its orthogonal grid planning seemed to perfectly embody the socialist zeitgeist of its time, and was quite a departure from the late 19th century planning trends of Cairo's other high-end residential districts. That very same modernist character was also carried on to the brutalist architecture of the various government buildings and model neighborhoods that were constructed early on in Nasr City, which eventually set the tone for the residential architecture of the settlement as a whole.

Although Nasr City seemed poised for an urban boom, shortly after its detailed urban planning was finalized in 1966, its development came to an abrupt stop due to the outbreak of the Six-Day War in June 1967. In the years that followed, the government's military spending to rebuild the army and maintain attrition warfare flung the Egyptian economy into stagnancy. As a result, the pace of all public sector works of construction and infrastructure in Nasr City dropped drastically. Also, middle class individuals who had purchased lots in the settlement were facing difficulties building their residences, and those who hadn't were either reluctant or unable to buy property there altogether. And so by the early 70s, Nasr City was far from being the Utopian middle class community it was meant to be. The majority of the settlement was nothing more than desert landscapes with empty road networks cutting through, and such grim character didn't change much over the following ten years.

During the 1970s and 80s however, the Egyptian society continued to exhibit rapid social mobility, arguably at a much higher rate than the 1950s and 60s. And while the trends of social mobility during both periods manifested mainly in a considerable growth of the middle class, they were however hardly induced by the same factors. That period saw a radical change to the socio-economic system that was established during the 50s and 60s, and the middle class that emerged by

the end of 80s as result was far from the homogeneous class which had endured for almost a 160 years.

The change of the social landscape in Egypt during that period was brought about by three interrelated factors. Those were the ruling regime's adoption of the Open-Door Policy; the migration of Egyptians to work in Arab Gulf States; and runaway inflation. The Open-Door Policy was essentially an economic platform which sought to shift the 50s and 60s' state-controlled economy towards free market capitalism. It was introduced by Anwar alSadat, Abd-alNaser's successor, in early 1974 and was intended to "open up" the Egyptian economy to the foreign and private sectors in hopes that they would displace the public sector as its primary engines, and in turn jump-start the war-crippled Egyptian economy and bring prosperity to society as a whole.

Despite the strong overtones of Capitalism inherent within the Open-Door policy however, the Sadat regime retained some of the 50s and 60s' socialist policies – most notably the subsidization of basic goods and services provided through the public sector, universal free education, and the employment policies obligating the government to provide job placements to all university graduates. Those policies were essentially kept in place in order to avert social unrest. And while they might have served such purpose, the state's otherwise full compliance with the Open-Door policy rendered them far less reliable than they were during the 50s and 60s. As a result large portions of the Egyptian society found themselves in considerable economic hardship.

Such hardship in turn prompted scores of Egyptians to temporarily migrate to the Arab Gulf States during the 70s and 80s in pursuit of high-paying jobs. At the time, those states' new and thriving oil economies had a high demand for professionals, and an even higher demand for labor of all sorts. Moreover, they offered hefty salaries and wages that by far trumped those offered by any of the domestic sectors in Egypt. Given the multitude of difficulties they were facing at home, many Egyptian professionals therefore opted to leave the country altogether and migrate to work in the Arab Gulf States for a number of years in order to support their families back in Egypt and amass enough savings to secure their futures. However, the greater majority of Egyptian temporary migrants were semi-skilled & unskilled workers, craftsmen, and peasants who hailed form the poorer, less educated masses. They were essentially hired as cheap labor; nevertheless, the wages that they were offered in the Arab Gulf States were still quite high by Egyptian standards.

Although migrating to work in the Arab Gulf States offered a lot of Egyptians a way out of their economic troubles, such a trend had quite the adverse side effect on Egypt's economy. The sizable remittances of Egyptians working in those states to their families back home was chief among a number of factors which brought about a rampant rate of inflation that burdened the Egyptian economy for the better part of the 70s and 80s. Needles to say, such runaway inflation made the already strenuous economic hardships of a great many Egyptians even more difficult. But at the same time however, entrepreneurs who dealt in and took advantage of the surging market value of highly sought-after items benefited immensely from the 70s and 80s' rampant inflation. During that period, many Egyptians were able to make fortunes virtually overnight by anticipating the price fluctuations of those items; and accordingly knowing when to buy them at a relatively cheap cost and when to sell them for a sizable return once their value had surcharged. Interestingly though, not all of those Egyptians were originally tradesmen or businessmen by profession. That sort of opportunistic entrepreneurial activity was particularly common among the Egyptian workforce returning from the Arab Gulf States, as well as craftsmen and workers who capitalized on the rising cost of services and the shortage of labor precipitated by the mass migration of the Egyptian workforce to those States.

Ultimately, the Open–Door Policy; the Egyptian workforce's migration to the Arab Gulf States; and runaway inflation, along with their various effects throughout the 70s and 80s, had a number of significant social outcomes. For one thing, the introduction of new veins of generating income, and the subversion of others, induced very high rates of both upward and downward social mobility, which – once again – translated mainly in an exponential growth of the Egyptian middle class. By 1991, such growth was quite evident in the stratification of the Egyptian population according to income. Over the span of almost 40 years since the July Revolution of 1952, the relative volume of Egyptians receiving a middle class income more than doubled from 19% to 45% of the country's total population (Amin, 2001).

Unlike the 50s and 60s though, the social mobility during the 70s and 80s deeply altered the long-standing homogeneous makeup of the Egyptian middle class; and as a result, by the early 90s the middle class had become hardly the same harmonious stratum of well-educated, public sector-employed bureaucrats and professionals that it had always been ever since its genesis. Among those involved in that drastic social transformation were small-time public sector bureaucrats and clerks, who found themselves up against insurmountable odds starting in the mid 70s and quickly fell down the social ladder. With them out of the mix, the middle class that emerged by the early 90s consisted of two very distinct groups. Professionals – such as doctors, engineers, lawyers, accountants, university professors, and teachers – accounted for one of those two groups, and as such, they were essentially the only remnant of the original middle class structure that survived the socio-economic upheaval of the 70s and 80s, but have since been finding it exceedingly difficult to maintain their middle class status. The second group on the other hand was made up of the influx of entrepreneurs who hailed from the lower classes and quickly ascended through the social hierarchy during the 70s and 80s to become the other major component

of the Egyptian middle class. That social group was basically comprised of all the lower class individuals who amassed considerable financial gains by capitalizing on the unstable economic circumstances in Egypt at the time and adopting the aforementioned opportunistic entrepreneurial activities as occupations and primary sources of income. Their newly found large incomes in turn saw them attain middle class status, and in some cases even upper class status, accounting for the majority of the increase in the relative size of both those classes between 1952 and 1991.

But perhaps the most significant social outcome of the 70s and 80s was the drastic change in the values of Egyptian society. With the rapid social rise of the entrepreneur class, acquiring an education was no longer the hallmark of the Egyptian middle class or the main method of attaining a higher status within Egypt's social hierarchy. Instead, starting in the mid 70s, size of income and wealth – regardless of their source – became the main criteria for societal stratification in Egypt, and the most common means of climbing the social ladder.

Thus, the Egyptian middle class that emerged by the end of the 70s and 80s, and which is largely the same stratum that still exists today, was a class divided. Neither of its two factions shared the same values or sources of income, and they were basically lumped together as one class solely on the basis of an abstract range of how much income they generated annually.

3 THE SOCIAL LOGIC BEHIND THE RISE OF NASR CITY AS AN URBAN ATTRACTOR SINCE THE MID 80S

In the context of such divide, a phenomenon that could be best described as *social emulation* became rather prevalent within the Egyptian middle class as its newer members resorted to imitating almost every aspect of its older members' lifestyles, often in an ostentatious manner, in order to assert their newly attained middle class status. This peculiar phenomenon manifested itself across a number of different domains. For instance, members of the new middle class were preoccupied with acquiring the same grade of goods and products typically consumed by the old middle class. But most importantly, they were also quite keen on situating their residences in the same neighborhoods where large populations of the old middle class were known to dwell. In a sense, such behavior was essentially a social form of a compensation mechanism. At that time, and despite the relative decline of their economic status, members of the old middle class – namely professionals – were still considered to be a social ideal to aspire to in the collective consciousness of Egyptian society. The members of the new middle class on the other hand had just attained their middle class status; and they had done so over a very short time span and not through the long-standing tradition of acquiring an education, but rather by accumulating wealth through practices that were then widely regarded as unscrupulous. It was therefore only natural for them to feel the need to associate themselves with that old, more established faction of the middle class. From their standpoint, a visible display of their ability to match the material attributes of the old middle class using their newly found wealth served such purpose; and proved to themselves, as well as to the rest of society, that they had indeed become part of the middle class.

The main argument here is that this notion of social emulation, as outlined above, played *the* central role in the urban boom of Nasr City which began towards the end of the 80s. Both this argument, as well as the outlined understanding of why and how social emulation operates, draw primarily on the works of Abraham Maslow and Jean Baudrillard.

Maslow's 1943 paper entitled "A Theory of Human Motivation" holds the key to comprehending the psychological drive behind the tendency of the members of a rising class to imitate the archetype of the class into which they have been newly introduced. In this paper, Maslow identifies five basic human needs and arranges them in an ascending order of satisfaction priority as follows: the physiological needs; the safety needs; the love and belonging needs; the esteem needs; and finally the need for self-actualization. Basically, he argues that an individual is typically preoccupied with satisfying the needs found at the lowermost tier of this hierarchy; and that once such goal is reached, he or she then moves on to the next, higher tier and seeks satisfying the needs it entails, and so on. This hierarchy of human needs is a rather popular concept, and its tiers are self-explanatory for the most part. What is of particular relevance here is the third and fourth tiers of this hierarchy; namely the belonging needs and the esteem needs.

The belonging needs are defined by Maslow simply as a condition wherein "[a person] will hunger for … a place in his group, and he will strive with great intensity to achieve this goal" (Maslow, 1943). His definition of the esteem needs, however, is a bit more elaborate:

> *"All people in our society … have a need or desire for a stable, firmly based, high evaluation of themselves, for self-respect, or self-esteem, and for the esteem of others. By firmly based self-esteem, we mean that which is soundly based upon real capacity, achievement and respect from others. These needs may be classified into two subsidiary sets. These are, first, the desire for strength, for achievement, for adequacy, for confidence in the face of the world, and for independence and freedom. Secondly, we have what we may call the desire for reputation or prestige (defining it as respect or esteem from other people), recognition, attention, importance or appreciation."* (ibid)

In the same paper, Maslow also points out that the hierarchal arrangement of the five basic human needs is not all that rigid; and identifies satisfying the esteem

needs before the belonging needs as the most common reversal within the hierarchy (Maslow, 1943). He argues that, for some people, satisfying the esteem needs takes precedence over satisfying their need to belong mainly due to the notion that a person who is most likely to be considered as part of a certain group is one who inspires the same kind of respect reserved for the members of such group. These people therefore seek "self-esteem and its behavior expressions more as a means-to-an-end than for its own sake". That is to say, they seek respect for the sake of belonging rather than for sake of esteem itself.

Extrapolating Maslow's arguments to the social context in Egypt during the 70s and 80s explains why social emulation was such a prevalent phenomenon at the time. By imitating their old middle class counterparts, members of the new middle class were, albeit indirectly, satisfying an innate human need to belong. As discussed earlier, despite the fact that their newly found wealth categorized them as members of the middle class, the then unconventional means by which they came to posses it casted doubts on their status as such. Acquiring and exhibiting the same material attributes as the old middle class was essentially their way of commanding the same kind of respect and prestige that society reserved for its members; which in turn gratified their desire to feel and be recognized as true members of the Egyptian middle class themselves.

Moving on from the realm of Human psychology and onto the field of sociology, Jean Baudrillard's 1970 book "The Consumer Society: Myths & Structures" offers a material understanding of how social emulation takes effect in a modern consumer society – which is precisely the sort of social structure that the Egyptian society was developing into during the 70s and 80s. In the section entitled "The Social Logic of Consumption", Baudrillard states that in a consumer society "you never consume the object in itself (in its use-value); you are always manipulating objects (in the broadest sense) as signs which distinguish you either by affiliating you to your own group taken as an ideal reference or by marking you off from your group by reference to a group of higher status". This explains why the members of the new middle class developed such a voracious appetite for acquiring the same goods and services as their old middle class counterparts. Their visible consumption of such "objects" was basically a "social signifier" that distanced them from the lower classes they had risen from, and associated them with the members of the old middle class who were the ideal reference of the higher-status group they had recently become part of.

In that same section however, Baudrillard also argues that given the very nature of manufactured goods and services, the visible act of consuming them is bound to become the least effective of social signifiers (Baudrillard, 2008). His argument is this: because those consumer objects are by definition mass-produced, they are therefore abundant and readily available to all. This in turn will make them "less and less expressive of social rank", and instead of being a means of social distinction, they will eventually have a completely opposite "homogenizing" social effect. From there, Baudrillard then postulates that "consumption (taken in the sense of expenditure, of the purchase and possession of visible objects) will gradually concede to other criteria and other types of behavior the preeminent role it currently plays in the variable geometry of status"; meaning that it will be replaced by new, more effective social signifiers. In that respect, he identifies *habitat* as the most important emergent means of social distinction in consumer societies. He states:

> *"Segregation by place of residence is not new, but . . . it is tending to become decisive, in terms of both geographical segregation (town centers and outskirts, residential zones, rich ghettos, dormitory suburbs, etc.) and habitable space. . . . Objects are less important today than space and the social marking of space. Habitat thus perhaps has an opposite function to that of other consumables. The latter have a homogenizing function, the former a differentiating function in terms of space and location."* (ibid)

In light of this statement, it is easy to understand why members of the new middle class fervently pursued residing among their old middle class counterparts. It was mainly because a *dwelling* and its *urban context* are by far the most visible, and least accessible, of consumer objects; and therefore the most expressive of social signifiers. It allowed members of the new middle class to communicate their association to the middle class ideal in a rather conspicuous manner by situating their residences in the same neighborhoods where their old middle class counterparts were known to dwell. Such an act amounted to putting up a literal social façade that concealed their lower class origins and showcased their new, higher status against a comparable middle class backdrop – *it basically assimilated them into the social milieu of the middle class by helping them physically blend in a middle class urban environment.*

Of all the residential neighborhoods in Cairo at the time, the use of a *dwelling* and its *urban context* as a tool of *social emulation* was the most prevalent in Nasr City – and it was such prevalence that fueled Nasr City's rapid urban development towards the end of the 80s. As it was discussed earlier, Nasr City was the only Cairene residential settlement that was conceived as a middle class neighborhood from the outset; and it continued to live as such in the collective consciousness of Egyptian society even after its development came to an abrupt stop towards the late 60s, and as it remained undeveloped throughout the following twenty years or so. The status of Nasr City as the quintessential middle class neighborhood, along with its underdeveloped character, were essentially what made it the most fertile urban medium for the manifestation of the abovementioned variant of social emulation when the demand for "middle class" residential property surged around

the mid 80s. As a result, by the early 90s, Nasr City had grown into one of the biggest middle class habitats in all of Cairo, and in such a way where its architectural typologies closely mirrored the deep social differences that divided the Egyptian middle class.

The socially driven demand for Nasr City was quite evident in the fact that, between 1986 and 1996, Nasr City's population grew at an annual rate of 8.2%; the highest of all of Cairo's high-end residential districts (elBahrawy, 2015). With professionals accounting for 55.5% of its 256,000 inhabitants in 1996, the highest percentage and one of the highest residential district populations in all of Cairo respectively, Nasr City was truly *the* residential hub of middle class professionals (ibid). Given the high real estate value in Nasr City at the time, it is safe to assume that the entrepreneurial new middle class accounted remainder portion of its population, making it truly the residential hub for the middle class as a whole.

A combination of residential ownership census data and urban observation in Nasr City strongly suggest that the settlement is also the hub of an architectural phenomenon unique to its professional middle class inhabitants. It is rather evident that the greater majority of Nasr City's bylaw-abiding apartment buildings, which stand at a maximum of 5 storeys, are in fact the extended family households of middle class professionals. Within that typology, each of the nuclear families of the household's different generations has its own apartment unit. Also, owing to their simple post-and-beam structure systems and their very modernist modular arrangements, the units in those apartment building–extended family households would typically undergo multiple alterations as the needs of their inhabitants change over the years.

Despite being the most prevalent in Nasr City, the apartment building–extended family house typology constituted only a fraction of the settlements' residential structures. The greater majority of said structures were towering condominiums that were in violation of Nasr City's building bylaws, and which housed unrelated nuclear families of both professionals and the new entrepreneurial middle class. Such condominiums were essentially the architectural manifestation of the socially driven demand for Nasr City. However, given that Nasr City's infrastructure was designed to serve residences of a 5 storey maximum height, the prevalence of the condominium typology soon took its toll on the urban quality of Nasr City as a whole.

4 THE SOCIAL [IL]LOGIC OF THE MIDDLE CLASS PROFESSIONALS EXODUS OUT OF NASR CITY SINCE THE MID 2000S

Starting in the mid 2000s, there seemed to be a mass exodus out of Nasr City towards New Cairo – a suburban settlement on Nasr City's eastern periphery which boasted a planning scheme that marked a return to the curvilinear and deformed grids of Cairo's late 19th century residential districts. This exodus is quite evident in the fact that between 1996 and 2006, New Cairo posted an annual population growth rate of 13.4%; the highest in all of Cairo (elBahrawy, 2015). Many of those existing Nasr City are middle class nuclear families that dwelled in its condominium typology, and who are seeking to establish extended family households in New Cairo. But given that the percentage of professionals dwelling in Nasr City dropped to 46.2% by 2006, as well as the rampantly growing trend of demolishing bylaw abiding apartment buildings in Nasr City, a considerable number of those abandoning Nasr City are extended families of middle class professionals that dwell in Nasr City's apartment building–extended family house typology. And while the move of the former group is justifiable, the move of the latter group makes no logical sense at all.

For one thing, there is little difference between the architectural typologies of Nasr City and New Cairo. When middle class professionals relocate their homes to New Cairo, they still construct those new homes as extended family houses. Although they are dubbed 'villas' in New Cairo, the internal organization of the villa typology is still comprised of apartments, each of which is typically assigned to a current or future nucleus family of their decedents. These might not be as typical as those in Nasr City's typology, but they are still apartments nonetheless. The only difference of note between both typologies is the architectural style of the building facades. In New Cairo, the prevalent architectural style can be best described as a gaudy derivation of Neo-Classicism, while the apartment building–extended family houses in Nasr City hardly boasts any style due to their very bland outward appearance. This is usually cited by middle class professionals as one of the primary reasons for relocating to the suburbs of New Cairo. Setting aside any commentary on taste and style, their justification is inherently flawed because of the very adaptable nature of the Nasr City typology. It is relatively easy to alter the outward appearance of an apartment building–extended family house so as to resemble the same prevalent style of New Cairo without the need to relocate there.

There is also the issue of how the villas of New Cairo are constructed. The floor plans of those villas more often than not follow a non-modular structural grid and employ structural systems, such as hollow block slabs and flat slabs, that maximize spans and in turn allow for larger, more open interior spaces. The prevalence of such structural systems is primarily driven by a desire for a more grand and luxurious character to the home. The downside to utilizing those systems, however, is that floor plans are much more difficult to alter. In comparison, the simpler and modular post and beam construction system of the Nasr City apartment building typology endows it with a very adaptive quality. That is to say it is far less likely for the villas of New Cairo to accommodate the changing needs of the extended families that live in them as opposed to the Nasr City typology which has done so for multiple

generations, and has the potential to continue to do so for generations to come.

However, the aspect in which the Nasr City typology has a clear advantage over the New Cairo equivalent is how many generations they can house simultaneously. With a maximum building height of 3 storeys for the villa typology in New Cairo, an extended family house can't even fully accommodate 3 generations simultaneously. Assuming that each floor has 2 apartments of a decent size, and that each generation has two descendants; that would leave 1 grandchild with no accommodation. And that is not taking into account extended families in which each generation would have more than 2 decedents. Whereas in Nasr City, where the original building bylaws allowed for 5 storeys, an extended family house for the same extended family can easily house 3 of its generations simultaneously with 3 apartments to spare. In other words, middle class professionals are essentially trading down when they relocate to New Cairo and, in turn, are compromising an inherent architectural characteristic that defines them as a social group. Not to mention, that leaving their extended family houses in Nasr City usually involves breaking up the extended family as most commonly each of the siblings of a household's second generation will construct their own extended family house, since if they were to build an extended family home together, the home would only be able to accommodate 2 generations simultaneously.

Finally, and most importantly, there is the question of the cost for middle class professionals to relocate their homes to the suburbs. Although real-estate value in Nasr City is still much higher than in New Cairo, when one takes into account that the value of their extended family home in Nasr City is going to be divided amongst its inhabitants, as well as the construction and permit costs of their new extended family homes, more often then not they hardly break even, or even end up losing money with their new acquisition. Such high costs have a deep impact on their economic standing as a social group, and in turn their status in Egyptian society, in which currently money is the main determinant of one's place in the social hierarchy.

The tragedy here is that most professionals are fully aware of all the abovementioned shortcomings of relocating to the suburbs. Yet, they are still resolved in their decision to move there. That is mainly because such a decision is not based on any rational reasoning, but is rather socially driven. The ideas of Norbert Elias concerning the social role of kitsch in a modern society, holds the key to understanding such drive:

> *"If we leave aside obviously utilitarian forms, any aesthetic work has for the "public", for the mass of the working population, the function of a leisure dream. This function gives our arts a very different face, compared to those of court, patrician or church hierarchies. The need of mass society for leisure pastimes . . . is supplementary to the primary needs for work and bread. It is never as vitally important as these, and the form it takes is determined by them – for example, by the constant strain of professional life, the desire to discharge feelings heavily suppressed in working life, or the tendency to seek in leisure substitute satisfactions for wishes not fulfilled by work. In face of the compulsive way in which professional life pushes the leisure activities of the industrial man in a highly specific direction, the individual art specialist is powerless. He may poke fun at such activities as much as he likes, deriding the leisure dreams and the taste of souls deformed by work pressures as 'kitsch', and mocking the 'sentimental' manner in which feelings pent up and damaged under the constraint of work are expressed. The need for that which is here called 'kitsch' is socially imposed, while kitsch itself, in the negative sense of the word, is the faithful reflection of a state of the soul engendered by industrial society. This endows the problem of kitsch with a seriousness with which it is not normally credited."* (Elias, 1998)

Although Elias' ideas apply to the abstract realm of art, they are quite pertinent to the contemporary social dynamic in Egypt. Those whom he refers to as "the working population who's souls [are] deformed by work pressures" are essentially middle class professionals, and what he refers to as their "leisure dreams" is their desire to relocate their homes to the suburbs of New Cairo. Their strong desire to move there is the outcome of the "constant strain of professional life, the desire to discharge feelings heavily suppressed in working life, or the tendency to seek in leisure substitute satisfactions for wishes not fulfilled by work."

Today's middle-aged Egyptian Professionals grew up in the 50s and 60s, at a time when professionals were revered as a social ideal, and were guaranteed a comfortable lifestyle and economic standing by the socio-economic system of the era. Accordingly, this generation worked hard and excelled in the realm of education in order to become professionals themselves. However, when they started their professional careers in the mid 70s, the socio-economic landscape in Egypt was drastically shifting in the wake of the introduction of the Open-Door Policy. Instead of leading the comfortable lifestyles they were expecting, professionals struggled to maintain their middle class status and a decent economic standing, and they continued to do so over the span of the last forty years. Now, they believe they are entitled to feel and project that they have indeed retained their middle class status in the face of such adversity. This is where relocating their homes to the suburbs of New Cairo comes in as a tool of achieving such a goal.

Forty years after the Open-Door Policy has been introduced, the radical change of the value system of Egyptian society has been firmly established, where size of income and wealth are the sole basis for societal stratification regardless of their source. In turn, the

much more affluent new middle class entrepreneurs became more socially confident. They no longer felt the need to reside in the same urban context as the old middle class in order to prove their worthiness of a middle class status. Accordingly, they relocated to the suburbs of New Cairo, making it the new urban mainstay of social status. This prompted the middle class professionals whose middle class status had been hanging by a thread for so long, and who now feel entitled to be recognized as still being a part of the middle class, to move to the suburbs as a means of social validation. That is to say, much like the social emulation by place of residence has contributed to the rapid growth of Nasr City throughout the 90s, it is now contributing to the rapid growth of New Cairo – only the role of who is emulating whom has been reversed. It is now the middle class professionals who are seeking the respect of others in order to feel that they indeed belong to the middle class. They are the ones whose sense of self worth is becoming more and more dependant on other people's opinions of them.

5 CONCLUSION

As Elias pointed out, it is futile for any critic to argue against the trend of middle class professionals abandoning their apartment building – extended family houses in Nasr City with the hopes of countering it. Any such arguments would fall on deaf ears, for the social [il]logic behind that move trumps any rational reasoning. Nonetheless, it is sad to see such typology, which – given its concrete structure – has an average life span of about 70 years, be abandoned before realizing its full architectural, not mention its generational, potential; and in turn witness the demise of Nasr City as a hub for a characteristic portion of the Egyptian middle class.

This issue is presently all the more pertinent given the recent announcement of the New Capital – a massive urban project to the east of New Cairo which seems to be slated to become the urban attractor of the post-Uprising Egyptian society. Much like Nasr City's ongoing demise 20 years after its urban boom, it seems like New Cairo is going to meet the same fate, deeming the premature disposal of architecture and urban attractors the new norm in Egypt.

Social and political agency of architecture: Performativity and the contemporary global city

J. Vela Castillo
IE School of Architecture and Design, IE University, Segovia, Spain

M.O. del Santo Mora
Escuela Técnica Superior de Arquitectura, Madrid Technical University, Spain

ABSTRACT: This paper proposes an approach to recent events taking place in urban spaces across the world that challenge the social and political frame that present-day globalization set up as a given fact. Some of this events, as different and variegated as they are, nevertheless hold in common an aim to regain for architecture its role as an operative frame, relying in its social and political agency rather than in its built aesthetical form. This paper will try to approach those events as the result of a certain performative agency of architecture, one that allows architecture to regain its original condition as the source of the political. To do so, we will discuss what performativity is and in which sense architecture is performative, to later briefly review its historical performative agency, ending with a contemporary example of this regained active condition of architecture in the city of Madrid: El Campo de Cebada.

1 FORE-WORD

1. There are some recent urban phenomena in different places across the world that deserve a close attention and that are in need of theoretical conceptualization.

2. These phenomena are multifarious, adopt many different faces, but can be joined under the general umbrella of *shared urban practices*. They involve the creation of powerful (though limited) social networks independent, if not directly at odds with established powers. Practice (and agency) are their key words.

3. They claim for, and demonstrate, the viability of a different "use" of public space. In doing so, they redefine terms as "use" or "public", since the way they work deconstruct common and established assumptions of what public, private, use, shared, common, consume and other similar worn words mean. In fact, they "create" "new" "public" "space" (the use of quotation marks is not trivial, or a mere figure of discourse, but essential: it marks the redefinition those terms suffer under the agency of these practices).

4. Although they are usually small scale interventions, bounded to fairly limited spaces and with experimental vocation (which should not be diminished as experimental, but appraised because its "experience" content), they have an infrastructural ambition. This infrastructural ambition points both to built infrastructure (ranging from ephemeral interventions to "street collaborative furniture" to more formal constructions) and to a more immaterial understanding of infrastructure: they produce relational networks and shared knowledge aggregators providing social infrastructure.

5. They work (but not always) in an ambiguous space regarding political, economical and even legal frames, hence its potentialities (and some of its difficulties). For example when wi-fi pro-common open networks are laid to connect people inside city areas, overlapping established telecommunication networks they push to its limits the concepts (and the legal definitions) of the public and the private, legal and illegal, business and agitation. If they are allowed to exist by the ruling power it is mainly because they are seen as "avantgarde artistic interventions", but they nevertheless contain very powerful and risky potentialities for the neoliberal-global capitalist practices (to be exploited).

6. They put together many different kind of actors and "intelligences" ("collective intelligence practices" is one of its possible definitions; there is also a very interesting platform of architects, designers, artisans and common people in Spain and Latin America called "Inteligencias Colectivas" http://www.inteligenciascolectivas.org/), regardless its background, technical knowledge and so on. The only requirement to participate in this practices is to be a citizen (not necessarily according to legal documents, since they will, of course, include illegal immigrants, people without fixed residence and so on) and to be eager to engage in a shared activity that produces, in turn, better urban environment and renewed community engagement.

7. Of course they promote, produce, and enhance people empowerment.

8. Environmental questions are significant: environmental regarding "green practices" (urban gardens,

clean and autonomous energy systems, recycling), but also environmental because they create new physical and especially social environments.

9. A shared, common language is needed for all those so different actors to engage in fruitful work (performativity). A composite language, one linked to spaces and sites ("placemaking"), to the actual places where these practices happen and to the end they address, the contemporary city (and its socio-political regime) and to the many actors they involve. A language open to recyclability and reuse (compost). A language worked with words but also with hands, since many of these practices involve common handwork to produce things and networks. A language close to the body, and to the lived body, but also a supplementary, prosthetic language, in which *techne* joins theoretical knowledge and the senses. An ordinary language that produces instead of a language that merely describes or states.

10. Our proposal is that architecture is this composite language. And this language is in the form of performativity.

2 WORD

What we try to propose from now on is an attempt not exactly to provide some answers to the questions and statements mentioned above (although some will be elaborated and even exemplified) but to offer a foundational ground, some theoretical remarks that allow us to understand those phenomena and to explore its operativity and the sustainability of its practices (i.e. its soundness, since are not foundations intended to be sound?) in the context of a different politics of spaces and bodies. This situations are in fact part of a widespread net of actions and happenings developing in Madrid and other cities in Europe but also (although with different and not necessarily the same local overtones) in other places across the world, including especially Latin America. In that sense it is a phenomenon that in many ways challenges the actual political dominion of global capitalism in favor of distinct collaborative alternatives of political representation and social constitution. Of course it is not our aim to address the full complexity of this phenomenon in the space of this paper, but to point to the key role architecture plays in these processes, to its regained condition as source of the political, and to explore some of the ways in which architecture and architectural design allows (or even enforces) this processes (its performativity).

To begin with we need to introduce first and provide some basic account of the term intended to act as this foundational ground from which architecture (and the following mentioned practices and situations) take its agency. So a short summary of theory on performativity and performativity concerning architecture follows. As performativity, precisely, performs, it does so in its intermediate condition, in the friction and resilience of bodies, in the relationships that arise in the borders and surfaces in which architecture opens up space to fields of signification. Therefore we will focus briefly in the in-between spatial condition in which meaning arises and in the necessary engagement of (historical) architecture and users in transformative practices. Finally, and to return to the foreword, we will focus briefly in a particular experience taking place now in Madrid ("El Campo de Cebada") that emerge as perfect example, in its always double condition of individual example and paradigmatical (*iterable*) dispositive.

2.1 *Performativity*

According to philosopher J.L. Austin (1962), there is a particular kind of linguistic utterances, that he came to name performatives, different to those that describe a fact or a particular state of things or make a statement about something, that put in motion some (original?) condition of language as action: so to say, they *produce* what they *say* by way of saying and acting *at the same time*. In that sense they are self-referential (there is no such thing as a referent that is outside and prior to the actual utterance – the speech act – to what they can refer). But more important, they imply a particular medium or context in which they are to be uttered to produce the desired action: they need a community to address and a formulary or ritual environment to be framed in. A very determined context. They need, in that sense, to be staged, immersed necessarily in theatrical drama. Using a topical example, for the words "I pronounce you husband and wife" have its full effect, the performative act of joining together two persons into the legal form of marriage produced by a celebrant, it is necessary on the one hand that the community context is determined and on the other that the utterance is produced following a strict set of rules (the first of one is its repeatability) in the form of a ritualized ceremony. Both conditions, then, try to determine as much as possible the circumstances that allow the utterance to have its effect, circumstances that need to be closely related with a particular and determined set of acts. It is not only the utterance, the actual words, which make the effect, but the especial way and place (medium) of saying that words, the act that goes along with them. In short: words and acts are knitted together in the performative act, and that should be made according very precise community rules. The relation with theatre performances is important, since action (body action) and speech both together produce the effect when adequately staged.

There is another important point that Austin makes clear: those kinds of utterances cannot be true or false, but they simply can be "infelicitous" or "unhappy" (or not). They are not related to truth, they are not laden with truth values, but rather they are judged according the effect they produce *a posteriori*. If truth (in the positivist tradition form which Austin comes) is permanent, *a priori*, independent of the context and unaffected by acts, performative utterances introduce a much welcomed stir. Welcomed because it moves the focus toward the event, toward the unexpected and

toward what is to be construed. Toward what is to come (French *l'avenir*). Performatives (or *illocutionary acts* as later Austin called them) imply producing something that does not exist before, and in that sense not only produce a new state of things but also put together the different actors implied in the utterance in a particular relationship of community. A relationship that is necessarily political, in the sense that on the one hand it implies an established political frame that set the rules and on the other in the sense that it proposes a certain relations of power that should be managed within its very relationship.

As is known some of the basic premises of Austin theory had been challenged, say deconstructed, by Jacques Derrida (Derrida, 1988), but nevertheless, the ambiguous relation between acts and meaning still is a productive one. In that sense, one of the most interesting consequences of performatives is that they highlight the close knit between what exists before and after the utterance, the agency of the act and the motion (bodily motion), but also that they imply the cohesion between the one who talks and the one who listen at a level beyond the aural, in a kind of politics of the performance.

Derrida's analysis focuses in part in the situations in which a performative utterance is quoted (as, for example, in theatre) and hence transported to another context. If Austin diminished those *parasitic* situations as unessential ones, Derrida asks himself rather if those apparently extemporary occasions do not present a serious challenge to Austin's theory, to the point of invalidating it, since in fact it is the general possibility of citationality the one which guarantees the very existence of performative utterances (Derrida 1988, 17). In any case, what these parasitic occurrences consistently show is the close relation with theatre of performatives. What happens, for example, when this performative utterances (or illocutionary acts) are produced *inside* (in the context) of a theatrical representation as part of it? They still produce their effect? The answer, we think, is not as easy as may seem at first, and may lie, precisely, in this *parasitic* condition. Of course, it is usually taken for granted that a marriage celebrated as part of a theatre play does not have effect in "real" life (although some plays and movies use to play precisely with this confusion, the *cinema inside cinema* condition), but the things are not so clear when we consider contemporary theatrical performances, in which the limits (the context) between what is theatre and what is not blurs. Think in the performances created by Marina Abramović in the 1970's (for example *Lips of Thomas*, 1975), in which the ambiguous condition of what is "theatre" and what is "real life" produces a dark in zone in which Austin's definition of performative fails. The interesting things is that, by failing, succeeds. Succeeds in the sense that, as Erika Fischer-Lichte explains, "the actions are self-referential and actually constitute reality, and therefore are capable, in whatever the manner, of producing a transformation in both the artist and the audience" (Fischer-Lichte 2011, 51. *Our translation*). So to say, they *perform* something, precisely by the transgression of the very *parasitic* condition they are the result.

What obviously interests us is this capacity of transformation, of production of new connections between people (and thence new meanings) of performatives, of engaging people in new relationships, that is to be crucial in understanding the operativity of the new urban practices addressed in this paper.

Finally, we cannot end with this point without addressing, although very briefly, another important development of the concept of performativity, the one undertaken by Judith Butler in the context of sex/gender relations and constitution of subjectivity. For Butler, what is important is "the understanding of performativity not as the act by which a subject brings into being what she/he names, but, rather, as that reiterative power of discourse to produce the phenomena that it regulates and constrains" (Butler 1993, 2). Departing from the strict context of the philosophy of language, Butler produces an important statement setting clear that performative acts not only produce something (and what produce is a relation), but that at the same time they produce the rules that regulate this same production (that nevertheless are subjected to the transformations derived from the very act they produce), setting the frame for its repeatability and variation (*iterability*) and in so doing opening the space to new relationships and meanings.

2.2 *Performative architecture*

How performatives relate to architecture and to the production architectural space? How they relate to the construction of public space and to its political condition? How architecture does what it says by way of its agency? What is architectural agency? Maybe too many questions to answer.

Our proposal here is that public space (the question that can be asked now is: "all space?"; a preliminary answer will say yes, although further elaboration is needed) is constructed through performative actions that came into existence through the very architectural framework they put in motion, creating a new set of relations (the phenomenon produced by performativity) defined by the architectural interventions actually built. In that sense, architecture or better saying architectural space (its *meaning*) defies its usual condition as an stable and pre-existent object, whose meaning is given as something that can be apprehended from the outside – by an individual or a collective subject – and from before, to be understood as the "frame in motion" that is built in the very moment is constituted (even in phenomenological terms) by (and in interaction with) a subjectivity. That subjectivity, in return, is constituted at the very same moment it confronts architecture -as Judith Butler (1988) explains, there is not a preexisting subject as such, but subjectivity that is produced in the friction with the very object it apprehends. Nor that architecture exists in a fixed way as an object, neither there is a social subject formally

constituted that apprehends intentionally this object as architecture, but is in the performative acts it promotes that "the phenomena that it regulates and constrains" are produced.

The question now is to trace the correspondence between performance (the play of the social actors in space, the constitution of this very social-political space) and built architecture. And this should be made in two directions: on the one hand architecture should be understood as the physical, built frame (not necessarily pre-existent), that allows performative acts to take place -of course this frame is not a neutral frame and imposes, like it or not, a certain discourse, enforcing some behaviors and preventing others as always happens with designs (Domínguez Rubio and Fogué, 2015). On the other, architecture as performativity itself: as the set of relations that arise in a certain space at a certain moment, iterable (but not repeteable, see Derrida 1988, 7) as the shared experience of meaning that springs in the shared experience (use) that constitutes architecture.

And since architecture is never a completely private affair, performativity produces always not a private space, but a public one (though with different levels of publicity, of course). In that sense, it is not the constitution of individual architectures that is at stake, but the constitution of the shared space in-between them, and then the constitution of a community for which this experience is meaningful. In public space this community is the social body that, in fact, represents itself to itself in this staged performativity. But how is in essence the constitution of the public space at large, in its political condition?

Public space is political, as architecture is (always political). Since public space depends on, relies upon, and is constructed both as a result and a confrontation of given socio-politico-economical conditions at a particular moment, it is necessary modeled by the existent political regime and by the one it promotes. But apart from that, public space as appears when performativity is at stake is rooted as political space, since it produces a shared common practice that generates effects of governance at the level of the city, the civic (the *polis*), and we can say it even constitutes the political subject within an architectural frame, proposing a different politics of community. This situation reminds us how democratic politics appeared in the Greek city-state (Athens as its real locus) in the slippage from the aristocratic power of the few (exercised form the Castle and the Temple) to the deterritorialized power of the *demos* (played in the unbounded, in the sense that is unfortified, open architectural space of the *agora*) and how the role played by architecture was determinant. As we proposed in another place (Del Santo Mora and Vela Castillo, 2013) it was the "architectonical construction of a certain type of space, a 'multipurpose' space that the community could feel as their own precisely because is empty, useless, *free*" the one which allows the *political* to appear. And is this space, in turns, the one which allows the community to recognize itself as community, providing with visibility in an open stage: the people can be reunited in a shared space, an "isotropic" space in the sense that it is not influenced, overshadowed, controlled by any particular power or institution, and plays freely a new set of relations and shared meanings.

2.3 *The (historical) performance of architecture*

We are used to think of architecture as an abstract operation far removed from the imitation of reality, as an art that belongs not to the figurative realm but to the abstract one, and as if instead than describing Nature it imitates Nature's way of doing. In that sense, architecture more than produce a fixed image of the existing environment puts in motion the possibility of understanding itself as environment, or what is the same as saying that architecture performs environment.

When G.E. Lessing in his *Laocoon* (1766) proposes his own system of the arts, he tries to establish how arts are related with time and space (with the concepts of duration and extension). He established that some arts were closer to space (meaning extension), to simultaneity and even to instantaneous-ness (say a picture) and that others are closer to time, in the sense that they are linked with duration, with development of actions along the course of time (for example a musical piece, a play or dance). Nowadays this strict division is difficult to maintain, but for us the important point is that this highlights the evidence that space-time is involved in art, that in different degrees and even in an unpredictable way it is the progression of acts framed in space-time conditions what allows meaning in arts to appear; and that it is even in such a ways that the process opens the way to the event, to the unexpected appearance of the new. Then, at the beginning of modern aesthetics, it is this eventful and productive condition of art what is established, and especially the discovering of the in-between space of friction between spaces and between space and time as source of meaning.

In this in-between space and time is where performance and art as performance appears. Since we apprehend reality through time and space, understanding art as perfomance (as what happens in-between space-time) is closer to our nature than understanding it as a fixed object apprehended from outside. In other words, this sense of performativity involves a tight connection between human being and world, making possible that very relationship from the in-between. Hence the realm of the interrelationship between in and out is opened, which is then transposed into the relationship between body and community. As an entangled system of inner and outer spaces in which bodily borders are crisscrossed, we can effectively find correlations either across vast distances and vast times or across minuscule distances and minuscule times, from the nearer of the body relations to the amplified relation of the social community. Performance opens the door, curtains drawn back, performance begins.

Although architecture has been almost always understood as the art closer to space (remember the

known statement by A. Schmarsow in his *The Essence of Architectural Creation* 1893: 'the very essence of architecture is space') than to time, it is clear that the opening to performativity and to the event implies the in-between of time and space, neither space or time alone, but the friction between them. The existence of the in-between demands, at the same time, that the understanding of space be made in the course of time and that time be apprehended traversed by space. But how this space-time notion affects the realm of architecture? Why this *performative* turn allows us to state that architecture itself performs?

In answering the initial point the first and straight consequence of this turning point in architecture is the challenge of how to introduce space-time in it. Attending to this, an immediate classic vision of the relation between space and time presents motion as the simple result of that connection. In this context came the idea of providing motion to architectural artefacts as done in the avantgarde proposals made by the Constructivists and Futurists at the beginning of 20th century. In them we find that either their proposals introduce in the 'artifacts' they produce elements driven by mechanical systems of movement or the artifacts in themselves were properly designed as objects that have the capacity to move in time across the space. Accordingly, the replacement of an inert stable object with the interactive one was a natural consequence of this turn to the space-time approach and to the performative experience. And consequently in this way architecture begins to express with clear evidence its potential agency to perform, and even to perform itself.

By the 1960's, clearly assimilated those previous efforts, new proposals came, with, of course, a greater technological display. Designs by Archigram, Cedric Price, or Haus Rucker-Co are well known in this sense. But what is relevant in them is not the advanced technology that the proposals clearly manifest but the use of this technology at the service of its performance, at the service of the ways in which architecture interacts with subjects, transforming both architecture and the subject alike in the interaction. Cedric's Price *Fun Palace* (1961–64) is especially interesting in this respect. Architecture ceases to be an utilitarian object set in front of the user-subject and transforms itself in an in-between *constructo* that interacts with the user in unexpected, ways producing unexpected results and, of course, unexpected meanings. Architecture is therefore shaped by people at the same time it is being used, or in other words, architecture, opened itself to the event. It is configured in each of the moment it is being used and consequently architecture depends on the user to acquire its final form, a final form that is final only till the moment that new users interact with it in different ways producing ever renewed meanings. In its constant mutability architecture is configured in ways that allows the interruption of time into space (interval) to appear and reconfigure the relations between architecture and its limits. What matters now is not the existence of an object in front of a subject (say user) but the constant interaction between them, the ebb and flow of its borders shaped as deepened surfaces in constant shift. In this way architecture unfolds its possibilities as appropriately framing the active agency of performance.

Of course this active agency as the proper (*oikios*) of architecture has been identified as an effective force of shaping reality across the past 20th century, as is evident in the frequent demand for new times to come in the avantgarde manifestos of nearly every modern architect, from Bruno Taut to Le Corbusier, from Walter Gropius to El Lissitzki. Nevertheless architecture is not only the supplier of what a user of the new times needed in his daily life, but it is an effective agent that activates in the user the real capacity to transforms himself into a new citizen and by extension, to transform the community which he partakes of into a new social structure. And this is also what we see today when architecture presents itself as an effective and qualified agency within space in cities to challenge cultural, social and political established assumptions.

2.4 *El Campo de Cebada*

After the conceptual basis are set and historical trajectory discussed, let's move, finally, to a contemporary example of those performative practices and languages that construct the shared public spaces of contemporary cites in its political constituency and that demonstrate, in action, de performative agency of architecture.

The experience of El Campo de Cebada in Madrid is a good example of those practices. El Campo came to life when some members of the architectural platform Zoohaus (in which different collectives as Todo por la Praxis, Zuloark or Basurama participate) joined an association of residents that lived around Plaza de la Cebada in La Latina distric of Madrid. It was around 2010, almost a year after the City Hall of Madrid demolished an existing structure and produced a vacant lot in an otherwise densely built quarter of the city that the initiative started (Lozano Bright, 2014). Owing to the world financial crisis that began in 2008 and the explosion of real state bubble in Spain in the same period, intended construction of new facilities, parking lot and new housing was halted.

After the initiative presented by this heterogeneous platform (christened El Campo de Cebada owed to the historical square, an old barley market – cebada meaning barley) the lot was finally handled by the City Hall to this citizens Platform for its use and management during a year, since then annually renovated.

Within this frame, conditions for the use of space, access, exploitation and so on were established by the collective "El Campo de Cebada" as a shared and participative enterprise, with only minor public funding. The space was then devoted to cultural use, developed in a free frame in which local residents and general public alike joined forces in such activities as theatrical performances, sports (the demolished structure was the only public sports facilities in the district), the growth of a communal garden (although tree growing

was specifically forbidden in the site, recycled wooden planters were set and a small urban garden sprang), different workshops (for example one called "handmade urbanism" in July 2013) and cinema projections, activities for children and so on, excluding nevertheless commercial uses. They even run a Summer University in 2013, with conferences from morning to midnight during a whole weekend, with great success.

Within this framework, different collectives of architects participate developing a series of experimental urban strategies, including the building of self-made structures under open source conventions (Corsin, 2014), following the Inteligencias Colectivas ("Collective Intelligences") strategy to distribute the designs freely through internet. They organized different workshops to develop, from design to actual construction, objects/prototypes of expanded urban "furniture", which they call "handmade urbanism", engaging both local residents and visitants alike, that later populate El Campo.

Of course these objects were used to infrastructure the space, and many of them still are there, but beyond that, they serve to demonstrate the performative character of architecture and architectural design: in that sense, what interest us of this experience in the context of this paper is the ability of architecture to produce meaningful spaces through the very agency it puts in motion, collaborative construction and use alike. Those artifacts, beginning with the collaborative design and the collaborative construction (using mainly waste materials, reused wood slats, pallets, rough building materials and so on), engaged people in new dynamics concerning the production and use of public space, appropriately staging their designs from its very inception, and hence developing new communal and political bonds. But they also introduced performative dynamics in the open space of El Campo (transplanted to other places, since similar designs were also build as different places as Matadero Madrid, as for example the designs called "Offffficina" or "Mamut" by Zuloark), acting as mobile devices (even physically: some of them had wheels) that enable transformative collective spaces to be ready for use. Spaces that in turn allow people not only use them, but transform and adapt them to the necessities of the

Figure 6. El Campo de Cebada, plural and singular alike (Source: El Campo de Cebada).

moment: stands for watching performances, small parliamentary structures, stages, tables, and so on. What is important is not what they are, but how they are used, how they interact and engage in fruitful changing relations, how they act or perform a certain play inside the open stage of El Campo. A play whose rules are staged at the very moment people engages in the play. Its performative capacities, then, charge the space with new meanings, meanings that are in constant transformation depending of the particular use at particular moments, creating a new set of architectural relations that, nevertheless, are in obliged change and negotiation. In that sense, performative architecture is strongly political, since it imply, even encourage, constant confrontation and negotiation, positing more democratic political environments. Human and architectural bodies, then, engage in new politics of space, constructing new meanings and sharing them at the public stage El Campo presents.

Curiously enough, given its alternative orientation and the "low" quality of the intervention (judged from conventional architectural parameters), El Campo de Cebada has been awarded with some architectural and artistic prizes, which points to one of the dangers inherent to these initiatives: its paradoxical demise by the ruling powers as mere "artistic interventions", consequently deactivating its political and transformative potential. But that was already posited by Manfredo Tafuri (1976) more than forty years ago in the context of historical *avantgardes* and contemporary *neo-avantgardes*. As said, it has been selected among the finalists in 2012 for the European Price for Urban Public Space, and awarded with the prestigious Golden Nica (Prix Arts Electronica) in the category of Digital Communities in 2013 and with one of the prizes of the XII Spanish Biennale of Architecture and Urbanism also in 2013.

At the moment, El Campo de Cebada is still sailing at cruise speed, though the City Hall recently (June 2014) reactivated the original building project for the site. Nevertheless, the experience, ephemeral as it should be, demonstrated crystal clear the performative capacity of architecture and the possibility, rehearsed in full fledge, of a different politics of space.

3 AFTER-WORD (CONCLUSIONS)

Performative architecture, as outlined in this paper, probably opens up more questions that the ones it answers: what seems to be important, in any case, is the operativity of the tool more than the actual and particular responses it can provide. In the context of recent architectural experiences in contemporary cities that challenge the established political, economical and social facts in the era of global capitalism, we tried to eschew different possibilities for political governance through architectural actions in shared urban contexts. The proposal of a performative architecture, one that through (but beyond) material practices would propose new exigencies and promote different social and political relations is not new, as in the brief historical summary we have shown, though maybe the emphasis in the understanding of architecture less as physical frame and more as the "subject" of some shared agency is. What arise would not, in any case, a set of examples of different single political constructions, but the capacity of architecture to articulate a new frame for politics itself (hence the reminder of Greek *agora*), through the opening up of space to new relations and meanings that can construct, in turn, a different politics of space.

Twin cities as urban laboratory of the contemporary social contradictions

C. Toscani
Politecnico di Milano, Milan, Italy

ABSTRACT: There are more than 16 twin cities in today's Europe. We call them twins since they were either born as urban entities next to each other, yet mostly with different administrative domination, or due to socio-political alterations they were detached throughout their growth histories. Despite their adjacent geographical location, different languages are spoken and diverse economic conditions are faced in those cities. The term "Twin Cities" was coined for the first time to describe the geographic condition of Minneapolis and Saint Paul. In Europe we can consider like a model of this twin phenomena, Tornio (FI) and Haparanda (SV). This comparison can represent a stimulating laboratory to trigger new collective figures of urban space, in order to discover better strategies and spatial devices of architecture and urban design. These devices will activate a process of effective integration along and through the border lines.

1 USA/EUROPE: DIFFERENT SCENARIOS

Although important changes have always occurred throughout history, it is evident that they have surged during this historic period, in particular Europe's geopolitical situation appears, in this sense, to have exposed all its weaknesses and the uncompleted elements. Its victim is the project of the Schengen area, born with the European Union, established in 1985, as a zone for the free movement of persons, is an extremely important result.

The Schengen Treaty establishes the abolition of border checks in 26 countries – 22 European Union member states and other countries including Iceland, Liechtenstein, Norway and Switzerland. Recently however this treaty is being undermined by acts of terrorism and substantial immigration flows: current news features extensive coverage of worries and potential action. Towards the end of January this year, six European states: Germany, Sweden, Denmark, Norway, France and Austria, reintroduced checks at their borders and requested the European Commission to suspend the Schengen Treaty for two years.

If we shift our focus from general international problems and attempt to reflect on the impact such events have on our cities, Z. Bauman's definition of contemporary cities as rubbish bins becomes clear: places where "global powers dump their problems so that they are resolved. For example: mass immigration is a global phenomenon, caused by global mechanisms. Not a single mayor of any city in the world has ever caused the migration of persons in search of bread, drinking water and other similar resources. (…) The problem arises from the outside, but must be resolved inside, for better or for worse. (…) cities are becoming laboratories where the best way to handle these issues is being studied." (Bauman, 2013).

Such issues stem from cultural differences, the ways and places of this coexistence of first emergency situations, but not only. Apart from Cittaslow mentioned in Bauman's text, so-called Twin Cities are extremely interesting laboratories and there are at least 16 in Europe alone. "Twin Cities" refers to a specific urban phenomenon where two cities are established in close proximity and forge relations of cooperation and completion. This particular urban conformation was theorised by the European Council which defined its characterising elements in a study, in order to render it classifiable under specific categories.

For two cities to be defined as Twins, it is essential that they share both morphological and economic-administrative aspects. They must be located on a national border, share a common historical evolution and their cooperation must be based on institutional foundations governed by standards. Often such cities are located on opposite banks of a river which has historically represented a territorial border. International relations permitting, the bond between twin cities may culminate in the elimination of state borders and the merging of two cities into a single body with a merely apparent administrative division.

It is evident that such cities are affected by aforementioned changes to an even greater extent and as such constitute a laboratory for research and the mutual comparison of experiences on how to handle similar situations, even in non-border cities. Therefore, as well as an interesting laboratory, in the sense described by Bauman, their location in the vicinity of borders means that they are constantly exposed to a greater degree of change; they also rapidly acquire characteristics inspired by resilience, also in terms of urban strategies which define new scenarios for the future.

This essay aims to compare two different yet equally paradigmatic cases: two American cities, Minneapolis and St. Paul, in the State of Minnesota, where the term Twin Cities was first applied (although neither possesses all the requirements to be defined as such), and what is defined as the European model: the cities of Tornio and Haparanda, respectively in Finland and Sweden.

It will be evident from this description that even though these two cities are twins, they both possess characteristics which appear in part to contradict this definition, not least their history, but also many others. Elements which tend to define a more or less extensive common project are contrasted by others which render this impossible.

On the one hand the definition of the term is etymologically unambiguous, however on the other hand, whenever it is used to describe their highly complex realities, it becomes somewhat ambiguous and less clear, although cities in the USA present considerable advantages and greater possibilities for cooperation in comparison to the European ones, where their differences will be more convenient to direct the future scenarios scenarios on this richness, which, as emphasised by H. Gadamer, can be spent as a school or laboratory from which the world can draw lessons.

In this respect, it is interesting to note the opinion of G. Steiner, who urges us to stop perceiving Europe as a potential economic, military and technological force in competition with the United States. According to the scholar, Europe should be valued for other qualities and therefore potential destinies and future tasks, deriving from a unique condition which is not even present in demographically varied cities in the USA, with striking linguistic and social differences often observable at a distance of 20 km.

2 MINNEAPOLIS AND ST. PAUL

Minneapolis and St. Paul were established approximately ten miles from each other, on opposite banks of the Mississippi river.

St. Paul was the first to be founded, originally as a natural port at a point where the river became navigable. The upper part of the river was inaccessible due to numerous rapids and the St. Anthony Falls which prevented ferry transit. In contrast, Minneapolis, originally known as St. Anthony, was established in the vicinity of the homonymous falls, the only ones along the entire river. Indeed their potential as an energy source to power mills constituted the most favourable condition for settlement for productive businesses in the area.

Over the next few decades, in the mid 19th century both cities established scarce contacts, insofar as they were separated by a vast, non-urbanised area which rendered their connection practically impossible. They continued to grow isolated until the early 20th century, when their reciprocal and individual expansion lead them to occupy the interstitial space which separated them. This qualified them as Twin Cities. This condition is truly remarkable for two large cities in the United States, insofar as they tend to be distant from one another and grow independently through the extension of peripheries and suburbs. The only other examples similar to Minneapolis and St. Paul in the United States are the so-called “Quad Cities” in Iowa and Illinois, and to a lesser extent, Dallas and Fort Worth in Texas.

Throughout the evolution of both cities, the territorial morphological factor is to be considered an element of separation which was gradually overcome by other factors.

The Mississippi river has always constituted a limit in the unification process of both cities, an obstacle to direct connection, its insurmountability proportionate to its width, the marshiness and inaccessibility of its banks. During the cities’ earliest historical phases the development of the road network was conditioned by the river’s course; later, urban development abandoned this reference and assumed a new regularity. Initially both cities developed in virtue of the presence of this natural element which determined their position, however this bond withered away upon the development of new means of transport and the transfer of production towards the periphery.

When modern technologies overcame the barrier of the falls, both cities were able to establish a connection across the river and in turn this required the common coordination of waters, through the establishment of a Metropolitan Council, one of the first steps towards Twin City status.

This inversion enabled both cities to emerge from isolation and grow in close contact with each other, evident in the morphological structure of connection networks, consisting of a regular road grid, transport infrastructures, as well as connecting bridges, without interruption, with the sole exception of areas along the river and near the historic centres, characterised by an irregular morphology.

Indeed from 1888, the area occupied by both cities had extended to such an extent that they converged, creating a need for a unified system of infrastructures for smooth access and transit, resulting in a common network of transport and services. Minnesota’s first ever electric tram line was opened during this period.

The term “inter-city” was used for the first time in 1890, designating the intercity tram line which connected Minneapolis and St. Paul; it went on to be used throughout the country to describe linking operations between cities.

Road and tram networks were a homogeneous, powerfully unifying force. The railway network, dating back to 1857, underwent a more complex development and still features distinctions today, given the sheer number of access points to both cities. This has been historically generated by the territory’s geological characteristics, not least the river.

The river valley at the confluence with the Minnesota river has always constituted a natural

barrier, preventing the crossing of lines from south to north. St. Paul is at the northernmost point of this valley and benefits from its vicinity to a break in the towering river side cliffs. Therefore it is the region's connection point with the south of the country.

In contrast in Minneapolis, which is closer to the wheat fields to the west and Nicollet Island, it was easier to cross the Mississippi river, an advantage exploited by northern routes. Therefore both cities initially developed as distinct railway centres.

It wasn't until later, with the fading of the distinct economic vocation of both cities – St. Paul for trade and its twin for industrial production –, that the need to connect them arose, with the addition of new railway lines while maintaining separate stations given the considerable distance between both city centres.

The development of a common public and private transport network was the very element which enabled expansion in areas which were yet to be urbanised, therefore it catalysed the union of both cities, not only from a morphological point of view, but also in terms of administration and economy.

Since the 19th century Minneapolis has held a considerable advantage over St. Paul in economic and demographic terms, however today, despite the persistence of a certain distance between both cities, this condition can be considered mostly psychological. In strictly economic terms, both cities constitute the heart of north-western America's economic system. Indeed this area is the second largest economic centre of the Midwest, after Chicago.

Both cities account for over half of gross domestic product in the state of Minnesota and are characterised by one of the highest concentrations of high technology businesses. The main economic activities of St. Paul involve the service, computer and medical equipment production, electronics and wholesale trade sectors. The city is also home to the nation's biggest meat farmers and is a centre of foreign trade thanks to its duty free services.

Unlike the railway system, both cities are served by a single airport – the International Airport of Minneapolis-Saint Paul, an essential hub for the management of trade and tourism. All of these changes would never have been possible without the will to define an administrative body to govern over potential conflicts. Indeed urban, economic and social evolution in both cities has understandably highlighted the impossibility of managing at least some important issues by local governments independently and separately. This awareness culminated in 1967 with the establishment of an administrative organ: the Metropolitan Council (Met). Its purpose was not only to coordinate government operations and planning for the Twin Cities, but also a wider area including the seven surrounding counties.

The Council has numerous functions: public transport, waste water treatment, territorial planning, city planning for municipalities, forecasting population growth and the maintenance of a system of regional parks and paths, as well as the definition of a reference framework for regional systems, including aviation, transport, parks and outdoor areas, water quality and the management of water resources.

Despite achieving remarkable progress, often the Council is unable to fully develop its own potential, due to its non-elective nature. The Metropolitan Council was established in response to common issues and offers an example of coordinated management, however each city has its own government which manages issues of a strictly internal nature.

Its actions are directed to arrage and manage specific problems rather than to provide a common scenario for both cities.

This ambiguity in the management system of both cities is also reflected in collective perception and therefore in social dynamics. Undoubtedly there are observable social divisions and the failure to recognise a unified landscape stems from a sort of historical rivalry linked to disparities in initial economic conditions. Perhaps the most obvious difference can be seen in the religious affiliation of inhabitants of both cities, palpable in the spatial and architectonic structures of the cities themselves: the large cathedral dome which dominates the hill of St. Paul, home to the Catholic Archbishopric, contrasted by the spires and towers of dozens of Lutheran churches dotted throughout Minneapolis, the zone's Protestant centre.

In any case, closer study of the origins of the population indicate that: three fifth of the population of Minneapolis is of German and Scandinavian origin, from the earliest migratory flow which occurred in the mid 19th century, followed by later immigration flows from Germany, Italy, Greece and Poland. Over the years the aforementioned have been joined by a large population of Somalis, approximately 40,000 citizens. In contrast, the first wave of immigration to the city of St. Paul dates back to the settlement of the Irish community on Connemara Patch along the Mississippi. From 1850, Swedish immigrants, who mostly settled in Swede Hollow, were followed by Poles, Italians, Mexicans and Afroamericans. Therefore other than those related to origin, it appears that there are not further or significant causes of divisions, nor linguistic or economic distinctions. This fragmentation appears to be the very cause of an inability to perceive both cities as integrated, and bound to a cooperative future of a collective reality, which has been achieved only in some aspects of management, such as water.

3 TORNIO AND HAPARANDA

Both cities originate from a single urban nucleus, identifiable as the city of Tornio. After the Finnish war between 1808–1809 (and Russia's victory over Sweden), Finland, until then Swedish, passed under Russian dominion, along with the city of Tornio. The city of Haparanda was thus founded on the Swedish banks of the Tornio river, to compensate for the loss of Tornio, which became a part of independent Finland in 1917.

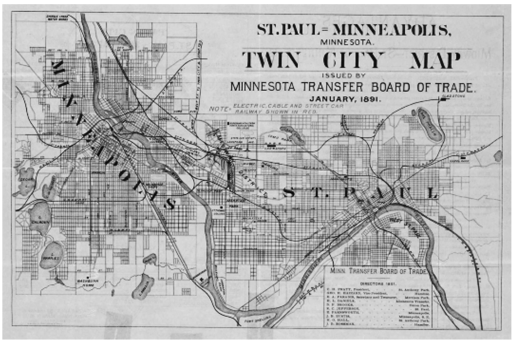

Figure 1. Minneapolis and St. Paul, transport map 1891. The two cities are called twin.

Despite these events, their borders were never really closed and both cities were only divided by the physical obstacle of the river mouth.

Today the population of Tornio is 22,000, mostly Finnish, whereas the population of Haparanda is 10,000, with a highly diversified linguistic component.

Today the border between Tornio and Haparanda is fully open, with an extremely high number of annual crossings, the extensive exchange of goods and numerous persons who cross the border every day, as though it barely existed.

Here too, the infrastructural element has played an important role in the permeability and rapid connection of various urban areas of both cities. Indeed from the 60s, both cities undertook the systematic planning of public and private infrastructure services, and more. Both have also forged cooperation in the sectors of industry, education and culture and after initial positive results, local authorities extended cooperation to other sectors such as the economy, tourism, trade and the environment. There is a vast array of agreements between both cities, from the definition of joint sports centre, to waste and water treatment, the construction, in 1987, of an institutional organ: the Bothniensis Province, which prepares and coordinates all cooperative activities between both cities and represents them in external relations. Numerous coordination activities are also linked to this official body, for the equal promotion of activities along the Baltic coast in order to exploit synergies of both cities.

Even though cooperation was active before the European Union, upon entry, there was an increase in the activities of the same cooperative policies, with the exploitation of specific programmes for their development. The "Pä Gränsen/Rajalla" project, which literally means "border", foresees the creation of a new joint city centre located on the border between both cities, works first began in 2003. The project was developed in an architecture competition launched in 1995, for the area's urban development through the construction of new residential and commercial buildings. After works had began, in 2006 the Swedish company IKEA opened a new store here, thus encouraging the arrival of many other commercial businesses.

Figure 2. Minneapolis and St. Paul, 1840 (Bettoni, Gerevini).

Figure 3. Minneapolis and St. Paul, 1860 (Bettoni, Gerevini).

This has bolstered the region's economy, with an increase in commercial activity throughout an extensive area of the territory, leading to a remarkable extension of the existing infrastructure.

It is no coincidence that the European road E4, which crosses the continent from Lisbon to Helsinki, passes through these two cities, creating an important trade corridor and facilitating exchanges between east and west. Both cities are also located at the centre of the European Union NEW10 corridor which passes from the eastern coast of the USA to Asia. Cooperation is not limited to economic development, indeed in 1998 a tourist office was opened, with the aim of improving the social integration of inhabitants and developing a sense of collective belonging in the cross-border zone. There are tangible results from aforementioned activities: an increase in cultural and educational exchange

Figure 4. Minneapolis and St. Paul, 1880 (Bettoni, Gerevini).

Figure 5. Minneapolis and St. Paul, 1930 (Bettoni, Gerevini).

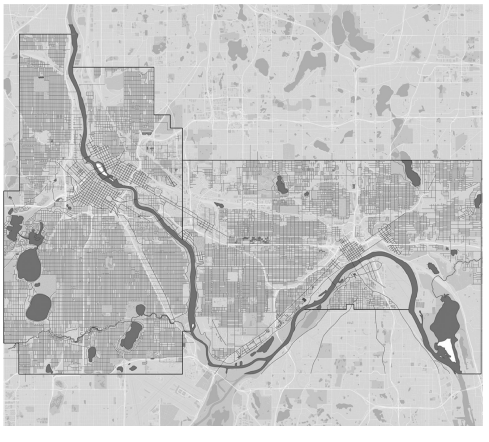

Figure 6. Infrastructural grid (Bettoni, Gerevini).

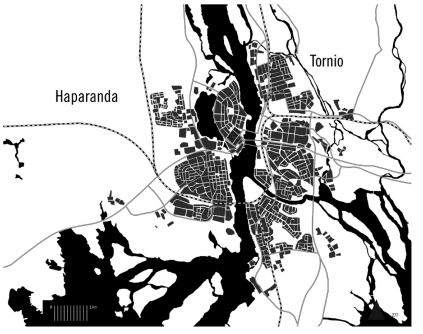

Figure 7. Tornio and Haparanda (Formaggio, Zanon).

Figure 8. Tornio (Formaggio, Zanon).

Figure 9. Haparanda (Formaggio, Zanon).

which perhaps more than other sectors, is crucial, in parallel with the construction of a shared urban space, for the development of urban solidarity, in terms described by Z. Bauman, solidarity of a "city per se" rather than a "city in itself".

An example can be seen in the school complex of Haparanda which contains a primary and secondary school, with students from both cities who learn the languages of both states. The next objective for university education is the creation of a cross-border campus for research and education, through the development of an extensive range of joint courses and exchanges (of personnel and students) between institutions.

This potential is evident in the case of Tornio and Haparanda, especially in this moment characterised by the continuous emergence of conflicts and new divisions (conditions which are absent in the USA). Although to a lesser extent, both cities are essentially an observation laboratory, where possible tools are being designed which are both necessary and experimental to social management as well as different urban scenarios.

Unlike Minneapolis and St. Paul, these two cities perfectly represent the twin cities model, indeed compared to other European cities, they may be considered the most evolved example of cooperating cities, in accordance with an envisioned future scenario which is collective and unified. As proof of the capacities and potential hidden within specific European geographic political conditions, there are remarkable distinctions between both cities in terms of history as well as their economic, demographic and social composition, the latter exacerbated by linguistic differences often reflected in exclusivist affirmations of identity.

In spite of this, the potential of transforming the border into a location of interaction and cooperation has emerged in some tangible projects.

4 CONCLUSION

We can easly affirm that the meaning of twin cities cannot be divided form the meaning of frontier, as a place, buffer, scene not a single line, but buffer and stage. So we can consider the entire urban fabric of a twin city an urban frontier.

K. Lynch, in his book The possible city, talks about the possibility to erect new border cities, either between states with a good relationship, or, in the opposite case, as international buffer zones where there is a conflict. Thus our challange is to think about those urban strategies that can best build common places along the borders, as "spaces where we can stretch our identity." (La Cecla, 1997).

In this case the reading of some writings Van Eyck is extremely motivating to understand precisely the potential to some points given by their nature interstitial, regardless of the dimensional scale.

A. Van Eyck explained the importance of considering the feature of twin within the process of project development: "To establish the in-between is to reconcile conflicting polarities. Provide the place where you can interact and re-establish the original twin phenomena." (Van Eyck, 2006)

This means that the urban project, dealing with the building fabrics, from a certain point of view is itself a unique space in-between, and not necessarily their edges. Hence, it should enhance the feature of by no means ignoring the differences, but rather activating multiple dynamics, functions and scales, which uniquely determinates the nature of space yet contains just the variety of existence and open future to surface. Then the architectural project can become the true spatial device: "It's an old forgotten truth: that diversity is not attainable through unity, unity only attainable through diversity." (Van Eyck, 2006).

Lines, pipelines, and the contested space of transcontinental fossil fuel transport

E.E. Moore
Department of Architecture, University of Oregon, Eugene, Oregon, USA

I.M. Volynets
Department of Architecture, Lviv Polytechnic National University, Lviv, Ukraine

ABSTRACT: The North American continent is threaded with highways, rail lines, pipe lines, and shipping lines for the transport of extraction equipment and for the transport of fossil fuels from the continental interior to markets in Asia. These lines and pipelines are critical to the future of the global climate and, as such, are actively contested in terms of conflicting property, corporate, human, and ecosystem rights. This contest reinforces the critical importance of this category in a taxonomy of architectural space. In this study, we apply traditional modes of architectural site analysis to this non-traditional architectural site. The resulting body of work invites reflection on the role of architectural criticism and design practice for the future of fossil fuels and for the future of the global climate.

1 INTRODUCTION

1.1 *Background: Fossil fuels and the Pacific northwest*

The management of existing fossil fuel reserves is a critical variable in the future of global climate change. According to the International Panel on Climate Change, limiting climate change will require "substantial and sustained reductions in greenhouse gas emissions" and that "the burning of coal, natural gas, and oil for electricity and heat is the largest single source of global greenhouse gas emissions (IPCC 2015)." In order to keep climate change below 2°C, 75% of existing fossil fuels must remain in the ground (Vaughan 2015).

In North America, the Pacific Northwest region sits directly between enormous geological reserves of fossil fuels—coal mounts, oil shale, tar sands, and natural gas fields—and Pacific ports for export of these fuels to Asia. The expanding energy markets in Asia and the availability of these fuels in North America, has put pressure on existing fuel transportation infrastructure across the Pacific Northwest.

Five refineries are now receiving or plan to receive crude oil by railcar from the Bakken shale formation in North Dakota. Railroads are moving 40 times more oil now than in 2008 (EIA 2015). Since 2012, the Pacific Northwest has faced proposals for four new coal export terminals on the Pacific Coast, two new oil pipelines, eleven oil-by-rail facilities, and six new natural gas pipelines with liquefaction for export (de Place 2015).

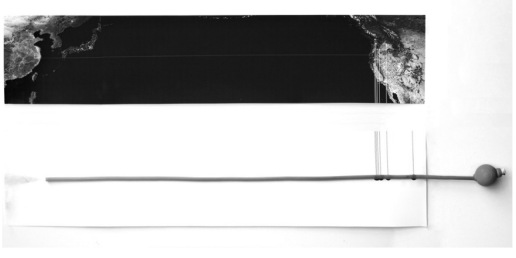

Figure 1. Coal line across Pacific Ocean by Susanna Davy.

1.2 *Site: Lines and pipelines*

In the United States, the primary focus of sustainability in architecture is on energy consumption in buildings. In the work described in this paper, we shift architectural design research "upstream" of buildings to the spaces of the *production* rather than the *consumption* of building energy. In this case, we are focusing on the Pacific Northwest as the "thin green line" between fossil fuel reserves in the North American interior and fossil fuel export across the Pacific Ocean to Asia.

1.3 *Design research: Morphology and manifesto*

In this study, we apply traditional modes of architectural site analysis to this non-traditional architectural site in a series of morphological studies of the space of existing and proposed rail lines, pipelines, and export ports. The morphological studies and the resulting

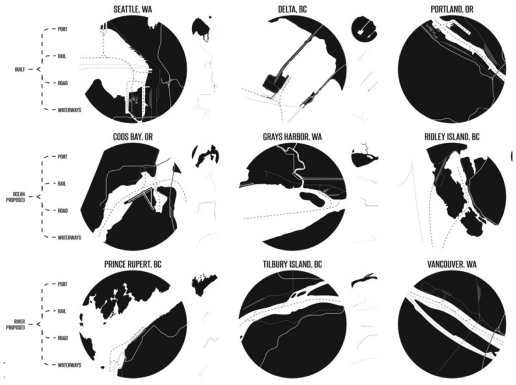

Figure 2. Morphological study of existing and proposed ports and river terminals by Will Searcy.

taxonomies are subjective constructions of new sites and are the groundwork for developing design manifestos for this new territory. The manifestos stand in for architectural program and drive the design for new ways of inhabiting the space of fossil fuel transport.

Using the format of the university architectural design studio as a vehicle, the process allows us to ask: What can a typological study of the space of fossil fuel transport in North America reveal about the nature of this territory as the location of one of the most critical contests in global climate change? How can such a study reflect on contemporary architectural practice and the role of architectural education and criticism to engage the issue of global climate change?

2 ANALYSIS

2.1 *Theoretical context*

2.1.1 *Analysis as product*

The work *Learning from Las Vegas* was the outcome of a studio that Robert Venturi and Denise Scott Brown taught at the Yale School of Architecture in 1968 that was called "Learning from Las Vegas, or Form Analysis as Design Research," that took a group of students to Las Vegas to investigate and analyze the city's forms (Venturi 1977). While the book was eventually a touchstone for postmodernism in architectural theory, the work it described was groundbreaking as it introduced and gave currency to 1) the idea of looking for lessons outside the canon of architecturally curated space, and 2) design processes based on analysis of formal or spatial typologies that conflate the process of analysis with that of establishing a point of view. In the case of *Learning from Las Vegas*, the book is simultaneously documentation and manifesto.

It is significant that a notable portion of design research that followed, including within schools of architecture, also attended to non-traditional space or *drosspace*, as designated by Massachusetts Institute of Technology (MIT) urban planning faculty member Alan Berger (Berger, 2006). Notable examples of studios in which the product was analytical studies of non-traditional architectural spaces that have also earned a broader audience include Rem Koolhaas' Harvard Project on the City in which teams of architecture students explored the spaces of shopping, Lagos, the Pearl River Delta, and Rome.

Like Venturi and Scott Brown's *Learning from Las Vegas*, Anuradha Mathur and Dilip da Cunha's investigations in the books *Mississippi Floods: Designing a Shifting Landscape* (2001), *Deccan Traverses: The Making of Bangalore's Terrain* (2006), and *SOAK: Mumbai in an Estuary* (2009) are rich compilations of drawings and photocollage in which the rich site analysis itself is the body of work. The work of Mathur and Dilip da Chuhna has been described as "notable for concentrating less on client-driven commissions than on issue-centered public investigations; they work to identify not conventional solutions but rather a range of possibilities, points of departure for transformative projects" (Pevzner, 2010).

The design work described in this paper is meant to uncover new perspectives on both the linear space of fossil fuel transport and the role of architectural design research in the context of climate change. The re-representation of the territory is meant to be both an end point—a body of work that stands on its own as documentation and manifesto—and a point of departure for future design.

2.1.2 *The expansive nature of architectural site*

Architect and writer David Leatherbarrow calls the broader influence that buildings have on their environment the building's "orientation." In *Architecture Oriented Otherwise* he explains his new use of the word in terms of a building's topographical, performative, and experiential context. In this way of thinking, the building is not an object but rather a place where things happen in relation to other things. A building's orientation is the influence it has on light, on an individual person or on a neighboring street (Leatherbarrow 2009, Moore 2013).

Climate change is a major disrupter of traditional notions of "site" in the practice of sustainable architecture. While ecosystem thinking has expanded the sphere of impact of building and community design decisions far beyond the localized site plan of modernist thinking, the definitively global nature of impacts of fossil fuel combustion blows past any existing boundaries of measured impact. Measured in terms of its carbon footprint, the impact site or the "orientation" of a building is the atmosphere.

This expanded site of architectural impact challenges the media and methods of architectural site analysis. What are ways of drawing site that account for the extreme local and global natures of environmental impacts? In the case of this study, the space of fossil fuel transportation is a space of both orientation and of impact. The design and use of this space has global repercussions and the physical nature of the site is a result of the way that the built environment is

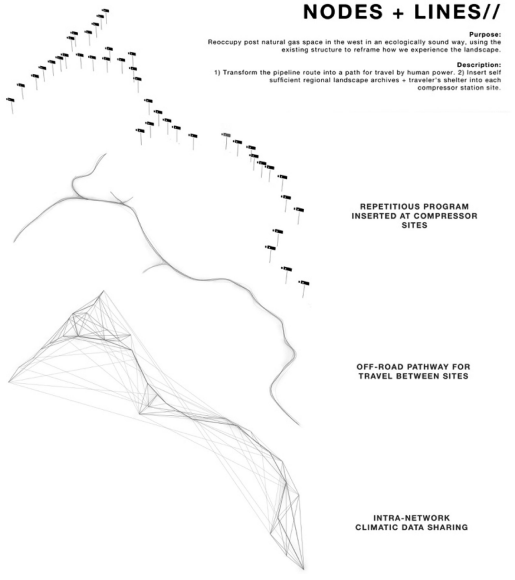

Figure 3. Reoccupation of post natural gas space by Jordan Frazin.

inseparable from the built infrastructure of fossil fuel transportation.

2.1.3 *The reflective nature of architectural site*

Lola Sheppard and Mason White, Canadian designers and founders of Lateral Office, conducted the architectural drawing and design project that became the project *Next North*. According to William L. Fox, curator of the Nevada Museum of Art Center for Art + Environment, who wrote in the catalogue for *Landscape Future: Instruments Devices, and Architectural Inventions*, an important exhibition that included the work of Lateral Office: "Next North" is "part of a program to help Artic communities understand where they live and design structures that interact in positive ways with the local environment. As a person working outside of the artic, my view of the work is the way it remaps the territory of the place, giving agency to matter and culture that is normally out of center of the cultural map" (Manaugh 2013).

MAP Office is another design practice that uses site drawing to give "agency to matter and culture." Referring to the title of their monograph *Where the Map is the Territory*, Robin Peckham of MAP Office in Hong Kong refers to the dictum of semantics that "the map is not the territory." As Peckham says, "we are looking at scenarios in which the map can actually become the territory as with the Boregesian case in which projects and attempts to map real space also affect what they purport to document and perhaps also vice versa" (Peckham 2011).

As in the work of Lateral Office and MAP Office, the act of drawing architectural space can be simultaneously the documentation of existing space and the construction of a new space. In this study, we are using architectural site analysis to draw "new" sites, or to demonstrate new ways of perceiving these sites and our role in operating within them.

In this study, the primary product of the design research should be insights into the role of fossil fuel infrastructure in conceptions of architectural space. The drawings should be reflexive—shaping the space and the perception of the space. As art critic, activist, and curator Lucy Lippard wrote about the role of art in *Undermining: A Wild Ride in Words and Images Through Land Use Politics in the Changing West*, there is use to asking questions that have no answers:

> *While entangling visual art with the cold realities of our current environment, some artists are realizing that they can envision alternative futures, produce redemptive and restorative vehicles with which to open cracks into other worlds, and rehabilitate the role of the communal imagination. Artists are good at slipping between the institutional walls to expose the layers of emotional and esthetic resonance in our relationships to place. They can ask questions without worrying about answers*. (Lippard 2013)

2.2 *Methodology*

2.2.1 *Studio as vehicle*

The work described in this study took place in an architectural design studio at the University of Oregon, using the studio model as a format to ask the research questions also listed above: What can a typological study of the space of fossil fuel transport in the Pacific Northwest of North America reveal about the nature of this territory as the of location one of the most critical contests in global climate change? How can such a study reflect on contemporary architectural practice and the role of architectural education and criticism to engage the issue of global climate change?

Overall, we asked each student to 1) develop a body of work in two and three dimensions to study the typological morphology of some category of the linear space of fossil fuel transportation, 2) develop individual manifestos connecting their personal convictions with their visions for the future of those spaces, and 3) develop a design or a series of design interventions with the strategies of "erasure," "disruption," and "daylighting" to make the visions in their manifestos manifest.

2.2.2 *Morphology*

The morphological studies took place over two to three weeks during which students were asked to research and document some category of linear space of fossil fuel transport, with a loose focus on the morphology and also the human relationships in the space. The resulting body of work included foci on 1) oil train transportation and oil spills through urban areas, 2) coal transportation rail, air born coal dust and air quality, 3) existing and proposed ports connecting rail lines to shipping lines, and 4) the relationship between residents' views on the coal industry and their proximity

to places of coal transportation and extraction. During this time, students read, drew, and carried out discussions in response to parts of Tim Ingold's *Lines: A Brief History* (Ingold 2007).

2.2.3 *Manifesto*

Following the making of their morphological studies, students were asked to develop a point of view about and an argument for what their "site" should be in the form of a short manifesto. Specifically, we asked the students to draft manifestos for the future of their particular site or for fossil fuel transport in the Pacific Northwest in general, considering that the manifesto would serve as the generating document for developing the functions of any design responses to the site. During this time, the students read the *Executive Summary for Policymakers of the IPCC* (IPCC 2015) and presented portions to their classmates. They also used the classic text *Programs and Manifestoes on 20th-century Architecture* (Conrads 1970) for reference.

In response to this potentially difficult challenge, students were very sure of and articulate about what their site should be in the context of climate change. On one end of the spectrum, some students argued for stringent mitigation—the immediate withdrawal of all natural gas pipelines and the use of only renewable resources that can be created regionally and shared among a network of buildings because, for example, "In this model, neighborhoods can be energy independent and will not have to rely on the greater, inefficient energy grid." At the other end of the spectrum, some students advocated for incremental divestment by not adding any more natural gas pipelines and optimizing the current use of existing lines, including by connecting people more directly to the sources of their energy. In nearly all cases, students were able to connect global issues of climate with a vision for the local inhabitation of the built environment of energy production.

2.2.4 *Design*

Following the revision of their manifestos, students were asked to do three one-week designs to bring the ideas in their manifesto to form. As a way of guiding the students in this broad task, we offered them three ways of operating on the morphological site with three design strategies: erasure, disruption, and daylighting. Some students chose to develop a singular proposal, using the three tools as ways to study the problem. Some students chose to offer three different small designs, using each strategy for one proposal. For "erasure," we encouraged them to imagine what could be achieved in the act of physical removal. For "disruption," we encouraged them to think of the way that linear space is defined by its disruption (in ports, borders or bridges). For "daylighting," we encouraged them to think about how design might bring new ideas to light.

As an example of how a student took on this series of assignments as separate but connected parts, one student (Hevey) developed a morphological study of the rail line that transports coal from the Powder River Valley in the Rocky Mountains to the ports on Washington's Puget Sound. Her morphological study documented the competition between the livelihoods that coal extraction offers small mountain towns and the threat that coal is to the future of the climate. Her manifesto affirmed that any design solution should offer alternative livelihoods for those currently employed by the coal industry and that simultaneously, coal should no longer be mined. For the design phase, she proposed that the rail line be repurposed to curate and make accessible the immeasurably valuable wildlands of the Rocky Mountain states along the rail line. To this end, she designed a full tourist guide to the rail line, including all trail, river, and mountain access by hiking trail, paddle, mountain bike, or horseback. For "erasure," she designed a stables train station for the coal mine for horse tours of the (future) historic mine. For "disruption," she designed a lodging rail station to connect to the continental divide trail. For "daylighting," she designed an overlook for the National Bison Park. In this case, this is three separate designs for one overarching idea.

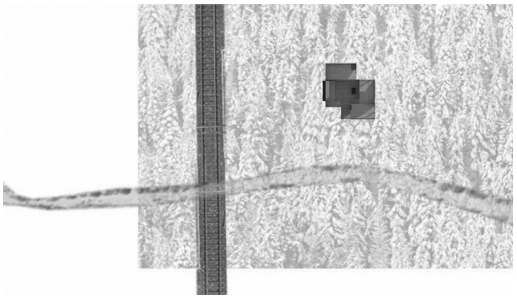

Figure 4. Coal rail ecotourism route by Gillian Hevey.

Figure 5. Disruption by Susanna Davy.

As an example of how a student took on these strategies with a single design, one student who did an impressive documentation and analysis of natural gas pipeline compressor stations (Frazin), proposed to removed a multi-state gas line (erasure), then to replace

the location of every compressor station with a lodging and archive (disruption), that serves to connect and to mark these locations in a way that taps into the depth of their landscape history and meaning (daylighting). In this case, these are three strategies applied to the same typological proposal.

3 CONCLUSION

3.1 *Findings*

I soon discovered, however, that it was not enough to focus only on the lines themselves, or on the hands that produced them. I had also to consider the relation between lines and the surfaces on which they are drawn. Somewhat daunted by the sheer profusion of different kinds of line, I resolved to draw up a provisional taxonomy (Ingold 2007).

3.1.1 *Morphological study*

The product of the morphological study is a large body of two and three-dimensional artifacts of architectural analysis of the space of fossil fuel transport. While the actual territory under study is infinitely complex, the documented and translated territory begins to reveal distinct commonalities and anomalies in the spatial typology. At the same time, the most important questions that were raised by the morphological studies were not about the forms of the fossil fuel transportation space as much as they were about the relationship between the transportation space and the people who live with this infrastructure.

While we expected that our choice to work with infrastructure space rather than so-called inhabited space was a choice to deal with human-less equipment, student work, such as that that takes on the physical bisection of a neighborhood by a large rail yard (Dominguez) or the project that studies the urban space of gas lines (Morales) revealed the degree to which our built environment in the Pacific Northwest is fundamentally shaped by the infrastructure of fossil fuel transportation.

3.1.2 *Manifestos*

While the compiled manifestos that the students wrote are not revealing on their own, they were very successful as tools for the students to shape their own design directions. It worked well for students to substitute their own ethical position for a functional program as a way of giving parameters to the design portion of the studio research. The manifestos continued to be important touchstones for reference during the critical development of the design work as the documents against which all design decisions could be measured.

This way of working in direct accountability to a moral position has potential for future work in teaching architectural design processes. The manifesto as design tool may serve as a partial answer to one of the initial design research questions: How can such a study reflect on contemporary architectural practice and the role of architectural education and criticism to engage the issue of global climate change?

3.1.3 *Design*

While the design work in response to the morphological studies and the manifestos continues, the structure of the design research has been effective in uncovering the space of fossil fuel transportation as the location one of the most critical contests in global climate change. Of the students' design proposals in response to the sites and ethical positions that they have established, all are profoundly relevant and thought provoking. In structuring this design research, we did wonder whether architectural design had a role in addressing climate change in terms of transportation space that is normally outside of the agency of architecture. In conducting the design research, we have found that there is a definitive role for architectural design thinking to be operating in this infrastructural zone.

Architectural design thinking, especially in using the tools of analytical site analysis and in programming based on established moral reasoning (manifestos), and creative design thinking has absolutely, in this case, generated new approaches to very challenging problems. The work reinforces the way that Lucy Lippard wrote, as above, that there is value in "slipping between the institutional walls to expose the layers of emotional and esthetic resonance in our relationships to place." And, as she writes, that there is value in "asking questions without worrying about answers." (Lippard 2013). In this case, we may have found answers, but only as a byproduct of truly plumbing the questions themselves.

Unknown knowns of architecture: Reconstitution of vitality in Boston City Hall Plaza

E. Sheikholharam
North Carolina State University, Raleigh, USA

ABSTRACT: There is an expanding body of knowledge on architectural psychoanalysis seeking to penetrate the underlying unconscious processes which influence design. Certain realities about architecture are not directly evident through historical scrutiny or empirical observations. In investigating the grounds for what has been often referred to as the failure of the Boston City Hall Plaza in functioning as a vital public space, mere reference to evident facts is carelessly inadequate. What is needed, on the contrary, is a different lens revealing the "unknown" of the project. The unconscious of architecture is shaped through, and emerges out of, an intricate network of social and political underpinnings which—despite their manifest intentions—are structured by repressed desires. This latent content is not immediately accessible to those involved in the design decisions. The message embedded in the mute language of architecture therefore, could be in blatant contradiction with the initial, occasionally utopian, intention(s). Using Boston City Hall Plaza as the embodiment of conflictual expressions, this paper employs a psychoanalytic approach as a theoretical basis in interpreting the project. The Lacanian notion of desire through Fredric Jameson's *The Political Unconscious* and Žižek's *The Parallax View* serves as the theoretical framework to explicate the psychoanalytic dynamics influencing the life of the plaza. The failure of similar urban renewal projects of the 1960s resides precisely in an inherent contradiction between the official institutions' unconscious desire for maintaining their control over basic internal processes and the public's demand for a fully democratic system. Recently, the attempts to revitalize the space have been focused on re-naturalizing the plaza by providing more trees. Hence, the solutions have been directed toward stormwater ecology, rather than human ecology. Similar to the "democratic" spaces of the 1960s that were never truly democratic, the contemporary "sustainable" designs are occasionally limited to a cynical representation of sustainability. The return of the repressed of Victorian brick walls of Scollay Square along with the paradoxical nature of utopian politics of the 60s constitute two major discourses elaborated within.

1 INTRODUCTION

For the obsessively politically correct culture of the official institutions in the United States, tolerance is expected to be a customary trait. A tolerance which is well manifested on political and economic levels, but not so much on urban and spatial domains. Immigration as a legal concept is tolerated, but an immigrant neighbor not so easily. Similarly, when public spaces are meant to be welcoming to all, space managers cannot condone spontaneous encounters. Assimilating the presence of a homeless in a public space is part of managers' expertise. On the other hand, tolerance has shifted over to some form of ignorance. The impassivity of the general public to big crisis appears to be a protective shield against the perpetuity of crisis. Nonetheless, it is symptomatic of a cultural malady—particularly when it comes to civic engagement with public spaces (Giroux 2003). The repression of social antagonisms and the modulation of class struggle within a new political order have generated a conflict-free public domain where the promised security can only be disturbed by an external threat. Giroux is fully justified in postulating the idea of externalization of social responsibilities: "security was framed within a sense of shared resentment toward those on welfare or other forms of state dependencies rather than organized around a sense of shared responsibilities" (2003). Furthermore, obsession with security—border security, financial security, etc.—signals an internal insecurity. Henry Miller (1987) dramatizes the condition of a "conflict-free existence" using the metaphor of "a man who would chop off his limbs in order to have artificial ones which will give him no pain." The concern here is not with the extremes (the agonizing imminence of economic crisis, political deadlocks, ecological catastrophes, etc.), rather with those ostensibly insignificant disturbances evident in the form of the poverty of a neighbor or the presence of the homeless in a plaza. Increasingly, the task of space managers is to eliminate all signs of antagonism from public spaces, substituting them with sterile images. The result is the liquidation of unsettling realities into our politically correct

social constructs. As Giroux (2011) points in his theory of Zombie Politics—the tolerance is the surrogate for "coma-inducing ignorance," where the concealed political dynamics "make unjust and repressive power invisible." Paradoxically, all the supposedly unbearable encounters (economic crises, ecological disasters, terrorism, racism) are already mediated or distorted by Media, so they no longer sustain their shocking effects. This is precisely the central point of psychoanalysis. As Slavoj Žižek (2006) observes, within our permissive culture, the most elementary transgressions become the source of traumas: a stranger's gaze as sexual harassment, or a stain on a window as an unbearable agitation. Here, the sterile neatness of the Boston City Hall Plaza appears to be "fine," yet this eerie calm is achieved at the expense of repressions on multiple levels.

In the attempt to eliminate all possibly disturbing signs, architecture plays an ambiguous role. As an immersive medium, it can function as yet another source for distress by generating more disturbing encounters or, quite the opposite, it could provide a desirable respite. Respite, when it is able to embody the collective fantasy or creates another version of reality (covering up the social predicaments by adding a representational veil). But, architecture has another crucial function. When architecture resists, that is, when it insists on exceeding the limits of what official ideology desires, the relationship becomes far more bewildering. In the case of the Boston City Hall (BCH), the fact that official managers could not tolerate the sole subject of excitement in the plaza and paved the pool with concrete is the quintessential symptom of this perplexity. It was already Manfredo Tafuri (1976) who diagnosed how market economy abandons any architecture at the moment when it strives to be an agent of change: "when architecture resists … capitalism simply withdraws it from service." Here, the conflicting desires have produced an architecture which no longer functions as a progressive agent. BCH acts as yet another medium—blithely adding more layers of falsification so that things appear to be right. The predicament of the space is not that it does not resist or that it is neutral—the design of the plaza is revolutionary on multiple levels. The problem resides in the moments when spaces themselves are conducive to depressing experiences. How then can we position the BCH within a psychoanalytic discourse?

We need to think of the context in which this project was undertaken. Boston City Hall and its plaza belong to the pedigree of urban renewal projects of the jubilant and impassioned era of hope and optimism of the early 1960s (Neyfakh 2012). The masterpiece emerged at the intersection of political aspirations for a new Boston with the progressive vision of I.M. Pei's urban design; and the architectural prowess of Kallmann, McKinnell, and Knowles, the designers of the City Hall building. Despite this felicitous symbiosis, the project has faced dramatic crises. Evidently, the enterprise had in its disposal all the means for success: a political will, social enthusiasm, financial resources, acute strategies, and marvelous designers. Why despite all the good intentions and fortunate coalitions the project was not as well-received as expected? To disclose the origins of this failure, it is inadequate to rely on what is evident on the surface. What is required, rather, is a way of penetrating the underlying realities. We need to ask: what kind of incommensurability of drives, what sort of repressions of desires, and what modes of alienation are in play? Without recourse to any elaborate discourse on psychoanalysis, Žizek's (2003) ironic remark on Donald Rumsfeld's notorious aphorism exemplifies the type of speculation which reveal the latent truth about the plaza.

In 2002, to justify the urgency of invading Iraq, Rumsfeld, the Secretary of Defense, offers three synthesis between known and unknown: "There are known knowns. These are things we know that we know [Saddam has weapons of mass destruction]. There are known unknowns. That is to say, there are things that we know we don't know. But there are also unknown unknowns–the ones we don't know we don't know [if Saddam has even more monstrous weapons]" (2011). But the fourth category—as Žizek (2004) noticed—was missing: the unknown knowns, "the things we do not know that we know." This is precisely the Freudian notion of the unconscious, that is, "the disavowed beliefs and suppositions we are not even aware of adhering to ourselves." We should ask similar questions about the plaza: what has been the unknown known of the space planner and design initiatives? But, how architecture can be psychoanalyzed?

As Adrian Johnston (2014) noted, Jacques Lacan affirms and frequently insists on Freud's discovery that the unconscious is not "an anarchic seething cauldron of unthinking animalistic instincts," but it is, indeed, structured. Later Lacan extends this claim through his famous dictum that "the unconscious is structured like a language" (Johnston 2014). Through linguistic structures, the analyst will be able to access the "intricate, labyrinthine web of ideational representations interconnected in multiple sophisticated manners" (2014). The unconscious "talks" and the analyst decodes its meaning through linguistic structures. Architecture, as a semiotic system, has a language where its signs are not necessarily bound to a predetermined meaning—its signifier is "enigmatic" (Jencks 2002). As Silvetti (1977) discusses, architecture is a "second-order semiological system," and the signified "is itself a signifying system." Architecture is not merely a frozen music, a medium of artistic expressions; rather, one could read through the mute language of architecture much deeper realities, namely, the concealed social antagonisms. This paper offers a pathology identifying the underpinning conflicts, unfulfilled promises, and repressed desires of this struggling space. It not only speculates the unconscious dimensions of the Plaza but also provides evident which affirm the subtle, yet determining, functions of such processes. Among many theoretical models expounding the psychoanalytic dimension of architecture, I will rely on modes of interpretations expounded by Anthony Vidler in

The Architectural Uncanny, Michael Hays in *Architecture's Desire,* and by John Shannon Hendrix, Lorens Eyan Holm, in *Architecture and the Unconscious*.

2 ANALYSIS OF BOSTON CITY HALL PLAZA

2.1 *History*

By the 1950s, Boston was in a state of economic decline and melancholic decadence. Troubled on multiple levels "residents, manufacturers, and businesses were fleeing the city, leaving behind acres of empty lots and boarded-up buildings" (Neyfakh 2012). Scollay Square, the district later named as the Government Center, was the apotheosis of urban deterioration. The city came to the conclusion that the neighborhood's unbearable condition had left no option but its demolition. Frustrated by the perpetual failure of partial solutions, "residents needed a 'new Boston"' (Wolf 2013). Revitalization of Boston, nonetheless, needed a physical framework. This new structure commanded new ways of thinking about space, but also about politics, civic relations, and social dynamics. Craving fresh ideas, Boston was ready to embrace a new spirit.

In 1961, the City of Boston commissioned the design for a master plan of the 64-acre district at central city's West End neighborhood and Scollay Square (Papadakes 1993). The urban renewal project, called Government Center Urban Renewal Plan, accommodated multiple governmental, civic, and municipal buildings as well as restoration of related historical sites (Cultural Landscape Foundation, CLF, 2008). Typical of such developments, the main buildings/functions have been backed up by infrastructures, notably new mass transit, and amenities such as hotels and retail facilities. The plan offered comprehensive guidelines including setbacks, open spaces, uses and heights. The new city hall was envisioned as the anchoring element connecting all the pieces. In late 1961, based on the master plan, City released the documents for City Hall competition—the first public competition since 1909 (Boston & Anderson 1961). When the jury received 256 entries, a controversial project by three young architects, Gerhard Kallmann, Michael McKinnell, and Edward Knowles garnered the most attention (Shand-Tucci 1999).

A paragon of architectural avant-garde, exhibiting an audacious version of brutalism and enriched by typological innovation, Boston City Hall was "often called the best public building of our time" (Eva 1974). Although architects have unanimously declared the building to be a refined symbol of the most paradigmatic modernist design principles, general public has expressed their relationship with the building very differently: "many regard the building as unwelcoming, cold, and ugly, while those who work inside complain about its poor lighting, ineffective heating system, and labyrinthine layout" (Neyfakh 2012). Despite their utopian intentions many of the projects realized in the 1960s were harshly criticized: predominantly they replaced the urban cores, the design solutions were not satisfactory. As Koolhaas claims, some have "devastated historic city centers" (1988). This might not be surprising. Attempts to superimpose the European piazza in an American context were particularly problematic, often leading to harsh, windswept places. As the landscape critic Daniel Jost (2013) has observed: "people hated them."

2.2 *Edge conditions and mismatched references*

Beyond scale and programming deficiencies, the predicament of the Plaza is primarily linked to its edges. To be precise, the problem of edge condition should be discussed within four mutually inclusive categories: proportions and heights (solid tall walls); immediate uses and programs (no activating function at edges); materiality and transparency (brutalist expression of brick and concrete walls and the scarcity of transparent surfaces); and finally, orientation and views (the disturbing configuration and rhythm of edges). The relatively steep slope of the plaza, "intended to recall Beacon Hill's historic brick streetscapes" (Cultural Landscape Foundation 2008) gives stairs a privileged position, rendering them as the primary means of articulating the land. Stair here function as both dividers and connectors. Since the vast terrain is not partitioned by specific uses, walls, or heavy vegetation, the only technique of subdividing the landscape has been the transformation of the terrain into series of stretched terraces. Shaped by continuously folding stairs, these terraces mediate the 20 feet of the grade change. As stairs rotate to form a series of terraces at the north end of the plaza, they direct the views. Although intended to target the views on City Hall, the overall implied orientation points out to the street steering attention from the plaza itself. Aiming at embellishing the plaza with its formal dynamism while distributing the energies and movements through the provided public domain, the indeterminacy of orientations—exacerbated by the seamless continuity of stairs—eventually betrays this premise. There is yet another paradoxical relationship between the stairs and their immediate corresponding surfaces. The indeterminacy of orientation along with the standstill dialectic between the stairs and their facing surfaces have dramatically vitiated the potentials of space as an active public space.

The views are terminated by the brutality of the solid brick walls with no opening or fenestration. Although the scale of the walls is not overwhelming (given the overall height of City Hall), and the horizontal spread of the stairs are for the most part in harmony with the dimensions of the surrounding buildings, nonetheless, the actual experience of space is indeed intimidating. As if the space has primarily been designed from an axonometric view rather than pedestrian's eye level experience.

Observations about edges and their problematic relationship with the space are analytical discourses, yet they provide clues for what cannot be seen through

mere observation. The plaza's mutually exclusive statements are analogous to contradictory statements in a dream which gives the analyst the means to interpret the unconscious symptoms. Later, the paper explains how the brick walls of the City Hall substantiate the return of the repressed of the Scollay Square's Victorian walls.

At the northern border, right in front of the John F. Kennedy Federal building's horizontal wing, the stairs stretch east-west—culminating in a gridded bosque of maple trees. The problem associated with this space is the immediate encounter between the building's base and the landscape as well as the suggested orientation. The paradox here is that precisely at the moment when an articulated edge is both appealing and much needed, it is missing. The space more than anything suffers from the dissolution of its edges. The Government building's facade, except for the central entrance as a vertical portal, is primarily a flat surface perforated by hundreds of modular windows—all equal in size and all equidistant. Again, building's connection to the ground instigated a problematic reference to that of City Hall where it sits on a solid granite base with minimum fenestrations and no visual penetration. Why such a grim countenance?

3 REPRESSION AND PROPER APPEARANCE

The desert of paved space at the middle of the plaza is problematic on multiple levels. While the northern part of the plaza is loosely defined by the surrounding buildings (partially articulated by the continuous stairs), and the south-west zone has been dedicated to the metro station, the middle part nonetheless, does not relate to any immediate use. A fact that should not be surprising: as a state-owned property, private enterprises are not welcomed.

The windswept desert of brick paving stands for nothing but a leftover space where all the indeterminacies and confusions of scale, proportion, orientation, and use are dramatically realized. Again the conflictual encounter of liberal democratic values and the desire for a proper appearance is evident here as if the space is intended to house the communist party's lofty speeches. The only difference is that the plaza is considerably bigger than the space facing the Palazzo Venezia where Mussolini delivered his propagandistic speeches in 6 June 1940 over his infamous balcony (Feinstein 2003). Except for some scattering music festival and a few sponsored events, the plaza barely witnesses the imaginary crowd it has been designed for—it does not have a life beyond those moments. Or, perhaps the collective unconscious of modern architecture, but also the ruling system, only condone the symbolic representation of democracy and not its messy reality.

The connection between the City Hall public plaza and the building's internal plaza reflects on the desire of architecture to reconcile social programs and governmental aspirations. Yet, the unconscious repression of real democratic expressions returns in the forms of those elements which their uncanny presence affirm an inner disjunction.

3.1 *Conflict of programming and the ideology of bureaucratic systems*

The plaza also suffers from the monotony of use and lack of supporting functions. There are no cafes, no activating uses associated with the space, no sheltering (except for the sparse trees), no excitement! The single entertaining feature, "a pie-shaped, sunken seating area with a large fountain in the northwest corner" of the plaza was taken out, "paved over with concrete in 2006" (CLF 2008). Again the conflictual nature of the ideology of bureaucratic system emerges where the formalities of an ideal institution (organized, rigid, and in some cases, machinistic) is in conflict with the playful and arbitrary nature of active public spaces. The space in front of Government Building exemplifies this incompatibility. As if the rectilinear open area is merely a leftover, putting up an appearance to symbolize the generosity of the official governing system in providing public space. The space is not necessarily expected to be crowded by an exhilarating and energetic public, it rather should remain empty—neat and clean. It is easy to read the mind of space managers as such: if the space would be inviting and comfortable to everyone, it means that it is inviting to homeless, too. Or do the city officials condone the "obscene scene" of adults sprawling on the benches, dipping their feet into the pool?

The quasi-utopian impulse has been reduced to a symbolic image. To follow Žižek's (2010) observation in the relationship between the class struggle and architecture, we could conclude that the city's official governing institutions with liberal/egalitarian values aims to represent democratic openness. The anti-elitist character needs to express generous openness to public. The representation of democracy, nonetheless, is provided by a realm of appearance where real hierarchies and exclusivities are dissimulated by an untroubled, sterile image of public space. With a psychoanalytic twist one can be skeptical of the basis of such conflict and ask a more radical question: are "average Americans" striving for real political commitments and civic engagement, or all that which is desired is this proper appearance? It does not come as a surprise that the campaign slogan, "Make America Great Again," has been so appealing to a thick crust of American culture. Make it great please! YOU do it—we do not want to be bothered.

3.2 *The return of the repressed*

Another way to analyze the contradictions of urban renewal projects' utopian ambitions and the unconscious desire of the established bureaucratic principles is through analogous conflicts between the modernist principles and the repressed elements of pre-avant-garde architecture.

Uncanny in Freudian definition refers to "familiar objects, once repressed, suddenly returning in unlikely forms" (Vidler 2003). As Anthony Vidler has already observed, "the uncanny of Surrealism was no more than the repressed of modernism." The Post–World War II version of modernism, nonetheless, bear radically different socio-cultural content from that of the 1920s and 30s. In contrast to the revolutionary nature of early modernism, the 1960's version camouflages the real of social antagonism and pathological conditions of its society. Žižek's (2010) reading of Claude Levi-Strauss on the structure of the Caduveo's facial decorations, an indigenous Brazilian tribe, reflects on the same relationship between the Real and a mode of representation which does not allow the reality to be seen. The tribe's facial masks and decorations have been "an imaginary solution to real contradictions," where hierarchy and class struggle have been concealed by the masks. These objects, similar to surrealist fantasy objects or modern architecture's stylistically confusing symbols, compensate for the "lack of properly functioning appearance" (2010).

But what has modernism repressed from the traditional mode of life? If "the uncanny is the rediscovery of something familiar that has been previously repressed" (Vidler 1992), what is the undead of the premodern architecture? Vilder identifies three domains for such repressions: 1) solid, bearing walls providing traditional privacy; 2) the bourgeois house and "its kitsch-like trappings of 'home"'; and 3) the object of everyday life which however mass-produced are still adorned with ornaments and "encrusted with historical references." To eliminate the damp basements and to dispose of stifling attics, Le Corbusier's Piloti raises the house in favor of clean and sterile spaces (1992). The unprecedented degree of openness and transparency provided by horizontal windows and Free Plan is antithetical to, and a surrogate for, the private interiors of traditional houses generated by thick walls and interstitial spaces.

One should add the fourth category: the solid masonry base. Functioning as a mediatory device between the ground surface and the main exterior walls. A disavowed concept abolished by Piloti. Nonetheless, it has returned in uncanny forms haunting the Pilotis. The solid podium and heavy base, which in their antagonism with the grid of columns disrupt the ground level's sterility, are emblematic of such a return. City Hall's heavy brick walls stifling the openness of the inner courtyard and thwarting the visual connectivity exemplifies the same phenomenon. To be in line with historic preservation concerns, many buildings feature red bricks implying the significance of the original "colonial or Victorian era sites" (Flint 2010). Yet, this presence and its unresolved inscription into the language of modern architecture are evocative of Deleuzian Disjunctive Inclusion (Žižek 2010). Characteristic of many urban renewal projects, they are obliged to include certain themes, memories, elements "whose existence are not part of its 'ideal-ego,' i.e., which are disjoined from its idealized image of itself" (2010).

Schabert (1989) traces the problem and finds the fictitious claim that "the Mayor's Office and the City Council Chamber [are] visible to all and directly accessible by a large stairway [from the entrance hall]." Elaborating on how transparency and unmediated access have been constantly filtered, he concludes that quite contrary to the premise, "architecture is used to protect the office of Boston's Mayor against the public's view" (1989). Disjunctive Inclusion finds its definitive expression precisely in this false representation of transparency when the Mayor's office was meant to be a metaphor for transparency, but the remote placement of windows in regard to the central public space doesn't allow visual connection to the internal mechanisms of the office.

3.3 *A psycho-pathological parallel*

The incongruous combination of traditional architecture's solid base and modernist's Piloti is analogous to Max Ernst's surrealist collages. Ernst's unsettling construct, "a horse gets mixed up with one's body" (Vidler 1992), finds its architectural parallel in City Hall's unresolved co-presence of the brick base and the slender concrete columns. The floating volumes hovering above the piers and the heavy fortress-like base pulling the building down follow two different formal principles. The two, nonetheless, have been held together by compositional prowess of the designers. This reconciliation of competing principles is central discourse in many canonical projects. Fredric Jameson (1991), interprets Frank Gehry's design for private houses "as an attempt to mediate tradition (old ornamented wooden structures) and alienated modernity (corrugated iron, concrete and glass)" which eventually and similarly to as Ernst collage painting results in "an amphibious" creature, as Žižek noted (2010). If Ernst's collages register sexual and mental ambiguities, here, the conjunctive synthesis of two architectural dispositions resulted in spatial ambiguity.

On a deeper level, the building embodies the incommensurability of a democratic, transparent system and a consolidated bureaucratic constitution, which despite its refined democratic aspiration, still function within the confines of rigid rules and hierarchies. Here the collision of the two underlying systems has found an external manifestation. Žižek (2010) reflects on a similar anomaly in the works of Daniel Libeskind and Frank Gehry: "their work often appears as a desperate (or joyous) attempt to combine two incompatible structuring principles within the same building … as if two principles are locked in a struggle for hegemony." Although Le Corbusier's Piloti was still the master-signifier for post-war modernism, by the 1960s a shift in architecture's big Other signaled a new historical epoch (Hays 2010). Not only did the return to Classical elements herald a stylistic shift, but, as Aldo Rossi observed and later Michael Hays (2010) echoed, this was the moment when modernism's socio-economic

relevance has subdued in favor of consumer society's new values.

3.4 *Spirit of the age and brutalism*

It is clear to see the project as a hybrid shaped by the symbiosis of two seemingly compatible styles: the emerging brutalism of the 50s—the official style of governmental and institutional clients—and a mode of expression inherent to the Russian Constructivist of the 20s and 30s. The project could be a conjunctive synthesis of two contemporary projects: Rusakov Workers' Club in Moscow by Konstantin Melnikov, 1927–28 and Lovell Beach House in Newport Beach, CA by Rudolph Schindler, 1926. On the formal level the three upper floors hovering above the slender concrete piers demonstrate a higher degree of similarities to the Sainte Marie de La Tourette, 1960, Le Corbusier's building. The point here is not merely formal, but ideological. The decision to design the building according to the style appealing to governmental institutions has been the emblem of architecture's political correctness. It is provocative to recall Paul Rudolph's insistence on engaging craftsmen in making bush hammered concrete finish. Does his advocacy for authentic labor share common ground with Marxist trajectory, disrupting or rather contesting the capitalist regime of development?

The interrelated notions of political transparency, democratic inclusivity, public service, etc., demand literal openness. For City Hall, if such a desire has not been physically denied, controlled or limited, the space remains too formal and too serious to be inviting. Both the building and plaza "were intended to create an open and accessible place for government, an exuberant statement of democracy and civic life. Needless to say, that's not the prevailing opinion today" (BSA 2016). The door is open but the gatekeeper is too daunting and intimidating.

4 DEFECTED DIALECTS

Is it possible to reconcile between the messy expression of democracy and the sterile representation of order? How could design provide a physical structure through which opposing tendencies interact without losing their identities and their distinct modes of operation? The predominant misunderstanding of dialectics finds synthesis as a middle ground, mediating between the thesis and the antithesis. Hegelian dialectics, on the contrary, does not abolish the differences to accede to a higher reality (Limnatis 2010). Rather, dialectic is the dynamic force allowing an asymmetrical coexistence of opposites. Similarly, the opposition of the two tendencies underpinning the plaza "conceals the fact that one of the poles already is the unity of the two—so, for Hegel, there is no need for a third element to bring the two together" (Žižek 2012). No wonder that instead of revolutionizing the antagonism between the new-liberal democratic capitalism and the pseudo-democratic architecture, the new design for the plaza is adding the third element: trees—the "synthesis." The main point in dialectics is the asymmetry of the relations where one of the poles is posited by the self-mediation of the other. The depressing spaces of the plaza are not a phenomenon alien from the utopian politics of the 1960s, on the contrary, it is the very symptom of liberal capitalism. The problematic space is the secondary reactive outcome. To escape the deadlock therefore, the solution does not reside in the third element, nor in the symmetrical balance between the two, but, architecture needs "to overcome the source of the problem, the antagonism at the very heart" of this conflict (2012).

5 PARADOX OF THE FUTURE PLANS

Within the ongoing discourse on revitalizing Boston City Hall and its plaza there are some explicitly design-oriented instances. The contributions are on two levels: first, provocations from open competitions, along with those voluntarily inputs and academic experimentations; second, the commissioned or sponsored projects. This is not to categorize these two genres as amateurish versus professional, but to characterize the differences in terms of time, budget, deliverables, and to some degree, their impact. Beyond the surface, nonetheless, the two type of projects are fundamentally different.

The projects designed through open/student competitions share the following traits: they have freely dismantled some of the basic principles underpinning the design of the plaza and city hall, such as spatial orders and functional structures; they also have questioned certain taken-for-granted assumptions such as the impossibility of appropriating part of a state-owned property for private use that might invigorate the space.

Originated by the Rotch Foundation, the 2010 competition called for the design of a history museum for the City of Boston (Rotch Foundation 2010). Despite their different design outcomes, all the competition finalists offered solutions to the same category of problems identified in this paper: the problematics of edge conditions, the brutality of solid walls, and the lack of activating uses. The recurring themes in all the schemes includes: the breaking up of the solid walls replacing them with transparent surfaces; attenuation of the threshold between the building and its surrounding; articulating edges and subdividing the unproportioned areas of the plaza; introducing small scale uses such as cafes and public facilities within the plaza itself.

On the sponsored contributions, in 2010, the U.S. Environmental Protection Agency (EPA) commissioned a comprehensive report to design a vision for City Hall along with incremental steps to realize the plan. The EPA also sponsored a three-day design workshop that brought together a remarkable number of experts from different fields to share their ideas on the reconfiguration of the plaza (EPA 2010). The report includes two scenarios, each dividing the public

space through slightly different configurations. The scenarios proposed by such "professional" coalitions have a radically different nature that of the students' inputs. Essentially conservative, two elements dominate in a majority of schemes: tree canopies and gathering spaces. All the existing elements and operations have remained untouched. In 2015, the City of Boston announced that the Property and Construction Management Department has commissioned three firms to collaborate on a "comprehensive roadmap for design and operational improvements to city hall and its plaza" (Boston 2015). Again, the design solutions did not go much further than promoting vegetation and lighting. Here comes the crucial question: why despite all the evident problems, the solution has been decidedly confined to stormwater management? Koolhaas (1988) argues that the residual which was holding the modern spaces together "was merely green," where "its controlled neatness a moralistic assertion of good intentions, discouraging association, use." Today nonetheless, the residual is "a hybrid of politics and landscape."

6 EPILOGUE

Despite all the affirmative evidence that the plaza needs a radical transformation, the collective unconscious of the official agencies and the mentality of design coalitions have not yet come to believe that the primary problem is ideological, not stylistic. Rather than the exchange of partial solutions, what is crucially missing is a radical reinterpretation of the underlying conflicts. Authorities put all their effort to serve the public—apparently engaging it in decision-making processes. But at the end it is the "City" who decides what the authentic needs are, but more importantly, what the public should desire. To serve, the ruling officials need an unbridgeable gap, an imaginary distance, between themselves and the public—externally organizing the flows of public desire within the provided physical and psychological structures. As Deleuze and Guattari (1983) argued, capitalism constantly generates new axioms or adds to the existing ones. This symbolic realm of rules, axioms, and predetermined structures is what in Lacanian psychoanalysis referred to as the big Other. If for the 1960s the axiom of the ruling ideology was a democratic state apparatus—where change can only be "a change within the regime of representation" (Nail 2012)—today the axiom is "sustainability." As Cohen and Naginski (2014) noted: "just as religion is the opium of masses, sustainability is now the opium of architects, policymakers and technocrats."

Recently, the attempts to revitalize the plaza have been focused on re-naturalizing the space. The fact that such a sensitive project was funded by EPA, an organization with an environmental agenda, reveals the unfortunate realities of funding issues. Sustainability, preservation, LEED, SEED, etc. are shaping the very horizon of our imagination. In his critique of historic preservation, Koolhaas (2014) argues how the concept of preservation has been used as a pretext to elude deeper questions about the urban life. Diverting the federal funds through a demonstration project has nothing to do with the real predicaments. Of course environmental predicaments should not be neglected. But, are water flows the central problems here or the concerns which the public could identify with?

To follow Althusser (1970), the predicament is not with Repressive State Apparatuses, but precisely with what he calls, Ideological State Apparatuses: those suppressive mechanism which we are not able to directly recognize. The design program for Plaza embodies a repressed desire for hierarchy and order. The transparency of the Mayor's office was meant as a metaphor for democratic transparency, yet its placement does not allow any views in. Rather than exposing the internal mechanisms in action, transparency simply provides a proper appearance.

To continue to live with the disturbing truth of the public domain is analogous to the enduring register of traumatic symptoms in the unconscious. I will conclude with a quote from Žižek (2014) which best exemplifies this melancholic existence: "What awaits me 'there' is not a deep Truth I have to identify with, but an unbearable truth I have to learn to live with."

Indian (public) spaces. Transitions and cycles

G. Setti
Department DAStU, Politecnico di Milano, Milan, Italy

ABSTRACT: Transition of urban structures requires a careful reflection about the role of time in the description of urban phenomena. If the mutations, albeit quick, appear much more under control in Europe, in other parts of the world the situation is visibly different. Therefore, this research describes the changes in the concept of public and urban space in the Indian context, particularly in the city of Ahmedabad, Gujarat. This constitutes a particularly interesting case because it shows the signs of a change of scale and of use of the space itself that cannot be ignored, besides it reveals the relations between times and places that assume different quality and characters during a single day. The research aims to explain the changes and mutations arising in a wide range of Indian public spaces that become case studies useful to describe and compare the definition of public space in that context.

1 PREMISE. TO IMAGINE THE CHANGE

"India! The land of antiquity. Its heritage is not confined to historic accounts of events and objects frozen in their own time and space, but is perpetuated as cultural and architectural traditions" (Pandya, 2013).

The nature of contemporary public spaces affects and determines the quality of cities and urban places, favors meetings, opens to dialogues and enables to observe and to build different scenarios in which a series of commercial activities and exchanges can be overlapped, so that we can find interactions between different uses and forms of living the transitional space. The interstitial space, which divides and characterizes the private sector from the public one, is the object of study of this research: Jan Gehl, who investigated for a long time the mutations in the uses and forms of public places, supports the need to bring the glance to the 'life between buildings' as a framework of critical thoughts regarding the ongoing transformations in the life of public spaces.

"Life between buildings had been forgotten, pushed aside by cars, large-scale thinking, and over rationalized, specialized process" (Gehl, 2000). By building methods and tools to ask the change, it seems essential to wonder about factors that influence the processes of modification of public spaces and urban places. Jan Gehl's book "How to study public life" it appears fundamental to systematically question the variety of people and activities that animate public places: how many, who, where, what, how long are questions useful to classify the complexity of lives, forms and behaviors that define public spaces in different contexts, not only in Europe.

To describe and to design urban spaces implies an understanding of their lives that inhabit them, pass through them and determine their character. Too often we forget and lose the interaction between human beings and their own uses of open and public spaces. "But while architects and urban planners have been dealing with space, the other side of the coin – life – has often been forgotten" (Gehl, 2000).

Which spaces and activities and how can we observe to collect and to document the ongoing transitions and the changes taking place in the definition of shared places? The survey tools cannot be determined uniquely, but they change and adapt according to the contexts; indeed the uniqueness of places, cultures and habits requires a reading of the mutations of the concept of public space through new eyes. It can be argued, therefore, that it is each place that determines, implicitly, instruments, ways and methods of interpretation of the relationship between public space and its own uses.

2 SHARING FORMS: VARIATIONS IN THE CONCEPT OF PUBLIC SPACE

The research looks at the Indian context as a scenario of an epochal transformation and an unprecedented urban challenge in which public space conditions are constantly modified. In this country places, culture and traditions play a fundamental role in the understanding of characters, and differences of public space compared to the European context.

The aim of this essay is to investigate the transformation of the conditions of shared spaces, beyond the known paradigms already studied in Europe. In many European scenarios, shared territories depend on rules, rituals, the claim of various rights and the appropriation of marginal and abandoned spaces.

"Sharing simply goes where there is the chance to go: in the residual spaces of urban fringes or in the symbolic heart of the city." (Bianchetti, 2014). In the European context, public space is often controlled, measured and designed: it is the square, the market, the porch. However, at the same time, sharing grows and develops exactly where the space is disrupted and fragile, where we can capture new spatial and social implications generated by the economic crisis. It is thus crucial to find new ways to build and use the public space in which time plays a fundamental role given that the rapider and rapider change of urban phenomena implies the redefinition of survey and reading tools for public spaces. If, in the European context, mutation and change, albeit fast and due to abandonment processes and economic contractions, appear under control; the impulse to growth is far from stopping in other contexts, especially in India.

Therefore, it is significant to investigate the ways in which the concept of public and sharing space has been declined and consolidated in other areas. From this point of view, India represents a context in rapid transformation, marked by an intense economical and demographical growth, but at the same time, strictly bounded to traditions and habits practiced from generations.

The necessity to open our glance and reflection on the Indian context has begun after an experience of research and work conducted at the CEPT University, Ahmedabad, from July 2014 to June 2015. Impressed by the fascination for the Indian population and for their beautiful lands, I was unarmed in front of the inability to consolidate and last over the time, typical of these places. India is a country in continuous and powerful expansion, where tradition and innovation, past and future are laboriously trying to find difficult balances. There are contrasting scenarios, heavy cultural and social contradictions that constantly change the use and the definition of Indian public spaces.

How can the concept of public space be defined in India? Are there differences between north and south, between extended urban areas and small villages?

The Indian context declares its necessity to find new forms and tools able to describe changing shared places, extremely fragile and subject to sudden modifications of use, even in a single day.

Discovering the concept and the use of public space in India is a challenge that starts from the premises of the European tradition and arises important questions about the transformation of places where traditions, cultures and rituals define life and urban space.

3 (INDIAN) PUBLIC SPACES?

Interstitial places, temporary markets, large bazaars, squares, mosques and so on: the public space in India assumes different scales, sizes and conditions. First of all, it is a place of exchange, and meeting, but also of work, as a consequence it can change many times in different ways during a single day.

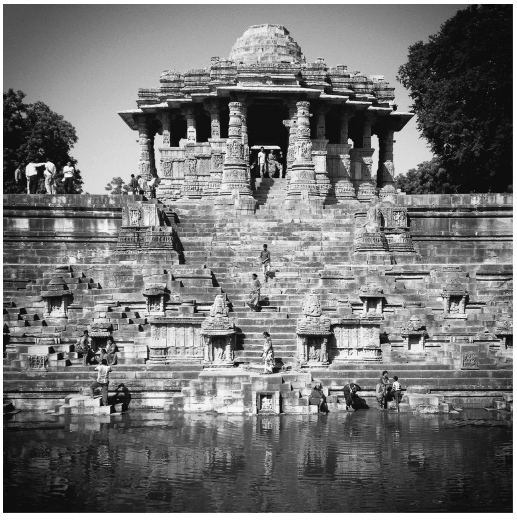

Figure 1. Modhera, Sun Temple: an example of a religious public space.

Transience and cyclicity of the concept of public space are its biggest qualities and, at the same time, its biggest exception that we can grasp comparing it to the European context. In India the urban space is vital, vibrant and dynamic, it undergoes continuous changes and transformations over a short period of time. This variable assumes a complex identity in the definition of spaces and urban fabrics: indeed, in the Indian conception, time is a cyclical phenomenon and an expression of a continuous chain of construction and deconstruction. From the belief in reincarnation, at birth and at death, most of the existence of men and cities is inextricably connected to the transformation of time and uses.

The research aims to document and interpret the intrinsic relationship between times and places in the definition of the urban character of the Indian context.

If, on one hand, the continuous and indispensable necessity of free spaces makes the unstable Indian context open to new interventions and grafts; on the other hand, the shortage of space shows the need of a continuous and quick change of what is already there.

The research will focus, with particular attention, on the city of Ahmedabad, Gujarat, expression of a rich mix of identities, times and uses of public space, as well as place of the coexistence of different cultures and religions. The research highlights the necessity for the architectural design to build new tools and strategies for the critical reading and analysis of the concept of public urban space.

Strategies needed to work in unstable and changing territories and to investigate dynamics in which religion, customs and spaces are blended together. The question, which goes through the text, is linked to the time of life and the use of cities and their spaces. What is the time of the public space in India? How do conditions and instances which define the limits for sharing places change?

Public spaces are essentially characterized by an empty or open space that is structured thanks to its urban built and settled edges; this is what we know from the European history. "(…) the void [in the natural environment] is unitary, closed and secret; in this [urban area] it is diversified, open and collective. Therefore, the public space is conceived as an urban void in which movement and variation are produced, which the passage of time and the human action are made explicit" (Espuelas, 2004).

In India, the void that should be seen as public space is, instead, a place full of activities, relationships, exchanges, temporary and permanent structures that constantly change places in few hours. It is an alchemy that overlaps time to places and defines the concept of Indian public space as a dynamic expression and cyclic transformation. "(…) constant juxtaposition of time over space is the essential premise of Indian architecture. This is a creative resolution under scarce resource conditions" (Pandya, 2013).

Indian public space lives and feeds from the dual concept of uniformity and differentiation, which involves an interpretation of the open and interstitial space, as a sap able to connect and bind different parts of a single system. We take into account the street as an element able to show the uniform heterogeneity of the Indian urban space. The road crosses urban centers, marked by the continuity of the urban facades, from the rhythm of the openings and the coordination of masses and volumes. At the same time, however, the continuity ensured by the settlement rules allows a careful and continuous variation in the use of colors, addition and subtraction of volumes, actions that emphasize the identity of each context. Similarly, public open space varies with great dynamism to allow an overlap of different activities and events, populate their margins and transforming the urban section in a vital and fascinating space.

4 AHMEDABAD: TRANSITION AND CYCLES

4.1 *Understanding a changing urban scenario*

Why Ahmedabad? For many, India is condensed in few places of great history: Mumbai and its cosmopolitan charm; Delhi, a place of contradictions and traditions; the spirituality of Varanasi that dips into the banks of the river Ganges. In my view, embarking on the journey to the discovery of India has been an experience that no description can convey.

It was the discovery of a varied, extreme, fascinating continent, the discovery of a unique idea of sharing, exceeded in Europe, which leads to share the housing space and the courtyard, where private life is concentrated into few, precious moments of solitude.

Mostly, India is chaos, it is the superimposition of urban layers, people, noise, traffic, car, sounds, smells and colors. Find your own way when you land in India, in any city of India, is complex because you are surrounded by smells and noises, by the cities that never cease to live and mark their time. The succession and the cyclical overlapping of events prevent you from breathing and you need occasionally to stop. It is exactly when I stopped that I learnt to observe India and, in particular, Ahmedabad.

Figure 2. Ahmedabad, Sunday Market. Temporary and permanent use of public spaces.

I learned to observe the use of its spaces and to question the value of public space in similar contexts.

What does it mean to understand or try to grasp the Indian space? That is a difficult question to which the text of J. Nehru, The Idea of India can try, perhaps, to give an interesting answer and a great suggestion. "India was in my blood … And yet I approached her almost as an alien critic, full of dislike for the present as well as for many of the relics of the past that I saw. To some extent I came to her via the West and looked at her as a friendly westerner might have done. I was eager and anxious to change her outlook and appearance and give her the garb of modernity. And yet doubts rose within me" (Jawaharlal Nehru, 1946).

Therefore, India needs to be understood, it must enter to undertake a critical reading and interpretation of its own spaces. The essay reads, through the city of Ahmedabad, some paradigmatic spaces in the Indian context by essence and structure, trying to find ties and conflicts with the paradigmatic figures in the European context.

4.2 *The square and bazar: Manek Chowk*

Manek Chowk is the most interesting transposition of the concept of urban plaza in the Indian context and, in particular, the expression of the public vitality that will be experienced in the city of Ahmedabad. The metamorphosis of the space of Manek Chowk is cyclical and continuous, because it develops during a whole day. Here the space changes dramatically beyond the time, it is a metamorphosis that embraces urban life and built-up system, which determines its borders. Its

high rate of transience and adaptation to change allows an ongoing (and infinite) flexibility of space.

The square becomes grazing, where cows settle in the early morning waiting for food, it is a collective ritual in which people organize to bring food every day. The same space becomes square, free ground for daily activities of urban market and temporary exchange.

During the day, intensity and density of the forms of activities build the space of Manek Chowk, marking the mixture of people, parking, shops and street vendors. Instead, from evening till late night, the square is transformed into a large open-air restaurant, where temporary spaces mutate and become more urban: a very different condition from that we are used to seeing in the system of open spaces in Europe.

Movement, time and space are intertwined in the attempt to build different scenarios of use and urban facilities. "Traditional Indian architecture is the story of movement and pauses where the kinesthetics of a space is fundamental to its experience and perception" (Pandya, 2013).

In the Indian context, I perceived with a strong clarity how much the time condition determines, in every moment, a new spatial condition: the public space that we find through India, in Delhi, as well as in Mumbai or Ahmedabad, is the superposition of layers, levels and strata; it is a sequence of different thresholds that gain or lose thickness during the day.

In opposition to what we are often accustomed to grasp, urban and public life is intensified at nightfall, when the weather becomes milder, showing how the sharing of space is the backbone of the definition of what is really public.

4.3 *The street: a system of public spaces*

From the square to the road, the research moves into the definition of one of the most public places in the Indian context: life usually takes place in the streets, its edges and borders.

Indeed, the street is conceived as a real public space where people inhabit its borders, cars, pedestrians and animals live together and the action of cross is a way to find the clearest path into a winding wave of elements that are piled together.

The road is also the favorite place for a quick meal. In Ahmedabad, the street that takes to the university is full of street vendors, small shops on four wheels, who, moving, determine the urban and public identity of a space that is not only a place of connection, but becomes a place of staying.

Edges, borders and limits of the Indian public space are transformed into vital lymph and determine the new vision of a public space that characterizes the context.

If, in Europe, we look at the square, its center and at urban void that defines the action of staying and sharing; in India and in Ahmedabad you live on the edge of the street, of the square or of the market. The high density of the space and the number of its inhabitants that are intertwined during the day make the 'border'

Figure 3. Pushkar: street market. The road becomes the space for the public market.

a living space and its thickness a place of sharing. To imagine a street as a public space appears curious as in the European context roads divide, because they are elements of fast connection, mainly dedicated to cars.

In India, instead they represent an extension of people's own home and the edge becomes a place for the coexistence of different activities. Ahmedabad, as well as most of the Indian cities, lives a different time, syncopated and discontinuous; it has been characterized by a different use of its edges: on its street corners it captures the teem of a commercial life, a great and continuous shop window that interfaces with the rest of the city. Therefore, the Indian street has a different identity, compared to the European context, because it is a relational space where temporary conditions follow by allowing the determination of spaces of transition between public and private.

4.4 *Sarkhej Roza: the mosque as a shared space*

Sarkhej Roza represents a fusion between architecture, monumental spatiality and different use, integrated and harmonious, of the space. It is a royal complex built from 1446 by the King Sultan Muhammad Shah, Ahmed Shah's son, the founder of Ahmedabad. The complex was built for subsequent additions of parts, starting from the mosque system to which, later, were added a large water basin, the tomb complex and the king and queen's pavilion used as a summer retreat.

Currently, the Sarkhej Roza complex represents a gathering place frequented not only by Muslims, indeed, as well as being a place of worship, it is also one of the most used public spaces. It is a symbol of integration, sharing and exchange, adjectives that well describe the expression of public space.

I remember when I first visited it on a sunny Sunday in August. I was in India for less than a month, disoriented. I arrived at the entrance and I took off my shoes,

Figure 4. Ahmedabad, Sarkhej Roza. Religious places become public and shared spaces.

a mandatory action necessary to enter the complex. Then I crossed the threshold and I felt absorbed in an unmatched and unprecedented space. Sitting around the pavilions were families, children, elderly people intent to enjoy the Sunday rest: some played, some ate, some chatted some prayed. All together.

The sequence of architectural and urban spaces defines ideal conditions for the use and enjoyment of Sarkhej, conceived as a summer retreat. Over time, it has been transformed in an open public place able to establish a platform for social interaction and sharing.

"The mood, identity, as well as the sanctity of each world are, thus, maintained. Each world exists, in its entirety, on its own and yet at a different scale, each world remains a part of the larger whole" (Pandya, 2013, p. 122).

Sarkhej Roza represents a sequence of parts that communicate with each other, this communication being sometimes visual, perceptual or conceptual and establishing continuous references between different architectural conditions.

Sarkhej shows how the relationships between visitor and space are the expression of a communicative process that here occurs in a spontaneous, intuitive and personal way.

The lack of alignment between the different parts of the complex invites the discovery of the space, not through a straight path but through a succession of different areas linked between them. The public space is 'lived' by each visitor in a different way, so it is intimate and personal experience.

A spatial tension between full and empty spaces, between masses and open spaces, articulated by architectural elements that mark rhythm and measure of the space; columns, pavilions, walls, and porches that gather defining visual and focal nodes: all these elements accompany the journey into the complex.

4.5 *Stepwell: the charm of forgotten spaces*

Finally, there is a fourth possible category in the classification here narrated, which does not pretend to be exhaustive, but to describe a sequence of places that can be considered as public spaces. It is the stepwell, a real architectural typology very common in the western, and warmer, part of India.

Once again, the mingling of functions and identity defines the public nature of these places; the stepwell was born as a device to collect and contain water, a highly valuable good in these areas.

In Ahmedabad we can consider the stepwell located at Adalaj, not far from the city, as a symbol of this category. Therefore, the stepwell arises as a technological device that, over the time, has been established as a religious and social place; whose charm resides in the richness of its decorated spaces and in the sequence of levels leading to the heart of the well.

For women who went to fetch water, the stepwell turned into a public social place, a time to rest from the toils of the day. Beyond its original purpose, now considered obsolete, the stepwell represents an urban architecture that has been able to travel through time, renewing itself.

Movement and perception make the place charming and evocative; to enter a stepwell is a journey, a process of crossing spaces that becomes event. At Adalaj, the stepwell has been turned into public space, it is a place for musical and theater performances that use diaphragms and differences of levels such as backgrounds or scenarios for the different representations.

Ultimately, the stepwell is an architectural structure organized around a central axis that invites to the descent through a sequence of steps and platforms. The entrance to the structure is arranged around the rotation of the axis that leads to the beginning of the promenade. A sequence of continuous changes of visuals and perspectives organize the space.

5 CHANGING SCENARIOS

We have seen how in India the public space assumes different configurations, indeed time conditions and the cyclic nature of the activities which follow during a day show how public space can be flexible and able to adapt and change in a short period of time.

It radically changes the consideration of the concept of public space that we find in the Indian context, where the idea of sharing becomes an element able to inhabit marginal places, often residual.

The survey to be conducted on these sites should be related to the observation of times, uses, density of activities and categories of people who inhabit and define these spaces. Therefore, it must determine other categories of investigation compared to what has been studied in Europe in the recent decades.

How is it possible to intervene or to change the construction and the use of public space in India? What

Figure 5. Jaisalmer, Rajastan. The street is the most relevant public spaces, in which everyone is trying to find its own space.

has been described shows the need to equip public and shared spaces with temporary and flexible architectural elements, able to quickly change the layout of an urban area.

In India we can and we must imagine that the architectural design will be able to communicate with the habits and the established traditions, promoting not only a revival of Western models, but fitting and supporting local activities that animate the shared spaces.

Here, it is necessary to provide temporary structures with different materials, able to ensure the equipment for markets or bazaars, and toilets that enable the large number of people, who usually frequent these places, to have access to basic facilities.

Moreover, it is necessary to integrate public space with facilities and equipment able to provide a better and safer use for visitors.

If you think about the examples in Ahmedabad, a place like Manek Chowk requires a timely job of cleaning and 'modeling' of its edges and borders to favor the permanence of the multiplicity of the still existing activities. Other contexts, such as Sarkhej Roza and Adalaj, live a different condition, because these public spaces were born around a cultural heritage that has been preserved thanks to the modification of its use and the opening to the city.

In this sense, the public use, although intensive, should look at the protection of quality and architectural heritage, maintaining the active coexistence of different cultures and people. Moreover, in Sarkehj and Adalaj it is possible to find a certain measure between the elements of the two complexes that let the space breath and make the perception less chaotic.

This is a completely different condition if compared to the Indian road, where the experience of public space is related to the intricate use of its margins and in the overlapping of different elements. It is on the road that we could intervene more, in its integrated design of layers and levels so that they allow a better organization of the space allocated to cars and pedestrians, but at the same time, it is necessary to provide places intended for street vendors who constitute the fundamental essence of Indian public space.

What role can the architecture design assume in unstable or changing conditions such as those described in India? What design and social tools can be used to facilitate the integration of practices and activities?

6 CONCLUSIONS

There is no unique answer about the issues arisen from this research, but different ways of inhabiting the public place that work through scales and conditions in which the architectural project remains in the background. The research, in fact, described daily uses, shared habits and practices, rituals of living a place that are often independent from the architectural forms or the design of those places. The study of Indian public spaces tells us to consider the informality of uses as a value and the architecture as a tool able to make the urban space flexible.

In conclusion, a space that daily changes imposes the assumption of different paradigms of investigation, based on urban times, spatial articulations and relational dynamics that define those areas: they are necessary not to lose the richness and the density of Indian contexts.

The squares in Portugal inventory and the creation of contemporary spaces

C.D. Coelho, S.B. Proença & S.P. Fernandes
Forma Urbis Lab, CIAUD, Faculty of Architecture, University of Lisbon, Lisbon, Portugal

ABSTRACT: Informed by the research work that makes up the inventory of public squares in Portugal, developed in the Faculty of Architecture of the University of Lisbon, part of the research team has developed two projects for very different public spaces: one for a church square in Bobadela, a small village near Coimbra, in the centre of Portugal, and the other one for a new square in the Azorean island of Santa Maria. The first square has been an important public space since the early Roman occupation of the site; the second is a completely new public space that was previously occupied by an urban block. The paper underlines the influences and relations between the architectural research developed in the Academy and the practice developed in the architectural Office in these two projects, i.e. how the research influenced the creation of reference spaces for the contemporary and future society.

1 THE SQUARES IN PORTUGAL INVENTORY

The term praça (square) is Latin in origin – *platea* – and it is used to identify a public space of an exceptional character that is morphologically distinct from the channel-like spaces that streets make. However, very different spaces correspond to this apparently clear morphology, covered by varied nomenclature and which in some way are not a cultural constant.

Although squares may not exist in certain cultures, in the West they are, by nature, an urban quality prerequisite. This importance dates back to the myth of the Greek *agora* and Roman *forum* as spatial supports for civic institutions of which we believe ourselves to be the heirs.

The fact that, in the late Middle-Ages and the Modern Age, the square has served multiple functions – commercial, political, social and religious – bordered by the public and private buildings of greatest importance in the city, has consolidated its collective character and has given it extra importance in comparison with the other urban public spaces. Its hierarchical superiority is evident in any type of fabric, not only due to the functions it supports, but also due to the finite nature of its space, its relative size or quality of its architecture, regardless of the origins behind its shape.

Nowadays, in spite of everything, the traditional square has retained much of its urban role. Although with new outlines, its production as an urban feature after the Modern Movement has seen it linked to what many were already calling "a nostalgic symbol for a lost urban quality".

By taking on the job of fact-finding, graphic restitution and illustrating the main examples of squares in Portugal, our intention is for our work to be a representative body of the diverse typology, the state of development, dimensions and usages of this so particular a type of public space. Our approach was one of taking exceptional public spaces that are generically labelled squares, even if the varied terminology in Portuguese differentiates between them, such as: "o largo", "o terreiro", "o campo", "o rossio", which in English equate to "the square" or " the public square". We excluded spaces that typologically act as a channel, like a street. If spaces, originally or at one time or another, had a clearly identifiable sub-type or affectation, as they developed the clarity of these distinctions often became foggy.

As urban features, the selected spaces are an integral part of the urban fabric, possessing a formal, functional hierarchical relationship with the other features that they comprise. In this way, analysis cannot ignore the context, and the spaces chosen were always approached as being part of a whole.

Our benchmark reference work was the *Encyclopédie de l'Urbanisme*, coordinated by Robert Auzelle and Ivan Jankovic, whose preface describes the work as "an irreplaceable instrument of work and culture". We believed that this study could meet these same objectives.

In this way, our aim was twofold in the way we approached the topic, that is, studying one of the components of the urban layout through classical representation methods of the structures, as well as using auxiliary illustrations and characterisations, carrying out analysis with all the due rigour of our field, yet remaining legible to the general public. On the other hand, it can serve as an instrument for practising urbanism, as well as teaching it, insofar as it studies the selected spaces in a methodical and comparable way

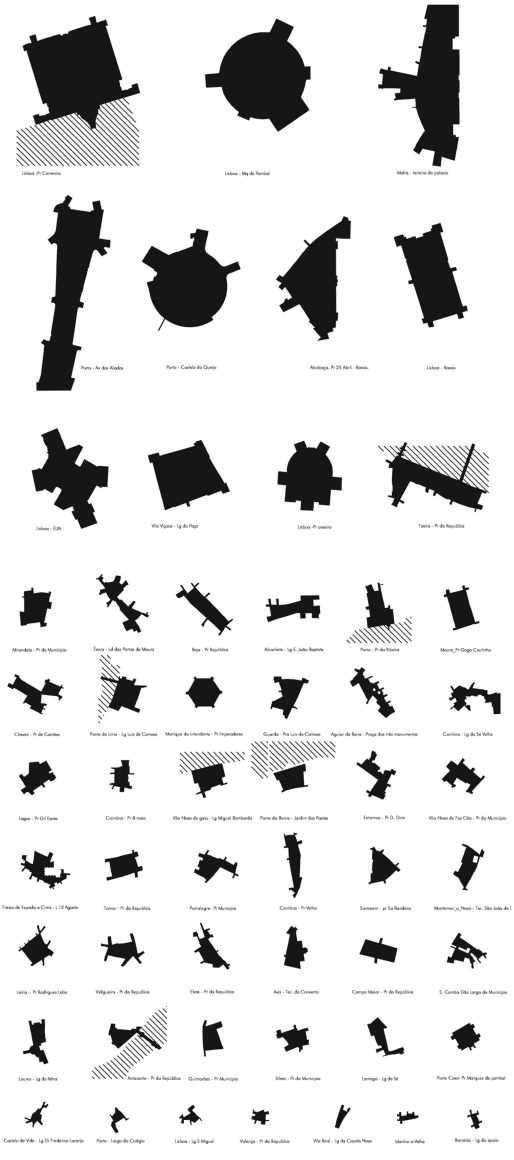

Figure 1. The Squares in Portugal – A Public Space Inventory. Squares layout comparative table.

as being examples. Its operational nature rests on the ability to be a reference for designing contemporary urban structures.

2 CONTEMPORARY DESIGN OF SQUARES

2.1 *From research to practice*

Informed by the research work that makes up the inventory of public squares in Portugal, published in 2007 and developed in the Faculty of Architecture of the University of Lisbon, part of the research team has developed at the same time two projects for very different public spaces: one for a church square in Bobadela, a small village near Coimbra, in the centre of Portugal, and the other one for a new square in the Azorean island of Santa Maria.

The first square has been an important public space since the early Roman occupation of the site; the second is a completely new public space that was previously occupied by an urban block.

Although the context and objectives of each project were different, the morphological recognition of each place was the common initial step of the design approach, with a similar methodology to the public squares inventory. Therefore, each space was represented with classically drawn features, such as plans and cross sections, as well as photographs of the environment, considering perspectives deemed to show the characteristics of the space, outstanding features and notes on details or the space's way of life, and a synthetic characterization text dealing with the urban nucleus, looking at historical development and morphological characterization, mapping the morphology of the space, its origins and its main uses.

This primordial physical and social interpretation of the place was the key for the design and transformation of each of the public spaces.

2.2 *Adro da Igreja, Bobadela, Oliveira do Hospital*

2.2.1 *Background*

Nowadays Bobadela is a small village in the Beira. What is so particular about it is that it marries the organisational and formal characteristics that can be seen in similar places with the architectural structures of a Roman city. This reality enables us to understand its origins, which date back to the establishment of a city of the Roman Empire. We do not know the name of this city today, nor do we know a great deal about how it developed with time, the points that stand out being when it was the municipal seat with a charter awarded by King D. Afonso III and, after the administrative reforms of the 19th century, when it was integrated into the Oliveira do Hospital Municipality.

The urban layout reveals the tension between the orthogonal nature of the Roman city, which can be seen in the alignment of the central area's buildings and the two backbone axes, one North–South which enabled the urban development of Senhora da Luz, and another East–West squashed in between the arch and the cemetery road, and the buildings and walls shaped by a snaking road, opened at the end of the 19th century, which encompasses the more central nucleus adjoining the Mother church.

The imbalance in the overlapping churchyard and forum can only be perceived through the different paving, as features that were of major importance in defining the Roman space cannot be seen today, such as the large temple located under the foundations of the 17th century mansion house. The continuing existence of a urban place in Bobadela that has brought urban centrality for almost two millennia is exceptional in urban development. Despite each cultural

period's changing roles, when loss of meaning justified removal of many of their buildings, one common space bolstering this evolution remains visible. The churchyard is still the small urban nucleus' most important space, marrying religious, administrative and social functions. It stands out as a symbolic, emblematic space for its inhabitants.

2.2.2 *Framing*

The remaining structures of the old Forum of the Roman city have a clear presence in the central area of the village, composing part of the whole built ensemble along with the church, manor houses and vernacular buildings. Although it has lost its significance and suffered a process of dismantling for about fifteen hundred years, it is still possible to understand the importance of the Roman city by the amount of existing traces, namely the east entrance of the Forum, the Roman Arch of Bobadela, classified as a national monument.

The space is demarcated to the south by the Mother church, an edifice that was rebuilt in the 18th century, and a massive old cedar tree, to the west by a sober 17th century mansion, to the north by a building constructed over the forum's north-eastern wedge, which is presumed to have been the Curia of the Roman city, whose walls include, together with reworked Roman features, constructions from differing periods, two highlights of which are a Manueline door and a protruding porch.

The eastern limit is not very well defined or consolidated, with various building and walls hugging the road's north–south axis. The Roman arch giving access to the forum plays the leading role as the composition's central feature. It stands out from the other major significant features, such as the pillory, the cross and even the small columned stretch.

2.2.3 *Design*

With the intervention undertaken in Adro da Igreja of Bobadela in 2006 it was intended to create a specific and identifiable space, able to merge in the same place two very different urban objects – the churchyard of the village and the Forum of the Roman city – allowing both its formal and functional coexistence, synthesized on an intervention that seeks an outstanding qualified architecture.

The planned rehabilitation will aim to give a new role to this area that plays, in the urban context of the village, collective functions of great importance. Thus, we intended to enhance the historical and aesthetic value of the set, aligning it with the daily life of its inhabitants, current depositary of these values.

The project stems from the strengthening of the Roman Forum elements and its compatibility with the existing urban context of Bobadela, valuing the buildings better architectural quality and mitigating the impact of dissonant buildings.

As the principles of the intervention are based on an enhanced reading of the Roman pre-existences, it proved essential in methodological terms, confirming the idea formulated for the reconstitution. In this sense,

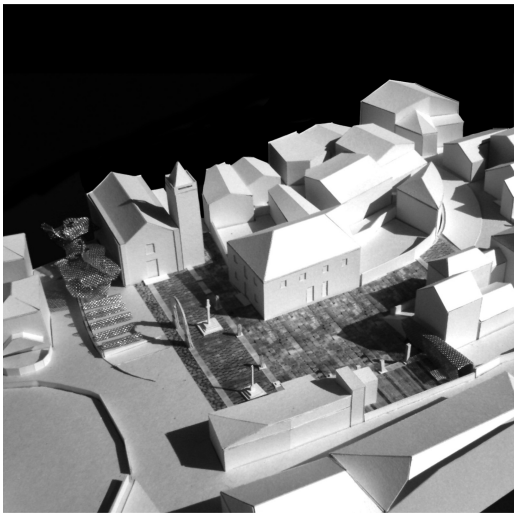

Figure 2. Adro da Igreja, Bobadela, Oliveira do Hospital, Coimbra. Project model.

places of archaeological survey were indicated strategically upon, focusing especially on the churchyard area and the likely limits of the Forum. The result of this operation and the traces found justified occasional adjustments in the development of the project.

The information obtained from the archaeological surveys has reinforced in the design of the square some hypotheses initially placed, particularly with regard to the constitution of the eastern gallery and the south limit of the ancient Forum, as well as rectify some intentions from the preliminary study of the project such as the drawing of the eastern extension of the *cardus*.

The solution is based, firstly, on the laying and recovery of pavements in the precise limits of the Forum, identifying the outer causeway, the outer wall, the gallery, the alignment of the colonnade, the courtyard and the basilica. These pavements are visually distinguished by the stereotomy of the granite pieces, in shape and size, noting clearly the alignments and accusing greater regularity in the gallery carpet than in the courtyard. The basilica, translating an interior space, is paved in recycled wood, with a level gap in relation to the ancient Forum courtyard pavement. The remaining spaces that did not belong to the Forum building are, as a rule, paved on the continuity of existing pavements.

Secondly, the solution proposed the strengthening of alignments using vertical elements, of which should be highlighted the rise and consolidation of the Forum northern wall, the elevation of the eastern wall of the Forum between the parish house and the road and also the placement of columns in the eastern alignment of the ancient colonnade and the north wall of the roman basilica.

Thirdly, we intended to create articulation elements between the Roman and contemporary structures, such as the ramp on the alignment of the arc, an operation

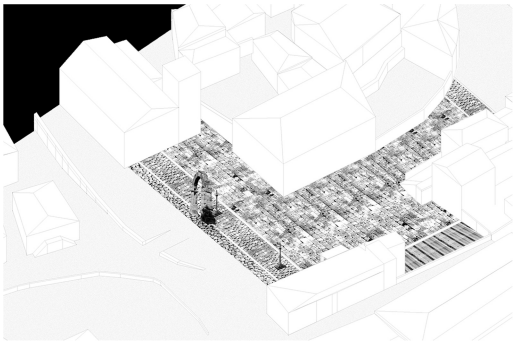

Figure 3. Adro da Igreja, Bobadela, Oliveira do Hospital, Coimbra. Pavements render.

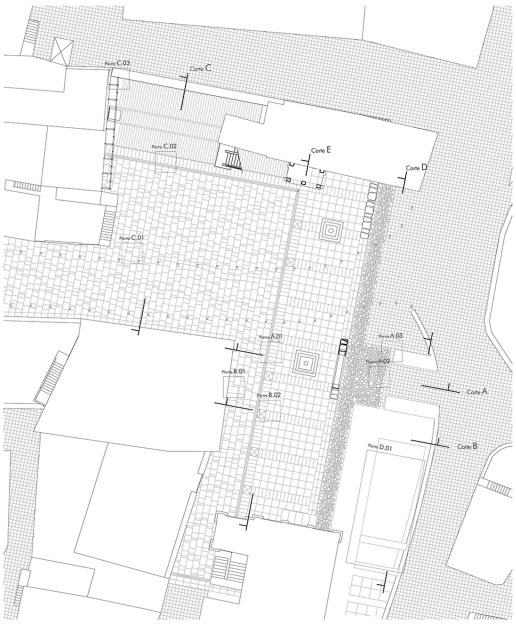

Figure 4. Adro da Igreja, Bobadela, Oliveira do Hospital, Coimbra. Plan of the project.

that required the relocation of the local pillory from where he was placed in the remodelling carried out at the beginning of twentieth century, in the alignment of the cruise cross. In this context, the design considered the extension of the boxwood garden by the east wall, the resulting composition designs with rigour small living spaces on a sand bed box.

2.3 *Praça Gonçalo Velho, Vila do Porto, Santa Maria, Azores*

2.3.1 *Background*

The urban nucleus of Vila do Porto is the foundational settlement of the human occupation of the Azorean Islands and dates back to the 15th century.

The main street that departs from the fort on its southern edge and runs along the ridgeline of the "hump" where the village sits structures both the urban layout its image. One of the features of this structuring urban axis is to be dotted by exceptional public spaces, squares that invariably are aggregated in pairs, one on each side of the main street.

Located on the southern and more ancient part of the urban nucleus, the urban block that gave origin to the new square had undergone a slow and progressive process of ruin, keeping standing only a small number of warehouses on its south edge. The space was open, without any kind of treatment and led to an informal occupation of car parking.

The creation of a public space in Frei Gonçalo Velho Street, part of the main axis of the village, constituted a commitment that the City Council of Vila do Porto took when purchasing a set of buildings in ruin. These void plots, since demolished, constitute assets of the municipality acquired under special conditions for the creation of a public space. The southern plots of the block, three of which were built, were acquired afterwards, thus allowing the full transformation of the urban block from private to public space.

2.3.2 *Framing*

The space, which was object of the intervention whose project started in 2002, is consolidated in its outer limits, as it corresponds to the simple amputation of an urban block. However, the characteristics of the

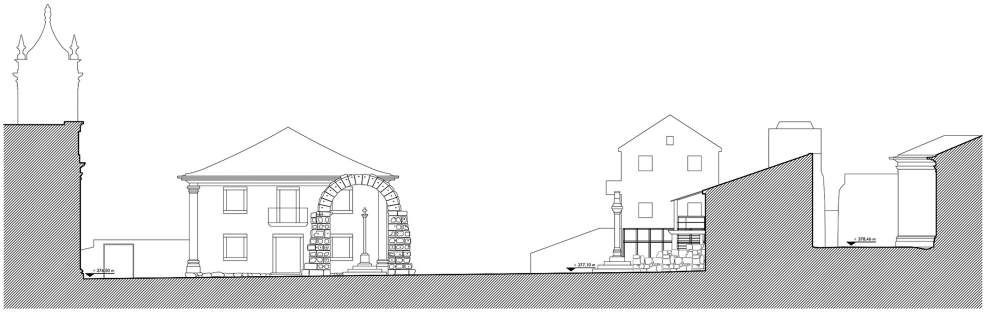

Figure 5. Adro da Igreja, Bobadela, Oliveira do Hospital, Coimbra. Cross section of the project.

built elements that define it are very distinct, existing both well-maintained buildings and in ruin, erudite and vernacular structures alike, good and dissonant architectural quality, and also contrasting dimensions.

The new urban space that was created was combined with Largo Luís de Figueiredo, a small preexistent square, in order to form a composite set of two exceptional spaces, articulated by the street Rua Frei Gonçalo Velho, with dimensions and characteristics comparable to the exceptional spaces that already dotted the structuring axis of Vila do Porto.

Although at the time of the project the space did not serve to support any special urban function, it is bordered by one of the urban blocks classified of interest of the "Ancient Area", with buildings of public ownership in ruin, which were supposed to be transformed into one of the new public facilities from those contained in the municipal development programs.

Nevertheless, this new composite exceptional space would always be an urban element of articulation, the nodal point between Rua Frei Gonçalo Velho and the beginning of Rua da Misericórdia, and also conforming an inflection of the structuring axis of the village.

2.3.3 *Design*

The project thus stems of the principle of the creation of an independent and identifiable space, referenced to an implied general evocation of the memory of the settlement itself that might be translated into an artistic element or embedded in the design of the space. It also sought to enhance the buildings of better architectural quality as opposed to mitigate the impact of the dissonant ones in a space that is to be of collective use, allowing mixed appropriations and contemplating some car parking spaces.

As acknowledged on the inventory of Squares in Portugal, the waves are used as a common composition motive of ornamentation of the pavement. Initially these waves appeared in the Lisbon Rossio and were later exported to other geographical overseas contexts, such as Brazil and Macau, or reinterpreted in more recent urban contexts, such as in the Expo'98 Rossio dos Olivais, but always as a two-dimensional design. The use of waves as a three-dimensional composition motive stemmed from the topographical nature of the space and the wish of evocating the overseas genesis of the foundation of the settlement.

The solution was based on the continuity of the pavement from the main street, Rua Frei Gonçalo Velho; the progressive waving of the topography of the surface gradually increases to the intersection with the supporting wall, an element that absorbs the gap to the lower level of Rua da Misericórdia. This ripple is more evident in northern top while it diminishes to the southern part of the square in order to allow uses and appropriations that require a more straightened surface. The dynamic effect of the waved surface is reinforced by a chromatic nuance achieved from the introduction on the black pavement of a progressive white marking on the edge of each wave.

In order to accentuate the pavement, predominantly black, it contrasts with the retaining, enclosing wall, white in vertical planes.

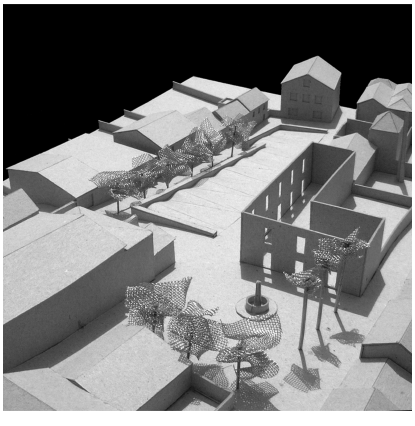

Figure 6. Praça Gonçalo Velho, Vila do Porto, Santa Maria, Azores. Project model.

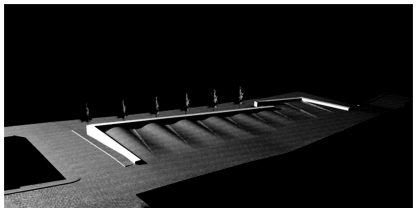

Figure 7. Praça Gonçalo Velho, Vila do Porto, Santa Maria, Azores. Pavements render.

Figure 8. Praça Gonçalo Velho, Vila do Porto, Santa Maria, Azores. Plan of the project.

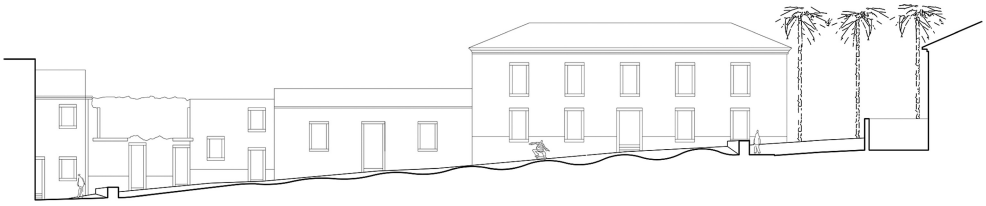

Figure 9. Praça Gonçalo Velho, Vila do Porto, Santa Maria, Azores. Cross section of the project.

This wall hides the parking spaces and regulates the placement of alignment trees. More than shading the parking spaces, the trees filter out the impact of dissonant buildings in the square. The rhythm of the waves and the trees is further enhanced by the water gargoyles, ripped in the supporting wall and connected to each of the trees in order to take advantage of the runoff water when it rains.

Here we introduced a dark red color note on the treatment of metals – grills, gutters, etc. – and the trees themselves – Paulownia tomentosa – flowering in red.

The materials chosen seek to ensure a great continuity with the flooring of "Ancient Area" of Vila do Porto, using cobbled black basalt and white limestone, recovering the vertical walls with plaster and whitewash of the village walls and using one of the species of trees previewed to be planted on the adjacent Largo D. Luís de Figueiredo. The introduction of a discreet contemporary note is given by the use of the rusted metal.

Lighting contemplates the continued existence of the street lighting framing the space, although introducing a new logic for the space itself. This accentuates the arboreal elements by illuminating their tops, and accentuates the design and shape of the floor through a skimmed light on the white face of the pavement of the waved surface, allowing an enhanced reading of the space during the nighttime.

3 MEMORY AND DESIGN

At the beginning of the 21st century, urbanism practice, the philosophy of intervention in cities and the idea of the city itself were showing less utopian signs than in bygone eras, due to several factors. These include the Modern Movement crisis and its models, and getting back to cities as points of reference, as well as the perspective of, if not disjunction in cities, then at least their illegibility in terms of traditional urban morphologic concepts.

In the more speculative predictions of the future of the city, the urban space as a support for human relationships, material and spiritual exchanges and even traffic has been superseded in favour of immaterial media, without either establishing the fate of the city's structures or introducing new morphologic models as a response to a different society. The 21st century city will naturally be different to the city of the previous century, I as this was from the industrial one, and this one from the city of Modern, Medieval or Ancient History. However, the inevitable end of the city that some predict is not a certainty, and what is more probable is that there will be developments towards new meanings which will contain the tensions between the city's structural legacy and its constant renovation. This object – the city – has always shown signs of obsolescence, due to its own nature and dynamics.

The policies of recuperating historical centres, so commonplace from the mid-20th century on, in a process increasingly apart from the phenomena of growth that has, in most cases, shaped urban peripheries, has support not only in theoretical musings, but also in public opinion, shaped as it is by a great deal of nostalgia and opting for the safe choice of preserving this value. We should not manacle urbanity to the historic centre, nor to the inevitability that urban renaissance has to make use of past shapes. However, the structural examples we inherited, which are part of our city life, will always be a driving force in new spatial conceptions.

The cases presented on this paper configure two examples on how an interpretation methodology of the urban space developed in the Academy and consisting in the recognition of the values of the spirit of the place, read in the morphology of the urban artifact itself, may contribute for the contemporary architectural and urban design of spaces with the evidence of their own memory.

Note on images: all plans are north oriented.

Evaluating sense of community in the public spaces of residential neighborhoods in Tehran, Iran

Hanieh Haji Molana
Kent State University, Kent, Ohio, USA

ABSTRACT: Sense of community is one of the significant theories in sociological and psychological research that investigates the relationship between physical environments, individuals' feelings, and interactions in a community. Previous studies in social science and environmental psychology indicate that the overall arrangement of a community and its architectural style, as well as many other physical environmental features, play a vital function in fostering and creating sense of community. McMillan and Chavis defined sense of community as "a feeling of belonging, a feeling that others matter to one another and to the group, and a shared faith that personal needs will be met through a commitment to being together." The advantages of sense of community are various and potentially embrace increased participation in community affairs and social activities, better physical, mental health, and well-being, finally improve people quality of life. This research evaluates several hypothesis from sociology and psychology to architectural studies that create and reinforce sense of community in distinct residential neighborhoods in Tehran, Iran. Data was obtained from individual interviews, indirect observation, and surveys. The analysis indicates the greater role of socio-demographic features instead of architectural factors on affecting sense of community. The presence of public spaces, green areas, and building layouts are not solely guaranteed to enhance sense of community. However, influential social variables like length of residency, socio-economic status, age, and gender, also affect residents' feelings, behaviors, and interactions that contribute to sense of community. The balance between social and architectural elements together will create a robust and resilient sense of community. Identifying the conditions that reinforce sense of community within residential neighborhoods is an essential task for researchers and designers to promote individuals' feeling of safety, security, civic responsibility and improve their physical and mental health. The findings of this study rely on residential areas in Iran, but can likely apply to residential neighborhoods globally.

1 INTRODUCTION

1.1 *Community*

Society is made up of three main components of communities, individuals, and physical environments. A large proportion of human experience and social interaction occurs in communities and physical environments in which we live. The community is where individuals learn to communicate, interact, behave, and share interests and problems; it is where cultural and social norms form and connect to a larger society. Community psychologists and sociologists, define two main sets of characteristics for community: structural and functional. (i) The structural factor consists of the people and the physical environment where people live and interact. (ii) The functional factor results from the structural patterning that includes the people's interaction in a particular physical environment, community participation and social networks (Giuliani & Wiesenfeld 1999). A "sense of community" is the result of the correlation between these two factors.

There are numerous definitions for sense of community in other disciplines. This research focused on MacMillan and Chavis (1986) articulation of a theory that suggested four elements form sense of community: membership in a group, a shared emotional connection, mutual influence on one another, and sharing of values among community members. These four suggested components dynamically work together to create and maintain sense of community among individuals in a community. At the neighborhood level, a strong sense of community makes residents have a greater feeling "*of safety and security, participate more in community affairs*", and help one another voluntarily in tough situations (Schweitzer 1996). Moreover, at the individual level, it improves a person's sense of self-efficacy, well-being, level of life satisfaction, and can help the individual to deal with stressors in their community in proactive ways (Davidson & Cotter 1991).

2 RESEARCH JUSTIFICATION

2.1 *Justification of objectives*

The author recognized the fragility of Iran's architectural identity which is threatened doubly by designers who dismiss the value of historic regional contexts and

the desire of wealthy clients to imitate European and American designs. By considering it as a threat to people's culture and identity, this research focuses on the relationship between built environments on sense of community.

The purpose of this paper is to evaluate sense of community by employing an ethnographic approach through qualitative research methods, in order to investigate the ways in which various aspects of physical environments (public spaces and building layouts). It also investigates socio-demographic features (class, gender, age, length of residency, expected length of residency, the presence of children, and quality of interaction) contributes to residents' sense of community. The study used three residential neighborhoods in Tehran, Iran. The author incorporated social science research methods to evaluate residents' sense of community to explain the results of observational research. The ideas presented in this article will apply equally to structural factors (neighborhoods) and functional factors (spiritual, behavioral, emotional).

The objectives of this study are to (i) analyze possible physical and social variables that strengthen or weaken sense of community, (ii) evaluate three different architectural styles and scales and how each contributes to sense of community (iii) assess the role of public spaces in people's quality of interaction and sense of community.

2.2 *Research questions*

The following research questions address the objectives of this study:

(i) What social and architectural variables strengthen or weaken sense of community?
(ii) How do public spaces in a community affect the residents' interaction and communication?
(iii) How do the four indicators of sense of community apply in the three case studies?

3 SENSE OF COMMUNITY

3.1 *Definition*

This research builds upon the earlier findings of Glynn (1981), McMillan and Chavis (1986), Chavis and Wandersman (1990), Nasar and Julian (1995), Talen (1999) and Obst, P., L. Zinkiewicz and S. Smith. (2002) in defining and developing sense of community. There has been no generally accepted definition of sense of community because of its multidimensionality. However, David W. McMillan and David M. Chavis (1986) introduced the most accepted theory and definition by using four leading indicators that maintain or create sense of community: membership, influence, integration and fulfillment of needs, and shared emotional connection. Based on these four components, they defined a sense of community as "*a feeling that members have of belonging, a feeling that members matter to one another and to the group, and a shared faith that members' needs will be met through their commitment to be together"* (McMillan & Chavis 1986).

3.2 *Components*

"Membership" is a feeling of belonging and having rights for being part of a group. People's adverse action, depression, and loneliness are some of the consequences of lacking this feeling in a community. Five attributes of membership include boundaries, emotional safety and identification, personal investment, and common symbols that work together to strengthen the sense of membership and a sense of who is part of the community and who is not (McMillan & Chavis 1986).

"Influence" is a mutual feeling. Both community and individuals have interrelationships with each other. The group can affect the actions, behavior, opinions of an individual. However, an individual can have an influence on the group or community (McMillan & Chavis 1986).

The third component "integration and fulfillment of needs" constitutes a substantial proportion of sense of community and plays a crucial role in community success. It is a motivator of behavior and maintains the positive sense of togetherness among members (McMillan & Chavis 1986). Shared value is a crucial concept in needs fulfillment. Members should be able to satisfy their needs to the extent that each member can share their needs, goals, priorities, and beliefs with each other (Cohen 1976, Doolittle & MacDonald 1978).

The last element "shared emotional connection" is where the people's feelings, perceptions, and spiritual bonds come into play. The more individuals interact and share history the more likely they have become closer and develop meaningful and fulfilling relationships within the group (McMillan & Chavis 1986). Cook (1970) in his research studied the importance of the quality of interaction; *"The more positive the experience and the relationships, the greater the bond. Success facilitates cohesion."*

3.3 *Advantages and disadvantages of sense of community*

Previous research in social psychology indicates that loss of "sense of community" in modern societies are due to industrialization, lack of local autonomy, the culture of mobility and large-scale bureaucracies. They believe that the overall layout of a community and architectural style, as well as many other physical features, play a vital function in achieving it (Nasar & Julian 1995)

Having a sense of community at the neighborhood level, can increase people's feeling of safety and security; encourage them to participate in community affairs and social activities, and having better physical vitality, mental health, and well-being—in terms of improved happiness and decreased anxiety (Davidson

& Cotter 1991). Consequently, it can improve the individual satisfaction, sense of self-efficacy and help individuals to deal with stressors in their community in proactive ways (Schweitzer 1996).

On the other hand, a strong sense of community can be neutral or negative. Based on Brodsky's (1996) research on resilient single mothers living in dangerous housing projects, having a sense of community can be harmful to families, in particular for children. The mother in her study preferred to keep her children away from youth groups or gangs in a community. She believed it was children's advantage to have a weak sense of community. From the perspective of mothers, children engaging with a community is equal to losing their values and therefore threaten the family's safety.

Strong communities are those that offer their members positive ways to interact, establish important events to share, resolve disputes positively, provide opportunities to honor members, resources and time to invest in the community, and opportunities to experience a meaningful connection between members.

4 SENSE OF COMMUNITY AND BUILT ENVIRONMENTS

The use of sense of community presented in this paper applies equally to its relationship with built environments and socio-demographic features of a community. Prior studies in New Urbanism asserted that the existence of public spaces, innovative architecture and site design, appropriate density and scale, and mixed land use can enhance the opportunity for interaction and create sense of community (Talen 1999).

Various studies with focusing on residential neighborhoods and sense of community showed the substantial impact of public spaces and green areas on the individuals' quality interaction and mental health. The work of Nasar and Julian (1995) on 54 residents in three suburbs of Columbus, Ohio revealed that the easy access to shared outdoor green areas and interior courtyards can improve the possibility of creating a stronger sense of community among residents. Their findings have some correlations with this research. The author's indirect observation and interviews with residents reached the assumption of the complex without public spaces, and green areas will not have the same strong sense of community as it has now.

Other studies focused on the relationship between residents' sense of community and the easy access to pedestrian paths, having front porches, variety of nearby commercials, recreational, and educational services in strengthening and reinforcing sense of community (Plas & Lewis 1996, Glynn 1981, Wilson & Baldassare 1996, Nasar & Julian 1995).

On the other hand, the relationship between sense of community and physical environment is not always successful. Kingston, Mitchell, Florin, and Stevenson (1999) by analyzing an existed database of 2,409 residents of a Northeastern American city, found out sense of community is more correlated with individual variables such as; income and level of education than the physical environment. However, the author caution that the study has not employed a set of complex environmental ratings to adequately investigate the link between the built environment and sense of community.

Besides socio-demographic factors, the presence of public spaces, green areas, pedestrian paths, and public amenities are not sufficient to create and foster residents' interaction and sense of community. Paying attention to creating active public spaces (not symbolic) with high quality is one of the crucial tasks of architects and designers to improve people's quality of interaction, communication, and positive feeling within a community.

5 SENSE OF COMMUNITY AND SOCIO-DEMOGRAPHIC FACTORS

Literature reviews in community psychology, and social sciences regarding sense of community and its relationship with social sciences demonstrate several contradictions in some socio-demographic factors, such as the length of residency, the level of education, and residents' age. This research with focusing more on these factors and testing them, besides other aspects, evaluates sense of community in three distinct residential neighborhoods.

Based on Glynn research (1981) factors such as length of residency, resident's expectancy to live, and the number of neighbors identifiable by their names, show the strengthen of sense of community. On the other hand, Davidson and Cotter (1991) developed a 17-item scale to evaluate the relationship between sense of community and subjective well-being in three distinct case studies in South Carolina and Alabama, did not find a correlation between residence length of residency and sense of community.

Other studies investigated residents' age and showed that older adults have a stronger sense of community (Wilson & Baldassare 1996, Davidson & Cotter 1986). However, Korte (1988) argued the concept of "community helping," which is one of the key factors in having a stronger sense of community, is more correlated with young people and with a higher level of education, as well as married people. Buckner's research (1988) showed that people with lower level of education can have a stronger sense of community.

Other socio-demographic features related to sense of community consist of the study of Wilson and Baldassare (1996). They investigated sense of community in a suburban neighborhood in Orange County, California. Surprisingly the results showed that 68% of residents believe that there is a strong sense of community among neighbors in the community. The authors found that the satisfaction with a level of privacy and localism were two important factors in having an overall sense of community. By privacy, the authors

mean a controlled interaction within a community, not withdrawing from people and social life. The residents believed that the desired level of privacy decrease unwanted interaction help individuals to have a lower level of personal stress, more positive relations with neighbors, and a stronger sense of community.

Beside all these findings, other studies showed the important role of women and children in fostering sense of community. Having children at home is associated with people interacting more in public spaces and participate in community activities (Obst et al. 2002, Nasar & Julian 1995). In most societies women traditionally have wider neighborhood networks, more intense relationships with their neighbors, and greater social interaction than men. Thus, we can conclude that matters of gender and gender roles require greater consideration in creating and reinforcing sense of community (Campbell & Lee 1992, Willmott 1987 & Fischer 1982).

Overall data analysis revealed that the significant socio-demographic factors that make the residents' sense of community strong are: residents' similar socio-economic level, long length of residency, expectancy to live longer in the community, safety and security, having children in families, community helping, and participation in community activities.

6 METHODOLOGY

6.1 *Case studies*

This part of the paper will explain the methods chosen to evaluate the relationship between sense of community and built environment. The research methods selected in this study were developed to measure sense of community within three different residential areas and to identify the various physical and sociological characteristics within residential neighborhoods that might affect sense of community measurements. The significance of this study and the methods used is their usefulness and transferability in evaluating sense of community in other residential or non-residential environments.

The primary focus of the research is to assess the interrelationship between sense of community and built environment in three different residential areas in Tehran, Iran: Sheikh Hadi residential neighborhood, Ekbatan residential complex, and Vanak Garden residential building. Each case study selected depend on; a) the architectural style (contemporary, modern, and traditional), and b) community scale with presuming that the assessment of sense of community is not similar among residents in each case study.

Chavis, Hogge, McMillan and Wandersman (1986), examined the McMillan and Chavis (1986) theory and definition of sense of community based on Brunswick's test. Research findings developed and empirically tested Sense of Community Index (SCI), which is widely used to measure sense of community among adults in a community. This paper also employs this questionnaire for measuring the residents' sense of community in the three case studies.

Research data collection built upon the qualitative research methods, such as individual interviews, indirect observation, and questionnaires (SCI). Each section focused on different aspects of sense of community. Individual interviews were focused on residents' length of residency, expected years of living in the neighborhood, their need's fulfillment, places of interaction, and their feeling as a member of the community. Indirect observation looked at the residents' quality of interaction and public spaces, community activity, resident's socio-economic level, and community boundaries.

Finally, the questionnaire (SCI) used was based on four components of sense of community, measuring the overall sense of community among residents. All research instruments were translated into Farsi (native Iranian language) in order to accurately evaluate sense of community.

6.2 *Sheikh Hadi Neighborhood*

Sheikh Hadi Residential Neighborhood is located in one of the most crowded, polluted and oldest areas of Tehran with approximately 33,000 population in 2007. The history of the neighborhood dates back to the reign of Reza Shah (King of Iran) in the 19th century. The area still keeps the arrangement and urban texture of the historic neighborhood and exemplifies a traditional sense of place. However, the visual image of the neighborhood at street level does not represent the qualities and patterns of historic Iranian architecture due to the demolition of vernacular designs and the construction of more modern buildings (Figure 1).

Easy access to all kind of urban amenities such as taxis, buses, metro, hospitals, schools, public libraries, museums, shops, and markets put the neighborhood in the heart of the city. Low-income families tend to live in the neighborhood due to the reasonable cost of living for poorer families to buy or rent affordable apartments.

Figure 1. Buildings in Sheikh Hadi Neighborhood, traditional vs. contemporary.

Figure 2. Public Park in Sheikh Hadi Neighborhood.

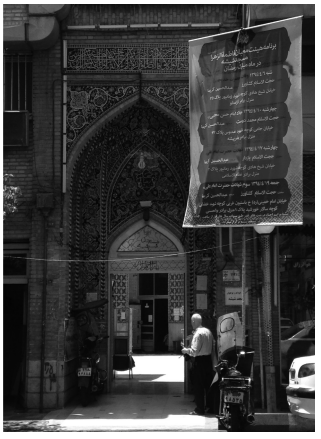

Figure 3. Mosque in Sheikh Hadi Neighborhood.

Sheikh Hadi neighborhood suffers from a lack of public space and especially green areas. The public park and mosque in the neighborhood are two significant places that bond residents together. The author collected research data from people in these two public places (Figure 2–Figure 3).

Questionnaire analysis in Sheikh Hadi showed that the percentage of each sense of community components (*membership, influence, integration and fulfillment of needs, and shared emotional connection*) is higher in women than men. Also, the overall percentage of sense of community among Sheikh Hadi neighborhood residents is greater than an average, which is 59%.

Coding the individual interviews indicated that the people can fulfill their needs within a community. Therefore they prefer to stay in a neighborhood. However, the lack of safety and security of the area makes the situation difficult for women to interact at night. Also, it should be noted that because of the residents' social and educational level, many of the residents are unemployed, with women and seniors forming the majority of residents with the time to support community. Therefore, women and seniors have more opportunity to communicate and interact in public places. This interrelationship between public spaces and residents give meaning and boundary to the park and mosque.

The authors' observation mapping and coding showed that the people interact at certain times of the day (the prayer times in the mosque, and before prayer times in the park). Also, besides the high quality of places, religion and faith keep people together and affect their quality of interaction and feeling like a part of the community.

Data analysis in Sheikh Hadi Residential Neighborhood indicates that the park and mosque in the neighborhood play a vital function in achieving and creating sense of community among residents. People's quality of interactions and communications in these two places are more than in other places such as shops, malls, museums, and libraries. In addition, socio-demographic features such as people's socio-economic level, age, length of residency, their expectancy to live in the neighborhood, community helping, having children, and need's fulfillment are contributing to fostering sense of community.

Figure 4. Ekbatan residential complex (Source: Google).

6.3 *Ekbatan residential complex*

Tehran (capital city of Iran) is deeply polarized. North of the city is where the rich and upper class live, and south is for the poor and the marginal. The Ekbatan complex is located in a neutral urban area, physically and socially accessible to many people. It is a planned town built as a project of modern apartment buildings in the western part of the city in the mid-1970s. The goal of the project was to create the most modern housing project in Iran, based on the European and American urban planning elements to control Tehran's population patterns (Dash 2015). It is the largest residential complex in the Middle East with 15,500 units for 70,000 inhabitants in three phases with all kind of amenities such as schools, a hospital, parks, libraries, mosque, shops, and malls (Figure 4).

Phase One of the complex was completed before the revolution in 1979. Consequently, many of the public spaces were changed. As an example, outdoor pools were filled, and residents were prohibited from using the rooftops. This research focuses on the

Figure 5. Public areas and green spaces.

Figure 6. Parkour and graffiti (source: Google).

residents in Phase One to evaluate sense of community and its correlation with built environment and socio-demographic features.

Questionnaire analysis showed that Ekbatan has the highest overall sense of community among all the other case studies which is %69. All sense of community components (membership, influence, integration and need's fulfillment, and shared emotional connection) are higher in women and young people than men.

Individual interviews and indirect observation revealed the reasons behind the strong sense of community among residents in Ekbatan. Architectural factors such as high quality of public spaces and green areas, building layouts, pedestrian areas, parks and public facilities (shop, mall, school, library, Metro, mosque, and sports center) play a significant role in improving people's quality of interactions, communications and positive feelings within a community (Figure 5). Accessibility to all kinds of services and needs keep people in the community and make them behave and feel like a large family.

Ekbatan is not only a residential complex but may also be considered also a lifestyle and an instigator of popular culture. It is the place where the street arts of parkour and urban graffiti started in Iran. The sense of community is stronger among young people, especially boys. They see Ekbatan as a part of their territory, which makes strong boundaries for community members and the complex (Figure 6).

Residents' similar socio-economic level, long length of residency, expectancy to live longer in the community, safety and security, having children in

Figure 7. Vanak garden residential building.

families, community helping, participation in community activities, educated and married people are most significant factors that make the residents sense of community strong in Ekbatan Residential Complex.

6.4 *Vanak Garden Residential Building*

Vanak Garden Residential Building was built in 2009–2010 and located in the Dehvanak region, which is one of the areas that upper-class families live in the central part of Tehran. The area was once full of large gardens; developers and property owners used green space to construct high rise residential buildings which have significantly changed the character of the area. Vanak Garden is the third case study to evaluate the residents' sense of community in contemporary design with a different building scale (Figure 7). The investigations link architectural factors and socio-demographic features in an attempt to assess sense of community among residents.

Interviews with the architect of the building demonstrate that the core idea of the Vanak Garden design was to improve residents sense of community and revitalize the old sense of place in a metaphoric way. This link was accomplished by keeping some of the original trees (as wooden sculptures, forming symbolic groves throughout the complex) and arrange the apartments around the central courtyard with a small fountain. In addition, features such as traditional materials used in the building, greenery, small sitting areas on each floor, and suspended gardens foster and create a positive visual experience intended to support interaction and improve the quality of spaces (Figure 8).

However, questionnaire analysis showed that despite the high quality of public spaces and shared areas, Vanak Garden Residential Building has the lowest sense of community among other case studies which is 37%. Men in the community are more involved in reinforcement of sense of community than women. Feeling of membership and shared emotional connection are the two lowest factors among residents that make the overall sense of community fragile.

Figure 8. Courtyard and green areas.

In contrast to research of Brown and Cropper (2001) and Jack Nasar (2003) regarding the New Urbanism design features in creating and supporting residents' sense of community, Vanak Garden, with having high quality of public spaces (courtyard and green areas) and preserving the original sense of place (with the aid of sculptural reminders of the original trees and materials used in the building) did not support their claim. Public spaces and green areas are more symbolic than active in a sense of creating and fostering the residents' quality of interaction and communication. Also, the building design and spatial arrangement are organized to preserve residents' sense of privacy, safety and security; this strategy for privacy between residential units directly challenges sense of community.

Interviews and indirect observations showed that the parking, entrance, and elevators are the places that residents interact and communicate most with one another, which does not have high architectural quality or value in contrast with the high quality of public and green spaces. Based on the author's experience in the Vanak Garden residential building, people were less sociable and declined to participate in this study. Most of the community members are employed and spend their time out of the complex.

The courtyard and public places are empty generally, and only families with children use public spaces and other facilities. Interviewing residences showed that children playing in the courtyard disrupt the residents' peace (because of their noise) and the residents' frown upon children playing in public spaces. Therefore, families take their children out of the complex for entertainment. In this case study, architectural features do not support the residents' sense of community and interaction.

In addition to architectural factors, the residents' socio-demographic features affect sense of community among community members. High socio-economic level and financially stable situations make people more independent and autonomous. Therefore, they tend to interact and communicate less with each other because they do not need each other's help. On the other hand, since the complex is relatively new, the limited duration of residency and expected the length of time to live in the community are doubly threatening the residents' interaction and the opportunity to create sense of community.

7 DISCUSSION AND FUTURE RESEARCH

This paper investigates three distinct residential neighborhoods in Tehran, Iran to evaluate residents' sense of community and assess the role of physical and social features each independently in affecting residents' sense of community, interaction, and communication.

By studying sense of community, built environment and socio-demographic features in residential neighborhoods, the author noticed the mutual relationship of sense of community with socio-demographic features, as well as built environment with sense of community. A strong sense of community can support, and over time, improve the quality of physical environments independent of people's socio-economic level. Also, based on a strong and healthy sense of community, people help other community members collectively to improve their quality of life, social status, well-being, and economic level.

Data analysis surprisingly indicates varying results derived from and between each case study. However, this variability reflects clear dissimilarities between the case studies and are at the heart of the insights and conclusions made in this study. Factors in creating or fostering sense of community are causal, variable, and independent. The role of architectural factors such as public spaces and green areas can play a significant role in creating or fostering residents' sense of community. Public spaces are like a heart and center of each residential neighborhood which can provide the opportunity for people to exchange ideas, culture and thoughts and collectively build the soul for their community *which is* sense of community. However, architectural factors such as public spaces do not solely promote or create sense of community among residents. Prominent variables such as the length of residency, age, gender, socio-economic level, and having children in a family can also strengthen or weaken residents' sense of community. The balance between socio-demographic and design features can create a robust and resilient sense of community among members.

Today, architects do not always know the people for whom they design buildings and do not know their actual needs. Many times their designs are generalizable and abstracted from the demographic information or building codes. This approach leaves out the social conditions embedded in a particular place and culture. However, there are problems with purely physical conditions, and in this study, Vanak Garden Residential Building is a prime example of an autonomous design (despite being derived from the history of the place) whose public spaces operate more like an artwork meant more to be looked at rather than used. For architects who want to understand the complex needs

of the people for whom they build, social research is bound to become a vital tool for understanding social conditions and issues (Zeisel, 1975).

This research shows the contribution of socio-demographic aspects in reinforcing sense of community. This is one of the elements for designers to consider when addressing social conditions in their designs. Architects should collaborate more with social researchers; approaching design from a sociological perspective will enhance and improve the quality of buildings and community design.

In addition, future research on the topic of sense of community should evaluate the role physical environments play in reinforcing social bonds in other places, such as students at universities or schools, patients in hospitals, and employees in their workplaces.

The new roof spaces. The legacy of Le Corbusier in the contemporary city

A. Como & L. Smeragliuolo Perrotta
University of Salerno, Fisciano, Salerno, Italy

ABSTRACT: One of the contemporary urban phenomena is the recovery of the vertical dimension of the city and the use of common spaces at the high level of the buildings. The shifting of activities to the roof – especially those traditionally at the lower or at the ground levels – is creating changes in the relationship among urban spaces, in particular in regards to the public sphere. The forerunner of the roof space use in modern architecture is Le Corbusier. This paper looks at the beginnings of the roof space concept, focusing on the specific role that Le Corbusier had in foreseeing the contemporary approach, developing issues and theoretical reflections in relation to the view from above, intertwining architecture, nature, and landscape, and leading to their integration within a broader territorial approach.

1 INTRODUCTION

One of the contemporary urban phenomena is the recovery of the vertical dimension of the city and the use of common spaces at the high level of the buildings. The observation of the city from above creates a new image of the urban reality and a new concept for architecture. In many cities roof spaces are now used for different goals: from urban vegetable gardens to outdoor cinemas, restaurants and cafés, and sports areas. The shifting of activities to the roof – especially those traditionally at the lower or at the ground levels – is creating changes in the relationship among urban spaces, in particular in regards to the public sphere. The view from above provokes reflections at a deeper level on the city design project in relation to the new possibilities and new ways of living the urban spaces, also investing the city nature itself.

The forerunner of the roof space use in modern architecture is Le Corbusier. This paper looks at the beginnings of the roof space concept, focusing on the specific role that Le Corbusier had in foreseeing the contemporary approach, developing issues and theoretical reflections in relation to the view from above, intertwining architecture, nature, and landscape, and leading to their integration within a broader territorial approach.

Le Corbusier roof-garden has often been diminished as a mere technical issue or as a simplistic reproducible solution. Even as one of the 5 Points for a New Architecture its meaning has been reduced through the slogan formula, often forgetting the thought hidden in it. Within Le Corbusier research, the roof-garden is not just one of the famous five points, but a totally new and fundamental spatial topic that explores the relationship between architecture and nature within the urban environment. It is along these lines that this paper unfolds, focusing on the thematic issues related to the shifting of the vision from that city above the city.

It is only in recent times that the landscape dimension within Le Corbusier work has been investigated. In 2013, the MoMA in New York hosted the important exhibition entitled *Le Corbusier: An Atlas of Modern Landscapes*, which highlighted the interest by Le Corbusier in the relationship between the design project, the city and the landscape, reading his design work through the landscape approach. Before that, little has been said in regards, with the exception of a seminal article by Caroline Constant and few other writings[1].

2 THE BIRD'S-EYE VIEW

The roof space is primarily for Le Corbusier the place of the conquest of the sight, it is the place from which to look far away. Le Corbusier roof spaces, whether in the city or in suburban areas, are all designed for the view from above. This is not just a new potentiality and pragmatic opportunity for the building; rather it opens up a new approach for the design project. The view from above affected Le Corbusier vision and consequently his ideas on architecture; for the architect, so highly connected to the way of seeing, architecture is in fact a process which starts from knowing how to see, as it is clarified by the famous sentence – *the key is looking … looking, observing, seeing, imagining, creating* – (1965).

[1] Constant, C. 1988. "From the Virgilian Dream to Chandigarh: Le Corbusier and the Modern Landscape". In Wrede, S. & Adams, W.H. (eds.) *Denatured Visions. Landscape and Culture in the Twentieth Century*, New York: The Museum of Modern Art.

Figure 1. Photo of the airplane in the landscape.

The view from above, and more specifically the bird's-eye view, is for Le Corbusier a fundamental topic since his youth and his development years. The importance of the view from above is experimented within nature and among the mountains: <All the years of my childhood were spent with my friends amongst nature […] We were always on the mountain peaks; the vast horizon was an everyday view. When the sea of fog below extended to infinity, it looked like the real sea which I had never seen>[2]. The aspiration to conquer the view from the summit in order to look over the ample horizon recalls one of the most famous image of contemplation of panorama, that of the wanderer above the sea of fog by Caspar David Friedrich. Similarly to the romantic sensitivity, Le Corbusier aspires to a meditative and enchanted relationship with the landscape, a condition in which the man and the architecture are projected in the boundless nature.

It is from the aircrafts, for which Le Corbusier was deeply fascinated, that it is possible to conquer the advantage standpoint and the view from above is strongly experienced. Even before having directly tried out the aircraft flight, Le Corbusier had already realized the importance that the view from the airplane would have had in architecture and in the interpretation of reality. He had in fact planned to include in his text *Urbanisme*[3] a chapter on the aerial view. A sheet[4] with images in sequence of top views of cities shows the note: <Making a paragraph on the view from the plane new state of things of the urban aesthetics as architectural sensation. Show then some plane views (topographical service) of Paris>[5]. The view from the

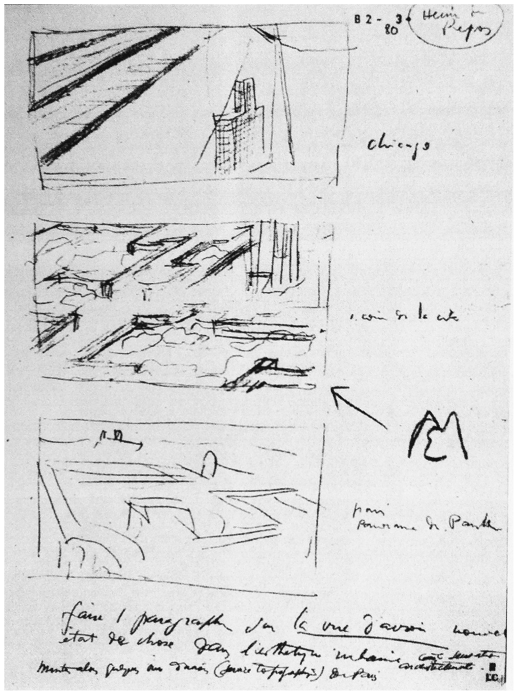

Figure 2. Le Corbusier sketch.

airplane is thus understood as carrier of a new aesthetic and programmatically used to communicate its power[6].

The fascination with the new means of transportation and in particular the challenge of the flight that had involved Le Corbusier since his childhood, will drive the architect to experience in person the airplane flight, offering the powerful vision of nature: <from the plane I saw sights that one may call cosmic>[7], wrote in *Precisions*, the text which followed the South American and Algerian experiences, that is when the architect systematically observed the territory from the airplane height. It is in this text that Le Corbusier clarifies and systematizes the concept of the aerial view. This is for the architect an extremely accurate picture of reality; the distance eliminates superfluous details and brings out the forms, the signs of the territory. The speed of the aircraft is such as to return a slow vision, unlike what takes place by car or by train, and even by bicycle, in which movement is sensed and the images are distorted. Le Corbusier is in fact not interested in the dynamic aspect, nor the representation of movement, like other photographers and avant-garde artists.

[7] Le Corbusier. 1979. Precisazioni sullo stato attuale dell'architettura e dell'urbanistica. Tentori, F. (ed.). Roma-Bari: Laterza. p. 14.

Figure 3. View of Rio de Janeiro.

Rather it's the broad and precise geographic image, like a drawing, and the relationship between man, the means realized by him and the greatness of the infinite space to be of interest to the architect. <At 500 to 1000 meters altitude, and at 180 to 200 kilometres an hour, the view from a plane is not rushed but slow, unbroken, the most precise one can wish: one can recognize the red or black spots on a cow skin. Everything takes on the precision of a tracing; the spectacle is not rushed but very slow, unbroken; along with the plane, it is only the steamer on sea or the feet of the pedestrian on a road that can give what may be called sight at human scale: one sees, the eye transmits calmly. Whereas what I call inhuman and hellish are the sights offered from trains and automobiles, even bicycles. I exist in life only if I can see>[8].

The observation at a great distance relocates the architecture and the cities within the cosmic dimension of nature and within the natural and climatic cycles. <From the plane we also understand a lot of things: the Earth looks like a poached egg, it is a liquid spherical mass surrounded by a constant feature of evaporation and condensation. You can see, from the plane, the formation on the plains of Uruguay of the clouds which will grieve the houses ... or you can witness a clash of clouds from which the lightning and the thunder will come>[9].

The territory is described accurately, observing the signs, the ruts on the ground, the ripples, the texture of the earth's surface. *Precision* allows us to discover and understand the places, revealing what would not be visible from below, like the houses with gardens hidden behind the streets walls in the M'zab region in Algeria: <Seen from above, the city opens its multitude of arcades on its multitude of gardens>[10] and one understands <with a quick glance at the bird's-eye view all the secrets that the city hides>[11].

The accuracy of the view also shows the city and territory's diseases; the plane is an accusation, says Le Corbusier, and it incites urgent action to be undertaken by the urban planner and the architect: <the bird's-eye view gave us the spectacle of our cities and the countryside that surrounds them, and this spectacle is ignoble. ... The airplane indicts! It indicts the city! It indicts those who govern the city! Today, with the plane, we have evidence, recorded on a photographic plate, we have reason to want to change something in architecture and urbanism>[12].

The images from the aircraft prepare for a new and modern consciousness: <Thanks to the aircraft, everything has become clear, when you have assimilated this topography – these bodies so lively and complex, when the difficulties are overcome, and you were full of enthusiasm, you felt the rising of ideas, you have entered into the body and the heart of the city, then you understood part of its destiny>[13].

The airplane view changes the way of interpreting reality and therefore architecture itself: <The airplane gave us the bird's-eye view. When the eye sees clearly, the spirit decides vividly>[14].

3 LE CORBUSIER ROOF SPACE AND THE UNTAMED NATURE

The roof-space is a definite and clear topic for Le Corbusier. It is not only commented as one of the 5 points for a new architecture, but it also constitutes an autonomous report within the *Complete Works*, using his home studio roof space in 24 rue Nungesser et Coli in Paris as a case-study[15]. Here the roof space, after a technical explanation, is essentially commented as the place for the observation of the surrounding territory and the relationship with nature.

The roof garden is a direct result of the use of reinforced concrete in constructions, with the constant moisture on the roof – guaranteed by the greenery and the earth – it reduces contractions and expansions of the material. From technical expedient – as <model protector of the roof>[16] – this space transforms itself: <The roofs of the city could also become places of poetry>[17], writes Le Corbusier. The roof space is a place of contemplation of the landscape and the city. Through architectural stratagems, views are design-controlled and open up to the horizon of the city. Elements like the vaults covering the spaces below, limit the view of the immediate surroundings, leading the eye towards the horizon. In a letter to his mother, Le Corbusier writes: <Really, it's magnificent. There's a view over the countryside with so sense of being perched up on the 7th or 8th floor, thanks to architectural stratagems. No giddiness that way. The garden a poem. Lawn, lilac, roses, and more, and what a horizon!>[18].

Figure 4. Roof-garden at 24 rue Nungesser-et-Coli, Paris.

Figure 5. Roof-garden at Le Lac (a) and at La Tourette (b).

The roof garden at 24 rue Nungesser et Coli is a place of observation of the city and it is also a place of observation and contemplation of nature. Here the vegetation is not designed but it is left to grow according to its natural and biological rhythm. It is the nature itself which builds the garden. <Instead of digging my garden, I let it grow,>[19] wrote Le Corbusier. In the roof garden space nature <regains its rights>[20]: <The sun rules, the wind (above there) rules>[21]. Vegetation grows luxuriant on the sides and on vaults. Le Corbusier observes the development process, describing the sensory aspect of the garden – the power of the sun and the wind, the beauty of nature. <A sycamore seed arrived on a stormy day: I am watching this latest arrival which threatens to become a giant. A bird brought a laburnum seed, and in the spring the dense yellow flowers jostle the near-by lilacs. Ten years ago I planted a sprig of lily-of-the-valley, now a hundreds of lilies-of-the-valley open each first of May>[22].

The solution of untamed nature, which Le Corbusier experiences in his roof garden recurs also in other projects. Through the description of the convent of La Tourette in the *Complete Works*, Le Corbusier defines a group of projects in which the topic of the roof garden is developed through untamed nature, highlighting the continuity of his research. <The roof of the convent itself, like that of the church, will be covered with a thin layer of earth left to the vicissitudes of the wind, birds and other carriers of seeds, assuring both water-tightness and isothermic protection. (The roofs of the small house on Lake Léman, constructed thirty years ago, the apartment house at 24 Rue Nungesser et Coli and various buildings in India are similarly constructed)>[23].

The untamed and wild nature, experimented by Le Corbusier starting from the design project of his studio/apartment, highlights the perceptual and sensory character of the roof garden space. Conceived not only as the extension of the internal space, the roof garden is a phenomenological place for contemplation, observation and contact with the outside. Here man finds a new dimension through the direct experience of the relationship with the elements of nature and the observation of the natural and urban landscape.

4 CONTEMPORARY UNTAMED NATURE

Le Corbusier experimentations on the untamed nature in the city anticipate the current debate on the landscape and in particular the approach of the landscape designer and theorist Gilles Clément. His ideas were put in practice in many parks and garden projects but – as Le Corbusier – it is in the garden of his own house that the primary experiments on the principles of *the garden in motion* are developed. <A valley east-west oriented, with a stream at the bottom, a dry place on the slope where to live, a cool side dedicated to plants for shade, some already old oaks, limited still relaxing horizons, sheltered from all the winds>[24]. And it is in this piece of land in the west of France that Clément builds his gardener's house[25] – the home of *La Vallée* – not far from the places of his childhood. Here Clément becomes the observer of nature and let nature <make the landscape>[26]. <The environment has already started to operate the selection. You do not need to add to the natural pressure of the physical and chemical conditions of the place, an ideological pressure to which nature would suddenly bend over>[27]. Over the years Clément monitors the changes, the evolution of the biological life of animals and plants living in the garden, and he records its natural motion. His job is to read the existing field at the initial moment of the

garden life, and to orient it based on its natural talent, then to follow its motion through small actions that do not prevent its natural growth. The goal is to <follow the natural flow of the plants, within the biological current that drives the place and direct it>[28]. The result is a garden that changes its form constantly. <Everything is in the hands of the gardener – writes Clément – It is him to conceive the garden. The motion is his tool, the herb his subject, life his knowledge>[29].

As Le Corbusier had noticed in his garden in Paris, here too, with the passing of time, new species and plants, not previously planted, are brought by the wind. Plants travel with the men and their wanderings together with the contamination lead – according to Clément – to the birth of new landscapes. This process is <a powerful sign of the potentiality within abandoned places>[30]. In the motion of species within the world can be found the sense of contemporary landscape design. <It is precisely in the seeds – writes Clément – that the essence of the biological message resides, that is the one that generates a dynamic order, generator of unknown gardens>[31].

The concept of untamed nature experimented in his small space becomes – as it happens for Le Corbusier – the key of reading for looking at the entire urban environment. After this initial experience, Clément will look at the city and at its complex abandoned spaces. The <wandering plant phenomenon>[32] is also present in the cities, especially in the waste lands. Those are the abandoned spaces, the spaces left over by the urban planning process, now days seen as a disease of our cities. These architectural voids are in fact not empty from the biological point of view; they constitute the so-called *third landscape*, a refuge for the species. They guarantee the presence of a biological life within the cities, that is today at risk because of the intensification of the urbanization. With the increase of the built surface, the waste lands tend to increase in number though to decrease in their dimension. The result is the creation of a fragmented whole of waste lands within the city that are not able, autonomously, to keep up the biological diversity. The communication among the waste lands ensure the biological continuity and the possibility of inventions arising from the meeting between species.

Le Corbusier fascination for the nature left in its natural state is Gilles Clément foundation of a new philosophy of landscape which sees in the waste lands – the abandoned spaces of the city – places full of life. Clément recognizes in these areas city fragments that can be sewed for the construction of a balanced urban landscape where man, nature and animal species coexist in the respect for diversity.

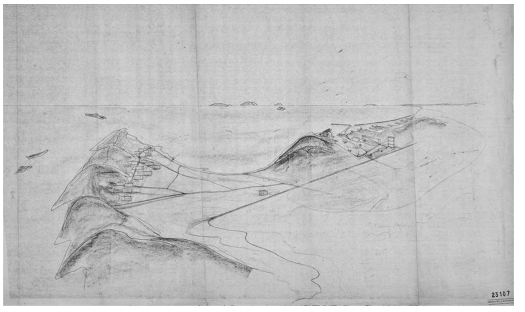

Figure 6. Le Corbusier sketch of the Unité in Marselle location.

5 ROOF SPACE ARCHITECTURE

The roof-garden space is for Le Corbusier a spatial theme criss-crossing through a variety of projects, a 'fil rouge' which becomes a narrative and interpretative thread throughout Le Corbusier work. From his own roof-garden in 24 rue Nungesser et Coli an investigation begins on the meaning of nature in the 'natural state' and also involves other projects, such as the Villa Le Lac. The relationship with nature and the process of selecting a composition of views through the control of the horizon are the two main topics within Le Corbusier roof-garden projects, variously developed in each project. Opposite to the Villa Le Lac condition, where the sight is initially enclosed and framed and then it conquers the possibility to space out on the roof, within the Beistegui Attic the view is gradually compressed along the ascending path leading to the solarium, which becomes a room without ceiling. Then, when designing Marseille Unité roof-garden, the process of creating a composite of horizon determined views becomes defined, and in turn shapes the architecture and the open spaces. From the urban dimension of the Marseille solution, the roof-garden topic finds a territorial measure in Chandigarh. Here, where all is roof, the relationship with nature acquires a new cosmic dimension: the sun, the stars, the earth, the rain, the wind, are now primary forces shaping the architecture volumes, they pass through them and fill them, giving meaning to their forms.

Relatively small scale projects, like the house on the Lake Leman, through the long distant view seem to enlarge their scale and become able to compare themselves with the large dimension, such as in this case the lake and the mountains. Urban scale projects like the Unités d'Habitation acquire even a larger scope: the urban dimension becomes a territorial dimension. In all the projects the relationship with the urban space goes beyond the area surrounding the building itself; rather than dealing with morphological, typological or urban issues, the design project involves topografic and geographical considerations. Context acquires a new meaning.

As a consequence, Le Corbusier does not find his references within the city realm, but outside of it. The

[28] Ibidem. p. 15.

[30] Ibidem. p. 136.

[31] Ibidem. p. 19.

[32] Ibidem. p. 53.

ocean linear, the view from the deck of the ship are more than once mentioned by Le Corbusier and a new set of signs from this world enter within the architect imaginary, and used for shaping the architecture. These signs create a space that is other from the urban space, it is a new space dedicated to the view from above, in order to peer into the vast territory and over the horizon, as the wanderer above the sea of fog by Friedrich.

6 TERRITORIAL VISIONS

Le Corbusier's view of the city from the height of his roof-terraces seems to find continuity in the contemporary scenario. Le Corbusier approach is the recognition of a new dimension of the city which he acquired through observation of the potentiality of the roof garden space. The view from above reveals the relationship with the city and the landscape, producing a radical change in architecture. The roof garden space becomes a fragment of the city project. As an element of a new concept of urbanism, the roof garden is designed in relation to the territory.

If the architecture is founded on the view, the roof space is the architecture *par excellence* being based on the observation potentialities and functioning as device controlling the views. All Le Corbusier projects – his home in Paris, his parents house on the lake, the Bestegui attic, and so on – are designed through the control of views. The roof space architecture is essentially developed through the technique of controlling the views, hiding where necessary, opening and highlighting the view toward the horizon and the geographical emergencies.

Le Corbusier moves to the roof space the dialogue with nature. Under the buildings – through the spaces between the *pilotis* – the city flows. The actual relationship with nature is instead moved to the space on the roof; and in fact it is through the character of space of nature that Le Corbusier explains and introduces the topic of the roof garden within the *Complete Works*.

Instead of being just a technical solution, Le Corbusier raised areas carry multiple meanings. Architecture is confronted with the cosmic dimension, that is with the existential condition of the man on earth, in his relation with the sun. The relationship with nature, within the simplicity of the untamed greenery, reinforces this vision. Nature is not just aesthetically contemplated; Le Corbusier follows the variation of the vegetation as an observer and not as a designer, seizing the vital and biological cycles. In this sense Le Corbusier seems to be the precursor of an ecological vision in which nature becomes a set of ecosystems. Architecture fits into the habitat. In many of his projects – especially those in India – Le Corbusier studies solutions of roofs and brises-soleil, which control and direct the dominant winds, making use of shadow and light.

Architecture becomes a means of orientation within the vast system of the territory. The top view from the roofs, more strongly than for other areas, establishes the role of architecture in the vast system. The design project must be able to read and rewrite the territory. Architecture becomes a project of topography and integration into landscape. Geography becomes the essential character, giving reason to the architecture, determining its meaning and identity.

The view from the roof spaces is conquest of a new dimension that is physical but also an advancement of meaning: the architecture is confronted with the territorial dimension. This will dissolve the dichotomy between city and country, which meet in the enlarged space. From Le Corbusier work it seems possible to extract the words in use in the contemporary realm: urban, landscape, ecology. Le Corbusier anticipates contemporary visions such as those which refer to the *Landscape Urbanism*, conceived as a way of looking at the natural territory and the man-made, joining the principles of landscape and urbanism. In his manifesto of Landscape Urbanism, Charles Waldheim explains the need for a convergence of the two disciplines, traditionally separated, in favour of <a new subject, a new language>[33], which invokes the landscape <as a means by which the contemporary city can be understood and addressed>[34].

7 CONCLUSIONS

Le Corbusier roof garden lesson lies in the close relationship that is achieved between the view from above and the design project. The roof garden is a medium, an intermediate element that holds together the scale of the building, the city and the landscape. The roof garden space is at the same time a fragment of the city and of the landscape and as such is designed within an enlarged vision, through a design control that could be called "geographical". Le Corbusier roof garden concept is therefore visionary and precursor of a sensitivity that only more recently affected the world of architecture and which attempted to overcome the dichotomy between the city and the landscape project. Within this enlarged vision and the need to establish continuity of relationships between city and landscape, Le Corbusier is close to the contemporary approach of the so-called *Landscape Urbanism* which aims at <a more promising, more radical, and more creative form of practice than that defined by rigid disciplinary categorizations [...], a spatio-material practice able to bridge scale and scope with critical insight and imaginative depth>. Le Corbusier intuitions are now at the basis of a shared knowledge which urges to think at the city through the medium of the landscape (Waldheim), where architecture is primarily under the sky before being within the urban environment (Corner).

ABSTRACT: This paper addresses how food preparation practices can help create a design model embracing social changes. The study involved pattern-language method, cross-fertilization, and sustainability. It intends to identify how it is possible to develop a self-sustainable habitat for food preparation as something that takes place in the city in a modern way and not isolated. On the one hand, by exploring an alliance between industry and design aimed at reinventing the local industry. On the other hand, by creating a catalyst system, interpreting the impact of liquid reality. The authors present a pilot project developed by master's design students and companies. The outcome of this study may be used as reference for local industry and design practice development. The paper highlights the value of the combination between industry and design as a mutual learning method. Both parties exchange knowledge, enhancing professional competences, proposing different meanings and creating new market opportunities in order to achieve changes in reality.

1 INTRODUCTION

In 2015, the Italian metropolis of Milan featured the Expo 2015, under the theme "Feeding the Planet, Energy for Life", highlighting the importance of conscious and responsible food choices, while Europe was facing new social phenomenon and foreseen challenges. On the one hand, there were citizens of Western Europe unsatisfied and eager for new experiences. On the other hand, there was the social challenge of refugee crisis. This new social complexity forced Western Europe States and institutions to rethink building and primitive human relations, and the acts of eating and inhabiting in order to fulfill a hybrid, changeable and illusory society. In fact, by the end of the 60's, Gilles Debord emphasized that the end of the millennium was characterized by illusory relations: "The reality of this blackmail accounts for the general acceptance of the illusion at the heart of the consumption of modern commodities: use in its most impoverished form (food and lodging) today exists only to the extent that it is imprisoned in the illusory wealth of increased survival. The real consumer becomes a consumer of illusions. The commodity is this factually real illusion, and the spectacle is its general manifestation." (Debord, 1967). Today, the complexities and contradictions of the spectacle society underline the existence of a consumer distorting perceptions, for instance, on migration flows. Unable to interpret the meaning of living in the sense that "We do not dwell because we have built, but we build and have built because we dwell, that is, because we are dwellers." (Heidegger, 1957). This means that to design something allows raising not only the semiotic question of meaning but also the normative (Latour, 2008), and subsequently the current issue of the flow of refugees may be interpreted through a problem pattern. The path towards understanding a complex system, such as a city facing new social challenges, relies on the architect' ability to provide design alternatives for parts of a whole. Interpreting the whole, we risk misunderstanding everything.

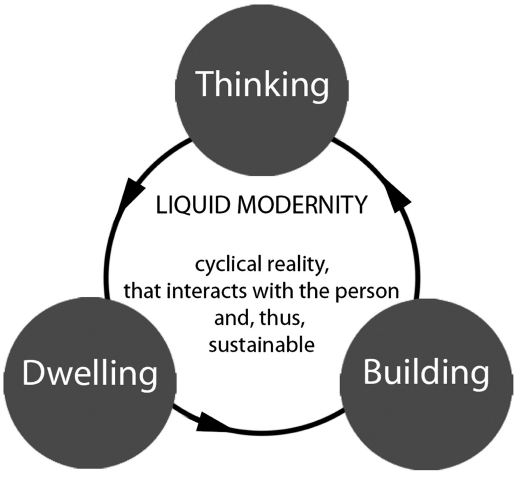

Figure 1. Dwelling/Thinking/Building System. Image by the authors.

On the one hand, consumers are increasingly inclined to spend money on "brands for causes" than direct charity. The expense associated with the gift causes more happiness than spending on him/her, which is a great opportunity (market) in time of crisis. Not take the cause of refugees is to lose a large audience. On the other hand, this situation allows architects, designers, artisans and the community to work together and not individually, and also, to implement a pilot solution in the city. This self-sustainable habitat for food preparation lends itself to installation in a marginalized area of the city, as a reference to a refugee camp, as a contribution to changing realities and mentalities. In this study, the authors chose to exchange knowledge in order to foster innovation and sustainability, recognizing this as a contribution towards the transformation of reality rather than a result from reality change. This also constitutes a unique opportunity to build a part of the whole while inhabiting a self-sustainable habitat to prepare one of the uses in its most impoverished form: food preparation. The field of design is ever changing, according to the complexity, fluidity and transformation that characterize the 'liquid modernity' (Bauman 2005). If transformation itself is a benchmark of reality, contemporary reality leads us in different directions and associations, with increasingly faster changes. The liquid modernity characteristics drive this study towards the application of a pattern-language oriented methodology (Alexander, 1977), focused in solving specific reality problems.

2 RESEARCH PROCESS

2.1 *Purpose*

This research departs from the notion of pattern-language as intuition intersecting fragments of complexity that define the whole, creating a pattern system that fluctuates according to current dynamics. "Pattern is born when one reproduces the intuitively perceived essence. When the intuition weakens, pattern becomes no more than a formal design. Design as such is no more than an intellectual composition." (Yanagi, 1990: 114). The current global crisis encourages alternative solutions. In fact, while twentieth century architecture focused on function and form, the architectural debate today focuses on relationships, limits, energies and culture.

2.2 *Related work*

One of the cases validating this research is Kenzo Kuma's interpretation of Japanese vernacular architecture as a model to think current reality. (Vitorino cit in Liotta & Belfiore, 2012: 119). As stated by Catarina Vitorino, an attempt to identify "local typologies and their responsiveness to micro-local conditions." (Vitorino cit in Liotta & Belfiore, 2012: 119). We expect to understand how patterns changed in space, verifying their ability to adapt to local and external factors interacting in the process. A pattern solves a problem in a way that "you can use this solution a million times over without ever doing it the same way twice." (Alexander, 1977). Christopher Alexander advocates that buildings should be adapted to places and individual needs, offering flexible design to meet the real needs. Another case emphasizing the role of culture in the design process is the framework developed by Barry Shore & Venky Venkatachalam (1995). This framework identifies stages in the design process that are influenced by culture, and the pattern they are likely to form. Therefore, it is possible to argue that "a design pattern systematically names, motivates and explains a general design that addresses a recurring design problem in object-oriented systems" (Gamma, Helm, Johnson & Vlissides, 1994). The solution may be implemented through problem-solving in a particular context, the problem of construction, housing and feeding in the current. On the one hand, there is the dilemma of static solutions for modern citizens that ask for experiences of pleasure and knowing. On the other hand, there is the problem of refugee situation that characterized present reality.

3 PARTICIPANTS AND METHOD

To reflect about teaching architects and designers for the twenty-first century is to think the foundations of a new rationality, reinforcing "designerly ways of thinking and designerly ways of Knowing." (Cross, 2006).

This approach aims to contribute to characterize an innovative design as one that cannot solve only one problem or target only one solution with no dialogue with the question, but rather a "semantic agent, interpreter of a purpose, producer of meanings through the shapes it produces, creating new circumstances and contexts that contribute to human freedom" (Soares, 2012). The methodological processes applied to innovative design cannot be understood as

Table 1. System of Patterns. Image by the authors.

Pattern	Pattern topic	Number of students
Pattern Energy	– Energy Uptake – Storage – Environmental impact	4
Pattern Vertical Surfaces	– Epidermis – Protection – Interaction	4
Pattern Horizontal Surfaces	– Layers – Connections – Courses	4
Pattern Equipment	– Efficient – Systemic – Connective	4
Pattern Structure	– Flexible – Light – Modular	4

linear or sequential. Their path has advances and drawbacks, questioning, criticism and several constraints. The model for Design practice is therefore a dynamic rationale, from the initial question (situation, problem) until the final solution. The project developed was entitled NmeeTon. As Tadhg MacCrossan (1995) states NmeeTon was, in a sacred space, a clearing in the midst of wooded grove or glade of ancient religions, such as Celtic religion or Ancient Greek. But it can also be a space artificially constructed. It means a place that cares. The NmeeTon Project was developed by 4 teachers and 20 students from the 1st year of the Integrated Masters in Design course from the Polytechnic Institute of Viana do Castelo, in the north of Portugal. The project consists on a 'wireless' space for food preparation, involving the undergraduate courses of Food Engineering, Civil Engineering, Environmental Engineering, and Renewable Energies, from the same university. NmeeTon was based on a partnership with the Portuguese construction company Costa & Sá, who financed the project, in collaboration with the stove company Gamadaric, and the cork products company Corticeira Amorim. As we intend to demonstrate, applied research at an academic experimentation level is able to become a key instrument to bridge the gulf between business and academia.

3.1 *First stage*

The project was developed in different stages. In the first stage, projectual thinking was defined as an ordering principle for the spatial structure, creating a 5 pattern system and related topics pattern, in teams of 4 students. During this 10-week stage, each group of students performed data collection, processing and analysis, allowing the development of a hypothesis with the following characteristics:

- The module should contain all the necessary equipment for food preparation;
- The module should have a minimum size of 12 m^2 and a maximum height of 3.00 meters;
- The module features and configuration should allow mobility;
- The module identity should relate to sustainability;
- The module should ensure open/closed configurations in a simple and practical way.

Upon defining the working groups and conclusion of data analysis and evaluation, there was a first meeting between the company team from Costa & Sá and the 20 students and teachers, in order to discuss the brief.

3.2 *Second stage*

In the following stage, during 5 weeks, each group of students developed patterns, able to be integrated in a single spatial configuration. Each team previously composed a set of sub patterns related to the chosen pattern. This pattern was structured in order to assure its execution through easily achievable solutions. Each pattern should be compatible with the patterns suggested by the other groups. This limitation required constant communication between the teams.

Also, each group developed a pattern by connecting to the teams from the other courses, such as Food Engineering, who created a book on hygiene and food safety guidance in Portuguese and English language, not only as a limit for the construction of the enclosure, but also as a guide for an ordinary user.

3.3 *Third stage*

This stage lasted 4 months, and articulated different moments with distinct natures. One of the moments was a workshop by the Chef Margarida Rego, godmother of the Nmeeton project, whose work is characterized by poorer use of food preparation to create aesthetic and playful solutions. This action was essential to adapt the functions of the act of cooking to the act of inhabiting. During the process it was also necessary to meet more often with the entrepreneurs. On the

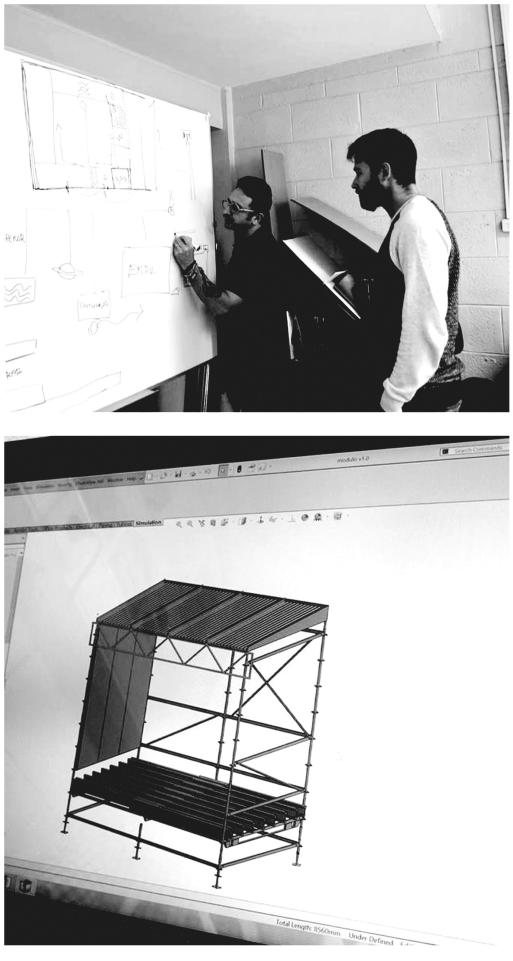

Figure 2. From top to bottom: Rush straw assembly from the Vertical Surface Pattern. Detail of black cork from the Structure Pattern. Image by student Alzira Dias.

one hand, some patterns required other technologies and other companies, calling for new partners, such as the stove company Gamadaric or Corticeira Amorim from central Portugal. Gamadaric allowed the development of a wood burning stove. The Corticeira Amorim allowed the development of isolating coatings, namely for a deep freeze appliance in cork, retrieving the early icebox concept. Project phasing required changes in projectual decisions, considering the pilot-project would be a self-contained functional prototype and not a volume model. In this sense, the project was built and tested at the university, and was open to criticism from students, teachers, entrepreneurs, and the community. When all patterns were connected and the whole resulted in dwelling construction, the components were dismantled for subsequent assembly before the community of Viana do Castelo. The space, about 28 cubic meters, has a separable structure, using materials such as metal, fiberglass and Corian, but also natural materials such as cork, wood and rush. An easily, detachable and transportable self-sustainable habitat for food preparation, when not in use. The NmeeTon space is self-sustainable and off-the-grid, since it does not rely on municipal water supply, sewer, natural gas, or electrical power grid. Instead it showcases innovative solutions such as the modern icebox to preserve food, a micro greenhouse for herbs, or a wood burning cooking plate & oven package. A biomass system that allows wood pellets as a biofuel; fuel clean, efficient and high calorific value. This option is focus on the emergent and changeable situations that, more often, characterized our time. It means, a self-sustainable space and off-the-gridd is stronger and prepared to reach social fluctuations phenomenon.

4 FINDINGS

4.1 *Advantages of the process*

- Involving native materials such as rush, black cork, and standardized materials such as metal tube allowed qualifying the product within the local culture while thinking globally.
- Design research also focused on technology, materials and marketing, linked to research based on a partnership between business and academia. A research model that may become a key tool to foster new relations between business and academia.
- The potential for crossing technologies, materials and companies should be investigated to create cross-fertilization (Cappellieri, 2005) and new business opportunities. The fact that the space doesn't need connections to any electrical or water services illustrates the self-sustainable feature of the unit, enabling its use in virtually any setting.

4.2 *Disadvantages of the process*

- Some of the project procedures were delayed due to the geographical distance between some companies.

Figure 3. From top to bottom: Rush treatment. Rush straw assembly for the Vertical Surface Pattern. Detail of black cork in the Structure Pattern. Image by student Alzira Dias.

- Rush picking takes place during Spring, which can limit the construction of the chosen sort of roof.

5 PROPOSITIONS FOR DESIGN

The propositions for this study were social, cultural, academic and entrepreneurial. At a social and cultural level, in 2015 Milan staged the Expo under the theme "Feeding the Planet, Energy for Life" drawing attention to the importance of conscious and responsible food choices, the NmeeTon project intends to stimulate new sustainable models merging tradition and innovation. The European migrant and refugee crisis also began in 2015, with a rising number of refugees

Figure 4. From top to bottom: Assembly of the Pattern Structure in the city. View of the façade. Image by student Alzira Dias.

and migrants seeking abroad for better living conditions. Thus, European consumers are more and more disposed to spend money on "brands for causes". The expense associated with the gift causes more happiness than spending on him/her, which is a big occasion for today's reality.

At the academic and entrepreneurial level, this project allowed students to connect with local production enterprises. In academic terms, a process-oriented design action is useful, since "today, Design research is a quest about specific reading instruments such as those from innovation methods studies promoted by companies in collaboration with designers and the creative world." (Verganti, 2001). This process connected companies from different sectors, which had never worked together. On one side, Costa & Sá a construction company that had never designed ephemeral self-sustaining structures, and on the other side, the cork company Corticeira Amorim, which had never produced this sort of solutions, opening a new horizon of collaborative production, and new interaction concepts with people, architecture and the city. Finally, Gamadaric was a stove company that although engaged in modern stoves seized the possibility to create a wood burning stove for underdeveloped countries. This project is currently being developed at a Master level and it is remarkable that it fostered three Master Theses in companies for students participating in the project. At a company level, it is expected to identify new business and market opportunities, both for the companies involved in the project and for local companies stimulated by this cross-fertilization.

6 CASE STUDY

6.1 *The sustainable intelligent process*

The development of the pilot project NmeeTon was based on an industry-design alliance, engaging different actors. The process can be defined as an interactive approach, with 20 Masters Students, teachers, artisans and industrialists. An open process combining idea development, discussion, prototyping and presentation; The project was presented in July 31, 2015, by the fishing docks of the coastal city of Viana do Castelo. Specifically besides the Social, Cultural and Artistic Intervention Association (AISCA), founded in 2009 by people from different backgrounds, including two former students from the School of Fine Arts of the University of Porto. AISCA headquarters are a modernized abandoned warehouse by the town pier, playing an important role in the transformation of the city. AISCA acts as an intercultural platform and space, offering workshops, seminars, concerts, exhibitions and projects. This association thus became one of the most active promoters of stimulant initiatives and incentives in Viana do Castelo, as for example the project "Sea Villages" (Aldeias do Mar), intended to requalify the abandoned seashore or forgotten cityscapes. The NmeeTon project was premiered by Chef Margarida Rego, who cooked several dishes for approximately 100 people who attended the inauguration. This action led to a widespread understanding of all actors intervening in the project.

On the one hand, the industries were challenged to leave their comfort zone and scope of production, accepting to participate in a project creating new opportunities for transformation. On the other hand, architects and designers had the opportunity to interpret specific technologies and materials. With this methodology, design students were able to develop new concepts and to intersect new experiences and different areas of knowledge. According to Francesco Morace: "(…) will always try to reach another meeting point between the aesthetic and ethical variables. What is worth today for enlightened businesses and entrepreneurs will be the universal key to identify new parameters of quality. The progressive meeting between goods and services will happen under

Figure 5. From top to bottom: Oven Detail. Chef Margarida Rego cooking inside the NmeeTon unit. Detail of freezer in black cork. Image by student João Pontes.

the jurisdiction of the alliance between ethics and aesthetics." (Morace, 2011).

6.2 *Product development*

The developed product is characterized by the intersection between artisan and industrial production. The new product emphasizes the characteristics of the materials, in their semantic value, including visual and tactile qualities. On the one hand, the new product highlights the practical role of materials, projecting materials such as the upper vertical pattern in rush, demanding the material to be picked up by the river, dried and combed mesh by mesh. The need to restore the typical rush culture in the Minho region (northern Portugal), finding in equipment design and architecture the setting to allow the profitability of an existing wealth of knowledge and to assure its survival. When design builds a correct connection between the productive qualities and the material culture history, it can also create a sustainable innovative product. Through artisan production and together with industrial production, we created a hybrid product with added value from both sectors. On the other hand, the NmeeTon highlights the aesthetic potential of materials, as the black cork relating to a metallic tubular structure, providing hot and cold sensations conveyed by the relationship between materials. Nowadays, the 'cautious designer' (Latour, 2008) who chooses a meaningful reflection about design education for the twenty-first century, projects manifestations of design education, developing connections with other professionals, academies, businesses, and people. If currently design teaching is based on a constant interrogation process, it is also the result of today's reality. And design teaching is hardly a project: it may be planned as a meta-project, related to the genius loci, to local productive entities, and with an entrepreneurial insight to promote sustainability and competitiveness. A rationality that enhances applied research projects to the development of products focusing on the valorization of the territory. This supports the notion that the development of Design discipline depends on the connection between enterprises, education and research, in a field of action that is always active, and not just sometimes. In this sense, it is vital for the productive sector to be increasingly versatile, due to a constant and growing customer demand, provided by the global world it is set upon. The proximity between industry and handicrafts may become strategic for the survival of the two sectors, creating geographically involved values, in other words, local, cultural, symbolic, qualitative values (Maldonado, 1999), which through sound design strategies are able to improve products' quality.

7 CONCLUSIONS

This research aims to understand how design and architecture research can contribute towards the future of the cities in the 21st century, considering the social fluctuations phenomenon, the contradictions and oscillations that characterize present reality, namely the migration phenomena and the dissatisfaction and the desire for surprise and new experiences that characterized the western citizens. In order to prove this thesis the authors use NmeeTon's case study developed between academia and the business sector. In terms of application, the NmeeTon project may expand the concept of agri-food sustainability, including products as well as production systems. The interest in defining sustainability is based on the emergent appreciation from all stakeholders that the future productivity and economic state of the agri-food system is dependent on the wellbeing of natural and ecological and sustainable funds. NmeeTon project

Figure 6. From top to bottom: Detail of the working bench and greenhouse in the NmeeTon cabin. Night view with lighting. Image by student João Pontes.

also allows experiences that will make users remember past memories or even a new experience by using the stove. Concerning the emotional value of everyday objects, Donald Norman (2004) advocates that memories reflect our life experiences; they remind us of family, friends and also experiences. This project may be an opportunity for all actors to transform amidst a reality in constant change. The architect and designer assessing the cultural value have the predisposition to reach an innovative and sustainable response. Innovative solution because through interpretation, the designer accepts time fragmentation and defines answers including the cultural factor, becoming an ever-renovated solution. A sustainable answer, because the process benefits from factors crisscrossing the context, such as time, communication or complexity, enabling interpretation while design process as a cyclic method; recyclable and therefore sustainable. A cognitive and dialectical process because being a path open to contrary and contradictory ideas, it becomes an innovative process leading to other ideas; a wide process whose final product quality will depend on the strength of the relationship between the parts constituting the product system. The alternative to assess and evaluate all appearances of the nature of new social challenges will allow the architect the right to choose when relating the individual to the world. In this sense, it is a productive action in which design works alongside other disciplines, interfering in reality, complex and difficult to define, instead of design operating on a dream-like reality. As a culture vehicle, architecture contributes towards preserving the cities' identity and also to uphold emotions in people's lives. It engages the thought of the uniqueness of the cities as an inspiring model for interpretation that stems from a base concept, assessing and reassessing prior to forwarding responses. The design of the cities is therefore hermeneutical and dialectical. Between the designer and the user then arises a new level of relationship, an experience of meaning exchange instead of a mere opportunity to communicate a message.

ACKNOWLEDGMENT

The authors gratefully acknowledge the financial support of the Costa & Sá company, recognizing the support of the President of the Polytechnic Institute of Viana do Castelo (IPVC), Professor Rui Teixeira, the Rresident of the Research Centre for Architecture, Urbanism and Design (CIAUD) at the Faculty of Architecture, University of Lisbon (FA/ULisboa), Professor Fernando Moreira da Silva, the students, the artisans and Chef Margarida Rego. This paper is partially supported by the Portuguese Foundation for Science and Technology – FCT.

Real estate, residency, design and sustainability: Reconsidering innovation and efficacy in development

S. Rajan
University of Calgary, Canada

B.R. Sinclair
University of Calgary + Sinclairstudio Inc., Canada

ABSTRACT: Real estate planning, design, development and building prove deeply complex. For nearly five decades developers have been doubling down, contractors have been cutting corners, architects and engineers have been copying and pasting, planners have been creating more rules, and bankers, lawyers, realtors and insurers have all profited excessively from a fundamentally broken system (Miller 2009). All the while, home owners have unknowingly and knowingly spent trillions of dollars on accommodation that lacks in either quality, cost, location, fit or all of the above. However, as long as the economy continues on an upward trajectory, the climate doesn't change too much and home buyers don't ask for anything more, the system will endure. Should we be changing anything?

Homes shape our communities, guide our relationships, characterize our identity, create intimacy and increasingly prove vehicles for funding retirement. Since 2008, average home prices have risen by 50% pushing family net worth up 44.5% (Marr 2015). The real estate, rental and leasing economy is equivalent in size to the educational services and healthcare industries combined and nearly 20 times larger than the arts, entertainment and recreation industries (Statistics Canada 2015). The housing sector is a life line to the economy and, if thrown off balance, has proven to be crippling. We remain dependent on a fragile system which, in many ways, doesn't function as well as we think or as well as we desire.

Today, 20% of Canadians face an affordable housing crisis, spending over half their income on their home (McMahon 2015). This problem is magnified globally, where an estimated 1.6 billion will be affected by an affordable housing crisis by 2025 (Woetzel 2014). Rising prices and lack of productivity within the construction industry contribute to unaffordability (LePatner & Jacobson 2007). This is intensified by a lack of innovation; only one construction and engineering company made it to Forbes 100 most innovative companies in 2014. Since the turn of the 19th century, the movement of architects and engineers from a craft practice model to a professional services model shifted liability onto developers and withdrew the creativity involved in place-making by creating a highly fragmented and arguably dysfunctional industry. As such, less than 5% of homes have an architect involved in the design (Brown & North 2011). The housing industry is also a great environmental concern. Buildings contribute to one third of global greenhouse gas emissions (Huovila 2009) and the urban sprawl of the last few decades has resulted in numerous negative externalities (Thompson 2013).

We cannot continue to rely on this broken system. Although new urban and minimalistic movements are becoming more prominent, a systemic change is needed (Zevon 2011). Purchasers should no longer forgo quality, cost, location or fit. By unveiling the venality of the current industry, and finding the cruxes for change, we can create a more innovative and integrative industry.

The present research critically considers the status quo, exploring aspects of the design and development industries that desperately need overhaul, integration, coordination and stream-lining. Holistic conceptual frameworks can be shaped and applied to tackle the daunting complexity of such systems (Sinclair 2009). To such ends the authors present a model for systemic reform that aims to shift priorities from profit and bottom-line thinking to place-making and quality of life, understanding that creativity, balance and reform are urgently required in order to see real progress in an endemically fragmented & problematic ethos.

Keywords: Real Estate, Residency, Design, Sustainability, Systems Thinking, Innovation

1 INTRODUCTION

The residential design and development industry grows increasingly complex in Canada and around the globe. This complexity is due to the involvement of numerous stakeholders with a diverse array of desired interests, experience, personalities and influences (Miller 2009). It isn't out of the ordinary

therefore that communication barriers exist between the different parties involved within the industry. Ultimately, this leads to inefficiencies, excessive profitability, negligence and lack of true consideration for the end user (NRCC 2002). Ironically, the system that should be designed and built for the resident might appear to be built more for the profitability of other stakeholders. This misalignment in power has created challenges within the industry from an economic, environmental, social and political perspective. Furthermore, the misalignment results in a design and development industry that is structured in a way that proves to be not very resilient. This is particularly concerning as the built environment challenges around the world are becoming increasingly acute (LePatner, 2007). However, in this challenge, there lies a great opportunity for the next generation of leaders to take initiative and reshape the industry. There must be a charge to create an industry that is more sustainable from an economic, social, environmental and political perspective. Sustainable not just in the ability to use without completely using up or destroying (Merriam-Webster's collegiate dictionary n.d.) but in the focus of this paper, sustainability refers to building and propagating longevity, resilience, equity and empowerment. It is with these considerations that we can generate truly holistic sustainability. The authors present methods and a model for improvement. Through greater awareness and the assistance of frameworks, stakeholders can reform their perspectives and alter their relative positioning within the industry. And through the assistance of intermediaries including entrepreneurs, actionable leaders and technology, change can be generated rapidly. The time to act is now, both diligently and swiftly, before it is too late.

2 WHAT IS BROKEN? WHAT IS THE RESULT OF THIS?

"People everywhere – independent of their particular background or education level – almost instinctively understand the importance of place ... few other forces, in my view have such transformational potential." – Aga Khan.

The incredibly complex and colossal design and development industry is broken in many ways. Economically, Canada and many other parts of the world are both fragile and reliant on the housing sector (Ladurantaye & Mckenna 2012). Environmentally, the negative impact of residential design and development is in many measures second to none (Huovila 2009). Socially, societies today struggle with both an identity and affordable housing crisis (Woetzel 2014). Politically and industrially, misalignments in power result in a system which is not resilient to the rapidly changing and compounding problems of the built environment that the world faces today. A deeper concern is that these problems are dealt with by stakeholders in silos as perceived interests tend not to be aligned. Therefore, they are dealt with disjointedly if at all. It is important that these challenges are acknowledged and considered comprehensively and collectively when attempting to understand their deep complexity.

2.1 *Economy*

The system is in fact broken in many ways. Financially, private investors are dependent on the gradual increase of housing prices. Since 2008, average home prices in Canada have risen by 50% pushing family net worth up 44.5% (Marr 2015). However, it is not only the home owners who carefully follow the housing market. Governments and economists use housing prices and housing starts to determine the health of the economy (Statistics Canada 2015). All of this seems logical given the real estate, rental and leasing economy is equivalent in size to the educational services and healthcare industries. And combined it is nearly 20 times larger than the arts, entertainment and recreation industries in Canada. Ironically, the industry seems to know its priorities – economics. (Statistics Canada 2015). However, as we have seen recently in the financial collapse of 2008, the housing industry if thrown off balance can be crippling. Ignorantly approving mortgages which residents can barely afford and the assumption that real estate always increases in value, renders our economy very vulnerable. It is clear that the valuation and approval techniques for homes must be reconsidered (Gjerstad 2014). Additionally, our focal point on housing starts as a metric for economic growth may also be flawed. Canadians build two new houses for every person added to the working age population (Rabidoux, 2015). This fuels the concern of depending on quantitative factors rather than truly meeting needs. These are only a few examples of inappropriateness and impracticalities of the economies of the housing sector. Undoubtedly, the reliance on housing as a mechanism for economic growth is both speculative and unsustainable.

2.2 *Environment*

Reliance on the housing industry to carry the economy has resulted in the development of a system which can output houses at a rapid rate with little consideration for environmental impact (Brown & North 2010). Unfortunately, without a profit motive this rate of growth coupled with a lack of consideration for environmental sustainability will endure (Kriese & Scholz 2010). The current housing industry is a significant environmental concern. Buildings contribute to one third of global greenhouse gas emissions (Huovila 2009) and the urban sprawl of the last few decades has created numerous negative externalities (Thompson 2013). The replacement of 'native' landscapes with development and the advent of concrete jungles has removed nature from our daily lives. This has caused many negative health and psychological

effects (Gobbo & O'Mara 2004). And the preconception that bigger is better has resulted in a desire for more space, opulence and the so called supersizing of our homes (Brown 2011). All of this, of course, comes at an expense to the environment and our precious resources. Unfortunately, this growth doesn't result in our happiness but a continual dissatisfaction and hunger for more (Kuo 2004). In recent years, the consideration for smaller and minimalistic living has grown (Zevon 2011). As well, there has been a rising popularity of rating systems, energy efficient appliances and LED bulbs to name a few (Friedman 2008). Unfortunately, the notion of environmental sustainability has been mocked with green washing and arguably only a few wealthy residential projects truly consider environmental attributes (Solomon 2005, Bray & McCurry 2006). For example, in Canada, only 1.54% of residential projects are LEED certified (CAGBC 2014). Despite a growing consumer sentiment towards environmental building, rating systems such as LEED and Built Green are far from truly holistic sustainable design (Bray 2006). Particularly, they fail to address the more spiritual and qualitative aspects of homes and lifestyle (Ben-Shahar & Golan 2014).

2.3 *Social (Identity)*

The most negative impact of an ever-growing residential industry is the emptiness it brings to our societies (Brown & North 2010). Homes are meant to shape our communities, guide our relationships, characterize our identity and create intimacy. Yet, they routinely fail to do this. There has been a true loss of consideration for identity and community in the process of residential design and development. A small degree of homes in Canada have an architect involved in their design (Brown & North 2010). Design decisions are barely grounded in any methodological understanding of the resident. They adopt a lowest common denominator approach to understanding resident needs and focus on the status quo. Design decisions are more driven by creating value for the bottom line than they are creating value for the resident (Adams & Watkins, 2002). As well, there is a strategic information gap between buyers and suppliers and the result is design decision makers that factor in a few characteristics such as number of bedrooms, square footage, location and quality of finishes. Consumers needs regarding living spaces are much richer and fine tuned (Gibler, Tyvimaa & Kananen 2014). However, suppliers choose typically not to value all of these various needs. Price and volume of sales are driven by only a few decision factors available to residents and the desire for developers to innovate beyond these factors is an unnecessary risk. After all, the stakes are high and risks for the many small developers can be substantive. A strategic and powerful veil ensures the fragmented residential development industry continues per status quo. (Gyourko & Rybczynski 2000).

2.4 *Social (Affordability)*

With the staggering rate of development and the speed by which homes are created, it would seem contradictory that 20% of Canadians face an affordable housing crisis, spending over half their income on their home (McMahon, 2015). This problem is magnified globally, where an estimated 1.6 billion will be affected by an affordable housing crisis by 2025 (Woetzel 2015). A heightened level of development and construction (housing starts) does not mean that needs are being accurately met. In order to meet needs, both accuracy and resources are required in unfathomable quantities. Including land and construction nearly 16 trillion dollars will be required to replace substandard housing and build additional units by 2025 (Woetzel 2014). Furthermore, with location, price and quality continually being sacrificed by home buyers and renters of many demographics, there is an apparent gap in the market (Marmolejo-Duarte & Ruiz-Lineros 2013). Partially, this is due to the lack of awareness of what is specifically required in market. Therefore, the need to bring the right product to the right market is crucial. (LePatner & Jacobson 2007). However, lack of capital, innovation, access to land, construction costs, waste and exuberance are abundant and further worsen the situation (Woetzel 2014). The benefits of creating affordable housing are intangible for societies and communities. Providing appropriate housing for lower income populations and improving the overall quality of housing will likely enable labor mobility, increase knowledge sharing, build resiliency in communities and increase quality of life (OECD 2014). Cracking the code on delivering affordable, sustainable and scalable housing will effectively create political, economic, social and environmental benefits across the board. In order to attempt bridging the affordability gap, innovation and reorganization are urgently required (Miller 2009). We need to dramatically challenge business-as-usual posturing and, in response, chart new and bold ways of seeing, thinking and acting.

2.5 *Politically + Industry*

Innovation within the residential design and development industry is hampered for numerous reasons. Two powerful stakeholders – the developer and financer are driven by bottom line profits (LePatner 2007). Therefore, the development or redevelopment plan of any land parcel is based on the highest and best value for that particular plot. Environmental and social innovations which are narrowly defined and determined are investigated only if they can be correlated to an increase in volume or price of sales (Eves & Kippes 2010). In both bearish and bullish markets, cost cutting measures or value engineering are often synonymous for innovation. Furthermore, horizontal and vertical fragmentation are prevalent within the industry. Developers, architects, designers, planners, builders and bankers tend to have their own measures of success. These interests are often not aligned.

Furthermore, the residential design and development industry is divided into numerous small firms who encounter variability in profits and therefore are limited to invest in research and development (NRCC 2002). Lastly, governments tend to lessen innovation in many cases by bringing about planning systems which are both bureaucratic and difficult to navigate (Adams & Watkins 2002). Design decision makers are often encumbered with constraints based on community, municipality and provincial code requirements and bylaws. Often coping with these obstacles alone leaves little time and capital resources to invest in innovation. Overall, the industry is far behind others when it comes to producing increasingly competitive products. Only one construction and engineering firm made it to Forbes 100 most innovative companies in 2014. Dismal innovation in the face of a broken and increasingly concerning industry is a wicked problem to say the least.

2.6 *Implications*

Concerns within the industry are growing increasingly worse. Since the turn of the 19th century, the movement of architects and engineers from a craft practice model to a professional services model shifted liability onto developers and withdrew the creativity and cohesion involved in place-making by creating a highly fragmented industry (LePatner 2007, Miller 2009). This fragmentation resulted in an asymmetry of information amongst key stakeholders. And inevitably, the information gaps have resulted in further vulnerability of our economy, harm to the environment, removal of identity from our homes, an affordable housing crisis, bureaucratic planning policies and lack of innovation throughout the industry. We cannot continue to rely on this fundamentally broken and troubling system. The present researchers stress that a dramatic systemic change is desperately needed to bridge these information gaps and connect stakeholder silos. Residents should no longer forgo quality, cost, location or fit. By unveiling the venality of the current industry, and finding the cruxes for change, we can create a more innovative and integrative industry.

3 HOW CAN IT BE FIXED?

"Everything should be made as simple as possible, but not simpler." – Albert Einstein.

It is evident that both a lack of mutual understanding amongst key stakeholders and increasingly complex problems hinder the progress and accessibility of an incredibly important human need. The authors present methods for demonstrable improvement. Strengthening the bonds within this industry will not be the responsibility of one key stakeholder alone, or a technological panacea, but rather numerous leaders empowered with technology innovations must arise to bridge these bonds. Collectively the industry must

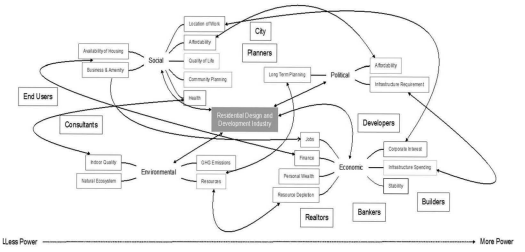

Figure 1. Model showing complexity and power struggles.

be educated to understand the broad implications of each stakeholder's actions. This can be supported and accomplished through the awareness and integration of holistic frameworks.

3.1 *Awareness + frameworks*

The residential design and development industries prove deeply complex. Stakeholders are in desperate need of better understanding each other's desires, jargons, principles and perspectives. Focal points and metrics of success are not only diverse amongst key players but also intensely dynamic.

Industry stakeholders must bring to light the divergent knowledge and burgeoning considerations of appropriately designing and developing in the world today. Using balanced frameworks can help different stakeholders realize what key assumptions they are making and how the implications of their decisions impact other stakeholders. Frameworks are both versatile and organic. Therefore, holistic conceptual frameworks can be shaped and applied to tackle the daunting complexity of different and demanding systems (Sinclair, 2009).

Figure 1 above shows the residential design and development industry mapping the key domains (economic, political, social and environmental) and a few key parameters of success for each domain. It also overlays key stakeholders and a few of their interrelationships. From this model, we see that power is associated with politics and economics more than social and environmental considerations as many of the more powerful stakeholders are motivated by political and economical considerations. Although the integral purpose of the industry is to serve the end user (LePatner & Jacobson 2007), the alignment of the industry's interests does not adequately do this. Clearly, a reconfiguration is required and a transfer of power towards other stakeholders. This may seem trivial, however, the model also helps us to understand interdependencies and the potential negative implications of the system continuing as per the status quo. Business as usual is unacceptable. Many of the social and environmental considerations have long term political and economic impacts. The domains cannot exist in their own silos.

Models can be powerful tools if they successfully build awareness and are administered across the industry amongst key players. They can serve as potent

catalysts for change. Awareness and knowledge can be shared and built in academia and through integrative workshops. However, to truly bring about widespread outreach, knowledge acquisition must be fostered through appropriate intermediaries and innovative channels of communication. This way it can reach the far corners of the industry and create more revolutionary shifts in mindset.

3.2 *Intermediaries and technology*

In a fragmented industry, the need for intermediaries to bridge the information gaps is vital. With the assistance of liaisons, we can create knowledge transfers that distribute value more evenly across the system. At each critical disconnect in the system, a clever design intervention can allow different stakeholders to see one another's perspectives. By building awareness for what should be considered, we can guide stakeholders into making more informed and therefore better decisions. Currently, the use of information technology, software and social media in the design and development industry is dismal (Littlefield, Bao & Cook 2000). There is a critical importance to engage various stakeholders by bringing them online applications and tools that foster both communication and education. In an era where information is readily available, we should be connected, integrated and sharing integral knowledge at rapid rates. In many ways knowledge is power. Positive attributes of using online tools and applications to invoke change include rapid prototyping, experimentation and engagement. However, it is important to recognize that these applications will not create change without actionable leaders backing the initiative. Leaders may include architects, engineers, developers, lenders, planners, builders, entrepreneurs or others who advocate change within the industry. These leaders must be driven, interdisciplinary and creative in order to innovate the right products, strategies and carry out effective implementation. A proposal for a four-phased design intervention using information technology that attempts to redistribute value and reform the industry is described below.

3.3 *Proposed solution*

Imagine an organization of stakeholders integrated through a social and informational network – sharing ideas and best practises at a rapid rate within an ever-growing, organized and interactive online application. The central goal would be to empower residents to take control in shaping their built environments and to drive innovation through transparency. Products, concepts, characteristics and stakeholders can be catalogued using an assortment of metrics and ratings, to an extent. The ratings and metrics can be established democratically and be designed to be organic so they can continue to reflect the needs of dynamic situations. They can also be directly compared, tailored, customized and optimized for particular projects, sites and people. The widespread use of this network would

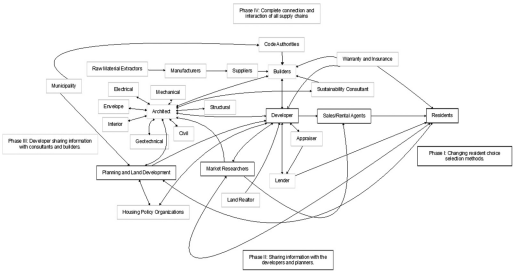

Figure 2. Model showing the current design and development industry.

result in greater accountability, scalability and shared research and development. It would be capable of bringing economics, efficiencies, more innovation, greater efficacy and appropriateness to residential design and development solutions. It is important to note that not all attributes can be associated to metrics and quantities. The application would provide guidance or an affirmation of a particular trajectory. It is still up to people to use their senses and intuition in making decisions. Qualitative aspects of the formula are vital yet commonly downplayed. Soft and hard facets of the system must be equally valued. An organic application with various functionalities may eventually find ways to capture the qualitative and convey emotions as we have seen with many examples in industry (Airbnb, Houzz, etc.). The authors present a four phase plan for implementing an ambitious and forward-thinking conceptual model. One goal of the present research is to develop and operationalize this approach moving forward. The phases of the model and current industry orientations are highlighted in Figure 2.

3.3.1 *Phase I*

The first phase will involve integrating and recalibrating the resident. It is important to first drive change through the customer as the remainder of the system will follow. This is because the system thrives based on the demands and purchase decisions of consumers (Stroebel & Kurlat). The erosion and diminishment of power within the system discussed earlier is partially due to the apathy and often negligence of the resident (Damery & Fisette 2001). Thus, residents can be given power with greater information to make more appropriate choices when it comes to their residences. They must be able to elect their desired characteristics based on unique personal needs. With optimal information, choices that are more reflective of lifestyle, community and sustainability will likely be made (the authors attempt to prove this). This phase will be tested by designing and piloting a comprehensive online application that improves the experience of decision-making and aims to modify choices by providing relevant information for the homebuyer. A process of market research will be followed by the design of a framework. This framework will be populated with

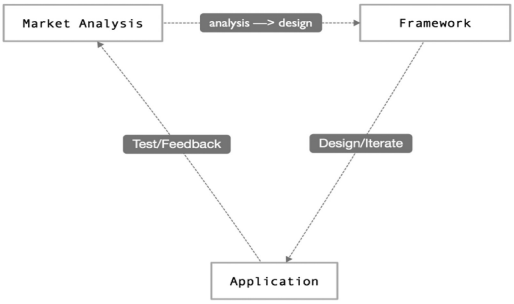

Figure 3. Process for designing and iterating application.

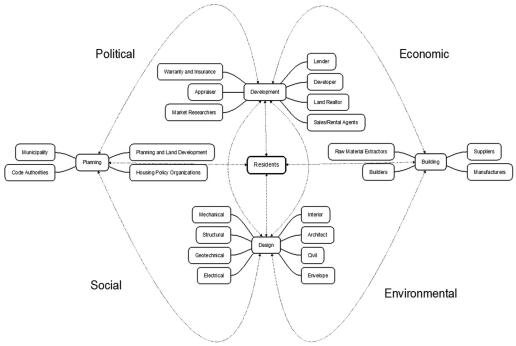

Figure 4. Reconfigured model for sustainable residential.

market data and be converted into an application. The application will be tested with a sample population then refined and redesigned until it is ready to launch publicly. An iterative process of designing and testing will ensure greater success upon launch. The process is summarized in Figure 3.

3.3.2 *Phase II*

With enough resident demographic information and desired characteristics populated into the network, information sharing with developers, market researchers, realtors and planners can begin. These stakeholders now understanding and having evidence for the desired characteristics of residents will begin to create feasible products that reflect these characteristics. Transparent qualities and ratings of homes can be compared and scrutinized. This will force stakeholders to ensure the products they are offering are appropriate and competitive. They may be required to reconsider and carefully evaluate the design and development of their products. Toward this end, a deeper consideration for place-making, quality of life and various other characteristics that are important to the end-users will take place. In many cases, the market may ask for unrealistic requirements. Developers, planners, market researchers and realtors cannot meet these needs alone. A more holistic strategy is key to progressing.

3.3.3 *Phase III*

Stakeholders from the second phase will begin informing designers, builders and lenders of the new requirement of residents that are known. These parties will then begin to create products that reflect those needs. In many cases, innovative products and services will be required to meet changing and more stringent and specific demand. New partnerships will begin to arise between various stakeholders who are like-minded or who see synergies through the application. Accountability for various teams will become paramount as the quality of residential developments can be compared and viewed globally.

3.3.4 *Phase IV*

The final phase will integrate the various supply chains of the builder, developer and lender. Ultimately, the authors aim at providing a fully integrated and responsive system online. Continuous feedback from new studies or innovative design interventions taking place in unique contexts will transfer rapidly through the network. For-profit and not-for-profit entities will be scrutinized the same way and competitive advantage without continual rapid innovation will be short lived. Products, concepts, characteristics and stakeholders will travel quickly and globally, finding the appropriate niches for their most suitable application. A revised model of the industry, placing residents front and centre, is outlined in Figure 4.

4 CONCLUSION

“The problem is that the scale, the speed, and the scarcity of means with which we have to respond to this process of urbanization, has no precedence in human history … so the role of the architect will be creating the right frame[work] so that the forces involved are channeled in the right direction.”
–Alejandro Aravena.

The residential design and development industry is, in the minds of the researchers, fundamentally broken. Over recent decades, economical and political factors have triumphed over social and environmental considerations. This has resulted in a highly vulnerable and short-term-focused system which is swiftly eroding our environment and draining the quality of life from residents, residences and communities. The current system (i.e. the status quo) must not endure. Responding to this dilemma, the authors presented a model for systemic reform and dramatic improvement. By creating awareness through the use of appropriate models and frameworks, and engaging technology as an intermediary in strategic ways, systemic reform can be created. The authors contend that our industry must transform in significant ways – it must arise anew in ways which value the end-user, has greater accountability for its actions and continually innovates in order to provide solutions that are more environmentally, culturally and socially conscious. Given the

undeniable role of housing in our lives, the unquestionable impacts of development in our economies, and the potential for design to make a positive difference, it is urgent for the players to creatively reshape our concepts, revise our constructs and restate our *raison d'etre*.

5 CONCLUDING COMMENTS

For certain, the cities of our future are designed to a large extent by city planning departments. These organizations design and plan decades in advance and consider the implication of urban plans for decades to come. These organizations are theoretically serving the interest of the people and citizens for which they are designing. However, often knowing the exact needs and understanding the future requirements of citizens is difficult. Values, interests, family compositions and lifestyles are continuously evolving. With such rapid change, cities must address these dynamic shifts. By giving a voice to residents and involving them in the discussions of the future of their cities can be of great value. In part, the city planning departments can both create this engagement and influence perspectives. However, developers, marketers, architects and builders may also play a critical role. By engaging in discussions with future customers for the products which they will be providing, they may create more reflective products while shaping the perspectives of their future customers. These entities are powerful in their ability to direct, control and empower resident opinions about their residences and communities. The media also has a significant influence on the perceptions of residents. All together, there are various ways of empowering and educating citizens on the subject of their residences.

Addressing dynamic shifts in values, interests, family compositions and lifestyle choices are not problems that cannot be solved through the acquisition of greater information and engagement of citizens alone. Development of architecture that is responsive to this change is necessary. We can for example create buildings and spaces which are agile. Where the effortless movement or flexibility in design allows diverse needs to be addressed. By better understanding the demographics and target markets, environments of multi-purpose or mixed-uses can be created with the right balance of spaces available for various family compositions and lifestyles. As property values and density continue to grow in the most desirable urban centres, space will become a more critical commodity. Therefore, it will be paramount that this space is utilized in the most efficient way possible as it is negotiated and renegotiated over multiple uses with various stakeholders.

Shell performativity as a tool for urban action

S. Vyzoviti
Department of Architecture, University of Thessaly, Volos, Greece

ABSTRACT: Within the financial glacier that has been settling into crisis stricken Greek urban centers the aging building stock of devalued and abandoned sectors has evolved into an experimental testing ground for architectural research. In this context the paper investigates small-scale and short-term interventions that challenge and upgrade current urban renewal strategies. The research hypothesis assumes that architectural operations which engage the building shell can acquire urban effects.

1 INTRODUCTION

As Western cities change character seeking new organizational systems for their deteriorated or redundant structures, small-scale and short-term urban interventions become more pertinent than large-scale and long-term urban development programs. Derelict urban areas and informal spaces become the terrain of alternative, citizenship empowering, urban actions. In de-industrialized and crisis stricken Greek urban centers an increasingly large amount of the building stock is unoccupied and manifests abandonment and dereliction. This emergent spatial surplus can be considered as a testing ground for the development of proposals that upgrade the currently fatigued notions of renewal and restoration.

To this end interventions that concern reconfigurations of the existing inactive buildings are investigated with an outlook to their urban effects. The focus lies on the building shell which in my research hypothesis is conceptualized as an urban artefact. Modifications of the shell are explored towards the orchestration of physical environmental conditions that constrain and support urban actions. Scenarios of expected use are often encoded into the design of objects in a normative manner. Instead, the notion of performativity provides the theoretical framework for a new signification and programming of the building shell revealing a field of opportunities for re-inhabitation.

Reconfigurations of the existing building mass empower the redefinition of the architect's professional expertise. Implementing the theoretical endeavor this paper discusses some speculative projects that are embedded into the contemporary Greek urban context as urban paradigms. In terms of design methodology the projects revisit design tools that have been habitually employed to configure urban space – the *urban poché* and the *streetscape* through the perspective of digital modeling.

2 THEORETICAL FRAMEWORK

2.1 *Aspects of performativity in architectural discourse*

The notion of *performativity* represents the current turn in architectural discourse to move away from describing architecture as purely a physical object but rather as a process (Smitheram 2011). Embedded in the digitally driven architectural design and fabrication methods (Kolarevic 2006) the concept of *performativity* refers to generative design processes as well as to responsive architectural elements such as dynamic facades and adaptive surfaces. The concept appears equally pertinent to the human centric architectural discourse providing a common ground between the two apparently conflicting schools of thought.

In the field of design research *performativity* is deeply associated with the notions of *function* and *use*. In the performative approach to the study of human-artefact engagement embedded in recent theories of computation use is viewed as a kind of making while users are considered as active performers of open-ended, unfolding and improvisational tasks rather than passive recipients of the designers' directives or automatic enactors of scripts and use plans (Vardouli 2015).

User centric representations of the experience of space relate performativity to the practices of the everyday referring to the reciprocity of daily performance with the assertion of identity in place. The idea of the performative body as an active creator has been exemplified in the spatial practices of urban subcultures with skateboarders as paradigm (Borden 2003). Spatial appropriation of informal and interstitial urban spaces by 'marginal' urban groups is considered as a creative engagement with the physical setting which demonstrates the latent possibilities that exist within such contradictory territories (Shaw & Hudson 2009).

The concepts, theories and general problematics of emergent spatial practices are crucial in the definition of a research by design agenda for redundant urban structures. Taking into account their state of abandonment standard functional analysis may be irrelevant. Instead, theories of improper uses – of people's appropriation and objects' affordances are better connected to the matter at hand. The notion of *affordance* (Gibson 1977) was introduced in ecological studies to describe the opportunities and risks, as possibilities for action that the environment provides to the animal. In cognitive science *affordance* refers to an object's ability to provide clues of its operation (Norman 1988 in Vardouli 2015) or a scenario of use encoded in an artefact to be decoded by the users (Vardouli 2015). Designing for performative human-artefact engagements entails a consideration of the artefact as interlocutor (Ackerman 2006). The artefacts' evocative or holding power depends on the right balance of freedom and structure. Its design ought to allow for personal reconstruction.

Behavioral models of emergent spatial practices that are constructed on the basis of empirical observation of insurgent urban groups that make use of available urban resources (Vyzoviti 2006) make explicit a probabilistic interrelation between the morphology of an appropriated location and the activity it accommodates. Human activity is constrained by the spatial envelope, though this should be considered as a necessary but not sufficient condition. This non deterministic stance to physical environmental constraints could be best described through Walter Benjamin's words as *indefinite and improvisational interpenetration of building and action* (Benjamin & Lacis 1925). In *Naples,* urban space is envisioned as a porous stone, the liveliness of its courtyards, arcades and stairways provide a condition of *porosity* that avoids the assertion of the definitive and preserves the scope to become a theater of new unforeseen constellations (Benjamin & Lacis 1925).

A performative stance to designing within available building resources ought to pursue reconfigurations of the existing that open up a field of opportunities for multiple potential appropriations. The orchestration of multiple artefact affordances may require design tools that intersect the computational and the human centric approaches. To this end a competent research agenda ought to combine the technological agility of digital design techniques with recent theories of use as a form of making. Intentionally avoiding a deterministic stance to the design of urban spaces and objects my investigation pursues the orchestration of physical environmental conditions as affordances that may support (or inhibit) emergent urban phenomena.

2.2 *A new signification of the building shell*

Emptied out of activity the building stock-redundant or deserted- becomes a contemporary ruin. The primary function of the building shell is reversed. Rather than an envelope that encloses a private interior it becomes the tectonic layer that surrounds public life. Such a conceptualization does not necessarily conflict the current intensity in the design of innovative new building shells; screens, smart, environmentally sensitive envelopes, dynamic facades, shafts, and inclined transitions. The focus on the shell empowers the redefinition of the architect's professional expertise towards an architecture of the surface, consisting on lightweight materiality that combines environmental sensitivity with digital craftsmanship.

I am particularly interested in the notion of surface as a minimum act of architecture. Departing from Semper's argument that the full force of architecture is to be found in the outer surface, the decorative layer through which the atmosphere seemingly percolates, Mark Wigley suggests that this may be just enough to construct architecture: *simply to pop up a surface that produces an atmosphere* (Wigley 1998). In this respect, superficial modifications of the existing building shell that are small-scale, lightweight and temporary bare the potential to acquire high architectural impact.

In the theoretical origins of digital architecture *surface* is conceptualized as a topological and pliable entity which provides a strategy *for the intensive integration of difference within a heterogeneous yet continuous system* (Lynn 1993). Working within the contradictory and sometimes incongruously diverse morphology of Greek city centers manipulations of the surface can accentuate the establishment of continuity between fragmented and residual spaces towards a perceptual and eventually inhabitable new whole.

2.2.1 *Learning from traceurs and skateboarders*

Conceptualized as an urban artefact, the building shell becomes embedded in narratives of multiple possible appropriations; its affordances are augmented by non-standard or improper usage. Observations of groups of *traceurs* (free runners) and free-style skateboarders in action provide empirical evidence that supports this argument.

The trajectory of a free runner in a session of parkour takes place on the roofs and terraces of two adjoining buildings. The path indicates-articulated in sequence-the locations where the constituent acts the activity system of when parkour take place (Fig. 1). In this case: crawling through the window onto the terrace, accelerating, jumping up, balancing on the pitch roof, climbing up the wall and the stairs, vaulting over the ledge, dropping from terrace to terrace, and repeating the last sequence in loops before accessing a stairwell to descend with a new combination of tricks. The free runner's trajectory connects areas of different altitudes between which transitions may seem impossible, absurd, or reckless considering their standard use. A virtual continuum –out of which a single surface model could be derived- is established by the runner's body that invents paradoxical continuities between dispersed building fragments (Vyzoviti 2013).

The documentation of free-style skate sessions at a generously designed public entrance of a culture

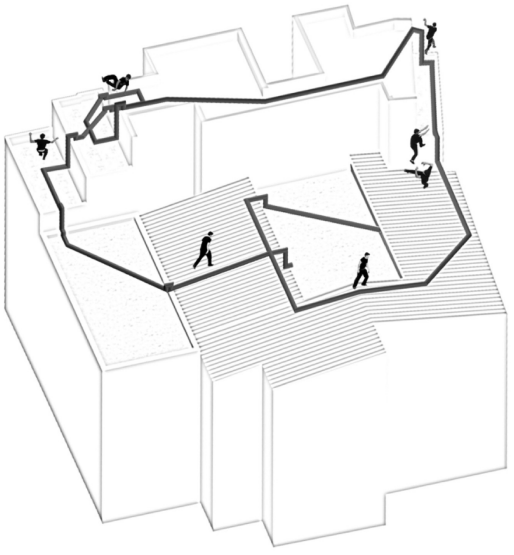

Figure 1. Documentation a free runner's trajectory of on the basis of participant observation (Vyzoviti 2013).

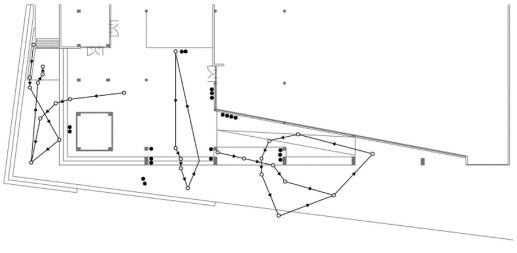

Figure 2. Digraphs of concurrent freestyle skate sessions on the basis of participant observation (Vyzoviti 2005).

complex (Fig. 2) includes digraphs of skate trick trajectories – grinds, ollies, and flips – deduced from observations. (Vyzoviti 2005) Architectural elements such as steps, ledges, ramps and columns facilitate distinct activities within the sequences of actions composing each trick. Skaters 'grind' the steps and the handrail, 'ollie up' the ledge and 'ollie down' the steps, 'flip' on the ramp and so on. The improper use of dispersed architectural elements through their articulation within skate tricks augments their affordance as urban artefacts. In addition a distributed, highly interconnected micro-location network is created in the establishment of continuity between distinct and dispersed architectural elements through their seamless incorporation within continuous skate tricks.

2.2.2 *From building shell to urban poché*

The practices of free runners and skateboarders make evident a reconfiguration of the available urban resources by making use. As diverse architectural elements are edited into coherent sequences within performative acts, the establishment of an operational continuity between them occurs. Consequently a new signification of the building shell arises: from distinct architectural elements to an operational field of solids.

Yet, the conception that urban space is configured through a spatial field of solids constituted by architectural elements is not novel. In the figure-ground theory of urban design the term *urban poché* connotes the configuration of urban voids through the walls, columns and other solids of buildings. This configuration of the public realm as a *poché* space outlined and delimited by the private building mass is habitually exemplified in the Giambatista Nolli's Map of Rome (1748). According to Roger Trancik the *urban poché* engages the buildings to their adjacent voids. Pursuing its continuous imprint on the plan can integrate the design of the public realm with the design of the private object (Trancik 1986). Taking advantage of the current digital design tools I propose an augmented understanding of the *urban poché* as a three-dimensional continuous surface enclosing the public domain.

3 CASES OF DE-INDUSTRIALIZED, CRISIS STRICKEN HISTORIC URBAN CENTERS

The investigation adopts the methodology of research by design. In accordance to the theoretical framework speculative projects for de-industrialized and crisis stricken historic urban centers are developed. Conducted within intensive design studios at the advanced architectural design post graduate program *INSTEAD_parapoesis* of the Department of Architecture, University of Thessaly in the academic years 2013–14 and 2014–15 two situated case studies in the country's major urban centers are discussed.

The first case focuses on the Quarter of the Francs (Frangomachalas) located in the western part of Thessaloniki's downtown. A thriving, cosmopolitan bankers' and goldsmiths' quarter in the first part of the 20th century, the area has transformed since the annihilation of the city's Jewish community -which constituted its major population group- during the WWII, into a high density, mixed use quarter of layers' and notaries' offices, textile industries, small scale manufacturing, warehouses, and gross handling and retail stores. During the past two decades it has gradually emptied out of manufacturing uses, and acquired the character of an urban zone in transition whose latent possibilities are revealed in the recent, fragile establishment of city's creative industries (Tarani 2011) nightlife and urban bohemia within its extents.

The second case focuses on Euripides Street located in the historic commercial center of Athens. The street manifests the transition from the neoclassical city – best exemplified by the Neoclassical Trilogy Complex at Panepistimiou Street that houses the Academy, the Library and the University of Athens, to the vibrant and problematic area of Koumoundourou Square that now hosts the Chinatown and the immigrants' enterprises and gathering places. Lying within the food market sector of the downtown the street is a characteristic sample of the urban fabric displaying high density

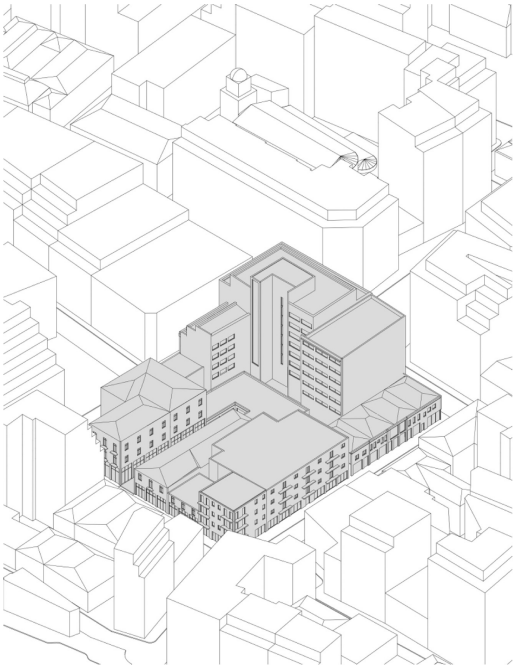

Figure 3. The mix of typologies and architectural styles in an urban building block at the Quarter of the Francs.

and mixed use in a typically Greek cross section: gross handling and retail stores on the ground floor, offices, small scale manufacturing and warehouses on the upper levels.

Having gradually emptied out of manufacturing uses during the past decades both areas of study demonstrate the character of a semi-abandoned urban zone in transition. Both possess a distinct ambiance, manifesting deterioration while at the same time making evident the traces of a thriving commercial past. Both present a mix of various building typologies and architectural styles within urban blocks. In this high density urban fabric, the generic high rise office and manufacturing buildings coexist with once glorious samples of early 20th century Eclecticism -in the Quarter of the Francs (Fig. 3), and Neoclassicism, in Evripides street. The redundant building stock, entrapped within the financial glacier of the recent Greek crisis withstands renewal allowing for bottom up incremental developments and provides certain affordances for experimental urban actions.

In this urban context the design agenda pursues the articulation of the theoretical framework into generative concepts and tools. The new signification of the building shell as a receptor of urban actions is considered as an architectural lever for the activation of the redundant building stock.

3.1 *Quarter of the Francs – Thessaloniki*

A typical cross section through the Quarter of the Francs reveals a high contrast in occupancy. The urban ground floor is porous, abundant in activity within arcades, narrow streets and secret courtyards. The high rise lays mostly unoccupied, still: a post-industrial ruin. As such the abandoned upper levels possess the nostalgic sensuality of decay, withholding opportunities for multiple temporary appropriations. The intention of the design agenda for interventions within the area was to unveil the potentiality of a porous condition above the ground floor through the discovery of available spaces in the upper building levels. Drawing from insurgent urban practices such as parkour, UrbEx, and graffiti, as well as the situationist practice of the *dérive* an urban walk was outlined. Three-dimensional trajectories were articulated within the existing networks of paths. These sequences of micro-locations were composed providing public access to discovered or invented or new common grounds to become available for a variety of urban groups.

The existing vertical circulation systems constrain the potentiality of the porous condition in the apparently impermeable upper levels. The definition of a three dimensional urban trajectory was employed as a design tool that enables the selective editing of fragments within a continuous path. Modifications of the building shell would accentuate the establishment of continuity by providing access. To this end, alterations in the vertical relief of existing building envelopes were combined and integrated with paving. The introduction of new circuits, entry points and destinations within existing urban blocks would promote an exploration of locality and a keen awareness of the ambience in the area. The attribution of public content to the abandoned facades, roof tops and shafts was expected to correspond to a material treatment of the building shell that could render its affordances perceivable.

In the '*Scaffolding*' project (Fig. 4) the incongruous but historically defined adjacency of generic high rise office and manufacturing buildings with the remains of the freemasons club *'losis veritas'* build in the late 1920's is considered as an opportunity to create a new public ground. A publicly accessible open air *piano nobile* is created on the roof of this contemporary ruin. The design proposal confronts the scarcity of urban open spaces in the quarter providing for urban action groups and local associations currently in need of gathering spaces. Employing a perceptually unifying grid the blind party walls of the two high-rise buildings are treated in a continuum with the roof of the ruin. The lightweight net structure can articulate and receive elements of urban furniture, projection screens, vegetation, steps and movable platforms. Access to the rooftop of the former *'losis veritas'* is orchestrated as a complicit use of the abandoned ground floor.

3.2 *Euripides street – Athens*

In the series of projects developed for Euripides street the notion of surface enables the departure from the two dimensional representation of the figure-ground plan to a three dimensional calibration of the street profile. The manipulation of the *urban poché* by section

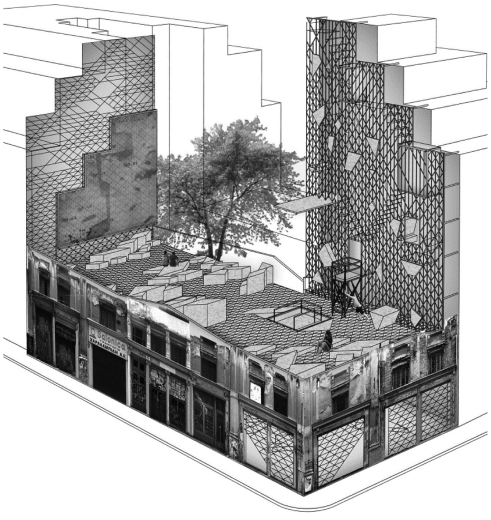

Figure 4. The '*Scaffolding*' project at the remains of the freemason's club '*losis veritas*' in the Quarter of the Francs.

was employed as design tool in order to document the complexities and reveal the potentialities inherent in the street profile.

Instead of an exterior boundary to a private interior, the building shell is considered as a porous tectonic skin integrated within a three dimensional surface that contains the street life. The current appropriation of the streetscape by groups of ethnic immigrants in the South end of Euripides Street is an extreme paradigm of an augmented condition of the urban poché. Architectural elements and urban objects– columns, doorsteps, ledges, lampposts, cars, bollards, carts and boxes – acquire a second life as an open air urban living room (Vyzoviti 2005). The integrative function of the concept of surface enables the inclusion – in addition to the building shell – of objects that may refurbish the street as they become inscribed in the practices of its inhabitants.

The '*Gardens of Evripides*' project (Fig. 5) pursues a systematic integration of vegetal elements into building shells along the street. Instigated by the discovery of a local delicacies shop green façade, it investigates processes of naturalization of the vertical relief that recall the currently lost manufacturing character of the area. Consecutive sections through the urban poché identified a number of south-facing high rise facades located opposite to low rise ones, which become the sites of implementation. The scenario for reconstructing local manufacturing businesses entails the installation of a digital fabrication laboratory (*FabLab)* in the premises of the abandoned warehouses.

The attribution of novel functions into a publicly accessible interior physically enlarges the street profile. It can also affect the processes of its transformation. In this case a robotic arm partakes in a number of tectonic transformations (drilling – printing – depositing seeds) altering the eligible for re-naturalization building shells along the street.

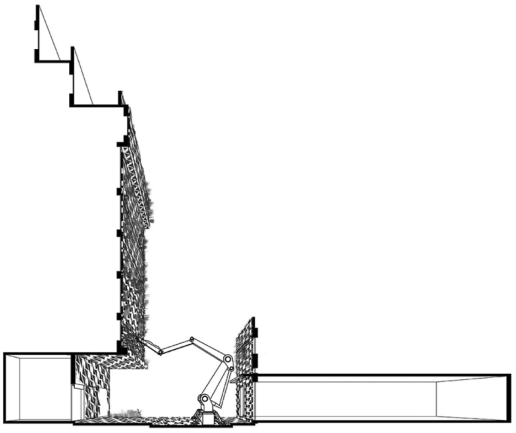

Figure 5. The '*Gardens of Evripides*' project.

In this project the orchestration of an incremental and hi-tech shell renovation process embodies a physical manifestation of performance.

In the *'Urban Canyon'* project (Fig. 6) the Evripides street profile is considered as a vertical terrain of activity. The redundant building shells are treated as a craggy and steep urban topography upon which a probabilistically augmented urbanity may be evoked. Standard rock climbing accessories such as steel hooks and rings are meticulously installed on selected facades inviting urban climbers and base jumpers to appropriate the abandoned buildings. Deployable hanging tent systems -known as *portaledges*- can be attached on the building shell. These temporary adobes hovering over the street may reveal some romantic framed views of the Acropolis. At the same time they contradict the spectacular subtly addressing the necessities of the new Athenian crisis enforced homeless.

4 CONCLUSIONS

In this paper I examined a new signification of the building shell as a receptor of urban actions. I analyzed the conceptual dimensions of performativity in architecture focusing on use-centric design discourses and particularly on the spatial practices of emergent urban groups.

I investigated small-scale and short-term architectural interventions that may activate the redundant building stock of de-industrialized and crisis stricken areas of historic urban centers in Greece. To this end I discussed a series of speculative projects situated in Thessaloniki and Athens which have been developed under my supervision in the academic studio. The urban poché and the urban trajectory have been employed as design tools. Their cross fertilization with narratives of performative acts and computational methods produced some counter intuitive and innovative proposals.

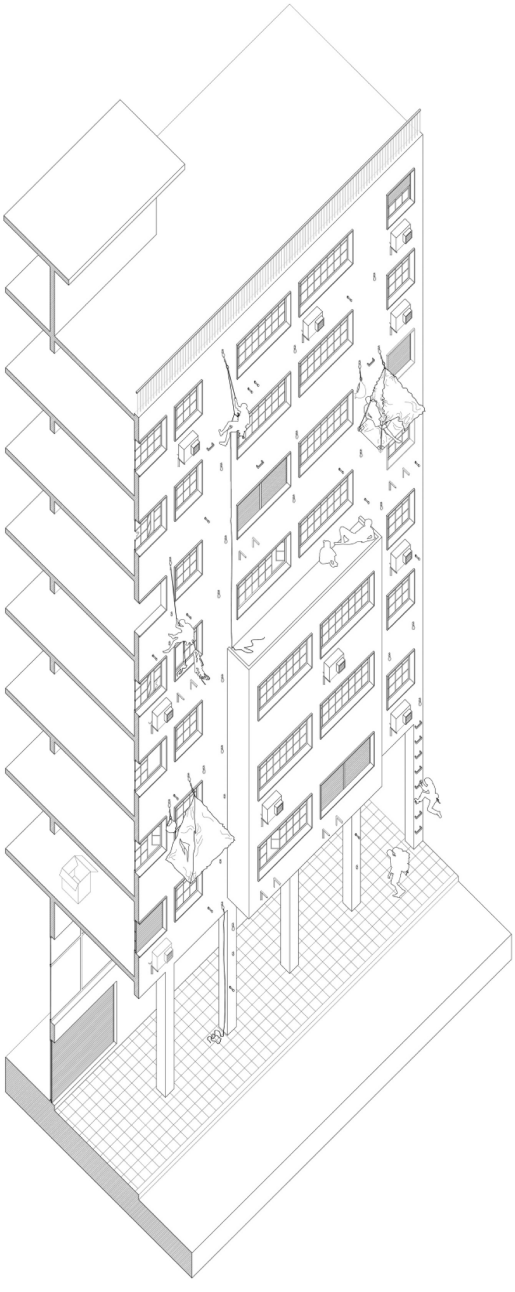

Figure 6. The '*Urban Canyon*' project.

Architecture traditionally displays elongated response time to cultural change. Socially urgent spatial necessities are often satisfied through reconfigurations of the existing available resources. In this respect the paper proposed a research agenda for the design of urban artefacts that are open to appropriation by providing conditions for usage that has not yet been acknowledged.

ACKNOWLEDGEMENT

Figures 3–6 comprise visual material from the projects developed under the supervision of Sophia Vyzoviti during the intensive design studios *Shell* and *Urban Poché Reloaded* at the advanced architectural design post graduate program *INSTEAD_parapoesis* of the Department of Architecture, University of Thessaly in the academic years 2013–14 and 2014–15. Figure 3 was produced by A. Ioannou and D. Dimitrakopoulou. The '*Scaffolding*' project presented in Figure 4 was developed by T. Papanikolaou and S. Psomiadi. The '*Gardens of Evripides*' project presented in Figure 5 was developed by E. Kalargali, K. Kallou and A. Kyroudi. *The 'Urban Canyon'* project was developed by I. Karras.

Machinic approaches_new methodologies for responsive environments

B. Uçar
Ted University, Ankara, Turkey

ABSTRACT: Recent examples of responsive environments denote a reciprocal relationship between the human and the machine, where the environment and the participant are considered as responding to each other and to the relations defined between them. This reciprocal condition is attained through machinic approaches, which alter the definition of the machine as mechanism, and consider the human and the machine as actively participating in the interaction process. In order to take full potential of this approach, and continue this reciprocal relationship, the designer of the process weakens the control over the process and embrace unpredictability. The paper considers the potentials of this approach, which offer the production of new conditions and relations while initiating significant methodological transformations in architectural design practice.

1 INTRODUCTION

Developments in sensing technologies, material science, engineering and information technologies enable the definition of flexible, sensuous, and responsive spaces that respond to the changing conditions, relations and behaviors of spaces and participants. Introduction of the concept of responsiveness to architecture alters the definition and experience of space in a radical way and questions the relations between environment, participant, architect and machine. These relations are triggered to become reciprocal and respond to the inputs provided by each other, which engenders new spatial experiences.

Shared by many parties (human, non-human), the responsive environment is defined in relation to the interactions between the participants and the environment. The information produced through their interaction enables the communication between them, hence defines the responsive qualities of the environment. In this advanced communication, both the environment and the participants affect and redefine each other. Through sharing and exchanging the information gathered and produced, the reciprocal relationship is attained, which can be considered as the significant feature of responsive environments. Ability to affect and be affected from the interaction process enables to sustain the productivity (not in terms of physical efficiency or operational accuracy, but rather as the continuity of the interaction) of the environment, since the participant and the environment constantly adapt and redefine the relations. In this constant redefinition, the responsive agent is not only the environment but also the participants, who actively take part in the interaction process rather than passively experiencing it.

2 DEFINITION OF RESPONSIVENESS THROUGH MACHINES

The concept of responsiveness and the definition of the responsive environments have undergone significant changes in the last two decades, where the environment is defined not only as being affected by the participants but also as an active agent that affects them. The reciprocal condition of the interaction process is defined and produced through machines, where the responsive environment holds the responses and experiences of the participants. In responsive environments, machines provide the engagement of participants and environment and enable their interaction with the information to define a continuous and simultaneous interaction. They do not only transfer and translate the responses of the participants, but also stimulates and provokes their behaviors, experiences and reactions. Therefore, the machines are also considered as participants of this interaction process that demand the contribution of all human and non-human parties. This shift in the conception of responsive environments alters the definition of the environment and enables new readings of the relations between the environment, human and the machine. This intricate relationship, defined through different parties, necessitates the reconsideration of the concept of machine in the definition of responsiveness. The active participation of the human and the machine in the interaction process alters the consideration of the machine as a passive computer mechanism responding to the inputs form the participants and the environment according to the already defined set of decisions, and introduces its active participation in the interaction process, which revises its focus on performance.

Although the machine concept is associated mainly with production and efficiency that relates it with mechanisms, it is also possible to reconsider this concept in reference to Deleuze and Guattari's definition of the machine. They suggest the consideration of the machine as being in continuous transformation that make new connections in order to transform and maximize themselves, while connecting and reconnecting to different machine(s), which are also in evolution and mutation processes (Colebrook 2002). They define mechanism as a closed machine that has a specific function and never transforms itself or produces new connections, where the machine does not have a closed identity like a mechanism. (Deleuze & Guattari 1983). It does not produce something determined by someone, but rather produces for the sake of production itself. (Colebrook 2002). This concept of the Deleuzian machine is related it with heterogeneity and dynamism and opposes the static conception of the machine as a mechanism. Therefore, consideration of the machine as a Deluzian machine, rather than a mechanism, re-problematizes the definition and design of interaction processes in the responsive environments.

In this sense, the paper considers three examples from different periods, which offer different approaches for the definition of responsiveness and the conception of the machine. They all have different approaches for defining the responsive experience, where the machine is conceptualized as being more than an agent of production and efficiency. Related with this discussion of machinic approach, the paper questions the methodological shifts defined in the architectural design practice. Along with that, the altered the position of the architect will be discussed in reference to the definition of the responsiveness through machines in these three examples.

2.1 *Unpredictability as a generative impulse*

The altered condition of the architect is also related with the definition of the interaction process, which enables continuous data exchange between the participants and the environment. When the responsive environment defined through machines is constantly transformed to provide new experiences and conditions, it continues to define new relations and inputs to the system. However, when the responsive environment responds to the similar inputs from the participants with similar outputs during the interaction process, it acts as a passive element instead of a provoking one. In such a case, the continuous interaction between the environment and the participants may blur and lead to predictable and similar experiences, which do not inherit variation of experience and relations. Therefore, it is possible to claim that predictability and similarity of the interaction between the environment and the participants may disrupt the continuity of the interaction process.

The concept of unpredictability can be conceived as a motivating aspect and a generative impulse for the variability of experiences defined by the responsive environment. Embracing unpredictability as a design strategy necessitates the reconsideration of position of the architect in the definition of the responsive environment and the interaction process. In order to take the advantage of this concept, the architect needs to weaken his/her control over the process and welcome inputs from the participants (human, non-human) even if they are not included in the pre-defined set of relations. This approach decentralizes the position of the architect in the design process and also enables to go beyond the conception of machines as mechanisms. It rather considers them as being in continuous transformation together with the other participants, which are also in transformation.

2.2 *Recasting the interaction process*

The paper considers three experimental projects, in which the machine concept is triggered to go beyond its mere definition as a mechanism; Yona Friedman's *Flatwriter* (1967); Cedric Price's *Generator* (1976–79); and R&Sie(n)'s *An architecture 'des humeurs'* (2010) projects. These projects introduce an interactive relationship between the machine and the participant through a responsive environment, where the space is defined through the inputs provided by the participants. The discussion on these projects is based on the architect's control on the interaction process and the productivity of the process, where provocative, unpredictable and indeterminate condition of human-machine relationship is compared with determinism of human-mechanism relationship.

Being influential in 60's with his flexible city concept, Yona Friedman proposed a system in *Flatwriter*, where the future inhabitants plan their apartments through an interface that responds to the decisions of the inhabitants (Lebesque & Vilissingen 1999). Although the project that was conceived for the World Fair at Osaka was not built, it was an influential project for the concept of responsiveness and the initial definitions of responsive systems. It allows the inhabitant to locate the future dwelling defined according to his/her preferences and decisions in a predefined infrastructure (Friedman 1971). In the proposed system, the user interacts with a keyboard of 53 keys having figures upon, through which the user implements his/her choice by inserting solid blocks within the infrastructure (Friedman 1971). The user is guided by the mechanism during the interaction process about his/her decisions about the possible consequences of his/her decisions. It provides warnings concerning the previously defined configurations and locations of the apartments introduced by other users (Friedman 1975).

The warnings provided by the responsive system can be considered as an intention to ensure maximum efficiency from the process and achieve the right combinations for the definition of the apartment. Although the project aims to define an active user that defines the output through the interaction process, the responses of the system are still limited with the design decisions of the architect. The user is not free in his/her

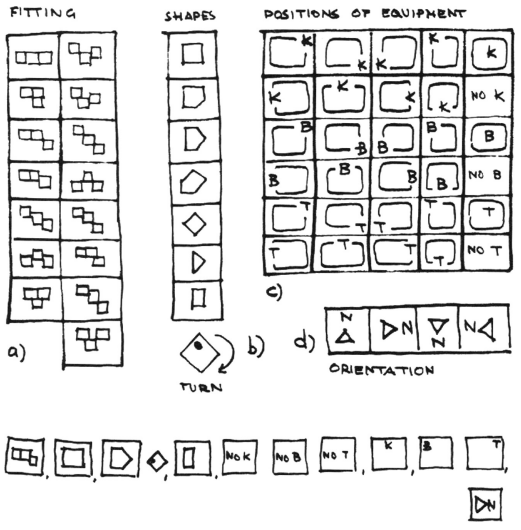

Figure 1. The repertoire of choices in flatwriter.

Figure 2. Electronic model and sketch of generator project.

decisions entirely and can fill the voids of the predefined infrastructure, without conflicting with the decisions of other users and the architect. In this process, the responsive system acts like a mechanism rather than a machine, since it only executes the commands of the architect according to the predefined repertoire and is passively involved in the process. Therefore, the architect is still the dominating figure in the definition of the built environment, interaction process and responses of the system. This is a common point in numerous recent projects of responsive environments, where the responsiveness of the system and the environment are controlled for the efficiency and performance of the system.

Another unbuilt example that holds the discussion of the altered position of the architect in the definition of a responsive environment through machines is the *Generator* project designed by Cedric Price in collaboration with John and Julia Frazer between 1976 and 1979. Designed as a visitor center, the project accommodates facilities like dance, theater, and exhibition, where the visitors actively participate in the definition of the event and the form of the building through interacting with the system. It consists of modules that enable the reconfiguration of the environment to respond to the visitors' experiences, choices and co-operations with he environment (Frazer 1998).

Price's definition of the responsive environment offers a reciprocal relationship between the machine and the participant, where they interact with and affect each other continuously. This relationship suggests the use of machines as participants of the system that creates new interactions and relations, rather than being simple mechanisms that technically enable the continuous transformation. The interaction between the machine and the visitor starts where the visitors are set in dialogue with a computer interface at the entrance of the center to state their preferences (Mathews 2007). The modules are adjusted according to the preferences of the visitor and different scenarios will be scripted to transform the environment (Furtado 2008). Endless variations will be attained according to the inputs provided by successive visitors and the environment will evolve into a collaborative one that is defined according to the interaction scenarios. One significant aspect about the project was related with the boredom condition, which suggests that the system will introduce random inputs to the environment to trigger the monotonous interaction conditions and to facilitate diverse spatial experiences (Price 2003). The system is designed to improve its own strategies for organization and make proposals about rearrangements of itself, which are unpredictable for the visitor and also for the architect (Furtado 2008). Therefore, in *Generator*, the proposed system not only responds and adapts to the preferences of the visitors, but also actively participates in the interaction process and introduces inputs to the environment and visitor.

Embracing unpredictable conditions and leaving the control to the participants (human, non-human) enables to assimilate the responses and preferences of the user in the definition of the environment, despite conflicting situations between different users. However, the conception of unpredictability in *Generator* is not associated with ultimate unpredictability of all process, but else with unpredictability of variation in form. In *Generator*, as compared to *Flatwriter*, the designer intends to attain the variability of conditions and productivity of the interaction process rather than controlling the form and output of the interaction, and hence allows certain conflicts and unpredictable conditions. However, it is still possible to trace a desire to control the process for sustaining the continuity of transformation through the unpredicted input of the system to the environment and the visitor. When the variation in form is not at the desired level, the architect is indirectly involved in the interaction process and interferes the responses of the machine. However, the centralized position of the architect as directing all the design and interaction process is getting blurred in this example to define a responsive environment through a participatory and reciprocal interaction process.

A recent example of responsive environment is proposed by R&Sie(n) titled as *An architecture 'des humeurs'* that alters the position of the architect through machinic approaches and introduction of unpredictability to the interaction process. It is a research project exhibited at Le Laboratoire (Paris,

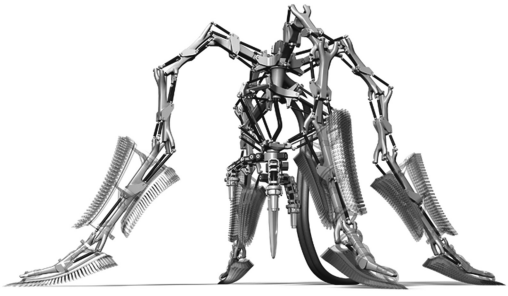

Figure 3. The machine used in the robotic process.

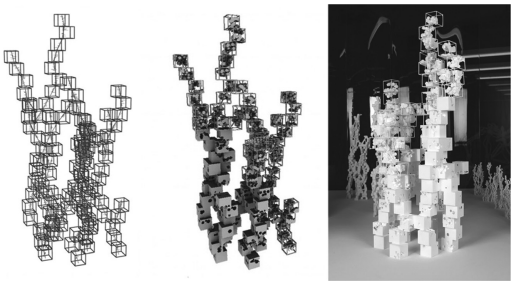

Figure 4. *An architecture 'des* humeurs' by R&Sie(n).

2010) that questions the relationship between the body, machine and environment. It offers a habitat according to the data obtained from the visitor and provides the spatial correspondence of his/her contingencies, conflicts, and desires. The visitor is confronted with a machine upon entering the exhibition area, which traces biological and physiological data for the production process ongoing simultaneously at another room (Zwingenberger 2010). During this interaction, a vapor is released that the visitor breathes in, through which the emotions of the visitor are detected. Through the vapor, four different moods are traced at molecular level, which directly affect the morphology of the future dwelling: Dopamine (the pleasure molecule), Adrenalin (the molecule of the ability to react to a need for energy), Serotonin (the molecule of melancholy or —depression‖), Cortisol (the molecule of anxiety or stress) (Zwingenberger 2010). Therefore, emotions, desires and needs of the visitor are traced through chemical secretions and also his/her responses to the questionnaire (neurobiological response). The conflicting situations -defined as misunderstandings- between the responses expressed verbally and traced chemically are intentionally constructed in the project to bring out a tension and an area of contradiction. The contradictions are processed through a script that is designed to acknowledge the definition of habitable morphologies according to the contradictions and contingencies of the visitor scanned through the interaction process (Roche 2011). Through this script, possible habitable morphologies of the future dwelling are prototyped by a robotic machine in parallel with the interaction process, which the visitor confronts after crossing to another room (Roche 2011).

The morphology is an end result of unpredictable expressions of the relations between the environment and the participant, where the machine is defined as producing new relations and embracing conflicts. R&Sie(n) explains their intentions about the proposed morphology and states that: '*The purpose is to emancipate ourselves from a conceptual logic that starts from a preconceived structure, and instead give rise to a physical matrix that reacts to the heterogeneities of human organization and adapts to the multiplicity of morphologies and the ambiguous desires of 'future purchasers'. This open source approach can replace the determinist and predictable typology usually employed for collective residences* (Roche & Naphegyi 2010). In *An architecture 'des humeurs'*, the unpredictability of the output and the deterministic conditions of the interaction process are triggered with a machinic approach, where the machine initiates blurriness and unpredictability for the visitor. François Roche defines these machines as schizoid machines, where they produce flows of information and pretend to the something while doing something else; they do not only act as a receptor that the visitor interacts with, but also maps the emotional states to be processes through the script in order to create the habitat for his/her desires, emotions and conflicts (Roche 2010). Since the principles of these decoding and recoding processes are not visible to the visitor, the process introduces unpredictability for her/him. The situation also creates unpredictability for the architect, since the inputs, conflicts and contingencies provided by the visitors and the outputs produced through the script are unknown for him. In this approach, the architect lessens his control over the process and form intentionally and leaves the control of the output to the participants: both human and non-human (machine). Therefore, it is possible to claim that the position of the architect as controlling the interaction process in the definition of responsiveness and responsive environments is altered in this example.

The considered projects are experimental projects that make use of computational design tools and strategies and alter the relationship between the architect, machine and the human participant to introduce responsive environments. Responding to various inputs provided by the participants and adapting to different conditions defined through the interaction process, they alter the definition of the machine, the relationship between the machine and the participant and also the authority of the architect. Common in all three examples is the concern for mapping the desires of the inhabitants and to respond to his/her desires, needs and emotions as much as possible through responsive environments. In each of these architectural projects, the relationship between the machine/mechanism, participant and the environment is defined through different interactions, where the position of the architect is also challenged. Not only each project offers a different technical operation, but

also conceptually offer different stands for the definition of the responsiveness, acknowledgement of conflicts and unpredictability.

In order to attain the desired level of responsiveness, they re-conceptualize the machine concept and alter their definition as mechanisms to participate in the interaction process and to attain a reciprocal relationship. These aspects are challenged more on Generator and *An architecture 'des humeurs'* projects as compared to *Flatwriter*. However, despite the deterministic approach and the strict control of the interaction process, *Flatwriter*, which is an initial example of responsive environments, can still be considered as an avant-garde project that questions the relationship between machine and participant and intends to alter the built environment. They all define the participant as the major party in the decision-making process and define the output according to the inputs provided by the participant. However, in *Flatwriter*, the participant's inputs are recognized within the limits defined by the designer, where the designer keeps the control of the process and the output. The interaction process in *Flatwriter* is more deterministic as compared to the other two projects, which leads to a repetitive interaction process of which outputs are predictable and controllable. Considering the proposed interaction scenario, it can be claimed that, the responsiveness of the process is limited intentionally by the designer to control the output.

On the contrary, in Generator and *An architecture 'des humeurs',* the participant is stimulated deliberately to go beyond the predefined inputs to emancipate the controlled outputs of the interaction process. Yet, in *Generator,* the architect interferes the process to ensure the continuity of interaction and the variation in the outputs. Despite the clear intention to leave the control of the process to the participants (human, non-human), which shifts the centralized position of the architect, it is still possible to trace the suppressed intention to control the process and the output. Through this approach, the designer welcomes the unpredictability of the outputs for him, and also the unpredictability of the interaction process for the participant. It is used as a strategy to increase the interaction between the machine and the participant and maintain the variation of the outputs. It is possible to trace a similar approach in *An architecture 'des humeurs'* about the consideration of unpredictability as a strategy to stimulate new relations and experiences. Compared to *Flatwriter*, in R&Sie(n)'s approach, the architect's existence in the process and the output is blurred, which even leads to his/her non-existence. Although the process and the interaction scenarios are still defined by the designer, his/her absence is intentionally sought to be able to define and experience the full potential of interactive processes.

Within this altered design process, in *An architecture 'des humeurs',* conflicting situations are embraced and even desired that introduces unpredictable outputs. The process is designed in order to hold and initiate these conflicting situations, of which outputs cannot be foreseen by the architect and the participant and hence cannot be manipulated. This allows substituting the predetermined typologies of conventional approaches, where the formal repertoire is limited, and introduces new relations, interaction patterns and morphologies to be discovered. Through this way, the spatial dialogues and their formal reflections are defined as a consequence of the ever-changing relationships between the machine and the participant. The structure that holds the habitat for the future residence is also designed to respond to the spatial conditions defined according to the desires, emotions and contingencies of the user. Opposing with the structure that is predefined as a grid in *Flatwriter*, in *An architecture 'des humeurs'*, it is conceived as a postproduction element, that is produced after the morphology of the habitat is defined (Roche & Naphegyi 2010). This emancipates the design ideas from the predefined rules and forms and introduces the simultaneous definition of the output according to the provided inputs, rather than selecting them from a large repertoire of possible outputs. In *Flatwriter*, despite the repertoire of various plans for possible apartments, the designer and the user are limited with this repertoire. Since the designer limits the outputs of the process before the participant interacts with the machine, the potentials of the interaction process are restricted with predetermined typologies and spatial negotiations.

3 CONCLUSION

Analyzing and comparing three examples from different periods, it can be claimed that through different approaches for the definition of responsive environment, the position of the architect and the already established relations between the architect, machine and the human participant are altered radically. Despite some discrepancies between these three approaches, it is apparent that there is an attempt to alter these relations in order to define spatial conditions responding to the inputs from the participant. Although not directly associated with, advances in technology, developments in computational strategies and increased computational capacities of the mechanisms also enable to embrace new strategies that reconsider and alter the already established relations between different parties of interaction. These advances stimulate the search for new experiences both for the architect and the participant, which also challenges the already attributed roles and positions.

In reference to these three examples, it is discussed that the position of the architect is altered in responsive environments, which are defined through machinic approaches. Since machines are considered as participants that produce new relations and connections during interaction processes defined through machinic approaches, they propose a direct relation between the machine and the participant. This direct relation excludes the architect and enables the definition of the

environment according to the inputs provided from the participants. Through this approach, it is intended to release the interaction process from the predetermined decisions of the architect and initiate new relations to be discovered. This intentional search to redefine the interaction process questions the presence of the architect and also alters his/her position. This can be considered as a significant shift introduced with the advances in technology and design.

Analyzed projects in the paper can be considered as distinctive examples, where the presence of the architect is questioned and redefined through different methods. Defining machines as participants of the process, where there exists a reciprocal relationship between the participant and the machine alters the definition of interaction and hence opens up new possibilities. Considering different approaches for the definition of the position and the presence of the architect, it can be argued that, the control of the process and the definition of the output is assigned more to the participants (human, non-human) in order to take full potential of the interaction process. As a consequence, the position of the architect is decentralized and the relationship between the machine, architect and the participant is re-conceptualized to produce new environmental conditions and new experiences. Considering the analyzed projects that decentralize the position of the architect, it can be argued that in order to take full potential of the responsive environments and the available technological advances, the architect weakens the control over the process and embraces unpredictability. This can be considered as a significant methodological shift, which initiates a change in the design and experience of built environments.

T.E.S.S. – An interactive sustainability lab

D.A. Kratzer
Philadelphia University, Philadelphia, Pennsylvania, USA

ABSTRACT: Given the opportunity to express and symbolize "sustainability" through the transformation of a recreational vehicle into mobile sustainability lab, a design team of nine architecture students from Philadelphia University and the SAVE Alliance/Green Allies Foundation struggled to find a core design approach and inspirations for form. The term "sustainability" has been assigned so many meanings it is difficult for designers to find its formal "image." Originating from an "environmental" foundation, innumerous aspects of our society are now considered through lenses of "sustainability." It is common to speak of financial, cultural, and political health relative to their ability to "endure." The "triple bottom line," "quadruple bottom line," or the recent rise of the term "resiliency" all become means to categorize and organize sustainable action strategies with the goal of steering toward a better future. For the uninitiated, it is easy to become overwhelmed by the ever expanding layers of the sustainability dialog. This paper expands on the team's search for a design form definition of sustainability which could inspire, the nature of interactive exhibits, and the RV design currently in fabrication.

1 SUSTAINABILITY

1.1 *The "sustainable" foundation*

We are such spendthrifts with our lives, the trick of living is to slip on and off the planet with the least fuss you can muster. Paul Newman

The SAVE Alliance/Green Allies Foundation is dedicated to the development of community environmental solutions through youth leadership. This development occurs through educational programs. Using the acronym for, "Students Against Violence to the Environment," the foundation advocates for sustainable action and environmental preservation with a mission of *"forging connections between students and communities that promote environmental sustainability both locally and globally."* (website). The foundation has delivered their message primarily through presentations to schools and on-going stewardship of the Althouse Arboretum – a living environmental classroom north west of Philadelphia. They are presently developing an active learning agenda where the presentations to schools shall incorporate interactive displays and demonstrations.

The foundation acquired a Dodge Sprinter recreational van with the goal of creating a mobile interactive sustainability lab later named T.E.S.S. It will be used to introduce, exhibit and educate students of various ages, backgrounds and economic status about the nature of sustainability. The educational programming is be interactive and include didactic dynamic digital displays, demonstrations, hands-on experiments and live/recorded presentations on the principals of sustainability. The goal for the foundation collaborating with Philadelphia University architecture students was to transform the RV into an "expressive" and "symbolic" "vehicle" to educate and communicate the value of sustainability.

Figure 1. Logo of The SAVE Alliance/Green Allies Foundation.

During the initial collaborative workshop, the project team quickly uncovered the layered dilemma that would affect the project from programming to fabrication – what is "sustainability" and how will the foundation deliver, and express, its content and message? What does, and/or should, sustainability look like? Does it have a common, identifiable "image?"

1.2 *A definition of sustainability?*

Vision: A world where students lead the way to a sustainable future.

The Save Alliance/Green Allies Foundation.

Figure 2. Daytime rendering of T.E.S.S. exhibit structure.

The etymological root of the term sustainability per Webster's Dictionary is the Latin *sustinere* – literally *up-hold* and *hold-up* and generally means *maintain, support or endure.* The current version of sustainability grew from the statement in the 1987 Brundtland Report from the UN World Commission on Environment and Development where "sustainable development" is *"that (which) meets the needs of the present without compromising the ability of future generations to meet their own needs."* Live now not at the expense of our future generations. While this definition provides fertile proposition, it is more akin to an ethical and moral compass heading. A search for clarity uncovered many "frameworks" which provide goals and guidelines. The "triple bottom line" appropriated from the economic thinking of John Elkington (1994) threaded sustainability through three "P's" – "profit, people & planet" and are often referred to as the "three pillars" of sustainability. There is also an "E" version – "economy, equity & environment." The subsequent "quadruple bottom line" begins to include design opportunities with the adding of "place" to the P's and a corresponding "experience" to the E's. To add more complexity, the 2005 the Official Agenda for Sustainable Development for the UN General Assembly Summit proposed 17 "Sustainable Development Goals" and 169 progress targets including: poverty, food, health, education, women, water, energy, economy, infrastructure, inequality, habitation, consumption, climate, marine-ecosystems, ecosystems, institutions, and even "sustainability" itself. 304 proposed indicators were developed to show compliance. Holling (1973) introduced the term "resiliency" to the arena which is a metric measuring to the ability of a system to recover from a shock or disruption. A clear definition of sustainability is elusive is ever expanding.

From an architectural viewpoint, discussions of technology offer some links to sustainable design thinking. For Peter McCleary (1983), technology is *"the discourse between societies and their natural environments in the production of the built environment,"* and includes *"the framework of thinking generated by this dialectical relationship between man and nature."* If we layer this definition of technology over the P's and E's, sustainable action might be focused on creating a more respectful discourse, or better yet *relationship*, between our society and natural environment through *how* we build – a result of what, where, why, for whom and how often we build. With this lens, building a shelter to protect from the weather, or even raising an umbrella, could be considered a technological act. Offering a bridge to the design professions, William McDonough's Hanover Principles (1992) aimed *"to provide a platform upon which designers can consider how to adapt their work toward sustainable ends."* This line of thinking led to the LEED Green Building Rating Systems, Building Living Challenge, and the Well Building Standards – to name but only a few of the frameworks that are used verify, guide and assess sustainable building.

As inspiration for expressive and symbolic design, sustainability suffers understandably from a generalist dialog. The discussion focuses primarily on the general topics and tenets which are difficult to argue with. We *do* need to develop and support a more respective relationship with our natural environment. We *do* need to better address waste, energy, water, pollution and the rest of the UN Summit Sustainable Development Goals. The vagueness of the term unfortunately allows any person, entity or municipality to self-define sustainability to align with their own agenda and enter the game. With so many differing definitions, agendas and pronouncements with few actual means to accomplish large scale change, it is difficult not to become numb to the entire subject. What is evident is convincing an audience on the importance of sustainability is finally unnecessary – the general public has caught up with the need to be sustainable regardless of whether they know exactly what that may, or may not, mean. As an added twist, the SAVE Alliance/ Green Allies foundation was unable to clearly state their own definition of sustainability and the specific methodologies they would utilize in their educational sessions. While the guideline frameworks provide vital road maps for navigating under the umbrella of sustainability they offer little imaginative grounds for symbolic design and form. The question of whether sustainability has an "image" remains.

A central tenet within sustainable building design methodologies is the need for a consensus on "guiding principles" by all stakeholders which will facilitate the decision making process. Utilizing the integrative design process, workshops eventually revealed at midterm that for SAVE Alliance/Green Allies "energy" was the central guiding principal and the symbolic core. Energy generation and use underlies all conditions of sustainability and was to be the underlying construct for the lab, the interactive exhibits and the "image" for the project. A more respective relation with our environment, and future, hinges on our appropriate use and, and need, of energy.

2 THE INTERACTIVE EXHIBIT

2.1 *The nature of exhibition and the artifact*

Exhibitions range from being either object oriented at one extreme, to concept oriented at the other. That is, objects or messages predominate.
David Dernie, (2006) Exhibition Design

In exploration of exhibit prototypes, the project team initially began work developing interactive displays on the themes of the four elements – air, water, earth & fire/sun. Each element was presented and then somehow effected in keeping with systemic approaches to sustainability. An air chamber was solar heated and the air rose through an indicator demonstrating the stack ventilation effect. Muddy water was poured into a geological container of differing materials that cleansed it. A wind turbine spun in the wind and operated a grinding wheel and electrical generator. The RV was heated with a passive solar system. The subconscious drive amongst the design team seemed to be to create an array of demonstration experiments rather than interactive devices. The question became will the RV promote interactive learning or simply be a rolling collection of demonstrations? The collective realization was that the basis of any exhibit or demonstration is an "artifact" whether actual or implied, which can act as a basis for engaged learning. A wind machine might demonstrate some principle but it is still an artifact. At a basic level an object or system of some value is offered for viewing ("showing/demonstrating") whether it is a three-dimensional object, a two-dimensional image, a digital projection, virtual construction or an installation that can be experienced. Such artifacts embody meaning inherently through their "realness" and actuality. For David Dean (1996), museums are primarily *"places to encounter actual objects – the real things"* which by nature embody social and cultural values framed through the lens of history. These objects have the power to transport us to other times and activate our imaginations about alternative realities and events. The ability of an artifact to impart viewers with meaning is directly related to the spectator's translation of the content – the process of developing a personal understanding of the artifact and its ephemeral context. The delivery of content and meaning is controlled by the exhibitor – the one doing the showing. With sustainability, though, there are many story tellers and much of their content is general and biased. Few systemic artifacts exist that make connections to one's life and experiential use of energy – the majority of the educational content has to do with attitude, interactions with our environment and how we live – our standards of living and most especially our lifestyles. The need to change our lifestyles to be more respective of our environment became a central guiding principle for the design team. Could the Lab be able to incite changes in our student's lifestyles? Unfortunately, most incentives for such a shifting of style focus on the bad repercussions of a negligent lifestyle such as pollution, death, and waste. While we might be numb to sustainability there is no question that nagging or threatening will do little to change lifestyles.

2.2 *Precedent for interactive exhibit: mathematica*

An interesting precedent where systemic artifacts promote interactive learning that might make personal connections is the ground breaking exhibit Mathematica: A World of Numbers … And Beyond, designed by Charles and Ray Eames in 1961. It marked a distinct shift in exhibition design by making the visitor an active participant in the unfolding of information. Moving beyond the static, didactic "one way" presentation, the installations were organized around the notion that the visitor affected the content – transforming the exhibit into a personal experience. This ability to translate information into an "interactive" learning condition created a dynamic and engaging platform from which to consider the nature of exhibitions and the presentation of didactic information.

Commissioned by IBM and initially located at the California Museum of Science and Industry, the project embodied the notion of the educational exhibit. The content was "rigorously researched by staff members and outside experts (who) were consulted regularly. Despite the fact that the exhibitions were packed with information, artifacts, and images, a great deal of care was taken to make them accessible – learning is interesting and 'fun.'" (Kirkham, 1995) The centerpiece of the work is a collection of mechanical kinetic interactive demonstrations of mathematical concepts such as Probability, the Mobius Strip, and Celestial Mechanics. Engagement by students in the subject matter is directly related to quality of their learning and the kinetics *"have proven to play an essential role in the encouragement of longer and deeper interactions with exhibits in Mathematica … exhibits that displayed motion were more socially engaging than static or interactive only exhibits."* (Constantine, Frankfeldt, Low & Schoenfeld 2004). The visitor initiated the machines and engaged with the mathematical concepts through physical presentation of content. In completion of the exhibit, the Eames combined the roles of curator, educator and exhibit designer in creating a clear and singular exhibit that remains vital, and in use, to this day. But a question emerges as to whether these types of interactive exhibits are truly conducive to interactive learning or just better in holding a visitor's attention.

2.3 *Interactive learning?*

In the case of Mathematica the interactive quality of the exhibits was limited to activating the machines.

While their kinetic qualities did result in greater viewer engagement, the exhibits conveyed their content in a single direction – exhibit to viewer. The observer had no ability to alter the information or direct the exploration. Akin to a "download", the content was delivered via a one-way curatorial conversation. It was certainly more "fun," as was the goal of the Eames's, but still inherently singular in effecting the thinking responses of its viewers. For Moreno and Mayer (2007) educational interactivity is a *"characteristic of learning environments that enable multidirectional communication a two-way action (between learner and teacher) in order to foster learning."* They add the qualifier of multimodal learning which incorporates both verbal and non-verbal content knowledge to the environment such that, *"an interactive multimodal learning environment is one in which what happens depends on the actions of the learner (where) the defining feature … is responsiveness to the learner's action during the learning."* In other words, the learning is directed by the student rather than teacher.

For the foundation RV, it became clear that the exhibits must be interactive in allowing the students to initiate, further and direct the learning. The events in the RV could not be just experiments that are watched, the viewer must be able to alter the outcomes becoming vital instruments in the success or failures of the outcomes. The students are placed in the positions of collaborative control – the same attitude that is needed by all members of our society if we are to better our relationship with our natural environment through changes in our lifestyles. The difficulty the design team had with this conclusion was the lack of actual exhibits on hand, an integrated design for T.E.S.S. would be difficult. It was decided that the project would become a "framing" device for the eventual interactive exhibits.

2.4 *Knowledge and learning*

With the goal of sorting out "interactive learning," "active learning," "collaborative learning," and "cooperative learning," terms which have become so prevalent in current pedagogical discourse, Ted Panitz (1997) proposes initiating definitions for the two terms he believes form the starting point for discussion. Collaboration is *"a philosophy of interaction and personal lifestyle where individuals are responsible for their actions, including learning and respect for abilities and contributions of their peers."* Cooperation is simply *"a structure of interaction designed to facilitate the accomplishment of a specific end product or goal through people working together in groups."* Panitz proposes the underlying premise for collaborative and cooperative learning is founded in "constructivist epistemology" and follows with an interactive teaching paradigm forwarded by Johnson, Johnson & Holubec (1991) where *"knowledge is constructed, discovered and transformed by students. Faculty create the conditions within which students can construct meaning from the material studied by processing it through existing cognitive structures and then retaining it in long-term memory where it remains open to future processing and possible reconstruction."* Panitz continues by quoting Ken Brufee (1995) who believes there are two types of knowledge to consider in the "constructive conversation" of education. Foundational knowledge "is agreed upon socially justified beliefs" – quantifiable knowledge such as correct grammar, mathematics procedures and history facts. Non-foundational knowledge, on the other hand – and of interest to this discussion- is "that which is derived through reasoning and questioning versus rote memory." "It is more likely to address questions with dubious or ambiguous answers, answers that require well-developed judgment to arrive at, judgment that learning to answer such a question tends, in turn, to develop." This idea of which type of knowledge the visitors of an exhibit can contemplate and interpret echoes David Dean's proposition (1996) that sophisticated exhibits should challenge both sides of the viewer's brain. The left brain for cognitive, quantifiable meanings/functions and the right brain appeal for imaginings, associations and intuition.

It became clear through early research presentations by the project team that in order to accomplish the goal of creating an interactive exhibit which promotes the visitor to develop personal judgments using simple didactic panels or digital displays would not be nearly enough. A means to develop an emotional response that engaged both quantitative and qualitative aspects of the topic was needed. If the audience was numb to such an important topic, it was paramount their attention be had. The team redirected its focus in a search for a means to reach a numb audience – wake them, shake them, impress them – and get their attention. Empathy became the central tool in placing one's self in the place of others as a means of understanding how our current processes of living fit must be reconsidered.

2.5 *Empathy*

Stephen Greenblatt, in his essay "Resonance and Wonder" (1991) proposed the two terms as distinct models for the exhibition of works of art. Resonance is *"the power of the displayed object to reach out beyond its formal boundaries to a larger world, to evoke in the viewer the complex, dynamic cultural forces from which it has emerged and for which it may be taken by a viewer to stand."* Wonder is *"the power of the displayed object to stop the viewer in his or her tracks, to convey an arresting sense of uniqueness, to evoke an exalted attention."* In order to grab someone's attention, empathy on the present and future of our environment was a requirement.

Empathy is a very common tool for designers and researchers to employ in projects and situations. Defined by Webster's as "the psychological identification with experiencing the feelings, thoughts or attitudes of another," the ability of designers to empathize the needs, desires and requirements of others is extremely important. Purposely avoiding the

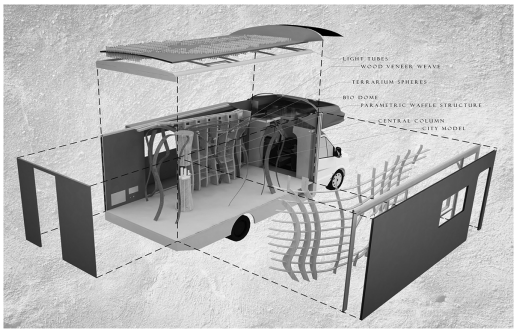

Figure 4. T.E.S.S. Axon component schematic.

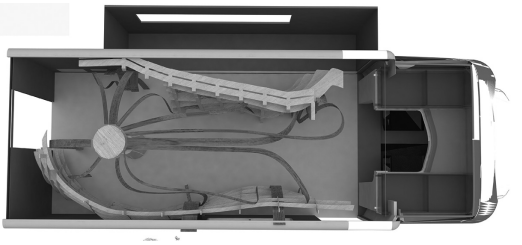

Figure 5. Plan View of T.E.S.S.

discussions on empathy in aesthetic and architectural perception theory here, the interesting component of empathy for the T.E.S.S. was the ability to establish emotional engagement in the viewer which could lead to interactive learning and the forming of individual viewpoints.

For Margaret Sutherland (2009), empathy in education has been used in three senses; learning by reproducing physical responses in watching others (often referred to as "motor mimicry"), learning by knowing what emotions others are experiencing, and learning by actually feeling the emotions others are experiencing. We certainly learn by watching others and mimicking what they do which can result in literal transference when we wince in reaction to other's physical pain. Knowing what emotions others are experiencing is of value but they are purely speculative – the greatest connection is certainly to experience some of the emotions others are feeling. This emotional connection catalogues information in our brains differently and enables easier recall and long term retention. Architecturally, John-Alan Johnson summarized in stating *"It is the emotional and esthetic power of empathy that makes the transference of human feeling and sensation at once so necessary and yet so difficult for understanding architecture."* For this project, making viewers understand the directness of sustainability and the importance it has on our lifestyles requires placing one's self in contextual situations different than their own. For the project team this entailed first and foremost creating an environment distinctly different that the students.

3 THE DESIGN

3.1 *T.E.S.S.*

T.E.S.S. an acronym for Transportable Environmental Sustainability Showcase. The students formulated the following design statement; *"T.E.S.S. is an inspirational sustainability incubator, educating the next generation on the importance and application of various sustainability concepts. T.E.S.S.'s modern interior greets visitors with an immersive, earthy environment that introduces sustainability in an energetic, interactive, and innovative way. The interior design and its integrated exhibits foster a memorable and inspiring experience for all its visitors."*

As a basic schema, T.E.S.S. will transport the interactive exhibits and demonstration materials to a target school which are then deployed outside of the RV. Students in groups of eight to ten enter into the RV where they participate in introduction sessions on the specific topics they will experience. The systems are explored through a series of interactive digital screen presentations which are to be "unfolded" by the students. Curricular content is presented as a series of questions the answers to which the students responds. Their answers activate a sequential series of additional questions continuing the cycle. Right and wrong answers are expressed through audio visual responses. The SAVE Alliance/Green Allies Foundation is currently exploring design systems for this digital curriculum delivery system. Upon completion of the introduction and the session's subject matter, students exit the RV by another door leading to the demonstration exhibits. The next group of students then enter and begin their round of introductions. Upon completion of the experiments, students re-enter the RV to review the guiding principles involved.

Within this schema, TESS is a gateway to frame the sustainability discourse. In order to satisfy the goal of grabbing the attention of numb students, it became critical to the project team that the internal environment be unique and a shift in context. The design incorporates a parametric plywood internal matrix skin which dynamically contrasts the rigid exterior RV. The poche space between the matrix skin and RV walls accommodates the tectonic systems and interstitial components of the exhibits and pedagogical content. The matrix skin itself has a depth pragmatically allowing for storage and display while parked and during transport. It became critical for the project team that the internal environment be also experientially different and empathetically diverse. Echoing the core criteria of energy as the organizational construct, the design focuses on daylight, the primal condition of the sun, and solar power generation and storage. Acrylic rods pierce the roof, weave through the parametric skin and layer under a thin acrylic plate floor connecting to lighting sources within the parametric wall poche. During the day, the sun lights the rods from above and changes in daylighting are acutely experienced inside the RV.

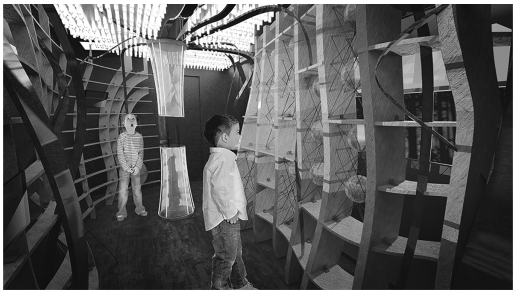

Figure 6. Daytime rendering of T.E.S.S. with solar lighting.

Solar panels charge batteries during the day which are connected to the lower end of the acrylic rods. As day turns to night, the lighting of the rods shifts from the sun above to batteries below that have been charged by solar panels creating a shift in lighting set to the timing of the sun in the sky. The primacy of the daylighting and powering through batteries of the rods at night from batteries exemplifies a powerful sustainable cycle which the team felt would generate awe and be a direct bridge between general principals and a specific system.

While the parametric skin creates an envelope which filters, supports and frames the foundation's discussion on sustainability almost as a background and storage device, the project team felt a counterpoint was needed inside the RV that could frame a special topic or unique focus. The idea was to connect the roof (sky) and the floor (ground) with a sinuous column of light. For Aldo Van Eyke, architecture is "the celebration of the realm where the ground meets the sky." The introduction of a vertical column mythically makes this connection. At the top of the column is a skylight through the roof. At the bottom of the column is a hole through the floor exposing the ground beneath. In the center is an area for special artifacts. With this device, the occupation of the realm where the ground becomes a literal link expressing the interconnected nature of our environment.

4 CONCLUSION

4.1 *A change in lifestyle*

The Save Alliance/Green Allies Foundation's primary goal is to alter world view of students in an attempt to foster a sustainable future – to encourage students to see the world in a different, and more respectful way. T.E.S.S. is intended to be an apparatus the same way the camera obscura altered the view and understanding of the world of its time. *To see differently*.

As a society, we have unfortunately become somewhat numb to the dialog of sustainability due to oversaturation. The green agenda is carried and furthered by any organization able to find a niche within its generalist frameworks. This "superficialization" will no doubt prove deadly to our species. Awareness of sustainability must be nurtured on an emotional level

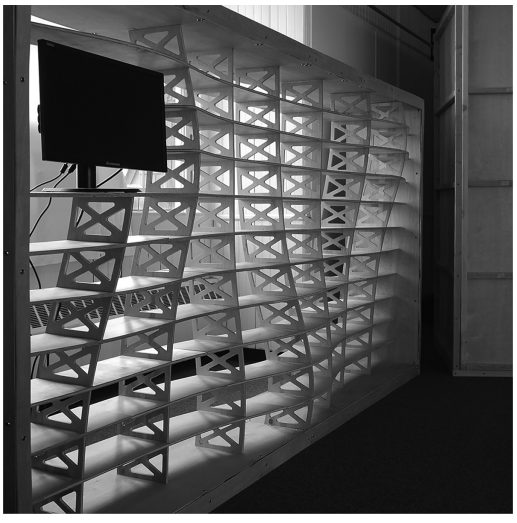

Figure 7. Fabricated section of T.E.S.S. parametric skin.

with available systems for improving the relationship with our natural environment actualized in a realistic, economic and widespread manner. T.E.S.S. offers a means to grab the attention of our youth and the interactive exhibits it frames can educate and change our ways of thinking. As Robert Vale aptly stated in his 1975 book from the previous energy crisis, developing a sustainable change in our environment requires not just changes in attitude but core changes in our lifestyle and standards of living. To accomplish this, the SAVE Alliance/Green Allies Foundation focuses on empowering students to incite change in our society.

ACKNOWLEDGEMENTS

This project was supported, and partially funded by, the Philadelphia University College of Architecture & The Built Environment Lab for Urban and Social Innovation (LUSI).

Life-cycle assessment of historical building reuse: Is the existing building the greenest building?

Ming Hu
University of Maryland, College Park, USA

ABSTRACT: Until now, little has been known about the climate change reductions that might be offered by reusing and retrofitting existing buildings rather than demolishing and replacing them with new constructions. This life-cycle analysis of Bent's house was carried out as an exploratory study to find out whether preserving historical buildings will have a quantifiable environmental impact beyond the cultural benefits that are known by the public. This research paper provides a comprehensive analysis of the potential environmental impact reductions associated with building reuse using Bent's opera house as a case study. Utilizing a life-cycle analysis (LCA) methodology, the study compares the relative environmental impacts and primary energy consumption of a historical building, building renovation, and new construction over the course of a 75-year life span.

1 BACKGROUND

1.1 *LCA introduction*

Life-cycle analysis (LCA) is an internationally recognized approach to evaluate the potential impact on the environment and on human health associated with products and services throughout their respective life cycles. "LCA requires life-cycle inventory (LCI) data for all materials and processes, a life cycle impact assessment (LCIA) method, and a software tool to do the work. LCI data is the inventory of all flows to and from nature due to a product or process – it's a long list of substances and quantities, which involves complex considerations in boundary, allocation methods and so forth. The LCIA method translates those flows into environmental impact potential." (Athena Sustainable Material Institute (2014). For North American construction projects, the LCI data should be North American in origin, and the LCIA method should be TRACI3; Athena software is based on TRACI.

1.2 *Approach and methodology*

According to ISO 14040 standards, a LCA is conducted in four phases. "The first phase, goal and scope definition, establishes the boundary conditions of the systems, defines a functional unit for the system, and enables equivalent comparisons with other products or processes. During the second phase, life cycle inventory (LICI), data is aggregated to determine aggregate inputs and outputs. In the case of a building materials study, this is often the quantity of materials used as well as the emissions associated with the production of those materials. In phase three, Life cycle impact assessment (LCIA), the LCI is translated using characterization factors, into impact categories, such as global warming potential. The fourth and final phase is interpretation, where data and results are analyzed to determine areas of relatively high environmental impacts and recommendations are made for improvements to the system. The four phases often occur in an iterative nature." (Thiel et al. 2013). Quite a few LCA tools and software exist that can be used to assess buildings: for example, BEES, ATHENA, Gabi, and Simpro.

Figure 1. Building materials and assemblies included in LCA.

2 STUDY OBJECTIVES

Located in the heart of Medina, New York, Bent's Opera House stands prominently at the corner of Main Street and Center Street. Completed in 1865, the opera

house was built from the now-famous Medina sandstone, which can also be found in places such Havana, Cuba, and was also used for London's Buckingham Palace. Named after the property's original owner Don Carlos Bent, the opera house has a rich and varied history. It was home to many plays, shows, commencements, elections, and other public functions. Over time the building fell into disuse but it is still considered a significant architectural landmark for Medina. In 1995 it was included in the National Register of historic places as a part of Medina's Main Street historic district. Bent's house has four floors with a total square footage of 23000 (Wikipedia, 2012).

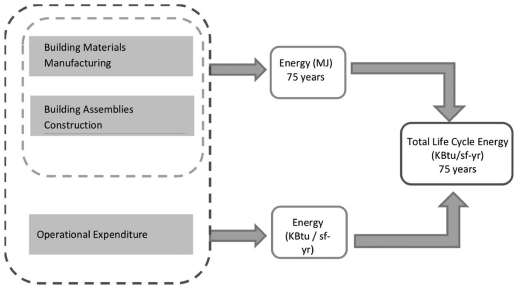

Figure 2. Impact assessment method.

2.1 *LCA boundary definition and LCI input*

The focus of this study is LCA of building material side energy consumption and environmental impact. The boundaries for the study include material extraction, product processing, delivery, demolition, and transportation. Benefits, and loads beyond the system boundary such as steel recycling, were excluded. This LCA includes the environmental impacts of Bent's house's building materials and operational expense. Three models have been examined: The first is based on the original material of the historical building (no additional thermal insulation added); the second is based on keeping the original historical building external walls and roof materials with additional thermal insulation; and the third is based on rebuilding the entire building with the same square footage and functions, to meet current international green construction (IgCC) code. Building mechanical, electrical, and plumbing systems are excluded from the material calculations because they did not exist in the original building.

Transportation of the building materials to the construction site, construction waste, and materials used for construction itself (i.e., temporary materials) are included in the calculations. The functional unit of this study is defined as the entire Bent's Opera House. Operational expenditure includes energy spent on heating, cooling, ventilation, water heating, lighting, and others. The major components of the material analysis, ranging from structural elements to interior flooring, are included. "Not included in the study were landscaping elements; interior finishes such as carpet tiling and paints were also not included in this study as they represent a small quantity of the building's total mass. Paint and interior finish represented only 2%–4% of energy and global warming impacts in previous building LCA studies." (Thiel et al. 2013).

Material inventory data were obtained through plans and project information provided by Bero Architecture and a site survey, including plans, elevations, sections, code analysis, and Revit models. A list of materials was extracted from the material schedule in Revit models then converted to an Excel database. The operational expenditure was obtained through a benchmarking method based on the Commercial Building Energy Consumption Survey (CBECS) building 2003 database (Energy Information Administration 2003). The operational expenditure's unit is kBTU/sf/year.

2.2 *Impact assessment method*

The LCIA phase was conducted using the combination of two impact assessment methods. The material-side life cycle primary energy consumption is analyzed using Athena IE4B. The Athena sustainable material institute is the pioneer of whole-building LCA in North America. IE4B is explained in detail in section 3.2, tools and data. The operational side of primary energy consumption is assessed using a benchmarking method. The benchmark database is the CBECS 2003 survey; the data-sets used in the study include offices and public assemblies.

The impact assessment categories reported from Athena included global warming, acidification potential, HH particulate, ozone depletion potential, smog potential, eutrophication potential, energy consumption, air emissions, water emissions, resource use, and land emissions. In this study, I have focused on global warming, HH particulate, ozone depletion potential, and smog potential.

3 RESEARCH GOAL AND MODELS

There have been multiple alterations to the building's interior, none of which are well documented. The basis of this study is the survey drawings done by Bero Architecture and the Revit model constructed from the survey drawings and filed measurements conducted by the researcher. Most building interior assemblies are based on field assessment.

3.1 *Goals*

The main goals of this LCA study are the establishment of a materials inventory and environmental impact references for the Bent's house. Exemplary applications of these references are in the assessment of future reconstruction or renovation of historical buildings similar to Bent's house. Furthermore, comparing the environmental impact of preserving a historical building with upgraded exterior wall insulation with that of reconstructing a new building according to

Table 1. Building assemblies included in LCA.

Assemblies Makeup	Historical Building	Renovation	New Construction
External Wall	Natural solid sandstone	Natural solid sandstone with additional fiberglass batt insulation R30	Brick cladding concrete backing with air barrier and fibreglass batt
Windows	Unclad wood window frame double pane glaze no coating air	PVC window frame double glazed no coating air	Fiberglass window frame double glazed soft coated argon
Doors	Solid wood door	Solid wood door	Fiberglass exterior door 50% glazing
Floor	Plywood decking @15 mm with 3.6 kPa	Plywood decking @15mm with 3.6 kPa	Concrete hollow core floor with love load 2.4 kPa
Columns	Softwood lumber with live lad 2.4 kPa	Softwood lumber with live lad 2.4 kPa	Precast concrete with live lad 2.4 kPa
Beams	Glulam	Glulam	Precast concrete
Roof	Plywood decking @ 15 mm without insulation	Plywood decking @ 15 mm with R40 insulation and waterproofing	Precast concrete decking with R40 insulation, EPDM cellulose and drainage
Foundation	Concrete @ 200 mm with average flyash %	Concrete @ 200 mm with average flyash %	Concrete @ 200 mm with average flyash %

IgCC can be seen as essential to help inform the decision-making process of policy makers in establishing quantified sustainable development guidelines for future historical buildings renovation, reconstruction, and demolition projects.

3.2 *Tools and data*

Two main software tools were utilized to complete this LCA study: a Revit model to take off the materials and the Athena sustainable materials institute's Impact Estimator for Building (IE4B) to assess the life-cycle environmental impact. Using the physical model, the schedule within Revit extracts the three-dimensional data and then a materials takeoff schedule is exported as an Excel file. The schedule had to be simplified by editing out the non-useful information, to make a clear spreadsheet. The useful data include: external walls, interior walls, columns, floors, roofs, foundations. These data are then manually inputted into Athena IE4B.

The IE4B software is designed to aid the building community in making more environmentally conscious material and design choices. The tool achieves this by applying a set of algorithms to the inputted takeoff data in order to complete the takeoff process and generate a bill of materials (BoM). This BoM then utilizes the Athena Life Cycle Inventory (LCI) Database, version 5.0.0125, to generate a cradle-to-grave LCI profile for the building. In this study, the IE4B model includes resource extraction, manufacturing, on-site construction, occupancy/maintenance, demolition, and recycling/reuse.

3.3 *Building analysis and assessment models*

In order to compare preservation, renovation, and new construction, three models were created.

The first step in creating a reasonable building model is to carry out a takeoff of the materials used. The takeoff for Bent's house was based on the Revit model we created based on survey drawings provided by Bero Architecture. Unfortunately, because of the age of the building, many of the actual building assemblies are hard to detect, so I made multiple assumptions. The takeoffs for Bent's house were done using the scheduling tool in Revit. The area condition is used to compute the surface area and basic geometry of the building. The count condition is used to compute the number of times the same instance occurs. A few major assumptions were made to complete this project: the foundations are raft foundation made of cast-in-place concrete; all floors are the same in terms of assembly and load; all columns on all floors are the same. The building systems included in the model are building envelope and major structural components; HVAC, lighting, and plumbing systems were excluded because they were not present in the historical building.

3.4 *Alternatives*

After the base-building historical building data had been manually put into Athena, two alternative sets were created based on the baseline building: a renovated building and a newly constructed building based on 2012 IgCC standards.

In the renovated building, external walls were added with additional R30 insulation; windows were replaced with fiberglass window frames with double-pane glass; additional R40 insulation was added to the roof; while floors, columns, and foundations were kept the same as those in the baseline building.

In the new construction, external wall were added with additional R30 insulation; windows were replaced with fiberglass window frames with double-pane glass; additional R40 insulation was added to the roof; wood columns were replaced with precast concrete columns; while floors and foundations were kept the same as in the baseline building.

4 RESULTS AND FINDINGS

4.1 *Building operational energy expenditure*

A benchmarking method has been used to determine the total site energy intensity. The data set came from the U.S. National CBECS 2003 version; the location was set to have ≤2000 CDD(cooling degree day), 5500–7000 HDD (heating degree day); the size was 0–25000 sqft; operation hours 0–90 hours/week; and the building was built before 1920. In order to capture as many buildings comparable to Bent's house as possible during benchmarking, the building type was set to administrative/professional office, bank/other financial, culture, mixed-use office, and other public assembly, recreation, social/meeting. In total, 19 buildings were found in the CBECS database with median energy usage intensity (EUI) 66.7 kBTU/sf/year. This number was used to calculate the total site energy consumption for the historical building's life span of 75 years. The same benchmarking process was repeated to determine the EUI for renovation and new construction, assuming that they are the same.

4.2 *Life-cycle energy consumption: material side*

Results from the three models were compared with the goal of providing information related to building reuse and renovation benefit. IE4B produced results for the following mid-point impact measures: total primary energy consumption, non-renewable energy consumption, and fossil-fuel consumption. In this study, I focused only on primary energy primary energy consumption, measured in MJ. The primary energy includes all energy "used to transform or transport raw materials into products and buildings, including inherent energy contained in raw of feedstock materials that are also used as common energy sources." (Carmody, 2003) In addition, the impact estimator includes indirect energy such as processing, transporting, converting and delivering fuel, and operating energy.

In general, the external walls of the Bent's house represent the highest total primary energy consumption, accounting for nearly 85% of energy consumed in life-cycle stages A through C. Next highest is floor assembly, which accounts for 6%. In the renovated building, external walls account for 78% of the total primary energy consumption and roof assembly is second, consuming 12% of the total energy. In the new construction, the external wall assembly still ranks highest; however, it accounts for only 54% of the total primary energy consumption and all other categories have a substantial increase in percentage: assembly of beams and columns ranks second, representing 32% consumption; and roof assembly, accounting for 8%, is the third-highest energy consumption category.

Within material primary energy consumption, operational energy is consistently much higher than embodied energy. In IE4B, operational energy refers to B6 stage and includes energy primary extraction, production, delivery, and use, usages that are only related to the building materials and assemblies. We need to make it very clear that "material operational energy" is different from "building operational energy expenditure," which we described in section 4.1. "Building operational energy expenditure" includes the energy used to provide space heating, cooling, ventilation, water heating, etc, for the occupancy. Through the comparison, I have three major findings:

1) The operational energy use is the most important stage through the entire building material life span in terms of total primary energy consumption.

Table 2. IE4B_v5_life-cycle stage.

Information Module	Supports?	Processes Included
A1 Raw material supply	Y	Primary resource harvesting and mining
A2 Transport	Y	All transportation of materials up to manufacturing plant gate
A3 Manufacturing	Y	Manufacture of raw materials into products
A4 Transport	Y	Transportation of materials from manufacturing plant to site, and construction equipment to site
A5 Construction-installation process	Y	Construction equipment energy use, and A1-A4, C1, C2, C4 IM effects of construction waste
B1 Installed product in use	N	n/a
B2 Maintenance	Partial	Painted surfaces are maintained (i.e. repainted), but no annual maintenance aspects are included
B3 Repair	N	n/a
B4 Replacement	Y	A1-A5 IM effects of replacement materials, and C1, C2, C4 IM effects of replaced materials
B5 Refurbishment	N	n/a
B6 Operational energy use	Y	Energy primary extraction, production, delivery, and use
B7 Operational water use	N	n/a
C1 De-construction demolition	Y	Demolition equipment energy use
C2 Transport	Y	Transportation of materials from site to landfill

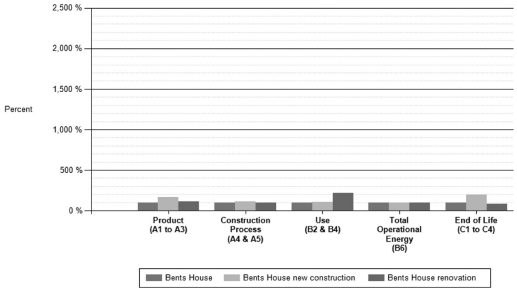

Figure 3. Comparison of total primary energy by life-cycle stage in material side.

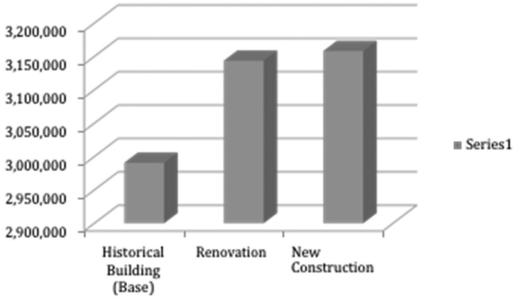

Figure 4. Overall energy consumption per year, life span of 75 years.

Table 3. Overall energy consumption per year, life span of 75 years.

	Material Energy Use (kBTU)	Year	Material Energy (kBTU/yr)	EUI Use (kBTU/sf/yr)	Area (sq)	Building Operational Energy Use	Total (kBTU/yr)
Historical Building (Base)	109,236,000	75	1,456,480	66.7	23,000	1,534,100	2,990,580
Renovation	109,840,000	75	1,464,533	73.0	23,000	1,679,000	3,143,533
New Construction	110,931,000	75	1,479,080	73.0	23,000	1,679,000	3,158,080

2) Apart from stages A1–A3 and C1–C4, the historical building has lower primary energy consumption. Overall, throughout the entire material life cycle, the historical building consumes 87% of the energy of the new construction and 97% of that of the renovated building.

4.3 *Overall energy consumption (material primary energy consumption + building energy expenditure)*

Owing to the insufficient thermal properties of the historical building exterior envelope and the long heating period in Medina, NY, the historical building consumes more building operational energy. However, because of the higher embodied energy embedded in the new construction materials, the overall energy usage of historical building is still less than that of the renovated building and the new construction. Overall, the historical building consumes 2,990,580 kBTU/yr, the renovated building consumes 3,143,533 kBTU/yr, and the new construction consumes 3,158,080 kBTU/yr.

4.4 *Life-cycle environment impact*

In this study, I have focused on the following mid-point impact measures: global warming potential, human health particulate, ozone depletion, and smog potential. The new construction has about 1.3 times the global warming potential of the historical building and 1.21 times that of the renovated building through life-cycle stages A–C. The new construction has about 1.45 times the smog potential of the historical building and 1.44 times that of the renovated building through life-cycle stages A–C. Trought the same life-cycle stages, the new construction has about 3.0 times the HH particulate potential compared with the historical building and 1.78 times compared with the renovated building, and about 1.1 times the ozone depletion potential compared with the historical building and 1.19 times that of the renovated building.

5 CONCLUSION

LCA is necessary when evaluating building reuse to understand how the embodied energy of materials is allocated during the phases of a building's use and whether building a new high-performance building could have even bigger and more negative environmental impact and higher overall energy consumption.

On the energy side, this study looked at both the embodied energy of major building materials and assemblies and building operational energy consumption in a building's life span of 75 years in upper state New York. The study compared three different models: historical, renovated, and new construction. It is important to note that the result is consistent: the new construction has higher primary energy consumption even though its advanced HVAC system might offset some building energy consumption in the operational phase. The assumption is that the longer the building life span, the closer the three model estimates will become; however, the payback period of using modern advanced materials in order to reduce operational cost will most likely exceed the building's functional life span, typically 60 years. As more and more buildings are targeted to become more energy efficient, we should not disregard the fact that the primary energy of the materials and building assemblies is important when we decide whether to retrofit or reuse an existing historical building or to demolish the old building and build a new one. Many studies in the past have largely focused on building operational energy expenditure. We now need to reconsider the important interplay between building materials and use phase performance.

On the environmental impact side, clearly new construction has a more negative impact in all aspects studied in this research: global warming potential, smog potential, ozone depletion potential, and HH particulate potential. There is an urgent need to develop a standard and guideline to regulate and monitor the impact of new and innovative building materials and systems based on a thorough understanding of their energy and environmental implications.

Culture, context + environmental design: Reconsidering vernacular in modern Islamic urbanism

S. bin Zayyad
University of Calgary, Calgary, Alberta, Canada

B.R. Sinclair
University of Calgary + Sinclairstudio Inc., Calgary, Alberta, Canada

ABSTRACT: The 21st century sees the Islamic regions as becoming some of the fastest urbanized areas on the planet. Local urban fabrics and existing buildings are often demolished in the name of progress, to make room for new, and often ostentatious, mega-projects, creating a scenario that is problematic in terms of conserving past history as well as providing inspiration for future generations. As extensive urbanization and globalization take hold, the character and quality of established cities in the Islamic world are under assault, with dramatic conflicts between traditional tenets, foreign influences and diverse interpretations of 'being modern' having serious and often little understood consequences. The current research examines how the demands of modern urbanism impact traditional centers of the Islamic world by considering emerging trends in Islamic urbanism through a critical examination of the vernacular. Using the city of Doha, Qatar as a case study, the authors explore the shifts of architecture as a coherent expression of local culture and context and question the interpretation of modern development in this ethos, and posit how environmental design might better resolve conflicts between traditional Islamic cultures (and way of life) and Western 'progressive' design. The paper concludes by recommending a more appropriate path for innovatively designing next generation buildings, communities and spaces that deploy aesthetic and applied basis of vernacular traditions, fostering greater meaning, inspiration and dialogue between and among architects, planners, governments and end-users. A model is proposed for proceeding in such creative, constructive and compelling directions.

Keywords: Design, Planning, Islam, Modernism, Vernacular, Systems Thinking, Holism

1 INTRODUCTION

> *The Middle East is becoming one of the most urbanized regions of the world. And as the place where cities may have first emerged, cities and urbanites remain most fertile objectives of study. Yet we are only just beginning to understand the social histories of these cities and the dynamic changes (or resistance to change) of these contemporary urban societies. (Bonine 2005)*

The influence and impact that globalization is having on the cities of the Islamic world proves far-reaching and consequential. The conflict between the integration of socio-cultural elements in the vernacular and modern urban developments is leading towards a clear division between those who see this as a loss of their cultural identity and those who view it as a step forward on the global stage. Polarization is evident and often problematic. The discourse on architectural form in the Muslim world is the topic of much debate. Forming a strong interaction with its natural surroundings, historically, Islamic structures were never the result of a formal master plan. They were instead the result of a diverse interpretation of the people who resided in these Muslim cities, giving them characteristics borne of reverence for the archetypal. The local knowledge, ecological and otherwise, was deep and meaningful. The prevalent view amongst many architects and urban planners is that "modern" or Western-influenced structures and planning are not always beneficial to the Islamic world, particularly in the Middle East (Bonine 2005). There are perceptions of solutions being out-of-place or foreign in character and context. The call for an "Islamic renaissance" or the demand for a return to the traditional structures and principles (Bonine 2005) runs in tandem with the growing urbanization crisis faced by a plethora of cities in the Islamic world.

2 ISLAMIC URBANISM

> *Let's start, let's move together, let's revive our cultures so that modernity is not only seen in the terminology of the West, but modernity is seen in the intelligent use of our past. (His Highness Prince Karim Aga Khan 2008)*

Figure 1. Old Doha Souq (Catnaps Design).

Figure 2. Katara Cultural Village, Doha (b.r. sinclair © 2016).

The faith of Islam unites its followers, who come from a rich diversity of societal circumstances and cultural expressions, across many facets of life. The idea of a hegemonic culture forced upon their identity through globalization, is anathema to the very ways of Islamic life. That being said, there is no dichotomy between *din* (faith) and *duniya* (material world) in the Islamic faith. The present researchers see the unification of this approach as most pertinent to the quest for a contemporary Islamic design expression. Muslims are required to carry out their worldly obligations within the ethics of Islam and are not allowed to make that division. As a result, human behaviour is measured by a set of practices developed and maintained within Islam – that covers all aspects of one's daily life, giving meaning and consistency in *all* human activities (Bianca 2000). In stark contrast, "… secular beliefs of modern Western civilization which, for the sake of "individualism", tend to ignore spiritual hierarchies and thus reject the idea of normative types of human conduct – without always recognizing that, by excluding service to higher realities, the human mind may become subservient to much more limited man-made ideologies and their constraints" (Bianca 2000). In other words and considered within an environmental design frame, the built environment within the Islamic faith has always been guided by the creation of models that express spiritual interpretation and meaning rather than transient ones that convey progress or development in the Western sense. The unquestioning belief in the divine order and its reflection in the traditional formal structures of Islam, such as the *souq* (market) or the *hamam* (baths), is a far cry from the mechanical representations of the very same structures that intend to capture and convey the modern interpretation of development.

This "clash of civilizations" (Huntington 1996) between the Islamic way of life and Western interpretation of progress in its urban form has been a topic of contention since the early–20th century. The combination of technological progress and economic growth resulted in transposing Western models of urbanization at global levels. The resulting architectural development of many Arab cities can be viewed as an accurate replication of Western cities with an inability to give deeper substance, purpose and, meaning to these creations. The authors contend that a sense of place must be a vital dimension of planning, architecture and urban design, and especially in an era where globalization can equate with homogenization of output and 'dilution' of character. Far more disastrous (if one can use the term), is the change in the socio-economic dynamics of many global cities. The introduction of a new value system foreign to the traditional ways of life, such as social segregation according to accumulated wealth, loss of cultural identity and downplay of history, and unfamiliar ways of inhabitation, is a far cry from the egalitarian principles of Islam. Such approaches have had a demonstrable and arguably deleterious impact on both the sustainability of the traditional settlement and the viability of the modern.

This paper is by no means trying to disparage Western forms of architectural and urban forms, thoughts or processes – rather, the authors ponder how contemporary principles and posturing be used in a selective manner in tandem with local traditions and values to better address current needs. By evaluating the former's achievements and failures, the possibility of an interdependence or symbiosis between the two (i.e., Islamic culture and Western modernism) can provide meaning, inspiration and dialogue and allow for the dissolution of the alien value system. The authors argue that such bridging is missing, overdue and essential. Rapid urbanization has had extensive and transformative changes in the Middle East. Citizen responses to globalization and foreign influences have been varied. Ranging from reverential regard to nonchalance to disbelief, to sadness that a certain way of life is disappearing, the reactions to urbanization are not always foreseeable. For example, studies by Sharon Nagy, an anthropologist, have shown how local socio-political factors have shaped urban plans introduced by foreign consulting firms in Qatar by altering the urban fabric through the influx of oil wealth (Bonine 2005). Changing politics, demographics, economic and ethical parameters all contribute towards satisfying business ambitions by borrowing tales from the *Arabian Nights* to reflect 'authentic' or local designs blended with modern structural concepts. These approaches need critical assessment, and critical

reimagination, in light of opportunities and obstacles confronting cities of the Islamic ethos.

3 URBAN RESPONSIBILITY

> *The architect is a member of a society and therefore reflects the values and behaviour of that society in his or her own behaviour. Yet, architects are both the keepers of a post heritage and the creators of the new. They mediate between the past and the future. Architects have a unique responsibility to create both the urban space that people relate to as well as the language of form and ornament that they identify with. Architects have, therefore, a special responsibility to address the need to symbolize a state of being and to reflect the aesthetic sensibility of themselves and their clients. (Serageldin 1996)*

It can be argued that the concept of urban conservation is more of a "trend" than a platform that can be used to reconcile the vernacular with the modern, especially in an Islamic context. Newer mega-projects are replacing older and locally crafted buildings, leaving behind very little of the heritage and thus distinctiveness for the younger generations. Such directions also translate into a loss of the indigenous social fabric so essential to place identity. This is particularly visible in the states of the Gulf region, often leading to a lamenting of loss (characterized in many ways, including both physical and cultural) from the citizens. Respect for past traditions and future conditions demands an understanding that is integral to the preservation of any architectural agenda. This is not *always* the case for the Gulf region that has undergone a metamorphosis from humble fishing and pearl-diving villages to cosmopolitan cities (Elsheshtawy 2008). The resulting fragile social fabric exists in an economically capitalist environment where consumerism is the dominant feature. There are other ways of doing business, especially in light of the common adoption of the 'Western is Modern; Western is Progressive' mantra.

Such types of development can be seen as creating an economic pressure affecting the socio-cultural sustainability, where the older generation are reluctant recipients of these associated forms of urbanity. These socio-economic changes are definitely reshaping the urban structure and form of these cities, in a divergent and arguably less-than-beneficial manner.

4 DOHA, QATAR

> *We have simply got to modernise ourselves. We're living in a modern age … You cannot isolate yourself in today's world. (Sheikh Hamad bin Khalifa al-Thani, 2000)*

The present paper explores Islamic urbanism, using Doha as a case study to explore the shift of architecture from the vernacular towards a global metropolis. Possessing over half of the world's total oil reserves, the Gulf region has attracted more than its fair share of global attention over the last decade. Recent urbanization and construction efforts along with the 'Dubaization' (Elsheshtawy 2004) of major cities across the area, has seen an arguably chaotic approach to the development of its architecture and urban design, resulting in grandiose, almost dreamlike structures that do not reference their cultural, physical or natural environments (Fraser & Golzari 2013).

Figure 3. Doha West Bay (b.r. sinclair © 2016).

Comprising of a total area of 11,586 square kilometres and only 15 metres above sea level, the peninsula of Qatar is bordered by the Gulf to the east, and Saudi Arabia to the west. With a population of 2.2 million (2014) and ruled by the al-Thani family since the mid-1800s, Qatar has the highest per capital income in the world at approximately US $105,000 (World Bank 2014). Formerly a British Protectorate until its independence on September 3, 1971, Qatar's urban development can be divided into 3 stages – first, the decline of the pearl industry in the 1930s, second, the export of oil in the 1950s (Figure 4) and last, the beginning of the construction boom in the 1980s (Elsheshtawy 2008). According to Salama & Wiedmann (2013), there has been little analytical discourse on the factors that influenced the urbanization process in Doha. The present authors contend that there are many holes in understanding Doha's rise, its embrace of Western expressionism in design, and its ability to effectively move forward with the appropriate urban guidelines to meaningfully develop and strengthen its urban fabric.

Khaled Adham's chapter on Doha's urban development in Elsheshtawy's book (*The Evolving Arab City: Tradition, Modernity & Urban Development, 2008*), addresses one gap by placing the process in a historical context but also within the framework of urban governance, describing in great detail the initial planning of the city around the old part of Doha, gradually leading to the development of the Corniche. What is

interesting to note is that no mention is made about the initial planning of Doha being carried out relative to the layout of an Islamic city. Jamel Akbar's study on the elements of an Islamic city emphasizes the creation of an Islamic built environment based on the relationship between the Muslims and their environment. Dictated by the values derived from it, Islam's influence on the form and function of its cities emphasizes the importance of achieving a strong coherence and compatibility with the community in both spiritual and worldly aspects. This is again, in the eyes of the present researchers, the *din* and *duniya* operating in concert. Akbar's study is interesting in that the four elements of the Muslim built environment reflect the early layout of the Islamic city from the 7th century onwards, where it was common for the soldiers of the newly-founded faith to cordon off an area in town where they set up a mosque and their residences and commercial space around it. The four elements of a Muslim built environment that he proposes and that are governed by Islamic principles are: (a) *fina*' (street space bordering property used by its owners) to maximize land use and provide shade; (b) dead-end streets to protect privacy; (c) *hima* (land that cannot be developed by individuals); and (d) public spaces (Bonine 2005). This clear integration of the socio-economic, spatial, cultural and administrative aspects, distinguishes an Islamic city from others, whether it is a street, a home, a mosque or a *souq* (Elaraby 1996). Taking a more integrative approach resonates with the aspirations and conduct of the present authors and their research in the region.

During the first half of the 20th century, Doha's settlements around its bay were divided into 8 districts or *ferejan*, based on the four elements of a Muslim built environment. A tribe or a large family occupied each district. Located parallel to the shoreline of the Persian Gulf, most of the alleys between these districts led to the harbor where most of the day-to-day activities were conducted (public spaces). The market place, the shops, as well as meeting places were all located in this area. It is interesting to note that apart from the *barasti* (dwellings with thatched roofs) and Bedouin tents that dotted Doha, homes ranged from one to two-storey dwellings, some featuring wind towers or *barajeel*. The architectural style of these structures including the non-residential ones was simple with very little to no ornamentation and were designed and constructed by a master mason and other workers (Elsheshtawy 2008).

With the decline of the pearl industry and the beginning of oil exports in the 1950s, new urban patterns began to emerge. Although the benefits of oil wealth were not applied immediately due to the conservative nature of the ruling family, as well as a lack of formal governance at the time, it was not long before this changed. British architects arriving to the Gulf Region during the 1950s found themselves facing a built environment unlike any they had encountered or studied before. Excess heat and over 300 days of sunshine were major factors considered in their initial design responses. More importantly, however, was the consideration of local traditions and culture when engaged in master planning and development activities. Although the call by some to ignore the historic aspects was present, the idea of building and integrating functionality into the design was even more challenging (Fraser et al. 2013).

The ruling elite centered attention to conservation of their cultural identity with the intense desire for modern technology. The influx of oil wealth only served to increase this aspiration to have the best, brightest and the most 'modern' as symbols of progress. Unfortunately, this may have led to a misinterpretation by the West, deeming this posturing as also having a desire for Western culture and politics. The concept of modernity, and its associated connotations, was seen to carry a certain prestige or stature, resulting in a desire to not only catch up with the developed world but to also be seen as the future of this modernization process (Fraser et al. 2013). It is important to note here that the design of many of these structures such as the Burj Qatar may have been intended to serve as a reminder that the new could exist alongside the old with no type of conflict whatsoever – shopping centres could exists alongside *souqs*, spas alongside *hamams* and Starbucks alongside the *gahwa shabya*.

The transformation from a coastal settlement to an urban metropolis within the span of a few decades took place in an environment where urban governance in the physical planning of Doha was still dominated by the ruling family. This was reflected in the new type of housing style – apartment buildings – that began to dominate Doha's skyline during the 1970s. The burgeoning new typology coincided with the arrival of expatriates, who came to take part in the design and construction activities. To accommodate commercial and residential growth, old neighbourhoods in the central areas of Doha were demolished and replaced with the high-rise buildings and modern structures such as shopping malls. It is obvious that the economic wealth brought in by oil and gas resources was instrumental in the rapid pace of urbanization in Doha. The rapid urbanization was also driven by the desire to be a leader and an exemplar (i.e., in a dramatically globalizing world) that gave rise to the grand mega-projects currently dominating Doha's remarkable skyline (Figure 3).

So what of the Islamic city?

5 PROPOSED MODEL – HYBRIDISM

> *Hybridity is a very complex notion. At its most basic level, it has meant the interbreeding or mixing of different peoples, cultures and societies. Hybridity thus does not emerge from the synthesis of different components, but from a space where elements encounter and transform each other. (AlSayyad 2001)*

Cultural forms of a society do not always arise from homogeneity but rather from an adoption and adaptation of concepts to their own building traditions to create a distinct urban form (AlSayyad 2001).

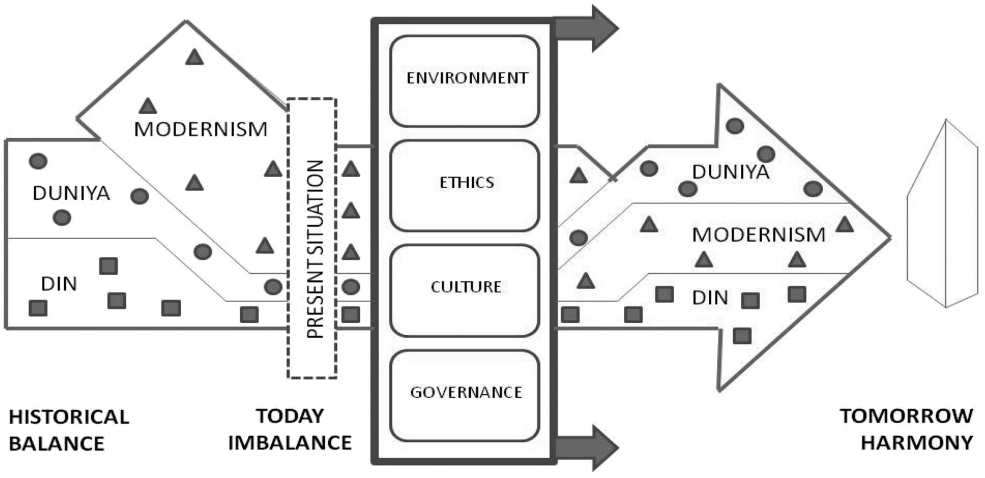

Figure 4. bin Zayyad + Sinclair Framework for Culturally-Appropriate Design in the Islamic World.

As previously mentioned, although similarities of built form exist in cities across the Islamic world, there are certain elements that are distinct or are distinguishable from each other. However, the intrinsic structure of Islamic architecture is always the same, due to the permanence of the basic and fundamental tenets that are adapted in accordance with vernacular forms (Rahman et al. 2014).

This begs the question – how can vernacular architecture, or perhaps more cogently and appropriately, 'architecture that is of its place rather than just in it' be reflected and realized in the urbanization process in the cities of the Islamic world?

Rather than creating a model within the paradigms of cultural autonomy or a neo-Islamist model based on Islam's Golden Age during the 8th century, or Westernization, what is required is a re-conceptualization of these three paradigms – a re-evaluation where the vernacular is not fixed in time but engages with the challenges that come with time, to produce a hybrid framework that is at once moral, organic and sustainable. Architecture is the perfect medium to bridge gaps between old and new and between the Islamic world and the West. The present authors suggest that deficiencies and shortcomings can be mediated in a convergent manner whereby the two perspectives (Islam and Modernism) are a continuum on the same spectrum. The following framework reflects how Westernization, or modernity is embraced when placed between *din* (faith) and *duniya* (material world). Inextricably linked to each other and strongly guided within the Islamic *tariqah* (path), this lack of separation also provides an accommodating environment (uncommon to other monotheistic faiths) to embrace foreign concepts that allow for spiritual interpretation as well as meaning and progress of not just Muslims but all of humanity in an arguably more ethical manner.

In our 'Framework for Culturally Appropriate Design' (Figure 4) we highlight that the arrival of Modernism to the Middle East proved overwhelming. Many traditions, architectural and otherwise, lost their balance of din and duniya. An obsession with the modern translated into a dilution of Islamic values, including those fundamental to city building. In considering a path forward, we call for a more holistic vantage point, which accommodates environment, ethics, culture and governance. The interplay of these aspects is intended to catalyze important consideration and discussion within the unique context of Islamic cities. A key objective is to wrap, or embrace, the Western or Modernist ways with qualities that are fundamental to Islam. By bringing Modernism into the *din* and *duniya* relationship there are greater opportunities for planning, architecture and urban design to find connection to local circumstances, conditions and culture.

In Islam, the quality of the interactions that take place within the aesthetics of the built environment, are reflected on the spiritual lives of the Muslims. In other words, the built environment is not only a physical representation of Islamic values but also a reflection of the beliefs, the cultures as well as *the needs and contexts of the world* inhabited today. That being said, it is also important to understand that each case merits its own individual solution, taking into consideration the context of not only the physical environment, but the economy, the existing institutional apparatuses as well as the available resources (Bianca 2000). Given the historical architectural achievements within the Islamic world, and the role that architecture has played in the aesthetics and spiritual expressions of the cultures Islam came into contact with, there is a gap between these past accomplishments and current practices. There seems to be a disparity when it comes to contextualizing the needs of the population in response to the infrastructure. This has resulted in creating a consumer environment in the Gulf region, where only top of the line creations are valued.

A few years ago, a survey on the education of the faculties of architectural schools in the Islamic world was conducted by the Aga Khan Award for Architecture. It was found that the vast majority had been educated in the West (Ivy 2001). This resulted in the

imposition of Western-style buildings as being the acceptable form of the architectural profession, and that such types of buildings were better in terms of quality and lifestyle. This did not give a sense of value to traditional cultures or forms of expression. Using modern materials to achieve the desired results is not enough. How then can the *din* and *duniya* be incorporated in the future planning of the Gulf region? What are the sources of inspiration, the sources of knowledge? The authors believe that it begins with education. It has to be part of the overall process and not the end result. Great attention needs to be given to structure and process in the creation of this intellectual space. It is important to study these historical achievements in order to be able to look forward and turn these heritage assets into an intellectual trampoline to generate ideas for building in a constructive and productive manner, beneficial to all mankind.

The second way in which the *din* and *duniya* can be incorporated in the future planning of the Gulf region is to recognize that design and technical issues of the built environment cannot be regarded in isolation from the cultural and religious values of the society. How can this be fostered? The creation of policies on the master planning of communities, urban design efforts, and public engagement is a requirement and should be a result of public-private partnerships. In the case of the Gulf region, collaboration between the government and civic institutions should form the platform upon which dissemination of information can be made accessible and transparent to all. Projects such as Katara Cultural Village (Figure 2) and Souq Waqif (Figure 5) in Doha, travel a long distance in their celebration of traditional values while being both of the present and aspiring to a brighter tomorrow. Future research aims to develop and delineate specific guidelines that can inform stakeholders and inspire environmental designers. While the adoption of such guidelines is no easy feat, the researchers believe that actions must be taken to raise awareness, at all levels, if more respectful, appropriate and harmonious districts and buildings are to be realized as the Gulf Region continues to expand and blossom.

Figure 5. Souq Waqif, Doha (b.r. sinclair © 2016).

6 CONCLUSION

> *Appropriate solutions to some of our most daunting problems will arise through the concerted efforts, open dialogue, and collective wisdom of the wide array of stakeholders, professionals, politicians, decision-makers, and citizens (both engaged and disenfranchised) who have the will and wherewithal to make a difference and to make the world safer, healthier, and better. It seems vital for us to critically examine, and question, our belief systems and their connections to the ways we define, refine, and realize progress. Architecture and Environmental Design, in both a philosophical and a practical sense, reflect as well as form greater aspirations, directions, and events of our times. (Brian R. Sinclair, 2015)*

The rapid expansion and urbanization of Islamic cities has been accompanied by a general embrace of Western ways of approaching and expressing design. To be Western is to be Modern, and to be Modern is to be Progressive. The present authors suggest that many important qualities have been eroded or lost by Islamic cities in the quest for their place on the global stage. The researchers developed an integrated framework that marries the traditional counterparts of *din* and *duniya* with the ever-present forces of Modernism. The framework posits a path whereby long-standing and time-tested values and beliefs can be in synchronization with contemporary metrics of success.

The end goal is to introduce more meaningful, potent and appropriate ways of planning and designing buildings, neighborhoods and cities of and in the Islamic world.

Beyond the passage: Analytical probe into the emancipatory potential of space

D. Ćorović & M. Milinković
Faculty of Architecture, University of Belgrade, Serbia

ABSTRACT: "Around 1910", writes Henri Lefebvre, "a certain space was shattered", pointing to the series of shifts in the Western culture, crucial for the evolution of modern thinking. This was also the time when the first glass-roof covered passage was designed and constructed (1910–12) in Belgrade's main shopping street. The country's capital, in the field of influence of powerful empires, was eager to catch up with the modern world. Some thirty years later (1941), the radically new transposition of the same theme was conceived through the unrealized project for the Hall of *Matica srpska* in Novi Sad. These conceptions, created in different but correlative geographical and historical conditions, are taken up in this paper as the subject for an analysis that examines the hidden emancipatory potential of this hybrid typology and the peculiar expressions of its protean capacity that gives us hints about the contemporary comprehension of public space articulation.

1 THE CITY PASSAGE AS AN EXPRESSION OF THE SHIFTING PARADIGMS OF A CHANGING SOCIETY

1.1 *The cunning meanings of a passage / an arcade*

A peculiar hybrid form of house and street – an arched or covered passageway, usually with shops on each side – first appeared in France, at the end of the 18th century with a name of Latin origin /passûs/: *passage*. To denote the same phenomenon, the similar term is now used in German, Russian, as well as Serbian, and some other languages, in countries that willingly imported and appropriated this French invention (*Passagen / nacca$$ / pasaž*). In English, however, another term was generally accepted, also of French, Occitan, Italian and ultimately Latin origin /arcus/: *arcade*. If used in other languages, the meaning of the words *Arkade / arcade / arkada* is closer to its original roots and its later Occidental and Oriental interpretations, and generally indicates a series of arches supported on piers or columns, or a covered thoroughfare formed by a row of such arches. In the first half of the 19th century, during 1820s and 1830s, around 150 such galleries were built in Paris alone, with any number of replicas promptly disseminated throughout the major European and North American metropolises.

When Walter Benjamin, in his unfinished *magnum opus Das Passagen-Werk* (*The Arcades Project*), 1927–1940, placed this architectural and cultural phenomenon as the central image of his speculative research, most of the 19th century Parisian passages were already destroyed, soon to be replaced by department stores and shopping malls. At the moment when the new glittering passage was opening in one of the most prominent Paris avenues, *Arcade Champs Elysees* (1926), Benjamin recalls the recent destruction of the famous *Passage de l'Opera* (1822–1925), to point out the meaning of lost traces of 19th century modernity. In "dazzling light and shadowy corners" (Benjamin [1927], 2002, 871) of the old passages, Benjamin sees the oblique traces of unconsciousness of the dreaming collective (Buck-Morss, 1989; Caygill, 1998).

Following Benjamin's intentions to retrace the previous century relics of modernity, this work zeroes in on two cases that explore the same architectural typology, only in radically different circumstances. They were singled out as insightful examples of the condensed public space that produces the set of dream-like images of exceptional intensity. Through this selection, analysis and juxtaposition, we evoke Benjamin's claim for liberation from "the realm of the dream, in order to experience present as waking world" (Benjamin [1928–29], 2002, 883–84).

2 THE GRAND PASSAGE IN BELGRADE, 1912

2.1 *The city context*

The first of its kind, the Grand Passage of the wealthy Serbian merchant and benefactor Nikola Spasić, designed by Nikola Nestorović, one of the most prominent Serbian architects at the time, was one of the highlights of Belgrade's early modernization at the beginning of the 20th century. At the same time, it can be considered an expression of cultural and social history, a reflection of its topographic conditions as well as its inherent symbolic meanings.

The most important task of the construction trade, understood in the most general way, in the 19th century, imposed by the political elite of Serbia, was to make

visible the new character of the modern, national state. However, both the traditional and more modern approaches were represented in the various areas of the system of government and organization of social life. The construction trade was gradually introduced into the frame of the government institutions, through the creation of a legislative base for its functioning and by establishing the conditions for providing architectural-engineering education in Serbia. At the turn of the century, architects and engineers, who had graduated from the Technical Faculty in Belgrade and often given government scholarships to continue their education at European universities, had increasingly more influence on the creation of the physical environment (Nestorović [1937], 1972).

According to M. Christine Boyer, the rise of working class protests in the 19th century resulted in the formation of the democratic sphere of public space, significantly modifying the controlled nature of the ceremonial places and disturbing its "bourgeois foundations of order" (Boyer, 1994, 8). Both the formation and disruption of capitalist urban order began in Belgrade only upon the termination of the strained coexistence of the two administrative governments – the Ottoman and Serbian – after the final retreat of the Turkish army from the Kingdom of Serbia in 1867. The end of the 19th century marked the beginning of intense modernization, in which time Belgrade took its place on the already established global landscape of the Industrial Revolution, although with all the specific features of its geocultural context (Wallerstein, 1991; Ćorović, 2015).

The capitalist development of cities, in most cases, followed market pressures which resulted in the degradation of space (Lefebvre, 2014). At the beginning of the 20th century, Belgrade experienced a similar situation. But 1912 saw a new, European town-proposal for the city by Alban Chambon, a French-Belgian architect, which called for a network of baroque directions and imposing public buildings on an idealized urban topography. The concept, however, completely failed to observe the complex historical and cultural heritage of the city. The true reflection of the city transformation was the regulation plan of the municipal technical services, titled "The Plan of the City of Belgrade with new regulation drawn, new street names written and blocks numeration prepared for the requirements of the cadastral survey, Scale 1:8000", 1912 (Ćorović, 2015). The urban modernization of Belgrade implied surveying, inspection, creation of the exact data base, namely, an approach to land as a resource and basis for state tax levying. Construction of the communal infrastructure systems continued in the first decade of the 20th century, along with regulation of the street network and landscaping and organization of parks and squares. New public buildings were constructed: hotels, banks, department stores, several elementary and high schools were built, and the construction of the National Parliament building began.

At the same time, the housing fund of Belgrade comprised mostly single story private houses

Figure 1. N. Nestorović, The Grand Passage, Belgrade, 1910–12, interior (photo: Živković and Antonijević, c. 1912; the Archive of the Serbian Academy of Sciences and Arts, Belgrade, sign. 14410-I-V-1351).

(82,74%), of which the majority was constructed by developers and intended for renting (78,37%) (Đurić, 1912). The population density of 62 inhabitants per hectare, was several times smaller than that of London, Berlin and Paris, but almost the same as Munich. A comprehensive study of the hygienic conditions of Belgrade dwellings in 1906–07, an initiative of the Office for Rehabilitation of Poor Housing Conditions of the Municipality of the City of Belgrade demonstrated, in addition to providing multitude other data, that almost 50% of the inhabitants lived in one room flats with or without a kitchen, as well as that the average amount of space, in cubic meters, of the living quarters in the flats for rent was almost half of that in flats owned by the tenants themselves (Đurić, 1912).

This was the context in which the main, commercial street, Knez Mihailova, acquired the new, and at that time modern, wooden "cobble". In 1912, the Grand Passage was opened in the very same street (Fig. 1).

2.2 *Nikola Spasić, a benefactor of architecture*

The merchant Nikola Spasić (1838–1916) initiated and financed the construction of four edifices in Knez Mihailova Street, the third of which, built immediately preceding the First Balkan War, was the Grand Passage (*Spomenica*, 1931; Borić, 2002).

Nikola Spasić was the descendant of a Serbian family, which, "desperately poor", emigrated to Belgrade from the countryside during the 1804–13 First Serbian Uprising against the Ottoman Empire (*Spomenica*, 1931). Spasić trained for 15 years as an artisan and merchant before opening, with his brother, the first leather workshop and store in 1865. The shop manufactured and vended "opanci", Balkan peasant footwear similar to the moccasin; this light, leather footwear was widely accepted as part of the Serbian national costume and was worn in the 19th century both in the city and the village. By the time of the Kingdom of Serbia acquired full independence in

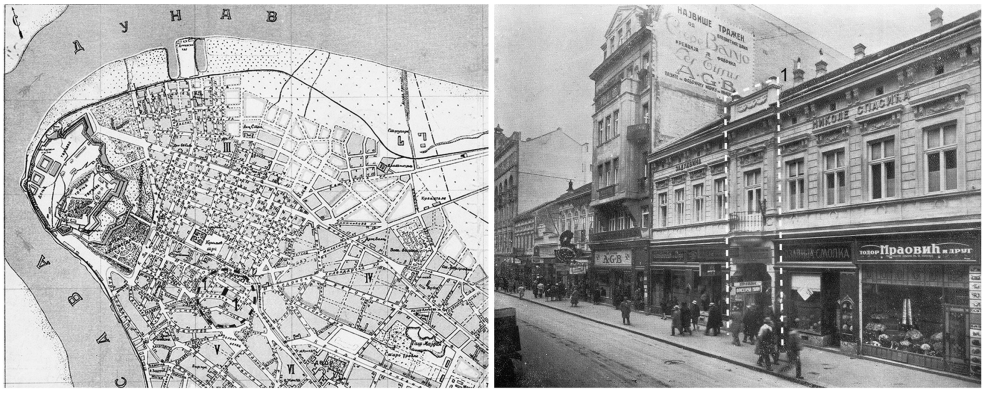

Figure 2. The location of the Grand Passage (1): a) Plan of Belgrade, 1921, 1: 15000, by lieutenant S. I. Obradović, detail (the Military Geographical Institute, Belgrade, sign. 1.5.18), b) A. Bugarski, the House at 19 Knez Mihailova Street, 1875 (from: *Spomenica Nikole Spasića*, 1931, n. p.).

1878, Nikola Spasić was sufficiently rich to completely withdraw from business. The value of the property that the Endowment of Nikola Spasić had at its disposal following his death was close to that of the Nobel Fund (Sofronijević, 1995; Borić, 2002).

Throughout his career, Nikola Spasić maintained a consistent professional attitude: he ran his business in the same way over the years and had an unwavering relation to his clients, which was reflected in his persistent, frugal, diligent self-control and modesty. This, coupled with his humanitarian work, would be how he would be remembered in the city of Belgrade (*Spomenica*, 1931). At the same time, for the architectural design of his buildings, he always selected the best architects, his buildings featured the latest technical devices, the construction material of the highest quality, with the entire building inventory procured from European centres. His will, drawn up in 1912, expressly forbade the sale of any of his buildings. Rather, it called for their exploitation in order to raise funds and thus finance all the undertakings of the Endowment of Nikola Spasić. The main goal of the endowment set by Spasić was the economic development of the nation.

For Nikola Spasić, the capable entrepreneur, the promise of architecture was a dream he pursued to the bitter end. Just a few days before his death on the island of Corfu, where he arrived as a war refugee, Spasić revealed in a letter, his hope that he would return one day to liberated Belgrade, accompanied by the renowned Viennese architect Konstantin Jovanović, who he planned to engage to design new remarkable edifices.

2.3 *The grand passage*

The single story house at 19 Knez Mihailova Street, with a large courtyard oriented towards Obilićev Venac Street, designed by architect Aleksandar Bugarski (Fig. 2b), was acquired by Nikola Spasić in 1910. Two years later, on the remaining land of the plot, a new building and the passage in-between were constructed, designed by Nikola Nestorović (*Politika*, 1912a, b; Pavlović, 2014). In late May and early June 1912, advertisements for stores and shops in the Grand Passage began appearing in the daily *Politika*. One of them advertised the opening of a cobbler shop, offering customers, in addition to expeditious work and fulfilment of all requests, a complimentary ticket to the cinema in the Grand Passage, provided they made a purchase of 20 dinars or more (*Politika*, 1912a). The knowledge of the presumed existence of a cinema in the Passage indicates a specific feature of this public urban space, the first of its kind in Belgrade (Pavlović, 2014; *Spomenica*, 1931; Borić, 2002).

A former student of the Technical University in Berlin (The Technische Universität, Berlin), architect and University professor, Nikola Nestorović, who had by 1910 already produced a significant opus of architectural design, scientific, pedagogic and publicist activity, found himself in the mature phase of his creative endeavor. He authored several books: *The Science on Styles*, n. d., *Agricultural Buildings*, *Manual for Farmers and Technicians,* 1901, *Damp Flats, Their Significance and Cause*, 1910, *Industrial Buildings,* 1926, *Building Structures*, 1927, *Buildings and Architects in Previous Century Belgrade*, 1937. He designed, either alone or in co-authorship, 68 business, public and residential buildings, some of which reflected the turning point in Belgrade architecture as examples of the first application of new structural, functional, stylistic and visual concepts. Some of these buildings in Belgrade are: Funds Administration building (1904) The Belgrade Stock Exchange building (1907), The Bristol Hotel (1912), The University Library (1925), Technical Faculty building (1931) (Pavlović, 2014, 419–32).

On Nikola Spasić's plot, towards Obilićev Venac Street, Nestorović designed a two-story, single-track building (Fig. 3). In the plot's central part, a covered inner courtyard was formed, from which one could exit both onto the commercial Knez Mihailova Street and Obilićev Venac Street, and then continue on down the hillside towards the Sava. Other than connecting the

Figure 3. N. Nestorović, the Building at 17 Obilićev Venac Street, 1910–12 (photo: Živković and Antonijević, c. 1912, the Archive of the Serbian Academy of Sciences and Arts, Belgrade, sign. 14410-I-V-1350).

Figure 4. N. Nestorović, The Grand Passage, Belgrade, 1910–12, interior (photo: Milan Savić, 1921; collection of M. Jurišić).

two streets, Spasić's Passage, at the time of its origination, was also the passage between the European and Oriental Belgrade.

The new building and the Passage included elements of Secession established in the Classicist order. The double pitch iron glazed Passage roof was located at first-story height, and the shop openings positioned on both sides of the Passage longitudinal axis, together with the windows above, made this space visually unique. The glass shop doors were as wide as the distance between the facade pilasters, positioned at regular, rhythmic intervals. Daylight got through as far as the passage interior and together with carefully composed architectural passage elements, made the passage seem open and ethereal (Pavlović, 2014). In the passage corners towards Obilićev Venac, at first-story height there were two niches: one held a bust of Nikola Spasić, and the other one, facing the first, most likely held a statue of the Greek god Hermes. The merchant and his alter ego, thus, could continue monitoring this place of multiple overlapping identities: a public space, shops, stores and cinema, protected urban passage, covered shelter, meeting and shopping place – all common experiences produced and provoked by modern urban culture. One of the images of this passage (Fig. 4) is also the image of that time: the photograph dated 1921, taken at the time of the funeral ceremony of King Peter I Karađorđević, it features funeral wreaths in the Grand Passage intended for the last farewell to the ruler, and it shows that they were maintained by the artisans and salespersons from the nearby shops.

3 THE CURIOUS CASE OF THE HALL OF MATICA SRPSKA IN NOVI SAD, 1941

3.1 *The passage and arcades of Nikola Dobrović*

The concept of covered passages, writes Marina Pavlović, never became the reality of Belgrade architecture (Pavlović, 2014). In 1939, at the location of the building forming Spasić's Passage towards Knez Mihailova Street, a four-story building was constructed, designed by architect Vladislav D. Vladisavljević. Above the other parts of the buildings which used to form the Grand Passage, new stories were constructed. It was then that the glass-cover over the inner courtyard was removed. However, the passage itself was preserved, and despite the additions, the connection between the streets was not blocked.

Nevertheless, in the period between the two World Wars, the passage as a category of architectural typology, and even more so as an expression of architectural design strategy, can be found in the series of projects of architect Nikola Dobrović (1897–1967). Being one of the most notable proponents of Modern architecture in both prewar and postwar Yugoslavia, Dobrović made an outstanding contribution to the development of architectural practice and thought, and designed and built his most significant buildings in the Dubrovnik region, in the period 1934–41 (Milinković, 2007; Ivanišin *et al*., 2015).

Arcades and passages are conceived in a series of his works, most notably in the competition project for the Terazije Terrace (1929/1930) (Fig. 6), a central place in Belgrade, where arcades appear as wide underground pedestrian passageways that connect two streets, covered and lit from above, with shopping windows on either side. In particular, this includes the project for the Kursalon in Dubrovnik (1929), and the competition project for the PRIZAD Palace in Belgrade, from 1937. The features that frequently occur in Dobrović's projects do not have the same formal and functional characteristics as the Parisian shopping passages, but Benjamin's inherent logic is consistently present in his work as an idea of space with emancipatory potential.

Still, the most pertinent case from the point of view of this analysis, is the project for the Hall of *Matica srpska* (*Dom Matice srpske*) in Novi Sad – the oldest Serbian scientific-cultural institution, funded in the Austro-Hungarian Empire – which was designed shortly before the Second World War broke out in the Kingdom of Yugoslavia. This project of Nikola Dobrović was never carried out, but the architect's

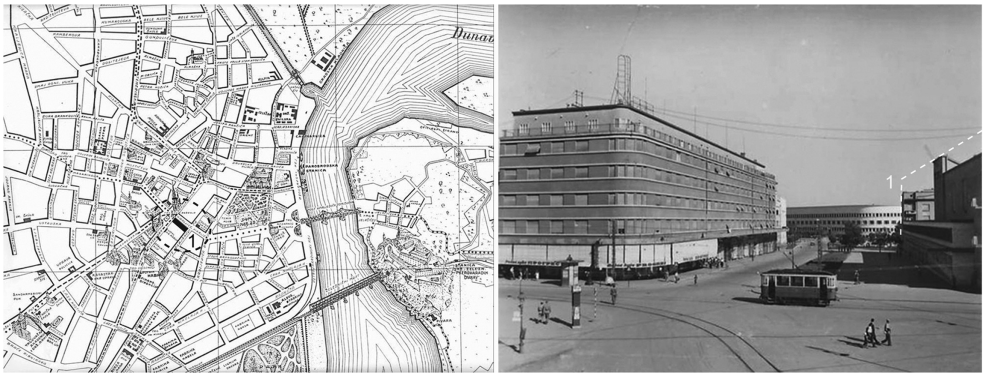

Figure 5. The location of the *Dom Matice srpske* (1): a) Plan of Novi Sad, 1929, by B. Svirèević (the Novi Sad City Museum), b) The Plaza in front of the Tanurdžić Apartments in Novi Sad, Đ. Tabakovič, built in 1934, across the site for the Hall of *Matica srpska* (a postcard, personal archive of M. Milinković).

ideas are specified in the extensive document, Technical Report in Addition to the Sketches for the New Building of *Matica srpska*, the sole remnant of the whole work. They reveal the architect's intensions to design a building for a modern cultural institution in the city, and "rising and multiplying of the new living possibilities" (Doborović, 1941, 4).

3.2 *The Hall of* Matica Srpska

During his stay in Novi Sad, in January and February 1941, Dobrović produced designs for three projects: Hall of *Matica srpska*, the Headquarters of the Bar Association and the Stadium of the Sportsmen's Club *Vojvodina*, all in Novi Sad. The designs for all three projects are missing, save for the one technical report for the Hall of *Matica srpska*. None of these projects has been published or discussed in detail in public. Considering that this was Dobrović's last attempt at getting any assignment before the war would interrupt all building activity, it may be presumed that the reason these projects remained unknown for a long time was actually the crucial moment in which they originated (Milinković, 2007).

The only preserved document is the technical report of the project for *Matica srpska*, where Dobrović explains in detail all three proposals presented in his project. It was submitted to the Main Board of the institution on March 26, the day before the Yugoslav government treaty with the Axis Powers was rejected amidst civil strife, and two weeks before the war actually began by the bombardment of Belgrade. The idea of constructing the Hall of *Matica srpska* came about just before the end of 1940. Although due to the impending war in Yugoslavia and the unstable economic conditions, it did not meet with the approval of all members of the managing board of the Institution. Still, eventually it was decided that Dobrović would be engaged to prepare the technical architectural analysis. It is obvious that desire for a new home of the institution of culture prevailed, even with smaller funds,

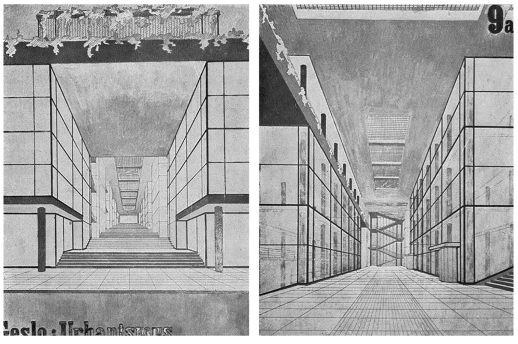

Figure 6. Nikola Dobrović, Project for the Terazije Terrace, 1929–30, Belgrade.

and, as believed, with a current opportunity of obtaining loans on favourable terms, which, at the expected dinar devaluation, would be repaid easily. On the other hand, some members voiced the difficulties of building in those same insecure economic circumstances, as well as the fact that not even the regulation line of the future building had been specified (Milinković, 2007).

The location of the plot anticipated for the construction was in the centre of Novi Sad, where the old building of this renowned institution already stood (Fig. 5). The new building, along with other existing buildings, was supposed to complete an urban block with the perimeter block construction. The plot dimensions were approximately 103 × 20 m, with a slope in the direction of one of the bordering traffic routes. According to the regulation plan, arcades were anticipated alongside this entire traffic route, and Dobrović, in his technical report informs the employers that this requirement has been met by the project. Viewed without the relevant graphic dossier, the very technical report of the architect Dobrović, includes exclusively written descriptions and calculations of the new building, indicating a clear shift from aesthetic issues to

its program strategies and considerations (Milinković, 2007).

3.3 *The technical report: Seeking new possibilities*

The structure of the building is heterogeneous, and "various rooms for various purposes" have been anticipated in it (Dobrović, 1941, 1). The library, archive, department of music and other cultural activities being the primary activities of *Matica srpska* and thus anticipated in the conceptual designs, were complemented by other, commercial functions. Dobrović's designs are missing the fourth, that is, first variant, as well as the proposals that refer to the organization of rooms on the ground floor and are in fact an attempt to provide, with obvious limitations and within given limits, certain concessions in favour of the community. The first version contained recommendations for positioning the cultural activities and proposed an arcade the length of the street front; the other two alternatives assumed the organization of commercial space that contained, as well as the street-front arcade, a longitudinal glass-covered passageway cutting through the main corpus of the building (Milinković, 2007).

Besides the office and residential part occupying the building floors, the organization of the basement was also the same for all three project variants: two auditoriums of different types were anticipated, of which the first was to be used for cinema projections and chamber music, while the second was meant as an integrated restaurant and cinema-variety show. The major difference between the first proposal and the two alternatives of this project is found in the basement organization: the first variant anticipates the coffee-room, whereas the alternative concepts call for commercial shops. Arguing in favour of the realization of the first variant and the organic relation between the coffee-room function and the cinema, Dobrović writes that the building would become the focus of urban life, absorbing both its present rhythm, and also future proportions. In the entire report, and also in the detail in question, Dobrović employs a rigorous, yet vibrant modernity. Not accepting historical inevitabilities provides Dobrović's project a utopian character and contains a latent critical reflection of the existing order, that is, it provides a relation of transgression and at the same time profound connection of an architect with the complex conditions of social reality (Milinković, 2012).

For the second project variant, namely the two alternatives with commercial shops, Dobrović's plans include the glass-covered passages, thus reinterpreting the functional essence of these spaces from the 19th century, as well as the Belgrade Grand Passage, with commercial and artisan trade shops and a cinema under the same roof. This coincidence, however, points to the intrinsic differences, namely to the change of paradigm. Fervently dedicated, in all three cases Dobrović deals equally with a whole series of social issues, considered from the point of view of functioning of an architectural object housing a cultural institution: from the possibility of establishing cooperation in financing its construction, to considering how to soften the consequences of the monopolistic placement of certain shops within the *Matica srpska* building, to securing the financial rehabilitation of other food and commercial establishments across the city and forming collective merchant companies that would ensure lower prices of products to the benefit of "the broader public". Dobrović explains his project as a constitutive part of the urban formation of Novi Sad, which, according to his opinion is still an amorphous urban community oriented more towards "organic life of its agricultural neighbourhood" (Dobrović, 1941, 4), than a product of the urban spirit. In that sense, as understood from the architect's explanation, this project is undertaken in order to be the new urbanity generator.

In its unique formal, structural and functional conceptualization, the project is characterized by simplicity, rationality and the logical application of a concrete skeleton bearing all of its own weight and any additional load (Dobrović, 1941). All the while, the facade comprises roughly cut square stones, 25 cm in width, in regular continual joints that produce a matrix. The whole project in this way, especially given its central location within the city of Novi Sad, subtly subverts the imposed requirement of a specific political representation. The simplicity of form and the visual elements of the building, the use of a specific construction system and the functional logic of the rational sequencing of rooms, along with the program strategies and plans – make this project a design for a new, socialist paradigm.

4 CONCLUSIONS AND OPENINGS

This search for the relics of these two particular 20th century passage/arcade projects, was faced with historical gaps and hidden traces. The original Grand Passage project has been lost in the meantime, the physical space transformed several times, and additional stories added over the decades. Similarly, the graphic attachments to Dobrović's project for the Hall of *Matica srpska* are still missing or at least unavailable, and the building designed has never been carried out. If we compare these two spaces, one constructed and one imagined, the main similarity is their mutual, seemingly paradoxical, characteristic: a solid flexibility at all levels of architectural discourse, manifested in relation to the public, the private, the political and the aesthetic sphere of society, manifested even to the course of history. The *spiritus movens* in the first case was a single person, a benefactor, or what Nikola Dobrović would name in his *technical report*, "a capable individual". Behind the second project there was a significant cultural institution that has initiated the ambitious venture. Since conceived in times just before the great wars commenced, in the second case literally just before, they did not become the repository for the social (un)conscious, as in the case of 19th

Figure 7. V. Maksimović, The Bezistan Passage, Belgrade, built 1953 (a postcard, personal archive of M. Milinković).

century arcades, but rather, became the dream-like images themselves.

Post-war, modern architecture in the Socialist Federal Republic of Yugoslavia, saw the establishment of new "benefactors" and new standards for open public space conception, such as the project of the Bezistan Passage in Belgrade, designed by architect Vladeta Maksimović in 1953. He designed two significant public buildings in the city center in that decade (*Investment Bank* building, 1954–57; and an office building, 1956), which shaped, among else, the new center of the modern city (Minić, 1960). In the particular case of Bezistan (the word being of Persian origin /bezistān/ meaning covered market), the passageway again became the locus of a dreaming collective unconsciousness. Innovations that were introduced through this project, like the new relationship between commercial, cultural and service sector, open roof canopy with a dome-like construction, together with a new kind of female allegorical figure (the sculpture *A woman With a Shell*, by Aleksandar Zarin, 1959), reflect the immense shift in the social structure (Fig. 7). In time, this space too fell into disrepair, just like the famed cinema "Kozara", adjacent to the passage, which did not survive the process of privatization and was then heavily damaged by fire in 2012. In the past several years, there have been attempts made to fully or partially revitalize the Bezistan Passage, yet it remains devastated and fossilized in the current social and political context.

The emancipatory potential of this special type of architecture, we would suggest, operates on two different levels. Passages are transitional places, in the way that human dwellings have become in the Modern paradigm (Caygill, 1998). As the loci inserted into urban tissue, passageways have become private, but simultaneously also public urban space or more preciously, neither private nor public – a passage is the architectural typology between the two, possessing the capacity to have different meanings inscribed onto it. This research is guided by the notion that this substantial quality of passages, if conceived as transient, ambiguous and double-edged, dependent on chance and contingencies, might contribute to prompting new forms of public life.

At the same time, the investigation of this distinct architectural typology might address the current debates on public space decline, burdened with many conflicted social, political, cultural and economic interests (Springer, 2011; Mouffe, 2005). Exploration of the historical perspective of diverse architectural tools, devices, concepts and apparatuses related to passages is enabling the search for diffused means in the analysis of the past. This allows the transformation of, as well as the release from, a previous paradigm, or, to quote Walter Benjamin, "the genuine liberation from an epoch, has the structure of awakening" (Benjamin [1928–29], 2002, 883). Thus the most significant emancipatory force, that surpasses and goes beyond the passage, can be found in separation from dreams past and in anticipation of the future (city). Architectural research that has the architectural typology of the passage as its subject can have as its goal – and achieve – awareness regarding the moment when breaking away from dominant strategies becomes inevitable.

ACKNOWLEDGEMENTS

For the historical material, the authors would like to thank the Military Geographical Institute, Belgrade, the Archive of the *Matica srpska*, Novi Sad, the Novi Sad City Museum, and the Archives of the Serbian Academy of Sciences and Art, Belgrade. The authors are grateful to the collector Miloš Jurišić, from Belgrade, for the photo of the Grand Passage from 1921, and for his help in identification of the Greek god sculpture in the Grand Passage, as well as to Željko Pavlić, for the technical support in the process of finalization of this paper. The authors would like to thank the anonymous reviewers for their constructive and insightful comments and valuable suggestions. The article has been translated by Jasmina Ninkov and Edvard Đorđević.

This paper was realized as a part of the project "Studying climate change and its influence on the environment: impacts, adaptation and mitigation" (43007) financed by the Ministry of Education and Science of the Republic of Serbia, within the framework of integrated and interdisciplinary research for the period 2011–2016.

Sustainability and design in heritage rehabilitation

A.P. Pinheiro
CIAUD Faculty of Architecture, University of Lisbon, Portugal

ABSTRACT: The sustainability issue is today of crucial importance when thinking and managing architecture and the environment. Building rehabilitation is a sustainable practice, especially when it comes to the rehabilitation of heritage buildings. Design is essential through the use of life cycle thinking, maximizing resource efficiency. Wherever possible, green roofs will be used so as to avoid introducing new types of finishes, at the same time it increases the thermal insulation and reduces the problem of disposing of rainwater. It will be made a management of the existing resources from rainwater, as gutters, downspouts, gargoyles and tanks, as well as the topography of the place and vegetation that contribute to the sustainability of the historic property. The Landscape Architecture will reinforce the sustainability of the historic place. We have selected as case studies the Rehabilitation of Portalegre Cathedral and the Faculty of Law, UL.

1 INTRODUCTION

The interventions' underlying cultural attitude must combine the design process with the principles of economy and environmental impact assessment. It is necessary to question the entire building life cycle, including systems and materials since their extraction, transport, application and disassembly.

Architectural Rehabilitation, and especially heritage buildings Rehabilitation, is intrinsically a sustainable practice as the existing structures represent energy that has already been expended, materials that have been extracted or collected, components which have already been produced – incorporated energy from past generations.

Rehabilitation also means to articulate the building's ages and must have as key concepts reversibility, sustainability, versatility and simplicity, always respecting the Heritage.

Thus, there are also other aspects that should be considered: installing an efficient energy system that takes into account the performance of the entire building and maintain its historic character and ambiance; examine whether the solar technology can be used successfully and if it will benefit the building without compromising its character or the place or the surrounding historic neighbourhood. It is essential to prioritize sustainable improvements, starting with minimal-invasive treatments that are less susceptible of damaging the building.

2 PORTALEGRE CATHEDRAL

The chosen case study refers to the rehabilitation of Portalegre Cathedral, cloisters and annex spaces, 1st prize of a Competition, authored by Ana Paula Pinheiro and Rui Barreiros Duarte (Fig. 1).

Figure 1. Portalegre Cathedral. Photo: SIPA FOTO 00524019.

The annex constructions done over time, either in the building or in the courtyard where a Room for Permanent Exhibition will be built, express interventions by addition that misrepresent the building's character, being necessary to remove them.

Other interventions made afterwards must be withdrawn in order to clarify the Cathedral's authenticity, and to permit an adequate natural light and avoid infiltrations.

The Rooms of Permanent Exhibition (Figs 2–3) and Temporary Exhibitions (Fig. 4) constitute spaces contained by walls, reversible and discrete. This visual quality and maintenance creates an interactive relation between full and empty, enhanced by the shadows' expression during the day. Overnight the artificial lighting stages the spaces between the new buildings and the ancient Wall.

Figure 2. Portalegre Cathedral: Longitudinal Section of the Permanent Exhibition Room. RBD.APP, 2016.

Figure 3. Portalegre Cathedral: Terrace View to the Green Roof of the Permanent Exhibition Room in the southwest courtyard. RBD.APP. 2015.

The mentioned buildings have roofs that will be visible from various places, assuming great importance in the enjoyment of spaces and views of the landscape. It is therefore proposed that these are green roofs, as the observer can enter his own world whilst moving around the building; they transport the imagination to calm locations that belong only to the meditative mind of the visitors.

2.1 *Green roofs*

Green roofs, also known as living roofs, are coated with vegetation planted in light soil over drain materials and waterproofing membranes.

They constitute a sustainable practice that has been gaining increasing importance in order to optimize energy consumption in buildings.

These roofs help to decrease the urban temperature, fighting the heat island effect.

Their greatest potential lies in the ability to cover with vegetal permeable material surfaces that otherwise would be waterproof, restoring the ecology of the place where the building is built.

The "protection from extreme temperatures can also reduce energy costs for building owners" and "in some conditions, a green roof can act as an insulator, while in others a thermal mass effect will act to diminish the temperature gradient above and beneath the roof as the system absorbs, then slowly releases, heat". (Snodgrass, McIntyre, 2010, p. 32).

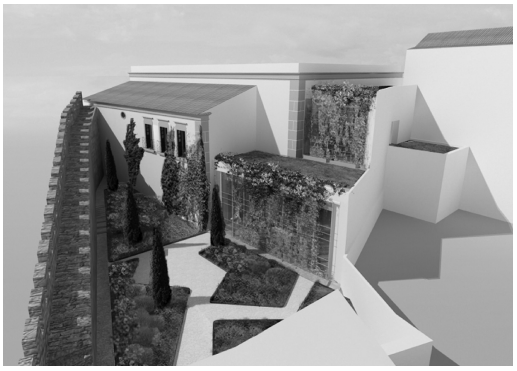

Figure 4. Portalegre Cathedral: South courtyard. Rehabilitation by RBD.APP. Landscape: ARPAS, 2016.

Thus the advantages can be described: contribution to the durability of the building; reduce the temperature range; reduce the heating and cooling costs; increased thermal insulation; micro and macro external environment temperature decrease; increased sound insulation; carbon emission reduction, mitigating air pollution; filtering of rainwater, contributing to pollution reduction, improving air quality; fixing of solvents; ecosystem recreation; attraction of songbirds and reduces the spread of fires (Braungart, McDonough, 2009).

The vegetation should be one that doesn't grow excessively, in order to maintain the character of the building, not being visible from the outside.

It is important to provide the use of a vegetal covering with little maintenance, by selecting sustainable native plants which are resistant to drought and do not require excessive watering.

Therefore, to ensure the success of plantations on the roof, a suitable substrate to ensure the needs of the plants – not only during the installation period, as during its future development – should be placed at the time of planting. This substrate will have a medium to coarse texture, and high capillarity and balanced drainage, providing a firm and durable structure for an extended vegetation cycle for any type of plants. Its specific gravity is reduced, contributing to a lasting and stable structure, ensuring good drainage.

Drip irrigation was used to restrain water consumption. It is intended to include a moisture monitoring system to protect the building from additional moisture and accidental flooding.

The chosen green roof is an extensive modular system like "Green Grid Roof System". The modules have a dimension of 1.20×0.60 m area and 0.10 m deep. The trays of the extensive modular system will come prepared, in this order from the bottom to the surface, honeycombed with drainage blanket with 0.02 m, with geotextile 250 g/m^2 and suitable land cover with 0.08 m minimum thickness. They have a weight of 75 kg/m^2 in saturated soil. The trays have a place to fix a part to move in an effective way. They will be planted with mixtures of plants of the Sedum type,

Figure 5. Portalegre Cathedral: Existing. Photo by RBD.APP, 2015.

which should have a minimum height of 0.10 m and of equal diameter. The plantation will be carried out in quincunx, so as to make a density of 44 plants per square meter. The set will have a 0.25 m thickness.

2.2 *Disadvantages of green roofs*

Although green roofs offer a wide range of advantages, there is also a series of disadvantages in what their implantation is concerned that might cause the necessity of considering other roof options:

– They weight more than traditional roofs;
– Cost of the system implantation;
– Cost of maintenance in case of making an inadequate choice;
– If not applied properly, the system can cause water infiltration into the building.

2.3 *Roofs*

It is fundamental to repair and maintain the historic roofs' materials in good conditions (Fig. 5).

The maintenance of roofing must question the materials used, their placement and operation techniques so as to avoid deterioration.

Some wood elements were detected with substantial section losses and a replacement should be expected in the ones in greater state of deterioration. It is estimated a replacement with a percentage higher than 50% on the wood elements of the roof.

It is essential to monitor the buildings so that there is a prophylactic action strategy, preventing problems detected afterwards.

2.4 *Rainwater harvesting*

The management of existing resources of rainwater, such as gutters, downspouts, gargoyles and cisterns, as well as the site topography and vegetation contribute to the sustainability of the historic property.

It is a traditional principle, which formed the basis of several civilizations, referenced in the territory with

Figure 6. & Figure 7. Portalegre Cathedral. Existing: Cistern (Left) and water canal (Right). Photo by RBD.APP, 2015.

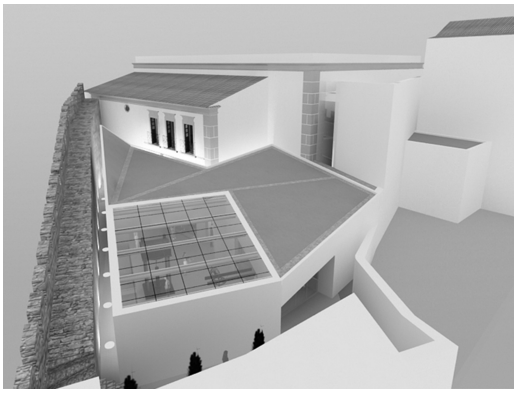

Figure 8. Portalegre Cathedral: Temporary Exhibition Room in the south courtyard. Skylight with photovoltaic cells in the glass. RBD.APP. Landscape: ARPAS, 2015.

infrastructures that can be mega-structures, such as the aqueducts example.

Cisterns correspond to a process of water collection and reuse developed by the *Order of Cister* in the convents and Cathedrals (Figs. 7–8). A process of capturing that is based on a significant cost reduction.

Green roofs filter rainwater as part of a natural system of storm water management, absorbing up to 70% of the water that falls on them. In addition, other resources will be used such as retention and filtering areas with a rainwater retention tank to improve storm water management and water reuse on site.

The Landscape Architecture, through the choice of local adapted plants and that consume little water will enhance the sustainability of the historic place.

2.5 *Renewable energies*

If it is possible to use renewable energies, these should be installed in compatible location with the site, or on a non-historic building or expansion, minimizing the impact on the historic building and site.

The initial solution predicted that the Temporary Exhibitions' building would be built in the south courtyard. The roof had a pendant that articulates with the slope of the Wall leaving a free path along the ancient Wall and next to the *Cabido* building (Fig. 8).

In this pendant there was a square area with a skylight with photovoltaic cells embedded in the glass. It allied natural light to the possibility of using renewable energies in a discrete and integrated way. Sunlight would be controlled by interior blinds. The photovoltaic cells had their presence diluted in the glasses that incorporated their energetic qualities. The research of new materials and techniques and the adaptation of technical systems to a cultural field is a path that has been steadily developing and that revolutionizes principles that so far were negative.

This solution was not approved by the *DGPC* (General Direction of Cultural Heritage), even though it was not visible from the outside of the Wall. It has however been replaced by another solution with less construction and without renewable energy. In this case, the green roofs are also used and green façades are used as natural shading, extending the existing image of the *Cabido* building with creepers on the façade (Fig. 4).

2.6 *Natural lighting*

Natural lighting is favoured in all rehabilitation. So, whenever possible, the historic windows previously blocked will be reopened adding natural light and ventilation.

2.7 *Design*

"*Design is a creative activity whose aim is to establish the multi-faceted qualities of objects, processes, services and their systems in whole life cycles.*

Therefore, design is the central factor of innovative humanisation of technologies and the crucial factor of cultural and economic exchange." icsid

In what museums are concerned, lighting should enhance the qualities of the exhibited pieces, cancelling the variations of the day and night, and of their transitions. When thinking about the versatility of lighting design, two questions arise: energy saving and expressing different types of acting, depending on the exhibited pieces' potential. Thus, these variables might enhance different qualities under different types of light and lighting conditions (Pinheiro, 2015, p. 128).

When exhibiting religious pieces it is necessary to create appropriate relations that manifest their sacredness and meditative atmospheres. One should reflect on the qualities of natural light, where the stained glasses – different in the north and south façade in the Portalegre Cathedral – creates, during the day, an ethereal environment sacralising the chapels.

The colour of light is of crucial importance in religious architecture, through stained glass windows and lighting design: on the articulation of spaces with exhibition displays and on the way to enjoy the exhibited pieces, explaining their physical and symbolic

Figure 9. Portalegre Cathedral: Permanent Exhibition Room in southwest courtyard. RBD.APP, 2015.

qualities. This aspect involves a natural and artificial light homogenization, especially if we are before the lighting of paintings.

The lighting enacts the spatial qualities, exploring environments and their sacredness, taking advantage of intensities, location, colour, the relations established between objects and the modelling of space.

The quality of the assembly results from different types of relations: the pieces together, along with spaces and the creation of moulded environments, having the light as material of construction.

In the case of an intervention in a building classified as a national monument, particular attention was given in the choice of solutions to propose to the facilities and on how to implement them, according to the Lighting of Historical Monuments criteria of Charter of Taxco 2009.

During the project the principles of Sustainable Design were followed. There was a concern to maximize natural light and conserve energy, specifying systems, fixtures, appliances and energy-efficient equipment. Solutions – that avoid the need to intervene in an irreversible manner and that are easy to uninstall – have been proposed, having created a dynamic solution that considers various factors, bearing in mind that the equity intervention conditions do not allow opening grooves on the walls and ceilings.

In the temporary and permanent exhibitions area and in the church, the installation of a centralized control system of general lighting, with dimmable, was proposed.

The exhibition halls will be lit with rails with projectors, using LED strips in the remaining spaces for ambient lighting. The used devices are equipped with LED light sources due to its higher yield and duration (Fig. 9).

In the Cistern access route, devices were used at low rate with lighting directed to the pavement. The Cistern vaults were lighted with projectors and complemented by others located outside to illuminate the well in the Cloister courtyard, simulating daytime natural light with a colour temperature of 5000 K.

In the Cloister, devices of ruler type in LED were placed on the arches and directed to the courtyard,

Figure 10. Faculty of Law, UL. Porfírio Pardal Monteiro, 1958. Photo by Ana Paula Pinheiro, 1994.

in its four sides. Uniform light was obtained over the entire courtyard with a colour temperature between 3000/3500 K.

The outdoor lighting of the courtyards, where the Exhibition Rooms will be built, was conducted with floor projectors.

The lighting of the main aisle of the cathedral took advantage of the existing chandeliers, where projectors of reduced dimensions were incorporated, in an adequate number to ensure the lighting of the main aisle vaults. Additionally, the installation of projectors on top of the chapiters of the columns was predicted.

The side aisles were illuminated from the pillars of the side chapels with targeted projectors to the ceiling of the vaults. In the altars the use of lighting through LED strips was predicted, placed on the side mouldings to light the ceiling, and LED rules to illuminate the arch. The carved altars were lit with steerable projectors, installed in a vertical rail and placed in the furthest corners from the vaults, allowing adjusting the required number of projectors (Gonçalves, 2015).

3 FACULTY OF LAW, UNIVERSITY OF LISBON

The Faculty of Law, University of Lisbon, corresponded to an intervention at the level of its Conservation, Restoration and Architectural Rehabilitation with Expansion by Ana Paula Pinheiro and Rui Barreiros Duarte.

1st prize of a Competition in 1994, it was inaugurated in 2001.

"The pre-existing building regained the original 'neatness' without being apparent that, for instance, a (localised) internal space reorganization took place, that the basement was changed into a serviceable floor by the lowering of the patios, or that the main entrance was renovated – with simplicity and without an unnecessary protagonist ambition.

In this intervention the proximity to Pardal Monteiro certainly helped to ponder the moments of discretion and the moments where the architect asserted his own work, thus resulting in a genuine rehabilitation of a relevant example of the 'Estado Novo' public

Figure 11. Faculty of Law, UL: rehabilitation RBD.APP, 2001. Photo by Sérgio Mah, 2001.

Figure 12. Faculty of Law, UL: main entrance. RBD.APP, 2001. Photo by Sérgio Mah, 2001.

architecture and its integration into the contemporary expansion." (Costa, 2009, pp. 18–22) (Figs 10–11).

The façades were cleaned with water jet and the dirtiest areas with silica jet; the windowsills were cleaned with fine sandpaper. Air conditioners were removed from the façades and placed on roofs. Inside, the terrazzo walls were cleaned with SIKA CLEANER.

3.1 *White roofs*

The white roofs are designed to reflect more sunlight, absorbing less heat than common roofs, decreasing the heat transferred into the building and improving occupants' comfort. They have easy maintenance, increasing the life cycle of the coverage and thus contributing to the reduction of the urban heat island effect.

The standard or dark covers can reach temperatures of 55°C or more under the summer sun. A white roof under the same conditions may be 10°C cooler.

Figure 13. Faculty of Law, UL: Circulations with natural light and view to the outdoor green area. RBD.APP, 2001. Photo by Telmo Miller, 2013.

Figure 14. Faculty of Law, UL: Secretariat with natural lighting and view to the outdoor green area. RBD.APP, 2013. Photo by Telmo Miller, 2013.

They are therefore suitable for hot climates, generating energy savings in refrigeration systems.

The covers of the existing building, as well as the expansion opened in 2001 are white roofs.

3.2 *Natural lighting*

The lighting and ventilation on Floor – 1, made possible by the courtyards pavement relegation, introduced new degrees of freedom for the functional reorganization of interior spaces that were previously occupied by warehouses and books depots of the library. This straight relation with the outside, allowing its visual enjoyment, as well as the creation of exterior accessible interaction zones, transformed the old basements in spaces occupied by new classrooms and administrative areas (Figs. 13–14).

3.3 *Design*

The purpose of design when building environments is to create the conditions for greater physical and aesthetical enjoyment of the spaces.

Tile panels were used as a graphic design example on how to communicate with the public and/or private users, bringing art to people and creating areas where we can think and dream in order to better act and create.

The tile allows an integrated thinking in terms of architectural conception, sustainability and design, answering to almost all the principles of Sustainable Design (Pinheiro, 2015).

In 2000, the design of all individual equipment was made, as a complement to the Architectural Rehabilitation – benches, flowerpots, exhibitors, dustbins – in order to create an identity and support living areas and the interaction of students, with elements that could be used both inside and outside.

The benches and flowerpots prototypes were executed in GRC, wood and stainless steel (Fig. 15).

However these were not used, and the Faculty opted, against the authors' will, to use ones offered by the Alumni that go against the design principles of the project (Fig. 13).

Figure 15. Exhibition *MEGARIM CON.VIDA*: Bench and Flowerpot designed for the Architectural Rehabilitation of the Faculty of Law, UL in 2000 by Ana Paula Pinheiro. Photo by RBD.APP, 2013.

In 2013 there was a new Rehabilitation, authored by the same architects, and Classrooms' and Workshops' furniture was designed and produced on the principles of sustainable design.

3.4 *Accessibilities*

Throughout the intervention there was a minimization of architectural barriers, making the building an inclusive space for mobility.

All areas were connected by reversible ramps, having an elevator been placed in the east ladder pump, allowing access to all the floors (Fig. 13).

4 CONCLUSIONS

Rehabilitation of Architectural Heritage, in addition to the preservation of the building, involves a thorough analysis of the roof and materials – conservation status, finishes, joints, gaps, settlement conditions – as well as the dynamic relations with water and wind.

The adaptation of interior and exterior spaces without destroying the identity of the whole, allows to introduce new services, boosting their enjoyment according to programmatic redefinition that make the buildings experienced by society. Design acts as a complement of Architecture, using life cycle thinking and maximizing resource efficiency.

One can conclude that the Rehabilitation of Architectural Heritage and Design constitutes an integrated set that must have in mind Sustainability.

From monument to embodiment: A social case for a more expansive representational strategy for architectural heritage

Seher Erdoğan Ford
Temple University, Philadelphia, USA

ABSTRACT: How do we tell the story of a 1600-year-old building? In architectural heritage, this question is one of representation. There is also the question, however, of choosing which story, or rather stories, to tell. St. John of Studius Monastery, later known as the Mosque of Imrahor, in present-day Istanbul, Turkey, is slated for an imminent and controversial renovation, which brings the issue of preserving myriad aspects of its tangible and intangible heritage to the forefront. A case like this exposes the urgency and significance of finding alternative modes of studying and recording buildings with complex histories through available and emerging digital tools. While effective cultural preservation projects utilize robust archiving methods, they also rely on design and representation so as to "come alive" as platforms for new scholarship and community engagement.

1 INTRODUCTION

The specific heritage site discussed in this paper is St. John of Studius Monastery Church, later known as the Mosque of Imrahor, situated in the historic peninsula of Istanbul and regarded as the oldest religious structure still standing in the region (Fig. 1). The site has not only a complex history but also a controversial restoration project in its future, which has brought the issue of preserving its tangible and intangible cultural heritage to the forefront.

Figure 1. Photo of the ruins taken from the minaret in the context of 1930s (Nicholas Artomonoff Collection 2011–2013).

Partially abandoned since the 1920s and currently dilapidated, our knowledge of the physical construction of the church and its cultural significance are based on field research supplemented by secondary resources on early Byzantine ecclesiastical architecture. While the exact date of its construction and the specific scope of the renovations the church has undergone over time are debated, scholars like Dirimtekin, Mango, and Van Millingen have illustrated detailed portrayals of the church's various distinct phases (Dirimtekin 1973; Mango, 1976; Van Millingen 1912). Literature on theoretical underpinnings of cultural heritage, specifically as it relates to new digital media, pose provocative questions on what constitutes cultural heritage, how we conserve its various aspects, and whether the objective is to deliver a single cohesive story or facilitate multiple narratives. Scholars engaged in a theoretical discussion of digital scholarship, such as Drucker and Presner, draw attention to the larger conceptual questions as to how we can leverage emerging technologies to foster new representation techniques and cultivate dialogue rather than merely answers (Drucker 2009; Presner 2014).

This paper frames an analytical discussion around a particular digital reconstruction project of the Byzantine basilica structure and uses this process and its results to draw arguments on the limitations as well as the opportunities for new strategies to represent architectural heritage in multiple contexts.

In terms of methodology, the paper first outlines the history and significance of the Studius church as a site of architectural and cultural heritage in relation to the transformation from Byzantine to Ottoman rule, and subsequently to contemporary Turkey. Upon establishing its geopolitical and historic context, the paper analyzes a specific digital modeling project in

terms of its technological and conceptual approaches and provides an overview of suggested taxonomies for organizing content. These taxonomies lead to a discussion on seminal examples of digital scholarship, which begin to suggest concrete design parameters to facilitate complex narratives for complex heritage sites.

The preservation of architectural heritage itself is a complex and interdisciplinary project, which can be resolved and, in fact, enhanced through design. More specifically, if considered as a spatial construct supported by digital scholarship tools, cultural heritage can impact communities and gain their alliance through sustained and authentic engagement.

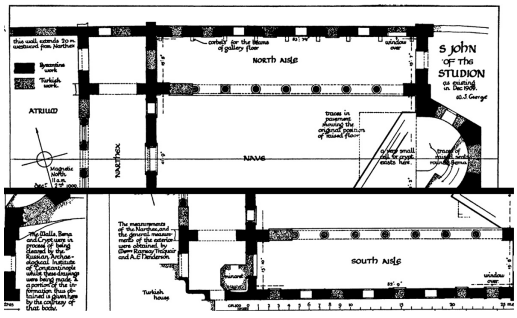

Figure 2. Plan of the basilica with notes describing some of the internal modifications over time (Van Millingen 1912).

1.1 *Background of the heritage site*

The oldest ecclesiastical Byzantine structure in present day Istanbul, the church of St. John Studius Monastery was erected around 450 A.D. by patrician Studion, possibly on the grounds of an existing parochial church, near the "Golden Gate" situated along the Theodosian city walls delineating the Byzantium of the time (Mango, 1976). Initially, the monastery housed the order of Acoemetae, otherwise known as the "sleepless monks," who characteristically held their services continuously throughout the day and night. The monastery began to gain larger prominence in the Roman Catholic community in the 8th century, when as many as 700 monks resided within its bounds (Dirimtekin 1973). The historian Van Millingen describes the monastery in the 11th century as a refuge for devoted monks, over-exposed emperors, and even dissidents—and as a focal point of clerical and intellectual culture in the Roman world (Van Millingen 1912). The Catholic Encyclopedia also tells us that the site acted as the burial grounds of holy bodies, the center of Byzantine religious poetry, and an educational community for calligraphy.

A classic example of early Christian basilica building typology, the church represented an application of this paradigm on a more squareish footprint of approximately 26 meters by 34 meters (Fig. 2). Most of the building-scale architectural elements are discernable from the remaining structure, including the three-bay nave extending in the conventional east-west direction with galleries over either aisle, an apse with a semicircular interior and three-sided exterior geometry, pillared narthex, and an underground cistern (Mango 1976).

Some of the elements that have not survived are the timber roof structure over the nave and intricate interior adornments that distinguished the Studius church from other basilica constructions "mass produced" throughout the Roman world in the Near East, North Africa, and Italy (Mango, 1976). Architectural historians, including scholars of architectural ceramics, describe the interior of the monastery as faced with marble panels, Corinthian capitals and architraves with remarkable polychrome plant ornamentation, and a marble floor constructed of *opus sectile,* an ancient inlay patterning technique featuring elaborate geometric motifs (Gerstel, Lauffenburger 2001).

While Mango's descriptions place the architecture of Studius in the early Byzantine context, Van Millingen and Müller-Wiener provide further analysis of the continuous re-building during later phases of the Empire as well as the complete neglect the monastery was in after the Latin occupation of 1204, when it became ostensibly a grazing ground for sheep. Upon the demise of the Byzantine Empire in 1453 and the settlement of Ottomans in Constantinople, all functions of the monastery ceased. Until the early 16th century, the grounds were used as a stone foundry, servicing the Ottoman Sultan's widespread construction throughout the city, including such significant structures as the Topkapi Palace (Inalcik 1969/1970). In around 1485, the Sultan's equerry, a high-ranking officer in charge of the stables, converted the monastery to a mosque, thereby inspiring the name Imrahor, which literally means the Stablemaster. Subsequently, the mosque was exclusively designated as a Sufi dervish lodge, or *tekke*, dedicated to the brotherhood of the Sunbuli, a branch of one of the most prominent Islamic sects. Interesting to note is that the interior decorative work of iconography and *opus sectile* survived until well into the 16th century, when the *tekke* not only functioned as a space for prayer for Muslims but also as a center for education of some of the most prominent calligraphy artists of the Ottoman Empire, paralleling a tradition established in the monastery by Christian monks in the 12th century.

Major physical modifications ensued from the programmatic changes related to liturgical practices, which incorporated more of the surrounding area around the basilica and almost doubled the footprint. The rehabilitation into a mosque entailed the addition of the minaret, a residence for the Imam, the leader of worship and the religious community, as well as the reconfiguration of the floor surface pattern to overlay the *mihrab,* the architectural niche oriented toward the Mecca, as is customary with all mosques around the globe (Fig. 3). Smaller scale modifications included new walls to replace the colonnade, infilled

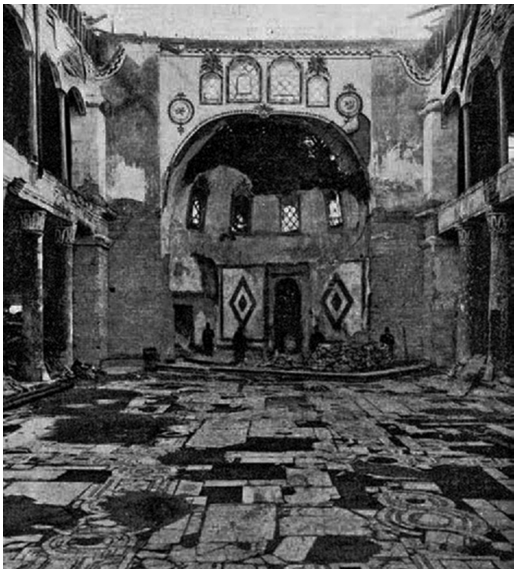

Figure 3. Interior view of the *mihrab* and *opus sectile* floor (Köse 2012).

windows and doors, and *sadirvan,* a pavilion-like fountain for ablution practices. Other major reconstruction recorded in the Ottoman state archives occurred due to environmental causes, such as the fires of 1718 and 1782, and the earthquake of 1894 (Köse 2012). Further analysis would provide detailed information on the specific chronology and materials of these alterations.

The latest phase of the series of rebuilding on the site is a renovation project undertaken by the Directorate General of Foundations administration, which has had jurisdiction over the property since the early 1920s, coinciding with the regime change in what is now the Turkish Republic (Köse 2012). Even though the building had been designated a museum by the administration in 1946, the premises was not open to the public and has fallen into decay—yet, it remains a draw for tourists on Eastern Orthodox pilgrimages as well as scholars. The planned construction agenda is to rebuild a mosque, a politically charged direction in terms of rehabilitation. The news raised controversy among various constituents, including the local and displaced Greek population who continue to regard the basilica as sacred, and others who reacted to the opacity of the process and the lack of information and details in regards to the architectural plans (Ziflioğlu 2013).

1.2 *Background of the digital reconstruction project*

The impending restoration of the Mosque, scheduled to start in late 2016, and the reaction it received foregrounded the urgency of devising inventive preservation strategies for architectural sites with multiple significant cultural identities. The revived focus on this piece of architecture coincided with the formation of the UNESCO Chair in "Management and Promotion

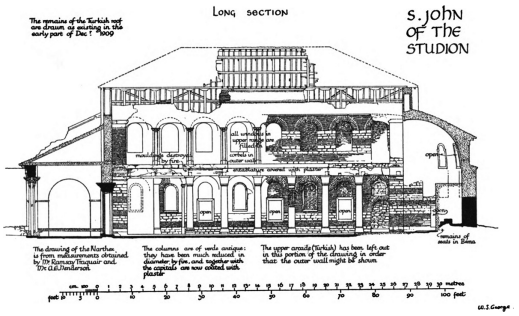

Figure 4. Longitudinal section with notes describing some of the internal modifications over time (Van Millingen 1912).

of World Heritage Sites: New Media and Community Involvement" at Kadir Has University in Istanbul. This initiative instigated collaborative efforts between other cultural institutions, industry partners, and the university. One such partnership was with Bilkom, the leading software distributor in Turkey, to work on a project involving new media with a team of students and faculty members at Kadir Has. The team agreed that the Mosque of Imrahor would be an appropriate first case study for a digital reconstruction project. Bilkom, as part of their social responsibility agenda, had undertaken a similar project for the ancient city of Pergamon in Western Anatolia, for which a tablet application to recreate specific perspectives of the historic site was launched. Similar to the Pergamon project, the goal of the Studius church reconstruction project was to produce digital models for the development of an application catered primarily toward touristic and educational visitors to the site.

The building information modeling software, ARCHICAD, is one of the programs Bilkom represents in Turkey. Therefore, one educational goal of the project was for a team of students to learn and practice the use of this specific platform. Along with digital modeling, the students also engaged in close analysis of existing documentation of the site and learned about the "layers" of history laminated on this architectural and geographic site (Fig. 4). Involvement with this project introduced the students to a community at the intersection of cultural heritage and new media—all aspects of which are outlined in the mission of the UNESCO Chair.

The students worked as the primary modelers, but they were also integral to the discussion surrounding the conceptual agenda of the project. The technological challenges stipulated a phased approach to modeling, in which the initial installment of the project would focus on a single aspect of the site's history. The team decided to transfer the Byzantine basilica in its 11th century condition, at the peak of its social prominence and architectural presence, to the digital environment of ARCHICAD. This decision entailed the task of deciphering and uncovering the later modifications carried out by the Ottomans. The relatively narrow focus was motivated by the academic calendar of the university

Figure 5. The layers of modification currently visible on the walls (photo by author).

as well as the steep learning curve the software initially demanded.

This author argues that the technical challenge of collaborating on the construction of a historic building in the digital environment created a critical limitation, reducing the physical, temporal, and inevitably, conceptual scope of the project. The major challenge with ARCHICAD was the question of how to represent or recreate the Roman masonry structure along with the series of intricate finish work within the interior, implementing a tool specifically tailored to contemporary standards and components of construction. The solution to this specific problem would be to make a model that would ultimately yield an image that was a visually accurate, idealized version of the basilica. Therefore, a "well-built and clean" model and a "finished" visualization of the basilica would essentially erase the sense of time—and represent a singular, arguably less accurate, rendition of history. The cleaner the image, the less it speaks to the character of the site and the nuances of its heritage. An image that generates a specific perspective at a particular location of the site would fall short of actually allowing "access" to its history and heritage.

2 THE NATURE OF THE CONTENT

A "noble ruin," in Cyril Mango's words, the architectural details of Studius can be visualized by comparing it to other examples in the area. Documentation available on the basilica incarnation of the building is heterogeneous and incomplete. Heterogeneity here characterizes the combination of quantitative and qualitative data, multi-scalar aspects of its construction, and the intersection of both scholarly work and personal accounts.

A stratified classification of quantifiable and qualitative data is unproductive from the perspective of the humanities disciplines that study ambiguities. It is an evasive task to distinguish between strictly informative and expressive images. As Drucker reminds scholars working within visual studies, all images embody an agenda (Drucker 2014). An investigation of what is known on this site must accommodate and, more importantly, relate to both types of data. In terms of measured data, the architectural drawings produced by Van Millingen convey an analysis of layers of construction that were discovered in the late 19th century (Van Millingen 1912). Additional documentation is available on the various construction projects the building went through after major earthquakes and fires in the city. Due to the incomplete nature of these drawings, and in order to find suggestive representations of what the spaces were like, researchers can reference the photos taken by Nicholas Artamonoff in the early 20th century and those included in the archives of the Council on Historic Heritage (Nicholas V Artamonoff Collection 2011–2013; Köse 2012). In addition to visual data, further investigations of other sensory experiences of the space, such as the sounds of the hymns during the Acoemetae chants or the call to prayer, would add yet another atmospheric layer to the story. This body of diverse representation begins to convey a sense of space as well as the life outside the walls of the basilica at different times in history.

A second type of variety occurs with scale. As a piece of architectural heritage, the building offers opportunities for critical research that ranges from the building's components to the wider urban fabric in which the building is situated. Documentation in the field captures the current condition of the wall assembly, which exhibits the typical Byzantine method of alternating bands of brick and stone coursing, along with the transmogrification the walls have gone through with discontinuous patches and fills (Fig. 5). At an even smaller scale, mosaic *opus sectile* with marble inlays prove to be of interest. Patterns and types of stone used in floor construction in the 11th century create connections with other Byzantine examples of mosaic work. On a larger architectural scale, investigation can include the basilica in its built context, and preliminary analysis shows the changing housing stock in its neighborhood, Yenikapi. The building has gone through numerous renovation projects, as well as has faced major damage and additions. At the scale of the city, the transformation of this part of the world from the 5th century Constantinople to the 21st century Istanbul calls for analytical mapping studies. The Studius monastery was situated relative to the Sea of Marmara, the city gates, and nearby stone foundries. It held a commanding position in the Byzantine era. The dissolution of the monastery complex and the rapid urban growth in the surrounding neighborhood buried the church within the denser urban fabric. In its current context, the ruin is precariously sited in immediate proximity to new construction developments and large swaths of densely populated blocks (Fig. 6). For these reasons, documentation of the building at a variety of scales from the object to the city is a challenging archival task and an even more difficult representational project. This body of information is essential to understanding the make-up of the building in its changing context.

A third type of heterogeneity in data exists between scholarly work and personal accounts. The question of what is historically relevant and individually significant has traditionally been definitively separated (Cameron, Kenderdine 2007). In order to be able to

Figure 6. Aerial view of the ruins in the contemporary urban context of Istanbul (Kudde & Ahunbay 2014, Fig. 1).

entertain open-ended questions and cultivate multiple readings with potential connections, however, a combination of scholarly and anecdotal, written, and oral histories is required. Personal connections with the building can be traced within various groups that inhabited the building in different ways. Some examples include the descendants of the Greek population of Istanbul, by now mostly displaced; the Sumbuli followers who were officially disbanded with the formation of the secular Turkish republic; the apprentices of the calligraphy program conducted in the mosque; and ultimately, the neighbors—including the daughter of the latest imam of the mosque—who are among the very few with de facto access, if only visually, to the basilica (Fig. 7). A record of these oral histories would suggest the multiple identities the building embodied for different social groups, which may be initially framed around differences but potentially yield salient commonalities.

Given the layers of seemingly disparate content on the site, speaking in terms of the building as a finished product is insufficient as far as it fails to capture the full breadth, depth, and character of its cultural heritage. A more apt framework is speaking in terms of a "landscape," as suggested by Jessop (Jessop 2008). The ongoing nature of change and complex sets of relationships suggest an ecological framework—or landscape—that, as a layered and dynamic entity, captures these qualities.

3 THE ORGANIZATIONAL STRUCTURE

An overview of the available sources of data establishes the complex nature of the content, which highlights the equally complex issue of how to manage and deliver this content. The nature of the organizational issue is two-fold, technical and conceptual, both of which comprise a design problem. As Drucker states in her article "Blind Spots," the very design of the content, the archival project, defines the intellectual engagement it will initiate, be it scholarly or personal (Drucker 2009). Therefore, this paper supports the argument that the technological task must serve the conceptual agenda.

The technical endeavor is one of building a flexible yet stable database that can manage large amounts of multi-media documentation. Software becomes an integral part of any digital scholarship project, introducing a level of precariousness to the project as technologies shift, update, and inevitably become obsolete. Much like the discussion of digitizing traditional media and archiving "born-digital" data, the preservation of the system is a secondary level issue. For the Studius project, the partnership with a commercial party specialized in software distribution promised sustained digital maintenance.

A more critical task is to establish the conceptual agenda to determine the framework in which information needs to live. Again, Drucker reminds us that no act of representation is neutral; furthermore, the mode of representation shapes our knowledge of the referent. For the digital reconstruction of Studius, Kadir Has University team resolved to recreate the basilica in its 11th century condition in a photorealistic manner. This type of a rendering exercise, given the nature of this cultural landscape, posits the question of what is real. A project focused on cultural preservation supported by new media might seek solutions to design problems of maintaining the layers, broadening the extents, and preserving the open-ended questions. If the question had not been "What does the building look like in the digital environment of BIM software?" but instead "How do we preserve the cultural heritage embodied in this piece of architecture?", the project would shift focus conceptually and technologically. The "product" would not be an image capture but rather a platform facilitating multiple narratives.

If the goal is to design a facilitator of multiple readings and not a vehicle for a singular message, what are some of the appropriate modes of representation? A familiar and established approach to storytelling in an expository sense is textual, or syntactically organized and following linguistic rules. This narrative structure follows a linear trajectory and a singular agenda, as well as eliminates overlapping stories (Refsland 2007). Cultural heritage sites seen as "landscapes" demand multiplicity, and therefore a medium that can accommodate layering and subjectivity. Any "finished" product, whatever the medium may be, commits to a single or dominant story (Paraizo 2007). A preservation project that focuses on memorializing an "intact" artifact digitally mimics and replicates the limitations of traditional, analog media. Digitally recreating an image does not fully utilize the emerging scholarship tools or take advantage of the possibility of designing an environment.

The next question is what are some of the narrative strategies available that might be unconventional but required to think about new tools. Software for Geographic Information System (GIS), Virtual Reality (VR), and data visualization are exciting and potentially robust opportunities for any future projects. However, the answer to the question above is not a response in terms of a type of software, but rather a set of design parameters. Upon consideration

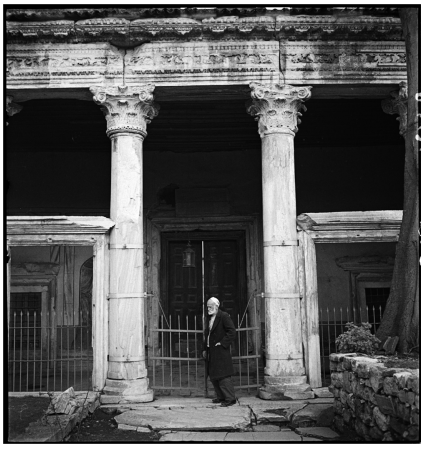

Figure 7. The narthex (Nicholas Artamonoff Collection 2011–2013).

of how to represent the history of the Monastery of Studius/Mosque of Imrahor with a conceptual agenda and technological framework in mind, several requirements emerge: layered organization, scalability, and multiplicity of access points. This paper argues that this set of attributes would ensure a solid foundation for how a robust yet flexible digital environment on cultural heritage might operate.

4 SPECIFIC EXAMPLES

The following examples implement experimental methodologies where the conventional modes of operation for any given medium are challenged. Specifically, they all exhibit layering, scalability, and multiplicity of access in ways that begin to suggest how these parameters might be incorporated in a spatial representation of architectural heritage.

The question of how medium-specific, therefore limited, renditions of the physical world might be challenged is not new. Étienne-Jules Marey and Georges Demeny, with their iconic work in the late 19th century, were exploring the still image as a medium to capture motion. In a series of studies with chronophotography, they were able to quantify the movement of the figure in space registered along a temporal sequence to produce a continuous sense of the body in action, form in flux (Fig. 8). The print medium embodies the dynamic body by visually layering each instance, such that two-dimensional work describes the three-dimensional object in time.

Another experiment in representation using a new set of layering techniques is the drawings of Bramante's Tempietto crafted by the architect Daniel Castor in late 1990s (Fig. 9). In this particular example of a strictly architectural study, Castor uses the drawing medium as a device to reveal what is physically hidden from view, superimposing the interior volume on the exterior envelope or interpolating a wireframe skeleton of the masonry structure, thereby establishing

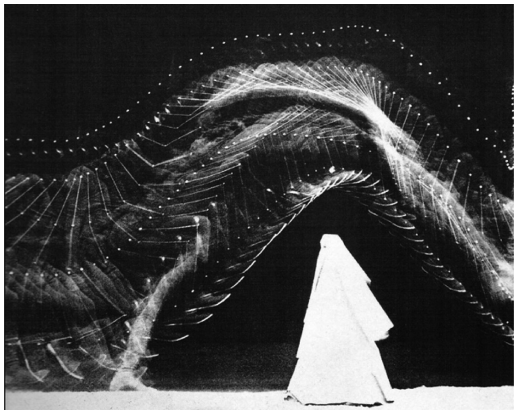

Figure 8. Title unknown (Demeny, Marey n.d.).

such a representational strategy that he s as "jellyfish" drawing. These layers of invention, interpolation, or inspection generate different readings in a way that challenges the common cognition of Tempietto specifically, or the objecthood of an architectural monument in general.

Another project that uses layering but on an urban scale through mapping is HyperCities, a collaborative initiative by UCLA, the University of Southern California in Los Angeles, City University of New York, and other community organizations (HyperCities 2016). A recent publication on this experimental platform defines HyperCities as what is and what is not: HyperCities is not a map or a finished piece of software, but a collection of laboratory projects testing the boundaries of mapping as a process of telling stories through geo-temporal structures (Presner 2014). Inhabitants of HyperCities are in a way virtual flâneurs, navigating through places and time as opposed to open and close windows or looking for a particular thing through a search field. As a collection, HyperCities projects typically implement the quantitative base layer of GIS or Google Earth but create knowledge by overlaying other types of stories across geography and through a temporal dimension, thereby effectively blending the notions of positivist and metaphorical mapping (Presner 2014). Characterized as "thick mapping," these projects allow for expansive wandering in a lateral sense, akin to the phenomena of "hyperlinking," as well as vertically in any one location, referred to as "drilling deep," harkening back to a geological act and reinforcing the depth of layers.

The HyperCities project also utilizes the notion of scalability in a spatial way, characterizing it in optical terms as "zoom." The user (or viewer or reader) "zooms in" to conduct close reading exercises and "zooms out" to see broader relationships and comparative patterns. When the ability to itinerate exists in an expansive environment, the change in scale of focus helps uncover different levels of information, to hone in, much like the way an architectural drawing will

Figure 9. "Jellyfish" drawing (Castor 1999).

convey a different level of detail on the same element at different scales.

Another project, conducted as part of an interdisciplinary course at UCLA, exhibits a similar take on using a variety of scales to narrate a variety of stories and casts the object scale along a vast temporal dimension. Andean Narratives starts with a very specific scope of study, a defined collection of ceramic pottery crafted in the South American region of Andes, ranging in date from approximately 100 to 800 C.E., and currently held in UCLA's Fowler Museum (Andean Narratives 2016). The student project zooms in to digitally and three-dimensionally scanned objects and zooms out to find complex patterns across geographical regions and historic time periods. The story of a singular vessel is available but also supported by the multiple other strands of knowledge an object may have relative to the other artifacts in the collection. In spatial terms, the design of the platform allows the researcher to have intimate proximity to the physical qualities of the vessel—its texture, color, form, and even weight. The design of the environment also allows for a critical distance that puts other kinds of information—cultural, social, and otherwise unknowable—in clear view. The analytical work conducted through data visualization encompasses geographic and historical space, allowing a researcher to filter data in multiple ways, thereby generating multiple access points. This is particularly significant when interactive platforms seek to engage scholars and community members with different agendas.

The final example is an experimental project that captures aspects of layering, scalability, and multiplicity of access by the application of virtual reality (VR) technology in a specific heritage site. David Finsterwalder of Realities demonstrates VR capabilities in the Ellwangen Excavation, where the user/visitor can inspect the entire urban-scale model, locate themselves within a specific point in the model, and experience the sensory qualities of the site (Ellwangen Excavation 2015). Where the visualization technology allows for unique opportunities for scholarship is the ability for the user to activate different kinds of information overlayed in the digital model and tagged onto specific elements.

5 CONCLUSION

Engagement with architectural heritage entails a variety of kinds of information and generates a multitude of stories. The archival work required for preservation efforts must aim to maintain a plurality of identities. In the social context, an authentic and sustainable sense of diversity can be achieved by a multi-layered culture of heritage. Therefore, the representation of heritage must facilitate access to large groups and encourage their engagement. This type of diversity will foster authentic ownership of the built environment, its history, and its community. If nuanced narratives can be preserved, or better yet "kept alive," history will resonate with individuals.

In addition to scholarly endeavors, cultural heritage will benefit from alliances on a personal level. Only if these connections are achieved, preservation will become an active undertaking, one that generates new scholarship and understanding of societies as opposed to a Sisyphean endeavor to save the past.

This paper argues that preservation of cultural heritage is not only an archival project but also a representational project. Further, the author proposes that any representation of this sort requires the design of a spatial-temporal construction, which can implement emerging tools of digital scholarship and new media. The author suggests specific parameters toward building a platform that would meet technical requirements and, more critically, a conceptual agenda of facilitating complex histories and fostering long-term stewardship of cultural heritage.

Towards an adaptive urbanism beyond hard control: The theories of Johnson and Lefebvre

N. Abbasabadi & M. Ashayeri Jahan Khanemloo
Illinois Institute of Technology, Chicago, USA

ABSTRACT: This paper examines the socio-spatial ideology towards an adaptive urbanism beyond hard control in works by Henri Lefebvre's, *The Right to the City* and Steven Johnson's *Emergence: The Connected Lives of Ants, Cities, and Software*. Both Lefebvre and Johnson understand urbanization as basically violent and dominated by uneven expansion of urban space. This process has been the dynamic force of transformation in society. They both strive to formulate a conception for a self-organized city free of hard control. Although their respective approaches differ in fundamental ways, they share several values. They both provide concrete critical tools, methods and clarifications for conceptualizing urban planning and politics.

1 INTRODUCTION

In *Emergence: The Connected Lives of Ants, Cities, and Software* (2001), Johnson imagines the city as a manifestation of emergence and offers characteristics of a city's bottom-up evolution. Emergence, in Johnson's conception, "has always been about giving up control, letting the system govern itself as much as possible, letting it learn from the footprints" (Johnson, 2001). This refers to a community being able to self-organize into a higher level system of awareness from bottom up, instead of being directed by an external controlling factor. Johnson goes on to argue that cities grow and operate as an adaptive self-organized system based on interactions with neighbors, pattern recognition and a form of swarm logic. For Johnson, the city is as a computationally self-processed urban configuration which is produced on the micro-level of social interactions, but which appears in phenomenological terms on the macro-level of urban form.

This theoretical approach is directly confirmed and translated into urban planning and design as parametric urbanism through the use of advanced technologies and digital tools. Planners and designers are attempting to generate, simulate and control organic patterns to surprising levels of complexity that can perform as the fundamental basis for understanding this process in the urban environment. However, the integration of demographic, cultural, and human factors into these systems has so far been neglected; and the gap between a simplified condition in the parametric design process and the actual complex urban context in the real world remains large.

In Johnson's theory, social interactions are a focal point, but he dismisses highly complex factors in the urban realm. His scientific approach is almost mathematical and biological. He continues where naturalists such as Charles Darwin and entomologists such as William Wheeler left off (Johnson, 2001). The problem with his approach is most apparent in the discussion of cities. Johnson sees them as the human equivalent of ant colonies: the economic and defensive imperatives that drive people into cities yield patchworks of neighborhoods and the development of functions that transcend those original needs. Under this kind of situation, Johnson's explanation of the organic society would have presumably missed a main part of its foundation in social reality.

Compared with Johnson, Lefebvre in *The Right to the City*, published in *La Droit à la Ville* in 1968, anchors his account of socio-spatial ideology towards city planning and design much more firmly in a story about the development of urban space associated with urban life. *The Right to the City* set out to satisfy the practical questions of social rights—not just the abstract "rights of man" and the citizen, but substantial rights relating to culture, liberty, and social groups, like labor and women, amongst others. He critiques approaches to the city that simplify and neglect the complexity of social, cultural and political dimensions in the real urban space. He understands the organicist approaches to city planning and design as "travesties of science" due to the unity of partial knowledge (Lefebvre, 1996). From this standpoint, scientism in Johnson's *Emergence*, accompanies the deliberate forms of operational rationalism and also tends to fail to care for the intricacy of human society. Lefebvre introduces a vision for a city in which users manage urban space for themselves, free of both the state and capitalist control. He defines a different kind of freedom from what rationalism and functionalism offer, based on the freedom of the Greek city. He conceives the transformation of traditional forms of political citizenship into the broader concept of urban

citizenship. He focuses attention on the role of the inhabitant or user of the city. Arguably, this is the experience of everyday life that authorizes one to a right to the city, rather than a user's nation-state citizenship. He strives to articulate a critical stance towards this process by providing indispensable critical tools for conceptualizing the urban space and its political possibilities.

In this paper we will not attempt to present comprehensive overviews of their conception of cities, nor do we intend to affirm one over the other. The focus is exploring the ways in which they cast their concrete critical tools, methods, and clarifications for conceptualizing the urban planning and design. Although they both have strengths and unique conception towards urban planning and design, their approaches can be critiqued in some aspects. In this sense, Johnson oversimplifies patterns of cities based on a limited analogy of living organisms, such as ants' colonies or networks of neurons, while Lefebvre's *Right to the City* is more radical in its class struggle and political position. This article seeks to connect and bridge the gaps between these two positions and outline their unique conceptions of urbanization, in order to present a more dynamic and holistic approach for dealing with today's urban complexity. Although both Johnson's theory and Lefebvre's ideology call for deep change, their ideas are eminently practical; they have critical responses to contemporary debates on the urban theory and practice to modify the current city towards a harmonious society and an adaptive urbanism beyond hard control.

2 EMERGENCE AND/OR PLANNED URBANISM

Are cities manifestations of emergence or planned processes? How do cities grow and organize over the years? The critical question is, what is the position taken in the present and possible near-future of design and planning in today's complex and uncertain era? What are the pitfalls of the parametric shift which has occurred in the practice of architecture and urban design process due to new technologies and infinite computing? In contrast to many approaches to contemporary architecture and urbanism, Johnson and Lefebvre offer critical theories and unique conceptions to address these issues and questions.

Johnson and Lefebvre both argue that cities are an outcome of emergent systems that refer to a self-organized phenomenon. Everything that is generally subsumed within the self-organized order is usually assumed to be a bottom-up phenomenon and a process by which the urban space is produced by aggregated individuals, not a central authority or external power enforcing precepts of urban design and planning.

Self-organized systems are those undergoing upward mobility through this process. Such systems will reach a critical point and jump into a new pattern of organization. In this sense, where planning is understood as synonymous with control, emergent order eventuates in the absence of control. This position leads to a conflict between notions of fully planned cities and uncontrollable phenomena of evolutionary urbanism. Now the critical question is: what comes of the absence of planning? It seems this is an oversimplification to assume that adaptive, evolutionary urbanism lacks all planning.

Figure 1. Yazd, Iran, 2016.
Source: https://www.google.com/maps/place/Yazd,+Iran/

Presumably pre-industrial and historical cities—such as organic growing cities in Iran, Pakistan, Egypt, among others—are understood almost as emergent systems. The architectural and morphological characters of these cities – before been modernized- align with the bottom-up and self-organized process. As an example, consider Yazd in Iran: a city in the middle of deserts where individual decisions were enabled to adapt to the harsh ecological condition and fit the natural and human landscape through long process of trial and error (Keirabadi, 1991). Such cities' organic growth is a result not of a lack of overall design but rather of smaller agents. Development of these cities is based on an organic process which is associated with the role of individuals, not a central authority. In this sense, the actions of individual and local decisions create the large-scale structure of complex order. The rules of emergence are holistically applied in all components and infrastructure of such a city. In this way, "one thing leads to another, and what began as the seizure of an accidental advantage may prompt a strong element in a design … it moves from need to need, from opportunity to opportunity, in a series of adaptations that themselves become interestingly coherent and purposeful" (Mumford, 1961).

"Natural or organic growth interwoven both in space and time" (Batty, Longley 1994). Through centuries, the city's spatial pattern has revealed the influence of nature, culture, and community. In this sense, a multidimensional approach has played a more comprehensive, unique and to some extent creative milieu on producing urban space.

We can now state that cities are as a self-organized system; raised, provoked, and sustained by humanity. This order is an independent phenomenon which manifests without full planning and design and is free from central power. As Johnson makes clear, the mechanism of organic city growth, organization, and operation

through an analytical comparison with the interaction of a 'super organism' of ants with the city where the neighborhoods of individuals solve their problems through local interactions collectively, which leads to global behavior. In the same way, local interactions and decisions of individuals on an organic city contribute to the creation of the 'complex order' of the city. Each ant acts on a system of low-level rules and feedback from its neighbors, which explains how "local information can lead to global wisdom" (Johnson, 2001). The feedback loop between neighbors is critical in city vitality. "Feedback is a way of transforming a complex system into a complex adaptive system" (Johnson, 2001). As Johnson discusses, each ant is not intelligent and only can do simple actions, although an ant colony shows a complex collective behavior. The underlying mechanism of this intelligence emerges from the social interactions among neighboring ants. Therefore, interconnected behaviors support the feedback loops. "All decentralized systems rely extensively on feedback, for both growth and self-regulation" (Johnson, 2001). However, this is a simplification of the image of complexity in the human world that ignores the complicated layers of human society in terms of cultural, social and political aspects.

The use of emergent and self-organized patterns in the urban design and planning as parametric urbanism has great potential to develop the systematic analysis and following arguments to alternatives for future cities. Parametric design as a technical procedure allows one to rapidly generate different design alternatives by simply changing the values of a particular parameter to facilitate decision-making during the creation process. We can now create, simulate and analyze self-organizing patterns to surprising levels of complexity that can perform as the fundamental basis of understanding the process in the urban environment through digital tools. Parametric practices are not similar to traditional digital design implementations regarding the capability of patterns to transform from one type to another through the design process, and to support generating and examining a large number of outcomes from a simplistic replacement of a particular parameter value. The parametric paradigm grants its resultant patterns the significant adaptability to modify and develop at any step of the design process, but ensuring the keeping of compatibility and orderly character.

Regardless of the high abilities allowed by parametric urbanism approaches and means for improving the urban quality and performance, the design is just responsive to formal, programmatic, and environmental parameters. Algorithms derived from nature or organic patterns are very popular in today's parametric urbanism. As organic cities in terms of the visual and statistical order "have led to the various biological analogies" (Batty, Longley 1994). In this case, the critical threat may be the imitation of living organisms on the basis of superficial similarities. So, the main challenges that are usually subsumed within self-organized manifestation through organic-derived patterns and algorithms in urbanism are ostensibly applications of superficial similarities, which only rhetorically reflect some qualities associated with the adaptive phenomena.

For example, works by designers such as Zaha Hadid and Patrick Schumacher in London and Istanbul can be seen as parametricism in urbanism, which fails because of the susceptibility to concession of only formal, functional and environmental aspects of design, while abandoning other essential parameters for the upswing of urban life. The complicated layers of culture and human values in these proposals have been dismissed, and the gap between a simplified model in the parametric design process and the complex urban realm remains considerable. In other words, critics such as Steven Johnson and designers such as Hadid and Schumacher claim their ideas surrounding city planning and design are connected with social interactions. However, they simplify their ideas based on reliance on formal characteristics of living organisms, not real complicated layers of the society.

On the other hand, planned cities were characteristic of the twentieth century. What is considered problematic urbanism by Johnson and Lefebvre in the modern era is an outcome of processes of industrialization. When modern planning parallels mass production, cities emerge as repeatable, predictable and controllable patterns and top-down plan processes. The urban is treated as "a fixed, unchanging entity—as a universal form, settlement type or bounded spatial unit ('the' city) that is being replicated across the globe" (Brenner and Schmid, 2015). This model opposes the fundamental concepts that used to apply in unplanned and pre-industrial cities, which in Lefebvre's term, are something unique and unpredictable; accessible through a process which is associated with creativity and art. Lefebvre imagines an ideal city as *oeuvre* (works of art and monuments) rather than *produit* (product), which arises from repeatable and serialized actions that is a manufacturing process. In this manner, the *oeuvre* can be considered as having use value and the *produit* is synonymous with exchange value. So, Lefebvre's image of an ideal city is characterized by the predominance of the *oeuvre* (*city-oeuvre*), until the use value of the city was eclipsed by the exchange value (Lefebvre, 1996). This formulation places the traditional city in extreme contrast to the rational and technologically driven regimes of modernist planning.

To a large extent, Lefebvre presents a radical criticism against modern urban planning and its vision of urban society. He criticizes the ideology of modern city planners. According to him, these planners' insight of the city is based on the idealized and rational model of the ancient city. "The agora, place and symbol of a democracy limited to its citizens, and excluding women, slaves and foreigners, remains for a particular philosophy of the city the symbol of urban society in general" (Lefebvre, 1996). So, Lefebvre criticizes this notion as a typically ideological extrapolation to which they add fragmentary understanding; "this purely ideological operation consisting in a passage (a leap),

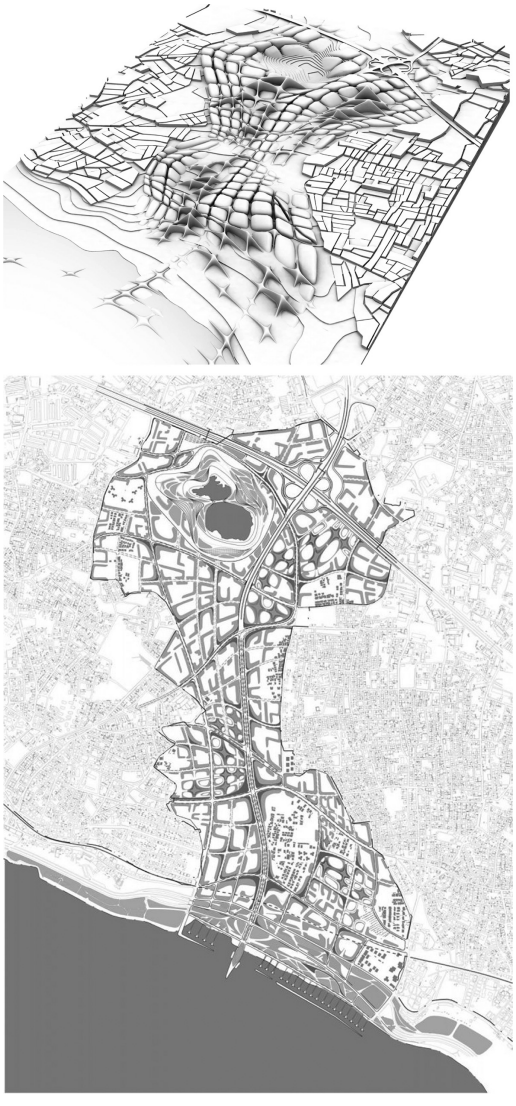

Figure 2. Parametric urbanism, Kartal Master plan proposal, Istanbul, Turkey, Zaha Hadid Architects, 2006.
Source: http://www.zaha-hadid.com/masterplans/kartal-pendik-masterplan/

from the partial to the whole, from the elementary to the total, from the relative to the absolute" (Lefebvre, 1996).

Lefebvre focuses attention on the role of the inhabitant or user of the city. Arguably, this is the experience of everyday life that authorizes one to a right to the city, rather than a user's nation-state citizenship. He offers the point that all city inhabitants should feel themselves to be a part of the emergent whole and have the freedom to make and transform their cities themselves. He believes that as this conversion heavily relies on the use of collective power, it is a common right of everyone (not an individual one) to be able to change through changing the urban space.

Lefebvre defines spatial ideology as a system of implications of the reality of space, owing to "political strategy" to execute what elite priorities – i.e. their aspiration and needs over the dominated classes. Lefebvre asserts "Urbanism as an ideology formulates all problems of society as questions of space and transposes all that comes from history and consciousness into spatial terms" (Lefebvre, 1996).

Both Johnson and Lefebvre's conceptions of city planning ideology are in close link with social interactions. In this sense, Johnson and Lefebvre evoke Jane Jacobs' ideas on urban planning in *The Death and Life of Great American Cities*. Jacobs explains "how cities work in real life, because this is the only way to learn what principles of planning and what principles in rebuilding can promote social and economic vitality in cities and what practices and principles will deaden these attributes" (Jacobs, 1992). They found a relationship between city ideology and space, which is understood as a social concept. However, their approaches are entirely different. Lefebvre's ideology in city planning is radical and in some cases problematic, such as Lefebvre's class bias in the vision of urban democracy. Johnson almost simplifies his ideology based on what Lefebvre understands as a 'travesties of science' - living organisms such as an ants' colony or networks of neurons or software.

3 REDEFING CONTROL AND URBAN NETWORKS

It is important to return to discussion of the other side of digitalized urbanism; as an inseparable part of today's urban approach that participates in the misinterpretation of control and freedom, and a certain mythology of the relationships that exist between networks, flow of information, and social equality. As Johnson pointed out, "Like any emergent system, a city is a pattern in time" (Johnson, 2001). We are living in the age of advanced information technology, network mapping, and infinite computing, which have significantly influenced our cities. In this sense, Johnson and Lefebvre argued, such massive technical systems interweave and infuse cities and daily urban life. In this way, the crossover between information communication technology and its applications in urban structure—between the surveillance and control of everyday life, rather than bottom-up order—could be considered as a focal point of a complex system that characterizes the new critical urbanism.

The techno-scientific approach mobilizes "the tools of natural science, mathematics and 'big data' analysis to analyze, and often to predict, inter- and intra-urban spatial arrangements" (Brenner and Schmid, 2015). The discourses surrounding electronic data collection systems, sensing and feedback systems, smart materials, intelligence, and interactivity and responsiveness all pertain to a "control society" in which information is "immediately fed back into the system" in real time (Shaviro, 2003). Existing extensive global networks

of sensors generates an abundance of electronic eyes and ears; furthermore, they potentially enable cities to be a stage of permanent surveillance by whoever has access to that information. In today's urbanity, citizens are always being watched and visible. This trend is inarguably pervasive, indeed almost ubiquitous. In the contemporary city almost all public or semi-public spaces such banks, offices, shopping malls, and streets are under surveillance and control.

Now, the question is: If a city is as Johnson defines is – a computationally self-processed configuration which can "generate emergent intelligence, a macro-behavior spawned by a million micro-motives, what higher level form is currently taking shape among the routers and fiber-optic lines of the internet?" (Johnson, 2001). Controlling the net is hard enough at present, but what if it starts getting ideas of its own? Will emergence or self-awareness arise unbidden in cyberspace? Johnson understands life on the internet, machine intelligence, and computer programs based on what evolves on their own and feedback loops in modern media networks that are intelligent, witty and tremendously thought-provoking. The networks idea derived from the cybernetic theories of the 1940s are as self-generating, self-organizing, and self-sustaining systems, which operate through several loops of feedback. Irrespective of the interactivity and dynamism of networks, they still create local solidity and retain internal homeostasis in situations or conditions that are not at equilibrium (Verebes, 2014).

We argue that we need to redefine our perception regarding control, to achieve more resiliency and flexibility. Networks now permeate the way we see the world; as densely distributed and intelligent. Our comprehension of network phenomena, like the self-governing nature of the rain forest, deepens our knowledge of the connectedness that exists in the broad industrial network, which libertarians insist upon as organic and natural. The networks could be seen as unbiased; they have the ability to deliver, control, publicize, connect, censor, and inform. They create new systems of collective organization. Through the advent of bottom-up organization, the stability and undeniable solidity of institutions could be equipped through the interaction among a host of agents, who have the ability to at least bring about transformation to institutions if they cannot displace them. In today's urbanity, in which everything is computerized, overly-connected, and mobile as a result of information networks, urban planning and design need to catch up to the interactivity and dynamism in networked, technologically effective, more supple and adaptable models of control.

4 CONCLUSION: THE POSSIBLE URBAN

What paradigms, if any, can be followed to generate, direct, and illustrate the present or near-term future of urbanism in today's complex and uncertain era? What position can be taken in design and planning—beyond raw imposition of control? The concept of adaptive urbanism beyond hard control proposed here addresses these questions through reading of key concepts in Johnson's theory and Lefebvre's ideology. In doing so, the proposal discussed their conceptual strengths, alignments, and divergences between their approaches, and their potential applicability in today's urban context. We try to hypothesize a hybrid approach that combines their concrete theories—albeit not in a deterministic way.

Both Lefebvre and Johnson conceptualize a self-organized city free of hard control. Although they share this theory, their respective approaches differ in fundamental ways. In this sense, Johnson more simplifies the process of urban organization. He compares human beings with living organisms and the software and computation world. He claims his ideas regarding city planning and design are connected with social interactions, yet he oversimplifies this attractively elegant theory by referring to characteristics of living organisms or information systems vis-a-vis their ability to respond to feedback and adapt to their environment, but with scant attention paid to the real, complicated layers of intersecting forces and feedback inhuman society. At the risk of overstating the obvious: cities are more advanced than ants' colonies and human behavior more advanced than ants.

Contemporary use of parametric technology in urban design and planning associated with the main challenge, which is subsumed within the organic-derived patterns and algorithms due to just partially underlying qualities such as flexibility and adaptability in generative systems. Parametric design methodology and computation has fundamental limitations and lacks cultural and social dimensions that contribute to the urban morphology. It fails because it is susceptible and adaptable more to formal, functional and environmental aspects. The key issues lie in no comprehensive approach of design, associated with urban life. It provides spatial and social solutions that have dismissed the labyrinth of human beings and human use of city. So, the gap between a simplified model in the parametric design process and the complex urban realm needs be filled through comprehensive understanding of urban life.

While Lefebvre's ideology is associated with urban life, a process underlying the role of citizen's in producing urban space beyond hard control—control of state and capitalism Cities can be mapped through the way people live them. A process of meeting the right to the city—the right to create urban space and liberty. He formulates the problem of the city as interpreting partial knowledge, and it application of this knowledge in technical or political context. Now the question is that how we can connect and bridge the gaps between these two positions, in order to present a more dynamic and holistic approach for dealing with today's urban complexity. We can call for better understanding of an emergent or self-organized process, a stepwise process of producing urban space that is adaptable and

responsive to feedback as citizens' rights are its focal point. The transformation we follow to affect moves us closer to an adaptive urbanism in uncertain and complex contexts, growing according to local rules and decisions which manifest in global order of a bottom-up system. In this, our approach tends to be scientific and biological with predominant emphasis on visual order—barring evocation of a broader and deeper perspective reflecting the daily life of the citizens. Their collective ideas can provide a more dynamic parallel to the social, political, and technological prospective in urbanism, compared to the relatively static and monolithic decision models advanced in previous eras.

Now, through the use of advanced technologies and digital tools, we can generate (rather than impose), simulate and loosely control self-organizing patterns to surprising levels of complexity that can perform as the fundamental part of understanding the process in the urban environment. With integration of demographic, cultural, and human factors into this computer-controlled model—which have so far been neglected—we can fill the gap. Parametric urbanism applied the present technologies. But the superficial similarities based on imitation of organic patterns in algorithms raises questions about parametric urbanism's abilities. Therefore, we must proceed with a certain degree of caution to avoid this issue. This theoretical approach in the contemporary urban design and practice should apply multidimensional character of emergence system in human scale.

While we argue that hard control of city planning, design, and operations cannot lead us toward solutions adaptable for the complexity and unpredictability of urban environments, realistically we cannot apply an entirely emergent process to urban design and planning. We ought not to assume that adaptive and flexible urbanism lacks all planning and relinquishes control over the city. Presumably this, too, would be an oversimplified and impractical approach.

Thus, rather than being constrained by the planned or controlled or emergence process of urban design, what needs to be theorized, tested, experimented upon, and applied is a heterodox approach of top-down and bottom-up processes that considers complexity and multi-dimensional levels in urban contexts. Therefore, we need a more dynamic *set of approaches* to deal with this complexity. We can now clearly state that use of emergence and self-organized processes in urban design and planning could close the gap between bottom-up processes, which have been applied in organic and vernacular architecture and urbanism, and the top-down design and planning structures which have been used in modern urbanism. We need to redefine our perception regarding control. Our cities require a degree of dynamism in design and planning, as well as flexible systems of control. In today's urbanity, in which everything is computerized, overly-connected, and mobile as a result of information networks, urban planning and design need to catch up to the interactivity and dynamism of networked, technologically efficient, more flexible and adaptable models of control.

Both Jonson and Lefebvre's imaginations toward tomorrow's urbanism may be seen as somewhat utopian, but we argue that this is precisely their strength. It seems what Johnson or Lefebvre is offering is not impractical; however, their ideologies call for deep change and in some cases have problems: Johnson with an overly scientific, mathematical, and biological approach, and Lefebvre with an ideologically committed vision. Both offer distinct potentials for resisting current urban issues and an opening to a conception of more harmonious social space and democratic urban politics – but not however, as an elegantly universal panacea. We argue that Lefebvre's *The Right to the City* and Jonson's *Emergence* are not the only possible solutions and not individually sufficient for defining adaptive urbanism and urban democracy alone.

IEP sites: Combining planning tools to address planning uncertainty

M. Bylemans, N. Vallet & M. Van Acker
Faculty of Design Science, University of Antwerp, Belgium

ABSTRACT: Dealing with uncertainty in planning is a much-discussed challenge. In academic research, different planning tools have been developed, to facilitate the planner's task of coping with uncertainty. Our paper reports on the use of an integrated planning method, in which we combine different planning tools to cope with the uncertainty of a self-elaborated spatial design. In particular, it concerns an explorative assignment on the design of a so-called 'Inclusive Economic Participation (IEP) site' for socially deprived citizens, located at the Colony of Wortel-Merksplas (i.e. Flanders, Belgium). In order to cope with different causes of uncertainty amongst which (I) uncontrollable social, political and/or economic changes in society, (II) contradictory statements within current spatial plans, studies and other policy documents, (III) a not well specified and unclear assignment, (IV) conflicting and ambiguous interests of stakeholders and (V) sudden and unexpected changes in opinions and attitudes of stakeholders, we have combined the planning tools of (i) knowledge gathering, (ii) partnership working, (iii) storytelling, (iv) visioning and (v) scenario-writing.

1 PROBLEM AND RESEARCH QUESTION

The planning field has been criticized over the years, because of its complexity, but also its inflexibility or ignoration of dealing with uncertainty (Rosenhead 1980; Meyers 2001). During the planning process, several decisions on the subsequent planning actions and outcome (i.e. a plan) must be made, in order to improve the future. However, it is often difficult to know the actual future in advance, let alone to predict the consequences of the proposed planning actions and outcome on an actual improvement of this unpredictable future (Meyers 2001; Klosterman 2013). As such, the planner's task of dealing with uncertainty is essential and important, but also difficult (Friend & Jessop 1969).

Discussing this difficulty has been the subject of many papers (Christensen 1985; Silva 2002; Balducci et al. 2011; Chakraborty et al. 2011; Myers 2011; Rasouli & Timmermans 2012; Abbott 2012; Klosterman 2013). Some of these papers focus on planning tools, as a strategy to control, reduce or constrain certain aspects of planning uncertainty (Chakraborty et al. 2011; Myers 2011; Abbott 2012; Klosterman 2013). However, these tools are rarely or never used in an integrated or combined manner. In this paper, we want to apply and evaluate such a combined approach, within a specific uncertain planning setting. In particular, we want to explore: How a well-considered combination of different planning tools can help planners to cope with uncertainty in a more comprehensive and flexible way (i.e. central research question)? By 'comprehensive', we mean coping with (nearly) all aspects of planning uncertainty, instead of only one or a few uncertainty aspect(s). By 'flexible', we mean responding in an adaptive and dynamic, instead of a rigid way. Planning uncertainties are present in the spatial design of a so-called 'Inclusive Economic Participation (IEP) site' for socially deprived citizens, located at the Colony of Wortel-Merksplas (i.e. Flanders, Belgium). In line with the planning literature, the following causes of planning uncertainty are present: (I) uncontrollable social, political and/or economic changes in society, (II) contradictory statements within current spatial plans, studies and other policy documents, (III) a not well specified and unclear assignment, (IV) conflicting and ambiguous interest of stakeholders and (V) sudden and unexpected changes in opinions and attitudes of stakeholders.

2 CONTEXT

2.1 *IEP site*

The concept of an 'Inclusive Economic Participation (IEP) site' is launched and elaborated by a multidisciplinary research team (Faculty of Design Science at the University of Antwerp, Belgium), consisting of researchers within the disciplines of both social sciences (i.e. (social) economy and management) and design sciences (i.e. architecture, urbanism and spatial planning). We define an 'IEP site' as a location that accommodates, and thus connects, public, (social) profit and/or private organizations that support and stimulate the economic participation of the growing amount of socially deprived citizens, both as a consumer of goods and/or services, and as a producer of labor (Termote 2006; Vranken 2010; Coene et al. 2011; Termote & Galand 2012; De Nys-Ketels, Vallet & Bylemans 2015). Such a joint or spatially concentrated

location seems to be necessary, as socially deprived citizens often lose their way in the substantial amount of already existing support initiatives. Given the more restrained mobility of socially deprived citizens (Lucas 2012), it is especially the spatial dispersion, and thus physical accessibility of these initiatives, that generates physical and mental barriers to actually benefit from these initiatives (Opdebeeck et al. 1998; Laenen 2001; Sannen 2002, 2003; Steenssens et al. 2007; De Corte & Kolijn 2012).

As the concept of an 'IEP site' is new and still 'under construction', it is not yet clear what the planning process and specific design features should look like. Presumably, these design features depend on the present and future challenges of a particular contextual setting: Who are the socially deprived citizens? Who are the partners involved? What are their inclusive economic participation ambitions? And what are the associated spatial and architectural needs and opportunities of the site?

2.2 *Colony of Wortel-Merksplas*

This paper reports on the results of a first explorative case-study research, realized within the particular contextual setting of the former vagabond Colonies of two Flemish municipalities: 'Wortel' and 'Merksplas'. Both Colonies are often seen as one colony, because of their geographical proximity.

The Colonies of 'Wortel' and 'Merksplas' are compartmental landscapes with a surface of respectively 552 and 480 ha. These colonies consist of an historical pattern of tree alleys and rectangular plots with meadows, wood- and farmlands. In addition, several original 19th century buildings (i.e. a chapel, a school, houses, industrial and farm buildings) and two newer 20th century buildings with the function of a prison, are present (De Borgher 1999).

The Colonies of 'Wortel' and 'Merksplas' were developed in 1822 and 1825, in response to the extreme poverty at that time in the Low Countries (i.e. Belgium, Luxembourg and the Netherlands). The benefits of their development were twofold. On the one hand, poor people (i.e. beggars, vagrants, orphans, disabled, etc.) were housed and provided with care, education and employment, in order to help them escape from poverty in a more structural way. On the other hand, poor people cultivated large amounts of farmland, which decreased the need of paid workers (De Borgher 1999).

After the abolition of the 'Law on Vagrancy' in 1993, both Colonies lost their initial function and a new destination had to be elaborated. Our concept of an 'Inclusive Economic Participation (IEP) site' is considered to be an interesting option, as it relates to the initial function of accommodating poor citizens. However, our 'IEP site' will have to coincide with other destinations, such as touristic activities for all types of citizens. As such, our 'IEP site' will not encompass the entire surface of these Colonies.

Because of its historical value and innovative concept of solving poverty, the Colony of Wortel-Merkspas, together with five Colonies located in the Netherlands, are trying to gain the recognition of 'UNESCO World Heritage' by 2018 (see also: http://whc.unesco.org/en/tentativelists/5841/).

2.3 *Planning and uncertainty*

Over the past 50 years, several scholars have made the link between 'planning' and 'uncertainty' (Friend & Jessop 1969; Marris 1987; Hoch 1994; Abbott 2005, 2009, 2012). Uncertainty in planning refers to a lack of knowledge about the future or a gap between what is known and what is unknown – but needs to be known – about the future, to make correct decisions, in order to change the future in a better way (Abbott 2005, 2009, 2012).

In related literature, several dimensions of uncertainty affecting planning are discussed. A distinction is made between 'environmental uncertainties' and 'process uncertainties' (Abbott 2005, 2009). While the former consists of uncertainties that relate to the planning environment or context, and can be experienced by everyone (Mack 1971), the latter consists of uncertainties that relate to the planning process, and can be experienced only by the people involved in this planning process (i.e. stakeholders and planners) (Friends & Jessop 1969). In our 'IEP site' case-study, both uncertainties are present.

When considering the specific nature of 'environmental uncertainties', it concerns the presence of (I) uncontrollable social, political and/or economic changes in society (Galbraith 1977; Bryson 1988; Marris 1996; Christensen 1999; Abbott 2005; Fitzsimmons 2006; Frame & Brown 2008; Innes & Booher 2010) and (II) contradictory statements within current spatial plans, studies and other policy documents (Fitzsimmons 2006). In line with the general Flemish 'trend', a social change in the group of socially deprived citizens can be noticed in the particular contextual setting of our 'IEP site' case-study. This group not only grows, but also becomes more diverse and thus is no longer limited to merely fringe groups in our society (Muffels et al. 1999). More often people are confronted with sudden far-reaching events, such as a resignation, bankruptcy, divorce or sudden health problems. As a result, even (highly) educated and wealthy citizens end up becoming socially vulnerable (Jans 2011; Spoor 2004). In our 'IEP site' case-study, contradictory statements within current spatial plans can be noticed in guidelines regarding the protected heritage. The conflicting opinions are present in whether or not architectural modifications can be made to its buildings. The master plan's basic standpoint is "not allowing architectural interventions unless these interventions are necessary, in order to restore the buildings in their original status". In contrast, the legal zoning plans or the so-called 'Provincial Spatial Implementation Plans' (i.e. 'PRUP's') allow architectural interventions whenever their added value and architectural quality can be proven.

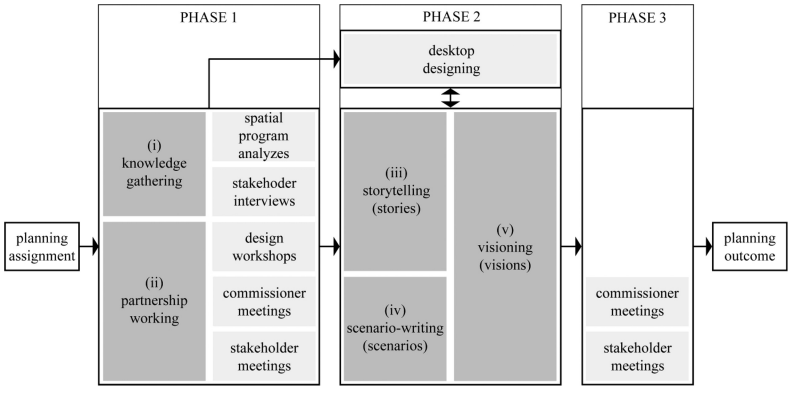

Figure 1. Planning process of our 'IEP site' case-study, showing multiple (iter)actions and planning tools, being used as a more comprehensive and flexible way to cope with the encountered uncertainties and to realize the planning outcome.

The specific nature of 'process uncertainties' can be found in three different aspects, noticed during our 'IEP site' case-study: (III) a not well specified and unclear assignment, (IV) conflicting and ambiguous interests of stakeholders and (V) sudden and unexpected changes in opinions and attitudes of stakeholders (Friends & Jessop 1969; Abbott 2005, 2009). An example of a not well specified and unclear assignment can be found in sudden and unexpected changes within the initial design instructions, given to the research team. Initially, a volume study was demanded on the position of new buildings, as a replacement of the demolished barns at the Colony of 'Merksplas'. However, when this volume study was finished and presented, it suddenly seemed no longer to be a policy priority, and it was removed from the initial design instructions. An example of conflicting and ambiguous interest of stakeholders, can be found in the impossibility to reach a consensus on certain planning and design instructions. The inclusion of (ex-)prisoners, as socially deprived citizens, is for instance heavily disputed by certain partners involved. Out of fear that (ex-)prisoners might scare off visitors and tourists, no consensus is reached during the first months of the already started design assignment. Eventually, a kind of consensus was reached as this particular target group was put 'on hold'. An example of sudden and unexpected changes in opinions and attitudes of stakeholders, is for instance the fact that certain partners involved, changed their minds about the redevelopment of the vacant attics at the Colony of 'Merksplas'. Initially, sleeping units for youth movements seemed a perfect fit. However, such accommodation seemed no longer desirable later on. Some partners involved suddenly were convinced that the capacity of these vacant attics was insufficient, to accommodate large groups of scouting and camping children.

3 PLANNING PROCESS: TOOLS

In the planning process of our 'IEP site' case-study, we used multiple (iter)actions and planning tools, as a more comprehensive and flexible way to cope with the encountered uncertainties and to realize the planning outcome (i.e. a strategic-spatial plan for an 'IEP site') (Fig. 1). A strategic-spatial plan consists of both strategic guidelines (for administrative and political policymakers of local governments, as well as managers of public, (social) profit and/or private organizations) and spatial guidelines (for architects, urbanists and spatial planners), as a way to facilitate the actual implementation of an 'IEP site'. As illustrated in Fig. 1, the (iter)actions are grouped into three main phases. The first consists of an initial set of data collection and analyzes actions, realized by means of spatial program analyses, stakeholder interviews, design workshops and both commissioner (i.e. 'Kempens Landschap'), and stakeholder meetings. In view of coping with the emergent uncertainties, we used two particular planning tools, being (i) 'knowledge gathering' and (ii) 'partnership working'. The second phase consists of a subsequent set of design actions, in which all data of the first phase is processed by means of 'desktop designing'. In view of coping with the emergent uncertainties, we used three particular planning tools, being (iii) 'storytelling', (iv) 'visioning' and (v) 'scenario-writing'. The third phase consists of feedback actions, realized by means of both commissioner and stakeholder meetings. In view of coping with the emergent uncertainties, we used the same planning tools as in the second phase. In the next paragraphs we will describe and illustrate the particular use of each previously mentioned planning tool.

3.1 *Knowledge gathering*

According to the literature, 'knowledge gathering' is a planning tool that focuses on collecting as much knowledge as possible, by the confrontation of various perspectives and types of data (Abbott 2012; Lau 2015). When used and applied in our 'IEP site' case-study, 'knowledge gathering' is realized in the first phase, when analyzing the spatial programs and interviewing the numerous stakeholders. The former reveals the societal, policy-related and spatial needs

or challenges of the Colony of Wortel-Merksplas, as well as numerous initiatives, to counter these needs or challenges. The latter reveals the motives of the numerous stakeholders interviews are held with, amongst which administrative and political policymakers of local governments, managers of public, (social) profit and/or private organizations, and professional experts on inclusive economics.

By combining the obtained information of both the spatial program analysis and the stakeholder interviews, we received a more complete set of detailed insights (i.e. knowledge) into the complex and dynamic future (i.e. uncertainties) of our 'IEP site' case-study.

3.2 *Partnership working*

According to the literature, 'partnership working' is a planning tool that focuses on letting partners with possible conflicting intentions communicate about proposed planning actions and their desired outcomes (Rosenhead 1980; Meyers 2001, 2011; Chakraborty et al. 2011; Abbott 2012). Within our 'IEP site' case-study, 'partnership working' is realized in the first phase, when organizing the design workshops and holding both commissioner and stakeholder meetings. The former consists of workshops with professional experts, within the disciplines of both social sciences (i.e. (social) economy and management) and design sciences (i.e. architecture, urbanism and spatial planning). The latter consists of two types of meetings. On the one hand, there are commissioner meetings with the organization 'Kempens Landschap'. On the other hand, there are stakeholder meetings with administrative and political policymakers of local governments, managers of public, (social) profit and/or private organizations and professional experts on inclusive economics.

By using design workshops and both types of meetings, we could clear out the complex and often ambiguous ambitions of all partners involved. As such, we could get a better or less uncertain grip on the joint 'preferred future'.

3.3 *Storytelling*

According to the literature, 'storytelling' is a persuasive planning tool that can be used by planners during the feedback phase, in order to inform the commissioner and stakeholders of the planner's way of thinking and to win them over to the planner's proposed planning actions (Throgmorton 1992; Myers & Kitsuse 1999; Meyers 2001; Klosterman 2013). Within our 'IEP site' case-study, we preferred the use of a 'visual' or 'graphical' storytelling technique, being that of 'organograms'. 'Organograms' are developed in the second phase, not only by processing the information and first ideas uncovered during the spatial program analyses respectively stakeholder interviews and design workshops, but also the continuous flow of creative and innovative ideas from the research team (i.e. planners), processed by means of 'desktop designing'. 'Organograms' represent the complex organizational structure of our 'IEP site' case-study, and each one uncovers a particular part or topic of this structure, as well as possible synergetic relationships between these different parts and topics.

To illustrate this, we give a particular 'organogram' on the topic 'tourism' (Fig. 2). During the planning process, a lot of preferred economic activity topics are taken into consideration. When evaluating the specific nature of these topics, there is clarity, agreement, and thus certainty, about only one, being that of 'tourism'. As such, the future redevelopment of our 'IEP site' case-study should be primarily focused on this type of economic activity. In contrast, there is no clarity nor agreement about other economic activity topics, such as 'care', 'education' and 'agriculture'. For some stakeholders it is not clear 'if' and 'how' these topics are compatible with 'tourism'. To overcome this uncertainty, all the possible synergetic relationships (dotted lines Fig. 2), between the different economic activity topics, are visualized in each 'organogram'. 'Children care' represents for instance an uncovered synergy between 'care' and 'tourism', and is suggested to be located in the existing children farm and/or suggested play barn. A second example concerns the suggestion of 'allotment gardens', indicating a synergy between 'agriculture' and 'tourism'. After all, the fruits and vegetables of these gardens can be used in the suggested restaurant, or sold in the suggested market hall, by means of both food packages and picnic baskets. A third and last example concerns 'educational projects', indicating synergies between 'education' and 'tourism'. This particular suggestion of the research team (i.e. planners) is a 'response' to the 'unwelcomed' target group of prisoners, as socially deprived citizens. By letting prisoners who work in the 'bicycle atelier' (i.e. at the prison of 'Wortel'), also repair bicycles from tourist, visitors and residents (i.e. at the 'IEP site'), prisoners can be involved as socially deprived citizens, without being physically present at the 'IEP site'. By letting prisoners who work in the 'furniture atelier' (i.e. at the prison of 'Merksplas'), also make furniture for this 'IEP site' (e.g. furniture for an 'exhibition space'), a similar result can be obtained.

By using 'organograms', we could not only show synergies between the different parts or economic activity topics, but also demonstrate where socially deprived citizens could be involved, either as a consumer of goods and/or services, or as a producer of labor. As such, 'organograms' are used to change and clear out the original opinions of stakeholders, who were not aware, familiar or convinced of certain planning options and outcomes (i.e. creative and innovative ideas of planners). Initial uncertainties thus become more certain.

3.4 *Visioning*

According to the literature, 'visioning' is a participatory planning tool that can be used by planners

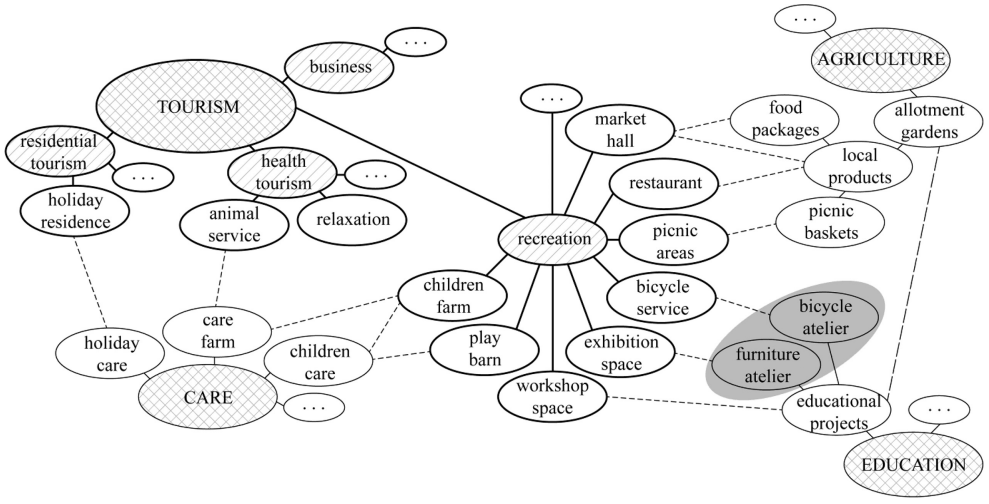

Figure 2. Organigram of 'tourism', showing possible synergetic relationships (dotted lines) with the other economic activity topics.

Figure 3. Present state of a particular location.

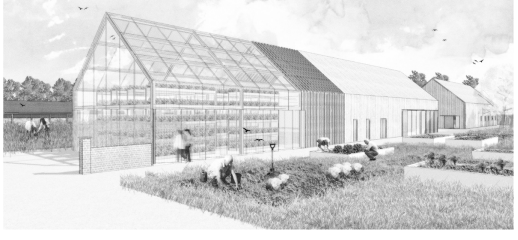

Figure 4. Desired future state or vision of the same location.

during the feedback phase, in order to let the commissioner and stakeholders develop (more) shared visions of a jointly desired future (Myers & Kitsuse 1999; Meyers 2001; Chakraborty et al. 2011; Abbott 2012; Klosterman 2013). 'Visions' are so-called 'simulations' of a jointly desired future, based on shared concerns and interests, regarding the development of a larger area or specific location in a city or town. 'Visions' are not a fantasy, but rather an image of what might be achieved within a city or town, given the available capacities and resources (Myers & Kitsuse 1999). As a technique to create 'visions', 'imaging' is used. 'Imaging' implies the capture, storage, manipulation and display of pictures or other visual representations (e.g. sketches, renders, 3D models, etc.) (Reinhard et al. 2010). Within our 'IEP site' case-study, 'visions' are developed in the second phase, based on not only shared concerns and interest uncovered during both commissioner and stakeholder meetings, but also the extra input of the research team (i.e. creative and innovative ideas of planners), processed by means of 'desktop designing'.

To illustrate this, we give two different images of one particular location at the Colony of 'Wortel', where presently some old barns are accommodated. In Fig. 3, the location is shown in its present state, while in Fig. 4, its desired future state is given, based on the identified shared concerns and interests of stakeholders. In order to find an appropriate reuse, the research team (i.e. planners) suggests to remove these barns and replace them by two new buildings (Fig. 4). The first will accommodate a greenery, grocery and workshop space, while the second a stable for therapy with horses for several groups of socially deprived citizens, amongst whom children and adults with autism. Additionally, allotment gardens can be installed in front of these buildings. The gardens can be used by everyone who is interested in gardening, but in particular by elderly people or people with a mental and/or physical disability (i.e. providing a meaningful day activity).

In short, by bringing the uncovered shared concerns and interests of the commissioner and numerous stakeholders together in a shared vision or single image, they recognize their own input, and clearly feel (more) connected with the cleared out and more 'certain' outcome of the planning process.

3.5 *Scenario-writing*

According to the literature, 'scenario-writing' is a sensitizing tool that can be used by planners during the feedback phase, in order to make the commissioner and stakeholders aware of alternative scenarios for

Figure 5. Museum-scenario for a particular building.

Figure 6. Wellness-scenario for the same building.

a possible future (Van der Heijden 1996; Myers & Kitsuse 1999; Chakraborty et al. 2011; Klosterman 2013). In contrast with 'visioning', 'scenario-writing' offers a much richer perspective, because of the exploration of all alternative options (Hopkins & Zapata 2007; Chakraborty et al. 2011; Klosterman 2013). Within our 'IEP site' case-study, 'scenarios' are developed in the second phase, based on all data collected during the first phase, and the extra input of the research team (i.e. creative and innovative ideas of planners), processed by means of 'desktop designing'. To do so, we have applied the approach of 'Research by Design' (De Somer & Van Der Veken 2012; Uyttenhove et al. 2012). This approach uses design methods from the disciplines of architecture, urbanism and spatial planning, in order to discover, depict and test different spatial possibilities. By doing so, the designing activity generates new knowledge, insights, practices and products (i.e. outcome). As such, 'Research by Design' does not primarily focus on the outcome or design result, but rather on the design process (Downton 2003; Schreurs & Martens 2005).

Within our 'IEP site' case-study, two alternative scenarios are elaborated for the reallocation of one particular building at the colony of 'Merksplas'. The scenario in Fig. 5, remains within the restrictions imposed by the commissioner, whereas the scenario in Fig. 6 is more open. The first represents a museum, for which the present building structure can be retained (Fig. 5). The second represents a wellness, for which the floor needs to be 'deepened', in order to install a new sunken water basin (Fig. 6). In addition, other architectural interventions are suggested. By lowering the windows and by removing a part of the floor together with a part of the roof, more natural light can be brought into the building. Because of the opening in the roof, right above the sunken water basin, this natural light reflects directly on the water. As a result, the effect of a Greek or Roman 'compluvium', or open space above a sunken water basin or 'impluvium', is obtained. Additional effects of these architectural interventions are the extra exposure of the beams and the provoked perception that the space seems bigger.

To summarize, alternative scenarios are used as an eye-opener for the commissioner and stakeholders, in order to make them aware of the added value that architectural interventions can generate. Uncertainties thus become once again more certain.

4 CONCLUSION

Fig. 7 indicates the possibility of coping with planning uncertainty in a more comprehensive and flexible way, when a well-considered combination of different planning tools is used (i.e. central research question). As shown in this figure, the combination of all five planning tools (right column Fig. 7) can address all five planning uncertainties encountered during our 'IEP site' case-study (left column Fig. 7). More certainty about both (I) uncontrollable social, political and/or economic changes in society, and (II) contradictory statements within current spatial plans, studies and other policy documents, is obtained by (i) 'knowledge gathering'. As a result, more information and detailed insights (i.e. knowledge) about these particular uncertainties is received. In addition, more certainty about the latter is also obtained by (v) 'scenario-writing'. All the contradictory statements are compared in alternative scenarios, in order to get more certainty about which one of these statements has the highest added value. More certainty about (III) a not well specified and unclear assignment, is obtained by (ii) 'partnership working'. By this tool, better arrangements about the assignment can be made. In addition, to avoid unexpected misunderstandings about the assignment, the products to be delivered are written out in a so-called 'assignment clause'. As a way to address the last two 'process uncertainties' of (IV) conflicting and ambiguous interests of stakeholders, and (V) sudden and unexpected changes in opinions and attitudes of stakeholders, four planning tools can be used. The first tool of (ii) 'partnership working' brings more certainty by clearing out the complex and often ambiguous ambitions of all partners involved. All the other tools of (iii) 'storytelling', (iv) 'visioning' and (v) 'scenario-writing', try to influence stakeholders during the feedback phase, and thus generate more certainty about certain planning actions (i.e. creative and innovative ideas of planners). 'Stories' are used as a way to change and clear out the original opinions of stakeholders who were not aware, familiar or convinced of certain planning options or outcomes, while 'visions' are used to let stakeholders feel (more) connected with certain planning options or outcomes. Finally, by presenting 'scenarios', stakeholders become (more) aware of all the possible planning options or outcomes, and thus get a better view on which one should be chosen.

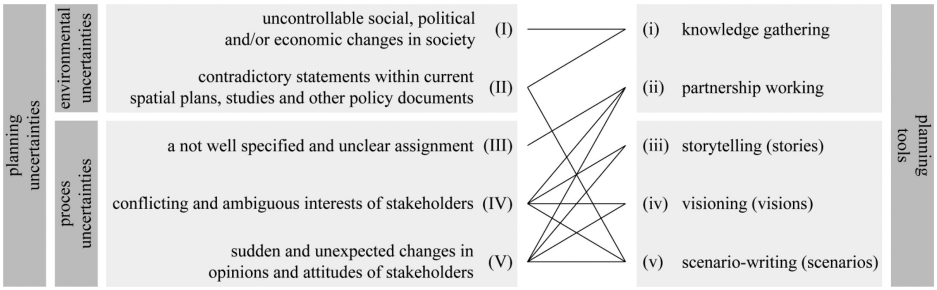

Figure 7. Well-considered combination of different planning tools, as a strategy to cope with uncovered planning uncertainties.

As such, and by combining all these different planning tools, the encountered planning uncertainty is dealt with in a more comprehensive way. A more flexible way of coping with planning uncertainty is realized by means of the creative and innovative ideas of the research team (i.e. planners), especially present in 'stories', 'visions' and 'scenarios'. These ideas are far more adaptive and dynamic, than the initial rigid ideas of most partners involved.

In view of new projects, we want to reuse the same planning tools from our first and explorative 'IEP site' case-study, as a way to address the possibly new encountered planning uncertainties. Due to a wider application of this 'toolbox', we can make more general statements about the effects of combining planning tools, but also which one is best and which one is missing in order to deal with (all aspects of) planning uncertainty. In addition, we want to examine the stakeholders involved, whether or not they experience the benefits of combining planning tools, in order to deal with planning uncertainty.

Social challenges meet architecture – from participation to digital fabrication

Susana Neves
ISCTE-IUL, Vitruvius FABLAB, Lisbon, Portugal

Alexandra Paio
ISCTE-IUL, Vitruvius FABLAB, ISTAR-IUL, Lisbon, Portugal

ABSTRACT: Society today faces new challenges and needs. Due to drastic climate changes, economic crises, war, or people looking for better knowledge or adventure, around the world the migration has substantially increased, either temporarily or definitive. This has a big reflection on the urban space. It is quite common to find in the same place coexistence between different cultures, as well as different age groups or social classes. How should the architect find a way to deal with these differences? How should the architect think and design urban space?

In this paper it will be explained how a team of architects respond to these questions. The action puts together multidisciplinary teams – architecture, design, digital fabrication, informatics, sociology and management – working with the experience of the final users to achieve solutions that contribute in a positive way to the daily life of an interior, exterior architecture or urban space.

Practical examples of these works will be given, focusing in three main groups: Workshops, Partnerships with local communities and Alternative Curricula in schools.

The paper aims to demonstrate the direct relationship between social challenges, users' participation and digital fabrication.

1 VITRUVIUS FABLAB – ISCTE IUL

1.1 *What we are and what we do*

In contemporary digital revolution, digital data can be transformed into material objects, namely by the further dissemination of digitally controlled production machines in FabLabs. For example 3D printers, laser cutters, CNC milling machines or robotic arms can produce objects on the basis of rapid prototyping, tooling and manufacturing (Walter-Herrmann & Büching, 2013). The Fabrication Laboratory (FAB LAB) was born at MIT's Center for Bits and Atoms (CBA) as a: (1) technical prototyping platform for innovation, providing stimulus for local entrepreneurship; and (2) platform for learning and innovation (Gershenfeld, 2007). FABLABs are open to who want to "move quickly from an idea or concept to a physical object or prototype, or (…) want to experiment with and enhance their practical knowledge of electronics, CAD/CAM, Design, 21st century DIY" (Eychenne, 2012).

In consequence, architecture is defined by computationally-based processes of form origination and attached with the fast development of machinery and computation tools. These interdependences constantly create new challenges and provide more tools that influence the creative process. Resources like Computer Aided Design (CAD), parametric design, bottom up design methodologies, Computer Aided Manufacturing (CAM) and Building Information Modeling (BIM) are evolving together with new logics of thinking, creating, producing and constructing.

It is in this context that Vitruvius FabLab – ISCTE-IUL (VFabLab) is born [Figure 1].

VFabLab is integrated in a university and it is also open to the public; it is a place where knowledge, fabrication and innovation is shared. The main goal is to explore new approaches to the architecture project, as well as to explore new ways to apply and transform materials in construction. We intend to develop automated techniques for producing architecture models, to explore modular systems for construction, and to make interventions in areas like product design, graphic computation and multimedia.

VFabLab develops projects from small scale to the real object, from draw through production and use. We are equipped with hand tools as well as CAD and CAM technology. The work connects industry, companies, individuals, schools and local communities. Companies can come to us to develop prototypes of objects or if they wish to research materials and techniques of construction and assembling. An individual person can make a rapid prototype of an object or develop an idea for a product or space.

Figure 1. VFABLAB, ISCTE-IUL. Workshops and Assembly areas. (Credits: Authors).

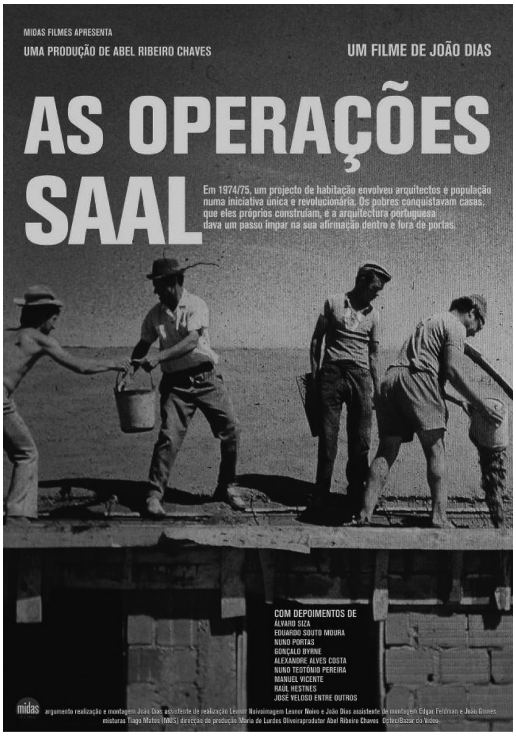

Figure 2. Documentary "As Operações SAAL". Directed by João Dias (Credits: Midas).

With the schools we connect the students with new technologies stimulating new skills either in education or cultural areas. The work with local communities goes through local association, gathering and developing ideas, creating meeting points with teams of different subjects with the aim of generating multidisciplinary projects.

Our course of action can be demonstrated in the practical examples given in this article that connects research, industry, education and society.

2 "SOCIAL CHALLENGES MEET ARCHITECTURE"

2.1 *Participatory architecture*

Participation in architecture comes from the 20th century 60's and the 70's it started by connecting new approaches in social housing (Jenkins & Leslie, 2010) (Jones, Petrescu & Till, 2005). In Portugal it had a big presence with SAAL (Serviço de Apoio Ambulatório Local/Local Ambulatory Support Service). [Figure 2]. In the 20th century 80's Giancarlo de Carlo (1980) believed, in the future, organization and form in architecture would come from the user, for him the project shouldn't have different parts as "defining a problem", "elaborating a solution" and "evaluating the results", for him a project was a "process" where participation implied the presence of users along every moments". There should be communication between architects and users, under standing the context and program of a design, achieving a proposal and the appropriation of the space should not be in different or independent parts of a project, they must connect and give information to each other, so the solution brings up something it will contribute for the user routine.

As Sanoff states (2007) "Participatory design is an attitude about a force for change in the creation and management of environments for people. (…) Citizen's working towards collective outcomes, has been described as visionary strategic planning, and deliberative democracy, all aimed at actions that shape and guide what a community is, what it does, and why it does it. Overall, studies in participation conducted during the past decade have referred to such bene?ts as citizen empowerment, increasing social capital and promoting a sense of community".

Today participatory architecture is a worldwide concept and it has no strict rules of approach, it has only guide lines that can be adapted to the context of every project (Jenkins & Forsyth, 2009) (Spinuzzi, 2005). The participatory design process can be presented in fields like: (1) redesign urban planning, bottom up methodologies; (2) implement alternative practices of city appropriation, group actions in the living context; (3) develop interactive interventions in public space, like associative proposals of urban farming; (4) increase social projects in emergency contexts; (5) apply strategies in informal architecture based on open source connections. Basically "from programmatic challenges to the life in the city, to the group proposals of urban and social encouragement, or reactivating repressed urban spaces, participation can endorse new and different ways of living the contemporary city" (Baptista, 2011).

According to Alejandro Aravena, winner of 2016 pritzker, "participatory design is not a hippie, romantic, let's-all-dream-together-about-the-future-of-the-city kind of thing. It is actually not even, with the families, trying to find the right answer. It is mainly trying to identify with precision what is the right question." In the redesign of the city of Constitución, in Chile 2010, after an 8.8° earthquake and tsunami had

devastated almost all city, Elemental studio used a participatory processes to understand the context of the situation and start asking people "what kind of city do you want? (…) express your opinions, participate!", they realized that more than preventing a next tsunami, they had to rethink the river front providing solutions for every year flooding as well as better public spaces, increasing a better connection with the river, which was the foundation of the city and get lost with private ownership of the river front (TEDGlobal, 2014).

Participation along the process of design can bring information that was not expected in the beginning, information that without it the intervention can be a failure.

3 "FROM PARTICIPATION TO DIGITAL FABRICATION"

3.1 *Participation in the digital fabrication process*

We are living in an era of globalization: drastic climate changes, economic crises, war, people migrating either temporarily or definitive; these are not only problems of a country, it has reflections in the whole world. The way we think cities and how communities react need to respond to those events and that brought us many questions on how should the architect work. Together with these challenges, architects also have to keep up with the constantly evolving technology. It is time to rethink the profession. Pedro Clarke (2014) supports that "there is a lot of work that needs to be done, it may not be the most glamorous job, but it is a work where architecture can once again show that it's relevant to society".

Parametric or CAD/CAM tools in the design process, allows the architect to change and adapt the project to the context of the intervention in real time and involving participatory design along the process. The computationally-based processes are the opportunity for the architect to be more close to the user needs.

This new communicating process gives easy access to the potential of digital tools either in drawing or in construction. It can be an approach that gives fast results in a context of fewer resources, it can complement the participatory design, by personalizing the action, adapting to specific cases it can generate an increasing flexible way to intervene (Ramalhete & Silva, 2014).

4 PRACTICAL EXAMPLES

All the projects here presented are supported by participative processes along the project and digital fabrication of a solution as a respond to local specific needs.

The interventions do not start on standards or pre-established concepts. The processes start in the experiences and uses of the public space. After we understand the routine of spaces we look for the needs of the users with them and only then we analyze how to intervene in the space. By the end of the project the intervention does not need to be presented and explained to the users, they had contribute along the process, so they know that what was built will respond to their needs and normal day routine.

Figure 3. INSITU 2013. Community table (Credits: Like Architects).

4.1 *Workshops*

4.1.1 *INSITU*

INSITU is a laboratory of intervention in architecture. It is now in 2016 happening de fifth edition, but we will focus on the second in 2013 [Figure 3] and third in 2014 [Figure 4] that happened at Bairro do 2° Torrão da Trafaria, in Almada, Portugal. This workshop is a partnership between Centro de Estudos de Arquitetura, Cidade e Território da Universidade Autónoma de Lisboa (CEACT/UAL) and Vitruvius FabLab (ISCTE-IUL), with the support of the local entities Câmara Municipal de Almada (CMA) and Junta de Freguesia da Caparica, and Madeivouga as sponsorship.

This workshop involves university architecture students (UAL + ISCTE-IUL), architects, public entities and the local communities that live in neighborhoods of informal construction. In the workshop, each intervention aims to respond to specific problems in a specific context and reality of that space. Participation of local community has a really important role, with decisions that are taken and made, from conception, through construction, promoting and maintaining the spaces (Ramalhete & Silva, 2014).

As a first part of the workshop, for a faster and more eficient aproach, in the second edition there was a previous work to understand the main problems of the neighborhood, in the third edition, architects get already involved in this part of the project. In the second part – the physical intervention – students and population get together with architects and organizing team to work on the solutions. The process encompassed three steps: (1) research, to understand the local problems and study the real secnario; (2) drawing, defining the specific intervention program; and

Figure 4. INSITU 2014. Shed (Credits: Bárbara Varela).

Figure 5. Community table from INSITU 2013 under the Shed from INSITU 2014. Intervention done by the users (Credits: Autors).

(3) fabricating, assembeling and built on site with the local community (Ramalhete & Silva, 2014).

With the people from next example (Pendão) there was a visit to Bairro do 2° Torrão da Trafaria, to show them what we do and what kind of approach we could do to their community as well, this visit also allowed us to understand what was the stage of the workhop intervention's a year after. It was surprising to see how some had almost desapired but with others, it was clear how well the interventions were received by the population and how they interacted with the proposals of both workshop editions, adapting it to their needs and maintaining it through weather and time. [Figure 5].

4.2 *Partnerships with local communities*

4.2.1 *Pendão*

The main project at Pendão, Sintra, Portugal, came from a CLDS (Contrato Local de Desenvolvimento Social/Social Development of Local Agreement) that identifies with local entities territories that need to be intervened. The CLDS team invited Aga Khan Foundation to manage the project in Pendão. This foundation works to "improve the welfare and prospects of people

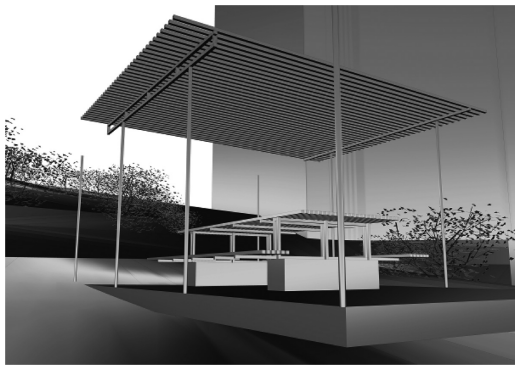

Figure 6. 3D Model of the community shed. Project "New Image" ("Nova Imagem") Pendão. (Credits: Vfablab).

in the developing world, without regard to faith, origin or gender. (…) Its projects encompass many of the determinants of the quality of life, including the natural and built environments in both urban and rural areas, food security, health, education, access to financial services and economic opportunity, as well as the cultural areas of traditional music, architecture and art" (Foundation A. K., s.d.).

Aga Khan Foundation created a urban reabilitation project, a PIC (Projectos de Inovação Comunitária/ Community Innovation Projects) called "Muda as ruas do pendão" in english "Change the streets of Pendão", with the aim of using the locals to participate and improve the social, economic, cultural and environmental state of their own neighborhood. The people from Pendão, as individuals or groups applied 17 projects for the area, partners like local entities (Câmara Municiapl de Sintra, Associação Mirante de Queluz, União de Juntas de Freguesia Queluz-Belas), Olho Vivo organization, Young HeArt project and Vfablab team are now working to complete those projects.

VFabLab role is to follow up the projects, discuss the different stages of the projects: through cultural and participatory activities, workshops and meetings with partners. To make possibly the users' ideas it was adopted a bottom-up methodology, so the population will not abandon the project, and with the available resources, create interventions that reflect the relationship between people (existed and created along the project) and the identity of the neighborhood [Figure 6 and 7].

4.2.2 *EB1 + JI Alfornelos*

This project was requested by a parent that knew what we have been doing and asked us to work with the school of his sun to make a better playground.

It is an ongoing project, located in Alfornelos Elementary School (Escola Básica 1° ciclo + Jardim de Infância), Amadora, Portugal.

We start by introducing VFabLab team and the projects that we do with the students. The team developed a workshop that explains architecture to children from 6 to 10 years old called Pequenos & Atelier

Figure 7. Stencil for the message "Este muro vai mudar!!" made in card board with CNC milling machine at VFABLAB. Project "For the sun to be able to shine in Rua do Sol" ("Para que o Sol brilhe na Rua do Sol"). (Credits: Bárbara Varela).

(ISCTE-IUL, Vitruvius FabLab, 2012). The students learned about architecture, geometry and a bit of why we were there. The next moment we start to work with all the groups of people that use the school: students, assistants, teachers and parents. In this moment we used a tool kit to understand with the users how was the school in the present and how it could be in the future (Sanders & Stappers, 2012). After analyzing which were the main concerns of the school it was possible to define the goals of the intervention: (1) painted games on the floor; (2) tables and places to seat; (3) a covered area for kids to play outside and to protect the parents when they are waiting in the beginning and end of the day for the children. In the next phase we put together the same groups and ask them to draw or make what they would like to have in the school. We understood that the common points were starting to get obvious and that is when the draw of the solution started, introducing digital fabrication in the outcome solutions by exploring short resources and fast production, always responding to the user's everyday needs [Figure 8].

4.3 *Alternative learning curricula in schools*

4.3.1 *EB2 + 3 Alcabideche*

In this project VFabLab team worked with students in a special level school program called vocational. It is still ongoing and it is an intervention in the

Figure 8. 3D Model of the project to EB1+JI Alfornelos exterior playground intervention. (Credits: Vfablab).

outside playground space at Alcabideche Elementary School (Escola Básica 2 + 3 de Alcabideche), Cascais, Portugal.

This project is a partnership between the project "Young HeArt" (Guterres, 2015–2016) (promoted by Aga Khan Foundation Portugal and financed by Calouste Gulbenkian Foundation).

The project supports classes from 7th to 9th grade and aims to associate the traditional way to work with wood to the digital fabrication processes having a real project as scenario. In the first moment, with the students, VFabLab team organized a visit for mapping the exterior playground context. This showed us how they live the spaces, what they enjoyed and what should change and why. The next phase inside the classroom students used areal views and plans of the school to put words and symbols of what is was for them the "School of the present" and the "School of the future". Then we start a process of shared knowledge between the traditional and the digital ways of working wood. The students explored hand drawing, CNC milling wood techniques to understanding the limits and advantages of traditional and digital fabrication, and when to use each process or when to mix them to accomplish the best solution. The next moment we look for the design that would better suit the space: a community table with some table games under a shed that could be used either in summer or in winter. Some tests were made in VFabLab and in the school classroom with the students to improve the solutions. The project is ready to be assembled in the school [Figure 9 and 10].

Figure 10. Students giving suggestions to the shed's project. EB2 + 3 Alcabideche exterior playground intervention. (Credits: Authors).

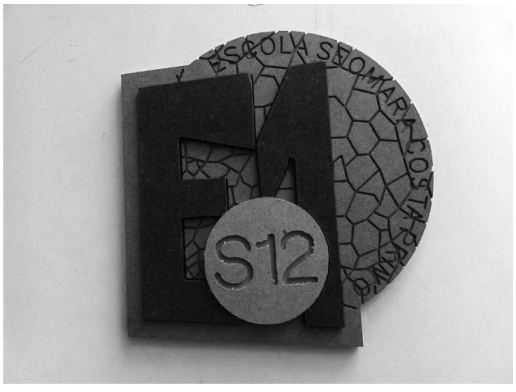

Figure 11. Classroom sign at Seomara da Costa Primo. (Credits: Susana Neves).

4.3.2 *Secundária Seomara da Costa Primo*

In this project VFabLab team was invited by the responsible entity of the vocational school program EPIS – Empresários Pela Inclusão Social (Entrepreneurs for Social Inclusion) at Seomara da Costa Primo Highschool, Amadora, Portugal (Social, 2006). This is a concluded project that happened with one class.

The students were attending CAD learning classes, knowing the basic notions of 2D drawing. The challenge was to use that knowledge and built an object to the common areas of the school building. The school had been recently rebuilt but due to lack of funding there were still many places that were empty and did not offer anything students could interact and relate with. The design process started by mapping the spaces with the students.

There were two intentions that immediately stand out: (1) classrooms had no sings identifying them; and (2) in one of the main common areas was missing a place to seat in group. The drawing process was fast and almost immediately because of the students' knowledge, we just explain what would be the limitations of digital fabrication and their creativity took control. We enhanced the proposals at the same time tests were been made and the next phase was just assembling the proposals on site [Figure 11 and 12].

5 [EXPECTED] CONCLUSIONS

From the practical experiences explored here it is possible to conclude that architects can respond to different social challenges by thinking and designing with the user along the process.

With the Workshops we have learned that architecture can have an effect in different ways. That giving this kind of opportunities to the architecture students and putting them out of their comfort zone – the classroom –, working with architects and the users, make them lose the fear of working in this kind of informal architecture and allow them to use digital fabrication as a way to respond to the users' needs fast and with less resources. These kind of Workshops also indorse new ways of practicing and teaching architecture.

Being in a project of an urban design, a partnership with local communities, made possible to achieve faster a physical objet, through the way how customized and personalized digital fabrication is, especially when using parametric design as tool along the process of design.

The work done in schools allowed us to better connect with young people and show them what we do and how we work. Thus, gives the opportunity to the students to qualify and connect them with new career

possibilities based on social and technological inclusion. For us these experiences are excellent tests of a new architecture process of thinking and making. We hope that the design process implemented at the schools can, in the future, be applied in an urban scale.

Using participation allied with digital fabrication design allows personalized design solutions, and makes possible to produce the physical intervention faster and with less resources.

In conclusion, by improving the design process through CAD/CAM tools and participation inputs on site, we can not only achieve better solutions but also create and increase "data bases" and "know how" that can be reused, adapted and updated in other projects.

ACKNOWLEDGMENTS

The authors would like to thank all the members of Vitruvius Fablab, ISCTE-IUL in particular Bárbara Varela. All the projects would not have been possible without the ideas, generous help and effort of the all participants. We are also grateful for the support of Filipa Ramalhete & Pedro Campos Costa (CEACT/UAL), António Brito Guterres (K'Cidade, Fundação Aga Khan), Prof. Alice and Gonçalo Pernas (EB1+JI Alfornelos) and Rita Vaz Pinto (EPIS).

Lifelong learning in the context of socialization and sustainable development

H. Melkonyan
Gyumri State Pedagogical Institute, Gyumri, Armenia

O. Turchanina & A. Castelbranco
Faculty of Architecture, University of Lisbon, Portugal

ABSTRACT: Social transition, fast changes and developments are causing serious challenges for individuals, social groups and organizations with socialization and sustainable development. It is possible to adapt effectively to these changes and challenges through the ability to change, by bettering and developing skills, which are typical to flexible, conformist type of behavior.

The aim of this study is to present the important role of learning/education, in particular, lifelong learning (LLL) and its features, which contributes to ensuring personal and institutional competitiveness, longevity and sustainable development.

1 INTRODUCTION

Modern societies are characterized by quick and often unpredictable changes. They cover all areas of social life: economy, politics, education, science, social relationships and so on. In particular, in the higher education system fundamental changes and reforms were carried out based on the Bologna Declaration, which was signed in 1999, and singled the beginning of Bologna Process. The reforms spread over the borders of the European Union to include 48 countries and these processes continue until today. The reforms relate to all the areas of the activities of the Higher Education Institutions (HEIs), such as management, study programs and curriculums, organizing and implementing the learning process, etc. The primary purpose of all this, as we know, is the creating of a system, which provides attractive and competitive educational services, as well as integration into the European Higher Education Area. "The decade that we have now embarked upon presents enormous challenges for Europe. The Europe 2020 strategy for smart, sustainable and inclusive growth rightly recognizes the key role education and higher education must play if our ambitions for Europe in a fast-changing global reality are to be realized" (Vassiliou 2011).

In order to adapt to these developments and changes, without suffering from important losses and disruptions, individuals, social groups and institutions are compelled to realize permanent research and tests. But their results are not always satisfactory, to urgently realize this objective, to solve it in substantial and long-lasting way. So, as one of the most important pre-requisite for ensuring the individual, institutional sustainability and competitiveness considered their inlaying resources and skills for adapting to a rapidly changing external environment, as well as their revelation and systematic management. Thus, it turns out that the challenges that arise because of change, can be resisted by having the ability to change. However, this process should come about in a smooth, non traumatic fashion: i.e., not as a revolution, but as an evolution. This will be more effective if done methodically, in a clear general direction and with certain principles. The effective implementation of this process can result in the development of flexible or conformist type of behavior. This means that "… the person accepts social values and goals, as well as the legitimate means to achieve them" (Khachatryan, A., et al. 2002). In this case, at first glance, it might seem that we are dealing with a passive behavior. Moreover, the name "conformists", sometimes considered as a not-so-positive, submissive type of behavior, without personal goals and actions. Actually, conformism is quite active, self-determined and, we believe, is a necessary quality, especially in the modern socio-economic, political, as well as educational and cultural context. This is the reason, that repeatedly use the words "to adapt", "conformists", but don't use the seemingly synonymous words "submissive", "passive". Because from the point of view of issue under discussion, they aren't synonymous, but sometimes even have contradictory meanings.

We should also pay attention to another important issue, that is the determination of the effective measures, tools for creation and development of

adaptable/conformists behavior. At first, we will talk about learning/studying, in broad sense of this word. In this case the process gets more systematic, regular, predictable and manageable, therefore, more acceptable to conformists.

Experts, who are dealing with the issues of development and longevity of organizations, mentioned that "… the degree of adaptation to the external environment and its possible changes due to ability of learning" (Kazhoyan 2004). Which is, in a way, also analogous to Darwin's theory of evolution.

In addition, the following features are noteworthy:

a) high degree of staff's cohesion and accurate perception of the organization's culture, which directly affect the process by which the employees are creating and shaping own values,
b) the respect and tolerance to the new/or opposing ideas and activities, which provides an objective assessment/self-assessment of the overall condition of organization/individuals and openness to learning.

All these features are more or less related to learning/education, in the broad sense of the word. Learning/study is more, than achievement of additional professional knowledge, but rather the acquisition of new knowledge in a different sphere of life, as well as the development of skills and capacity building, which can be applied in the given situation.

People not only learn in the classroom or auditorium, but they are learning in real-life conditions as well. Anyway, all organizations learn to adapt to the external environmental changes. Learning is an important component of the organizational culture (Kazhoyan 2004).

For society, especially during the period of social changes, there is two types of learning, which is distinguished by Chris Argyris (https://hbr.org/1977/09/double-loop-learning-in-organizations). According to him, learning involves the detection and correction of mistakes, which takes place when something wrong happens, and the results and the objectives of the action do not corresponded. He separates two types of learning: single-loop and double-loop.

a) Single-loop learning takes place, when the detection and correction of mistake does not require changes in the values of individual, group or organization.
b) Double-loop learning takes place, when error detection and correction requires changes in the values, objectives and strategies of the individual and the organization (https://hbr.org/1977/09/double-loop-learning-in-organizations).

As an example, we can mention that if we want to shape and develop typical traits for adaptive, conformist type of behavior, it is more effective, if we apply double-loop learning. That is, at the first stage of learning, we must make some changes in our perceptions and re-evaluate our values. As we have noted already, this type of behavior is sometimes associated with not-so-positive, so-called submissive qualities. Accordingly, in this case does not arise the desire to develop unacceptable and negative qualities and abilities. So, if we consider that during the first loop adaptation and conformism give possibility for competitiveness and sustainability, then it is possible on the second loop of learning to teach how to develop the relevant skills and competences.

Chris Argyris indicates that the double-loop learning is necessary, when individuals and organizations are going to make good decisions in the rapidly changing and, often, in uncertain context. By such approach, the learning (study, training) actually becomes as a tool for the formation and development of skills for knowledge and human resource management. And as a result, it promotes the revision of cultural values, norms and perceptions, as well as to the creation and adoption of new values and strategies.

During social changes, learning organizations receive important role and mission. Peter Senge considers that such organization:

a) encourages the vertical and horizontal learning inside and outside of the organization,
b) constantly encourages the exchange of information among its employees.

In this context, the concept of lifelong learning gets special role and meaning. If the changes are continuous, their adaptation and integration process becomes continues. Naturally, the learning process accompanies individuals and organizations during their entire lifetime. In this regard, HEIs should pay particular attention to the creation and development of opportunities for implementing lifelong learning, considering it a part of their social responsibility and as one of the important educational services provided to the society. Due to above mentioned reasons, it is important to use those learning methods and technologies to promote educational accessibility, democracy and quality assurance. In particular, features of open learning, as a new educational concept and philosophy, is implemented through the modern methods of e-learning and distance learning (Diagram 1). Since these methods and technologies, which are called Learning Management Systems (LMS), not serve only the purpose of providing information, but rather the creation and distribution of knowledge and new ideas, they promote individual activities by students and increase their involvement in the learning process. These systems enable the formation of participatory communication, creating a partnership between teachers and learners. And these are, as we know, one of the primary requirements of Bologna Process and the pre-requisite for improving the learning process.

Perhaps, mainly due to this fact, in Prague in 2001 lifelong learning was defined as a separate action line in Bologna Process. Thus it becomes possible to ensure the implementation of the main purpose of the Lisbon Recognition Convention. That is, to recognize the qualification given in any European country in other countries as well, excluding any

discrimination against the holder of the qualification (http://www.ond.vlaanderen.be/hogeronderwijs/bologna/documents/Lisbon_Recognition_Convention.htm). Due to this, the LLL actually has an impact on all the aspects of European higher education: academic mobility and exchange, mutual recognition of qualifications, distance learning, etc.

In 2001 the idea of European Lifelong Learning Area was formed, which aims to promote European cooperation in this sphere. In particular, the following aspects are highlighted for the LLL development:

a) recognition of prior learning outcomes,
b) development of flexible learning paths and the National Qualifications Frameworks, which will include LLL programs as well,
c) LLL and its connection to the social dimension of higher education (www.ond.vlaanderen.be/hogeronderwijs/bologna/news/EQF_EN.pdf.)

In 2007, the European Parliament adopted the "Recommendation of the European Qualifications Framework for LLL (EQF)", which includes general, vocational and adult education and training programs, as well as all of the higher educational qualifications.

In 2008, European University Association in collaboration with many beneficiary organizations from European Higher Education Area, developed the "European Universities' Charter on Lifelong Learning" as a tool for implementation and development of the special role and participation universities in the process of the creation of Europe of Knowledge. This Charter particularly says: "Universities now need … to enhance the development of a creative lifelong learning environment that is open to a more diverse population of learners, and thus respond to societal needs for the modernization of higher education. Fully integrating lifelong learning to the mission of universities is essential to enhance the creativity and innovation profiles of institutions" (www.eua.be). This will enable the universities to become: "… remarkably resilient and adaptable institutions, continually developing their role as society evolves" (www.eua.be). As a result, the universities will take over a new role, serving as a model for society, simultaneously increasing the knowledge and skills of their own employees through lifelong learning.

2 ANALYSIS: LEARNING AS THE TOOL OF ENSURING THE INDIVIDUAL/INSTITUTIONAL SOCIALIZATION

Due to the fact, that the Republic of Armenia signed the Bologna Declaration in 2005 in Bergen and joined the Bologna Process, the higher educational reforms have been systematically realized since this period. Now, all Armenian universities carry out activities to create modern educational services based on the principles and requirements of the Bologna Process. One such HEI is the Gyumri State Pedagogical Institute (GSPI) which primarily serves the educational needs and demands of population in one of the northern district of Armenia-Shirak region and Gyumri town.

GSPI was founded in 1934 and throughout its history has had both success and difficulties. In particular, during the years following the devastating earthquake in 1988, GSPI faced serious challenges, when the socio-economic and political changes were being carried out throughout Armenia. Within this period the Soviet Union had collapsed (1991), and as a result, Armenia faced partial economic blockade. As a result, the demands of the labor market completely changed the requirements of the higher education.

Sometime later, since 2005, deep reforms were initiated in higher education system, as Armenia joined the Bologna Process.

And now, when we look back, and try to assess and evaluate the journey which GSPI has accomplished, we can see that actually it was able to withstand and overcome these difficulties and tried to integrate to the modern educational environment mainly due to the fact, that, at first, it is a self-organized institution, which evaluates and mobilizes its own internal resources, trying to understand the inner logic and main directions of the changes and challenges. After that, GSPI has started a fundamental reform process, which still continues today.

This process has two main directions:

a) the first is the introduction of new, modern specialties, which was accompanied by the relevant professional and logistical development. Its main goal was to satisfy the educational needs and demands of the labor market and the society,
b) the second direction is learning/study, in a broad sense of this word, as already has been mentioned above.

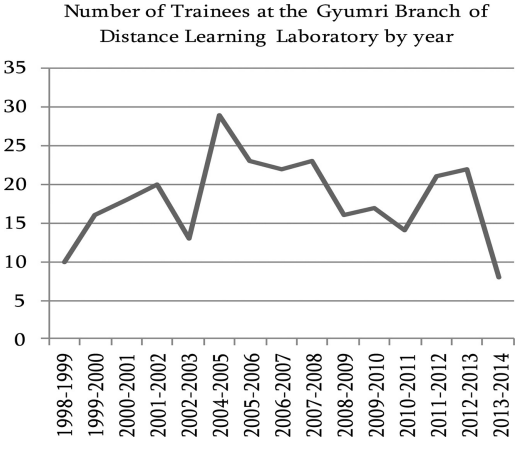
The GSPI's academic/administrative staff and students have not only learnt new professions, but also have learnt the new, modern methods and technologies of teaching, studying and administration, as well as acquired skills and competencies, which they can apply in this process. Moreover, this process of learning is going on today and, we believe, it will always continue, if we want to stay a competitive and sustainable HEI.

In order to be more precise and objective, we have tried to briefly present some activities that have been done in GSPI. Alongside the introduction of new specialties and the use of new teaching methods and technologies in GSPI, we would like to note the fact that distance and open learning systems were introduced in GSPI, starting from the late nineties, in the frame of the projects "Creating a System for the Training of Social Work and Social Policy and Administration as a Specialty within Institutions of Higher Education in the Republic of Armenia" (JEP-10202-96, for 1997–99 years) and "Armenian Distance Learning Network" (JEP-21133-2000, for 2001–2003 years) of the TEMPUS program funded by the European Commission. The activities of these projects in Armenia

were coordinated by the Department of Sociology of Yerevan State University (YSU). The main objective of the projects was to develop and to implement distance and open learning systems and perform the short-time training courses in "Social Work" specialty.

We will now briefly present the situation, in which the Armenia, particularly Gyumri, and the higher education system were like during this period (from 1992 to 2000).

Armenia, as a former Soviet Union Republic, was in a process of transformation. Social, economic and political systems were trying to adapt to the new situation and to implement the reforms. The educational system, in particular, the higher educational system could not be isolated from this process. It tried to respond to the demands of the emerging market economy by the establishment of new, modern specialties. One of them was the profession of "Social Work", the need for which was particularly highlighted by the fact, that after the severe consequences of the devastating earthquake in 1988, there was a need to implement appropriate professions for social support. But in Armenia at that time such professions did not exist. To fill this gap, the YSU started to cooperate with the leading Universities of USA, UK, Germany, and in these activities were included those Armenian HEIs, which are located in an earthquake zone, particularly, Gyumri State Pedagogical Institute and Vanadzor State Pedagogical Institute. In the framework of the above mentioned Tempus Projects the professionals from these HEIs were trained at the YSU, Open University of UK, London School of Economics, Fachhochsule of Frankfurt am Main, by the profession "Social Work and Social Administration". Simultaneously, these HEIs also studied the open and distance learning systems, as well as the opportunities and options of their introduction to the Armenian HEIs.



As a result, in 1997 at GSPI the profession "Social Work" was introduced and the Gyumri Branch of Distance Learning Laboratory of YSU was established. Here, through the use of distance and open learning components, short-term training courses in "Social Work" were organized, after the graduation of which, the participants were awarded with Certificates. This is an interesting option for networking in the educational system, because there were lectures and presentations conducted not only by the lecturers from GSPI, but also from partner universities, such as: YSU, London School of Economics and Political Science, Open University of United Kingdom. The students of this Educational Center are the employees of the Social Service Centers in Gyumri, Region of Shirak, beneficiaries and employees at local and international charity NGOs, as well as representatives of various socially vulnerable groups.

For this case study, as can be seen from the Table 2, the number of trainees participating in the "Social Work" courses at the Gyumri Branch of Distance Learning Laboratory of YSU, were initially relatively few (see years of 1998–1999).

Table 1. Number of Trainees at the Gyumri Branch of Distance Learning Laboratory by Gender.

Year	Male	Female	Total
1998–1999	3	7	10
1999–2000	7	9	16
2000–2001	3	15	18

2013–2014		8	8
Total	38	234	272

Table 2. Number of Trainees at the Gyumri Branch of Distance Learning Laboratory by Year.

Later on, during the period of 2000–2008, their number has gradually increased, as on one hand there is awareness regarding the profession, and on the other hand, there is high social and labor market demand. This is due to fact that trainees in this profession are mostly workers from both public and non-governmental organizations, or have decided to look for a job in that field. This means that our stakeholders were highly motivated, and that had a positive impact on their academic performance.

It should be mentioned that their number gradually decreased in 2009–2011 and especially in 2014. This can be explained by the fact, that the Gyumri Branch of Distance Learning Laboratory, as well as GSPI's "Social Work" Department almost completely satisfied the demands of Shirak Region's labor market during the past ten years (2005–2015 years).

As we can see in the above mentioned Table 1, most of the trainees of Gyumri Branch of Distance Learning Laboratory are women (234 from 272 trainees, 86%). We think that one of the main reasons for this is the fact that in post-soviet period, since 1992, the position and role of women have changed in the Armenian reality. In particular, if during the Soviet period (1920–1991 years), especially due to national traditions, the Armenian women were considered mainly as mothers and caretakers, then, after the Armenia's independence from the Soviet Union in 1991, the emerging civil society has reviewed some traditions and the role of women in society has significantly changed. After these changies, Armenian women started to have a greater participation in the social, political and economic processes.

The second reason was the devastating earthquake of 1988. Some women, who lost their children or relatives because of earthquake, couldn't stand the loss and isolated themselves from the society. The other part, on the contrary, became more active in social life, finding solace and comfort in it. They were trying to help, support not only the women, who had loss, but also the families which were socially disadvantaged.

After these changes, Armenian women started to have a greater participation in the social, political and economic processes.

In order to institutionalize the women's involvement, various governmental and non-governmental organizations have been created. These organizations worked in the interest of women, carried out informative trainings and courses for them.

In addition, we believe that the social care sector is more familiar to women in particular. They, on one hand, protect and support representatives from various socially vulnerable groups, and on the other hand, they try to realize their rights. By receiving relevant professional education, they could ensure the effectiveness of this process. Perhaps, due to this fact most of the trainees of Gyumri Distance Learning Center were women (Table 1). They are mainly employees or beneficiaries from governmental or non-governmental organizations that are realizing a social care.

When we analyze composition of the trainees by age (Diagram 2), we can see that the majority of the participants are middle aged (40–50 years old) and have already studied in the field of another specialty. And now, due to their current work, additional training is needed. In this case, of course, they preferred more flexible and free open and distance learning course. Taking into account this fact, new activities are currently in process in order to organize and implement new specialties, in particular in the sphere of "Public Relations" (PR), "Human Resource Management" (HR), "Social Pedagogy", "Jurisprudence" at Gyumri Branch of Distance Learning Laboratory.

In addition, GSPI performs activities in order to start a process in the Correspondence Learning Department to combine the elements of "traditional" and distance/e-learning. Because these two learning systems do not exclude each other, but rather create additional opportunities for making education more efficient and accessible: "Flexibility in higher education has also been enhanced by the ongoing development of new technologies. Distance learning, e-learning and the recent development of open universities in a number of countries, including Greece, Spain, Cyprus, the Netherlands and Norway, illustrate how the traditional higher education institutional landscape is changing. Meanwhile, established higher education institutions are also launching a range of distance and e-learning programs, providing a broader range of study opportunities for the mainly, though not exclusively, working adult population" (Eurydice 2011). Due to this: "… currently, there is a lot of research into how to effectively combine online learning and face-to-face meetings in what are called 'hybrid' courses or 'blended learning'. Hybrid courses combine the best of both worlds" (https://moodle.org/mod/data/view.php?d=55&rid=6824).

In GSPI the project "Institutional Building and Human Resource Development in the Field of E-Learning in Caucasus", was another notable initiative invested and developed in the field of distance and e-learning systems in 2012–2014. The project was funded by GIZ (Deutsche Gesellsheft fur Internationale Zusammenarbeit (GIZ) GmbH) and Federal Ministry for Economic Cooperation and Development, and coordinated by the Armenian National E-Learning Network.

The goal of this project was to develop a strategy for e-learning, create an electronic platform for partner universities, preparation of study materials, as well as training for specialists for online learning and e-learning system management. Within this project, at GSPI a working team was formed, that has developed "Guideline for use of the ECTS-Credit System" and published it on the GSPI's website.

After the completion of the project, the working team of GSPI continued to contribute to the students and lecturers with the knowledge and experience received in the frame of the program and GSPI is currently involved in the National E-Learning Network.

The team is currently working on a pilot project carried out in GSPI. It aims to create and implement an e-learning course for BA students, with 1 ECTS-Credit workload. Simultaneously it is developing the "Guide for organization and implementation of the e-learning process".

3 CONCLUSIONS

In accordance with what has been presented throughout this paper, the following conclusions can be reached.

In the past, universities were seen as organizations, producing knowledge and graduates, but have become an integral part of the environment, where they are

situated. By facing these challenges, universities will assume responsibility for education and research based on the advancement of sustainable development. And in this sense, we should take into account the perception and definition of sustainable development, by which: "… according to the concept of sustainable development of Republic of Armenia, the sustainable development emphasis the self-recovering and dynamic adaptation skills' development to the changes rather than the maintaining in perfect stable condition" (www.gov.am/files/1322.pdf).

The concept of the sustainable university should include all dimensions of sustainable development (environmental, economic, and societal ones) and political will (top management commitment) to make changes, including structural ones, to achieve the objectives. Therefore, this university could be defined as: "A higher education institution, that addresses, involves and promotes, on a regional and a global level, the minimization of negative environmental, economic, societal, and health effects in the use of their resources in order to fulfill its main functions of teaching, research, outreach, partnership, and stewardship among others as a way to help society make the transition to sustainable life styles" (http://www.uml.edu.com/CITA.lusiv.pdf).

In other words, universities generate and implement changes, and they are in turn subject to the impact of these changes. So, fast and sometimes unpredictable changes are the constant companions of social life, which brings new challenges for individuals, groups, social institutions and the whole society. One of the more efficient means for adaptation to these changes and challenges is the ability to change, by shaping and developing new skills, being flexible and having the ability to create a conformist type of behavior.

Learning/study is the most effective tool for new knowledge and capacity building, and for ensuring sustainable development. Nowadays the concept "Education for Sustainable Development" (ESD) is already used, and has a wider meaning then just "Environmental Education" (EE). Since the changes are performed during lifetime, the learning/study process goes throughout life and is lifelong.

New learning/educational technologies, e.g. e-learning, distance and open learning, blended/hybrid learning, are excellent tools and methods for implementing lifelong learning.

Universities, as educational, scientific and research centers, should pay appropriate attention in their course programs, to create strategies for the implementation of lifelong learning. As it will enhance the competitiveness and longevity of universities, ensuring their flexibility and rapid response to the labor market demands and to environmental challenges which are faced by humanity as a whole.

Measuring urban ageing. Città Giardino Torino: A resilient archipelago for the elderly

Davide Vero
Politecnico di Torino, Torino, Italy

Beppe Giardino
Photographer, Torino, Italy

ABSTRACT: Disruptive demographic trends show a world that is rapidly ageing. The goal of this paper is to measure the possible fallout of the demographic phenomenon on the physical environment through multiscale analysis – from the city to the house – and identifying the diachronic processes of adaptation and manipulation. In order to reach the geographical dimension of the phenomenon, the data related to the ageing population in the city of Turin were merged with the urban fabric. The ageing mapping obtained from this analysis shows the substantial convergence of the "public city" with the one of the elderly, with the exception of the neighbourhood of *Città Giardino*. Through the case study of *Città Giardino* in Turin and his story – made of continuous transformations – the paper points out the dynamic process of adaptation and some resilient practice. In particular, the analysis highlights the physical transformation and the tendency to place attachment, reinforced by new patterns of use of the existing private and public buildings. Within an invisible crisis and in a context of little institutional awareness, *Città Giardino* offers the opportunity to rethink urban policies and to organize a governance strategy in a longer time perspective. Moreover, the research identifies a housing stock that represents a possible resource for a more inclusive habitat.

1 INTRODUCTION

The world is rapidly ageing: the number of people aged 60 and over as a proportion of the global population will double from 11% in 2006 to 22% by 2050. By then, for the first time in human history there will be more elders than young (aged 0–14 years) in the population (World Health Organization 2007).

According to the United Nations Population Fund (2007), "developing countries are ageing at a much faster rate than developed countries: within five decades, just over 80% of the world's older people will be living in developing countries compared with 60% in 2005. The older population is growing from far more rapidly–in 2007 expanding by 2.6 percent per year–than the population as a whole–at 1.1 percent."

Population ageing has been described by demographers as the result of two humanity's greatest victories: increased longevity, or victory over death and disease; and reduced birth rates, or victory over unwanted childbearing (United Nations, Population Division 2000). The shift toward more aged populations is not the result of some inevitable evolutionary development in the human organism but rather a product of a process of societal "modernization". This phenomenon has gone hand in hand with that of urbanization and industrialization.

This unprecedented global process has profound consequences and implications for all facets of human life, including the economic, the social, and the political sphere. Furthermore population ageing is enduring, pointing out a process that is unlikely to be reversed in the future. According to Simpson (2015) the sociodemographic transformation has in most recent times been largely interpreted in terms of two forms of crisis. The first is a future crisis of dependency both for economic and health reasons. The second is a crisis of programming of architectural and urban settings, which were previously dominated by the young. This interpretation adds another issue, introducing a reflection on the relationship between demographic and urban change, and architectural transformation.

In this respect, recently there has been an increased interest and research on the ageing population and the relationship between demographic change and the environment into the three strands.

It is possible to trace three lines of research. The first is related to the clinical studies (Environmental Gerontology), while the second focuses on the policies and actions to promote age-friendly urban spaces and to facilitate active aging population (Plouffe & Kalache 2010, Handler 2014). Requirements for the ideal city open to critical perspectives on this topic, studies more oriented towards a qualitative redefinition

of the question starting from the existent (Buffel, Phillipson & Scharf 2012).

Finally, the partial description of the housing phenomenon linked to ageing, that of retirement communities and the related migration (King, Warnes & Williams 2000, Simpson 2015).

These heterogeneous literature is focused on the theoretical debate and on the models, avoiding the direct observation of the spaces and their transformation (Smith 2009). By contrast, this paper aims to show the blueprint of ageing in the city, analyzing the current situation in a precise context in order to identify a possible connection between ageing and urban transformation. The final goal is to measure the fallout of the demographic and social phenomenon on the physical environment – using the topics proposed by the World Health Organization as reading keys – and identifying the diachronic processes of adaptation and "manipulation" of the physical environment (Pynoos 1992).

2 MAPPING THE AGEING CITY

2.1 *Ageing data and urban description*

Research needs to be placed in a particular place and time. The city of Turin is the background for the evaluation of urban practices, uses of space and the physical layers that have affected the territory, through the lens of ageing highlights and weighs up the traces of the transformation. In order to measure ageing on the urban scale we refer to population ageing data in order to identify the geographic distribution of older people in the city.

The data provided by the Turin Registry Office (2015) for the whole city show an uneven map of ageing, with a higher concentration of the elderly population in the south. In fact, the statistical indicators such as the ageing index, average age and the structural dependency ratio locate the areas most affected by the phenomenon in the districts of Mirafiori and Santa Rita (Circoscrizione 2). Furthermore, the graphs of the population show that this area also has the lowest percentage of foreigners in the city.

The southern area of Turin is characterized by the massive presence of factories and infrastructures related to production, these are the places that made Turin one of the economic capitals in the Italian "boom" during the second half of the twentieth century. It was a period of great transformation, where the agricultural land became the place of car industry (Gabetti 1977), above all the FIAT factory, firstly with the complex of Lingotto (Olmo 1994) and then Mirafiori (Olmo 1997). Along with the industrial fabric was developing its infrastructures, roads and services, but above all the land was consumed by urbanization (Magnaghi et al. 2005, Mazza & Olmo 1991). The landscape of farmsteads that characterized the South of the city quickly disappeared under the pressure of thousands of people arriving in the city in search of employment. The different products of "modernization" generated a new city, expanding the boundaries, changing the spaces and building a new society.

The in-depth analysis of micro-data and the mapping of demographic dimensions within the territory of the city required the selection of smaller geographical units. Census areas in Turin provide precise groupings of people based on the ageing index, the population composition ratio between the elderly (65 and over) and the young (0–14 years). This work of mapping (Fig. 1) shows a detailed picture of the contemporary situation, a non-homogeneous carpet with high concentrations of elderly people.

The evaluation threshold for the ageing index, has been placed on the higher values of 300%, this means that these areas have at least three senior citizens per child, which is twice the national average, estimated at 151.4%, while for all the municipality of Turin is 199.6% (ISTAT 2014).

By overlapping the demographic data and the cartography some particular areas it arise, in particular three zones corresponding to what is called the "public city" (Di Biagi 2008): "a urban form that created in the twentieth century in Europe from an question of housing, [. . .] the belief spread that it was the task of the community to respond to the need for housing of disadvantaged social groups". In this sense the "public city" becomes a metaphor for the different seasons of the city, characterized by specific tools and precise forms. This process began in Turin in the early twentieth century, with isolated dwellings, than increases after the war, firstly with apartments buildings in series, and later with entire blocks.

The first important consideration of this work is to outline the convergence of the "public city" of the 60's and 70's with today's city of elderly. The second step is to identify and define the area of study among those that emerge from previous mapping. The choice fell on the territory that seemed to offer the highest level of morphological complexity, an area formed by the border with the municipality of Grugliasco and two main roads: Via Guido Reni and Corso Allamano.

At first glance the area appears as an archipelago made of fragments, these islands are inhabited by a number of different buildings from the high-rise dwellings to an urban village made villas (Fig. 2). This village is named *Città Giardino*, Garden City, whose name only seems to refer to the urban model theorized by Ebenezer Howard in 1898.

The towers and the linear buildings were the result of public policies for the economic and social housing, especially the law 169 of 1962.

Within this tissue lie the services, the road infrastructure, the commercial network and, the public space system.

Observing the area is possible to underline another key aspect: the heterogeneity is not only morphological, but also relates to modalities and practices that generated it. This urban section shows the change in the contemporary landscape – aged with the

Figure 1. Map of the ageing index in the south of Turin.

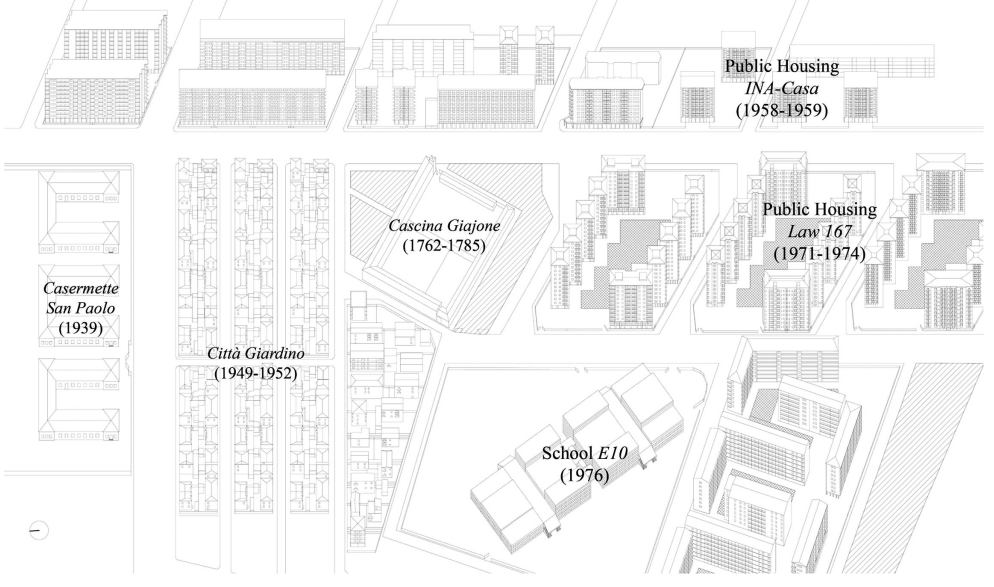

Figure 2. Front isometric of the study area.

inhabitants – and the same is true for the models and the imaginary that had been proposed for an expanding country. Those lifestyles and uses of space today appear distant and no longer coherent with the new requirements and with the recent social emergencies.

2.2 *Methodology*

At this point it is crucial to reconstruct the entire process, starting from history, from the individual stories described by the case study.

The tools to accomplish this route are proper of an analytical survey, the method and the instruments were diversified in an attempt to preserve the dynamism of observed urban practices (Blau & Rupnik 2007): maps, charts and drawings are intended to show a faceted situation, in the reading of the ageing.

In particular both archival research (drawings, documents and journals) and direct exploration of the places were necessary. The spatial experience is supported by the use of photographs, interviews, meetings with actors and inhabitants (Bonomo, 2013, De Pieri

et al. 2013). It is a way "to talk" the case study, gathering useful information and collecting the many "microstorie" (Ginzburg 1979) that lie behind inhabiting. These are precious modalities, useful to tell a different story, as complete as possible. Moreover, these items represent the possible traces that reconstruct the overall picture, directing research towards the most interesting results.

In this regard, the analysis and description advance some issues regarding the forms of living, typologies, habits, practices, and devices, related not only to architecture but to the project in general. Dynamism and tension reveal the forces at play, the modes of action and the possible conflicts. From these shared elements and strengths emerge strategies of action and the ability to foreshadow the urban future, all seen within a broader vision, in which the research questions the relationship between the inherited living spaces and the deep social and demographic change.

3 CITTA' GIARDINO AND MIDDLE-CLASS CITY

3.1 *Urban village*

The area is located in the periphery north-west of Turin, on the border with the Municipality of Grugliasco. At the time of his birth was far from the rest of the city, which in a few decades would have incorporated.

Especially after the Second World War was immersed in an agricultural landscape, characterized by farms and large estates, but not far from the factory of Mirafiori-FIAT and from that of Pininfarina.

In 1947 the Società Torinese Città Giardino (S.T.C.G.) bought land to build a new city, made up of 400 villas with their own garden and equipped with all facilities. At that time Italy was facing the housing problem for all those people who were displaced in the II World War or who had lost their homes. It was a wide real estate transaction propagated throughout Italy: ac "the most impressive group of houses that will never built [. . .] composed of six or eight rooms, each arranged so as to be divided into more accommodation of two, three or four bedrooms. Each unit will be accompanied by various services essential to modern lifestyle and standard of living. All villas have the the ornament of a garden completely fenced".

(quotation from La Stampa Sera, 12–13 novembre 1948).

A "hybrid" solution, an urban village consists of independent two floors, with cellar and all the possibility of expansion.

Furthermore, the S.T.C.G. proposed in its offer also a number of works of infrastructure and services for the community including park, pool, service building, school and church. The houses were designed for a young middle class, made up of artisans, workers and employees in the automotive industry.

Figure 3. *Città Giardino* internal roads.

Despite the inauguration of the first house in 1949 the work were slow, only to only to stay permanently with the company's bankruptcy.

The many people who had bought land, marrying the design of *Città Giardino*, they found themselves in front of building sites not yet completed, the total lack of services and infrastructure works. To cope with this situation of isolation and impasse residents founded the Consorzio Pro Città Giardino, with the objective to finish the work and obtain official recognition from the city, full recognition will come only in the 70s.

On the ground there were only excavations and the first concrete structures, in fact there were few finished homes. The cooperative sought support in the City of Turin in order to overcome the serious crisis and uncertainty, due to the bankruptcy of the company. The works slowly resumed in 1951, there were to be solved the problem with the basic services of urbanization, that was totally covered by the inhabitants of the *Città Giardino*.

Meanwhile, the surrounding town grew, filling the void with private and public building (Fig. 3). Between the 60s and 70s the residents of *Città Giardino* had saw a fence of buildings growing around them. In particular the INA-CASA projects (Di Biagi 2001) and then those of the Law 167 (Caramellino et al. 2015), trying to give shape to the growing urbanization. Together with the houses had stood new services, especially churches and schools that were trying to sew together urban and social fabric.

3.2 *Public housing*

The law 167 of 1962, "Provisions to promote the acquisition of areas suitable for the construction of economic and social housing", played an important role in the process of expansion of big Italian cities between the 60s and 70s and is often remembered as the provision behind the construction of some of the big public housing estates. The law offered the municipal authorities tools to purchase land for assignment to public bodies, cooperatives and, in some cases, private organizations, at subsidised cost, for the

construction of housing for medium or low income families (Caramellino et al. 2015). According to De Pieri (2015) one of the aims of the law consisted, from the start, in favoring a consolidation of the urban middle classes, simplifying access to housing by large segments of the public.

The law 167 was implemented in Turin with a plan for economic and social housing (Peep) in 1963. This plan did not overturn the comprehensive logic and the lines of the city's expansion. In particular it confirmed the radio-centric growth upheld by the general town planning policies (Mazza & Olmo 1991, Di Biagi 2008). The northern areas of Turin were built largely by public bodies (Iacp, Gescal, sometimes with the collaboration of FIAT), while the western and the southwestern areas the cooperatives had a greater weight. These operations focused more evidently on building fragments of a middle-class city, not always so different from the surroundings city built by the market.

The logic of adaptation to the fabric of the existing city and fragmentation was also used for the area around *Città Giardino*. The construction began in 1971 with the designed area named E10 (corso Cosenza). The site was divided into a series of operations managed by different cooperatives (related to the Democrazia Cristiana party), which built a series of buildings clustered around courtyards. In particular these ten or seven-storey building adopted two specific typologies: the tower and the linear block. Furthermore, these buildings were characterized by two garage floors below ground, a *pilotis* ground floor a great differentiation of the apartments – representative of the emerging middle class –, a garden, standardized building technologies and a great differentiation of the apartments. The size of the apartments ranged from 70 to 110 square meters, consisting of entrance, living room, kitchen, two or three bedrooms and one or two bathrooms. In addition, all the apartments had double exposure, balconies and were served by a staircase and elevator system. The buildings perfectly represented the new middle class, with its demands and its lifestyle.

The plan for the area also provided the construction of a church and a school, typical elements of the law 167, to provide services and to make cohesive the ever-expanding community. These public buildings were completed after the construction of residential buildings, in particular the church in 1972 and the school in 1976.

3.3 *Social pattern*

Città Giardino highlighted a social pattern linked to the scheme of arrivals, from early pioneers to the family chains, which brought friends and family to live in the same area. In fact, families of *Città Giardino* not came from Turin, but from the surrounding countryside or by other small rural realities, such as Asti and Cuneo.

This specific social structure can explain a precise ideological component: the specific Italian immigration. According to Foot (2004) from the analysis emerged a number of conservative values, "the desire to reproduce the life of the ordinary village with small houses, gardens, vegetable gardens, terraces and balconies." Moreover, it could emphasize an individualistic and economical desire, represented by the choice of family ownership of land and houses.

In contrast, the underlying ideology in *Città Giardino* was not only conservative. In fact, had produced a strong community that formed strong bonds of solidarity and organization for the common good. The most important example was the establishment of a consortium that would protect the people and would allow the completion of the work. The *Pro Consorzio Città Giardino* in the 50s and 60s was able to obtain permission to build and the habitability of houses. Furthermore the inhabitants had completed the construction of the basic infrastructures: electricity and water, distribution, paved roads, and drainage system, without the help of the municipality (Libert 2003).

As it regards the buildings constructed by the law 167 pursued an urban and social mix between public and private and middle-class oriented operations. In most cases there was a coincidence between the residents and the employees of FIAT. Through interviews it was possible to reconstruct many of the paths that led to the purchase of these houses. In particular, the inhabitants were attracted by the modernity of these apartments, both for the life in the new condominium and for the solutions adopted in the construction (spaces, materials and services).

The design of these buildings provides a separation from the rest of the city with some devices such as gates and green barriers. The buildings and their inhabitants were isolated, a separation both physical and social, within a system other fragments.

3.4 *Built environment and mobility*

Within the study area there were two other elements: the farmstead of *Giajone* and military station San Paolo. These initially had a minor role, except with time become the central places. In the first case, after years of abandonment, in the late 80s it was redeveloped to become a new pole with the municipal library and other services for local residents. In the second case the station were returning to take on a military role after years in which it were the refuge for many people looking for work and hunting home.

The urban fabric was innervated by commercial facilities, especially in *Città Giardino* it was a trade of proximity, characterized by small shops. These shops that did not withstand the new market pressures in the 80's and the shopping mall born near the neighborhood. At the same time there had been a fundamental change in mobility, the roads that skirt the area became increasingly busy, changing into multi-lane roads.

4 CONCLUSIONS

The rich history of the area shows a dynamic and complex process through which is possible to provide some interpretations.

Figure 4. *Città Giardino*, back of houses.

Figure 5. *Città Giardino*, interior of the house of Maria Nella.

First of all the case study area works like a Petri dish, a reading of the wider urban renewal, both in its epochs and in its instruments. Along this period the transformation also had took place in *Città Giardino*, a less visible change, made of small additions (Fig. 4). In particular, the housing added a floor or a veranda, the garden also changed with the addition of a garage or a warehouse in place of the flower. Other changes took place inside houses, new modern facilities replacing existing one, the internal organization was changing to accommodate the changing needs of the inhabitants (Fig. 5). While in the other residential buildings, those of the law 167 on social housing, there have been no changes. The inhabitants are aged in their homes without being able to adapt the buildings to the new challenges posed by ageing. In fact, the condominium regulations and building regulations do not allow a change of the functions and structures.

Through direct observation and reconstruction of the different levels is possible to highlight a city designed for a specific period and for a specific population, that of the middle class.

A population that is concentrated in certain areas of the city, the same areas now affected by ageing. It is a city within a city, made up of homes, public spaces, services and behaviors. The mutation in the uses of space and forms may be clues to the interpretation of urban aging.

Since the proposed division of the World Health Organization (2007) there are some topics in specific areas for the age-friendly city. In particular, the attention is focused on the physical environment: outdoor spaces, housing and transportation. This topic goes hand in hand with the social environment.

As part of the ageing in place *Città Giardino* highlights certain aspects of typology, in particular it comes to changed housing and needs of the inhabitants. The direct observation shows a series of devices that have gone to change the volume and the shape. Most of the houses were raised at least a plan, they added a garage for cars, closed their previous balconies with a veranda, the space around the house was paved and a number of roofs were built. The rooms of the house have increased and they have been renewed, older rooms have been merged and expanded. Some devices designed for the elderly were added, especially as regards the accessibility of the distributional spaces and in particular for stairs and the bathrooms (Fig. 6).

The changed needs and habitat does not seem to be matched by a change of ownership. Families who first arrived at *Città Giardino* still reside there, showing a resilient process. Most of the time the house was divided, hosting within the same family with parents and children. Few newcomers *Città Giardino* still appreciate the housing solution. Through interviews it was possible to detect the reasons for this success: the freedom provided by the stand-alone solution, the possibility of a green space in an urban setting and proximity to services.

In this real estate resilience framework it appears important to note two elements, the first resides in house prices, significantly higher than the neighboring buildings. Second, it should be resumed the ideological component that acts both at the community level

Figure 6. *Città Giardino*, interior device for elderly.

and on the individual household. In particular, *Città Giardino* operates as an urban village, closed not only physically but also socially, a kind of gated community consisting of different combinations that tend to close and isolate the settlement. This factor is crucial in reading the practices and the internal behaviors of *Città Giardino*.

To the dwelling resilience corresponds public services that slowly adapt to the changing needs of the elderly population, it is the case of the open spaces and schools in the area. The only exception is the *Cascina del Giajone*, converted to services, which had become a gathering place for the entire population.

Within an invisible crisis *Città Giardino* is not only a blueprint of ageing, it represents an opportunity to rethink policies and projects weighed for a morphological and functional change. In a context of institutions little conscious of the phenomenon, it is necessary to measure the needs of the "new" residents, compare and organize a strategy of governance along a longer time perspective.

This perspective could start from the existing housing stock and from public buildings underused in order to activate new resources – freed through the placing on the real estate market of a range of new properties – generated from sharing the existing buildings (Polci 2013). The new housing policy would have positive effects for the elderly owners and users – economic and social – and for the dynamics of the entire city.

Social sustainability in urban context: Concepts, definitions, and principles

Asma Mehan
Politecnico di Torino, Torino, Italy

Farzaneh Soflaei
Tsinghua University, Beijing, China

ABSTRACT: This paper focuses on the concept of urban social sustainability to explore main themes and dimensions by a comprehensive comparative overview. The first objective of this research is to clarify the social sustainability definitions, principles and frameworks through reviewing the existing literature. Later, it attempts to recognize the major factors affecting social sustainability in urban context focusing on satisfaction of human needs. As a result, to connect between theory and practice, Maslow hierarchy of needs has been chosen on the subject of human needs in urbanism. Finally, spatial qualities made by reflecting these needs to space designing such as Comfort, Privacy, Legibility, Diversity, Public Participation, Visual Richness, Sense of Place and Identity. In addition, reviewing studies conducted in different urban scales (Micro/Medium/Macro units) revealed that previous attempts on urban social sustainability emphasized more on Macro Scale (city) and Medium Scale (Neighborhood) units especially emphasizing on urban renewal and regeneration strategies especially in developed countries.

Keywords: Sustainability, Social Sustainability, Urban Social Sustainability

1 INTRDUCTION

In recent decades, Social Sustainability has gained an increased awareness as a fundamental component of Sustainable Development and Sustainability. There are various studies conducted on social sustainability as one aspect of sustainability or sustainable development. However, concise review of related literature shows that the definitions on social sustainability are quite complex; therefore, this research will provide a clearer framework for achieving a comprehensive definition of social sustainability in urban context. This study is aimed for social sustainability of future and contemporary cities by drawing conclusions on "What are the parameters for enhancing social sustainability in contemporary urban contexts?" In order to answer this question, this article studies theoretical background related to social sustainability, definitions, frameworks, perspectives, dimensions, and finally investigating the concept of social sustainability in urban context. The aim is to present a framework, which can be, considered for wider use of sustainable design by urban designers, planners, and policy makers concerning social sustainability.

2 HISTORICAL EVOLUTION OF SUSTAINABILITY

In the 1920s, the ideas of Modernism began to surface in urban planning. By the late 1960s and early 1970s, many planners felt that Modernism's clean lines and lack of human scale sapped vitality from the community, blaming them for high crime rates and social problems (Smith, 1997). Since the late 19th century, the problems resulted from modern urban development has appeared as different urban crisis in three dimensions of environment, social and economic, which has made these communities unsustainable and instable and made experts think about other methods of urban development patterns. Some planners argue that Modern lifestyles use too much many natural resources, polluting or destroying ecosystems, increasing social inequality, creating urban heat islands, and causing climate change. In this regards, the term of sustainability was first developed by United Nations released the Brundtland Commission Report, which defines sustainable development as development which meets the needs of the present without compromising the ability of future generations to meet their own needs (Sen, 2000; Partridge, 2009). In the beginning, the

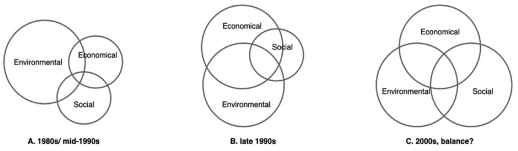

Figure 1. Different dimensions of sustainability and their relative importance through time; A. Importance of Environmental Aspect (1980s/mid-1990s), B. Importance of Economical and Environmental Aspects (Late 1990s), C. Balanced Importance of all three Aspects (2000s)
Source: (Colantino, 2010).

notion of sustainability was narrowly linked to environmental and resource diminution caused by current ingestion patterns. These very narrow considerations were widened by the UN-Conference on environment and development in the Rio de Janeiro in 1992. For the first time, the Agenda 21 explicitly mentioned the human development and social dimensions of sustainability (Harun et al., 2014). The report suggested that social sustainability is aiming to preserve the environment through economic development and poverty alleviation, but it did not recommend any practical perspective (Landorf, 2011).

3 CONCEPTUALIZING SOCIAL SUSTAINABILITY

Sustainability embraces three equally important aspects/pillars –environmental, economical and social, which need to be balanced (Dempsey et al., 2011; Davidson & Wilson, 2009; Mak & Peacock, 2011; Barron & Gauntlett, 2002). Among the three stated pillars, social aspect of sustainability is the least studied (Ghahramanpouri et al., 2015) and only has been seriously considered after the year 2000 as an integral part of sustainability that should distinctively debated (Dempsey et al., 2012; McKenzie, 2004; Lamit et al., 2013). Colantino (2010) argued that, Environmental and economic pillars dominated the sustainability debates since its beginning whilst it is only in the late 1990s that social issues were taken into account within the sustainability agenda (Figure 1). As a result, there are few practical resources that directly address the question of "how to create places that are socially sustainable?' (Woodcraft et al., 2011).

Scholars believe that regarding the social aspect of sustainability; there are still uncertainties in definition, criteria and measurement system until now (Landorf, 2011; Bramley et al., 2009; Bostrom, 2012; Mak & Peacock, 2011; Laguna, 2014). Such vagueness has given rise to many efforts by scholars to recognize the crucial role of social aspects and through the second interpretation; they attempted to discuss social sustainability to become re-socialized (Maloutas, 2003). Today, there is a little consensus over the definition of social sustainability, and many varied definitions have been proposed (Manzi et al., 2010). Such variation can be explained by following reasons extracted from previous works as follows: Concept intangibility (Littig & Griessler, 2005), Multi-disciplinary Approach (Colantino, 2010; Ahman, 2013), Multifaceted nature (Ghahramanpouri et al., 2015), Dynamic characteristics (Colantino, 2010; Dempsey et al., 2012), Context-dependent (Maloutas, 2003; Dempsey et al., 2011) and conceptual flexibility (Bostrom, 2012).

Table 1. Translation of the human residence to spatial qualities in urban design. Source: (Authors).

Theoretical Framework	Researchers	Urban Social Sustainability Definitions
Conditions Framework	(Chiu, 2002)	Social sustainability relates to social norms and conditions in that any environmental or economic decision must not exceed the community's tolerance for change.
	(Laguna, 2014)	A condition where an extended set of basic needs are met for all residents regardless of their race/ethnicity, age, religion, gender, socioeconomic status and/or level of ability and the highest possible level of social inclusion and participation in community life is promoted.
Measurement Framework	(Colantino, 2010)	Traditional hard social sustainability themes such as employment and poverty alleviation are increasingly being complemented or replaced by the emerging "soft" and less measurable concepts such as happiness, social mixing and sense of place.
	(Barron & Gauntlett, 2002)	Socially sustainable communities are equitable, diverse, connected and democratic and provide a good quality of life.
Future Focus Framework	(Chiu, 2003)	Social Sustainability is the maintenance and improvement of well being of current and future generations.
	(Magis & Shinn, 2009)	Social Sustainability concerns the ability of human beings of every generation to not merely survive, but to thrive.
Process Framework	(McKenzie, 2004)	Social sustainability is a life-enhancing condition within communities, and a process within communities that can achieve that condition.
	(Holden, 2012)	A process of urban development, supported by policies and institutions that ensure harmonious social relations, enhance social integration and improve living conditions for all groups.

3.1 *Defining social sustainability*

Among those who work on this concept, researchers try to theorize this multidimensional concept in relation to society, people and Built Environment (Woodcraft, 2012). King (2008) and Littig and Griessler (2005) suggest that social sustainability means the satisfaction of basic human needs and the subsequent continuation for future generations. So 'Human' is the main focus in the definition of social sustainability concept (Dempsey et al., 2011). Various definitions of this concept have been provided in different frameworks (Table 1).

4 URBAN SOCIAL SUSTAINABILITY

Due to the extensive applications of social sustainability concept in built environment disciplines, there is an increasing trend among researchers to view the concept from an urban design perspective and identify related aspects that contribute to this concept (Chan & Lee, 2008; Davidson & Wilson, 2009; Dempsey et al., 2011). Studies, in which social sustainability concept is viewed with an urban design lens, usually refers to the physical aspects while evaluating the impacts of built environment design on this concept (Secher, 2014). In the notion of urban social sustainability, The chronological analysis indicates how traditional themes, such as equity, poverty reduction and livelihood, are increasingly been complemented or replaced by more intangible and less measurable concepts such as identity, sense of place and community stability and security (Glasson & Wood, 2009). Urban social sustainability initially had been searched in urban and rural contexts of developed nations. The most prominent example is the one adapted for city of Vancouver in the year 2005 as this framework encompasses definitions and relevant detailed policies. These components are underpinned by equity, security, adaptability and social inclusion and interaction-as the four guiding principles of social sustainability (Ghahramanpouri et al., 2015). In Australia, Porta and Renne (2005) studied the social sustainability of small-scale built environment units (i.e. public spaces or streets) utilizing formal indicator concept. For their measurement, they used some urban fabric indicators including permeability, land use diversity, accessibility, public/private realm, natural surveillance, employment density and number of buildings. Chan and Lee (2008) studied social sustainability of urban renewal projects in Hong Kong and suggested a list of six important parameters including; preservation of local characteristics, townscape design, accessibility, provision of social infrastructure and availability of job opportunities. More recently, studies have been conducted on developing and less developed countries; for instance, Dave (2009) studied seven characteristics including facilities and amenities, living space, health, community spirit and social interaction, sense of safety and neighborhood as a place to live, in order to search the relationship between social sustainability and urban density in a developing country. However, Ahmed (2012) utilized eight criteria comprising layout quality, integration of public spaces, priority to pedestrians, healthy environment, safety, privacy, vitality and social interaction and participatory decision making, while researching in Emirati city. In another study, Karuppannan and Sivam (2011) studied design parameters including accessibility and permeability, open space, safety, legibility, aesthetic and social infrastructure in an Indian neighborhood. Ghahramanpouri et al. (2015) conducted a research in Kuala Lampur streets and measuring factors including quality of place, participation and accessibility, adaptability, place attachment, legibility, street amenity, food and economic services, heritage and local culture and permeability.

4.1 *Urban social sustainability indicators*

Reviewing existing definitions of social sustainability in related literature suggested that there are common characteristics: First Factor; Future Focus (or Long-term viability and promotion); it is indicated that social sustainability is primarily about valuing and protecting positive aspects of cultures (McKenzie, 2004) and promoting current conditions-encompassing individuals, communities and societies, and also ensuring the qualities for generations to come. It focuses on continuing ability of an urban setting where survivals of human beings in addition to community thriving conditions are guaranteed for generations for a long time. Second Factor; Satisfaction of needs (basic needs and access to resources); It relates to both human and society; Relevant to individuals, it follows Maslow's hierarchy of needs, and covers physiological (food, water, health and safety), social (relationships, confidence and mutual respect) and self-actualization (creativity and morality) levels (Ahman, 2013). On the other hand, it is about provided opportunities and available resources in society in community level. Third Factor; Socially cohesive and physically integrated urban unit; It is about relational aspects of society but also on individual and personal aspects. The significance of inter-relationships between social and physical worlds is highly elaborated in the current extensive social sustainability literature. In many existing definitions of social sustainability, physical setting is considered as being conductive to social cohabitation, socially integrated and promoting well being and quality of life of the diverse group. Such communities are described as well balanced and well connected that can fulfill a wide range of those living or working there (Bacon et al., 2012). In table 2 different parameters of social sustainability in relation to urban studies have been collected through academic references.

4.2 *Scale-based and approach-based urban social sustainability studies*

Urban social sustainability have been scoped from macro level; regional and city (Barron & Gauntlett, 2002), to medium level urban units such as urban districts (Yung et al., 2011) like "Central Business District (CBD)", "Historical District", neighborhood (Dempsey et al., 2011) and urban public space as Micro scale built environment. Studies on the three different urban units (macro, medium and micro Scales) were brought in Table 4 based on the existing literature, social sustainability of micro-scale urban built environment like public urban spaces of the cities has been identified as the least studies, which needs to further researches. However, another Category that includes social sustainability in urban context is Approach-Based studies. As represented in Table 4, dominant

Table 2. General aspects in reviewing social sustainability in relation to urban context. Source: (Authors).

Aspects (Reviewing "Social Sustainability" in "Urban Context ") Related References (Academic References that highlighted related aspect)
Social Equity
Includes equity of access to key services (including health, education, transport, housing and recreation) highlighted in almost every references (Landorf, 2011) (McKenzie, 2004)
Satisfaction of Human needs
Relevant to individuals, it follows Maslow's hierarchy of needs, and covers physiological (food, water, health and safety), social (relationships, confidence and mutual respect) and self-actualization (creativity and morality) levels (Ahman, 2013)(Ancell & Thompson-Fawcett, 2008) (Littig & Griessler, 2005) (Littig & Griessler, 2005) (Laguna, 2014) (Ahman, 2013) (Maslow, 1954)
Well-being, Happiness
(Barron & Gauntlett, 2002) (Castillo, Price, Moobela, & Mathur, 2007) (L.H.Chiu, 2003) (Magis & Shinn, 2009) (Bacon, Cochrane, & Woodcraft, 2012)
Quality of Life
It is the sum of factors that contribute to the social, environmental and economic well being of citizens. It covers aspects such as well-being, happiness and satisfaction. (Weingaertner & Moberg, 2011)(Polese & Stren, 2000) (McKenzie, 2004) (Colantino, 2010) (Weingaertner & Moberg, 2011)
Social Interaction, Social Mixing (Cohesion and Inclusion)
It is about right and opportunities to participate in community and interact with other members of community. It encompasses cohabitation of culturally and socially diverse groups in societies where people Involve in a wide variety of social activities and preventing social exclusion. (Colantino, 2010) (Polese & Stren, 2000) (McKenzie, 2004) (Ancell & Thompson-Fawcett, 2008) (Bramley, Dampsey, Power, Brown, & Watkins, 2009) (Dempsey, Brown, & Bramely, 2012) (Bacon, Cochrane, & Woodcraft, 2012) (Colantino, 2010)(Sedaghatnia et all, 2015) (Mehan, 2016 a)
Pride, Sense of Place and culture (Identity)
It is about people's precipitations of a certain place. It mainly relates to a positive sense of attachment, dependent and identity that people feel about the place they live (Dempsey, Bramely, Power, & Brown, 2011)(Colantonio & Dixon, 2011) (Yung, Chan, & Xu, 2011) (Dempsey, Bramely, Power, & Brown, 2011)
Sense of Community
It is about social interaction of people living in a given area, related with sense of community or place attachment (Dempsey, Bramely, Power, & Brown, 2011)(Barron & Gauntlett, 2002) (Castillo, Price, Moobela, & Mathur, 2007) (Bramley, Dampsey, Power, Brown, & Watkins, 2009) (Colantino, 2010) (Landorf, 2011) (Bacon, Cochrane, & Woodcraft, 2012)
Future Focus
Social sustainability is primarily about valuing and protecting positive aspects of cultures (McKenzie, 2004)(McKenzie, 2004) (Magis & Shinn, 2009) (Ghahramanpouri et all, 2015)

studied approaches in urban issues are; Housing and density, urban renewal projects in historical areas, urban form, urban rehabilitation, urban regeneration and restoration issues. Glasson and Wood (2009) highlight the growing array of social sustainability assessment tools within urban Regeneration Strategies in UK. In another study, Yung et al. (2011), examines the attributes and factors that contribute to social sustainability in the rehabilitation of historic districts in Shanghai, China. However, Ancell and Thompson-Fawcett (2007), tried to develop a model of the social sustainability of medium density housing in New Zealand, Australia. However, in developing and less developed countries, Pakseresht and Fazeli (2011) discuss about the need for a social sustainability-based strategy for designing regeneration plans of Tehran, Iran. In another research, Ahmadi et al. (2011), propose the restoration strategies of Naghsh-e-Jahan Square to achieve social sustainability based on users' vision.

4.3 *Major factors affecting social sustainability in urban context*

Regarding the previous discussions, Social Sustainability in urban context can be considered as "Sustainable City", in which the basic needs of its residents must be met. And, on the subject of human needs in urbanism, generally, Maslow's hierarchy of human needs is popular. On the other hand, it was mentioned that the spatial qualities are defined based on the human needs. In other word, spatial qualities can be made by reflecting these needs to space designing. Table 3 provides a translation of Maslow's hierarchy of needs to the qualities that are intermediated in urban planning and design. According to the Table 3 There are some qualitative factors for each need. It means while a designed space possesses the mentioned qualities, it can establish a long-term relationship with the users to achieve socially sustainable community.

Table 3. Translation of the human needs to spatial qualities in urban context. Source: (Authors).

Human Needs Residents	Spatial Qualities in Urban Design
Physiological Needs	Comfort/Public Services/Firmness and Balance
Safety Needs	Privacy/Legibility/Safety
Belongingness/Love Needs	Social Amenities/Social facilities/ Sense of Place and Identity
Esteem Needs	Inclusiveness/ Preservation of Local characteristics
Self-Actualization Needs	Diversity/Public Participation
Beauty Needs	Visual Richness/Visual Proportions/Visual Distinctiveness

5 CONCLUSION

As mentioned above, among the three stated pillars of sustainability (Environmental, Economical and Social

pillars), social aspect of sustainability is the least studied and only has been seriously considered after the year 2000 as an integral part of sustainability. As social sustainability is a context dependent concept, various frameworks for defining Social Sustainability Indicators have been provided as conditions, measurements, future focus and process framework. Reviewing existing definitions of urban social sustainability in related literature suggested that there are common characteristics in scholars' definitions including; Satisfaction of Human needs, Future Focus, Social Interaction, Social Mixing (Cohesion and Inclusion) and improving Quality of Life. It was determined in previous sections that social sustainability literature is fragmented, complex, vogue and chaotic; Such variation can be explained by following reasons extracted from previous works as follows: concept intangibility, dynamic nature, multi-disciplinary approaches, Context dependent, multifaceted nature and different scale, scopes and perspectives about issue. Reviewing studies conducted in different urban scales revealed that previous attempts on urban social sustainability emphasized more on macro-scale urban places issues like cities. This research concluded that there has been little discussion on micro-scale urban public spaces like streets and public squares. Analyzing the studied urban approaches such as housing, urban renewal, urban form, urban rehabilitation, urban regeneration and restoration in social sustainability literature shows that urban form and regeneration strategies to achieve social sustainability are the most studied issue which shows the context dependent nature of

social sustainability discussions. In addition, since the spatial qualities are defined based on human needs, Maslow hierarchy of needs has been chosen for translation of human needs to spatial qualities in urban design. As a result, Comfort, Firmness, balance, Privacy, Safety, Legibility, Social Amenities, Sense of Place, Identity, Inclusiveness, Diversity, Public Participation and Visual Richness are some of recognized factors affecting urban social sustainability.

ACKNOWLEDGEMENT

Selection of the documents from different urban related disciplines –including Urban Studies, Urban Planning, Urban Sociology and Urban Design limited to those published during 2000 to 2015, written in English and downloaded from Polytechnic University of Torino (Italy) database (including JSTOR, Emerald, Science Direct, Taylor and Francis Online, Springer link, Wiley Online Library, Web of Science, Pro Quest, SAGE Online and others). This paper has been extracted from the PhD thesis entitled "Effect of Public Squares on Social interactions in Iranian Cities (Based on Social Sustainability Approach)" by Asma Mehan under the supervision of Professor Sergio Pace and Dr. Farzaneh Soflaei at Politecnico di Torino, Department of Architecture and Design, Torino, Italy, December 2015.

Mind the GAPs: Are urban planners defined by generational mindsets?

Maria Del C. Vera
University of Nevada, Las Vegas, USA

ABSTRACT: Current societal changes signal that accelerated shifts stemming from the genesis of gaming is transforming the ways we design, interact and perceive the physical world around us. In asking *Are Urban Planning Practices Generational Mindsets?* this article seeks to expand on the growing studies that explore the mindset and expertise of seventy-five and a half million Americans presently at the cusp of entering this nation's workforce. The thesis of the paper agues that millennials are surrogates of planners, a premise which can help to elucidate how gamification and data-driven processes challenge the quality and production of socio-spatial definitions as game theory forwards the urban planning processes of our time.

1 INTRODUCTION: GAMERS AND MINDSETS

A year ago, while blogging with *idgafrith, [–]csolo112* exclaimed …

> *Ok, I never played a SimCity game before 2013. I love it, man. I sunk hours into building cities, and trying to get them just the way I want them. There are bugs and issues, yes, and it's awful that they released the game like that. But I still love it to bits. I can zone out and just play for like 6 hours at a time and not even realize it. Cities of Tomorrow does add some cool stuff, but it's really differentiated from the base game. I still don't use the Cities of Tomorrow stuff in every city, because the base game is still enjoyable to me.*[1]

This post is one of the many affixes serving to depict millennials, a termed coined by Howe and Strauss, authors of Generations: The History of America's Future, 1584 to 2069 and Millennials Rising: The Next Great Generation. By their definition, millennials are individuals born within a twenty-year period starting in1980 and ending in 2000. Close to seventy-five and a half million Americans encompass this age bracket, a stunning number that rendered [–]csolo112 words all the more remarkable for inscribing in readers a caricature of what is presupposed to be the lifestyle of the incoming workforce. This type of pervasive rendition peddled by McGonigal, a game designer, disclosed that "by the time Millennials reach age 21, s/he has spent about 10,000 hours gaming," a number that is equal to the time spent in school from 5th to 12th-grade. (TED 2010) It is the amount of practicing time required to become a craftsman, per Richard Sennett's 10,000 hour-practice; or seven years of the 10 Year Rule essential to achieve extraordinary breakthroughs in any given discipline according to John Hayes, 1989.

As games increase in popularity and mature its immersion power, the sheer number of gamers coming of age emphasizes the impact their cognitive role will have in shaping the future of our world. For this reason, in 2011 when Nick Shore declared Millennials are Playing with You, his essential message to Harvard Business Magazine readers was not about their video gaming habits but rather about the ideological portrait he is painting of millennial's and their meta-game-mentality that as he states enables them to gamified all aspects of life. (Shore, 2010)[2]

2 GAMERS

The explorations and understandings of how playing expands through time lead researches to associate gaming with learning. This phenomenon is also linked to social and spatial definitions, traced to Huizinga's writings "Homo Ludens: A Study of Play-Element in Culture" published in 1944.[3] Today, with the increasing popularity of video gaming, it is common to believe that gaming is embedded in all aspects of our socio-cultural fabric. Evident by a series of recent studies, gaming is a way of exploring new uncharted territories, of willingly venturing into learning about diverse modes of socio-cultural engagement and of figuring out how to reprocess all kinds of rules. Additionally, studies that aim to distinctly separate analog from digital games are noting that all players are keen at tweaking and calibrating their techniques almost instantly, constantly improving and learning from inputs, using emerging data and personalizing their synaptic connections to strategically win.[4] For these reasons, when paleoanthropologist Ian Tattersall says that homo-sapiens hone the ability to abstract realities and pursue new improve methods that significantly alter their physical surroundings, the logic of Nick

Shore's declaration that millennials are playing with you implies imagination. It is not simply that gamers possess unique and innate powers to think strategically; but that there is a long-standing trajectory from Homo Erectus to Homo Sapiens that has incrementally improved our cognitive abilities to ensure survival.[5] In other words, from Tattersall's and Shore's accounts, it is possible, even permissible to grasp a gamer's mental condition as a reflection of mankind's pursue towards perfection, a long-standing expedition if you will towards imagining utopia.

3 UTOPISTS

Utopia is the one idea profoundly rejected by contemporary planners. In 1997, at Centre de Cultura Contemporània de Barcelona [CCB], Robert Fishman declared _*"we can no longer share the fundamental assumption that lies behind this image [Plan Voisin]: that is both possible and desirable to completely rebuild our cities and our societies according to some new and better model."* For Fishman, it was clear then as now that we are *Beyond Utopia: Urbanism After the End of the Cities (1998) and that the city is no longer the place for the dynamism of civilizations to take form.*[6] Conversely, one could also argue, through numerous generational cycles and according to gaming studies, that the city is now becoming a platform which continuously folds and unfolds in a myriad of ways through the will and whim of multiple influences. In fact, it is probable that by tweaking, calibrating, relying on inputs and outputs of data and personalized synaptic connections that strategical urban concepts and designing processes within today's cities signal a pursue toward utopian ideals where everything is seemingly perfect.

As we learn to retrofit, substitute, mutate or expand design according to expertise, it would be false to say that utopian strategies are stored away in opprobrium or that they along are the future of city planning; just as it would be a mistake to place utopia under extinction. Today, utopists are not pure ideologies or urban planners, not even film directors or cultural producers; instead, utopists are complex strategical thinkers using gaming platforms as well as real life scenarios that shape new worlds. Utopist own endless potentialities to evaluate the past, present, or future methods of urban development. Presently, they are game designers of games like SimCity and Skyline, and players actively creating and altering different gaming compositions to render seemingly new urban scopes.

Under these assumptions, ambitious utopian proposals from the 20th century are now relegated to gaming experiments, first played out as analog proposals, then built to fail and now as virtual compositions that are ultimately rendering new unrecognized milieux. In fact, Ada Louise Huxtable, who dedicated her writing career to critique architecture, in her article The Real Fake and The Fake Fake (1997) signaled the process. Writing about the spatial reproductions of places like Venice or New York New York in Las Vegas as an evolving phenomenon that redefines real architecture for the fake. Her article alluded to the experiential transitions we humans undergo as we adapt to recognizing the outrageously fake for the real place. Perhaps, this was the way Huxtable attempted to explain that an occurrence in spatial experiences was shifting, and our modes of experiencing space are now instantly reproducible, places where __ *"extraordinary things are happening."*[7] More importantly, through her writing, she recognizes that Las Vegas has transcended from a place of gaming for entertainment to a sandbox game that entertains.

4 GAMERS OR UTOPIST

Indeed, games prelude future planning practices by extrapolating ensconced utopias from their stigma of improbable perfection. In our milieu, among game designers, computer scientist, game theorist and speculators we are finding new ways to calibrate the city. Here, unlike the utopist of our near past, game designers create an array of codes that demystify perfection and enact games which have the capacity to fold and of unfold over and over again in an array of different ways. Also, through games, game designers are leveling the planning field and developing reflective tools to grasp desires for customizing bits and pieces of utopias rather than attempting to make one complete utopian states. It silently critics urbanist that stand on the sidelines, emancipated from actively participating in solving urban's pressing urgencies. It is a wake-up call, as millennials learn through gaming how to turn downtowns into technocratic cities like Google-towns, Ikea-lands, and Zappo-landias. These new kinds of urbanity serve as windows for urban planners to see the world absent of urban design processes. A warning to stop imagining grand big solutions and start collaborating in compositions that interact within existing cities; igniting new leveraging methods that can effectively affect _the cities of tomorrow. In essence, the current urban revolution denotes that a quest for smaller, manageable utopias are the renewed raw material that urban gamers, designers, and urbanists can hone as they seek to regain planning expertise.

5 DICHOTOMIES

T Urban dreams and ambitions should not bracket into age groups, or to one designer, they are collective knowledge, a process in time that gains from new inputs, judicious planning, and tactical actions. They are evolutionary goals. Current spatial enthusiasm is not gear to enrich speculators or rooted in building edifices or designing personal spaces but rather in imagining "improve" lifestyles. It is the opposite of how 20th-century city planners envision growth. Residues of that century remain and those interested

in immediate rewards and in augmenting territorial gains struggle against the evolving aspects of human imagination.

Returning to Ian Tattersall's view and the idea that human imagination is the tool for future endeavors, forwards the point that we are the *Masters of the Planet* and creativity is not a rarity but rather the fundamentals of progress __*"The capacity for abstract thinking is the key to our success. All our creativity stems from it. But abstract thinking is not only useful for making art. Early hunters, for example, reporting back on the movement of reindeer herds, would be disadvantaged if those hearing the report could not make the mental leap of faith needed to understand that these herds existed even though they had not seen them."*[8]

Under this impetus of how abstract thinking evolves lies, the means to link different creative mindsets rooted in game designing with planners. Here and specifically to their disparate utopian proposals one could argue that the 20th-century planning was like gaming a type of scenario, an extravaganza, and a spectacle; too encompassing and difficult to accept in one gulp. The consideration is also how one can explain why so may of those proposals were left incomplete, as part of world fairs or local political ambitions. The dissatisfaction with grand plans and encompassing urban designs is what makes games like SimCity, Skyline, and other planning games challenging. But if Tattersall is right, if we are all seekers of efficiencies and improve realities __Do we hold the potential to test and envision new proposals as part of a continuum towards improving experiential realities? Can we all make the mental leaps required to planning?

6 FORMULAS

From Hayes, Howe Sennett, Strauss, Tattersall and others, it is encouraging to note that through time humans improve their cognitive abilities, advancing concepts, layouts, and modes of interfacing with one another. The basic principles for how these practices evolve and are commonly understood in history, criminology, economy, biology, sociology, evolutionary studies, political schemes, and other life scenarios. It all starts with the acceptance of rules. In gaming and planning rules determine the process for how outcomes unfold. Yet, rules are just one part of a broader system that deals with understanding calibration, definition of concepts, tactics, layouts, and actions. In the case of planning, to affect urban scenarios, it remains necessary to know city charters, and the protocols instituted within these charters to engage in developing amendments that can cause an effect. Rules, therefore, are the basis to observe details and identify changes. But, rules are not just useful for the continuum of great societies, planning futures, they are also part of how altering and seizing emerging opportunities occur.

Currently, within our existing urban conditions, opportunities to intervene in planning affairs reminisce stages of 20th-century mindset. Back then, projects focus on proposing large-scale interventions, the size of cities, the kind that seemingly eradicate old detriments. For instance, Patrick Abercrombie's proposal for Greater London (1944) based on the pretext that social problems are resolved through overall planning. (Batty and Marshall 2009) There, efficiencies of transport, public open spaces, mix use buildings, and public areas focus on facilitating the flow of the car. It was a time when planning visions encompass urban, suburban, and outer country sites. By mid-century urbanist like Niemeyer, Sert, Wren, Wright and others responded to their times by shifting their focus toward inner city spectrums; with the exception of Le Corbusier, who innately possessed the ability of a game theorist dealing with modeling scenarios inside, outside and within pockets of the inner city. It is his sandbox approach to planning that inspired the thesis of this paper, which suggests that gamers are the current surrogates of planners. It leads to the reconsideration that the strength of urban planning is based on scenarios similar to those now emerging in gaming. The switch is an opportunity to propound that rules of both analog and digital games are inherently necessary to host and examine urban possibilities which can yield new spatial experiences.

7 GAME-ON

Ever since the early 20th century, be it Paris, Chandigarh, Rio de Janeiro, Algeria or any remote sandbox, Le Corbusier methodologically advance rules and codes using mathematical logics. He set methods to organized playoffs according to place. His goals like those of SimCity or Skyline gamers was to augment living standards and avoid chaos, congestion, pollution or collapse. He like current gamers instinctively focus on optimal outcomes and to ameliorate urban performances.

8 STRATEGIES

1. Modulor: an anthropometric scale/rule base on numerical proportions from the golden ratio.
2. Machine-á-habiter: a dwelling defined by modulor
3. Cité-Radieuse: one city block form by stacking hundreds of machine-á-habiter dwellings equipped with sporting, medical, shopping and child care facilities.
4. The Skyscrapers: luxurious steel and glass buildings shaped as cruciform to let natural light and fresh air into the executive +/−8000 units that would be provided luxury living and working standards for all its inhabitants.
5. Ville Contemporaine: a place complete with infrastructural grids for public buses, rail systems, cars and planes to move freely among Skyscrapers, Cité-Radieuse, Machine-á-habiter and public parks.

9 PLAYOFFS

- 1922, 10 machine-á-habiter units built on the Bassin d'Arcachonpart.
- 1926, 50 machine-á-habiter units built for workers working for Henry Frugé.
- 1925, Plan Voisin/1st Ville Contemporaine proposed for Paris – France.
- 1929, Modern Brazil, 2nd Ville Contemporaine proposed for Rio de Janeiro – Brazil.
- 1930, 1st proposal of Cité Radieuse, Brussels-Belgium's
- 1933, Plan Obus, 3rd Ville Contemporaine proposed for Algeria – Africa.
- 1947, 1st built Cité Radieuse, Unité d'habitation in Marseille – France.
- 1951, 1st proposal for a complete city with governmental buildings, cultural centers, and Ville Contemporaine in Chandigarh – India.

Indisputably, like a game theorist, in adding, subtracting, curving, and squaring the inhabitable logics of Cité-Radieuse, Skyscrapers, Machine-á-habiter – and Ville Contemporaine, Le Corbusier was always looking to optimize the characteristics of his sandbox. He adjusted and tweak scenarios to improve his inputs, using emerging data on site, synoptically connecting his building parts in organized ways that strategically repurpose ideas for specific sites.[9]

The desire to build anew in the 21st century is less rooted to one master planner. In fact, technocrats driven by data and numeric logics are already imagining new urban fabrics. In Las Vegas, Tony Hsieh – Zappos CEO has ignited his gaming plan. Starting in 2010 as he looked to relocate 1,200 employees from Henderson Nevada to Downtown Las Vegas via third-party fixers, he encountered a friendly political machine in the City of Las Vegas. Soon to the surprise of most speculators and realtors Vegas leaders ceded 60 acres of downtown to Hsieh. It is a unique experiment, a full-scale sandbox granted with the hope of economically revamping a city in decade. Exceptional incentives that surpassed Hsieh's relocation bid (Medina, 2010) is granting Zappos's CEO the ability to become a policymaker and to spearhead the playoffs of a live-scenario simulating SimCity games. Six years after its initiation, the shuttered Fremont Street is unveiling a new commercial corridor based on sweat equity investment from young entrepreneurs and start-up wannabes. It is a revolving door game where investors who take risk win or loose. One can not say it is an amusement park, but it is a series of retro hotels accommodated for micro-living around stations to eat, drink and be merry that have mostly crowed when annual events like life is beautiful concert, or miniature burning man cubes are laced between, holiday activities.

In retrospect, the outcome is not surprising, on June 25, 2011, when Paul Carr [PC] from Huffington Post, spoke to Tony Hsieh [TH] (computer scientist who graduated from Harvard with a track record for developing successful startups), about his 350-million-dollar experiment in Downtown Las Vegas, the following was said:

TH: "This will be a completely different area in the next five years," he says, "we're bringing food, live music, an entertainment scene; we've even talked about opening a charter school. Did you ever hear of the game Sim City?"
PC: "Of course."
TH: "Well, for us it's like playing Sim City in real life. One tagline we've come up with is 'from Sin City to Sim City'…"
PC: He pauses.
TH: "…you know, like adding another little hump on the 'n'".
PC: It's impossible not to love Tony.[10]

10 THE FUTURE

Neither Le Corbusier or Hsieh can stand as exemplary models to spearhead _the cities of tomorrow. Their for-profit agendas lack the means to invigorate meaningful life to any given socio-cultural place. As millennials become the first true digerati and a significantly large workforce in the planet, they will impact and possibly ignite a reshaping of urban design. Their task lies in developing improve rules and codes that safeguard urbanity and forwards intelligent socio-spatial environments. If the past century privileged the car, this century would privilege life. The observation is simple, the future of urban forms lies within inform solutions, stemming from data and gaming expertise base in analog, digital and crowdsource gaming, using intelligent software that can update rules and codes according to collected data from diverse environmental conditions. Perhaps, new economics can begin to reconsider a collage of inner – outer, urban and suburban conditions; less focus on singular mindsets, set on blank sandboxes and more attentive to the local conditions of human behavior.

11 CONCLUSION

Absent of models and inundated in a sea of retrofitted plans, Millennials are faced with one critical choice that will force urban thinkers to attend to greater solutions beyond the ones that prioritized the car, banks, and speculators. Within this century when it will be possible to ignore parking, assemble and disassemble units through improve zoning, and add algorithms based on need and environmental data, the questions left unanswered is __How? The theoretical angled from which I proponed to improve planning practices lies in the idea of scale. What once constituted distance and networks has ultimately change and it is necessary to embrace that the future of city planners will be in using gaming logics, organic interventions, and human ingenuity that may favor the development of improving environments in the absence of blank sandbox or flat screens. Perhaps the goal is not to look

back at decaying ideas but to engage in the challenges of real sites, with real buildings, and real people, gaming in ways that provide new influx into dysfunctional infrastructures.

One possible point of departure is to regain civic understanding, clean up the planning processes that once favored the automobile and learn to identify urban pockets, collaborative endeavors, and unknown opportunities. This all translates to a different mode of learning and practicing urban planning, one less center on idea development and more focus on problem solving agendas.

Red light at night to enhance cognitive functioning for society's special needs groups

E.V. Ellis, D.L. McEachron & E.W. Gonzalez
Drexel University, Philadelphia, Pennsylvania, USA

D.A. Kratzer
Philadelphia University, Philadelphia, Pennsylvania, USA

ABSTRACT: While human life expectancy may be increasing due to advances in public health, technology and medicine, there are serious questions as to whether the quality of human life can keep up with this increase in longevity. Postindustrial society is experiencing a proliferation of light-related disorders and diseases specifically because our technologically-based society can operate 24 hours per day in illuminated indoor environments. Natural changes in daylight synchronize and help coordinate the body's circadian rhythms, which determine sleeping and eating patterns, brain wave activity and hormone production. Disturbing circadian rhythms by changing the 24-hour light/dark cycle can lead to jetlag, seasonal affective disorder (SAD), delayed sleep phase syndrome (DSPS), and other abnormalities, and is implicated in various diseases and disorders, including cancer. These effects are particularly pronounced with special needs populations whose physiological systems are already under more pronounced stresses such as children with autism spectrum disorder, older adults with dementia and homeless individuals.

1 INTRODUCTION

In June 2012 at their annual meeting in Chicago, the House of Delegates (HOD) of the American Medical Association (AMA) declared that light at night results in adverse health outcomes (Blask 2012). The Council on Science and Public Health recommended that the AMA support the need for developing and implementing light technologies at home and at work that minimize circadian disruption, while maintaining visual efficiency. Adverse light effects can be minimized by using natural daylight or daylight-matching electric light during the day and a new HOD policy recommends dim red lighting in the nighttime indoor environment.

Research has shown that individuals working in natural sunlight are more productive, more effective, and happier than those who work under traditional artificial light (Perrin 2004). Natural changes in daylight synchronize and help coordinate the body's circadian rhythms, which influence every biochemical, physiological and behavioral parameter in the human body. Disruption of circadian rhythms can lead to jetlag, seasonal affective disorder (SAD), delayed sleep phase syndrome (DSPS), and other abnormalities, and is implicated in various diseases and disorders, including cardiovascular disease, psychiatric disorders and cancer (McEachron 2012). Furthermore, the Council on Science and Public Health recognizes that exposure to excessive light at night, including extended use of various electronic media, can disrupt sleep or exacerbate sleep disorders (Blask 2012).

The dLUX light lab at Drexel University has developed an LED lighting system that auto-tunes natural daylighting in its full diurnal changing color spectrum and light intensity during the day and changes to dim red lighting during the nighttime hours. This 24/7 LED luminaire mimics the full spectrum of natural daylight in both color temperature and light intensity. Through a combination of white and RGB (red, green, blue) LEDs the lighting system is programmed to change color throughout the day to mimic the full spectrum of natural daylight from dawn to dusk; to change in color from the amber rising sun to the red setting sun and to illuminate the indoor environment with a low-intensity red light throughout the nighttime hours.

This integrated 24-hour 7-day daylight-mimicking LED lighting system was installed in the 25-men dormitory at St. Columba Safe Haven for Homeless Men and evaluated in three phases: Phase I LED downlights as usual; Phase II LED downlights in the daytime (6 am–9 pm), red downlights at night (9 pm–6 am); Phase III gradual onset/offset daylight LED downlights in the daytime, red downlights at night. Resident data was collected for all three phases using a Demographic Form and the standard research instruments PANAS (Positive And Negative Affect Schedule) Scale and WEMWBS (The Warwick-Edinburgh

Mental Well-being Scale). Additionally, staff performed a dormitory check every hour of the day to determine if the residents were awake, sleeping, or out of the dorm. The six months of staff observations of 24-hour day bed-checks of the 25 person dormitory were used to evaluate the effects of the light.

2 EVOLUTIONARY CHANGES

2.1 *Introduction*

Human beings are the result of biological evolution rather than engineering design. It is impossible to overstate the implications of this rather simple sentence on human health, well- being and productivity. This is because of the existance of two vastly different rates of change – cultural and biological evolution. As the rate of cultural evolution continues to accelerate, there is evidence of a growing disconnect between the artificial environments humans create and the environments to which our ancestors were adapted. Despite the incredible adaptability of human beings, there are limitations and these limitations may now be beginning to impact the interaction of humans with the artificial structures they create. How we deal with this impact will determine the quality of life for millions of our fellow citizens.

2.2 *Background*

The process of biological evolution is primarily dependent on the twin mechanisms of random mutation and natural selection. This has rather profound implications for the interaction of humans with their environments – natural or artificial. First, evolution proceeds by way of increasing and decreasing gene frequencies over generations, irrespective of how these changes are produced. Thus, it is possible – and often observed – that the welfare of individual organisms is sacrificed in order to promote gene propagation. As a result, evolutionarily determined physiology and behavior may or may not promote the welfare of the individual processing those traits. Second, random mutation does not necessarily create the best adaptations even when those adaptations would benefit gene propagation. The adaptations observed in individuals may or may not fit with the expectations of a design engineer. Third, organisms are always best adapted to their ancestors' environment. It is the ancestors who succeeded in propagating their genes over, not the current representatives. Although rapid evolution is possible, significant change is generally dependent upon generation time and organisms with relatively long generation times – such as humans – take longer to adapt to new conditions, at least biologically. Fourth, emotions are part of evolution and thus likely to be one method by which genes promote behaviors that result in their own propagation.

These factors generate a variety of compromises between *adaptation* – the evolution of a relatively fixed set of physiological parameters – and *adaptability* – the ability to adjust to a diverse set of environmental conditions. In predicting which strategy is likely to be favored, several factors must be considered: stability of the environment, impact of the specific environmental factor, advantage of prediction, etc. One major physiological adaptation which has evolved due to the extreme stability and impact of an environmental factor (the Earth's rotation creating day and night) is circadian rhythmicity. It is such a powerful physiological adaptation that all eukaryotic organisms on the Earth have evolved one or more circadian clocks to provide organization and scheduling of every biochemical activity, physiological and behavioral activity. It is, as the phrase goes, 'in our very DNA'.

Why is this important? It is important because humans have inherited a circadian organization from our ancestors that organizes virtually every aspect of our physiology. It is important because physiological control systems in humans – from the cardiac cycle to metabolism to brain management – all have rhythmic components whose activities are regulated by these circadian clocks. It is important because biological rhythms are so fundamental to living organisms that humans cannot eliminate those influences on health and well-being. And finally, it is important because human ingenuity has generated lighting, structures and schedules antithetical to good temporal hygiene with well-documented negative impacts on human health.

3 THE CIRCADIAN SYSTEM

3.1 *What are circadian rhythms?*

There are a multiple of biological rhythms in the human body, ranging from the millisecond rhythms in neural networks to the near second cycles of the heart, 20 minute glycolytic cycles, hourly pulsatile rhythms in hormone secretion through seasonal cycles in conceptions, births and psychiatric episodes. Playing a central role, both in terms of frequency and in terms of impact, are the so-called circadian rhythms. Circadian (Latin for 'about a day') rhythms are endogenous or self-generating oscillations that organize human physiology and behavior and, until recently, scheduled those activities into a temporal ecological niche. Although there are many tissues and cells that express circadian rhythms within the human body, the overall control of the circadian system lies in a small bilaterally symmetrical pair of cell groups (called nuclei; sing. nucleus) located in an area of the human brain called the hypothalamus. This overarching circadian clock or pacemaker is found in the suprachiasmatic nuclei or SCN for short.

Like all circadian pacemakers, the SCN express oscillations with a frequency near but not exactly 24 hours. In the absence of any environmental cycles (called *constant conditions*), this endogenous oscillator is free to express its own inherent frequency,

which, in humans, is about 24.5 hours. This frequency is called the *free-running frequency* and implies mechanisms that allow the internal period of the circadian clock to be adjusted so as to match the period of the day/night cycle. This ability to synchronize to an external environmental cycle is called entrainment and those environmental cycles capable of generating entrainment are called *Zeitgebers* (Ger. 'time-giver'). The most powerful of the known Zeitgebers is the alternating cycle of light and darkness produced by the Earth's rotation. Although there have always been other sources of light (fires, moonlight, etc.), until recently, the most powerful and consistent source of lighting input to the eye has been solar radiation.

The mechanism of entrainment to light/dark cycles is complex and need not concern us here. What is important is the observation that the lighting needed to see objects (called photopic vision) and the lighting used to entrain the SCN do not have exactly the same spectrum. The lighting which generates the highest impact on the SCN is shifted towards the blue-green end of the visual spectrum and is centered around 450 nM. Interestingly, light at the dark amber-red range of the spectrum still impacts photopic vision but is thought to have little or no effect in terms of entrainment or other effects on the SCN and thus, the overall circadian system (McEachron 2012).

3.2 *What has the circadian system evolved to expect from the external environment?*

During the solar day-night cycle, light intensity increases gradually (sunrise), then displays a powerful, sustained intensity (daylight) followed by a gradual decrease (sunset) and then a prolonged period of profound darkness (night). Combined with these intensity effects, there are also changes in wavelength, beginning and ending with red-yellow wavelengths bracketing periods of blue-white light and near blackness. Considering illuminance alone, the darkness provided by a moonless overcast night might provide only some 10^{-4} lux of lighting, while full daylight reaches 10,000–25,000 lux and direct sunlight provides 32,000–130,000 lux (http://stjarnhimlen.se/comp /radfaq.html Hoffman 2006). The actual lighting changes in both intensity and wavelength will depend on the location of the observer on the Earth's surface, the ecology (ex., forest cover vs. open grassland) and other variables, but clearly biological systems have evolved in environments which can provide gradual illuminance changes covering 6–9 orders of magnitude.

This evolutionary expectation has shaped the manner in which circadian systems entrain to the external environment. For example, circadian systems are typically more sensitive and react with greater levels of change when exposed to light during periods which would normally be dark than during similar times during daylight. In addition, for both evolutional and mathematical reasons, gradually changing light/dark cycles are far more powerful Zeigebers than square waves (simply turning lights on and off at regular intervals) (McEachron 2012).

3.3 *To what is the system actually exposed in modern urban environments?*

If circadian systems have evolved to expect and adapt to gradually changing lighting with varying wavelengths and intensity changes covering multiple orders of magnitude, what do human clocks actually encounter in modern urban environments?

If we focus on a well-studied environment – residential facilities for the elderly – the results are disturbing. In one study, it was reported that nursing home residents only experienced an average of 9 minutes of light over 1000 lux per 24-hour day (Ancoli-Israel 1997). In another study, sixty–six institutionalized elderly were observed over a three-day period. The average lighting exposure was only 54 lux with merely10.5 minutes of exposure over 1000 lux (Shochat 2000). In another review of 53 nursing homes, illumination was considered scarcely adequate or insufficient in 45% of the hallways, 17% of the activity areas and 51% of the residents' rooms (Berson 2002). Thus, it is not surprising that sleep problems and disorders are often reported for nursing home residents, even when such problems were not reported prior to admittance (Clapin-French 1986, Regestein 1987).

This is not an issue isolated to such facilities. In a study on undergraduate students, Baynard and McEachron (2011) reported that students at an urban university suffered from significant sleep loss. Many undergraduates live in dormitories ill-suited for stable entrainment and adequate sleep. Shared dormitory rooms often do not isolate light and sound effects between roommates, leading to inadvertent light exposure at night. Most such accommodations require students to walk down brightly lit hallways to get to the bathroom facilities, again leading to significant light exposure if activities are undertaken at night. Additionally, the ability to block out light from the external environment is often limited, making darkness difficult to achieve even under the best of circumstances. Studies indicate that sleep deprivation in this population is associated with poor academic performance (Lee 2015). These issues are also being noticed in hospital environments as well (Pilkington 2013), and so the questions of appropriate design for circadian stability and temporal hygiene are becoming more persuasive for architecture and architects.

3.4 *What are the consequences of circadian disruption?*

Shift work, which often results in such disruption, was reviewed in McEachron (2012). The majority of studies report negative effects associated with shift work. These effects can be broadly classified as behavioral problems, abnormal or disrupted sleep (Akerstadt 1981; Foret 1976, Knuttson 2003) , reproductive issues (Fido 2008, Su 2008), gastrointestional complaints

(Caruso 2004, Pietroiusti 2008), metabolic abnormalities (Ghiasvand 2006), increased risk for cardiovascular disorders (Suwazono 2008; Tuchsen 2008) and an enhanced susceptibility for certain cancers (Davis 2006, Hansen 2006, Schernhammer 2003). The behavioral problems range from decrements in performance (Boivin 2007, Harrington 1994) to depressed mood (Healey 1993) to increases in neuropsychological problems (Costa 1981, Koller 1981). Numerous reviews have been published linking shift work with various health problems (Boivin 2007, Harringon 1994, Haus 2006).

Human studies tend to be correlational in nature and thus cannot be used to establish causality – shift work may simply be correlated with the observed results and not causal to them. Thus, it is critical to the contention that architectural designs be modified to include temporal hygiene because of the numerous animal studies that have been done which do establish causal links between circadian disruption and gastrointestinal disorders (Larson, et al. 1994; Press, et al., 2008), cardiovascular disease (Penev 1998, Roenneberg 2005), and cancer (Filipski 2003, 2004, 2005, 2006, van der Heilingenberg 1999).

3.5 *What can be done?*

Thus, disturbed or desynchronized biological rhythms carry serious consequences. It is estimated that between fifty and seventy million people in the U.S. suffer from some kind or sleep disorder or disturbance (Report from National Academy of Science). While artificial environments are often designed with multiple windows or specific "sunrooms" for institutionalized residents, it is not always possible to bring daylight to building interiors in general, leading to inadequate daytime levels of lighting. This situation can be exacerbated due to institutional lighting levels that not only do not provide residents with the biologically required full spectrum of light throughout the day, but also do not provide total darkness at night—difficult to do when caregivers need to work throughout the night monitoring patient health and safety, as well as fulfilling administrative tasks. As a result, lighting may be too dim in the daytime and too bright at night to generate an effective timing signal for human biological rhythms, which rely on both the amplitude and waveform of the day/night differences in lighting to convey time-of-day information to the brain.

4 LIGHTING FOR A CHANGING SOCIETY

To maintain health and save energy it is important to either use or mimic *the full spectrum of natural lighting* applied with the proper amplitude, wavelength and waveform to foster circadian entrainment and temporal hygiene. This is not merely a matter of altering existing lighting but also of designing new facilities with the need for rhythm coherence in mind. Humans are not computers and do not operate in the same manner 24/7. They are the result of evolution and carry that legacy with them. In regards to time of day, buildings should adapt to the temporal requirements of their occupants to ensure the best outcomes in terms of health and quality of life.

In the meantime, what can be done with existing structures? In an attempt to find out, the study team investigated the use of nocturnal red lighting and gradually shifting solar-day mimicking LED lighting in a residential facility for homeless men.

5 RED LIGHT AT NIGHT

5.1 *Rethinking privacy for dwelling in public*

The residential program at St. Columba offers residents service coordination, personal recovery services, health care, education, and social enterprise and employment opportunities. Residents are encouraged to participate in recovery-oriented activities that lead to personal growth, well-being and self-sufficiency with a focus on moving to permanent housing. Forty homeless men live at St. Columba accommodated in a 25-bed dormitory on the first floor and fifteen single rooms on the third floor. This residential program is housed in two Philadelphia twin homes, which were joined in the 1980's to create one united residence for homeless men. The 1980's redesign was labyrinthical, with no views to the exterior from the community spaces and no landmarks to guide the resident through the network of spaces.

BAU Architecture was retained to redesign the interior. The first floor toilet and shower facilities were dangerous: there was only one way in and out of each of the two rooms and there was no privacy for the private functions intended to occur there (Fig. 1). While the design was compact, it was also very dangerous and the men were afraid to use the facilities. The bathroom was redesigned to provide for safety and security through exposure. While private functions could remain private and protected, there is now ease of visibility into the bathroom and within the room without increasing the square footage (Fig. 2). The rest of the three-story facility was redesigned to allow views into the community spaces and views from those spaces to the exterior, which opened up the interior to provide orientation and visual landmarks while moving throughout the facility. The overall goal of the redesigned interior environment was to support the residents' transitioning to become members of the broader society.

5.2 *A pilot project at a residential facility for homeless men*

At the St. Columba safe haven residence for homeless men Drexel University's dLUX light lab has partnered with Project H.O.M.E. to install its solar-day mimicking LED lighting system in their 25-bed dormitory. Research has shown that LED Solid State Lighting is more energy-efficient and longer lasting with lower

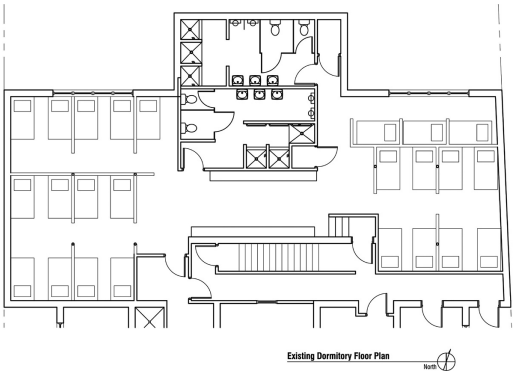

Figure 1. Existing first floor 25-Bed St. Columba dormitory. (By author).

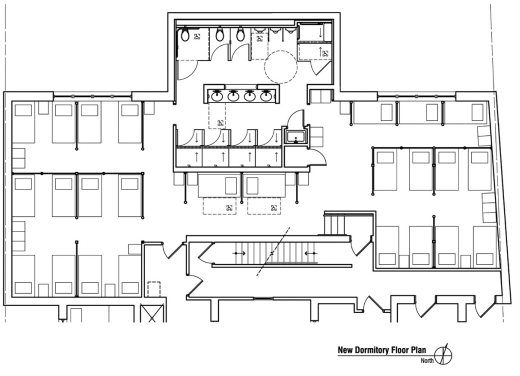

Figure 2. New first floor 25-Bed St. Columba dormitory. (By author).

lifecycle costs than other light sources and that natural daylight controls the body's circadian rhythms and affects overall wellbeing. dLUX is installing a fully programmed, automatic integrated LED lighting system in the 25-bed dormitory that simulates the optimal color and intensity of natural daylight throughout the day to regulate the men's circadian rhythms (Fig. 3). In lieu of complete darkness at night, the gradual onset and offset lighting dims to the red spectrum to provide light at night for general mobility and so staff can monitor the residents' wellbeing. Automatically controlled blackout shades were installed over the dormitory windows: the shades go down at 9 pm and up at 6 am. The goal is to prevent disrupted sleep patterns and the negative behaviors associated with sleep deprivation and to promote the residents' overall health and well-being.

The individuals in this study were otherwise homeless men living at St. Columba Safe Haven for Men in Philadelphia, PA. These individuals were able to come and go as they pleased but were encouraged to participate in various programs designed to promote self-sufficiency. The question can be then asked: if these individuals are exposed to environmental lighting outside of the residence, how efficacious will the solar-day mimicking lighting be for them?

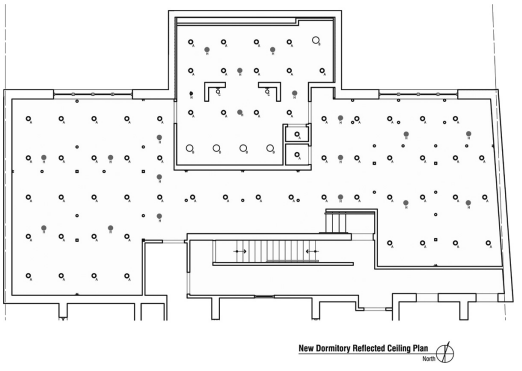

Figure 3. New lighting for 25-Bed St. Columba dormitory. (By author).

The effects of lighting on circadian clocks are not uniform across twenty-four hours and there is both experimental data and a theoretical basis for the concept that a gradual onset and offset of lighting with diminished red light at night will provide a substantially more powerful synchronizing signal for circadian rhythms than current artificial lighting in the facility (McEachron, 2012). Thus, despite the residents' mobility during the daylight hours, the dawn- and dusk-simulation, combined with dim red lights at night, should provide a powerful stimulus for temporal hygiene. This was the purpose of the study – to determine if lighting cycles of this kind can have beneficial effects on residents' wellbeing and sleep.

5.3 *Study protocol*

The original study consisted of three phases.

5.3.1 *Phase 1: Baseline*

After the Institutional Review Board (IRB) at Drexel University approved the study protocol, residents who consented to be in the study completed a demographic form and two questionnaires (PANAS: Positive and Negative Affects Scale; and WEMWBS: Warwick-Edinburgh Mental Well-being Scale) at baseline.

5.3.2 *Phase 2: Red light conditions*

For three weeks, residents were then exposed to standard lighting during the daytime mimicking current conditions with LED lighting, but lighting at night was provided using dim red lights as shown in Fig. 3. At the end of three weeks, residents who consented to be in the study completed the two questionnaires (PANAS and WEMWBS) to determine the impact of the red light conditions on residents' well-being.

5.3.3 *Phase 3: Solar day mimicking and red light conditions*

Immediately after data were collected in phase 2, for the following three weeks, residents were exposed to a time-varying lighting system with intensity and

wavelength variations mimicking the solar-day cycle. This was combined with red lighting at night at all the downlight locations shown in Fig. 3. At 6 am the lights gradually shift in color and intensity from dim red light at night to a bright 6500 K daylight at 9 am. The downlights remain at the daylight-corrected color and intensity until 6 pm at night when they gradually dim to red at 9 pm. Residents who consented to be in the study completed the demographic form and two questionnaires (PANAS and WEMWBS).

5.3.4 *Initial results*

Fourteen residents signed the consent form to participate in the study. Seventy-seven percent were African Americans and 23% were Caucasians. The mean age was 51 years (SD = 13.8). The mean number of years in formal education was 13 (SD = 3.28). The majority were single, and 15% were married. The following challenges were encountered during the implementation of the study: attrition rate was high because participants were transient residents, lack of participant's compliance to complete the questionnaires, and technical difficulties in installation of the lighting system causing a delay in starting the study, and damage to the automatic blinds. Because of the residents' lack of adherence to complete questionnaires on Phases two and three, the research team used the staffs' documentation on residents' sleep on Phase 3, when residents were exposed to a time-varying lighting system with intensity and wave length variations mimicking the solar-day cycle to assess the residents' response to the changes in lighting.

Although a complete analysis of the staff data is still in progress, based upon staff and resident comments, red night lighting seemed to have a calming effect in the environment and improved residents' sleep. Residents indicated that they appreciated having the red lights at night. The research team plans to conduct a feasibility study and replicate the research protocol in the future to assess the effectiveness of the changes in lighting on sleep and quality of life.

6 CONCLUSION

Temporal hygiene is both an old and a new problem. It is an old problem insofar as circadian rhythms and the ability to synchronize physiological and behavioral rhythms with the solar day/night cycle is one of the oldest adaptations which evolved on Earth. It is a new problem that has arisen due to the artificial structures and indoor lighting human engineering has created, which has isolated people from the temporal ecology of the external environment. It will be up to the next generation of architects and designers to determine the best designs to retain the advantages of our artificial environments while simultaneously promoting the temporal hygiene necessary to fully enjoy the advantages brought by the new technologies we develop.

Classroom design for children on the autistic spectrum

A. Mokhov & E.H. Steinfeld
University at Buffalo SUNY, Buffalo, USA

ABSTRACT: Social justice movements significantly changed design culture over the last twenty years. The disabilities rights movement, in particular, has had a profound impact on building design. But there has been more attention to accommodating mobility and sensory issues than cognitive issues. Built environments can pose many barriers for people on the autistic spectrum (AS) due to their unique cognitive structures. Although design for people on the AS has received attention by designers and architects, existing design guidelines often lack a scientific basis and may lead to questionable outcomes. Further, useful knowledge from scientific research is not being applied consistently in design for this group. To bridge the gap between research and practice, the authors applied knowledge translation methods to the existing scientific knowledge on the AS to produce design recommendations for classrooms. This paper describes the knowledge translation process used to identify key knowledge in this field and examples of how it can be applied in design. The implications for future research on the topic of knowledge translation in design for the Autistic Spectrum (and design in general) are provided.

1 INTRODUCTION

Built environments discriminate against people with disabilities if they include barriers that limit access to services and resources intended for all building occupants and visitors. "Barrier free design," an early paradigm for designing to eliminate discrimination, focused on addressing physical disabilities. Universal design, sometimes called "inclusive design" or "design for all," is a newer paradigm. It recognizes that all people share the experience of barriers (Steinfeld and Maisel, 2012). Improving accessibility, usability, and social participation opportunities through design is a benefit to all. Universal design emphasizes giving attention to a broader range of disabilities and also recognizing that people are limited in the use of the built environment for other reasons as well, e.g. low income, intolerance and stigma. In essence, universal design provides a conceptual framework for practicing social justice through design.

Children on the Autistic Spectrum often have profound limitations in social and communicative function, and may have restricted and stereotyped behaviors and interests (Volker et al., 2010). In addition, they usually have problems in processing sensory information.[1] The learning environment (LE) is where children started to interact with society and learn skills that may help to shape their whole life. The typical classroom is a site of dynamic social interaction and intense sensory and cognitive challenges. It presents serious barriers for many children on the AS (e.g., see Kanakri, 2012; Ben-Sasson et al., 2013). This may have a detrimental impact on these children at the very beginning of their life and thus prevent them from fulfilling their full potential.

For architects, design for children on the AS can be a complex design problem that is difficult to resolve without the appropriate knowledge. Although design ideas that seem to have worked in the past can be provided by stakeholders (e.g., parents, teachers), they may not address the complex causal factors underlying the distinctive behavior of this group of children, and result in solutions that work for only a few individuals and are less than optimal. Objective scientific knowledge, augmented by theory, is needed to better understand the complexity of cognitive processes of children on the Autistic Spectrum. An understanding of these systems and their role in person-environment interactions can help to provide high-quality design criteria (for review see Gifford, 2007).[2] This is not to deny the very real value that life experience can provide in design. Rather, a foundation of scientific knowledge can provide a lens through which experiential knowledge can be evaluated and understood.

[1]There is an evidence that children on the Autistic Spectrum may respond atypically to visual, auditory, vestibular and tactile stimulation (see Hilton et al., 2010). However, their atypical reaction to visual and auditory stimuli have the strongest empirical support. (Mottron et al., 2006).

[2]Design recommendations based on practical experience should not be discredited. However, they should be given careful scrutiny, just like intuitive suggestions from designers themselves, to evaluate whether they are supported by theory and/or scientific evidence. This "triangulation" can lead to a more informed process and identify new directions for scientific research and theory development.

Knowledge about the cognitive processes of people on the Autistic Spectrum can be divided into "non-social" and "social" cognition. Among the most understood non-social cognitive traits for people on the AS are:

- *Unusual focus on details (i.e., local bias).* This means that people on the Autistic Spectrum, who have this trait, may tend to see "trees first, not forest" to a greater degree than other individuals (Iarocci et al., 2006; for review see Mottron et al., 2006). From the neuroanatomical perspective, it is believed that focused vision can be caused by inappropriately functioning attentive mechanism ("top-down" modulation) (see Frith, 2003; Happe & Frith, 2006).
- *Executive function (EF).* EF is an umbrella term for cognitive processes involved in a goal-oriented behavior (e.g., actions planning, shifting of goals) (Kenworthy et al., 2008; also for review refer to Hill, 2004). It is suggested that problems with EF may be linked to atypically functioning attention and prefrontal brain areas (Kenworthy et al., 2008; Frith, 2003).
- *Atypical sensory processing* (i.e., either enhanced and decreased), which may occur in different sensory modalities (see Belmonte & Yurgelin-Todd, 2003, Kanakri, 2012, Kern et al., 2007, Baranek et al., 2007 Lockner et al., 2008). Empirical evidence for atypical processing of visual and auditory information is the most established (e.g., see Mottron et al., 2006 ,Bertone et al., 2005; Belmonte & Yurgelun-Todd, 2003).

Limitations in social cognition underlie the difficulties that children on the Autistic Spectrum might experience with socialization. Brain areas responsible for consciousness and emotional processing likely have a big impact on the understanding of mental states (see Frith, 2003).Social cognition of people in the Autistic Spectrum is explained by the theory of "mentalizing deficit", i.e., the inability to understand what is on others' minds (Frith, 2003). Complex mental states (e.g., irony or sarcasm) may cause more problems than basic emotional states (e.g., fear) (see Frith, 2003; Jones et al., 2011).

2 METHODOLOGY

Even though the integration of interdisciplinary knowledge in architecture is a normal practice, the systematic approach to its translation from scientific research into design is uncommon, especially when the knowledge source is scientific research with no obvious relationship to design.

Knowledge about AS was translated into design guidelines using the systematic approach described in detail below. Through the extensive literature review, Key Knowledge (KK) was identified that uncovered typical problems children on the Autistic Spectrum might encounter in their environment. Design Guidelines and Strategies were then proposed to solve these problems.

The studies included in the literature review addressed the following research questions: *What cognitive and neural "abnormalities" are most inherent to the Autistic Spectrum? How these "abnormalities" can affect the interaction between person and environment?* In most cases, studies do not provide the obvious answer to the second question.[3] However, it was critical to identify the potential role of a particular cognitive feature in a person-environment (PE) interaction since it can identify implications for design. To identify this potential role, additional research on similar topics (especially, studies generalizing their findings to real world situations) and concepts from *environmental psychology* were considered.[4]

The literature review was based on the following inclusion criteria: (1) a relationship of the work to established cognitive and neurological theories about the Autistic Spectrum (e.g., Theory of Mentalizing); (2) presence of supportive empirical findings from other studies addressing the same topic; (3) a relationship of findings to high-functioning children on the Autistic Spectrum; (4) publication of the article in a peer-reviewed journal(s). Some studies concerning the lower functioning population on the Autistic Spectrum were also reviewed if their findings could be generalized to a high-functioning population. In addition, if a study was theoretical and had a number of revisions, the most recent revision was reviewed.

The search was conducted using databases that provide knowledge from cognitive psychology and neuroscience: *PsycINFO*, *Psychology and Behavioral Sciences Collection*, *PsycARTICLES* and *PsycTESTES*. For social cognition, 1437 studies were found; 28 studies were reviewed. For non-social cognition (including executive functioning and atypical sensory processing), 986 studies were found; 100 studies were reviewed.[5]

Based on the reviewed literature, the basic knowledge addressing the research questions was identified and analyzed. Finally, the knowledge was summarized into twenty-one concepts representing the Key Knowledge (KK) statements. Twenty-six Design Problems ("Problems") were derived from the KK that cast the KK into a framework for design. Problems were derived by logical inference to a particular condition or environmental feature, which made it easier to translate them into design implications. Essentially, the Problems summarize and interpret the KK statements

[3] Essentially, the lack of direct implications for design in psychological and neurological studies increases the gap between both basic and applied research and between studies of the Autistic Spectrum and environmental design for this population. This gap is a major challenge for translational research.

[4] For review on concepts of environmental psychology see Gifford, 2007.

[5] The references of the reviewed studies were analyzed and additional search was done on any references concerning the research questions.

to provide designers with clear and concise design criteria accompanied by explicit links to underlying knowledge. Design Problems provide a *comprehensive* framework for application of design responses and concern various aspects of the environment, including but not limited to: spatial organization; informational and product contexts; and thermal, acoustical and visual (lighting and color) conditions.

To aid designers in translating the Key Knowledge (KK) to actual design interventions, design recommendations in the form of Guidelines and Strategies were provided. The Guidelines represent the most general level. They can be applied to numerous design contexts and support the creativity of designers. Strategies provide more specific information about how to fulfill the Guidelines and benefit designers that do not have additional knowledge regarding the Autistic Spectrum.

A review of literature in relevant design disciplines was also conducted to identify potential ideas for design solutions and design parameters. Existing design standards, recommendations and empirical studies in building physics were used to understand how issues of indoor acoustics, lighting and air quality could be addressed.[6] The research on impact of color on person-environment (PE) interaction was also considered (see Bosch, Cama, Edelstein & Malkin, 2012). Relevant concepts and theories from the field of environmental psychology were considered, including the concepts of privacy (e.g. see Altman, 1975; Sommer, 1969), wayfinding (e.g., Garling & Evans, 1991) and the theory of situated concepts (Barsalou, 2009). The latter provides an overview of how people process and categorize the information necessary for their actions in the context of different situations (for review see Barsalou, 2009). In addition, sources on the anthropometry of children were considered (Weber, Lehman & Schneider, 1985). This information is especially useful for addressing Design Problems concerned with product design (e.g., furniture parameters). Finally, existing design guidelines for the Autistic Spectrum were reviewed to identify and assess current guidelines and criteria on design for the Autistic Spectrum (see Humphreys, 2008; Ahrentzen & Steele, 2009; Paron-Wildes, 2013).

3 EXAMPLE OF KNOWLEDGE TRANSLATION

3.1 *Key knowledge 4*

People on the Autistic Spectrum have an increased sensitivity to early "low-level" stimulation (i.e., the first perceptual responses occurring in the primary visual cortex) (Belmonte & Yurgelun-Todd, 2003; Mottron et al., 2006; Mottron & Burack, 2001). This may lead to excessively strong reaction to bright color and light, complex textures, rich patterns, and complex contours of objects (see Hilton et al., 2010).

3.2 *Problem 4*

A high level of visual stimuli can create a sensory overload.

3.3 *Guidelines and strategies*

G 4.1: Prevent clutter (Fig. 1).

S 1: Provide storage containers and cabinets for each activity area.

– Storage containers and cabinets should be located close to spaces where the particular activity occurs so the material/toys may be immediately removed when they are no longer needed.

S 2: Provide information board(s) in specific spaces of a classroom to prevent cluttering a classroom's walls.

S 3: Consider using movable boards or table letterboards in each activity area of the LE to transfer the information from walls to areas where it is most relevant.

In addition to Problem 4, there are three more Design Problems derived from Key Knowledge 4. One of them is *Problem 8*.

Bright and intense colors may become a reason for a stress.

3.4 *Guidelines and strategies for problem 8*

*G*8: Prevent exposure of students on the Autistic Spectrum to bright and intense colors in the LE (Fig. 1).

S 1: Use colors in a neutral, minimally saturated palette for background elements of the environment (i.e., elements of environment that usually deserve least attention; e.g., walls and floor). Make sure that excessively high contrasts between objects and background are avoided.

S 2: If items with saturated color(s) are provided to attract attention (e.g., posters), the number of those items should be limited.

– Especially, minimize the use of intense *reds*.

S 3: Primary colors could be used for small objects. Extreme saturation, however, should be avoided entirely.

Figure 1 on the following page represents a mainstream elementary classroom designed to address all Guidelines and Strategies developed through the research project. The annotations highlight only the Guidelines and Strategies discussed above.

Table 1, located on the following page, summarizes all the key knowledge and related design problems identified. Due to limitations on space, details, citations to the literature, and the full set of guidelines and strategies are omitted. It is important to note that not

[6] For review of standards reviewed see IESNA, 2000, and WHO, 1990; for review on empirical studies concerning thermal comfort and indoor air quality see Bako-Biro et al., 2012; Choi et al., 2014; Huang et al., 2014; Ormandy & Erzatty, 2012.

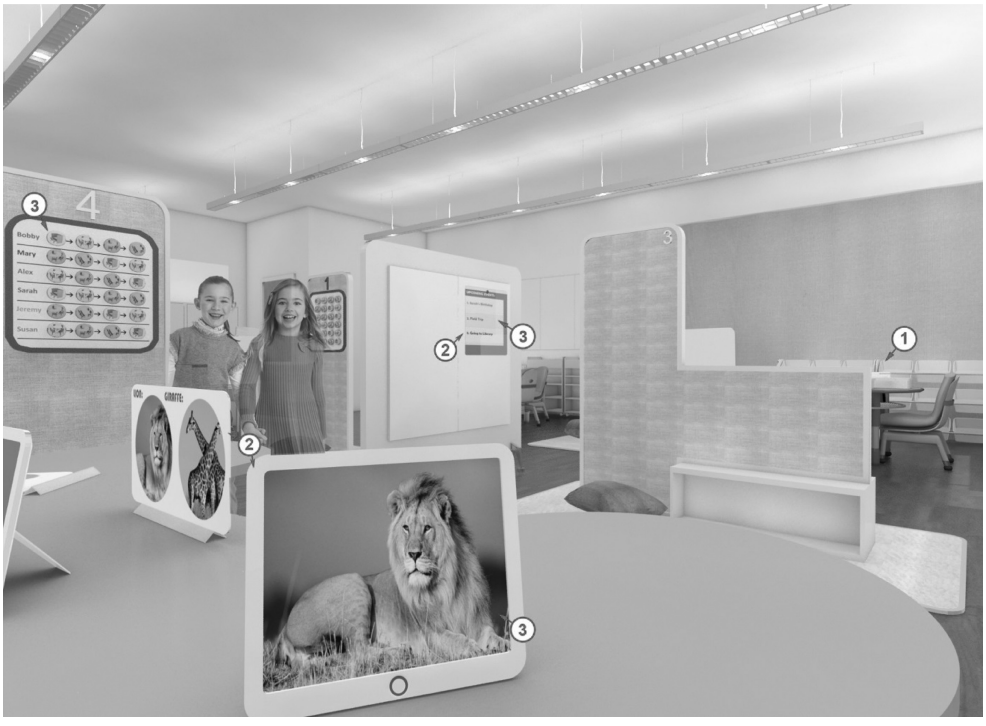

Figure 1. Interior of elementary classroom. Source: Authors.
Annotations: 1 – Storage for learning material is provided near each study zone to control cluttering; 2 – The information board in the center of a classroom and letter-boards on the school desks help to bring the hierarchy in the informational environment; 3 – The overall palette of the classroom is subdued and contrasts are diminished. This provide "soft" visual experience and may help to attenuate irrelevant stimuli and accentuate the relevant ones (e.g., learning tasks, schedules and other important information as highlighted by annotations).

Table 1. Summarized Key Knowledge and Problems.

Key Knowledge (KK)	Problems (P)
KK1: Reduced cognitive and behavioral flexibility can create problems and great stress when transitioning from one occupation/task to another.	P1: An environment that has an *abrupt* change between different activities may be confusing and distressing.
KK2: Exceptional visuospatial abilities lead to distress at small changes in the environment.	P2: Changes in the visual profile of a learning setting after classes may cause inappropriate reaction of students when they return.
KK3: The cognitive mapping process based on episodic, item-related memory rather than on abstract cognitive representations.	P3: Wayfinding will be difficult if there is a lack of visual landmarks and cues on a circulation path and if those cues are visually isolated from each other.
KK4: Excessively strong reaction to bright color and lighting, complex textures, high contrast and complex contours of objects.	P4: High levels of visual stimuli can create sensory overload. P5: Direct and indirect glare, flashing light and very bright light may be exhausting and may hinder the learning process. P6: Sharp contrasts of light and shadows, complex textures and visually expressive artwork may be distracting and disturbing. P7: Complex and unusual shapes may be highly distracting. P8: Bright and intense colors may became a reason for outbursts and stress.

(*continued*)

Table 1. Continued.

Key Knowledge (KK)	Problems (P)
KK5: Sensitivity to high spatial frequency (i.e., average number of spatial elements per unit area).	P9: Objects with many details may reduce attention and cause distraction.
KK6: Negative reaction to inharmonic sounds. Harmonic sounds (e.g., classic music), however, can have a positive and even therapeutic effect.	P10: Loud high-pitch sounds and noise can be highly distressing and may disturb the learning process. P11: A learning environment should accommodate the requirements of music therapy.
KK7: Highly reliant on visual cues in maintenance of postural stability and motoric functioning.	P12: Lack of appropriate visual stimuli can cause clumsy movements and feelings of disorientation.
KK8: Hypersensitivity to tactile stimuli, especially high-frequency vibrations, "fine" textures and hot or cold surfaces.	P13: Materials with high thermal conductivity and fine, "tickling" textures can cause an overload in tactile stimulation and highly irritating experiences.
KK9: Enhanced visuospatial and auditory perception can be a basis for a developing "savant" skills in drawing and music.	P14: The school program and learning environment should accommodate an interest in music and art.
KK10: Development of savant abilities after an encounter with a material-catalyst. KK11: Savant skills can be generalized from one learning material to another by detection of structural similarities.	P15: Failure to provide an access to a specific learning material (i.e., visually clear and well-structured) for students will prevent students from reaching full potential and can hinder the access to culture and development of abstract thinking.
KK12: High-functioning people on the AS have problems with posture and locomotion.	P16: People on the AS are in a greater risk for muskuloskeletal problems due to inactivity
KK13: People on the AS may be inaccurate while executing tasks required a long sequence of complex actions, however, they can use compensatory mechanisms to accomplish such tasks (i.e., "systemizing").	P17: Complex tasks consisting of a large number of required actions, especially multitasking, may be unusually challenging for students on the AS. A failure to accomplish task can be the reason for anxiety and reduction in motivation.
KK14: People on the AS might be unable to construct concepts that lie beyond the present reality (e.g., concept of place based on its function) but be able to construct the concepts that are visually evident (e.g., table and chairs of the same color as a concept associated with a place for study).	P18: Elements of the environment that are not linked by a common visual feature (e.g., color) limit the abilities of those on the AS to construct concepts (i.e., mental images of objects or environments). This leads to a diminished capacity of action planning and hinders goal-oriented behavior.
KK15: People on the AS can have problems in perception of complex stimuli leading to a reduced situational awareness (e.g., walking people; book falling from the shelf).	P19: Intrusions into personal space and undesirable encounters with other people are more likely since people on the AS are less aware about movements of others. P20: Unstable objects can become a serious threat to safety in the LE.
KK16: Perceptual connections are enhanced when stimuli are organized in a regular manner (i.e., objects set up on the same axis) the sense of clarity and pleasantness can occur.	P21: The visually disorganized LE may hinder comprehension and diminish clarity.
KK17: Some individuals on the AS have limited ability to perform motor tasks requiring strong coordination of actions (e.g., trying to reach the book standing on the tiptoe).	P22: The environment that does not provide an easy physical access to functionally important items may seriously limit functioning and performance of students.
KK18: Selection between two competing alternatives is believed to be limited.	P23: Choices for action that look similar may be confusing and may increase anxiety.
KK19: Weak immune defence against external infections.	P24: An environment that exposes students to inappropriately low temperatures and infections are particularly dangerous for people on the AS.
KK20: Lack of fear in response to real dangers and excessive fearfulness in response to innocuous objects or situations.	P25: Interaction with objects and activities may cause injuries (e.g., scissors) are particularly dangerous for students on the AS.
KK21: Diminished interest in collaboration, acceptance and avoidance of rejection.	P26: Avoidance of collaborative environments can negatively affect overall motivation for learning.

all people on the Autistic Spectrum have all the behavioral, cognitive and health conditions identified in the key knowledge summaries. In fact, the great variation among individuals adds to the challenge of designing learning environments for this group. Flexibility and options, therefore are critical overarching design goals to provide educators with an environment that can be easily adapted to the specific needs of the students in a class.

4 CONCLUSIONS

The current study provides a knowledge translation model as a tool for producing design recommendations for elementary classrooms accommodating the needs of high-functioning children on the Autistic Spectrum. The model supports systematic and transparent knowledge transfer from the fields of cognitive psychology and neuroscience. The proposed model provides a valuable framework for other applications of scientific knowledge in design. Moreover, the method for translation of scientific knowledge and its integration into design can be useful as a prototype for knowledge translation in other domains. The main limitation of this work is that formulated Guidelines and Strategies are not yet tested. The next step in this initiative will be the implementation of the proposed design recommendations and assessment of their efficiency through Post-Occupancy Evaluations (POE) and experimental studies (see Gifford, 2007). A second limitation is that the proposed design recommendations are mostly focused on interior design. This provides simple and cost-effective design solutions that can be applied to re-design of existing learning spaces to facilitate mainstreaming. Nonetheless, design solutions of other types and character (e.g., the spatial organization of buildings) are a worthy topic for investigation that would help broaden the application of the key knowledge identified.

ACKNOWLEDGMENTS

Dr. Sue Weidemann, Adjunct Professor, and Dr. Korydon Smith, Associate Professor at the Department of Architecture, University at Buffalo, provided support and advice during the research phase of the project. Dr. Martin Volker, from the Center on Autism Research at the University at Buffalo, provided invaluable general advice about the Autism Spectrum and guidance in the literature review. Dr. Andrew Marcum, Post Doctoral Fellow at the Disability Studies Program, University at Buffalo, provided very helpful criticism of a draft of this article.

The impact of patient room design on airborne hospital-acquired infections

A. Copeland & A. Sharag-Eldin
Kent State University, Kent, Ohio, USA

ABSTRACT: Transmission of airborne diseases in healthcare facilities is an increasingly important concern. This, in part, is due to the reduction in funding from insurance companies for hospital-acquired infections (HAI) and the consequent economic impact of an influenza outbreak in a hospital. With increasing cases of HAI in the USA, it became necessary to examine the current ventilation standards for healthcare facilities. While design guidelines have focused on recommending appropriate ventilation rates, it ignored the delivery of conditioned air to occupied spaces and the impact of room layout relative to the placement of air supply and return. The paper will also estimate the probability of infection based on air change effectiveness, and the relative spatial relationship between HVAC air delivery system and room design. The resulting outcome is a guideline intended to support health facility designers.

1 INTRODUCTION

Today's regulatory air quality standards for healthcare facilities effectively maintain heating, cooling, and ventilation requirements in the acute patient room by fulfilling overall air change rates. American Society of Heating, Refrigeration, and Air-conditioning Engineers or ASHRAE require that air changes occur to keep fresh air continuously entering spaces. However, this guideline does not suggest how to remove effectively contaminated air that may be caught in dead zones affected by room design. The standard does not consider that the air being mixed in the ventilated spaces is allowing clean air to be mixed with contaminated air.

These airflow patterns created by the ventilation contribute to air-temperature, distribution, thermal comfort, air quality, and the possibility of airborne pathogen transmission within a space or spaces. Airflow patterns of existing rooms need to be studied in order to understand pre-existing relationships between location and type of supply diffusers, supply airflow rates, supply temperature, return air location and size, infiltration, furniture arrangement, heat sources and location of the patient and others in the room.

Influenza was chosen in part because of its seasonal and continued yearly effects on populations as well as its lower quantum level. The quantum level explained more fully in the risk assessment method portion, is a measure of the infectious material present and the pathogenicity of that material (Wagner et al. 2009). Other airborne threats such as Tuberculosis and SARS would yield a larger quanta production rate.

Studies have been done proving influenza as an airborne threat within hospitals at close range like that in patient rooms (Blachere et al. 2009, Brankston et al. 2007). However, there have only been a few significant studies showing how airflow patterns can be affected by supply and return vents as well as room configuration. A review article lead by Dr. Yuguo Li in 2007 found only 40 studies focusing on ventilations impact on airborne transmission in the built environment cataloged between 1960 and 2005. Of these forty studies, only ten were deemed conclusive by a team of multidisciplinary reviewers. These conclusive studies had met the teams determined the evidentiary threshold, and provide strong evidence on ventilation effects of airborne transmission of diseases including Tuberculosis, SARS, Influenza and chickenpox (Li et al. 2007).

Most recently a study using computational fluid dynamic modeling was completed by Khankari. Two mechanical placements were tested in one patient room to show resultant airflow patterns (Khankari 2015). The information gathered from this study can be significantly furthered by looking at two common patient room designs and computational fluid dynamic models to test a plethora of supply and return air locations relative to the patient, caregiver, and door.

The following study using a calibrated model verified by field measurements of air distribution patterns in patient rooms. In addition to airflow patterns, the CFD algorithm is used to determine the age of the air to measure the effectiveness of the recommended air changes in the standards delineating through graphical and numerical means the potential location for concentrated airborne contamination. It is also intended to encourage the development of design codes and standards that take into account airborne pathogen transmission in places where the patient is most vulnerable to infection from visitors or staff.

2 RESEARCH METHOD

2.1 *Room criteria and selection*

The geometries selected and tested in this paper correspond with the general trends in the healthcare design field. While shapes and sizes of rooms can differ drastically, three average room sizes were selected to correspond with small, medium and large patient room sizes.

The room sizes are as following 21.4 m^2 (230 ft2), 27.87 m^2 (300 ft^2) and 34.84 m^2 (375 ft^2) all inclusive. The sizes address the possibility of the implementation of universal or acuity adaptable rooms in all sizes and critical care patients in the larger room size (Brown & Gallant, 2006).

The patient rooms used for the simulation follow the FGI Guidelines for Hospitals and Outpatient Facilities 2014, thus having private bathrooms, and glazing that is no less than 8% of the floor area of the room served (2014 FGI Guidelines for Hospitals and Outpatient Facilities 2014).

Each room tested is rectangular in shape and propose either an inboard bathroom located at the entrance of the patient room or outboard bathroom, located along the exterior wall of the room and building. The bathrooms are placed on the headwall, or where the patient's head is located near the wall in bed with supply air being placed above the patient bed and return located near the door to the patient room. The supply diffuser is a 4-way diffuser supply air with six (6) air changes per hour calculated by room's volume from finish floor to 6 ft above.

2.2 *Computational fluid dynamic modeling*

Computational Fluid Dynamic Simulation focuses on the numerical and algorithm modeling of fluid flow and heat transfer processes. Given boundary conditions including climate, internal energy sources, and HVAC systems CFD simulates a building's likely internal or external airflow.

The numerical solution of the airflow simulation uses differential equations to find values of flow quantities at certain points of a system. These values are then converted to a system of algebraic equation that represent the interdependency of the flow at each point (Sayma 2009). The points correspond to a grid or mesh used by the modeling system.

2.3 *CFD modeling*

IES VE has been tested and fully validated under ASHRAE Standard 140. The IES VE program allows for dynamic thermal simulation, including design load calculations, and simplified computational fluid dynamic modeling. IES VE primarily focuses on integrated graphics-driven results, however, does allow for simple numerical analysis based on points located within the graphic model.

IES VE uses the k-epsilon turbulence model to find the turbulent viscosity of a 3D space. The standard

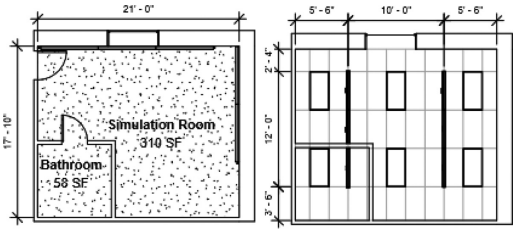

Figure 1. (Left) Simulation room layout, (Right) simulation room ceiling plan

k-epsilon model is widely accepted due to its applicability to wide-ranging flow situations primarily looking at internal flows with weak streamline curvature models. The equation solves for the kinetic energy turbulence and the dissipation of the kinetic energy (Awbi 2003).

While the standard k-epsilon turbulence model is accepted it has limitations when more complex flows are being studied, and the length scale for the determination of turbulence can only be speculated. The RNG k-ε or renormalization group model and low Reynolds number k-ε model are more accurate when considering forced convection or mixed convection turbulence models, while the Large Eddy-Simulation (LES) model is a more accurate predictor of flows with strong streamline curvatures (Awbi 2003).

IES VE's MicroFlo 3D Computational Fluid Dynamic modeling application was used to simulate different conditions. Boundary conditions such as America's northeast climate were applied to the model through the Apache application that uses weather data to provide an environment for the evaluation of a building and system design. Thermal comfort conditions were regulated by specifying HVAC system and placement based on ASHRAE 170, 2013 healthcare patient room standards including required air changes per hour (ACH) and humidity.

MicroFlo produces a visual representation of an internal space's airflow based on velocity, concentration of CO^2 and local mean age of air. Local mean age of air (LMA) is the amount of time a parcel of air has been in certain areas of the simulation space. Higher values indicated areas with poor ventilation.

2.4 *Calibration*

In order to calibrate IES VE an educational nursing simulation room was tested with field measurements to prove that results gathered from IES VE would be correct. The nursing simulation room was located in Northeast Ohio and had an overall area of 34.19 m^2 (368 ft^2). The field measurements were taken on two days November 2nd and November 23rd, 2015.

2.4.1 *Field measurements*

Field measurements were performed in the nursing simulation room, 5.43 m (17.83 ft.) (L) × 6.4 m (21.0 ft.) (W) × 3.05 m (10 ft.) (H), with the bed located on the same wall as the bathroom shown in

Table 1. Boundary Conditions for Patient Rooms.

	Flowrate	Temperature	
	CFM*	°F	°C
Small Room	252	70	21.1
Medium Room	315	70	21.1
Large Room	400	70	21.1

*CFM based on required 6 air changes/hour per ASHRAE 170

Table 2. Simulation Room CFD Simulation compared to field measurements

Height ft.-in.	Average Velocity – Simulation ft. /mins.	Average Velocity – Field Measurements ft. /mins.
0′-6″	4.74	5.625
3′-6″	8.15	10.375
6′-0″	12.11	12.5

figure 1. The air is supplied and returned through linear slot diffusers located at the ceiling. The room is illuminated by six $2' \times 4'$ fluorescent lights, one located within the bathroom. Measurements were taken at 3′ grid intervals, at 0.15 m (6 in.), 1.1 m (3.5 ft.), 1.8 m (6 ft.) above the floor. A TSI indoor air quality meters model 8386A and 8760 were used to measure temperature, humidity, carbon dioxide and air velocity at nine specific points.

The boundary conditions that would be completed by IES VE were also collected; like wall surface temperature, outside temperature, and current weather conditions.

IES VE run of simulation room. The simulation room's CFD run had boundary conditions estimated from the field measurements, including outside temperature as well as surface temperatures. The supply air was delivered through slot diffusers that were equivalent to 360 cfm, approximately 6 ACH. The simulation room also used perimeter radiators located on the exterior walls, causing higher surface temperatures on the respective walls.

2.5 *CFD runs of patient rooms*

The selected six room designs for patient rooms were tested through IES VE, similar to the simulation room specific data was collected through the micro flow runs at three specific heights .15 m (6 in.), 1.1 m (3.5 ft.), 1.8 m (6 ft.). Each room was supplied with 6 ACH, the required ACH per ASHRAE 170. This required 252 cfm for the small, 315 cfm for the medium, and 400 cfm for the large patient rooms in order to satisfy the required 6 ACH.

The results all pertain the same climatic influence, boundary conditions that coincide with February 8th. Each result is reflecting sixty minutes of time, the length of time for the required amount of air changes to take place.

2.6 *Data analysis*

2.6.1 *Risk assessment: Wells-Riley equation vs. Gammaitoni-Nucci equation*

Local mean age of air and Velocity of air vectors in the different patient rooms are analyzed to see if any significant differences were seen in various room sizes or layouts.

The risk of transmission is evaluated using the steady state Wells-Riley equation and non-steady state Gammaitoni-Nucci equation. Exposure times can vary in patient rooms from days for a patient to as little as a few minutes for a staff member. Thus, the risk of transmission is influenced by chance events (Beggs et al. 2010).

The Gammaitoni-Nucci equation is a modified version of the Wells-Riley equation that reflects the exponential increase in the number of new cases of infections in a room. The Gammaitoni-Nucci equation takes into consideration the transient behavior of transmission over shorter periods of time, and that not every newly infected person may infect another due to their short time in a particular space (NOAKES et al. 2006). The equation considers room volume, which varies per room size, ventilation rate, and the quanta production rate. The quanta production rate is best explained as the infectious dose required to infect 63.2% of the people in the affiliated enclosed space.

The mean quanta production rate for influenza that is used for the Gammaitoni-Nucci equation is 100.0 quanta/h, value for a highly contagious case (Rudnick & Milton 2003). However, there is still dispute over an official range of quanta production rate for Influenza; it can vary from 15-128 q/h depending on which steady or non-steady state Wells-Riley equation used to determine the quanta production rate.

The equation assumes ventilation as a large factor in particle removal while it is a significant source, many other sources also factor in pathogen settlement (Rudnick & Milton, 2003). For Influenza A, an important factor in pathogen removal is inactivation through settling, thus removed from the air but not the space entirely. The equations do not take into consideration that outside factors such as temperature, humidity and settling can have an impact on a person's risk of airborne infection.

3 RESULTS

Each CFD run resulted in velocity quantities and local mean age of air approximations that differed based on room size and layout, inboard vs. outboard. The LMA or local mean age of air and known volume of the rooms were then used for a risk analysis of Influenza A in those respective rooms using the Wells-Riley and Gammaitoni-Nucci equations.

3.1 *Simulation room CFD run*

The simulation room's CFD model ran closely to the documented field notes. The boundary conditions

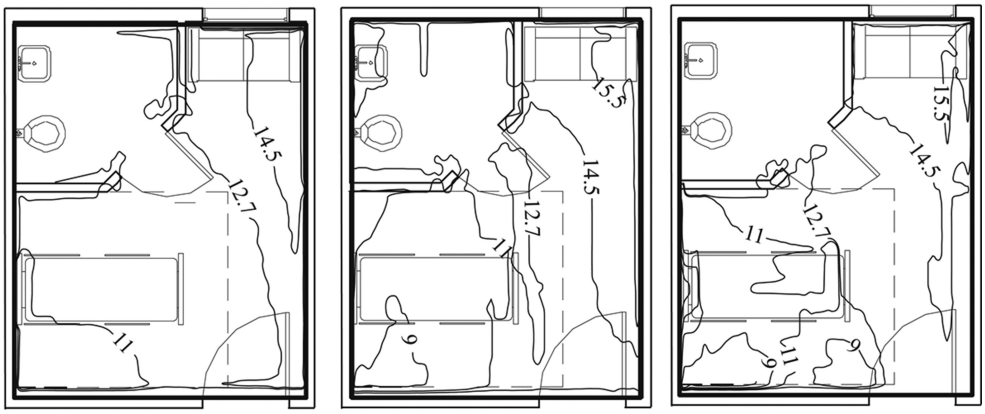

Figure 2. Small outboard room (left: 0′–6″ AFF, middle: 3′-6″AFF, right: 6′-0″ AFF) LMA in minutes.

were controlled by the data obtained from the field measurement like surface temperature and input air temperature. Table 2 shows the averages for each differing height level for the simulation room CFD model compared to that of the field measurements.

3.2 *Room comparison*

3.2.1 *Size*

The selected rooms varied in size; small, medium and large. Figure 2 shows the differences of air age in the different patient rooms. Overall, the size did not have a large impact on velocity and air age; rather design had an impact on the mean air age at different areas in the room.

3.2.2 *Layout*

3.2.2.1 Inboard patient room

The inboard CFD model showed that the air is circulated relatively consistently among all room sizes, and the local mean age of air is similar throughout the rooms, ranging from 10.9 minutes to 12.7 minutes. Local mean age of air is older or higher in the bathroom if the door remains open, resulting in air age of 14.5 minutes. This, on average would approximately result in 6 ACH per hour, each air change taking on average 10 minutes.

3.2.2.2 Outboard patient room

The outboard patient room is relatively different when it comes to local mean age of air throughout the space. The CFD model shows that the back zone in all the outboard rooms have older air parcels as shown in figure 2. This area has air that is an average of 15 minutes old, which would be the equivalent of 4 ACH while the area around the patient bed has an average air age of 10.5 minutes which would result in the required 6ACH.

This air change discrepancy is significant the risk of transmission will significantly increase in the areas of poor circulation. The following mathematical risk assessments show the increased risk associated with the poor circulation.

3.3 *Risk assessment*

The Wells-Riley steady rate and Gammaitoni-Nucci non-steady rate are mathematical models that predict the rate of airborne transmission. The Gammaitoni-Nucci model is better suited for short-term exposure models. However, both will be used and compared to understand the risk of transmission. Each room is analyzed using the average ACH. Thus the outboard will be broken into zones and analyzed according to the different LMA associated with the different zones of the room. The differing LMA would result in a different ventilation rate for that space, so instead of the required 6 ACH there may be less in poorly ventilated areas.

3.4 *Local mean age of air*

The mathematical risk models predict the transmission of airborne disease and are based on flow rate or the ACH. However, a dimensionless equation that shows how efficiently different room airflow structures remove contaminants regardless of the flow rate can also be utilized (Bartak et al. 2001). The following table 3 shows the efficiency of the airflows in the six rooms. The outboard rooms were broken into different volumes based on average local air age to understand the changing efficiency rates with relation to the local mean age of air at points within the room.

3.5 *Comparison between mathematical risk assessment models*

It is important to understand the above table shows three drastically different equations, and in turn drastically different results. The Wells-Riley results show the potential for new cases in an exponential increase or decreasing form. If the results are less than 1 ($a < 1$) the pathogen would be removed or settled before infecting any of the susceptible targets while the results that are greater than 1 ($a > 1$) would result in increasing pathogen transmission. Therefore, the zones that were identified as poorly ventilated in the

Table 3. Mathematical Risk Assessment Models and Efficiency of Airflow in Patient Rooms

Room Design and Zone	Wells-Riley *	Wells-Riley with required 6 ACH	Gammaitoni-Nucci	Gammaitoni-Nucci with required 6 ACH	Airflow Efficiency (Bartak et al., 2001)**

22.1 m^3 @ 14.5 LMA	2.0411	0.3410	0.4087	6.82%	3.4752
Large Inboard	0.3708		0.0611		0.5097

*Solves for P, a dimensionless exponential increase of new cases **The lower the number, the higher the efficiency of airflow

outboard design have an increasing chance of infection, while the inboard room and better-ventilated areas in the outboard would not.

The Gammaitoni-Nucci results are based on percentages. Thus, the results that are shown as decimals could also be shown as the equivalent percentage (i.e. large inboard: $0.0611 = 6.11\%$). Again, like the Wells-Riley model the inboard rooms have well-mixed air resulting in a low percentage of people that will contract Influenza through the airborne route. Contrastingly, the particular outboard room zones that have nominal ventilation result in a probability of infection of 35–40%. It is important to note that this model predicted at the likelihood of an individual who has been in the room with the infected for an hour.

Furthermore, if 15 minutes were used as the exposure time rather than an hour the probability of a susceptible person being infected would decrease (i.e. Small outboard patient room, the poorly ventilated area decrease by 86% from a 35% probability of infection to a 5% probability). The required 6 ACH in a well-mixed and ventilated room would drastically decrease the probability of a person becoming infected. However, depending on room design parts are not getting ventilated properly, and the air age is increasing.

Lastly, the equation used by Bartak and others takes the relationship between air age in the room of certain volumes to find the efficiency of the airflow, while not considering the ventilation rate. Similar to the Gammaitoni-Nucci model, if 6 ACH were achieved everywhere in the room regardless of the design, the airflow efficiency in the rooms would be improved.

4 DISCUSSION AND CONCLUSION

4.1 *Significance*

The main regulatory source for healthcare facilities' ventilation systems is ASHRAE 170. The standard is also included as part of the FGI Guidelines for Hospitals and Outpatient Facilities 2014. According to ASHRAE, non-critical patient rooms should receive 6 ACH, with a minimum of 2 outdoor ACH. Many studies have been completed that have been the basis of ASHRAEs regulations that dictate 6 ACH. However, from this study, not all patient rooms can be considered suitable with 6 ACH. The design has to be taken into consideration when writing and considering minimum ventilation standards.

While the airflow in the inboard patient rooms was effectively shown by the local mean age of air, the outboard patient room airflow was less than effective for circulating fresh air. The rooms tested were linear in design and less suitable room designs may be found if tested.

The outboard design's least effective space is what is used for family and visitor zones. The regulations primarily have supply outlets located over the patient beds to protect the patient from airborne infection. However, this leaves visitors and staff more susceptible to airborne infection like Influenza A as well as other more transmissible diseases.

The airflow effectiveness is necessary to prevent airborne disease within the room. As seen using the mathematical risk assessment models the air age has a large impact on Influenza A infection probability.

Thus, ventilation with room design in consideration can effectively be a primary measure against airborne infections like Influenza A or another airborne disease. However, ventilation regulation needs to focus on how design impacts spaces and its result on the ventilation needs.

4.2 *Limitations and considerations*

This study primarily focused on two designs of patient rooms which leaves many geometric configuration untested. Thus, it would be suggested that room designs are tested to understand ventilation properties for better efficiency and prevention measures

The supply and return air were also only tested at one location with the supply air above the patient bed and the return near the exit. Other placement could have shown more effective ventilation strategies, and should be considered to maximize effective airflow. While other ventilation strategies should be explored, 6 ACH have been found to be adequate as long as the room is receiving the adequate airflow that allows for the required ACH. Thus, possible added supply to evenly distribute air may also be an ideal strategy.

Limitations of the CFD modeling include the software used IES VE is a simplified CFD program that is based more on visual representation. Thus, LMA numbers are based on produced contours and not actual data points. Furthermore, a more complex system could produce more data per cell better to understand small air vector characteristics like eddies instead of the general room level airflow analysis. The Standard k-epsilon turbulence model is also found to over-predicts the gas turbulence kinetic energy which results to a high turbulence viscosity, and an estimated over mixing. Thus, the result could be showing slightly better conditions than what exists in the rooms (Tian et al. 2007).

The mathematical equations assumed an hour of exposure while many times visitors or staff are in the areas for shorter periods of time. The quanta used for Influenza, $q = 100$, is suggested as a highly infectious strand. There is controversy over the actual quantum of a disease due to significant variance quanta can have. The quanta itself measures the infectious material present and the pathogenicity of that material. However, the consideration for droplet evaporation and settlement is still disputed (Wagner et al. 2009).

The equations are also based on an assumption that the room air is well mixed and has a proportional distribution of quanta or infectious material throughout (NOAKES et al. 2006). Due to this assumption, the equations were used in the different zones that have visibly different airflow efficiency as shown by the CFD models.

Lastly, other airborne diseases could have a significantly higher or lower risk of infection based on their quantum level. A study by Qian estimated that the SARS quantum level ranged from 2460–4680 contingent on filter efficiency. These quanta levels are drastically higher than the tested Influenza quanta level and would lead to a faster and more devastating transmission rate (Qian et al. 2009).

Quality of life by design: Study of space usage for affordable housing in Harbin, China

Mohan Wang & Hongyuan Mei
School of Architecture, Harbin Institute of Technology, Harbin, Heilongjiang, China

Xuemei Zhu
Department of Architecture, Texas A&M University, College Station, Texas, USA

ABSTRACT: Chinese government provides affordable housing in the cities to help cope with the housing shortage for rural-to-urban migrants. But there is limited research on these residents' needs and preferences. This study examined the space usage in affordable housing for migrants, and provided corresponding design recommendations for improvement. A post occupancy evaluation was conducted using mixed methods including design analysis, surveys (N = 0), and semi-structured interviews (N = 9). Findings revealed three main problems, including: (a) space being too cramped (mean usable floor area = 37.20 m^2) for the household size (mean = 3); (b) storage space being insufficient; (c) space arrangement not accommodating multifunctional usage. Based on these findings, potential design strategies were proposed to improve space arrangement and quality of life in affordable housing.

1 INTRODUCTION

China is now witnessing "the largest migration in human history" (Avent 2012). The trend of rural-to-urban migration has continued for over 30 years. In the next two decades, there will be another 320 million rural migrants moving to cities in China, which is equivalent to the total U.S population (Pierson 2011). This leads to the population boom in urban areas, and as a result, the shortage and unequal distribution of resources, especially housing (Ford 2007). While moving to the cities for employment opportunities, the migrants face a huge gap between their low income and the high housing cost in cities (Sicular et al. 2007). As a result, some of the new migrants from rural areas have to live in undesirable environments, move from place to place frequently, and/or be separated from their families for a long time period.

On the other hand, Chinese government provides affordable housing for low-income urban populations, including rural-to-urban migrants, to help cope with the housing challenge. During China's 12th Five-year Plan (2011–2015), 36 million affordable housing apartments were built, accounting for 20% of China's total housing supplies (by both market and government).

Such projects are supported by the government as one of the most important initiatives directly related to residents' well-being and quality of life. They are provided for purchase or renting at prices that are much lower than the market housing price. In order to reduce the construction cost and ensure affordability, they typically feature small dwelling sizes and address minimal functional needs. The building area of each affordable apartment is strictly limited by provisions published by the government. For example, the per capita living space of affordable apartments should not exceed 60% of the local average. This means an upper limit of 60.00 m^2 per dwelling unit and 15.67 m^2 per person based on China's national average in 2005 (Jiao 2008). The government expects improvement for affordable housing in the coming years, with the per capita living space reaching 20 m^2 by the year of 2020 (Ministry of Housing and Urban-Rural Development of PRC 2004). But that is still a tight space limit. In such contexts, the efficiency of spatial arrangement becomes especially important in these affordable housing projects.

Previous studies on these affordable housing projects have examined the design of dwelling units, building arrangements, and neighborhood open spaces. There are two main trends in this line of research. One trend is to examine how different locations, climate, or policies impacted residents' attitudes. For example, Sun (2014), Zhou (2011) and Wang (2008) used surveys in Changchun, Wuhan and Beijing respectively to examine the affordable housing residents' spatial preferences and needs. The other trend is to develop new methodologies for the design and provision of affordable housing. For example, Li (2014) and Zhang (2013) studied how to apply the modular design methods into the affordable housing projects in order to enable more efficient construction. Feng et al. (2012) developed a design process for

affordable housing, in which the future residents could be involved from the beginning of the project development.

Despite these studies, no post occupancy evaluation has been conducted to investigate residents' satisfaction with their current affordable housing, and to explore potential improvement for these living arrangements. Further, no previous study has given special attention to the population group of rural-to-urban migrants, which is one of the main target groups for affordable housing in China. Considering the urgent needs for large-scale constructions of affordable housing in China, this is an important research area that warrants more studies.

2 BACKGROUND AND STUDY SETTINGS

This study addresses this gap of knowledge by conducting a post occupancy evaluation of three affordable housing projects in Harbin – a major city with 9.94 million population in Northeast China. Located above 45 degrees north latitude, Harbin is known for its extremely cold winter weather and the longest winter duration among major Chinese cities (Harbin Government, 2016). The city government invested heavily on the affordable housing development. From 2008 to 2013, over 10 billion Chinese Yuan (about 1.5 million U.S. dollars) was invested to plan and build affordable housing projects, which housed over 148,000 residents with a total of 820,000 m^2 living space. However, because of the cold weather, more building areas are occupied by the thermal insulation materials compared to warmer areas, resulting in a lower ratio for the usable areas in the dwelling space. How to make the limited dwelling space more efficient is a significant challenge for the city.

The study settings are three newly developed, exemplary affordable housing projects in the city, with similar locations, dwelling unit sizes and occupancy rates. They are also all mixed income communities that provide both affordable housing and commercial housing. Although the total building area and the population are somewhat different across three projects, the average size and design of affordable dwelling units are approximately equal. These provide an opportunity to pool the data from these projects for analysis.

Project I is one of the largest affordable housing projects in the city of Harbin. Constructed in the center of a newly developed residential area, it is 10 kilometers away from the original downtown area. This project provides seven types of dwelling units for affordable housing, with a total building area of 69,800 m^2. It houses 1,256 low-income families with over 40% of them being rural-to-urban migrants. For Project II, the building area for affordable housing is only 4,900 m^2, which is much smaller than that of Project I. Located 9 kilometers away from the downtown area, it has six types of dwelling units that accommodates 95 low-income families, within which about 60% are rural-to-urban migrants. Project III is located much closer to the city center, being only 4 kilometers away. It provides four types of affordable dwelling units and houses 106 families, among which 53% are rural-to-urban migrants.

3 OBJECTIVE

The primary aim of this study was to better understand the space usage pattern and the environmental needs of the rural-to-urban migrants living in these affordable housing projects. The secondary aim was to provide corresponding design recommendations for future development based on study findings. This post occupancy evaluation was conducted in 2014 and included three phases: initial design analyses, neighborhood surveys, and semi-structured interviews. The first two phases were intended to identify the space usage problems and expectations of the residents. As a follow-up, the third phase was to provide recommendations for future projects in order to optimize space arrangement and improve quality of life.

4 METHODS AND RESULTS

4.1 *Design analysis*

Design analysis was conducted through systematic reviews of the original construction documents, to identify the basic information about projects such as locations, construction times, and design details. We also calculated the average dwelling size per unit and per person.

The three neighborhoods were designed and built in similar years and located in newly developed residential areas, which were several kilometers away from the city center. They were designed based on the same guidelines and built in similar city environments (Table 1). As shown in Table 2, although the building sizes and populations of these projects were different, the average dwelling sizes per household and per person were similar. What is more, the average usable area per household (37.20 m^2) and per person (12.37 m^2) were much smaller than the national affordable dwelling unit standard of 60.00 m^2 and 15.67 m^2, respectively. These results implied that the space might be too cramped for daily use. This situation might be partially due to the low ratio of the usable area in northern cities like Harbin where the weather was extremely cold in winter, and as a result, thick thermal insulation materials are used.

4.2 *Surveys*

Surveys were conducted to obtain information about the current living behaviors, needs, and existing problems from the rural-to-urban migrants who lived in these affordable apartments, and to gain in-depth understanding about the reasons for these problems as well as potential opportunities for improvement. Survey results were also used to guide the development

inside the walls.

of the semi-structured interviews in the following phase. In each selected housing project, questionnaires were administered in person to 35 adults living in the affordable apartments, and researchers were present when respondents filled out the questionnaires and available for answering questions. Non-probability sampling and screening questions were used to recruit rural-to-urban migrants.

The questionnaire included seven sections organized according to spatial functions. It asked about respondents' opinions about and preferences for the space usage after moving into the affordable apartments, as well as their personal and social factors that might have influenced these outcomes. The usage efficiency of different functional spaces were addressed in the surveys. Also included was a set of questions about the residents' attitudes to certain facilities in the apartments. Most of the questions were developed by the China Architecture Design & Research Group, and several new questions were added by the researchers based on the specific construction and usage characteristics in Northeast China. The final surveys took 15–20 minutes to complete. After the survey results were collected, valid and complete surveys were included in analyses using Excel 2013. Descriptive statistics were examined.

Sample Characteristics. A total of 90 valid responses were collected, yielding a response rate of 85.7%. The sample included 41.0% of females and had a mean age of 48. The sample households had a mean family size of 3 persons. In terms of education level, 4.5% had Bachelor's or higher degrees; 28.9% was trained in and got the diploma from certain technical colleges; 18.9% had high school diplomas; 17.8% had middle school diplomas; and 29.9% had other types of lower education. The household incomes per month were diverse, with 22.2% in the 3,000 or more Chinese Yuan category; 34.4% in the 2,000–3,000 Chinese Yuan category; 31.1% in the 1,000–2,000 category; and 12.3% in the 1,000 or lower category. As for the occupation status, over 44.4% were unemployed; 30.0% were employed; and 25.6% were retired.

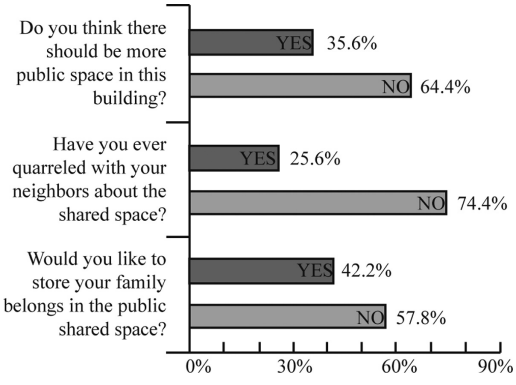

Figure 1. Percentage of respondents reporting opinions about public space in the affordable housing building.

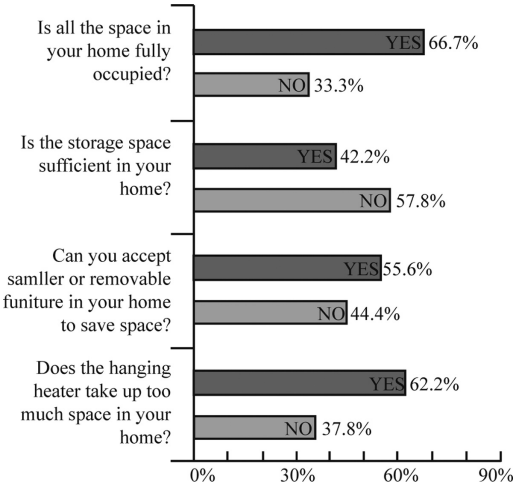

Figure 2. Percentage of respondents reporting general opinions about private indoor space.

Descriptive Statistics. The 34 questions were divided into seven sections based on functions, including two general sections for public spaces and private spaces, respectively; and five sections for specific functional areas including the living room, bedroom, kitchen, restroom, and balcony. In the first section about public spaces in general (Figure 1), 64.4% of the respondents reported there was no need to increase the area of the public spaces in the buildings; 25.6% reported they had quarreled with neighbors for reasons related to shared space; and 57.8% thought they could not store their belongings in the public space, such as public corridors Figure 2 shows results from the second section about private spaces in general. Because of the limited space, over 60.0% reported that all the space at home was fully occupied and there were no extra space to place more furniture or facilities. Only 42.2% considered the storage space to be sufficient in their apartments. About 55.6% would accept smaller or removable furniture because of the cramped space. Further, the survey asked for residents' opinions

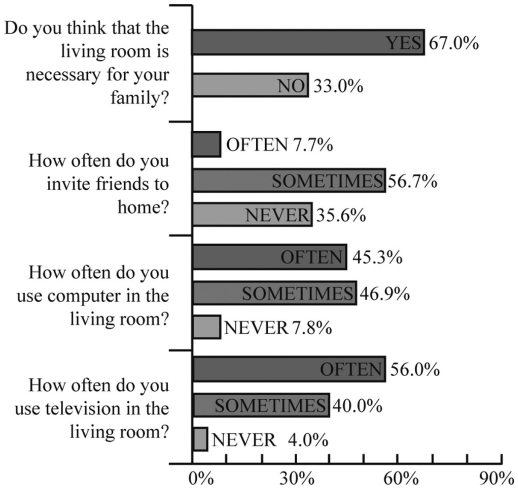

Figure 3. Percentage of respondents reporting specific opinions about living room.

about the steam heater hanging on the wall, which is more common than the underfloor heater and the air conditioner in Northeast China. Over 90.0% of the respondents thought the hanging heater took up too much space in the rooms and made the space more cramped.

In the third section about the living room (Figure 3), 67.0% considered the living room to be necessary for family daily use, but only 56.7% used the living room was to meet friends. Furthermore, 35.6% said they never invited friends to their living rooms after moving into the apartments. In more occasions, they used the living room for family entertainment. The percentage of respondents who used the computers and televisions in the living room was 92.2% and 96.0%, respectively. As for the fourth section about the bedroom (Figure 4), 49 out of 90 (54.4%) thought it would be better to provide floor-to-ceiling wardrobes in order to better use vertical space. In that way, a smaller floor area would be occupied to obtain the same storage volume. However, most of them (78.9%) did not like using bunk beds for saving space.

The fifth section is about the kitchen (Figure 5), which was considered necessary by most of the affordable households (92.3%). About 66.7% of the respondents cooked at home almost every day, and 25.6% cooked at home occasionally. When it comes to the space saving issues, more respondents (62.3%) preferred smaller refrigerators, which could be placed near the stove. Conversely, fewer people would like to use open kitchens and removable stoves to save space. This is probably because of the cooking habits in Chinese culture, which tend to produce heavy smoke from heated cooking oil. In the sixth section about the restroom (Figure 6), 57.8% of the respondents preferred having more space for storage. However, 68.9% of the respondents preferred pedestal pans for comfort although they occupied more space than squatting pans.

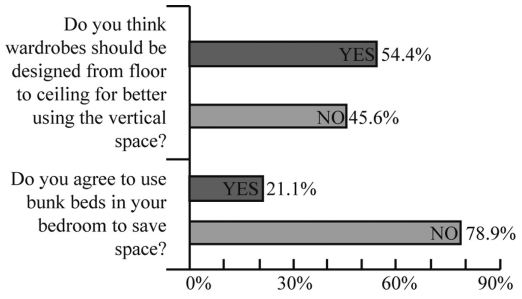

Figure 4. Percentage of respondents reporting specific opinions about bedroom.

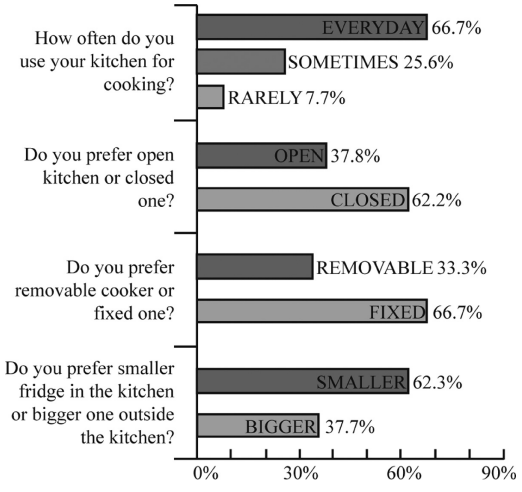

Figure 5. Percentage of respondents reporting specific opinions about kitchen.

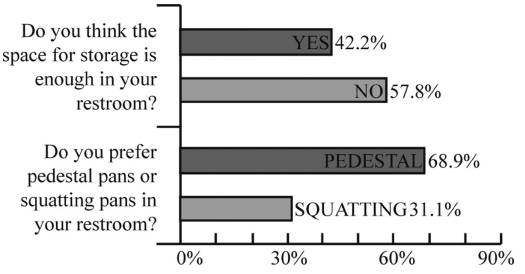

Figure 6. Percentage of respondents reporting specific opinions about restroom.

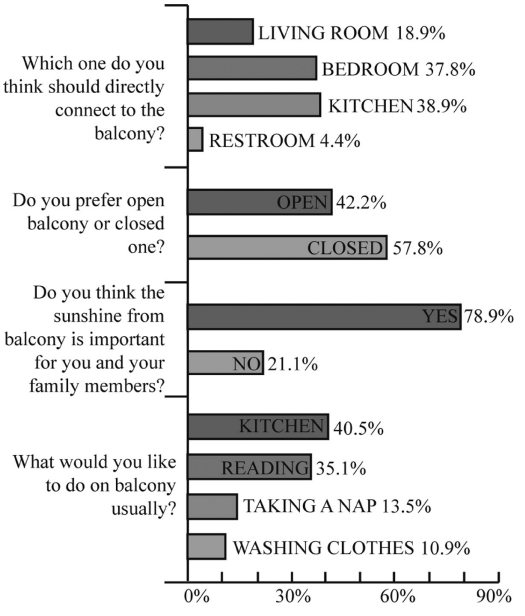

Figure 7. Percentage of respondents reporting specific opinions about balcony.

Figure 7 is the last section and focusing on the balcony. The percentage of residents who considered that balcony should be directly connected to the bedroom and the kitchen was 37.8% and 38.9% respectively, which was more than those who preferred direct connections between the balcony and the living room (18.9%) and the restroom (4.4%). In addition, survey participants preferred closed balcony (57.8%) to open ones (42.2%), likely due to the extremely cold winter in Northeast China. About 78.9% of the respondents thought that sunshine from the balcony was indispensable, and would like to do some reading or cooking there.

The survey results indicated two main problems about the current space usage: (a) the space for storage was not sufficient for most of the households; and (b) the space arrangement did not accommodate multi-functional usage. In addition, it also indicated several possible solutions for improving space arrangement, such as fully utilizing the vertical space for storage and integrating more extra functions to each room. These results were used to develop the semi-structured interview in the next phase.

4.3 *Semi-structured interviews*

Semi-structured interviews were conducted to gather further understanding about the space usage problems and the users' expectations based on results from the two previous phases. The researchers interviewed the residents according to the research protocol and recorded the conversations, drew the current layout of the dwelling unit, and took photos of the space arrangement and environment in the units. The interview protocol included 51 questions, which covered seven sections as those in the survey, and also addressed the three main problems found in the two previous phases. The interviewees were asked whether there were such problems in their apartments, and what they thought could be done to improve it for better quality of life. Content analysis was used to analyze the data from the interviews.

Nine subjects (five females and four males), with three from each neighborhood, were interviewed at their homes. One were over 60 years of age; three

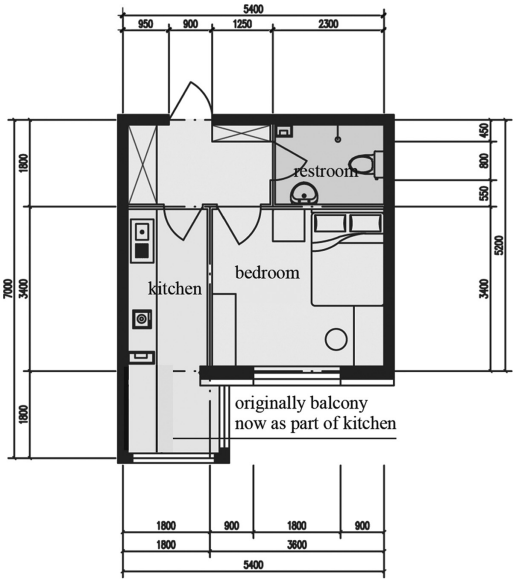

Figure 8. Improved arrangement to combine different functional spaces.

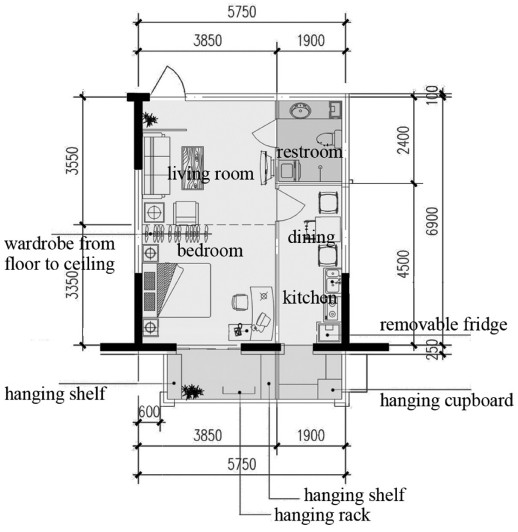

Figure 9. Improved arrangement to efficiently use the vertical space.

were in the 50-to-60 age group; three were in the 40-to-50 age group; and two were in the 25-to-40 age range. In terms of the family structure, three of the families consisted of a couple; one consisted of a son and an old father; three were composed by a couple and their single child; and the other two were composed by three generations including a young child. Residents' durations of living in the affordable neighborhoods ranged from one year to four years. The content analysis reconfirmed those common problems found in earlier phases such as the cramped space for family usage, shortage of storage space, and lack of accommodations for multiple functions in a single room.

Based on the results from this and other previous phases, several design recommendations were provided to solve the identified problems in terms of (1) cramped space, (2) limited storage space, and (3) lack of flexibility to accommodate multiple functions.

Recommendations for better usage of the cramped space. The majority of the participants reported that they could accept smaller furniture, appliances, and renovations of other facilities in order to cope with the cramped space of the affordable apartments. They identified many facilities at home that could be smaller, such as the sofa, table, and refrigerator. However, five out of nine interviewees said they could not accept smaller kitchen sink because of their cooking habits. Some respondents used removable furniture or facilities at home. Two of them used removable tables and chairs in their kitchens, and one young mother reported using a removable baby crib. Several participants indicated that they would like to use an underfloor heater rather than a hanging one to save space. What is more, some of the residents agreed to combine different functional spaces together to improve efficiency (Figure 8). For example, one of the participants connected his kitchen with the living room, so that he could have more space for dining; one older lady took out the wall between the balcony and the kitchen to gain more kitchen space.

Recommendations for increasing the storage space. All the participants indicated that full usage of the vertical space was one of the best solutions to increase the storage space. Most of them prefer wardrobes that fully utilize the floor-to-ceiling space in bedrooms, and hanging cupboards in kitchens. They also like the storage space in the background wall for television, which is a commonly used decoration in Chinese homes (Figure 9). Among the nine participants, six did not like the floor cabinets that can be used for both storage and sleeping, because many people thought sleeping on the floor without heating was not good for health. Further, few people would like to place their family belongings in the public space, outside their apartment, due to safety concerns.

Recommendations for multifunctional usage of the space. A majority of the participants used their rooms for mixed functions (Figure 10). Six residents used their bedrooms for both sleeping and meeting guests, and two put desks and computers in their bedrooms to make it study rooms when necessary. Some residents also used the balcony for other functions: three of them used the balcony as kitchen and dining areas, and one young lady used the balcony to wash and dry clothes. In a special case, one three-generation family put the baby crib in the living room, so that the living room became a temporary nursery. For such multifunctional usage, the size, scale, connection and orientation of the rooms should be taken into account while designing the dwelling unit. What is more, the arrangement of

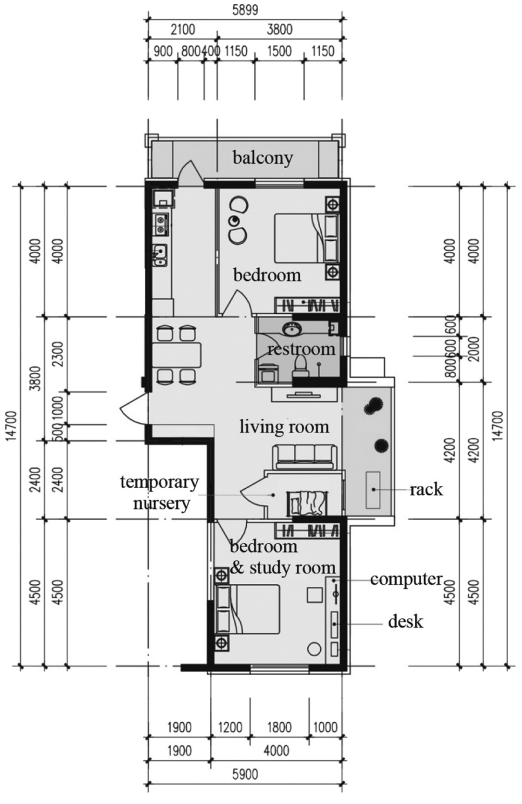

Figure 10. Improved arrangement to use the rooms for mixed functions.

the apartment should be easy for residents to change when necessary.

5 CONCLUSION

Despite the important and informative findings, this study has several limitations. First, a non-probability sampling was applied in the survey, and the results may not be representative of the study populations. Second, the sample sizes for both surveys and semi-structured interviews were relatively small. Third, the analysis in the paper was limited to descriptive analysis and content analysis, and did not explore the impacts of multiple factors on people's satisfaction or quality of life.

Despite these limitations, this research provides insight into the space usage patterns as well as residents' needs and expectations for the affordable housing in Northeast China, with a special focus on the understudied population of rural-to-urban migrants. This is an important yet understudied area with significant design and policy implications. The results provide evidence for possible improvement of spatial arrangement in future affordable housing projects. The post occupancy evaluation reveals three main problems about the space usage, including (a) the space being too cramped (mean usable floor area = 37.20 m^2) for the household (mean size of = 3 persons/household); (b) the storage space being insufficient and the vertical space not being fully used; (c) the space arrangement not accommodating multifunctional usage. Further, the findings also reveal several possible solutions for these problems that can better meet residents' expectations.

The multiple-methods applied in post occupancy evaluation research prove to be informative. Results from different methods can be triangulated, and information from one study phase could become the foundation of the next. For example, the design analysis of the selected projects provided extra support for the analysis of the survey results. Furthermore, the interview results helped provide recommendations for problems identified in the survey phase. Future studies should consider multiple methods when possible, and employ multivariate analyses to examine the impacts of personal characteristics and diverse design features on residents' satisfaction of their living environments and equality of life.

6 FINANCIAL SUPPORT

This work was supported by the China Architecture Design & Research Group and the China Scholarship Council. The funding sources had no direct involvement in the writing of the report, or in the decision to submit the article for publication.

Permanence to allow change. The archetypal room: The persistence of the 4 × 4 room

G. Ledent
Université Catholique de Louvain, Brussels, Belgium

ABSTRACT: Nowadays, the permanence of architecture is challenged as inhabited spaces become obsolete at an increasingly rapid pace. This obsolescence is mainly due to the fast evolution of ways of life, construction techniques, and aesthetic codes.

Instead of trying to meet point by point those fast changes, another way to address obsolescence would be to consider what is not subject to change in the short term.

Through architecture history, traditional housing types convey a sense of permanence. Through their constant improvement process, types leave aside contingent elements only to retain the essential. This sense of permanence can be traced in early domestic manuals as well as in the housing studies carried out by the Italian school of typology.

In all those housing types, the plans display at least one room encompassing a 4 × 4 meter surface. The permanence of such a room is interesting as it allows functional, technical and aesthetic variations. As such, it allows societal variations and can be a lever for future design.

1 INTRODUCTION

1.1 *A world of changes*

We live in a world of constant changes. Those changes affect the inherent characteristics of architecture. Indeed, as well as various consumer goods, inhabited spaces become obsolete at an increasingly rapid pace. This obsolescence is mainly due to functional, technical and aesthetic transformations. First of all, ways of life evolve at a rate that has never been experienced in human history. Social as well as family relationships have never been as diverse as they are today. Secondly, construction techniques are evolving rapidly. What seems to be forefront construction materials and building technologies are outdated even before being implemented. Finally, aesthetic codes do not achieve more stability as yesterday's fashion is already outdated today.

To address those changes, one could try to meet them point by point (Ledent 2015). But several difficulties emerge regarding that approach. Firstly, it is almost impossible to address those changes simultaneously. Secondly, architecture requires time. By the time a building is built, the changes it was trying to address are already passé. Finally, the changes themselves are ephemeral. Hence, anything that seemed to be relevant one day is soon outdated.

1.2 *Archetypes and contingencies*

For all these reasons another way to address constant change would be to consider what is not subject to change in the short term. In that sense, a distinction must be made in architecture between what is permanent – archetypes – and what is changeable – contingencies. On the one hand, archetypes are defined as the resilient and slowly evolving features of architecture. They are the underlying principles of architecture. On the other hand, contingencies tend to change according to transitory cravings. They are the superficial features of architecture, as they experience a quicker depreciation in time. Consequently, any kind of architecture relying too much on the latter would expose itself to a swift obsolescence.

Archetypes give insight into how to address constant changes in our societies. Indeed, by nature, archetypes display permanent features, beyond change. Therefore, they allow for secondary variations on a functional, technical and aesthetic level.

1.3 *Domestic architecture*

The question of resilience in domestic architecture is particularly relevant since it is by far its most important production in terms of quantity.

Traditional housing types exemplify the permanence of archetypes. The interest of such building types lies in their very nature. Indeed, the most prominent characteristic of a type is that it is the result of a long and constant sedimentation process of uses and techniques in order to attain the quintessence of local dwelling needs. Therefore, through their constant improvement process, traditional types leave aside contingent elements to retain only the essential, the underlying structure of housing.

In order to best illustrate this, domestic treatises as well as typological analyses are examined.

1.4 *The archetypal room*

Within those domestic archetypes, the room stands out as a resilient feature. Being the smallest dimension in the human dwelling, the room can be considered as the core on which the principle of resilience can be tested.

2 DOMESTIC MANUALS AND TREATISES

Domestic treatises provide a good overview of how housing was thought but also built and inhabited through history. Indeed, even though those treatises claim to be theoretical, they are always based on real cases. Hence, treatises provide a wealth of information on dwelling constitution as well as local uses and social statuses.

For the sake of a framework that is generally representative of housing history, three treatises are examined: Serlio's, Le Muet's and Durand's. The sample selected stretches over a long period of time (four centuries), and has had a tremendous influence on domestic architecture all around Europe. Moreover, all three are richly illustrated.

In order to examine the persistent characteristics of the room constitution, the attention is drawn to the smallest abodes displayed in the three treatises. Indeed, starting from the premise that the archetypal room is a resilient feature of all dwellings, the smallest dwellings must display at least one such room. Moreover, in many cases, those minimal dwellings form a basic layout from which all other housing arrangements seem to emerge.

2.1 *Serlio, Sesto Libro d'Architettura*

Sebastiano Serlio's treatise is particularly significant since it is one of the first architecture books based on illustrations rather than text. Compared to other treatises of the time, his work can therefore be regarded as an illustrated architectural manual. More importantly, Serlio depicts the houses of the poor unlike his forerunners who believed such dwellings did not require any expertise in art (Rosenfeld, 1978).

Two kinds of building plans are displayed in Serlio's treatise: country and urban dwellings. Among them, the smallest country dwellings display a similar floorplan: two adjoining rooms with a front porch surrounded by a garden. Those dwellings demonstrate a series of differences in the construction techniques (wood vs stone), number of floors as well as a risen ground floor.

In his depiction of the plan, Serlio writes about a main room – *stanza* – accommodating the household. Its dimensions vary from 10 to 13 *piede* (3.5 to 4.5 meters, the Venice *piede* being equal to 0.35 meter). Alongside this room, a secondary chamber can be found, housing either a stable (for the *contadino*) or a kitchen (for the *artefice*).

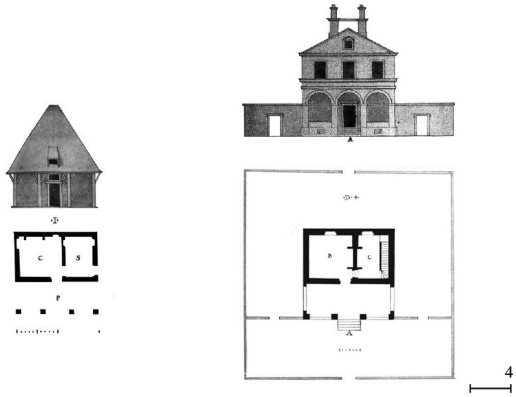

Figure 1. *Casa del povero contadino* and *del povero artefice*.

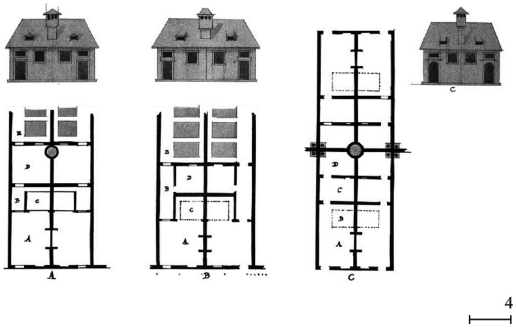

Figure 2. Casa del povero artifice nella citta.

The smallest urban compositions present three double or quadruple row houses of two storeys. Serlio explicitly mentions the fact that they are drawn from real-life examples. Those craftsman houses are located far from the city plazas and places of nobility. They are deep and narrow and are built between two vertical party walls. They all display a main room on the street side with a contiguous sleeping alcove. In the depth, various arrangements can be found with a well, a courtyard and sometimes a vegetable garden.

By definition, urban conditions entail some kind of dwelling congestion. In this case, the houses are stacked alongside the roads. Hence, the width of those houses is crucial in order to provide as many abodes as possible within the city walls. Interestingly, the smallest houses illustrated by Serlio have a width of 10 to 12 *piede* hence, approximately 3.5 to 4.2 meters. Referring strictly to the Italian author, this seems to be a width below which organizing a proper dwelling seems difficult.

The depth of the minimum country houses is equivalent to the width of the urban houses. Those dwellings being the smallest, this gives an indication of the minimal dimension of the room. More interestingly, all the layouts display at least one square room whose sides are equivalent to this depth/width. Hence, all designs display a 4 × 4 meter room. Serlio refers to this room

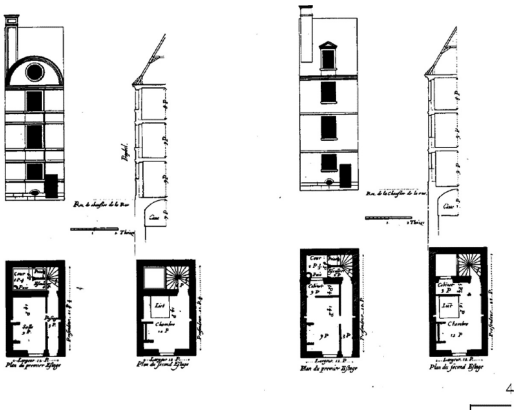

Figure 3. Le Muet, *Première place* and *Deuxième place*.

as the *stanza*, the multifunctional family room of the time. It is a place for family gathering, eating as well as sleeping.

In addition to its size definition, the *stanza* does not present any systematic design in terms of openings or technological means. Indeed, the number, the size and the placement of the windows and the doors are different from one version of the treatise to another. Similarly, the positioning of the hearth varies from one version to the other. Hence, the topological configuration of the room seems to prevail on formal or technical contingencies.

2.2 *Le Muet, Manière de bien bastir pour toutes sortes de personnes*

Analogously, the book published by Pierre Le Muet in the 17th century can also be referred to as a housing manual. It displays various designs for town dwellings that range from very narrow houses to large palaces. They are classified according to *la place,* the width of the lots they occupy.

The first two drawing boards display multi-storey houses. They are set on a 12-*pied* wide plot (4 meters, the French *pied de la toise de l'Ecritoire* being equal to 0.33 meter). Both designs present a combination of interior rooms with a backyard. The staircase is not included in the interior spaces but it is placed at the rear of the dwelling. It can then be accessed through a corridor on the ground floor. This disposition enables the rooms on the upper floors to have a maximal width of 12 *pieds*. The main difference between the two houses can be observed in the depth of the lots that vary from 21.1 to 25 *pieds*. In the deeper design the additional depth is occupied by an additional *cabinet*.

The *première place* proposes one room on every floor of the house. Its size ranges from 9×14 *pieds* (3×4.6 meters) on the ground floor to 12×14 *pieds* (4×4.6 meters) on the upper floors. The *deuxième place* displays comparable rooms to which a narrow cabinet has been added on the side of the courtyard.

Interestingly the same remark applies to both Serlio's urban houses and this case. Indeed, Le Muet does not present any housing design for an interior width of less than 4 meters as if it was a minimal width to conceive a proper dwelling. Once again too, the houses display at least one room encompassing a 4×4 meter surface.

2.3 *Durand, Partie graphique des cours d'architecture faits à l'école royale polytechnique*

In the early 19th century, Jean Nicolas Louis Durand had a tremendous influence on architecture through the publication of his *Recueils*, his *Precis* as well as his *Leçons*. In his books, Durand presents a systematic and rational classification of buildings and building elements. As such, Durand's illustrations were meant to serve as design examples, as a generative typology.

Among the various building patterns displayed in Durand's illustrations, the *maison à neuf cases* stands out as a prototype of a generic house. It is illustrated both in the *Leçons* and the *Precis* where the French author presents various alternatives of the house with different construction techniques. While the exterior appearance of the building varies from one construction technique to the next, the floor plan always remains identical.

The house is designed as a two-storey high square composition with a risen ground floor. The plan is very plain. It displays a nine-square grid drawn on a 4 meter pattern presenting two different sizes of rooms: 4×4 and 4×8 meter rooms. The rooms are arranged according to an *enfilade* principle. No corridors can be found as all rooms are directly accessed from the neighbouring chambers. The composition is very regular and symmetrical. All openings (windows and doors) are equivalent in size, around 1 meter, the sole exception being the front door which is slightly wider. The openings are arranged in one line centered on each room. Minor differences can be found between the *Leçons* and the *Precis.* These relate to the proportion of large/small rooms and the presence of a staircase.

Interestingly, in this theoretical exercise, Durand focuses directly on the 4×4 meter room as the basic module for designing his house. The spaces have no predefined function as if that pattern was able to shelter any kind of program.

2.4 *Resilience*

This analysis highlights the resilience of a 4×4 meter room in domestic treatises. It can be regarded as a basic feature of housing design. In addition to this resilience, this room is remarkable in three other respects.

Firstly, in terms of dimensions, this particular room is able to accommodate any kind of living needs from the polyvalent family room – *la Salle* or *la Stanza* – to bedrooms … No exclusive functional determinism can be found in this layout.

Secondly, it does not seem to be affected by construction technologies as Durand's proposal clearly exemplifies.

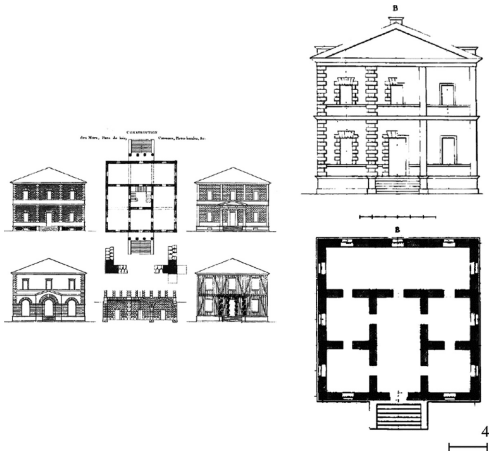

Figure 4. Durand, *La maison à 9 cases*.

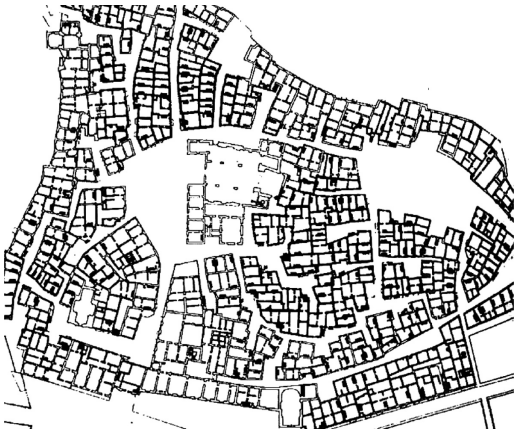

Figure 5. Polignano a Mare, survey by Caniggia and Maffei.

Thirdly, the openings – doors and windows – or any kinds of artefacts that might possibly influence the looks of the space are very diverse. They do not seem to guide the layout of the room.

Hence, this room appears to be a permanent feature able to accommodate variations on a functional, technical or formal level. On this basis it can be regarded as a genuine archetype.

3 THE ITALIAN SCHOOL OF TYPOLOGY

Even though domestic treatises are rooted in empirical studies, they remain theoretical. Hence, another way to analyze domestic types would be to look into what customary domestic architecture has produced in practice. In our western societies, it is generally acknowledged that vernacular types have ruled upon the production of domestic architecture until the 1920's with the advent of modernism. Arguing for a *tabula rasa*, modernist architects tore apart the conventions of the traditional types along with the qualities that local experience had carefully stored in them over the centuries.

Authors such as Amos Rapoport or Ulrich Doepper have explored the scope of vernacular architecture quite thoroughly. But although their analysis is richly documented, it is not systematic. Conversely, the Italian school of typological studies based on Saverio Muratori's method was the first one to carry out a systematic analysis of traditional housing types. Although initially limited to the Italian peninsula, they provide a good overview of the constitution as well as the genesis of traditional housing types before modernist architecture.

3.1 *A method*

Saverio Muratori's method relies on an analysis of manmade artefacts in order to extract its principles of behaviour, formation and alteration. Those principles define the inherent characteristics of each manmade structure. Bringing to light those principles is essential as they act as a reference system for any socio-cultural environment. Muratori and his successors pay specific attention to the traditional and most common building fabric. Unlike the Nolli plan, they do not limit themselves to monumental architecture.

Once those principles are revealed, they can be a keystone for future design. Instead of introducing alien ideas as the modernist movement did, the typological method proposes to design as a continuous interpretation of what already exists. This method presupposes that any architecture project could be closely linked to a prior and thorough typo-morphological analysis.

3.2 *Caniggia, Maffei, Lettura dell'edilizia di base*

Gianfranco Caniggia and Gian Luigi Maffei continued the analytical work started by Muratori. Their book, *Interpreting basic building*, tries to shed light on the immanent laws of the creation and development of manmade structures on various scales: building, city fabric, town and territory.

The focus of this paper will only be on the building scale. According to Caniggia, the major shift caused by modernism can be traced into the way it proposes to understand and produce buildings. He makes a simple distinction between buildings and architecture. On the one hand, buildings constitute the general and anonymous built context. Caniggia refers to buildings as a spontaneous production. Buildings are artefacts erected without the builder having to think twice. As such they are frequently disregarded by scholars. On the other hand, architecture relates to specific emergences. They are signed buildings usually commissioned by the ruling power (e.g. the detailed buildings in Nolli's plan). However, with the advent of the modernist movement, this distinction is no longer meaningful since all buildings are considered as possible emergences. The Italian theorist proposes hence to constrain those emergences and produce buildings that relate to the continuity of typological processes.

The analysis of the creation and development of building types carried out by Caniggia is both syntopic

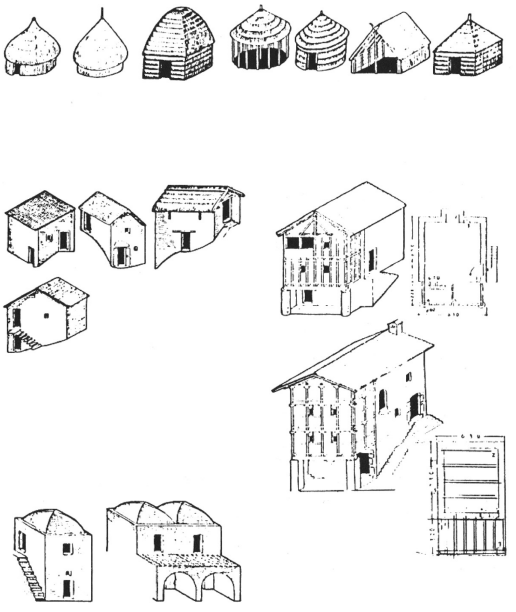

Figure 6. Basic types.

as diatopic as they are found in Florence, Rome and Genoa with comparisons with Como and Milan. The Italian author tries to understand the genesis of local types through a systematic study of ancient building fabrics.

Among basic buildings within the city, the row house – *casa a schiera* – is the most common building type. As such, it can be regarded as a less personified roman *domus*. In their analysis, the authors trace back the origin of the row house to a common root, the mono-cellular dwelling house. This basic root can be considered as the *foundation matrix of the typological process* (Caniggia and Maffei, 2001).

The origin of such mono-cellular dwellings is the elementary cell (e.g. the night shelter in the pastures). Remarkably, this basic cell can be considered a genuine and complete dwelling. Hence, it can by definition accommodate all human needs on a functional, technological and formal level. Indeed, it is able to shelter the functions of family life; provide the dweller with a protective and steady construction; and produce the image of what is acknowledged as a dwelling in the collective consciousness.

Based on this assumption, Caniggia presents the evolution of urban housing in Florence Rome and Genoa as an evolution of this elementary chamber. According to the Italian theorist, this elementary cell can take various forms but always presents a surface of around 25 square meters.

Yet, looking closely at Caniggia's drawings, two elements can be noticed. First of all, the grid on which all the dwelling evolutions are analyzed is a 5 × 5 meter grid. However, all the dwelling walls are drawn on the inside of the grid. Assuming that such a party wall is about 30 cm, the dimension of the basic cell is 4.7 × 4.7

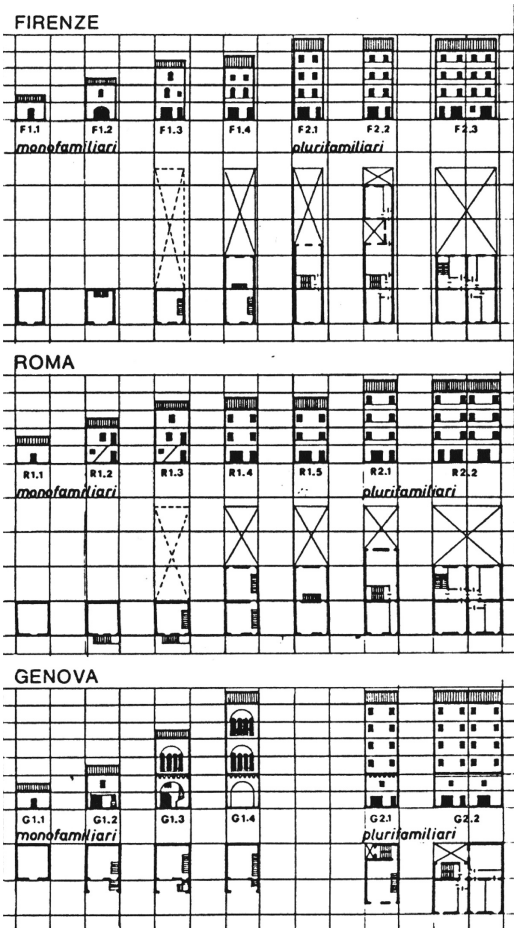

Figure 7. Diachronic mutations of the basic type.

meters in Rome and Genoa while it is 4 × 4.7 meters in Florence. Moreover, in the multi-floor dwellings, the position of the staircase reduces those dimensions by the width of a flight of stairs. In such dwellings, the average width of such a flight of stairs is approximately 70 cm. Those stairs are placed either perpendicular or parallel to the street, reducing the size of the *sala* to a minimal 4 × 4 meter surface. In that regard, the specific analysis of Florence conducted by Caniggia (Caniggia, 1994) adds to the validity of this observation. The *casa a schiera* is presented as an evolution of the *corte-schiera* that displays a minimal distance between the centers of the party walls of 4.5 meters.

3.3 *Resilience*

Once again, looking at the smallest dwellings, the 4 × 4 meter surface seems to be a constant.

Interestingly, the traditional types exposed by Caniggia have survived and are still inhabited today. More interestingly, none of them are occupied the way they used to be a century ago. Indeed, ways of life have evolved, technological knowledge has developed, and tastes have changed. Yet, thanks to their polyvalence,

those dwellings have passed the test of time. Hence, they have proven to be genuine archetypes.

As is the case with the examples exposed by the Italian school of typological studies, the same applies to various types around the world. Traditional building types, through their constant improvement process, allow inner variations on three levels. Firstly, they permit secondary alterations on a functional level. Types do not respond unilaterally to function. On the contrary, they display topological interactions rather than functional ones, syntactical associations rather than semantic ones. This characteristic has allowed local types to be reinvested throughout the ages with new functions or other ways of life. It is the case, for example, with the traditional Dutch *herenhuis*, or the Belgian bourgeois row house of the turn of the 20th century.

Secondly, types allow transformations on a technical level. In most traditional types, structural or technical issues are dealt with genuine architectonic means and not with technology added to the building itself. That is the case, for instance with the *haveli*'s wind pavilions in Jaisalmer, where natural cooling is comprised within the genotype of the house.

Thirdly, types enable evolutions on a formal level. In that regard, traditional European housing types do not command the building's exterior appearance. For instance, Riga's traditional 19th century housing revolves around the same floor plan with a high variety of façades distinguishing the city for its *Art Nouveau*'s identity.

4 CONCLUSION

In a world of constant revolutions, instead of dealing with them directly, a new paradigm could be sought: addressing resilience. This resilience states that the permanent structures of architecture work as a framework (Leupen, 2006a) within which change can occur. This approach can be paralleled with other disciplines such as anthropology or linguistics that claim that deep structures of human behavior exist allowing for cultural or temporal variations.

In the field of architecture, those deeply rooted structures are called archetypes. Archetypes can be regarded as a *degré zero* of architecture. They form a resilient frame within which change can occur on a functional, technological and formal level referring directly to the three founding principles of Vitruvius. Moreover, this resilient frame can also accommodate variations on an individual level, allowing for personal interpretations.

To comprehend those archetypes in the specific sphere of domestic architecture, time-tested housing designs have been looked into through the study of several treatises and typological analyses. The choice of domestic manuals and traditional types is no innocuous exercise. Indeed, by definition, both leave aside contingent elements to retain only the essential. Hence, they are particularly relevant in the light of a quest for archetypes. Interestingly, the examples explored revolve around a basic dwelling cell encompassing a minimal surface of about 4×4 meters. The permanence of such a room in the smallest abodes demonstrates its necessary presence to sustain human dwelling needs. But this permanence also reveals its capacity to accommodate changes on various levels since those designs were able to pass the test of time. As such, this archetypal room can hence be considered as a key element for future sustainable housing designs.

Versions of collectivity in housing architecture: From the modern to the post-human

Charikleia Pantelidou
Aristotle University of Thessaloniki, Thessaloniki, Greece

ABSTRACT: Today, collectivity is projected as a key notion in order to cope with an increasing scarcity in an era of multileveled crisis. In such context collective modes of life are suggested as a means towards economical adequacy, environmental sustainability, social solidarity and political request, a tendency that has explicitly affected architecture. In this paper, the ways that architecture of housing realized collective living, as well as the correspondences between meanings of collectivity and forms of housing, are examined. Through a critical overview of emblematic architectural examples from the Modern to contemporary times, an investigation of the social and political function of collective housing, mainly in our era, is aimed.

1 INTRODUCTION

An inherent attribute of our era is a new understanding of the relationship between the individual and the social – in the field of spatial concerns translated as the relationship between private and public space – which is based on two simultaneous transformations: on the shrinkage of the social and the public, as well as the expansion of the individual and the private, to the intermediate quality of the collective. In this sense, the collective has been projected as the new realistic and acceptable version of the social and the public, while at the same time receiving contents and meanings of the individual and the private in a framework of pursuit of a multi-leveled sustainability (Ibelings 2009, Lootsma 2009). Despite the apparent paradox of this widening of the collective, it is a fact that our contemporary world seems to be structured of communities instead of societies, and groups instead of individuals (Jameson 1991).

In this climate, a renewed interest on collective housing is revealed in the last decades. Collective housing, in its literal sense, has marked the era of the socialist transformation, in an attempt to cope both with the housing crisis emerged due to migration to the cities and to construct the new subject of the new society. In the Western world, after a retreat of mass housing architectures in favour of the private house and the suburbanization, which accompanied the elimination of the welfare state (Cupers 2014), collective housing reappears in the period of neo-liberalist capitalism suggesting contemporary ways of common living. The shift from the private house to collective housing is related to a displacement of interest from the individual to a more collective unit, the group. However, such reposition of interest does not seem to imply a retreat of the contemporary individualism in favor of collectivity, in a sense of a reinforcement of the social and the public over the individual and the private, given that individualism is a key of the postwar Western culture (Bauman 1997).

While collective housing has been an architectural suggestion of urban dwelling from the industrial era to our times connected to common living, the certain kinds of implied collectivities, in terms of proportioned junctures between the social and the individual, differ from time to time and type to type. In this paper, I examine the evolution of collective housing from the Modern movement to the contemporary architecture seeking a critical interpretation. Through analysis of emblematic architectural examples and consideration of the context where they have been created, I ask how collective housing architectures dealt with the concept of collectivity in the course of time and especially what is on stage now. Notwithstanding, the examination of the ways in which architectural design managed collectivity is an issue related to the socio-political relationship between space and subject.

Views and ideas are not independent from historical condition and everyday living, and the formation of the relationship between the individual and the social, the private and the public, is related to the ways that people were organized in social entities and performed their living practices. This provided, I am going to examine collective housing in response to the process from the creation of mass society in the late 19th century towards mass democracy of the 20th century second half and the nomad culture of our days, while architectural discourse will provide our study with the ways that the architectural phenomenon was being understood in each period.

2 CONNECTIONS BETWEEN THE INDIVIDUAL AND THE SOCIAL: THE COLLECTIVE SUBJECT

The relation of the subject to the collective quality is one of controversy and disagreement, ranging between a Liberal inherent individualism and a Marxist social human being in the course of Modernity and Postmodernity. The next lines will shed light on this issue.

In bourgeois society of 19th century, the individual was considered as a self-regulated, autonomous entity, though identified in reference to the social norm through the process of labour. Proceeding to mass society in 20th century and the civil society of today, the individual is increasingly separated from the social as a whole, and individual autonomy is considered as an end in itself and acknowledged on the basis of its nature rather than through the possession of social attributes (Kondylis 1991, Sennett 1974). Such subjectivity is based on the extremely individualist end of self-realization released from any external bond, but at the same time is constituted through the embodiment of the Symbolic other and the social externality. While Psychoanalysis and Critical Linguistics uncovered the reality of a decentred subject, which is incapable to be determined by itself (Romanos 2002), socio-political conditions contributed to the transformation of the relationship between the social and the individual.

As long as technological progress has achieved an increase in production, an extended consumerism audience could be searched within a mass of equals, which means that the consumerist mass society needed democracy in order to be legalized (Kondylis 1991). The emerged legal equality of people in mass democracy acknowledged individuality as based on sentiments, emotions and instincts, as well as on the claim for their satisfaction, while society and the state were charged to provide the individuals with the necessary goods and services for the realization of their individuality. Today, while self-realization still characterizes the relationship between the individual and the social, we face a generalized decline of the social and its subject, the society, and the transfer of their responsibilities to the individual being the only referent to its own life. A great plurality of groups, which emerged after the retreat of the national state, provide fields where the individuals participate temporarily and locally in a process of multiple identifications, instead of carrying heavy and stable identities. Instead of implying a moral retreat of individualism in favour of the common good, this political exaltation of the group and the collective represents an alternative possibility which substituted the historically convicted politics of a social totality connected to the economic dimension and the production system (Jameson 1991).

The collective subject has been shaped hand in hand with an increasing radicalization of individuality, which resulted in the end of separation between the public and the private realm and the creation of a secondary reality through marketing and advertising (Ellin 1999). In such context, the destruction of a reasonable distance between the private and the public life led to the withdrawal to an increasingly expanding private zone, and was related to the 'human, all too human' everyday discourse, contributing to the elimination of the Political (Lipovats 2002).

From another point of view, in bourgeois society the collective subject has been identical to the family, which was considered as the political unit and was well articulated in the social structure, functioning as a parameter of a stable self-identity and reserving a supportive significance for the status quo. In the course of the industrial, technological and informational era, the collective subject has been shifted from the family to the social movements and the groups of any kind. In this context, while the postmodern collectivity was of a hybrid nature which allowed to simultaneous references to both individual and the social, the modern kind of group collectivity introduces neutrality as the escape route of any enchaining individual fixation and social commitment (Jameson 2005).

Indeed, the Lacanian Real acknowledged the non-representable as a possibility towards the New (Zizek 1989). Such exception from the Symbolic, which provides meaning to our action and practice, opens a desirable perspective towards freedom, a creative perspective against the iron cage of cultural and social framework. Since the Real can not take place in institutional public space where the dominant versions of reality are represented, it seeks spatialization to brief, liquid, spontaneous, unorganized, void versions of publickness, which break away with any power meaning. The contemporary turn to micro-narratives, micro-politics and micro-economies found spatial correspondence to urban segmentation and dismemberment (Knox & Pinch 2006), and the modern emphasis to collective space – instead of the public space – belongs to this evolution. Collective space is a response to such orientation of our era and seems to adapt a double, contradictory political role supporting both the modern, radicalized pursuit of freedom and the dominant, decentralized system of global networking. In this context, collective housing appears in multiple formations ranging from politically radical to socially conservative spatial groupings, while it also includes both nostalgic and innovative forms of togetherness.

Architecture as a socio-cultural field is intertwined with ideas and conditions, expressing and influencing life modes and practices. In the next chapter, I examine collective housing from the Modern to our era, searching for the meanings and significations of suggested modes of communal life, as well as for the ways with which collective housing responded to the transformation of the relationship between the private and the public in the course of the time.

Figure 1. Collective space and creation of community.

3 HOUSING ARCHITECTURE AND THE COLLECTIVE: A CRITICAL OVERVIEW

In the same manner that prisons are indicative of the cultural level of a society, one could say that housing offers a valid manifestation of the levels of publickness, sociability and openness of a society, in other words of the relationship between the individual and the social. The ways that the individual and the social are each time perceived in relation to each other, significantly specify the architectural variations in which the relation of private and public space acquires meaning as antithetic or complementary, aggressive or conciliatory, pure and clear or blurred and fluid. In this sense collective housing as a place of direct coupling of private life with the social level has been variably formed both in its historical presence and contemporary production (Figure 1).

Although collective modes of life can be traced back to the utopian settlements of the early 19th century, collective housing has been socially connected with the Soviet Constructivism's architectural movement (Cooke 1990, Fernades et.al. 2013). As long as architecture was expected to contribute to the construction of the new world, the new subject had to dwell new spatial types against bourgeoisie's bonds to the family and the single house (Teige 1999). The Narkomfin Building in Moscow, a large scale construction with individual minimum duplex apartments and collective facilities, represented the new aesthetic of a social condenser which would embody avant-garde in the everyday life. Since such housing model contradicted the inhabitants' need for more individual space, alternative typologies suggesting linear arrangements of separate houses for each household were conceived (Bliznakov 1994).

Modern architecture was oriented to mass society, while interior space and ergonomy seemed to be indifferent about the subjective time and the individual histories of the inhabitants, aiming to destroy the bourgeois individualism. Inspired by the communal dwelling typology, Le Corbusier developed a housing type of common living, which resulted in the Unités d' Habitation buildings (Frampton 2001). Marseilles Unité, considered to represent collective housing's approach of Modern architecture in the Western world, was articulated in up-going and down-going interlocking apartments on the sides of five superimposed internal streets, included 337 apartments ranging from units for bachelors and childless couples to those for large families, while a series of social services were also accommodated within the building (Frampton, 2002). Irrespective of its influential sources, the Unité's subject enjoyed privacy and family, while the suggested collectivity was accomplished through urban groupings of individual and collective activities protected within the building, in the form of an association bounding together the inhabitants of a small village (Jencks 1973). Despite his theories on the urbanization of the architectural scale, as expressed in the relocation of the traditional city's street corridors within his houses or in the integration of urban uses within the building, Le Corbusier was critiqued for failing to conceive of urbanism in terms of public space, as he replaced the contingent urban scenery with an intensive geometric technology resulting in a subjective incorporation (Hight 2009).

Opposed to the Unité, Smithsons involved housing in the pursuit of a collective way of life in terms of human association (Smithson 1968). Their suggestion, regarding the urban organization, of the categories of the house, the street, the district and the city and their realization at the Golden Lane project denoted an attempt to advance the urban environment through architectural enforcement of social cohesion and community life. The integration of the streets-in-the-air, where all the family apartments opened, in the residential complex revealed a conception of the private in convergence with the urban. In such view, the public quality granted its primacy to the collective. In specific, against the isolated 'Unité' and 'neighborhood' communities, Smithsons envisioned a collective space with full urban qualities, the shaping of open, urban communities.

Inasmuch the Modern nexus between the collective and the urban quality seemed to be unsuccessful in constructing collectivity in propinquity to the social-public body, Aldo Rossi searched for the lost meaning of the building corridor in order to enhance interpersonal relationships and rescue architecture from the whirl of individualism and consumerism. Gallaratese housing highlighted the corridor typology of the 19th century Milan apartment block, in order to symbolize the varied interpersonal relationships in a life mode occurring in everyday sequence (Frampton 2007, Weston 2004). Aiming to take up the beginnings of Modernism again in order to overcome the functionalism of the International Style (Klotz 1988, Hays 2009), Rossi's phenomenology introduced the corridor as a place of everyday experience where inherent accumulated memories and meanings would be released between the inhabitants.

At the level of interpersonal relationships, though in a different sense, collectivity has also been pursued

by Structuralist architects. While Phenomenology acknowledges interiority over exteriority and, thus, subjectivity over the external world, Structuralism perceives the subject as part of a signifying unified system where it can nevertheless develop its own identity (Gelernter 1995, Hays 2000). The architectural translation of such approach of reality was the consideration of space in terms of structural relations among its elements, which prioritized intermediate areas and collectivity over privateness and publickness. As long as a specific area in a building, settlement or the city, acquires its meaning in relation to the adjacent areas and its position within the spatial structure, there emerge multiply identified areas where differentiated and even antithetical qualities come together. As Aldo van Eyck highlighted, the very essence of the twin phenomena is in fact complementary, not contradictory (Hale 2000: 157). In this sense, the stairways in the residential complex Documenta Urbana in Kassel acquire the public quality of a vertical street being suitable for accommodating everyday meetings of the neighbors, while intermediate spaces created through the double entrances to the private apartments bring together both private and common space qualities.

Another aspect of the structuralist approach in architecture of collectivity refers to the user participation in the shaping of space, as was the case with Hertzberger's Diagoon Housing in Delft, Lima Housing in Berlin or the Central Beheer Office Building in Apeldoorn, where common actions and decisions of the inhabitants gave identity to the neutral areas integrated within the built whole (Hertzberger 1991). In terms of flexibility, and in a more mechanistic way, participatory design in housing was found in John Habraken's (1972) theoretical claims for the separation between 'supports' and 'infills' of the building, where the differentiation between the act of building and the process of dwelling guaranteed uniqueness for the individual units without giving up the idea of the collective. Such considerations for individual freedom tell about a subject who acts individually, momentarily and locally, while it functions as a part related to the other parts of a collective structural whole.

Flexibility and self-realization remain key characteristics of our contemporary reality of liquidness and blurriness. By the advent of the information era and the domination of a synchronic time over space, space and society were segmented into innumerable pieces of a diversified reality (Tscumi 1996). The view of a world as an integrated system of related parts is substituted by the attendance of reality as an inherently imperfect network of combined elements. In such context the consideration of the collective forsakes the connection between the whole-social and the part-individual, and considers the latter in a state of independency. The contemporary significance of groups is a reality articulated in a wide range of (no)commitment. Diversity – and the notions associated to it – makes here the dominant concept under architectural creation.

Sejima's Kitagata Housing in Tokyo provides an exemplary case regarding the segmented, combined, diversified contemporary reality, seeking new ways of collective living. As the architect points out, inasmuch the contemporary collective housing ought to accommodate all kinds of collective living between people, and not just families, its base unit becomes the single room, no more the apartment (French 2008: 178). The overcoming of life stereotypes and the acceptance of difference, as proclaimed in the contemporary intellectual production, are spatialized in a a-hierarchical arrangement of four same sized rooms, each of them corresponding to a distinct domestic use. The rooms are combined in apartments freely, depending on the circumstance, providing a single door to the access corridor for each room, instead of a central entrance door for each apartment. On the opposite side of the block, a fully-glazed corridor-like verandah provides a common spatial field where some rooms are expanded. Here, the distinction between private and public space is neutralized as on the one hand (room) privacy is merged with the collective use and displayed to the public view, and on the other hand it is given extreme concern through the provision of room individual access to the collective corridor area. Such neutrality allows the assumption of a collectivity consisted as an inherent quality of individuality, being open to freedom, while the arrangement – instead of articulation – of individualities makes possible an eventual variety of combinations in a world targeting at innovation.

Instead of combination of ultimate elements, collectivity is structured through the synthesis of already articulated spatial pieces, in MVRDV'S Silodam Housing in Amsterdam. A range of dwelling types is grouped together, according the criterion of similarity, into distinct neighborhoods including 4–8 house units (Costanzo 2006). Organized horizontally and vertically, through circulation and common use spaces, each neighborhood represents a vertical version of collective living in the urban configuration, while being in open connection to the 'public' spaces of the building. As is also the case with the 'sky plaza' in the Mirador building in Madrid, urban diversity is intertwined with the collective quality, displaying the multiplicity of the groups in a building arena where the public space is reconsidered. At the same time, the emerged substitution of the 'house' by the 'neighborhood' belongs to the new morphologies of the city and confesses an arbitrary preference of our era to the collective instead of the individual, as it is already remarked.

In the spectrum of contemporary housing one ought to add the exclusive buildings and settlements, known as gated communities, where a kind of privatized collectivity is constituted as related to exclusion and homogeneity in a world perceived as unstable, dangerous and hostile (Figure 2). Although they constitute solely spatial communities without real human bonds between their inhabitants, they do form contemporary collectivities in terms of private governance and gated territory. Derived from the sharp individualism of our era, gated communities introduce a new form of urban configuration which is structured through the

Figure 2. Exclusiveness and homogeneity in gated community.

networking of integral, private-collective spaces and the decline of public space (Pantelidou 2012, 2015).

On the other side, contemporary housing collectivities following a 'hyper-collective' living mode display in the last decades a considerable presence in a large part of the world (Vestbro 2000), in an attempt of people to deal with the symptoms of today societies. Communal space for basic everyday activities and participation to the maintenance and creation of their common areas compose housing examples of a collective quality related to a social interaction which seems to be absonant to the contemporary individualism.

4 CONCLUSION: RECONSIDERING ARCHITECTURE OF COMMON LIVING

Some approaches to architecture claimed for its representational function and meaning transmission, while others consider architecture as a field of interaction and ongoing process between both user and space and the users with each other. Irrespective of their differences, they all, in a way or another, refer to the issue of communication. As Lacan has shown, communication is never perfect. There will always be something which would have remained unspeakable and incomprehensible through the process of communication, related either to the filter of ideology, or the interference between body and exteriority or the lack of transparency between the signifier and the signified. In such field of uncertainty, architecture of housing draws upon the concept of collectivity aiming either to influence or express or activate the subject.

Architecture of housing is connected to the concept of collectivity through the ways that the latter is being interpreted in the period of the architectural creation. Modern vision of purity and order was supported by the idea of unity, which brings to the forefront issues on freedom and oppression (Bauman 1997). The collective was identified to society and the state, which in postmodern times has been darkened as totalizing and compulsive. Connected to the idea of unity, the collective-social-public was meant to homogenize the private parts, and it was homogeneity that provided one of the major platforms for critique against Modern housing architecture and led the next generations towards diversity, disruption and vagueness.

Architecture of collectivity is articulated to the emblematic dichotomy of Modernity and Postmodernity between safety and freedom (Bess 1996). Community established a pivotal point which gave and acquired meaning in relation to this dichotomy: for the communitarians the community's safety would provide freedom, while for the opposed side freedom was placed outside community's safety. Postmodernity made a clear choice in favor of freedom as opposed to safety and certainty, and the notion of community had to be translated in analogous ways, released from ethical ties. The architectural implications of such choice included the preference to smaller spatial scales, as well as the shift from city planning to urban design. At the same time the environmental crisis and the new demographic data due to migrations and wars imposed the need for urban density, while the mechanism of privatizations set its own decisive parameters to the urban development.

Contemporary collective housing appears in an architectural postwar sequence following mass housing and the expansion of single house urban sprawl, seeking to place together in the urban environment both density and community (Segantini 2008). In this context, we face today a multi-ranged content of collectivity expressed through multiple architectural types. In specific, collectivity as a way of everyday life is suggested in relation to tight modes of co-habitation and sacrifice of privacy, loose links of co-existence in the same place or symbiosis on a common field of dwelling, while architecture of housing correspond to these models of common living by introducing an obvious variety in terms of scale, form and spatiality.

Architecture is always in a communicative process with the world, which means that the variable forms it appears with have to find a minimum answer out there. The convergence of the dichotomy between society and individual to the notion of the group (and community) is closely related to the assignment of the common affairs to the private bodies after the retreat of the national state. The socio-spatial groupings of the individuals have come as an answer to the incapability of carrying life burdens, and the contemporary collective housing in its diversified appearance seem to belong to a large extent to this process. At the same time, the lack of transparency of the subject with itself does not allow for harmony between the individual and the collective, and the contemporary housing of collectivity seems to comply with this. As addressing the contemporary approaches of diversity, density, flexibility, and the reconsidered relationship between the private and the public, housing architecture translates collectivity in reference to individuality and within the limits that the latter poses in the contemporary context.

The demolition of space in the information era and the restoring of time in human lives in the form of a synchronous reality consisted of events and moments is related to nomadic subjectivities without stable binding identities, pointing out to a radicalized, as inherently decentralized, individual constituted in and by multiplicity (Braidotti 2013). Today architecture's

demolition of boundaries between the private and the public, the nature and the culture, the urban space and the building, goes beyond the Postmodern ambiguity and creates new forms of space which transcend conventional understandings of quality and value, referring neither to the one nor to the other pole of the duality. Such orientation to neutrality calls for new ways of individual being and collective life, aiming at destructuring once ever otherness and the inequities coming together. On the other hand, to the extent that collectivity is built devoid of common perspectives and grounds between the inhabitants and, furthermore, without any reference to the social level, a political void is opened where actions of resistance are bent and the absorbent functions of culture and economy are intensified. It seems that the dichotomy between 'community and freedom' has not yet been abolished despite the intentions. Architecture is not the main responsible for such tusk, but to the extent of its cultural and political nature it is entrusted to provide us with places for an ongoing practice of common living towards the fulfillment of the wide spectrum of our human and social needs and desires.

A more versatile and adaptable dwelling, for a changing society

H. Farias
CIAUD – Centro de Investigação em Arquitectura, Urbanismo e Design, Faculdade de Arquitectura, Universidade de Lisboa, Lisboa, Portugal

ABSTRACT: Dwelling, a central theme of architecture, has always been an unsolved issue, both in the quantitative and qualitative dimensions. Today, dwelling must meet the profound social, labor and technological changes that occurred in recent decades, and brought different and evolving requirements to the house. A clear dissociation between emerging ways of living and proposed housing models, heirs of rationalist modern architecture, can be observed. Addressing this question, several authors have pointed to different strategies as a way to find a more suitable house for the accelerated transformation of contemporary ways of dwelling: flexibility, adaptability, functional ambiguity and spatial de-hierarchization. The article aims to frame these concepts and contribute to the establishment of strategies and design tools developed to promote a more open-use and versatile interior domestic space.

1 INTRODUCTION

Dwelling is a central theme of research for the architectural discipline, in as much the house was, is and will always be, central to human life and human society. The permanent nature of dwelling contrasts with a continuous transformation of the living spaces, since the experiential and social transformations of the human being, over historical time, match a continuous evolution and modification of domestic space.

The issue of dwelling is, thus, for architecture, always a problem to be solved, both in its quantitative dimension – particularly in underdeveloped or developing societies – and qualitative, in a generalized way.

Today, with the profound changes we can witness in society, the new demands that labor issues begin to establish in the home, and the profound changes introduced in the house by new technologies, especially information technologies, there has been a clear dissociation between emerging lifestyles and the proposed housing models.

It can be stated that housing models generally proposed and built today are maladjusted to the inhabitants' needs and that most of the houses people inhabit, heirs of the proposals of modern functionalist architecture, can be characterized as rigid models in terms of their functional predetermination, their spatial configuration and partitioning, and their hierarchy, both of circulation and of dimension of its different living spaces. This situation reduces their ability to adapt, over time, to different functional requirements, both family and work related requirements.

To address this issue, several authors and practicing architects have pointed out different strategies as possible ways to finding a more suitable dwelling to the accelerated transformation of contemporary modes of living.

These include the concept of flexibility (or active flexibility) – understood as the possibility to physically transform the dwelling space, so that it responds, in a more rich and varied way, to the needs of the inhabitants; and the concept of adaptability (or passive flexibility) – understood as the capacity of the dwelling space to be able to fulfill different uses and forms of appropriation, without having to change physically.

The concepts of versatility, functional ambiguity and *de-hierarchization* of the house emerge as possible answers to the idea of adaptability: the first, proposing that dwelling spaces should not be designed as monofunctional, but developed to allow different functions and distinct possibilities of use; the second, understood as the possibility of proposing spaces without functional predetermination, designed as functionally opened, for its architectural features, to different possibilities of use and appropriation; the third, the idea of dwelling *de-hierarchization* understood both as the possibility of proposing a higher equivalence of shape and size of housing spaces (thus avoiding a hierarchical relation between them), and as the increase of possibilities of circulation (and hence of relationship) inside the house.

The article aims to briefly characterize the framework of social, labor, and technological transformations that have occurred in recent years, and have contributed to the need for diversification of housing solutions. The article also aims to frame the concepts of

flexibility, adaptability, versatility, functional ambiguity and *de-hierarchization* of domestic space, drawing on several authors and on different design examples. Although these examples come from different geographical and cultural contexts, European, American, Asian, – thus evidently reflecting cultural, architectural and dwelling specificities – it is understood that they provide design principles and strategies that can be adapted and reused in other contexts. Finally, the article aims to contribute to the provision of a basis for the establishment of principles and strategies for the design of a new home, thought for today and for tomorrow.

2 SOCIAL, LABOUR AND TECHNOLOGICAL CHANGES

Human society exists in constant evolution and transformation. The house as *"a key component of the material culture of a particular society and (...) as a primary territory for the expression of identity and living particularities of individuals who cohabit in it"* (Pereira, 2010) is directly involved in these changes, slowly incorporating and expressing, in its form and organization, the changes in lifestyles of its inhabitants.

However, the acceleration we have witnessed in recent years, in the social change and the transformation of ways of life, lead us to the conclusion that housing, as it today is designed, built and proposed, has become inadequate to the needs of the inhabitants it intends to welcome. It is not surprising therefore that in the introduction to the book *Casa Collage – Un ensayo sobre la architecture de la casa*, Xavier Monteys and Pere Fuertes put the following question: "How many (architects) are actually building a house that people need in the 21st century?" (Fuertes & Monteys, 2001).

2.1 *House and social change*

According to Ignacio Paricio and Xavier Sust in *La vivienda contemporánea – Programa y Tecnologia* (Paricio & Sust, 2000), the major changes that have occurred in recent years, relevant to the topic of dwelling architecture relate, first of all, to the question of profound social transformations.

As the most important of these recent changes, these authors point out: the increased longevity of people; the significant decline in the birthrate and the consequent decrease in the average size of the family; the declining number of marriages and the increase of non-marital and other forms of family life or family grouping; the increase of age of young people leaving the parental home; the delay in the age of marriage and, consequentially, in the birth of children; the increase in the number of separations and divorces and the consequent increase in the number of single-parent families, single-person households and composed families; the emergence of other forms of living together in the house, besides the traditional family household. (Paricio & Sust, 2000). Sandra Marques Pereira adds to this list, signaling out the importance of individualization and diversification of the family composition, and pointing out the appearance of a significant number of couples without children, families of DINK (double-income no kids) and LAT couples (living apart together). (Pereira, 2010).

Apart from these issues, these authors also indicate transformations at the level of growth and redistribution of wealth in society and in terms of values ??and habits of society, as key factors of transformation of contemporary dwelling.

Among a long list of issues, we highlight the ones that seem most relevant to rethinking the contemporary house: the introduction of electrical and mechanical appliances in the home, with a resulting improvement in dwelling comfort; the dissemination of audiovisual appliances and telecommunications in the house; the transformation of family relationships between different generations; the importance given to body hygiene, body care, and to the protection of privacy; the increase in the number of women incorporated in the labor market; the growing equality between the sexes; the growing importance of leisure activities, developed in the home.

2.2 *House and labor and employment change*

In addition to the profound social changes, the transformations that recently have been acknowledged in terms of labor and employment also become relevant for understanding the changes in the habits and ways of life of the dwellers.

On the one hand, we are witnessing a period of great mobility for reasons of employment: many families and individuals have to move to ensure a regular and secure job; many have to move for career reasons or to follow a job opportunity, also as a result of the globalization of companies and the labor market.

This labor mobility raises a number of different issues to housing: on the one hand, the growing demand for smaller homes, for individuals living alone – sometimes temporarily – close to the workplace; one the other, the growing need for houses that can accommodate other models of life and lifestyles, in as much as each individual or displaced family carries with them a set of cultural values and modes of living that determine the use and appropriation of the dwelling space. Also, with the new technological possibilities, the house is now able once again, as in medieval times, to include the workplace within the dwelling structure, for a significant number of different professions.

In fact, this growing trend to be able to work from the home, is becoming an interesting choice for many persons and companies, mainly because of the savings it can mean: personal savings in terms of avoiding travel cost and time between home and work; and company savings in terms of diminishing space requirements in the workplace. Working from home also provides a different way to develop the profession, less conditioned by schedules, rules and

other entrepreneurial conditions and more adapted to the rhythms of family or individual life. For the design of the house, this data also is relevant: the house, as was the case up to the late Middle Ages, can once again incorporate a workspace. Depending on the kind of work developed, the activity may require, or not, an autonomous space with a specific characterization. In some cases, the development of the profession in the home may entail an autonomous relationship of the working space with the exterior, for example. All this should be taken into account, when considering a dwelling for today.

2.3 *House and technological innovation*

Finally, the house has undergone a profound transformation through the technologies that have continuously been invading its interiors. A first period of significant change – especially from the second half of nineteenth century until the beginning of the twentieth – can be associated with the progressive search for modern comfort, through the introduction, in the home, of all the commodities that technology could offer, in the period: electricity, gas, running water and plumbing began to slowly become common in the domestic interior (Rybczynski, 1989), thus assuring a level of comfort that never before had existed in the house.

A second important moment can be witnessed in the middle of the twentieth century, mostly after World War II, and as a direct result of the significant technological advances that stemmed from the war effort. This is the time for electrical appliances to invade the home, a time featured by a significant incorporation of equipment and devices in the house, that were to transform domestic life: washing machines, dryers, ovens, refrigerators and freezers, heaters, blenders, among many others.

More recently, and with an equally great impact on the dwelling, the multiplication of audiovisual and telecommunications equipment came in to transform radically the life of the house. At first, the location of the main audiovisual and communication equipment constituted different *foci* that organized the mode of use of a particular dwelling space: the radio and the stereo system, and the centralizing presence of the television set in the living room; the location of the landline phone in the living room or in the entrance hall, are examples of the relationship established between equipment, space and use.

But the technological evolution of these devices has led to their gradual spread around the house, first with the proliferation of phones and television sets, still as fixed pieces of equipment, in living rooms, bedrooms, kitchens; then with the emergence and proliferation of mobile devices – mobile phones, laptops, tablets, etc. – that don't belong to any space: they are wherever its user is. The relationship between space, equipment and use ceases; there is no longer a focus that unifies the members of the family; each inhabitant establishes his own centre.

All of these issues contribute to the realization that the house is in a paradoxical situation: on the one hand, the activities that dwellers develop in the house are generally the same as they have always been; on the other, there is a major transformation in the way these activities are carried out.

The house today has a very diverse population, with different and varied demands, needs and preferences and, in some cases, of high specificity, generating occupations and uses also of great diversity; the acceleration that characterizes the changes that have been taking place leads us to believe that this is not a closed process but, on the contrary, it is a growing tendency. More and more the house will be the host of different, transforming and evolving lifestyles and modes of living.

For all these reasons, a reflection on how the house should accommodate this present diversity, and try to foresee its future adequacy, by providing a wider range of answers to the growing demands by expanding its usability, seems to be fully justified.

3 RETHINKING CONTEMPORARY DWELLING

> *"What we are looking for is a way of thinking and acting that can lead to a different 'mechanism' (in linguistic terms you would say a paradigm) which is less fixed, less static, and which is therefore better equipped to meet the challenge that the twentieth century society in all its complexity puts to the architect."* (Hertzberger,1991).

In order to meet the challenge facing the design of dwelling, trying to give it a wider range of answers to the growing demands and need for diversity, several authors, starting from the 60s and 70s of the twentieth century, began discussing and proposing the ideas of flexibility, adaptability and versatility as possible answers to a more open conception of domestic dwelling space.

More recently, the idea of ambiguity or functional indeterminacy was introduced in the architectural debate, for which contribute the principles *de-hierarchization* of the internal organization of the house. We shall approach these different concepts, attempting to frame them and pointing out the main contributions of the principle authors who have reflected on them.

The idea of flexibility within the domestic space is a very comprehensive concept with distinct interpretations for different authors. This concept presents itself as an appropriate response to the excessive determinism of the house, as an opportunity to respond to the identified social changes and the evolution of lifestyles; and as a response to present-day dissociation between proposed housing models and emerging ways of living. (Paricio & Sust, 2000). For Monique Eleb-Vidal "flexibility poses the problem of habitat

adaptation to the ways of life of users, while at the same time sets the possibilities of appropriation of dwellings by the dwellers" (Eleb-Vidal, 1995). In other words, flexibility may be the key factor for the possibility of a dwelling design that gives answer to the question of how to propose a spatial and constructive structure – which is by nature static and long-lasting – that can adapt to different inhabitants, with distinct and changing social, cultural, and space-use characteristics. Also, as Eleb-Vidal points out, a design that is more open to a richer and more varied appropriation by the dwellers.

Although more commonly associated with the ability to physically change the shape of the domestic space – through mobile walls, sliding doors and folding panels, etc …– the idea of flexibility must be viewed in a more comprehensive way, as the possibility of creating greater use and greater versatility in the house and should especially be thought of as a matter of potential (Fuertes & Monteys, 2001). As Rem Koolhaas states in *S, M, L, XL*: "Flexibility is not the exhaustive anticipation of all possible changes. Most changes are unpredictable. (…) Flexibility is the creation of margin – excess capacity that enables different and even opposite interpretations and uses of space." (Koolhaas 1995).

In this sense, the concept comprises both the idea of active flexibility and the idea of passive flexibility; these are two types of strategies – which can complement one another – that can contribute to the design of a renewed house, a house more open to different use and appropriation, better prepared for the evolution of dweller use, more able to allow and host changes in family composition and life, and more capable of receiving the future incorporation of new equipment and activities.

By active flexibility we can understand the solutions that are characterized by the possibility that they offer the inhabitants of physically changing the shape of the interior spaces of the dwelling.

In this category we find technical solutions that seek to distinguish, from the outset, in the design process, the fixed and perennial elements from those that may be designed as movable or changeable components; taking advantage of the possibilities of the latter, solutions based on the idea of active flexibility propose the use of moving/moveable parts (or elements that can be installed and removed easily) that can ensure different interior configurations of the domestic space. Among these flexible space-defining components one can find: light construction walls, easy to assemble/disassemble, or even moveable; sliding or folding panels and doors; easy to install/uninstall cupboards, cabinets and wardrobes, working simultaneously as storage and as spatial partitions, etc.

According to Monique Eleb-Vidal, this space transformation approach can be seen in two different ways: as initial flexibility and as permanent flexibility (Eleb –Vidal, 1995).

In the first case, the principle is that future inhabitants can choose the configuration of the interior of their dwelling, thereby participating in the design of their home, but only at the initial moment of its occupation. This approach, with direct implications for the architectural design, but also for the very construction process, is particular interest in the role that each family or individual can play in shaping a specific solution for the internal configuration of the home, thus allowing for a better match between dweller's needs and aspirations, appropriation and domestic space. It is less interesting in the long run, because it does not propose solutions designed to accommodate future change, in family structure and family life, transforming and evolving dweller use, etc.

As an example of the possibilities of initial flexibility we can find John Habraken's Project called Supports. In this housing scheme, Habraken starts from the distinction between what he named support – referring to the building's physical structure and infrastructure – and infill – referring to inside space configuration and equipment. This distinction clarifies what is fixed and unchanging and what is configurable and changeable; it is the infill elements (walls, doors, cabinets, cupboards, wardrobes, kitchen and bathroom equipments, etc.) that ensure the flexibility of the solution as they allow, within the support, the permanent elements of the building, every home to be designed and finished according to the needs and desires of the initial dweller population (Habraken, 2000).

Permanent flexibility, still a proposal based on an active flexibility strategy, proposes technical solutions that seek to ensure the possibility of changing the inside domestic space throughout the dwelling's lifetime.

Monique Eleb-Vidal proposes the subdivision of this concept into three different sub-items: mobility, an idea that implies a rapid change of the dwelling space, throughout the day, depending on the activities that take place therein; evolution, implying the possibility of modifying the internal structure of the home in the long term, according to family change or use transformation over time; elasticity, corresponding to the possibility of modification of the dwelling's usable surface, by addition or subtraction of compartments (or sets of compartments) to house (Eleb-Vidal 1995: 103).

In the case of permanent flexibility, the main idea is to design moveable or moving components that allow, in a simple way and in the short or long time, for the adapting of the house to future change and to modifying use and appropriation needs of the dwellers.

As an example of this type of approach, we can point out Steven Holl's housing design for the city of Fukuoka in Japan, built in 1991. In this housing ensemble, Holl designed a flexible interior configuration for the apartments based on the proposal of a set of mobile elements – revolving and sliding doors, panels and cabinets – to ensure the possibility of spatial transformation of the interior of the house, both on a daily basis and also as a long-term possibility (Holl, 1996; French, 2008).

By passive flexibility – also named by some authors as adaptability – we can understand the idea of ensuring different possibilities of use and appropriation in the domestic interior without physical alteration of its space structure.

As stated by Gerard Maccreanor in his article *Adaptability*: "Adaptability is a different way of viewing flexibility. The adaptable building is both transfunctional and multifunctional and must allow the possibility of changing use; living into working, working into leisure or as a container of several uses simultaneously." (Maccreanor, 1998).

Reis Cabrita and Baptista Coelho, long-time researchers in the field of housing architecture in LNEC (Portugal's National Laboratory of Civil Engineering, in Lisbon) also support the idea of adaptability as central to the design of the domestic interior. Cabrita and Coelho indicate dimensional and organizational characteristics of different compartments of the dwelling as responsible for this spatial possibility (Cabrita & Coelho, 2009).

These authors appoint a set of design principles for ensuring the adaptability of housing interior spaces, among which are: design of the different spaces of the house without significant dimensional variations; design architecturally neutral spaces to minimize the functional determination of each compartment; design and position openings (doors and windows) so as to minimize their possible space-use limitation, and maximize different uses in each compartment; design circulation spaces and areas in order to increase their capability for other uses; design spatial configurations that encourage and multiply the relationship and spatial connection between different compartments of the dwelling (Cabrita & Coelho, 2009).

The idea of passive flexibility or adaptability is directly related to the concepts of versatility, spatial ambiguity and functional indeterminacy, advocated also by several different architects and authors.

Herman Hertzberger is one of the supporters of the idea of versatility as a means for a richer architecture, characterized by a higher possibility of appropriation. In his book *Lessons for Students in Architecture*, Hertzberger clearly states his disagreement with the idea of active flexibility: "Although a flexible set-up admittedly adapts itself to each change as it presents itself, it can never be the best and most suitable solution to any one problem; it can at any given moment provide any solution but the most appropriate one. Flexibility therefore represents the set of all unsuitable solutions to a problem". He instead proposes that "the only constructive approach to a situation that is subject to change is a form that starts out from this changefulness as a permanent – that is, essentially a static – given factor: a form which is polyvalent. In other words, a form that can be put to different uses without having to undergo changes itself, so that a minimal flexibility can still produce an optimal solution." (Hertzberger, 1991).

The idea of functional and spatial ambiguity arises from the motivation to counteract the excessive functional predetermination that most of the current housing solutions – being heirs to modern-movement housing research and realizations – still present.

In fact, under the influence of the process of rationalization of the design process that occurred from the beginning of the twentieth century, the design of the modern functionalist house is primarily based on the idea of optimizing space, being founded on a three different leveled predetermination: an objective determination of domestic activities and functional requirements that the house had to ensure; the determination of the 'right' shape and size of each compartment to accommodate these activities, functions and needs; the determination of the relationship between each of these spaces, also dictated by purely functional assumptions. This results in a housing space configuration, whose spaces are rigidly hierarchical, both from the point of view of its size and area, and from the point of view of its position and relative spatial relationship.

Ambiguity – both functional and spatial – can thus be understood as the possibility of designing and proposing dwelling spaces without functional predetermination, that is, open, because of its features – its area, shape and architectural characterization, – to different possibilities of use and appropriation. Ambiguity points the way for the *de-hierarchization* of the dwelling space.

In *Complexity and Contradiction in Architecture*, Robert Venturi, defending a more passive than active flexibility, introduced the idea of ambiguity stating that "the room with a more general than specific purpose, and with removable furniture instead of movable partitions, provides a flexibility that is more perceptive than physical (…) This valid ambiguity promotes a useful flexibility." (Venturi, 1995).

Xavier Monteys and Pere Fuertes also defend the idea of spatial and functional ambiguity as a means to achieving a house more open to different use and appropriation: "we can assure that the greater the specialization of the house has been, and more undefined spaces have disappeared from its internal structure, the greater has been the loss of flexibility in the dwelling." (Fuertes & Monteys, 2001). These authors argue for a greater formal and dimensional equivalence between different compartments of the house and a greater functional indeterminacy in the spaces design as a means to a more rich and interesting home. Paricio and Sust are also among those who support the idea of an ambiguous partition of the house, as a possibility to expand the versatility of the use of space, without the need for physical transformation (Paricio & Sust, 2000).

Finally, the idea of *de-hierarchization* of the dwelling space, which appears as an idea that brings together some of the previous topics: on the one hand, it refers to the dismantling of the traditional (and modern) dimensional and formal hierarchy of the house compartments, being supported in the same concept of functional ambiguity of spaces. The proposal is thus to establish formally and dimensionally equivalent dwelling spaces, so that this indeterminacy constitutes

an opening to use, that is, that each dwelling space can accommodate the development of various and changing household activities.

On the other hand, it refers to the dismantling of the relationships traditionally established between the different compartments of the house, suggesting that the circulations should be incremented and even duplicated, circulation redundancies should be proposed, in order for the house to liberate itself from the excessive hierarchy of movement between the spaces of the house.

In the search for the idea of *de-hierarchization* of the dwelling space, some authors have pointed out the fact that many of pre-modern urban housing solutions have internal spatial organizations where we can find features and qualities that today we are seeking for the design of a renewed home: low functional predetermination of spaces; formal and dimensional equivalence between compartments; circulation multiplication and increased communication links between different compartments; duplication of entries to the home; existence of different kinds of spaces in direct contact with the exterior of the house.

All these features extend the possibilities of use and appropriation of the house, allowing different models of life and their change and evolution over time. Thus, they constitute spatial organizations that should be considered relevant case studies for the analysis and verification of the ideas outlined; also for the establishment of principles and strategies for a more flexible home.

4 FLEXIBILITY STRATEGIES: SOME GUIDELINES FOR THE DESIGN OF THE DWELLING SPACE

The achievement of flexibility in the domestic architectural space has to be considered from the beginning of the design process, in as much as it is deeply related with structural, infrastructural, spatial and tectonic features. In this sense, it is not a method that can be introduced in a design process; to be consequent, it should be a foundation to the design development.

Without intending to be exhaustive, this final part of the article aims to point out some of the most important design strategies that can be used – and have been by several architects in the last thirty to forty years – in the pursuit of the possibilities of flexibility in the domestic space. Although they are analyzed separately, the most interesting results emerge when different strategies are developed simultaneously, resulting, in the best cases, in dwellings with a radically different spatial configuration, opened to different and changing use, and more adaptable to social and cultural specificities.

4.1 *Building stratification – the mobile and the fixed*

As we have seen, especially for active flexibility, a clear definition of what is fixed and what can be changeable or moveable in the house is fundamental to any design solution. The possibility of a flexible domestic space is conditioned, firstly, by the fixed and permanent elements and the way these may allow for a variable use.

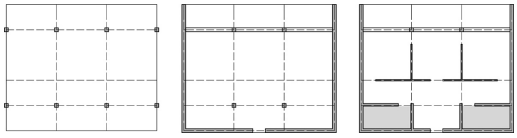

Figure 1. The fixed and the mobile.

Several authors devoted their study to the relationship between the different architectural elements that define the building, focusing on how their design should permit and maximize flexibility and transformation: Habraken (2000), as we have mentioned, differentiated between *support* and *infill*; Leupen (2006) proposes the ideas of *frame* and *generic space*; Brand (1997) suggests that a building is composed of 6 layers: *site*, *structure*, *skin*, *services*, *space plan* and *stuff*. Each one of these authors identifies a set of elements that have longer life cycles and are more difficult to alter, change or remove; and the elements more prone to transformation. They propose a design that ensures the independence of these different layers or elements, so that the change is possible in the less permanent ones, without affecting the others. In other words, in a flexible solution different building layers should be independent, so that one layer doesn't hinder the possibility of change in another layer. In a flexible residential building, structure, skin, services and space should thus be designed as autonomously as possible.

4.2 *Dwelling facilities – rationalizing and liberating domestic space*

Another important strategy for the design of the flexible house is related with dwelling facilities – mainly kitchens and bathrooms, but also technical and storage rooms: their design solution and their position in the interior space. The main idea is to design these spaces as efficiently as possible, to organize/concentrate/arrange them in the most optimized solution; this will have benefits of two different kinds: on the one hand, liberating as much space as possible for the rest of the dwelling's uses; on the other, rationalizing domestic infrastructure – water supply, plumbing, fume exhaustion, etc.

Different design strategies have been followed to attain these goals. These can mainly be divided into two basic options: the design of linear bands of facilities and the solution of designing these facilities as nuclear blocks. In the first case, these technical bands can be set along one (or more façades), leaving the interior of the house free for use and appropriation, or they can be set as an interior band, acting as a dividing element for the remaining space of the house. In the second case, the nuclear blocks, grouping facility rooms, can be set on the periphery of the dwelling – setting the rest of the

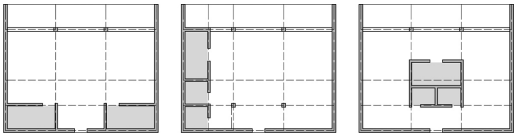

Figure 2. Rationalizing facilities, liberating space.

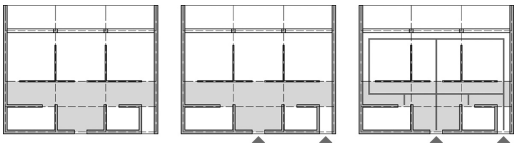

Figure 4. Circulations and entries.

space free, or they can be designed as 'free-standing' volumes, positioned in the middle of the interior space, acting as an organizing element for the dwelling space.

4.3 *Mobile partitions – transforming interior space*

As was argued before, this strategy starts from the understanding and clear distinction between what is fixed and unchanging in the residential building – structure, infrastructure, technical facilities, and tectonic envelope –, and what can be mobile, configurable and changeable: walls, doors, cabinets, cupboards, wardrobes. These components can be designed to be sliding, folding, and moveable components, or to be easily installed and removed whenever necessary.

Based on these possibilities of transformation, the interior space of the home can be altered: different rooms can be joined or separated; the spatial disposition of the house can be more or less divided. These transformations can occur on a daily basis, if the elements are designed for easy movement, or only thought of for long-term change, in a more lasting transformation of the interior structure of the home.

4.4 *Circulations and entries – increasing the possibilities of domestic appropriation*

Another strategy is related with circulation and the definition of entrances to the house. As was argued when discussing the idea of *de-hierarchization* of the domestic space, strong hierarchy of circulation and mono-functionality characterizes modern dwelling models.

The idea behind this strategy is to counter this situation through three types of solutions: firstly, the design of circulation areas – entry halls, corridors, and

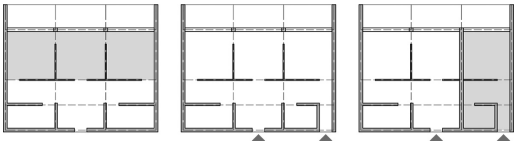

Figure 5. Ambiguous spaces; expansion/retraction of the house.

distribution spaces – so as to render them multifunctional. This proposal is based on the idea of providing larger dimensions and area to these spaces, so as to increase their use potential. Secondly, design alternative circulation paths through the house, so as to increment relationship between compartments, avoiding the 'efficient' mono-circulation of the modern house. Thirdly, based on pre-modern dwelling models that had two (or more) entries to the house, design alternative entrances to the house, connecting different functional sectors to the exterior, so as to increase the possibilities of interior-exterior physical relationship, and thus augment the potential use and appropriation of the dwelling.

4.5 *Ambiguous spaces – increasing the possibilities of domestic appropriation*

This strategy is primarily related to the idea of adaptability. The idea is to design the different spaces of the house – normally named as living room, dining room, bedroom, children's room, study, library, among others – as undifferentiated rooms, both functionally (without pre-determinacy) and spatially. This means designing the main rooms of the house based on an equivalence of dimensions, area, shape, architectural features, inside-outside relationship and circulation relationship (with other rooms). A house based on this kind of design solution will assume the ideas of adaptability and polyvalence as its main objective, proposing an open use and appropriation of its interior spaces by the dwellers, in as much as it is not designed for a functionally predetermined purpose or for a programmed circulation.

4.6 *Expansion and retraction of the house*

Finally, the idea of an elastic house, that can grow or shrink according to dwellers needs, is the last flexibility strategy presented. The idea is to design a housing system in which the apartments can change their spatial limits, through a design that allows for rooms to be separated or included in the house.

Based on this principle, and taking advantage of other ideas like multiple entries and careful location of facilities, design solutions can propose: solutions with groups of houses with varying dimensions and areas; solutions where larger houses that can be split into smaller ones; solutions that allow for the separation of one or two rooms from a house in order to cerate an autonomous working space or a studio apartment; among others.

5 FINAL CONSIDERATIONS

Social, labor and technological changes are reflected in contemporary lifestyles and modes of dwelling, which are also in continuous change. The inherited housing models of the modern period feature a spatial and functional rigidity that hinders their suitability and adaptation to the needs of the dwellers, both present and future.

Flexibility, in its various aspects, presents itself as a possible way for the design of a more adapted and suitable home for each dweller, and also more open to future needs and aspirations. Strategies for the design of a more flexible and adaptable dwelling have been introduced, developed and implemented during the last decades, but their study and application should be furthered, to give answer to the growing need for a more suitable and adequate provision of dwellings, in a time of accelerated social, labor and technological change.

The pursuit of flexibility in the design of the contemporary house is justified because, as Alan Colquhoun once said, "the demands of modern life are so complex and changeable that all attempts by the architect to anticipate them will result in a building unsuitable for its function." (Quoted by Eleb-Vidal, 1988).

Dutch experiment in co-creation in a collectively commissioned housing project

T.T. Veeger
Chair of Architectural Design and Engineering, Department of the Built Environment, Eindhoven University of Technology, Eindhoven, The Netherlands

S.J.E. Maussen
Chair of Real Estate, Department of the Built Environment, Eindhoven University of Technology, Eindhoven, The Netherlands

ABSTRACT: Only a small percentage of the new homes built in the Netherlands in the last decades have been built by private commissioning (11.2% in 2012, www.statline.cbs.nl). The major players in the Dutch housing market are the commercial developers and the social housing corporations, the latter focuses mainly on the segment of tenants in the lower income category. This contrasts greatly with neighbouring countries like Belgium and Germany. The percentage of social housing is very low in Belgium; more than three quarters of the Flemish people own their own individual house and the development of large-scale housing projects is limited. In both Belgium and Germany, the role of the architect is strongly geared towards the practice of private commissions. It is also a statutory requirement for a client to hire an architect in both countries. This differs significantly to the situation in the Netherlands where the architect focuses mainly on the design of large-scale housing projects. The Dutch Government policy is currently geared towards the encouragement of private commissioning and wants to achieve a significant growth in the segment of Individual project development (IPD) and collectively commissioned housing development (CCHD). (30% of the new homes built in a year) A CCHD project is a building project with self-management: a group of several clients work together to acquire a (construction) site, hire an architect and select the contractor who executes the project. In most cases, the clients are also the future residents of the housing development. Developing a collective housing project means that shared parts such as the facade, foundation and community facilities are collectively designed in consultation with the group, while the individual clients still have much freedom of choice in the design of their own home. This has consequences for the professional role of Dutch architects and the way they react to the changing role of their clients. The design methodology and attitude of the architect in the design process in a CCHD project is very different to the traditional way in which a Dutch architect works. In addition to his design qualities, his organizational and social skills also become important in order to adequately deal with a collective group of 20 or 30 clients. This paper describes the process of developing a CHD project and a case study where an architect has experimented with the evolving design process and the (im)possibilities of co-creation in Collectively Commissioned Housing projects.

1 INTRODUCTION

Until the Second World War was common for residents and business owners in the city to build one or more houses for private occupation or pension provision. The city was built 'step by step' and 'brick by brick'. Each resident and entrepreneur realized their residentials wants, resulting in the current Dutch inner cities, full of variety and surprises, where citizens like to stay, work and/or live. It is a reflection of the way of living (together) and of society (Baas, et al., 2015). Since the mid-20th century a supply-driven development model for housing is the common practice in the Netherlands. This was strengthened by the development of the large-scale VINEX projects in the 90's. Although the supply-oriented development form has resulted in reducing the quantitative housing shortage, there was little regard for the wishes of citizens. Because insufficient attention was paid to the various living requirements of the customers, this supply oriented development became more and more criticized. In response to that, the government stated in a their policy document: Wonen in het jaar 2000": 'Mensen, wensen, wonen, (Ministerie van Vrom, 2000, p. 6) that demand driven development will be encouraged. One of the five core themes in this document has the slogan 'Citizens first' (Ministry of VROM, 2000, p. 6). The citizen is central in the housing policy. This refers mainly to citizens as producers' and not merely as consumers'. Citizens themselves must

be able to shape their lives , make choices and take responsibility (VROM, 2000). Private commissions, whether or not collectively, will be seen as an important means. In addition, trends such as citizens becoming more assertive and individualization, reinforced this renewed focus on private commissioning (Dammers et al, 2007). Private commissioning has both an individual and a collective side. In private ownership, new residents are involved in the entire development process, so that housing preferences are largely realized. This creates a more differentiated supply of dwellings and a greater involvement in the environment. Collective initiatives (collectively commissioned housing development, abbreviated CCHD) on the Dutch housing market are a relatively new phenomenon. During recent years this kind of initiatives increases as also in other sectors, like the energy sector and health care. A shift towards more collective initiatives is particularly perceptible in areas in which working on a larger scale is advantageous. By taking part in innovative networks and cooperations consumers are increasingly becoming producers (De Moor 2013, Rotmans 2012). Rotmans following Toffler, talks about prosumers. This leads to a shift of tasks and responsibilities towards civil society. An advantage of this development is that it leads to more involvement of citizens and a more efficient way in which societal tasks can be carried out. A disadvantage is the larger degree of responsibility of "collective" citizens, such as the need to attain a certain self-organization and the risks that are involved in the cooperation process. Therefore, the question arises whether citizens are able to bear these new responsibilities (De Moor 2013). In view of this, different professionals, such as architects, process supervisors, constructors etc. are involved to support these initiatives. In this contribution, both the possibilities and the limits of collectively commissioned housing development (CCHD) are explored in relation to the changing role of the architect.

2 COLLECTIVELY COMMISSIONED HOUSING DEVELOPMENT

Three forms of development with participation of future residents are, according to Boelens en Visser (2011), Participatory Commissioning, Collective Private Commissioning (CPC) , and Private Commissioning. The focus in this paper is on Collective Private commissioning. Boelens en Visser (2011) define CPC as 'a form of commissioning in which a collective of like-minded private parties acquire a piece of land or pieces of land and jointly decide how, and with which parties, the homes, private spaces and sometimes even public spaces are to be laid out and constructed. The ministery of VROM defined CPC as 'a special kind of project development, where a group of future residents has full legal control over and is responsible for the use of land, design, construction of the houses and the surroundings environment (Maussen et al., 2011). These definitions also apply when seeing CCHD as a process

Preparation	Development	Implementation	Management
Development association Municipality (Local) Municipality (province) Facilitator (Architect)	Development association Municipality Facilitator Architect	Development association Municipality Facilitator Architect Contractor Supervisor	Development association Municipality

Figure 1. Actors in phases in CCHD process.

in which the leading party is a group of individuals, united in an association or foundation, who are also the future residents and have full decision-making power at every stage of the project. They acquire the land and develop, a complex of houses (individual or apartments), with the help of an architect accompanied by consultants and contractor. The group as a whole has control over the entire complex while the individuals separately have control over their houses (Kapedani, 2011).

3 PROCESS AND ACTORS

3.1 *The CCHD process*

The CCHD process can be divided into four phases in which the development phase typically lasts the longest (Maussen, 2011). The stages to be distinguished are: preparation, development, implementation and management. In each phase there are different players with different motives in the process. According to Janzen (2015) the Actor Network Theory (ANT) offersa theoretical basis for the elaboration of these actors. Figure 1 shows de actors in the CCHD process.

The 'leading actors' within a CCHD process are the actors who organize the network. They determine how other actors should act and they have much influence on the process. The four leading actors in the CCHD process are, the Development Association, the Municipality, the Facilitator and the Architect.

3.2 *The role of the architect*

The involvement of users and tenants at an early stage is increasingly crucial for a successful development. Architects become advisors of the client and are often involved in various partnerships. They are mainly called upon because of their communication and process skills.

For architects this approach leads to more is greater equality with the client (Doorn, van, 2014). In some cases, the architect might even be the initiator of a CCHD project. The architect is the expert in the field of technology and aesthetics. He is an important actor in the design phase of the project. The architect is expected to design the project so that it fits the budget, the requirements of the client, meets government regulations and technical conditions. The

architect is commissioned by the CPO group (expert-team Eigenbouw 2014). The architect draws up a contract with the development association in a CCHD project. Because the number of participants in a CPO project may vary, the designs, in many cases, develop overtime. In the design process there are a number of stages; urban design, sketch design preliminary design, final design, and technical design. In each stage the design is further refined. It is important that there is sufficient interaction between the development association and the architect and that both parties can take part in thinking about the design. The architect for instance, can offer various choices to the association, so the association may exert influence the result. In the phase of the urban design/preliminary design the architect and the association jointly look for the allotment that best fits the budget of the participants. In addition, an estimate is made of the number of dwellings, and the main form and layout of the buildings is being elaborated. Since ground costs are a substantial part of the price of a home this is where the foundation for a successful project is being formed. The large commitment of the architect gives added value to the fit that is strived for (Hemmen 2004). This will advance the meeting of individual needs but also the making of concessions for the group. The architect has a double role as a mediator and a designer. At the same time a greater say of the end users means that the architect has to play more modest role as acting as a 'designing advisor' and project manager rather than an architect 'pur sang' The final design follows the preliminary design. Building systems, materials and installations are determined together with the end users. The (collective) option list is worked out, constructions are established and final choices with respect to sustainability are made. The final floor plans of the homes with kitchen and bathroom are worked out. On the basis of these documents the building permit is requested. The specifications and drawings to request the price a contractor are be made in the next phase. In the contract stage, the architect has an advisory role. During the realisation, the architect has the role a supervising consultant. The daily monitoring of the construction is in the hands of a supervisor.

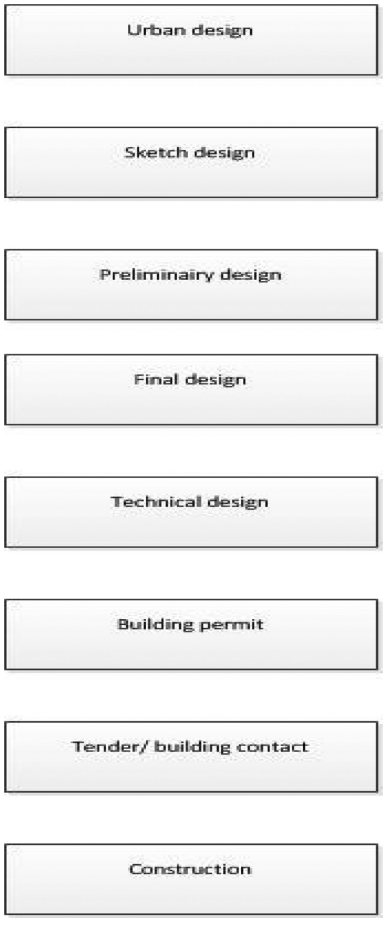

Figure 2. Design phases in a CCHD process.

4 COMPETENCES OF AN ARCHITECT

In these projects the social skills of the architect are important. This applies to cooperating with other parties in the building industry, and also to communicating with end users in co-creation projects. It requires empathy and a certain modesty with respect to one's own ego and taste (Mierlo, van 2014). Guarding the architectural and functional quality, is of course the main task of the architect. The challenge for the architect is to explain the quality of the design and the associated design decisions to the participants. It seems that in many cases, architects should play a less prominent role as an architect. The consumer askes for "real" architecture, the functionality of the solution is more important. At the same time, clients respect for architectural knowledge of the architect. His ability to present integral solutions which are more than the sum of its parts, is also seen as a unique quality of the architect (Doorn, van, 2014). Van Mierlo, (2014) confirms that architects who are able to translate latent needs into successful products in addition to the defined requirements, may surprise the consumer. According to Hermans (2014) the relational and analytical skills of architects and the extent to which they are able to design a high-quality total solution to the problem, are often the decisive factor for success. According to Looysen (2014), the architect should be careful when dealing with the balance between facilitating and taking initiative. That means that an architect has to continuously ask himself the question; 'what can I decide and when is collective decision-making needed?'. This is possible only with preper understanding of the group and the process. Professionals should not deal with various issues among themselves. In the end, the participants in the CCHD project are the principals contractors.

5 CASE STUDY: A COLLECTIVELY COMMISSIONED HOUSING PROJECT IN CASTEREN

5.1 *Introduction*

Project: 34 starter houses
location: Zandtsraat Casteren
architect: van den Pauwert architecten
project architect: T.T. Veeger
Facilitator: BIEB Eindhoven
Contractor: van Bree Someren

The construction of 34 starter dwellings in 2005 in Casteren, (a small village in the south of the Netherlands and part of the municipality of Bladel), was a joint initiative of the municipality of Bladel, together with the village council of Casteren and a "self-build" starters collective. The aim of this initiative was to promote the quality of life in this small village. Due to the increasing house prices in the rural area of Bladel in the last decade, it was no longer possible for starters to buy a reasonably priced house in their own village. They were forced to move away and therefore the average age of the population has gone up dramatically in the last decade. A community with a higher proportion of older inhabitants creates a loss of facilities in the village, such as the primary school, shops, the bank and a doctor (11).

The province of Noord-Brabant considered the project in Casteren as an example for how to deal with the problems of an aging population in the countryside, so they agreed to carry out this pilot project for a period of 5 years. Infill development was allowed without consequences for the maximum housing quotas of the municipality of Bladel. In the "village plan" the municipality provided the opportunity to build with the restriction that the project should not affect the character and urban quality of Casteren. The starting point for the municipality was that the starters collective should take the lead in the development and should take all steps itself to develop a final plan which would be reviewed by the municipality. To allow this process to proceed properly, the starters collective consulted the Eindhoven office bureau BIEB, who is experienced in supporting starters collectives. Besides the design of the dwellings, the urban plan was also developed with the architect. The municipality reviewed the total plan and the subdivisions when it was completed.

5.2 *The process*

The starters united themselves in a collective that had to develop and build the project. This would decrease the total cost of developing the project for the buyers. The municipality provided a location, an abandoned old farmhouse in the centre of Casteren. The municipality prepared the site for construction and sold it to the starters for a reduced price of €166/m^2 excl. VAT and with an average building plot size of 200 m^2. An additional requirement imposed by the municipality that the final price of the housing should remain

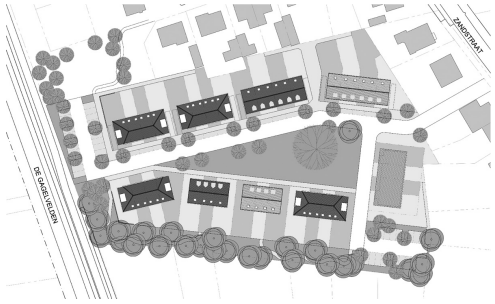

Figure 3. Final urban plan.

below €158,000, ranging in price between €110,000 and €135,000, was succeeded at completion. Another requirement was the introduction of "socially bound ownership" which means that for the next 30 years, when moving, the houses should be sold back to the local housing corporation which puts the house back on to the market as a starter home. Possible increases or reductions in the price of the house will be settled with the ex-starter for 65%, so the price reacts in a certain way to the housing market. In this way, the price of the property will stay in comparison with the housing market but the house will remain available for starters for the next 30 years.

5.3 *The area*

Casteren is a loosely clustered village with an open to very open typology. The village is predominated by semi-detached and detached houses in an informal and traditional rural dwelling pattern. In the centre, there is an ancient triangular village square where the old building structure is preserved, with the church as a landmark of the village at the intersection of the Zandstraat and Kerkstraat. The social services and the cafe are located here. Several other square-shaped spaces are also provided within the village. This theme plays a role in the design of the urban plan for the building plots in the project for the starters on the Zandstraat.

5.4 *Co-creation of the urban plan*

The starting point of the process was the maximum input of future residents in the development of the plan. The plan was developed by the architect, in close collaboration with the group of starters, after an intensive study of different alternatives. To provide the future residents with a better understanding of all the alternatives, the advantages and disadvantages were discussed: for example parking on their own plot or a shared public parking lot, living in a courtyard or individually in separate buildings, etc. The presentations were accompanied with examples of realized projects. The alternatives of "Campus", "Castle", "Strips" and "Es" were discussed (figure 3). After an intensive study of the alternatives, the group chose the plan of the "Es", an infilling with a triangular plaza enclosed by a number of building blocks

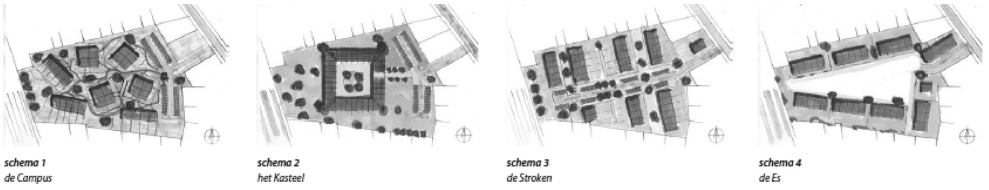

Figure 4. Alternatives in the urban plan.

Figure 5. The Ateliers.

whose maximum length is equal to the size of a long farmhouse. Such a space in a small village is called an "Es" and is a spatial element that occurs frequently in the Brabant landscape.

The village of Casteren has been developed in the last century in an informal way, the houses are built one by one over a long period and they differ in form and architecture. This theme is reflected in the plan so that it connects with the existing character of the village. Variation in height, architecture and shape of the new housing provided a diverse character. A total of 34 houses were realized with a variety in size and appearance and grouped into blocks of 4 houses. Sufficient space is maintained between the blocks, similar to the buildings in the surrounding village. On the west side of the plan, a free view to the surrounding fields is maintained so that it keeps the existing relationship with the countryside. The central square got a "green" character with existing trees. A row of existing oaks where saved on the south side. The plan is accessible from the central square by car. A new path for cyclists and pedestrians connects to the slow traffic circuit in the village. Parking is solved on the road and several houses have got their own parking space on the lot. There are two small parking lots for homes that are not located directly on the road, somewhat out of sight from the main square. The plan assumes a parking ratio of 1.5 parking spaces per house.

5.5 *The design of the houses*

A plan of action was made for the design of the houses so that the urban plan was developed together with the maximum input of the future homeowner in the development of their own house. They could chose a design based on one of the four basic types.

Figure 6. Housing.

In this way, the architect could react on the demands of the starters with their diversity of needs in terms of size, architecture and construction costs.

For two different types, the façade was designed in a modern and a traditional architecture style with the same interior plan. A change in layout of the house was possible for all the starters. The costs were adjusted by the building contractor during tender, so that future discussions in price were prevented. In this way, a maximum of flexibility for the future buyers was ensured.

A special block of four houses named "the Ateliers" was designed in a specific style of architecture. Materials like aluminium cladding, galvanized steel columns, anthracite-coloured brickwork and an aluminium roof were used in the block. Varnished Oregon pine wooden frames combined with laminated beams under the roof and wooden roof sheets creates a warm ensemble. Two buyers chose to incorporate a free-standing spiral staircase to connect the upper floor to the living room giving the atrium a strong spatial effect.

6 CONCLUSION

The amount of collectively commissioned housing projects is increasing in the Netherlands. It reacts to the policy of the Dutch Government, which is gearing towards the encouragement of more private commissioning to achieve a significant growth in the segment of Individual project development (IPD) and collectively commissioned housing development (CCHD). (30% of the new homes built in a year). It produces besides a stronger involvement of future residents in the project and a considerable saving in the final house price (between 15% and 25%). Besides the design of the houses, the new owners are actively involved in the development of the urban development plan in consultation with the architect. This has a tremendous effect on the social cohesion of the new neighborhood. These kinds of projects have consequences for the professional role of Dutch architects and the way they react to the changing role of their

Figure 7. “Building party” starters project de Weebosch.

clients. The design methodology and attitude of the architect in the design process in a CCHD project is very different to the traditional way in which a Dutch architect works. The project in Casteren has been a showcase and has dragged national attention to this way of working. National television has covered the project and it has been an example for many more starters projects. It shows that it could be successful but more study is needed to compare the different methods used by architects in this type of co-created projects.

The sun for all: Social equity and the debate on best solar orientation of high modernist housing

U. Poerschke
The Pennsylvania State University, University Park, PA, USA

ABSTRACT: The Modern Movement of the 1920s developed a preferred housing scheme that arranged parallel building rows to run from north to south, with bedrooms facing east and living rooms facing west. This strict orientation scheme—known as *Zeilenbau* (line building)—was more or less unanimously shared among the architects of High Modernism. However, their arguments for *Zeilenbau* varied widely: improved hygiene; cost reduction in the building industry; accommodating the day rhythm of working families; implementing scientific investigations in the design process; aesthetics; and others. This paper focuses on the discussion about the relationship of social equity and best sun orientation by studying particularly one proponent of this argumentation: Hannes Meyer. Investigating this debate in High Modernist architectural discourse can help us reflect and critique today's newly occurred debate on strict building orientation with its very different emphasis on energy efficiency.

1 SOLAR ORIENTATION IN EARLY TWENTIETH CENTURY HOUSING

Throughout architectural history, from antiquity to today, we find a clear preference to orient main spaces in residential buildings toward south (in the northern hemisphere). Spaces with south windows receive the most sunlight in winter and the least sunlight in summer, which is for both seasons the preferred case. However, the Modern Movement of the 1920s developed a preferred housing scheme that orients spaces to east and west—with bedrooms facing sunrise and living rooms facing sunset. This strict orientation scheme—known as Zeilenbau (line building)—was shared more or less unanimously among modern architects, including Walter Gropius, Ernst May, Walter Schwagenscheidt, Hannes Meyer, Ludwig Hilberseimer, Otto Haesler, Le Corbusier, Mart Stam, and the wider circle of CIAM members. Particularly around 1929, many Zeilenbau schemes were built, such as Siemensstadt (Berlin) 1929, Hellerhof (Frankfurt) 1929, Dammerstock (Karlsruhe) 1929, and Haselhorst (Berlin) 1929 (Figs 1–4).

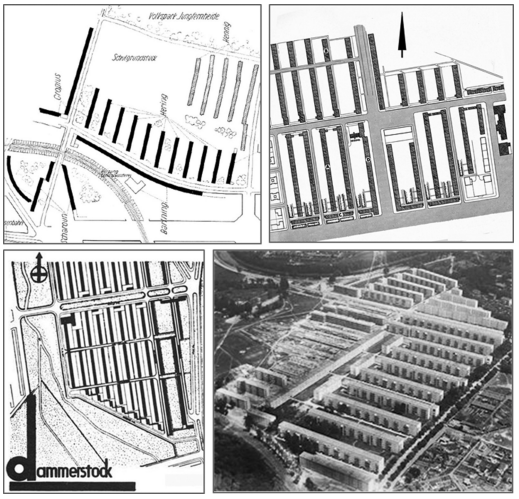

Figure 1–4. Left to right: Siemensstadt (Berlin) 1929, Hellerhof (Frankfurt) 1929, Dammerstock (Karlsruhe) 1929, and Haselhorst (Berlin) 1929 (open sources).

The arguments for this orientation varied widely, thus indicating that justifying a scheme that contradicted the common orientation of many centuries was a problem. These arguments were embedded in the broader topics of the time:

a) Improving hygiene: In the early twentieth century hygienic living conditions were widely demanded and closely connected to urban design. "In radical Zeilenbau, hygiene means exclusively sun orientation," said Adolf Behne in 1930 (165).
b) Implementing scientific investigations in the design process: Basing architecture on increased knowledge of sociology, psychology, technology, construction economy, and environmental studies (wind direction, daylighting, noise) served as justification of building form. Scientifically studying the people's general "life processes" (Gropius 1988: 114; Meyer 1928: 13) was employed to define the optimal housing orientation for the majority of people.
c) Social equity: People of all classes should have equally access to sunlight; providing social housing in the *Zeilenbau* layout was considered the best path to cover this demand.

d) Building for the masses: To accommodate the day rhythm of working families architects determined that sunlight was needed in bedrooms to the east when workers got up, and in the living room to the west when they came home from work.
e) Aesthetics: Despite the fact that most modern architects denied an aesthetic approach to architecture, a repeated formal language could be found in many *Zeilenbau* estates. Only few architects tried to justify *Zeilenbau* aesthetically, for example Georg Lüdecke, who stated that an east-west running building with the main rooms only facing south and the smaller serving rooms—kitchen, bathroom, staircases, etc.—only facing north, became thinner. Such a multi-family house "would look too thin with its low building depth" (Lüdecke 1930: 1480).
f) Cost reduction in the building industry: Lüdecke's argument was also an economical one. Since deeper buildings have a higher floor area–to–facade ratio, less facade surface needs to be built for the same floor area. In his words, the "multi-family house […] needs for economic reasons a larger building depth" (Lüdecke 1930: 1480).

This paper focuses on the discussion about the relationship of social equity and best sun orientation, analyzing primarily one proponent of this argumentation, his writings and projects: Hannes Meyer. His theses will be contrasted by those of modern architecture critic and social activist Adolf Behne who identified *Zeilenbau* and strict sun orientation as inadequately equalizing the society.

2 SUN EXPOSURE AS A CLAIM FOR SOCIAL EQUITY

The general request for more daylight in mass housing had a longer tradition than the debate on best solar orientation in *Zeilenbau*. This request emerged from the critique of dense building blocks in overcrowded cities, particularly London and Berlin. We can find this demand, for example, in Ebenezer Howard's *Garden Cities of To-Morrow* of 1902. In it he contrasted the city in which "the sunlight is being more and more shut out, while the air is so vitiated that the fine public buildings, like the sparrows, rapidly become covered with soot," with the countryside—"that beautiful land of ours, with its canopy of sky, the air that blows upon it, the sun that warms it, the rain and dew that moisten it" (Howard 1902: 16, 13). In his famous diagram of "The Three Magnets" he mentioned "foul air" and "murky sky" as disadvantages of the town, and "fresh air" and "bright sunshine" as the advantages of the country (Fig. 5). Obviously, the Garden City, as the combination of town and country, was intended to combine all advantages. Howard's book was about socio-economic aspects of urban planning. Best orientation of housing was not addressed in his version of the Garden City, but instead the proportion of streets, "so wide and spacious that sunlight and air may freely circulate" (Howard 1902: 39).

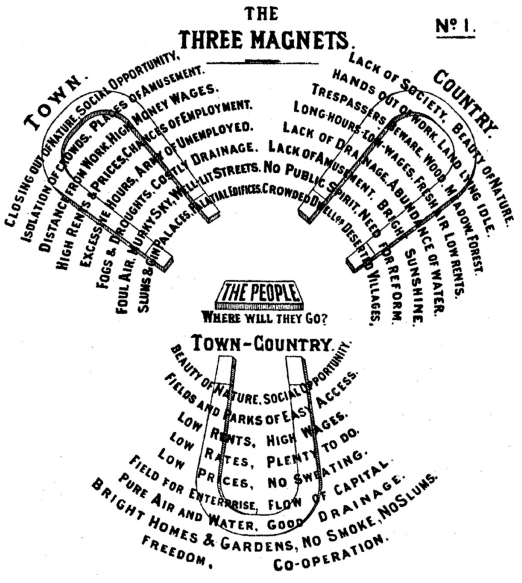

Figure 5. Ebenezer Howard, *Garden Cities of To-Morrow*, 1902: 16.

3 EARLY ZEILENBAU: OTTO HAESLER

Twenty years after Howard's seminal book we can still frequently read the general demand for "sun, light, and air." The question of best solar orientation of housing did not come to the fore before the second half of the 1920s. One of the earliest housing projects that focused on orientation and propagated *Zeilenbau* was Otto Haesler's Georgsgarten in Celle, Germany, in 1926–27 (Poerschke 2015). Haesler's main argument for this orientation was that sun should shine into rooms exactly when people used them: bedrooms in the morning, living spaces in the evening. Over the course of only a few years, his building layouts became more and more specialized by providing small sleeping cells to the east and bigger family rooms to the west (Figs 6–7). Such layouts did not allow flexible uses and had to be occupied very much in exactly the intended way. Voices more radical than Haesler claimed that the masses would learn good living by such strictly defined layouts. Fritz Block, for example, stated in 1927 that a rigorous designation "of all rooms in small apartments should be carried out wherever possible." For Block, this seemed particularly necessary "for the large mass of the working people that must be educated and influenced. […] The worker is highly skeptical of the liberating feeling that we wish him to achieve by new building" (Block 1927: 46, 41). Adolf Rading stated that "there is no purpose anymore of asking occupants; they do not know their needs anymore. […] Therefore it is urgent, as a first step, *on a purely human and social basis and in concert with the economic situation, to determine the housing needs and to build apartments accordingly*" (Rading 1927: 47, emphasis original). This implied that new housing would help occupants learn good dwelling.

4 HANNES MEYER

Hannes Meyer (1889–1954) stands out as one of the architects of High Modernism with highest social ambitions. Already early in his career he became intensively engaged in social questions of housing and urban planning. He was active in the Swiss land reform movement and joined a building cooperative. In 1912/13 he moved to England to live for a year with a relative near London. He visited garden cities such as Letchworth and worker model villages such as Bourneville and Port Sunlight (the latter's name stemming from a popular product of the Lever Company and not from an utopian urbanistic idea of access to sunlight). Before and after his stay in England Meyer worked on housing projects such as the working-class estate Garden City Grünau in the office of Johann Emil Schaudt (1911–12); the estates Margarethenhöhe, Garden City Hüttenau, and the workers estate Breitenborn in the office of Georg Metzendorf (1916); and several other housing complexes while working in the building administration of the Krupp company (1916–18). During the first half of the 1920s he also worked for several non-profit housing corporations (Winkler 1989). All of this laid the basis, as he later stated, "to regard works of art, architecture, or urbanism never outside of the social foundations, from which they emerge" (Meyer 1980: 346).

The first housing estate he built under his name was the Freidorf project in Basel, which he started designing in 1919. After its completion Meyer lived in Freidorf from 1921 to 1926. The orientation of the town houses did not seem to play a bigger role in this scheme (Fig. 8). The estate avoids any building blocks and consists of rows parallel to the streets, leading to gardens unfavorably oriented to the south-east and north-west. Creating symmetric streets and rectangular squares was obviously of higher importance than the best sun orientation of the garden or house. Stated in other words, the appearance of the whole seemed to be more important than the optimization of the single part. Meyer described in 1925 the Siedlung Freidorf, with its parallel building rows of similar appearance and a centered community area, to be a symbol of "simplicity, equity and truthfulness." However, in the same article, he criticized Freidorf already as "a compromise; socially between individual and community, formally between city and countryside" (Meyer 1925: 49, 51).

In 1926 Meyer started a partnership with the architect Hans Wittwer (1894–1952). According to Klaus-Jürgen Winkler, it was Wittwer who brought into the partnership not only excellent design skills, but also a broad knowledge of technologies, and particularly of daylighting, that Meyer quickly absorbed (Winkler 1989: 61). Two spectacular competitions of this partnership became famous, both of which emphasized solar orientation: the 1926 Petersschule (St. Peter's school) in Basel (Fig. 9) and the 1927 League of Nations Building in Geneva (Figs 10–11). Both of them include building wings running strictly from north to south with orientation of classrooms and offices to east and west.

In the journal *bauhaus* the Petersschule project was presented in revised form and included illumination graphs and extensive daylight calculations. For the office wing of the League of Nations Building Meyer and Wittwer asserted that the floor height was "calculated from the illumination coefficient of the work surface" and that the entire complex "was only the result of traffic diagrams, lighting diagrams, insolation diagrams" (Meyer 1927: 6). Both projects claimed that building for a new society necessitated ideal east and west orientation, and, vice versa, that ideal orientation expressed a new society.

At the same time, in 1926, Meyer published in the journal *Das Werk* his first famous pamphlet, "Die Neue Welt" (The New World) which provided an enthusiastic vision of society. Meyer claimed that the "demands we make on life today are all of the same nature

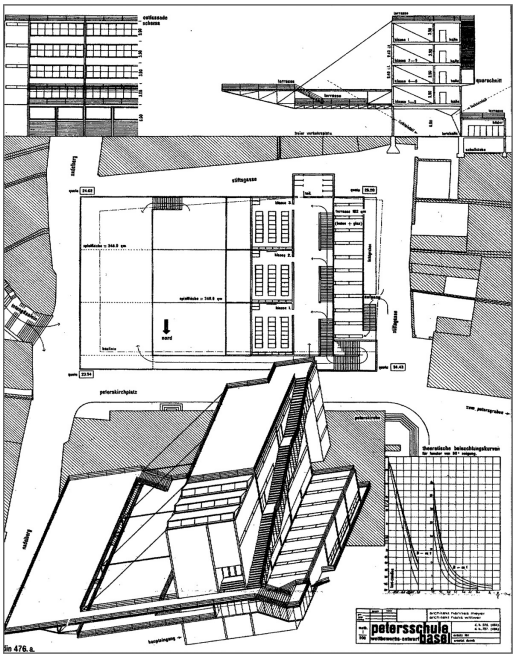

Figure 9. Competition entry for the Petersschule in Basel with illumination graphs (*bauhaus* 1927: 2).

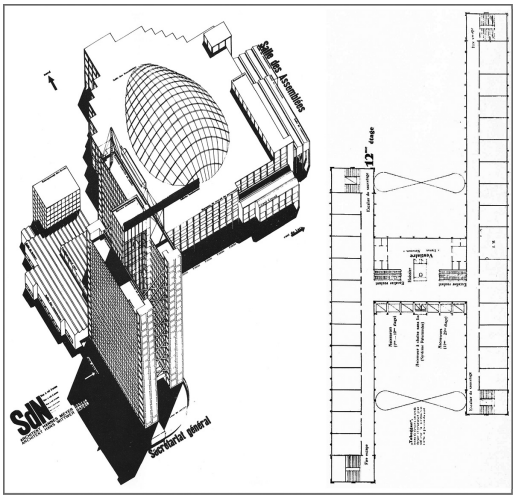

Figure 10–11. Competition entry for the League of Nations Building in Geneva. Isometric view and floor plan of office tower running strictly north-south (Schnaidt 1965: 23, 31).

depending on social stratification. The surest sign of true community is the satisfaction of the same needs by the same means. The upshot of such a collective demand is the standard product. […] The degree of our standardization is an index of our communal productive system" (translated in Schnaidt 1965: 93). Meyer stated that the architect's task is to build for the people's needs, which implied, first, that "the people" had similar needs that could be scientifically investigated, and, second, that it was the obligation of the hour that architects think of themselves as being a part of that same people. These two ideas of equity of people and subordination of the individual under the community, both expressed in standardization, were themes that he carried further and combined with daylighting and other environmental studies. In his pamphlet "bauen" (building), published 1928 in the journal *bauhaus*, Meyer reached a stage where he embraced Wittwer's knowledge on solar orientation and daylighting and related it to his own vision of society:

"[…] in its basic design the new dwelling house becomes […] a biological apparatus serving the needs of body and mind. […]

1. sex life 2. sleeping habits 3. pets 4. gardening 5. personal hygiene 6. weather protection 7. hygiene in the home 8. car maintenance 9. cooking 10. heating 11. insolation 12. service

these are the only requirements to be considered when building a house. we look at the daily routine of each person living in the house and this gives the function diagram for father, mother, child, infant and other occupants. […]

we calculate the angle of the sun's incidence in the course of the year and in relation to the latitude of the site, and with this knowledge we determine the size of the shadow cast by the house in the garden and the amount of sun admitted by the window into the bedroom. we work out the amount of daylight falling on the working area of the interior and we compare the heat conductivity of the outside walls with the humidity content of the outside air. […] where color seems psychologically indispensable, we include its light reflecting value in our calculations. […] we consider the body of the house to be an accumulator for the heat of the sun …

moreover, as one of the final forms in which the welfare of the nations is to be realized, the new housing estate is a purposively organized work which engages the energies of all and in which co-operative effort and individual effort join forces in a common cause."(in Schnaidt 1965: 95–97, modified)

This quote summarizes three themes that clarify Meyer's vision of architecture in its relatedness of daylighting (among other technologies), the individual and the society. First, Meyer demanded the study of the day rhythm of "typical" individuals; second, he called for technical surveys of the environmental context; and third, he proposed that connecting both is a step to achieve an architecture for a new society.

5 BAUHAUS TEACHING

In 1927 Hannes Meyer became a faculty member of the Bauhaus and in 1928 its director. In Meyer's tenure many student assignments incorporated diagramming of sun positions and the insolation and shading within rooms. This diagramming was not restricted to housing designs but was also included, for example, when

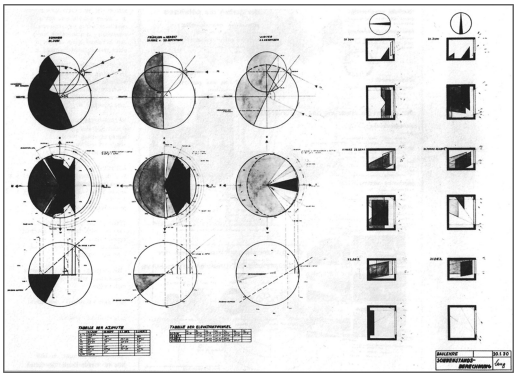

Figure 12. Bauhaus student Lothar Lang's analysis of direct sun and shadowed areas in rooms with different orientations. Assignment for Hans Wittwer's class (Winkler 2003: 78).

designing school projects. Hans Wittwer followed Meyer to the Bauhaus in the second half of 1927 and started teaching environmental technology, including lighting, heating, ventilation, and installation. Many solar analysis assignments resulted from this teaching, such as the one by Lothar Lang (Fig. 12) (Winkler 2003, Kieren 1989). Meyer himself taught "analytical building," part of which was the study of the family members' day rhythms. Meyer's and Wittwer's courses, together, resulted in the reciprocal connection between the topics of daylighting and social architecture. Cross referencing the courses led to the orientation of many spaces—class rooms, hotel rooms, and rooms within apartments—to east and west, defining that direct solar radiation had to enter a space exactly when people used it. (Obviously, this did not allow flexible uses at different times of the day.)

The building projects and competitions during these Bauhaus years showed sun and lighting studies everywhere. The most famous example was the school of the ADGB (Federation of German Trade Unions) completed in 1930 (Figs 13–15). Here, sun studies for the bedrooms were extremely important "for friendly reassurance, for creative rest" (Meyer 1928: 14). A housing example is the extension of the Törten estate. The first part of this estate was designed and built under Walter Gropius's directorship, with the main focus being on industrial fabrication of standardized building elements, while lighting considerations played a minor role. In the second building phase under Meyer (1928–30), streets were organized to run from north to south. Single-family houses paralleled these streets and were designed in three different types as detached, angle-shaped and row houses (Figs 16–17). In addition, multi-family buildings were designed—with living spaces and bedrooms facing south, and bathrooms, kitchens, balcony accesses and stairs facing north (Fig. 18). Only these apartment houses were built.

Mixing north-south running single-family row houses with east-west running balcony-accessed multi-family apartment rows could be seen in several

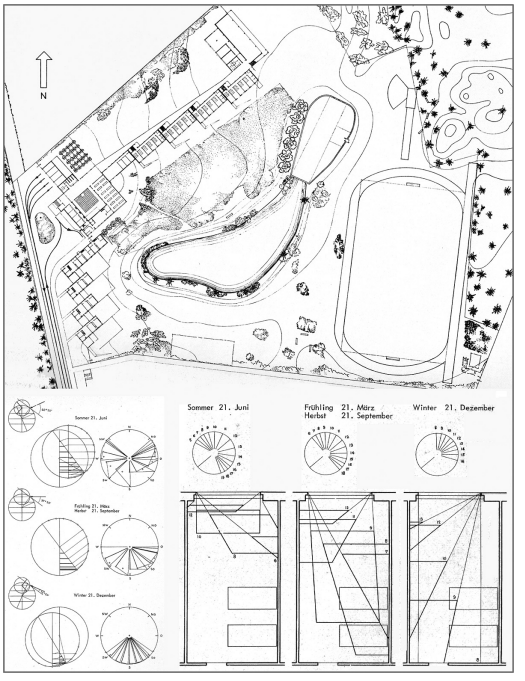

Figure 13–15. Hannes Meyer, Hans Wittwer, and Bauhaus students. School of the ADGB (Federation of German Trade Unions) in Bernau, completed 1930. Site plan and sun studies for bedrooms (Schnaidt 1965: 42, 43, 51).

other modern housing estates, for example, in Ernst May's Westhausen estate of 1929–31. The two building types were considered to be complementary to each other. High cost-effectiveness might have been

the strongest argument for the balcony-accessed buildings. The two types provided some social mix of occupants while their standard was kept equal. With respect to daylighting the descriptions of the Törten estate emphasized that no north-facing bed- and living rooms were designed in order to "guarantee the greatest possible insolation of the whole apartment" while the serving rooms (hallway, bath and kitchen) "isolate the unit from the traffic on the balcony and from rough northern weather impacts" (quote from 1930, in Winkler 2003: 83). It should also be mentioned that, under Meyer's direction, from 1928 on, several architects started teaching in the architecture program, such as Ludwig Hilberseimer, Mart Stam, and Anton Brenner. Hilberseimer and Stam had strong urban design expertises, including *Zeilenbau*, and certainly influenced the designs and orientation schemes of housing estates undertaken by the Bauhaus students.

Meyer's justification for *Zeilenbau* and rooms facing to east and west was eventually not only one of social equity, but, even further, of achieving a collectivist society. Also Hilberseimer believed in this collectivist approach, when he wrote in his book *Groszstadt Architektur* that the "building of housing, particularly of mass housing, is not subject to individual but to collective design" (1927: 25).

The approach to equity in a collective society took a scientific route. The ideal that all people should have equal living conditions meant, when applied to housing, that adequate standards for the collective had to be defined. One such standard was the access to daylight. The orientation of apartments had to be scientifically justified and, vice versa, the studies of sun orientation were understood to be an example of a scientific approach to architecture. Empirical studies of the people's "life processes" (Meyer 1928: 13), from which insights for design orientation could be gained, were one method of this approach.

After his dismissal from the Bauhaus in 1930, Hannes Meyer lived in the Soviet Union until 1936, where he found new opportunities to conceptualize large housing estates and even whole industrial towns. One example is the development of the industrial town Sozgorod Gorki near Molotov in 1932. Planned for 45.000 people, the design for the town consisted mainly of north-south running building rows. Some of them were turned ninety degrees—similar to the balcony-accessed multi-family houses in Törten—in order to create spatial rhythm, emphasize the street, or connect outdoor spaces between rows to natural areas. Where such building rows followed east-west streets, they were never positioned on the north side of the streets, which would have led to opening the apartments to northern gardens. Also, topography played a role in situating and sizing different functions (Fig. 19).

Ten years later, after Meyer had relocated to Mexico, he had the opportunity to develop another large housing estate for 11.000 workers, the 1942/43 Lomas de Becerra (Fig. 20) (Möller 2015: 66; Schier 1989: 32). The strict scheme of north-south running buildings had again not changed here. While Meyer was very critical of many endeavors of his Bauhaus time, the analyses and findings related to sun orientation were not called into question and served as the general justification for equal living standards.

6 CRITICAL COMMENTARY: ADOLF BEHNE

The architecture critic and social activist Adolf Behne (1885–1948) commented in the late 1920s and early 1930s on the *Zeilenbau* housing projects and addressed in particular the topic of sun orientation that he identified as a dogma of the time. He used the debate on solar orientation to exemplify what is at risk in society. In contrast to so many architects who requested the subordination of the individual under the collective, he emphasized individual freedom and the value of diversity within a socially oriented society. Reacting to the debate on housing orientation he expressed that no single orientation preference could ever be the ultimate

ideal for housing and that instead a variety of orientations are necessary to serve the divers lifestyles of a society. On the occasion of a critique of what became the most famous *Zeilenbau* estate, the Dammerstock, he explained his concerns regarding strict orientation schemes:

"Dammerstock would be right if our wind rose had only east and west, if the sun went back and forth between east and west on the shortest way, without touching north and south. But since the sun, from man's view, marks four cardinal points, which deeply became part of our consciousness, Dammerstock seems to be a torso. […] According to the most consequential architects, man has to go to bed toward the east, has to eat and answer mother's letter toward the west, and the housing unit is organized in a way that he cannot make it differently. […] The housing unit that is too specialized does not gain value of living, it looses it. […] Dammerstock's method is a dictator's method; it is the method of an either-or." (Behne 1930: 164)

With his critique of fixed dogmatic orientation Behne pointed to the lack of flexibility in how to occupy rooms in an apartment. The floor plans of modernist housing, including their specificity in solar orientation, did not facilitate different occupations when needed. He summarized: "Social complexity demands a variety of building orientations." (Behne 1930: 164).

7 FINAL REMARKS

Adolf Behne warned in 1930 that the schematic and monotonous layout of building rows with preset room assignments did not reflect the society altogether. This critique is applicable to all dogmatic orientation discourses, no matter which direction rooms are eventually facing. The example of modernist *Zeilenbau* can help in today's newly occurred debate on building orientation. In light of energy efficient building, architects have returned to the preference of south orientation for all bed- and living rooms for the one, purely technical reason of energy reduction. As in High Modernism, architects are convinced that there is only one possible orientation, particularly for housing: this time, however, to the south. As in High Modernism, the argumentation is radical and directly related to one of the most relevant question of the day: this time, however, it is about sustainable building with a minimized energy footprint. Obviously it would be absurd to ignore the energetic benefits of south orientation in housing and the need to embrace centuries-old strategies of passive heating and cooling. In addition, however, the orientation controversy of High Modernism, including its critique, reminds us of the social relevance of such technical questions. It shows that the discourse on solar orientation must go far beyond technical questions and instead target the core question of social meaning in architecture, which addresses the balances of the individual and society. The actual task for architects is to transcend and elevate this technical approach toward meaningful architecture.

Neighbourhoods with single-family houses growing old

H. Müller
School of Architecture, Civil Engineering and Geomatics, University of Applied Sciences and Arts Northwestern Switzerland, Switzerland

ABSTRACT: Cities and neighbourhoods are affected by demographic change in many ways. In order to make a successful ageing in place possible, it is necessary to adapt not only flats but also neighbourhoods to the demands of an ageing society. In this context the single-family house, one of the most common building types in Northwestern Switzerland, plays a special role. On the basis of a cross-evaluation of strategies, practical examples and research studies, planning measures for the adaptation of neighbourhoods to the demands of an ageing society were developed and applied to contrasting case examples in the context of test plans. It turns out that neighbourhoods with single-family houses show different potentials for a successful ageing in place. The central criterion seems to be the proximity to a centre or the connection to public transport. While mobile shops and delivery services could contribute to a successful ageing in place in peripheral areas, densification offers a variety of options in central locations.

1 INTRODUCTION

In the future, demographic change will have an ever-increasing impact on society. Cities play a special role in this context. On the one hand, they are confronted with a number of problems caused by this change. On the other hand, great potential to influence this change positively is found in the ways cities adapt, e.g. in the project *Global Age-Friendly Cities* of the WHO (2007). In particular residential areas with single-family houses built between the 1950s and the 1980s virtually experience a 'double aging process': The houses have 'matured' and so have their inhabitants, who as young families once realised their dream of their 'own home', who have aged almost collectively, and who have to decide next whether they can and want to stay in their 'own four walls' in their local neighbourhood.

This article presents results of the interdisciplinary research project *Home and Identity in Ageing Neighbourhoods with Single-family Houses*. The project, led by Prof. Christina Schumacher in collaboration with Dr. Hannes Müller of the *School of Architecture, Civil Engineering and Geomatics,* Prof. Dr. Klaus R. Schroeter and Dr. Christine Matter of the *School of Social Work* is part of the *Strategic Initiative Ageing* of the University of Applied Sciences and Arts Northwestern Switzerland.

2 APPROACH

One of the aims of the project is to develop and test architectural and urbanistic strategies which facilitate a successful ageing in place for elderly inhabitants. As a type of settlement the neighbourhood with single-family houses plays a special role: With a percentage of over 65% of the building stock of Northwestern Switzerland it is the dominant type of building (Bundesamt für Statistik, 2004). Precisely for the settlements built between the 1950s and the 1980s a particularly problematic demographic development is predicted for the near future (Krajewski, 2015). On the basis of a cross-evaluation of strategies, practical examples and research studies, planning measures for the adaptation of neighbourhoods to the demands of an ageing society were developed. In a first step, these measures were matched to the general parameters and the dynamics of the Swiss settlement type 'neighbourhood with single-family houses'. On this basis, two contrasting case examples were chosen. For these the realisation of the measures was evaluated with the help of test plans. As a result, planning strategies were developed for the regarding cases in order to adapt them better to the demands of an ageing society.

3 AGEING IN PLACE

Today's popular label 'ageing in place' usually stands for interdisciplinary approaches or rather attempts to generate options for staying in a chosen environment. 'Ageing in place' is not a fixed and clearly defined term but rather a dynamically changing idea. Although it is today generally understood as the ability "to remain in one's own home or community in spite of potential changes in health and functioning in later life" (SCL & MetLife, 2013), ageing in place is not a cohesive concept or even a theory but rather a kind of organising principle owing its political legitimation to

supranational proclamations and programmes (OECD, 1994). On an academic level the discussion traces back to the early approaches of environmental gerontology and to geographical gerontology, which developed from human geography, and leads up to contemporary concepts of ecological gerontology (Claßen & Tesch-Römer, 2014; Friedrich, 1995; Wahl, Mollenkopf, & Oswald, 1999) and to the different ideas of aging in place (Callahan, 1993; Lee, 2009).

Architecture and urban planning have regarded the demographic change and the resulting consequences on a neighbourhood level as a peripheral topic for a long time. They mainly focused on the planning of age-appropriate housing or inpatient care facilities (Kreuzer & Reicher, 2008). Since a few years the perspective has shifted away from the individual building. Most recent surveys, for instance, underline the relevance of the living environment or rather of the neighbourhood for living in old age (Höpflinger & Wezemael, 2014). For planning, therefore, the question occurs: Which (urban) planning measures and parameters could contribute to a successful ageing in place on a neighbourhood level?

Defining elderly people as a homogenous group with homogenous demands on their neighbourhood would obviously fall short. Referring to the matching model of ecological gerontology (Carp & Carp, 1984; Kahana, 1982), the research project analyses numerous mismatches between elderly persons and their neighbourhood. For these cases (urban) planning measures are developed in order to guarantee an independent and self-determined life in a familiar living environment despite a decline in competences.

4 SETTLEMENTS WITH SINGLE-FAMILY HOUSES

For a long time the privately owned home has been a synonym for the ideal of individual living which embodies autonomy, privacy and identity (Häussermann & Siebel, 1987; 2000; Häußermann, Siebel, & Wurtzbacher, 2004). It represented the desire to live in a green environment, to have family and property (Bourdieu & Steinrücke, 1998; Junker, 1985). It correlates with what is perceived as a normal form of family life and the accompanying settlement type, the neighbourhood with single-family houses, has not been considered problematic for a long time (Aring, 2012; Berndgen-Kaiser & Krajewski, 2015). With the changing demographic conditions, however, neighbourhoods with single-family houses could become a problem for neighbourhoods and cities very soon (Eisinger & Schneider, 2005; Krajewski, 2015). There is evidence that this type of settlement could for the first time lose its attractiveness and population (Berndgen-Kaiser et al., 2014). This development is ascribed to changing employment histories or rather the shift of workplaces (Häussermann, Läpple, & Siebel, 2008). In Switzerland this is most visible in a strong demographic rejuvenation in the urban centres. The suburban neighbourhoods were shaped by the influx of families in the 1970s, in particular. If the ageing residents stay in their single-family houses and if no young inhabitants move to the neighbourhoods in the course of a structural redensification, fast demographic ageing is predicted for these neighbourhoods. The periurban spaces of Switzerland show a similar demographic structure to the suburban spaces. However, they were shaped by the influx of families in the 1990s, and a similar development to the suburban neighbourhoods seems possible (Höpflinger & Wezemael, 2014). In particular peripheral or poorly connected neighbourhoods with single-family houses register a sharp fall in demand (Credit Suisse, 2010).

In order to describe the development of demographically homogenous neighbourhoods with single-family houses, the concept of 'threefold cyclicity' developed by Schnur (2010) is suitable. He assumes structural, planning and demographic cycles for a neighbourhood. The shape of these three cycles and their relation to each other are dependent on the individual, local parameters. For an ideal-type, homogenous neighbourhood with single-family houses one can sketch the following development: Before starting the construction of the buildings there is high planning activity in the neighbourhood. By the end of the building process it rapidly drops. It only rises again with a problematic development of the neighbourhood and a new planning cycle starts. The demographic composition of the neighbourhood is relatively heterogeneous in the beginning. Over the years the neighbourhood with single-family houses is not characterized by nuclear families anymore but almost entirely by elderly single- or two-person households. If they die or leave the neighbourhood new families move in and the next demographic cycle starts. The structural cycle describes the need for renovation in the neighbourhood, according to Schnur. But it could also be understood in terms of the matching of resources and skills of the residents with their buildings and the infrastructures of the neighbourhood. After the completion of the buildings and the move-in there are only few deficits and both the building and the infrastructures correspond to the demands of the nuclear families living there. In the course of time the need for renovation rises steadily, or rather the spatial configurations and parameters might not match the changed

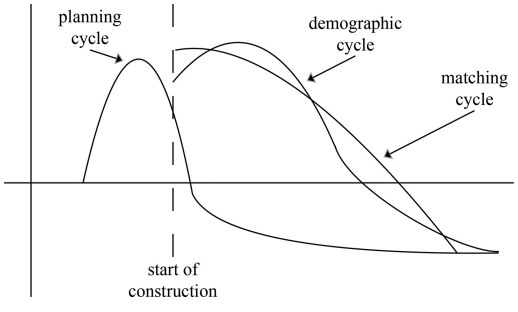

Figure 1. Development of an idealtype, homogenous neighbourhood with single-family houses.

living conditions of the inhabitants anymore. Parameters which were suitable for a nuclear family might not be ideal for an elderly single- or two-person household anymore. A new cycle starts when building and infrastructure are renovated and adapted to the altered demands or new inhabitants move into them. These cycles do not necessarily have to undergo a crisis (Nuissl & Bigalke, 2007). In Switzerland the proximity to an urban centre, or the position at transport corridor, seems to be an important factor for this.

5 CRITERIA AND MEASURES

Although this topic has received relatively little attention so far, a number of planning approaches for age-appropriate conceptions of neighbourhoods exist. On an international (e.g. WHO, 2007), regional (AGS Schwyz, 2006) and in particular on a communal level (e.g. Stadt Bern, 2014; Stadt Wuppertal, 2010) different actors deal with this topic. On the basis of a cross-evaluation of such international, national, cantonal and communal strategies, practical examples and research studies (e.g. Friedrich, 1995; Großhans, 2001; ISRW, 2011; Kreuzer, 2006; Kreuzer & Reicher, 2008; Saup, 1993; Schnur, 2010) five subareas have been identified within the framework of the research project which are central for an (urban) planning adaptation of a neighbourhood to the demands of an ageing society: living space, mobility, local supply, assistance and care, leisure time and (social) activities.

Below the subdivisions and their regarding measures are presented in order to then match them with the general parameters of the Swiss settlement type 'neighbourhood with single-family houses'.

5.1 *Living space*

Living space also takes a central role in a neighbourhood-related perspective. When reaching post-retirement age and in particular with restricted mobility the significance of one's own home can increase strongly (Höpflinger & Wezemael, 2014). Especially in cases of physical limitations barriers can occur in the flat which can sometimes be reduced only with considerable effort. But also change of the household form, e.g. because of children moving out or the death of the partner, can result in a home which does not fit anymore. Here a barrier-free adaptation or moving into a more suitable home in the same neighbourhood can, depending on the individual situation, be the better solution.

As the name says, the spatial programme of single-family houses is primarily directed towards the needs of families. The living space which stretches over several floors is typically dimensioned for two adults and for two to three children. Single-family houses which were constructed between the 1960s and 1970s often do not match today's demands anymore when it comes to the floor plans, the size of rooms and the views to the outside (Gutmann, Pletzer, & Schweizer, 2004). Here a particularly problematic aspect is this building type's resistance to change and conversion (Krause, 2014).

Because of the many thresholds and steps in front of and in the building, staying in the single-family house is often not possible for persons with restricted mobility. In some instances barriers can be removed comparably easily. The additional installation of a lift, however, is a substantial change and connected to relatively high costs (Schumann, 2008). Therefore, the aim to offer a wide range of barrier-free flats for household forms beyond the nuclear family seems hard to implement in this settlement type.

5.2 *Mobility*

During old age the length of single ways and the overall distances covered decrease while the mobility within walking distance increases. With a decline in mobility the access to local supply shops, to medical facilities, or to friends and family can become difficult. Without the possibility of using a car the individual radius of mobility shrinks. Depending on the previous mobility pattern, this can be a sharp break for persons concerned. It can make an independent and self-determined life in the familiar environment more difficult or even impossible (Kirsch, 2015; Kreuzer, 2006). Therefore, a barrier-free, local public infrastructure within walking distance is of particular importance in a neighbourhood. Concrete measures involve, for example, a continuous, barrier-free walkway system, a clear division between the different types of traffic and a good connection to public transport.

Neighbourhoods with single-family houses are regarded as a settlement type which only became possible with the spread of the car. Hence, it is the primary means of transport here and the street areas are adapted to its demands. Planned for residential use only, there are attempts to keep the traffic in neighbourhoods with single-family houses as low as possible. In ideal cases a single distributor road connects the whole neighbourhood. In the core of the settlement transit traffic is avoided through a road network which branches out into blind alleys. Normally neighbourhoods with single-family houses are linked through the bus lines of the public transport system. In the 1980s in Switzerland settlements next to transport corridors were also connected to the suburban train (Bosshard et al., 2015; Häußermann & Siebel, 2000).

In principle the low traffic in neighbourhoods with single-family houses promotes a mobility within walking distance. Furthermore, a basic distinction has to be made between centrally located neighbourhoods, or rather neighbourhoods located at a transport corridor, and peripheral neighbourhoods. In peripheral locations it might not be possible to access offers and infrastructures outside one's own neighbourhood without a car, while this is well possible in well-connected neighbourhoods. Therefore, centrally located neighbourhoods with single-family houses seem to match the demands of an ageing society while peripheral locations show difficult parameters here.

5.3 *Local supply*

The ability to provide for oneself is key to an independent and self-determined life. For this to be possible there should be sufficient supply within walking distance and without barriers in the neighbourhood. This includes for instance: bakeries, newsagents, grocery stores, chemists' shops, banks, hairdressers, doctors and pharmacies. A maximum distance of ca. 500 metres is considered ideal here (ISRW, 2011).

As a product of the Fordist city the neighbourhood with single-family houses is oriented towards residential use only. A mix of uses is uncommon or even forbidden in this settlement type. Furthermore, it is an unattractive position for offers by local suppliers because of the low housing and population density and because of the missing transit traffic (Wölter & Zimmer-Hegmann, 2008). The building typology, a detached house surrounded by a private garden, makes commercial use difficult, too. Because of these factors local supply tends to stay outside the typical neighbourhood with single-family houses. In view of the decreasing mobility and the related importance of local supply, neighbourhoods with single-family houses seem to offer a poor framework for an ageing society.

5.4 *Assistance and care*

Just like independent supply, the fields of assistance and care are important for a successful ageing in place. Assistance makes everyday life easier; care services are essential. Besides conventional nursing homes, local centres for day care or short-term care or forms of assisted living. Assistance services, for instance for shopping or doctor's visits, can increase the quality of life substantially. Outpatient care, in Switzerland Spitex, is regarded as a spatially relatively independent element.

With a high percentage of elderly people even neighbourhoods with a low population density can show a high demand for assistance and care services. Neighbourhoods with single-family houses are generally not a problematic location for facilities like nursing homes, assisted living, and forms of shard living. In particular small institutions and privately initiated projects could be realised here in terms of decentralised care.

5.5 *Leisure time and (social) activities*

After retirement the importance of the living environment as a place for social contacts and for leisure activities increases. Long-term inhabitants could also turn to numerous existing contacts in the neighbourhood (Höpflinger & Wezemael, 2014). By valuing public spaces, barrier-free, high-quality places can be created. Parks or community gardens which are oriented towards persons with physical of cognitive limitations offer attractive leisure activities. Besides clubs and churches, meeting places in the quarter can facilitate finding contacts. Finally, it is possible that community housing projects contribute to a stronger integration of residents in the neighbourhood (Müller, 2015).

In the settlement type neighbourhood with single-family houses public space plays a minor role. Parks, places or particular streets, which can be a stage for public life in an urban context, are an exception here. The private home and especially the private garden let public spaces appear obsolete. Yet, it is questionable to which extent this idea can hold true (Moser & Reicher, 2002). The garden in particular can become a challenge in cases of increasing physical limitations. If neighbourhoods aim at integrating residents through a community centre or café, a neighbourhood with single-family houses are a difficult location. A facility which is located in the town centre usually reaches more residents.

In view of these parameters an upgrading of public space in a neighbourhood with single-family houses seems difficult. A qualification of the adjacent landscape, however, offers a promising approach. In line with the idea of living in a green environment, barrier-free, high-quality places close to nature and with a wide range of leisure activities can be created here. Nevertheless, for an integration of the inhabitants in this type of settlement, community housing projects seem to be more realisable than establishing meeting points in the neighbourhood.

6 STRATEGY CASE EXAMPLES

As case examples two contrasting neighbourhoods with single-family houses in Northwestern Switzerland were chosen. The guiding assumption for the selection was that for neighbourhoods with single-family houses the connection and the proximity to a centre are decisive factors for a successful ageing in place. Case example A is the well-connected neighbourhood. The centre of the neighbourhood is ca. one kilometre, the urban centre Basel ca. six kilometres away. Access to the suburban train is within a maximum of 1.8 kilometres, to the tram within a maximum of 850 metres and to the next bus stop within a maximum of 450 metres. The residents of case example B generally depend on a car. Although a bus line exists, it is not an attractive alternative because of its low frequency. Analysing the structure of the buildings and the settlement and considering the regional contexts suggest different strategies for adapting to the demands of an ageing society for the case examples.

Neighbourhood B shows a problematic future perspective. It is a residential neighbourhood without local supply or other offers. Because of the low population density, a regular local offer is economically not possible and it is unrealistic for the near future as no increase in population is expected. Without a car it is difficult to maintain an independent and self-determined life in the neighbourhood. A successful ageing in place could be made possible by mobile solutions. These might include a mobile village shop, transport services for shopping trips or a market with automats. The latter, for instance, was installed in the

Swiss neighbourhood of Kägiswil in the rooms of a former village shop in the centre of the settlement and offers about 140 products for everyday use (BUNBR, 2014). A further possibility seems to be a supply provided by internet shops. However, taking into account that only 12% of the over 80-year-old Swiss living at home have internet connection, it is questionable to which extent this actually succeeds (Höpflinger & Wezemael, 2014).

Case example A already shows good parameters for a successful ageing in place. Although there are no non-residential buildings in the neighbourhood itself, supermarkets, a number of doctors, a home for the elderly, or rather a nursing home, and even a meeting point for senior residents are accessible within a radius of less than 1.5 kilometres. Only the possibilities of living space show deficits. For case example A the strategy is to create heterogeneous forms of living space. Through this the neighbourhood becomes attractive for households beyond the nuclear family, too, and the overall population can become demographically more heterogeneous. With reference to the above-mentioned model of the 'threefold cyclicity' by Schnur, this would moderate the demographic wave. In order to create diversified possibilities of living space, altering existing buildings seems obvious. The study by Beyeler (2010), for instance, shows that this is possible despite the stated resistance to change and conversion. Still, new living space needs to be created in order for new residents to move to the neighbourhood before a demographic cycle is closed. Two possibilities arise here: An outward extension or a structural redensification. The former seems problematic in the light of the political call for holding back suburban sprawl often discussed in Switzerland. Because a particular potential for inner development is stated for the settlement type 'neighbourhood with single-family houses' and because there is currently a high demand in living space in case example A, this approach seems promising (Bosshard et al., 2015; Metron, 2011). The detailed ownership structure of this settlement type might be problematic in case of a redensification. Yet, investigations such as Gutmann et al. (2004) or Frei's (2011) point out possibilities here. Just by conversions and extensions within an existing single-family house a remarkable potential for living space can be unlocked (Gutmann et al., 2004). Because a number of buildings in case example A do not make use of the existing possibilities in building law, there is further potential for redensification through extension or reconstruction. The Danish community housing projects for seniors (*Seniorbofællesskaber*), for instance, show that very good, barrier-free solutions are possible for new constructions within the building type 'single-family house' (Age Stiftung, 2011). The biggest potential, however, lies in the regarding alterations of building law. Especially properties next to access roads are particularly suitable for a partial redensification of the neighbourhood structure.

Decisive for a success of this strategy is that the neighbourhood takes on an active role in this process. Within the framework of information campaigns it can inform residents about the possibilities of redensification and barrier-free restructuring measures and thus initiate a development in the neighbourhood at an early stage. Especially the cooperation of neighbourhoods with unions and foundations for multigenerational community housing projects seem to be a promising approach. Housing projects like the Zurich Kalkbreite with a broad range of flats for communities, families, couples and singles demonstrate ways of successful multigenerational housing (Weidmann, 2014). Building more densely could in turn make uses possible which would not be profitable in a conventional, decentralised neighbourhood with single-family houses: shops, doctors' practices, a better connection to public transport, a meeting point in the neighbourhood, or care facilities.

7 CONCLUSION

It becomes apparent that within this settlement type individual neighbourhoods with single-family houses show very different potentials for a successful ageing in place. The central criterion seems to be the proximity to a centre and the connection to public transport. Because of the homogeneous use of the neighbourhood, residents rely on local supply outside their neighbourhood. In poorly connected, peripheral locations independent and self-determined housekeeping is difficult without a car. In central, well-connected neighbourhoods, on the contrary, one can resort to public transport or reach the centre by foot. For the less-connected neighbourhoods with single-family houses establishing mobile services and the possibilities of internet shopping seem promising. By contrast, well-connected neighbourhoods have a more comprehensive framework for action. A partial redensification can produce barrier-free flats and make the settlement also attractive for household forms beyond the conventional nuclear family. After all, the redensification of neighbourhoods with single-family houses is an answer to the question discussed throughout Switzerland: How can the growing demand for living space be met without further soil sealing?

Dwelling and family diversity: Analysis of housing units and households in Lisbon

A.S. Moreira & H. Farias
CIAUD-Centro de Investigação em Arquitectura, Urbanismo e Design, Faculdade de Arquitectura, Universidade de Lisboa, Portugal

ABSTRACT: Western society has undergone numerous changes. Alterations in family composition are the most noticeable. The traditional nuclear family which has been the basis for housing design since the Modern Movement has decreased in importance and other family compositions are now more representative. The paper focuses on the analysis of housing units occupied by different households to ascertain dwelling uses and transformations to satisfy inhabitants' demands and needs. The research is based on case study analysis, through post-occupancy evaluations and enquiries. Two groups of housing units in Lisbon are analyzed, so to understand if contemporary units serve contemporary inhabitants better than one century old dwellings. The main purpose of the paper is to analyze how we use our homes and also to allow for the identification of the dwelling's spatial or functional shortcomings, so that future projects and designs can be more suited to contemporary society and families.

1 INTRODUCTION

1.1 *Scope and motivation*

Portuguese population has evolved and family transformations in the last decades are the most noticeable. The traditional nuclear family which has been the basis for housing design since the Modern Movement has decreased in importance and other family compositions are now more representative, such as single people, double income no kids (DINK), aged person alone and single parents, among others. This transformation of one of the most pivotal society entities has a direct influence in housing design and project brief as well as housing use.

The main goal of this paper is to analyze two different housing units – one from the beginning of the 20th century, the other from the beginning of the 21st century – occupied by different households, with the objective of ascertaining house use and housing adequacy to dwellers' needs and demands, both spatial and functional. This analysis should allow for a realization of how modern society perceives and uses its dwellings and, as a result, the identification of the latter's shortcomings in order to adapt future projects to contemporary society and families.

This research, grounded on the study of contemporary society, particularly on the analysis of the use of the housing unit, functional and spatial demands, should thus allow for a real contribution for the society in which it is based, favoring the improvement of living conditions, highlighting once more the social role of the architect as a researcher and designer.

1.2 *Societal changes*

As afore mentioned Portuguese family composition has undergone several changes in the last decades. These changes are attested in Censuses reports. According to *Instituto Nacional de Estatística* (*Statistics Portugal*) *in the last decade family transformations and that of its place in society have accentuated* (INE, 2011).

The most relevant alterations are the following: decrease of family's average dimension from 2.81 people in 2001 to 2.58 people in 2011 (in Lisbon this value is even lower at 2.4 people per household); a notable increase of one-person families (from 17.3% in 2001 to 21.44% in 2011), with relation to population ageing; the decrease of children (64.76% to 58.79%) and, finally, the increase of single-parent families (an increase of 36% in a decade). As per Statistics Portugal, in the 2011 Census report, *the increase of the proportion of single-parent families in the total of families, of approximately 4pp between 2001 and 2011, reveals the alteration of family living model that modern society has undergone* (INE, 2012).

2011 data reveals that the two-person household is the most frequent, followed by the three-person, single-person and only then the four-person household. The same data show that there has been a significant percentage increase of two-person and single-person households in the last two decades, accompanied by an also significant decrease of relevance of the four-person and five or more-person households in the Portuguese society (Figs. 1–2).

	2001	2011
Classical families (number)		
Portugal	3 650 757	4 043 726
Average size		
Portugal	2,81	2,58
(%)	2001	2011
Single person classical families		
Portugal	17,3	21,44
Classical families composed of elderly person (65 or more) alone		
Portugal	8,79	10,06

Figure 2. Table illustrating family average dimension (second row), percentage of single-person families (third row) and percentage of single-person families composed of and elderly person (65 years old or more; fourth row). Source: Statistics Portugal, 2012.

These statistical data support the importance of a reformulation of housing design and functional programme to better serve these new households and their needs.

2 ANALYSIS

2.1 *Methodology*

In order to understand house-use and occupant's needs and opinions towards the dwelling it became evident that Post-Occupancy Evaluation was the most adequate methodology, since it permits the identification of house-use, spatial and functional alterations and the inhabitant's assessment of the dwelling and aspirations regarding the ideal home.

Post-Occupancy studies have become more common and relevant in housing and occupant satisfaction analysis, being central in the work of many architects and teams with the objective of transforming dwelling interiors so that they become more adequate to effective use. In Brazil, POE (Post-Occupancy Evaluation)

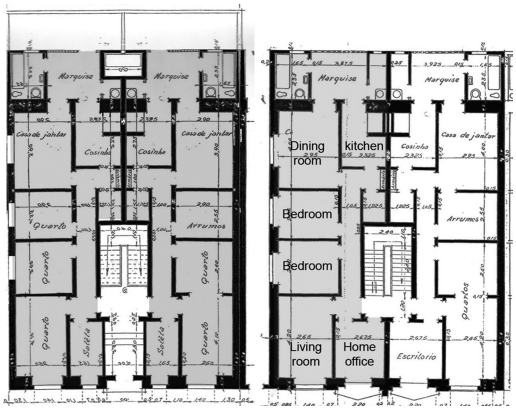

Figure 3–4. Ground floor and first floor plan with indication of analyzed units.

have been having great development, being relevant studies by of Ornstein, Villa and Rheingantz. In Portugal these studies are still in need of greater progression, being relevant the works of Ramos, Pereira (1984), Portas (1979) and Pedro, the last three for the same institution, LNEC – Laboratório Nacional de Engenharia Civil (*Civil Engeneering Nacional Laboratory*).

In this paper a comparative evaluation (Villa & Ornstein 2006) as well as an evaluation with ecological method (Macfarling & Heimstra 1978 *apud* Villa & Ornstein 2006) is suggested. This last method consists of the observation of inhabitant's behavior without variables manipulation. The POE is based on this observation, by means of visiting the dwellings, and also in an inquest divided into two: household characterization and dwelling characterization. The latter aims at understanding the dwellers' satisfaction towards the unit and its room's areas, layout and privacy; the time spent in the unit; the room where the dweller mostly spends his time in; the rooms where he/she develops other activities; concluded alterations and why; which alterations would the dweller like to have done, why and why they haven't been executed already and, lastly, the description of the ideal dwelling.

Parallel to this POE and aiming at spatial and functional configuration characterization, a space syntax analysis (as introduced by Hillier and Hanson) by means of justified graphs is executed, in order to schematize the dwelling's organization.

2.2 *Dwelling characterization*

2.2.1 *Early 20th century building*

Built in the beginning of the 20th Century, the first case-study building is composed of three-bedroom units that are comprised of dining room, kitchen, toilet, kitchen support area, bedrooms (one of the ground floor units initially had a closet space instead of the third bedroom) and a small living room in ground floor units and an office in all other floors.

For this paper three units were analyzed – the two ground floor units and one on the first floor (Figs. 3–4).

Ground Floor Unit E

Household characterization – single person alone, elderly

Amount of time inside the unit, daily – more than 8 hours/day

Duration of inhabitation – more than 20 years (46)

Currently occupied by a single person (it was once occupied by 2 to 3 people of the same household) this unit has not been altered in layout. The only alteration has been a functional one – the two rooms near the entrance, initially a small living room and a bedroom, were transformed into an office and a formal living room respectively.

As for the dweller's satisfaction towards the unit's area and that of the several rooms, a value of 4/5 was attributed to the kitchen and to the unit in general, although the remaining spaces individually only got 3/5, indicating that they are considered somewhat small. Space for furniture also got 3/5, corroborating the previous result. Nevertheless, the dweller is satisfied with the unit's layout and considers it to be adequate to the family's needs (value 5/5).

Regarding room use, the inhabitant stated that the dining room is where she spends most of her time and where other activities take place such as intellectual work (as in the kitchen and office), watching TV (as in the bedroom) and entertaining. House work is exclusive to the kitchen. These answers show us that the dining room is the nuclear space of the dwelling, which is easily understood when analyzing the floor plan where it is notable that this space is the one with bigger dimensions and better proportions and being situated near the kitchen support area, the one with better natural lighting conditions. This fact is attested by a space syntax analysis, namely the representation of the layout through a justified graph (Fig. 5), where we see that the most integrated (central) spaces are the dining room and the kitchen.

When inquired about alterations the dweller would like to execute, the need for storage became evident.

Ground Floor Unit R

Household characterization – DINK, retirees

Amount of time inside the unit, daily – both less than 5 hours/day

Duration of inhabitation – 5 to 10 years

Unlike the previous unit in the present case-study alterations have been made, prior to present dwellers inhabitation: the three rooms near the entrance (initially living room and two bedrooms) were transformed into one single space – a common living room –; a closet was transformed into an office (without natural lighting) and the dining room into the master bedroom (Fig. 6). These consist of layout and functional alterations and although the dwellers weren't the executioners they agree with them.

With regards to satisfaction towards the dwelling, both inhabitants agree that it suits the family's needs (5/5) although they state that room dimensions aren't ideal (unit area and individual rooms' areas received 3/5). This may lead to the statement that a single-family house is their ideal dwelling, one with *generous areas*.

As for the spaces where the couple spend more time, the husband marks the office (even though he is retired he still develops professional activities at home) and the wife the living room. It's in these spaces each of them develops intellectual work. Entertaining and watching TV pertain to the living room and house work to the kitchen. Neither feel the need of a different space where to develop other activities nor do they express the need or will to do further alterations, either spatial or functional.

1st Floor Unit E

Household characterization – single parent (mother and daughter)

Amount of time inside the unit, daily – both less than 5 hours/day

Duration of inhabitation – 5 to 10 years

This unit has also been altered in both layout and room function. The two spaces near the entrance have been unified and used as a living room (spatial and functional transformation); the two middle bedrooms

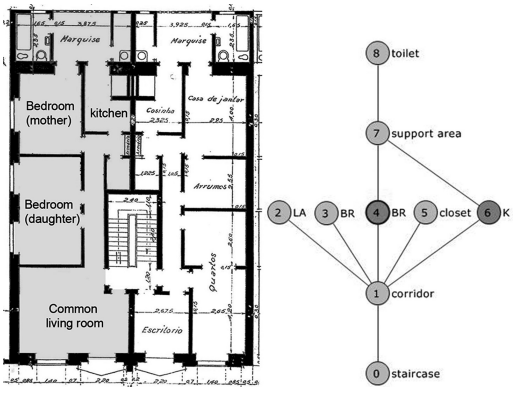

Figure 8–9. Current 1st floor unit E plan with current use indication and justified graph schematizing dwelling layout. O-Office, LA-Living area, BR-Bedroom, DR-Dining room, K-Kitchen

have also been merged together to accommodate the daughter's bedroom (spatial transformation); the dining room was transformed into the mother's bedroom (functional transformation) (Fig. 8). As in the previous unit, these transformations were also carried out prior to this family's inhabitation, the difference being that the mother does not agree with them, the daughter does.

In terms of satisfaction towards areas, both consider that the rooms are well dimensioned (4/5). The daughter believes the dwelling to be suited to the family's needs (4/5) and the mother to be extremely suited (5/5). The daughter highlights the shortage of space for furniture (3/5) and both feel the need for more storage area (especially closets in the bedrooms). When asked about the ideal dwelling, both value characteristics such as *spaciousness* and *good areas*, and the daughter states the need for a bigger bathroom.

Regarding space use both entertain and watch TV in the living room (this space bears social functions as well as common family activities) and both do house work in the kitchen, where the mother also develops some intellectual work, whereas the daughter tends to do the same in the bedroom. Since the mother uses the kitchen for her intellectual activities she asserts the need for a space that would fit this demand. The daughter would like to have a private exterior space, a yard.

2.2.2 *21st century building*

The current case-study consists of a public investment housing ensemble in essence destined to young people but in fact inhabited by all kinds of households (in age and composition). Housing typologies encompass studios, one-bedroom, two-bedroom and three-bedroom dwellings. For this paper, as with the previous case-study, three units were analyzed: two one-bedroom units and one two-bedroom unit (Figs. 10–13), inhabited by households other than the nuclear family.

T1a Unit

Household characterization – single person alone

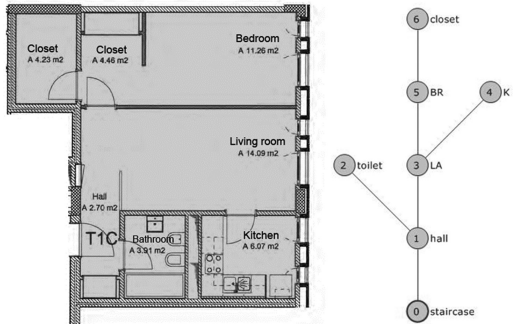

Figure 10–11. Plan and justified graph of the one-bedroom unit (T1a and T1b).

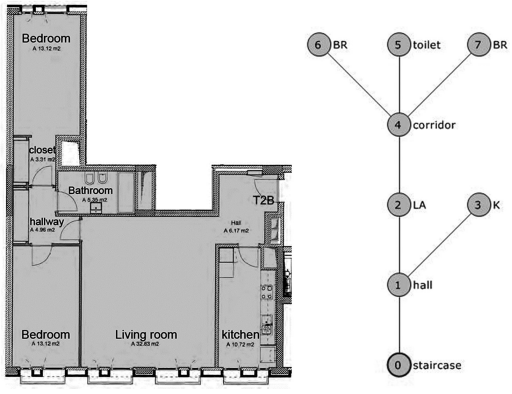

Figure 12–13. Plan and justified graph of the two-bedroom unit (T2).

Amount of time inside the unit, daily – 5 to 8 hours/day

Duration of inhabitation – 5 to 10 years

In this unit a single and simple alteration was observed – the elimination of the separating panel between the entry hall and the common living room. This does not qualify as either functional or spatial transformation due to its little effect in overall use or spatial feel.

Having a total of usable area of 49.85 sm, the dweller's satisfaction towards its dimension is average (3/5), stating a complete dissatisfaction towards the kitchen area (1/5) and an average satisfaction towards the common living room area (3/5). Only the bedroom area and apartment layout are awarded 4/5. In terms of adequacy to the family's needs, the value is less than average (2/5), signifying that the demands of the inhabitant are not met by the dwelling.

The living room is the space where the dweller most spends her time, being the room where she entertains, watches TV and also develops intellectual work. This accounts for the recognition of the need for another space, a home office, to develop this activity, a demand not met in the present dwelling.

When asked which alterations would she like to have done, only aesthetic ones are mentioned which

could be related to the fact that a small apartment does not permit many spatial or functional alterations. As for the ideal dwelling, the inhabitant highlights the aspiration for bigger balconies, a patio and a big kitchen, which are also indicative of the present dwelling's shortcomings.

T1b Unit

Household characterization – single person alone, elderly

Amount of time inside the unit, daily – less than 5 hours/day

Duration of inhabitation – 1 to 5 years

T1b unit is also occupied by a single person living alone, according to whom no alterations have been done to the existing layout. Unlike the previous case study's dweller, this inhabitant, regarding a similar unit, shows a greater degree of satisfaction towards it (4/5) and towards rooms' area (4/5) with the exception of the kitchen which area was classified as average (3/5). The space where the dweller most spends time is the common living room, where she also develops all other main activities – entertaining, watching TV, house work and intellectual work.

The dweller is content with the apartment saying that it serves her needs and therefore characterizes it as the ideal dwelling for the meantime.

T2 Unit

Household characterization – DINK

Amount of time inside the unit, daily – 5 to 8 hours/day (her), more than 8 hour/day (him)

Duration of inhabitation – 1 to 5 years

Like the previous unit, the two-bedroom variant shows no alterations to the original layout. Both dwellers find the total area satisfactory (4/5) but state dissatisfaction towards the kitchen area (2/5) and characterize the bedrooms as being average (3/5). Opinions differ in the degree of satisfaction towards the living room area, which the wife finds excellent (5/5) and the husband average (3/5), as well as dwelling layout which is satisfactory to the husband (4/5) and average to the wife (3/5). The couple spends more time in the living room, stage to other activities (entertaining, watching TV, house work and intellectual work) and state the need for bigger outdoor space. Apart from this, they also highlight as shortcoming the poor natural lighting and construction materials, characterizing the ideal dwelling as one having big balconies, good areas and storage and good materials.

3 FINDINGS

As mentioned earlier, the scope of the paper is the analysis of the relation house-use and family diversity, through the study of two types of units occupied by emergent households. The main goal is to understand how two different units, built a century apart, respond to the needs and demands of contemporary families, and in what degree are these dwellings formally and functionally adequate.

According to the POE based on observation (*walk-through*) and an inquest, it is notable that the older dwellings, in their initial layout and programme, are not adequate to current households and their needs. In two of the analyzed units alterations to layout have been made demonstrating some dissatisfaction towards room dimension and indicating the need for bigger areas. This area increase, attained through room merge, also indicates that very fragmented and compartmentalized interiors (smaller areas) are not presently desirable. The observed interiors may also be an indication that smaller households, by not needing many private spaces (bedrooms), tend to prefer room dimension instead of quantity. The main alteration in two of the dwellings was the merging of two spaces to contain the living room, which leads to the conclusion that common living spaces for social activities are the ones that should present bigger dimensions.

Apart from layout transformations there were also functional ones, *i.e.*, the change in space use. This alteration could be related not with the type of household but with society evolution and its concept of dwelling, privacy and comfort. In all older dwellings the bedroom facing the street gave way to other uses, being the bedrooms relegated to the interior of the unit, therefore more private. Rooms near the entrance and street are used as living room or common living room (living and dining room), with a more public character (to entertain visitors and with a closer connection to the street), for social activities and common family life.

A notable fact is also that of the diverging opinions in the mother-daughter household, the one that presents more differences in the satisfaction inquest. This could be explained by the different needs of the two members regarding the domestic space, as opposed to a married couple that tends to develop activities together in the same spaces and therefore have similar opinions towards them.

As for the results of the newer dwellings, it is curious to realize that the overall feeling of adequacy to the family's needs is much lower than that of the older units. On average, the newer units register 2.75/5 in adequacy whereas the older ones 4.8/5. This could lead us to conclude that contemporary layouts fail to better serve the needs of the households. A possible reason could be the lack of opportunity for transformation of a too rationalized and, in the present case, almost minimal area dwelling: over-rationalized layouts and programmes do not give way to personalization and individualized use. Sust (2000) states that *the reduction of dwelling area makes it difficult to respond to inhabitants' needs and limits flexibility and therefore the diversity of use*. Oliveira (2001) also highlights spatial flexibility as a characteristic that can prolong a dwelling's adequacy, better relating to social alterations and needs throughout its life span. Nonetheless, the degree of satisfaction towards the total area of the unit is very similar in both older (3.6/5) and newer dwellings (3.75/5).

Unlike the older units, in the newer dwellings no alterations were registered, either to layout or space use. This could be related to the fact that current layouts correspond to the expectations of modern society, placing the social functions and common spaces near the entrance and the more private functions and spaces in a deeper level (as represented in the justified graphs) In fact, the average degree of layout satisfaction is 3.75/5 in the newer dwellings, curiously not much different from that of older dwellings (3.6/5). As for room dimension, overall in the newer dwellings a more than average degree of satisfaction was registered, with the exception of the kitchen that registered and average of 2.25/5 (in the T1 units the kitchen is extremely small, 6.07 sqm – Portuguese housing legislation, RGEU, establishes a minimum of 6 sqm for this space, an area that remains unchanged since 1951 when it was first written and when the minimal Modern Movement areas were *in vogue* and when, in Portugal, social housing was the main focus of the architects).

As a similarity between all dwellers, almost all members of the different households develop intellectual work in the living area, when there is no specific room for it, which indicates a demand for introducing such spaces in future briefs. Furthermore, in both cases – older and newer dwellings – people's aspirations are very similar: bigger areas, the need for outdoor space, good location and good lighting conditions.

3.1 *Conclusions*

Although the research is in an initial phase, hence discussing the article only two case studies, the comparison between early 20th century dwellings and 21st century ones made evident that in their original layout and programme the former do not suit emergent households' needs and demands, but curiously, appear to be more flexible and allow for transformations that enable a better adequacy to intended use than the latter. Furthermore, close to minimal interiors (in area and number of rooms) could not be adequate to smaller households inspite of the reduced family composition, one reason for this being the change in working habits that dictates that many people now work from home and have the need for a specific space to develop a professional activity.

The author believes that the conducted analysis was important in the way that allowed for a comparison between two very different housing units – a more fragmented but curiously more flexible older dwelling and a rational and rigid newer dwelling – which permitted the realization that space use and adequacy could probably be finer in non-determinate and non-immutable spaces. From this perspective, it would be interesting to compare results of the same analysis of a loft-type dwelling where nothing is determined and possibilities are endless. It is also important to note the relative limitation of having only two case studies, in a research that is now initiating and that will be built upon a more numerous array of examples.

To conclude, the author considers that it is important to reiterate the relevance of POE as an analytic tool, that allows for the understanding of the needs and demands of dwellers and thus to better design for contemporary and future society, in conjunction with Space Syntax theory that enables a better layout study, clarifying relations between spaces and their meaning and functionality for the dwellers.

It is thought that this paper is relevant in the investigation of Housing and its relation with society and that it can shed some light on dwellers actual needs and opinions towards inhabited spaces in order to better design for the future so that adequacy to ways of living and household characteristics are achieved.

Equality of energy efficiency for low-income housing in the Mississippi Delta

Emily M. McGlohn
Mississippi State University, Starkville, Mississippi, USA

Emily Roush-Elliott
Enterprise Architectural Rose Fellow, GLCEDF, CSTC, Greenwood, Mississippi, USA

ABSTRACT: Within the context of an increasingly connected society, a growing awareness of the concentration of wealth among a small minority, and the threats posed by climate change; access to healthy, affordable and efficient housing is an imperative in the design of equitable communities. Not all sectors of society have access to housing that satisfies even the most basic needs of shelter or efficiency. As architects, we seek to shift this paradigm beginning with an understanding of baseline conditions. This paper chronicles efforts to determine the energy efficiency rates of a sample of low-income housing in the Mississippi Delta as a first step toward developing solutions for fair, sustainable housing.

A clear picture of energy efficiency, or inefficiency, in existing low-income housing in the Mississippi Delta does not exist, and the rate of air infiltration in this housing sector is an understudied subject. Blower door tests are typically performed on new housing to insure they meet current code mandated air infiltration standards, but blower door tests can also be used to measure the "as-is" air infiltration condition of a home. In this study, blower door tests were performed on 27 houses in Greenwood, MS, to determine how many air changes per hour (ACH) are occurring in real living conditions. This data was collected as a first step toward understanding and addressing the health and financial burdens imposed on the homeowner by inefficient housing.

Preliminary results show that older homes have a much higher ACH rate – sometimes too high to even measure – than newer housing. On average, homeowners of typical existing housing are expected to spend approximately $150 during a typical December to maintain 65°F (18°C) indoors – a significant amount for a region where 40% of the population lives below the poverty level (US Census Bureau, 2014) This can be attributed to era construction techniques and a lack of maintenance. Additionally, results show a strong correlation between high ACH rates and window air conditioning units that are not seasonally covered or removed.

The value of this research is identifying the monetary costs and health burdens associated with low-income housing in Greenwood, Mississippi, and providing a framework for responding to these burdens through recommendations to non-profits, housing authorities, municipalities, developers, and architects. The study is a first step within a larger framework, but begins the process of allowing professional architects, academics, and students to define the value of the role of design beyond the aesthetic, applying the expertise of the field to contemporary economic, social, and environmental challenges.

1 INTRODUCTION

1.1 *Energy efficiency, thermal comfort, and utility costs*

As society becomes more concerned with healthy environments, climate change, and conservation of natural resources, architecture has responded with clean, energy efficient housing options.

Energy efficient housing is defined in many ways. Grondzik and Kwok in *Mechanical and Electrical Equipment for Buildings* define efficiency as "the ratio of system output to system input." They define energy conservation as "saving energy by using less," and energy efficiency as "both conservation and efficiency efforts in buildings" (Gronzik, & Kwok, 2015). These simple concepts are the basis for many measures of conservation such as limiting air leakage through the enclosure. The 2015 International Residential Code (IRC) recognizes that a complete air barrier system is necessary for energy conservation. The latest IRC requires the enclosure to be tested and that air infiltration rates not exceed 3 ACH50 in the climate zone in which Mississippi belongs (ICC, 2014). Tighter enclosures prevent air leakage, which conserves the energy invested in the interior thermal environment. As a result utility costs are reduced, which saves money for the occupant.

Interior thermal environments, as defined by The American Society of Heating, Refrigeration, and Air Conditioning Engineers' *Standard 55* are comfortable when "that condition of mind that expresses satisfaction with the thermal environment" is reached (as

cited in ASHRAE, 2009). ASHRAE also states, "in general, comfort occurs when body temperatures are held within narrow ranges, skin moisture is low, and the physiological effort of regulation is minimized" (ASHRAE, 2009). Perception of positive thermal comfort plays a role in the well-being and health of the home's occupants and is partially dependent on the integrity of the enclosure.

1.2 *Recognizing housing inequalities*

Home energy efficiency provides three advantages to an occupant: less fuel is used, which also benefits a larger society, the indoor thermal environment is more comfortable, which helps keep the occupants healthy, and less money is spent, which means more financial resources are available to the home occupant. These important advantages are even more critical to occupants of low-income housing.

Safe, affordable housing is a societal right; yet it is not available to everyone. This fact is well documented in a recently published report entitled *The Art of Inequality: Architecture, Housing, and Real Estate*. The authors of this report state "affordability is generally determined by whether one's income can pay for essential goods and services without causing undue financial hardship. Housing is one of these essential goods" (Martin, Moore, & Schindler, 2015).

1.3 *A broader discussion*

This study examines three samples of low-income housing in the Mississippi Delta, a historically impoverished region of the United States, to understand air infiltration rates as compared to each other and to nationally accepted standards. Air infiltration rates are then used to project the cost burden a family must carry due to heat loss through air infiltration.

1.3.1 *Predicting air leakage*

To fit this study into context within a broader discussion about air infiltration, housing type, and income, a 2003 report by the Indoor Environment Department at the Lawrence Berkeley National Laboratory was reviewed. This study aggregated and analyzed over 70,000 air leakage measurements from across the United States. This data was collected from a variety of sources, the main one being weatherization programs in Ohio, Alaska, and Wisconsin. The purpose of this study was "identify house characteristics that can be used to predict air leakage." In short, the authors found that low-income houses have higher air infiltration rates by almost two times as compared to the amount of a conventional home. They also summarized that older homes are more leaky than newer homes (Chan, Price, Sohn, & Gadgil, 2003).

Since most of the air leakage data came from the Midwest, these conclusions do not extend to the South. The authors say a much in their report:

> *The results for low-income houses, for the difference between low-income and conventional houses, are probably correct for the Midwest but are much less certain for the rest of the country (for which we have no data on low-income homes.) . . it seems reasonable that the Midwest results might apply elsewhere in the country, but this inference cannot be tested with the present data.*
>
> *Chan, Price, Sohn, & Gadgil, 2003*

Within the Southeast, Midsouth, and Deep South, air leakage data was not available from Mississippi, Alabama, Louisiana, Kentucky, or Tennessee. This helps to identify a need for a study such as this one.

1.3.2 *Air leakage by region*

In a study by Grot and Clark, approximately 250 low-income residences across the country were tested for air infiltration. Weatherization techniques were employed afterwards and then tested again for improvements. Houses tested in South Carolina, Georgia, and Louisiana were the closest to the Mississippi Delta in terms of climate and history in this study (Grot & Clark, 1979).

The average air exchange per hour rate at 50 Pascals was 36.6 for all the houses tested. In the houses in South Carolina, Georgia, and Louisiana, the average was 95ACH50. New Orleans, Louisiana had the highest at 195.8 ACH50. No houses were tested in Mississippi, yet expectations for high air infiltration rates are established for this study (Grot & Clark, 1979).

1.4 *Baptist Town, Greenwood, MS*

Understanding the location of this study is important to its significance. Greenwood, MS lies at the edge of the Mississippi Delta, an important agricultural region with great culture and struggle. Baptist Town is a historical African-American neighborhood that claims many blues musicians and most recently, was the setting for the 2011 film *The Help*. This neighborhood has over five hundred residents, though less than 32% are employed and only 28% hold a high school diploma according to a 2009 study on Baptist Town (Community Development Project, 2009). Although a cohesive and active community, it has been left out of mainstream society. The typical housing stock is largely inadequate in terms of accepted comfort and efficiency standards.

As the focus of an Enterprise Community Partners Rose Architectural Fellowship, Baptist Town recently received 11 new affordable homes for its residents. The Mississippi Emergency Management Agency (MEMA) donated these premanufactured "Katrina Cottages" to the Greenwood-Leflore Fuller Center for Housing (via the City of Greenwood) for placement in Baptist Town and sale to low-income families. Through an application process, individuals were selected to be able to purchase a cottage through an affordable mortgage program organized by the local Fuller Center chapter. The coordination of cottage installation took place during 2014 and 2015

and was led by author, Rose Fellow and Greenwood Leflore Carroll Economic Development Foundation (GLCEDF) employee, Emily Roush-Elliott.

1.5 *A partnership with Mississippi State University*

As part of the final stages of the Baptist Town Cottage project, a grant was awarded to the GLCEDF to study energy efficiency rates in the new installation of cottages as compared to existing housing stock in Baptist Town. In partnership with Mississippi State University's (MSU) School of Architecture and Audit Squad – a group of students interested in building performance, this study was developed under the guidance of author and assistant professor, Emily McGlohn.

1.6 *Objectives and goals*

The objective of this study is to measure air infiltration rates of as-is conditions of a sample of low-income housing to determine the average dollar amount a family spends on heating due to air infiltration.

The goal of these tests is to determine the monetary costs and health burdens associated with typical low-income housing in Greenwood, MS.

Another goal of this study is to determine if current efforts to improve low-income housing in this community are paying off in terms of energy and monetary savings.

Long-term goals of this research include a strategy for improving energy efficiency rates and indoor air quality standards in low-income housing. Local housing authorities, non-profits, and low-income housing developers in Mississippi can implement the resulting strategies. Data can be distributed through MSU's vast network of county extension offices. Baseline information is necessary as a first step.

1.7 *Expected outcome*

The expected research outcome is a baseline metric of energy efficiency rates and anecdotal information regarding existing low-income housing in Greenwood, MS. It is hypothesized that the newer, premanufactured housing is more energy efficient, therefore more cost efficient for homeowners.

The long-term outcome of this research is a complete strategy for home energy efficiency improvements for low-income housing in Mississippi that is available to non-profits, housing authorities and others.

2 METHODOLOGY

2.1 *Introduction*

The methodology measures base air infiltration conditions of a sample of low-income housing in Greenwood, MS. Manual calculations estimate energy and cost expenditures due to air loss through infiltration. Through identification of common problematic areas of infiltration, suggestions are made to reduce rates of air infiltration.

2.2 *Sample*

A sample of low-income housing was identified before data collection began. With assistance from the GLCEDF three categories were identified and clients were contacted by the GLCEDF to request participation. Each resident was given a $25.00 gift card to a local store for incentive to participate. Images of each housing type are found in the following section as Figures 1, 2, and 3.

2.2.1 *Housing type A*

The first category, Housing Type A, represents the new installation of "Katrina Cottages" that were donated to the City of Greenwood, MS, by MEMA. Eleven Type A houses are in this sample.

Residents of the Baptist Town neighborhood applied for these homes based on need and income. Assistance in acquiring an affordable mortgage was given by the Fuller Center and GLCEDF. These homes were built approximately 10 years ago as emergency housing after Hurricane Katrina. A surplus of homes exists and it is common to see these buildings in Mississippi repurposed as affordable housing, hunting camps, or rental properties. They are premanufactured and range from 800 to 400 square feet. They are made of are 2×6 stick frame construction, insulated with either cellulous or fiberglass batts, and clad with cementitious lap siding. They rest on a pier foundation.

Participants from this sample have been previously selected from the applicant pool to receive a Katrina Cottage. The majority of these new homeowners have income of less than 30% AMI (area median income) which equates to under $9,000 in Leflore County in 2016. All homeowners are currently living in their cottages.

Figure 1. Image of Housing Type A, "Katrina Cottage."

2.2.2 *Housing type B*

The second category, Housing Type B, represents non-cottage housing completed by the Greenwood-Leflore Fuller Center for Housing – formally a branch of Habitat for Humanity. Six houses in this category are a part of this study. Homeowners in this category applied for these houses through the Fuller Center and have been living in them for more than 10 years.

These houses are approximately 15 years old. Their construction type is typically stick frame with wood siding. Their insulation type is unknown because no efforts to deconstruct these houses took place. They are approximately 1,000 square feet. Participants from this sample were identified and contacted through the GLCEDF.

2.2.3 *Housing type C*

Housing Type C represents typical low-income housing in Greenwood, Mississippi. Eleven houses were selected for testing in this category to match the number of houses tested in Housing Type A.

These houses range in age but were typically built in the 1950s and 1960s with additions built over time. Their construction type is stick frame with wood siding, replacement vinyl siding or other lapboard material. Insulation levels are unknown. All houses selected for testing rest on a pier or raised foundations.

Figure 2. Image of Housing Type B, "Fuller Center Housing."

Figure 3. Image of Housing Type C, "Typical Low-Income Housing."

Selection criteria for this sample are: between 1,000–1,200 square feet, stick frame construction, raised foundation, and local to Greenwood, MS. Participants from this sample were secured through the applicant pool for Katrina Cottages installed by the GLCEDF.

2.3 *Equipment*

The tools necessary to carry out this study included a Retrotec blower door tester and a Bosch laser distance measurer. While other measurements were not necessary, temperature, relative humidity, carbon dioxide, and carbon monoxide were recorded at each house. Tools necessary for this were a multi-meter, carbon dioxide meter, and a carbon monoxide meter. All tools were purchased through previously awarded grants.

Air infiltration levels of each house, tested with the blower door tester, were measured in air changes per hour at −50 pascals (ACH50).

2.4 *Funding and schedule*

Enterprise Community Partners and the GLCEDF funded this research study through a grant to Mississippi State University and the School of Architecture. Data collection began in July and ended in September of 2015. Greenwood, MS, is approximately 90 miles from MSU's campus and day trips were made where 3 to 4 houses were tested in one day. Undergraduate research assistants were trained and hired to assist in data collection. Their tasks consisted of measuring and drawing each house, set-up of blower door tester, and assistance in measuring air infiltration rates.

2.5 *Data collection protocol*

In advance of data collection, a protocol was established to insure uniformity. Students and faculty followed a step-by-step procedure that was developed in the previous semester. This protocol is a modified version of the 2015 International Building Codes air leakage test procedure. Since "as-is" conditions were being tested, not strictly the building enclosure, window units were not removed and fireplaces were not covered. The chart below summarizes the protocol for this study.

Table 1. Data Collection Protocol.

Step Number	Description
1	Gain permission to test.
2	Introduction to the team, explanation of study, and exchange of gift card.
3	Measure the house, and sketch a floor plan.
4	Calculate the square footage and volume of the house.
5	Install the blower doorframe and fan.
6	Open all interior doors, and close exterior doors and windows.
7	Turn gas appliances to pilot light.
8	Record measurements.
9	Breakdown and thank you.

2.6 *Data analysis*

Using Microsoft Excel, the recorded data was transformed by several calculations. The goal of the analysis was to convert ACH50 to kWh, which is easily calculated into a dollar amount.

Calculations were used from several sources including the Energy Star Home Sealing Specification from October 16, 2001 and series of heat loss calculations provided to the researchers by a colleague. These equations are listed below.

To convert ACH50 to ACHnat (Energy Star, 2001):

$$ACHnat = \frac{ACH50}{LBLFactor} \quad (1)$$

where ACHnat = "the natural air changes per hour in a building; and LBLFactor is "a factor based on climate region, number of stories of a building, and sheltering from wind which is used to convert to estimated air changes in a building by natural means, without a fan" (Energy Star, 2001).

To determine heat loss due to air infiltration:

$$Q = 0.018 * V * K * \Delta\text{Taverage} * \text{t} \quad (2)$$

where Q = heat flow in Btu, 0.018 is the heat capacity of air at sea level, V = volume of house in cubic feet, K = ACHnat, Δ Taverage = temperature difference in °F between indoors and outdoors (assume an average outdoor temperature in December for Mississippi of 45°F and 65°F indoor temperature), and t = 1 hour.

To convert heat flow into kilowatts:

$$kW = \text{Btu per hour} / 3412.142 \quad (3)$$

where 1 Btu per hour = 0.00029307107 kW.

Kilowatt hours (kWh) consumed in each house during a typical December due to heat loss through air infiltration is determined by kW*744 hours, the hours within the month of December.

The cost of electricity due to heat loss through air infiltration was calculated by kWh*$.12, the average cost of one kWh in area of the study.

2.7 *Delimitation*

This study measured the "as is" conditions of each house. Air infiltration through the enclosure was not able to be isolated. Duct work, fire places, exhaust outlets and air conditioning widow units were not covered.

Where as 11 houses in Type A were tested and 10 houses in Type C were tested, only 6 houses in Type B are apart of this study. Ideally, an equal amount of houses in each sample would have been tested, but due to time and limited contact with the homeowners, only 6 houses were tested.

The cost results that are discussed later in this paper represent the theoretical electrical cost that air infiltration would impart on a resident. In reality, each home is heated with a variety of fuel types that have different costs per Btu. For simplicity of comparison, it is assumed that each occupant uses electricity to heat his or her home.

3 RESULTS AND ANALYSIS

In this section the results of the 27 blower door tests, an analysis of the results, and general observations of the houses in the study are shared.

3.1 *Air infiltration rates per housing type*

All results from the tests are shared in Table 2 below. Note that a dash in the table means the blower door could not hold pressure in the house. The highest ACH50 recorded is 84.55 and the lowest is 7.76. The averages for each category are at the bottom of the table. The average is used to determine the financial costs for each category.

3.2 *Heat loss and financial cost due to air infiltration*

Using equations (1) and (2) from section *3.6 Data Analysis*, heat loss (Btu) due to air infiltration is calculated for each house, where then the average is calculated for each house type. With heat loss in Btu,

Table 2. ACH50 for each house measured in all three housing types.

Type A		Type B		Type C	
#	ACH50	#	ACH50	#	ACH50
A1	12.4	B1	15	C1	–
A2	9.42	B2	14.9	C2	–
A3	10.75	B3	18	C3	51.15
A4	11.3	B4	23.3	C4	36.05
A5	16.6	B5	20.4	C5	43.25
A6	7.76	B6	24.1	C6	–
A7	8.22			C7	84.55
A8	9.04			C8	–
A9	9.42			C9	–
A10	8.22			C10	25
A11	12.1				
Avg.	**10**	**Avg.**	**19**	**Avg.**	**48**

Table 3. Average amount of heat loss (Btu), kilowatts, kilowatt hours for a typical December, and financial cost for each house type due to air infiltration.

Unit	Type A	Type B	Type C
Btu	914	2,318	4,655*
kW	.26	.68	1.36*
kWh for December	199	505	1,015*
Financial Cost	$23.93	$60.66	$121.81*

*Lower value than reality because 50% of Type C houses were too leaky to hold pressure during blower door test, therefore not included in the average.

kilowatts can be estimated using equation (3). Kilowatts are easily calculated into Kilowatt hours with an estimated time of heat flow.

4 DISCUSSION

As each house was measured, general observations were made about the condition of the building. A summary of these observations follows as well as a discussion of the results.

4.1.1 *Observations of housing type A*

These houses have the lowest average ACH50 as was expected with an average of 10ACH50. They are newer, premanufactured, have central heating and air or a ductless mini-split, and constructed of 2x6 framing. On average, these homeowners spend approximately $24.00 on electric energy due to heat loss through air infiltration a month during the winter. This is 80% less than occupants of Housing Type C – a significant amount of difference.

During the blower door test, common areas of air infiltration were identified. The mechanical closet, around the tub insert, and the washing machine outlet box were consistently a problem in each cottage. These gaps can be filled with caulk or spray foam as necessary to further reduce air infiltration rates. The average ACH50 is 10, which is within range of the IRC standard of 3ACH50. An effort to weatherize these homes can make improvements that bring them closer to ideal air infiltration rates.

4.1.2 *Observations of housing type B*

Houses in this category performed as expected. They are 15 to 20 years old and not intentionally constructed to be airtight. They all rest on a slab foundation, which helped with lowering ACH, and use central heating and air conditioning. On average, Type B homeowners spend $61.00 on electric energy due to heat loss through air infiltration in a month during the winter. This is 50% less than occupants of Housing Type C, and 40% more than occupants of Housing Type A.

Common areas of air infiltration were under doors and surrounding the mechanical closet that directly connected to the attic. A smaller number of houses were tested in this category so these observations are not conclusive, yet improvements are possible with door sweeps and weatherstripping on the mechanical closet door.

4.1.3 *Observations of housing type C*

This category of housing performed the most inefficiently and proved to be the most costly to maintain thermal comfort. Fifty percent of the houses tested (5 out of 10) were not able to hold pressure during the blower door test meaning they were so leaky the equipment could not get a measurement. On the houses that could be tested, the average ACH50 is 48 – 16 times higher than new air infiltration standards set by the 2015 IRC! This extremely high rate equates to a homeowner paying around $122.00 a month in electricity costs due to air infiltration to maintain 65°F indoor temperature during an average December. This is 6% of the monthly area median income, and 16% of the monthly income of individuals who applied for a Katrina Cottage.

Figure 4. Makeshift insulation around a window AC unit. It is apparent that most homeowners do not remove or cover these during the winter.

Major areas of air infiltration in these houses varied and include the junction between the original house and additions, cracks in walls, floors, and ceilings, holes due age and to a lack of maintenance, and window air conditioning units that are not covered or removed. Figure 4 shows an example of an AC unit.

5 SUMMARY

The results of this study highlight several important aspects of the sample of low income housing in the Mississippi Delta. First, the newer, premanufactured housing, Type A, proved to be the most efficient. With simple weatherization strategies, these houses could be improved even further to the advantage of the homeowners. Type B housing performed as expected and did not impose a financial burden on the homeowners. The most surprising result was the cost burden the inefficiencies of the typical low income housing, Type C, imposes on a family. These occupants pay more than 6 times the amount the residents of the Katrina Cottages pay and 3 times as much as occupants of Type B Housing.

These results highlight the need for a strategy to address air infiltration in existing low income housing in the Delta.

6 CONCLUSIONS

6.1 *Follow-up and weatherization kits*

Although the results are interesting, they are meant to inspire change and improve the living situations

of Mississippi residents. In an attempt to improve the observed existing conditions, weatherization kits were assembled and installed in houses with compliant homeowners. The kit included caulk, spray foam, door sweeps, weatherstripping, window film, window air conditioner unit insulation, and two hours of labor to install the kit. Two local residents from Baptist Town were trained to install the kits and were paid for their time.

Although the weatherization kit cannot solve large structural problems, ACH can largely be reduced through simple measures like filling gaps and installing weatherstripping. Currently, the installers are working to offer this to each participant. Plans to return to Greenwood and blower door test weatherized houses are underway.

6.2 *Mississippi State weatherization board*

The United States Federal Government offers a low income weatherization program that is available though most states. Renters and homeowners can apply for complete weatherization of their home. If they qualify, it comes at no cost to the family and includes an energy audit, new insulation, and other measures to improve efficiency. The director of the board is aware of this study and suggested the participants of the study may qualify for complete weatherization. A meeting in Baptist Town is being scheduled for any interested homeowners.

Unfortunately, to qualify for this weatherization program, a house must meet several structural requirements such as a roof with no leaks, a floor with no holes, and walls without major damage. Many times low income housing in this region does not qualify because of these issues. Anecdotally, many of the houses in Type C would not qualify. This means there is a subset of low income families with no options for improvement.

7 NEXT STEPS

This portion of the study is concluded but many new questions have presented themselves. The most pressing issue is the improvement of the typical housing. Basic weatherization kits will not improve the houses enough and the state weatherization program cannot help homeowners with houses in disrepair. It is not feasible to simple tear down and rebuild or move families to new houses. Places like Baptist Town are important to the fabric of Delta communities and must be preserved.

New, innovative ways to solve this issue are necessary. Funding is being sought to continue looking for a solution to place families in healthy, affordable housing where they can thrive. As society makes progress in building efficiency, every sector must be included.

Housing of prime social need – Polish traditions of socially engaged architecture

N. Przesmycka
Lublin University of Technology, Lublin, Poland

ABSTRACT: The article presents the results of research on the contribution of Polish architectural thought and urban theory concerning the problems of socially engaged architecture. At the dawn of the twenty-first century, we unceasingly encounter the problem of housing shortage; however, changes of the broadly-understood conditions have occurred. Changes have affected the family model, the role of women in it, job opportunities, or the financing of the construction of one's own house. A question arises whether the achievements of Polish architectural thought in the area of socially engaged construction could be of use also today.

1 INTRODUCTION

"The architect should be appointed to solve complex problems, and not only be allowed to do the strictly architectural work." (Wieczorkowie 1933).

Polish traditions of socially engaged architecture date back to the interwar period. At a time when the housing shortage was most acute, and fast-growing cities could not provide lodgings for their newly-arrived residents, the perceptions of the architect's work radically changed. Architects, who had so far offered their services to wealthier customers, began to look for solutions aimed at providing low-cost, functional and healthy housing for the widest strata of society. At the same time one of the "missions" of architects was broadly understood public education, such as identifying new aesthetic and ergonomic qualities, aimed at a more rational use of household space, or promoting the use of modern construction materials.

2 PUBLICATIONS AND DISSEMINATION

The work of many Polish architects of the interwar period and those working shortly after World War II was affected by their leftist social views. The work of architects begins to encompass not only the concept of the building but also the design of the assembly process of factory made items or even finding beauty in the strong rhythm of repetitions (Roguska 2011).

Architects' work began to go well beyond the scope of design itself for the sake of wider community involvement. Catalogues with typical designs of houses of different standards as well as manuals and guides aimed at persons building their houses, issued in Poland since the 1920's, manifested a high level of sensitivity to the existing socio-economic situation. In the first period shortly after Poland regained its independence after nearly 200 years of partitions, we can find in these projects an attempt at determining the national Polish style. In the 1930's, the trends inspired by international functionalism already dominate as does the desire to standardize and even prefabricate in order to reduce the overall cost of investment.[1]

In 1926, Szymon Syrkus, along with Barbara and Stanisław Brukalski, Bohdan Lachert, Józef Szanajca and Helena Niemirska founded the creative group Praesens, which two years later became the Polish section at the Congrés Internationaux d'Architecture Moderne (CIAM).

International Congresses of Modern Architecture (CIAM), which were initiated in the 1920's, regularly delineated the tasks set for the architects. The primary goal was to improve the quality of life of people in degraded urban environments. The discussion which had ensued during the congress was the turning point in the perception of the social role of the architect (Kucharzyk 2011). For the first time the need for teamwork was stressed. In the interwar period, the human dimension in the work of an architect was strongly emphasized.

The development of socially engaged architectural thought was fostered by the work of two married couples of architects: Helena and Szymon Syrkus and Barbara and Stanisław Brukalski.

[1] Standardization and prefabrication in the architecture of the twentieth century stemmed from the philosophy of rationalism and the era of industrialization. Typicality understood as a result of spontaneous processes, in contrast to an intended standardization, has always been a feature of mass architecture and a result of improvement and selection of solutions on grounds of their function, material, tradition, and culture and civilization of different eras in general (Quoted from: Roguska 2011).

The Syrkuses were a married couple of architects, whose influence on urban thought and pro-social philosophy in design spanned also the postwar period. They designed housing estates for the Warsaw Housing Cooperative and the Polish Social Insurance Institution (ZUS). They also designed a few experimental single-family houses implementing the latest trends in architecture. The WSM housing estate in Warsaw's Koło district (construction works began in 1947) is considered as the Syrkuses' greatest achievement in the postwar period.[2] The Syrkuses' design theory relied on standardisation and prefabrication, which was to be primarily reflected in the more rational course of the construction process. In his publications in specialist press, Szymon Syrkus put forward demands that the house should be constructed of such parts, which could be produced at the factory; the production of elements was to be moved to the factory in order to make it a year-round process, free from seasonal restrictions of wet technologies (mortar, plaster). He promoted the introduction of dry assembly using mechanical force and the reduction of structural, building and installation elements to the lowest number of standards possible, which would be the result of long and in-depth research (Surkus Sz. 1928).

Barbara Brukalska (1899–1980) and Stanisław Brukalski (1894–1967) are considered as the leading representatives of Polish functionalism and creators of the concept of cooperative housing development. Since the late 1930's, they jointly designed cheap, functional buildings with simple bodies and subtle elements of art, which were well integrated with the surrounding space (Syrkus H., 1984). After World War II, Stanisław Brukalski was the co-designer of the reconstruction of Warsaw's New Town.

The most active place of exchange of ideas and experiences in the field of socially engaged architecture was specialist press, which was also addressed to a wider public. *Dom Osiedle Mieszkanie* Magazine (House, Estate, Apartment) issued in the years 1929–1939 are examples of journalistic activities of architects and urban planners aimed at promoting social engagement of architects.

In the interwar period, private tenement housing began to wane. Investing capital in real estate for rent, which was popular even immediately before World War I, ceased to be profitable. However, most people were still unable to afford to build housing for themselves. One of the elements meant to stimulate construction business were competitions organized by various institutions, e.g. by the national Bank Gospodarstwa Krajowego. Residential buildings were built under the support of state-backed Cooperatives, local governments (Committees for the Expansion of Polish cities), and private investors under the framework of patronage housing estates (e.g., Solvay factory in Mątwy near Inowrocław).

3 "SMALL HOUSE OF ONE'S OWN"

Polish architects of the interwar period focused not only on design but also on the possibility of financing construction projects. Savings and construction funds as well as loans and mortgages were promoted as a form of support for the development of residential construction.

In the 1930's, one of the responses to the demand for housing were the designs of small individual houses.

The suburbs of interwar Polish cities began to grow significantly. New small houses were erected by small entrepreneurs, office clerks and, less often, workers. Over 80% of these investments were situated in the outskirts of cities. What is interesting, along with the economic crisis of the 30's, the number of building sites, rather than decrease, was still increasing. This phenomenon was largely due to building projects started by people (mainly workers) who had been saving funds for many years to build their own home. It was more economically viable than paying the rent; these persons were also unable to obtain a mortgage on account of their very low income rate. After 1932, when prices had fallen dramatically, building materials also became cheaper while small savings "were actually doubled." Many people were beginning to build with little financial means and were erecting buildings of a minimum size and most often by themselves. These unfinished houses were almost immediately inhabited. From the social point of view, it was important that any such construction exempted municipalities from responsibility for housing shortage. On the pages of national press, socially engaged architects suggested that municipalities should secure land for future development, by buying up and dividing land into plots and then selling them to the poorest investors at preferential prices. The possibility to purchase smaller and therefore cheaper plots would allow less wealthy investors to build their own houses at a relatively higher standard. It would also make it possible to clarify the legal status of properties. The activities of local governments would concentrate on promoting the construction of more economical terraced or semi-detached houses. Other perceived economic benefits of promoting small-scale development included the fact that smaller plots could be located closer to the areas already having access to municipal infrastructure; it would also be easier to provide access for the newly designed plots of the same length and the roads would serve a greater number of connections. When establishing "settlements of terraced houses" one would be also able to immediately allot land to building development intended for public use.

State institutions also dealt with promoting the idea of affordable single-family housing, possibly built by the owners' own means. The 1926 competition by Bank

[2] Among others, their own house in Warsaw (1927–1928), and the WSM estates in Żoliborz (1927–1939). This housing estate was entered in 1992 in the register of monuments (urban layout and housing development with greenery).

Gospodarstwa Krajowego, whose goal was to design standardized low-cost houses, is an example of such activity. The purpose of the competition was to design three types of model houses:

A with two rooms, with the possibility of add a third room.
B with three rooms, with the possibility of add a fourth room.
C with four rooms, with the possibility of add a fifth room.

The competition, however, did not include the design of a model house of the smallest type (with only one room), on account of which it was partially criticized.

Widely propagated were cheap construction technologies (Fig. 1, 2). It was advised to lay the foundations on small reinforced concrete stilts, to build houses with no basement, or merely small circular cellars, to use concrete blocks as well as wooden structures of walls. Flat roofs were promoted (as they featured a smaller surface area to cover) while the attic was considered as unnecessary as long as the building provided another place for storing "junk" and drying clothes. In order to reduce the cost of pitched roofs, their structure was designed to make use of densely spaced boards instead of traditional rafters (Hempel 1933). The body of the building alone could also bring substantial savings, if one avoided having too many windows or made sure to concentrate all fittings in one place. These principles are valid to this day.

Civil engineering exhibitions were of great importance in the dissemination of knowledge. In 1926, the 1st International Exhibition of Modern Architecture was held in Warsaw (*Blok*, 1926). Exhibitions devoted to Low cost Individual Houses were also held periodically. Fully-furnished buildings were erected on exhibition grounds in the 1:1 scale.

4 MULTI-FAMILY HOUSING – EXAMPLES OF SOCIAL HOUSING DEVELOPMENT

In interwar Poland, ideological discourse on housing environment was mainly prominent amongst leftist architects associated with CIAM, the group Praesens, and with housing cooperatives, especially with the Warsaw Housing Cooperative. The design of the housing estate in Rakowiec in Warsaw was preceded by an extensive preamble, consisting of several chapters: the functional housing estate, the residential district, transport, collective coexistence. The size and capacity of the housing estates, the division of estates into settlements, childcare, education of youth, food supply, spatial configuration of the settlement (Jałowiecki 2009). The manifesto of the group Praesens read: "Despite modest furnishings of housing units, we do not believe that the design of Rakowiec was a denial of the principles of improvement of housing standards. Housing shortages are compensated for by the common house, designed on the same plot. The house will include a shared bath house, a club, a kindergarten and a mechanized laundry, where the residents of the housing estate will be able to do the laundry more comfortably and cheaply than the owner of a 6-room flat forced to do the washing" (Syrkus H. 1976).

Before World War II, Koło in Warsaw's Wola district became another geostrategic place for building modern housing estates. In the years 1937–1938, the Workers' Estates Society (Towarzystwo Osiedli

Figure 3. WSM housing estate, 2015. Photo H. Trammer.

Figure 4. WSM housing estate, 2015. Photo H. Trammer.

Robotniczych – TOR) was established. TOR existed not onluy in Warsaw but the idea spread over all cities in Poland. [Koło Housing Estate] It was founded for the working class population–people who were to live in small, cheap but modern apartments. After the war, the area of Koło remained popular. Helena and Szymon Syrkus designed for the Warsaw Housing Cooperative (WSM) a housing estate with a variety of three-storey buildings. The design of the estate was completed in 1947 (Fig. 3, 4). In the same year, the construction works on the estate began (ended in 1951). The WSM housing estate was built next to the TOR estate, south of Ożarowska St. Since these two housing estates adjoined, they were distinguished with two names, the former estate of TOR became known as Koło I while the new post-war housing estate was called Koło II.

The architectural solutions adopted while designing the TOR housing estates were aimed at constructing housing of prime social need, while ensuring the best possible framework for living in the neighbourhood. The term "social housing estate" was formulated during the period of Nazi occupation by Helena and Szymon Syrkus, who, together with Barbara Brukalska, were the main promoters of the idea of social housing estates in Poland. Polish social housing estates of the interwar period were characterized, however, by an escape, in their spatial form, from rigid and schematic estates of the row development approach. This does not mean that the guidelines contained in the "Athens Charter" were not adhered to, but other forms of building development were sought, which would make it possible to individualise the separate sections of the estate.

Before 1939, the history of contemporary Polish architecture did not differ from the general trends in the European or world architecture. The split with the European sphere of architectural and urban planning influence occurred only after World War II when Poland was pulled into the Soviet sphere of domination.

The period 1945–1950 in architecture was dominated by reconstruction of the entire state, which literally needed to rise from the ruins. Military action was particularly reflected in the state of the city of Warsaw, of which 85% lay in ruins. For this reason, from the very beginning, that is as early as in 1945, the Office for the Reconstruction of the Capital (BOS) was established under the leadership of Roman Piotrkowski and Zygmunt Skibniewski. In the first place, the city centre as well as the destroyed historic development were rebuilt while the construction of housing estates was carried out until 1956 in the style of socialist realism (Machaczka-Świadek, 2006).

Since 1950's, the construction of social housing estates began to be criticized by the authorities as an example of a bad imitation of the concepts from the Anglosphere. This period can be considered as the start of a new era in residential construction, particularly noticeable in the socialist countries and commonly referred to as the era of mass construction (Kania 2010). The existing norms of the first period of post-war Polish state had a close influence on the development of multi-family housing. The norms stipulated 10 m^2 for employed and studying persons and 5 m^2 for non-working persons. They also provided for a kitchen, a bathroom, and a hallway. The average surface area of apartments was 37 m^2.

The emergence of a new structural unit (this problem had been studied since 1954) in the form of a large prefabricated element – the large panel, led to the adoption of standard 5- and 11-storey types of residential buildings as they proved to be the most favorable ones from the point of view of construction and manufacturing industries. After World War II, the concepts of standardization and repeatability were extended in Poland to include other areas of design. For two decades, series of design solutions were being accumulated in catalogues; they met stringent standards, were adapted to prefabrication, and were designed for repeated use, regardless of the character of their intended future location.

Architects perceived the shortcomings of total standardization and prefabrication, but they could at most demand the so-called open, i.e., flexible standardization. There was no place for a comprehensive theoretical reflection (Roguska 2011).

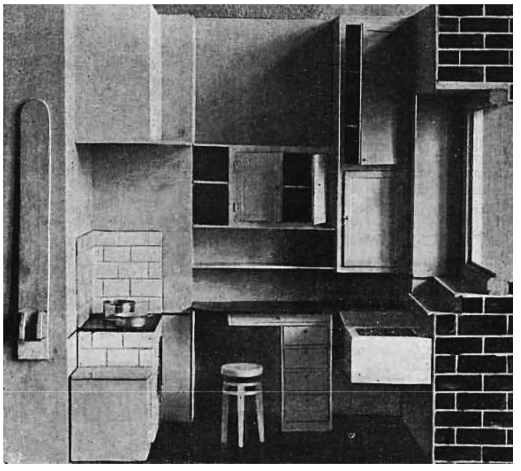

Figure 5. Modern kitchen, the model project. Architects: Brukalski, Source: Dom, Osiedle, Mieszkanie, 1929 (1).

5 INTERIORS

Pro-social approach in the design of the interwar period was manifested not only at the level of urban planning and architecture, but also in interior design. In the Warsaw Housing Cooperative, the group Preasens[3] together with the Workers' Society of Friends of Children (Robotnicze Towarzystwo Przyjaciół Dzieci), branch in Żoliboż, organized an exhibition entitled An Exemplary Apartment. It was located in one of the 120 typical apartments. The characteristic feature of the apartment's furnishing was how it was meant to accommodate five persons in the household's small area. It promoted the rational use of small living spaces through the introduction of convertible beds, bunk beds, and built-in wardrobes. Folding tables, occasional tables, and toolboxes.

Barbara Brukalska, like many other female architects of the first generation of women educated in this profession brought to design a strong build-up of empathy. She undertook to design a small, functional, and organized kitchen, with standardised dimensions and fittings, modelled on the "Frankfurt Kitchen" by Grete Schütte-Lihotzky, but adapted to the conditions of Warsaw's Żoliborz and derived from the knowledge of local habits and realities.[4]

Barbara and Stanisław Brukalski also dealt with furniture design. Their creations were characterized by a rational form, inexpensive materials and modernity.

The interwar period was the time when the first Polish architects began to deal more thoroughly with the problems of designing children's rooms (Kowalska 1929). Concepts presented in the pages of professional press by Polish designers were focused on creating a space where the children could feel at ease and at home, and which they would care for. It was recommended to keep the pieces of furniture simple, preferably white, and to allow for damage during play (Skibniewska 1974). *The strongly socially-oriented idea of a housing unit, freshly crystallized just after the war, collided with the decreed ideology of communism. However, it seems that it was not the above-mentioned confrontation which had put an end to this idea but rather the need to intensify urbanization processes as well as increasing social expectations* (Wojtkun 2012).

6 CONCLUSIONS

The 20-year long interwar period and the times of rebuilding the country after the war, along with the continuation of the idea of a social housing estate revealed new values in the design of housing and living spaces. Visionaries of architectural thought, such as Helena and Szymon Syrkus, Barbara and Stanisław Brukalski, and many other socially engaged creators propagated and implemented solutions improving the living conditions of the inhabitants of the country by designing functional interiors. They made use of the most technically advanced and modern solutions. Of key importance was the multifaceted design phase which involved equal partnership of various stakeholders (local authorities, residents, banks, loans funds, designers, cooperatives, etc.). In a short time, there grew a relationship between designers and residents of buildings, instilling in them a sense of ownership and care of the space and, above all, creating standards of low-cost houses and apartments.

The discussed contribution to the theory of twentieth century architecture should translate into our times, in order to adapt to contemporary realities and restore the role of the architect–specialist, who should not be merely a contractor. In today's era of cities focusing on the development of capitalism, the social role of the architect is disappearing. The soaring number of development investments and mass purchases of real estate by banks have created a barrier in the relationship between architects and users and transferred the decision-making processes from the level of collaboration of designers and residents to the level of investors' economics.

Vietnamese workforce housing research and design

David Rockwood
University of Hawai'i at Mānoa, Honolulu, USA

Tran Duc Quang
Da Nang University of Science and Technology, Da Nang, Viet Nam

ABSTRACT: This paper outlines research and design for housing rural-to-urban migrants in Viet Nam, focused on Da Nang City. Global capital flow in primary economic segments – manufacturing, services, and tourism – have infused developing countries with new knowledge and capital. Global forces produce internal migration in developing nations given the transition from agricultural to industrial and service economies. Around 7 million Vietnamese are expected to relocate to urban areas by 2019 to seek entry-level employment in the industrial or service sectors, and will be challenged to afford housing meeting minimum standards. Also, Viet Nam's population is concentrated in low-lying coastal areas vulnerable to storm surge and tropical cyclones. Finding a solution to housing urban immigrants is critical to stabilize and grow the economy. This entails managing the movement, health, and welfare of people and minimizing out of country migration. In response, the Vietnamese government is implementing sustainable and resilience initiatives, and has a low interest loans program to encourage apartment ownership for qualifying individuals.

The research sought design solutions for affordable, sustainable, and resilient housing for Viet Nam's urban immigrant workforce. The authors led research conducted in summer 2014 under the auspices of a Fulbright Specialist Grant in Urban Planning at Da Nang University of Science and Technology (DUT) involving a team of DUT lecturers and students. The team first researched and documented the development of Vietnamese urban infrastructure, planning, housing, and construction. Research on extant affordable housing indicated most were lacking in addressing basic needs of thermal comfort, sanitation, floor area, and social spaces. From these findings, design criteria were formulated, including: (a) Affordability – land, construction, energy, and maintenance cost; (b) Sustainability – embodied energy, passive shading and cooling systems, water re-use, and urban farming; (c) Resilience – structural integrity, water resistance, elevated floor levels, and protected building systems; and (d) Social Needs – community spaces, urban amenities, and unit types addressing varied family types.

A prototype housing block was designed incorporating the identified design criteria. A site was selected in Da Nang's primary industrial zone comprised of 395 hectares, 10 km northwest of the city center, that includes factory, warehouse, school, park, commercial, and housing uses. Housing blocks are subdivided into 5 m × 20 m parcels intended for medium density row house development accommodating multi-generational family living. The prototype housing block structural bays conformed to the 5 m lot width, and 2 story apartment units were stacked and accessed by interior "streets", thereby incorporating row house typology with increased density and inclusion of communal spaces. Given the density, a primary challenge was addressing human thermal comfort and providing public and semi-public social spaces.

The project was presented to the heads of the Da Nang Urban Planning Institute, who noted the merits of the project and who encouraged future research to optimize cost, size, and fit to demographic, environmental, and other conditions. Overall, the prototype housing design appears as a promising first step to find more optimal solutions to the current and ongoing Vietnamese workforce housing problem.

1 INTRODUCTION

Recent global trends include the shift of manufacturing and service functions from developed to developing countries as a means to minimize costs and maximize profits. Significant foreign investment in the developing world has precipitated unprecedented fiscal growth and a radical transition from agricultural economies to industrial and service based economies.

This effect is best seen in China where millions of rural people have moved to expanded or newly constructed industrial cities. A similar phenomenon is seen in Viet Nam, though on a smaller scale due to the significant difference in overall population. These shifts align with recent liberalized policies including the transition from a centrally controlled socialist economy to market socialism, and the granting to individuals the right to obtain long-term land leases.

The Vietnamese government and foreign investors first concentrated on the coastal cities given that they had sufficient infrastructure to connect with the global production network, a larger available workforce population, and conditions to grow the manufacturing and service sectors. The creation of new job opportunities prompted major rural-urban migration, with 6.6 million people relocating between 2004–2009 (Le & Nguyen 2011). The scale and impact of the migration was not fully anticipated, and the government has been slow to respond. Only limited housing and related policies have been implemented to adequately address the crisis. When worker housing is provided – either by government or a factory owner – it is often substandard and lacking in surrounding urban amenities.

2 ECONOMIC AND DEMOGRAPHIC SHIFTS IN VIET NAM

The Nguyen dynasty collapsed after French colonial occupation. The French enlarged and built new cities and transportation infrastructure to capitalize on economic resources in mining, industry, and shipping. After French occupation ended in 1954, Viet Nam was divided into North and South, each with different political structure, causing mass intra-country migration. During the 30 years of the Viet Nam War, Northern residents vacated the cities to avoid airstrikes, whereas in the South, people moved to the cities to avoid rural guerrilla warfare. Sai Gon grew from 1,485,295 inhabitants in 1967 to 3,498,120 inhabitants by 1975 (Tran 2012)

In the 10 years following the end of the Viet Nam War, political uncertainty, U.S. economic sanctions, and other conditions created widespread poverty that fueled significant out of country migration. United Nations High Commissioner of Refugees (UNHCR) statistics indicate that from 1975 to 1997, 839,288 Vietnamese arrived in UNHCR camps in South East Asia and Hong Kong (Robinson 1998).

The *Doi Moi* reforms initiated in 1986 led the transition from socialist collectivized land holdings to a market economy which allowed individuals or entities to obtain long-term land leases. This gave exchange value to land (Kemper *et al.* 2015). In 2001 Viet Nam enacted the Law on Foreign Investment and signed the Agreement on Viet Nam-U.S. Trade. These policies helped spur significant foreign investment, and global economic interests invested heavily in Viet Nam in order to capitalize on inexpensive labor and infrastructure (Huyen 2015). As a result, cities developed economically with associated improvements in living conditions, such as education, health care, and higher wages. Data from 2011 shows average Viet Nam urban resident income of 3,968 USD/year vs. 2,041 USD/year for rural residents (General Statistic Office of Viet Nam 2016). Due to factors including rural poverty, vulnerability to varied crop yields, and poor infrastructure, rural families are motivated to send one or more family member to an urban center for work to raise living standards and diversify income (Nguyen & Locke 2014). The majority of rural-to-urban migrants are unskilled and find entry-level industrial or services positions (Le & Nguyen 2011).

The new urban immigrants provide the human resource for the rapidly expanding manufacturing and service markets. However, rapid urban population increase presents a number of challenges in providing adequate infrastructure, schools, and healthcare facilities. With economic development, the cost of living and housing rise, making affordable housing difficult to secure, and causing such development to be built away from the urban centers in industrial areas that are often polluted, and that have few amenities, such as parks and public spaces. Most affordable housing constructed to date – either by government or factory owners – have been found to lack acceptable space, sanitation, ventilation, and temperature control (Le *et al.* 2011).

3 ENVIRONMENTAL MANAGEMENT

As with many developing countries, Viet Nam deferred more stringent environmental protection policies in order to maximize production. To grow the economy quickly, the country exploited inexpensive labor and natural resources. Significant pollution and Co_2 emissions have resulted from unregulated industrial and energy production (Zimmer *et al.* 2015).

Viet Nam is vulnerable to climate change. In the last 50 years there have been increases in average temperature, rainfall, sea level, storm frequency and intensity, floods, salinity in coastal freshwater bodies, and drought. (Phan & Ngo 2013).

Climate change has caused many negative effects to food and ecological security, human health, infrastructure, and economic growth. In 2008, the Viet Nam government approved the National Target Program to Respond to Climate Change. Legislation on climate adaptation was enacted, focused on: (a) ensuring food security and water resources, (b) actively coping with rising sea levels, and (c) managing sustainable forest growth. In 2009 the Support Program to Respond to Climate Change (SP-RCC), an initiative of the Viet Nam government and development partners, attracted over 1 billion USD for 65 projects from 2012 to 2020 that concentrate on meteorological monitoring systems, forest protection, farming, safety, housing, sustainable development, emissions reduction, waste management, and recycling (Social Republic of Vietnam – Government Portal 2016).

4 HOUSING CRISIS

Assuming the Da Nang population projections are accurate, around 1 million additional people will require housing within the next 15 years. A large percentage of these people are expected to migrate

from the rural areas in Viet Nam, and will be seeking entry-level service or industrial positions. This population's monthly salary is estimated to be around 150 USD, and they will be challenged to afford quality housing. The Viet Nam government has many policies to support foreign and domestic investment, and to provide housing for low and average income people by tax relief and low interest loans. The government plans to support affordable housing with 1.5 Billion USD in low interest loans for qualifying apartment types and individuals (Ministry of Construction 2016). Therefore, the research focused on this primary current and anticipated need for housing people working in the industrial and service sectors in Da Nang.

5 DA NANG CITY

Da Nang is the fourth largest city by population in Viet Nam and the largest city in the south central zone. The city is situated on the main supply routes connecting Ha Noi and Ho Chi Minh City. Da Nang is located on the East Sea and serves as a major shipping port. Its warm weather and beaches draw a large domestic and international tourist population. The city has recently attracted significant foreign investment, and has developed a strong economic base in the service and industrial sectors. For these and other reasons, Da Nang has grown rapidly from a population of around 673,000 in 1997, to about 1 million in 2014. The population is expected to double to around 2 million in the year 2030 (Da Nang Urban Planning Institute 2016).

Da Nang's urban district occupies 241 square kilometers, situated on a low lying plain bordered to the north and west by the Annamite Mountain range, and to the east by the East Sea. The Han River divides the main urban district into west and east zones.

Da Nang is situated at 16 degree North latitude and has a hot and humid tropical climate with two distinct seasons. The rainy season yields an average of 400 mm rainfall per month, and extends from September through March, and the dry season yields an average of 70 mm rainfall per month and lasts from April until August. Relative humidity ranges from 75% to 85% over the course of the year. (Da Nang Statistical Office 2016).

Da Nang is the third largest economic center in Viet Nam after Ha Noi and Ho Chi Minh City. Da Nang's Gross Regional Domestic Product (GRDP) in 2014 was 2.3 billion USD, divided into the following percentages: Agriculture, forestry and fisheries 2.62%; Industrial and construction 36.26%; and Services 61.12%. (Da Nang Statistical Office 2016). The overall economy, as measured in GDP per capita, is significantly higher than that of the whole of Viet Nam, and has grown 700% between 1997 and 2010 (Da Nang Statistical Office 2016).

The latest available population statistics (2010) indicate that Da Nang had 926,000 total residents (722 persons/km^2), with the most dense urban district containing 167,000 residents (19,000 persons/km^2) (Da Nang Statistical Office 2016), comparable to other highly urbanized cities. The six districts comprising the urban core had 700,000 residents (2,800 persons/km^2) (Da Nang Statistical Office 2016).

The row house is by far the predominant type in Da Nang given its accommodation for typical multi-generational family living, small lot size, and ability to include ground floor commercial space. A small percentage of apartment buildings are found distributed in various parts of the city, with a concentration of luxury condominium projects located near the ocean or riverfront. Da Nang has 10 affordable housing apartment blocks, with the majority located at the urban edge (Da Nang Construction Department 2016). A small percentage of villas are built in the outskirts of the city, often in luxury resort developments.

In contrast to Ho Chi Minh City and Ha Noi, Da Nang is a relatively small and newly developed city. The city government has taken a proactive planning role through its Da Nang Urban Planning Institute. Thus, Da Nang has developed urban infrastructure that currently serves the city well, and that is poised to support the anticipated rapid future development. The Institute has completed detailed plans for the year 2030. It is expected that these plans will be implemented with only minor variations (Da Nang Urban Planning Institute 2016).

6 WORKFORCE HOUSING PROTOTYPE DESIGN CRITERIA

6.1 *Occupant accommodation*

Da Nang City 2010 statistics indicate that 57% of people are employed in the services sector, and 33% in the industrial sector. Approximately 50–75% of this population fall below the median income level of 2,000 USD per year (Da Nang Statistical Office 2016). This would equate to around 500,000 people currently in need of affordable housing. The projected 2030 population increase could raise this number to around 1 million people.

A typical migration pattern is seen whereby one or several members of a rural family migrate to work in the city, and send remittances home to the family. After the first migrating individual is established, s/he may be joined by other family members, and and may marry and have children (Le & Nguyen 2011). Family size and constellation may shift, and with it, the need for varied accommodations. Single individuals may be housed in dormitory facilities, whereas families may prefer more private contiguous space.

Based on the available information, the following criteria were formulated: (a) Provide food, education, and health services close to living units to decrease transportation time and cost; (b) Provide varied public and semi-public areas within and adjacent to housing; (c) Provide various unit types to fit the needs for singles and families.

6.2 *Affordability*

Housing development cost is principally dependent on land and building construction costs. Land cost can be lowered by building in edge city locations, and by building higher density. Viet Nam uses hand techniques for primary construction operations. As the economy develops, labor rates will likely increase (Imai *et al* 2015). This may cause more industrialized and pre-fabricated methods to be implemented in order to lower construction cost.

Based on the the research on construction cost, the following criteria were formulated: (a) Retain use of concrete slabs and frames, but consider using reusable forms to speed construction; (b) Consider greater use of small sized prefabricated elements, such as frame elements and wall panels; (c) Consider greater use of slab post-tensioning to decrease concrete volume and weight; (d) Develop modular prefabricated systems to speed construction; (e) Develop rationalized floor and roof slab construction, such as lift-slab methods; (f) Design using rationalized systems and modules to decrease the number of special conditions and operations needed.

Lower construction cost may result in lower rents for affordable housing residents. Other occupant costs may potentially be decreased by use of the following criteria: (a) Minimize electrical utility costs though shading and natural lighting and ventilation; (b) Locate housing near places of employment to lower transportation costs; (c) Provide access to low-cost government loans for apartment ownership; (d) Provide on-site gardens for occupants to grow their own food; (e) Offer retail space useable by residents to generate supplemental income.

6.3 *Environmental control and human comfort*

Because Da Nang daytime temperatures range between 31–39°C, with relative humidity levels between 74%–84%, interior comfort levels are exceeded in unshaded, uninsulated, and inadequately ventilated buildings. Only a small percentage of houses use air conditioning due to installation and utility costs.

The following criteria promise to improve human thermal comfort, while keeping initial construction costs to a minimum: (a) Build houses in compact clustered arrangement for self-shading in the block; (b) Orient buildings to minimize east and west sun exposure on exterior walls; (c) Use shading devices to protect the building envelope from direct sun; (d) Offer occupant control over moveable sunshade elements; (e) Insulate the building envelope and use radiant barriers and reflective surfaces to decrease thermal transfer; (f) Use cross and stack natural ventilation strategies; (g) Orient houses and blocks to prevailing winds during the hottest months of the year.

6.4 *Sustainability*

Vietnamese building construction is mostly comprised of fired clay brick and concrete. Brick, sand, and aggregate are locally sourced. Brick is typically fired using fossil fuel or by burning wood or rice husks, adding to air pollution and CO_2 emissions. Portland cement is highly energy intensive to make, and produces high CO_2levels (Nguyen 2013). The following criteria promise to reduce the carbon footprint of construction in Viet Nam: (a) Replace fired clay brick with concrete masonry; (b) Use recycled glass as an aggregate for concrete and mortar; (c) Use unfired clay brick in low or non-structural applications; (d) Use non-mortar, mechanically fastened masonry to allow building disassembly and material re-use; (e) Use fly ash as a substitute for Portland cement.

In the residential segment, energy use for air conditioning far exceeds any other type of consumption. To decrease electrical demand, the following criteria are recommended: Maximize shading, natural ventilation, and daylighting.

The supply of fresh water is sufficient for the current use patterns and population, and this capacity exceeds what is anticipated for 2030 (Da Nang Urban Planning Institute 2016). Fresh water is supplied to the city from the Annamite Mountains that border the city to the north and west.

Storm water is collected in the city's storm water system, and is processed in wastewater treatment. A small percentage of buildings currently include rainwater-harvesting systems. A majority of surfaces in the urban core are comprised of hardscape materials. Water saving plumbing fixtures are not used extensively.

To improve water quality and availability the following criteria were defined: (a) Use porous paving surfaces to allow water to return to the ground; (b) Use local rainwater collection systems. The rainwater can be used for irrigation, as greywater, or treated for potable use; (c) Use water saving plumbing fixtures.

6.5 *Resilience*

Due to the low elevation of developed lands and their immediate proximity to the ocean, Da Nang is vulnerable to climate change effects, including increased frequency and magnitude of tropical storms, sea level rise, and storm surge. Most buildings are able to resist these effects as they are constructed using water-resistant materials. Compact urban form helps shield many buildings from wind exposure and concrete frames are constructed to resist hurricane force winds. The majority of inhabited floors are situated above flood levels. Da Nang's building stock is more resilient than many other coastal cities; however, improvements could be made. The following criteria should serve to generate more resilient future construction: (a) Elevate the majority of habitable living space above storm surge levels, (b) Designate below grade spaces for service-only functions; (c) Use porous paving and slope grades to swales and retention basins; (d) Maintain high standards for structural design and resistance to high winds; (e) Use building materials resistant to water damage and mold.

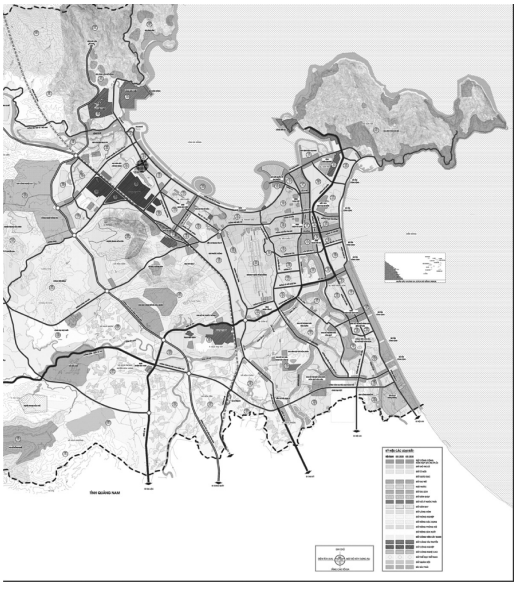

Figure 1. Da Nang land use.

7 WORKFORCE HOUSING PROTOTYPE DESIGN DESCRIPTION

7.1 *Site selection*

The prototype design is intended to address people working in industry, and a site in the industrial area was selected to allow workers to live close to their place of employment. The industrial zone has been planned in detail by the Da Nang Urban Planning Institute. Each detailed planning area typically consists of a mix of uses, including schools, health services, open space, commercial, and residential. Mixed use planning was supported in this project as it provides for more sustainable development by decreasing commuting distances, supporting community interaction, and providing a more vital urban environment. Mixed use is typical in Da Nang and other Vietnamese cities, and conforms to the current urban social and cultural norms. Blocks are typically laid out using the standard 41.5 m deep × 150 m long dimensions, and contain lots 5 m × 20 m. A block in the Hoa Hiep Nam, Lien Chieu District northwest of the city center was selected (Figures 1–3). This block has one long frontage on a major street, and an opposed long frontage on a minor residential street (Figure 3). This configuration offered a greater challenge and allowed commercial uses to be more integrated in the design.

7.2 *Fit with urban context*

In a typical planning project the prototype design would likely be interspersed with 5 m wide row houses. To fit with the neighborhood scale and urban morphology, the prototype is based on a 5 m grid. However, to achieve lower cost development (scale of construction and units per land unit area), a higher density than typical row house development was sought, while still providing public open space (Figure 4).

The intended construction materials conform to Vietnamese norms; however, recycled glass aggregate and fly ash are proposed for the concrete mix, and concrete masonry is proposed for wall infill of the concrete frame. Post-tensioned slabs are designed to reduce concrete volume.

Figure 2. Ariel view of site area.

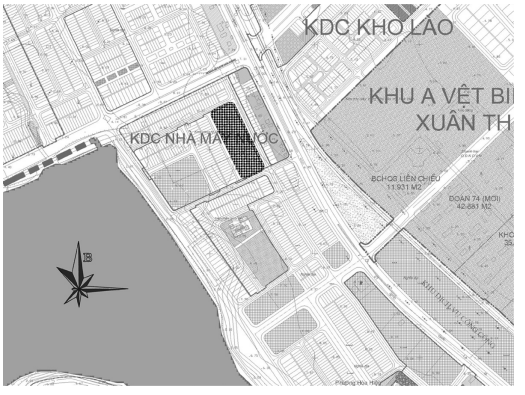

Figure 3. Planning map with building site.

Figure 4. Exterior rendering of prototype.

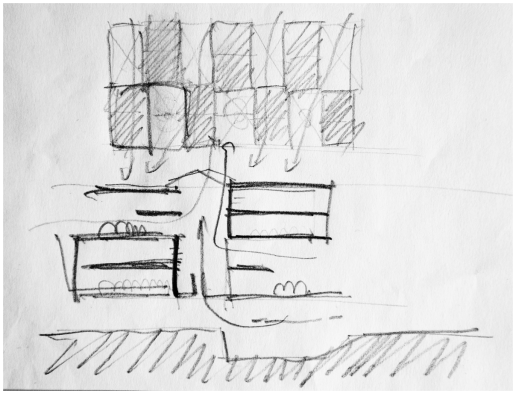

Figure 5. Concept sketch.

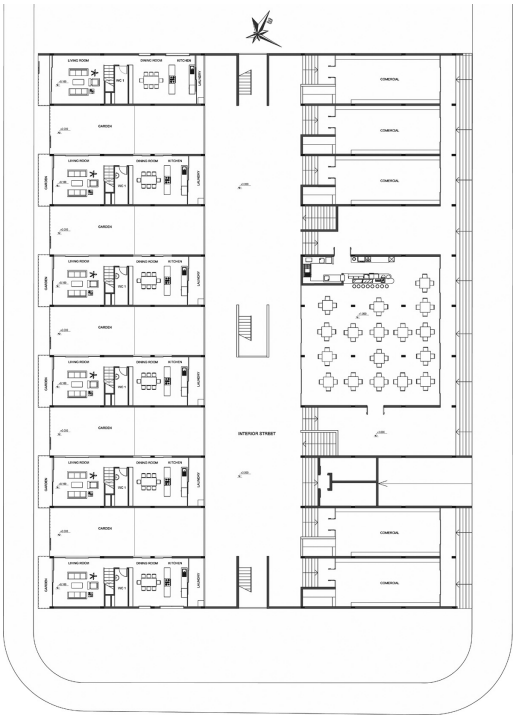

Figure 6. Entry level plan.

7.3 *Building typology*

Vietnamese urban residents are familiar with row house living, and the row house type was adapted using the concept of "stacked row houses". In this concept, a second layer of two-story row houses are placed above a first layer of two-story row houses. The design prototype is therefore a hybrid of row house and apartment typologies. Apartment buildings having typical double loaded corridors do not offer sufficient cross ventilation, and narrow corridor width discourages community interaction. In the prototype design attention was given to the internal circulation space to

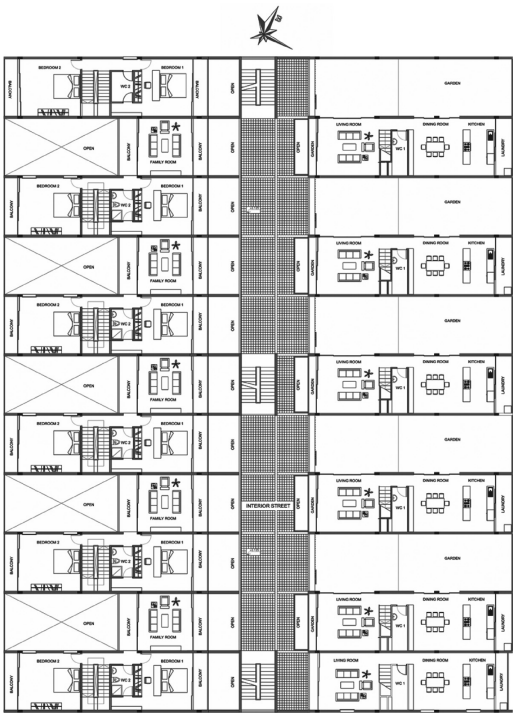

Figure 7. Second level plan.

serve communal activities, while also offering vertical and horizontal paths for natural ventilation (Figure 5).

The lowest level on the commercial side of the prototype design contains parking space. From the parking level people can access the "Interior Street" where they may take the stairs to the apartments, or enter the commercial spaces (Figure 6). Commercial spaces are also entered from the primary street. Occupants or guests of the apartments can also enter the interior street from the cross street, or from a small public space between the two buildings. Multiple access points from commercial and street areas is one strategy used to help integrate the prototype with life in the surrounding neighborhood.

7.4 *Community spaces*

On the second level (Figure 7) two-story apartments are entered on the commercial side of the building. The non-commercial side contains the second floor of the two-story units that are entered at the street level. This alternating pattern of entries to apartments continues up on the additional levels. Each interior street is "single loaded" in that entry to apartments occurs on one side of circulation. The interior streets are wide enough to encourage occupants to gather, and may be planted to take on the feeling of gardens (Figure 8). The width between apartments and the between the apartments and the street offers privacy. Conversely, people in the apartments can choose to interact with people in the interior street. Other common public and

Figure 8. Interior street rendering.

semi-public spaces include commercial ground floor spaces, small park spaces at the end and middle of the block, and a rooftop terrace having social, recreational, and community garden areas.

7.5 *Occupant living accommodation*

The prototype contains five apartment types to accommodate varied family types. Each type uses a row house organization, with the most public space located at the entry, and with semi-public and private spaces located toward the back. Two story apartment types have a stair located at the center of the plan, and contain the most private spaces (bedrooms), and in some apartment types, a family room on the upper level. Several apartment types contain an adjoining garden space.

7.6 *Environmental control and human comfort*

The prototype design could be built in different planning areas, and have varied orientation. Measures were taken to provide shading in any anticipated orientation. Each apartment's exterior enclosure is protected from high angle south sun and low angle west or east sun by an overhang and fin walls. Sliding adjustable louver doors allow occupants to control shading, ventilation, and privacy.

8 CONCLUSION

The rural-to-urban migration statistics show a high demand for affordable workforce housing in Viet Nam. The government's low-interest loan program may be a part of the solution to incentivize the building of affordable housing. However, other measures that concern urban, architectural, constructional, and other issues need to be developed to find more appropriate solutions to improve new urban immigrant's living conditions. The research and design conducted in this phase of work attempted to account for human and cost factors to begin to address the current housing crisis. Design criteria were formulated under the headings of occupant accommodation, affordability, environmental control and human comfort, sustainability, and resilience in order to focus on aspects that were deemed most critical.

The design prototype was a first attempt to address the identified design criteria. By providing greater density than typical row house development, and building away from the urban core, land costs per unit are reduced. Other measures to reduce occupant costs include passive shading and ventilation design features to lower utility costs, providing space for productive gardens, and locating the housing within walkable distance of employment. Incorporated commercial space gives occupants the ability to generate supplemental income. The design encourages community interaction by providing a variety of public and semi-public spaces and connections to the urban public space. Passive design strategies including self-shading in the block, daylighting, shading, building orientation, and ventilation help to improve thermal comfort. By investigating recycled construction materials, rainwater collection, porous paving, and water re-use, and other methods, the design promises to decrease impact on the natural environment. Resilience is addressed by locating inhabited space above storm surge levels, using water-resistant materials, and maintaining high structural design standards.

While the research so far has helped to point out the various issues that need to be addressed, and has indicated some strategies for addressing Viet Nam's affordable housing crisis, still much remains to be done. Additional investigations will need to be completed to lower construction costs, and these measures must be linked with policy and planning by government and assistance grants.

Knowledge management in post-disaster resettlement housing

Barry Ballinger & Kapila D. Silva
University of Kansas, Lawrence, USA

ABSTRACT: The design community's response to natural disasters indicates that designers have difficulty in meeting the complete sheltering needs of displaced people. While many designers propose innovative solutions to emergency and transitional shelters for post-disaster relief, they seem to lack the knowledge necessary to produce permanent homes that successfully address the concerns of the displaced. Post-occupancy research on post-disaster resettlement housing reveals that designers repeat common mistakes, especially with the attempt to emulate the formal aspects of vernacular settlements of the affected communities. While the necessary knowledge is available for successful resettlement design, that knowledge seems to be inadequately managed for easy access and use in the discipline of architecture. Effective Knowledge Management (KM) in post-disaster resettlement design would aggregate lessons learned in resettlement successes and failures, organize an appropriate response to resettlement, build a conceptual framework for resettlement, and disseminate the knowledge among design professionals. In this paper, we discuss the need, approach, and substantives of KM in regard to post-disaster resettlement planning and design. We argue that KM in this particular case should be both 'mechanistic' that deals more with explicit knowledge systems and 'organic' that deals with tacit knowledge. Both are equally important when dealing with KM, because disciplines and professions are guided by mechanical standards of practice that are often taken for granted by the practitioners, but professionals also enlist organic artistry to solve indeterminate problems. A balanced approach to post-disaster planning should have *mechanical* approaches that 1) consolidate the settlement instead of relocating them, 2) design of settlement/dwelling models and variations, 3) make room for adaptations, and 4) adopt traditional practices to housing construction and disaster response. It should also have *organic* approaches that 1) include the users in the design process, 2) study the patterns of settings and activities, 3) provide support structures, and 4) change perceptions on building standards. If these approaches were codified into an operational knowledge management system, it would legitimate disaster resettlement efforts.

1 INTRODUCTION

Natural disasters leave millions of displaced people, and recent conflicts in Syria, Iraq, Nigeria, and Israel/Palestine are creating an unprecedented refugee crisis as well (UNHCR 2015). Whether these people settle in North America, Europe, or return to their home countries, there is a growing need for permanent housing. Architects and planners will be pressed to meet an emerging demand. Post occupancy evaluations on post-disaster resettlement (henceforth PDR) housing reveal that designers repeat common mistakes (Silva 2011). One example of this can be found in Kirinda, Sri Lanka. After the 2004 tsunami, an internationally known architect designed homes for a predominately Muslim community, but the homes failed to provide culturally appropriate privacy and gendered use of space (Silva 2011). Designers attempt to emulate the formal vernacular patterns of the affected communities while failing to emulate the process, values, and meaning associated with the houses (Oliver 2006, Oliver-Smith 1996). In other examples, displaced people are resettled far from existing income sources and social networks (Davis 2006, Oliver-Smith 1991, Silva 2011). Often, newly built homes go unoccupied while people chose to rebuild their destroyed homes (da Silva 2010). Much of PDR failures can be linked to community exclusion (Pyles 2007). In our objectivist-focused search to provide 'shelter and warmth' we have done some things right, but "have failed to recognize the complexity of shelter as 'house' and 'home'" (Davis 2006, p. 147) or included the community in resettlement efforts. The difficulty in disaster relief is not that problems cannot be solved; it is that, uncoupled from behavioral considerations, our solutions become solely physical (Davis 2006, Schön 1987). While many designers propose innovative solutions to emergency and transitional shelters for PDR such as rapidly deployed tents (Davis 2006), rapid development of permanent structures fail to adhere to dynamics of culture. Their speedy deployment "implies that there has been a failure to consult adequately with interested parties" (Alexander 2004, p. 6). People affected by disasters need more than protection from elements, security, and a place to keep their things; they are often deprived of their way of life (Davis 2006). It is very important to make appropriate housing decisions because designers' redevelopment efforts can

either reinforce existing patterns of marginalization (Alexander 2004) or become sources of democratic mobilization (Oliver-Smith 1996).

While the necessary knowledge is available for successful resettlement design, that knowledge is inadequately managed for easy access and use in the design disciplines. In this paper, we argue for formulating an effective knowledge management in PDR. Knowledge management (KM) is a tool for creating, storing, transferring, and applying knowledge. KM is used by firms and institutions to codify their knowledge into a 'task-performing system' that allows them to solve problems consistently – giving them a competitive advantage (Kamara et al. 2002, p. 54). Effective KM in PDR design would first create and aggregate lessons learned in resettlement successes and failures. We accomplish this by making tacit knowledge into explicit knowledge. Secondly, KM would build a conceptual framework for PDR that imbues resettlement efforts with knowledge of local or vernacular processes of housing production. Thirdly, KM would disseminate the knowledge among design professionals and students through publishing research, workshops, and coursework. Lastly, KM will help us organize an appropriate response to resettlement. We accomplish this by creating networks of first responders when the need arises.

2 INTEGRATED KNOWLEDGE

Before describing how KM can help designers, some examination of knowledge is needed, because the failure of PDR is primarily due to an incomplete understanding of what constitutes knowledge. This exercise is critical to developing KM for PDR because understanding the kind of knowledge needed "has a bearing on the KM strategy adopted" (Kamara et al. 2002, p. 54). The epistemological foundation of knowledge itself must be considered before we can assume that there is helpful knowledge out there waiting for us to manage it. We should question the nature of this knowledge, its ownership, and its truthfulness and validity. In our postmodernist condition, we hesitate to make absolute claims on knowledge because it signifies 'truth', and "fails to address the relative, dynamic and humanistic dimension of knowledge" (Nonaka et al. 2000, p. 7). Therefore, to navigate our world we must use heuristic mechanisms that produce contextualized actions. Difficult situations arise when we lack knowledge that is appropriate to the task, and we are left powerless. Sometimes our lack of codified values leads us to take knowledge for granted. In those situations, we risk defaulting to the normative theories and fads that govern our profession (Scarborough et al. 1999), instead of vigilant analyses and substantiated theories (Wiig 1997).

Our epistemological underpinnings give us functional truths that we call knowledge. For example, we may know that trees are living plants, and this knowledge is functional because it helps us derive benefits from studying them. This is an *objectivist* epistemology that "holds that meaning, and therefore meaningful reality, exists as such apart from the operation of any consciousness" (Crotty 1998, p. 8). Therefore, what we think about a tree has no bearing on what the tree actually is. This is only one kind of knowledge that we need for solving problems (von Hayek 1945). On the other hand, a *constructionist* epistemology informs us that "truth, or meaning, comes into existence in and out of our engagement with the realities in our world … Meaning is not discovered, but constructed" (Crotty 1998, p. 9). This means that the tree has no meaning outside of our interaction with it. The temptation at this point is to choose sides, risk forming an unhelpful dichotomy, and miss out on helpful knowledge. Designers could adopt a loose definition of *constructionism* as their epistemological stance simply because of the utility it provides in dealing with culture. However, since they must create physical objects, any framework of PDR must include some degree of objectivism. A heuristic approach will give designers some "conceptual and practical resources" to build a theoretical framework for their task (Maxwell 2013, p. 39–43). This epistemological exercise leaves us with a functional philosophy that allows us to work between objects and their meaning.

Privileging vernacular form over vernacular processes shows that objectivism has dominated the design community's PDR efforts. We have created innovative solutions, but have missed the cultural meaning associated with *dwelling* as a verb (Davis 2006, Silva 2011). Martin Heidegger (1971) argues that humans build as a means of dwelling. The act is congruent with one's livelihood and reconciliation with nature (Rapoport 1988). Here we see that building and dwelling have both objective and constructive meanings. Because of this, constructionism becomes an important *state of mind* to acquire when designing for PDR. However, we should move in between the object and construct, because the need to provide physical structures called 'houses' is governed by implacable realities such as thermal dynamics and gravity. We also need to recognize the contextual 'constructions' of the people we are trying to help. This suggests using *organic* (or tacit) and *mechanical* (more explicit) processes to bring together the cultural meaning with the object (Kamara et al. 2002).

The difference between *organic* and *mechanical* processes can be witnessed in professional practice. Many behaviors in professions are not canonized into explicit guidelines. These behaviors are not necessarily 'in the book,' rather; they are a set of competencies allowing professionals to solve problems by selecting from normative procedures, but also allowing them to reconcile conflicting information (Schön 1987, p. 6). The information available to practitioners to guide them 'solve problems by selecting from normative procedures' is a *mechanical* process while 'reconciling conflicting information' is an *organic* process. Therefore, knowledge as an object and knowledge as a construct are not necessarily epistemological

dichotomies; they are functions of *mechanical* and *organic* processes.

3 KNOWLEDGE TYPOLOGY

We have set knowledge as an *object* in contrast to knowledge as a *construct* and have suggested that separating *organic* and *mechanical* processes helps us reconcile the two. In order to describe how this works and what it means for KM we need to discuss knowledge in more detail. According to Alavi and Leidner (2001), there are five alternative perspectives on knowledge that have implications for KM (p. 109). For the sake of our argument, it is helpful to think of these perspectives more in terms of types of knowledge rather than 'alternative perspectives' because types of knowledge allow concurrent or consecutive use while alternative perspectives force us to choose between them. If epistemological perspectives of knowledge are actually types of knowledge, then they are not mutually exclusive, and understanding them will help us resolve our objectivist vs constructivist dichotomy.

3.1 *Knowledge as an object*

Considering Knowledge as an *object* is part of an objectivist paradigm because it "posits that knowledge can be viewed as a thing to be stored and manipulated" (Alavi & Leidner 2001, p. 110). In the architecture profession, we consider knowledge as an object (Boano & Hunter 2012), which can be codified into building codes, zoning regulations, and design standards. When we consider this in terms of PDR, we understand why designers think that rapid provision of housing solves resettlement needs (Silva 2007). We think in terms of square meters per occupant, building cost per square meter, R-values, and sustainable materials. If people are in need of these things, the quicker we provide them the better. Certain disciplinary expectations could be propagating such practices. For example, designers are often evaluated on the objects they create, and are rewarded if their objects look compelling in architectural publications (Hawthorne 2011). Objective knowledge feeds our need for certainty, which can leave other alternatives unexplored (Ibert 2007); but designers should not abandon objectivism completely. There is useful objective knowledge within design disciplines and a research infrastructure for creating objective knowledge that can address problems in PDR.

3.2 *Knowledge as a condition of having access to information*

Another way of viewing knowledge under an objectivist epistemology is the condition of having *access to information*. This type of knowledge is a condition of having storage and retrieval systems containing explicit knowledge (McQueen 1998). In many cases, the ability to find information is a component of action, but having 'access to information' does not tell us how to use that information (Alavi & Leidner 2001, p. 108). In other words, even if the information is accessible, the person accessing the information needs the capability and desire to act on it. Ian Davis (2006) worked with the United Nations to create guidelines for *Shelter after Disaster*, (p. 147-148). Even with access to this information, the desires of designers often supplant these guidelines (Davis 2006), and top-down approaches to PDR remain common (Twigg 1999, p. 52). The United States' Federal Emergency Management Agency (FEMA) (2011) have explicit guidelines in a report titled *A Whole Community Approach to Emergency Management: Principles, Themes, and Pathways for Action*, but these have not been included in an integrated framework that includes the study of vernacular processes. There is great advantage to having the mechanism of retrievable information, but information alone cannot solve the PDR problem entirely.

3.3 *A process: simultaneously knowing and acting*

Knowledge as a *process* is part of a constructivist epistemology because knowledge is a function of actors responding to conditions in real-time: it is an organic process governed by situations, relationships, and experiences. Donald Schön (1987) observed that this tacit knowledge manifests itself in abilities that often defy explanation. If this tacit knowledge defies explanation, is it no good to us? Nonaka et al. (2000) operationalize knowing-in-action by giving it a socio-spatial dimension. They argue that knowing in action is a dynamic process where organizations and individuals create knowledge in social settings through shared interactions. Austrian economist Frederick von Hayek (1945) discusses the socio-spatial character of knowledge as diffused instances of contradictory knowledge carried by individuals that reveal themselves in time and place. Therefore, tacit knowledge can still be of use to us, if we are situated in the right social context. Knowledge as a process, therefore, can be seen in the dynamic interrelations between people in a given setting.

3.4 *A state of mind*

Another constructivist type of knowledge is knowledge as a *state of mind*. Nonaka (1994) describes knowledge in terms of 'intentions' that seeks to appropriate information from one's environment to apply to a given task (p. 17). As we have argued, the need in PDR is rooted in understanding the affected people's culture. If we consider knowledge to be a *state of mind* in which we build empathy with people affected by disasters, we have the opportunity to branch beyond ourselves to gain emic perspectives (Nonaka et al. 2000). This means the focus should be on anthropological methods of gathering knowledge. Anthropologists have studied people's responses to disasters since the discipline began and can provide needed data on vernacular knowledge (Oliver-Smith 1996).

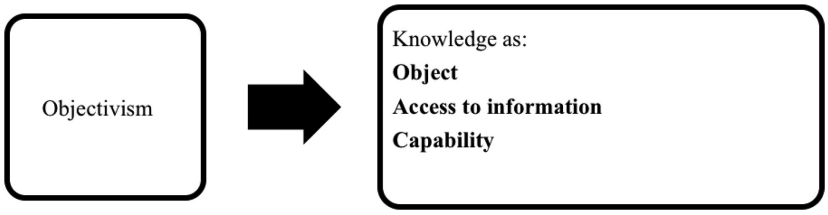

Figure 1. Objectivist Knowledge.

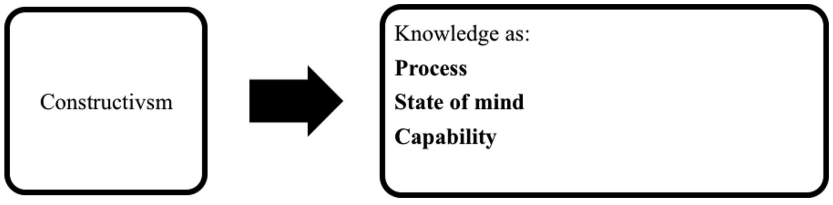

Figure 2. Constructivist Knowledge.

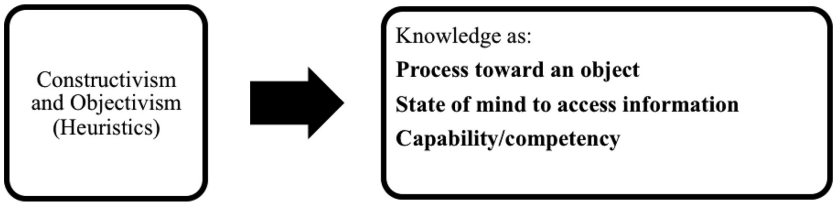

Figure 3. Integrated Knowledge.

3.5 *A capability*

None of the knowledge types discussed so far are self-contained enough to base our KM, because they do not reconcile the mechanical and organic processes that KM requires. Knowledge as a *capability* has become the focus of knowledge management (Nonaka et al. 2000), because this type of knowledge is not limited to either objectivism or constructionism, and it is neither exclusively mechanical nor organic. Thinking of knowledge as a *capability* frees designers from epistemological limitations since it focuses on learning from information at hand and negotiating the environment based on both the object and the construction (Davenport & Cronin 2000). If we need to learn from the tree as an object, we not only need the state of mind but also the capability for it. In many PDR situations, we will also need the capability to learn how meaning is constructed around the tree. If we need to learn the best way to site a house in Java, for example, we need the capability for that knowledge. If we need to know how Javanese people perceive gendered space, then we also need the capability to learn that.

If we have a strictly objectivist epistemology we will think of knowledge as an *object* or *access to information* that will tell us everything we need to know. Even so, we will need the *capability* to extract knowledge from the object in order to use it (Figure 1). If we have a strictly constructivist epistemology, we will consider knowledge as a part of a *process* that can only be understood within a certain context or *state of mind*. Again, we still need a host of *capabilities* in order to interpret the phenomenon (Figure 2).

If we take a heuristic approach, we can think of organic *processes* as movements toward an *object* and organic *states of mind* as movement toward *access to information*. We need to understand the dynamic interrelations of people in time and space that lead to objects (Kellet 2011). Additionally, we need to have an anthropologist's *state of mind* in order to produce *accessible information*. An example of this is Amos Rapoport's (1988) observations on the processes and products of vernacular settlements. In order to understand vernacular structures, Rapoport points out the importance of studying cultural processes that create vernacular forms. Understanding the behavior and human systems of people before they are impacted by disasters, and understanding how people respond to disasters will lessen the chance of making inappropriate design decisions (Oliver-Smith 1996). Thus, an integrated, heuristic approach to knowledge would look like Figure 3.

4 KNOWLEDGE MANAGEMENT FOR DISASTER RESETTLEMENT (KM FOR PDR)

The way we conceive of knowledge will affect our entire KM endeavor (Kamara et al. 2002), so

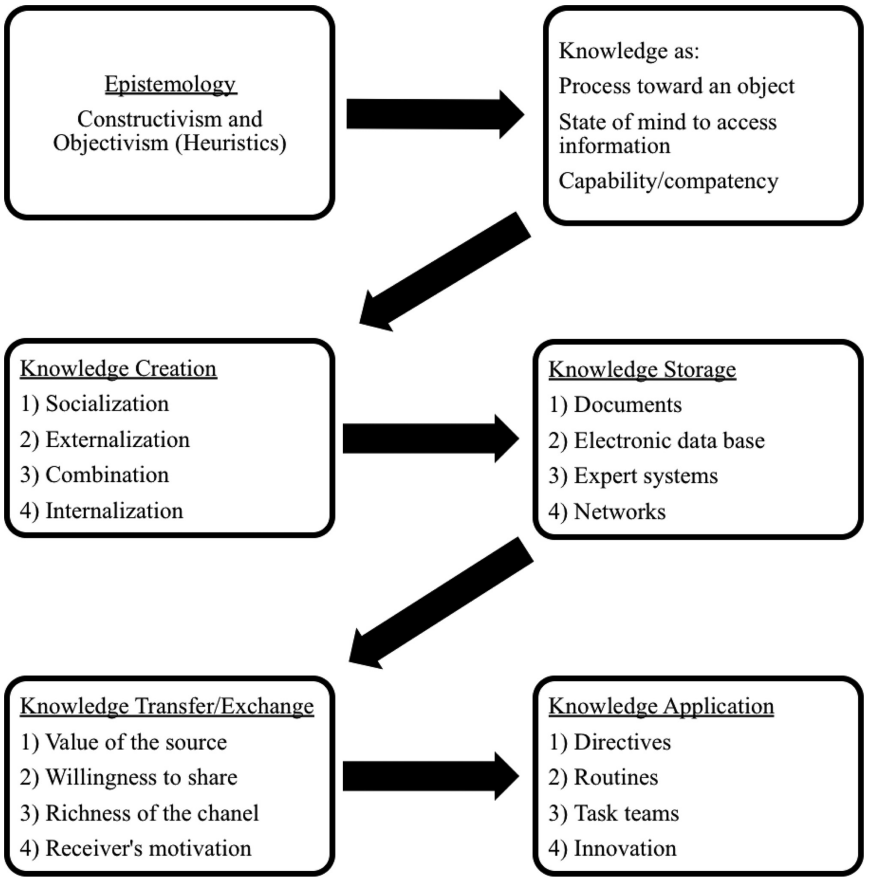

Figure 4. Knowledge epistemology and KM framework.

developing an epistemology based on the capability to negotiate both organic and mechanical processes will affect how KM for PDR works. As briefly stated above, KM is the creation, storage, transfer, and application of knowledge. Knowledge creation refers to a "continual interplay between the tacit and explicit dimensions of knowledge" that occurs on the individual and collaborative level in a shared context (Alavi & Leidner 2001, p. 116). Therefore, before we create knowledge we must have the capability to create the best environment for knowledge creation. Knowledge storage refers to the process of storing knowledge in a retrievable format. Therefore, we must have the capability to know what knowledge to store and how to store it. Knowledge transfer assumes there is a top-down process where experts impart knowledge to capable receivers (Wiig 1997). Others argue that knowledge transfer could be an exchange, in which we learn from other disciplines as well as from local wisdom/indigenous experts (Oliver-Smith 1996). Before we can exchange knowledge, we must have the capability to effectively impart as well as receive it. Lastly, the application of knowledge deals with the tools used to ensure the creation, storage, and exchange of knowledge is carried out (McQueen 1998); before we apply knowledge, we must have the capability to create meaningful and flexible tools to help sustain our efforts. The following sections will give an outline of how KM for PDR might manifest if the extant theories of KM, PDR, and vernacular studies were integrated into a systematic KM for PDR (Figure 4). KM for PDR is discussed for each phase of PDR process, i.e., *preparation*, *response*, *recovery*, and *mitigation* (Chua et al. 2007).

5 KNOWLEDGE CREATION

Nonaka et al. (2000) identify four processes of knowledge creation: *socialization, externalization, internalization, and combination* (SEIC) (p. 8). Each has organic and mechanical elements. According to Nonaka et al. (2000), *socialization* produces knowledge that can only come through a process of spending time together and co-presence (p. 9). Therefore, socialization is based on knowledge as a process. *Externalization* is simply making one's tacit knowledge sharable by making it explicit (p. 9). *Internalization* occurs when the group's explicit knowledge becomes tacit or even habitual (p. 10). Externalization and internalization can be viewed as states of mind with the goal

of making information accessible and operational. The *combination* process synthesizes existing explicit knowledge into something usable by the organization (Nonaka, et al. 2000). To facilitate this process, organizations create knowledge worker systems (KMS) in which 'knowledge workers' operate as individuals or work groups to keep KM goals in the forefront of the organization's efforts (Chua 2004, Nonaka et al. 2000). In other words, knowledge workers are all the people who participate in establishing and maintaining KM efforts.

5.1 *Knowledge creation for PDR*

Silva's (2011) research on PDR efforts in Sri Lanka creates mechanical and organic guidelines or values[(i)]. These are examples of explicit knowledge created through the *externalization* process by field research and literature review. All these have specific applications in KM for PDR.

Mechanic:

1) Consolidate the settlement instead of relocating the displaced (Oliver 2006, Silva 2011) and establish territorial claims (Davis 2006),
2) Design models and variations for housing (Rapoport 1988, Silva 2011),
3) Make room for adaptations and design for incremental growth (Rapoport 1988, Silva 2011), and
4) Adopt traditional practices to housing construction and disaster response (Silva 2011).

Organic:

1) Include the users in the design process (Rapoport 1988, Silva 2011, Turner 1977, Twigg 1999, Zhang 2012),
2) Study the cultural patterns of settings and activities (Rapoport 1988, Silva 2011),
3) Provide support structures (Davis 2006, Silva 2011), and
4) Change perceptions on building standards (Silva 2011).

5.1.1 *Preparation phase*

We need to aggregate these principles through *socialization, externalization, internalization,* and *combination*. The first step is creating what Nonaka et al. (2000, p. 8) refer to as the shared social context where capable researchers will refine these principles and generate more knowledge through close interaction. This interaction can occur in "conference sessions, research seminars, professional association meetings, practitioner gatherings, and official government meetings" (FEMA 2011, p. 2) as well as informal gatherings. Through this, knowledge workers will emerge to fill the various roles of PDR.

5.1.2 *Response phase*

Creating knowledge during the response phase of disaster resettlement would involve making our tacit knowledge explicit and our explicit knowledge operational. We do this through anthropological fieldwork of affected areas. In other words, studying the cultural patterns of settings and activities (Rapoport 1988, Silva 2011). The creation of knowledge for PDR, whether it is in Sri Lanka or Greenwood, Kansas, should include an 'accounting' of the affected culture (Agar 1996, p. 128). By doing rigorous fieldwork, we avoid enframing the affected community based solely on the visual characteristics of their buildings.

5.1.3 *Recovery phase*

Creating organic and tacit knowledge during the recovery phase will happen throughout the design and construction process (Nonaka et al. 2000). This includes observing the process, being involved in the process, talking to others who are involved, and theorizing about it (Agar 1996). The theorizing part is important because it is through theory that knowledge starts to become explicit (Schön 1987). However, creating tacit knowledge is no less important than making tacit knowledge explicit (von Hayek 1945), and in the design field, designers create tacit knowledge through close interaction and collaboration (Schön 1987). This collaboration should not only exist between professionals; in fact, it should rely heavily on participation from the affected community. FEMA's (2011) first three principles for an integrated, community approach to emergency management demonstrate the importance of knowledge creation during the recovery phase. **1) Understanding community complexity**: Since communities are impacted by many factors and interdependencies, it is important to understand the complexity of the setting, including "demographics, geography, access to resources, experience with government, crime, political activity, economic prosperity, and forms of social capital such as social networks, social cohesion between different groups, and institutions" (p. 6). **2) Recognizing community capabilities and need:** Communities can often collectively find ways to address needs (p. 8). **3) Foster relationships with community leaders:** These gatekeepers will help to identify existing activities and activists in which to frame efforts and help as well as help build trust with the community (p. 10).

5.1.4 *Mitigation phase*

In the mitigation phase, knowledge workers will create knowledge through coordinating lessons learned, performing post-occupancy evaluations, analyzing data from fieldwork, evaluating findings against extant theories, and placing the research into a wider theoretical framework. In addition, data could be used to identify possible sources of future risk to the affected community (Alexander 2004), such as mechanical issues like poor drainage and lack of escape routes and organic issues like economic vulnerability and weak social networks (Wickramasinghe 2015). Involvement with

[(i)] These should be considered values rather than guidelines because guidelines are subject to misapplication. For example, if they are viewed merely as guidelines, designers can use them as a checklist without ever truly engaging the public. As values, they are internalized.

the local community will foster reciprocal knowledge creation that will help establish resilient communities (FEMA 2011, Oliver-Smith 1996). FEMA's (2011) fourth principal deals with the knowledge creation during the disaster mitigation phase: **4) Build and maintain partnerships:** Mitigation can be achieved through maintaining public-private partnerships because maintaining local control of the economy helps build resilient communities (p. 12).

6 STORAGE/RETRIEVAL OF KNOWLEDGE

Knowledge is stored in physical documents, electronic databases, systems of human experts, and social networks (Alavi & Leidner 2001). After knowledge is created through the SEIC process, it must then be saved in a retrievable form. This is mostly a mechanical process. However, there needs to be an organic process as part of knowledge storage, or knowledge workers will not know what knowledge is worthy of storage, and what knowledge leads "to [maintaining] the status quo by reinforcing single loop learning" (Alavi & Leidner 2001, p. 118). Making too much out of the storage of knowledge risks turning the whole process into a static paradigm, because it moves KM "towards knowledge as commodity, and away from the localized, socialized context of practice" (Scarborough et al. 1999, p. 673). This implies that people within the social context mentioned earlier are no longer needed because the objective knowledge for a particular task is readily available. Knowledge storage depends heavily on the states of mind of knowledge workers because stored knowledge can lead to rigidity that hinders innovation (Nonaka et al. 2000).

6.1 *Storing knowledge for PDR*

The mechanical process for storing knowledge created in PDR involves organizing research and human contacts into a usable database. The organic process of knowledge storage for PDR is dependent on having a *state of mind* that seeks to *frame* the data within the affected culture's perspective, because without that state of mind, knowledge workers risk enframing affected people by paying attention to limited data (Schön 1987). Anthropologist Michael Agar (1996) warns that an ethnographic researcher's account of a phenomenon needs to 'approximate' the account of the studied group (p. 129). If a designer perceives only chaos and squalor in a particular group's settlement, and stores data accordingly, we may not know how the studied group perceives their settlement. We argue that researchers who study both the process and product characteristics of vernacular settlement have the state of mind for accessing the best information for PDR because they emphasize the cultural meaning, not only of the object (house), but also of the process of building the house. Therefore, a shared social context is not only needed for knowledge creation, it is also needed for storage.

6.1.1 *Preparation phase*

One of the most important aspects of KM is not necessarily know-how, but it is know-who, which means, "knowing who to contact when there is a problem" (Chua 2004, p. 59). Knowledge will be stored during the preparation phase in internal expertise directories (Nonaka et.al. 2000). These expertise directories will include data from previous research on PDR, names of knowledge workers, descriptions of their various roles, and detailed descriptions of the social context.

6.1.2 *Response phase*

The field notes, videos, audio, photos, surveys, and other data collected during on-site research should be stored in physical and digital databases, such as university libraries and relevant government agency archives. These data can be used to build knowledge of affected communities where physical site visits are viewed as too costly or dangerous.

6.1.3 *Recovery phase*

During recovery (or the actual design process) many meetings will be held, site visits and presentations made, and sketches and documents will be created. These should be stored in the databases mentioned above. This is a mechanical process that designers have a long history of doing well. The organic part of this phase means knowing how to conceptualize the settlement's physical characteristics. In some cases, designers will need to change their perception of building standards (Silva 2011).

6.1.4 *Mitigation phase*

Storing knowledge during the mitigation phase will come after knowledge workers actively observe local participants to evaluate whether the design process reflects the goals of political, economic, and social stakeholders (FEMA 2011, Zhang et al. 2015). This will allow us to avoid 'core rigidities' and 'competence traps' that may form if we merely go through the motions. The affected community must always be our greatest source of data; the end-users, not necessarily the designers, will determine what acceptable living conditions are (Silva 2011).

7 TRANSFER/EXCHANGE OF KNOWLEDGE

The social space of KM is created when knowledge is transferred to others. Knowledge transfer is dependent on the capability of the transferor to communicate the information, the transferee to absorb it, and the fertility of the social space where transfers take place (Cohen & Levinthal 1990). With this in mind, the need for a robust social space for KM for PDR becomes clear.

7.1 *Transferring knowledge for PDR*

KM for PDR is an emerging research topic, so researchers with initiative will build the momentum to shape it. The exact nature of social context, in terms of

PDR, is up for debate, but we propose it should include researchers interested in vernacular processes, as well as designers involved with humanitarian architecture that empowers the users. This is why it is important that researchers with empathy for vernacular research become the knowledge workers who channel their knowledge to students and professionals. Knowledge workers, who frame problems in the same way, though coming from diverse disciplines, will have the capability to give and receive knowledge (Schön 1987). Content of KM for PDR can then more accurately be transferred within an intentional framework.

7.1.1 *Preparation phase*

During the preparation phase of knowledge transfer, knowledge workers can enhance their capabilities by, first, placing PDR into a broader framework of vernacular settlements, which creates a robust theoretical framework that legitimates this effort. Second, creating a network of theorists will foster a motivational force to share and receive this knowledge. The last effort to enhance knowledge workers' capability is twofold: 1) Offer continuing education and certification for practitioners who participate in PDR (Silva 2011), and 2) incorporate this knowledge into design schools (*ibid*). Knowledge workers need to evaluate student and professional work based on cultural understanding as well as physical attributes (*ibid*).

7.1.2 *Response phase*

The difficulty of transferring knowledge to other professionals and students during the response phase comes from the sporadic nature of disasters. Knowledge workers can prepare for the disasters but cannot know when they are going to happen. Therefore, the fieldwork listed above cannot be easily planned as hands-on course work, and there is no other way to truly transfer this type of knowledge without fieldwork. However, the purpose of storing this knowledge is to help designers make informed decisions. Therefore, when on-site research is not possible, designers can use the response phase for reviewing data stored in past PDR efforts or ethnographic archives.

In addition to transferring knowledge to designers, it is important to transfer knowledge to the affected community. Knowledge workers do this through taking on roles of community organizers who facilitate community decision-making rather than being the sole decision-maker (Silva 2011). In this way, the KM for PDR will include the affected community as part of the knowledge worker system in a horizontal, reciprocating structure. When disasters do occur, on-site 'rapid ethnographic assessment procedures' can help designer and communities with informed planning (Pyles 2007, p. 324).

7.1.3 *Recovery phase*

The transfer of knowledge in the recovery phase happens through collaborating directly with the community through design workshops and construction projects (Barbosa 2013). The community should be included in the design and building process (Rapoport 1988, Silva 2011, Turner 1977, Twigg 1999, Zhang 2012). FEMA's (2011) fifth principle is **empowering local action**; which deals with creating a reciprocal knowledge transfer between the community, designers, and governments during the recover process (p. 14).

7.1.4 *Mitigation phase*

After the recovery phase, knowledge will be transferred through educating locals about the design process. *Knowledge workers* do this through addressing cultural, economic, and political interests and connecting all stakeholders to broader emergency management programs (FEMA 2011). This process will ensure that the community's entire needs, not just their physical housing, are understood. Since the affected community is usually the first responders in a disaster (Oliver-Smith 1996), it is important that they are aware of resources available to them.

8 KNOWLEDGE APPLICATION

Application of knowledge in KM is more than just the *use* of knowledge. It refers to creating guidelines for *how* knowledge will be used. This does not necessarily mean knowledge should be codified into prescriptions for use. Scarborough et al. (1999) warns that the 'codification and commodification' of knowledge for easy application tends to lose the rich human component of KM (p. 673). One way to direct how knowledge will be used is through independent task teams who follow an organic process that brings intangibles together, filters them through a theoretical framework, and makes action possible (Alavi & Leidner 2001).

8.1 *Application of knowledge for PDR*

It seems impossible to exclude knowledge use or application from creation, storage, and transfer. Indeed, each KM for PDR component mentioned above is dependent on knowledge application for its success. For example, knowledge creation during the recovery phase is dependent on collaboration during the design process. Knowledge is used by knowledge workers and reciprocated by the community. The success of KM for PDR will depend on knowledge workers' ability to receive the directives and internalize them into routines. It is not enough to create, store, and transfer this research and then issue directives for its use. Dynamics of time and space create 'indeterminate zones' (Schön 1987, p. 6) that override directives, and, in that case, far from being helpful – routines will nullify the benefits of KM for PDR. We have already discussed the need for knowledge workers to have a state of mind for contextualizing knowledge and allowing the setting to determine what is and is not important; however, there is a risk that our social context would become an echo chamber that is resistant to interpretation outside of the established framework. Therefore, knowledge workers should create independent task teams to critique their

PDR efforts, independently research the settings to verify if knowledge workers' findings approximate the meaning of the affected community, and verify whether or not rigidity is hindering data gathering and interpretation.

8.1.1 *Preparation phase*

Knowledge workers can use the preparation phase of KM for PDR to create directives. These directives could be based on FEMA's *Whole Community Design Standards*; however, they should also include directives for creating task teams to evaluate the appropriateness of PDR efforts. Task teams should act independently from the greater network of PDR knowledge workers to make sure stakeholders are involved. These task teams should not be members of social context that was created through the SEIC process. They could be members of the affected community, NGOs, government officials, or other stakeholders. However, PDR efforts should not be unnecessarily hindered by learning curves. If time and energy are spent bringing task teams up to speed, that time could have been used engaging the community. Task teams should have some foundation in community organizing and advocacy, as well as knowledge of PDR and design.

8.1.2 *Response phase*

It is important that knowledge workers do not smuggle unhelpful biases into the process that might invalidate their work (Agar 1996). There are many ways that task teams can help validate knowledge workers' efforts during the response phase of PDR. Jane Jacobs' (1961: 440–441) three 'habits of thought' provide ways to avoid that problem. The first habit of thought would allow task teams to "think about process" while knowledge workers focusing on all the other aspects of PDR (p. 441). The next habit of thought requires "working inductively, reasoning from particulars to the general" (p. 440). This is important because inductive reasoning helps identify forces and processes that actually are pertinent to settlements (p. 441). In other words, instead of allowing external data to describe how things ought to be, inductive reasoning will allow task teams to gain the displaced people's account. The last habit of thought will inform task teams that settings provide clues in small quantities that reveal how larger systems work (p. 440). Through this, task teams may find that arrangement of homes, gendered spaces, window placement, outdoor kitchens, and so forth are critical components of settlements. Thinking about process, working inductively, and seeking to understand the particulars of a phenomenon are implicitly discussed above as part of the integral framework of KM for PDR; however, keeping these 'habits of thought' independent will keep them from being diluted by directives, routines, guidelines, and standards.

8.1.3 *Recovery phase*

During the recovery phase, knowledge workers will work with communities to create appropriate housing. This is the fundamental goal of this whole effort. In addition, knowledge workers will work with stakeholders and task teams to create new directives, routines, and codify new standards to be applied in the next PDR effort.

8.1.4 *Mitigation phase*

The work of knowledge workers and task teams during the mitigation phase of knowledge application is to revisit PDR projects to 'verify and validate' that all stakeholders' needs were met (Barbosa 2013, p. 9). This is not only a way to evaluate the fitness of PDR efforts, but also a way to identify tacit knowledge that may go unnoticed by knowledge workers. Identifying tacit knowledge and making it explicit is how knowledge workers can innovate. The whole purpose of this KM effort is to help designers make appropriate decisions in resettlement; therefore, innovation is the key. We need to allow this process to inform us and keep innovating until we get it right.

Table 1 is a draft of what the KM for PDR process might look like.

9 CONCLUSION

Ian Davis (2006) writes about two divergent approaches to sheltering. The first is the 'commercial option' in which governments hire large builders to achieve rapid recover, and the 'livelihood option' in which displaced people participate in decision-making and construction on their shelters and economy (p. 153). The first provides shelter quickly but leaves the people out of the process entirely. This sometimes leads to inefficiency and marginalization (Twigg 1999). The second allows for all of the vernacular process, but takes a long time. When people are in immediate need for housing, the 'commercial option' provides the most direct approach. However, designers can speed up the 'livelihood option' if we have a robust knowledge management system in place. This paper is an attempt to start this conversation, so that future PDR efforts will be more responsive to community needs.

We argue for an integrated epistemology for PDR. Far from being mutually exclusive, we posit that objectivism and constructionism and organic and mechanical processes are integral to managing the complex issues of PDR. Disaster resettlement requires both objects and understanding of the objects' meaning. It is important to bear this position in mind as research on KM for PDR develops, because privileging one over the other could have disastrous consequences.

After positioning PDR within extant theories of KM, we drafted an explicit theoretical framework of KM for PDR. This framework will seek to involve the affected community in the knowledge creation, storage, transfer, and application components of KM as well as the preparation, response, recovery, and mitigation phases of PDR. In addition, we argue that knowledge workers involved in this effort should come from diverse disciplines such as anthropology, community activism, designers involved in community

Table 1. KM for PDR framework.

KM Process	Phases of PDR			
	Preparation	Response	Recovery	Mitigation
Creation	• Create social space where like-minded researches can generate and codify knowledge	• Do field work in disaster stricken locations and with disaster management groups • Local communities will be the source of knowledge	• Collaborate with locals during programming, design, and construction	• Coordinate lessons learned and perform post occupancy evaluations • Identify possible sources of future risk (Alexander 2004, p.7) • Build partnerships with communities
Storage	• Create a detailed description of social space • Create databases of experts • Make a list of knowledge workers and their roles	• Store field notes and record activities with video, audio, or photography • These should be kept in a physical or digital database accessible for knowledge workers	• Maintain design documents and record design process	• Research local participants in their efforts to build sustainable infrastructure • Describe sources of risk in publications or research community and locals (Alexander 2004, p.7)
Transfer	• Place PDR into a broader theoretical framework of vernacular settlements • Create network of theorists to share and receive knowledge on PDR • Develop curricular and professional incentives for studying PDR	• Organize on site data gathering • Help organize and mobilize the community	• Collaborating with affected communities will allow reciprocal knowledge transfer • Empower local action	• Enlist local participants in building sustainable infrastructure. • Teach locals about risks • Inform locals about the design process
Application	• Create independent task teams	• Task teams will evaluate work independently of knowledge workers	• Create new directives, routines, and codify new standards for future PDR efforts	• Task teams will evaluate the work • Identify routines that have developed • Innovate

mobilization, and researchers who appreciate vernacular processes.

Finally, this theoretical framework is a synthesis of disparate theories but remains incomplete. It requires further research, examination, and scrutiny. This effort can only become KM through the SEIC process within a social space that is yet to be created. Socialization can come through discussing these ideas at conferences; externalization can come through publishing PDR research; internalization can come through scrutinizing the framework presented in this paper; and combination can come through bringing diverse disciplines into the KM for PDR effort.

Jewish neighbourhoods in prewar Poland – an attempt at typology

M. Hanzl
Lodz University of Technology, Lodz, Poland

ABSTRACT: This paper provides a summary of larger research which explores the most typical neighbourhoods inhabited by Jews in the prewar period. Several case studies reveal different levels of acculturation, different functions in terms of the dominant professions in a settlement, varied periods of Jewish presence, and sizes of the communities. Despite the fact that the multiplicity of factors influencing the physical settings through the everyday use of space may seem enormous, an in-depth analyses shows certain general patterns. While the meaning of certain elements did not change a great deal through the ages, new threads appeared, not only through acculturation and modernisation, but also as a consequence of factors such as the rapid growth of the Hasidic community or due to the influx of Russian Jews at the end of the 19th century.

1 INTRODUCTION

1.1 *Idea*

Physical structures are considered artefacts of the cultures and societies which built them (Rossi 1984). In order to understand the influence of various social groups we need to grasp the variety of cultural patterns and examine their relations with the built environment at a given time. This focus has recently become more and more present in architectural and urban design and morphology research, and the current study, referring to the cultural meaning of physical urban space, may enrich the already defined ontologies, e.g. the one proposed by Lopes et al. (2015) and Beirão (2012).

1.2 *Case study*

The current paper is structured around the case study of the Jewish presence in two central Polish districts: Mazovia and Lodz, in the period before World War II. The complexity of the culture once present there gives us the opportunity to verify its impact on the physical structures and to look for typology which could let us grasp its richness and provide understanding.

1.3 *Content*

After this brief introduction and presentation of the background, the method of classification is defined and afterwards applied. The final part summarises the outcomes and gives an overview of future research avenues.

2 COMPLEXITY OF CULTURE

2.1 *Complexity as theory in urban studies*

The context that has served so far as the main source of knowledge about the culture of usage of space no longer suffices today, in the period of rapidly progressing urbanisation and migrations of large groups of people, who bring their own habits and behaviours. The need to design places that answer actual human needs is becoming progressively more urgent. Lefebvre's call for a single discipline of urban science (2003) requires a more heuristic approach and a more efficient use of the knowledge from various disciplines involved in urban design. The fragmentation and specialisation of science as well as historically established divisions result in huge discrepancies in terminology and in language used by researchers of various backgrounds.

Some of those problems, which exist especially on the margins of social and technical fields, have already been addressed in the field of complexity science (Portugali 2006), namely the relations between the culture of everyday life and usage of space. The cultural background, the way people representing various groups perform activities specific to them on a daily basis yields an understanding of the settings they tend to create, the overall schema inscribing into the more general framework of the cultural structures as defined by Levi Strauss (1963).

This relation manifests itself at all scales, starting with the regional one, when analysing the patterns of people's distribution, through the town level, in which various subgroups choose different places following their preferences related to lifestyle and resulting from their social status, up to the neighbourhood level, where the way people use space influences the sociometric layout of urban structure and also its physical form, while acquiring the meaning connected to a given cultural group.

2.2 *Complexity of Jewish life in prewar Poland*

The processes of the acculturation of the Jewish population which took place in Poland before the Holocaust deserve attention, and not only from their historical

point of view. The longterm stability of their coexistence in a multicultural society was associated with the specific spatial organisation and distribution of various groups and their threads in this vibrant community. The spatial organisation allowed both for the continuation of the former high context orthodox culture, still rooted in the Medieval Ages, and for integration, which was usually reflected by moving to lower context environments.

The form of the physical settings resulted from the spatial practices occurring there. One of the factors affecting the urban environment most was the level of spatial integration, which mirrored the degree of cohesion inside the community. Everyday practices and activities, embedded in the physical urban settings, gave rise to the spatial order which reflected them. Recognition of the culture related behaviours ruling the formation of urban structures requires the in-depth analysis and understanding of everyday Jewish life, which, in its variety, manifested itself in the villages, towns and cities of central Poland.

2.3 *Acculturation processes*

Acculturation manifested itself in two ways, first, as an adjustment to the surrounding culture and progressing Polonisation, which lacked an ideological background, and was prevalent in the rural areas, second, the changes which were based on a strong ideological background, initially from the Haskala and Jewish Enlightenment movement. The second was far more visible in cities, especially within large Progressive Judaism communities.

As Polonsky (2014) proves, the results of the census of 1921, namely the discrepancy between two values: the one on declared religion and the one on declared nationality, indicate the level of acculturation. Taking into account the availability of Polish language education, which catered to the majority of Jewish children between wars, this thesis may be true, as the numbers indicating Jewish nationality were usually much lower than those describing Moses faith, the current study assumes the latter a decisive factor.

3 METHOD

3.1 *Three typological levels*

The hierarchy of types necessary to properly picture the complexity of the various lifestyles comprises three levels: that of region, town and neighbourhood. The upper level, in the form of a database, shows the collection of circa 2500 places where Jews lived before World War II, including cities towns, villages, manors and also smaller settlements, with the Jewish population counting from a few people up to many thousands. The intermediate level refers to those towns or cities which, containing a Jewish population large enough or with a long tradition of Jewish presence characterised with a mixed profile, made the strict definition of Jewish lifestyle impossible as there were various groups of differing acculturation levels, dominant occupations, etc.

The level of neighbourhood refers most often to a predominantly Jewish part of any village or town which used to host a Jewish community. In larger, mixed profile settings it may also refer to a part of a city with a specific character and of lesser or higher acculturation degree. Due to its limited size, the current paper provides the most representative observations only, with the whole systematic and background study presented in a book concluding the current study.

3.2 *Approach, sources*

As the sources are fragmented, showing only pieces of the variety of this culture which vanished abruptly, a more reliable picture may be derived based on statistical data. The current study is based on elaborated results from the First Polish Census of 1921, as the results of the second (1931) were never published in their elaborated, final form. A model, in ArcGIS, has been created, which juxtaposes the census data with other resources, summarising Jewish ways of life in prewar Poland. The model contains information on the size of a Jewish population in a given place (of 1921), its share in the whole population, and the profile of the community. The integration of multiple sources to achieve a more holistic picture of the Jewish culture which backgrounded the current considerations, allowed for a more in-depth understanding of the novelty of solutions and multiplicity of observations. Additionally, it has also provided a backdrop against which an explanation of the form of historical settings becomes available in the way Levi Strauss's structural analysis suggests. Following the methodology proposed by Rappoport (1990, 2003), the appearance of outdoor urban spaces has been of principal concern and served as an additional source of information on the ways of life.

4 RESULTS – REVIEW

4.1 *The regional level*

The demographic dynamics are comparatively high for the Jewish population, yet quantitative thresholds need to be defined in order to assess their representation in the settlement network of central Poland and provide an image at a given moment. In 1921, of the total number of 345 settlements in central Poland with a Jewish population larger than 50, 70 had a Jewish population of 50 percent or more of the total population.

Among the multiplicity of towns and villages in central Poland, some of them very small, others reaching up to several hundred thousands, Jews were present in the more urban ones – in 1921, in the 70 mentioned above, 25 possessed the status of a town, 27 were urban settlements and 10 still villages, most of them quickly urbanising, to become towns in future, or suburbian colonies outside the larger settlement (Table 1). The quantity of settlements with over 50 Jews where they

provided for 30 and more percent of the total population or larger, reached up to 182 (Figure 1). Moreover, nearly all towns in central Poland had their own Jewish community.

Table 1. Jewish settlements larger than 50 people and providing for more than 50% of the total population (GUSRP, 1925).

	Quantity	Jewish population	
Profile*	Number	people	%
Towns	25	1429–6812	50–82
Urban settlements	27	218–3809	50–97
Villages	9	57–1085	53–100
Settlement	1	139	60
Summer resort	1	1108	63
Manors	2	65–148	52–54
Colonies	5	73–270	57–100

* Classification follows the one of the 1921 census.

In the case of smaller settlements, depending on the overall Jewish population in a given region, Jews were generally equally spread within villages, with individual groups often counting no more than 5 individuals, which may point at a single family.

The classification of a town's profile refers mostly to those settlements with a population larger than 50, usually hosting a Jewish *kehilla*, religious community. In the case of smaller settlements, the profile was chiefly rural, with Jewish families catering to the basic needs of the surrounding communities in terms of commerce and often also tavern-keeping. In larger communities, there were also some other basic crafts offered, traditionally tailoring, shoemaking, etc. Additionally, in many manors, small groups of Jews resided, perhaps current or past leaseholders (Fig. 2). The scale of this phenomena varied between counties, depending on the importance of the manor economy in general, and the role of agriculture as such. Nonetheless,

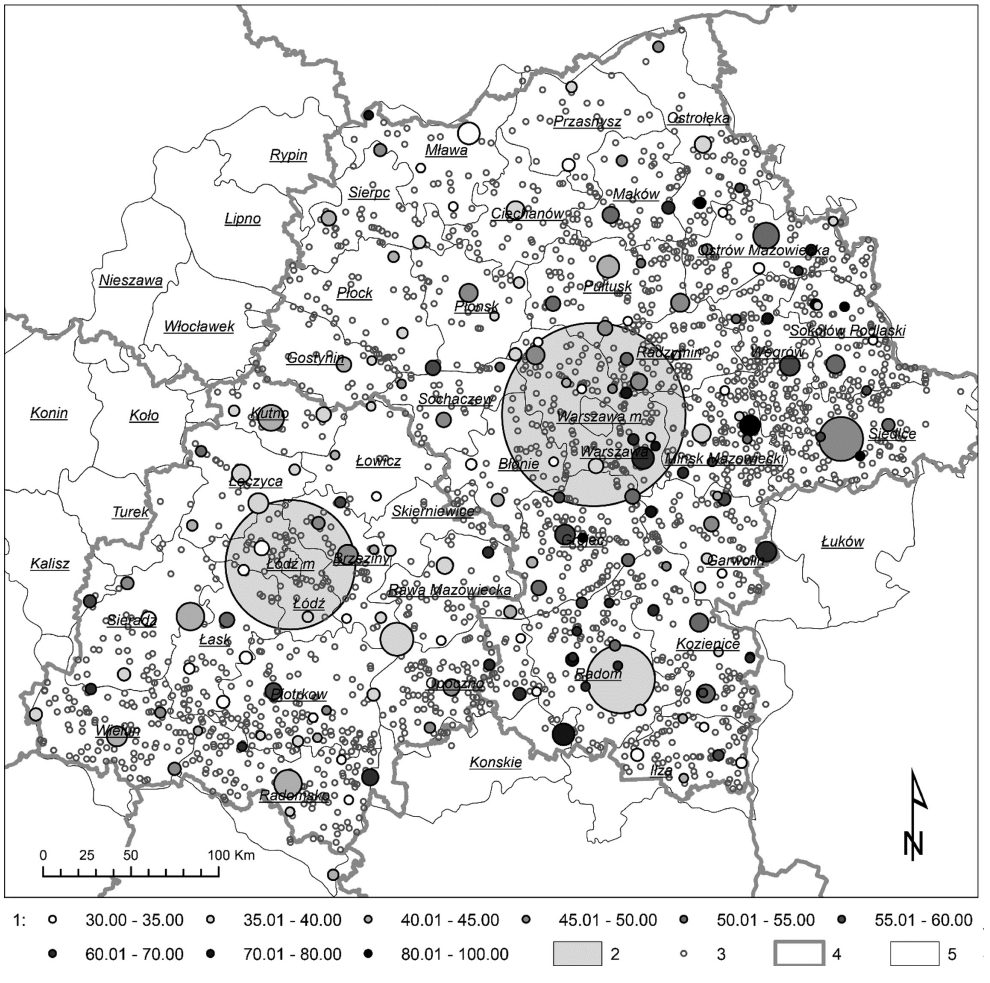

Figure 1. The main patterns of distribution of the settlements with Jewish population share higher than 30% and the quantity over 50 people in the regional scale, 1 – percentage of Jewish population in towns and villages, dots' sizes describe size of a Jewish population in 1921, 2 – regional centres: łódź and Warsaw, 3 – remaining towns and villages with Jewish population, 4 – contemporary voivod-ships borders, 5 – pre-war counties' borders.

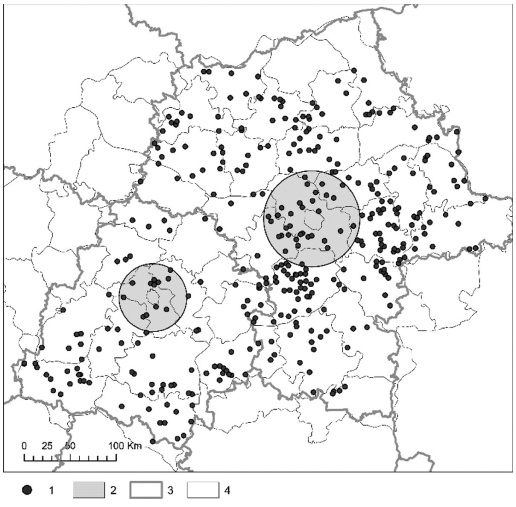

Figure 2. Distribution of manors with Jewish dwellers. 1 – manors, 2 – regional centres: Łódź and Warsaw, 3 – contemporary voivodships borders, 4 – pre-war counties.

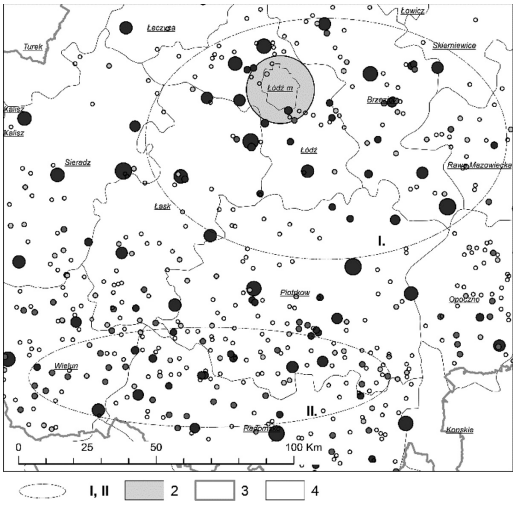

Figure 3. Types of settlement patterns in the regional scale: I – industrial, II – rural, 2 – regional centres: Łódź, 3 – contemporary voivodships borders, 4 – pre-war counties.

in some counties such as Łowicz, apart from major towns, Jews were barely present.

When analysing the distribution of the Jewish population in the scale of a region (Fig. 3) two main patterns are noticeable, corresponding to the two main types of prevailing economies: agrarian and industrial. The main difference between the two patterns refers to the regularity of distribution, and its internal dynamics.

4.1.1 *Industrial development*

The two most important cities in the region, Warsaw and Lodz, considered Jewish metropolis (Guesnet 2015), became at the same time two main nodes of the urban network, attracting people from the surrounding counties. Moreover, the strip of textile industry towns spanning from Tomaszów to Zgierz, already founded in the period of the Kingdom of Poland thanks to the government initiative dating back to the times of Stanisław Staszic, flourished. The main urban centres were those thriving thanks to industrial production, with time, huge masses of people developed specialised services, satisfying both their own needs and those in the regional scale.

When analysing the patterns of distribution of the Jewish population down to the smallest groups, a dynamic emerges, with Jewish settlements gathered along major access roads. It is clearly visible which locations attracted Jews the most, which ways they took to travel, where they stopped, etc. The whole pattern, genuinely dynamic, is more explicit in the regions of Warsaw and Lodz, the two most important industrial and administrative centres of Poland. In the region of Lodz, the locations where the smallest groups of Jews lived spread along the more important roads, e.g., from Lodz to Warsaw through Stryków and Głowno, from Lodz to Koło and Poznań, joining Lodz and Warsaw through Brzeziny, etc. In the areas surrounding Warsaw, Jews located themselves first of all next to the railway lines, some of them built catering to their needs, e.g., of the line to Góra Kalwaria. With time, the railway influenced the development of the culture of summer resorts e.g., in Otwock, Świder and Falenica.

4.1.2 *Rural development*

In the southern part of Piotrków, Radomsko, Wieluń and Sieradz counties the patterns remained more regular, static, with nodes equally distributed, which could have been due to their prevailing rural character. The density of very small Jewish concentrations south from Piotrków Trybunalski grew considerably, which could be attributed to the long term traditions of settling there, probably broken by the short period of Prussian rule. Another reason for settling there may have also been an extremely shallow layer of coal in the region of Bełchatów, with slightly similar phenomena occurring also close to Rogoźno, more to the north. Besides this, the Jewish population was proportionally higher, similar to the overall numbers of people in towns and villages. The high densities, with all their consequences in terms of economic constraints imposed on Jews, could have led to the Jewish expansion into rural areas.

Yet, despite the large sizes of villages in Wieluń county, the Jewish population there was quite limited, provided for up to 10 percent of the total number of inhabitants, except for a few towns and manors. When examining the overlap of patterns of Jewish distribution there with the background settlement pattern, an interesting phenomenon emerges, actually, the total sizes of Jewish rural communities in Wieluń county is similar to those in Radomsko and the south part of Piotrków county. What was different is that in Wieluń county a similar group of say 30 Jews lived within the administrative borders of one village, whereas in Radomsko and in the south part of Piotrków county a group of thirty Jews would be scattered in a few

small villages located one next to another, a cluster structure allowing them to maintain direct links with their community. The similarities in settlement patterns may result from the roles which Jews performed in the rural society, and the demand for their services, which did not differ that much between the two discussed regions (Fig. 3). We must remember the need of a threshold of 10 men over thirteen in order to satisfy minyan quorum requirements for public prayers. Each Jew belonged to a religious community kehilla, with whom they had to maintain easy and undisturbed contacts, which required spatial proximity. So either they stayed in a town where kehilla was located or, moving to the countryside, remained in the proximity of a larger settlement, keeping travel distances feasible.

Similar patterns were observable east from Warsaw, in Mińsk Mazowiecki, Siedle and Węgrów counties. While in the direct region of the capital its influence is clear, further to the east more static patterns prevail. This again could have been the predominating role of the agrarian economy. Nevertheless, in this region the Jewish population share grew much higher than elsewhere, which was reflected in the growth of both small, rural concentrations and larger urban centres.

Table 2. Basic range of communities' profiles.

Profile	Examples	Jewish population	
		people	%

	Falenica	1108	63
	Głowno	1430	59

4.2 *The town level*

The variety of Jewish culture in pre-war central Poland found its reflection in the variety of neighbourhoods inhabited by Jews. Each town had its own history, own specific reasons for development and growth. The Jewish population changed over time, first growing then declining, when the gentile citizens of many towns obtaining a privilege *non tolerandis judeorum* or pogroms purging Jews out of towns. In some towns Jewish zones were created, or they collapsed and even in some cases lost their charters because of fires. Reasons for growth were multiple, in the era of industrial production the most common were related to the development of specific industries, the most often being textile or leather garment production. Despite this, many towns and villages continued as formerly, servicing the neighbouring country with minor crafts and commerce.

Table 2 shows the basic range of community profiles, with several examples for each type. The main typology refers to the professional profile, with the division into market-based, thus commercial settlements, administrative centres, and industrial, in this number, textile industry centres.

There were also numerous religious centres, in most cases growing around a court of a Hasidic or Orthodox rabbi. Among centres of religious cults, the most spectacular examples of rapid growth were Ger (Góra Kalvaria), Przysucha and Aleksander (Aleksandrów Łódzki), all of them seats of famous Hasidic rabbis.

The presence of a specialisation did not however exclude other activities, with commerce and crafts represented in all Jewish settlements. What is more, professional profile changed over time. While smaller settlements maintained their unique profile and specialisation, along with growth as well as with time, their development led to complexity, and the overlap of several characteristics. These processes, accompanied by progressing acculturation and assimilation, made districts inhabited by Jewish groups of specific features such as social status, education, professional profile, religious observation, etc. The phenomenon is most explicit in the case of large metropolis, like Warsaw and Lodz, but it is also observable in cities with long traditions of Jewish presence, in this group Radom, Płock or Siedlce.

On the other hand, rapidly developing towns and villages gained new extensions, such as colonies and suburbs. This rapid suburbanisation proceeded with Jews gravitating to these new urban centres. They took an active part in their development, often informal, just outside a town's administrative borders, on private grounds, as in the case of Lodz Bałuty. In some cases, like in Koluszki, a former village which grew strong due, first, to the construction of the Warsaw Vienna Railway and later on thanks to the connections to Lodz and further to Kalisz and Poznań, with the important railway node there. Several smaller villages in its direct proximity urbanised, this way leading to the growth of the succeeding town and also attracting Jews. Jews who settled in the neighbouring villages in most cases profited from the existing community facilities of the core one, altogether forming a thriving community. Such a cluster may or may not become an actual town, Koluszki obtained its township in the postwar times, in 1949.

4.3 *The neighbourhood structure*

In many towns, the districts inhabited by Jews grew more urban than the surroundings, with the

Figure 4. The sociometric layout of paths and alleys on the backdrop of the reconstruction of the non-existing quarter between Nad Łódką Street, Stodolniania Street and Północna Street in Łódź. The quarter, inhabited mainly by Jews, was demolished by Germen in 1939. The reconstruction has been done for the purpose of the making of large-scale model of the quarter by a team of the Musem of the History of the City of Lodz: Michał Gruda, Adam Brajter, Bolesław Polewczyk, modelling team: Bartosz Michalski, Sebastian Matusiak. 1 – main confirmed commercial paths, 2 – remaining internal paths, hypothetical, 3 – location of gates in tenemants, 4 – unconfirmed gates, 5 – streets, 6 – streets which do not exist, 7 – distant landmarks, 8 – landmarks, 9 – remaining spots, 10 – river Łódka, 11 – buildings' layout based on the model reconstruction 1939, 12 – buildings' layout based on German maps of 1939, source State Archives of Lodz, 13 – plots borders 1939, 14 – buildings 2000, plots borders 2000.

urbanisation pressure and densities higher than elsewhere. Jewish citizens often flocked to historic medieval cores, which usually hosted local markets. There they preferred locations next to the river valley, which, firstly, were available and much cheaper because of the flood danger and, secondly, catered to their needs in terms of religious customs. While the plan of a town after the arrival of Jews remained relatively unaltered, especially when speaking of the network of public streets and squares, the urban blocks became replaced with new, masonry structures of a much more urban character, e.g., in Brzeziny near Lodz. Also, the way space was used changed, from more fragmented and linear, into one integrated around typically Jewish focal points, which reflected the three main spheres of life: *sacrum* – represented by

a synagogue, house of study, ritual bath, *profanum* – concentrated around work – and represented by market place, and *domicile* – in the twentieth century represented by a backyard.

The transformation of the former parcellation, explicit in the plans of towns inhabited by Jews at the turn of the eighteenth century, followed a different social organisation. The community – kehilla very strong, practically independent from the town's regulations, functioned separately from the surrounding town, even if well integrated into its structure, catering to the needs of a town's citizens and visitors. This position had its reflection in the urban structure, with interior space within Jewish quarters seemingly unordered and uninviting to visitors, for Jews serving as extensions of their dwellings and space of interior circulation, the last observation confirmed with the tradition of *eruvim* – temporary cords distinguishing private space during Sabbath.

As a rule, in traditional Jewish neighbourhoods streets were narrower than elsewhere, which is a proxemic feature of Jewish culture, where interpersonal distances are, as a rule, smaller than in the case of Polish culture. Besides this, they used available passages, including informal ones, backyards and nooks for internal circulation within urban blocks, this way enriching the former sociometric layout. A non-existing quarter in Lodz, the one which was demolished in the beginning of World War II by Germen during the creation of the Lodz ghetto, may serve an example of such a network of internal connections within an urban block (Fig. 4). The internal passages served various purposes, some of them official and easy to confirm, as they were used by locals and by visitors as places of commerce, some by turn less formal and used by local citizens only, their exact placement remains subject to hypothesis.

Hubka (2005) attributes the dense, non-geometric spatial layout of the Jewish districts in small towns of the eighteen century to the incremental growth and restrictions placed upon the Jewish community through legal regulations.

The set of features specific for Jewish neighbourhoods, which manifested themselves most clearly in the most prevalent Jewish orthodox neighbourhoods, dissolved along with acculturation and mixing with other cultures. The transition from a high context culture towards a lower definition of context was reflected in the form of urban structures. While architectural forms were typical for a given period, the general atmosphere and idiosyncrasy of the character of the neighbourhood persisted.

The set of main features specific for Jewish prevalent neighbourhoods:

- variety of building forms, diversity of styles, materials, lack of homogeneity,
- much greater irregularity of facades in Jewish neighbourhoods, both in vertical dimension and in corrugation of facades,
- the presence of edifices and forms, both public and private, belonging to Jewish culture,
- the core location of Jews constitutes the most densely populated part of the city,
- alteration of the original form to suit the needs of the community as a continuation of the former state, with respect for the former partitions, etc.,
- a dense and tightly interconnected sociometric layout as a reflection of the rich community life,
- the concentric character of the spatial layout with three main focal points: synagogue, market and courtyard.

The features which are listed in the current paper are explained in more depth in other articles stemming from the current study (Hanzl 2013, 2014, in press).

5 CONCLUSIONS AND RESEARCH AVENUES

This paper provides a summary of a part of the larger research of an exploratory character which exemplifies the most typical neighbourhoods inhabited by Jews in the prewar period. Several case studies reveal varied level of acculturation, different functions in terms of the main professions dominant in a settlement, different periods of Jewish presence and the varied scale of the community. The multiplicity of factors influencing the appearance of the physical settings through the everyday culture of the use of space may seem enormous, however, after in-depth analyses, some systematics is possible. While the meaning of some elements remained virtually unchanged through the ages, new threads appeared, not just acculturation and modernisation, but also, e.g., as a consequence of the huge development of the Hasidic community, or thanks to the influx of Russian Jews at the end of the 19th century.

In the current article, the main synopsis of the data-base model of the Jewish population in central Poland (the current Mazovian and Lodz voivodships) in 1921 are discussed, based on census data. An attempt at classification of larger, more urban centres is given, distinguishing such types as industrial, including textile industry towns, administrative and commerce centres, and religious centres. The settlement network of smaller Jewish concentrations is also discussed, pointing at the presence of more dynamic and more static patterns linked to more rural or more industrial economies, respectively. The regularities of distribution, against varied backdrops of general settlement patterns in different regions, have been noticed, which I believe is the result of the actual occupation profile specific to the Jewish culture and the historical circumstances. The urban growth processes have been noticed and discussed as well.

Further research aims at more in-depth illustration of the above characteristics, with the analyses of individual case studies.

ACKNOWLEDGEMENTS

The current study is a part of the research project financed by The National Science Centre of Poland

UMO-2011/03/D/HS3/01630, entitled: *"Morphological analysis of urban structures – the cultural approach. Case studies of Jewish communities in the chosen settlements of Lodz and Masovian voivodeships"*. Part of the methodological research was performed in SENSEable City Laboratory, Massachusetts Institute of Technology within the framework of a Fulbright Senior Research Award.

Refugee shelter: Cheap, fast, lightweight and sustainable

Olivier Chamel
Florida A&M School of Architecture + Engineering Technology, USA

ABSTRACT: The recent and ongoing conflicts in the Middle East and Africa have brought renewed awareness to the issues facing displaced populations around the world and to the need of providing adequate shelter for them. The housing needs of refugee families continue to pose a great challenge to the international community and to organizations such as the United Nations High Commissioner for Refugees (UNHCR) because they affect a broad range of populations across vast geographic areas and require the resolution of a complex design problem. Currently there are a number of shelter prototypes available for distribution though an assessment of these options suggests that more research could be conducted to propose competitive solutions in terms of overall efficiency and cost. When it comes to designing an emergency shelter the challenge lies in the ability to create a comfortable, healthy and structurally sound yet lightweight building that can be fabricated inexpensively and in a sustainable manner.

The prototype we are presenting would function both as a short term and long term housing solution. The concept not unlike other shelter solutions is based on a flat pack prefabricated modular system that can be assembled in a matter of hours with few simple tools. The prototype is based on a modified version of a structural insulated panel system in order to meet stringent weight and affordability requirements.

The paneling system used for walls and roof is fabricated by laminating Fiber Reinforced Plastic over rigid insulation boards using a formaldehyde free adhesive. The roof panels are thicker when compared to the walls in order to provide adequate insulation in hot climate applications. The assembly of the entire shelter can be completed in a few hours by connecting wall and roof panels with metal clips. The building is safely anchored by means of a ground anchoring system which connects the bottom of the walls directly to the ground. The flooring system is composed of an extruded and interlocking plastic paneling system.

Key design features of this shelter prototype include high insulation value, ease of assembly, access to natural light and affordability. These housing units allow natural cross ventilation and should only require minimal heating in cold climate. A small photovoltaic system provides enough energy to power LED lights and charge a cell phone battery.

This project was initiated in a special study course where students proposed a series of prototypes as part of a small design competition. The project is nearing completion of its design phase and is scheduled to be built as a prototype to verify feasibility before it can be presented to the UNHCR and a number of non-profit organizations.

The recent and ongoing conflicts in the Middle East and Africa have brought renewed awareness to the issues facing displaced populations around the world and to the need of providing adequate shelter for them. Unfortunately the issue of displaced populations is not a new phenomenon and some of the refugee settlements have been in existence for years and in some cases even decades. The largest refugee camps are currently located in Africa and South Asia but overall they spread over a geographic area stretching from Turkey to Thailand and encompass vastly different climate zones. In addition to dealing with difficult living conditions, malnutrition and poor health and hygiene these populations are usually housed in shelters that offer only limited relief against a variety of weather conditions. Many refugee settlements use tents as they are inexpensive, easy to install and provide a very basic form of shelter that may be acceptable in dry climate zones. Nevertheless desertic and semi-desertic climate zones present another problem as they often experience large day and night temperature variations which pose additional challenges in terms of comfort. Based on these climatic considerations alone, shelters ought to be designed as an insulated and sealed enclosure with regards to airflow and moisture while at the same time allowing natural ventilation in order to deal with hot and humid conditions. In addition to fulfilling the requirements we just mentioned and in order to be viable, refugee shelters should be inexpensive, lightweight and easy to transport and assemble. The life expectancy of such structures also mandates that they meet certain durability standards and are able to withstand repeated impacts, wind load forces and moisture intrusion for several years.

There are currently a number of shelters in use ranging from precarious tents to fully functioning prefabricated units outfitted with plumbing fixtures and electric appliances. Recently IKEA developed an inexpensive, lightweight and easy to install shelter prototype that is positioning itself as a balanced solution between cost and quality. The housing unit they developed though does not feature a specific insulation component as it is presented as a temporary housing solution and considered an improvement over the tent option.

Based on the current refugee population; the war in Syria alone has created a displaced population of 4.5 million, there seems to be a need for housing solutions which provide a safe and comfortable environment without necessarily offering other amenities such as plumbing fixtures and electric appliances as it is the case in more long term refugee housing. It seems crucial that while a viable shelter should be inexpensive and easy to assemble it should also offer a climate controlled environment for malnourished populations and families with young children living in precarious conditions.

This project is motivated by a deep concern for vulnerable populations as we hope the power of good design can contribute to the resolution of a difficult housing problem and help people in dire need of better living conditions. Within that context we focused on developing a pragmatic building structure rather than making an architectural statement. The idea is to design a shelter based on a customize version of a Structural Insulated Panel system (SIP) in order to provide structural integrity, insulation and moisture protection. The inherent nature of the panelized system lends itself to a flat pack shipping solution so the design challenge lies in the ability to meet stringent cost requirements and design a kit of parts easy to assemble.

1 DESIGN CONCEPT

Because simplicity of assembly and weight are crucial factors in the feasibility of this prototype the design itself was very much driven by these specific requirements. Another important issue to consider was the overall size of the housing unit as it relates to individual panel dimensions and determines the overall volume of the building flat pack. The dimensions of the pre-fabricated panels were therefore based on the clearance available inside a typical $8' \times 8' \times 20'$ shipping container.

The building concept for the shelter unlike most current SIP construction is based on the idea of a continuous insulated envelope encompassing floor, walls and roof. The floor panels are laid over a rigid framing system which rests on leveling legs. The wall panels are installed along the perimeter of the floor structure and receive shed roof panels which span from wall to wall. Consequently the envelope is also the structure. The dimensions of the floor plan are $9' \times 15'$ with a top of wall elevation of 7 feet on the low side and 8 feet on the high side. This translates into a roof pitch slightly higher than 1 inch per foot. All panels are slightly less than 4 feet wide (to fit inside a shipping container) and composed of a 2-1/2 inch layer of expanded polystyrene (EPS) sandwiched between two layers of .075 inch fiber reinforced plastic (FRP). The FRP panels are flat and come in an off-white mat finish in order to limit heat absorption. They are glued under pressure using a non-formaldehyde adhesive.

The housing unit is equipped with a single door with a continuous hinge and 4 operable windows to bring natural light and allow cross ventilation when needed. All windows and doors are integrated within the paneling system. It is assumed that the housing unit would be installed with its length facing north and south as clerestory windows are located along these walls. The width of the shelter would logically offer limited sun exposure on the east and west therefore limiting heat gain. The clerestory windows placed on the high wall allow light to reflect on the sloped ceiling and increase daylighting inside the unit. The window placement alternates on the opposite long walls in order to balance the amount of light coming from the north or the south and achieve relative good day lighting inside the entire unit. The purpose of these high windows is to enable daylighting so there is appropriate illuminance for a range of daily activities inside the shelter while preserving privacy. A two-foot roof overhang over the short elevations assumed to face east and west shades the windows located on these sides and provides protection outside the front door. Cross ventilation can be achieved by creating air flow between an operable window located inside the front door and a small window on the opposite end wall.

All connectors have been designed to ensure overall rigidity of the structure and weatherproofing. The interior spaces of the housing unit are flexible and can be divided into two separate zones using a lightweight track and curtain system. In terms of access to power, a small photovoltaic system charges a lithium battery which powers 4 LED lights inside the unit along with a cellular phone charger.

2 ASSEMBLY PROCESS

In addition to being inexpensive and lightweight this Insulated Shelter Unit (ISU) prototype displays structural integrity especially as it relates to lateral loads and uplift. By means of a series of appropriate connectors the assembly of the overall structure addresses lateral loads and insures structural continuity from the foundation system to the roof. The flooring system composed of insulated panels is rigid enough to support the occupants' concentrated loads without deformation. Another key feasibility requirement relates to the speed of construction and the ability for two people to complete the entire assembly in less than five hours. The fact that the concept of this housing unit is based on a structural panel system as opposed to a

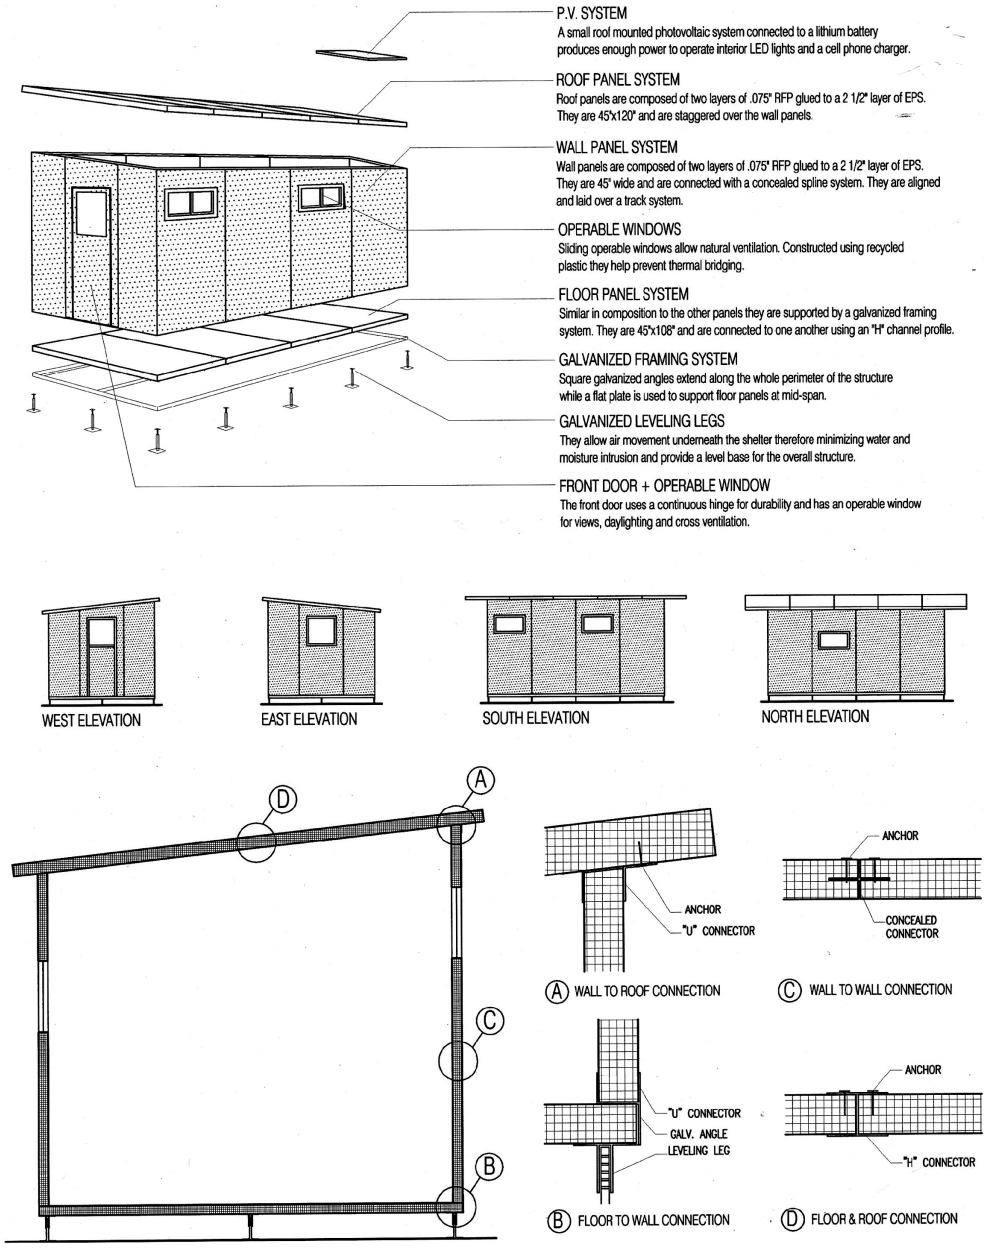

Figure 1. Insulated Shelter Unit specifications (graphics by author).

frame + skin concept does simplify and speed up the assembly process. Another advantageous property of the panelized system has to do with the fact that the Expanded Polystyrene (EPS) insulation acts as a vapor barrier and therefore prevents moisture penetration.

2.1 *Phase 1: Floor framing*

The first step of the construction consists in positioning 2 parallel rows of galvanized leveling legs on the ground. The leveling legs are secured to the ground by means of a galvanized anchor. The leveling legs located along the perimeter of the building receive a corner angle connector whereas the the legs located in the center receive a flat connector. Both anchor/leg and leg/angle connections are achieved with a simple pin system. Once the first two rows of framing supports are laid (perimeter connectors are the only ones anchored to the ground) floor panels are positioned in order to determine the location of the third row of leveling legs. That way the installers are using the floor panels to insure that the floor is square. The leveling of the support frame is achieved by the vertical adjustment of the support angles relative to the leveling legs.

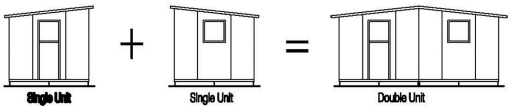

Figure 2. Configuration options (graphics by author).

The angle is able to slide inside the leg and the connection is achieved by placing a galvanized pin through aligned holes. This framing system provides a continuous square angle around the perimeter of the structure and a flat plate spanning mid-way to support floor panels. The purpose of the framing structure is to create a level base and elevate the shelter to protect it from ground water and moisture. The space located underneath the structure is ventilated. Laying out the floor framing structure is by far the most delicate and critical phase of the overall assembly as it will affect the proper assembly of the rest of the structure.

2.2 *Phase 2: Floor*

Once the floor framing has been leveled and anchored, the floor panels are laid and screwed to the galvanized support angles. A spline component is inserted between each floor panel to increase the rigidity of the overall floor system and prevent moisture intrusion from the ground. Screws connecting panels and splines are driven from the top of the floor panels to prevent moisture intrusion inside the shelter.

2.3 *Phase 3: Walls*

Following the assembly of all floor panels a custom connector/track is screwed to the galvanize perimeter angles in order to cover the edge of the floor panels and provide a track for the wall panel. This prevents moisture and rain to penetrate at the perimeter of the floor system. Wall panels are then positioned over the track using an "H" profile connector.

2.4 *Phase 4: Roof*

"U" shaped connectors are placed on top of the wall panels in order to receive the roof panels. The roof panels are screwed from the underside through the connector just mentioned. Depending on the latitude where the shelter is to be installed the roof overhangs can be adjusted to provide proper shading for the clerestory windows. On the short side of the unit the overhangs remain 2 feet due to the need of the roof panels to be staggered above the wall panels and insure overall rigidity. A spline system using an "H" profile is placed between roof panels in order to achieve rigidity and waterproofing.

2.5 *Phase 5: Finishes*

Once the structure is completed a small photovoltaic system is installed on the roof and connected to a lithium battery in order to power four interior LED lights as well as a cell phone charger. A lightweight track system is anchored to the underside of the roof panels to receive a sliding curtain and allow some privacy inside the shelter.

We took the time to provide a detailed description of the shelter assembly as it is key to determining the viability of the overall shelter design. As it is usually the case with prefabricated shelter units they need to be assembled quickly and accurately by untrained people, which presents an additional challenge. In this case the assembly has been broken down into a series of clear and simple steps that can be easily understood. The entire construction process has been planned for 2 people without prior experience working for 5 hours. To further simplify assembly each construction component is clearly labeled and graphically referenced in an assembly manual.

The most delicate phase of the overall process consists in properly installing and leveling the floor support frame. The rest of the unit's construction is very straight forward as different panel components are assembled by means of specific connectors. The size of the building panels were purposely kept to a minimum due to shipping requirements but also to keep their weight to a managing level for 2 people. For instance the roof panels weight 100 pounds which is an acceptable load for 2 people to lift on top of the wall structure. The physical assembly of all the different components can be achieved by using a portable drill powered by the fully charged battery supplied with the photovoltaic system. The entire unit can also be assembled using a screwdriver as the high-torque screws provided will easily penetrate the prefabricated panel.

In addition to an easy assembly the Insulated Shelter Unit (ISU) presents a series of features that are mindful of sustainable design and construction practices. The basic design idea is to create a continuous insulated envelope so comfort can be achieved with no reliance on external energy sources. As an added bonus insulated panels provide good sound insulation which contributes to comfort inside the unit. In that same logic the careful placement of windows on a number of different walls creates daylighting opportunities. Finally the photovoltaic system supplies power in a sustainable manner.

In terms of materials the windows, door and all connectors are made of a rigid recycled plastic. This material is appropriate as it presents good insulation values and does not significantly offset the R-value of the insulated panels. The panels themselves are manufactured by gluing FRP panels to a layer of EPS using a non-formaldehyde adhesive.

A preliminary cost analysis indicates that the ISU can be built for approximately 4,000 USD but we expect the cost to decrease as we explore production processes and material sourcing more thoroughly. Another important quality of the ISU is its ability to be used in a variety of ways. To that end the open floor plan layout along with the placement of windows provide a variety of options in terms of use. The installation of

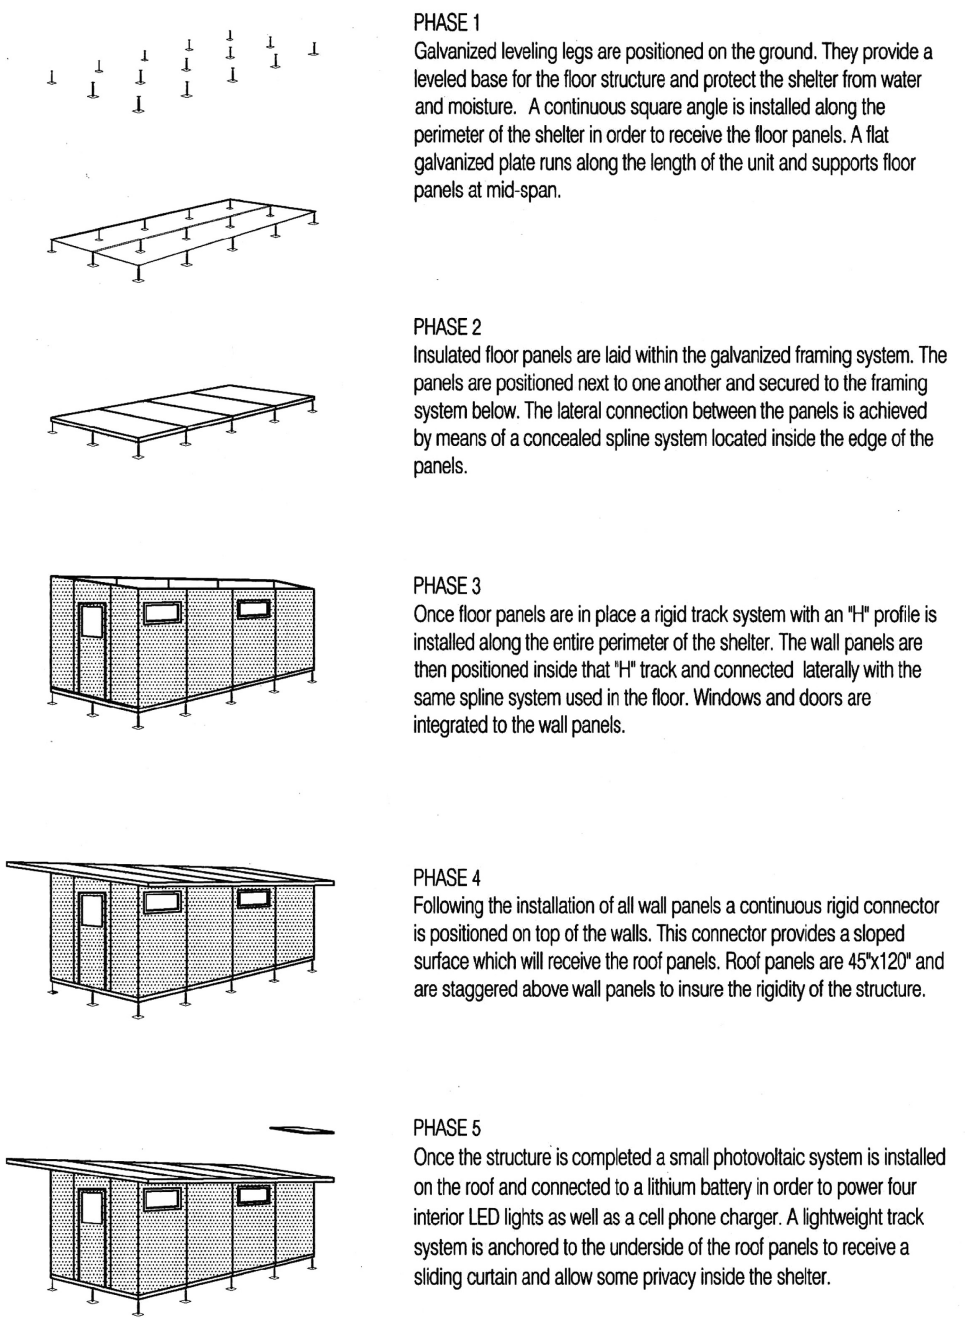

Figure 3. Assembly phases (graphics by author).

the curtain system for privacy is also valuable in that regard.

At a larger scale the ISU can be used as a modular unit and it is possible to combine 2 basic modules in order to create a bigger unit which could then be used by a larger family.

Insulated Shelter Unit Facts

Estimated Cost: 4,000 USD
Weight: 1,500 pounds
Wall, Floor, Roof R-Value: 9.625
Packaging Volume: 140 cubic feet/4 cubic meters

Assembly Time: 5 hours
Tools: power drill or screwdriver

This project which was initiated through a design assignment given to student in a special study course has attempted to respond to a difficult design problem and propose a prototype for an Insulated Shelter Unit that would position itself as a balance solution with regards to function, quality and cost. Although not all technical details have been resolved as of yet the prototype we are presenting remains relatively inexpensive, especially when compared to similar rigid shelter concepts, while focusing on functionality and comfort. The current design for the ISU illustrates a design methodology geared towards looking at every components or assembly sequence and trying to make it simpler, less expensive and more sustainable or in other words develop a socially responsible design approach.

"Hospitality now!" from meeting migrant needs to rethinking contemporary urban dwelling. A critical review of two studio experiments

J. Kent Fitzsimons
Ecole Nationale Supérieure d'architecture et de Paysage de Bordeaux; PAVE Research Laboratory

ABSTRACT: When addressing housing issues posed by "south-to-north" migration, architectural thinking seems to settle for redesigning the minimal living unit. The reliance on small, repeatable modules betrays a certain bias toward conceiving of urban development as the accumulation of single-family cells. This holds true whether the migrant's refuge is a high-design cabin or a low-technology shack. Yet crossing the history of population movements with the history of cities reveals that significant urban-scale architectural innovations occur when the housing question is carried beyond the paradigm of tents, cabins and containers. This paper consists of a critical reflection on two design studios at the Bordeaux School of Architecture and Landscape Architecture (EnsapBx, France) that addressed current migration phenomena in order to contribute to thinking about urban dwelling in general, as well as about the role that architects might play and the expertise that they might employ in this context.

1 INTRODUCTION

War and political instability in general in more or less distant countries have provoked an acute housing problem for member states of the European Union. In many European cities, thousands of people who fled their homes in Syria, Afghanistan, Eretria, or Iraq seek shelter in addition to the nourishment and administrative aid that they desperately require. On a daily basis, residents of affluent societies come face to face with scenes that recall the refugee camps run by prestigious international organizations in unfamiliar landscapes seen only on television.

For architecture students who are sensitive to the plight of local homeless populations, or of the Romani people, or of the working poor who can not afford decent housing in the current real estate market in many cities in Europe, it is difficult to ignore this new manifestation of spatial, domestic and architectural distress. The needs of those who incarnate what has come to be called "the migrant crisis" certainly merit the attention of future architects concerned with social justice.

However, the best way to use the architect's skills and tools to contribute to managing the migrant crisis in a humanitarian way is not as obvious as it may seem. Just as conventional homelessness (if it may be called so) is not simply the result of poorly designed apartment buildings or a scarcity of units, solving the housing crisis for the large numbers of foreign nationals who, whether for political or economic reasons, have spent large sums and taken great risks to live more or less temporarily in Europe, is not a classic design problem.

During two consecutive Fall semesters (2014 and 2015), a design studio course at the Bordeaux School of Architecture and Landscape Architecture in France (*Ecole nationale supérieure d'architecture et de paysage de Bordeaux*, EnsapBx) attempted to harness architectural thinking to develop a better understanding of the challenges and opportunities that the current migration situation posed for cities in France and to formulate proposals that might help to improve conditions for people who had been violently uprooted from their habitual place of dwelling. Though the studio was not conceived or presented as a form of research, it appeared after the fact that, as a whole, the student work made it possible to develop a conceptual framework that contributes to knowledge about dwelling in the contemporary city.

This paper presents the context, framing and organization of each of the two versions of the studio, and describes some examples of the resulting student work. For each of the semesters, it classifies student proposals into different categories and discusses how, as a whole, they articulate important architectural issues above and beyond the sanitary, security or human rights considerations generally addressed in relation to migrant housing. Considered as research retroactively, each version of the studio produced a principal result. The first demonstrated the urban dimension of the migration crisis along two main findings: the surprising heterogeneity of the legal status of people and spaces in urban environments, and the efficiency of

reciprocity between individual and collective needs in creating urban infrastructure and amenities. Together, these add complexity to our understanding of urban dwelling, whether or not in relation to migration specifically. The second version of "Hospitality Now!" found that inventive coordination relative to the built environment is as much architectural work as designing new structures. It throws light on the importance of the architect's synoptic understanding of the myriad actors and factors that must be coordinated in order to create possibilities for dwelling, stressing that the ability to design places must be complemented by the ability to design situations that align resources, willpower and spatial potential. As a whole, the two studios develop knowledge about how architecture may not only contribute to adapting cities to significant new population movements, but also help to reconsider the notion of dwelling and the architect's role in its coming to be.

2 PEDAGOGICAL CONTEXT

These studio investigations took place at EnsapBx, which, as one of France's twenty public schools of architecture, delivers the national architect's diploma. The work was done in a fifth-year architectural design studio, which is the last design course that students take before proposing a topic for their individual diploma project (*projet de fin d'études*).

The studio topic was offered in the context of a three-semester program of studies called "Metropolitan Dwelling and Architectural Design". This program assembles theory courses, research seminars and design studios around housing issues, with an emphasis on contemporary aspects of dwelling in urban contexts. The first two studios in this suite cover fundamental aspects of housing design, including standards and norms, lifestyles and practices, overall project economy, and site and cultural specificity. With these bases in place, the third semester of design teaching takes a more experimental approach. It explicitly thematizes the question of dwelling, and by extension the knowledge about how people live that is usually mobilized in housing design. This studio focusses on living situations that challenge common thinking about the relationship between architectural form and domestic life in order to break from generic models of family structure, values, and needs. To this end, the programs that have been used in the recent past include emergency shelters, student housing, nursing homes, and halfway houses.

The design process usually begins by breaking down the standard program for the chosen type of housing environment, usually with the help of texts drawn from historical or fictional literature that discuss ideal societies or, on the contrary, dystopian social organizations. The intention is that students recognize that seemingly natural correlations between spatial forms and social forms are in fact the result of historical circumstances, political decisions, and cultural reproduction. By freeing architectural form and space from the rigid equations that tie them somewhat arbitrarily to predefined social content, it paves the way for using design to explore alternative hypotheses about how people might dwell together.

In light of these pedagogical objectives, housing issues related to population migration and immigration clearly seemed an appropriate topic. The "Hospitality Now" studio was therefore proposed in this third semester of the suite. On the one hand, it would allow students to work on a critical contemporary issue, and perhaps contribute to improving the situation for people living in dire situations, either directly through proposals for better housing environments or indirectly by enlightening governmental and non-governmental agents involved in the matter about certain aspects of the problem. On other hand, studying the migrant experience as a case of "dwelling in the world" would also bring students to reconsider the notion of dwelling applied to ostensibly "normal" people, and thus develop their critical capacity for more standard future projects, whether in an academic or professional context.

3 VERSION I: FALL 2014

The first version of "Hospitality Now! Dwelling Through the Lens of International Migration" took place in Fall 2014. It was co-taught by the author with Luca Lotti, architect and associate professor at EnsapBx, Justine Reverchon, architect, professional firefighter and lecturer at EnsapBx, and Laura Rosenbaum, architect and doctoral student at the school. The studio took the form of a semester-long exploration that concluded with proposals for housing projects in Bordeaux. The studio topic was defined in the context of growing concern over the repeated mass drownings in the Mediterranean Sea and of mounting tensions in Ceuta and Melilla, where immigrants from sub-Saharan Africa camp on Moroccan territory outside Spanish enclaves, hoping to overcome fences, walls and barb wire to set foot in these European outposts.

Stephen Cairns argues that the architectural community tends to uncouple two "profoundly integrated global phenomena": that more than half of the world's population now lives in urban areas, and that, at any one time, "three percent of the world's population are international migrants" (Cairns, 2009: 73–74). Migration has been a constituent feature of urbanization in all periods. It would therefore be important to address the migrant crisis beyond the provision of emergency shelter, and to understand its implications for urban growth. In that spirit, the studio postulated that European cities might anticipate new housing needs spurred by a probable increase in immigrant populations and treat them as opportunities for thoughtful and innovative urban development, rather than as burdensome states of exception.

An initial five-week phase consisted of research into the phenomenon of south-north migration toward

Europe. While this work placed particular emphasis on housing issues, a broad tableau was painted of immigration, with topics including its history, its economic aspects (the cost of safe conduit as well as aspects related to employment and remittance payments), the profiles and itineraries of migrating populations, the governmental and non-governmental organizations involved, and representations of immigrants. The forty-two students enrolled were broken into groups of three or four, each of which produced research on one of the thirteen topics. The objective of this phase was to produce a common basis for subsequent design proposals, with each group sharing its findings through text and illustrated presentations.

This phase was enriched by a variety of material and guest speakers. In order to stimulate research, each group was assigned a film that deals with the subject of immigration, such as *It's a Free World* (Ken Loach, 2008), *Le Havre* (Aki Kaurismäki, 2011), and *Eden is West* (Costa Gavras, 2009). Instructors invited Alessandra Siarri, deputy mayor of Bordeaux in charge of social cohesion, to share her insight on local housing and poverty issues. Later in the semester, anthropologist Michel Agier, who had just published *A World of Camps*, an edited volume including contributions about refugee camps and other informal settlements around the world, gave a public lecture sponsored by the studio and sat on the midterm project reviews.

After the initial research and documentation phase, each group was asked to place their study topic into relation with two other topics that had been developed by other groups. This phase, called "*problématisation*", aimed to identify a kind of Gordian Knot regarding the question of hospitality for migrant populations. The pedagogical hypothesis is that a seemingly intractable problem may be solved by thinking "outside the box", a commonly recognized skill for designers. As projects moved forward, three distinct strategies emerged: working on the interior border condition; situating migration in the context of contemporary mobility; and developing reverse hospitality.

3.1 *Working on the interior border condition*

Some student groups seized on what may be called the "spatial exception" of foreign nationals present illegally in France. With laws voted in 2003 and 2010, France went from a legal framework where the detention centres for illegal immigrants constituted extra-territorial zones in which exceptional laws apply (as in border control zones), to a regime in which the illegal immigrant him- or herself generates that extra-territorial space on the very ground where he or she stands. As Michel Agier points out, with these laws, "extraterritoriality is the foreigner's very place: although he may be physically present, he is administratively held outside of national territory" (2011). The country's exterior is no longer a fixed location to which certain individuals are brought for detention; it precedes each footstep that an illegal immigrant takes. Agier expresses the resulting paradoxical spatial dimension by observing that many migrants are "outdoor prisoners […] cast aside on the inside" (Agier, 2014).

Struck by this spatial warp and its concrete implications for spatial fluidity and borders, students produced a cartography of Bordeaux that revealed that a number of spaces benefitting from exceptional territorial status punctuated the otherwise homogeneous national space. Some of these exist by law, such as border conditions, duty-free zones in ports, and of course consulates and embassies. Others owe their reality to unwritten tradition, such as church grounds where the religious authority can prevent police action in the name of sanctuary, or schools where the director can exercise similar powers for the sake of the children's well-being. Hospitals and city halls were also identified as traditional places of exceptional hospitality. Putting the notion of interior border conditions into relation with the extra-territoriality that had become consubstantial with certain migrants proved to be a potent starting point for some projects.

3.1.1 *Hospitalis urbs*

One proposal imagined that a group of extra-territorial migrants could live together in a building lifted above street level. It posited that the concentration of such individuals in one place could constitute a territory in its own right: a country for statelessness. The building was raised on monumental columns over a small plaza next to a major covered food market in Bordeaux. Floating between the ground and its underside, a horizontal plane structured the ascent while also serving as as a landing for accessing the parking garage on the market building's roof. This plane furthermore provided a permanent covered area for the temporary stalls on the plaza that normally use parasols for protection from sun and rain. The border condition was thus made horizontal (rather than vertical), giving particular significance to vertical ascension in the city, while also playing down the gravity of the situation through its association with more banal, quotidian activities such as shopping and parking.

The site choice was strategic: the "Capucines" was the city's wholesale market before that activity's change in scale required that it move further out from the city center. The neighborhood therefore historically welcomed immigrant populations, from Spanish and Portuguese to more recent North African and Sub-Saharan African populations. As Arnold Reijndorp observes, "[w]hen in a foreign city, immigrants look for places where they suspect they can deal with the situation, such as markets where routines are the same all over the world" (Reijndorp, 2009: 98). The students' hypothesis was that residents of this particular dwelling could benefit from the urban life provided by the market and its immediate vicinities, and perhaps even from work opportunities, without straying too far from their "safe house" located on the other side of their ad hoc border.

The question of who would control the border, and the border's relative impenetrability, was not addressed

specifically in this project. However, it nonetheless drew attention to the many other situations where the threshold between regular public (and thus policed) space and a space of national exception is effective through its symbolic power rather than through brute force, for example the door of a church. The nuances of spatial rights were thus clearly posed.

3.1.2 *Terrific extraterritoriality*

Another project emphasized the notion of the "hospitable city", over and against national and European policies. The student group identified sites in Bordeaux where a border condition could be exaggerated, and where housing for irregular migrants could be associated with other programs that might also benefit from extraterritorial status: programs that would be freed from certain "legislative extremes" that apply to commerce and behaviour on the national territory. In the students' word, their aim was to provide "places that serve as asylum and as entry into the hospitable city". To that end, and in a reverse reference to the principle of *jus soli* or the right of birthplace (or more accurately "right of birth-soil"), all their architectural interventions were separated from the ground and located over the buildings or grounds of institutions that historically benefit from a tacit legislative exception where hospitality and refuge are concerned: City Hall, the Courthouse, Saint André Hospital, and the Cathedral.

For example, the project proposed small towers between the Cathedral's flying buttresses, in which housing units for illegal immigrants would coexist with greenhouses for growing marijuana. More than a simple rhetorical gesture, this intervention blended different aspects of the history of medieval churches as places of asylum, of medicinal herbal gardens, and of architectural experimentation. In another intervention, a tax-free market was installed on the roof of one the wings of Bordeaux's City Hall, serving as a threshold between the street and housing units for refugees. The argument was that, if airports could house duty-free shops by virtue of their extraterritorial port status, then the virtual border condition generated by the municipal government's relative sovereignty could justify a sanctuary for activities considered illegal by the State. While the issue of unfair commercial competition was not addressed, this intervention served to draw attention to the actual heterogeneity of ostensibly homogeneous space, and the potential for further disruptions to provide hospitality at the local rather than national level.

3.2 *Situating migration in the context of contemporary mobility*

3.2.1 *Hotel city*

Some projects recontextualized the migrations under study by drawing attention to broader changes in residential practices that are due to the increased mobility made possible by—or alternatively imposed by—contemporary means of transportation and economic systems. In the project "*La Ville-Hôtel*", one group explored how architecture might articulate the coexistence of diverse kinds of particularly mobile populations, from high-end nomads such as sports and entertainment stars to clandestine migrants, passing through common tourists and business travelers. The project was sited at a strategic location outside the historic center, where a radial light rail line intersects the circular boulevard, affording easy access to numerous important locations in the city, including professional sports facilities, convention centers and of course the central core. The proposed building consists of a type of hotel that integrates an existing light rail station, a new park-and-ride facility, an internet café in the lobby area, a beauty parlor on the top floor, and a small conference facility halfway up.

This strategy, which accepts the world in which populations that differ in terms of means and motivations find themselves subject to the same injunction to move, might be understood in relation to Arnold Reijndorp's notion of the "The City as Bazaar". Evoking the positive effects of globalization, Reijndorp refers to a "new global familiarity, where the rules and the language are the same everywhere, which enables us to travel and explore new environments without encountering any obstacles. […] Through the familiarity of the signs and the transparency of the familiar procedures, that space is democratic: the traveling businessman, the mass tourist, and the refugee can all find their way in it perfectly" (Reijndorp, 2009: 98–9).

3.3 *Reciprocal hospitality*

In another form of inversion, some projects took the migrant program as an opportunity to improve urban life for "legal" residents.

3.3.1 *Shared hospitality*

One group postulated that water, as an element that combines functional and symbolic dimensions, could be the basis of an architectural intervention that resolved migrant needs while providing new amenities for all. Two principle uses of water were explored: food preparation, and bodily hygiene and pleasure. Since kitchens and washrooms would be needed for the housing units, the required infrastructure could be "tapped into" in order to provide public amenities in a currently unserved space. Set beneath the centenary sycamore trees that line the edges of Bordeaux's immense *Place des Quinconces*, the proposal included permanent outdoor kitchens designed for large scale public use, a splash pool, and a bath house and sauna, in addition to the apartments nested between the ground plane and the crown of leaves.

The *Place des Quinconces* houses a transit hub for local light rail and regional bus service, a large parking lot for access to the historic city center, and a fairground that welcomes alternatively circuses, antique fairs, funfairs and open air concerts. It also lies tangent to the riverfront linear park, which is used in particular by joggers, bikers and skaters for sporting purposes.

The project is sited in relation to this co-presence of urban functions and practices that, while diverse, could all benefit from the introduction of water-based functions in public space. In this way, the housing for migrant populations is integrated into urban life and serves as a pretext to provide amenities for multiple user groups. Beyond the standard discourse on the benefits of mixing populations, this project demonstrates how architecture can cast the migrant's presence in positive light by leveraging a technical level of building human settlements (water provision) to generate a symbolic level (shared access to an urban resource).

This project also introduced the figure of users who are neither immigrants nor permanent residents, but temporary residents participating in cyclical official urban events such as circuses, fairs, and other itinerant programs that remain very much part of urban life in France and other parts of Europe.

3.3.2 *Welcoming the natives*

This project is based on three different timeframes of asylum seekers and migrant populations: five days, corresponding to an emergency situation; five weeks to five months, waiting for administrative procedures, for news, for work; and five years, during which one begins to take root in a new country. On a site structured by remnants of city fortifications, a linear park, monumental buildings from the 19th century and more recent houses aligned on the street, the project develops spatial conditions such as the insertion, the articulation, and the lean-to in order to generate a rich architectural ensemble conducive to different forms of appropriation in relation to the three timeframes. A careful survey of neighbourhood commercial, cultural and institutional establishments allowed the group to identify new programs that might act as an interface between the general public and the inhabitants of this specific housing environment, such as a hammam sauna installed in a 19th-century market hall, an outdoor projection space for watching movies in good weather, and a language school.

3.4 *Findings from "Hospitality Now! 1.0"*

The work from this studio recalls two important dimensions of dwelling in urban environments, and increases their understanding by adding the factors of alterity and precariousness that migration entails. First, urban spatial heterogeneity is far more complex than the familiar opposition between public space and private space. Embassies, duty-free zones, elementary schools and church grounds are conditions of extra-territoriality that punctuate the city as an invisible geography of exceptions to common law enforcement. Furthermore, the threshold situations that regulate the relationships amongst these spaces are often effective more by convention and symbolic power than by brute force. The student work also disrupted the illusion of legal territorial continuity through the multiple levels of French government, for example with the relative (if limited) sovereignty of municipal mayors or religious officials with respect to national prerogatives on immigration. In the pedagogical case discussed here, this geography was identified and then exploited in order to develop housing proposals for individuals whose legal status constitutes, in France, a unique case of extra-territoriality. However, the relevance of this finding is not limited to that case. By drawing attention to the effective heterogeneity of ostensibly homogeneous space, the global effect of multiple student design projects contributed to knowledge about the urban substrate for any architectural intervention.

Second, the reciprocity between individual and collective aspects of dwelling in the city operates on two intersecting planes: the social and the economical. Furthermore, leveraging between the two planes allows for increased efficacy. Many students quickly associated housing production with considerations for public life, the latter manifested through proposals for urban activities, amenities and services. This was undertaken not only in the name of the familiar refrain about mixity and integration. It articulated a consciousness about urban efficiency that was sought through double-usage and economies of scale. From this perspective, the design problem at the base of any urban development is how to have the accumulation of relatively small, repetitive interior spaces also produce exterior spaces and infrastructure that correspond to collective needs at the public scale, which are highly diversified and contrasted. City building would therefore be understood as the careful search for equilibrium between the individual and the social group through spatial and infrastructural reciprocity. As a whole, the work is a reminder that the problems raised by population movements are not only sanitary, geopolitical or legal in nature, but also fundamentally urban.

4 VERSION II: FALL 2015

One year after the initial attempt to work on migration issues, the population exodus from Syria, Afghanistan and Eritrea was increasing dramatically. This introduced unexpected dynamics into what had previously appeared to be a stable European spatiality. The disordered suspension of the Dublin Regulation regarding asylum seeker applications by Germany, Austria, and Hungary initiated the confusion, followed by the Czech Republic's and then Sweden's reintroduction of border controls with Shengen area partners. In the context of France's decision to welcome an extra 24 000 asylum-seekers, the second version of "Hospitality Now" was a shorter, five-week exercise that explored how architects might act in this crisis situation. This time, the author co-taught with Justine Reverchon.

Like the Fall 2014 studio, the exercise eschewed the "cabin fever" that often plagues architectural attempts to address migration, in favor of less stigmatizing and more situated, urban solutions. But it also attempted to better incorporate economic aspects into the process, and demanded that students interact with elected officials, municipal technical services and

non-governmental organizations. This was intended both to develop certain practical skills that future architects require and to suggest that not all questions for architects may be answered by designing new objects ex-nihilo.

The studio topic was presented at a movie house in Bordeaux, right before a public projection of Jonas Carpignano's 2015 film *Mediterranea*. The film follows two friends who leave Burkina Faso for the promise of a better life in Europe. While a fictional work, the film articulates with the real events that culminated with the riot in Rosarno, Italy, in 2010. The vivid depictions of the arduous trip across land and sea, the living conditions in urban squats, the hard manual work, the relationship with local populations, and the relations with family at home sustained through digital social networks set the tone for the exercise.

As in 2014, a collective brainstorming session helped to identify a dozen research topics, each of which was developed by a group of students. Each group was expected to produce a chapter for a guidebook for municipalities that intended to welcome asylum seekers, as well a summary project that demonstrated how accommodations could be provided quickly and at minimal cost. Because of the short length of the exercise, project ideas had to be developed almost concurrently with the research.

Two categories of projects emerged. The first identified the temporal dimension as powerful lever for generating spatial possibilities. This may be related to Michel de Certeau's definition of "tactics": practices that play with time in order to counter the spatial domination of those who can project "strategies" onto a given territory (de Certeau, 1984). The second kind of project carefully considered economic and regulatory factors in order demonstrate how new housing opportunities could easily be found by exercising "public power".

4.1 *Playing with time*

4.1.1 *Shared building plots*

In this project, student work consisted of carefully studying regulations concerning construction rights. The group learned, for example, that structures qualifying as "emergency housing" may be erected for a maximum of one year without need of requesting a building permit. The French Law on Experimentation was also studied: it allows local authorities to create exceptional regulation for a limited amount of time.

The group proposed that a few households from the same urban block could alternate hosting a temporary housing unit for asylum seekers in their garden. This would allow the foreign resident to stay in the same neighbourhood (for professional, educational or social reasons), without requiring that any particular host request a building permit for permanent construction, or that the municipality grant such a permit. They proposed moreover that local authorities could reduce property taxes for households agreeing to this measure. This would draw concerned citizens and municipal officials together into the same "tactical" operation, at minimal cost and with minimal risk of third-party objections.

4.1.2 *Heritage as a housewarming gift*

Another group associated hospitality with building heritage. Observing that many national monuments are un- or under-occupied, the idea was that, rather than looking for space in the already saturated social housing stock, heritage buildings could be outfitted for temporary residency.

In this scenario, displaced people would find themselves housed in prestigious or significant architectural works that represent the history of France. In order to test this idea, the group identified a modernist firefighter barracks that had been listed on the national historic monuments register in 2009. Located at the foot of Bordeaux's historic Stone Bridge, the apartment block floats on pilotis above the fire station and affords spectacular views of the city and the broader landscape. Built to house about fifty families, only six of the main building's apartments are currently occupied.

The fire department will be leaving this site for a new facility in 2020. Speculations on the building's future use include a luxury hotel or a relocated School of Architecture and Landscape Architecture. In the meantime, minimal investment for comfort and security improvements would make it inhabitable. This project creates space for emergency migrant housing by exploiting a heritage building's particular temporal condition. This is an example of tactical architectural work situated at the intersection of considerations for spatial quality, regulatory constraints, construction budgets, symbolic dimensions, and urban institutional dynamics.

4.1.3 *Dwelling beyond the cell*

One project resulted in a radical reconsideration of contemporary housing standards by recalling not-so-distant urban lifestyles and linking them to current developments in some social groups. The group started by analyzing France's system of Asylum Seeker Welcome Centers (ASWC, *Centres d'accueil de demandeurs d'asile*, or CADA, in French). Students noted in particular that, while an ASWC gathered all domestic comforts and amenities in one place, it was generally situated far from the city center. This inhibited exchange with local inhabitants and thus social and cultural adjustment, as well as making it difficult to benefit from the advantages of urban life.

As an alternative, the group sought to create domestic conditions for asylum seekers in central neighborhoods. Rather than simply propose to occupy existing apartments, the project took the urgent timeframe and the general housing shortage as determining constraints. It proposed making the most of existing resources, such as the wash facilities in municipal sports facilities and the kitchens in elementary schools, in order to simplify the design, construction and installation of modular units destined primarily for rest

and retreat. The domestic environment thus expands beyond the limits of the "existence minimum" unit, stretching to include facilities marked for special access and thus embracing a broader urban space. This spatiality would of course be heavily structured by time, as access to certain amenities would depend on the operating hours of their principal function.

In a scenario set in Bordeaux's St-Michel neighborhood, the group demonstrated how one such "micro-neighborhood" would associate the basic shelters with a university cafeteria, a hammam, a municipal library, and a fresh food market, all within few minutes walking distance. This proposal of course raised a number of issues, such as strict hygiene regulations for school cafeterias, managing the cohabitation of different populations in changing rooms and shower facilities, and the discomfort potentially induced by separating domestic functions with exterior space. However, by recalling a recent past in which many households used public bath houses and community food preparation and consumption was still commonplace, the project cast light on how contemporary European society's individualistic tendency is progressively mapped onto domestic and urban space.

4.2 *Public power*

4.2.1 *Small town hospitality*

Another group explored the hypothesis that emergency hospitality could be decentralized, with municipalities of all sizes welcoming asylum seekers and refugees in numbers proportional to their populations and means.

Following a national call for solidarity in September 2015, Angoulins (population 3700), a town on the Atlantic coast just south of La Rochelle, expressed its interest in welcoming one or two families of asylum seekers. During a meeting with the town's mayor, the students learned that the local post office's unoccupied staff apartment had been identified as a potential housing opportunity. Located in the town centre, this second-floor apartment would need some improvement before being able to house new tenants.

The students decided to develop an architectural punch list to identify the renovation work, appliances and equipment necessary to make the unit compliant with regulatory standards and appropriate for the expected occupants. This data served to draft a budget for the project, which could be used by Angoulins to request state funding to help with costs. Two scenarios were studied: keeping the large three-bedroom apartment as a single unit, and dividing it in order to accommodate two households. The group intended that their punch list could be used in by other cities facing the same situation.

4.2.2 *Tactical finance*

Some students learned that 7% of housing units in Bordeaux lie empty, often because of the owner's financial incapacity to renovate the apartment. The group looked into the different subsidies and funding available for housing in general, and for migrants, asylum seekers and refugees in particular. The city of Bordeaux alone provides a number of subsidies and bonuses to encourage housing improvement and availability; these funds are linked to criteria such as putting a vacant unit back on the market, asking below market rent, and improving energy performance. The metropolitan government also has a budget line to encourage getting empty units occupied, and the Gironde county government provides general subsidies for renovation work.

The students found that approximately 40,000 euros could be mobilized to make a vacant, substandard apartment fit for inhabitation, one third of which could be financed by the national housing improvement agency (*Agence nationale pour l'amélioration de l'habitat*, ANAH) provided that it be used as social housing for twelve years. In others words, these students designed a financial plan that could demonstrate to reluctant landlords—public and private alike—that it is viable to mobilize unused building stock to temporarily absorb the new arrivals without taking space in existing much-needed social housing. In this project, coordinating funding sources for housing from four levels of government constituted a form of design thinking in itself. The work also revealed that the French government's exceptional provision of 1000 euros per unit destined for asylum seekers ultimately accounted for a very small part of the overall budget that the students were able to assemble, and that it could not stimulate any action on its own.

4.3 *Findings from "Hospitality Now! 2.0"*

Exploiting the temporal dimension in order to free up space for occupation; showing how to distribute the housing demand over a maximum number of municipalities; coordinating disparate funding sources so that seemingly impossible renovations become plausible, even desirable: each of these tactics demonstrates how the inventive coordination of time, space, resources and people is architectural work in itself, even in the absence of new construction. They design the situations that are a prerequisite for designing inhabitable space. This involves specifically bringing together different actors, each of whose segmented view prevents the emergence of potential solutions: residents of a city block, local elected officials, county fire department services, national government agencies for aiding asylum seekers, heritage site guardians, and private developers, for example. Not to mention navigating France's legendary "millefeuille" of administrative and governmental levels. What transpires is a figure of the architect as specialist of the built environment and of the many ways its use can constitute a mode of dwelling. As in the first version of the studio, but through different means, the studio not only contributed to training future architects and to identifying housing solutions for displaced people, but also produced knowledge about the conditions of contemporary architectural practice.

5 CONCLUSIONS

The overarching objective of these two studios was twofold. First, they aimed to address a current housing problem that could benefit from the work of students interested in social aspects of architecture. Second, they sought to use the issue of migrant housing to ask broader questions about how we dwell in the world; in other words, to go from meeting migrant needs to considering urban dwelling as a general, shared phenomenon undergoing important mutations.

To that end, architecture was not conceived solely as an instant remedy to the problem, where the project might be built in an immediate future for the comfort of a few individuals. Architecture was used rather as a way of "figuring the world" such that the political, legal and cultural factors that weigh on architectural and urban production could be better understood. Those factors are also levers for improving the situation for the tens or hundreds or thousands of people who find themselves on the move in unfamiliar lands. Indeed, they may even be more powerful than solely spatial solutions. Many of the projects clearly articulated how harnessing the forces the precede form-making can lead to relevant and efficient proposals, while also drawing attention to some ideas about dwelling that, while we may take them for granted, might better be reconsidered.

A final remark concerns a danger with this studio topic. The fascination with alternative lifestyles and their corresponding architectural forms can cause us to forget that many standards that we take for granted are the result of hard-won battles against poor living conditions. In European history, those conditions resulted when pure market forces reined unfettered by legislation, or when war-related destruction caused severe housing shortages. Witness the veritable shanty-towns or *bidonvilles* that developed like a shameful crown around Paris after the Second World War, or the insalubrious and overcrowded blocks in its center whose demolition and reconstruction lasted well into the 1980s. A careful balance between the enticing prospects of new forms of dwelling and the defense of high standards should be sought, whether for new arrivals or for longstanding populations.

Integration of Turkish migrants in Germany: A case study in polarities

İ. Öz & A. Staub
Pennsylvania State University, University Park, Pennsylvania, USA

ABSTRACT: In 1961, the Federal Republic of Germany and Turkey signed a Bilateral Recruitment Agreement that would answer the demand for cheap labor in West Germany's growing post-war economy. From 1961–1973, German industries recruited 7000 Turkish workers. In 1974, the guest-worker program was halted, yet migration continued due a family reunification program that allowed workers' families to migrate to Germany. This paper examines how from 1974 to 1980 the Turkish population formed ethnic communities in two German cities, Berlin and Stuttgart. Using spatial analysis methods, we show how in Berlin, the Turkish population created distinct ethnic enclaves, while in Stuttgart, despite a similarly high percentage of Turks, communities remained smaller and more dispersed. We theorize that the different developments of Turkish migrant communities in the two cities are due to differences in available housing and variations in each city's social integration programs.

1 INTRODUCTION

In 1961, the Federal Republic of Germany and Turkey signed a recruitment agreement that would answer the demand for cheap labor in West Germany's growing post-war economy by allowing for the recruitment of temporary "guest workers". From 1961–1973, 7000 Turkish workers were hired, most of them in the areas of metallurgy, construction and manufacturing located in larger cities such as West Berlin, Munich, Stuttgart, Hamburg, and Cologne (Wilpert, 1986). Only 15% were women. In 1974, German laws were changed to allow the migration of guest workers' families. This caused the Turkish population in West Germany to increase to 1,546,000 by 1981, making it the country's largest foreign ethnic group and dramatically changing German demographics. (*Daten und Fakten zur Auslandersituation*, 2002).

Turkish settlement patterns within German cities have not been uniform. In Berlin, for example, Turkish immigrants have formed large, culturally distinctive enclaves within the city, while in Stuttgart, the Turkish population has established micro-societies that are spatially harder to pin down. In other words, in Berlin we find a spatial segregation of Turkish migrants, whereas in Stuttgart, the Turkish population appears to be spatially more integrated.

This paper examines the spatial patterning of Turkish enclaves in Berlin and Stuttgart between the 1974 and 1980[a]. Spatial patterns in the two cities are quite different, and we theorize that such patterns are indicative of a paradoxical process based on urban typologies and municipal policies: Turkish exclusion by the German population on the one hand, and assimilation into the German culture on the other.

2 ETHNIC ENCLAVES, SEGREGATION AND INTEGRATION

Housing for guest workers initially consisted of temporary barracks. As residency restrictions fell away, guest workers started to move into urban centers; after 1974, when workers were allowed to bring their families to Germany, the concentrations in the larger cities, especially in West Berlin, Munich, Frankfurt, Stuttgart and Cologne, increased dramatically (O'Loughlin & Gelebe, 1984, 1).

Ethnic enclave theory predicts that enclaves typically start to form by the clustering of immigrants around particular areas of potential labor. In a typical scenario, immigrant workers congregate within walking distance of their employment, defining certain neighborhoods as communities based on ethnic identity. New arrivals follow these existing ethnic networks, further cementing neighborhood identity. This results in a reciprocal process, whereby neighborhoods offer immigrants a sense of economic security and belonging, which in turn attracts more immigrants (Golab, 1982; Massey, 1985; Portes & Manning, 1986).

Alejandro Portes has suggested that enclaves provide a sense of security to their members. Immigrants lacking the necessary skills to enter the primary labor market can avoid the alternative – job markets where they are exploited as cheap labor for unskilled jobs – by seeking employment in ethnic enclaves (Portes 1998). Although ethnic enclaves increase the social and economical capital immigrants have, they also confine such immigrants to a limited economical sphere. For this reason, enclaves have been called "mobility traps", disadvantaging ethnic minorities through a defined

and permanent economical position (Borjas, 1986; Bates, 1987). Douglas Massey has suggested that as the pace of socio-economic mobility decreases, immigrant groups tend to display higher levels of segregation, while rapid rates of economic mobility eventually lead to patterns of assimilation (Massey 2001).

Changes in spatial patterns lead to changes in social processes. In the literature on transnationalism, the immigrant enclave is defined as a space where immigrants transfer their own cultural identity, language and practice to a new urban and national context (Sassen, 1996). Although some scholars view transnationalism as a mere transplant of national identity from the home country to the country of residence (Voight-Graf, 2004; Ehrkamp 2005), others have viewed transnational spaces as hybrid spaces that bring together cultures to form a new hybrid identity (Argun, 2003; Çağlar, 2001; Hall, 1991; White, 1997). This hybrid lifestyle challenges top-down implementations of integration policies, and challenges power relations through dialog (Kraidy, 1999; Hinze, 2013).

Once Turkish families arrived in Germany, German policy prioritized rapid cultural assimilation in order to preserve the characteristics of mainstream German culture. Rather than promoting a form of integration into German society that would allow Turks to preserve their identity and support the Turkish community, the German government has defined integration in ways that opposed what was percieved as traditionally Turkish (White, 1997). While the regular introduction of immigrants into the mainstream culture affects the national identity of the host country, it also creates subjective and socially constructed definitions of "foreigner" and "mainstream" (Alba and Nee, 2005). Popular reactions to immigrants' religious, cultural and ethnic differences have become institutionalized through the implementation of integration policies, as these policies are usually designed to make the relocated population fit into the mainstream (Triandafyllidou, 2001).

The term "integration" has been extensively used in political debates and in academia; however its meaning is rarely defined. Brubaker (2001) and Ehrkamp (2006) point to the ambiguous use of the term without providing a satisfactory definition, while Dörr and Faist (1997) and Joppke (2007) attempt no definition at all as they use the term in their analyses of ethnic diversity. The ambiguous nature of the term, along with the lack of a comprehensive definition, has led policymakers to adopt the term "integration" as a politically correct term to describe the concept of assimilation.

In the next section, we show how the level of spatial integration – defined here as a mixing of ethnicities in the urban fabric – has taken place between the Turkish and German populations in two German cities, Berlin and Stuttgart, between 1974, the year "guest workers" were allowed to bring their families, and 1980, when Turkey's military coup changed immigration patterns once again.

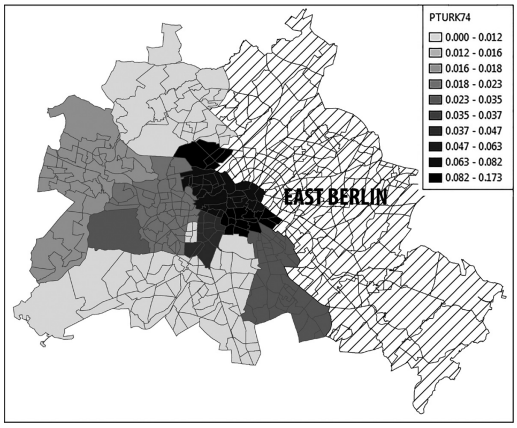

Figure 1. Percentage of Turkish population in Berlin in 1974. *Analysis based on data from the Amt für Statistik Berlin-Brandenburg 2015.*

3 BERLIN

Between 1974–1980 the percentage of foreign nationals in Berlin increased from 7.4 to 10.7, with 53.2 and 49.1 of them being Turkish nationals in 1974 and 1980 consequetively (*Amt für Statistik Berlin-Brandenburg*). Turkish immigrants quickly settled into older, working-class neighborhoods, such as Kreuzberg, Neukölln, Wedding, and parts of Schöneberg. By 1973, when guest worker programs officially came to an end, Kreuzberg had a 18 percent Turkish population. This was followed by 12 percent in Wedding, 8 percent in Schöneberg and 7 percent in Neukölln (*Amt für Statistik Berlin-Brandenburg*). These districts were attractive to guest-workers because they held the majority of West Berlin's tenement housing stock, which was the only cheap housing available to the guest workers (Hinze 2013). The administration of Berlin, fearing that the increasing concentration of immigrants would force out local residents, banned further movement of Turks to Kreuzberg and Wedding in 1975 (Hartmann, Hörsch & Neujahr, 1998). This led to clustering in new areas over the course of the 1970s.

Figures 1 and 2 demonstrate how the spatial density of the Turkish neighborhoods changed from 1974 to 1980 using a Moran I value test[b]. Neighborhoods with a high degree of Turkish spatial clustering can be clearly discerned, indicating that Berlin's Turkish community was spatially represented as physical neighborhoods. This is born out in Figure 3, which shows that spatial dependency increased over time; or in other words, that spatial clusters consolidated. The statistically significant and increasing value of Moran's I index in Figure 3 also shows increasing interconnection of the population between 1974 and 1980. The data thus shows that while the percentage of Turkish population increased within the urban context, this same population settled within or around

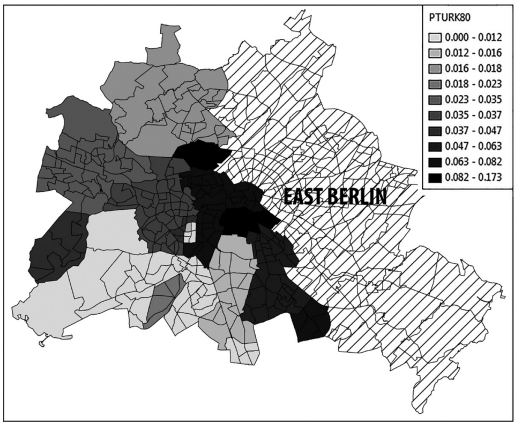

Figure 2. Percentage of Turkish population in Berlin in 1980. *Analysis based on data from the Amt für Statistik Berlin-Brandenburg 2015*.

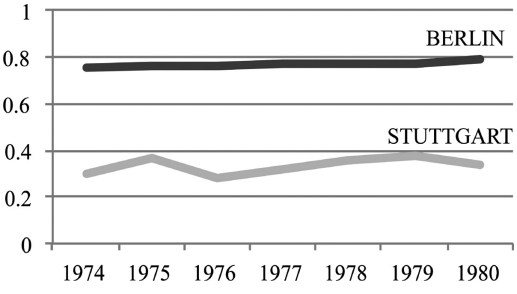

Figure 3. Moran's I value analysis for the percentage of Turkish population living in West Berlin and Stuttgart 1974–1980. *Analysis based on data from the Amt für Statistik Berlin-Brandenburg 2015 and Landeshauptsdadt Stuttgart Statistiches Amt 2015.*

existing Turkish quarters, consolidating a pattern of spatial segregation.

4 STUTTGART

Stuttgart, Germany's sixth largest city, is located in one of the country's strongest industrial regions. Due to its developed technology sector, Stuttgart has attracted guest workers from southern European countries and Turkey since the mid 1950s.

Although Stuttgart had a higher percentage of foreign nationals than Berlin did between 1974 and 1980, the percentage of Turks was not as high as in Berlin – 1.9 percent in 1974 and 3.9 percent in 1980. Due to the two cities' overall population differences, Berlin's 1980 Turkish population was much greater that Stuttgart's in absolute numbers, comprising 114.306 compared to 17.373 residents respectively (*Amt für Statistik Berlin-Brandenburg,* 2015 and *Landeshauptstadt Stuttgart Statistiches Amt*, 2015) (Table 1).

Table 1. Population statistics of Berlin and Stuttgart in 1974 and 1980. Source: *Amt für Statistik Berlin-Brandenburg 2015* and *Landeshauptsdadt Stuttgart Statistiches Amt 2015*.

		Berlin	Stuttgart
Population overall	1974	2.225.392	614.697
	1980	2.179.618	579.947
Turkish population	1974	87.948	11.633
	1980	114.306	17.373
Percentage of foreign population	1974	7,4%	13,1%
	1980	10,7%	17,7%
Percentage of Turkish population	1974	3,9%	1,9%
	1980	5,2%	3,1%
Percentage of Turkish population within foreign population	1974	53,2%	14,5%
	1980	49,1%	17,5%

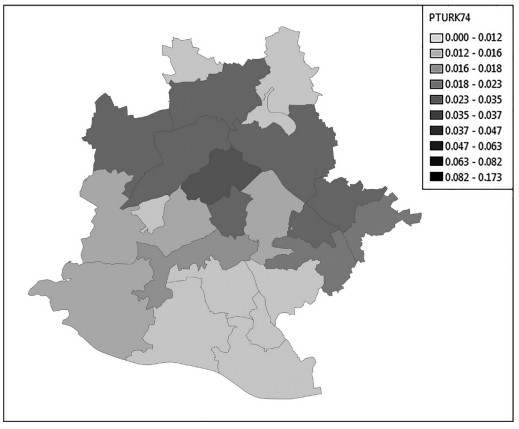

Figure 4. Percentage of Turkish population in Stuttgart in 1974. *Analysis based on data from the Landeshauptsdadt Stuttgart Statistiches Amt 2015.*

Turks originally settled in the outlying industrial wards and around the city center (Figures 4 and 5), and while Stuttgart's overall population density increased from 1962 to 1977, the spatial residential pattern of immigrant residents remained the same; or as O'Loughlin put it; "there is no evidence of a movement of foreigners to specific wards and of Germans from those wards [….] As long as the movement is not to destinations different from those of Germans, dominance of certain enclaves by foreigners cannot occur." (O'Loughlin 1980, 271). Thus, while Stuttgart exhibits pockets of immigrant households at the street and block scale, no evidence is present at a ward (district) scale (O'Louglin 1980, 274).

The lower values of Moran's I index in the case of Stuttgart indicates that while spatial clustering of Turks occurred to some degree, compared to Berlin, this degree of spatial clustering was not as significant. The high value of Moran's I index for Berlin, along with the positive slope of the graph, with the value of the index increasing from 0.75 to 0.79 from 1974 to 1980, indicates a very high level of spatial clustering. The value of the same index for Stuttgart,

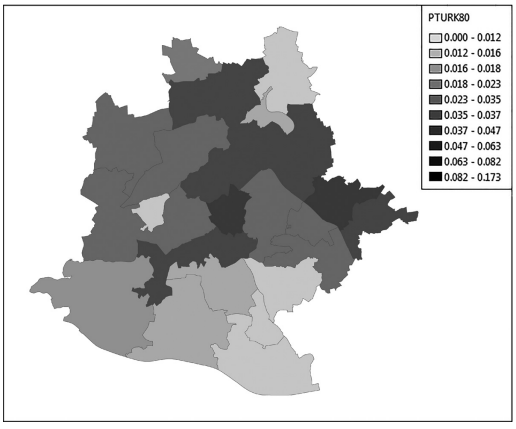

Figure 5. Percentage of Turkish population in Stuttgart in 1980. *Analysis based on data from the: Landeshauptsdadt Stuttgart Statistiches Amt 2015.*

fluctuated around the values of 0.3 and 0.4, indicating a much lower level of spatial clustering. This lack of Turkish spatial clusters and the fluctuating values of Moran's I index for spatial dependency can be taken as a more integrated Turkish community in the district level (Figure 3).

5 DISCUSSION

Our data shows that between 1974 and 1980 Turkish communities showed a greater degree of clustering in Berlin than in Stuttgart. More specifically, we found clear enclave formation in the former and smaller, scattered concentrations in the latter.

We hypothesize that two factors are primarily responsible for the different degrees of spatial clustering. The first is related to each city's existing housing typologies as well as laws regarding access to state-subsidized housing, and the second is Stuttgart's greater efforts to socially integrate the city's foreign workers. These factors have contributed to the distinct patterns of enclave building, assimilation and integration.

When Turkish guest workers moved to Stuttgart in the 1970s, they were quickly faced with the lack of affordable housing in the city. This lack of cheap housing led the Turkish population to avoid concentrating in specific localities (Schwarz 2014). Instead, Turkish workers moved into pockets of existing poor-quality housing, especially in the areas where older and post-war housing units are located. Such housing made up but a fraction of the neighborhoods' total housing stock, avoiding neighborhood concentrations (O'Loughlin, 1983, 202). Much of the Turkish population settled into nineteenth century housing that surrounds the medieval core of the city. Despite the influx of foreign workers, the area retained its social prestige, and many wealthy residents lived side by side with immigrants whose residential locations were determined by the location of their industrial work places (O'Loughlin, 1980, 259). Although a distinction between guest workers and other foreigners existed in the spatial configuration of Stuttgart's urban structure, especially between high-income white-collar workers from northern Europe and low-income unskilled workers from southern Europe and Turkey, the dynamic nature of the migration along with the patterns of chain migration prevented the formation of ethnic enclaves (O'Loughlin, 1980, 264–265).

Berlin, too, had a great deal of nineteenth-century housing, yet in the areas settled by Turks, much of this housing took the form of speculatively built tenement housing that had been left to deteriorate after World War II. Added to this, Berlin's government put controls on access to newer "social housing" (*sozialer Wohnungsbau*), which required a minimum amount of square meters for each resident to control overcrowding (Freiburghaus, 1974). Because of the larger family size of many rural Turkish migrants, entering the social housing market was thus out of question.

Berlin's nineteenth-century housing was originally designed to accommodate families from various social strata within the same structure. A small number of opulent apartments made up the perimeter of the blocks and were reserved for wealthier residents, while a large number of courtyard-accessed apartments remained for workers (Geist & Kürvers, 1980).

This tenement housing, now in disrepair, offered Turks cheap rents and the opportunity to accommodate their families in the smaller units, aiding in the construction of Turkish ethnic enclaves (Figure 6). As Turks moved into the high-density areas of Kreuzberg and Wedding, this situation led to limited interactions between Turks and Germans within the greater German urban context. The school structure and professional stratum also evolved to serve this portion of the community, causing most of the later generations of Turks to be socialized within the same communities and neighborhoods. This situation in turn reproduced the existing segregation at the neighborhood level.

In the context of Stuttgart and Berlin, visibility becomes a very important concept within the Turkish guest-worker migration discourse. The differences in visibility through the presence of immigrants in certain areas of the city, along with the material culture they bring with them, not only indicate a hybrid, transnational culture. The physicality of this immigrant culture becomes a lens for national and international identity and integration discourse.

From the German perspective, rapid assimilation of the immigrant population became socially prioritized as a strategy to preserve the characteristics of a mainstream German culture. Rather than promoting an integration into German society that would still allow Turks to preserve their identity and support the Turkish community, Germans have constructed "integration" as a concept that stands in opposition to what was percieved as traditionally Turkish (White 1997). The problems associated with such policies are hard to deny, as a regular introduction of immigrants into

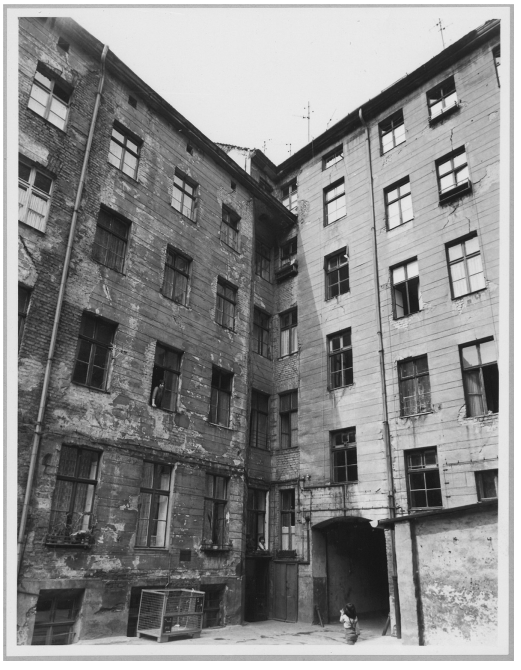

Figure 6. The courtyard of a 19th century tenement house in Waldemarstrasse 70, Berlin-Kreuzberg. Photo by Bert Sass, 1970 (Source: Landesarchiv Berlin).

the mainstream culture affects the identity of the host country as well as creating subjective and socially constructed definitions of foreigner and mainstream (Alba & Nee 2005). Popular reactions to religious, cultural and ethnic differences between newly arrived immigrants and the national mainstream become institutionalized through the implementation of integration policies which were designed to make the migrant population fit the mainstream (Triandafyllidou 2001).

In a country like Germany, where policies of integration are largely produced and implemented at the local level, different definitions of "integration" have led to different implementations of policy. One effect has been the different levels of spatial segregation in Berlin and Stuttgart. In Berlin there were no overarching integration policies until recently. Integration was defined in terms of cultural behaviour, leading to the German authorities imposing an expected behavior ideal on immigrant populations. According to Horrocks and Kolinsky, this has led to a perceived "schizophrenic identity" among Berlin's Turkish population, who perceive themselves as neither German nor Turkish (Horrocks & Kolinsky, 1996). We argue that a top-down approach that defines integration as assimilation is one cause for urban segregation; a point that corresponds to Çağlar's view that by denying organic social and cultural integration, Berlin's Turkish population has been coerced into living in secluded cultural enclaves, not only for economical reasons, but also because by confining immigrants into ghettos, their visibiliy was limited and complexities caused by integration were avoided (2001).

Çağlar defines such cultural enclaves as the ultimate expression of a refusal of cultural diversity that views immigrants as a "spatial and temporal extension of a prior identity rooted in locality and community," (Çağlar, 2001; see also Malkki, 1992). Following this view, the era covered by this study saw the ghetto image in the Federal Republic of Germany as identified with Turks who lived in inner city districts like Kreuzberg, Tiergarten, Wedding and Schöneberg. Although such ghetto formation can be seen as immigrants' refusal to socially, culturally and most importantly spatially integrate, Çağlar points out that the preventative measures taken by the authorities were largely responsible for such segregation (Çağlar, 2001).

Stuttgart has adopted a different approach towards integration. Although central integration efforts were not started until 2001, with the establishment of a network called "Alliance for Integration" (*Bündnis für Integration*), Stuttgart has nevertheless adopted a visionary approach towards Germany's perceived "foreigner problem". In the 1970s, when much of the population still regarded foreigners as guest workers, the mayor of Stuttgart, Manfred Rommel, called foreigners living in the city "Stuttgartians" and took actions to socially integrate this migrant population. In 1971, Stuttgart established the first advisory commitee on foreigner issues (*Auslanderbeirat*) with members taken from the municipal council as well as the community of foreigners themselves. The policies this committee developed aimed to prevent the formation of immigrant ghettos. In order to prevent enclaves, Stuttgart adopted a policy whereby only a certain percentage of any given structure was allowed to be occupied by foreigners (Güneş, 2016). These integration policies, combined with the spatial distribution of the housing opportunities for the immigrant population living in Stuttgart, resulted in less clustering and less visible physical boundaries between different groups within the urban context.

The ethnic enclaves in Berlin were not only consolidated spatially by providing visible borders, but also by social and economic consolidation through the establishment of immigrant networks. Although the existence of Berlin's ethnic enclaves reproduced this social and economic stratification through creating 'mobility traps', they were not entirely responsible for reproducing further urban segregation. The definition of integration adopted in Berlin, which assumed Turkish assimilation as its goal, paradoxically led to the reproduction of spatial clustering and exacerbation of a perceived "foreigner problem".

The approach to integration taken by the Stuttgart government deserves further study. Following the 1970s, Stuttgart took many steps towards the integration of the foreign population, culminating in large-scale policies implemented in 2001. Today, Stuttgart is considered a model study in the field of immigrant integration.

In the light of the contemporary problems related to the European refugee crisis, the studies of integration proved to be necessary and valuable. Although European countries have taken short-term actions such as providing safe and secure shelters to refugees, they are still far from coming up with long-term actions related to integration. Although patterns of current refugees' resettlement into the Europe differ from Turkish-German interaction patterns, our research presents social/spatial outcomes of different integration approaches and strategies. As refugees from some countries, such as Syria, will likely stay in Europe permanently, our research would be a valuable contribution to understanding successful integration strategies for the future.

6 NOTES

a. In 1980, a military coup in Turkey led to a new exodus of migrants, most of whom emigrated for political reasons. This paper examines 1974–80 as the years where Turkish communities became spatially established.
b. Moran's I value tests the spatial dependency of a certain variable. In other words, positive and high values of Moran's I value would indicate higher spatial autocorrelation, meaning high or low values of an attribute are likely to be clustered in space while with negative spatial autocorrelation; locations are surrounded by areas with very different values. The value of Moran's I index is typically between −1 and 1.

Architecture "with the other 90%" – An African story

Milia Lorraine Khoury
Faculty of Informatics & Design, Cape Peninsula University of Technology, Cape Town, South Africa

ABSTRACT: Taking direction from the well-received exhibition *Design with the Other 90%: CITIES* (2011–2012) in America, this paper will refer to the notion of 'Architecture "with the Other 90%"'. By making reference to collaborative community-led architectural projects emanating from the African continent to illustrate the shift towards 'Architecture "with the Other 90%"' in addressing spontaneous urbanism in these regions. The main case studies that will be analyzed in the discussion is the Makoko Floating School in Lagos, Nigeria by NLÉ Architects lead by Kunlé Adeyemi (NLÉ Architecture & Design, 2016a) and the Design Indaba 10x10 Low-Cost Housing project by Luyanda Mpahlwa, from MMA Architects, for a family home in Freedom Park (Mitchell's Plain, Cape Town) (Design Indaba, 2016a). This paper's central focus is to illustrate a shift in social responsibility design and approach in Africa by referring to interdisciplinary architectural and design projects that are community-led, participatory, human-centered and promotes active citizenship.

1 INTRODUCTION

As if reciting a litany, the cities of the developing world read as: Ahmedabad, Bangkok, Buenos Aires, Cape Town, Caracas, Dakar, Dehli, Dhaka, Kampala, Manila, Mexico City, Mumbai, Nairobi, Rio de Janeiro, São Paulo and so on. These cities, as most cities in the developing world, are synonymous with spontaneous urbanism and the informal city. Often the terms 'spontaneous urbanism', 'informal settlements' and 'the informal city' sound like politically correct euphemisms for the more loaded words of 'slum', 'shantytown', 'township', 'barrios', 'favelas' that exist in these cities. It is here, in these informal settlements that the collective desire of the community and that of the powers that be often clash. As Séverine Roussel and Philippe Zourgane noted in *Architecture and Vegetation: hybrid home spaces*:

"Spontaneous urbanism is interesting in the sense that it has not been designed by the administration. Thus the relation with power is here different. Those arrangements are the result of body desire, and not the result of regulations and laws. Michel Foucault in "Security, territory, population" reminds us the importance of the link between control, regulation and city: 'It is because a police regulates cohabitation, circulation and exchanges that cities have been allowed to exist'." (2006: 50)

Thus, the spontaneous developments of informal settlements have historically been framed in the negative, as its' formation has not been regulated by an administration. Over the years, there has been an effort to change the negative connotations and discourse attached to the informal city or the unplanned city. One such project, which aimed to address this issue, was the exhibition *Design with the Other 90%: CITIES* (2011–2012) organized by the Smithsonian's Cooper-Hewitt National Design Museum in America. The exhibition showcased architectural design projects that engaged local communities in informal settlements in the design process, which ultimately lead to participatory and co-design processes and practices in these regions. Using the *Design with the Other 90%: CITIES* exhibition as a departure point, this paper will present and illustrate an ongoing tendency and shift in social responsibility architectural projects on the African continent in particular, that are collaborative, participatory, community engaged/community-led and which in turn encourages active citizenship. This shift will be illustrated by referring mainly to the following architectural projects: the Makoko Floating School in Lagos, Nigeria by NLÉ Architects lead by Kunlé Adeyemi (NLÉ Architecture & Design, 2016a) and the Design Indaba 10x10 Low-Cost Housing project by Luyanda Mpahlwa, from MMA Architects, for a family home in Freedom Park (Mitchell's Plain, Cape Town) (Design Indaba, 2016a).

2 DESIGN "FOR" AND "WITH THE OTHER 90%"

The prequel to the *Design with the Other 90%: CITIES* (2011–2012) exhibition was the 2007 exhibition *Design for the Other 90%*, its' premise was to address the fact that the majority of the world's seven billion population live in cities and one billion live in informal settlements within urban areas (Fig. 1). Of which the majority are in the Global South. It is projected that this number will double by 2030.

The exhibition showcased design solutions which tackled the basic needs of 90% of the world's

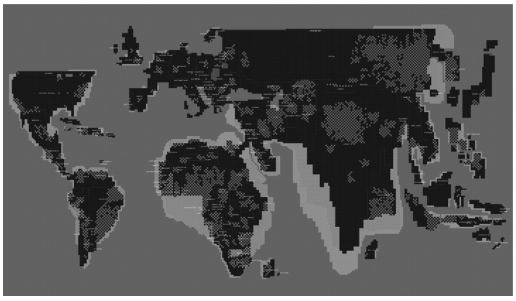

Figure 1. Informal Settlement World Map. Designers: Christian Werthmann, with Elizabeth Randall and Fiona Luhrmann, Harvard Graduate School of Design. United States, 2011.

population in these urban areas i.e. sanitation and clean water and over-crowded living conditions (Smithsonian Cooper-Hewitt National Design Museum, 2016). It also aimed to re-address the fact that in the past design practice in particular, has largely focused on 10% of the world's population in the production of mostly luxury goods. These series of exhibitions by the Smithsonian Cooper-Hewitt National Design Museum attempted to rectify this imbalance and promoted design for social responsibility and social change. Hence, designing for 'other 90%' of the world's population (Smith (ed.), 2007: 19).

In conceptualizing the sequel to the 2007 *Design for the Other 90%* exhibition, the curators heeded the criticism leveled on the first exhibition and replaced the "for the Other 90%" with the more inclusive terming of "with the Other 90%". Which ultimately speaks of including the communities who benefit from the design intervention in the design process. Thus, moving away from a patronizing type of "design tourism" visible in many social responsibility design initiatives in recent years (Arieff, 2011). With regards to architecture and social responsibility, it also heralds an opportunity and move towards creating 'Architecture "with the Other 90%"' and not only "for the Other 90%". Which has become more and more visible recently. As will be illustrated with the case studies below.

3 MAKOKO – "THE VENICE OF LAGOS"

"After today we shall berth in a row
With dreams floating in semblance
Of boats hauling desires to shores
Where there's everywhere on minds
And power settles for repose and luck."

– 'Makoko – Dreams on Water' is a poetry and photography collaboration between photographer Toye Gbade and poet Jumoke Verissimo (Verissimo, 2011)

Makoko has been called both "The Slum on the Lagoon" and "The Venice of Lagos"/ 'The Poor Man's Venice' (Fortin, 2012), the one a disparaging description and the other a more romantic one. However, this does cite a duality of contrasts at play. Makoko, was originally established as largely a fishing and logging community on the lagoon in Lagos (Nigeria), which has thrived informally for more than a hundred years. Its' over one hundred thousand residents created wooden frame houses on stilts in the lagoon to overcome the costly prices of land acquisition and building costs. Thus, making these homes the cheapest housing units available in Lagos (Adeyemi, 2012: 101). Further, canoes are used by residents in Makoko as the main mode of transportation to and from the mainland and on the waterways. Currently Makoko faces numerous problems, of which the foremost issues relate to basic needs of housing, education, sanitation and facilities. The other issues are as a result of the consequences and the affects of climate change, particularly rising sea levels and rainfall. Additionally, Makoko is constantly under threat by developers because of its' prime waterfront location. Which resulted in Lagos authorities forcibly removing and destroying some homes there in 2013. Consequently this led to community unrest, protest action and clashes with the authorities. Further, Lagos is also rapidly expanding and is one of the fastest growing cities in the world, with estimations of becoming a megacity by 2025 with a population of 25 million. Increasingly the local government has been unable to address the basic needs of the growing population in Makoko, leading to overcrowding, rampant disease, poverty, unemployment and crime. Also education levels amongst the residents are low, with many not obtaining a secondary education (Riise & Adeyemi, 2015: 58).

Amsterdam-based architectural firm NLÉ – lead by Nigerian-born architect Kunlé Adeyemi – aimed to address the issue of low education rates in Makoko by proposing the design of the Makoko Floating School in 2010 (Harvey, 2015: 27). There is one English-speaking primary school in Makoko on repossessed land, however the changing water levels make access at times difficult for the local children (Riise & Adeyemi, 2015: 59). Construction commenced on the Makoko Floating School in September 2012 and was completed by March 2013. In the design process, they took into account the rising water levels and tidal changes (due to climate change) and decided on a floating building or 'watercraft' rather than the traditional local building on stilts (NLÉ Architecture & Design, 2016b). Creating a floating or movable building also allowed for the bypassing of having to obtain building and planning rights from the authorities, as is the case when one builds on land. As Adeyemi stated: *"Do you need planning approval for a boat"* (Harvey, 2015: 28). Additionally an A-Frame structure would provide space for solar panels on the roofing and several levels with sufficient space for four classrooms (which is enough space for approximately 100 students) on the 2nd floor and a green recreation space on the 1st floor. The 220-squared metered A-Frame or 'pyramid building' is 10 meters high with a 100-squared meter

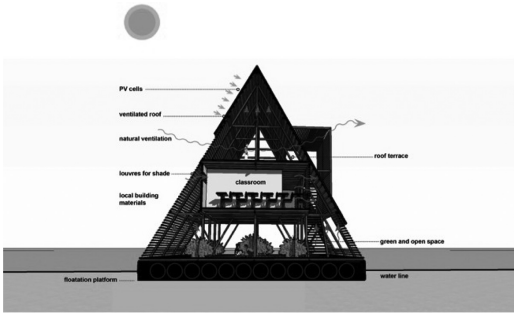

Figure 2. Makoko Floating School Diagram by NLÉ Architects.

Figure 3. Makoko Floating School floatation base being constructed.

floatation base, the building's shape also allows for a low center of gravity for a tall/ vertical structure. The floatation platform of several recycled plastic barrels additionally collects rainwater (Fig. 2).

Throughout the process, NLÉ engaged the Makoko community in the design and building process, consulting and negotiating with the local chiefs (the *Baales*) and the Makoko/Iwaya Waterfront Community leaders. Locally sourced sustainable building materials like Eco-friendly bamboo and wood from a local sawmill were also utilized in the building process and they employed local artisans and community members (Fig. 3). By employing untrained local community members in the building of the structure, it was in the hope of teaching them the building techniques utilized that could be translated in the construction of their own homes (Collins, 2013).

Additionally, the building presents Eco-friendly and sustainable solutions, by using renewable solar energy, reducing waste production and incorporating a water and sewage system and further the transportation system via canoes that has a low-carbon footprint (NLÉ Architecture & Design, 2016b). Adeyemi is adamant that in most of his architectural projects that it is essential to build locally and harness local human and natural resources (Harvey, 2015: 28). This also aligns with the design philosophy of the Rwandan

Figure 4. Makoko Floating School by NLÉ Architects.

architect Christian Benimana who adopts what he calls 'Lo-Fab', which refers to locally fabricated and built architecture and architectural components (Benimana, 2016). The Makoko Floating School is currently being utilized by the local community (Fig. 4) and has also been presented by NLÉ as a prototype building for not only Makoko but other rapidly developing African water cities, like Ganvié on Lake Nokoué in Southern Benin (Adeyemi, 2012: 101). However, more so than just presenting a prototype to address rapid urbanization and create buildings that are environmentally conscious and sustainable, it is the collective community's ownership of the Makoko Floating School that is additionally noteworthy. As Jessica Collins noted when she visited in 2013:

"*Yet a more immediate impact of the new building was the powerful sense of ownership that Makoko's inhabitants derived from it – even before the doors to the school were opened. As the only public space in the area, it has become a vital meeting-point for the community where, when classes are out, market ladies park their boats and fishermen steal some shade to mend their nets".*

4 DESIGN INDABA 10X10 LOW-COST HOUSING PROJECT

As like Lagos, Cape Town (South Africa) is a city of extreme contrasts. Arriving and landing in Cape Town by airplane – like a modern-day Icarus – affords a rose-tinted view of a beautiful natural landscape. Touch down on the N2 national highway en route from Cape Town International Airport and the reality of the city becomes more apparent on ground level. Saddled alongside the highway are the informal settlements of Khayelitsha, Nyanga, Guguletu and Langa, which dissipate as you near the city center. The highway road skirts Table Mountain, swaying you in various directions, if you choose to move towards the sea and Atlantic seaboard and you will be greeted by another city more akin with the French Riviera or the Costa del Sol than the southern-most tip of "Africa". The curator

Shaheen Meerali (1959–) makes a similar observation on a visit to Cape Town in 2001:

"As one drives out from the airport, the usual shanty towns and hamlets which are found in and around the airports of most Third World countries line the streets that pave the diameter of the airport. […] As the view of black South Africa recedes from the motorway and the view of Cape Town 'proper' becomes more apparent, so does the apparent disparity of the colonised and the 'colonisers' abodes. Two cities, twinned by the horrors of the recent past: a geography created by magnetic opposites. Cape Town spawns high rise and Spanish villas, painted white with long winding approach roads lined with fan palms. One has to be careful and water one's eyes by blinking often. The long plane journey might have mistakenly brought you to some wrong destination such as the south of Spain or France, with Le Corbousier [sic] inspired designs of private mansions, Madrid style villas with terra-cotta roof tiles, manicured garden with their bourganvillia [sic] and crazy paving. The schizophrenia does not end there, the further we travel away from the black enclaves, the grander and more exclusive and expensive the white thoroughfares become. […] Cape Town is a divided city: in terms of its economic abilities, geographic location and cultural spaces. […] Apartheid is not post, apartheid is real". (Meerali, 2001: 85–86)

Thus, the above extract postulates that the experience of Cape Town is ambiguous and contradictory and that it is a city of extreme opposites. As on appearance it can be classified as a city that is in reality two cities co-existing as one, due to possessing both so-called "First World" and "Third World" characteristics or having both a European and an African face.

South Africa's Apartheid past has been well documented. Apartheid laws like the Group Area's Act (1950) had a distinctive impact of the urban design of the Apartheid city and Cape Town in particular. The implementation of much of the Apartheid legislation led to the creation of segregated living areas on the outskirts of cities and towns. In 1950 the Apartheid government passed the law the Population Registration Act, which classified and separated people into racial groups as "Whites", "Coloureds" (relating to the descendants of the indigenous Khoi-San and the Malay slaves), "Natives" and "Asians" (Subirós, 2007: 22 & 24). They then passed a law, which made it illegal for people of different races to live in the same area; this was called the Group Areas Act (District Six Museum, 2015). One of the most documented enactments of the Group Areas Act was the forced removals of District Six in Cape Town, as in 1966 District Six was declared a "whites only" area. District Six was one of the most racially integrated areas in Cape Town, were races from mixed race and ethnic backgrounds lived and worked alongside each other in a area in close proximity to the city center and the harbor. There are several harrowing images of houses being razed and of the forced removals of 60 000 inhabitants in District Six to the Cape Flats – a sandy barren wasteland on the outskirts of the city. Presenting a dialogue between the city center and the periphery. The poetic responses to the forced removals resounded and echoed the poignant and defiant stance that memory does not forget:

"Gone
Buried
Covered by the dust of defeat –
Or so the conquerors believed
But there is nothing that can
Be hidden from the mind
Nothing that memory cannot
Reach or touch or call back".

– Don Mattera, 1987 (District Six Museum, 2015)

As noted above, many of the forcibly removed former residents of District Six and it's future generations live in what is known as the Cape Flats, which consists of several outlining 'townships' and suburbs on the urban periphery. One such settlement is Freedom Park in Mitchell's Plain on the Cape Flats. Whereas Makoko in Lagos was as a result of spontaneous urbanism, Mitchell's Plain came about as a result of the forced removal process and the Apartheid regime's social engineering processes, which in turn created peri-urbanism scenarios on the outskirts of many South African cities.

One of the architectural design projects that aimed to address the disparities amongst the citizens in Cape Town, particularly in terms of housing like in Mitchell's Plain, was the Design Indaba 10x10 Low-Cost Housing project (Design Indaba, 2016a). Design Indaba, an independent organization established in 1995 under Africa Interactive, hosts an annual international design conference and exposition and supports/funds several design initiatives through-out the year (Design Indaba, 2016b). The 10×10 Low-Cost Housing project objectives were aligned to the Design Indaba's vision of "create a better future, by design". Ten local architects were teamed with ten international architects from the Design Indaba conference speakers' alumni to collaborate on designing ten low-cost housing projects *pro bono* in 2007. The houses needed to be produced within the budget requirements for the South African government sponsored Reconstruction and Development Programme (RDP) housing scheme. The brief was as follows: "*The objective was to come up with affordable, attractive, innovative responses to the urgent need for housing for the urban poor. Sustainable design, construction and operation principles were to be incorporated*" (Design Indaba, 2016). Thus addressing a sustainable housing need not just in South Africa but also worldwide. The design by Luyanda Mpahlwa, from MMA Architects, for a one family home in Freedom Park (Mitchell's Plain, Cape Town) was the first to get planning approval from the City of Cape Town's local government. Mpahlwa drew on traditional indigenous building methods like the mud-and-wattle technique and instead of using bricks and cement constructed a double-story timber frame house with sandbag infill (Fig. 5).

Thus, constructing an energy efficient house that does not require much electricity or skilled labor to

Figure 5. MMA Architects, 2007. Design Indaba 10×10 Sandbag Houses, Freedom Park (Mitchell's Plain, Cape Town).

Figure 6. MMA Architects, 2007. Design Indaba 10×10 Sandbag Houses, Freedom Park (Mitchell's Plain, Cape Town).

construct. Many community members were engaged and physically involved in the construction of the Jonker family home. This design by MMA Architects received the acclaimed international design award the Curry Stone Design Prize in September 2008. An organization which awards design projects that find solutions to improve people's lives and living conditions around the world. Subsequently, ten such sandbag houses have been completed by Design Inbada in Freedom Park, Mitchell's Plain (Fig. 6).

The direct beneficiaries of this project, the community members were given workshops on the building process. As a result, local members of the community (largely women) gained experience and knowledge of sustainable building methods (Fig. 7) and were employed in this project (Design Indaba, 2016a). Again community involvement was essential in this project's implementation. As Mpahlwa (2007) noted:

"*Sandbag construction was a novel concept, especially in the township context, where single storey, low density […] housing is the norm. The designers thus developed a strong relationship with the community, providing the information and assurance they needed to take ownership and gain acceptance of this experimental housing type".*

Figure 7. MMA Architects, 2007. Design Indaba 10×10 Sandbag Houses, Freedom Park (Mitchell's Plain, Cape Town).

5 CONCLUSION: ARCHITECTURE "WITH THE OTHER 90%"

Both the Makoko Floating School and the Design Indaba 10×10 Low-Cost Housing project engaged the community in the design process and used sustainable processes and low-cost locally sourced materials. Further they also provided prototypes for future sustainable building methods and designs for these communities in these historical informal settlements. Increasingly with projects of this nature, there has been a shift away from the cult of the "Starchitect" and creating 'Architecture "with the Other 90%"". An essential aspect of this type of community engagement in the designing and building process, is "trusting that people can do it" (Smith (ed.), 2011: 4). Further, it promotes active citizenship, collective ownership by the community and collective building. Nevertheless, it is vital to mention, although there have been increasingly more-and-more architectural projects over the years addressing housing needs in informal settlements by non-profit organizations like Habitat for Humanity, What Design Can Do, Architecture for Humanity, Architecture Sans Frontieres and so on, some of these projects have been design interventions by outside volunteers. Creating what Alison Arieff termed as "design tourism" (Arieff, 2011). Therefore the community did not benefit from the transference of skills and knowledge in the construction of some of these structures, to ensure longevity and sustainability of these design interventions. Hence, the need for 'Architecture "with the Other 90%". For architectural practice to adequately address the societal challenges we are currently faced within this present-day, it needs to engage the essential ingredient of the 'human'.

The Senegalese photographer Omar Victor Diop stated at the Design Indaba conference in 2015 that: *"In Senegal we do not have many resources but we have people"*. This statement in essence epitomes much of the story of what many have experienced as a sense of community in most African countries. Often the media's or the popular image of Africa is either highlighting an African 'destination' or 'humanitarian

crisis'. Thus, the image that is presented is not one of resilience and community (namely the spirit of *Ubuntu*). Nor what lessons can be learnt from Africa. *Ubuntu* is defined as follows:

"*According to an old Zulu maxim umuntu nguumuntu ngabantu- "a person is a person through (other) persons". It is only by acting with humanity toward one's fellow man that a person can be one with the spirit of his people and be worthy of veneration after his death. This is the essence of the African spirit of shared humanity that is known as 'ubuntu'. According to Archbishop Tutu Ubuntu 'speaks about our interconnectedness. You can't be human all by yourself, and when you have this quality – Ubuntu – you are known for your generosity"'* (The FW de Klerk Foundation, 2011)

Besides harnessing the spirit of *Ubuntu* and community in building sustainable and humane housing, there also needs to be a process of humanizing spaces like the 'slum', 'shantytown', 'township', 'barrios' and 'favelas'. As the Venezuelan architect Alfredo Brillembourg (from Urban-Think Tank) often recounts of what residents in informal settlements regularly relay to him: *"You call it a slum, but we call it our home"*. Additionally, Brillembourg states that *"Informality is the new normality"* and *"We need a new way of dealing with the city. The laws do not comply with what is happening on the ground"* (2016). The "incremental housing" projects by Chilean architect Alejandro Aravena from the architectural firm Elemental also present new ways of practicing or dealing with the reality of "informality". Where government sponsored housing projects are built incrementally and the remainder of the house is customized or retrofitted by the dweller (Smith (ed.), 2011: 118–119). Similarly, Brillembourg has adapted the idea of "incremental housing' to his ongoing project entitled Empower Shack in BT-Section, Khayelitsha in Cape Town (Urban-Think Tank, 2016). Collectively all these processes and activities lead towards and engage with 'Architecture "with the Other 90%". New paradigms or perspectives are required. By terming certain urban developments as spontaneous urbanism defines and explains the activity engaged by a community as being a spontaneous activity towards creating housing or infrastructure for that community. Whereas the term 'informal settlement' labels the output of this spontaneous activity and additionally in turn also vilifies it, as not being a legitimate place; just because it was not planned by an authority or administration. This is ultimately where the problem lies. These spaces need to be humanized even in our perceptions, only then can we collectively find solutions together.

Regeneration of barrack complexes as means to sustainable development

M.M. Rudnicka-Bogusz
Faculty of Architecture, Wrocław University of Technology, Wrocław, Poland

ABSTRACT: In garrison towns, army constituted focal point of social and economic life. Military infrastructure contributed to city's modernization. Through generations, historic army barracks were a reminder of past splendor for the citizens. As a result of turbulent geopolitics in Lower Silesia in the 20th century these objects, once venerated by the natives were handed over to newcomers, for whom they held little sentimental value and then were altogether abandoned and left for ruin. Nowadays, they are sold to private investors who raze them to the ground or disfigure them in the process of adaptation. Regeneration of these versatile compounds is ecologically, economically and psycho-sociologically beneficial, however should be properly supervised, so that they are not deprived of their original characteristics, but serve as evidence of history while fulfilling their new functions. Without them the cultural landscape of garrison towns will become unintelligible to both previous and present inhabitants.

1 SUSTAINABLE DEVELOPMENT AND THE HERITAGE

The word that is the key to understanding today's world is "global". Unlimited communication, world-wide spread of commerce and popularization of international style resulted in unification of standards and tastes. Paradoxically this has led to renewed veneration for regional culture and vernacular architecture. Regionalism is now on demand. In the 21st century people are more mobile than ever, seeking employment, a place to live or vacationing in most remote corners of the Earth. But as they do they look for peculiarities in cultural landscapes to relate to. People who move around have a strong longing to find a place they belong and a sentiment (sometimes unconscious) for what they left behind (Woods, 1982). These regionalisms distinguish places from each other and draw or repel possible migrants and tourists (Stouffer, 1960). The foundation for these regionalisms is the cultural landscape formed in the course of history.

According to a formal definition, a cultural landscape represents the combined works of nature and of man, which are illustrative of the evolution of human society and settlement over time, under the influence of the environmental, economic and cultural forces (Operational Guidelines For The Implementation Of The World Heritage Convention, UNESCO, 2015). In other words cultural landscape is the essence of the identity of a local community. Therefore it must be as versatile as possible so as to fully represent its historical background allowing future generations to understand their origins and preserve the traces of those which have disappeared. Along with natural deposits, cultural landscape is the greatest resource available to man. Cultural and natural heritage form a complimentary resource, which must be preserved for the planet's sake (UNESCO World Heritage Convention, 1972, Article 4).

To preserve cultural landscapes and maintain regional identity that originates in them, but allow progress, the world needs to develop sustainably. A sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs (Report of the World Commission on Environment and Development: Our Common Future). The concept of sustainable development is based on the idea, that the civilization of man can shape and utilize the environment in such a way that it enables it to function on the highest level of evolution possible, without negative consequences and irreversible changes to local natural and cultural landscape. It has been observed, that most mainstream studies concerning sustainable development take into consideration only natural capital and natural heritage, leaving out cultural heritage. Luckily major significance of cultural heritage to human wellbeing and its potential contribution to social, economic and environmental goals gain ever wider acknowledgement.

For whatever can be said of sustainable development in the realm of natural resources, can also be said of cultural heritage. Both natural and cultural capital is non-substitutable. The function of natural capital can be disseminated into four categories in terms of utility for human wellbeing (Dietz & Neumayer, 2007). It provides the basic life-support functions, the raw materials for production and direct consumption, and assimilates their waste products. But it also provides the visual amenity of a landscape. Same can be said of cultural capital. Cultural heritage also plays an important role in local life-support by providing economic

development and basic amenities, such as dwelling. It attracts investments (via tourism) and facilitates locally-based employment, which in addition contributes to self-awareness of local communities and care for local properties. Correspondingly protection of exceptional heritage properties cherished by people is considered "an intrinsic contribution to human wellbeing" (UNESCO on sustainable development) for its powerful symbolic and aesthetic dimensions. The acknowledgment and stewardship of the diversity of cultural capital enhance the feeling of belonging and contribute to the social cohesion of a community.

Consequently, the fullest and most complete cultural landscape is such that contains the most complete transcription of region's history or more exactly not only historic monuments and cultural heritage, but also historic architecture *sensu largo*, that was not declared monument. This leads to a paradoxical conclusion, that sustainable development which is in its essence a process of change is only possible through a petrification of cultural landscape. According to Werner Hediger, this discrepancy is the consequence of the dual nature of the process. Alike many scholars he distinguishes between "weak" and "strong" sustainability. The "weak sustainability" paradigm implies that the value of a man-made capital is greater than the natural capital (Neumayer, 2013) and is the compromise between economic growth and preservation of cultural landscape. On the other hand "strong sustainability" paradigm demands that ecological and cultural capital be kept intact (Hediger, 1999). It seems clear, that if societies are to evolve and progress in the spirit of sustainable development, it would have to be "weak sustainable development".

Endorsing sustainable economic development is in heritage preservation's best interest. It is the most effective way to save endangered cultural heritage sites (www.sustainablepreservation.org) and should not be curbed. Especially underprivileged communities can only be motivated to care for their heritage by tangible benefits that can be drawn from long-term maintenance as an alternative to other profitable uses, such as looting, agriculture and razing under residential and commercial construction. If heritage becomes an asset not a burden in economic growth it will be willingly cherished and nurtured. This stands in accordance with the World Heritage Convention, which urges State Parties "to adopt a general policy which aims to give the cultural and natural heritage a function in the life of the community and to integrate the protection of that heritage into comprehensive planning programs" (UNESCO, World Heritage Convention, 1972, Article 5).

Here we come to the notion of "sustainable preservation". The notion comes from the idea that the most sustainable technique of construction is preservation of existing properties, which saves resources and energy and is ecologically-friendly in terms of recycling. This generally fits the EU urban development policy, which is fixed on reurbanization of cities. This is due to the adopted principles of environmental protection and resource recycling, including priority of land reuse before appropriation of new building sites (Billert).

The preface of the UNESCO 1972 Paris Convention states that deterioration or disappearance of any item of the cultural or natural heritage constitutes a harmful impoverishment of the heritage of all the nations of the world. Understandably not all historic objects can be preserved and only the most iconic, significant and representative – the ones that the UNESCO Convention calls "of outstanding value" – can become cultural heritage under protection (UNESCO, Convention Concerning the Protection of the World Cultural and Natural Heritage, 1972). This term boils down to either a unique artistic creation, scholarly historic value, or typological qualities (ICCROM, Proposals By The International Centre For The Study Of The Preservation And The Restoration Of Cultural Property, 1976). However, interest should be placed not only with the obvious choices, possessing the exceptional features mentioned above, but also with the less evident properties with potential for scientific value if properly exposed (ICOMOS, Proposals Made By The International Council On Monuments And Sites, 1976).

2 MILITARY COMPOUNDS IN THE LIFE OF THE CITY

Maintaining as many historic objects as possible is indeed the way to sustainable preservation not only from an economic, but also a spiritual point of view. Regeneration and adaptation of historic architecture can indeed be the way of establishing prestige and achieving gentrification (Rudnicka-Bogusz, 2012). Especially in societies, which had gone through some trauma – deracination, war, social or economic exclusion, racial segregation – historic objects that connect communities to their grand historic past can help them heal or maintain their identity.

There are many examples of post-war restorations that brought some consolation and closure to the communities. As a part of a post-war nation-unifying movement the Royal Castle in Warsaw which was razed to the ground by the Nazis got reconstructed in the years 1971–84. The Dresden Lutheran church *Frauenkirche*, destroyed in carpet bombing air raids in 1945, lay in rubble for 20 years in the middle of Old Town, until combined grassroots effort of donations and foundations culminated in its reopening in 2005. Also in Leipzig, St Paul's Church was restored due to popular demand. The 13th century church survived the World War II only to be demolished for ideological reasons (Wolle, 2003). In its place Leipzig University built a campus extension. In the beginning of the 20th century the university began modernizing its properties and when the citizens petitioned for reconstruction the church, the university agreed.

However, not only the declared monuments spark this type of devotion. For instance, in 1996 Leipzig

was the scene of a public dispute, when during demolition of a shopping mall from the 1970s, a *fin de siècle façade* of a department store was uncovered. To the citizens the department store represented the golden era of commerce in Leipzig, when rich merchants and entrepreneurs founded exquisite boutiques and shops, where bourgeois could stroll and socialize in the atmosphere of accessible luxury. Through marches and petitions citizens voiced their support in favor of upkeep of the Leipzig soul through restoration of the rediscovered building.

For garrison towns in Silesia it was the barrack complexes that were the focal point of social and economic life. They were also important to the local communities who were living in their immediate proximity, giving them the *genius loci*. Their significance is somewhat proven not only by the economic data showing substantial growth after the arrival of the military, but also by the analysis of postcards from the period. On these postcards only most venerable and noteworthy objects were represented and a significant number of these edifices, among castles and courts, are indeed barracks and officers' messes.
